Basic purpose of a HIL simulation is to test a complete, manufactured control system or some part of it without making real experiments at the controlled plant. On the other hand, testing of the control unit mounted and installed at the real plant is performed during commissioning and after these tests the new unit is officially proclaimed completed if it performed satisfactory. Although HIL testing cannot altogether substitute commissioning testing, the number and the duration of tests during that latter phase can be substantially reduced (according to some reports, up to 95% of the testing can be performed without experiments on the real plant). Even when commissioning testing is mandatory, many faults and possible improvements can be noticed during HIL testing and subsequently dealt with in this earlier phase, which is much simpler and less expensive at this time. In particular, the operator interface can be thoroughly checked, finely tuned and adapted to customer suggestions through HIL simulations.

HIL testing is invaluable when difficult-to-achieve, undesired or potentially dangerous operating modes and situations are to be tested without dangers, possible damage or great expenses unavoidable if such experiments were to be performed on a real plant. In addition, HIL testing of the control system can be performed simultaneously with the development and construction of the plant itself, before it is completed and ready for mounting of its controller. In such way the development cycle can be substantially quicker, which is of paramount financial importance for larger projects with tight development schedules.

III. TURBINE GOVERNING SYSTEM MODELING

General layout of turbine governing model for a water turbine is shown in Fig. 2. The model consists of three main parts: the governor, the turbine with water intake and the electric power unit with electric grid influences. In the case of HIL simulation, the governor is not a part of the simulator. However, the off-line simulator variant with the governor included in the model has been also developed for the purpose of governor analysis and design.

The simulation model has to be versatile, covering wide range of plant operating modes and events. Modeling accuracy which can be achieved is often limited by imprecisely known parameters. Fortunately, HIL tests in this case do not require extraordinary accuracy.

A. Turbine Governor

The turbine governor controls water flow through the turbine, and therefore its rotational speed and mechanical power output (load) [3]. The control signal is the opening of some flow control mechanism, in most cases wicket gates at the turbine stator. Modern turbine governor consists of the electronic part with control algorithm

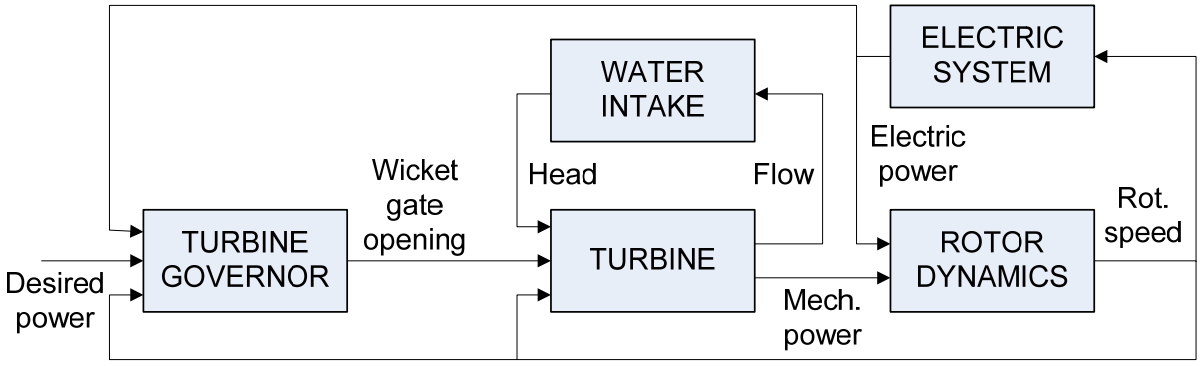

Figure 2. Simplified block-diagram of turbine governing system

running on a digital processor and the hydraulic part which acts as the control signal amplifier and operates the opening mechanism via hydraulic servomotor.

Basic control algorithm of the turbine governor contains three basic controllers acting in a two-step cascade, with the speed controller or the load controller as the first step and the opening controller as the second step. Selection of the controller for the first cascade step depends on the power unit operating mode. All three controllers are typically implemented as some variant of PID (Proportional-Integral-Derivative) algorithm. The algorithm also contains parameter gain scheduling, signal filtering, magnitude limiters and rate limiters, speed regulation characteristics function which enables load control to be obtained through speed controller and vice versa, start and stop sequences, manual and remote control modes and, if desired, additional control loops. Most of these additional functions can be omitted if the governor is included in the simulator.

Hydraulic servo unit is pretty complex non-linear system, but it can be substantially simplified if it has to be included in the model. Basic model consists of a first-order lag and integrator with limited input and output.

B. Turbine and Water Intake

Water turbine is mathematically described with two non-linear characteristics: the flow characteristics and the load or torque characteristics. For the case of the Francis turbine, they can be written as

$$\begin{aligned} q_T &= f_q(y_P, h_T, w_N) \\ P_m &= f_P(y_P, h_T, w_N) \end{aligned} \tag{1}$$

where q_T is flow through the turbine, P_m turbine mechanical power output (load), y_P wicket gate opening, h_T water head (difference of headwater and tailwater level given as height value with dynamic losses included), and w_N turbine speed. Similar equations are valid for other water turbine types as well. For example, characteristics of a double regulated turbine (Kaplan, bulb) have the same form as (1), but with additional input y_R, which is the pitch angle of the runner vanes. For the sake of convenience, the opening y_P (as well as y_R) is given as linear position of its hydraulic servomotor piston.

The most accurate representation of relation (1) is given by hill diagrams obtained during model tests with the unit turbine model performed by its manufacturer. These non-analytical diagrams are, however, pretty cumbersome to use. In the case of three or more independent inputs they become totally impractical. Workarounds and simplifications are possible, but they limit hill diagrams towards nominal steady-state turbine operation. In particular, large deviations from nominal speed are not within their scope.

Less accurate analytical non-linear models are approximations of a hill diagram. One of them is the IEEE model [2], which for normalized variables takes the form:

$$\begin{aligned} q_T &= y_P \sqrt{h_T} \\ P_m &= A_T h_T (q_T - q_{NL} w_N) - D_a (w_N - w_B). \end{aligned} \tag{2}$$

Adjustable model parameters are turbine gain A_T, turbine flow at which the generator has null load q_{NL} and turbine throttle coefficient D_a, while w_B is nominal turbine speed. This model is also not valid for turbine starting and stopping sequences, but it can be extended to include them as well with introduction of additional terms or variable model parameters.

Mathematically, water intake is tightly coupled with the turbine. It has to be modeled with differential equations. The most accurate representation uses partial differential equations, but the following simplification is good enough in most cases:

$$\begin{aligned} \dot{h}_T &= \kappa (q_D - q_T) \\ \dot{q}_D &= (h_S - h_T - h_L) / T_w . \end{aligned} \tag{3}$$

This model uses an additional variable, water flow at the penstock inlet q_D. The model parameters, dependent on penstock dimensions and materials, are pressure wave expansion parameter κ and water acceleration time constant T_w. Static head h_S depends on the water level in the reservoir and is considered to be constant. Head loss of the water intake is represented by the term h_L. Basic head loss is proportional to the flow squared with the loss coefficient k_L, as $h_L = k_L \, q_T \, |q_T|$. Additional oscillation-throttling term is needed for small flow values.

For short water intakes, water can be modeled as a non-pressurable fluid ($q_T = q_D$), which simplifies (3) to

$$\dot{q}_T = (h_S - h_T - h_L) / T_w . \tag{4}$$

C. Power Unit and Electric Grid

When modeling equations of the turbine and power unit speed w_N, two cases are possible. If the unit is connected to a large electric grid, then it can be supposed that any influence of the unit on the grid frequency is negligible (infinite electric grid hypothesis). In that case, the unit speed is determined by the grid frequency f_N (converted into the equivalent unit speed), $w_N = f_N$. Electric power of the unit is then calculated as equal to the mechanical one with subtracted conversion losses.

On the other hand, if the unit is the only power producer at the grid, then the following equation holds:

$$\dot{w}_N = \frac{1}{T_m} \frac{P_m - P_e}{w_N} \tag{5}$$

where P_m is mechanical and P_e electrical power of the unit. Mechanical time constant T_m is determined by unit's moment of inertia. For the range of small unit speeds the denominator of (5) has to be limited with some $w_\varepsilon > 0$ in order to avoid division with zero. Electric power of the isolated unit is modeled as determined by the external load P_L as:

$$P_e = P_L + D_p (w_N - f_N) \tag{6}$$

with grid throttling coefficient D_p as a model parameter.

With the substitution $P_e = 0$, equation (5) is valid for the case when the unit is not connected to the grid; braking is then achieved with negative values of P_m.

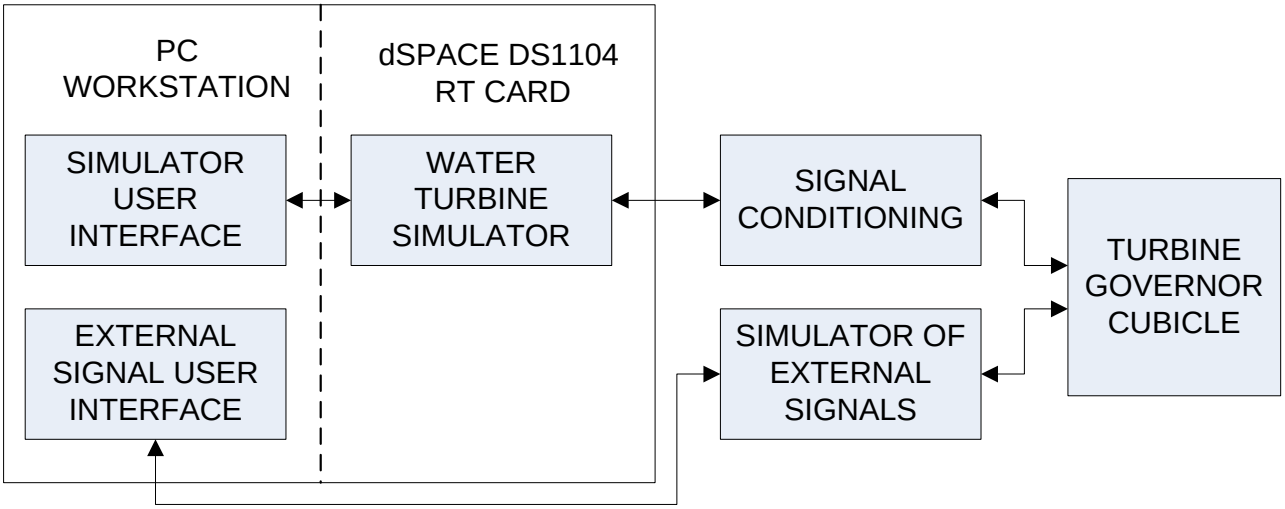

Figure 3. Block diagram of hardware-in-the-loop turbine simulator

IV. WATER TURBINE SIMULATOR

Simulator of the turbine governing system has been prepared in the *Matlab-Simulink* programming and simulating environment (*The MathWorks, Inc.*) following the principles outlined in the previous section. The off-line variant runs on the PC workstation within *Simulink*, while the HIL variant (Fig. 3) has to be compiled to real-time code before downloading to the DC 1104 R&D controller board (*dSPACE GmbH*) with a dedicated real-time processor. The real-time controller board is embedded in the PC workstation and uses its customized connector board (also provided by *dSPACE* – Fig. 4) for easier connecting to the process signals, in this case turbine governor cubicle (Fig. 5). Signal conversion between the two units is needed, since the real-time board uses exclusively analog voltage signals of ±10 V and binary logic signals of 0-5 V, while the turbine governor typically operates with analog current signals of 4-20 mA and binary signals of 0-24 V. Simulator of external signals deals with signals needed by the governor, but not included in the turbine model. In this case (Fig. 3) it was implemented with a CompactRIO Real Time Controller hardware platform (*National Instruments*) with user interface as a *LabView* application on the PC workstation. Signals simulated in this way include alarms originating from turbine wheel and turbine bearing, alarms indicating various malfunctions in the turbine governing system

Figure 4. PC workstation with embedded dSPACE real-time controller board and its connector board

Figure 5. Turbine governor cubicles of HPP Lešće prepared for HIL testing

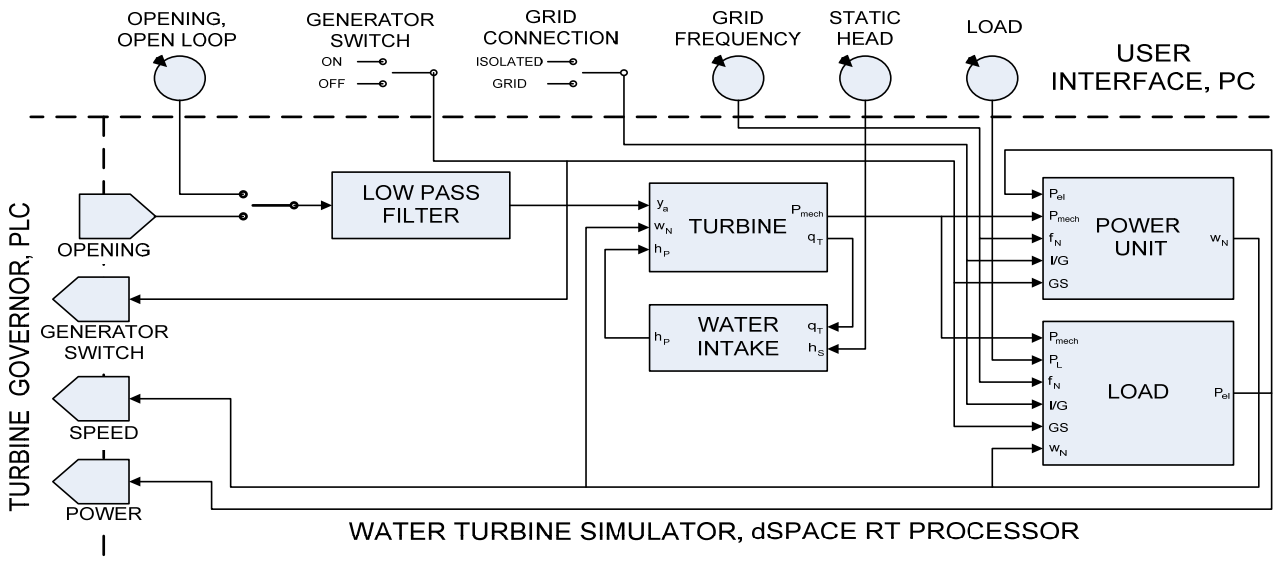

Figure 6. Real-time application of HIL simulator and its interfaces

itself (hydraulic system, sensors, power supply loss), signals indicating fulfillment of additional conditions required for turbine start, commands from remote operator stations, additional indications of turbine runaway, additional emergency stop requests, and the like.

Fig. 6 depicts signal flow within the HIL simulator and between it and its interfaces for the case of a Francis turbine. The governor provides the opening signal which is filtered and given to the turbine model coupled with the water intake model; the turbine model calculates mechanical power which is then sent to the power unit block and the load block, which calculate speed and electric power, respectively; these two signals are thereafter returned to the governor, together with the generator switch position set at the simulator user interface. The user interface is implemented within *ControlDesk* (*dSPACE*) at the workstation running the simulation (Fig. 7); it provides representation of the most important simulator signals and also enables setting of several Boolean and numeric simulation parameters via virtual switches and knobs or direct numerical input, as preferred. Besides the generator switch position, electric grid type (isolated or infinite), grid frequency, load and static head are set in this way. All these parameters can be changed manually during the HIL simulation. The user

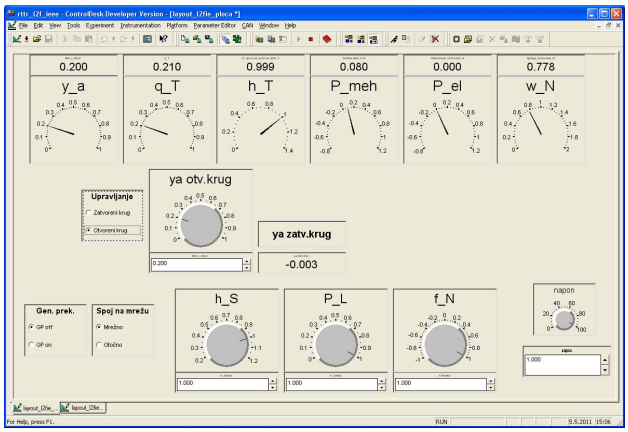

Figure 7. User interface screen of HIL simulator (ControlDesk)

interface also enables open-loop turbine control using manually set opening for the purpose of checking the operation of the simulator itself.

During a HIL simulation, most important signals of the simulated turbine are being recorded at the turbine governor with data acquisition system PersonalDAQ 3000 (*IOTech/MCC*) and associated software ServiceLab (*ServiceLab/NI*). The same equipment for data acquisition is used during tests performed on real turbines (Fig. 8).

HIL testing of a turbine governor performed within FAT testing encompasses all governor functions and elements, starting with the basic functionality and going towards more complex functions: start and stop sequences, reaction to alarm signals, opening control, speed control, power control, switching between several control modes, sudden loss of load, testing of additional systems and equipment. Initial governor parameters are set before the HIL testing with the help of the off-line turbine governing model. The parameters, as well as control sequences, are then being tuned and modified in two steps: during HIL simulations and during commissioning.

V. PERFORMED TESTS

The simulator has been used to develop and test turbine governors of several hydro power plants. Turbine governing system of all three units of HPP Lešće was subject to HIL tests before delivery to the plant. In this case governor cubicles were tested together with hydraulic power units and auxiliary drives. Hydraulic servo was not tested, but appropriate hydraulic circuit with servo valve and cylinder was set on a hydraulic test stand. In contrast, HIL testing for the main units of HPP Čakovec involved only governor cubicles. In this case hydraulic system of the turbine governor was included in the real-time model. Further differences from the previous case were caused by different turbine type: HPP Čakovec has double regulated bulb turbines and short water intake, while HPP Lešće has Francis turbines. And finally, work performed for the main units of HPP Senj included only off-line simulations.

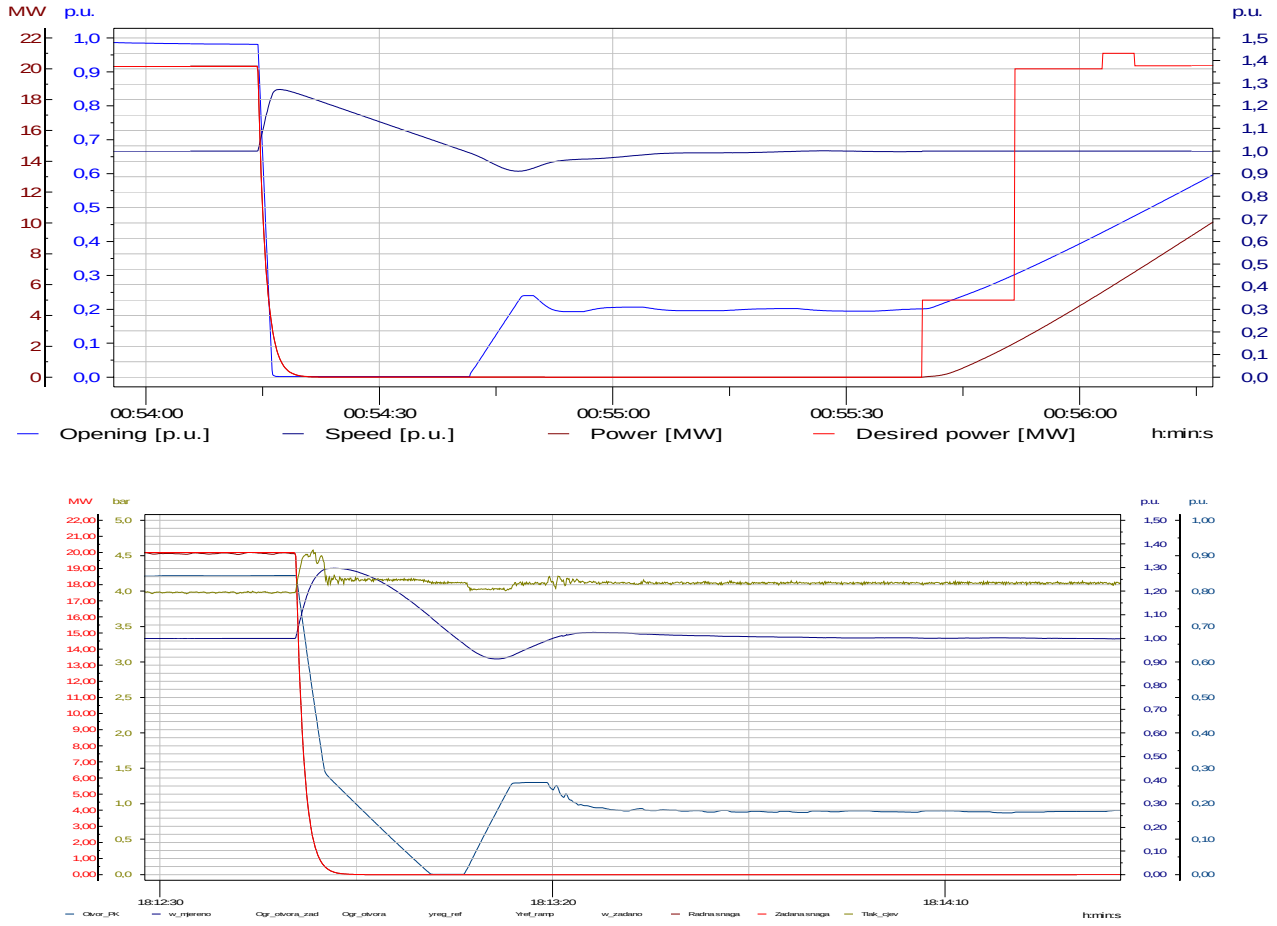

Figure 8. Comparison of response to loss of load at 20 [MW] power of the HIL simulator (top) and the real plant (bottom), unit B of HPP Lešće. Opening and speed given in relative units [p.u.], and active power in [MW].

This power plant also uses Francis turbines, but with much longer penstock than HPP Lešće, which is moreover at Senj shared by all power units.

All HIL tests were performed in the presence of representatives of the customer. As expected, no major faults with the tested equipment were encountered. Suggestions and additional requests of customers were discussed and, if agreed, subsequently implemented. These were mostly some minor modifications of the operator interfaces of tested cubicles, but several dealt with improvements of governing sequences.

Fidelity of the turbine model to the real plant achieved for HIL simulations has been quite satisfactory, in spite of rather simple shape of the selected model. As an example, comparison of responses to loss of load of the model and the real plant is shown in Fig. 8. Similarity of the speed response is good enough for the purpose of HIL simulations. Much of the observed difference can be ascribed to different closing sequence, with some influence of imprecisely set parameters and neglected secondary effects. In fact, pretty high degree of fidelity can be achieved if the model is finely tuned after the recorded plant responses, but this was not possible in this case since the plant was in the process of construction during HIL tests. It can be concluded that a more complex turbine model is not required for this application.

VI. CONLUSION

HIL simulator described in this paper has significantly improved the quality of FAT tests for turbine governors. In this way governor software and hardware can be pretty thoroughly checked and modified according to customer's suggestions prior to mounting at a real plant, which significantly helps in the latter commissioning phase.

Abstract – Use of FluidSIM software allows a variety of advantages in development and design process of a turbine governing system and similar hydraulic systems on hydropower plant facilities, like system visualisation possibilites through design process and keeping track with real-time simulation parameters exchange. In paper, design and parameters check process is given, while conducting a real-time simulations. The major parameters are explained as well as the way of choosing and setting of hydraulic components. The goals for hydraulic system design process on hydropower energetic facilities are given. The principes of hydraulic part of turbine governing system functioning and it's implementation in FluidSIM Hydraulics software is explained. Results of simulation are given and compared to real masurement results obtained from accomplished system on a hydropower plant in Republic of Croatia. Presented software is in use in Control engineeering department of Brodarski Institute in Zagreb, Republic of Croatia.

I. INTRODUCTION

In paper, design process of hydraulic part of a hydropower plant turbine governing system is given, as well as all the benefits accomplished with FluidSIM software implementation in the process. For speed and power governance of a turbine-generator assembly on a hydropower plant, needed power for hydromechanical equipment manipulation actuators is provided by electrohydraulic system.

Hydraulic part of a turbine governing system and similar systems in hydroenergetic facilities (monitoring and governance of turbine regulation, dam spillway gate equipment, etc.) is of vital importance for correct functioning and safety of the object and its enviroment, and in their design, development, reconstruction or modernisation process, accuracy of technical construction process and precise system guidance possibility is important. Furthermore, while designing systems as described, from major importance is to focus on safety part of the system, that must be fail-safe, considering its importance and possible brakedown aftermath. Usual progress of a hydraulic system realisation, from demand to commissioning, is given on the flowchart.

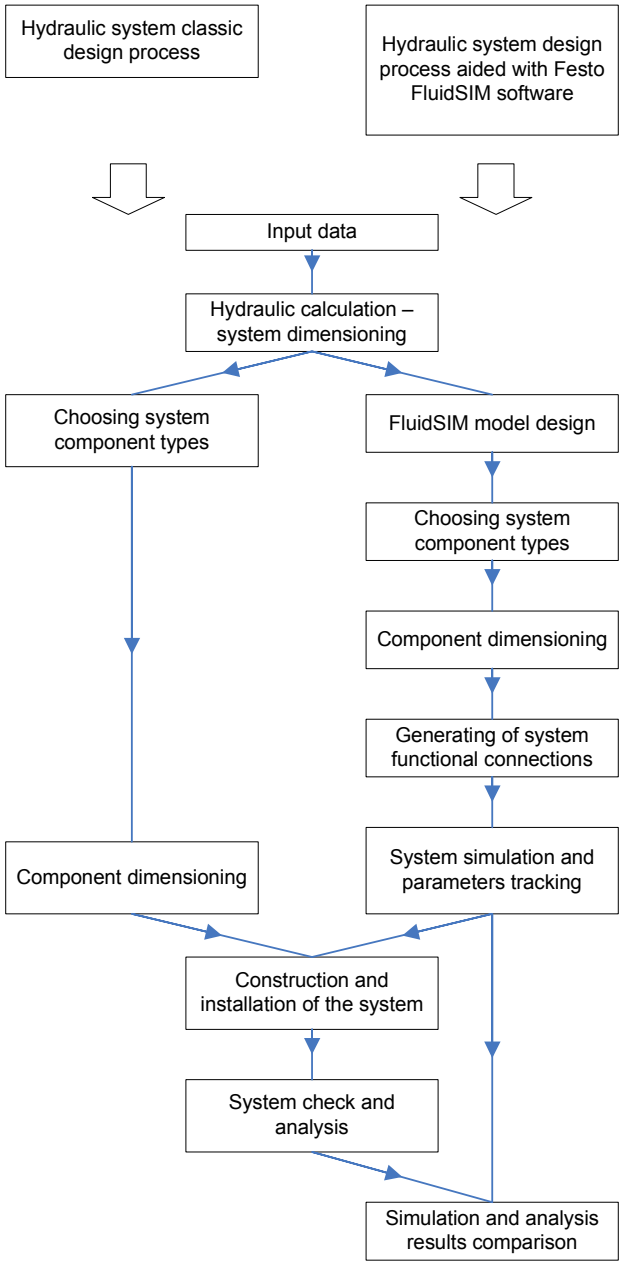

Fig. 1. Flowchart of „classic“design process and FluidSIM aided design process of hydraulic part of a turbine governing system

II. ADVANTAGES OF FLUIDSIM SOFTWARE IMPLEMENTATION IN DESIGN PROCESS OF TURBINE GOVERNING SYSTEM HYDRAULICS

As basis for turbine governing hydraulic system design calculation, demanded working parameters of the system are given, like the amount of force needed for manipulating with wicket gate vanes ring (Francis type of turbine) and amount of time needed for its transition from starting to final condition (the rate of openness 0 ÷ 100 [%]).

With input parameters, system design process is conducted, step-by-step, beginning with hydraulic servo motors, system working pressure, maximum flow calculation, hydraulic installation dimensioning, hydraulic bladder acculumators dimensioning (for accumulation of hydraulic energy), drive pumps and electromotors dimensioning, and overall hydraulic system volume calculation, in accordance with profession regulations [1].

During system dimensioning, given guidelines for system working pressure values, amount of accumulated energy and allowed flow speed through hydraulic installation are observed, what then defines nominal opening size for hydraulic components. Next step is choosing the components that completely fulfill the conditions set for the system and ones given by the client. System defined in this way is ready for construction and closing factory acceptance tests (FAT). At the end, field test and analysis of the system are obtained, and the system is commissioned.

Regarding to „classic“, above described system design, FluidSIM aided design process allows an engineer to have a momentary visualisation of linking and testing of system parts, as well as a whole system, before entering a construction phase. After choosing component type and dimensioning it, it is possible to perform a „real-time“ simulation of the system while monitoring fluid flow amount and direction as well as system working parameters like servo motors response depending of system components settings.

Beside above mentioned advantages, various hydraulic components variations are possible, while observing the impact to the system. Parallel to „real-time“ simulation conduction, it is possible to acquire a graphic output of system parameters change in the form of state values diagram, what then becomes the basis for analyse and corrections entering.

Carried-out simulations in FluidSIM software give affirmation of correct system component choice and dimensioning, by satisfactioning required manipulation times as well as required manipulations number in case of power supply fail.

Essential advantage in a possibility of comparison of simulation results with system testing prior commissioning result, as well as FAT testing results, must be emphasized.

In extension of paper, the hydraulic part od turbine governing system on unit C (Unit for biological minimum) of Lešće hydropower plant (HPP) in Republic of Croatia is given. Software has also been used for construction of Technical solution of reconstruction of hydroelectrical drives of spillway gates on Čakovec HPP dam, and on Reconstruction project of hydroelectrical drives of spillway gates on Varaždin HPP dam. In current year, software will be used for design of hydraulic model for Dubrovnik HPP Unit A and B turbine governing system replacement.

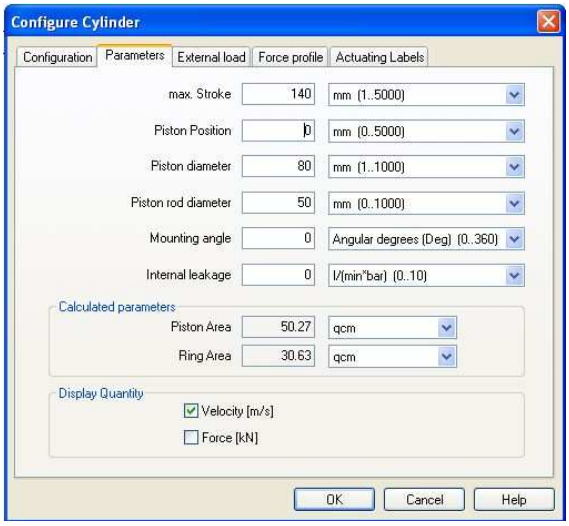

Fig. 2. Setting of wicket gate vanes servo motors parameters fraction

III. DESIGN AND SIMULATION OF HYDRAULIC PART OF TURBINE GOVERNING SYSTEM ON LEŠĆE HPP

As an example in useage of FluidSIM software in a design process, the design of hydraulic system for turbine governing on Lešće HPP Unit C (unit for biological minimum) is taken. Lešće HPP is the first HPP constructed and build in independent Republic of Croatia, that was completed in 2011. Shown example refers to Unit C, which role is a production of electric energy for HPP own needs. Therefore, following characteristics for Unit C are given :

- type of turbine : Francis, horizontal
- installed water flow $Q_i = 2,7$ [m^3/sec]
- constructive water drop = 41,32 [m]
- power rating with constructive water drop and installed flow $P_t = 1006$ [kW]

As a base for hydraulic calculations, boundary times for opening and closing of executive hydraulic actuators, and maximum force (turbine wicket gate vanes closing with maximum water pressure and flow) needed for wicket gate vane ring manipulation are taken.

$$F_{MAX} = F_{ND} \text{ x } k \quad (1)$$

F_{MAX} [kN] - maximum force as basis for hydraulic calculation

F_{ND} [kN] - needed calculated force closing the wicket gate vanes ring with maximum water flow and pressure

k - safety coefficient

$F_{MAX} = 6,4 \times 3,5 \cong 22,5$ [kN]

System model is made using Festo FluidSIM Hydraulics v4.2. After design according to hydraulic calculation [2], system components are dimensioned and input parameters like hydraulic pumps pressure, system pressure, safety valve settings, hydraulic resistance curve and leakage of componets are set.

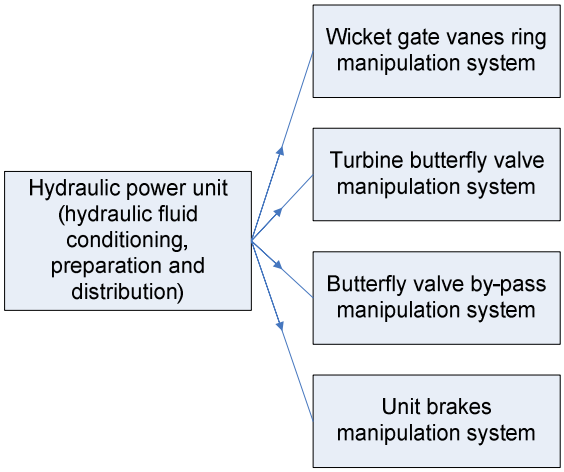

Fig. 3. Display of sub entities of hydraulic part of turbine governing system for Unit C at Lešće HPP

System model simulations are performed, with recording od following data :

- Time needed to fill up the bladder accumulators with hydraulic energy
- Time needed to perform the manipulation with wicket gate servo motor
- Time needed to perform the manipulation with butterfly valve servo motor
- Time needed to perform the manipulation with butterfly valve by-pass servo motor
- Time needed to perform the manipulation with unit brakes
- Pressure amounts for different simulation condicitons

During simulation time, following parameters were changed, so optimal reaction times could be achieved :

- Setting of main proportional valve opening level (4 ÷ 20 [mA] equals opening value of 0 ÷ 100 [%])
- Setting of throttle valve opening level (0 ÷ 100 [%])

Fig. 4. Hydraulic turbine governor system for Unit C, Lešće HPP

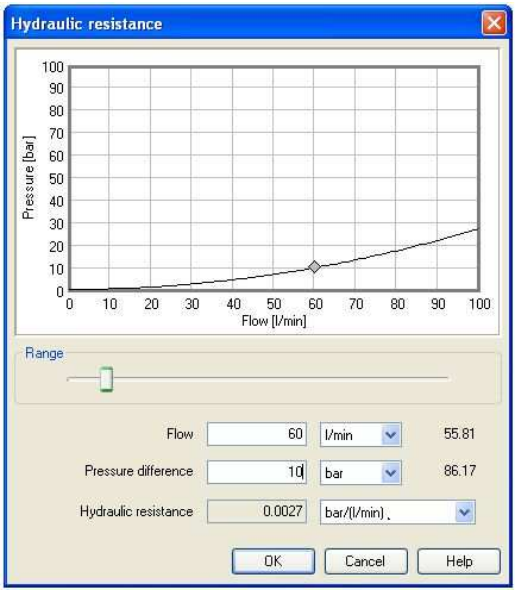

Fig. 5. Setting the hydraulic resistance curve for applied 4/2-way type of valve

Following conclusions were made from simulation of hydraulic turbine governing system. Hydraulic calculation and chosed type and size of components were correct. Components functional connections (either pressure or pilot signal lines) were established correctly, confirmed by hydraulic flow simulation in the system.

Accurate functioning of hydraulic emergency stop system as final safety protection in turbine governing system (putting the turbine-generator assembly to a stop when nominal turbine rpm-s are overstepped or if power supply fail occures) is confirmed. As well, possibility of executing the needed manipulations is given time frames is confirmed [3].

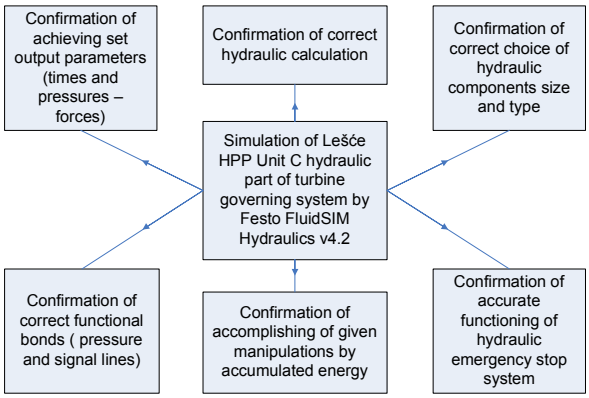

Fig. 6. Lešće HPP Unit C hydraulic part of governing system check by using Festo FluidSIM

According to project documentation demands, hydraulic system must hold enough hydraulic energy to be able to, in case of power supply fail, safely and completely accomplish three full manipulations with wicket gate vanes servo motor (one manipulation equals a full cylinder rod transition,from one to antoher final position, and back).

By using two 50-liter hydraulic bladder accumulators with 60 [bar] nitrogen pre-charge pressure simulation proved that this requirement was fulfilled. In case of emergency, with adiabatic state change assumption [4], when pressure rises from p_{Tmin} = 66 [bar] to p_{RTmin} = 85 [bar], inside of two hydraulic bladder accumulators there is 14,9 [lit] of accumulated fluid, what satisfies and exceeds the amount of energy needed to accomplish three full manipulations [2].

p_{Tmin} - minimum pressure in hydraulic system needed for the hydraulic actuator to be able to close the wicket gate vanes

p_{RTmin} - minimum pressure in hydraulic system, i.e. pressure when hydraulic pump is activated

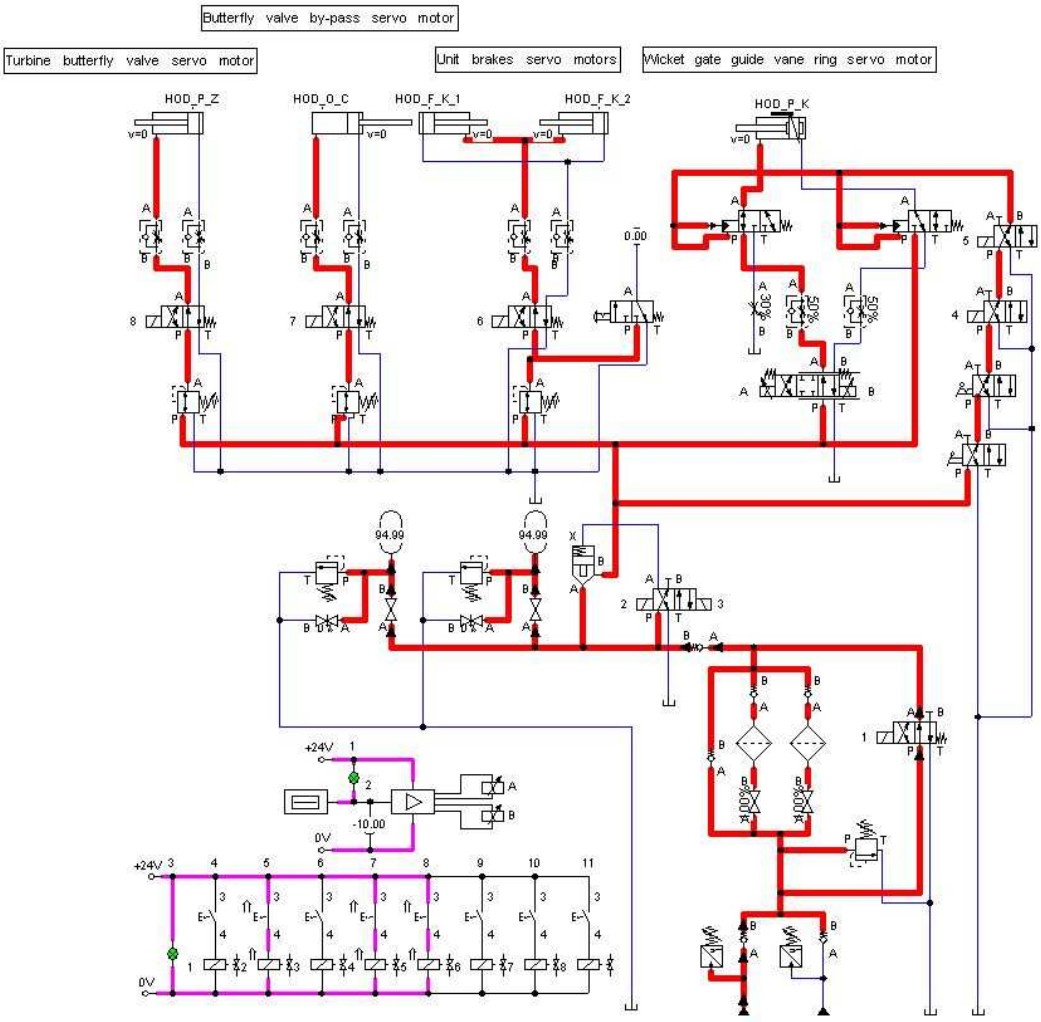

Fig. 7. Simulation in progress – Festo FluidSIM Hydraulics v4.2.

Obtained simulation results with previously set variables are in accordance with results of FAT testings and testing done prior to comissioning of Lešće HPP. Hereafter, comparison of FluidSIM simulation and field testing results is given. For data acquisition and analysis, data acquistion system was used, that comprises of power supply source, pressure transducer (Siemens), position transducer (RDP Electronics, Series DWP), data acquisition device IOTech Personal Daq 3001, and laptop computer with ServiseLab 7.0 software.

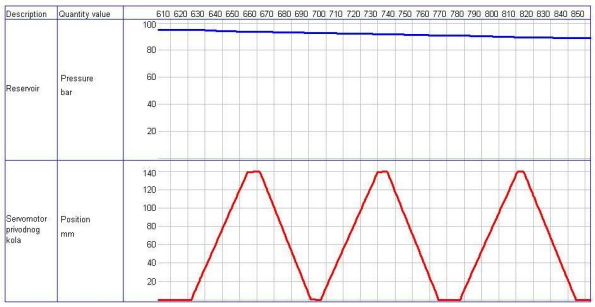

Fig. 8. System pressure drop with three full manipulations (power supply fail – FluidSIM analysis)

During conducted on-site testing of three manipulations possibility, there was a Δp = 7,3 [bar] pressure drop recorded in system bladder accumulators, from initial 95 to final 87,7 [bar] [5]. During FluidSIM model simulation testing, recorded pressure drop was Δp = 7 [bar], from initial 95 to final 88 [bar], what proves correct functioning of simulated system.

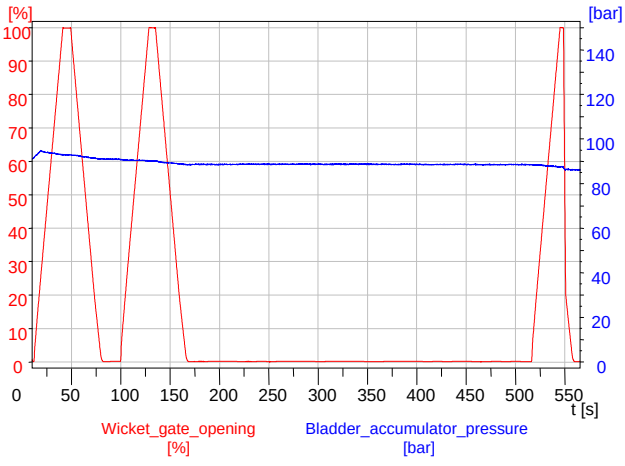

Fig. 9. Recording of three full wicket gate vanes servo motor manipulations (simultion of yhdraulic system pumps power supply loss) – measurements [5] taken after system installation

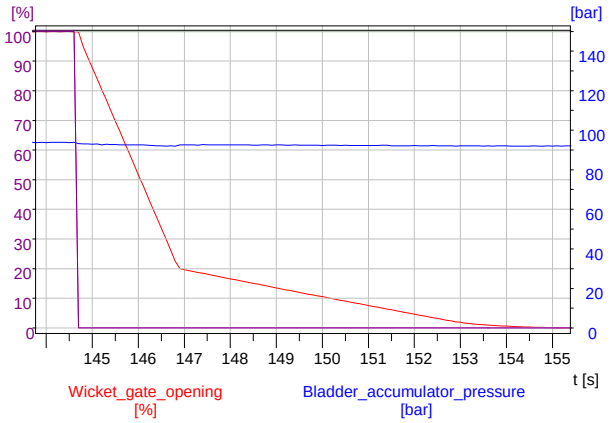

Fig. 10. System response to activation of emergency stop signal , Lešće HPP, Unit C

System performance in case of activating emergency stop (rapid closing of wicket gate vanes) signal is tested, for turbine-generator assembly safety reasons. Triggering the emergency stop system is possible by cutting-off hydraulic pilot line pressure, either by mechanical activation or by electrical signal to electromagnetic valve.

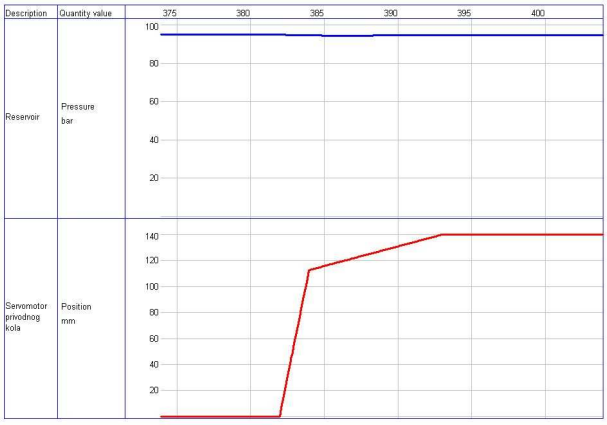

Fig. 11. System response to emergency stop signal activation, FluidSIM simulation

Hydraulic pilot pressure cut-off can occur from various safety reasons [6], while the uniform reaction consists of wicket gate vanes proportional valve isolation by a pair of 2-way hydraulic valves, entering the wicket gate vane closing loop. On above given graphs, transition from normal working state to emergency closing state is shown, comparing on-site system test results with FluidSIM simulation test results.

IV. CONCLUSION

Advantages of FluidSIM Hydraulic software application, in objective to modernise hydraulic turbine governing system and similar systems on hydropower facilities, are possibilities of visualisation the system in making and simulating it prior to its construction.

FluidSIM represents usefull engineering tool in design process, that allows monitoring of output values by changing previously elisted parameters, therefore enabling to system designer easier pick and tune of system components.

Advantages as system working visualisation, tracking of pressure changes and actuators stroke in correlation with passed time, simple exchange of system parts and wide choice of available changeable parameters in system components characteristics tune are the reason for what this software is used on a Control engineering department of Brodarski institute in Zagreb, Republic of Croatia.

Abstract - Marine vessels (surface and underwater) present dynamic systems which are difficult to control due to their complexity, hydrodynamic effects and external forces. Moreover, cooperative control and guidance of these systems presents a task which still presents an intriguing research topic in the area of marine robotics. This paper presents a guidance method based on virtual targets (VT) applied to marine vehicles. The proposed algorithm is derived using a Lyapunov based approach which guarantees convergence and stability under external disturbances. Firstly, the VT algorithm is applied for path following of a single vehicle. It is demonstrated that this algorithm is convenient for following of conventional paths (line, circle arc, spline). Secondly, the VT algorithm is applied for cooperative control between two marine vehicles. The following formations of marine vessels will be described and analyzed: vehicle following – where one vehicle is the „leader" followed by the „follower" vehicle at a predefined distance; and the „wingman problem" where two vehicles are required to follow a joint path at a constant predefined distance between them. Simulation results of the described algorithms will be given in the paper as well as the discussion on their quality.

I. INTRODUCTION

Marine robotics in general presents an interesting and challenging area where the application of control theory presents an essential part. This comes directly as a consequence of harsh environment in which marine vehicles operate, characterized with unpredictable disturbances (waves, winds and currents). Exploring the sea depths is one of the biggest tasks for the future. Thanks to development of advanced control theory and technological improvement, nowadays, the main interests of marine robotics are focused on cooperative control and guidance of marine vessels. Development of the multi-vehicle frameworks and thereby including more vehicles in cooperative missions, lead us to design more complex control systems.

This paper deals with virtual target algorithm in cooperative control of marine vessels. The work presented in this paper will be elaborated on an overactuated marine surface platform which development has been published at MIPRO'11 conference, [3]. The platform is developed at the Laboratory for Underwater Systems and Technologies (LABUST) by a group of students. This paper address simulation results of the described algorithms obtained in MATLAB, so only some important technical characteristics of the platform will be mentioned in following part. The marine platform which mathematical model is used in simulations is actuated with four thrusters in an X-shaped configuration which enable motion in surge, sway and yaw degree of freedom. This configuration is highly convenient for dynamic positioning as well as path following. Marine vehicles are often designed to be overactuated; they have more actuators than strictly necessary to maneuver. In this case, four thrusters are used to control three degree of freedom: surge, sway and yaw. This property guarantees reliability in the case of faults in the actuators. Platform development comprises driver electronics for the thrusters, a GPS unit, a compass, batteries and a single board computer used for sensor integration and control. These components enable manual control from the ground station as well as autonomous operation mode. The communication with the ground station is accomplished using a two-way wireless link. A schematic representation of the hardware infrastructure implemented inside the platform can be seen on Fig. 1. The control algorithm which enables autonomous movement is implemented on a single board computer. This systems configuration has proved to be convenient for laboratory use and testing of control and guidance algorithms.

The main motivation for building this type of a platform was, firstly, to introduce students to the area of marine robotics. As the project evolved, the task was to build a rather small, portable platform which will be used in the field for the purpose of assisting divers in underwater navigation and communication with the ground station. Further on, the developed platform will be used in cooperative guidance of unmanned underwater vehicles. This application would allow more precise underwater localization and online mission replanning. The relevance of the envisioned project is significant from the educational side, and the interdisciplinarity through marine robotics.

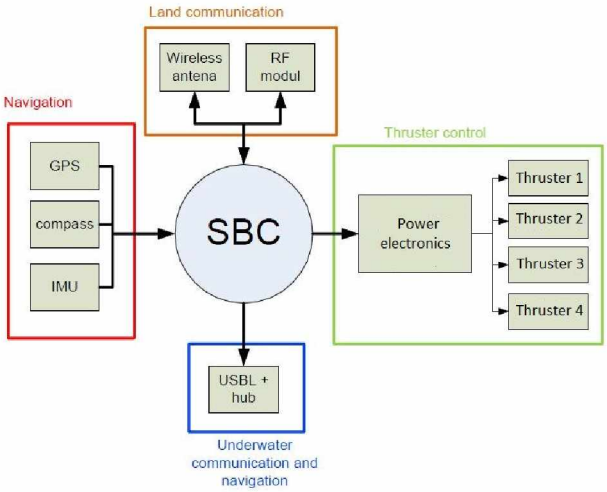

Fig 1: Schematic representation of the hardware infrastructure

This paper presents the next step in research activities regarding the guidance algorithms which include simulation results obtained using virtual target algorithm in order to achieve cooperative mission execution. It should be mentioned that the developed simulation model assumed that the dynamics of the platform were uncoupled.

The paper is organized as follows. Section II describes the mathematical model of the basic motion of the marine platform used in simulation. In section III, a brief introduction to virtual target algorithm is given and in section IV this algoritm is expanded to path following approach and multi-network framework cooperative control. In section V, simulation results are presented and finally, in section VI some conlusions are made and guidelines for future work done.

II. MATHEMATICAL MODEL

A. The marine platform model

The mathematical model of a marine platform is defined using two coordinate frames: an Earth-fixed (inertial) frame {E} described with axes N (pointing to the north), E (pointing to the east) and D (pointing down so that the NED frame forms a positively oriented coordinate system); a body-fixed coordinate system {B}, which is usually attached to the centre of gravity (CG) of the vehicle and is described with three axis x, y and z pointing respectively in the same directions as the NED frame when x and N are aligned, [4]. The mathematical model of a marine platform is described with an assumption that the platform is moving only in the horizontal plane, i.e. only translation in the $N-E$ plane and rotation about the z axis is possible.

The platform's speeds are defined in the fixed coordinate frame {B}: surge u and sway v speeds are translation speeds in the x and y axis directions, respectively, and yaw speed r is rotational speed around the z axis. Earth-fixed coordinate frame is used to define positions x and y in the horizontal plane and orientation ψ of the platform. The motion of the platform is achieved by applying surge (X) and sway (Y) force and yaw (N) moment.

The schematic representation of the mathematical model is given in Fig. 2.,[8]. The *kinematic model* in the horizontal

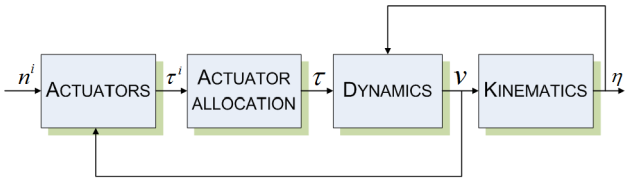

Fig. 2. Block-diagram of the mathematical model used to describe marine vessels.

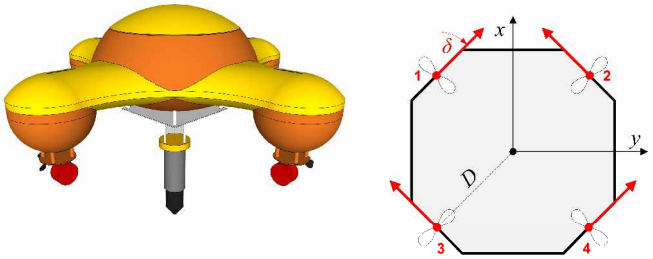
plane is given with (1). The *dynamic model* is assumed to be uncoupled so each controllable degree of freedom (DOF) can be modelled separately. In addition to that, since the platform is symmetric in the horizontal plane, the same model (and the parameters) can be used to describe surge and sway dynamics, as shown with (2) and (3) where α_u is a constant parameter and $\beta(u)$ and $\beta(v)$ are drag parameter which are speed dependant and include all speeds, the drag parameter can be approximated with a constant term, i.e. $\beta(u)=\beta(v)=\beta_u$, [5]. In a similar manner, yaw model is given with (4) where α_r is inertia and $\beta(r)$ drag. The τ_{uE}, τ_{vE} and τ_{rE} represent external disturbances and unmodelled dynamics of the system, [7].

$$\begin{bmatrix} \dot{x} \\ \dot{y} \\ \dot{\psi} \end{bmatrix} = \begin{bmatrix} \cos\psi & -\sin\psi & 0 \\ \sin\psi & \cos\psi & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} u \\ v \\ r \end{bmatrix}. \quad (1)$$

$$\alpha_u \dot{u} + \beta(u)\cdot u = \tau_{uE} + X, \quad (2)$$

$$\alpha_u \dot{v} + \beta(v)\cdot v = \tau_{vE} + Y, \quad (3)$$

$$\alpha_r \dot{r} + \beta(r)\cdot r = \tau_{rE} + N. \quad (4)$$



a) b)

Fig. 3. a) Virtual model of the platform for dynamic positioning and b) x-shape actuator configuration.

The *actuator allocation* matrix gives relation between the forces exerted by thrusters (τ_1, τ_2, τ_3 and τ_4) and the forces that act on the rigid body (X, Y, N). For the case of the *Platform*, whose actuator configuration is given in Fig. 3b) and $\delta = 45°$, the actuator matrix is given with (5) where D is shown in Fig.3.b).

$$\begin{bmatrix} X \\ Y \\ N \end{bmatrix} = \begin{bmatrix} \cos 45° & \cos 45° & \cos 45° & \cos 45° \\ \sin 45° & -\sin 45° & -\sin 45° & \sin 45° \\ D & -D & D & -D \end{bmatrix} \begin{bmatrix} \tau_1 \\ \tau_2 \\ \tau_3 \\ \tau_4 \end{bmatrix}. \quad (5)$$

Since four actuators are used to control three degrees of freedom, this presents an overactuated system. This allows for the design of fault tolerant control algorithms, [6]. The inverse actuator allocation matrix cannot be found (since the matrix is not square), but a pseudoinverse can be calculated instead, [10].

The actuators can be simply modelled using an affine model given with (6) where n^i represents the individual thruster's control input (commanded rotation speed, input voltage, etc.), K_T is the thruster coefficient and τ^i is thrust exerted by the i-th thruster.

$$\tau^i = K_T \left| n^i \right| n^i \quad (6)$$

The nonlinear static thruster characteristic can easily be compensated within the control algorithm, [7], [11].

III. VIRTUAL TARGET ALGORITHM IN PATH-FOLLOWING

This section describes only fundamental concepts and problem formulation of the use of virtual target algorithm for single-vehicle guidance. For details and whole kinematic error modelling, interested reader can refer to [12], [13]. Before we deal with the essence of the problem, the kinematic model (1) is represented with

$$\begin{aligned} \dot{x} &= U\cos\psi_e \\ \dot{y} &= U\sin\psi_e \\ \dot{\psi}_e &= r \end{aligned} \tag{7}$$

where

$$U = \sqrt{\dot{x}^2 + \dot{y}^2} \qquad \psi_e = arctg\frac{\dot{y}^2}{\dot{x}^2} \tag{8}$$

With already defined Earth-fixed (inertial) frame {E}and a body-fixed coordinate system {B}, a *Serret-Frenet* frame { } ≔ [0] is defined,[15]. Virtual target attached to {F} moves along predefined path. Whole problem can be easily explained with reference to Fig.4.

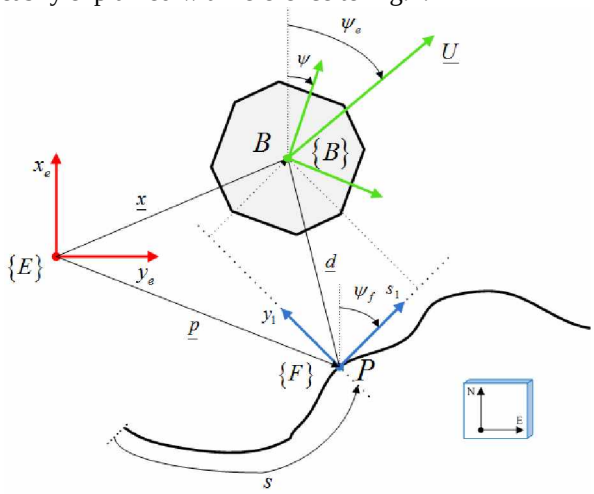


Fig.4. Vehicle parameters and frame definitions

After some mathematical calculations, the following kinematic error model is obtained and expressed with respect to the frame {F}

$$\begin{cases} \dot{s}_1 = -\dot{s}(1-c_c y_1) + U\cos\beta \\ \dot{y}_1 = -c_c\dot{s}s_1 + U\sin\beta \\ \dot{\beta} = r - c_c s \end{cases} \tag{9}$$

where $\dot{s}$ is speed of virtual target, attached to the frame {F}, is path curvature, U is vehicle's total velocity and is difference between vehicle's direction of motion and orientation of virtual target which is the same as local path tangent at point P. Control demands can be formulated as follows. After some transient time, platform must be in origin of {F} frame, which means that and converge to zero. Second task is to reduce β towards zero. When these requirements are fulfilled, path following is achieved. In order to design control law which ensure convergences both the vehicle and virtual target, one of the possible Lyapunov's function candidate is chosen.

$$V_E = \frac{1}{2}\left(s_1^2 + y_1^2\right) \tag{10}$$

Computing its time derivative and after substitutions are made, with proper choice of ˙, ˙ becomes negative – definite. Choosing

$$\dot{s}^* = U\cos\beta + k_2 s_1 \tag{11}$$

as control signal which guarantees that ˙ < 0, a new additional degree of freedom is introduced in the control structure. The speed of virtual target later takes a part in defining yaw rate reference. Considering the candidate Lyapunov function:

$$V = \frac{1}{2}(\beta - \varphi)^2 \tag{12}$$

and choosing control law:

$$r^* = \dot{\varphi} - k_1(\beta - \varphi) + c_c(s)\dot{s} \tag{13}$$

$V \le 0$ is secured where is nonnegative controller gain and φ is angle of approach which is modelled as function of lateral coordinate. The approach angle is instrumental in shaping transient maneuvers during the path approach phase. The following hyperbolic tangent shaped function, parameterized by > 0 and 0 < < − has desirable properties due to inherent saturation.

$$\varphi(y_1) = -\psi_a \tanh(k_\varphi y_1) \tag{14}$$

The advantages of proposed kinematic control laws are in following. Asymptotically convergence to zero of the variables β, and is achieved, classic singularity of the path following problem is removed and vehicle can perform following of various kinds of the paths.

The above kinematic control law applies to the kinematic model of marine vehicles only. Using the backstepping techniques, this control law can be extended to deal with the vehicle dynamics. However, after that yaw rate reference is determined, a classic I-P controller is designed for yaw rate control,[9]. Backstepping technique supposes that process parameters are very accurately determined. If we have some uncertainty in mathematical model control signal can experienced chattering which is not acceptable behaviour, [12]. The complete control structure used for simulation can be seen on Fig. 5. Low level control is an I-P controller designed according to second order binomial model transfer function as desired behaviour. High level control is based on the virtual target algorithm.

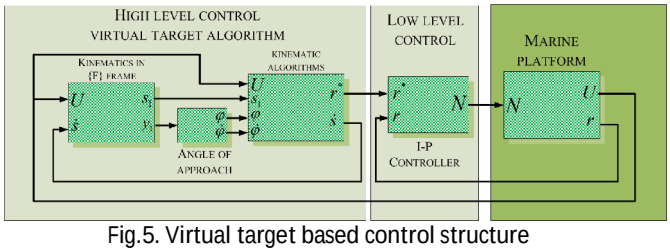

Fig.5. Virtual target based control structure

IV. COOPERATIVE CONTROL OF MARINE VESSELS

In this section, intention is to expand control algorithm and show have to efficiently use them to control several vehicles in order to achieve cooperation between them. Guidance and control of cooperative missions is demanding

task and still presents a challenge in the area of marine robotics. Two or more marine vehicles operating together form a multi-vehicle framework, [1], [2]. Usually, one vehicle is the leader which executes some mission objectives and the rest of the vehicles (followers) follow his movements in some way. In the continuing part of this section, two coordinative tasks will be described. Each of them use single vehicle path following algorithm based on virtual target. With the virtual target based approach, coordination task is completely uncoupled from single - vehicle path following task.

A. Vehicle following

In vehicle following scenario, the Leader has to perform some motion. Through the communication link, the Leader sends basic navigation information to the Follower and then Follower vehicle reconstructs online the path to be followed. For instance, Leader follows a predefined path and Follower has to follow a Leader, maintaining a desired distance between them. Also, Leader vehicle can be open-loop controlled by human operator, [14]. As already mentioned, Follower vehicle follows the path shaped by Leader vehicle at fixed or variable distance, measured in curvilinear abscissa of the reconstructed path. Further on, if we add more vehicles in multi-framework system, a relation Leader – Follower can be generalized. One vehicle will be ultimate leader which only executes its own mission. Next in the Leader hierarchy will be second vehicle which is at same time the Follower of ultimate Leader and also a Leader to the vehicle below in hierarchy system. At the bottom is simple Follower as a tail of such a formation system. Whole framework act as a giant snake and some collision avoidance algorithm must be applied in order to prevent ultimate leader crashing with the followers while performing sharp manoeuvres. Collision avoidance is beyond the scope of this paper and an assumption of smooth path with small curvature is made. The vehicle following approach proposed in this work is based on the single vehicle path – following guidance technique for each vehicle. In addition, to achieve desired distance between formation members, the vehicle's surge speed must be controlled according to the error from desired distance from local Leader. So, the curvilinear distances between the Leaders and Followers are defined as the difference between respective curvilinear abscissas Δ = – .

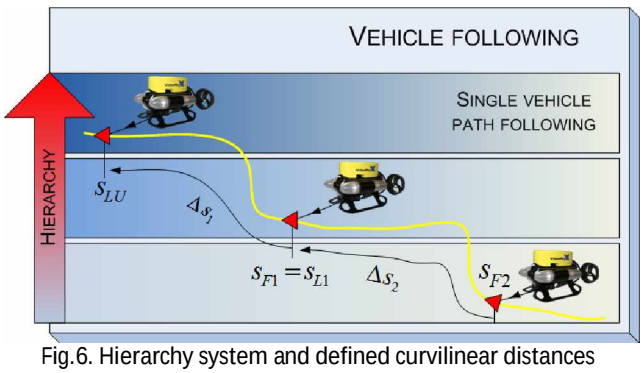

Fig.6. Hierarchy system and defined curvilinear distances

Thus, the task is to design a control law in order to reach a desired distance *. Defining the distance error as = Δ – *, the implemented solution to make → 0 is in the form of tangent hyperbolic function added with feed-forward Leader surge force signal. The final form of the surge control law is

$$X^* = X_L + k_u \tanh(k_e e_s) \qquad (15)$$

where and are tunable controller gains. With the properly calculated surge force Follower vehicle produces required surge speed to maintain desired distance.

B. Wingman problem

One of the most common formation tasks is holding parallel formation while vehicles move along different paths. As in vehicle-following, Leader executes manoeuvres while Wingmen vehicles must maintain parallel formation with respect to the Leader vehicle.

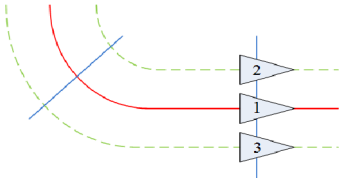

Fig.7. Example of parallel vehicle formation

Obviously, speed of the wingmen vehicles must be controlled to accomplish parallel formation. To achieve cooperation, each vehicle is controlled with virtual target based approach. Their virtual targets are used for the cooperation purpose.

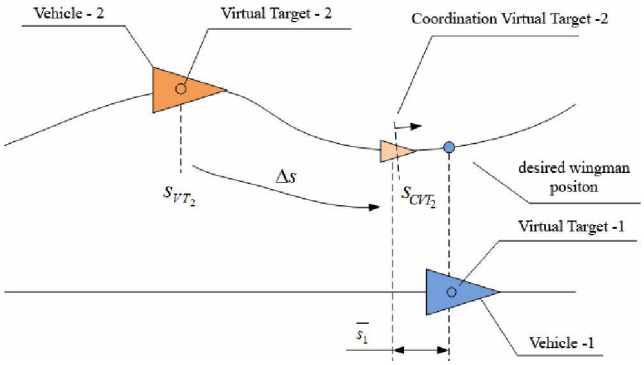

Fig.8. General wingman problem network

The key idea is to add a new virtual target, Coordination Virtual Target (CVT) for each wingmen vehicle. Controlling the speed of CVT, desired position of CVT is determined. Control law which ensures proper CVT curvilinear speed is

$$\dot{s}^*_{CVT_2} = U_1 \cos\bar{\beta} - \bar{k}_2 \bar{s}_1 \qquad (16)$$

where is total velocity of Vehicle-1, ¯ is the difference between the local path tangent given by position of the CVT and the virtual target of Vehicle-1, ¯ is projected longitudinal error, and is a tunable gain. CVT behaves like the virtual target for Leader, moving on the path of Wingman vehicle. When CVT is set on the path of wingman vehicle, curvilinear distance can be calculated. With reference to Fig. 8., Vehicle -2 is a wingman vehicle and formation position error is Δ = – . To obtain completely parallel formation * is set to zero.

V. SIMULATION RESULTS

In this section, simulation results are presented in order to illustrate the performance of the previously proposed guidance algorithm. The simulation case study which is presented here consists of two cooperation scenarios and this paper is focused only on them. Video and results of all other scenarios with different mission paths can be found online at http://labust.fer.hr/media/virtual.

A. Vehicle-following simulation results

The first scenario includes vehicle following for three vehicles where path to be followed is a circle with and constant path curvature which is in this case . At the moment the Leader is positioned at the origin of the NE coordinate frame and it is commanded to follow the circle. The first Follower is positioned at point and the second at point . Throughout the whole simulation reference distance between vehicles was kept at . Recorded responses of vehicle distances in the term of curvilinear abscissa can be seen in Fig. 10. Follower-1 generates path for Follower-2, so distance error must be observed relative to the vehicle- l which is in front of him. Fig.9. gives the path for all three vessels during the simulated mission. The control errors are shown in Fig. 11. and it is clear that after initial overshoots the vessels reach zero steady state error. An overshoot is direct consequence of efforts to get closer to the vessel as soon as possible.

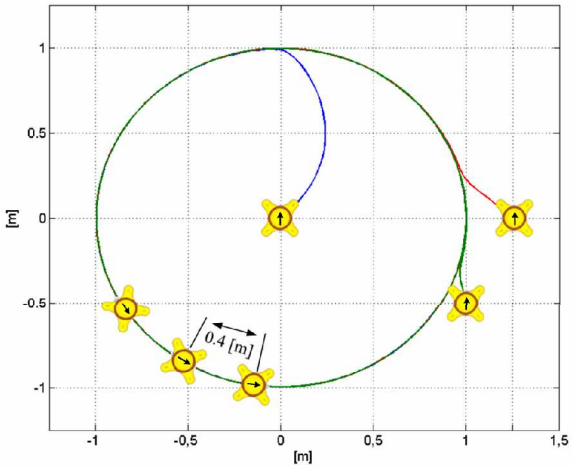

Fig.9.The paths of the vessels during simulation

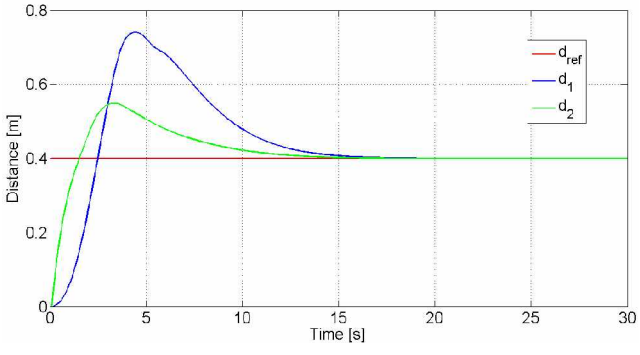

Fig.10.Distance between the vehicles

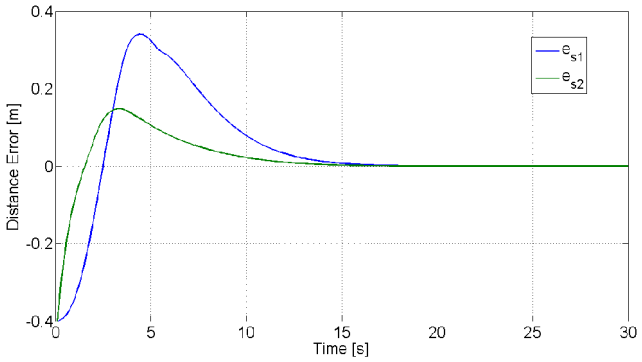

Fig.11. Response of distance error

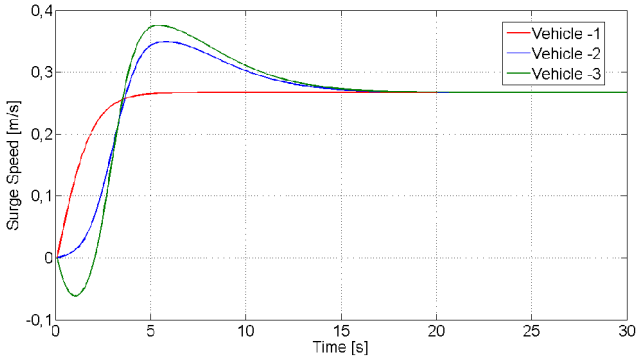

Fig.12. Surge speeds of the vehicles

B. Wingman Problem Simulative Results

For the Wingman framework simulation, a motion coordination task between three vehicles is presented. Leader vehicle executes same path following as in vehicle following (circle with) while other two vehicles have to follow concentric circles with and , respectively. During the whole simulation, desired parallel formation position is successfully achieved. Fig. 13. shows the convergence and maintenance of the desired formation while performing the path following tasks. It is obvious that vehicle which has to cross the longest path must have the largest surge speed. In Fig. 14. surge speeds of the formation members can be seen. Leader speed has smooth asymptotically response while Follower speeds are results of controlling surge forces in order to achieve the coordination task.

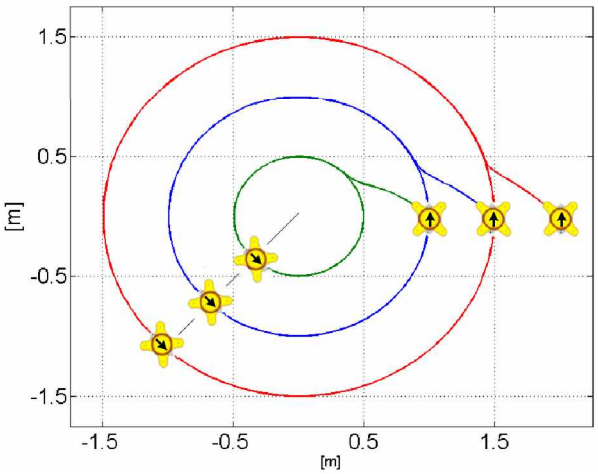

Fig.13. The paths of the vessels – The wingman problem

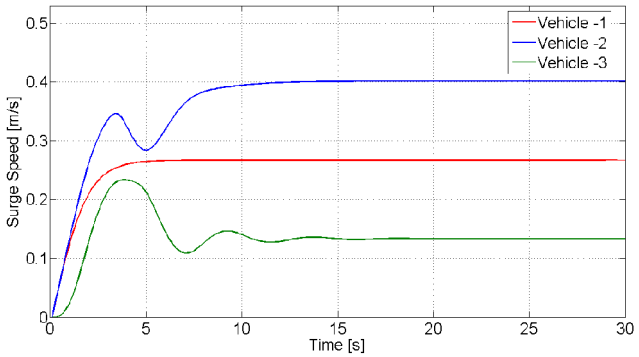

Fig.14. Surge speeds of the vehicles

It should be noticed, the Leader commanded surge force was kept constant throughout the whole simulation which resulted in a constant steady-state cruising speed. The Wingman vehicle surge forces are calculated according to (15). After transient time, even surge speeds of the Wingman vehicles are in steady-state. Considering that circles are concentric and differences in a radius between Leader vehicle and Wingman vehicles are same, the absolute difference between surge speeds would also be same.

VI. CONCLUSION AND FUTURE WORK

In this paper, a relatively new control approach in marine applications has been described. Firstly, single vehicle path algorithm is developed with the aim of expanding on cooperative tasks. Use of virtual target as control technique provides highly decoupling between the coordination system and each individual vehicles control system. The system stability and the performance of control system are shown in simulation results. The simulations prove the functionality of the proposed control law.

The future work will include implementing the developed virtual target algorithm on a real vessel to be used in field conditions. After successfully applied single vehicle path following algorithm, our final goal would be to achieve cooperation between two or more vehicles in field conditions.

ACKNOWLEDGMENT

The work was carried out in the framework of a Coordination and Support Action type of project supported by European Commission under the Seventh Framework Programme "CURE - Developing Croatian Underwater Robotics Research Potential" SP-4 Capacities (call FP7-REGPOT-2008-1) under Grant Agreement Number: 229553.

The authors would like to thank all the students who participated in the development of the laboratory marine platform.

Abstract - The construction of one-man-portable marine vessels presents a challenging task. One such vessel, the marine platform described in this paper, is actuated with four thrusters in an X-shaped configuration which enable motion in surge, sway and yaw degree of freedom. This configuration is highly convenient for dynamic positioning as well as path following. The platform is built in the Laboratory for Underwater Systems and Technologies and it comprises driver electronics for the thrusters, a GPS unit, a compass, batteries and a single board computer used for sensor integration and control. These components enable manual control from the ground station as well as autonomous operation mode. The communication with the ground station is accomplished using a two-way wireless link.
This paper focuses on the description of technical characteristics of the components as well as their integration. In addition to that, special attention is given to the control software developed in LabVIEW and its performances. Preliminary test results are given proving the functionality of the described technical system.

I. INTRODUCTION

Demand for small marine platform in marine robotics is very high, and its construction takes big part in whole project of creating an autonomous vessel. This one-man-portable platform is designed to be used on sea and lake for numerous applications, e.g. dynamic positioning, path following, virtual target algorithm, etc.

The platform is designed and developed at the Laboratory for Underwater Systems and Technologies (LABUST) by a group of students on master programme. It's made from polyester resin and some technical characteristics are shown in Table I. The platform is actuated by four SeaBotix® thrusters positioned in such a way that they form an x-shaped configuration as shown schematically in Fig. 1.b) what allows the design of complex guidance and control algorithms, especially dynamic positioning algorithm. The platform is equipped with two single board computers and with various positioning and communication devices which allow autonomous work with other vessels or divers and manual control by operator from the ground station.

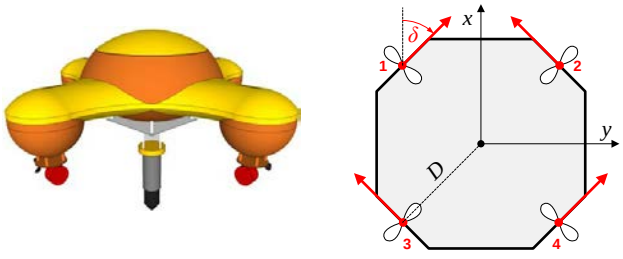
As LABUST already developed two platforms for testing in the pool in laboratory conditions [2], the main motivation for building this type of a platform was to construct the platform which could be tested in real and harsh environment in which marine vehicles operate, characterized with unpredictable disturbances (waves, winds and currents) and to assist divers in underwater navigation and communication with the ground station. Further on, the developed platform will be used in cooperative guidance of unmanned underwater or surface vehicles. This application would allow more precise underwater localization and online mission replanning. The relevance of the envisioned project is significant from the educational side, and the interdisciplinarity through marine robotics.

This research is divided into three steps:

- Step 1 includes the design of the small overactuated marine platform and acquisition of navigation devices;
- Step 2 includes integration of navigation devices, communication with ground station and software testing [1];
- Step 3 includes the design and implementation of algorithms for dynamic positioning, path following, virtual target, etc.

Step 1 was successfully ended in July 2011. and platform was ready for testing in pool conditions (Fig 2.).

This paper presents the next step in research activities regarding the implementation of navigation devices and testing them. It also presents how connection is established between platform, ground station and other vessels or divers. The results presented show that proposed navigation and communication devices can be used on a real system in real-time environment.



a) b)

Fig. 1. a) Virtual model of the platform for dynamic positioning and b) x-shape actuator configuration.

Step 3 is work currently in progress and the preliminary results are reported in [3] and laboratory tests can be seen in [7] and [8].

TABLE I. SOME CHARACTERISTICS OF THE PLATFORM

Height [m]	**0.35**
Width [m]	**0.707**
Length [m]	**0.707**
Weight [kg]	**≈ 25**

The paper is organized as follows. Section II describes general information about all devices used in platform. Section III presents testing of GPS module and gives experimental results in real environment. Section IV presents application interface in LabVIEW for control and communication. The paper is concluded with Section V.

Fig. 2. Platform for dynamic positioning constructed in LABUST

II. DEVICES USED IN PLATFORM

A. Advantech PCM-3362 single board computer

The single board computer used in platform is equipped with Intel® Atom processor with Microsoft® Windows operating system. This system is used for sensor integration because some navigation devices work only on Microsoft® Windows platform. Single board computer is used because of its reduced size and very low power consumption which is very important due to battery autonomy.

Fig. 3. Advantech single board computer

The computer is connected with wireless module and real-time single board computer via Ethernet, and its USB ports are used for connecting navigation devices to the system. LabVIEW application used in this system collects all data from sensors and sends it to real-time computer. Application communicates with other vessels or diver via USBL module and with ground station via wireless module.

B. National Instruments sbRIO-9642 real-time single board computer

The real-time computer from National Instruments with 400MHz real-time processor and 256MB of non-volatile memory is used for deterministic control of platform. Main LabVIEW application runs on this module and receives data from sensors or ground station to control the platform and other vessels autonomously or manually. sbRIO is connected via RS-232 port to driver electronics which drives the SeaBotix® thrusters. This module is used due to its high performance which could not be achieved with common single board computer.

C. USBL module

USBL (Ultra-short baseline) [4] is underwater acoustic localization method. It consists of transponder, transducer and control unit. Transponder is fitted on underwater vessel or diver which communicates with control unit via transducer and calculates position according to transducer position which is obtained from GPS module

Fig. 4. National Instruments sbRIO-9642 module

Data which control unit sends to single board computer is described in Table II. From this data the projected distance between platform and underwater vessel or diver must be calculated, as shown in Fig. 5. Projected distance can be easily obtained by simple equation

$$Projected\ Distance = \sqrt{(SlantRangeFromUSBL)^2 - (z)^2} \quad [1]$$

BearingFromUSBL [rad]	**Transponder bearing**
USBL_z [m]	**Depth of transducer head**
USBL_yaw [rad]	**Transducer heading**

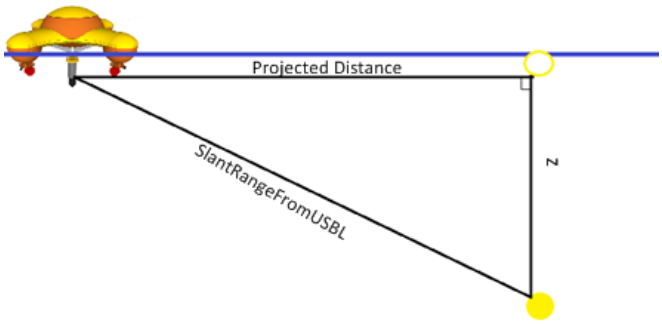

Fig. 5. Relevant measures obtained from the USBL sensor

D. GPS module

GPS module communicates with computer via USB port and sends NMEA sentences [6] with frequency of 10Hz. NMEA sentence which is used for acquiring GPS data is shown in Table III. Every GPS has horizontal and vertical variable error [5] in calculating the exact position which is big problem for dynamic positioning when platform moves with slow speed and has very little variation of position. GPS error can be calculated using S/N ratio obtained from each satellite to which it is connected. Error information which is important for platform positioning is called HDOP (Horizontal Dillution of Precision)

E. Compass module

Compass module works same as GPS module. It can be connected to computer via USB port or RS-232 port with output frequency of 40Hz. Module sends NMEA sentences which data is shown in Table IV. This module also has 3-axis accelerometer which can be used for speed and position measuring.

III. TESTING OF GPS MODULE

GPS module was tested prior to platform construction completion therefore it was done on ground. Couple of tests were done with two GPS devices; one is GPS module which is used in platform and the other is built-in GPS module in Getac B300 notebook which has output frequency 0.5 – 1Hz. One test was done in environment with many obstacles which interfered with visual connection of GPS module with satellites and the other test was conducted with clear view to the sky. Results show better reception with GPS module used in platform with higher output frequency than built-in GPS module which is visible in Fig. 7. and Fig 8.

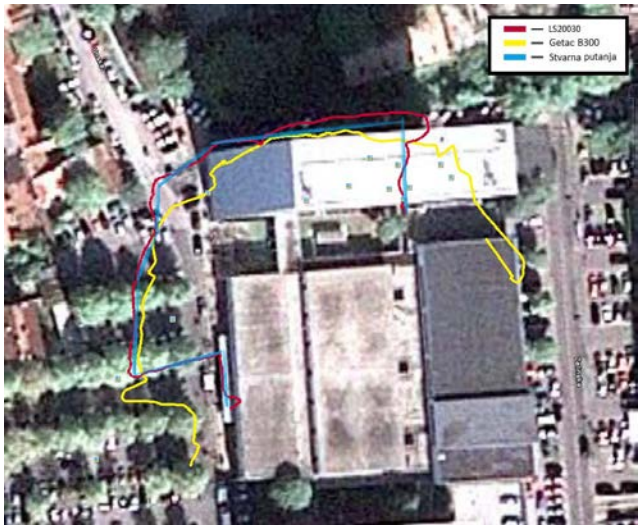

Fig. 7. GPS testing – different output frequency – noisy environment

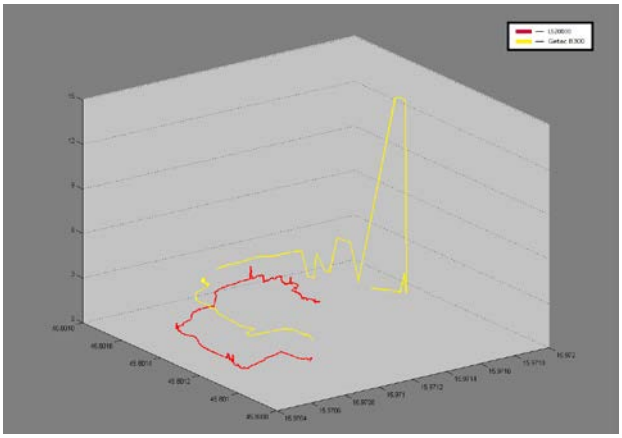

Fig. 8. Horizontal dilution of Precision – different output frequency – noisy environment

Results show that GPS module used in platform has better reception, always has more satellites connected and essentially smaller horizontal dilution of precision than the built-in GPS module. In second test HDOP is very low due to clear view to the sky and more satellites connected to GPS and that leads to very good tracking (Fig. 9 and Fig.10). It means that GPS module which is intended to be used in platform is well-chosen and with implementation of Extended Kalman Filter (EKF) will give good basis for dynamic positioning.

Fig. 9. GPS testing – output frequency 10Hz – clear view to the sky

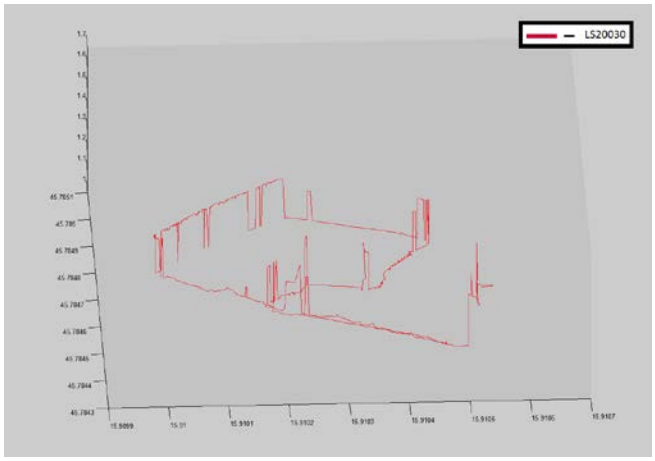

Fig. 10. Horizontal dilution of Precision – output frequency 10Hz – clear view to the sky

IV. LABVIEW APPLICATION

With real-time single board computer from National Instruments using LabVIEW environment imposes as the right choice. With LabVIEW, connecting the platform with ground station gives immediate access to platform control as well as monitoring of measurements on the platform. Real-time module gives numerous possibilities in design of controller and complexity which could never be performed on stock single board computer with desired efficiency. Single board computer also controls the other underwater and surface vessels via RF and USBL module. Whole concept of control is shown in Fig. 11.

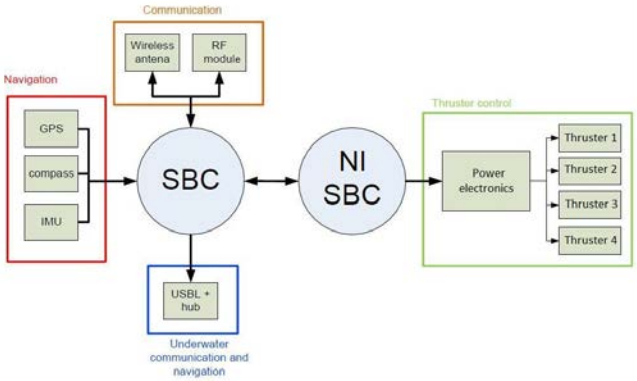

Fig. 11. Schematic representation of the hardware infrastructure

V. CONCLUSION AND FUTURE WORK

This paper describes the implementation of navigation and communication devices and testing of navigation devices. In addition to that, special attention is given to the control software developed in LabVIEW and its performances. Preliminary test results of GPS module are given proving the functionality of the described technical system.

The experiments were carried out in the Laboratory for Underwater Systems and Technologies (LABUST) at the University of Zagreb. The main task of the experiments was to verify the functionality and accuracy of GPS module.

The future work will include implementing complex controller for platform and other vessels. The final goal of this project is to achieve cooperation between marine robotics and human divers where the proposed platform will serve as an aiding system in diver navigation and communication with ground station will give more possibilities in research of underwater treasure.

ACKNOWLEDGMENT

Evolution of automatic robot control with genetic programming

***Abstract*—This paper investigates the problem of automatic control of a robot model in an arbitrary two-dimensional environment. The robot control is based on behavior evolution with the use of genetic programming (GP). A simulation environment is developed which allows automatic synthesis of different behaviors suited to the environment and user requirements. The influence that different robot properties and learning mechanisms have on the evolved behavior are studied in depth. The results show that the presented approach is able to produce effective control procedures.**

I. Introduction

Autonomous mobile robots are becoming more and more important and available to a widening range of uses - from autonomous vehicles to household appliances. They are expected to solve tasks that humans are not able to cope with in real-time conditions, or at least to simplify the tasks humans perform on a daily basis. This requires extensively autonomous robots, because with growing complexity of the problems it will be no longer possible for the programmer to take all eventualities into account from the outset. Developing robust control programs is an active research issue in many environments.

Lately, this development has also been performed as an evolution process, where appropriate logic is automatically generated with the help of evolutionary algorithms [1], [2], [3], [4]. This paper is an example of this approach, where genetic programming (GP) is used to evolve control algorithms for the desired robot behavior. The main advantage of the presented method is its reusability for different target functionalities of the evolved control program - e.g. finding a route, mapping an unknown environment etc.

In addition to the approaches previously described in the literature, this paper briefly investigates the generalization ability of the method and suggests the means to obtain it. We also include memory capabilities to the control program and show the advantages it may have to the development of target behaviors in a complex environment. Finally, the performance of the algorithm and quality of the obtained solutions is improved with the algorithm parallelization in a distributed manner.

To evolve the control algorithm, we use simulated robots with sensors with arbitrary placement. Simulating robots allows investigation of variable architectures and rapid prototyping, which is, compared to experiments with real hardware, less expensive. Additionally, simulation process is fast and easily reproducible.

The remainder of this paper is organized as follows: Section II states the problem and simulation environment, as well as related work on the subject. Section III describes the genetic programming and related evolution of the control algorithm; Section IV presents experimental results and efficiency analysis, and short conclusions are given in Section V.

II. Automatic Control of a Model Robot

The problem of automatic control design may be formulated with various assumptions; one of the most distinctive features is the knowledge of the environment. The environment may be predefined and given as an input to the robot, i.e. we may have the information about the topology which may be used by the control algorithm. On the other hand, the autonomous agent may have to discover the topology of the environment, and any previous information about it is unavailable. In this work we concentrate on the latter case, where the aim is to develop a desired behavior in an unknown surroundings.

The model of the simulated robot is mostly equivalent to the model from [5], where a wall following behavior was evolved. The robot has 12 sensors, equally distributed over 360 degrees, which report the distance to the nearest wall as a floating point value. These sensors are the only direct information the robot is given about its environment. As the robot moves, the sensor data changes accordingly, depending on the room topology.

The robot's ability to move is implemented with the following possible actions:

- turn left 30 degrees;
- turn tight 30 degrees;
- move forward by a constant distance and
- move backward by a constant distance.

The control program has to generate one of these outputs as a result to any combination of current robot state and sensor input values. After the defined action is performed, new input values are collected and another step may be taken. Finally, the robot has the option to stop any movement if a certain condition is met (i.e. a target position is reached or a time interval has elapsed).

In the simulation process, the robot is simulated within an appropriate software framework in discrete time steps. In each time step, input sensor values are calculated and fed to the control program, which decides upon an action. The action is then simulated by updating robot position or orientation and the process is repeated. The program is presumed to produce one action at a time, as opposed to a series of actions.

Using a different program, various target behaviors may be developed. The control program itself may be human-made or previously evolved with genetic programming, which is detailed in the next section.

III. Genetic Programming Applied to Behavior Modeling

A. Genetic programming

Genetic programming [5] is an optimization and machine learning technique that uses evolutionary concept to automatically discover symbolic procedures (functions, programs) to the problem at hand. The main idea behind GP is that the solution to the problem may be represented as a (computer) program, in most applications in the form of a tree (which allows mapping to any procedural language). The elements of the programs (tree nodes) must be predefined by the user and must be sufficient to describe the solution to the problem (e.g. mathematical and logical functions, actions such as move forward, turn left etc). The algorithm randomly generates programs (potential solutions) and evaluates each program on a predefined set of test cases (e.g. how well does the program control a robot). Each potential solution thus receives its quality estimate - the fitness value - which is then used in the selection process.

The selection process imitates natural evolution where weaker individuals (solutions) are eliminated, and better individuals survive. Additionally, better individuals also participate in recombination, where two (or more) individuals are combined to form a new solution. The algorithm also incorporates a mutation mechanism, where a single individual is subject to a change, with a relatively small probability. The process continues, building new generations from old ones, until a suitable termination criterion is reached. These criteria usually include finding a solution of the desired quality or performing the algorithm for a predefined amount of time. The examples of human-competitive results of genetic programming may be found in [6].

B. Evolving a robot with GP

In this work the control program is represented as a tree, where each node may server as an input, perform a certain logical function or a certain action. There are two main types of tree nodes which every generated program contains - terminal and function nodes. Terminal nodes are the leaves of tree program structure; they don't have children nodes and they return certain value which may be used by their parent function node.

Terminal nodes in this application can be one of the following:

- 12 different nodes (S01, S02, ..., S11) that return the distance from one of 12 sensors surrounding simulated robot;
- a node which returns dynamically computed shortest distance among all the sensors (SS);
- nodes which perform one of four basic motor functions (MF - move forward, MB - move backward, TR - turn right, TL- turn left), in which case they also return the shortest distance from three front sensors.

Function nodes are the inner nodes of a tree and have at least one child node. In our implementation each function node controls the program flow in a specific manner. Function PROGN2 is the simplest function node which is used for connecting parts of program together. It evaluates both of its two subtrees in sequence, and returns the value from the second one. Function IFLTE stands for 'If Less Than or Equal' and has a total of four child nodes. It is used for deciding on a behavior based on results from the first two of its nodes. If the value received after traversing the first subtree is less than or equal to the value received from its second subtree, the third subtree will be traversed and its value returned, and if not, the fourth subtree will be traversed and its value returned.

In this work we also include the optional memory functions, denoted IMEM1 and IMEM2, which have the ability of keeping the track of the internal state of the robot. Function IMEM1 requires that the robot keeps track of coordinates of walls he was already close to in his run. The function then controls the program flow by checking the table of visited walls; if there exists a wall which is directly in front of the robot, it evaluates and returns the first subtree. If such a wall doesn't exist, it evaluates and returns the second subtree value.

Function IMEM2 has three child nodes, and it requires remembering the history and location of previous robot actions. It decides which subtree will be evaluated by checking if the table of all actions for the current position contains the action from the first child node. If it does, it evaluates and returns value from the second subtree, and if it doesn't, the third tree's value is evaluated and returned.

The inclusion of memory functions may serve the purpose of completing the tasks whose solution cannot be represented with a stateless program. An example of this problem includes the task of visiting the walls in an unknown room which has inner walls that are not connected to any of the outer walls (see Fig. 2). This kind of control problem was successfully solved with the help of these functions.

An example of an evolved control program comprising of the described nodes is given in Fig. 1.

In this work we used two different target behaviors. One goal is visiting all walls in an arbitrary unknown room, and the other is traversing the whole room surface. The examples of both evolved behaviors are given in Fig. 2 and 3.

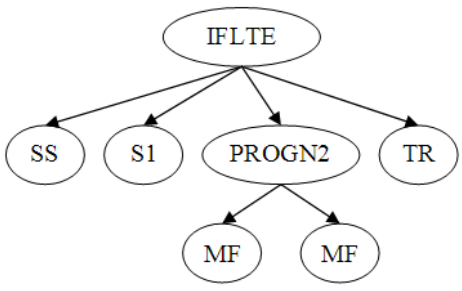

Figure 1. An example control program (genetic programming tree)

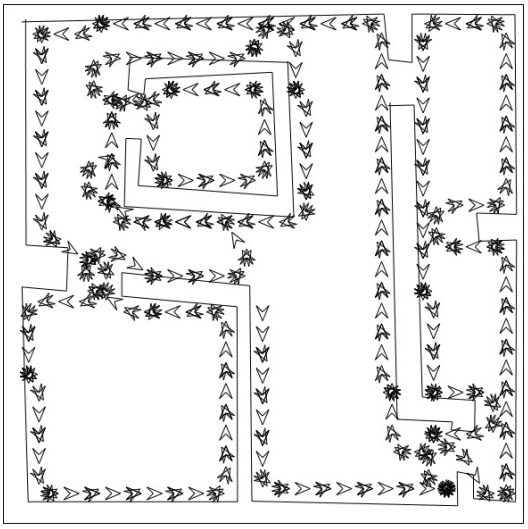

Figure 2. An example of an evolved behavior: following walls in unknown room

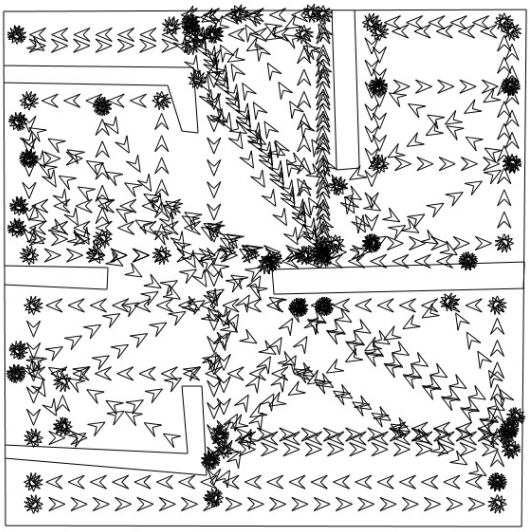

Figure 3. An example of an evolved behavior: covering an unknown room

C. Evaluating a control program

During the evolution process, a great number of candidate solutions (control programs) is created that have to be evaluated. Evaluation is performed by simulating the robot movements in a given environment using the selected program. Each solution (individual) is given a fitness value that is used in a selection process and represents the individuals ability to compete with other individuals.

In both of the goals used in this work it is required that the robot drives over a set of targeted positions. Because of this property, the fitness function value is defined by the number of visited discrete *target locations* (each location is counted only the first time that the robot moves over it). The target locations in the simulation process are set in a uniform grid over the room surface or along the walls. The fitness value of a control program is thus represented as the total number of visited target locations. Although the number of target locations depends on the desired behavior, room shape and the number of rooms used in the learning, all the scores in the results are scaled to a maximum value of 100.

Additionally, each action a robot performs (a single movement or a single rotation) is presumed to take a constant amount of time, and is represented as a single simulation *time step*. If two different evolved programs visit the same number of target locations, the one which has visited them in less time steps is considered better.

It is important to note that, to evolve one or the other behavior, no modifications are needed in the GP evolutionary system other than the appropriate calculation of the fitness function. In other words, to evolve a different (custom) behavior, only the fitness function needs to be altered, whereas the functional and terminal tree elements may remain the same.

IV. Results and Analysis

The following experiments aim to evaluate the GP efficiency in evolution of the target robot behavior. The following parameters were used in all experiments, unless stated otherwise:

- population size of 1000 individuals;
- termination condition of 500 generations;
- at least 10 repetitions for all configurations.

A. Initial tree depth parameter

The purpose of this experiment is to empirically estimate the appropriate initial tree depth that any solution may attain. This parameter is one of the most influential ones in genetic programming [5]. On one hand, it should be large enough to allow the creation of the programs of needed complexity, i.e. the ones that can represent the solution to the problem. On the other hand, it should not be too large so the search space is appropriately limited and so that the complexity is maintained at the lowest possible level.

The experiment was conducted by learning on 10 manually selected rooms and summing the fitness function of the same program on all the rooms. The convergence results are presented as the average score of best individuals in all the repetitions (i.e. average fitness value of best individuals at a certain generation across all repetitions). The convergence rates are shown in Fig. 4, and the corresponding average number of time steps in Fig. 5. The actual values for best individuals at the end of runs are given in Table I.

While the solutions with initial depth of 3 are clearly worse than the others, the results show that there is no significant statistical difference between solutions with depth of 4-7. On the other hand, the average size (number of nodes) of solutions with initial depths greater than 4 was several thousand, whereas with depth 4 it averaged on a few hundred at most. For these reasons, the initial depth of 4 was chosen for the remaining experiments.

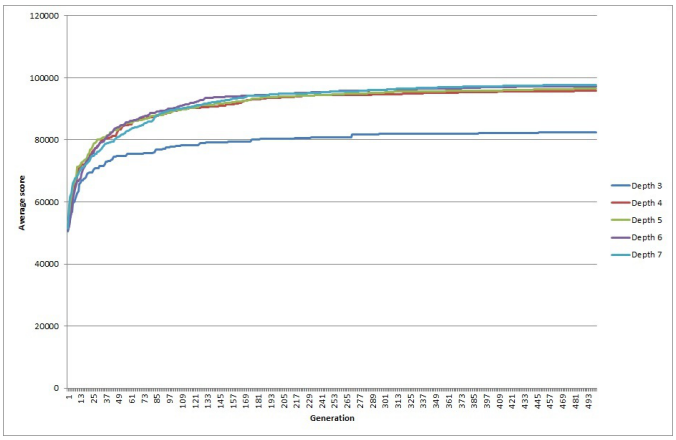

Figure 4. Average score for different initial tree depth

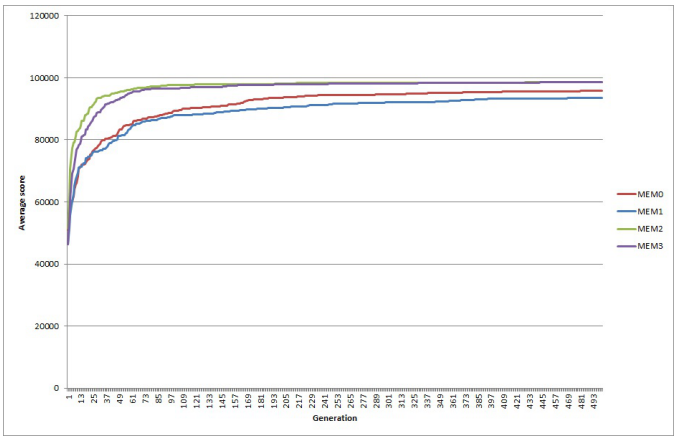

Figure 6. Average score for different memory configurations

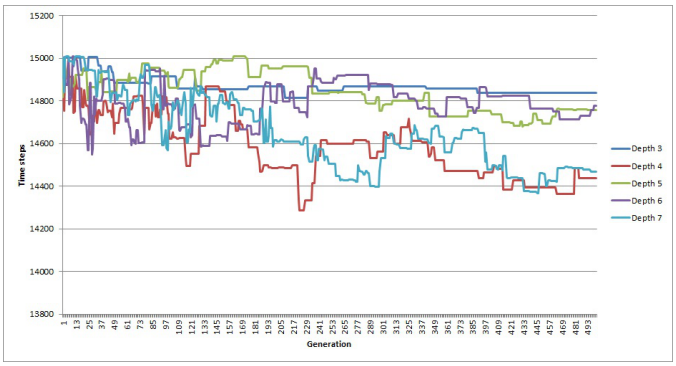

Figure 5. Average time steps for different initial tree depth

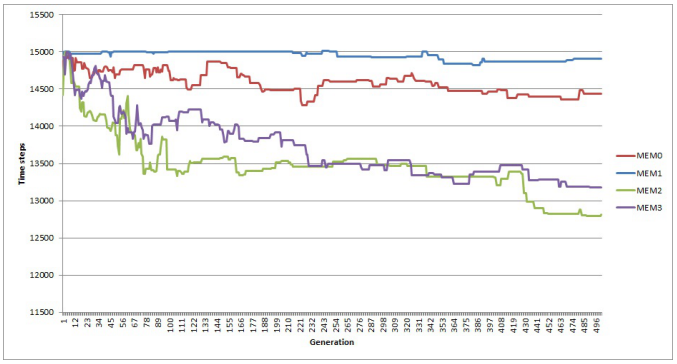

Figure 7. Average time steps for different memory configurations

B. The influence of memory functions

In this experiment we tried to estimate the influence of implemented memory functions (IMEM1, IMEM2, Sec. III) on the efficiency of the evolved control programs. A total of 4 configurations are investigated with learning on 10 different rooms as in the previous experiment, with the following notation:

- MEM0: memory functions are not used;
- MEM1: function IMEM1 is included in the function set;
- MEM2: function IMEM2 is included in the function set;
- MEM3: both functions IMEM1 and IMEM2 are in the function set.

The convergence results for these configurations are given in Fig. 6, and the corresponding average time steps in Fig. 7. Table II shows the fitness values of best individuals and their distribution at the end of the runs. The results indicate that the inclusion of IMEM2 function is beneficial to the evolution of control programs, while the IMEM1 function can even degrade the average solution quality. This suggests that, while it may complicate the development and implementation, a memory function such as IMEM2 is highly desirable in achieving complex behaviors.

C. Single-population and multiple-population GP

Since the evolution process may be quite time-consuming, and it should also be repeated a number of times to obtain the best possible result, a common extension to many evolutionary systems is their parallelization [7], [8]. In this work we chose to implement a distributed algorithm, which may be deployed on a network of computing nodes, as well as on a single multi-core machine [9].

Apart from the speedup, the parallelization may also result with different algorithm properties, such as the improved convergence rate or probability of finding the global optimum.

Table I
FITNESS VALUES OF BEST INDIVIDUALS FOR DIFFERENT INITIAL TREE DEPTH

Depth	3	4	5	6	7
Min	74.8	91.2	94.2	95.4	95.4
Average	82.5	95.8	96.5	97.3	97.8
Max	89.8	97.7	98.2	99.0	99.1

Table II
FITNESS VALUES OF BEST INDIVIDUALS FOR DIFFERENT MEMORY CONFIGURATIONS

Mode	MEM0	MEM1	MEM2	MEM3
Min	91.2	89.2	97.8	97.9
Average	95.8	93.6	98.7	98.6
Max	97.7	96.8	99.3	99.3

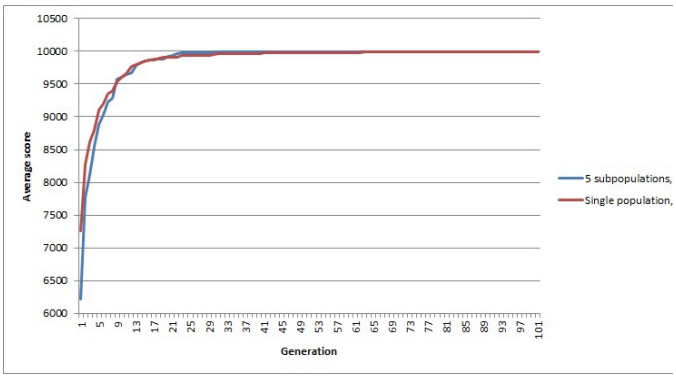

Figure 8. Average score for sequential and distributed algorithm

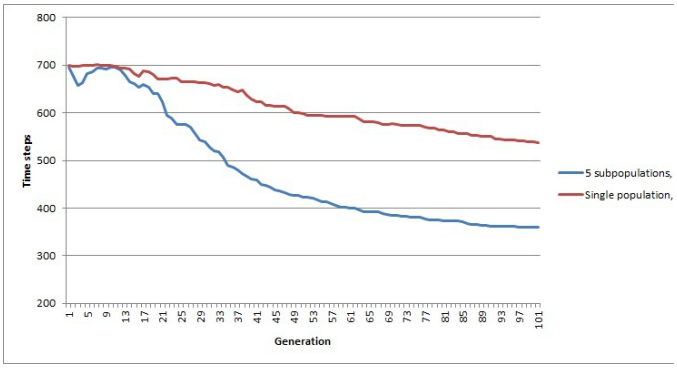

Figure 9. Average time steps for sequential and distributed algorithm

In this experiment we compared the following configurations:

- single population (single island), 2000 individuals;
- 5 subpopulations (islands), 400 individuals each.

In the distributed version, the migration interval is 5 generations, the number of migrants is 10% of the island population, and the migration pattern is a fully connected graph. The convergence results and number of time steps are shown in Fig. 8 and Fig. 9. The difference in fitness values are negligible in this experiment, since both variants exhibited similar average score. On the other hand, the solutions evolved in the distributed version achieved better results in terms of total number of time steps, which is shown in more detail in Table III. This indicates that the distributed version may have the potential to generate better solutions in terms of program efficiency, while maintaining the same fitness value level.

D. GP generalization ability

The last experiment considers the quality of the evolved solutions when used in an unseen environment. In the learning process, the control programs are evolved using the simulation of the robot in one or possibly more different rooms. After the control program is evolved, it should be tested in a previously unseen environment to asses its generality. The problem of GP generalization ability has been studied before [10] and the findings suggest that including a number of test cases (e.g. simulated rooms) may be beneficial in the search for more general solutions.

Table III
TOTAL TIME STEPS FOR BEST INDIVIDUALS, SEQUENTIAL AND DISTRIBUTED ALGORITHM

	5 islands, 400 individuals each	1 island, 2000 individuals
Min	220	292
Average	359.55	536.95
Max	700	701

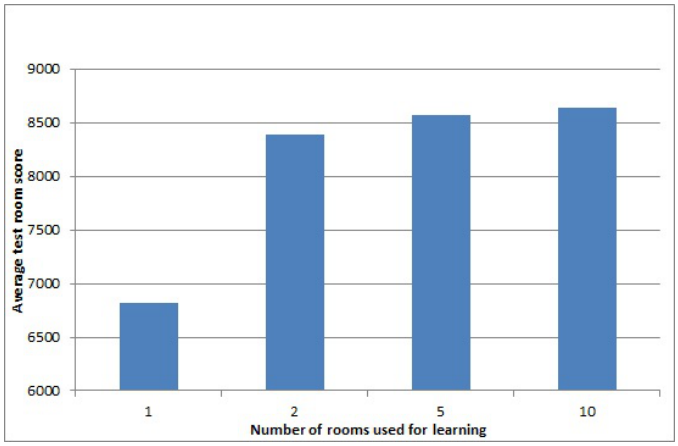

Figure 10. Average score for different number of learning rooms

Table IV
FITNESS VALUES OF BEST INDIVIDUALS, DIFFERENT NUMBER OF LEARNING ROOMS

	1 room	2 rooms	5 rooms	10 rooms
Min	6.85	3.85	45.6	16.8
Average	68.2	83.9	85.7	86.4
Max	100	100	100	100

In this experiment a total of 60 rooms were available in the learning process, and in each configuration a different number of randomly selected rooms is used in every algorithm run. The number of learning rooms assumed values of 1, 2, 5, and 10. After the learning process, following the standard machine learning paradigm, the best solution from every run is evaluated on a single room that was unavailable in the evolution process. The results in terms of average fitness are shown in Fig. 10 and in terms of total time steps in Fig. 11.

The presented results clearly indicate that the increased number of learning rooms enables the control program to behave better in an unseen environment. Note, however, that this does not guarantee good behavior in every instance, since the generalization ability depends greatly on the features of rooms that are used in the learning process.

V. CONCLUSIONS

This paper presents the use of genetic programming in the evolution of control programs for a robot in a simulated environment. The results show that this method is able to produce control programs that satisfy the functional requirements of robot behavior. Additional results may be summarized as follows:

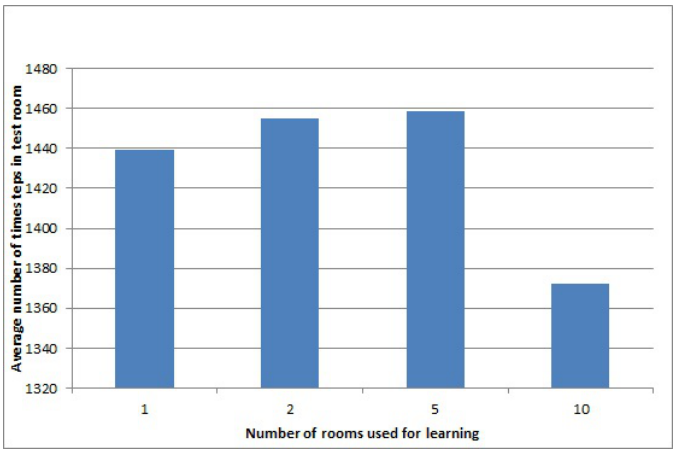

Figure 11. Average time steps for different number of learning rooms

- the memory capabilities of the control programs may be beneficial and are necessary for certain complex behaviors;
- distributed genetic programming may produce results of better quality;
- a larger number of learning instances is necessary for successful generalization.

Further work in this area may include the implementation of this approach for a real robot with actual sensor inputs. In this paper only the simulation results are reported, but in a real-world scenario the input noise must also be taken into account, and its influence on the solution quality must be evaluated.

Automated Design of Combinatorial Logic Circuits

***Abstract*—This paper deals with automated design of combinatorial circuits with the use of *Cartesian Genetic Programming* (CGP). The synthesis is based on user specifications of network functionality, while the network structure may be predefined. The results show that CGP approach is able to match the desired functionality while preserving other performance criteria, such as latency and number of gates. Additionally, the evolution process may use Verilog network descriptions as input files, which facilitates the design for larger number of inputs and test patterns.**

I. Introduction

The design of combinatorial electronic circuits is a complex task requiring a significant effort and time cost of the involved experts. This process may include the identification of appropriate target gate type and technology, minimization and optimization subject to various domain specific constraints (such as timing, number of gates, etc.) and mapping the design onto the target device [1]. Lately, this problem has been addressed with a black-box approach where evolutionary algorithms, such as genetic algorithms and genetic programming, have been used to evolve the desired functionality and other aspects of the target circuitry. This approach has come to be known as *Evolvable Hardware*, which is a generic term used to denote various methods of designing electronic circuits with evolutionary metaheuristics [2][3].

In this paper we present an application of *Cartesian Genetic Programming* (CGP) to design combinatorial circuits and evaluate its efficiency. The procedure is fully automated, without the need for human expert intervention in the process. The target circuitry is evolved based on the desired logical functionality. The definition of the circuit functionality is based on two components: first a behavioral description of the network is defined in Verilog. The system then internally builds the executable simulation module and the internal truth table which is used in the evolution process. The results show that the presented approach may produce solutions with full compliance with desired functionality.

The rest of this paper is organized as follows: Section II briefly revises this area, while in Section III we describe the CGP and the structure of our evolutionary system. Section IV describes the use of Verilog for the specification of circuit functionality, and Section V gives examples of the application and the obtained results.

II. Automatic Synthesis of Combinatorial Circuits

As the production of electronic circuits increases, the demand in both financial and time resources calls for different design methods. The traditional approach includes assigning human experts for the development of functional components, but this may quickly become inefficient for a large number of networks with even slightly different requirements [2]. Partial or complete automation of this task has become an active area of research which includes various algorithms and technologies.

One possible approach to this problem is the use of evolutionary algorithms (EA), in which the desired functionality is automatically constructed using the principles of evolution. In an EA, a set (population) of possible solutions (individuals) are created and modified in a sequence of iterations (generations), to yield improved properties over time (in the evolution process). In each generation, all the individuals are evaluated and their quality is usually represented with a single *fitness value* (e.g., the number of correctly mapped outputs for a set of input vectors). Individuals undergo random changes using a mutation operator and they combine their structure creating new solutions with a crossover operator. Finally, based on their fitness, the selection operator imitates the natural evolution by selecting better individuals for the next generation.

The evolution process is stopped when a predefined criterion is met, e.g. when a 'satisfactory' solution is evolved or after a predefined time has elapsed. The final solution is usually the best individual from the last generation.

This approach is stochastic, and does not guarantee finding an optimal solution in every run (e.g. a circuit with full functionality). On the other hand, the evolution can be repeated many times with no additional effort, which can produce acceptable solutions with variable success rate. Although this method may be used to synthesize various types of electronic circuits, in this work we concentrate on combinatorial circuits only.

A common method of evaluation of candidate combinatorial circuits includes a set of input vectors and a corresponding set of output values. The number of successfully mapped outputs may be directly used as a fitness measure.

However, there are other network properties that may be taken into account, such as the total number of gates, number of levels, propagation delay etc. These properties may be explicitly included in the fitness function, which can lead to multi-objective evolutionary algorithms. In this work we consider a single fitness value based only on functionality, as is the case in most of similar applications [4][5][6], but additional properties are also examined and reported. One advantage of evolutionary synthesis is that it offers a set of potential solutions (instead of just one); if there are more individuals with the same level of functionality, we may choose the one which exhibits better performance in the desired secondary objective.

III. Network Design with Cartesian Genetic Programming

A. Cartesian Genetic Programming

The *Cartesian Genetic Programming* (CGP) was actually inspired by the structure of FPGA components [1][7][8]. In CGP, a representation (also known as *genotype*) of a potential solution is a vector of constant length consisting of natural numbers. The vector is used to construct a directed graph, which in turn can be interpreted as an FPGA structure, where cells are represented with graph nodes and connections with arcs in the graph. An example CGP individual and a corresponding directed graph are shown in Fig. 1.

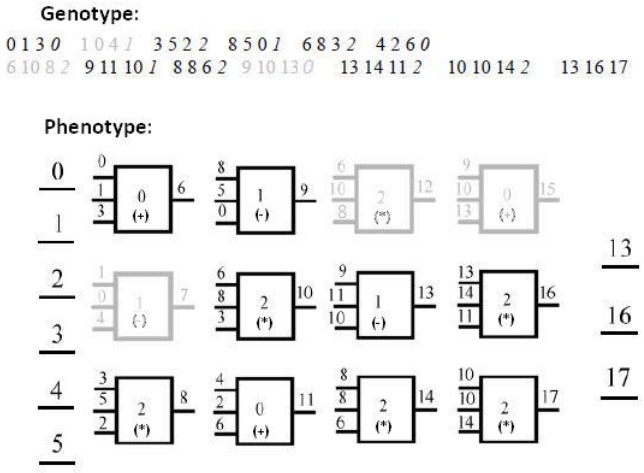

Fig. 1: CGP example; mapping genotype (vector) to phenotype (directed graph) with 6 inputs, 3 outputs and 3 functions in squares (0 as summation, 1 as subtraction and 2 as multiplication). Grey nodes represent unconnected nodes to the outputs.

In this example, each node has an equal number of inputs (3) and a single output. Each node performs one function from a set of predefined functions (descriptive symbols are in brackets), which is denoted with a single index value. In this way, each node is represented with four values in the vector: the first three are the inputs, and the fourth one is the function index. The position of those values in the vector corresponds to the node placement in the graph (top to bottom, from left to right). Node outputs are connected to input(s) of nodes in the next column (or further than the next one); nodes in the same column cannot be connected. The node interconnectivity is defined by the *levels back* parameter, which determines how many previous columns of nodes may have their outputs connected to a node in the current column (the primary inputs are treated in the same way as node outputs). In this example, levels back parameter is two columns.

The CGP allows for redundancy in its representation, which may be caused with the following [9]:

- *node redundancy* occurs if a node is not connected (directly or through other nodes) to any of the outputs;
- *functional redundancy* is caused with a number of nodes comprising a function that could be represented with a smaller number of nodes;
- *input redundancy* occurs if an input is not connected with any of the nodes.

Node and input redundancy are considered beneficial, since they allow *neutrality*. Neutrality represents presence of multiple different vectors with the same fitness value during evolution process. Functional redundancy, on the other hand, is undesirable since it increases the solution size and the problem search space.

An important component in using CGP is the definition of parameters, since they may have a great influence on the quality of solutions. The parameters that are inherent to the CGP include the number of rows and the number of columns in the representation, as well as the number of input connections for nodes in the graph. The choice for these parameters should be guided with the expected complexity of the combinatorial circuit we are trying to synthesize; this is a crucial decision and the one which needs the greatest amount of domain knowledge.

Additional parameters must be defined that are a part of the initial problem, such as the number of inputs and outputs of the network, the set of functions that can be used as graph nodes and levels back parameter.

B. Evolution of Combinatorial Circuits

In the process of evolution, first an initial population of solutions is created randomly, following predefined rules for generating valid individuals [9]. The population size must be defined beforehand, and it remains constant during the entire run. In each generation, all the individuals are evaluated (more detailed in Sec. IV) and being subjected to genetic operators - mutation, crossover and selection.

The CGP defines common crossover and mutation operators, which allows this genotype structure to be used in any evolutionary algorithm. There are many variations of these, but here we only describe the variant used in this work. The mutation operator chooses a random point in the vector that represents an individual, and randomly changes the value at the chosen position. Following predefined rules, the change in the chosen value will depend on the position in the vector (i.e. whether it represents an input of a node or its function), so the operator always yields a valid individual [9].

The crossover operator creates a single new individual (child) from two existing individuals (parents). The operator itself is relatively simple, due to the CGP structure: a single crossover point is selected as a random position in both parental vectors. The first part of the child, before the crossover point, is taken from one of the parents and the other part is taken from the other parent. No additional conditions are verified, because this operation always produces a valid individual.

The selection operator is a part of the evolutionary algorithm and is not inherent to the CGP itself. In our experiments a

simple roulette-wheel selection was used for parent selection [10].

IV. Circuit Specification using Verilog

As mentioned in Section II, the circuit functionality may be defined with the truth table which defines the desired output for every possible input. However, if the number of inputs and outputs is larger, the truth table becomes cumbersome to handle and construct, especially when devising multiple circuits. An alternative way of defining the circuit function - and not its internal structure - is using a hardware description language. The approach and implementation presented in this work allows circuit description in Verilog [11].

The choice of Verilog as a description language was guided with the availability of tools for conversion of Verilog specification into program code that could be used within the CGP evolutionary algorithm. CGP was implemented with the help of *Evolutionary Computation Framework* (ECF), which is a C++ framework implementation of various evolutionary techniques [10]. The conversion from Verilog to a C++ code was made possible with the Verilator tool [12][13].

Verilator takes as the input a Verilog description of the circuit and generates C++ code that is able to simulate the desired network behaviour. Additional functionality is added, in the form of wrapper files, that allow the simulator to be called from the evolutionary system [9]. The simulator can be called every time a potential solution needs to be evaluated, and the simulator output is compared to the output of candidate circuit from the population.

To avoid repeated simulation for the same input vector (repeating the calculation to obtain the same output), a separate *input generator* module is devised that uses the simulator to generate an internal truth table of the predefined size [9]. This allows faster evaluation of different individuals and is a complete automatic process (invisible to the user).

The input generator accepts an additional parameter that defines the percentage of the truth table that will be used (and generated) for fitness evaluation, which may be denoted as *domain coverage* [9]. For instance, if the coverage is 50%, only one half (randomly chosen) of possible inputs and corresponding outputs will be used for candidate circuits functionality evaluation. This feature is added since for larger number of inputs the truth table may be of considerable size and can greatly slow down the evolution process. It is important to note that, if the domain coverage is less than 100%, in every generation a new partial truth table is generated randomly which covers the denoted percentage of test vectors.

The final output of the evaluation is an integer fitness value in the range of $[0, n]$, where n is the actual size of the internal truth table.

A. Limitations

It is obvious that the Verilog language allows the definition of different types of networks and with different modes of description. Verilog description that is of interest here should be behavioral, where only the functionality is defined and not the internal structure (as opposed to a synthesizable description) [11]. Furthermore, only combinatorial circuits must be defined, with no memory elements (e.g. a description containing a `reg` keyword). This condition is not checked automatically, and we rely on the designer to be able to specify the behaviour of a combinatorial circuit only.

V. Results and Analysis

The experiments described in this section were designed to answer the following questions:

- Is the CGP able to provide a functionally correct network?
- What is the influence of CGP parameters (such as number of rows and columns) to the quality of results?
- What is the quality of the results considering internal structure, in comparison with human-made circuits?

All the experiments are made with a 100% domain coverage, i.e. all the possible input combinations are included in the truth table. The following parameter settings are used in the experiments, unless stated otherwise:

- population size of 50 individuals;
- termination condition is 200 generations without improvement of the best individual;
- number of repetitions is at least 10 for each parameter set;
- the initial function set contains functions AND, OR and NOT.

A. Test Case: binaryToESeg_Behavioral

This test case covers the conversion of a binary coded digit to 8-segmented display, with only the signal for the "E" segment as shown in Fig. 2 [11]. The number of inputs is 4, thus covering 16 possible input vectors, and a single bit is the output. An example of a human-made solution is shown in Fig. 3.

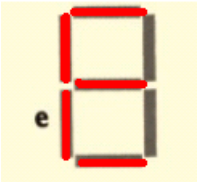

Fig. 2: 8-segmented display with only the "E" segment functional signals.

The CGP system was executed with different genotype sizes (row and column number) and different levels back parameter values. Population size was set to 100 individuals. The convergence of the CGP system is described using the maximum and average results of best individuals out of all repetitions for each parameter setting. The results for this experiment are shown in Table I.

CGP was able to produce five correct solutions (functionally correct), with three solutions better than human-made solution; an example of a correctly produced circuit is given in Fig. 4. It

TABLE I: Results for test case: binaryToESeg

CGP parameters			Fitness value	
Rows	Columns	Levels back	Mean	Maximum
4	4	1	14.7	15
4	4	2	14.6	15
4	4	4	13.9	15
4	8	1	14.3	15
4	8	4	14.7	16
4	8	8	14	15
8	8	4	14.9	16
8	4	1	14.7	16
8	4	2	14.8	16
8	4	4	14.2	15
8	8	1	14.8	16
8	8	8	14.2	15

can be seen that the best obtained CGP solution incorporates a smaller number of nodes and the same number of levels as the human-made solution.

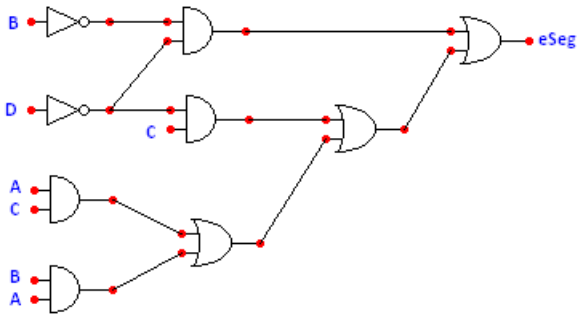

Fig. 4: Solution produced by CGP for the "E" segment problem (binaryToESeg_Behavioral).

B. Test Case: synCaseWithDefault

This example from [11] takes 3 single-bit inputs and a single output, comprising the truth table of size 8. The human-made solution to this problem is shown in Fig. 5.

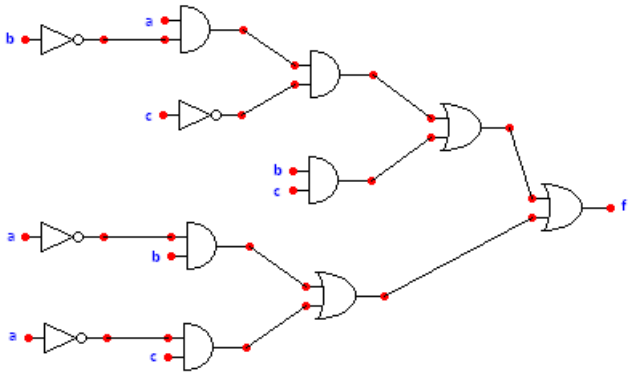

Fig. 5: Human-made solution to the 3 single-bit input and single bit output problem (synCaseWithDefault).

The first experiment obtained results with average quality shown in Table II.

Total number of correct solutions (with fitness 8) was five, with one solution as good as human-made solution and two solution better than human-made solution (one of them is shown in Fig. 6).

TABLE II: Results for test case: synCaseWithDefault (basic function set)

CGP parameters			Fitness value

5	3	3	6.1	7
5	5	1	6.7	8
5	5	2	6.4	8
5	5	5	6	6

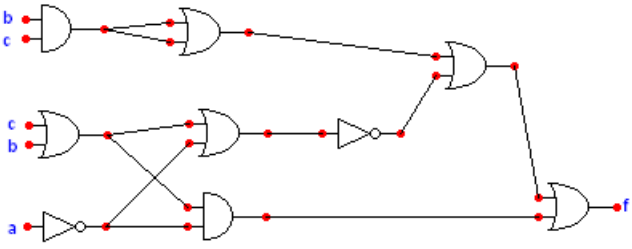

Fig. 6: Solution produced by CGP with basic function set for the 3 single-bit input and single bit output problem (synCaseWithDefault).

In this case an additional experiment was made with extended function set, comprising AND, OR, NOT, XOR and XNOR functions, which produced 29 correct solutions with 25 better than human-made solution. The purpose was to

investigate whether a better solution, in terms of the number of nodes and levels, could be evolved. This proved to be true, as CGP produced three solutions with only 4 nodes; the convergence results are shown in Table III, and one of the best obtained circuits is given in Fig. 7.

TABLE III: Results for test case: synCaseWithDefault (extended function set)

CGP parameters			Fitness value	
Rows	Columns	Levels back	Mean	Maximum
3	3	1	7.1	8
3	3	3	7.1	8
3	5	1	7.1	8

5	5	2	7.7	8
5	5	5	7.1	8

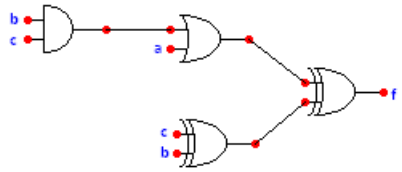

Fig. 7: Solution produced by CGP with extended function set for the 3 single-bit input and single bit output problem (synCaseWithDefault).

C. Test Case: oneBitFullAdder

This is an example of a full adder which takes 3 bit inputs and 2 outputs [11], with the maximum fitness value of 16 (2 outputs for every input combination). A human-made solution is shown in Fig. 8.

With the default set of parameters, the CGP was again able to produce a correct solution, for combinations of row and column numbers shown in Table IV.

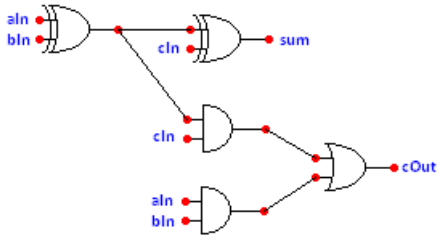

Fig. 8: Human-made solution for the full adder problem (equivalent to the solution produced by CGP).

The structure of three best CGP solutions was equal to the human-made solution in this case, which is the best known solution with this function set [11] (total number of correct solutions was 17).

TABLE IV: Results for test case: oneBitFullAdder

CGP parameters			Fitness value	
Rows	Columns	Levels back	Mean	Maximum
2	3	1	13.9	14

4	4	4	14.4	15

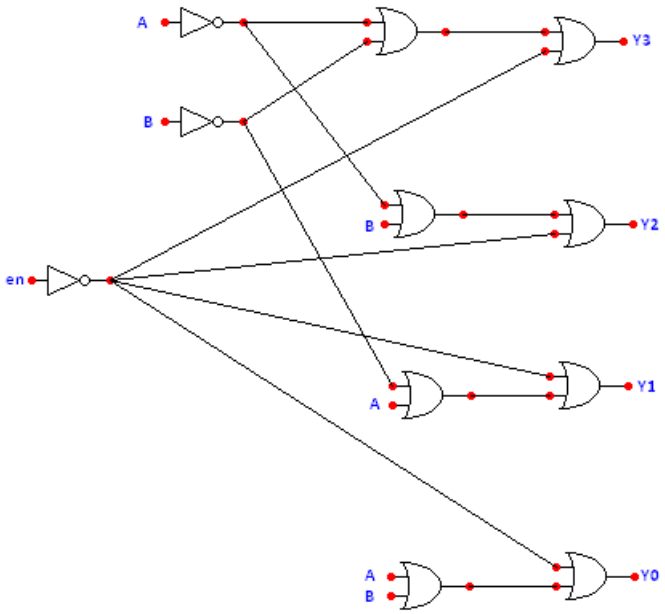

Fig. 9: Human-made solution to the decoder 2 to 4 problem (decoder2To4).

D. Test Case: decoder2To4

The final example is a 2 to 4 decoder with 3 inputs, including the `enable` signal [15].

The maximum fitness value is 32, which corresponds to 4 correct outputs for every combination of 3 inputs. The default set of parameters was used, along with the population size of 100 individuals. In this experiment the CGP was also able to produce 8 correct solutions, as shown in Table V. An example of a CGP solution is given in Fig. 10.

In this case the CGP solution was not of the same quality as the human made circuit, as shown in Fig. 9, since it includes one additional level and a single additional node. However,

TABLE V: Results for test case: decoder2To4

CGP parameters			Fitness value	
Rows	Columns	Levels back	Mean	Maximum
4	6	3	30.4	32
6	4	1	30	32
6	6	6	30.5	32
6	8	4	30.9	32
6	8	8	30.7	32

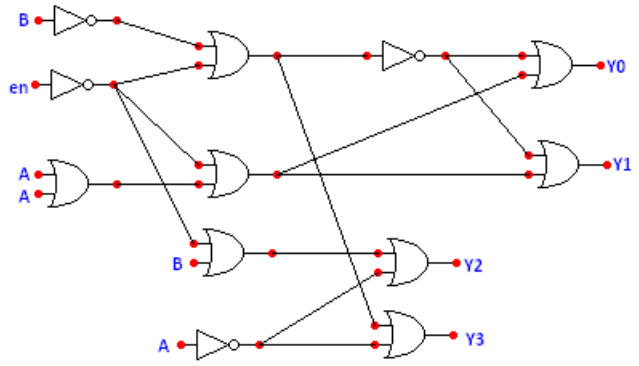

Fig. 10: Produced solution by CGP for the decoder 2 to 4 problem (decoder2To4).

the functionality is still preserved with only a small difference in network structure.

E. Discussion

The answer to the first question is clear: CGP is able to provide multiple different functionally correct networks for all test cases.

Considering the second question, the influence of CGP parameters to the quality of results, it shows that parameters close to human-made solutions produce the best results. However, if a better solution exists, human-made solutions can be used as a starting point where parameters (such as number of rows and columns) are gradually reduced until fitness value shows to be increasing.

The third question about the quality of the results, considering internal structure in comparison with human-made circuits, provides interesting results. The first test case (binaryToESeg_Behavioral) and the second test case (synCaseWithDefault) produced better solutions than human-made ones. The third test case (oneBitFullAdder) produced solutions equal to the human-made solution. However, the fourth test case (decoder2To4) did not produce any better solutions. Considering the complexity of certain test cases, we can conclude that the results reflect that complexity.

Since our primary goal was to find functionally correct solutions (in which we succeeded), the fact that CGP can also implicitly performs the optimization and produces better solutions shows how neutrality is an important feature of CGP.

The only heavy downside was a time-consuming evolution process, that depends on the size of the solutions (individuals in population).

VI. Conclusions

This paper describes the use of *Cartesian Genetic Programming* (CGP) for automatized synthesis of combinatorial circuits. The main purpose of this approach is the simplification of the design process usually requiring human expertise. The results show that the CGP-based evolutionary system is able to produce solutions that satisfy the functional requirements. Additionally, the results show good properties regarding the total number of gates and network levels. The presented application allows network behaviour specification with Verilog, which can facilitate the design process for larger number of input combinations.

***Abstract*—Modern wind farms typically comprise a large number of wind turbines spread on a relatively small area. The closely spaced turbines are aerodynamically coupled since they share the common energy resource. The aerodynamical coupling is described by the wake model, which explains how the change in the energy extraction of a single wind turbine affects the operating conditions of other turbines. Wake models provide the basis for optimization of wind farm operation. The paper shows that at wind speeds lower than rated the wind farm power production can be increased by optimizing the rotor speed of individual wind turbines. Furthermore, at wind speeds above rated the power production can be redistributed among the turbines in the wind farm in order to equalize the loads and thus prevent excessive wear and tear of the exposed turbines.**

I. Introduction

The increase in world population and life standard requires corresponding increase in energy production. Fossil fuel power plants still hold the main part in energy production. Due to their negative environmental impact and limited fossil fuel reserves, much effort is invested in research of renewable energy sources, like wind energy. The nominal power, efficiency and dimensions of wind turbines have been greatly increased during last few decades. Today, the wind turbines are rarely installed as stand-alone power sources, more commonly a larger number of turbines is grouped into the wind power plant, i.e. the wind farm.

The wind farms today are typically composed of a large number of wind turbines on a relatively small area, which causes the turbines to share the common energy resource. The wind turbines extract a part of energy from the wind flow which causes a decrease in wind speed behind them. This speed deficit behind wind turbines is also called wake. Wakes cause aerodynamical coupling between wind turbines in wind farm. Due to wakes, every change in level of power extraction of a single wind turbine affects the turbines located downwind.

Traditionally, wind farm is operated as a collection of individually controlled wind turbines [8], which is not necessarily production-wise the best operating strategy for a large number of closely-spaced turbines. When a wind turbine is individually controlled it operates at its locally optimal operating point, which assures it extracts the maximum available power from the wind at its rotor. If one observes a row of turbines aligned with the wind, this control strategy allows the first upstream turbine to extract the power from the undisturbed wind flow. The wind turbines behind it experience the smaller wind speed since they are situated in the wake of the first turbine and therefore they produce less power then the first turbine. The idea we investigate in this paper is: if the power extraction of the upstream wind turbines is decreased, would the cumulative production of the turbines in the row be larger? In this paper we try to achieve such increase by model based optimal wind farm control relying on wake models.

Another opportunity for the wake model based optimization investigated in the paper arises in cases when the wind farm is required to track the externally provided power reference. This operating scenario is becoming increasingly common in the grids with large penetration of wind energy where wind energy is present at the regulating market, see e.g. [9]. Operating below the rated power under high winds provides opportunity for reallocation of wind turbine loads. With classical wind farm control the wind turbines in the front of the row produce the most power and therefore suffer the highest loading and wear. The optimization of power production based on the wake model can be used to reallocate production and loading and thus increase the operating life of the wind turbines that typically suffer the most damage.

The paper is structured as follows:
Section II describes the wind turbine and wind farm models used in the paper. Section III discusses the possibility for wind farm power optimization at lower wind speeds. In Section IV the idea of load optimization/reallocation is presented. Section V concludes the paper.

II. Wind farm model

In this paper we consider the wind farm that consists of eight wind turbines aligned in row parallel to the prevailing wind direction, see Fig. 1. The distance between the wind turbines is 400 meters. This setup is chosen because in this scenario the aerodynamical coupling between individual turbines is the strongest.

To obtain the wind farm model for wind farm optimization we require the model that inputs the mean speed of the wind flow and the control variables for each of the wind turbines. The wind farm model outputs are the power production and loads at every wind turbine. To obtain such a model we need to combine the model of the wind turbine, which links the wind turbine inputs to its production and loading, and the wake model, which links the operating conditions on one turbine to operating conditions on the turbines downwind from it.

Fig. 1. Wind farm layout

A. Wind turbine model

We use the NREL offshore 5 MW baseline wind turbine model developed at National Renewable Energy Laboratory, [3]. It is a model of 5 MW conventional horizontal axis three-bladed upwind variable-speed pitch-controlled wind turbine implemented in Matlab. Diameter of turbine rotor is 126 meters and tower height is 90 meters. It can operate at wide range of wind speeds: from 3 m/s to 25 m/s, while it achieves rated power at 11.4 m/s. More technical data about the wind turbine model can be found in [3].

In this paper we look at the stationary wind turbine model. The core of this model is the wind turbine aerodynamics, that describes the power capture and the aerodynamic forces that act on the wind turbine rotor due to wind stream.

The power captured by the wind turbine, P, is modeled according to the relation:

$$P = C_{\mathrm{P}} \cdot \frac{1}{2}\rho A v^3, \tag{1}$$

where C_{P} is the power coefficient, ρ is the air density, A is the rotor area and v is the velocity of the free wind stream approaching the rotor. Notice that $\frac{1}{2}\rho A v^3$ is the power available in the wind and C_{P} denotes a portion of available power captured by the wind turbine.

Similarly, the thrust force that acts on the rotor in the direction of the wind can is modeled by:

$$F_{\mathrm{T}} = C_{\mathrm{T}} \cdot \frac{1}{2}\rho A v^2, \tag{2}$$

where C_{T} is the thrust coefficient and $\frac{1}{2}\rho A v^2$ denotes the kinetic energy of the wind stream.

Both power and thrust coefficient depend on the way the turbine is operated, i.e. they depend on the blade pitch angle, β, and the blade tip speed ratio, $\lambda = \frac{\omega_{\mathrm{r}} R}{v}$, where ω_{r} denotes the rotor speed.

The control inputs of the wind turbine model are ω_{r} and β, v is an uncontrollable input, while power P and thrust force F_{T} are the outputs that represent wind turbine production and loading.

B. Wake model

The wake that occurs behind the wind turbine as a consequence of its energy extraction is a complex phenomenon driven by different forces and interactions. In literature different models of wakes are found depending on the downwind distance from the wind turbine on which the wake is modeled. In that context we distinguish near wake models and far wake models, see [4]. The near wake model describes the phenomena directly behind the rotor (within one rotor diameter), while the far wake models describe the phenomena further downwind. In this paper our focus is on the far wake models.

To describe the influence of wind turbine states on the far wake forming the axial induction factor a is typically used. The axial induction factor is introduced in the actuator disc theory (see [10]) to describe the wind velocity variation that occurs when the wind passes the wind turbine rotor. According to this theory the axial induction factor is related to the power as:

$$C_{\mathrm{P}} = 4a(1-a)^2, \tag{3}$$

and to the thrust coefficient as:

$$C_{\mathrm{T}} = 4a(1-a). \tag{4}$$

According to this relations the axial induction factor is a function of pitch angle and the tip speed ratio, which can be estimated from the known power and thrust coefficients.

There are several different ways to model the far wake, but most appropriate for the controller design is the engineering model found in [2]. This model contains simple expressions suitable for fast calculation. The wind speed is considered normally distributed with the mean value v and standard deviation σ, which represents the wind turbulence. At this point we are only interested in the mean wind speed.

In this paper the following expression for wind deficit is used ([2]):

$$v(x,r) = v_0 - \Delta v(x,r). \tag{5}$$

where $v(x,r)$ denotes the wind speed at distance x from the wind turbine and at the radial distance r from the wind turbine hub, v_0 is the speed of the free wind stream in front of the turbine. Δv denotes the speed deficit due to turbine power extraction, which is modeled as:

$$\Delta v(x,r) = 2a v_0 (\frac{x}{2D})^n e^{\frac{-\alpha r^2}{\gamma^2(x)}}, \tag{6}$$

where D is the rotor diameter and parameters n, α and $\gamma(x)$ are experimentally determined.

C. Multiple wakes

To model a wind farm for optimization one needs to compute the wind speed deficit at the position of each turbine. If one considers the wind farm layout depicted in Fig. 1 it can be noted that, for example, wind turbine denoted WT3 will be in wakes of both WT1 and WT2, while WT8 will be in wakes of all other turbines. So it is necessary to model the wake merging.

According to [2] the wind speed deficits obtained from the model (6) are additive, i.e. the influence of wakes of different turbines at a certain location should be summarized:

$$\Delta v_{\Sigma}(x,r) = \sum_{k=1}^{n} \Delta v(x_k, r_k), \tag{7}$$

where x_k denotes the distance between the point (x,r) and the k-th wind turbine along the x axis, and r_k denotes the radial distance between the point (x,r) and the center of the k-th wind turbine.

The wake effects in the considered wind farm are depicted in Figure 2. The x and y axes denote the horizontal location in the wind farm (the system origin is at the location of WT1). The vertical axes denotes the wind speed at different locations. In the figure one can notice the basic characteristics of wakes: the wind turbines cause a sharp drop in the wind speed, while the wind speed recovers further downwind.

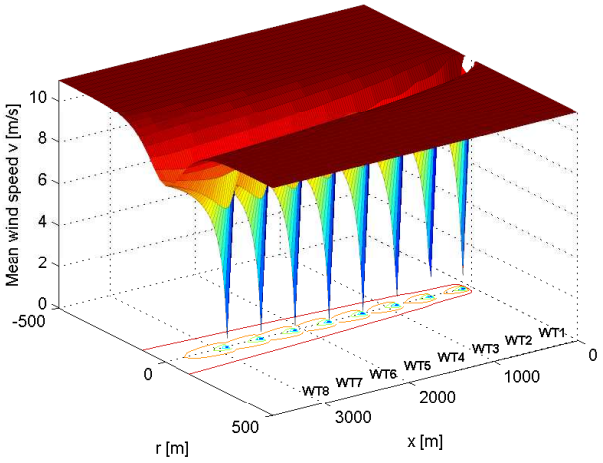

Fig. 2. Mean wind speed at wind farm area

When considering the wind farm control it is more appropriate to depict wake effects at the wind turbines. In Figures 3 and 4 the markers denote wind speed deficit and the power produced at particular wind turbines. Notice that at wind speed of 13 m/s the pitch angle is larger than zero. This is because at that wind speed the available power is larger than nominal. The produced power is then limited to nominal by blade pitching. From both figures it can be noticed that wind turbines captured in the wake produce less power. The largest drop in wind speed occurs between the first and the second wind turbine, while further on the difference is smaller. In Figure 3 it can be seen that the depth and the length of wakes depend on the mean wind speed. This is even more obvious in Figure 4 where the power produced at different figures is denoted. It can be noticed that the first turbine in a row produces much higher power than the others, which is due to the fact that the produced power is proportional to the third power of the wind speed (see (1)).

III. Power Optimization

The primary objective of every power plant owner is to maximize the power production because the power production directly translates to income. So we first investigate is it possible to increase the power production by using wind farm model based optimization.

The control of a single wind turbine is very well researched area, see e.g. [10], and a control approach for maximization of power production is very well established. The pitch angle is generally not used for power maximization, it is held at a value that ensures maximal power extraction, which is typically

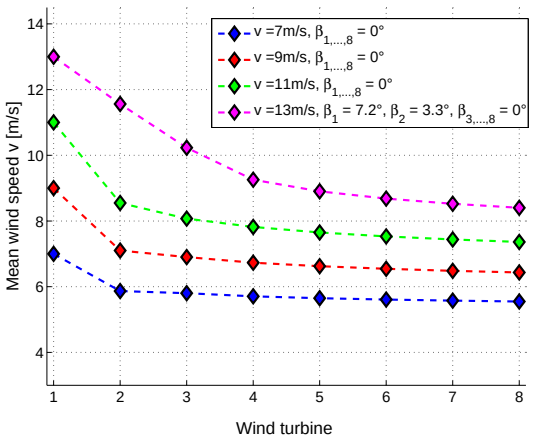

Fig. 3. Mean wind speeds at wind turbines

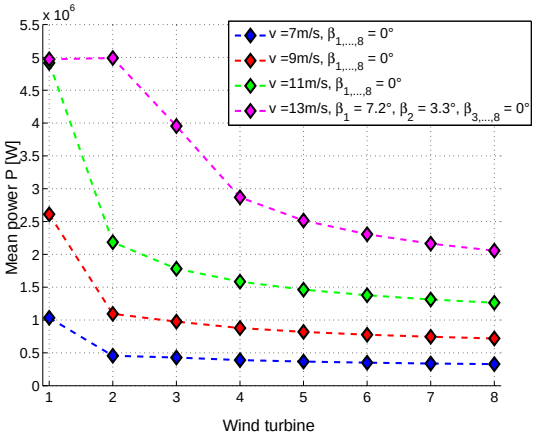

Fig. 4. Mean turbine power at various wind speeds

denoted as $\beta = 0°$. Further, it is observed if the power coefficient as a function of tip-speed ratio has a distinctive maximum. Keeping the operating point at that tip-speed ratio (denoted optimal tip-speed ratio, which is 7.5 for the turbine at hand) maximizes the extracted power. The optimal tip-speed ratio is maintained by adapting the generator torque.

When there is coupling between the wind turbines it is quite possible that the control tactics that is optimal for a single turbine no longer renders the maximal power output. In this section we test this hypothesis.

A. Problem analysis

The wind farm model described in Section II is composed of eight turbines and contains a large number of free parameters. Furthermore, the system is described with implicit equations and contains look-up tables for turbine coefficients. Therefore, it is hard to analyse this problem. Instead, we first look at some smaller examples to deliver the illustrative examples

First we consider the system containing only two wind turbines in a row. By changing the tip-speed ratio of the last turbine and thus effecting its wake no increase in power can be achieved. But if we change the tip-speed ratio of the first

turbine and weaken its wake we might obtain more power at the second turbine. Therefore we set the second turbine to operate at optimal tip-speed and change the tip-speed ratio of the first turbine. The Figure 5 shows the obtained power surplus (difference between the obtained power and the power obtained when both turbines operate with $\lambda = 7.5$) as a function of the tip speed ratio of the first turbine. It can be seen that in this case the power surplus is negative, so it is not possible to gain any power surplus by changing the tip-speed ratio of the first turbine. The second turbine can not compensate the power drop on the first turbine despite its increased wind speed.

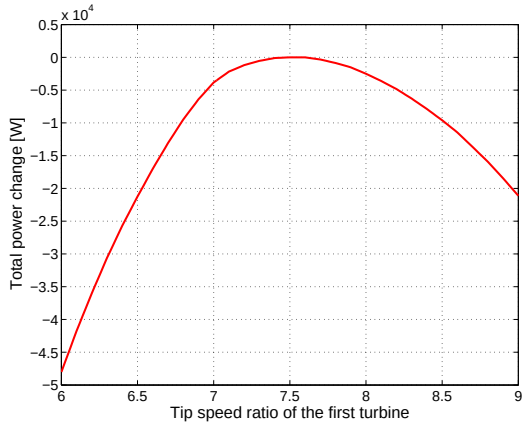

Fig. 5. System of two wind turbines - first turbine influence

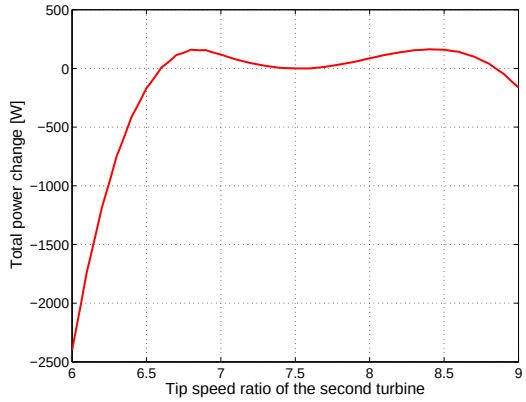

Fig. 6. System of three wind turbines - second turbine influence

However, if we add the third turbine at the beginning of the row and only keep its tip-speed ratio at the nominal value we are getting an entirely different picture. The result of such simulation is shown in Figure 6. It can be seen that surplus of power can be achieved. This demonstrates that there is the possibility of increasing the power production of the wind farm by coordinated control of the entire wind farm, which considers the wake coupling of wind turbines. However, we also notice the nonlinear character of the problem at hand. Even in this simple case the function of power surplus is nonconvex and therefore it is very hard to locate the global optimum.

B. Problem setup

For the general wind farm setup one can not find the optimum by enumeration, as it is done in the simple demonstration cases in the previous section.

The goal of the optimization problem is to find the rotor speed of every wind turbine for which the wind farm achieves maximum power. The problem, for n turbines, is set as follows:

$$\max_{\omega_1,\ldots,\omega_n} \quad \sum_{i=1}^{n} P_i(\omega_i)$$
$$\text{subject to} \quad \begin{cases} w_{min} \leq w_i \leq w_{max} \\ 0 \leq P_i \leq P_{max} \\ \dfrac{\partial C_q}{\partial \lambda} < 0 \\ (1), (6), (7). \end{cases} \tag{8}$$

There are several constraints which must be met. The rotor speed ω must be between minimum allowed and rated. The maximum power that turbine can provide must be positive and less or equal to rated P_{max} = 5 MW. To ensure that the operating point is stable, the torque coefficient (C_q) curve must have negative slope in that point [1].

This optimization problem is a nonconvex, both in the cost function and in the constraints. There is no readily available solver that can handle such optimzation problems and guarantee that the achieved optimal point is indeed the global minimum of the problem [5].

The problem is solved by using the sequential quadratic programming algorithm implemented in Matlab function `fmincon`, [7]. To increase the probability of finding the global minimum of the problem at hand we use the `GlobalSearch` function implemented in Matlab, [6]. This function uses several iterations of `fmincon` to find the best solution.

C. Results

The results obtained by using proposed functions and algorithms are shown in Figure 7. The states (rotor speed, tip speed ratio, wind speed, power) of optimally controlled wind farm are compared with the states of traditionally controlled one. The main difference in control approach is noticeable in comparison of tip speed ratios. The tip speed ratios of every turbine in traditionally controlled (non-optimized) wind farm have the same value of 7.5, for which every turbine works at its optimal operating point. In the optimized wind farm, only the last turbine in a row works at its optimal operating point because it does not effect any other turbine. As the result, wind speed on every turbine, after the second one, is increased. The first turbine remains the same power production. Even though it has maximum impact on speed deficit in wakes, it also has the largest share in the wind farm power production, so there is no benefit in reducing its power. The second and the third turbine decrease their power production and minimize wakes

behind them. The power gains on other turbines results in an increase in total wind farm power production. The most power surplus is generated on the last two turbines, they seize the power the turbines in front saved. The detailed results can be seen in Table I.

IV. LOAD OPTIMIZATION

At the wind speeds larger than rated all turbines work at rated rotor speed and they are controlled by changing the blade pitch angle. There is enough wind energy available and every turbine can work at its rated power, which is due to mechanical and electrical constraints the largest power it can permanently produce, so there is no opportunity for maximizing the power extraction. However, if the wind farm must follow the power reference that is lower than the rated power, the load optimization may be considered. This operating mode is used when the wind farm is obliged to participate in grid regulation, or it can not deliver its maximum power due to faults in transmission lines.

The loads considered here are wind turbine structural loads, particulary the tower bending moment and blade bending moment. The tower bending moment is the sum of the moments caused by the thrust on the rotor, the aerodynamic force on the tower, and the eccentricity of the nacelle. The blade bending moment originates from the axial force on the rotor blade and the tangential force due to gravity.

A. Problem analysis

The goal of a load optimization can be minimizing total load of the entire wind farm. However, that goal is very hard to achieve without sacrificing the power.

We consider different type of optimization where the load is evenly distributed among the turbines. In the case when each turbine produces the same power very large difference between the turbine loads emerges due to wake effects. This leads to uneven wear and tear of the turbines and therefore possible malfunctions, maintenance requirements or shorter operating life. We aim to reallocate the power in the wind farm such that every turbine suffers the same amount of the load.

B. Problem setup

The problem that equalizes the turbine loads while the wind farm follows the power reference is set as follows:

$$\min_{\beta_1,\ldots,\beta_n} \quad \sum_{i=1}^{n-1} \lambda_{\mathrm{b}}(M_i^{\mathrm{b}}(\beta_i) - M_{i+1}^{\mathrm{b}}(\beta_i))^2 + \\ + \lambda_{\mathrm{t}}(M_i^{\mathrm{t}}(\beta_i) - M_{i+1}^{\mathrm{t}}(\beta_i))^2 + (P_{ref} - P_{total})^2$$

$$\text{subject to} \quad \begin{cases} \beta_{min} \le \beta_i \le \beta_{max} \\ P_i \le P_{max} \\ \dfrac{\partial C_q}{\partial \lambda} < 0 \\ (2), (5), (7) \end{cases} \tag{9}$$

The average tower bending moment at the i-th turbine M_i^t and the corresponding blade bending moment M_i^b are obtained from the expressions in [2]. Those expressions determine the average values of the moments as function of axial induction factor under the preassumption of standard distribution. The scaling factors λ_{t} and λ_{b} are used to balance between different requirements.

This problem is also solved with Matlab function `fmincon` [6]. The active-set algorithm, which proved to be better in this case than the `sqp`, was used.

C. Results

The simulation results for the wind speed of 15 m/s are shown on the figure 8. The blade pitch angle, tower and blade bending and power of the turbines with equalized loads are compared with the traditionally controlled wind farm where each wind turbine operates at power reference $\frac{P_{ref}}{N}$, where N is number of turbines. The significant power and load reallocation was achieved with minor changes in the blade pitch angles. In the power equalized wind farm, the lowest loads has first turbine in a row and the last has the highest. To equalize the loads it was necessary to decrease blade pitch angle of the first turbines, which increased their efficiency, and to increase blade pitch angle of the last few turbines.

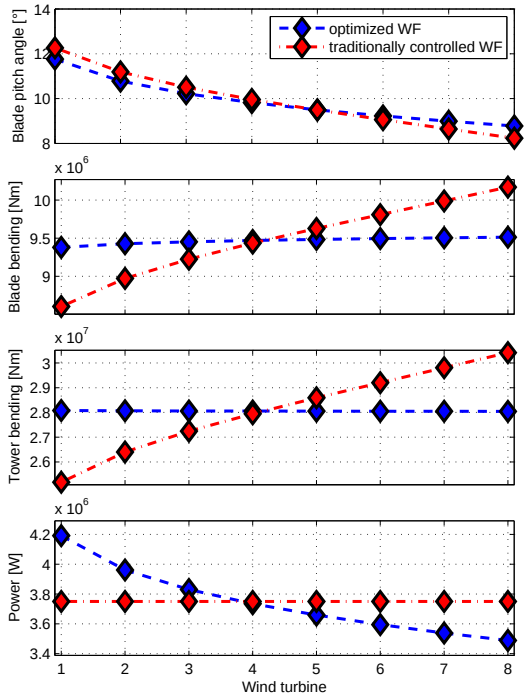

Fig. 8. Simulation results for mean wind speed 15 m/s

A detailed overview of the power and load is shown in the Table II. The table only lists the changes in the tower bending moment, while the changes of the blade bending moment are very similar. The link between percentage change of power and load is noticeable. In both cases, the wind farm produces power equal to the given power reference of 30 MW.

V. Conclusion

In this paper the optimization of wind farm optimization based on wind farm modeling is investigated. The wind farm model is used to describe the coupling between turbines that occurs due to wakes.

Two different optimization objectives are used based on the operating regime in which the wind farm operates. At lower wind speeds, the goal is to maximize the produced power. By taking into account the effect of turbine coupling the gain of 2.85% in the produced power was obtained.

TABLE II
Results for mean wind speed 15 m/s

	M_{WF} [MNm]		M_{WT} [MNm]		P_{WT} [kW]	
Equalized power	224.8		25.2		3750	
			26.4		3750	
			27.2		3750	
			27.9		3750	
			28.6		3750	
			29.2		3750	
			29.8		3750	
			30.4		3750	
Equalized load	224.5	-0.15%	28.1	+11.5%	4191	+11.8%
			28.1	+6.3%	3962	+5.6%
			28.1	+3.0%	3830	+2.1%
			28.1	+0.4%	3735	-0.4%
			28.1	-1.9%	3659	-2.4%
			28.0	-3.9%	3595	-4.1%
			28.0	-5.9%	3539	-5.6%
			28.0	-7.8%	3489	-6.9%

At higher wind speeds where the nominal wind farm power is achieved, the goal was to optimize wind farm loads. In traditional wind farm control there are the turbines that are more exposed to loads and therefore also to increased wear and tear. By reallocating the power production the loads in the wind farm are equalized and the high loads on certain turbines are evaded.

***Abstract*—The use of wind power has been increasing rapidly over the last few decades and according to all predictions this trend is likely to continue. At the same time, the need for better cost effectiveness of wind power plants has stimulated growth in wind turbines' size and rated power. On the other hand, the growth of wind turbines' size has also increased the structural flexibility and the loads wind turbines are exposed to. In order to design advanced controller that reduces structural loads and fatigue and that enables optimal energy conversion in a wide range of wind speeds, suitable wind turbine mathematical model is needed. Due to aerodynamic forces acting on wind turbine blades, standard wind turbine mathematical models are very complex and therefore not suitable for controller design. The scope of this paper is derivation of simplified wind turbine mathematical model which includes both aerodynamic effects and structural deformations and yet it is simple enough for controller design.**

I. Introduction

The use of wind turbines has grown rapidly in recent decades and that trend is likely to continue. The main reason for this is a constantly increasing power consumption, which necessitates introduction of new power plants. At the same time the climate change concerns prompt for an immediate action in reducing the greenhouse gas emissions. Another important factor is concentration of natural reserves of fossil fuels in just a few supplier countries in the world. In order to take care of climate change and to reduce dependency on energy import, the European Union (EU) has set the goal to achieve 20% share of renewable energies in the overall energy consumtion by 2020 [1]. Since nowadays wind is the most promising renewable energy source, it is expected that wind energy will have a major role in achieving that goal. Wind turbines have no greenhouse gas emmisions and wind is free and practicaly limitless source of energy, so wind turbines represent a good solution for both climate change and energy import dependency.

By the end of 2010 the total power of wind turbines installed in Europe equalled 86 GW. The European Wind Energy Association (EWEA) targets 230 GW of installed wind power capacity in Europe by 2020 and 400 GW of installed wind power capacity by 2030, which would produce 26-35% of the EU's electricity, depending on total demand at the time. Some studies show that Europe has enough wind potential to entirely accomodate energy consumption [2]. European Renewable Energy Council even suggests that it would be possible for EU to achieve energy system that is entirely based on renewable energy by 2050, where wind power is expected to have over 20% share in the electricity generation [3].

Such ambitious goals for renewable energy cannot be achieved with the current state of technology, so a constant research and development is needed. To be able to pursue set goals, wind turbine dimensions and rated power will have to increase. However, with the increase in wind turbine dimensions, the loads that wind turbine has to withstand increase significantly. An attempt to make such large constructions (modern 5 MW wind turbines have tower height over 100 m) rigid would result with massive and expensive structures, which in turn would make the whole wind turbine cost-ineffective. Therefore, modern wind turbine construction is very flexible, and the flexibility becomes more emphasized with the increase in wind turbine size [4]. Because of that, wind turbine control system, in addition to wind turbine power and rotor speed control, has to accomplish other objectives such as reduction of structural loads and reduction of tower and blade oscillations. An advanced control system that actively reduces loads [5] and structural oscillations [6], will enable further increase in wind turbine dimensions and rated power, making them even more cost-effective.

To design such advanced wind turbine controllers, appropriate wind turbine mathematical model is needed. Due to the nature of aerodynamic forces acting on wind turbine blades, wind turbine mathematical models are typically very complex and result in implicit equations. Such models can describe wind turbine behaviour very accurately [7], but due to their complexity, they are not suitable for control system design. Experimental identification of wind turbine mathematical model suitable for control design is explained in this paper. Proposed mathematical model is accurate enough to describe wind turbine structural deformations and loads and it is simple enough to be used in control system design. Since the main control challenges regarding the wind turbine safety are during the high wind speeds [8], in this paper, wind turbine mathematical model is identified for such wind conditions. With minor modifications, the same procedure could be used to identify wind turbine mathematical model for low wind speeds as well.

The paper is organised as follows: Wind turbine physics are explained in Section II. Experiments used for obtaining

the data needed for identification are explained in Section III. Identification of blade, tower and rotor speed submodels are described in Sections IV, V, VI, respectively. Finaly, in Section VII, identified submodels are merged into single wind turbine mathematical model and then validated.

II. Wind turbine physics

The main sources of wind turbine loading are aerodynamic loads on wind turbine blades, gravity and inertia [9]. Loads from wind turbine blades are propagated to the rest of the turbine, but due to the rotation of the rotor, loads on non rotating parts of wind turbine (nacelle and tower) have different characteristics and frequency response compared to the loads on wind turbine blades.

When modelling wind turbine flexibility, one has to take into account the flexibility of the blades and the flexibility of the tower, where the tower is generally more flexible than the blades. To describe motion of the blades caused by flexibility, blade coordinate systems are defined as shown in Fig. 1 – one coordinate system is assigned to each blade. Origin of the blade coordinate system is placed in the blade root and the axes are oriented as follows: the abscissa (x-axis) is parallel with wind direction and the applicate (z-axis) is perpendicular to x-axis and it is parallel to with blade longitudinal axis. The ordinate (y-axis) is perpendicular to other two axes and with them forms right-handed Cartesian coordinate system. It should be noted that the blade coordinate system is fixed to the blade, so it rotates together with the blade, i.e. wind turbine rotor. Flexibility of the blade is then observed as the movement of the blade tip (or any other part of the blade) along x-axis and y-axis of the blade coordinate system:

$$\tilde{F}_{bl,i} = M_{bl}\ddot{q}_{bl,i} + D_{bl}\dot{q}_{bl,i} + K_{bl}q_{bl,i}, \tag{1}$$

$$\begin{bmatrix} x_{bl,i} \\ y_{bl,i} \end{bmatrix} = C_{bl}q_{bl,i}, \tag{2}$$

where $q_{bl,i}$ is state vector that describes flexibility of the i-th blade, $\tilde{F}_{bl}$ is effective force causing blade deformation, $x_{bl,i}$ and $y_{bl,i}$ are blade deflections and M_{bl}, D_{bl}, K_{bl} and C_{bl} are model matrices of appropriate dimensions.

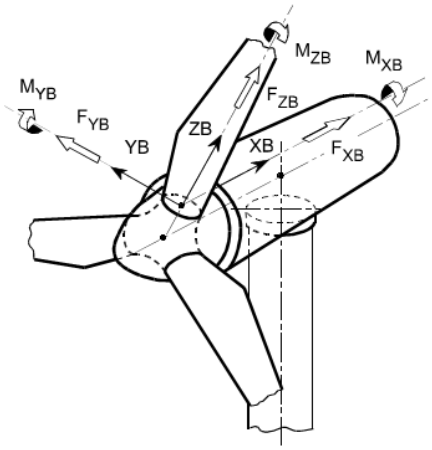

Fig. 1. Blade root coordinate system (Source: Germanischer Lloyd [10]).

To describe the motion of the tower, tower coordinate system is defined as shown in Fig. 2. Origin of the tower coordinate system is in the tower top when wind turbine is not subjected to aerodynamic loads. The abscissa is parallel with wind direction, the applicate is pointing vertical upwards and the ordinate is perpendicular to other two axes and with them forms right-handed Cartesian coordinate system. The tower coordinate system is fixed relative to the ground and the flexibility of the tower is observed as the movement of the tower top (or any other part of the tower) along its x-axis and y-axis:

$$\tilde{F}_t = M_t\ddot{q}_t + D_t\dot{q}_t + K_tq_t, \tag{3}$$

$$\begin{bmatrix} x_t \\ y_t \end{bmatrix} = C_tq_t, \tag{4}$$

where q_t is state vector that describes tower flexibility, $\tilde{F}_t$ is effective force causing tower deformations, x_t and y_t are tower deformations and M_t, D_t, K_t and C_t are model matrices of appropriate dimensions.

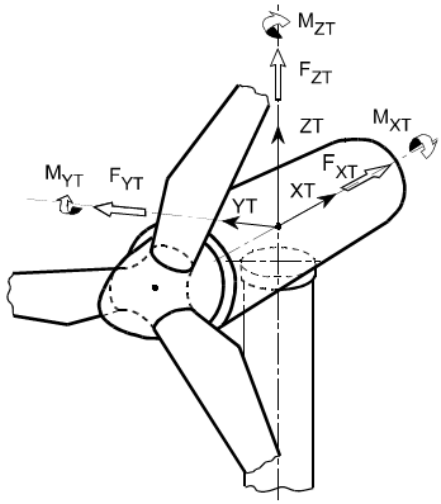

Fig. 2. Tower top coordinate system (Source: Germanischer Lloyd [10]).

It should be noted that movement of blade coordinate systems relative to tower top coordinate system causes azimuth dependent transformations of loads from one coordinate system to another. Since rotor azimuth is never constant while wind turbine is operational, obviously wind turbine mathematical model is time dependant. That causes different frequency response of the loads on the rotating part of wind turbine, compared to the loads on nonrorating part of wind turbine, as it is shown in [11].

III. Experiments for model identification

The goal of the identification is to find linear wind turbine mathematical model around an operating point. Wind turbine mathematical model is identified in state space while taking into account wind turbine physics described in Section II. The following dynamics are included in the identified model:

- deflections of each blade in x-axis of the blade coordinate system (one mode per blade),
- deflections of each blade in y-axis of the blade coordinate system (one mode per blade),
- tower deflections in x-axis of the tower coordinate system (one mode),
- tower deflections in y-axis of the tower coordinate system (one mode),
- motion of the rotor,
- servo system for each blade (second order system each).

To cope with azimuth (i.e. time) dependancy of wind turbine mathematical model, it is divided into several submodels and each submodel is identified separately. Furthermore, identification of each submodel is carried out in two parts – first, submodel is identified with only blade pitch reference signals as inputs, and then it is augmented with effective wind speed signals as additional inputs. Therefore three open-loop experiments are conducted for model identification. In the first experiment, wind turbine is excited only by pitching the blades and in the second experiment, wind turbine is excited only by varying wind speed. Measurements from those two experiments are used for model identification. In the third experiment, wind turbine is excited both by pitching the blades and by varying wind speed and the measurements are used for validation of the identified model.

All experiments are carried out in professional wind turbine modelling and simulation tool GH Bladed [12] using data for 2.5 MW wind turbine. GH Bladed incorporates very accurate nonlinear wind turbine model and it is the industry standard software for the design and certification of wind turbines.

A. Excitation of wind turbine by pitching the rotor blades

In the first experiment, wind turbine is excited only by pitching the rotor blades (while the wind speed is kept constant). As the blade reference signal, PRBS (Pseudo Random Binary Signal) is used. Characteristics of PRBS are suitable for process identification and therefore it is commonly used for such purpose [13]. Note that cross-correlation of two different PRBS signals is practically negligible. Therefore, wind turbine is excited by simultaneously pitching all three rotor blades – for each blade, different PRBS is used as blade pitch reference. Simply put, the fact that the cross-correlation is negligible means that it is possible to determine which part of wind turbine response is caused by which blade, which is essential for process identification.

Since, experiments for identification are performed in GH Bladed, instead of regular blade pitch servo system, much faster one is used. Hence, blades are able to track blade pitch reference practically instantly, considering the rest of wind turbine dynamics, i.e. actual blade pitch angle keeps the characteristics of PRBS which are suitable for identification. Therefore, actual blade pitch angle (instead of blade pitch reference) is used for process identification. Obviously, measurements obtained in the described way can only be used for identification of wind turbine structural dynamics and not for identification of actual blade pitch servo system. If it is necessary to identify blade pitch servo system as well, then additional experiment with actual servo system should be carried out.

Besides PRBS, several step changes in blade pitch reference are also recorded. Obtained measurements are used for validation of each submodel.

B. Excitation of wind turbine with varying wind speed

In the second experiment, the blade pitch angles are kept constant and the wind turbine is excited only with step changes of wind speed. In this experiment PRBS is not used, because PRBS wind speed is not realistic wind speed profile and it is not possible to simulate it in GH Bladed. But if the blade pitch reference PRBS is chosen well, it is reasonable to assume that all relevant wind turbine dynamics can be identified using only blade pitch reference as the excitation signal. Also, it is reasonable to assume that dynamics that can be excited by varying wind speed can also be excited by pitching the rotor blades. Therefore, to include wind speed into wind turbine model, it is sufficient to observe how the varying wind speed excites wind turbine dynamics that are already identified based on pitching of the blades.

C. Measurements for model validation

In the last experiment, several consecutive step changes of blade pitch reference and wind speed are simulated using regular blade pitch servo system. Once the complete model is identified (using data from the first two experiments), measurements from this experiment are used for model validation.

IV. Identification of blade mathematical model

As described in II, the flexibility of wind turbine blades can be modelled with (1). State space representation can be directly written as:

$$\begin{bmatrix} \dot{q}_{bl,i} \\ \ddot{q}_{bl,i} \end{bmatrix} = \begin{bmatrix} 0 & I \\ -M_{bl}^{-1}D_{bl} & -M_{bl}^{-1}C_{bl} \end{bmatrix} \begin{bmatrix} q_{bl,i} \\ \dot{q}_{bl,i} \end{bmatrix} + M_{bl}^{-1}\tilde{F}_{bl,i}. \tag{5}$$

Forces acting on blades are the result of rotor speed ω, blade pitch angle β_i and wind speed $v_{w,i}$, so they can be written as:

$$M_{bl}^{-1}\tilde{F}_{bl,i} = B_{bl} \begin{bmatrix} \omega \\ \beta_i \\ v_{w,i} \end{bmatrix}, \tag{6}$$

where B_{bl} is matrix of appropriate dimensions. Therefore identification of blade mathematical model is equal to identification of matrices $-M_{bl}^{-1}D_{bl}$, $-M_{bl}^{-1}C_{bl}$ and B_{bl}.

Blade deformations can be modelled with arbitrary number of modes both for deformations in rotor plane and deformations out of rotor plane. In this paper only one mode is chosen for each direction of deformations, so vector $q_{bl,i}$ can be chosen as:

$$q_{bl,i} = \begin{bmatrix} x_{bl,i} \\ y_{bl,i} \end{bmatrix}, \tag{7}$$

where $x_{bl,i}$ and $y_{bl,i}$ are blade tip deflections along x-axis and y-axis of the blade coordinate system, respectively.

Obviously, if one chooses more than one mode, the vector $q_{bl,i}$ should be augmented with additional states. The most straightforward approach would be to augment vector $q_{bli,i}$ with deflections of different parts of wind turbine blade. E.g. to model blade deformations with two modes of motion, one could choose blade tip deformation and deformation of the blade halfway from rotor centre to form vector $q_{bl,i}$.

As described in Section III, model matrices are first identified without wind speed $v_{w,i}$, using data obtained from the experiment with constant wind speed, as described in Subsection III-A. Then model is augmented with effective wind speed $v_{w,i}$ and appropriate elements of matrix B_{bl} are identified using data obtained from experiment with constant blade pitch angles, as described in Subsection III-B.

As it is expected, it is shown that the same blade mathematical model can be used for each rotor blade.

A. Modelling the blade loads

Blade loads are caused by aerodynamic forces (which depend on wind speed and blade pitch angle) and as reaction to the blade deformations. Note that gravity loads are not observed because in this paper only linear models are being identified. Blade loads can be expressed as:

$$F_{bl,i} = C_{F,bl} \begin{bmatrix} q_{bl,i} \\ \dot{q}_{bl,i} \end{bmatrix} + D_{F,bl} \begin{bmatrix} \omega \\ \beta_i \\ v_{w,i} \end{bmatrix}, \tag{8}$$

where $F_{bl,i}$ is vector comprised of blade loads in characteristic points. In this paper, forces and torques in blade root along each axis of blade coordinate system are chosen. C_{bl} and D_{bl} are matrices of appropriate dimensions that are determined through identification.

Matrices $C_{F,bl}$ and $D_{F,bl}$ that minimise difference between loads (8) and measured loads are found by numerical optimisation. As well for blade deformations model, it is shown that the same loads model can be used for all blades.

Although it is not shown in this paper, the same method can be applied to determine loads on any other part of wind turbine, e.g. wind turbine tower.

V. Identification of tower mathematical model

Flexibility of the tower is modelled in the same way as the flexibility of the blades. State space equation follows from (3):

$$\begin{bmatrix} \dot{q}_t \\ \ddot{q}_t \end{bmatrix} = \begin{bmatrix} 0 & I \\ -M_t^{-1}D_t & -M_t^{-1}C_t \end{bmatrix} \begin{bmatrix} q_t \\ \dot{q}_t \end{bmatrix} + M_t^{-1}\tilde{F}_t. \tag{9}$$

Forces causing tower deformation are the result of the loads on rotor blades and the blade deformations. Since blade loads can be calculated from blade deformations $q_{bl,i}$, forces causing tower deformations can be expressed only with blade deformations, blade pitch angles and wind speed.

Because of rotation of the wind turbine rotor, both blade loads and deformations have different influence on the tower, depending on blade azimuth position ϑ. Since influence of each blade on the wind turbine tower changes periodically, it can be modelled with sine and cosine functions. To this end, it is convenient to use d-q transormation:

$$T_\vartheta = \frac{2}{3} \begin{bmatrix} \frac{1}{2} & \frac{1}{2} & \frac{1}{2} \\ \cos(\vartheta) & \cos\left(\vartheta + \frac{2\pi}{3}\right) & \cos\left(\vartheta + \frac{4\pi}{3}\right) \\ \sin(\vartheta) & \sin\left(\vartheta + \frac{2\pi}{3}\right) & \sin\left(\vartheta + \frac{4\pi}{3}\right) \end{bmatrix}. \tag{10}$$

So instead of using actual values for blade deformations, pitch angles and wind speed on each blade, its values in d-q coordinate system are used:

$$\beta_{dq} = \begin{bmatrix} \beta_0 \\ \beta_d \\ \beta_q \end{bmatrix} = T_\vartheta \begin{bmatrix} \beta_1 \\ \beta_2 \\ \beta_3 \end{bmatrix}, \tag{11}$$

$$v_{w,dq} = \begin{bmatrix} v_{w,0} \\ v_{w,d} \\ v_{w,q} \end{bmatrix} = T_\vartheta \begin{bmatrix} v_{w,1} \\ v_{w,2} \\ v_{w,3} \end{bmatrix}. \tag{12}$$

In the same way, vector describing blade deformations in d-q coordinate system $q_{bl,dq}$ can also be calculated.

Now, forces causing tower deformations can be expressed as:

$$M_t^{-1}\tilde{F}_t = B_t \begin{bmatrix} q_{bl,dq} \\ \beta_{dq} \\ v_{w,dq} \end{bmatrix}. \tag{13}$$

To obtain tower mathematical model, matrices $-M_t^{-1}D_t$, $-M_t^{-1}C_t$ and B_t have to be identified. Identification is carried out similarly to the identification of the blade mathematical model.

To model tower deformations, only one mode of motion is chosen both for x-axis and for y-axis of the tower coordinate system:

$$q_t = \begin{bmatrix} x_t \\ y_t \end{bmatrix}. \tag{14}$$

First, model matrices are identified using data obtained with constant wind speed, and then the model is augmented with wind speed, as it is described in Section IV.

VI. Identification of rotor speed mathematical model

Wind turbine observed in this paper has direct transmission between rotor and generator and the drive train can be considered rigid. Therefore, very simple mathematical model can be used to describe the rotation of the rotor: Obviously, if one wishes to model drive train flexibility, proposed mathematical model should be augmented with additional states.

The aerodynamic torque that causes wind turbine rotation can be expressed by the loads on the rotor blades, therefore blade pitch angles and wind speed are chosen as model inputs. Also, tower top speed $\dot{x}_t$ is chosen as model input because it directly influences relative wind speed on the wind turbine (e.g. if the wind nacelle is moving into the wind, relative wind speed on the rotor increases and vice-versa). The following rotor speed mathematical model is used:

$$J_t\dot{\omega} = A_\omega\omega + B_\omega \begin{bmatrix} \dot{x}_t \\ \beta_{dq} \\ v_{w,dq} \end{bmatrix}, \tag{15}$$

where A_ω and B_ω are model matrices of appropriate dimensions. Note, that wind turbine mathematical model in this paper is identified only for high wind speeds. In that region, generator torque is typically kept constant and because of that it is omitted from the identification.

VII. Complete wind turbine mathematical model

Submodels described in previous sections are merged into single wind turbine mathematical model with variable parameters:

$$\dot{x}(t) = A(\vartheta)x(t) + B(\vartheta)u(t), \tag{16}$$
$$y(t) = C(\vartheta)x(t) + D(\vartheta)u(t), \tag{17}$$
$$\dot{\vartheta} = \omega. \tag{18}$$

Model matrices have variable parameters due to the d-q transformation used for identification of certain submodels. It can be easily shown that variable model matrices can be expressed as:

$$A(\vartheta) = A_0 + A_{cos}\cos\vartheta + A_{sin}\sin\vartheta, \tag{19}$$
$$B(\vartheta) = B_0 + B_{cos}\cos\vartheta + B_{sin}\sin\vartheta, \tag{20}$$
$$C(\vartheta) = C_0 + C_{cos}\cos\vartheta + C_{sin}\sin\vartheta, \tag{21}$$
$$D(\vartheta) = D_0 + D_{cos}\cos\vartheta + D_{sin}\sin\vartheta, \tag{22}$$

where all matrices on the right side of the equations are constant.

State vector x consists of the following states:

- position of each blade tip along x-axis and y-axis of the blade coordinate systems, $x_{bl,i}$ and $y_{bl,i}$, $i = 1, 2, 3$;
- velocity of each blade tip along x-axis and y-axis of the blade coordinate systems, $\dot{x}_{bl,i}$ and $\dot{y}_{bl,i}$, $i = 1, 2, 3$;
- position of the tower top along x-axis and y-axis of the tower coordinate system, x_t and y_t;
- velocity of the tower top along x-axis and y-axis of the tower coordinate system, $\dot{x}_t$ and $\dot{y}_t$;
- rotor speed, ω;
- pitch angle and pitch velocity of each blade, β_i and $\dot{\beta}_i$, $i = 1, 2, 3$.

Therefore the identified model has 23 states in total:

$$x = \begin{bmatrix} q_{bl,1} \\ q_{bl,2} \\ q_{bl,3} \\ q_t \\ \omega \\ \beta_v \\ \dot{\beta}_v \end{bmatrix}, \tag{23}$$

where $\beta_v = \begin{bmatrix} \beta_1 & \beta_2 & \beta_3 \end{bmatrix}^T$ is the vector containing pitch angles of the each blade.

Input vector of the identified wind turbine mathematical model comprises of blade pitch reference signals $\beta_{r,i}$ and effective wind speed on each blade $v_{w,i}$:

$$u = \begin{bmatrix} \beta_{r,1} \\ \beta_{r,2} \\ \beta_{r,3} \\ v_{w,1} \\ v_{w,2} \\ v_{w,3} \end{bmatrix}. \tag{24}$$

Loads in the root of the blades are chosen as model output y.

A. Blade pitch servo

For the completeness of the wind turbine mathematical model, blade pitch servo system is described in this Subsection. Pitching of rotor blades is important for wind turbine control and safety system, so blade pitch servo system is significant part of wind turbine mathematical model. Typically, blade pitch servo system has pitch speed limitations and if they are to be accounted for while designing wind turbine controller, it is necessary to have good model of blade pitch servo system.

In this paper, blade pitch servo mathematical model is assumed to be known in advance, i.e. it is not identified. But, since blade pitch servo model does not depend on wind speed, it can be easily identified by using PRBS as blade pitch reference and recording actual blade pitch angle. Typically the same blade pitch servo model can be used for each rotor blade.

In this paper, the following second order blade pitch servo mathematical model is used:

$$\begin{bmatrix} \dot{\beta}_i \\ \ddot{\beta}_i \end{bmatrix} = \begin{bmatrix} 0 & 1 \\ -100 & -20 \end{bmatrix} \begin{bmatrix} \beta_i \\ \dot{\beta}_i \end{bmatrix} + \begin{bmatrix} 0 \\ 100 \end{bmatrix} \beta_{r,i}. \tag{25}$$

B. Model Validation

Model validation is carried out using data recorded when wind turbine is excited both with blade pitch angle and wind speed changes (see Subsection III-C). To show a good match between identified model and validation data, several wind turbine responses are shown.

First, rotor speed response is shown in Fig. 3. Obvoiusly, a good match between identified wind turbine mathematical model and GH Bladed can be observed. Note that accurate rotor speed response is important because parameter variations of the model matrices depend on rotor speed (see (18)).

In Fig. 4, deformations of the tower and the first blade are shown. Again, a good match between identified wind turbine model and GH Bladed can be observed. It is important to note that tower deformation represents the nonrotating part of wind turbine, while blade deflection represents the rotating part of the wind turbine. Therefore, the identified model describes wind turbine dynamics well both for rotating and nonrorating parts of wind turbine.

Lastly, to show that blade loads are modelled well in identified wind turbine mathematical model, blade out of rotor plane bending moment is shown in Fig. 5.

Obviously, it can be concluded that identified wind turbine mathematical model describes wind turbine behaviour well and it can be used for designing of advanced controllers for load

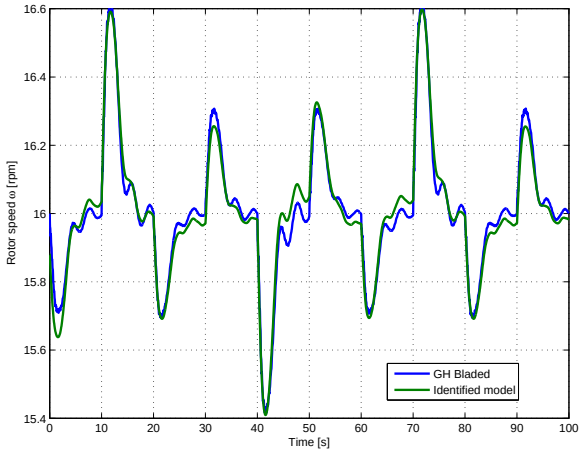

Fig. 3. Validation of identified wind turbine mathematical model – rotor speed response.

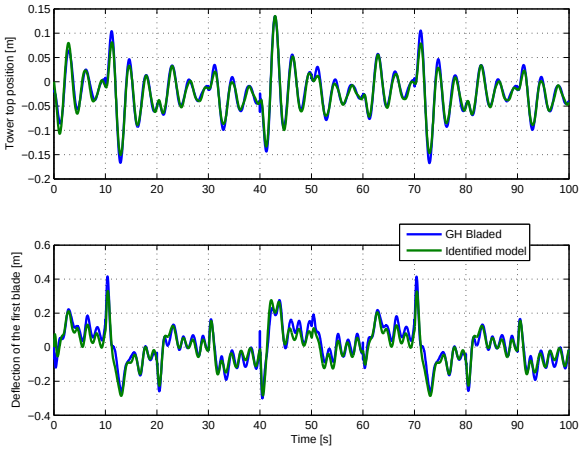

Fig. 4. Validation of identified wind turbine mathematical model – deformations of the first blade and the tower.

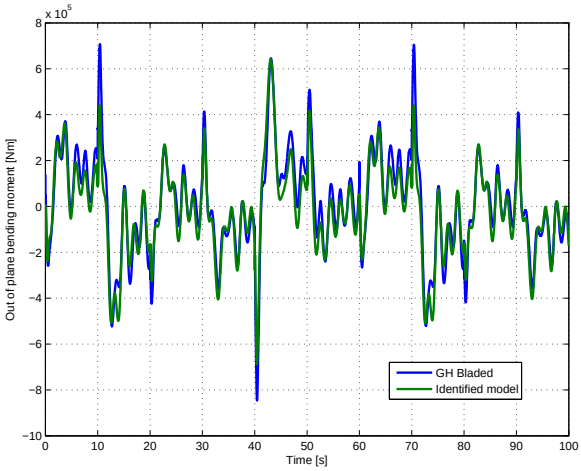

Fig. 5. Validation of identified wind turbine mathematical model – out of plane bending moment of the first blade.

reduction or for reduction of structural oscillations. Because of its simple form (linear model with varying parameters) it can be easily used for control system design.

VIII. Conclusion

Accurate wind turbine mathematical models are well documented in the literature, but due to aerodynamic effects on wind turbine blades, they are typically too complex to be used for control system design. In this paper, much simpler wind turbine mathematical model is derived. Such mathematical model is suitable for control system design, but it also models wind turbine structural deformations and loads accurately.

First, basic wind turbine physics are described. Based on the described wind turbine physics, several identification experiments are carried out in GH Bladed. Wind turbine is divided into submodels and identification of each submodel is described in the paper. At the end, identified submodels are merged into single wind turbine mathematical model and validated using measurements from GH Bladed.

Validation results show a good match between identified wind turbine mathematical model and GH Bladed – both for rotating and nonrotating wind turbine components. Furthermore, the identified wind turbine mathematical model describes structural deformations and loads well, which is essential for advanced controller design. Since the identified model has simple form (linear model with varying parameters), it can be concluded that it is suitable for design of advanced control algorithms.

Abstract - Computer consumers are the largest group of computer users, many of which are highly creative and experts in their area. Despite the fact they have no formal education in computer programming, they want to express their creativity and develop their own applications which will satisfy their needs. Nowadays, consumers can build their own personalized software artifacts using Geppeto (Widget Parallel Programming Tool) by building personalized workflows and dataflows over widgets, small standalone Web applications. However, computer consumers are prone to making mistakes while programming, which results in bugs in their applications. Consumers require assistance of skilled programmers in order to build dependable and error-free applications. This paper discusses new debugging methods based on professional debugging techniques, which will be understandable to average consumer. These methods will allow consumers controlled execution of their applications in order to find and remove bugs. Methods described in this paper are suitable for debugging consumer applications in a widget-oriented consumer programming environment like Geppeto, and include animated step-by-step execution of the consumer's application, adding breakpoints within widget composition and introducing interactive backtracking in order to detect erroneous widget.

I. INTRODUCTION

Computer consumers are the widest group of computer users, which have no formal education in computer programming [1,2]. Many of them are highly creative and experts in their area of interest. They are keen to use professional and personalized applications which satisfy their requirements by their functionality and ease of use. In order to achieve the best quality of experience, as well as express their creativity, consumers build their own applications out of predefined software components made by professionals.

The most common form of software artifacts suitable for consumer's usage are World Wide Web applications [1]. Widgets are small standalone applications displayed in a Web browser. Widgets are equipped with graphical user interface for the interaction with the background process, which is usually a Web based source.

Consumers select a set of widgets relevant to their field of interest and build personalized data flows between widgets by interconnecting their graphical user interfaces. In order to develop complex personalized applications, consumers have to manually interact with multiple widgets, which is impractical. Consumers can use Geppeto (*Widget Parallel Programming Tool*), for automating widget interconnection [1,2,3,4]. Geppeto is a consumer-oriented framework for building workflows of consumer's applications, developed at the University of Zagreb, Faculty of Electrical Engineering and Computing (FER). Applications are built by using widgets as building blocks.

Lacking sufficient education, average consumers, unlike the professional programmers, do not understand the main concepts of programming crucial for development of new applications. Therefore, consumers are prone to making mistakes in their application, even more than the professional programmers, introducing bugs and errors in their applications. While professional programmers have many debugging tools and methods available, none of them are suitable for consumers and their level of knowledge.

This paper discusses new debugging methods based on professional debugging techniques which will be understandable to the average consumer.

The paper is organized as follows. Debugging methods available in professional programming environments are described in Section 2. Section 3 provides an overview of existing debugging methods in various consumer and end-user oriented systems. Section 4 proposes new debugging methods applicable to widget-oriented consumer programming environment. Section 5 gives a short example of consumer's debugging.

II. DEBUGGING

The programming process is divisible into several principal stages: formulate problem, generate plan, code, debug, and verify [5]. Programmers, even most experienced ones, write programs that contain errors. The first indication that a program is incorrect is usually an externally visible symptom, such the wrong value being printed or the system encountering a fatal problem. This externally visible symptom is called a *failure*. A failure is caused by an erroneous internal state (called an *error*) of the program. This error could be an incorrect value for a variable or the program executing in the wrong place. An error state is usually preceded by another error state. This chain of errors can be followed back to the cause. The

cause of the initial error is an algorithmic fault in the program. In debugging, these faults are called *bugs* [6].

Debugging is the process of identifying the root cause of an error and correcting it [7].It contrasts with testing, which is the process of detecting the error initially. Debugging is a difficult job because the programmer has little guidance in locating the bugs. To locate a bug that caused an error, the programmer must think about the causal relationships between events in a program's execution. There is usually an interval between the time when a bug first affects the program behavior and when the programmer notices an error caused by the bug. This interval makes it difficult for the programmer to locate the bug. On some projects, debugging occupies as much as 50 percent of the total development time. For most programmers, debugging is the hardest part of programming [5].

Debugging is a process that has several important and unavoidable steps. First step is to reproduce an error by bringing the program into a previously encountered erroneous state. This task can be very demanding, because some programs do not have reproducible and deterministic behavior, such as highly parallel programs. After the bug is reproduced, the input of the program may need to be simplified to make it easier to debug. This simplification can be done by using divide-and-conquer approach. Programmers than use different debugging techniques to determine the location of the bug [8].

Tracing is debugging technique of watching (live or recorded) trace statements, or print statements that indicate the flow of process execution. Remote debugging is the process of debugging a program running on a system different than the debugger. Post-mortem debugging is debugging of the program after it has already crashed. Related techniques often include various tracing techniques and/or analysis of memory dump of the crashed process. The dump of the process could be obtained automatically by the system or by a programmer-inserted instruction [8].

Modern integrated development tools provide developers with debuggers – specialized tools used in debugging process. Debuggers are used to examine program states, to control execution of a program and to track down the origin of the problem in the code. During debugging, it is very important to change one thing at a time, and to keep an audit trail of changes made in the code. After the bug has been removed from the code, the program has to be tested again, in order to prevent new bugs inserted in the code during the debugging.

III. DEBUGGING IN CONSUMER-ORIENTED PROGRAMMING

Consumer-oriented paradigm has become the most common form of programming in use today [9], but there has been little investigation into the dependability of the programs that consumers create. This is problematic because the dependability of these programs can be very important. Errors in consumer applications, such as formula errors in spreadsheets, have cost millions of dollars [10]. This problem has been recognized and some solutions have been proposed.

"*Interrogative debugging*" technique has been presented for the event-based programming environment Alice. Consumers pose questions in the form of *"Why did…"* or *"Why didn't…"* that the system answers by displaying visualizations of the program. This work builds on their model of programming errors [11], which classifies errors and their causes. Other strategies are *statistical outlier finding* [12] and *anomaly detection* [13], which use statistical analysis and interactive techniques to direct consumer programmers' attention to potentially problematic areas during automation tasks.

Since the spreadsheet paradigm is very popular amongst consumers considerable efforts nave been put into work supporting program comprehension and debugging by end users in the spreadsheet paradigm. This includes devices to aid spreadsheet users in dataflow visualization and editing tasks. Similar groups of cells are recognized and shaded based upon formula similarity, and are then connected with arrows to show dataflow. This technique builds upon the Arrow Tool, a dataflow visualization device [14].

In What You See Is What You Test (WYSIWYT) methodology [9, 15], consumer can test a spreadsheet incrementally as it is being developed by simply validating any value as correct at any point in the process. Behind the scenes, these validations are used to measure the quality of testing in terms of a test-adequacy criterion. These measurements are then projected to the user via several different visual devices, to help them direct their testing activities.

Consumer mashup programming tools, like Marmite and Vegemite, implement execution control elements, which can help consumer in the debugging process [16, 17, 18]. Every mashup element has start, stop and play buttons, which consumer can use in controlling the workflow of his mashup. Additionally, Marmite and Vegemite have separate window where consumer can see the data set changes after applying each building block, and therefore observe dependencies between data and control flow.

Study of cognitive processes during debugging revealed that debuggers for consumer programmers should have the following features [9,19]:

- Animated view of execution
- Display of action data correlated with focus in the action history
- Incrementally-generated history of action execution
- Access from action values to the action history that processed them
- Access from action history to the corresponding action data

IV. DEBUGGING IN WIDGET-ORIENTED CONSUMER PROGRAMMING ENVIRONMENT

In widget-oriented consumer programming environment like Geppeto, consumers create their own personalized widgets by combining previously developed

Fig. 1. Controller

widgets into one composite widget [2]. Consumer can choose the set of widgets which provides the required set of functionalities for consumer application. Widgets are loaded into Geppeto container by entering widget's URL into container interface [3]. These widgets are considered source widgets for the composite widget. After loading the chosen widgets, consumer adds a programmable widget to container.

Programming in Geppeto consists of two steps: defining the user interface of consumer's composite widget and defining the composite widgets logic by building a personalized data flow through selected widgets [20].

Designing the user interface of a composite widget is done by adding graphical user elements from one or more other widgets that consumer has chosen as source widgets. Adding elements is done via the right click menu which can be brought up when the mouse pointer is over a user interface element.

When programming the data flow and the logic behind the composite widget, actions are specified using the right-click menu. Defining a sequence of actions is done by selecting "When clicked" action on an element. Actions of source widgets are defined by option "click" done on action buttons of source widget. Consumer can use input elements to type in text. Communication between source widgets is done by copying output of one widget and pasting it to input of another widget. All sequences the user generates can be viewed and reorganized in a table which is stored together with the generated composite widget.

Consumers understand the level of abstraction of graphical user interfaces and data flows, as well as the concept of widgets and widgets composition. Therefore, debugging tools should be exposed to consumers as widgets as well.

Figure 1 shows the *"Controller"* widget. It enables controlled execution of consumer's application through an animated step-by-step execution. When clicked on the *"Add Watch"* button, a drop down menu is displayed, where consumer can choose between several composite gadgets loaded in the container. Consumer can enter how many actions in a sequence will represent one step of the controller. The *"Play"* button executes one step. Sequence of actions is animated by highlighting the GUI element of the source gadget which is the object of the current action. Consumer can now observe the correlation between data changes and actions that processes that data in a controlled environment,.

Figure 2 shows the *"Debugger"* widget. By clicking on the *"Add Break"* button, consumer can add a breakpoint in the composite widget control flow. A table of actions is displayed, where consumer can choose one action and add a breakpoint after it. After defining a breakpoint, a new gadget, *"Breakpoint"*, shown on Figure 3, is inserted into the consumer application. GUI of the *"Breakpoint"* widget is defined by the GUI element of the source widget affected by the action following the breakpoint. In addition, the *"Play"* button is added, so that consumer can continue execution of his application after the breakpoint.

By clicking on the *"Trace"* button of the *"Debugger"* widget, a table of actions is shown. Consumer can backtrack an erroneous widget by building dependencies between widgets. Consumer can grade each output value of a widget as correct one (√) or incorrect one (X). When an output of a widget is marked as incorrect, the system automatically highlights widgets responsible for calculation of the incorrect value, like the widgets that give input values to the observed widget. This interactive process helps the consumer to concentrate only on widgets that can possibly be faulty, and guides him through the debugging process.

V. CONSUMER DEBUGGING EXAMPLE

This section describes the simple consumer-programmed application, where previously described debugging techniques will be demonstrated. The goal of this application is to sum two numbers, *A* and *B*.

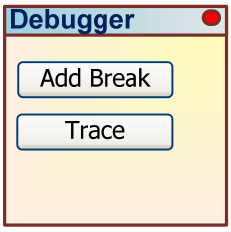

Fig. 2. Debugger

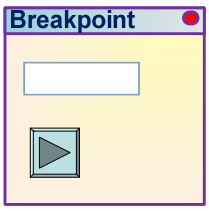

Fig. 3.Breakpoint

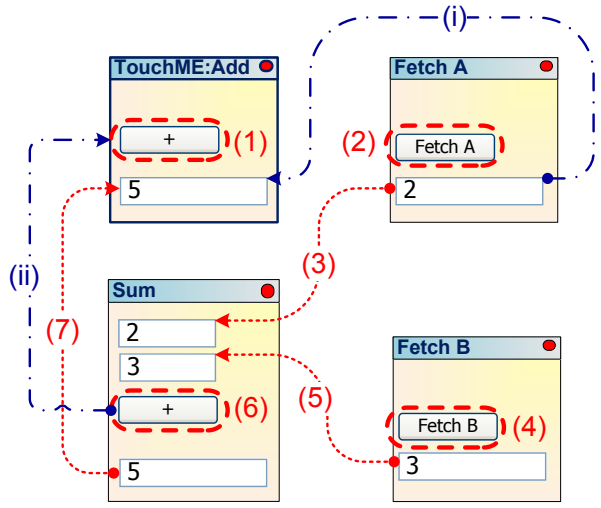

Fig.4. Consumer application

Consumer selects source widgets, *"Fetch A"*, *"Fetch B"* and *"Sum"* and loads them into the container. Consumer than creates a programmable composite "TouchMe" widget called *"Add"* and defines widget's GUI and behavior using Geppeto. Graphical user interface (GUI) of the composite widget is defined. Consumer adds the *"+"* button from the *"Sum"* widget (i) and the textbox element from the *"Fetch A"* widget (ii).

To build the workflow logic, the consumer selects *"+"* button at the composite widget and defines set of actions after selecting *"When Clicked"* option in the Geppeto drop-down menu (1). Consumer clicks on the *"Fetch A"* button of the *"Fetch A"* widget in order to fetch value of variable *A* (2). He copies value of variable *A* to the first input field of the widget *"Sum"* (3). Then he clicks on the *"Fetch B"* button of the *"Fetch B"* widget to get the value of variable *B* (4) and copies it to the second input field of the *"Sum"* widget (5). After clicking on the *"+"* button, the value *A+B* is displayed in the output field of the *"Sum"* widget (6). The consumer copies that value from the "Sum" widget to the output data field of the composite "Add" widget (7). The table of consumer-programmed actions that define data and control flow of the composite widget can be seen in Table 1.

TABLE 1. TABLE OF ACTIONS

Click fetchA @ fetchA
Copy A @ FetchA to A @ Sum
Click fetchB @ fetchB
Copy B @ FetchB to B @ Sum
Click + @ Sum
Copy S @ Sum to res @ Add

In order to control the execution of his application, consumer adds new widget, *"Controller"* to his application. The Consumer than adds watch to the composite "Add" widget via the user interface of the *"Controller"* widget, and sets the step on 1 action.

When consumer clicks on the play button, the first action will be executed. Controller widget will click on the *"Fetch A"* button on the *"Fetch A"* widget, which will be highlighted (1). After the second click on the play button, the output box of the *"Fetch A"* widget and the first input box of the *"Sum"* widget will be highlighted (2), and the value of variable A will be copied from widget *"Fetch A"* into the widget *"Sum"* (3). On the following consumer's clicks on the *"Play"* button, actions (4) to (7) from the table of actions will be executed respectively with highlighting of the affected graphical user interface elements.

To add a breakpoint in his application, the consumer uses a *"Debugger"* widget, displayed in the Figure 5. When clicked on *"Add Break"* button, a table of actions is displayed (i). The consumer can see list of actions and chooses to add a breakpoint after the first action (ii). After defining a breakpoint via the *"Add Break"* button, a new gadget, *"Breakpoint"* is inserted into the consumer application. GUI of the *"Breakpoint"* widget consists of the input field of the "Sum" which is the destination of copy action where breakpoint was added (iii).

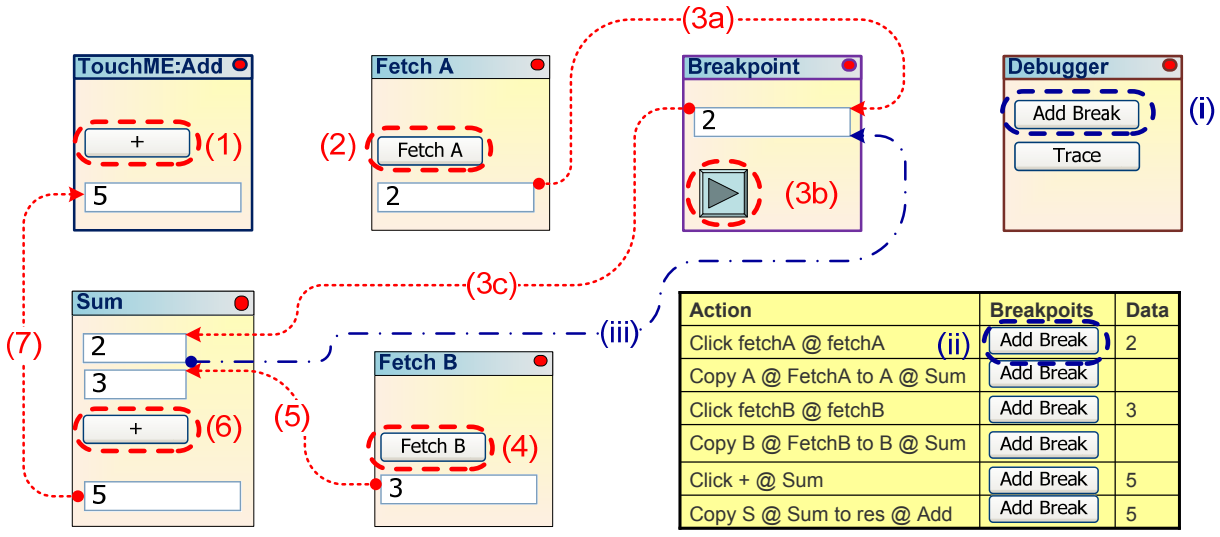

Fig. 5. Adding breakpoint

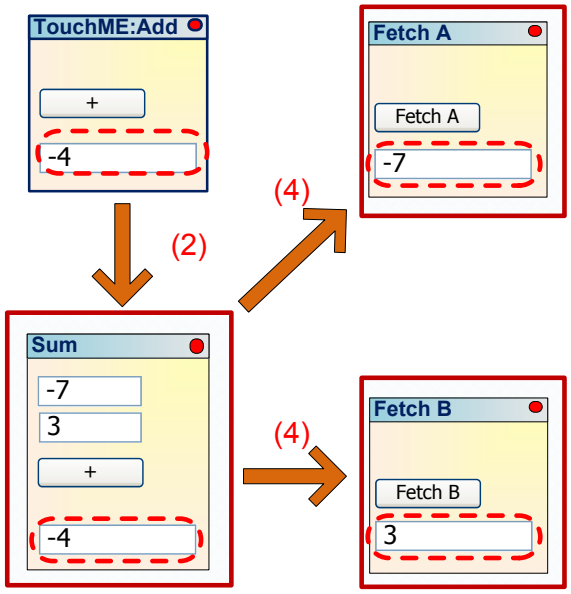

Action	Corr	Data	
Click fetchA @ fetchA	?	-7	
Copy A @ FetchA to A @ Sum	✗		(6)
Click fetchB @ fetchB	✓	3	(5)
Copy B @ FetchB to B @ Sum	?		
Click + @ Sum	✗	-4	(3)
Copy S @ Sum to res @ Add	✗	-4	(1)

Fig. 6. Backtrtacking erroneous widget

Now, the consumer starts his application by clicking on the *"Add"* button of composite *"Add"* widget. Actions will be executed sequentially as displayed in the table of actions until the action (2) is finished. Action (3a) will copy the value from widget *"Fetch A"* into the textbox of *"Breakpoint"* widget and the execution will be halted. Consumer can now see the values of his data sets after actions prior to break point. After clicking on the *"Play"* button (3b), value from breakpoint widget will be copied into the first input field of the *"Sum"* widget (3c). The execution will continue from action (4) until the last action in the table of actions.

In case the consumer's application didn't produce the expected result, consumer must find out which widget from his composition is responsible for that error, in order to debug his application. The *"Trace"* option of the *"Debugger"* widget can be used backtrack an erroneous widget by examining correlations between widget actions and data set changes. Tracing is shown in Figure 6.

The consumer detected that his application, composite widget *"Add"* produces the wrong result. Variable A and B should be positive, yet the result of their summation is negative. The consumer marks the output value of the *"Add"* widget as incorrect, *"X"* (1). The debugger automatically selects the widget *"Sum"*, that is responsible for the output of widget *"Add"* (2). The consumer now examines actions of widget *"Sum"*. Addition is marked as incorrect, *"X"*, (3). The debugger selects widgets "Fetch A" and *"Fetch B"* which provides an input values to *"Sum"* widget (4). The consumer examines action of selected widgets. He marks action at *"Fetch B"* as correct *"√"* (5), and action at *"Fetch A"* as incorrect *"X"* (6). Therefore, the bug has been detected, and the widget *"Fetch A"* is labeled as faulty. The consumer must reprogram his application, and replace the faulty widget *"Fetch A"* with the correct one.

VI. CONCLUSION

This article addresses the problem of debugging in the consumer-programming oriented environments. Consumers are prone to making mistakes in their applications, and need assistance of experienced programmers in order to write reliable software. However, because consumers are different from professional programmers in background, motivation, and interest, their needs cannot be addressed by simply repackaging techniques and tools developed for professional software engineers. Debugging methods available to professional programmers are not suitable for consumers, since they do not have necessary knowledge of programming process.

New debugging methods based on professional debugging methods are proposed, that are appropriate to average consumers and that will motivate them to debug their applications. These methods are designed for debugging consumer applications in a widget-oriented consumer programming environment, and include animated step-by-step execution of the consumer's application, adding breakpoints and interactive detecting erroneous widget.

Reliability Modeling for SOA Systems

G. Delac, M. Silic and S. Srbljic
University of Zagreb Faculty of Electrical Engineering and Computing, Croatia
{goran.delac, marin.silic, sinisa.srbljic}@fer.hr

Abstract - Service-oriented architecture (SOA) is a popular paradigm for development of distributed systems by composing the functionality provided by the services exposed on the network. In effect, the services can use functionalities of other services to accomplish their own goals. Although such an architecture provides an elegant solution to simple construction of loosely coupled distributed systems, it also introduces additional concerns. One of the primary concerns in designing a SOA system is the overall system reliability. Since the building blocks are services provided by various third parties, it is often not possible to apply the well established fault removal techniques during the development phases. Therefore, in order to reach desirable system reliability for SOA systems, the focus shifts towards fault prediction and fault tolerance techniques. In this paper an overview of existing reliability modeling techniques for SOA-based systems is given. Furthermore, we present a model for reliability estimation of a service composition using directed acyclic graphs. The model is applied to the service composition based on the orchestration model. A case study for the proposed model is presented by analyzing a simple Web Service composition scenario.

I. INTRODUCTION

Service-oriented architecture provides guidelines for development of loosely coupled distributed systems. At its core are services, applications deployed on various network nodes accessible through a unified interface. The most common implementation of SOA is the *Web Services* technology (*WS*) [8]. However, other approaches in implementing SOA are also possible, like utilizing the *REST* architectural style. One of the greatest advantages of SOA is the ability to combine several services and redeploy them as a new service with added-value, i.e. service composition. This makes SOA particularly popular in designing enterprise systems, since different parts of business process functionalities can be deployed by various organizational units. Furthermore, the service composite behavior is easily modified and thus the SOA-based systems provide great flexibility in environments where demands constantly change. However, designing service compositions also presents additional challenges since the services can be deployed by third parties over which the composition designer has no control. A possible concern in such an environment is the necessity to design a composition with a specific level of reliability.

In this paper we introduce a software reliability growth model for service composition development. The basis for reasoning about service composition reliability is the knowledge of reliability for all atomic services that are used as composition's building elements. We define a model used to estimate the reliability of atomic services by utilizing a testing framework. Furthermore, we propose to model the reliability of a service composition by using directed acyclic graphs. In addition, a simple method for detecting weak points in the composition reliability model is introduced. We propose to strengthen the weak points by utilizing fault tolerance methods. Finally, we give an overview of the existing methods for service reliability estimation.

The rest of the paper is structured as follows: In Section 2, an overview of the existing methods used to calculate reliability of SOA-based systems is presented. Service composition development model aimed at improving the composition reliability is presented in Section 3. The model is complemented by a service composition use case example. Section 4 concludes the paper with discussion on model's accuracy.

II. RELATED WORK

In [1] authors present a model used to estimate the reliability of the Web services platform. A general framework for testing and reliability assessment for Web services and its integration into the Web service architecture is presented. The proposed reliability model takes into account both the reliability of an individual (atomic) Web service as well as the overall reliability of service compositions. In order to avoid the usage of monitors for fault detection in atomic services, a voting method is used. The applied approach is similar to N-version programming [10]. Each atomic service has to be assigned a set of services with equivalent functionality. The faults are detected by applying the majority vote principle, i.e. the fault is detected if consensus cannot be reached. The presented model for atomic services calculates the reliability in regular time intervals based on the vote outcomes in each interval. A clear advantage of this approach is the ability to measure the reliability during system's operation. However such an approach implies the usage of multiple variants or replicas of the same service in order to estimate reliability, which is resource demanding. The reliability values of atomic services are used to compute the overall service composition reliability. Specifically, the model estimates the reliability of a scenario defined by a set of operations performed on the atomic services. Each scenario is weighted by its execution rate and can consist of operations executed in a sequence, concurrently or repetitively, i.e. in a loop.

The approach considered in [2] calculates the overall quality of service of an individual service in a service composition. The estimated quality is to serve as guidance for the developers to detect weak points in their compositions. For each service a quality matrix is

maintained which can hold multiple quality parameters. For reliability purposes authors suggest monitoring availability and accessibility. Also, an involvement matrix is used to define how relevant the functionalities of a particular service are in a service composition. By utilizing these two matrices weight factors for each service can be calculated. The weight factors are multiplied by service quality parameters to get the overall quality of service. The authors propose a monitoring environment in which the services are accessed through a unified mediator. The mediator performs quality measurements and stores the results in the repository. The analyzer then extracts the measurements from the repository and performs the reliability estimations.

In [3] the authors propose to add fault tolerance support for service-oriented systems by extending the SOA meta model. The model is extended with additional components that provide means to model fault detection and mitigation processes. The basic components used are: monitor, comparator, selector and policy. When a fault is detected, monitors are placed in the model to localize the faulty behavior to a specific component. Then, the component is replaced by the selector with a functionally equivalent component that displays correct behavior. To detect the functionally equivalent component, a comparator is used. The comparator scans service descriptions available in the service registry and groups the services according to their similarity. Finally the policy component holds all the policies for the selector component which can take into account time, cost and dependability parameters. The main disadvantage of this model is dependence on similar services created by the comparator component. The service descriptions often do not contain enough useful information to properly group services. In addition, although proper monitor placement is crucial for the model's performance, it is not addressed by the authors.

A framework for selection of optimal fault tolerance strategies for Web services is presented in [4]. The authors suggest harnessing time-redundancy and space-redundancy strategies as well as their combinations to facilitate fault tolerance for Web services. A model used to calculate failure rate and response time based on the values for individual services is presented. The model is implemented as a distributed evaluation framework. The framework should be run by an independent third party and its main purpose is to relieve the users of the necessity to measure performance of Web services. With the measured performance parameters an evaluation can be performed for each fault tolerance strategy. The results are further processed by a utility function, matching them with the user requirements. Based on the calculated utility function, the optimal fault strategy for a particular service and user requirements is suggested. In order to cope with the varying performance of web services, a dynamic reconfiguration approach is presented in which service performance parameters and user requirements are frequently updated to recalculate the optimal strategy. However, although frequent testing can have an impact on the service performance itself, it is not addressed by this paper. The authors outline that the approach is valid only for stateless services and that the quality of service parameters could be extended.

In [5] the author proposes an approach based on service level replication, i.e. space-redundancy method, to construct a fault tolerance framework for web services. The approach is founded on the consensus-based replication algorithm inspired by Paxos protocol family. During each client request one replicated service takes the role of primary replica. The primary replica communicates with other replicas attempting to reach the consensus on the given client request. If the request is supported by the majority of replicas, the primary replica returns the response to the client node. During the next request, another replica can take the role of the primary replica. The presented approach is lightweight, since it can be easily integrated with the existing WS infrastructures. Although no additional infrastructure, such as monitors or mediators is required, replicated services need to be modified to implement the consensus protocol.

In [6] the author presents a methodology to select an optimal web service composition based by QoS and risk parameters. If more than one viable service composition is possible, the optimal one is selected in two steps. First, the composition with the best QoS parameters is selected, i.e. the composition in which each atomic service performs the best. Second, the composition plan is described with a Petri net and then translated into a fault tree used to calculate the overall composition risk. Finally the composition is modified by selecting appropriate services on basis of finding an optimal balance between the QoS and the overall composition risk. The author suggests performing the optimization by linear programming or a genetic algorithm, which could be impractical in cases where services rapidly change their QoS parameters.

In [7] the author presents formal approach that allows a workflow architect to develop and evaluate complex composite Web Services in the terms of reliability. The article analyses workflow patterns considering a specific set of patterns from control-flow perspective. Control-flow defines the execution order of a set of activities that are incorporated in Web Service composition. Furthermore, the author narrows the set of workflow patterns to the set of relevant workflow patterns from the reliability point of view. In addition, the authors use pattern-specific formulas in order to express the overall pattern reliability. Also, in the article the authors use reduction algorithm that recognizes workflow patterns in Web Services composition and calculates reliability for that particular part of composition and collapses it into a single task. The process is iterated until the whole Web services composition is collapsed into a single pattern and its reliability is calculated. In this article, the authors did not present the reduction algorithm and did not answer how the reliability factors of the elementary Web Services are calculated.

In [12] authors provide a formal model for predicting the reliability of Web Services. The distinction is made between three types of services: atomic services, tight composite services and loose composite services. For atomic type of services, the presented model uses collected data from service usage history. This requires

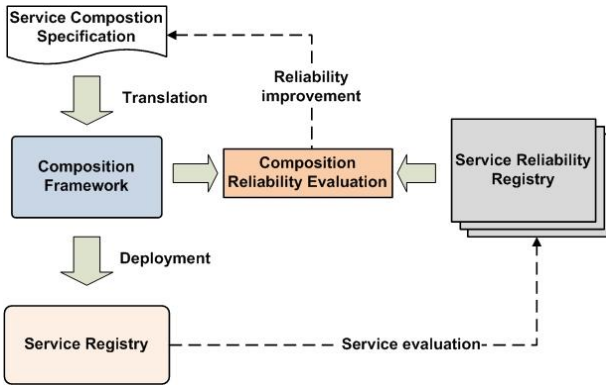

Figure 1. Service Composition Development Model

the extension of the UDDI model, which is presented in the article. The extended model assumes tracking service usage and collecting usage data. For composite type of services, the presented model considers both the overall structure of the composite service and the reliability of each atomic service that is a part of the composition. The model isolates elementary composite structures and defines formulas for their reliability calculation. Authors also describe the recursive algorithm for composite structure reliability computation in pseudo-code. Algorithm assumes recursive substructure recognition and reliability computation until the elementary structures are recognized and their reliability calculated. However, the substructure recognition algorithm is not described in the article.

III. RELIABLE SERVICE COMPOSITION

In this paper we introduce a model for service composition reliability estimation. We argue that this model can be used to aid the service composition development process by improving the overall composition reliability. The presented approach is based on the development model shown in Figure 1. The elements addressed by the model are briefly described below.

Service Composition Specification is a description of composite service's functionality. Specifically, it defines the interaction between various services which is needed in order to achieve the desired functionality for a given composition. Interaction between services is defined as a sequence of service invocations. The services used to construct service compositions will be referred to as atomic services in the rest of the paper. When designing a service composition specification, the necessary condition is to satisfy the functional requirements of the composition logic. However if the functional requirements can be met by constructing more than a *single service composition specification*, the non-functional requirements, such as various quality of service parameters, can be taken into account. In the presented model, service composition specification can be defined by utilizing business process modeling languages, like *BPEL* [11], *CL* [13], *SSCL* [13], *Husky* [14], or other modeling notations. The specification can be generated by humans or automatic service composition frameworks.

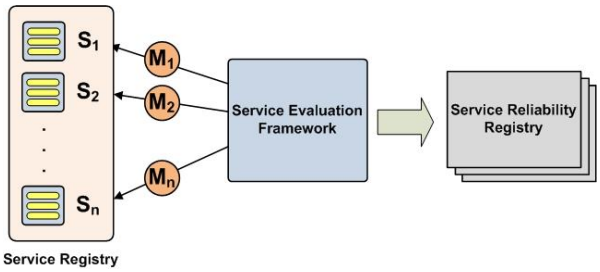

Figure 2. Service Composition Reliability Modeling

Composition Framework translates the *Service Composition Specification* into its implementation. The framework estimates the overall reliability of the service composition based on the reliability of each atomic service. The reliability values of atomic services are accessed from the *Service Reliability Registry*. The constructed reliability model is used to detect the weak points in the composition and suggest improvements to the *Service Composition Specification*. Reliability model generation and composition improvement methods are further discussed in the following sections. Once the reliability requirements are met, the *Composition Framework* is used to deploy the service composition and add it to the *Service Registry*.

Service Registry contains the list of available atomic services and all the necessary information needed to properly invoke their functionality. An example of Service Registry implementation are UDDI based registries for Web Services. It should be noted that compositions can also be registered in the *Service Registry* and used as atomic services in other compositions.

Service Reliability Registry stores the reliability values for all methods of each atomic service. The values are obtained by performing reliability evaluation measurements used to gather information on actual service performance. The reliability measurement for atomic services is discussed in the following subsection.

A. Reliability of Atomic Services

Crucial prerequisite in predicting the reliability of a service composition is the ability to reason about reliability of each atomic service included in the composition logic. In this paper, we consider a service evaluation model presented in Figure 2. Estimation of atomic service reliability is done by performing measurements on the deployed services which are accessible through the service registry. The measurements are performed by the evaluation framework. For each service $S_1 \ldots S_n$ from the service repository a corresponding monitoring process $M_1 \ldots M_n$ is maintained. Each monitoring process is responsible to periodically test the service by invoking all its methods. In the proposed framework, reliability of each method is stored separately. One of the approaches to predict reliability is to maintain the history of the method's invocation attempts. The reliability can then be estimated by dividing the total number of fault occurrences by the number of invocation attempts. The Service Evaluation Framework should provide means to detect Byzantine faults, i.e. both the

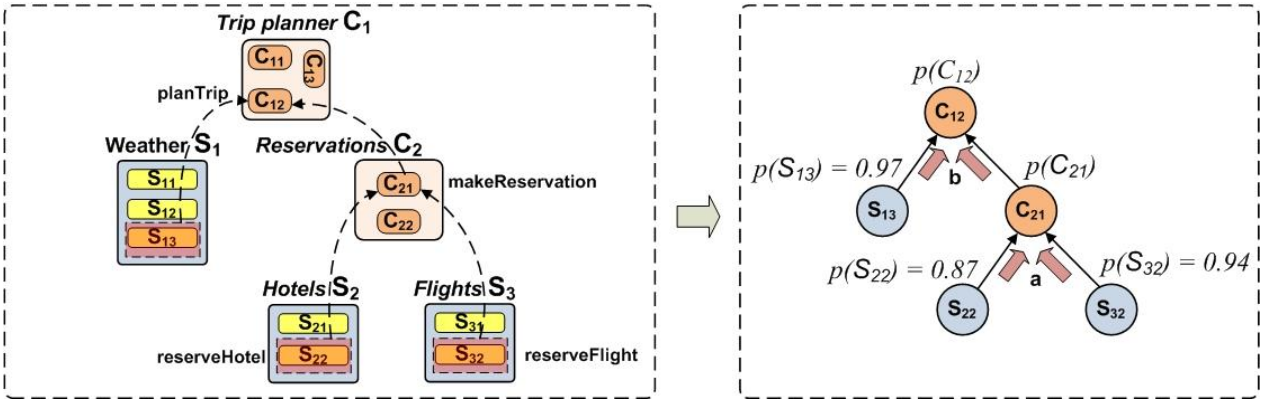

Figure 3. Service Composition Reliability Modeling

faults caused by the lack of service, as well as faults caused by improper service, like returning corrupt data. Therefore, the reliability for a service method can be modeled by the equation:

$$r_{i,j} = (a_{i,j} + c_{i,j}) / n_{i,j} \quad (1)$$

where i is the service identificator, j the service method identificator, $a_{i,j}$ and $c_{i,j}$ are total counts of failures related to availability and service correctness respectively and $n_{i,j}$ the total number of executed tests.

In order to get a precise reliability measurement, the service tests should be relatively frequent, but, on the other hand, they should not have a severe impact on the service's performance itself. In addition, the tests should be run for some time to get a wider usage history. On the other hand, the service responses should be tested thoroughly to detect if the service is operating within its specifications. Therefore, the test coverage should be high and include corner cases. These issues are not in the scope of this paper. For the reasons mentioned above, in would be impractical to strain the service composition designers with the necessity to create and execute service tests before the service composition can be implemented. Therefore the *Service Evaluation Frameworks* should be run by independent third parties whose responsibility would be to maintain the *Service Reliability Registries*. An approach similar to service level agreement (SLA) can be used to construct such an environment.

B. Service Composition Reliability Model

A simple service composition that will be used as a use case example for the reliability prediction model throughout the paper is presented in Figure 3. Specifically, we analyze the reliability of the *planTrip* method exposed by the *Trip planner* composite service C_1. The method is used to plan a trip according to weather conditions at the destination and the possibility of reservations. This is done through *makeReservation* and *getWeather* methods exposed by *Reservations* C_2 and *Weather* S_1 services respectively. It should be noted that the *makReservation* method is exposed by the composite service C_2 that utilizes *reserveHotel* and *reserveFlight* methods of services *Hotels* S_2 and *Flights* S_3 to check if the reservations are possible. Reliability of all the methods exposed by atomic services is previously measured and can be accessed through the *Service Reliability Registry*.

We introduce a model for overall service composition reliability prediction based on the directed acyclic graph approach. When reasoning about service composition reliability, it is clear that the reliability of each atomic service has impact on the overall composition reliability. We further define the model below.

Graph node stands for the reliability of an atomic (composite) service method S_{ij} (C_{ij}), where i is the service identificator and j the service method identificator. The atomic service node has no incoming edges, while the composite service node can have both the incoming and outgoing edges.

Graph edge leading from an atomic (composite) service node S_{ij} (C_{ij}) to composition node C_{ab} denotes that the composition C_a is dependent on service S_i (C_i) since its method b invokes the method j of S_i (C_i). Therefore, the edges are oriented in the causal direction, since they point from the cause (atomic service), to effect (service composition).

It should be noted that cycles in the presented graph model are not allowed. In effect, cycles in service invocations are not possible and are therefore not supported by the proposed model.

An example of the proposed model for the *Trip planner* composite service is given in Figure 3. The method *planTrip* (C_{12}) of the service composition C_1 is modeled as node C_{12} in the directed acyclic graph. Similarly, nodes S_{13} and C_{21} are assigned to methods *getWeather* and *makeReservation*. Since the method C_{12} invokes methods S_{13} and C_{21}, such dependence is denoted by directed graph edges from service nodes S_{13} and C_{21} to C_{12}. Similarly, since the method C_{12} is constructed by composing methods *reserveHotel* (S_{22}) and *reserveFlight* (S_{32}), an edge pointing from nodes S_{22} and S_{32} to C_{12} exists in the presented graph model.

We define a service composition reliability prediction based on the directed acyclic graph. It is assumed that the failure of any atomic (composite) service method S_{ij} (C_{ij})

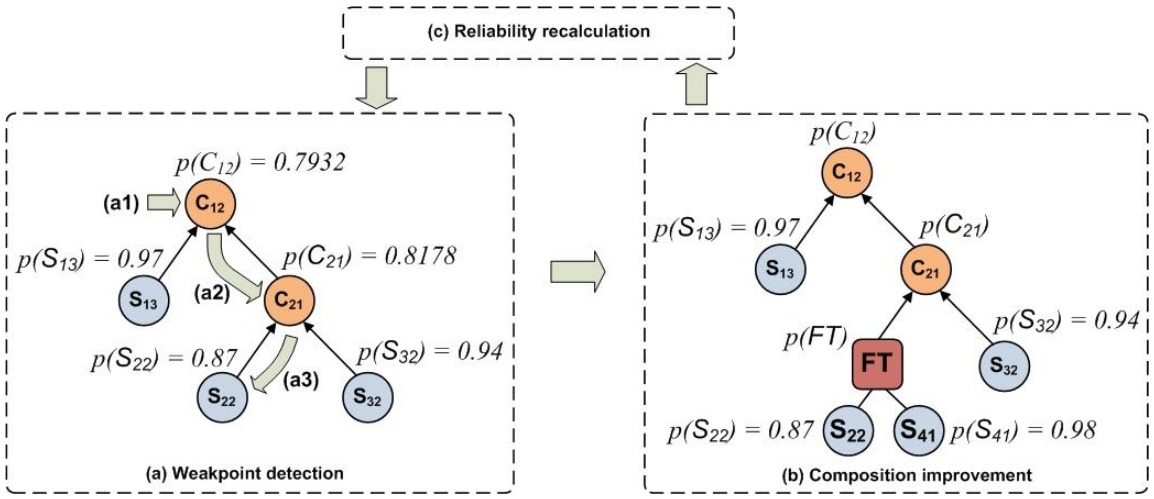

Figure 4. Service Composition Improvement Cycle

invoked by C_{ab} will lead to the failure of the composition method C_{ab}. In addition, we consider all failure occurrences in services S_{ij} (C_{ij}) to be conditionally independent. Therefore, the reliability prediction for a graph node C_{ij} which has n incoming edges $S_{1,1} \ldots S_{n,m}$ can be calculated by the following equation:

$$p(C_{i,j}) = p(S_{1,1}) \cdot \ldots \cdot p(S_{n,m}). \quad (2)$$

Since the atomic service in a service composition can be another composition, the depth of the acyclic directed graph can be greater than 2, as presented in example on Figure 3. Thus, the overall reliability is calculated in the causal direction, starting with the atomic services, i.e. services with no incoming arcs. Consequently, for the example in Figure 3, first the reliability of C_{21} is calculated (a) $p(C_{21}) = p(S_{22})p(S_{32}) = 0.8178$ and then the reliability of the service composition method C_{12} (b) $p(C_{12}) = p(C_{21})p(S_{13}) = 0.7932$.

C. Reliability Improvement Method

The presented directed acyclic graph reliability prediction model can be used to improve the overall service composition reliability. In this paper we introduce a reliability growth model presented in Figure 4. The improvement cycle defined by the model consists of: *weak point detection*, *composition improvement* and *reliability recalculation*. First, a weak point in the model is detected (a). The detected weak point is then improved to increase its reliability (b). Finally the overall reliability prediction of the service composition is recalculated by utilizing the model defined in Section 3b (c). The iterative process of service composition reliability improvement is continued with step (a) until the desired composition reliability has been achieved.

Weak point detection method presented in this paper is based on traversing the directed acyclic graph in the non-causal direction, i.e. opposite of the direction in which the reliability prediction is calculated, starting at the composition node. In each step, the next node is selected by choosing the one of the underlying service nodes with the lowest reliability value. This process is repeated until an atomic service is reached, i.e. a node with no incoming arcs. The located atomic service is considered to be a weak point in the service composition. An example of the presented weak point detection method applied to the *Trip planner* service model is given in Figure 4a.

The entry point for the algorithm is the node of the evaluated service method. In the given example, service composition method *planTrip* is analyzed and thus the node is C_{12} selected (a1). In the next step, node C_{21} is selected over node S_{13} because $p(C_{21}) < p(C_{31})$ (a2). Finally the node S_{22} is reached since $p(S_{22}) < p(S_{32})$ (a3). Node S_{22} is the detected weak point since it has no incoming edges to continue the search.

Once a weak point is detected, the overall composition reliability can be improved by performing modifications to the node in question. A possible solution is to change the corresponding atomic service with a more reliable one, if such a service exists in the service repository. If no such change is possible, we propose the introduction of fault tolerant services. The fault tolerant services are a wrapper around several other services that expose the same functionality. Therefore, fault tolerance is achieved by utilizing space redundancy, meaning that if one of the redundant atomic services fails, others can compensate for this failure. For example, services S_{22} and S_{41} in Figure 4b are redundant.

Several strategies can be used to construct the fault tolerant service *FT* [9][10] which performs both the fault detection and mitigation. For example, if the recovery blocks strategy is used, the reliability of the fault tolerant service can be calculated as follows:

$$p(FT) = 1 - p(\neg S_{1,1}) \cdot \ldots \cdot p(\neg S_{n,m}), \text{ where } p(\neg S_{i,j}) = 1 - p(S_{i,j}) \quad (3)$$

and $S_{1,1}$ … $S_{n,m}$ are redundant atomic services. Once the improvements to the composition are complete, the overall composition reliability is recalculated.

For the service composition example given in Figure 4b, the weak point S_{22} can be strengthened by applying one of the improvement strategies. Let us assume that another service for hotel reservation is available in the service registry and that the reliability of corresponding method is $p(S_{41})=0.98$. We can apply the described fault tolerance approach based on recovery blocks by replacing node S_{22} with a fault tolerant service *FT*. Service *FT* uses both the services S_{22} and S_{41} to improve the reliability by compensating in cases that one of the services fails. The reliability of node *FT* is calculated by utilizing equation (3): $p(FT) = 1- (1 – p(S_{22}))(1 – p(S_{41})) = 0.9974$.

Finally, the overall service composition has to be recalculated. The reliability estimation for node C_{21} equals: $p(C_{21})= p(FT)p(S_{32}) = 0.9375$. Finally, the reliability for method C_{12} is reestimated to: $p'(C_{12})= p(C_{21})p(S_{13}) = 0.872$. Thus, the reliability estimation for the method C_{12} has improved by $p'(C_{12}) - p(C_{12})=0.1443$ as a result of strengthening the weak point S_{22} with a fault tolerant service *FT*.

IV. CONCLUSION

In this paper we presented an overview of methods used to model service composition reliability. A model for service composition development aimed at increasing the composition reliability was introduced. In order to calculate the reliability prediction, it is necessary to know the values for reliability of each atomic service participating in the service composition. A brief overview of an atomic service evaluation model based on the testing framework was given. The composition reliability prediction model is constructed as a directed acyclic graph, where nodes present service method reliabilities and edges composition dependabilities. Furthermore, a method for composition improvement has been introduced. The method applies a simple strategy to locate weak points in a composition. A weak point is detected by traversing the graph and selecting the component with lowest probability in each step until an atomic service is reached. The weak point can then be further improved by replacing it with a more reliable service or by utilizing fault tolerance methods, like *recovery blocks* or *N-version programming*. The iterative process of calculating overall composition reliability and improving weak points is repeated until the desirable reliability level is reached.

The accuracy of the model presented in this paper is influenced by the accuracy of reliability estimation for atomic services. As stated in Section 3a, the accuracy of this estimation depends on the frequency of conducted tests, as well as the test coverage for the faults related to improper service. Furthermore, the assumption that a failure in one service will cause the failure of the entire service composition can cause an overestimation. This is due to the fact that not all the services might be equally crucial for the composition's normal operation. In such cases, our model will estimate the reliability to be lower than the actual value. Introducing weight factors representing the influence of a service on the composition can further improve the model. Thus, the future research efforts will be directed at investigating how efficient and quickly, i.e. in how many steps, the proposed reliability growth model converges towards the desired reliability. Additionally, the application of other improvement methods and their impact on the model will be considered.

Abstract – Number of internet users as well as number of large distributed computer systems has increased dramatically in the last decade. Large distributed computer systems serving lot of users are usually oversized in order to be able to keep up with user demand surges. However in many usage scenarios workload spikes are rare and systems operate on 20%-30% average utilization. Underutilized systems are shown to be power inefficient and different strategies are proposed to tackle this issue. In this paper we present an overview of different power saving techniques that target different types of systems and workloads.

I. INTRODUCTION

Internet services such as web search, mail, social networking and cloud computing are becoming increasingly popular. This increase in popularity generating a lot of revenue motivates companies to fight for their users by both improving their services as well as enhancing user experience. Improvement in user experience generally comes from high availability and performance guarantees. Performance guarantees and high availability are achieved by over engineering systems which in turn leads to a lot of underused system capacity over extended time periods. It is shown [1][2] that large datacenters are largely underexploited with 20%-30% average utilization. Oversized systems lead to increased power usage that can be leveraged by different saving schemes.

The problem of internet services growth causing increase in energy consumption was recognized by EPA in 2007 report to U.S. Congress [3]. The report estimated power consumption to increase twofold in five years time. More recent study by [4] shows that increase in energy consumption is actually about 36% in the U.S. and 56% worldwide. Lower than expected increase in electricity use is attributed to the 2008-2009 economic crisis and the use of virtualization technologies in data centers. Exploitation of virtualization technology is considered an energy preserving technique.

Energy preservation is not a new goal in computer system design. Miniaturization of the technology and rise of mobile devices in late 80s and through the nineties forced hardware manufacturers to improve battery technology and implement power management techniques into their products. However these techniques are of limited availability in modern server systems which make power efficient designs more difficult to come up with.

Different strategies for energy conservation are proposed on different optimization levels. Location of new data centers are being carefully selected according to climate conditions [5]. Natural sources such as wind and nearby rivers are used to prevent electricity to be spent on cooling the equipment. On the other hand hardware manufacturers can employ several energy saving techniques in order to make power efficient system design possible. On a software level, which includes operating systems and data center management software, different schemes are used to improve data center energy efficiency.

In this paper we give an overview of different system design techniques (both hardware and software) that can be used to decrease power usage in data centers. Section II contains description of hardware components, their energy consumption and designs that can be used (some coupled with appropriate control software) to preserve energy. In section III we present commonly used data centre architecture as well as some of the representative workloads used to estimate power efficiency of different techiques. In section IV we give classification and comparison of different energy saving techniques.

II. HARDWARE BASED POWER OPTIMIZATION

Hardware design is a starting point for every energy optimization technique. Software based strategies are engineered to exploit on different hardware provisioned energy modes taking given workload into account. Energy consumption by a typical data center server made from commodity components is given in Table I [6]. Additional power conversion losses and cooling overheads in modern facilities can be approximately modeled as a fixed percentage of the computing power [6]. However some authors [7] specifically tackle power conversion losses

TABLE I. SERVER COMPONENTS ENERGY CONSUMPTION

COMPONENT	POWER DRAW		
	Peak Power	*Count*	*Total*
CPU	40W	2	80W
Memory	9W	4	36W
Disk	12W	1	12W
PCI Slots	25W	2	50W
Motherboard	25W	1	25W
Fan	10W	1	10W

and propose a more power efficient power supply design.

In this section we break down CPU, hard drive and power supply energy consumption and reveal hardware optimizations that can be exploited to optimize energy consumption of these components.

A. CPU

CPU is a main single power hog component in computer systems. It consumes about 40% of total energy (depending on server design) when fully loaded. The main problem is that CPUs rarely operate at 100% utilization and CPU power consumption is not proportional to utilization.

Generally electronic device power consumption according to Ohm's law is:

$$P = C \cdot V^2 \cdot f$$

where C is capacitance, V voltage and f operating frequency. Although this equation does not take utilization into account, hardware manufacturers came out with designs that are able to manipulate voltage and frequency and even turn off unneeded parts of the circuitry. This is done by employing hardware design techniques such as clock gating.

Some authors [8] argue that Ohm's law is oversimplification for power consumption in modern CPUs and they propose different empirically based power models such as:

$$P(f_i, U_i) = a_{i3} \cdot f_i \cdot U_i + a_{i2} \cdot f_i + a_{i1} U_i + a_{i0}$$

where f_i and U_i are discrete combinations of frequency and utilization and a_{ij} constants are obtained experimentally by curve fitting the model with experimental results.

Modern processors employ several power saving techniques which are abstracted by power states. Power states for Intel desktop processors are shown in Fig. 1 [9]. Computer system can be in one of the 3 main states: working, sleeping or mechanical off. If the system is working then CPU or some of its cores can enter one of the *C* states. Each *C* state defines parts of the CPUs that are inactive causing the energy consumption to decrease. Higher *C* states have lower electricity usage due to more CPU parts being disabled, but they also require longer wakeup time. Measurements on a Dell Vostro 430s system running at 2.93Ghz reveal entire system power consumption in *C0* CPU state to be about 110W [10]. Power usage decreases by 45%, 50% and 60% when CPU is forced to *C1E*, *C3* and *C6* states.

When CPU or some of its cores is in active mode (*C0*) it is possible to control its performance and power consumption by entering into one of the power states (*P0..Pn*). Power states are discrete states with predefined frequency and voltage combinations that are used to preserve energy when system is not fully utilized. Although power usage is decreased when CPU clock is scaled down it takes longer time to perform computations on lower frequencies and this must also be taken into account when simulating energy saving techniques.

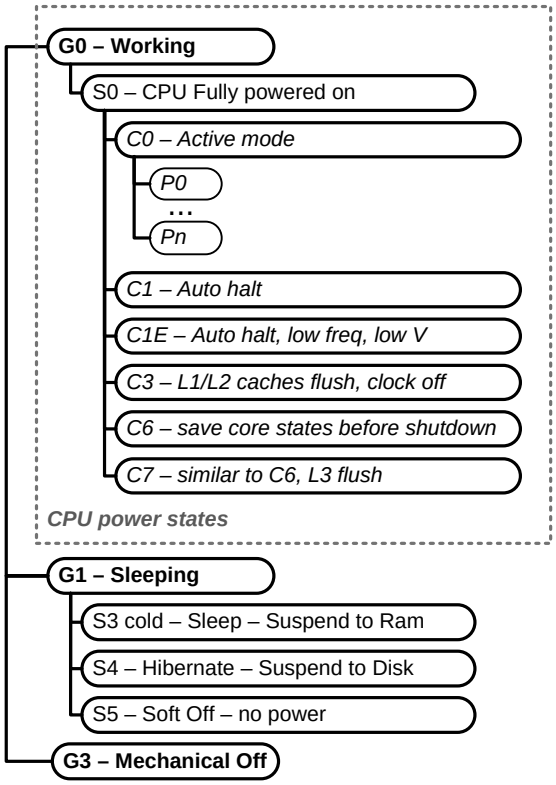

Figure 1. Sytem/CPU power states

B. Hard drives

Hard drive power consumption ranges from few watts up to 15 watts mostly depending on the platter rotation speed. Hard drive manufacturers have also recognized needs for power savings in large data centers and they have introduced several power states controllable by SATA or SAS interface. Seagate [11] modern hard drives consume from 23%-54% less energy in power saving states with wakeup times ranging from 0.5 to 8 seconds.

C. PSU

Power supply units are designed to convert AC to DC current that is used by the computer components. Modern power supplies that are most commonly used are very efficient when under full load, but this drops down to 50% efficiency when system is idling [7].

PSUs are not designed to be controllable by software in order to respond to energy since utilization can be automatically determined from the electrical current drawn by the system. Although power supplies are not controllable externally their models are sometimes used in simulation of power saving techniques.

III. DATA CENTER ARCHITECTURE

Data center systems are usually designed as a multitier architecture having load balancer on the front, followed by application servers as a second tier taking the requests and a data tier serving information to the application servers. In many cases both application and data tier have a degree of redundancy and parts of the system that are being idle can be temporarily put to sleep or shutdown. Application

tier machines are usually easy to turn off since they contain no data possibly needed by subsequent requests. Data tier is more complicated to deal with since possibility of turning off the machines depends largely on data replication and redundancy schemes. These schemes may need to be altered in order to allow for certain subset of data tier machines to be safely turned off in low utilization scenarios.

Some of the energy saving schemes target a bit different or simplified versions of data center architecture, while others use a single machine to experiment on.

IV. ENERGY SAVING STRATEGIES

Classification of energy saving strategies is not straight forward and it can be done using various criteria. Some of the criteria include target system hardware and software architecture, type of workload used or a type of hardware optimization exploited. In this paper categorization is made depending on type of hardware optimization exploited. Most of the energy conservation strategies manipulate either CPU states or use system sleep states at off peak times. Server consolidation and virtual machine usage are also techniques used for power saving in computer systems. Following subsections describe different energy saving strategies. Summary of techniques, workload environments, software architecture and energy gains is presented in Table II.

A. CPU states manipulation techniques

First work on CPU frequency manipulation techniques used time intervals in which CPU frequency was fixed [12]. At the end of one interval workload in the next interval is estimated and CPU frequency is adjusted. Workload prediction is based on the previous time interval (PAST strategy) and energy savings are calculated using simulation of the single computer system. Energy consumption is reduced up to 50% depending on workload trace (several unix workstation user traces were used).

These theoretical results are put on trial in real hardware [13] using pocket computer with StrongArm CPU. CPU was configured to work on 2 base voltage levels (1.5V and 1.23V) and clock was adjusted accordingly. PAST strategy is used to predict workload in the next time interval. Several applications are used in workload trace and results are not promising. Real time applications such as MPEG decoding and text to speech conversion are shown to be choppy because system couldn't react fast enough on changes in load.

Simulation of web cluster with two different workloads (Winter Olympics 98 [14] and financial web site) reveal power savings of 22%-42% [1]. Savings were greater for the financial web site since Olympic web site has greater average utilization and more balanced workload over time.

Since CPU frequency/voltage control and C states transition is now built into modern OS schedulers research on energy savings on one Intel i7 based machine is performed [10]. In experiment different frequencies and different CPU C states were employed. Usage of different CPU C states was enabled by using custom Linux *cpuidle* governor [15]. Employing higher and more energy efficient C states is assumed to be beneficial in low utilization scenarios. In high load scenarios deeper C states would be of little use since longer wakeup times would cause observable power usage overhead. Results show that frequency and C state optimizations independently lead to lower power consumption. This was shown to be applicable to both MPEG decoding and web server workload scenarios with average system utilization between 7% and 28%. Overall power savings were up to 50% of total consumed power compared to the system that is always on and working on top frequency (*P0* state).

B. Optimization using single sleep state (turn on/off)

Transition of the machines between sleep states and powered on states can be exploited to conserve electrical energy. Sleep states differentiate on both power usage and wakeup times. Typical sleep states that are most frequently implemented and used are S3 (sleep) and S4 (hibernate). Transition to these power states takes about 5-10 seconds for S3 and 30 or more seconds for S4 depending on amount of memory that needs to be stored on the hard drive. Wakeup from both states to state S0 takes approximately same time. Power consumption of the entire computer system in both states is typically less then 5W so there is no justifiable difference to use S4 state due to its much longer transition state.

Simulation of a web cluster using 8PCs with controllable outlets to perform switch on/of is performed to measure power savings achieved by the use of PID (proportional-integral-differential) feedback controller [16]. One feedback controller is used for each running PC in order to compute excess resource demand. Proportional, integral and differential components are used in order to reflect past and current resource demand as well as the latest demand trend. Feedback from all PCs is collected and decision for turning computers on or off is done using the highest excess resource demand. In order to accommodate for resource time wasted in switching cycles each PCs nominal capacity is reduced. Accommodation for workload spikes is done by keeping fixed percentage of spare resources active.

PID based technique is tested on two workloads – one involves load balanced lowly utilized web cluster and the other use of common single machine applications such as MPEG encoding and SPEC 2000 benchmark. For single machine applications it is assumed that there exists a mechanism for application migration between different machines. Results show 38% in energy savings for web server workload [17] with 30% spare resource capacity and up to 45% with only 15% spare capacity. Simulation of computer cluster workload running MPEG encoding and SPEC 2000 benchmark reveals 35% energy savings.

Strategy VOVO+DVS that combines switching machines on and off and CPU frequency manipulation techniques is evaluated on a simulation of a web cluster [1]. Main idea is to keep a number of machines at optimal frequency. If the average frequency of the system drops below theoretically calculated limit then some of the machines are turned off. Conversely if the average

frequency of the system needs to be increased beyond optimal power band (due to increased load) then additional machines are being turned on.

Evaluation is performed using simulation of two workload traces and energy savings reported are 33%-50%. In cases where CPU frequency manipulation was turned off energy savings achieved by solely turning machines off were in 22%-42% range.

The most general discussion on potential benefit of the sleep states simulates a number of hypothetical sleep states with different energy requirements and various wakeup times [18]. Analysis shows twofold increase in performance per watt for slow changing workloads and efficient sleep states. Efficient sleep states require low energy (few watts) and have small wakeup times (less then 20seconds).

C. Optimization using multiple sleep states

Usage of multiple sleep states together coupled with CPU frequency control in multitier architecture is exploited in [8]. Theoretical model is calculated that determines number of machines needed in separate tiers in order to conform to predefined service level agreement (SLA). Two policies are used to control behavior of the system: active capacity policy and spare server policy.

Active capacity policy (ACP) determines number of machines and their frequencies needed for system to operate according to SLA and with lowest energy requirements. First step of ACP includes finding minimal number of machines so that any individual tier will conform to SLA. Afterwards additional machines are added needed for entire system to work within SLA. In the second step frequencies at each tier are adjusted to minimize energy consumption. Distribution of machines and CPU frequencies to tiers follows the theoretical model computed by minimizing total active power consumed. Variables over which Lagrange multiplier minimization is performed are frequency and number of machines in a tier.

Spare capacity policy (SCP) determines number of machines optimally needed in each of the sleep states. If current system status doesn't meet the requirements number of machines are transitioned to appropriate sleep states. Optimal and demotion are two SCP policies that put servers to sleep. Optimal computes theoretical optimal number of servers for predicted workload while demotion policy keeps timers for a number of machines in a given state and when timers run out transitions to deeper sleep states are triggered. Workload prediction is done by PI (Proportional-Integral) feedback controllers.

Measurements of both SCPs and single or multiple sleep states where made on a three tier architecture (web server, application server and database) managed by a front load balancer. This architecture is deployed on a 12 node computer cluster where both web server and application server tier are allowed to run on variable number of machines. Power savings are greatest when multiple sleep states (S0, S3, S4) are used (22%-36%). Optimal SCP policy is shown to almost always

outperform demotion with average power savings of 25%-35%.

D. Optimization using multiple sleep states in heterogenous systems

Since multiple sleep state usage proved to be advantageous in power saving, this approach is extended to a heterogeneous architecture/multiple sleep state technique [19]. Motivation for multiple architecture solution is brought to light since typical server processors used in data centers such as Intel Xeon [20] have no support for sleep states. In order to make these systems perform in a power efficient manner hybrid system made of Intel Xeon and Intel Atom CPUs [21] is proposed. Intel Xeon processors are dedicated to handle the base load, and Atoms are used for quick reaction to load bursts since they expose a number of sleep states with short wake up times.

Algorithm for machine wake up iterates over each type of a machine (Xeon and Atom) and tries to predict amount of workload in time it takes for the observed machine type to wake up. In this way if surge in workload is expected shorly a lot of Atom machines will wake up. If there is a longer demand for computation power expected Xeon machines will power on too. Procedure for machine power down (putting to sleep) is similar in nature. Load prediction methods employed include Last Arrival, Moving Window Average and Exponentially Weighted Average. Last Arrival assumes workload in the next interval will be the same as current workload, Moving Window Average computes an average workload over a past time frame while Exponentially Weighted Average takes into account last predicted load rate and last seen load rate with different factors.

Simulation results show 27% improvement in energy efficiency running Wikipedia workload trace when baseline comparison is made to the computer cluster designed to handle peak load at most. Additionally it is noted that power used is proportional to the work done in any given time. Moving Window Average prediction method is shown to be the best by underperforming theoretical optimum for only 10%.

E. Virtual machine and server consolidation techniques

It has been shown that systems with low average utilization are not power efficient. Large systems are usually comprised of different services distributed among distinct machines. Consolidation of several services (such as web server and mail server) on a single machine can be beneficial if workload spikes for consolidated services are not likely to occur simultaneously. Main drawback of this approach is that consolidation of services within same host operating system involves significant human effort.

Natural extension of server consolidation approach is exploitation of virtualized environments where different services in separate virtualized OS environments (virtual machines) run on a predefined set of hardware. Allocation of virtual machines to hardware can be done by one of several virtualization technologies.

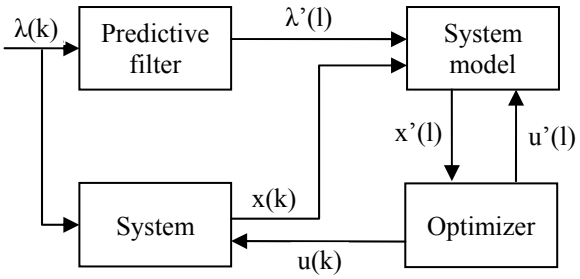

Figure 2. Limited lookahead controller

The goal of virtualization efforts is to minimize hardware/energy costs while maintaining specified SLA. There is a set of parameters needed for dynamical tuning of virtual machines [22]. Parameters include number of virtual machines (VM) provided to each service (application), number of hosts on which to allocate the virtual machines, CPU share of the host to be given to each VM and the number of host machines to power on.

In order to dynamically determine given set of parameters future load is predicted and different possible futures calculated using limited lookahead controller (Fig. 2) [22]. Prediction of input *λ'(l)* in some future time *l* is performed by predictive filter. Sytem model calculates new system state *x'(l)* according to predicted input and system control *u'(l)* in some time *l*. Optimizer tries several different parameter settings *u'(l)* for any calculated future system state. This leads to a construction of a tree of possible futures and trajectory with best predicted outcome is chosen.

LLC is tested on a heterogenous 6 machine computer cluster using 2 different services competing for hardware resources. Results obtained by simulating World Cup 98 workload [17] reveal 22% power savings over 24 hours while still maintaining service level agreement.

Simplified approach to VM scheduling is performed on the amazon ec2 testbed [23]. Since usage of amazon services doesn't provide information on power savings, minimization of total costs is set as optimization goal. Costs depend on VM rental costs and penalties for not conforming to SLA. Load prediction is done by linear regression over 15 minute system history. Future system load and needed machines are predicted by adjusting hysteresis parameters. Hysteresis is used to prevent system for overreacting to workload change.

System model is constantly evaluated and adjusted to resemble real system. Simulated system is shown to meet SLA as well as maintain cost as a linear function of system load.

V. CONCLUSION

In this paper we presented an overview of different energy saving techniques. These strategies enable significant power savings in underutilized systems. Since most of the systems are overdesigned to handle peak loads we can conclude that usage of energy saving techniques can be widely adopted.

Strategies for reducing energy consumption analyzed in this paper include CPU state manipulation techniques, sleep state exploitation and usage of virtual machines. CPU state manipulation techniques are implemented in most operating systems and deployed on mobile and desktop systems. Reported power savings obtained by CPU manipulation techniques range from 20%-50%.

Sleep state exploitation can be employed for systems where machines are not required to be constantly turned on. In low utilization scenarios machines can be put to different sleep states in order to save energy and be woken up in case of load increase. Synchronization of workload and number of active machines is not easy to make and involves keeping spare machine capacity as well as tuning of load prediction algorithms. Power savings reported in using sleep states range from 17%-50%.

Usage of virtual machines is the newest and probably most used power saving technique. It is usually employed by hosting companies that rent out virtual machines. Power savings reported by small scale simulation reveal 22% power savings made by shutting down unneeded hardware. Real world power savings of a virtualized data center are hard to estimate because there is no easily identifiable baseline scenario.

The main problem of power saving is compatibility with existing system architectures. Some large systems require most of the machines to be constantly available since they contain data that can be accessed at any time regardless of system utilization. Power savings of greatest magnitude are possible in cases in which systems are designed from scratch targeting energy optimization.

Abstract - In order to assure the Quality of service (QoS) for some real time applications software schedulers tend to raise the OS tick frequency. Most of the times this is not a convenient solution because the imposed additional overhead can lead to a task deadline missing plus an application failure. It is possible to minimize this overhead by performing the task context switch operation in a dedicated hardware component. This paper presents a custom designed architecture with multi pipeline registers and a dedicated hardware scheduler meant to improve context switch and scheduler times compared to traditional software schedulers.

I. INTRODUCTION

The presented architecture has been specially designed to speed up task context switches and scheduler times in time critical applications. This design offers a time improvement which is lower with almost two orders of magnitude over traditional software schedulers. Usually a software scheduler has to save the CPU registers on the stack, and perform the scheduling activity. Then the context of the task that follows to be executed must be fetched from the stack. The impact of these actions are dependent on the number of registers that must be saved and restored, the width of the registers, the width of the memory bus and the time needed by the scheduler to compute which task is next in line to be executed [1],[2]. This can lead to a significant jitter [3],[4] that can perturb or even crash the real time application due to deadline missing [5],[6],[7]. Our design is replacing the stack saving policy with a remapping algorithm that allows the new tasks to be executed from the very next clock cycle. More than that, the Multi Pipeline Register Architecture (MPRA) allows a very high throughput of the pipeline as each task has it's own dedicated pipeline registers and switching from a task to another will not imply any flushing or instruction discarding. A remapping sequence implies remapping both register file context and pipeline registers at the same time.

Other designs are based on a mixed software-hardware architecture where the software is responsible with context switching and the hardware is performing the scheduling operations [6],[8],[9],[7],[11],[12]. Such designs are not always the best solution as they may impose an additional overhead due to data transfer between the external hardware scheduler and the CPU.

External hardware schedulers have also been used for multiprocessor systems [10]. Using an external hardware scheduler proves also to be a good solution from the power consumption perspective [13] as tests revealed that the power consumed by a software scheduler to complete the same job is higher. Having an external dedicated hardware component allows building more reliable applications as error detection and correction functionality can be moved from the CPU side to the hardware scheduler side and gives more time for the CPU to perform other tasks. The Hardware Scheduler Engine (HSE) runs a scheduling algorithm and between each falling and rising edge of a clock cycle will generate the address of the task that follows to be executed. HSE will hold active the address of the pipeline register block and the corresponding address for the register file as long as there are no other conditions (hardware or software) that trigger a change in the current address.

II. ARCHITECTURE DECSRIPTION

Our design is based on a modified MIPS architecture [15] that was specially adapted to support the operation of the hardware scheduler as a part of the CPU itself. The design utilizes a set of four pipeline registers for each task that are used to hold the running instructions of the CPU. Each task also has its own independent program counter (PC) register that holds the newest instruction fetched from memory. The register file is built around a banked architecture that allows very fast context switch by simply remapping the active context of the task that needs to be executed. The architecture uses a common memory for holding both instruction and data. The data and instruction memory block presented in Fig. 1 and Fig. 5 are one and the same. The instruction set is composed of three operand type instructions that operate with both registers and immediate values. The instructions are grouped in six category types: arithmetic, logic, data transfer, conditional jump instructions, unconditional jump instructions and special instructions.

MPRA is a multi-pipeline register architecture with 5 stages: instruction fetch (IF), instruction decode (ID), execute (EX), memory access (MEM), register write back (WB). The CPU contains the following pipeline registers for each task: Instruction Fetch-Instruction Decode (IFID), Instruction Decode-Execute (IDEX), Execute-Memory access (EXMEM), Memory access-Write back

(MEMWB). The concatenated strings of two pipeline stages are used for the register names just to give a clear understanding where they are situated. For example EXMEM means this register is situated between Execute and Memory Access stage.

For Fig. 1, Fig. 2, Fig. 4 and Fig. 5 the arrows used to symbolize data transfer between stages can originate either from a particular field of the pipeline register meaning that only that field is transferred. It can also use an explicit notation like "*Instr[31,11]*" where multiple fields are transferred at once. In this case the arrow originates from a region that is common to all fields being transferred. For size and space considerations the names of the pipeline register fields are abbreviated and the size in bits is listed under the field name. IFID register holds the instruction that is fetched from the data memory and also the address of the next instruction that is to be executed in the next clock cycle. Control signals PC write and IFID write (Fig. 1) are used to inhibit writing into these registers whenever the Hazard Detection Unit (HDU) must stall the pipeline. Those signals are generated by the HDU. Multiplexors M1, M2 and M3 are used to feed the address of the new instruction into the PC. As we will see there are five possible sources of data for the new PC (Fig. 1): from the register file when a "ret" instruction is executed, the address from a conditional branch instruction, the address from an unconditional branch instruction, the address of the next instruction to be executed, and a 32 bit absolute address that can be loaded from a register.

The memory from Fig. 1 is a multi-port memory that supports both reading and writing from/to the same memory location in the same clock cycle. The access that is specific for this stage is an instruction read.

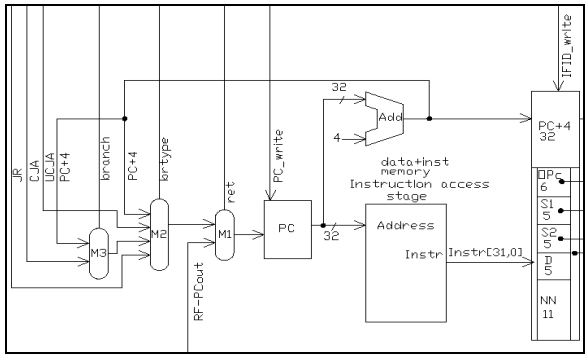

Figure 1. IF stage, PC and IFID pipeline registers

JR-Jump Register, CJA-Conditional Jump Address, UCJA-Unconditional Jump Address, PC-Program Counter, OPc-Opcode, S1-Source1, S2-Source2, D-Destination, NN-Depending on the instruction type this field is not used or is used as an immediate or offset, RF-Register File, M1,M2,M3 – Multiplexors used for PC selection

The register file access (Fig. 2) is performed in the ID stage. This happens simultaneously with Control Unit (CU) instruction decoding and is intended to bring a performance improvement independent of whether the operands are used by the decoded instruction or not. The register file is a multi-port memory that is capable of performing up to three simultaneous operations (two reads and one write) in the same clock cycle even for the same register address. Our design is using a 2^6x24 bits ROM to implement the control unit. The 24 control signals are used to control the EX, MEM and WB stages. Multiplexor M4 is used by the HDU to insert a bubble whenever the stalling of the pipeline is needed. The register file has been designed to support immediate register context switching for function calls using a stack-free architecture. The stack has been removed so that register to memory saving overhead is totally eliminated.

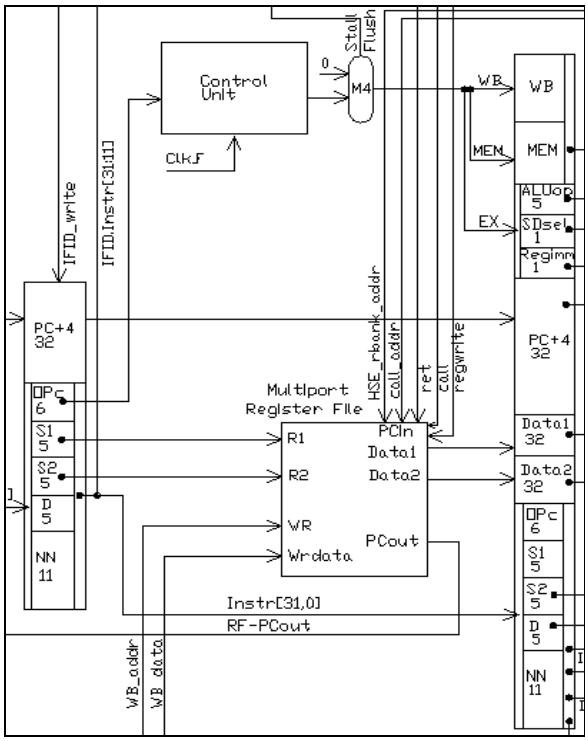

Figure 2. ID stage, IFID and IDEX pipeline registers

EX- A group of signals generated by the Control Unit (CU) that take effect in the Execute stage, MEM- A group of signals generated by the CU that take effect in the Memory Access stage, WB- A group of signals generated by the CU that take effect in the Write Back stage, HSE_rbank_addr- Register bank address generated by HSE. This signal is used to select the active register bank (Fig.3), RegImm-Register/Immediate, Sdsel- Source/Destination select, ALUop- ALU operation control signals, WB_addr/WB_data- Data and address to be written into the register file coming from the Write Back stage, Clk-System Clock, regwrite- register write, RFPCout- Value to be loaded into the PC from the Register File.

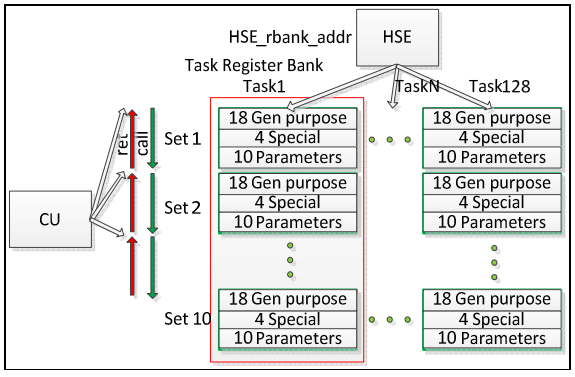

Figure 3. Register file organization

However part of the stack functionality is now built in the register file. The register file contains 32 registers of 32 bits for each function's context. Each task contains 10 independent function contexts that allow chaining of up to 10 function calls. From these 32 registers, 10 registers are used for argument and data passing between functions,18 registers are general purpose and 4 are special purpose. Fig. 3 shows the organization of the register file. A grouping of 32 registers belonging to a task will be called a *register set* and the grouping of 10 register sets makes a *task register bank*.

The CU is responsible of decoding the "call" and "ret" instructions and generating the appropriate control signals for the register file. However these signals are run through the pipeline to maintain a correct logic for the execution of the software code. Whenever the control signal for the "call" instruction is activated, the register file maps the next context that will be used for the new function and copies the contents of the 10 parameter registers and the returning PC into the correspondent registers from the new mapped context. Those parameter registers are used as input-output, that means a "ret" instruction can use them to transfer data into the returning function context. Function context switches (Register Sets) can be operated only by the CU by activating the appropriate control signals and forwarding them into the pipeline registers. The remapping of the Task Register Bank (Fig. 3) is performed only by the HSE in the same time with the remapping of the whole set of pipeline registers for that task. The addressing of the active Task Register Bank is done by the HSE using the HSE_rbank_addr signal (Fig. 3). This is an 8 bit wide signal that allows addressing up to 256 tasks, however, for the current implementation only 128 tasks are used.

The Arithmetical and Logical Unit (ALU) supports both registers and immediate values as operands. The selection between register and immediate is done with multiplexor M8 (Fig. 4). When a 16 bit immediate value is used as operand the destination register changes its position in the instruction fields and multiplexor M9 (Fig. 4) is used to make this selection. Just to give an example Conditional and unconditional jump addresses are computed in parallel by two separate simple adders that are represented in Fig. 4 so the ALU will be used only for arithmetic and logical operations. When the offset of a conditional branch is fetched from the instruction field this is signed extended to 32 bits and left shifted with 2 to impose a memory alignment of 4 bytes. For the conditional jump instructions that have a 16 bits immediate value, the relative jump is up to a 256K boundary. For the unconditional jumps this range extends to a value of 2^{28} bytes. The "jr" instruction gives the possibility of using a 32 bits absolute address as jump destination allowing a jump to any memory location from the 4G address space. Multiplexors M6, M7 and M10 (Fig. 4, Fig 5) are controlled by two dedicated forward units that forwards data into the ALU when a data dependency between instructions appears. If a hazard condition is detected then HDU will use multiplexor M5 (Fig. 4) to flush MEM and WB control signals to prevent inadvertently changing the CPU state.

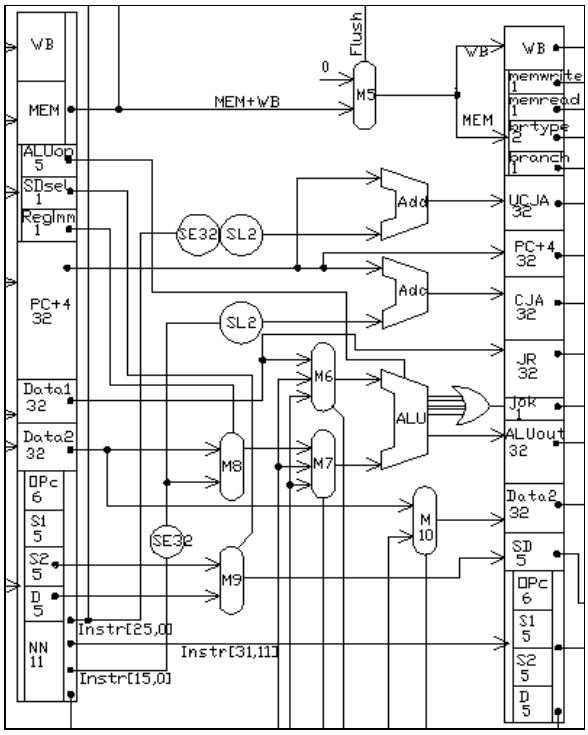

Figure 4. EX stage, IDEX and EXMEM pipeline registers

SE32-32 bits sign extender, SL2-2 bits left shifter, MEM-a group of signals generated by the CU that take effect in the Memory Access stage, WB- a group of signals generated by the CU that take effect in the Write Back stage, jok-jump ok, JR-Jump register, UCJA-Unconditional Jump Address, SD-Source/Destination, CJA-Conditional Jump Address, memread/memwrite – memory read-write control signals, ALUout-Arithmetical and Logical Unit result, Add-simple adder, Flush-signal generated by the HDU that is active for flushing the pipeline register EXMEM. This action is needed to prevent the accidental writes of the memories in the MEM stage.

MPRA implements two forwarding units that are responsible for solving the data dependencies that occurs in the MEM stage. One example is the execution of a "lw" followed by the "sw" instruction. Reading the data from the register file implies stalling of the pipeline until the previous operation is completed. By the time the data is needed in the memory write sequence the result is already available from the "lw" instruction in the MEMWB register. The forwarding hardware solves the dependency by using the result from the MEMWB pipeline register and making it available for the next instruction in the next clock cycle. The data to be written in the register file in the WB stage comes from two possible sources: memory and ALU. There are situations however where the forwarding hardware cannot solve all data dependencies between instructions. If an instruction provides a result later than the time where it has to be consumed by the following instruction then the forwarding hardware has no effect and this is where the HDU (Fig. 6) takes action. A dependency like "lw" followed by an arithmetic operation that uses the data fetched by "lw" is one example. The problem is resolved in two steps. First the HDU inserts a bubble into the pipeline and delays the execution of the arithmetic operation until the loaded data is fetched from the memory. At this point the fetched data is available in the MEMWB pipeline register and the next step would be

to write this information in the register file in the WB stage but this would imply stalling the pipeline an additional clock cycle. This is something to be avoided for performance reasons. At the point where the data is already present in the MEMWB register the forwarding hardware takes action and forwards the data directly in the EX stage of the arithmetic operation.

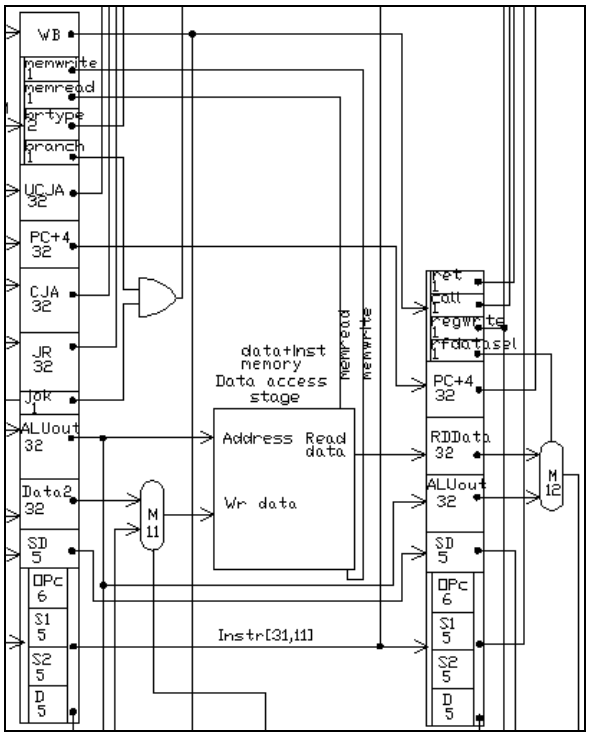

Figure 5. EXMEM and MEMWB pipeline registers.

WB- a group of signals generated by the CU that take effect in the Write Back stage, memread/memwrite – memory control signals, brtype-branch type, jok-jump ok, JR-Jump register, UCJA-Unconditional Jump Address, SD-Source/Destination, CJA-Conditional Jump Address, ALUout-Arithmetical and Logical Unit result, OPc-Opcode, S1-Source1, S2-Source2, D-Destination, ret-return, regwrite-register write, RDData- Read Data, rfdatasel-signal that selects what data is to be written in the register file-ALUout or data from the memory

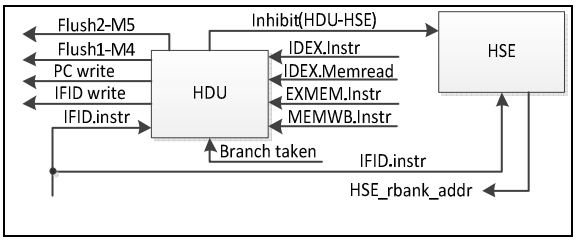

Figure 6. HDU control signals

The pipeline stalling procedure consists of two steps. First the "PC_write" (Fig. 1) and "IFID_write" (Fig. 2) control signals are de-asserted to prevent loading new instructions into the pipeline, and, in the second step, bubbles are used to flush the contents of the pipeline registers. The main goal of this action is to make sure there are no write signals active that can change the internal state of the memories (memory - for data write access). We can imagine a hazard situation generated by a conditional branch that is taken. Normally the CPU will use a "branch never taken" assumption and it will fetch the following instructions based on the space locality principle. If a branch is taken then the already loaded instructions after the jump instruction must be discarded and never executed.

III. HSE UNIT

HSE is the key functional unit of the proposed real time CPU architecture. The role of this block is to remap the pipeline registers and the application context registers of a task that is ready to be executed. Unlike the hardware scheduling techniques that were mentioned in the introductory chapter, in our design the scheduling unit is part of the processor itself and is directly controlled with dedicated instructions. The implementations described above use the hardware scheduler for computing the next task to be executed. The actual context switching process is performed in a classic manner by a commercial processor. In most cases the performance gain is not significant because the context switching process is identical to a software scheduler. Whenever we talk about an external scheduler there is a performance penalty that adds to the context switch time, due to the communication between the CPU and the scheduler over MMIO or communication busses. In order to assure the timing expectations of hard real-time applications the HSE is using a remapping technique to change the task contexts. It is more time efficient to simply remap the contexts of the tasks instead of saving and restoring the registers from the stack. Usually context saving time is dependent on the number of registers to be saved and the number of save/restore sequences. Just as an example to have an idea about the time requirements, a software scheduler can require between 100 and 500 clock cycles to perform the context switch including the scheduler time. HSE performs both scheduling and the task context switch in ½ clock cycles. This means the new task to be executed has its execution data loaded and ready to be processed starting from the next clock cycle. The worst case scenario happens when the pipeline registers contain a "sw" instruction. For this case the time needed to perform a context switch is 3 clock cycles. This design uses shared memory to transfer data between tasks so the "sw" instruction execution is given a higher priority against other CPU operations. The execution of this instruction must be finished before a new task is started. By doing so we assure that the next task to be executed will load consistent information stored by the previously executed task. The pipeline registers are constantly monitored by the HDU and the presence of this particular instruction ("sw") will activate the Inhibit signal (Fig. 6) so that HSE will avoid switching contexts during this 3 clock cycle time.

Some engineers noticed that a hardware scheduler may also impose a performance penalty due to improper usage of a pipeline at full capacity. As for any case of conditional or unconditional branch, a pipeline is flushed to preserve the coherency of the program if a branch is taken. Same goes for hardware schedulers where a big number of context switches would finally lead to an improper usage of the pipeline and possible problems

related to timing constraints being missed. HSE is not imposing any pipeline time or performance penalty. Since each task has its own pipeline registers, launching another task will not require any pipeline register flushing or instruction discarding. Each task pipeline will stay full at all times as long as each task will not run branch instructions that are taken.

HSE uses a unified priority space for both interrupts and tasks (Fig. 7). This organization prevents low priority interrupts to perturb the execution of high importance tasks. The general rule is that only the interrupts assigned to a current task and the interrupts assigned to higher importance tasks can interrupt a current running task. The interrupts assigned to lower priority tasks are postponed until there is no higher priority task or interrupt to be executed. The configuration of the system is very flexible so it is up to the user to decide if the interrupts can or cannot interrupt the tasks. The interrupts (IST) and hardware activated tasks (HAT) [14] are preordered based on the descending priority in the Service Request Register (SRR). If the interrupts sources are routed in the left hand side of the SRR then the execution of interrupts takes precedence over tasks. Fig. 7 presents a configuration where interrupts and tasks priorities are mixed. All the periodic tasks must subscribe to the system timer and have the comparator modules programmed for the desired execution period.

The control of the HSE is done with dedicated instructions which will be explained in the next chapter. One particular instruction is used to provide information about the status of the executing task. The instruction is inserted into the pipeline at the end of each task's main loop to signal the HSE that the main loop of the executing task is finished and the control can be transferred to a lower priority task that is waiting to be executed. All tasks must be organized with a main loop and it's the compiler which will transparently insert the signaling instruction at the end of the main loop. An exception to this rule is the least significant task which does not require any signaling instruction. This task is used only as an idle task. If there is no signaling mechanism then the execution of the application will always remain stuck in the highest priority task and the lower priority tasks will not be dispatched. The feedback information coming from the signaling instruction is also used by the HSE to detect catastrophic errors in the program execution. If one task reports the signal instruction more than once per programmed time period then this is an error condition. Also if the signaling information is not received from the task in its allotted time period then the watchdog unit will consider this as a critical error and will take corrective measures. By default the most important task is predefined for a fail-safe functionality. The HSE has the capability to independently place the system in a fail-safe state if a catastrophic error is detected or if the number of errors reached a predefined maximum value. The same fail-safe task can be used by the HSE to place the system in a defined state if an undefined instruction is executed or a division by zero was attended.

The scheduling function has been intentionally kept to a simple form to minimize hardware complexity. It is totally up to the user how the arrangement of tasks is done in the SRR. Implementing a Rate Monotonic Algorithm (RMA) implies positioning the tasks with the higher execution rate in the highest priority locations while implementing an Earliest Deadline First (EDF) algorithm implies placing tasks with the closest deadlines in the highest priority locations.

SRR-Service Request Register, MR-Mask Register, ISR-In Service Register, HAT-Hardware Activated Task, IST-Interrupt Service Task

IV. HSE CONTROL

HSE is controlled with dedicated instructions (Table I) that are part of the MPRA architecture design. HSE instructions are independently decoded in the HSE in the ID stage based on the information from the IFID pipeline register. *Schedenn*, *scheddisn* instructions can be used to enable/disable execution of both interrupts and tasks. *Schedn* instruction can be used for scheduling both higher and lower priority tasks. Normally it makes no sense of using this instruction to schedule a higher priority task as long as the scheduler is performing automatically this operation at each clock cycle. If a higher task that is not yet activated for execution then using this instruction with the task number as a parameter will determine the execution of that task even if it was not previously activated by a hardware event. Running this instruction will mark the task active in the SRR. This instruction will not have any effect on tasks that have been previously disabled for execution with a *scheddisn* instruction.

TABLE I. HSE CONTROL INSTRUCTIONS

Instruction name	Description
eni	Enables global interrupt execution
disi	Disable global interrupt execution
scheden	Enables hardware scheduler
scheddis	Disable hardware scheduler
schedenn	Enables scheduling of task N.
scheddisn	Disables scheduling of task N
schedn	Forces scheduling of task N
signaln	Signals end of task main loop

Forced scheduling of a lower priority task is possible using the *schedn* instruction. Starvation situations with lower priority tasks waiting for IO resources or similar situations are not a problem with this fully preemptive hardware scheduler. *Scheden* and *scheddis* can be used to totally disable the scheduler (e.g. during the execution of a critical section) and to re enable the scheduler. *Eni* and *disi* are used to handle the execution of the interrupts. *Signaln* is not used to activate any task but just to inform

the HSE that the main loop of the current task has ended so the HSE can switch to another task. This instruction is automatically inserted by the compiler at the end of the main loop of each task. As described previously, this signal is checked by the watchdog of the HSE to see if the system is still running fine.

V. DIFFERENCES OVER MIPS ARCHITECTURE

Our design uses independent simple adders for calculating the conditional and unconditional jump addresses. These values are calculated even if the instruction is not a jump instruction. The 32 bit sign extenders and the shift left units have been moved from the decode stage into the execute stage. Reason for this is just to save some space in the pipeline registers. For the future implementations the 32 bit sign extenders and shift left units will be moved back in the decode stage to maintain a balance between the propagation times of the two stages. The design supports the *JR* instruction that allows jumping to any memory location in the 4G address space. The handling of the PC with *call* and *ret* instructions has been implemented in the register file. The MIPS architecture is used just as reference but all the functional blocks: ALU, Forwarding Units 1 and 2, HDU, register file, pipeline registers and datapath are custom designs. The field organization of the pipeline registers is different compared to the MIPS architecture.

The register file has a special design that allows context remapping using a task address that is generated by the HSE. This custom design of the register file eliminates the need of using a stack for saving and restoring the context of the functions. Each bank (Fig. 3) has 10 register sets of thirty 32 bit wide registers that can be used for function calls without the need to save the contents of the registers on the stack. The register file automatically performs operations of moving parameters and return values from one register set into another. The 10 parameter registers from each register set will be used for passing parameters to the called function. When a function is returned the parameter register can contain return data if any. Both register file and the program/data memory are built using a multiport architecture. This means they can support multiple reads/writes in the same clock cycle. The register file supports four simultaneous operations (three reads and one write) while the program/data memory supports two simultaneous operations (one read and one write or two reads).

The major and most important difference that comes to support the real-time requirement of our design is a multi-pipeline register organization that allows very fast task switching without affecting the throughput of the pipeline. Each task has its own set of pipeline registers that are activated by the HSE in parallel with the register file bank remapping for the next task to be started.

VI. CONCLUSIONS AND FUTURE WORK

The presented architecture describes the concept of a high speed context switching processor that can perform both context switching and scheduler operations in a dedicated hardware component. The design totally eliminates the communication overhead that is specific to already existing mixed hardware-software designs with external hardware schedulers. The performance of the hardware scheduler is two orders of magnitude better than software schedulers, which makes it perfect for real time applications where a high number of context switches is performed. The minimum context switch time is ½ clock cycle and the maximum time is 3 clock cycles if the pipeline contains a "sw" instruction. A future paper will describe in more detail the performance of this design implemented on a Virtex6 XC6VLX240T FPGA device. In future revisions we will try to improve how the register sets (Fig. 3) are used depending on the number of function calls. For situations where the number of function calls has not reached its limit, the free registers will be used as a fast access general purpose memory.

Abstract - In this paper we present a solution of a gateway device for smart homes with the ability to interact with IPv6-enabled home devices over 6LoWPAN, answering to the need for the creation of ubiquitous, energy-saving home networks. The gateway also supports the traditional IPv4 interfacing over WiFi and Ethernet. UPnP over IPv6 is fully enabled so that all devices can be easily found by the UPnP discovery from any node in the network. Finally, the gateway enables the devices to be visible by a cloud server, which in turn enables a variety of web applications for home control to interact with home devices by using asynchronous API calls. In the paper the details of the proposed cloud-enabled smart home architecture are given, including the realization of the gateway device, 6LoWPAN end nodes and basic cloud services demonstration applications.

I. INTRODUCTION

Recently home automation systems have been challenged with the two outstanding needs: the need for the high interoperability between home devices and the need for user interfacing to the system from different end points (internet, mobile phones, TV sets, etc). Requests for low power consumption for home automation-enabled devices introduced new home connectivity standards, such as Zigbee. This, in turn, required centralized device mapping and identification, explicit pairing procedure and a complex translation of commands/events to the semantics needed by user interfaces. The result is the most frequent use case encompassing the central controller with a variety of connectors and an end-user application that needs to be installed to every client device.

Migration to IP-based protocols in the home automation realm resolves most of the aforementioned concerns. Growing support for IPv6 and its large address space enables the integration of large numbers of small devices to the IP network, such as bulbs or switches. The introduction of 6LoWPAN wireless protocol enables these devices to be compatible with IPv6 while maintaining low power consumption. Now UPnP can be used to perform automatic discovery from many client devices without the need to install client software. Device presentation page can be served in the form of a simple web UI to any of these end devices. The complete set of events/commands can be mapped to the cloud server, so that the home automation system becomes visible over the internet and easily accessible by the different web applications which provide users with home control options.

Solutions of the cloud-enabled gateways for home automation are scarce. Digi provides Zigbee to IP gateways that are integrated to their cloud servers [1], however, each device needs to implement a required Digi API to be visible by the cloud server. There are also solutions based on Zigbee and OSGi framework [2]. Home gateway with the specific regard to energy efficiency is presented in [3]. A gateway solution for IPv6 wireless sensor networks over 6LoWPAN is presented in [4]. However, neither one of these solutions is fully UPnP/IPv6 enabled nor it facilitates the integration with both home devices and the cloud server and provide seamless device discovery. Additional problems encountered are related to the restrictions of UPnP, which uses link local IPv6 addresses during the discovery. This prevents the devices to be visible across bridged networks. UPnP also makes it difficult to integrate IPv4 and IPv6 devices simultaneously (solution in this regard is proposed in [5]). Available memory on the client devices is considerably low, rendering the integration of 6LoWPAN, UPnP and HTTP-based interfacing even more complex.

In this paper we present a home automation gateway resolving most of the aforementioned problems, with the support for IPv4/IPv6, UPnP over IPv4/IPv6, 6LoWPAN and cloud computing. In the next section, we give details of the gateway architecture and basic concepts. In Section III we give the results of the evaluation.

II. GATEWAY ARCHITECTURE

The gateway is based on a small form factor embedded computer with the support for WiFi and Ethernet, whereas the support for 6LoWPAN is achieved by the addition of the 6LoWPAN USB module (Figure 1).

Linux-based operating system is used as a backbone for the gateway software. The software is comprised of the following blocks: (1) IPv4/IPv6 routing block; (2) UPnP replication block; (3) Cloud proxy block; (4) Configuration block; (5) Device manager and (6) Application manager. The block diagram of the software architecture is shown in Figure 2.

This work was supported in part by the Ministry of Education and Science of the Republic of Serbia under the project 44009.

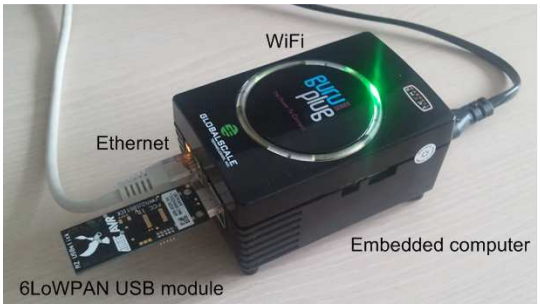

Figure 1. The presented gateway device with the 6LoWPAN extension module

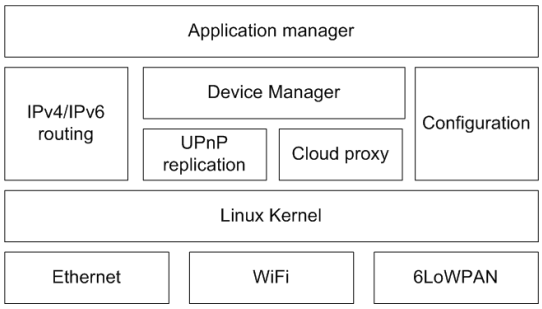

Figure 2. Block diagram of the software architecture for the gateway solution

The IPv4/IPv6 routing block performs the configuration of the system so that all IPv4 requests are translated to IPv6 and vice-versa (similar as in [6]). Additionally, it enables routing of packets coming from WiFi or Ethernet interface, to 6LoWPAN interface. This way all IPv6 home devices using 6LoWPAN are accessible from any standard IPv6-enabled client that is connected to the gateway over WiFi or Ethernet.

The IPv4/IPv6 routing block is implemented in the form of Linux bash scripts, 3rd party software *radvd* [8] and the translation software. The script called *gatewayboot* is being invoked upon the gateway startup, and is using *gatewayloader* script to configure the required routing. The steps required include the following:

- set appropriate IPv4 and IPv6 addresses to all network interfaces (`usb0` – 6LoWPAN adapter, `eth0` – Ethernet adapter, `eth1` – WiFi adapter):

```
ip address add 192.168.0.1 dev usb0
ip address add 192.168.0.2 dev eth0
ip address add 192.168.0.3 dev eth1
ip -6 address add aaaa::1/64 scope global dev usb0
ip -6 address add bbbb::1/64 scope global dev eth0
ip -6 address add cccc::1/64 scope global dev eth1
```

- set appropriate forwarding:

```
echo 1 > /proc/sys/net/ipv6/conf/all/forwarding
```

- start *radvd*:

```
radvd start
```

- start translation software:

```
./ipv4_ipv6
```

The UPnP replication block performs the discovery of the devices on the 6LoWPAN network and creates a copy for each UPnP root device discovered, to provide visibility of all UPnP devices in all networks bridged within the gateway. Device description XMLs and presentation pages are not cached in the gateway but remain hosted by the home devices.

UPnP replication block is implemented as a separate application using *libupnp* [9] to perform the discovery, UPnP device shadowing and other UPnP-related operations. The discovery is executed periodically on all interfaces, and all the devices are shadowed so that they become available on all available interfaces. Shadow copies of UPnP devices retain global addresses of their XML descriptions and presentation pages. Home clients performing the discovery will then continue to communicate with the device via the IPv4/IPv6 routing block, instead with the shadow copy of the device. An instance of UPnP replication application is started for every available interface:

```
./upnpreplicator eth0
./upnpreplicator eth1
./upnpreplicator usb0
```

The remaining blocks (Cloud Proxy, Device Manager and Application manager) are all implemented within the application *main.*

Device Manager is communicating with the UPnP replication application by using a socket-based API, to obtain the list of all devices available and their presentation URLs. Then, device manager uses HTTP protocol to communicate with the devices, obtain their state and parameters, and send commands to them.

The Cloud Proxy block communicates over the internet with the cloud server using XML-based socket communication. It informs the cloud about all the changes in the home automation system, such as the active devices and their states. Additionally, the cloud proxy is responsible for the reception of all command requests issued by the cloud server, and their routing to the device manager for execution.

Cloud API was made easy to install and use when programming various web or standalone applications. It is a HTTP-based API, so it can be easily accessed from any device that has the internet connection. The following API methods are among the most significant: (1) list all devices in a given home; (2) list all devices in a given home for a given area (room); (3) list parameters for a specific home device; (4) get value of a device parameter; (5) set value of a device parameter; (6) get a device event state; (7) send command to a device; (8) disable or enable a device etc. One example of an API call obtaining current brightness percentage of a light in the home would be:

```
GET
http://192.168.237.205/homecloud/api?getparam&home=133&
device=28&param=3 HTTP/1.0
Authorization: Basic cm9vdDp2ZW50dXJl
```

with the response:

```
HTTP/1.0 200 OK
Content-type: text/plain
Cache-Control: no-cache
value=70
```

Configuration block serves configuration web pages so that the gateway parameters can be configured. Configuration web pages allow basic operations with the devices, including the setup of device parameters and the execution of test scenarios. Test scenarios consist of a sequence of text-based commands to devices, and a description of a resulting state to be observed. This way the commissioning of the system is facilitated for the installers.

Application manager initializes the device manager, cloud proxy and the configuration block. Additionally, it runs the UPnP replication application. Application manager contains the application entry point, and encapsulates the gateway application. The bash script *gatewayboot* is responsible for starting up the gateway application upon the startup of the embedded computer.

III. Evaluation Results

The evaluation of the gateway was performed with the following outstanding goals: (1) comparison of energy consumption and responsiveness of the home automation system based on the proposed gateway with the similar solutions in the field, (2) implementation of end user application based on the cloud API and (3) control of IPv6-enabled devices with no specific application required.

In order to compare energy consumption and responsiveness, the gateway was installed and connected to the 6LoWPAN enabled dimmer switches. Two usage scenarios were created. The first scenario involved UPnP discovery from a tablet PC, and control by using the device presentation page. The second scenario tested the use of a simple web application that was created to set dimming level on a specific switch, by communicating to the cloud server via asynchronous calls. Setup concept and the web interface are shown in Figure 3.

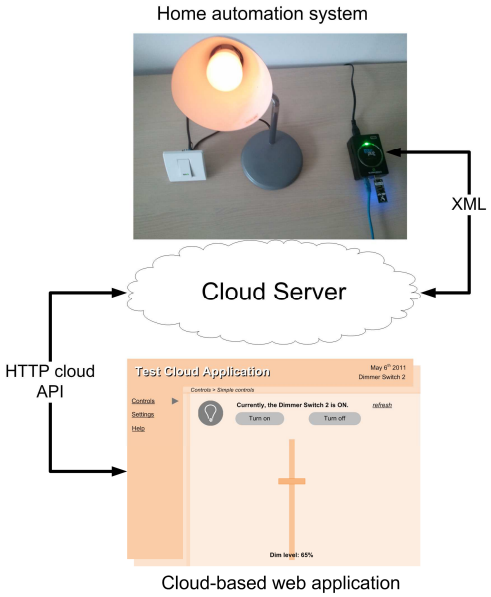

Figure 3. Setup concept for cloud computing using gateway and web UI

Response time was compared with the commercial Control4-based solution [7], which controlled dimming from a web navigator or a touch panel. Energy consumption of a dimmer switch using 6LoWPAN and the presented gateway was compared to the Control4 Zigbee dimmer and the HC300 controller. The purpose of this comparison is only to provide indication as opposed to strict evaluation, given the differences in design and functionalities of different gateways and controllers. The results are shown in Table I.

TABLE I. Response Time and Energy Consumption Comparison

Setup / Use case	*Response time (ms)*	*Energy consumption (mW)*
Proposed gateway + 6LoWPAN dimmer		5000+80
Control4 HC300 + Zigbee dimmer		26000+350
Proposed gateway – web dimming	~2100	
Control4 – web dimming	~3400	
Proposed gateway – offline dimming	~250	
Control4 – touch-panel dimming	~450	

The results show that the presented solution is comparable both in the energy consumption and performance to the current de facto standard for residential home automation with Control4. Available cloud API enables the creation of vast variety of web applications, thus providing scalability.

A modern end user Android application for the home system based on the implemented gateway device was implemented (Figure 4). The application enables the creation of scenes, whereas each scene can be assigned hotspots corresponding to the appropriate device placement. Scenes are captured from the real home environment by using the embedded camera. User is able to control devices (toggle on/off, set dim level on a

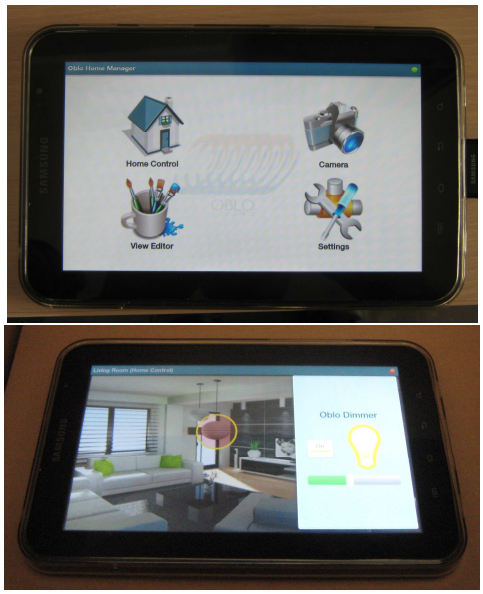

Figure 4. Android-based home control application using the cloud API

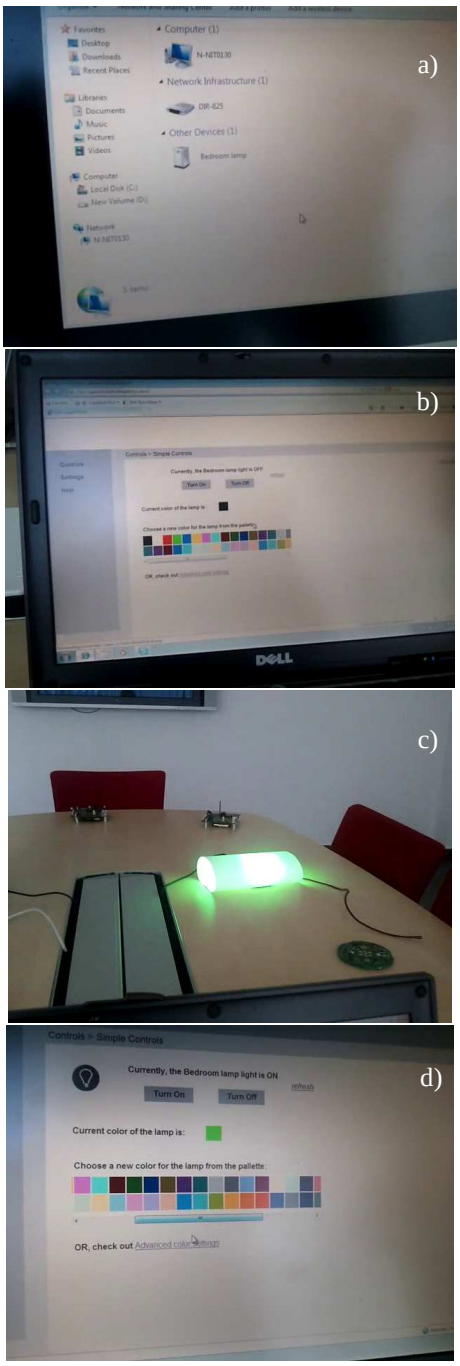

Figure 5. Controlling IPv6-enabled lamp by using its own presentation page via the gateway (no specific client software is required): a) network page showing a found lamp device via UPnP; b) presentation page of the lamp as shown in the browser; c) color of the lamp set to green by using the presentation page and d) status of the presentation page is updated.

dimmable lights etc) by using an intuitive user interface. User is able to access and control the home from any place by using his mobile phone or tablet, whereas the only requirement is the internet connection.

The proposed gateway is expected to fully demonstrate its potential once the IPv6-enabled home devices get widely deployed in the homes. For the evaluation purposes, IPv6-enabled RGB lamp with the support for UPnP was set up to host presentation pages. These presentation pages could be accessed from any device in the network equipped with web browser. The example in Figure 5. shows the laptop screen with a lamp detected in the local network via UPnP. After double-clicking the icon of the dimmer, the presentation page popped up in the browser. The presentation page then allowed basic control of the lamp, such as changing the light color. This scenario showed the benefit of IPv6-enabled home automation system, in which the need for dedicated client-side applications is avoided.

IV. CONCLUSION

In this paper a solution of the home automation gateway supporting the integration of home devices over IPv4/IPv6 (WiFi, Ethernet, 6LoWPAN) and UPnP over IPv4/IPv6 was presented. The key benefits of the gateway are low power consumption, large supported address space and the integration to a cloud server. The usage of the gateway in average homes would facilitate the interoperability and use, being that the adoption trends of IPv6, UPnP and 6LoWPAN are increasing. Eliminating the need to have dedicated client software for each end user device would hopefully increase the adoption rate by the consumers.

Energy management in the public building sector – ISGE/ISEMIC model*

prof.dr.sc. Željko Tomšić*, mag.ing. Ivan Gašić*, dipl.ing. Goran Čačić**
* Faculty of Electrical Engineering and Computing/Department of Power Systems, Zagreb, Croatia
** United Nations Development Programme – Energy Efficiency Project in Croatia, Zagreb, Croatia
zeljko.tomsic@fer.hr

Abstract – This paper introduces Intelligent Information System for Monitoring and Verification of Energy Management in Cities (ISEMIC) web application that connects processes of gathering data on buildings and their energy and water consumption, monitors consumption indicators, detects any anomalies or irregularities in time, sets energy efficiency targets and reports energy and water consumption savings. ISEMIC enables use of smart meters within an energy management for the first time in the region, along with an analytical part which enables intelligent estimation of energy consumption based on multiple criteria. In the public sector is enormous potential for energy and water savings and thus a large area for ISEMIC web application implementation. ISEMIC web application is developed in July, 2011. Purchase of smart metering equipment and establishment of smart metering infrastructure on institutions of project partners responsible for ISEMIC web application development is in conduction after which a full pilot run will be started. The potential impact of this project is very large and it would be a great example how significant savings can be achieved by systematic energy monitoring and management provided by the use of ISEMIC web application.

I. INTRODUCTION

The role of cities is getting more complex due to growth of population, impact on climate change and the need to increase energy security. To meet these requirements, transformation of cities must be initiated in all resource management activities and critical infrastructures, beginning with improving the energy efficiency of public buildings. The role of energy management in achieving sustainable development of cities in the future is great.

Systematic energy management (SEM) in the cities is centered on alteration of human behavior, changes in the existing organizational structures and application of technical measures to improve energy efficiency is a key prerequisite for the development of the skills and gain of the knowledge required for utilizing the existing potentials of enhancing energy efficiency and sustainable development in the cities. Fully establishment of SEM assumes maximizing the potential of achieving energy efficiency improvements in order to transfer the knowledge through the continuous process of energy management in cities to citizens, which would initiate the process of changing their perspective and behavior towards energy consumption. This energy management process would create a basis for the exploitation of the potential of energy efficiency improvements not only in the public sector, but in whole administrative area of cities.

The introduction of the SEM is nowadays unthinkable without the use of modern information systems and technologies and introducing advanced IT systems is the first logical step toward applying the concept of "smart cities". The ultimate goal of introducing the "smart city" concept is achievement of environmentally friendly, efficient and sustainable urban infrastructure that will provide to citizens all necessary services in an economically and environmentally friendly way and additionally the life quality in the cities.

Today, in energy analysis and statistics is common practice of conducting analysis of energy consumption trends at the national level which are then adjusted to the level of individual cities. But in most cases aggregated approach to the analysis of energy data doesn't give us good insight into the appropriateness and effectiveness of selected energy policies on the national level, nor on the local level. If we want to dispose with reliable information about the actual effects of implementation of selected policies at the local level, or if we want to get insight whether they should be corrected and adapted it is necessary to introduce regular monitoring of implementation and evaluation of the effects of conducted energy policies at the local level. The realization of this approach is possible only with the application of methodologies for continuous collection of key data in short and regular intervals at the local level in order to specific effects can be identified and achievements of the implementation of policies can be reduced to the level of each individual city.

II. ISEMIC WEB APPLICATION DEVELOPMENT

In the residential and service sector, information on energy and water consumption is commonly only provided on a monthly basis. Frequently the recipient of the information has no benchmark to assist in determining whether consumption levels are normal or excessive. There are two gaps or barriers which need to be addressed. First, there is a need for a system that provides higher-quality, more detailed information on a more frequent basis. Second, the system should have the capacity to

* The project is funded by SEE-ERA.NET PLUS

analyze the information received and act on the parameters available to correct possible malfunctions. To overcome these issues, an integrated information system is required, enabling both entries of manual readouts (and accompanied by appropriate education of the staff in the building where energy and water is consumed) and reception of data from intelligent metering systems that capture real-time data.

The Energy Management Information System (EMIS)[1] is software developed in Croatia to help in implementation of energy management programs in public buildings. The initial version of EMIS was implemented without significant analytical engine for data analysis and in the period of initial version development accent was put on creating a network of people regularly monitoring and manually entering consumption data in EMIS via the web. The initial version had no smart meter input capability. These two missing features were the focal point of further development of EMIS and thus providing it with the key functionalities that are base of ISEMIC. The development of improvements of the initial EMIS platform with new functionalities of continuous remote energy consumption data collection, methodology and tools for past energy consumption data analysis using regression model, least square method, best-fit lines, scatter trending as well as setting and cascading targets using correlation analysis and risk analysis using probability distribution for planning improvement measures for the buildings owned by a city, county or ministry are transforming EMIS into ISEMIC (Figure 1).

The new version of EMIS application with embedded ISEMIC functionalities is in use in Croatia. Alpha version of application is accessible from July, 2011 on server and it can be accessed by following the link: http://161.53.66.25:8080/IsemicIntro/.

III. ISEMIC WEB APPLICATION DESCRIPTION

In the following chapters the basic short description of ISEMIC functionalities embedded in EMIS are described.

A. *ISEMIC web application architecture*

ISEMIC architecture has three levels (Figure 2):

- Web browser on the client side as user interface tool;
- Apache Tomcat as servlet container;
- Oracle database as data storage

[1] Energy Management Information System - EMIS is a web based application that was developed as an integral part of the UNDP Croatia project "Removal of barriers for Energy Efficiency in Croatia. (No. CRO/00/G31/A/1G/99)". The project is financed by the United Nations Development Program (UNDP), the Global Environmental Facility (GEF) and the Environmental Protection and Energy Efficiency Fund (EPEEF) and implemented in cooperation with the Ministry of Economy, Labour and Entrepreneurship of Croatia

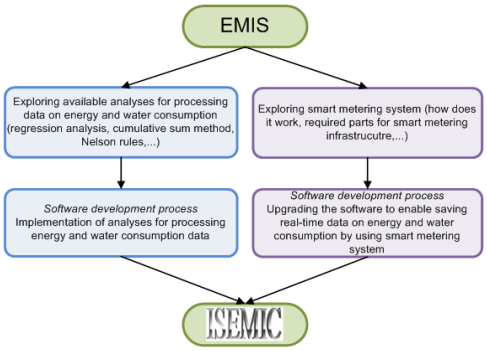

Figure 1. Upgrading EMIS to ISEMIC

Users connect to the application via http protocol (https for user identification).They are obliged to enter their username and password which aren't related to the database credentials.

B. *Users and user roles in ISEMIC web application*

Five different user roles are provided in ISEMIC; the system is designed in a way that can support an unlimited number of roles, but these five mentioned roles are preconfigured:

- System administrator (SA),
- Energy administrator (EA),
- Energy manager (EM),
- User (U) and
- Guest (G).

One user can have different roles on different objects.

SA can perform absolutely all operations in ISEMIC, but his main function is administration of whole application, from database backup to monitoring entered documents and photos.

Main function of EA is creating new lower roles (EM, U and G) and objects. He can edit and delete the information about roles and objects. Usually there is one or two person(s) on city, county or ministry level with this role. EA sets goals and limits of energy consumption and has the ability of deleting (false) entered bills. He also deals with data analysis, printing reports and graphs, remote reading monitoring, etc.

EM is a role whose primary function is oversight on certain part of the building. It can be a person in charge for energy, as well as the person in particular agency that requires data for specific data analysis.

U is a role primarily responsible for entering daily and weekly consumption readings. He also monitors remotely entered consumption data; enters monthly bills has the ability to change the wrong input, but not deleting entire bill. He can also edit object general, construction and energy characteristics.

G can only monitor the consumption of certain building(s) for which he is in charge and print reports and graphs on that building(s) or compare them.

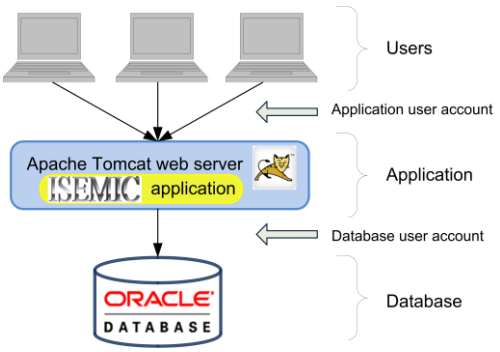

Figure 2. ISEMIC web application architecture

C. *ISEMIC web application structure*

Below, application structure for SA user role will be explained because it has embedded all possible functionalities developed in this project. Other user roles don't have their corresponding functionalities; they have reduced SA permissions. How much it is reduced depends on exact user role (EA, EM, U or G). ISEMIC application outline is shown on Figure 3.

ISEMIC web application main menu bar consists of seven main application modules on the left side (Figure 3): *Home*, *Security*, *Objects management*, *Reports and graphs*, *GeoAdministration*, *EnergoAdministration* and *Design*. Each application as its own menu bar – ribbon divided on working groups (which includes function buttons). Each function button has its own working cards ribbon and by click on desired working card its corresponding workspace is opened (Figure 3). In the right corner of the main menu bar are information about status and activities: *Alarms* (indicates the number of alarm messages), *Msg* (indicates the number of unread messages), *User* (user name of the logged in user), *Edit* (by mouse click on the label, a window for changing password and e-mail address is opened), *About program* (by mouse click on the label, a window with basic information about the parties contributed to the software development) and *Logout* (click to terminate the work in the application and logout).

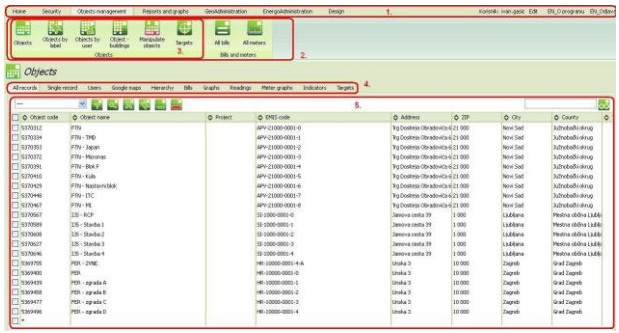

Figure 3. ISEMIC web application outline

1. Main menu bar
2. Menu bar – ribbon
3. Working groups (includes function buttons)
4. Working cards ribbon
5. Workspace

D. *Data analysis in ISEMIC web application*

Data analysis is the main advantage of ISEMIC web application. Manual inputs, as well as data entry through smart meters must pass the check procedures for the value and time consistency to be saved in the ISEMIC. Regression analysis (Figures 4 and 5) is most often used for past energy and water consumption data analysis. It shows how a dependent variable – energy consumption – is related to the independent one – for example temperature, by providing an equation that allows estimating energy consumption for the given temperature. The relationship between independent and dependent variable in most cases is in linear form which means that the relationship between the points in the graph can be approximated by a straight line and expressed by a linear equation. The resulting line will go through the center of data scatter and therefore is called best-fit line. It has a particular property – sum of the vertical distances of data points from the best-fit line is equal to zero. The correlation coefficient indicates how well a best-fit line explains variations in the value of dependent variable.

Within ISEMIC, cumulative sum (CUSUM) technique is used to track achieved savings (Figure 6). It expresses savings at any time and enables a direct comparison with the target amount of energy that should be saved. Actual savings are defined as the consumption or costs after the improvement, taken from the agreed baseline consumption, which would be the case if projects of efficiency improvement weren't implemented.

ISEMIC has the ability to review entered consumption and its monitoring according to the method called Nelson rules.

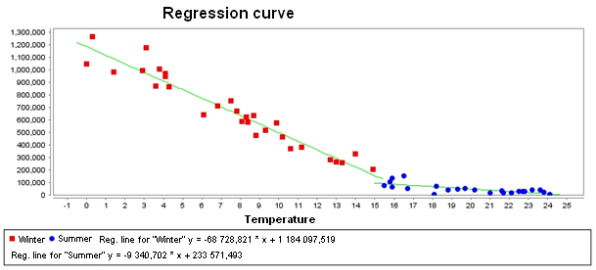

Figure 4. ET curve by temperature

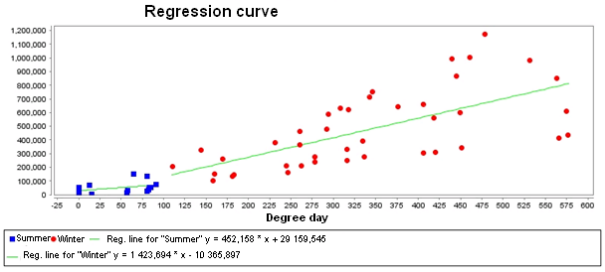

Figure 5. ET curve by degree day

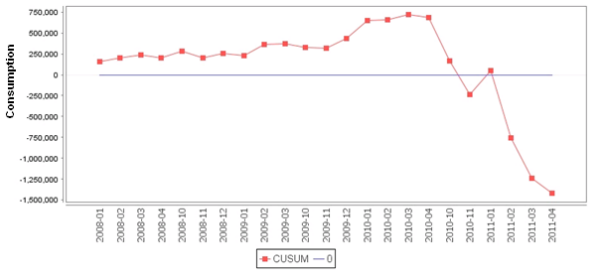

Figure 6. CUSUM curve

E. Setting energy efficiency targets in ISEMIC web application

The procedure of setting energy efficiency targets and their display on the graph is shown in flowchart on Figure 7. Goals can be set as:

- a linear reduction (percentage);
- a new line based on selected points of best efficiency or
- a new line formed on newly defined basis points.

As the result ISEMIC generates new target line equation.

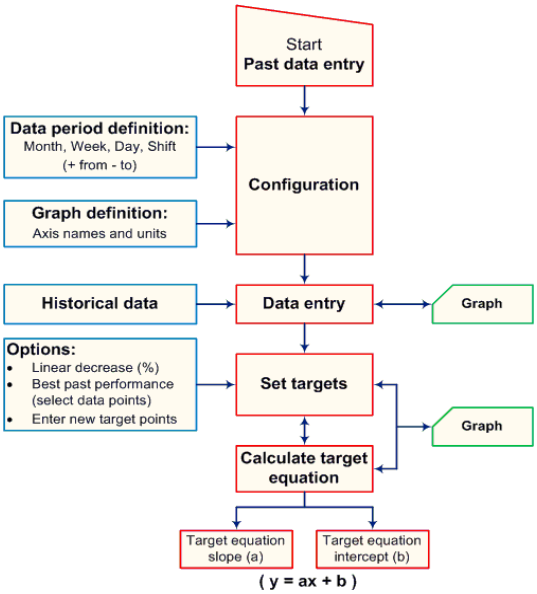

Figure 7. Procedure of setting energy efficiency targets

IV. CURRENT RESULTS OF ISEMIC WEB APPLICATION IMPLEMENTATION

Energy and water consumption data of building complex belonging to Faculty of Electrical Engineering and Computing (FEEC) are entered from bills during period from 2007 – 2010 into the ISEMIC and some of the obtained graphs are presented below.

The first graph (Figure 8) shows the share of each energent in total cost with tax for each year. Next three graphs (Figures 9,10 and 11) show electricity, heat and water total consumption of whole complex of FEEC for each year. It is also possible to view total cost with tax, monthly consumption and monthly cost with tax for each energent.

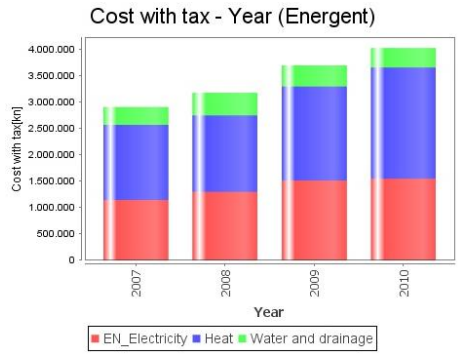

Figure 8. Share of each energent in total cost with tax

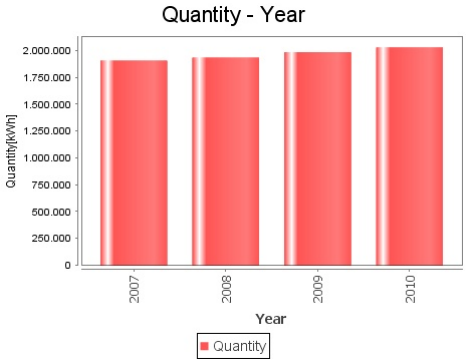

Figure 9. Electricity consumption for each year

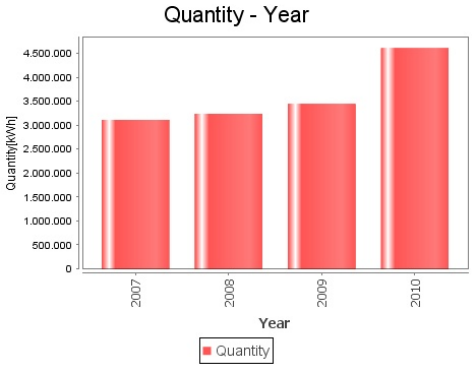

Figure 10. Heat consumption for each year

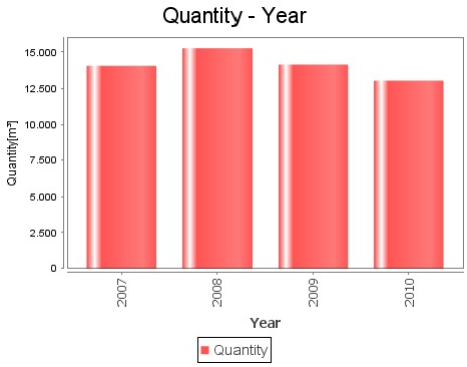

Figure 11. Water consumption for each year

Last graph (Figure 12) shows monthly CO_2 emission during period from 2007 – 2010 caused by electricity consumption. It is also possible to view monthly CO_2 emissions caused by consumption of other energents.

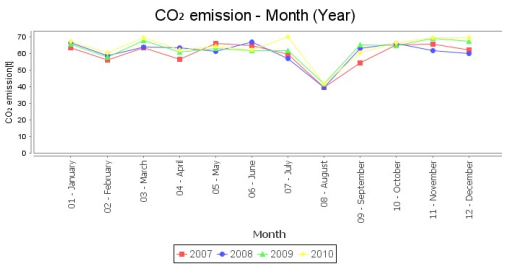

Figure 12. Monthly CO_2 emissions caused by electricity consumption

Purchase of smart metering equipment and smart metering infrastructure is in conduction after which more grained energy and water consumption data will be available.

Real time metering of electricity consumption on a daily basis of whole complex of FEEC is currently established and connected with the ISEMIC. Next two figures (Figures 13 and 14) show daily electricity consumption for whole complex of FEEC in January 2011 and 2012. Red points represent total daily consumption during higher tariff, while blue points represent during lower tariff. It is expected real time consumption metering of other energents (heat and water) of whole complex of FEEC will be established in near future, as well as real time metering of energy and water consumption of individual buildings.

V. INNOVATIVE ASPECTS

ISEMIC web application can become very important tool for energy management in public buildings. It will enable local and national authorities to lead by example and have a tool to help in proving positive effects of increasing energy efficiency and installation of smart meters.

ISEMIC creates added value in the following ways of presenting new, ready-to-use concepts:

- Interconnectivity with smart meters subsequent to creation of data bridges, which enables consumption monitoring on a daily basis or more frequently;
- Use of ICT for energy management in buildings as a service rather than a product (only an internet connection is needed);
- Use of algorithms that support expert knowledge and decision makers by discovering patterns of energy usage to identify waste, to find opportunities for change and to set targets for improvements;
- A streamlined, robust system of determining baselines of consumption using regression analysis on past consumption data, defining consumption targets and verification of savings using the CUSUM technique;
- System of accounting for exceptions on outlier values of energy consumption, which are commented by the technical person in the building as well as the city energy manager;
- Monitoring for changes in energy performance to evaluate the effect of improvements that have been made, to check whether consumption targets are being met and to provide evidence of progress towards improved energy savings.

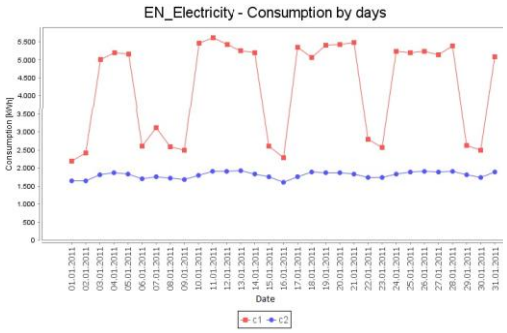

Figure 13. Daily electricity consumption for January 2011

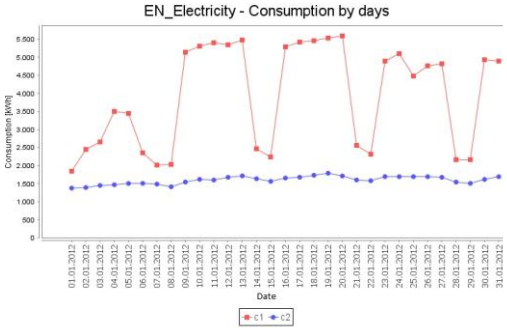

Figure 14. Daily electricity consumption for January 2012

VI. CONCLUSION

It is expected that ISEMIC will improve energy efficiency in buildings, raise building users' awareness of energy consumption and utilize measurements from smart meters. Examples from praxis show that introducing an energy consumption monitoring system raises employee awareness on energy expenditure, which leads to 5% of energy and water savings without any additional investments in energy efficiency measures. After full ISEMIC implementation and implementation of some simple energy efficiency measures it is expected that energy and water savings will reach at least 10% of current consumption expenses [5]. It would be a great example how significant savings can be achieved by systematic energy monitoring and management provided by the use of ISEMIC. After successful project finish it is expected that city, county or ministry will show higher interest to connect public buildings in their ownership with the ISEMIC web application and start systematic energy monitoring and management. Connection of private buildings with ISEMIC is expected in further future; with development of remote data reading systems and supporting IT infrastructure ISEMIC will have an important role in development of the concept of „smart cities“.

Active Reduction of Power Transformer Noise Based on Synchronous Averaging of the Residual Noise Signal

Dubravko Miljković
Hrvatska elektroprivreda, Zagreb, Croatia
dubravko.miljkovic@hep.hr

Abstract - Power transformer noise is a low frequency periodic noise concentrated in narrow bands around harmonics of twice the power grid frequency. The dominant cause of power transformer noise is magnetostriction of the transformer core material. A method for the active reduction of transformer noise based on synchronous averaging of the residual noise signal is introduced. The algorithm is not numerically intensive and is hence suitable for implementation on a microcontroller.

I. INTRODUCTION

Power transformers produce low frequency noise with the most important spectrum components, in a view of noise level, in the frequency range bellow several hundred Hz, [1]. The increasing energy demand brings transformers closer to the residential areas and the characteristic low frequency humming noise is often cause of widespread complains. Traditional means of controlling noise radiated by large electrical power transformers involve the passive methods like construction of large barriers or full enclosures which result in maintainability and cooling problems. Active noise reduction (ANR) reduces unwanted noise by introducing an antinoise of equal amplitude but opposite phase and is particularly efficient at low frequencies present in transformer hum. After brief introduction into nature and sources of transformer noise, method for active noise reduction is proposed based on synchronous averaging of residual noise signal.

II. TRANSFORMER NOISE

Transformer noise is caused by a phenomenon called magnetostriction. A transformer is magnetically excited by an alternating voltage and current so that it becomes extended and contracted twice during a full cycle of magnetization, [2]. The act of magnetization by applying a voltage to a transformer produces a magnetic flux. The degree of flux determines the amount of magnetostriction and the noise level.

A. Sources of Transformer Noise

During its operation transformers produce energy in form of noise and vibrations (vibroacoustic energy). Main sources of vibroacoustic energy are, [1, 2, 3]:

- transformer core vibrations as an effect of the magnetostriction phenomena
- the transformer vibrating windings
- vibrating structural components
- devices of transformer cooling system (fans, oil pumps)

In this paper emphasis is given on noise reduction, although noise and vibrations are mutually related. The vibration behavior of the core structure has a significant role in its dynamic interaction with the surrounding fluid, the core mounting and various other parts connected to it, so that it has eventually an influence on the overall noise generation process.

According to the method of cooling, power transformers can be classified into following categories:

- air-cooled, with natural air flow or fan-cooled
- oil-filled, sometimes with forced circulation of the oil by electric pumps and even use of water-cooled heat exchangers

These types differ slightly regarding propagation of vibroacoustic energy to the outside world (oil cooled has additional transit medium). Air-cooled transformers of lower power are often installed inside transformer station, radiating noise mainly through the transformer station metal door with ventilation openings. In oil-filled transformers vibrations of the core are transmitted to oil tank which vibrates and radiates noise, [1, 2, 3].

Noise level produced by the transformer is dependent on their power, size and load. Transformer acoustic noise is a hum characterized by spectral spikes at harmonics of the fundamental frequency which is twice the power grid frequency, Fig. 1.

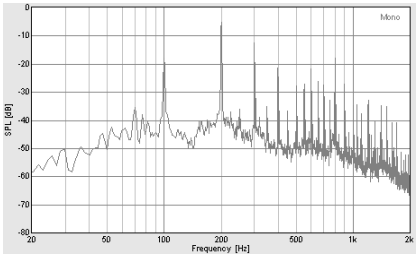

Figure 1. Transformer noise contains harmonic components at multiples of twice the power grid frequency

B. Noise Radiation of a Power Transformer

Transformer is usually closed by transformer casing plates or transformer station metal doors (with small ventilation openings) that can be described as vibrating plate, [1, 4]. Power transformer as a source of noise can be simulated with good approximation as an array of point sources, [1], Fig. 2. This also gives us an idea how to arrange multiple secondary sources for active noise reduction (in a same way as point sources to match the spatial distribution of sound from the primary source).

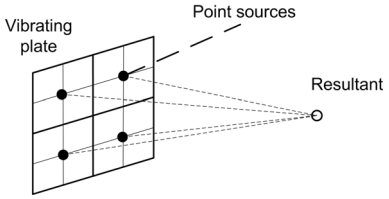

Figure 2. Model of noise radiation from transformer casing plates

Noise produced by transformer is usually air borne, while transformer vibration is ground borne. The classical material structures are very good conductors of vibro-acoustic energy. It is important to isolate vibrations by avoiding solid connection from vibrating transformer to a solid structure, otherwise it will transmit vibrations.

III. ACTIVE NOISE REDUCTION

Active noise reduction (ANR) is a reduction of unwanted noise by generating an acoustic signal that interferes with the noise [5, 6, 7], It is achieved by generating a signal identical in sound pressure level but exactly reverse in phase to the offending noise, Fig. 3. This signal must closely match noise both in amplitude and phase.

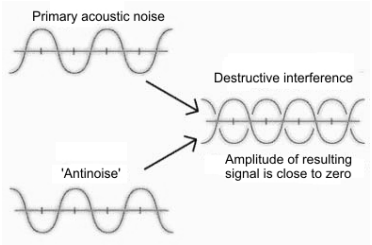

Figure 3. Principle of active noise control

Passive methods (sound absorbers, barriers, dampers, mufflers and silencers) are very effective in reducing a broad spectrum of audio noise, but do not achieve high attenuation for low frequencies (below 500 Hz). ANR has advantages over passive methods at these low frequencies. Main approaches for ANR are feedforward method, feedback method and synchronized waveform synthesis, [5, 6, 7, 8]. Early implementation attempts were analog, while today practically all solutions are digital and mostly implemented using adaptive digital filters. Achieved noise reduction can be local and "global". In case of local noise reduction secondary source is placed near the ear of the listener, where it creates small zone of silence. "Global" noise reduction can be achieved by placing secondary souce(s) near the noise source itself.

First active noise reducing system for transformers was proposed by Conover in 1956, [5]. He placed a loudspeaker close to the transformer, Fig. 4. System used reference signal in form of full wave rectified low voltage signal (60 Hz in USA) from transformer. The rectified signal was passed through three narrowband bandpass filters (120, 240 and 360 Hz), [9], Fig. 5. Amplification and phase shift for each of three channels were adjusted manually by a skilled human operator.

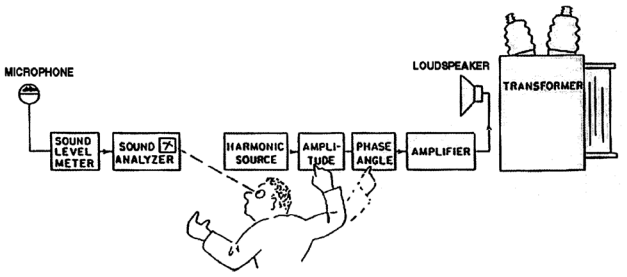

Figure 4. Manually adaptive, feedforward active noise reduction system for transformer noise proposed by Conover in 1956, from [5]

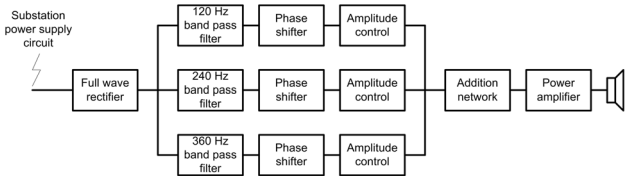

Figure 5. Block diagram of Conover's analog system

IV. METHOD FOR ACTIVE REDUCTION OF NOISE

Proposed method is the synchronized waveform generator, the waveform is calculated by synchronous averaging of the residual noise signal (used as an error signal). The waveform synthesis generator stores canceling noise waveform samples in unique contiguous memory addresses. These samples represent the required waveform to be generated and to produce canceling noise waveform for the secondary acoustic source: loudspeaker.

A. General Description

Block diagram of the proposed system is shown in Fig. 6. The system is dependent on existence of the synchro signal that can be obtained, eg. from inductive loop in proximity of transformer, full wave rectification of collected signal and level/slope trigger. The waveform memory array contains an averaged residual error signal and is addressed by the counter driven with a clock signal equal to the sample rate. The counter is periodically reset by the synchro signal (at the beginning of each period). Initially the waveform generator is empty. During the adaptation process waveform stored in the waveform memory array is updated by averaging stored samples with incoming samples of the residual noise (error) signal.

B. Waveform Memory Arrays

Input signal enters the waveform memory array at the position of a pointer, p_i. The pointer p_i is incremented after each input sample with the sample clock signal. When the synchro signal arrives, the counter is reset and the pointer again points to the first position in array. The loudspeaker and the microphone are generally placed some small distance apart. Sound propagation time

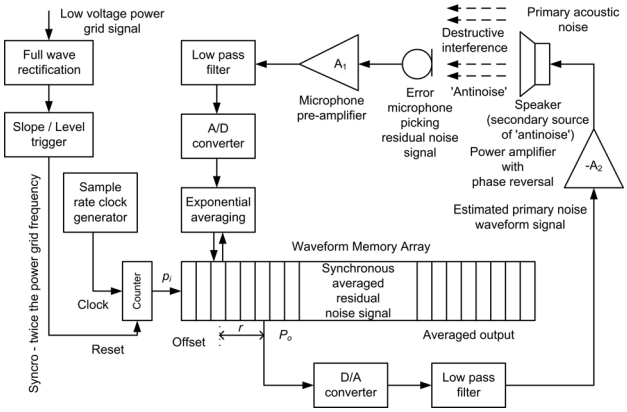

Figure 6. Block diagram of a system

through the air must be considered and output signal selected from position offseted by *m* samples:

$$m = \frac{df_s}{v} \tag{1}$$

where *d* is the distance between the loudspeaker and the microphone, *v* sound propagation speed in the air and f_s is the sample rate.

It is also necessary to consider an additional small time shift of *n* samples for correction of the phase shift θ_P in the secondary source at the frequency of the calibration tone (described later in more detail) with frequency f_P (twice the power grid frequency) and sample rate f_S.

$$n = \frac{\theta_P f_S}{360 f_P} \tag{2}$$

Final correction (in number of samples) is given by:

$$r = m + n \tag{3}$$

When second pointer p_o reaches the value equal to the length of the previous period *M* it wraps around the array from the beginning:

$$p_o = (p_i + r) \bmod M \tag{4}$$

New value of *M* can be read from the counter just before it is reseted with the arrival of new synchro signal.

C. Timing signals

Two timing signals are present in the method: clock signal and synchro signal.

Sample rate is governed by the clock signal. Frequency of the clock should be about hundred times higher than the frequency of the synchro signal.

The system operation is synchronized by the synchro signal from controllers power supply. Full wave rectified signal is fed to the level/slope detector generating pulses of twice the power grid frequency, Fig. 7.

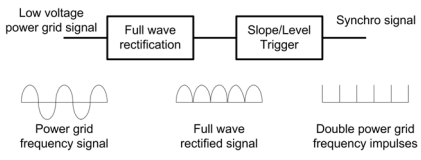

Figure 7. Generation of synchro signal

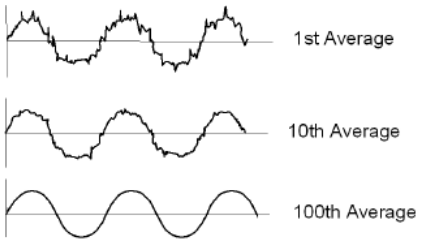

Figure 8. Synchronous averaging

D. Signal Averaging

Synchronous averaging is a digital technique for extracting periodic signal from noise. For averaging process to be successful three conditions must be fulfilled: the signal waveform must be repetitive, the additional noise must be random and uncorrelated with signal and the temporal position of each waveform period must be precisely known, [10]. The transformer noise to be reduced is of periodic nature and with addition of various environment noises. Synchronous averaging can reveal periodic component that, with opposite phase, can be used to drive the secondary acoustic source, i.e. the noise reduction loudspeaker.

Process of synchronous averaging is illustrated in Fig 8. The start of each period must be triggered from a repetitive event in the signal, such as synchro impulse of frequency equal to the twice of the power grid frequency. The initial waveform is quite noisy, the second waveform after ten averagings shows considerably less noise and after hundred averagings the third waveform is almost clear periodic signal.

Input noise signal captured by the error sensor, *f(t)* has a deterministic signal component *S(t)* and a noise signal component *N(t)*:

$$f(t) = S(t) + N(t) \tag{5}$$

Let *f(t)* be sampled every *T* seconds. The value of each sample in an instant of period (*i*=1, 2, …, *n*) is sum of a deterministic signal component and a noise signal component:

$$f(iT) = S(iT) + N(iT) \tag{6}$$

There exist two types of averaging, arithmetic and exponential.

- Arithmetic averaging of periodic signal after averaging of *m* signal periods is described by (5).

$$\frac{1}{m}\sum_{k=1}^{m} f(iT) = \frac{1}{m}\sum_{k=1}^{m} S(iT) + \frac{1}{m}\sum_{k=1}^{m} N(iT) \tag{7}$$

After numerous iterations noise (random) components of sum cancel each other and only periodic component remain.

- Exponential averaging ($\hat{x}_k$ denotes averaged signal in iteration *k*) is defined by (8):

$$\hat{x}_k = (1-\alpha)\hat{x}_{k-1} + \alpha x_k \tag{8}$$

$$0 < \alpha < 1 \tag{9}$$

New sample x_k is averaged with sample $\hat{x}_{k-1}$ previously stored in memory. For waveform of a signal with a period of *M* samples process is described by following equations:

$$\hat{x}_k(1) = (1-\alpha)\hat{x}_{k-1}(1) + \alpha x_k(1) \quad (10)$$

$$\hat{x}_k(2) = (1-\alpha)\hat{x}_{k-1}(2) + \alpha x_k(2) \quad (11)$$

$$\cdots$$

$$\hat{x}_k(M) = (1-\alpha)\hat{x}_{k-1}(M) + \alpha x_k(M) \quad (12)$$

Exponential averaging has the time constant τ that depends on the value of α and a signal period T_{sig} (of M samples with sample rate f_S):

$$\tau = \left(\frac{2}{a} - 1\right) T_{sig} \quad (13)$$

$$T_{sig} = \frac{M}{f_s} \quad (14)$$

In comparison with the arithmetic averaging where all averaged samples are of equal importance, exponential averaging with forgetting factor (1- α) emphasizes last samples and is more suitable for tracking of nonstationary signals. In real application the value of coefficient α is around 0.01-0.02.

When the system starts with operation, the waveform memory array is empty with all memory locations containing zeros and there is no signal at the loudspeaker, hence there is no reduction of noise. All present noise is picked as the residual error signal by the error microphone and samples of this error signal are exponentially averaged with empty values in the memory array. After the first period array is not empty any more but contains (although with a small amplitudes and envelope) a replica of the noise signal. This signal now drives the loudspeaker and cause small reduction of noise. Now there is again a residual error signal, but this time slightly lower than in previous period. This signal is again averaged with corresponding samples of waveform stored in the array. Little by little, the waveform stored in the array closely resembles noise signal both in waveform and amplitude.

Factor (1- α) present in exponentially averaging (8) is important in practical realizations for stability reasons. When implemented with finite word-length due to the limited range and precision of the fixed-point data type, the multiplication and addition operations can lead to quantization errors during the process of truncation and saturation. Over time, these quantization errors might accumulate until an overflow in the filter coefficients occurs. Same problem would also be caused with a very slight DC component present in microphone preamplifier and/or A/D converter.

E. Influence of the secondary path

The secondary path response includes frequency and phase response of the loudspeaker and the microphone. Frequency responses of a microphone and a loudspeaker are generally flat (within few dB in a frequency range of interest) and their influence to the convergence is negligible (waveform generator will adapt to a slightly different amplitude of signal). The main problem is phase shift in the loudspeaker. This phase shift is frequency dependent and hinder accurate alignment of output and error signal during averaging. Phase response of the microphone is illustrated in Fig. 9, and of the loudspeaker in Fig. 10. Phase response of the microphone is quite flat across large frequency range, however loudspeaker doesn't have that flat response. Reasonably flat and slowly

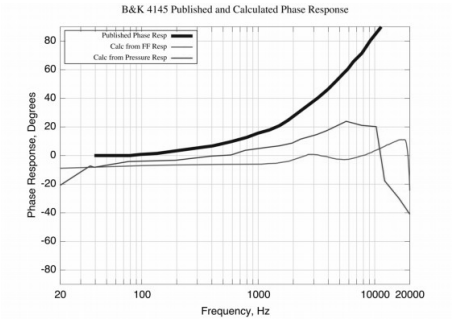

Figure 9. Example: phase response of the microphone

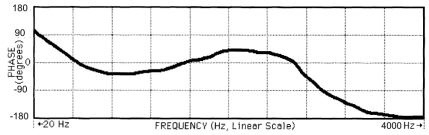

Figure 10. Example: phase response of the loudspeaker

changing phase (no sudden 180º changes) characteristics is common, however in some cases phase correction may be necessary (simple passive solution may suffice).

F. Calibration of sound propagation time

It was already mentioned that sound propagation time between the loudspeaker and the microphone must be considered and determined. Due to phase characteristics of the secondary source it is also necessary to consider additional small time shift for correction due to phase shift θ_P and group delay of the secondary source at the frequency of the calibration tone. Calibration process is performed before first use by generating short sinusoidal pilot tone at the frequency of most interest f_P (twice the power grid frequency) and is based on correlation function between signal of the generated pilot tone x_1 and signal picked from the from microphone during calibration, x_2. Correlation values are calculated for time shifts τ_Δ, (15) using floor and ceiling function, distance d (with 25% tolerance), speed of sound v, sample frequency f_s, power grid frequency f_p and maximal 90° phase shift). The largest correlation value with corresponding τ_Δ is determined:

$$r_{12}(\tau_\Delta) = \frac{1}{N - \tau_\Delta} \sum_{n=\tau_\Delta}^{N} x_1(n) x_2(n - \tau_\Delta)$$

$$\tau_\Delta = \left\lfloor 0.75 \frac{df_s}{v} - \frac{90 f_s}{360 f_p} \right\rfloor, \cdots, \left\lceil 1.25 \frac{df_s}{v} + \frac{90 f_s}{360 f_p} \right\rceil \quad (15)$$

$$r = \arg\max_{\tau_\Delta} \left(r_{12}(\tau_\Delta) \right) \quad (16)$$

where r is the time shift represented in number of samples for which highest correlation value between two signals $r_{12}(m)$ is determined. Value of r includes total sound delay produced by sound propagation through the air and phase characteristics of the loudspeaker, as determined in (3).

G. Convergence Properties

Convergence is dependent on the accurate alignment of averaged and new samples, as in (1), (2), (3) and offset r in Fig. 6. It includes time delay due to sound propagation time between loudspeaker and error microphone and a group delay due to phase characteristic of the loudspeaker. Convergence is assured for all frequency components in a signal with phase shifts θ_i within an interval:

$$\theta_i \in [-90°, +90°] \quad (17)$$

Convergence speed is proportional to the product:

$$\alpha \cos(\theta_i) \quad (18)$$

The higher the α and the lower the phase shift θ_i within the secondary path, the faster will be the convergence. When the phase shift approaches close to 90º the convergence is becoming very slow. If phase shift θ_i is outside this interval the algorithm will not converge but diverge. Frequency shift in the secondary path for each and every frequency component used for noise control in loudspeaker must be within previous interval for system to converge.

Higher frequencies with a phase shift outside the interval can be eliminated by low-pass (usually switch capacitor) filter with cut-off frequency at 1-2 kHz, following the D/A converter. This way eventual rare frequency components that don't fit in ±90º phase interval will be eliminated by low pass filters before A/D and after D/A. Such filters are parts of digital control systems with analog signals anyway. This filtering also eliminates part of environment noise and speed up the convergence.

H. Numerical Complexity

The method is numerically very simple. In exponential averaging we have just one addition and two multiplications. Even when one use offsetted pointer (by *r*) from (3) all operations with pointers can be implemented with two pointers (p_i and p_o, from Fig 6), and no additional mathematic operations.

V. SIMULATION AND RESULTS

Simulation was performed using the recorded noise signal of power transformer (including low amount of environment noise). The signal from the microphone was captured using a notebook and built-in soundcard. In this simulation value *r* from (3) was set to zero. Algorithm was implemented in C.

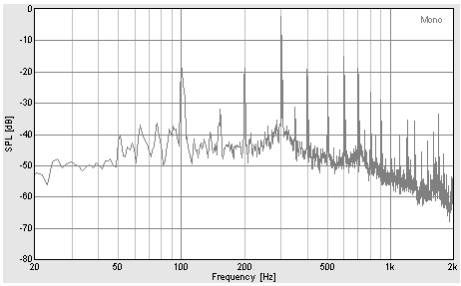

Figure 11. Transformer noise - ANR is off

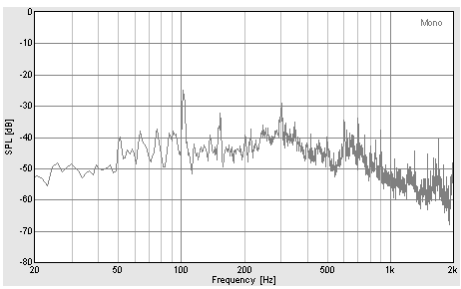

Figure 12. Transformer noise - ANR is on (reduced harmonics)

Following situations have been considered: stationary noise and two examples of dynamically changing noise levels ("Dynamic tracking I" and "Dynamic tracking II" with artificially inserted 3 dB noise level step and deep). After 3 dB noise level changes new convergences have been achieved in less than half a second. Achieved noise reduction in frequency domain is illustrated in Fig. 11 and Fig 12. Noise, control signals and residual noise in time domain are presented in Fig. 15 - 21.

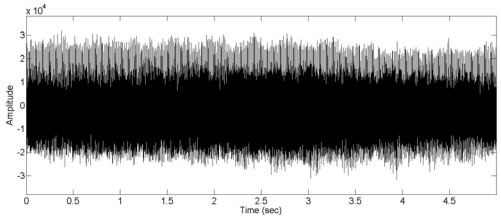

Figure 13. Stationary noise signal

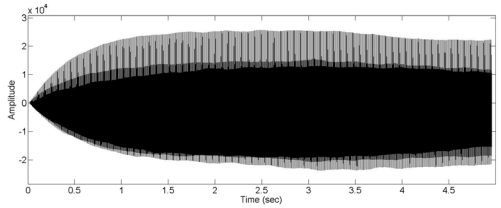

Figure 14. Secondary (control) signal

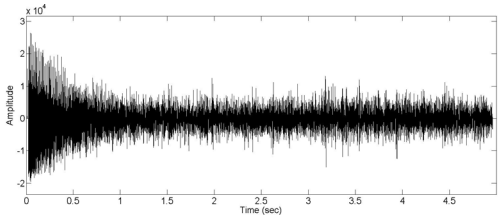

Figure 15. Stationary noise: Residual noise signal

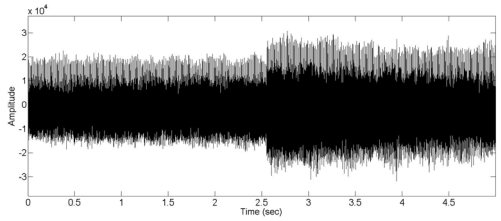

Figure 16. Dynamic tracking I: Primary noise signal

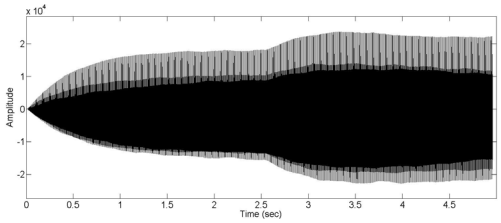

Figure 17. Dynamic tracking I: Secondary (control) signal

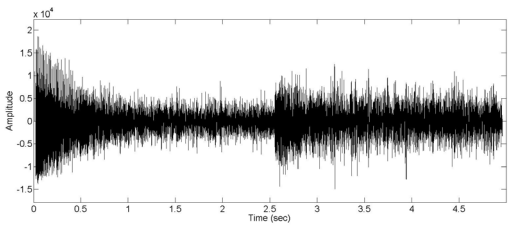

Figure 18. Dynamic tracking I: Residual noise signal

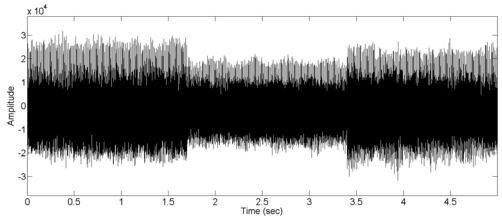

Figure 19. Dynamic tracking II: primary noise signal

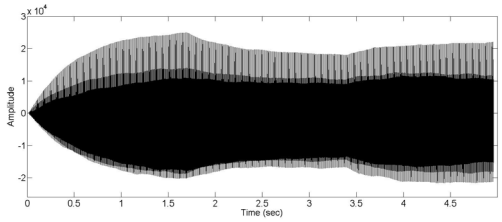

Figure 20. Dynamic tracking II: Secondary (control) signal

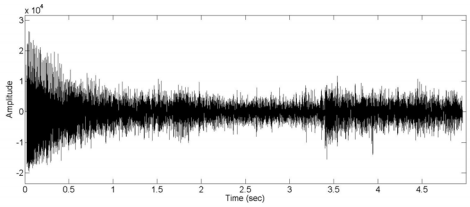

Figure 21. Dynamic tracking II: Residual noise signal

Achieved ANR attenuation results are presented in Table I. The A-weighting that has been widely adopted for environmental noise measurement is also included.

Table I ANR ATTENUATION RESULTS

Attenuation	ANR off	ANR on	Difference
Average *RMS* (dB)	-8,3 dB	-22,1 dB	13,8 dB
Average *RMS* (dB) A-weighted	-14,7 dB	-26.3 dB	11,6 dB

Moderate but realistic values have been achieved, comparable with other methods.

VI. CONCLUSION

Transformer noise is periodic low frequency noise caused by magnetostriction, dominated with harmonics at multiples of twice the power frequency. Passive noise reduction is of limited efficiency at low frequencies. On the other hand active noise reduction is well suited for such low frequency noise.

Simple, intuitive and numerically efficient method for active reduction of transformer noise is introduced that is based on waveform generation using synchronous averaging of residual noise signal and is suitable for the reduction of periodic transformer humming noise. Method uses single microphone for picking residual noise and additional synchro signal that can be obtained from the full wave rectified low voltage power grid signal.

Determination of the time delay in acoustic path (including phase shift in loudspeaker) is accomplished by calibration process using short pilot tone before the first use of the device. Active reduction of transformer noise must operate correctly regardless of load and ambient conditions, hence algorithm is adaptive and track changes with sufficient speed (convergence in a part of a second).

Due to low numerical complexity method can be implemented in very cheep hardware, like conventional microcontrollers. The method doesn't use additional reference microphone for picking the reference noise signal (avoiding acoustic feedback from the loudspeaker). However, lacking this additional information about noise, tracking of the noise dynamics is not so fast as what could be achieved with broadband feedforward methods, but still fast enough to track changes in transformer load. It is also necessary to perform initial calibration of the system to determine sound propagation time due to distance between loudspeaker and error microphone, and group delay due to phase shift in a loudspeaker. However, similar tasks are also performed in various advanced and complex variants of feedforward methods (eg. FXLMS by on-line injecting additive random noise signal into secondary path).

Noise reduction achieved using simulation with recorded transformer noise is similar to values obtained with other methods. In practical realizations it would often be necessary to use multiple secondary sources together with multiple driving channels, possibly considering acoustic interactions between individual channels.

Engine Fault Detection in a Twin Piston Engine Aircraft

Dubravko Miljković
Hrvatska elektroprivreda, Zagreb, Croatia
dubravko.miljkovic@hep.hr

Abstract - Due to the inherent reliability of aircraft engines examples of engine faults are very rare. Hence, it is very difficult to devise mathematical models necessary for the fault detection. However, in case of twin engine aircrafts it is possible to detect potential engine faults by comparing parameters of both engines. In ideal case these parameters should be quite similar and their discrepancy could provide warning of the pending engine problem or failure. A method that uses statistically determined intervals is proposed.

I. INTRODUCTION

In most twin-engine light aircraft, the power plant is a four-stroke reciprocating engine with a direct drive to a propeller. Aircraft piston engines are relatively reliable devices. Engine failure is rare, thankfully, but does happen. Most engine damage which leads to failure does not occur all at once. If a pilot operates an engine in a way that causes excessive heat, stress or wear, it may take months before damage to the engine is severe enough to be detected by the pilot. By monitoring engine parameters it is possible to detect minor engine problems before they become large ones.

Alarm levels for warning alert (that require immediate crew awareness and corrective action) commonly set at the engine monitor are universal for all phases of flight and provide only detection of serious faults. Twin engine aircraft has two essentially the same engines. Fine detection is suitable for caution alert (where corrective action may be required) could be achieved by noticing the asymmetry of engine parameters. It is highly unlikely that both engines will fail in the same way at the same time with the same changes in corresponding engine parameters. Comparing engine parameters between the two engines enables fine detection of minor problems. Engine monitor log analysis can be performed after the flight using the proposed procedure and suspicious minor problems may be automatically labeled in the log for closer attention of the mechanic.

II. AIRCRAFT PISTON ENGINE

Piston engine is a heat engine that uses one or more reciprocating pistons to convert pressure into a rotating motion. Most common aircraft piston engine are horizontally opposed, air-cooled four-, six- and eight-cylinder engines. In the past radial engines were also common. Engines have old fashion but reliable fixed-timed dual magneto ignition systems (no use of electronics). Propellers are generally directly driven by an engine, although gearbox speed reductors exist on some higher power engines.

Engine problem, is likely to manifest itself as a partial engine failure in the first instance (e.g. cylinder failure). Total engine failure is more rare event and is defined as off the ground, total and mechanically caused (i.e. rod, crankshaft, stuck valve). Piston engine reliability data is shown in Table I. These numbers are obtained from pilot experiences participating in high traffic newsgroup *rec.aviation.ifr* with pilots reporting total hours flown and number of experienced partial and total engine failures, [1]. Piston engines are roughly seven times less reliable then jet engines. Engine monitoring can increase operational reliability of piston engines.

TABLE I. Reliability of typical piston engine (total failures)

Aircraft ownership	MTBF (hours)*
club	≈ 20.000 (18,390)
private	> 30.000 (30,775)

*exact numbers derived from participant responses are in parentheses

The failure rate is not uniform, and depends a lot on how the aircraft are maintained and utilized (club vs. private airplane). Generally, better results are obtained for simpler engines like (I)O-240, (I)O-320 and (I)O-360 then for more complex and powerful injection (I)O-520, (I)O-540 and particularly turbocharged engines (TIO) where the turbo failure cause very significant power loss. In terms of engine reliability simpler designs give better results. Statistics is skewed toward four cylinder engines because they are most common among light airplanes.

III. ENGINE MONITOR

The main source of engine information available to pilot are several gauges indicating engine rotational speed (RPM, tachometer), oil pressure, oil temperature, exhaust gas temperature (EGT) and fuel flow. These gauges give very basic information about the engine condition. More advanced solutions exist today in form of engine monitors. Such engine monitors cover much more engine data then basic gauges in a cockpit (about dozen of parameters that are also recorded and can be analyzed later), Fig. 1. Adequate skill is needed for correct engine monitor data interpretation. Beside engine condition monitoring, these engine monitors can be used for improved engine

Figure 1. Engine monitor display (EDM 760) for twin-engine aircraft

operation (fuel economy). Piston engine is not particularly efficient and only a small portion of the energy from combustion produces movement of the piston during the power stroke. The greatest part of energy passes into the exhaust pipe as hot gasses. By monitoring the temperature of exhaust gasses it is possible to assess the quality of the combustion process. Diminished efficiency of the combustion process that generates power indicates engine problems like low compression, non-uniform fuel distribution, faulty ignition, and clogged injectors, [2].

Engine monitor used in an experiment records numerous engine parameters that are listed in Table II and shown in form of bar graph and digital display. Parameters are displayed and recorded at the programmed interval of between 2 and 500 seconds (in case of EDM 760 default setting is every 6 seconds). Voltage parameters are also recorded but they are not used for engine diagnostics.

TABLE II. Monitored engine parameters

Parameter	Description
EGT	Exhaust Gas Temperature
CHT	Cylinder Head temperature
OIL	Oil Temperature
TIT	Turbine Inlet Temperature
CLD	CHT Cooling Rate*
DIF	EGT Span**
FF	Fuel Flow***

* fastest cooling cylinder, ** difference between the hottest and coolest EGT, *** with the fuel option installed

The used engine monitor (EDM 760) has several programmable alarms limits related to engine parameters. Default alarm limits are conservatively set (by JPI) below engine manufacturers (Lycoming and Continental) recommendations, Table III. If a parameter gets out of its normal limits, the digital display will blink indicating the value and abbreviation of the problematic parameter. Because the temperature values of EGTs can assume different ranges depending on the current flight phase (climb, cruise) or engine run-up, monitor doesn't provide alarm limits for individual EGTs, it calculates the DIF parameter instead. The value for DFT is the difference between the hottest and coolest EGTs. This EGT span is important for monitoring the values of EGTs, [2].

Default alarm limits are set to encompass all flight regimes ("one fits all"). If one would have information about the current flight regime these limits could be

TABLE III. Default Engine Monitor Alarm Limits

Measurement	Default Low Limit	Default High Limit
CHT		450 °F 230 °C
OIL	90 °F 32 °C	230 °F 110 °C
TIT		1650 °F 900 °C
CLD		-60 °F/min -33 °C/min
DIF		500 °F 280 °C

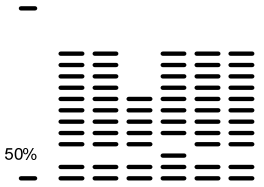

Figure 1. Intake valve or valve filter

Figure 2. Dirty fuel injectors or fouled plugs

set to different levels for each flight regime. Automatic detection of the flight phase would require additional flight and engine parameters (altitude, speed, vertical speed and engine RPM with provisions for faulty sensor). However, these parameters are rare readily available in digital format in general aviation aircraft (ageing fleet of average age 25+ years, still depending on analog gauges).

Engine diagnosis charts supplied with the engine monitor can help diagnose various engine faults, [2]. There are 15 general patterns that indicate particular faults, two examples are illustrated in Fig. 2 and Fig. 3.

IV. Possible Approaches

One possible approach for the early detection of engine problems would be to collect numerous engine monitor logs depicting various examples of engine failures. Combined with the large number of examples of normal engine it would be possible to train a pattern recognition system using collected labeled examples, [3, 4]. However in reality, because engine failures are quite rare, it would be very difficult (without organizing large scale voluntary action) to obtain a sufficiently large number of recorded engine failures (together with numerous examples of various faults to cover all important situations).

Another approach is to use some of novelty detection techniques, [5]. Novelty detection is a paradigm in which model of normality is constructed from normal system data. The primary objective of novelty detection is to examine if a system significantly deviates from the initial baseline condition of the system, Fig. 4. Novelty detection methods are particularly suited for applications where most data is available from normal system operation and failures are rare.

Most common novelty detection approaches are statistical and rule based approaches.

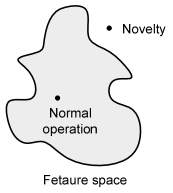

Figure 3. Novelty pattern in a feature space

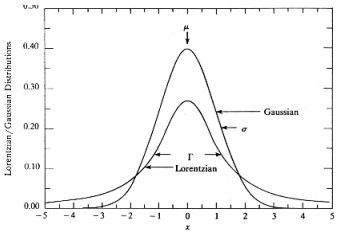

Figure 4. Gaussian distribution and deviations, Lorentzian for fat tails

In statistical approaches stochastic distribution is used to model the empirical data. Common assumption behind measured data is a Gaussian or normal distribution (mixture of normal distribution can also be used). If empirical distribution has very extended wings, Lorentzian may be appropriate. Pattern is considered a novelty when probability density function falls bellow a threshold (often associated with 3σ distance from the mean μ in case of normal distribution), Fig. 5. Determination of the appropriate threshold could be quite difficult task.

Rule based techniques automatically generate rules (or use rules devised by an expert) which capture the normal behavior of a system. Here are simple examples:

IF parameter < LIMIT1 THEN ALARM
IF parameter > LIMIT2 THEN ALARM
IF parameter < LIMIT1 OR parameter > LIMIT2 THEN ALARM

Engine monitor used in an experiment has default settings in form of following rules (limits from Table III):

IF CHT > 450 THEN ALARM
IF OIL < 90 OR OIL > 230 THEN ALARM
IF TIT > 1650 THEN ALARM
IF CLD < -60 THEN ALARM
IF DIFF > 500 THEN ALARM

V. DESRIPTION OF THE METHOD

A. General Idea

Both engines on twin engine aircraft are the same with possible one small detail: on aircraft with counter-rotating propellers there are left and right turning engine, these engines are essentially the same with difference in cylinder firing order. Most (almost all) piston-engine airplanes offer a three-lever engine control setup that dates back more than 50 years. Two levers control the engine (power and mixture) whilst third lever controls propeller pitch (that has also great influence on engine RPM). In twin engine aircraft these levers are organized in a way that power, mixture and propeller pitch levers are positioned side by side as illustrated in Fig. 6. Generally, engine levers are always advanced in unison, the exceptions being during ground operations (startup,

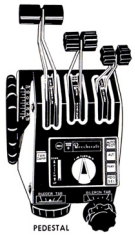

Figure 5. Engine control quadrant: power, propeller and mixture levers

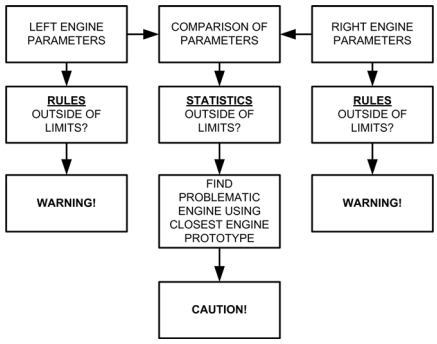

Figure 6. The general idea behind the method

shutdown, engine run-up with magneto checks), engine failure (simulated or real) and leaning procedure (adjust fuel/air ratio - mixture adjustment at altitude change).

Engine parameters are collected from engine monitor probes installed on an engine. It is expected that in normal operation parameters from left and right engine will be almost identical. By comparing parameters from the left and right engine small discrepancies could be detected. Default alarm levels (set by rules and limits, Table III) are still operative and ensure severe fault detection, while asymmetry of the engine parameters is used for finer detection of smaller problems, Fig. 7.

B. Engine Parameters

Following parameters are collected or calculated by the engine monitor, N_C is the number of cylinders:

- Exhaust Gas Temperature for cylinders 1-N_C
- Cylinder Head Temperature for cylinders 1- N_C
- Oil temperature: OIL
- Turbine Inlet Temperature: TIT
- Fuel Flow: FF
- Cooling Rate: CLD

Other parameters (battery voltage, remaining fuel etc.) collected by the monitor are not used in this method.

There is a considerable spread of engine parameters during various phases of the flight, as shown (example of CHT values) in Fig. 8 that prevents use of tighter alarm levels (tightly set alarm level suitable for one flight phase would be busted in other flight phase). While the spread of individual engine parameters during the flight is quite large, spread of differences of parameters collected from two engines on a twin engine aircraft is significantly smaller, Fig. 8. When the difference between parameters Δp_i is small relatively to parameters better results could be achieved with relative difference $\Delta_r p_i$ between parameters $p_{i,L}$ and $p_{i,R}$ from the left and right engine, Table IV:

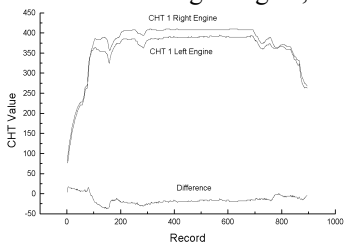

Figure 7. Example of CHT values for the same cylinder on the left and right engine and their difference

$$\Delta_r p_i = \frac{2(p_{i,L} - p_{i,R})}{abs(p_{i,L}) + abs(p_{i,R}) + \varepsilon} \quad (1)$$

Relative difference removes the influence of parameter magnitudes and the term ε, $\varepsilon << 1$, prevents zero divisions.

TABLE IV. Parameters and their relative differences Δ_r

Parameter		Relative difference
Left Engine	Right Engine	
$EGT_{1\text{-}Nc,L}$	$EGT_{1\text{-}Nc,R}$	$\Delta_r EGT_{1\text{-}Nc}$
$CGT_{1\text{-}Nc,L}$	$CGT_{1\text{-}Nc,R}$	$\Delta_r CGT_{1\text{-}Nc}$
OIL_L	OIL_R	$\Delta_r OIL$
TIT_L	TIT_R	$\Delta_r TIT$
FF_L	FF_R	$\Delta_r FF$
CLD_L	CLD_R	not used for statistics, rules limits only

When considering parameters used in the method it is possible to distinguish two classes of parameters:

- Direct parameters – direct measurements, determined without considering values from other measurements

Direct parameters are snapshoot of the moment and include following readily available engine parameters:

EGT, CHT, OIL, TIT, FF (description in Table II)

- Derived parameters – determined from values of other measurements (differences or even time difference)

Derived parameters reflect the EGT parameter span or changes of parameters over the time (fastest cooling cylinder and rates of cylinder's temperature changes):

DIF (EGT span), *CLT* (negative values shown only), *ΔCHT*

Beside available engine monitor parameters temperature differences *ΔCHT* in one minute interval for cylinder heads are introduced in this method (one for each cylinder):

$$\Delta CHT_i = CHT_{i,k} - CHT_{i,k-20} \quad \text{one minute span (6s record)} \quad (2)$$

Simple difference between left and right engine is used:

$$\Delta(\Delta CHT_i) = \Delta CHT_{L,i} - \Delta CHT_{R,i} \quad \text{(due to small differences)}$$

Parameters *CLT* and *ΔCHT* reflect temperature changes of an engine. All parameters are organized in two vectors, for the left engine $\boldsymbol{v_L}$, (N_C is the number of cylinders):

$$\boldsymbol{v_L} = [EGT_1, \ldots, EGT_{Nc}, CHT_1 \ldots CHT_{Nc}, \Delta EGT_1, \ldots, \Delta EGT_{Nc}, OIL, TIT, FF] \quad (3)$$

and for the right engine $\boldsymbol{v_R}$:

$$\boldsymbol{v_R} = [EGT_1, \ldots, EGT_{Nc}, CHT_1 \ldots CHT_{Nc}, \Delta EGT_1, \ldots, \Delta EGT_{Nc}, OIL, TIT, FF] \quad (4)$$

C. Decision Criterion

The decision is based on thresholds imposed on relative differences (simple difference for $\Delta(\Delta CHT_i)$):

$$T_{EGTi,LOW} < \Delta_r EGT_i < T_{EGTi,HIGH} \qquad i=1,..,N_C \quad (5)$$

$$T_{CHiT,LOW} < \Delta_r CHT_i < T_{CHTi,HIGH} \qquad i=1,..,N_C \quad (6)$$

$$T_{\Delta,CHTi,LOW} < \Delta(\Delta CHT_i) < T_{\Delta,CHTi,HIGH} \qquad i=1,..,N_C \quad (7)$$

$$T_{OIL,LOW} < \Delta_r OIL < T_{OIL,HIGH} \quad (8)$$

$$T_{TIT,LOW} < \Delta_r TIT < T_{TIT,HIGH} \quad (9)$$

$$T_{FF,LOW} < \Delta_r FF < T_{FF,HIGH} \quad (10)$$

A suspicious condition is detected when at least one of inequalities is not fulfilled. If asymmetry of parameters is detected than one should be suspicious about condition of one of engines. However there is still no information which engine is causing the problem, as both engines may still be well within default alarm limits. In that case engine parameters are normalized and compared with normalized prototype patterns from a pool stored for each engine and chosen using nearest neighbor rule.

The prototype pattern is a vector $\boldsymbol{v_P}$ that consists only of following $2N_C$ components:

$$\boldsymbol{v_P} = [EGT_1, \ldots, EGT_{Nc}, CHT_1, \ldots, CHT_{Nc}] \quad (11)$$

D. Pattern Normalization

Normalization is performed by determining the highest *EGT* among all cylinders of an engine. Then all *EGT* and *CGT* values are divided by the previously determined highest *EGT* value.

$$EGT_{MAX} = \max(EGT_i) \quad i=1,\ldots,N_C \quad (12)$$

Normalized *EGT* values, *NEGT* are:

$$NEGT_i = \frac{EGT_i}{EGT_{MAX}} \qquad i=1,\ldots,N_C \quad (13)$$

Similarly, normalized *CHT* values, *NCHT* are:

$$NCHT_i = \frac{CHT_i}{EGT_{MAX}} \qquad i=1,\ldots,N_C \quad (14)$$

Components of the normalized pattern are within intervals:

$$0 <= NEGT_i <= 1 \qquad i=1,\ldots,N_C \quad (15)$$

$$0 <= NCHT_i <= 1 \qquad i=1,\ldots,N_C \quad (16)$$

The normalized prototype pattern now has following $2N_C$ components:

$$\boldsymbol{v} = [NEGT_1, \ldots, NEGT_{Nc}, NCHT_1, \ldots, NCHT_{Nc}] \quad (17)$$

E. Normalized Prototype Patterns

Four normalized prototype patterns are determined both for the left and right engine using previously available engine data. They are determined by analysis of engine operation log at points where average *CHT* for all cylinders crosses for the first time temperature levels 200, 250, 300 and 350 ºF, Table V (to avoid unsupervised clustering procedure). Various engine operation regimes are covered, i.e. engine is not represented by single normalized prototype pattern for all the duration of flight. Patterns are normalized to minimize influence of different parameter magnitudes from various flight phases, Fig. 8.

TABLE V. CHT temperatures for prototype patterns

Pattern	CHT transition temperature* (ºF)
1	↑ 200
2	↑ 250
3	↑ 300
4	↑ 350

* temperature up-transitions

F. Detection of Suspicious Engine

Normalized pattern from each engine is compared with closest normalized patterns from a pool of stored patterns using the Euclidean distance measure. Closest normalized prototype is chosen for each engine considering CHT of individual cylinders and CHT

transition temperature from Table V using *k*-nearest neighbor algorithm. The *k*-nearest neighbor algorithm assigns the object to the class most common amongst its *k* nearest neighbors, [4]. In case of six cylinder engine 6-NN rule is applied. Closest pattern is the one whose CHT transition temperature is closest to CHT values of most cylinders. This procedure selects the correct normalized prototype pattern even when one or more CHT values are outliers (e.g. due to a cylinder failure). Once the closest normalized prototype pattern is chosen, Euclidian distances between vectors of engine parameters represented in normalized engine pattern and selected normalized prototype patterns are determined for both engines. In general, for an *n*-dimensional space, the Euclidean distance is given by

$$d(p,q)=\sqrt{(p_1-q_1)^2+(p_2-q_2)^2+\ldots+(p_i-q_i)^2+\ldots+(p_n-q_n)^2} \quad (18)$$

$$dist_{E,P}=\sqrt{\sum_{i=1}^{i=N_C}\left(NEGT_{E,i}-NEGT_{P,i}\right)^2+\sum_{i=1}^{i=N_C}\left(NCGT_{E,i}-NCGT_{P,i}\right)^2} \quad (19)$$

Average values (and hence appropriate differences) are larger for *NEGT* than for *NCGT*. Equalization term is introduced based on average ratio *NEGT* and *NCGT* (across all cylinders *i* and all records *k*) from engine logs:

$$R=\frac{1}{N_C N_R}\sum_{i=1}^{N_C}\sum_{k=1}^{N_R}\frac{NEGT_{i,k}}{NCHT_{i,k}} \quad (20)$$

Value for *R* is approximately set to value 4.2 (not to complicate (19) with introduction of the variance for each parameter). N_R is the number of records, and N_C cylinders

$$dist_{E,P}=\sqrt{\frac{1}{R^2}\sum_{i=1}^{i=N_C}\left(NEGT_{E,i}-NEGT_{P,i}\right)^2+\sum_{i=1}^{i=N_C}\left(NCGT_{E,i}-NCGT_{P,i}\right)^2} \quad (21)$$

Appropriate distances for left and right engine are given by:

$$dist_{E,L_i}=ED\left(v_E,v_{P_{L_i}}\right) \qquad i=1,...,4 \quad (22)$$

$$dist_{E,R_i}=ED\left(v_E,v_{P_{R_i}}\right) \qquad i=1,...,4 \quad (23)$$

Engine whose normalized engine pattern $\boldsymbol{v_P}$ is further distance to selected normalized prototype pattern is indicated (or labeled) to be suspicious.

G. Determination of Thresholds

Thresholds are determined from extracted statistical data supplied in engine monitor logs. Decision for this time period was made considering MTBF values of piston engines and maintenance intervals (50, 100 and 200 hours for engines). In a real life we are generally not satisfied with the notification of the failure, but the notification of the impeding failure, so maintenance and service actions can be taken in advance, before the failure happens. It is decided that for each parameter there should be one caution alert within 100 hour period, T_{ALERT}, much lower then estimated MTBF. It seems reasonable to label suspicious parameter spread in an engine monitor log that will appear for particular parameter once in T_{ALERT} period and be brought to the attention of the mechanic. This is a balance between detection sensitivity and not generating too much burden for a mechanic. Frequency histograms of parameter differences (levers advanced in unison) are shown in Fig. 9-14 (one example shown for $\Delta_r EGT$ and $\Delta_r CHT$). Normal distribution is assumed for all differences. For each difference mean value and standard deviation from engine monitor log is calculated across all records:

The mean value for parameters p_i is determined by

$$\mu_{p_i}=\frac{1}{N_R}\sum_{j=1}^{N_R}p_{i,j} \quad (24)$$

and the standard deviation is determined by

$$\sigma_{p,i}=\sqrt{\frac{1}{N_R}\sum_{j=1}^{N_R}\left(p_{i,j}-\mu_{p,i}\right)} \quad (25)$$

where N_R is the number of records)

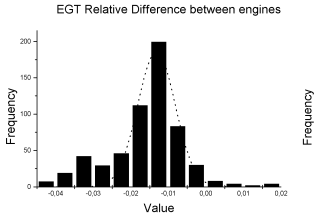

Figure 9. $\Delta_r EGT$ example

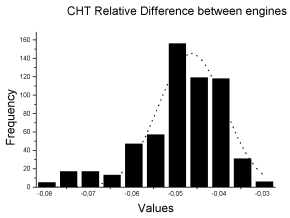

Figure 10. $\Delta_r CHT$ example

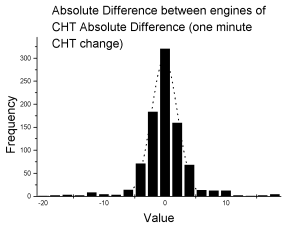

Figure 11. $\Delta\Delta CHT$

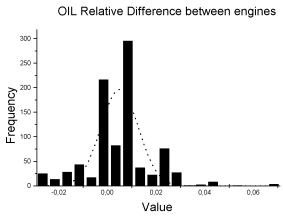

Figure 12. $\Delta_r OIL$

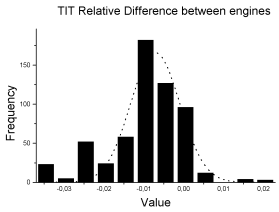

Figure 13. $\Delta_r TIT$ - Turbine Inlet

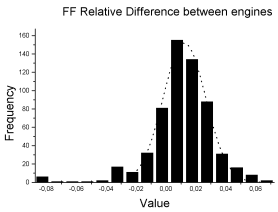

Figure 14. $\Delta_r FF$ Fuel Flow

Due to the lack of available examples of engine failures, determination of acceptable deviations from the mean (for determination of lower and upper limit) is accomplished by the determination of the standard deviation σ of the normally distributed values in frequency beans, and using multiple of σ, [6]. Acceptable deviations from the mean values are determined based on the reasoning that an unacceptable parameter value happens at average once during the T_{ALERT} period. The N_R is number of records within T_{ALERT} period (100 hours) is given by

$$N_R=\frac{T_{ALERT}}{T_R} \quad (26)$$

T_R is duration of one engine log record (default value 6s) As there will be at average one such "alert record" for each parameter within 100 hours probability *p* is 0,999983:

$$p=\frac{1}{N_R} \quad (27)$$

Proportion *r* of data values within *z* standard deviations of the mean is defined by:

$$r=erf\left(\frac{z}{\sqrt{2}}\right) \quad (28)$$

where

$$r = 1 - p \tag{29}$$

and *erf* is the error function

$$erf(x) = \frac{2}{\sqrt{\pi}} \int_0^x e^{-t^2} dt \tag{30}$$

When observations under considerations are distributed according to the Gaussian distribution, 68% of observations fall within σ, 95% within 2σ and 97% within 3σ of mean. From the available T_{ALERT} and the duration of the engine log record T_R the probability, p, is determined, followed by r, and finally z. For given p=0,999983, value for z is 4.3006. Referent mean values $\mu_{P_i,G}$ and standard deviations $\sigma_{Pi,G}$ are determined from the previous engine monitor logs of a good engine. Log analysis is performed after flight. We are looking for a record that appears at average once during T_{ALERT} period. All parameters values p_i form each record of a good engine (i.e. $p_{i,TG}$) will fall within predefined interval around mean, $\mu_{P_i,G}$ (i.e. within the acceptance interval defined by the lower and upper thresholds, T_{LOW} and T_{HIGH}):

$$T_{LOW} = \mu_{p_i,G} - z\sigma_{p_i,G} \tag{31}$$

$$T_{HIGH} = \mu_{p_i,G} + z\sigma_{p_i,G} \tag{32}$$

$$p_{i,TG} \in \left\lfloor \mu_{p_i,G} - z\sigma_{p_iG}, \mu_{p_i,G} + z\sigma_{p_iG} \right\rfloor \tag{33}$$

where $\mu_{P_i,G}$ is the mean of the parameter p_i from a good engine, $\sigma_{pi,G}$ standard deviation of a parameter value p_i from a good engine, i = 1,…,N_P , N_P is the number of parameters. On the other hand for one or more parameters values p_i of the problematic or failed engine (i.e. $p_{i,TF}$) following relation will apply:

$$p_{i,TF} \notin \left\lfloor \mu_{p_i,G} - z\sigma_{p_iG}, \mu_{p_i,G} + z\sigma_{p_iG} \right\rfloor \tag{34}$$

Relations (33) and (34) use (5)-(10) in a different notation.

VI. RESULTS

Several engine monitor logs were available form previous flights supplied with the EZTrends software, [7]. Analyzing log data from longest available flight (Flight sample #192, 1,46h) parameter differences have been determined. The first part of the log (engine start-up, magneto check and run-up) and the last part (shut down) were omitted as these are obvious situations of asymmetric engine operation. Mean values, standard deviations and thresholds are shown in Table VI. Relative parameter differences are within few percents.

TABLE VI. Mean, Std. Dev. and Thresholds (z=4.3006)

Parameter difference (p_i)	Mean $\mu_{Pi,G}$	Std. Dev. $\sigma_{Pi,G}$	Lower Threshold $\mu_{Pi,G}$-z $\sigma_{Pi,G}$	Upper Threshold $\mu_{Pi,G}$+z $\sigma_{Pi,G}$

*for $\Delta\Delta CHT_i$ simple differences are used instead of relative differences

VII. CONLUSION

It is expected that in normal operation both engine parameters will be almost the same. Comparing engine parameters between two engines may enable fine detection of minor problems. Proposed method combines rules (limits on the engine monitor parameters of the individual engine) and statistical approach (using relative differences with the exception of $\Delta\Delta CHT$). Threshold limits for comparison of parameters are calculated using statistical data from engine monitor logs considering the T_{ALERT} period (using engine maintenance interval). After detecting asymmetry of parameters, suspicious engine is detected by comparing the engine parameters with parameters of stored prototype patterns. Default alarm limits for individual engines (simple rules) are preserved for the detection of severe engine problems. Procedure is performed off-line as part of the analysis of recorded data after the flight. The engine log file is parsed and records with discrepancy of parameters between engines are automatically labeled as suspicious and can be brought to attention of maintenance personnel. This enables faster and more precise scan of the engine monitor log than simple visual inspection of engine parameter curves. With additional field tests and determination of reliable thresholds (including an additional time threshold defining the minimal parameter deviation period for issuing the caution alert) it would be possible to consider the real time version of the method implemented in some kind of the engine monitor with indication of the engine parameters asymmetry in a cockpit.

Stochastic Approach on Hash Cracking

Goran Martinovic, Luka Horvat, Josip Balen
Faculty of Electrical Engineering, Osijek, Croatia
goran.martinovic@etfos.hr

***Abstract*—Hash functions are used everywhere today, from wireless communications to password storage. Some of them are proven to be mathematically insecure, but still the only way to crack most of them is a brute-force or dictionary attack. Brute-force is usually discarded as an option since it consumes huge amounts of time. Dictionary attack is a regular approach on hash cracking. The attack is performed by selecting words from a dictionary and comparing their hashed value to the obtained value. Word selection is usually done sequentially, which indicates a very long execution time if the searched word is located at the end of the dictionary. This paper introduces a stochastic approach on word selection in a dictionary attack and shows that the approach is desirable if the searched word is found in the second half of the wordlist.**

Keywords - dictionary attack; hash cracking; randomization; stochastic approach

I. INTRODUCTION

Hash value is a fixed-size bit array that "presents" an arbitrary block of data. Hash value is created with a hash function using a block of data as its input. Functions are made so that any change to the input sequence should induce a change in the hash value. Most frequently used hash methods exploit bitwise operations to produce message digest. An important property of the hash function is that there should be no two different inputs that can induce the same hash value (collision resistance). Also, hashing functions are one-way functions. Therefore, there should be no analytic way for obtaining an input sequence from its hashed value. However, some of today's hashing techniques have been proven as collision irresistible and analytical ways for their cracking have been found. In [1], authors explain how to crack an MD5 hash using collision attacks, and in [2], even newer hashing standards are exploited. Still, hashing is considered the safest way for storage and transfer of delicate information such as passwords. Most standards apply numerous iterations of hashing sequences to produce the final value and store or transfer it, which complicates the analytical cracking process.

Breaking hashes is usually brought down to preimage attacks that can take huge amounts of both time and processing power. Preimage attacks, also known as brute forcing, are usually unpractical because their complexity depends on the digest size (search takes 2^L steps, where L is the number of bits digest is made of). Hash attacks can be online or offline. In [3], authors explain the background of undetectable online password guessing attacks in authentication based protocols, and in [4], authors expand the Dolev – Yao model to give the theoretical background of offline dictionary attacks.

This paper concentrates on the offline hash cracking method with the hash value obtained. When this is the case, an attacker usually has the time to conduct his attack in a variety of ways. Loads of free tools are available online [5] and all of them support parallelism. Some can use the power of graphics cards or other devices, as described in [6] and [7], which can improve the cracking rate by a couple of hundred times. Online services [8] offer password cracking on the desired set of characters – for cash. Those tools usually use dictionaries (wordlists) or pre-computed rainbow tables and brute forcing is rarely considered. Although wordlists are usually sorted, binary searches and similar ones are out of the question due to hashing. Therefore, most hash cracking techniques rely on grabbing lines sequentially from the wordlist, performing certain hashing on them, and comparing hashed values to the captured one. This methodology is known as a dictionary attack. Lines grabbing is done sequentially which leads to a worse case running time of N steps, where N is the size of the wordlist. This process is equal to any array search algorithm, except most of the processing power here is spent on the hashing.

The idea given here is quite straightforward: What if a randomized word selection can find the desired word in fewer steps than a sequential one in a dictionary attack? The goal of this paper is to show when the stochastic passphrase search will outperform the sequential one and why.

The rest of this paper is organized as follows. First, a dictionary attack is described in Section II. Arguments for using the stochastic approach are given in Section III. In Section IV, an algorithmic solution is described. Experimental results and their evaluation are given in Section V. Section VI concludes this paper.

II. DICTIONARY ATTACK

A dictionary attack is a technique usually used to crack password-protected security systems, like computers or servers. An attack is performed by grabbing words from dictionaries and entering these words as a possible passphrase. Dictionaries are wordlists with a prearranged list of words and words grabbing is done sequentially. Dictionaries can be arranged in a way that phrases with higher probability of success are in the beginning, and vice versa. Used dictionaries in this work are arranged alphabetically. Dictionary attacks have a high efficiency if the passphrase is an ordinary word. Furthermore, dictionary attacks are often used in finding the key necessary to decrypt an encrypted message or document. In breaking cryptographic hash functions, a dictionary attack is performed by selecting a word from a dictionary,

performing certain hashing on it and comparing the hashed value to the obtained value.

In [4], three different examples of dictionary attacks are presented:

- Native vote protocol: If the sender encrypts his vote with the public key of the receiver, only the receiver can decrypt the message with his own private key and register the vote. However, if the attacker knows a finite set of values that vote can take, than he encrypts these values with the public key and compares encrypted values with the vote. The attack is successful if the vote equals one of the encrypted values.
- Handshake protocol: A sender generates a random number and sends it encrypted with a password to a receiver. Both a sender and a receiver know the password. After the receiver decrypts the message, he computes the sent number plus one, and returns it to the sender. If the password is chosen poorly, the attacker tries to decrypt both messages by guessing the password. The attack is successful if it finds two values such that the second value equals the first value plus one.
- Enhanced Kerberos protocol: A sender and a receiver communicate over the server which provides a secret key. The password between the receiver and the sender is assumed to be very strong but the password between the sender and the server is set up by the user and it could come from a dictionary. However, this protocol implements some protections against dictionary attacks using the nonces, the confounder and the timestamps. If the clocks of the sender and the server are not well synchronized, the attacker can replay a copy of an eavesdropped message within the clock skew and perform the attack.

III. STOCHASTIC APPROACH

A negative side of randomization and its implementation in search algorithms is that they are time consuming. Using the solution that can be found in [9], execution of randomized search could be up to four times longer than sequential one. On a three million words long wordlist, randomized search took on average 1.2883 seconds, while the sequential one took 0.3161 seconds. This difference would be huge if the searching is the only operation executed per search. It must be kept in mind that with every examination, a real cracking program has to carry out a certain amount of hashing (the number of hashing iterations is usually measured in thousands). RAR passwords, for example, apply up to 262144 iterations of SHA1 (Secure Hash Algorithm) [7] and that requires great amounts of processing time – much more than simple operations applied from [9]. Due to aforementioned, it can be assumed that a one whole iteration of grabbing a word, hashing it and comparing to the captured hash value lasts nearly the same as if it is done either sequentially or at random.

Since all words in a wordlist must be examined, the number of steps of the stochastic approach in the worst case is the same as sequential. Furthermore, probability *P(X)* that a word will be at line 5 of a wordlist and at line *N-5* is equal in both approaches, but the probability of a stochastic search algorithm to hit any line at the beginning of the search is the same for all lines. This is due the wordlist being sorted alphabetically, not by decreasing probability of success, and the search algorithm not being biased towards certain parts of the wordlist (meaning that the algorithm works on the principle of discrete uniform distribution). Random variable *X* has a discrete uniform distribution over set *S = {1, 2, ..., k}* (where *k* is a natural number) if (1) holds.

$$f(x) = P(X = x) = 1/k,\ x \in S \qquad (1)$$

$$P(X \in S) = 1$$

Wordlist is countable and every word in this list is unique, therefore every word is a discrete variable. This induces the same overall running times in both searching approaches when hashing is included. But, if a word that the program is searching is located in the second half of wordlist, the best case running time of a sequential approach is *N/2*, while that of a stochastic approach is still 1. Note that sequential and stochastic algorithms search the whole wordlist with the same probabilities of each element to be picked. However, the wordlist is sorted and sequential search always starts from the beginning and it always performs search from the first to the last word. Contrary to this, stochastic search retrieves words randomly. Therefore, if the word we are searching for is closer to the end of the wordlist, at the beginning of the search best case running time of a classical approach is very high while stochastic is still 1.

However, if the word being searched for is found at the beginning of the sorted wordlist, the probability that a sequential approach will find it first is greater than the one of the stochastic approach. The probability that random search will find the searched word in less than *X* steps at the beginning of the wordlist is less than *X/N*, where *X* is the number of steps required for a sequential approach to find the word.

IV. ALGORITHMIC SOLUTION

When comparing stochastic and sequential approaches on hash cracking, two different metrics were observed. In the first case, we assumed that the time difference between random and sequential search can be negligible due to its insignificance compared to time consumption of hashing iterations. Therefore, only plaintext words are compared. As measure of efficiency an average number of iterations needed to found the correct word is used. In the second case, experiment was conducted with included MD5 hashing with 30 hash iterations. The metrics was an average time needed to found the correct value. The solutions were developed under C++ language and a pseudo code can be seen in Algorithm 1.

A publicly available wordlist is taken and loaded into RAM as a dynamic array of strings (variable *str* in Algorithm 1) where each element is one word (one line

Algorithm 1 WordSearch (wordlist, test_case)

```
str ← wordlist
major_counter ← 0
for i ← 0 to 10000 do
        x ← rand() mod(test_case)
        answer ← hash(str[x])
        for j ← 1 to N do
                hit ← hash(str[j])
                if (answer = hit) break
        for k ← 1 to N do
                temp ← rand() mod(N)
                hit ← hash(temp)
                if(answer = hit) break
                _temp ← str[k]
                str[k] ← str[temp]
                str[temp] ← _temp
        major_counter ← (j - k) + major_counter
        return (major_counter/10000)
```

from the list). The program allocated 230 MB of RAM to hold 6 million words. The first problem encountered was a limit of *C++ rand()* function that even after some redefinition of constants in libraries, could not return a value larger than 0x7FFF or 32767_{10}. Therefore, problem solution was designed in the way that every digit is randomized individually with values 0 – 9. Consequently, a 7-digit number can be generated with certainty that no values are missed. The next problem was redundancy of random values but a solution to this problem is proposed in [9]. With implementation of these lines all obstacles were removed, and a solution was ready to be coded. For a sequential solution, *for* loop that checks elements in a sorted wordlist from index 1 to *N* was used. When the searched word is found, the overall number of *for* loop iterations is assigned to the corresponding counter in the case when metrics is an average number of iterations. In the case when metrics is time, the duration of each execution was measured. A stochastic solution basically also runs in the *for* loop that goes from 1 to *N*, but this time the current state of iteration is not used to check elements, rather the index for checking is randomized, as shown in Algorithm 1. After the element is checked, it is swapped with the element indexed by the current iteration of the *for* iteration, and therefore this value could be checked only once. After the element is found, the overall number of *for* iterations is assigned to the corresponding counter or the duration of each execution was measured. At the end, a *major_counter* is calculated as a difference between the overall number of sequential iterations and the overall number of random iterations needed to find the searched word. This whole procedure is repeated for 10,000 times in order to obtain greater precision in measurement. The average value of *major_counter* is used in comparison of the sequential and the stochastic process in the case when metrics is the average number of iterations. In the case when metrics is time, the difference of the average execution duration for the stochastic and sequential approaches is used in the comparison.

The search process comprises nine test cases. In the first, searched word is located in the first 1/5 of the wordlist. In the next test case, the word is located in the first 2/5 of the wordlist, and so on. In the last test case the searched word is located in the last 1/5 of the whole wordlist. Table I shows locations of the searched word for all nine test cases.

Ranges in Table I have been selected in order to show the relation of the position of the searched word in the wordlist to the difference of steps taken by each process or in the time domain for the comparing the time needed to find the searched value. Since the wordlist is sorted, it can be assumed that when the searched word is near the beginning of the wordlist, sequential search will be faster. In contrast to this, randomized search should show increasingly better performance than sequential if the searched word is located at the end of the wordlist.

TABLE I. RANGES OF PICKED WORDS

Test case	Parts of wordlist taken for selection				
1	1/5	1/5	1/5	1/5	1/5
2	1/5	1/5	1/5	1/5	1/5
3	1/5	1/5	1/5	1/5	1/5
4	1/5	1/5	1/5	1/5	1/5
5	1/5	1/5	1/5	1/5	1/5
6	1/5	1/5	1/5	1/5	1/5
7	1/5	1/5	1/5	1/5	1/5
8	1/5	1/5	1/5	1/5	1/5
9	1/5	1/5	1/5	1/5	1/5

V. EXPERIMENTAL RESULTS

Five sizes of wordlists have been used for the testing purposes, containing:

- 0.3×10^6 words
- 0.6×10^6 words
- 1×10^6 words
- 3×10^6 words
- 6×10^6 words

For each size of the wordlist there were nine test cases. Therefore, in each of 10,000 iterations of a certain test case a word the program is searching for is located in the particular range of the current wordlist. Still, the scope of both sequential and stochastic search is the whole wordlist.

In Fig. 1, results of comparing an average number of iterations in all five sizes of wordlists are shown. On the *X* axis there are test cases from 1 to 9, and on the *Y* axis an average value of *major_counter* is shown. Considering *major_counter* showing an average difference of the number of iterations needed for the sequential search and the number of iterations needed for the stochastic search, it can be seen when the stochastic process outperforms the sequential one and vice versa. The value of *major_counter* in the first four test cases for all five wordlists indicates that if the searched word is located in the first 4/5 of wordlist, the sequential process finds the searched word in less iterations than the stochastic process does. The sequential process has the best results in all five test cases in comparison with when the word is located in the first 1/5 of the wordlist. In the first test case with 0.3 x 10^6 words, the sequential process has 41.20% better search results while in the biggest wordlist with 6 x 10^6 words search results are 37.71% better. In the test case 5, when the domain is the whole wordlist, both sequential and stochastic processes have almost equal results. This means that if we do not know in which part of the wordlist the searched word is located, the average number of iterations needed to find the searched word is nearly the same for both processes. In test cases 6, 7, 8 and 9 it can been seen that if the searched word is located in the last 4/5 of the wordlist, the stochastic process shows better results. If the searched word is not located only in the first 1/5 of the wordlist (test case 6), the stochastic process already shows 5.24% better results in 0.6 x 10^6 words big wordlist to 13.12% in the wordlist with 6 x 10^6 words. In test case 9 when the word is located in the last fifth of the wordlist, the stochastic process shows around 40% better results in the wordlist with 0.3 x 10^6, 3 x 10^6 and 6 x 10^6 words, 30.53% for 1 x 10^6 words and 22.65% for a 0.6 x 10^6 words big wordlist. From this we can conclude that our hypothesis of the stochastic process outperforming the sequential one when the searched word is not located at the beginning of the wordlist is valid.

Fig. 1 f) shows experimental results for all five sizes of the wordlist. The difference in gradients is due to the size of the wordlists. From this line graph we can conclude that experimental results for all sizes of wordlists show almost linear distribution through test cases. For bigger wordlist sizes, the number of iterations of the sequential process increases with the wordlist size and it is much greater than the number of stochastic iterations if the searched word is located at the end of the wordlist. From this we can conclude that for large wordlists a significant increase in performance could be obtained with the stochastic process if the searched word is closer to the end of the wordlist. In test case 9 of the largest tested wordlist, the stochastic process is faster for an average of over 2 million steps or 39.35%.

Due to the long execution time, in the time domain experiment only wordlist with 1 x 10^6 words was used. As shown in Fig. 2 and similar as in Fig. 1, sequential

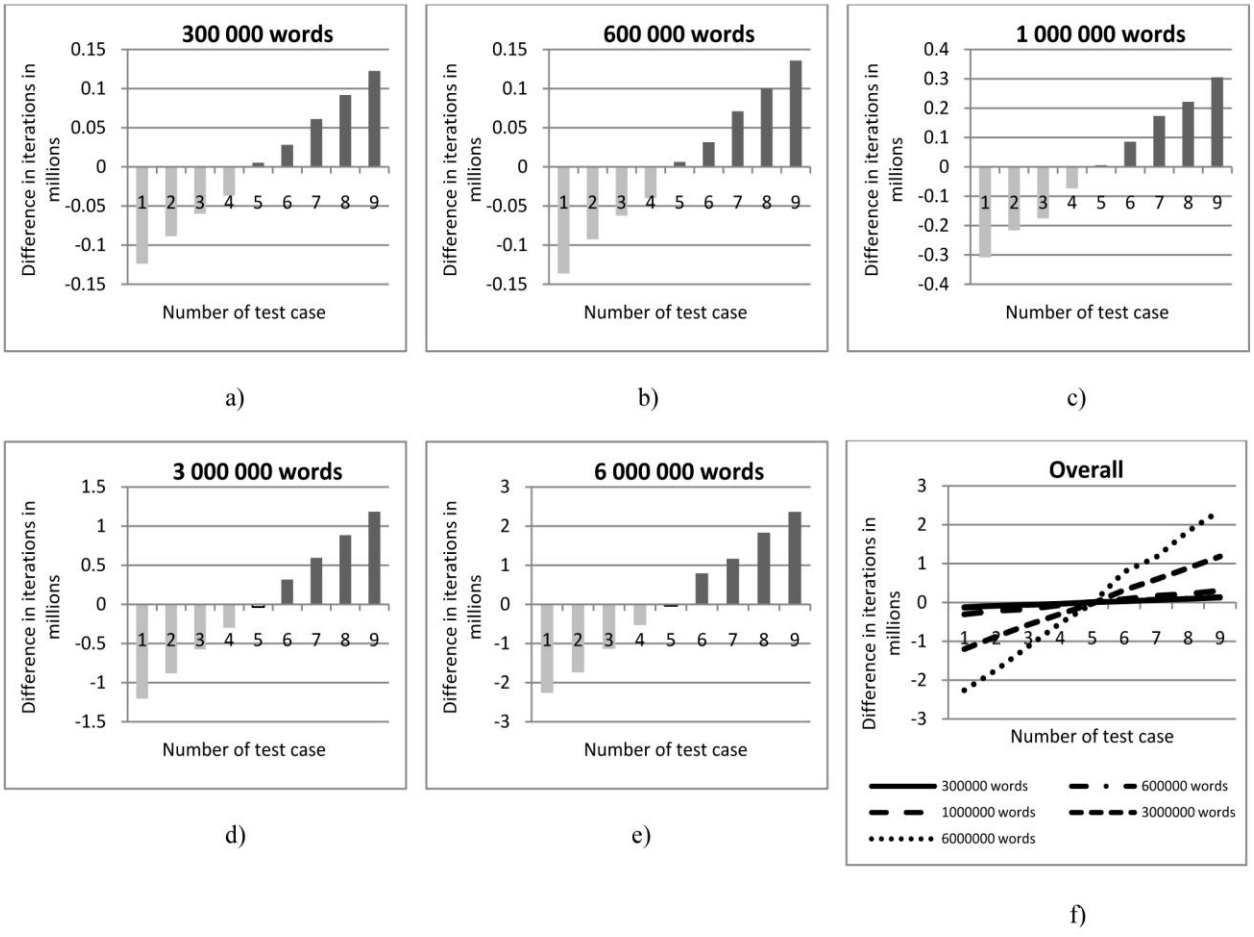

Figure 1. a) - e) Major_counter values for different wordlists sizes through cases. f) Overall results of testing.

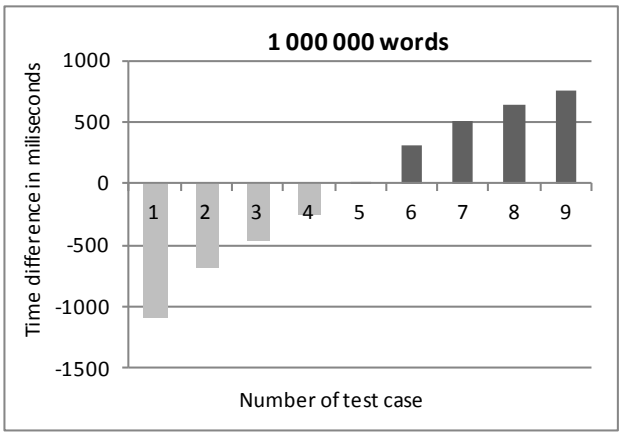

Figure 2. Comparison in the time domain

approach shows better results in the first four test cases. In the test case 5 results are almost similar. When the searched word is located in the second half of the wordlist, stochastic approach shows shorter average time needed to find the corrected value with included MD5 hashing. These results confirm the hypothesis that due to the long duration of hashing iterations, sequential and stochastic approach lasts nearly the same in every execution.

It can be concluded that a stochastic approach outperforms the sequential one in cases when the searched word is located in the second half of the wordlist. However, since the most users (attackers) do not know in which part of the wordlist the searched word is located, the stochastic approach does not guarantee a lower number of iterations than the sequential approach.

VI. CONCLUSION

Dictionary attack is one of techniques used in hash cracking. An attack is performed by selecting words from a dictionary and comparing their hashed value to the obtained value. As the dictionary is sorted, the word selecting is done sequentially and if the desirable passphrase is located at the end of the dictionary, worst case running time is often very long.

This paper shows that randomization can be desirable in some search cases. Experimental results show that when the searched word is placed in the second half of the wordlist stochastic search needs fewer steps to find it and therefore, it decreases the search time. This difference of steps taken, increases as the size of the wordlist increases. On a regular basis, stochastic search is not better or faster – it is as fast as the sequential one on a large pattern. This paper gives another point of view on the problem of an offline dictionary attack, and another type of an approach to performing it. This solution could be implemented in any search method with linear time complexity such as simple array searches, string matching algorithms [10] or rainbow cracking techniques.

Abstract - In this paper it is presented one approach for creating testing environment of devices based on touch screens. Focused subject is testing of Android based devices, precisely required software to perform it. Android application has been developed that detects touches on screen, then packs them in formatted messages and sends them to central point where they are interpreted. Beside this paper proposes model of complete testing environment that would proved fast, inexpensive automated solution for verification of touch screen devices. Base for this paper is previous research done on stimulation boards that provide fast and controlled way of simulation touch events based on electric capabilities of capacitive touch screen. Implemented environment has been tested using commercial Android mobile phone to confirm software functionality and to analyze behavior of stimulation boards.

I. INTRODUCTION

In last two decades portability of devices has significantly improved. Devices that presented great testing platform for improvements were mobile phones. Higher independency thanks to better battery technology and efficient power consummation made possible for people to relay more on portable devices. Following this portable devices become more powerful pieces of hardware that enabled developing and running complex software structures on them (operating systems and wide choice of applications), in other words they become "smart". These days we are experiencing enormous expansion of smart-device (smart phones, PDAs (Person Digital Assistants), tablets, e-book readers, media players etc.). Beside newly available features provided by software components, one of the important features that is becoming inevitable is how this devices interact with user. Old-fashion button oriented device control is being replaced by touch-screens. Market research show that number of mobile phones with touch-screen capabilities has grown from 3% in 2008 to 23% in 2010 with predictions that by 2014 half of mobile phones will be based on touch-screen technology [1]. Even studies that were preformed on early touch screen devices showed that users work faster and with acceptable precision using touch-screen interface comparing to mouse [2]. With more and more devices relaying on use of touch-screen to interact with user new models for GUI (Graphical User Interface) of application need to be investigated. Many studies are preformed to analyze what are the best ways to design UI of application to be more attractive, one of those studies is performed by Balagtas-Fernandez and offered as example [3].

As number of produced devices rapidly increases, demand for faster production of equally (or even more) reliable products is also rising. Main foundation for solid product, beside good production process, is quality verification system. Verification systems are mainly separated in two major groups: manual and automated. Dustin, in his book, [4] points out that testing process should not completely relay on automated testing, although manual testing is labor-intensive and error prone it should not be completely avoided during testing. He presents one case study that compared automated testing performance to manual testing and significant improvements in speed are concluded [4]. Another example of automated testing implementation is given in [5] demonstrating how speed of verification increased by factor of 5, comparing to manual testing previously preformed. This project has been mainly driven by previous work in the field of black box testing and automated verification systems for TV. Proposed system is based on solution already described in [6], with purpose to verify of television sets[6]. Goal of presented system would be to finally become an integrated part of complex testing environment presented in [5] and [7].

In today's production environments testing and verification of touch-screens is based on mechanical stimulation making this systems large and limited in speed [8]. There are two touch-screen technologies widely used in modern devices: capacitive and resistant. Capacitive displays are integrated in proximally 50% of produces touch-screen devices. This paper is based on research done in [8] demonstrating alternative method of stimulating touch-screen displays using electrical stimulation instead of mechanical. Since it is based on electrical stimulation used solution is limited only to capacitive-based devices.

This papers main goal is to present component of proposed system for automated testing that has main purpose to verify touch-screen responsiveness to stimulation. We will attempt to point out main advantages, but also limitations of presented environment. In following section system components developed as part of earlier studies are presented and how they interact with newly developed modules. Section III describes in details Android data collection application, targeted PC application and communication between them. Section IV presents some measurement results perform on system. In Section V we describe model of final testing environment that will be based on results from this paper and previous ones.

This work was supported in part by the Ministry of Education and Science of the Republic of Serbia under the project No. 32030

II. SYSTEM OVERVIEW

Implemented system for this paper consisted of 4 components:

- Touch source (stimulation board or real finger)
- Android phone with touch-screen
- Android application for touch-detection
- PC server for data acquisition

Further sub sections describe system components in details. On Figure 1. is diagram describing system environment. First goal of this system of would be to confirm functionally of stimulation board using commercial devices tested and verified (smart-phones and tablets). Another purpose of this work is to became base for more complex verification environment for touch-screen devices.

A. *Stimulation board*

Reference [8] describes in detail how stimulation board is implemented and physical effects that is based on. In short it is based on introducing the grounded conductor in capacitive touch-screen sensor environment. Two methods are proposed (one using a MOSFET and other using orthogonal conductive lines) and benefits and flaws of each approach are described in [8] . But witch ever approach is used it would be controlled by Field Programmable Gate Array (FPGA) and same API would be used for control of stimulation board.

B. *Android application*

For purpose of detecting touch-screen events software component on tested device needed to be implemented. Approach was taken to relay on present system APIs available on device. Reason for this is that we wanted to detect only events that are actually reported by system. Actual events on touch-screens are filtered and processed by device vendor driver and general system driver and then presented as system recognized touch events. Android-based device was selected because of two important reasons, first one being that, according to research [9], at end of 2011 43,7 % of smart-phone

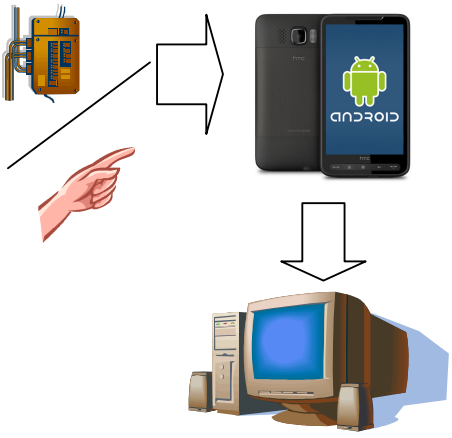

Figure 1. System components

devices are running Android operating system and second reason is existence of good development environment for Android applications. Task of implemented Android application is to collect touch events detected by system and to report these events to server. In current implementation communication between phone and acquisition server is preformed over TCP network, using set of predefined messages. Communication between phone and server is in detail described in next section. Application is developed to support multi-touch events. Android system can detect up to 4 simultaneous touch events. Beside touch coordinates some Android devices can provide information about amount of pressure applied by user (this information is calculate by area cover by finger, not actually by pressure measuring) , so this data is also presorted to server.

For development of Android application Java programming language is used in Eclipse IDE (Integrated Development Environment) with Android SDK (System Development Kit). Targeted version of Android operating system is version 2.2.1 and higher, this version is chosen because it is firs version optimized for tablets.

C. *Data acquisition server*

This software component is running on Windows-based PC. Currently implementation represents simple data acquisition and logging server. It is accepting connection form device, collects messages from phone and logs them into the file. This version is very basic and covering only essential functionalities need to verify communication workflow between servers and phone. Further development is currently in progress, and server functionality is growing in complexity. Idea is that, beside data acquisition and logging, server also performs display of events in graphical environment more acceptable to users. Server code was developed in C++ code using Microsoft Visual Studio 2008.

III. IMPLEMENTATION

A. *Software modules*

Two applications were implemented for this paper: collection application (mobile client) and acquisition application (server). Significant attention was focused on development of Android application with imperative to process touch events coming from system efficiently. Android application is split in two independent modules:

- *MultiTouchSensor* – task of this module is to collect touch events from system
- *CoordianteSender* – task of this module is to deliver collected data to server application

Since network related tasks (connection establishment, sending etc.) are not very time efficient touch detection and sending operation needed to be separated by these two modules. To provide communication between these two modules shared double-ended queue.

MultiTouchSensor module is optimizes to process received events as fast as possible and passes them to queue, from where events are received by *CoordianteSender*, packed into the protocol messages and sent to acquisition server. Communication sequence between modules is given on Figure 2. Android operating system detects 3 different types of events:

- ACTION_DOWN – when user pressed the screen
- ACTION_UP – when user lifts finger from screen
- ACTION_MOVE – when user moves finger on the screen

These events are converted into protocol messages and sent to server side for analysis. Android system has specific behavior when ACTION_MOVE event occurs to continue reporting coordinates of finger event even when there is no movement. Reported coordinates are presented in pixels according to device screen resolution. To prevent overloading communication with server these events are filtered so only move events that have change in position coordinates are sent to server. Algorithm for event filtering can be exhibited on Figure 3.

B. Communication protocl

Application and server are exchanging set of defined messages that provide enough information to server so it could track events on device. Three types of messages have been defined: for touch start, for touch end and for movement.

Message for beginning of touch is carrying information about touch index (ordinal number), coordinates of touch and pressure information. Keyword *TBegin* is used to identify these messages. Expression below demonstrates format of this message:

TBegin 2 179.23753 196.91711 0.21176472

Message describing end of touch event is defined with keyword *TEnd* . This message has two parameters: index of ended touch and number of remaining touches. Example of message where second finger is raised from

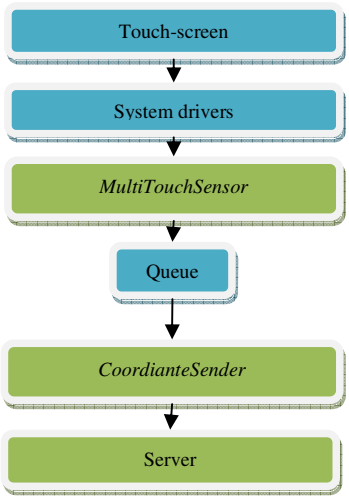

Figure 2. Software module interaction

screen and one more finger left touching screen is given:

TEnd 2 1

Most complex message type is that describing movements. This message is sent when ever movement of fingers is preformed on screen. Data that is part of these messages is in order: number of active touches, x coordinate of first touch 1, y coordinate of first touch, pressure of first touch one, x coordinate of second touch, y coordinate of second touch, pressure of second touch etc. As mentioned before maximal number of simultaneous touches is 4 on Android devices. Message reporting movement doesn't actually consist of information witch finger did move. This task has been given over to server side to determine. This was done to minimize implemented logic on device side and minimize processing on sender side. Example of movement message when 3 fingers are on screen:

TMove 3 349.56012 482.9275 0.21176472 175.48387 271.5285 0.28235295 106.04105 577.43524 0.18823531

All this messages are sent as arrays of characters using standard TCP (Transmission Control Protocol) connection between server and Android application.

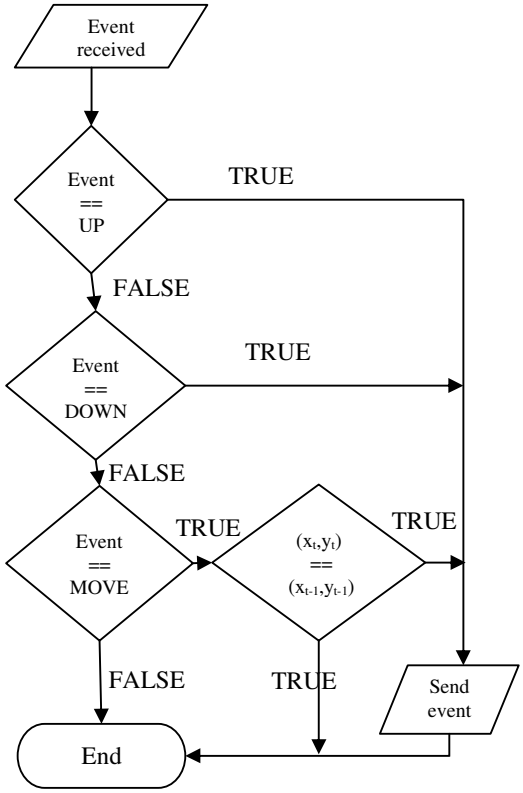

Figure 3. Flowchart of event filter

IV. PREFORMANCE ANALYSIS

In this section we will state some performance results measured on current implementation. For measuring HTC Desire S mobile phone was used, connected to wireless network, and PC running server, also connected on wireless network. Purpose of test is to observe how fast can server receive and process events. Information that we also acquired is ratio of event detected by device. Average data for different number of simulations touches are available in TABLE I. , beside simple tests with multiple touches on screen, one special test was

preformed with 4 simultaneous touches active and, early mentioned, filtering algorithm for events removed to simulate maxima activity in system. From measured data we can see that using this communication environment we are not able to perform in real-time. This is not a blocking issue since analysis of data doesn't need to be performed in real-time, what is important is that order of reported messages is kept do provide us with correct history of event occurrences. Major reason for delay in communication is usage of TCP protocol and wireless network, since it is not always the best solution for real-time communication.

TABLE I. AVERAGE NUMBER OF EVENTS PRODUCED BY DEVICE AND RECEIVED BY SERVER IN 30 SECONDS

	Event generated by device	Event received by server
1 touche	660	278
2 touches	1047	540
3 touches	1759	1208
4 touches(no filter)	3967	2674

Testing with actual stimulation board has been preformed, but the board didn't provide stabile enough behavior to perform more detailed analysis. Board was able to stimulate screen successfully but there was also some false detections of touch events when there is no activity from the boards. Since this research is still on-going we can expect more detailed results, more information about board performance can be found in [8].

V. FINAL VERIFICATION SYSTEM MODEL

This chapter will describe model of verification system that we propose. System relays on work presented in this paper and previous ones. Main idea is to create closed system that will on one side control stimulation board and create activity on touch-screen and on the other side collects data reported by system on tested device. After data is collected it can be analyzed against preformed input and conclusion regarding device/touch-screen functionality can be made. Proposed system can easily be integrated in environment for serial production to provide fast and verification of products. On Figure 4. model of proposed system and its component can be observed.

VI. CONLUSION

In the end we can say that in scope of this paper developed components are explained and theirs functionality is confirmed. Some performance analyses have been executed to demonstrate how system is performing. From this data we concluded that TCP protocol and wireless network are not best solution to achieve communication between device and data acquisition server. Work in this paper provided essential information need to confirm usability of proposed system

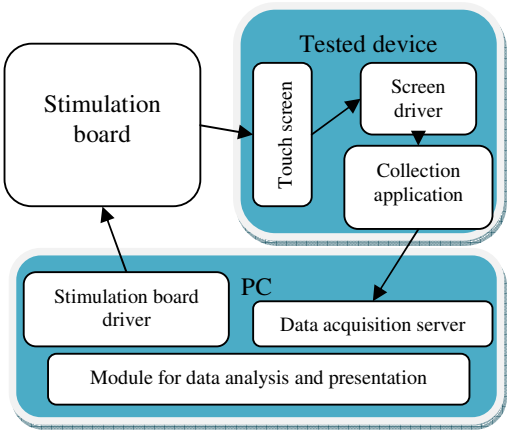

Figure 4. Proposed system model

and provided good foundation for continuance of work. Future development will mainly depend on results of stimulation board research, if results prove to be acceptable further work will focuse on implementation of missing component of proposed system, manly on PC server application. Drivers and API for stimulation board will be implemented and appropriate GUI will be developed to enable creation of test scenarios and analyze result of preformed results. For improvement in communication USB connection between device and server is considered as alternative that could provide efficient data transfer.

Abstract - Many mainly chronic healthcare conditions affect human mobility and locomotion. Measurement and observation of this kind of capabilities can be impacted by subjective feelings of the clinicians. In the end, the results obtained may become inaccurate and inconsistent. This paper shows how information technology based on 3D human body motion tracking detection capability can help to provide a better and more appropriate assessment method. Moreover, the measurement results can be directly stored into the database system for future comparisons with new measurement data. In this way the clinician can easily document and observe how the treatment affects the patient as well as the progression of patient's recovery.

I. INTRODUCTION

It is very often that measurement of human locomotion can provide deeper support to clinical observation and thus indirectly influence clinician's decision. There is a number of modern, commercially available, computerized (semi) automatized measurement systems enabling efficient and highly accurate quantitation of movement, and thus contributing to clinical evaluation and diagnostics of various movement patterns, the most basic among them being human gait. In spite of this, it is fair to say that current state-of-the-art in the field still lacks a complete standardization, as thoroughly elaborated for instance in [1] and [2]. This paper shows a new approach to provide easier and more accurate human locomotion properties analysis that can provide helpful information for diagnostics and treatment of the disease. The purpose of the system is to bring new image and signal interpretation tools to clinicians.

Some chronic diseases heavily impact the behavior of human body locomotion by e.g. altering the amplitude or slowing down the reaction time of the limb movements. Parkinson's disease and Ankylosing spondylitis (AS) for instance may be given as examples. The most obvious symptoms for Parkinson's disease are motor-related, including tremor, rigidity, slowness of movement, and postural instability. When AS is considered, one of the components related to the AS assessment includes measurements of Bath Ankylosing Spondylitis Metrology Index (BASMI, for range of movement). BASMI requires clinicians to use various types of measuring devices (like tape measures, rulers, or some special measuring equipment) to obtain "objective" measures [8]. In some other applications, electrogoniometry is used, where angles between body segments are measured. The implementation of such measurement system uses mechano-electrical transducers or rotational potentiometers. Considering some requirements of such solutions, like constant voltage to the fixed connections on the body and certain invasiveness, the configuration of such systems is not an easy task [1]. Opposite to that, the non-invasive solution explained here does not require any connection to the human and does not influence human or his locomotion in any way. The detailed data acquisition is done by collecting and extracting it from the vision subsystem.

II. METHODS AND EQUIPMENT

The objective is to determine approximation of mechanical human body model composed of segments interconnected by joints. Further step should be a calculation of movement properties based on the virtual body model acquired digitally through measurement process. Currently available concept analyzes the application of the natural interaction technology as a tool for body motion tracking implementation.

A. Natural Interaction Concept

Natural interaction can be expressed as a term of experience, the way to communicate between humans. The key assumption here is that people interact with technology as they do in a real life, through gestures, movements, expressions etc. Therefore, the natural interaction is following and expanding the traditional ways of interacting with computers only through the mouse pointers and keyboard strokes but instead enables direct manipulation of the objects involved in interaction. Additionally these modalities of interfaces are easily understood by the spectators which enable social interaction experiences [10].

The term Natural Interaction (NI) refers to a concept where human-device interaction is based on human senses, mostly focused to hearing and vision. The portion of the NI usage which is of interest in this paper includes

Body Motion Tracking feature, where full body motion is tracked, analyzed and interpreted.

Built on the available open source standard, one of the most appropriate technology is "OpenNI" (Open Natural Interaction). It is a multi-language, cross-platform framework that defines interfaces for utilization of Natural Interaction. The main purpose of OpenNI is to form a standard that enables communication with both vision and audio sensors together with vision and audio perception middleware. The latter are the software components that analyze audio and visual data recorded from the scene, and comprehend it. It is therefore possible to write algorithms on the top of raw data formats based on the track of real-life (3D) scenes by utilizing data types that are calculated from the input of a sensor-like representation of a full body.

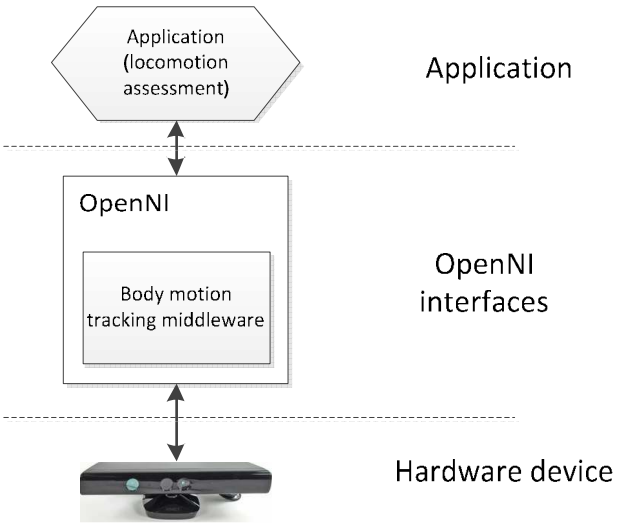

Figure 1. Three layers of the natural interaction analysis solution.

As visible in Figure 1, the solution is separating the communication entities into three layers in this process. At the input device level we can position hardware for capturing visual scene. In the core of a second element we find the body motion tracking middleware which is wrapped with OpenNI implementation of the communication interfaces. These interfaces implement an interaction between sensor and middleware components. Finally, at the application level, natural interaction software implementation is used to process and store retrieved data and properties and presents the results to the user of the analysis system (e. g. clinician).

B. Sensoring Device

The body tracking has becoming more and more popular due to its applicability to many areas, like virtual reality, computer gaming, biostatistics etc. The roots can be found within motion capturing research. It begun in the late 1970's with the rotoscoping method when Disney studios traced animation over film footage of live actors playing out the scenes. In the early '80s biomechanics laboratories started to use computers for human motion analysis, and the exoskeleton was build based on the digitalized output of the potentiometers fixed along the joints on human body. Around the same time the experiments were made with the optical tracking of the human body. They used small markers attached to the body and series of two or more cameras whose outputs were combined to calculate three dimensional position of each marker through time [11].

The modern initiative here is considering the vision techniques implemented with the cameras as a way to analyze the natural interaction expressions made by observed human. The reliable cameras used for this approach should be sensitive only to the near infrared spectrum illuminating the environment without interfering the human's behavior in any way [10].

Released recently, new motion controller for Microsoft's Xbox 360, named "Kinect" (from "kinetic" and "connect"), uses an array of cameras and microphones promising a new level of natural interactivity. Its use of infrared readings to put together a surprisingly accurate and responsive 3-D model of the scene and especially human body determination is incomparable to the previous camera-based controllers. Kinect's optical setup is what allows it to track the movements in real time. It is made of two main parts: a projector and an IR (infrared) VGA camera. The former bounces out a laser across the entire field of visibility, which is then picked up by the camera to separate human from other obstacles on what's called a 'depth field'. The recorded image is processed through a host of filters so that Kinect can recognize persons and other objects. Major advantage of this device is its ability to convert body part identification into a skeleton with moving joints, by specialized embedded algorithms for these purposes. The system does all this continuously at 30 fps (frames per second). Developed originally as a controller for gaming purposes it soon has been identified as a serious device for many other applications, extending the NI experiences and lowering the costs of usage of other devices with similar purposes. Just for a comparison, there are professional devices or labs which could benefit by more improved accuracy and sampling rates. For instance such labs are achieving the measurement up to millimeters accuracy where sampling rate for 3D kinematic measurement is extended up to 100 fps.

Kinect controller used for objective of this paper is to provide a simpler and cheaper device that can be widely used by providing the enough measurement quality that can be used for the purpose of patient kinematic measuring. This is also confirmation of a radical development in human-computer interaction, from green screen, mouse and keyboard, touch and multitouch to "no-touch" interaction [12].

C. Model

The usual approach when examining the patient's locomotion by clinicians is to make subjective observation and, as proposed in this paper, to invoke the sensoring device to support and expand the observation capabilities and to perform the patient data recordings. The implementation of the model presented here should extend the old approach when measuring was performed only by manual measurements. Possible process that could be considered is presented in the figure 2.

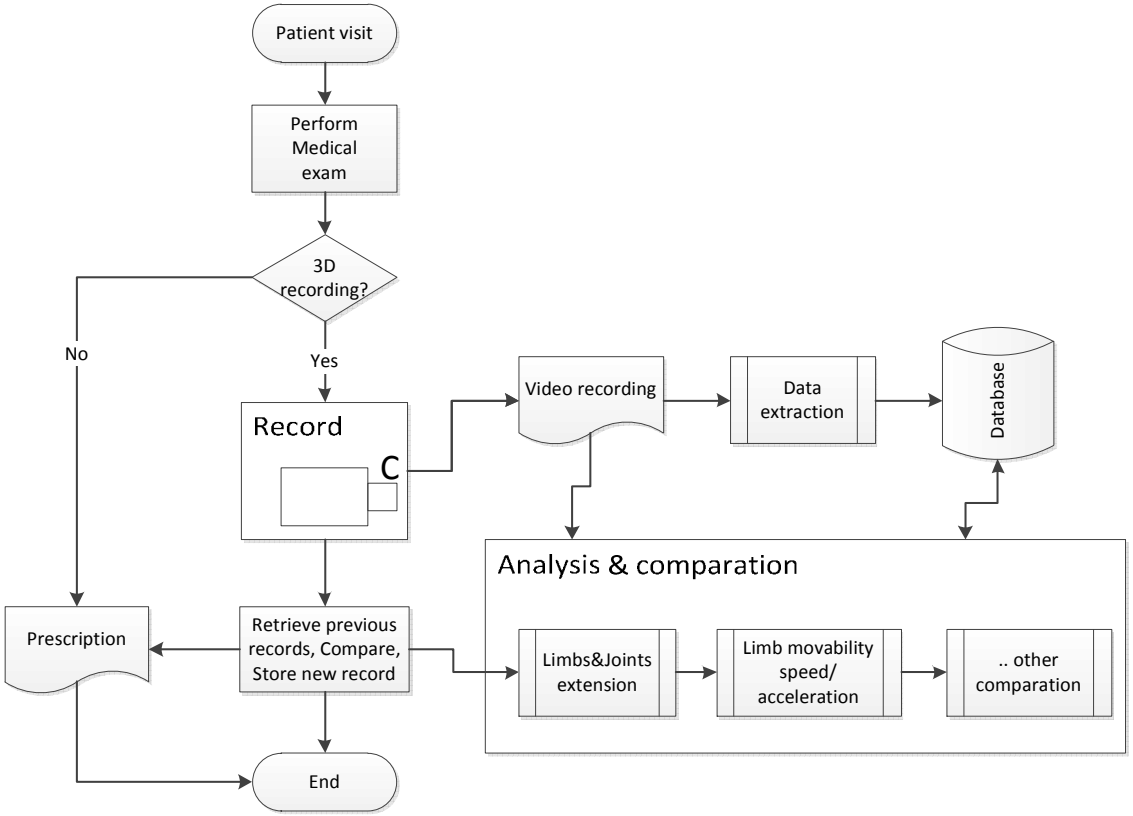

Figure 2. Locomotion analysis as optional procedure during medical examination.

The scenario of the patient behavior and movement task execution during the recording session should be predefined and responsive to the activities affected by disease or treatment. Clinician performs the medical examination of the patient and decides weather or not the 3D recording should be taken. In case it should be executed, the recording is to be made responding the predefined scenario, like e.g. "reach the floor with hands as fast as you can". The recording is stored to file system document and, based on it, the data are to be extracted by direct invocation of OpenNI middleware component and stored in specific data format to the database. This enables graphical representation and comparison of the current and previous data, if they exist.

Graphical presentations include the playback of the movement, i.e. processing of the stored video record. In addition to the playback, the database is read to present interesting extracted points on the same screen. Further analysis could include direct presentation and comparison of those points at the same screen and same time which, in the end effect, could be processed by software component to execute calculation of important values (quantities). Some interesting values are e.g. distances between the joins, representing the limb reachability change or the speed/acceleration of the specific movement. Depending on the size of the values that are changed, the progression of the patient condition is evaluated. By applying this approach, in principle, more objective assessment about treatment influence to the patient's health could be gained.

III. RESULTS

Comprehendible, understandable 3D to 2D data transformation that actually translates the scene is needed. The sensor itself provides the raw output data, usually represented as a depth map, where each pixel is represented by its distance from the vision part of the sensor.

As a next processing step, it is possible to use middleware to process this raw output, and produce a higher-level output, which can be understood and used by the applications. It is possible to identify human figure within the scenes determining the current location and orientation of the joints of this figure. The capabilities which are of the interest in supporting patient healthcare assessment are outputs of the skeletal data of the patient. This data includes the locations of the skeletal joints and tracking of the skeleton positions. One possibility of the processed screen may look like presented in the figure 3.

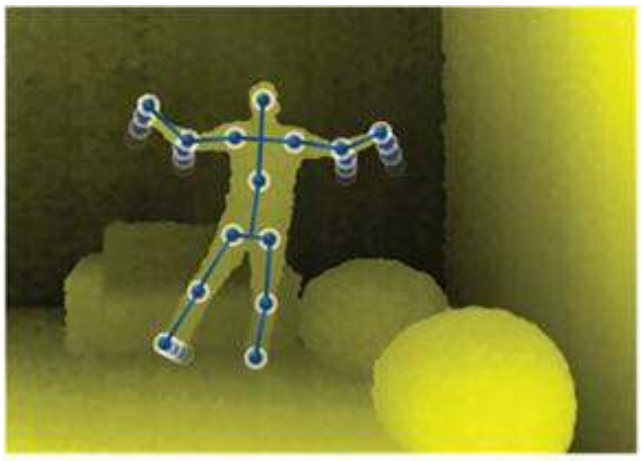

Figure 3. The skeleton'sjoint points and limbs extracted in one recording session [3].

The application of the natural interaction sensor is considered to be configured in a controlled environment with the fixed positions of the sensoring device. Based on the capability of computing system to calculate the perspective of the extracted scenes, it is also possible to allow some minor differentiations of the analyzed data, so it should be possible that recordings which are taken in completely different environments are also comparable. The sensor itself belongs to non invasive sensor family that do not disturb patient in any way. Based on the capabilities, some additional applications of such system could be seen in a gait analysis where the observed human is examined during walking/running task execution on a treadmill. It is necessary just to provide constant power supply to the system, therefore system is not limited to time window of the measuring or to permanent storage of the recordings and extracted data. This is not the case when other battery powered acceleration sensors are used for similar purposes [4].

IV. CONLUSION

Information systems and technology are becoming the heart of the efforts to improve delivery of the care in the most effective and efficient way [9]. There has been some change where to address the IT capabilities and by considering it together with a model of ubiquitous computing we can recognize the aspect of switching from just "IT" to "assistive technology". Therefore, sensor-enhanced healthcare can take a major role in extending quality and efficiency of care by providing more accurate specific analysis and securing objectiveness in e.g. the assessment phase of medical treatment. The appliances of the natural interaction sensor are becoming a very helpful tool, especially in the area of virtualizing human body locomotion from which there is a possibility to extract and process data in order to find the interesting locomotion pattern changes.

As the applications of NI sensors and human body tracking is receiving increasing attention in recent years it is also expected that tracking algorithms should evolve providing higher accuracy and lowering computational costs at the same time. One of such improved approach is progressive particle filter [13]. Until there will be some changes implemented within the device's and framework software some additional improvements for solution in this paper could be seen in many ways.

For example, what will happen if the environment where the sensor is positioned is changed by some other influences, like room switching? In order the old data to be used in changed surroundings the extraction of the data should not depend on the position or distance between the patient and NI sensor. Therefore the perspective extraction can be observed providing the "general", not-influenced data. This is already achievable when measuring the speed of the patient's movement as there is minimal influence to the exact starting and ending points of the movement, but instead, the time between starting and ending exo-skeleton position is measured. When using general, non perspective dependent, extracted data the can be applied to the exact positioning and movability of the joints too, which makes system not influenced by its relocation. This way the solution is securing usable stored data even if the physician's room is e.g. completely changed.

The other improvement is already being experimented. It goes into direction of remote application so that the patient does not need to physically appear at the examination lab but instead the NI sensor can be installed at the patient's house allowing (with minor educations) the easy usage of the examination tool and extending it by directly connecting the evaluation session to the physician's office through internet communication channels. This additionally enables daily usage of the solution which can benefit in almost promptly detection of serious disease conditions, which can be extended by triggering condition to the physician's or hospital offices, so reaction time can be faster resulting in providing care exactly where and when it is needed.

Abstract **- A wireless sensor network (WSN) consists of spatially distributed autonomous sensors to *monitor* physical or environmental conditions, such as temperature, sound, vibration, pressure, motion or pollutants and to cooperatively pass their data through the network to a main location. The more modern WSNs are bi-directional, also enabling *control* of sensor activity. The development of WSNs was motivated by military applications such as battlefield surveillance; today such networks are used in many industrial and consumer applications, such as industrial process monitoring and control, machine health monitoring, and so on. The possibilities for WSNs have excited scientists and researchers, the business community, military and government officials, and consumers alike for many years. The potential applications for WSNs and transducers (sensors combined with actuator mechanisms) are limited only by the imagination. Sensing alone is not enough for many applications—the ability to act on the sensory data is also required. A small, battery-powered platform capable of actuation is needed. This paper discusses the experiences with the implementation of WSN in bringing new content to museum visitors, making the visit more interesting and thus, attracting more visitors. Visit to a museum will become a much more interesting and fun. On the other hand, exhibits in the museum would be under better control and a lot safer. Every smallest change in temperature and light in the exhibit's surroundings or movement of exhibit piece would be automatically detected.**

I. INTRODUCTION

The paper describes two software packages (SW): security SW – which uses sensor abilities to monitor exhibit surroundings, and visitor's SW – which communicates with exhibit sensors and identifies them. Each exhibit piece is equipped with a wireless device, which continuously broadcasts its address for visitor's SW to pick up and on regular time cycle broadcast sensor readings for security SW. Each visitor would receive PDA type of device, which would after identifying the exhibit, display content for it. The content could be text, audio, video or images, depending on the exhibit. Visitor SW also displays current position on the museum map. Map can be used to guide the visitor through the museum, either by standard guide tours or by choice, if visitor wishes to see certain exhibit. Exhibit sensors monitor light, temperature and acceleration. This information is broadcasted after fixed period of time (if every reading is within given range) or immediately, if some of the readings go over a given threshold. Security officer is presented with the map of the museum, where every exhibit is displayed with light, temperature and acceleration readings (which translates into position of the exhibit).

II. SPECIFICATIONS OF USED SENSORS

For implementation of this idea, SunSPOTs were used. They were readily available solution, which is easy to obtain and it consists of everything that is needed for this kind of application – it's programmable, battery powered, with integrated two-way radio and all the sensors that were needed.

The Sun SPOT development kit, contains two different configurations:

Basestation SPOT - The basestation has an eSPOT main board without a battery or an application board. Power is supplied by a USB connection to a host workstation. The basestation serves as a radio gateway between other Sun SPOTs (and theoretically other 802.15.4 devices) and the host workstation.

Free Range SPOT - This unit contains the main board with a rechargeable LI-ION prismatic battery and an example of an eSPOT daughterboard, the eDEMO board.

The eSPOT main board is host to a 32bit 400MHz ARM9 processor running a Java VM, 2.4GHz network radio transceiver and power management circuitry. The ARM9 processor core voltage is 1V and I/O voltage is 3V. It has 64K internal ROM which is not used and two internal 16K SRAM that are used. Peripherals actively used are USB 2.0 device, dual USART, three timer/counters, dual SPI interface, TWI (I2C) interface, JTAG TAP controller and external bus interface (EBI). The wireless network communications uses an integrated radio transceiver, the TI CC2420 that is IEEE 802.15.4 compliant and operates in the 2.4GHz to 2.4835GHz ISM unlicensed bands.

The eSPOT application board connects to the eSPOT main board with a Hirose DF17-30 connector, acts as an SPI slave in communication with the

eSPOT main board and contains SPI flash memory for storing configuration information. General purpose application board digital output accelerometer with three sensitivity ranges, temperature sensor and light sensor.

Some other options are also available. What is important is that they are programmable, and have a set of hardware that is required by this application: radio and possibility of adding accelerometer, humidity and temperature sensor, and similar. One of these options is Waspmote. [10]

Waspmote is a sensor device specially oriented to developers. It's advantage over SunSPOT is that it works with different protocols (ZigBee, Bluetooth, GPRS) and frequencies (2.4GHz, 868MHz, 900MHz). Also, thanks to analog and digital inputs provided by microprocessor, large number of sensors can be attached, enhancing exibit node functionality. The Waspmote IDE is based on open source Arduino platform compiler, which is a cross-platform application written in Java. The Real Time Clock (RTC) can be used to set a common time base in all the Waspmotes in a network. This allows network to remain synchronised.

Another option that is commercially available is Ubi-Mote2 [11]. It's not as good solution as SunSPOT, as its sensors have to be added on different daughter boards, which increases the size of the node. Better solution will be UbiSense1 (from the same manufacturer - The Knowledge Park Centre of C-DAC, Bangalore), which is still under development. It will have all the necessary sensors (accelerometer, temperature, humidity and light sensors) integrated already in bought package.

III. SECURITY AND VISITORS SW

Practical implementation of this idea consists of two SW packages and wireless sensor nodes which have three different roles. According to their role, sensor nodes are split in exhibit nodes, visitor nodes and security nodes. The central points of both SW packages are exhibit nodes.

A Exhibit sensor nodes

Each exhibit piece would be equipped with one sensor node which has two roles – broadcast its address for visitor SW and monitor surroundings of the exhibit for security SW. Figure 1. shows exhibit node flow chart.

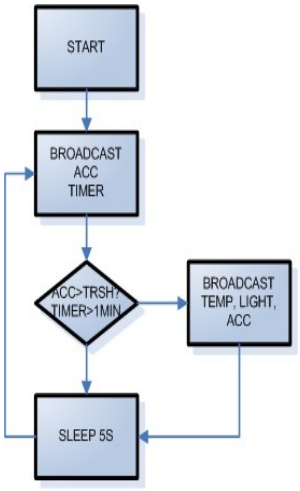

Fig. 1 Exhibit node flow chart

Exhibit nodes work in 5 second cycles. At the beginning of each cycle, node "wakes up", initializes radio to low power broadcast on determined frequency and sends its unique address. Radio power can be tuned so the broadcast signal would cover certain distance. Unfortunately, there is no precise translation between radio broadcast power and the distance the signal covers because of many variables, so the distance of signal coverage is difficult to calculate. Radio power used is determined by several factors: how many exhibit pieces are expected around it and how close they are, presence of obstacles, etc. After radio broadcasts its address, data from sensors are read. One of the advantages of this system is that wireless nodes are flexible in what sensors can be attached to it. SW works with nodes which have acceleration, light and temperature sensors, but more can be added e.g. humidity sensor. Sensor data is compared to given thresholds and if some of the values are above the given limits, signal is set to the main node program, which, after that signal is received, changes radio power to maximum and changes frequency to the one of security SW and sends out sensor data. That data is received by security SW and status of that node changes and alerts the security SW user. If all sensor data are within given limits, nothing is broadcasted further and node sleeps for 5 seconds. After 12 cycles (approximately one minute), regardless of sensor data, node sends out its data to security SW, so that SW would know that node is working properly. Operating in this mode is not perfect, but some compromises have to be taken, so battery life can be prolonged. That's why nodes are inactive for 5 seconds. In case that constant power source can be provided, this sleep mode would become unnecessary, allowing for constant sensor readouts, more sensors attached to the node, more frequent security SW update, which gives better control and overview of exhibit surroundings.

B Visitor sensor nodes

Second role that nodes have is visitor sensor nodes.

They are attached to a PDA or tablet like device that is able to display different kind of content - text, audio, video and similar and together with that device, visitor nodes make visitor SW. Sensor part of visitor SW works by flow chart pictured in Fig 2.

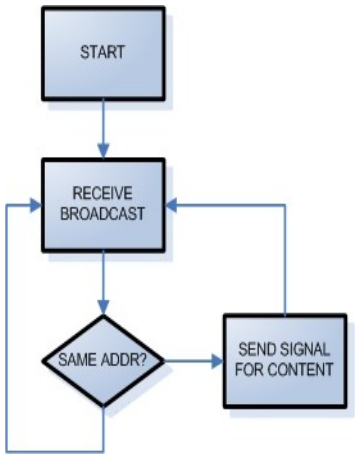

Fig. 2 Visitor node flow chart

Visitor nodes "listen" for broadcasts of addresses so they could recognize exhibition pieces and display appropriate content. In visitor's SW storage, all content is associated with exhibit broadcasted addresses. Each exhibit has unique ID (address) and receiving that ID triggers content that is tied to that exhibit piece. The main idea is to avoid situations that visitors devices show constantly new content when user is walking through museum, so there is a simple check which should display content only for exhibitions users are interested in. Once one address is received, node places that value in temporary variable. In next receiving cycle, again some broadcasted address is received. New value is compared to the temporary one and if they are the same, it is presumed that user is staying in the vicinity of desired exhibit and command for displaying correct content is triggered. If new address is different from the temporary remembered value, than temporary value is discarded and newer address becomes temporary one. Another function of visitors SW would be an interactive map. Museum map is placed in SW storage and each room is filled with exhibition pieces and their addresses. That way, once the first exhibition piece is recognized and its content is displayed, relative position on the museum map of the user is also marked. Since that map also holds information about other exhibitions, that device can be used to guide the visitors to the locations they want to visit. Since visitors nodes are attached to a larger device with a battery with higher capacity, battery life of nodes is not a problem.

C Security sensor nodes

Security sensor nodes listen for broadcasts from exhibition nodes. Security and exhibition nodes operate on different radio channel than exhibition and visitors nodes, so there will be no signal interference. Security nodes can receive two types of broadcasts from exhibition nodes. One is when accelerometer reading is below threshold. In that case, node sends temperature and light sensor readouts which are displayed on the security SW map which shows museum maps with all exhibitions. Second type of broadcast is when exhibit accelerometer reading is above the threshold. Than exhibit node sends a broadcast which changes the state of the exhibit in security SW from green (everything OK) to red (problems). Security SW has a database with all exhibition's addresses and their locations, so locating certain exhibit piece on the map is very easy. Security sensor node flow chart is shown on fig 3.

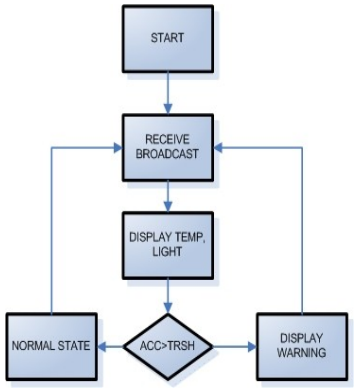

Fig. 3 Security node flow chart

Every time a broadcast is received from exhibit node, time of broadcast is saved. Those times are periodically checked (every minute). Since exhibit nodes by their programming have to broadcast at least once a minute, if time of broadcast is more than 2 minutes, state of exhibit is changed on the map of security SW. Lack of broadcast indicates that there is no enough power for full strength broadcast and batteries need to be replaced, the whole node stopped working or node is out of range (exhibit piece stolen).

IV. FURTHER DEVELOPMENT

There are two general directions for further development and improvement of this work. One is node programming improvement and the second one is SW improvement.

A Node programming improvement and further development

Major concern for this kind of application is scaling. How will the SW and nodes behave once many nodes are broadcasting and trying to receive those broadcasts? Since all the transmitting is done by exhibit nodes and they only broadcast without requiring feedback, connection exhibit - visitor nodes

should scale without any problems. Big concern is that exhibition nodes do not interfere with each other when broadcasting for visitor nodes. For that reason, careful measurements have to be done for radio transmitting power, since separating exhibitions enough for certain radio power might not be an option. There should be a table of values for radio power and desired length of signal coverage. Bigger issue is scaling of the connection exhibition - security nodes. Once there are many exhibition nodes present, there is a possibility that, due to high number of concurrent broadcasts, some of the broadcasts are lost, which will cause problems with security SW. Luckily this problem can be solved by simply scheduling broadcasts of exhibit nodes. This does not have to be done on all nodes separately - nodes can be programmed in that way, when they are turned on for the first time, they schedule themselves in such way that no nodes will broadcast at the same time. This has to be done periodically, for example when new node is introduced.

B SW improvement and further development

Biggest improvements and development can be made in visitor's SW. It would be possible to implement guided tours, with visitor's devices guiding the users through the museum by previously determined routes. Other development would be a system of recommendations, where visitor's SW would, after several exhibits are visited, recommend similar exhibitions. The list of similar pieces could be made by museum experts or by visitors themselves, which would bring a social network element in museum visit. One of the more interesting uses of visitor's SW would be gathering of statistical data. If SW would remember all locations visited by users, it would be possible to rearrange exhibitions so the most interesting ones (most visited) would be separated further away, thus avoiding bottlenecks and crowding of the visitors, making the visit more enjoyable.

C Exhibit change improvement

One thing that needs improvement is the state of WSN after exhibit change – as exhibit pieces change, so does their position, sensor ID and data that needs to be presented to the visitor. Currently all these changes have to be made manually, by museum staff, and one exhibit piece at the time. This is not a favorable solution for museums that often change exhibits. Unfortunately, solution is not a simple one. Nodes do not have spatial awareness so it is impossible for them to recognize their position – their position is determined manually in security and visitors SW. Nodes do not contain exhibit information, so that info has to be entered in visitors SW manually. One thing that can be improved is relaying sensor IDs to security and visitors SW, but since those SW have to be updated manually for node position, this is not a very large improvement.

V. CONCLUSIONS

Disadvantages include high possibility of malfunctions caused by improper handling and time of implementation. Time of implementation can become an issue in museums that often change exhibits, since every exhibit change includes fitting exhibit pieces with new sensors, entering new sensor data into SW (visitor and security), entering exhibit location in both SW, as well as equipping visitor SW with new exhibit information (which will be displayed to the visitors).

There are many advantages of implementing e-museum. Better control of exhibits, improved security, better experience for visitors, to name a few, but also the versatility of the concept. This concept is applicable to many areas: all kinds of exhibits, fairs, ZOOs and all other which include bringing content to the visitor.

ACKNOWLEDGMENT

We would like to thank professor Veljko Milutinovic (University of Belgrade, Serbia) for the invitation to participate in Senzations'09 summer school, which has encouraged us to do this work. We would also like to thank professor Ljiljana Gavrilovska (University of Skopje, Macedonia) that provided us with the equipment with which the project was implemented.

Syncronization of Information Systems - Case Study

Davor Cafuta, Ivica Dodig, Dalibor Grgec
Polytechnic of Zagreb, Vrbik 8
Email: {davor.cafuta,ivica.dodig,dalibor.grgec}@tvz.hr}

***Abstract*—The purpose of this paper is to give an insight into an informatization and automation solution that in itself generated new problems. The paper describes a case study on the administrative applications used at the Polytechnic of Zagreb and proposes a solution for interfacing them. It shows how a lack of simple feature can make a system unusable and initiate a complex improvising solution to deal with it. The methods proposed are based on open-source and education licensed software and can be used in similar situations. The future implementation upgrade is proposed in the conclusion.**

I. INTRODUCTION

THIS paper intention is to present a case study about the today's most significant problem in information system evolution. There is a global idea about automation and informatization of every concept in our working environment. Due to obsolete or erroneously working parts of the information system there are potential risks in information management, particularly, problems can occur in synchronizing different standards technically or logically.

The Polytechnic of Zagreb[1] is the largest Croatian polytechnic. It carries out eight different study programs: Mehatronics, Civil engineering, Electrical engineering, Computing and IT. Due to the fact that the Croatian government finances the University Computing Centre of University of Zagreb, the Polytechnic of Zagreb is provided with several IT software packages which will be discussed later, in section II.

Synchronization between different software solutions should be done automatically and they should be adapted to specific needs of the Polytechnic. For example, the data set and interface should take into account that the Polytechnic of Zagreb has four departments and eight study programs. Due to lack of necessary support from the provider of the information system, improvisation for achieving synchronization is necessary. This paper describes a concrete case study implemented at the Polytechnic of Zagreb. It is intended to warn software developers about the cases where developing an extra application or service may be a wrong option if synchronization or cooperation with a previous or interfacing service is not properly established. It may also give some guidance to system administrators for solving typical synchronization problems.

In section II we will discuss the services that need to be synchronized and explain most of the interfaces. The main synchronization problem is explained in section III. Section IV describes a proposed solution. Section V resolves links to other services. Finally, a conclusion is presented in section VI.

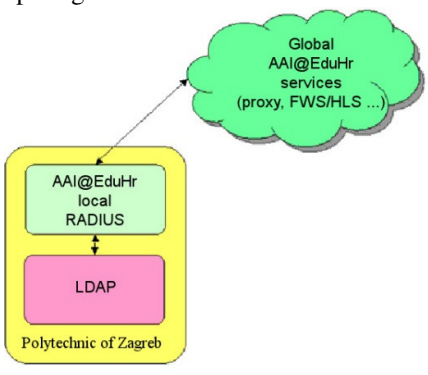
II. SERVICES

In this section services that should be connected will be described:

A. *Croatian Academic Authentication and Authorization Infrastructure*[2]

Croatian Academic Authentication and Authorization Infrastructure is a part of eduroam paneuropean society. Eduroam[3] (education roaming) is the secure, world-wide roaming access service developed for the international research and education community. Eduroam allows students, researchers and staff from participating institutions to obtain Internet connectivity across campus and when visiting other participating institutions by simply using their own laptop.

Every student, teacher and employee should have AAI@edu.hr account. AAI@edu.hr service is maintained by SRCE[4] (University Computing Centre of University of Zagreb). The service is decentralized as shown in figure 1. The main directory of the Polytechnic (@tvz.hr) is locally stored and maintained by local administrators. In our case study the local directory is stored on the server bit.tvz.hr. The services available on the server are LDAP and FreeRadius. The main local directory is automatically replicated with the main directory (@hr). Radius is enabled on both a local server and on a global one positioned in the University of Zagreb computing centre. University departments and other institutions are responsible for maintaining accuracy of the directory. As services are maintained locally, read and write to directory @tvz.hr is enabled by using local LDAP access. Departments are advised to use web based application provided by the computing centre.



B. *Academic University Infromation System*[5]

ISVU (*Higher Education Institutions Information System*) was founded by the Croatian Ministry of Science, Education and Sports. The information system is fully centralized and maintained by SRCE (University Computing Centre). Access is possible only through user application developed for the system and used by Student administration service and teachers for keeping the students' records.

There is a separate user web application for students and other for teachers used for only some administrative purposes.. Every student has an account. This account is separated from AAI@edu account.

The project was declared to be completed in year 2006 despite some obvious inadequacies, mostly because of the shortage of financial resources for further development.

This system is the central service for every department as it consists of students' records and information about teachers and employees.

C. *Web site moj.tvz.hr*[6]

Every student and employee of the Polytechnic of Zagreb has access to the web site moj.tvz.hr. Due to the connection to other resources, records are stored in local MySQL database.

D. *Mail server @tvz.hr*

The mail server is implemented on Linux Debian using postfix and dovecot. Every student and employee has a Linux account. Selected accounts have access to shell (to create local web sites).

E. *Other services (Moodle and TcExam)*

Due to the trend towards e-learning, other services are deployed on employees' request. To increase security of on-line exams multiple instances of e-learning services are created. Due to increasing demands for synchronizing student and employee identification and authentication data, the load and the amount of data in a database is rising. This change resolves in putting MySQL database of the Internet site moj.tvz.hr as central database for student and employee records.

III. MAIN PART

In most departments of the University of Zagreb services A-E are separated. Student administration service is responsible for ISVU by using user application. Other services are maintained by local administrators upon student or teacher request. The main shortcomings of this approach are:

- Missing connection between student administration service and local administrators. Context of Index (document) is checked to valid the student rights to account.
- Student and employees have to regenerate their account yearly as failed or graduated students have no obligation to contact local administrator.

The main problem is the interface between ISVU and AAI@edu infrastructure and the fact that one service has a decentralized approach and the other a centralized one.

To resolve this problem, ISVU offered one-way synchronization to AAI@edu. This synchronization enabled automatic creation and deletion of AAI@edu account at the request of department. The main shortcomings of this synchronization are as follows:

- If a administrator deletes student data from the database and reregisters on the same account, the AAI@edu account will not be created (burned-in record in the ISVU database). This problem may be corrected through additional effort of the Student administration service.
- Due to the fact that there are no available fields in AAI@edu database, ISVU does not provide study program names in AAI@edu database. When the feature was requested, ISVU administration responded that there is no available field in AAI@edu infrastructure.; AAI@edu responded that there is no need for that field, in spite of the fact that a study program name is essential information for our central database, as the Polytechnic of Zagreb carries out eight study programs.

On enabled ISVU to AAI@edu one way synchronization, an internal scheduler script can be implemented to achieve one-way synchronization of AAI@edu and MySQL database of internal web site. Due to the missing field, other ways of synchronizing the study program name parameter had to be found.

After a successful synchronization, MySQL database of internal web site can be used as a master database to other services (D-E) providing information using web services or other scheduler scripts. Further development can be simplified as source and destination services can be modified to accommodate procedure. This synchronization will be described in next sections.

To simplify user management other means of password recovery should be enabled. In the provided infrastructure only local administrators can reset password. The problem lies in the ISVU architecture which has separate username and password for accessing student administration in ISVU and separate for AAI@edu service. The student administration service has privileges to reset ISVU account but does not have privileges to reset the AAI@edu service account. Even if they gain privileges there is a potential risk that maintaining two parallel databases can bring problems if the Student administration service makes an oversight resetting the wrong account type on a daily basis. if the Student administration service had to take up some of the tasks of local administrators, this will result in an additional workload.

Our feature request to ISVU was: Implement AAI@edu password change through ISVU student application as that

would not change practice of the Student administration service. The Student administration service would reset the ISVU student application account, and a student would reset AAI@edu account using his/her ISVU student application. This feature request was put on hold and has not been implemented so far.

IV. MAIN EXTRACTION PROBLEMS

After implementing the ISVU one-way synchronization with AAI@edu the main synchronization script has to be programmed. A Simplified algorithm for the main script is:

- For every student in AAI@edu database
  - If a student doesn't exist in MySQL database
    - Create entry in MySQL database
    - Create entry for every module
- For every student in MySQL database
  - If a student doesn't exist in AAI@edu database
    - Delete entry in MySQL database
    - Delete entry for every module

The module approach enabled other services to be instantiated upon creation or deletion of a student record in ISVU. Modules will be better explained in the fifth section.

After a successful synchronization, the problem with the missing study program name had to be resolved. A study program name is only available in ISVU database which can only be accessed through ISVU user application for the Student administration service, written in Java, or through a student, teacher or database warehouse web portal.

The database warehouse web portal is simple as synchronization interface due to many open-source web-testing solutions. The example is SeleminumHQ[7]. Testing of every suspicious new record would be a simple but adequate solution. Listing 1 shows listing of php script connecting and extracting info from selenium server installed on Windows XP. Extraction is performed for every student that has the field *studij* (study program name) empty in MySQL database. This script would be started after the main synchronization script. Suspicious records are marked by students upon requesting option "this is not my main study program name". Due to requested privileges we believe that students would use this option to correct mistakes in a database or inaccurate information when students change the main study program.

Listing 1: Php-cli selenium client script

```
<?php

  require_once
'PHPUnit/Extensions/SeleniumTestCase.php';

  class               Example               extends
PHPUnit_Extensions_SeleniumTestCase
  {
    protected function setUp()
    {
      $this->setBrowser("*chrome");
      $this->setHost($ip_sel);
      $this->setPort($ip_port);
      $this-
>setBrowserUrl("https://www.isvu.hr/");

    }

    public function testMyTestCase()
    {
      $this-
>open("https://user:password@www.isvu.hr/skladiste
");
  $this->click("//input[@type='image']");
      $this->waitForPageToLoad("30000");
       $this->waitForPageToLoad("30000");

>click("ctl00_PageBody_PopisDetaljnih1_TreeViewDet
aljnit8");
      $this->waitForPageToLoad("30000");
      $this-
>click("ctl00_PageBody_PopisDetaljnih1_TreeViewDet
aljnit11");
      $this->waitForPageToLoad("30000");
      $this-
>click("ctl00_PageBody_PopisDetaljnih1_btnBrowseQu
ery");
      $this->waitForPageToLoad("30000");

  include_once
("/home/www/mojtvz/php/config.php");

  $link1=mysql_connect($ip,$ login,$ pass);
  mysql_query("SET    CHARACTER    SET    'cp1250'",
$link1);
  mysql_selectdb($baza,$link1);

  $obav=mysql_query("SELECT  *  FROM  osoba  where
ldap2='ISVU' and studij='';");
  for($i=0;$i<mysql_numrows($obav);$i++){
      $vadi=mysql_result($obav,$i,"nadimak");

      $this->type("T139", $vadi);

      $this->click("ctl00_PageBody_BtnRunQuery");
      $this->waitForPageToLoad("30000");
  sleep(5);
  $cijela=$this->getHtmlSource();
  //echo $cijela;
  sleep(5);

  $cijela1=strstr($cijela,'<span
id="ctl00_PageBody_lblRowCount">');
  $cijela2=strstr($cijela1,'<script
type="text/javascript">',true);
  $obav=mysql_query("UPDATE       osoba       SET
studij='$cijela2';");

  }
  $this->stop();
  }
  }
  ?>
```

The database warehouse synchronization solution was rejected due to extensive amount of records that has to be fetched and transferred. An additional problem occurs in the fact that the warehouse is synchronized once a day. This concludes that student account can be created and

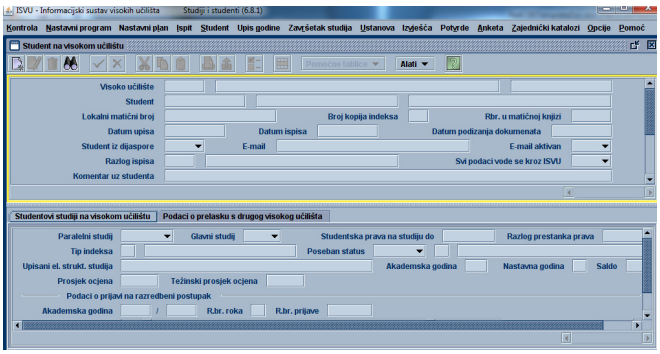
information about study program name would be available in next 24 hours.

The teacher ISVU web application does not have options to collect information for study program name using student's name or distinguishing student's number.

The student ISVU web application does contain this option but the access to this application is not possible due to lack of initial student password. This approach would create extra load to the Student administration service that would have to copy initial password to our database.

The main ISVU application is the only available application used by the Student administration services, written in JAVA and executed locally as a stand-alone application. The application uses standard JAVA GUI and applies keyboard shortcuts for actions (figure 2). For further development, we set up a goal to use a programming language to develop a robot to emulate the user's behavior, extracting and writing data from the Java GUI ISVU application. The identity of the emulated user was chosen in a way that the possible damage in case of the application error is minimized.

Figure 2. ISVU main Application written in Java



To minimize the development effort, Microsoft Visual Basic 6 was selected as a programming language. The application is started using a scheduler. On the start the application loads the ISVU program file (exe). After sleeping for several seconds it is trying to find windows using a known windows name (windows API call) (listing 2). It is estimated that first ten windows would be enough to search due to the application started recently and a virtual machine with Windows XP is only used for the purpose of robot extraction. When found, a window will be switched in foreground and a password will be sent. ISVU uses the function key F10 as enter so it is sent to start the login process. The sleep time of 40 seconds was estimated during a testing period. After that period the application checks for error windows. If there are no error windows, it concludes that a user is logged in. If there are error windows, it kills the ISVU application and repeats the procedure. If it fails for the second time, it gives up and sends an e-mail to the administrator. The administrator can use a VNC[8] to connect to the machine and check behavior during the load. After few modifications of parameters in a test phase, we finalized the stable system which is used today.

Listing 2: VB 6 robot code

```
  ' Display the hWnd.
   task_hWnd = InstanceToWnd(task_id)

  ' Display the new process's caption.
   buf = Space$(256)
   buf_len    =    GetWindowText(task_hWnd,    buf,
Len(buf))
   buf = Left$(buf, buf_len)

  ' find correct window by name
   For i = 1 To 10
         task_hWnd = GetWindow(task_hWnd, 3)
          buf = Space$(256)
          buf_len  =  GetWindowText(task_hWnd,  buf,
Len(buf))
          buf = Left$(buf, buf_len)
                                '     found     correct
windows
          If  (buf  =  "Identifikacija  korisnika")
Then
                        '    bring    application    in
        focus!
              AppActivate  "ISVU  -  Informacijski
        sustav visokih učilišta            Studiji
        i studenti"
              SendKeys "PASSWORD", True
              ' ISVU uses F10 as enter
              keybd_event VK_F10, 0, 0, 0
              keybd_event         VK_F10,         0,
KEYEVENTF_KEYUP, 0
                                                 '  wait
for logon process
              Sleep 40000
              Exit For
          End If
    Next i
```

After logon, the application uses the keyboard shortcut and the copy-paste operation to move between windows and to enter or read information from a dialog box. In a particular case, the application opens a student information dialog box, enters study program name and executes operation that retrieves all students' records. Carrying out the copy-paste procedure it checks if it received information (a blank field means unsuccessful or a field containing first student unique id means successful). If the information is received, it exports information in CSV using shortcuts and entering a unique file name. After being saved, the file is loaded by the main application and interpreted. This procedure is repeated for every study program name. By using this solution, in relatively small amount of time (approximately one hour) all student information is extracted and MySQL database is synchronized. This approach also works in the cases when ISVU and AAI@edu one-way synchronization is broken as it will immediately notify a local administrator about differences that were encountered during extraction and synchronization. We are using this information as additional check because we do not expect to see larger differences. In the case they are found, a robot will notify the administrator using e-mail and the synchronization is aborted. After a successful extraction

operation, an e-mail is sent to a special mail account which can be checked periodically serving as a log of the system. Listing 3 shows an example of code which simulates human clicks.

Listing 3: parts of VB6 robot code (extracting data)

```
  citaj sql, "SELECT * FROM smjerovi WHERE
isvu_account_vidljiv=1"
      For j = 1 To sql.RecordCount
          smjer = sql("sifsmjer")
      Print #1, "Vadim smjerove:" & smjer & " &
Date & ", " & Time"
    List1.AddItem "Smjer" & smjer
                  keybd_event VK_F7, 0, 0, 0
                  keybd_event       VK_F7,       0,
KEYEVENTF_KEYUP, 0
                  Sleep 100
         DoEvents

              For i = 1 To 9
                  keybd_event VK_TAB, 0, 0, 0

```

Constants written in capital letters are defined in separate module using Windows API calls[9]. The application has been in use for two years. The number of errors has been significantly reduced by repeated studies of email logs. To make sure that the start of the robot is fully independent and with equal chances for success in data extraction, a scheduler was set up. Its task is to perform a clean restart of

the computer one hour before the application starts. , After a series of tests has been done, problems with the application are mostly due to external issues: network connectivity problems, the application hang error, unavailability of the ISVU service or some other operating system induced error (unexpected new window start), etc.

The second goal in the main extraction was to enable students to reset a forgotten AAI@edu password. Local administrators were in charge of this. ISVU link to AAI@edu enabled the usage of ISVU for password resetting. Student administration service had to take over that task. The Polytechnic of Zagreb has approximately 6000 students inducing 3-10 forgotten passwords every month. As students have another detached username and password for the ISVU web portal, mistakes started to happen and wrong passwords were reset leading to disappointment in student and administrators population.

As those two accounts could not be merged by username or password another approach was proposed to the ISVU developing team. The Student administration service could reset ISVU web portal account (which they did before) and students themselves could reset AAI@edu password through ISVU web portal. ISVU has never implemented this request.

To achieve a similar effect we developed a separate administrator web page which a student will use for resetting the AAI@edu password. The question was how to establish student identification and authentification? Student identification number, date of birth, name or surname is data which could be easily reproduced by a third person who could get access to the student's password. The answer is in the fact that we need to confirm identification and authentification using the ISVU student web portal.

A web testing tool was proposed for this job. Selenium HQ was complicated to implement as a separate Selenium HQ server was needed. Simpletest[11] PHP web testing unit was used to confirm identification and authentification of a student by using a username and a password from the ISVU student web portal..

Simpletest provided a browser object which emulates client (student) connecting to the ISVU student web portal. Listing 3 shows the simple way of checking if a user can log on to the ISVU student web portal using the data he provided with. If the login is successful the AAI@edu password is reset.

Listing 3: Simpletest testing password

```
  $browser = new SimpleBrowser();
  $browser->ignoreFrames();
  $browser->useCookies();
  $page                =                $browser-
>get('https://www.isvu.hr/studomat/aplikacija/');
  $page                =                $browser-
>post('https://www.isvu.hr/studomat/aplikacija/',
array('formID'                                  =>
'loginweb.jsp_form1','jmbag'=>$_POST['jmbag'],'pas
sword'=>$_POST['loz'],'akcija'=>'Login'));
  $page                =                $browser-
>get('https://www.isvu.hr/studomat/aplikacija/');
   if(strstr($page,"Neispravna lozinka!")!=FALSE){
              //WRONG PASSWORD
   }elseif(strstr($page,"Ne                postoji
student!")!=FALSE){
              //UNKNOWN USERNAME
   }else {
              //SUCCESFULL LOGIN
  }
```

To prevent the service from being exploited in a brute force attack, a captcha and IP address logging are implemented. In case that ISVU raises the security, thus disabling Simpletest usage, SeleniumHQ can be used. Selenium HQ uses a real browser in his server to achieve web testing, thus it cannot be prevented from checking data.

V. LINK TO OTHER SERVICES

To provide single-sing on services to other system three types of approach are used:

- Radius service
- Web service of custom design
- Complete implementation of requested service (used for e-mail)

Radius service is implemented primarily for access to a wireless network available on locations. Radius is also used as recommendation for teachers that are trying to create their own portals for students. An example of a portal could be Joomla, Moodle or TcExam that can be installed with radius authentification module. Data for radius service is provided by MySQL database of web site moj.tvz.hr. AAI@edu radius service cannot be used as it does not contain a study program, the name of a student, of a department and of a teacher.

A web service of custom design is intended for services programmed without support for Radius or that are unable to be reprogrammed to use radius due to their limitations (ex. closed code or hardware). This service enables simple encrypted client/server communication over the web. Security is crucial and based on encryption algorithm and source client network signature. Currently the service is used for custom written exam testing software and for class enrolment using mobile devices.

The third and final issue to deal with was e-mail implemented on UNIX server (Debian Linux using Postfix). The Postfix Virtual mail server connected to MySQL database was not an option as shell accounts for some users needed to be accessible. Many existing solutions found on the web were investigated and tested and finally the decision was to make our own approach.

A command line PHP script named account_server was written as a service on e-mail server. UDP messages were used to inflict task to this service. Tasks that could be

inflicted to script are: ping, create, check, remove and reset account. Listing 4 shows the script. A startup script for this service is introduced in rc.x directory where x is current run-level on the mail server.

Listing 4. Account server script for mail server

```
  /* Allow the script to hang around waiting for
connections. */
  set_time_limit (0);

  /* Turn on implicit output flushing so we see
what we're getting
  * as it comes in. */
  ob_implicit_flush ();

  if (($sock = socket_create (AF_INET, SOCK_DGRAM,
SOL_UDP)) < 0) {
     fwrite($s,"socket_create() failed: reason: "
. socket_strerror ($sock) . "\n");
  }

  if (($ret = socket_bind ($sock, $address,
$port)) < 0) {
     fwrite($s,"socket_bind() failed: reason: " .
socket_strerror ($ret) . "\n");
  }

  do {

  $from="";
  $port="";
  $buf="";
  socket_recvfrom($sock, $buf, 4096, 0, $from,
$port);
  if($from=="192.168.10.11"){
   fwrite($s,"received from remote address $from
and remote port $port\n");
  $buf=decryptData($buf);
   fwrite($s,"OPSLUZUJEM: received $buf from
remote address $from and remote port $port\n");
  $komanda=explode("#",$buf);
  if($komanda[0]=="TVZ"){
          if($komanda[1]=="?"){
                 //provjera rada
                  fwrite($s,"PING-PONG\n");
                  $msg="!";
         }
         if($komanda[1]=="F"){
                 $user=$komanda[2];
                 $pass=$komanda[3];
                 $ret="";
                 passthru("checkpasswd_web  $user
$pass >/dev/null",$ret);
                 fwrite($s,"FINGER:$user
$ret\n");
                 $msg=$ret;
        ….
        }else{
               $msg="PROTOKOL?";
           fwrite($s,"WRONG PROTOCOL\n");
  }
  $msg=encryptData($msg);
  socket_sendto($sock,  $msg,  strlen($msg),  0,
$from, $port);
  }
          $nesto="";
  } while (true);
  socket_close ($sock);
```

The account server enabled remote administrating of user account through the faculty web page. This approach enabled the option to create users with or without e-mail and enabled the usage of single username and password for all services.

To simplify further administration Postfix Virtual Alias maps were implemented. To improve the reliability of the e-mail service, aliases were stored in local database on the e-mail server opposite to storing them in the main web database. This enabled disturbance-free work of the e-mail server in case of web server database failure. The main web page has access to this server so administration is performed on the main Internet site. The complex function of the system is hidden from the system administrators.

Ping task implemented on the account server enabled constant check of availability of the service. During the testing phase, checks were performed on a minute base, and in the production phase on a daily base.

The most difficult issue during the implementation was the preparation for synchronization of all services. During this period, there was a constant occurrence of unknown or duplicate user account that had to be adjusted for synchronization to start. Even synchronized databases, tend to became unsynchronized over some period of time.

With this synchronization in a production phase, we are able to move on to other related projects (active directory synchronization, live-edu account synchronization and mobile acquisition of students using RF-ID card).

VI. CONCLUSION

This paper presented a case study of the Croatian Academic information system and infrastructure that had to be improved by adding interfaces which enabled its full integration and functionality by the merit of Polytechnic of Zagreb. Initially provided information system was not able to synchronize information in several databases or extract data necessary for processing. Interfaces were not standardized or well-documented. Support from the system provider was missing or inadequate.

In total, five different interfaces were implemented, enabling the data exchange among LDAP database, proprietary database system, web site based on MySQL and common UNIX mail server user database.

The system is in use for over two years and reliably synchronizes the data of more than 6000 users.

Since this solution is a of improvisation, it is vulnerable to user interface or LDAP schema changes.

The trend in cloud computing also led the Polytechnic of Zagreb to analyze live-edu or google-edu services as an approach to implementing share point services for calendar and documents. Currently we are revising which services to test and how to implement synchronization.

Database System Performance in Correlation with Different Storage File systems

T. Kramberger, D. Cafuta, I. Dodig,

Polytechnic of Zagreb
HR-10000 ZAGREB, Vrbik 8, CROATIA
e-mail: {tin.kramberger, davor.cafuta, ivica.dodig}@tvz.hr

Abstract - today databases are widespread over many applications. Information load is constantly increasing. This rapid grow is applied to databases. It could be suspected that choice of the file system used for storage can determine the database query response time. In this paper we performed several measurements of database responses on different file systems according to query load. Response time on standard database operation INSERT, SELECT and DELETE was measured and correlated.

Keywords: Database, File system, performance

I. INTRODUCTION

One of database definition is collection of records or information which is stored in a systematic way. Database volume started to increase as trend of connecting different databases started to emerge (eg. road maps database can be connected to road works).

Two main issues in using large database systems are protection of data in case of failure and I/O bottlenecks. Not adequate protection of data in worst case can be repaired with use of database backups. Backups should be created in short time periods to full proof system in case of database lost. Other protection methods include RAID mirror systems and load balancing to secure even ballast in case of multiple database servers and replications on network.

Simplest solution to deal with I/O bottleneck is in investments into hardware. Upgrading CPU and RAM makes database server faster but raises expenses and it does not provide full proof system. In case of disk failure some file systems require significant amount of time or even cannot recover from error. Complexity of the file system (design, implementation and configuration) is proportional to features like recovery and redundancy.

Fixing I/O issues without investments in new hardware requires knowledge in areas specific to file system features. This process can be consuming, costly and risky due to potential of losing data and making unplanned downtimes. Choosing different file system for database storage may decrease I/O bottleneck, resolve problem without investments and even introduce new features which can results in increased reliability of the database server [1].

Linux operating system which is commonly used as database server provides large variety of file systems. Kernels are constantly upgraded with new file systems adding new features and maximizing the speed of I/O operations. A newer file system sometimes does not make better performance in I/O operation time, due to improved reliability which requires additional operation on disk [20].

In this article the focus is showing file system dependence on database performances. Chapter 2 describes database storage solutions. File systems will be presented in chapter 3. Testing methodology is presented in chapter 4. Results are shown in chapter 5. Chapter 6 summarizes this paper.

II. FILE SYSTEM

Database storage can be divided according to locations for storing data. Storage on file system, usually called cooked files, uses file system on server. In opposite to cooked files RAW partitions are used to avoid file system I/O functions and use specially programmed functions which are the part of database management system. RAW partitions store data according to specification provided by database management system.

Because operating system file systems are not designed to boost performance on database storage, RAW partitions have significantly better results. As constant developing is increasing efficiency of file systems, difference in performance becomes smaller. Advantage of file system storage is easier access to database storage files unlike RAW partitions. Files stored on file system are visible to user and can be copied or moved using standard file system commands. Using file system storage associates reliability and recovery with file system recovery and reliability, opposite to using RAW partitioning which associate reliability and recovery with database management system engine. File system storage still has a problem in redundant-cashing. Data is buffered in database server buffer and in I/O storage buffer. This problem can be avoided by configuring database management system and operating system kernel.

There are numerous file systems on operating systems: Ext2, Ext3, RaiserFS, Ext4, ZFS, FAT32, NTFS, etc. Due to our limitation described in chapter 5 we could not test all of these file systems in our case study.

Ext2 (Extended File System) is the oldest file system released in January 1993 as successor of Ext file system. Ext2 has been Linux file system for many years and is still used as RAM disk file system and when non-journaling file system is required. Ext2 has proven to be stable and quite lightweight in terms of overhead. The downside is lack of journal. Journal is file system data and or metadata log which is kept in separate part of disk. In case of failure disk can be reconstructed using the data from journal [2][3].

Ext3 is successor of Ext2 implementing journal option. There are three different mount modes: journal, ordered and write back. Journal mode logs all file system data and

metadata changes. It is the slowest of the three Ext3 modes but most secure mode to enable reconstruction of disk in case of failure. Ordered mode logs only changes in file system metadata but only write these changes if file data write into disk is confirmed. Write back mode is the fastest Ext3 mode as it only writes metadata changes into journal before data disk file write is confirmed. In case of failure file can be reconstructed but this mode does not guarantee that data in the file is correct. Ordered mode is default file system mode. Ext2 mode is compatible with Ext3 mode meaning that you can mount an Ext3 file system as an Ext2 because the layout on disk is exactly the same. This enables existing file system repair tool and tuning of the system. Ext2 partition can be easily switched to Ext3 partition without copying files. Ext3 is based on binary trees to enable fast indexation of files. [4][5]

RaiserFS is one of the common stable journaling file systems. It was introduced in 2001 by Namesys company under GPL licence. ReiserFS is based on balanced trees. Balanced trees are more robust in their performance, and are a more sophisticated algorithmic foundation for a file system. Advantage of RaiserFS over Ext file systems is block sub allocation which makes RaiserFS more space efficient. RaiserFS as the newest file system after ext4 should have the best overall performances. RaiserFS implements only metadata journaling meaning that file data is not journaled. There is a patch (RaiserFS v.3) to implement full data journaling but file system API does not support it. From the application point of view, there may be an inconsistent data in file after recovery. [6]

Ext4 is newest of all mentioned file system developed in October, 2006 as a compatible improvement of Ext3, featuring support for larger volumes and support for extend. Extend is a continuous area of storage reserved for a file. When starting to write a file, a whole extend is allocated at start, disabling file fragmentation in file system. These improve speed of read operation on disk. Ext4 has the same modes as Ext3 depending on usage of journal: journal, ordered or write-back. In case of normal size databases, Ext4 should not show large differences than Ext3. [7]

File Allocation Table (FAT) is the name of computer file system architecture and a family of industry standard file systems utilizing it. The FAT file system is technically relatively simple yet robust. The name of the file system originates from the file system's prominent usage of an index table, the FAT, statically allocated at the time of formatting. The table contains entries for each cluster, a contiguous area of disk storage. Each entry contains either the number of the next cluster in the file, or else a marker indicating end of file, unused disk space, or special reserved areas of the disk. The root file directory of the disk contains the number of the first cluster; the operating system can then traverse the FAT table, looking up the cluster number of each successive part of the disk file as a cluster chain until the end of the file is reached. As disk drives have evolved, the maximum number of clusters has significantly increased, and so the number of bits used to identify each cluster has grown. The successive major versions of the FAT format are named after the number of table element bits: 12 (FAT12), 16 (FAT16), and 32 (FAT32). Each of these variants is still in use. The FAT standard has also been expanded in other ways while generally preserving backward compatibility with existing software.[8]

FAT32 provides the following enhancements over previous implementations of the FAT file system. It supports drives up to 2 terabytes in size (Varies on used operating system for example Microsoft Windows 2000 only supports FAT32 partitions up to a size of 32 GB). FAT32 uses smaller clusters (that is, 4-KB clusters for drives up to 8 GB in size), resulting in 10 to 15% more efficient use of disk space relative to large FAT or FAT16 drives. Reliability is based on relocation of the root folder and usage of the backup copy of the file allocation table instead of the default copy. In addition, the boot record on FAT32 drives is expanded to include a backup copy of critical data structures.

The root folder on a FAT32 drive is an ordinary cluster chain, so it can be located anywhere on the drive. The previous limitations on the number of root folder entries no longer exist. In addition, file allocation table mirroring can be disabled, allowing a copy of the file allocation table other than the first one to be active. These features allow for dynamic resizing of FAT32 partitions. As it is the oldest and simplest file system we could expect that it should have better performance.

NTFS supersedes the FAT file system as the preferred file system for Microsoft's Windows operating systems. NTFS has several improvements over FAT such as improved support for metadata and the use of advanced data structures to improve performance, reliability, and disk space utilization, plus additional extensions such as security access control lists (ACL) and file system journaling. It also supports large volumes and powerful storage solution such as RAID. The NTFS on-disk format has five released versions. The latest version 3.1 was released in autumn 2001.

NTFS is a Journaling file system and uses the NTFS Log to record metadata changes to the volume. It is a critical functionality of NTFS (a feature that FAT/FAT32 does not provide) for ensuring that its internal complex data structures (notably the volume allocation bitmap), or data moves performed by the defragmentation API, the modifications to MFT records (such as moves of some variable-length attributes stored in MFT records and attribute lists), and indices (for directories and security descriptors) will remain consistent in case of system crashes, and allow easy rollback of uncommitted changes to these critical data structures when the volume is remounted. The Volume Shadow Copy Service (VSS) keeps historical versions of files and folders on NTFS volumes by copying old, newly-overwritten data to shadow copy (copy-on-write). The old file data is overlaid on the new when the user requests revert to an earlier version. This also allows data backup programs to archive files currently in use by the file system. NTFS is a robust, self-healing file system that offers several customizable features that affect how well NTFS performs in a given environment. Some of these parameters are global and others are specific to individual NTFS volumes. By examining specific storage needs and then tailoring your NTFS volumes accordingly, some significant increases in your systems' disk performance can be achieved.[9][10]

ZFS is a combined file system and logical volume manager designed by Sun Microsystems. The features of ZFS include data integrity verification against data corruption modes, support for high storage capacities, integration of the concepts of file system and volume management, snapshots and copy-on-write clones,

continuous integrity checking and automatic repair, RAID-Z and native NFSv4 ACLs. ZFS is implemented as open-source software, licensed under the Common Development and Distribution License (CDDL). The ZFS name is a trademark of Oracle. One major feature that distinguishes ZFS from other file systems is that ZFS is designed from the ground up with a focus on data integrity. That is, protect the user's data on disk, against silent data corruption caused by e.g., bit rot, cosmic radiation, current spikes, bugs in disk firmware, ghost writes, etc. [11]

Data Integrity is a high priority in ZFS because recent research shows that none of the currently widespread file systems such as Ext or NTFS nor Hardware RAID provide sufficient protection against such problems. [12] For ZFS, data integrity is achieved by using a (Fletcher-based) checksum or a (SHA-256) hash throughout the file system tree. ZFS has no "fsck" repair tool, common on Unix/Linux file system, which examines and repairs data. Instead, ZFS has a repair tool called "scrub" which examines and repairs Silent Corruption and other problems. As testing were made on Solaris ZFS should be the best integrated file system in kernel.

III. DATABASE

In this article focus is on open source database servers used in Linux environment. Two most common database servers are MySQL and PostgreSQL. As Oracle introduced free version of database servers for development in this paper it is used as representative of commercial database performances.

There are small differences in open source database server features like automatic conversion of code pages, object-relational extension, XML support and user defined data types, but both servers are compatible with SQL'92 standard and ACID standard. ACID standard describes critical features of database engines to protect data integrity: Atomic, Consistent, Isolated and Durable. ACID essentially means that when a transaction is performed within a database, either the whole transaction is successful and the information is written to the database or nothing is written.

MySQL offers multiple storage mechanism. MyISAM and InnoDB are most common used. MyISAM has been default storage engine prior to MySQL 4.X. InnoDB is most recent default storage engine. InnoDB provides MySQL with transaction-safe storage engine that has commit, rollback and crash recovery capabilities opposite to MyISAM. These features increase multi-user concurrency and performance. InnoDB has been designed to be competitive with commercial databases offering cooked file storage or RAW partition storage. [13]

PostgreSQL uses only one storage mechanism named PostgreSQL storage system. To further increase performance level oversized attributes in tables are stored out-of-line storage in separate file. This technique is called TOAST (The Oversized-Attribute Storage Technique). PostgreSQL storage system supports all features as InnoDB except it can not use RAW partitions as storage space.[14]

Oracle is most commonly used commercial database engine. Data on Oracle can be stored in file system or RAW disk space. To further enhance performance of database Oracle has developed Oracle Clustered File system (OCFS). In terms of the file interface it provides to application, OCFS balances performance and manageability by providing functionality between those provided by RAW file systems or typical file system. [15]

RAW partitioning storage engine directly depends on quality of database engine software. Results gathered in RAW partitioning storage speed testing apply to specific version of database software used during testing. Newer or obsolete version may show large differences in performance and reliability as recovery from failure. File system storage also depends on software version but large differences in different versions of database software can be outbalanced by file system performance boost between different file systems. If the speed difference can not be significantly increases reliability features becomes significant. [16]

IV. TESTING METHODOLOGY

The most used way to measure database engine performance according to type of file system storage is to measure response time to SQL queries. For that purpose the script was built to measure database query response time. Queries were executing write, read and delete actions. Write action executes INSERT query according to SQL standard. As index needs to be rebuilt, write action should be the slowest action on database. Read action executes SELECT query according to SQL standard. Read action should be the fastest query. DELETE action represent delete query.

All query data was randomized. Commit was made after 1000 queries. As base operating system Ubuntu 11.10 was used with database engine PostgreSQL 9.1.1. Hardware was Dual CPU Intel U7300@1.3GHz, 4GB RAM@800MHz, internal SATA and external SATA 3Gb/s 320GB 16GB cache data hard disc drive. All measurements were executed on installed operating system in real environment.

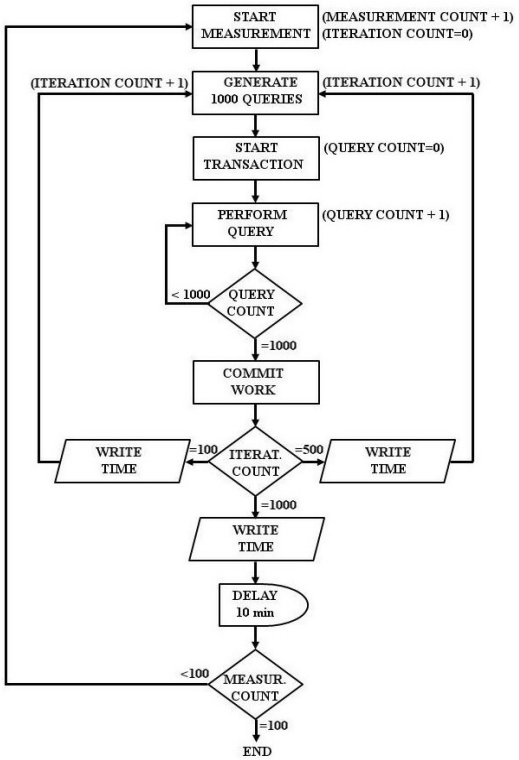

Figure 1. Testing methodology alogorithm

Measurements were made on exactly the same partition using 10% of the data hard disc drive. Partition was formatted to tested file system. Every measure was performed according to algorithm shown in figure 1.

One hundred measurements were taken for every file system using one of three actions: insert (write), select (read) or delete. Between measurements pause was made precisely 10 minutes to allow operating system to perform other activities. Every measure was consisted of 1000 iterations.

Iteration was one database transaction. Database transaction was timed. One database transaction commits 1000 database operation. Sum of transactions time was taken for 100 iterations (100000 rows), 500 iterations (500000 rows) and 1000 iterations (1000000 rows). Average size of all measures was calculated with isolated maximal deviations.

V. RESULTS

First set of results were obtained using the write, read and delete actions on Ubuntu operating system using PostgreSQL database management system. File systems that were measured include: ReiserFS, NTFS-3G, FAT32, EXT2, EXT3 and EXT4. Measurements illustrated very similar results. According to obtained results it is hard to recommend the fastest file system storage option.

In computer engineering, a cache is a component that transparently stores data so that future requests for that data can be served faster. The data that is stored within a cache might be values that have been computed earlier or duplicates of original values that are stored elsewhere. If requested data is contained in the cache (cache hit), this request can be served by simply reading the cache, which is comparatively faster. Otherwise (cache misses), the data has to be recomputed or fetched from its original storage location, which is comparatively slower. Hence, the greater the number of requests that can be served from the cache, the faster the overall system performance becomes. In case of our measurements several level of caches are enabled. Level will be considered from lower to higher implementation complexity.

Disk buffer called disk cache or cache buffer is the embedded memory in a hard drive acting as a buffer between the rest of the computer and the physical hard disk platter that is used for storage. This cache is performing similar actions as it is not directly depended upon file system implementation source code.

Second level consists of file system implementation code. Because this code is specific to file system, the effort will not be taken to disable specific implementation details. Many file systems do have options which can be used to tune specific implementation. Due to complexity of these options default implementation of the file system will be used in case study for measurements.

Third level is consisted of operating system call implementation code in operating system kernel. Assumption was made that this cache is responsible for obtaining similar results on Ubuntu. Extended search did not reveal any working method to disable this cache. Other approach was adopted to force database engine to bypass operating system disk cache. PostgreSQL database engine has an option to bypass operating system cache (O_DIRECT-direct I/O write) [17][18][19].

Fourth level applies to database engine cache. The effort to disable this cache was not taken due to believe that randomizing the data streams imply on vanishing influence on the result.

Due to PostgreSQL implementation limitation on Ubuntu Linux operating system cache could not be bypassed. New measurements were taken on Solaris, Open Indiana build 151a with PostgreSQL 8.4 database engine on same hardware. Testing methodology described in chapter 4 was applied. Figure 2 presents write action on Solaris operating system using PostgreSQL. Figure 3 represents read action in same circumstances. Figure 4 represents delete action. Graphs show execution time according to number of queries on different file system. Measures were taken on different operating system file systems: NTFS-3G, FAT32, EXT2, EXT3 and native ZFS.

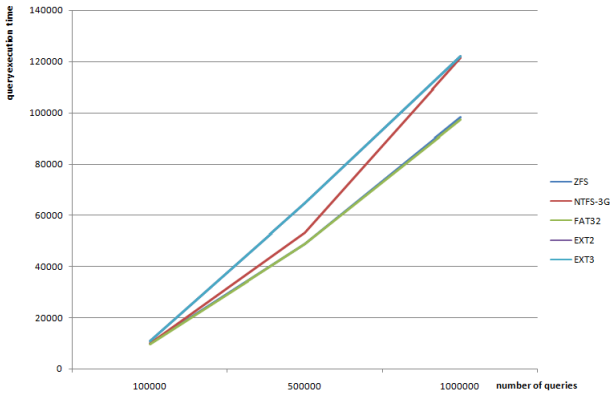

Figure 2. Solaris write (execution time according to number of queries on different file systems)

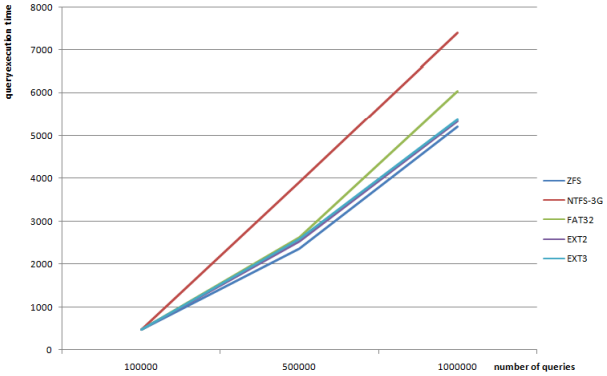

Figure 3. Solaris read (execution time according to number of queries on different file systems)

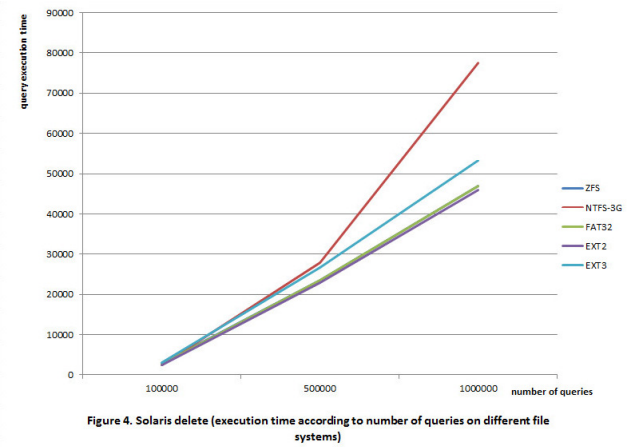

Figure 4. Solaris delete (execution time according to number of queries on different file systems)

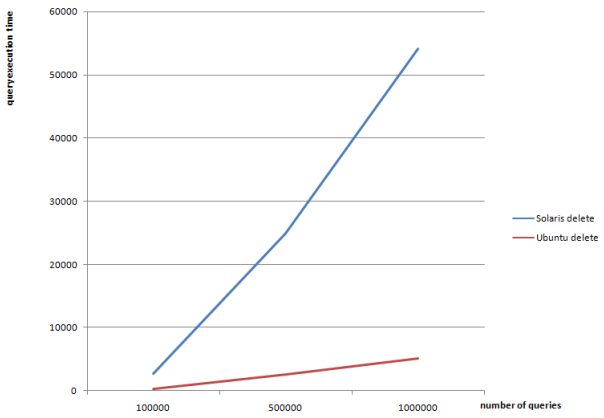

Figure 7. Solaris vs. Ubuntu delete

The large differences can be seen on figures 2-4. It was asumed that older file systems were faster than newest. This assumtion is based on code complexity of the newest file systems and on fact that hardware is more advanced today resulting in better performance rate for older file system today [20].

Further analization was tried to present differences beetwen system with and without the filesystem cache. Average of all measurements on different filesystem ware taken dependetly on cache (Ubuntu) or no-cache (Solaris) performance. Graphs show execution time according to number of queries. Graphs are presented in figures 5-7.

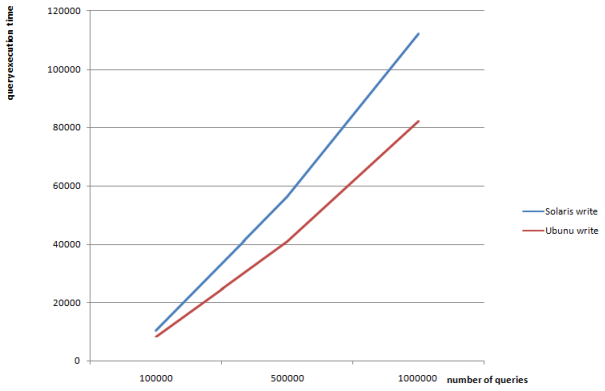

Figure 5. Solaris vs. Ubuntu write

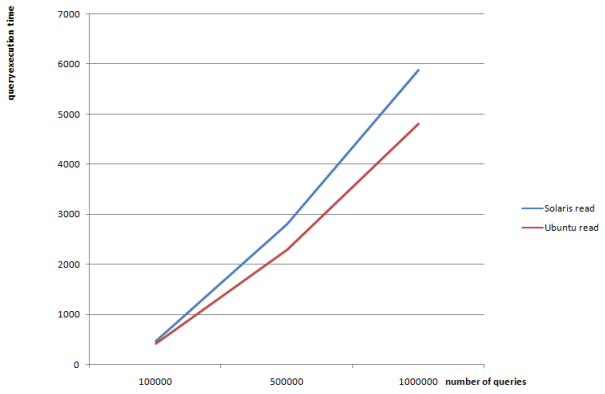

Figure 6. Solaris vs. Ubuntu read

Using graphs 5-7 it could be concluded that system with operating system cache is faster. Based on previous assumption it could be concluded that file system choise does not effect database performance.

VI. SUMARY

Today databases are widely spread in many application even in very specific surroundings ex. embedded system devices. Different surroundings require different approaches in hardware. In some cases file system speed could make differences in device viewed from user perspective. The main goal of this paper is establishing major differences between common file system storage options for database management systems.

First measurements showed that the operating system cache makes significant influence in database operations. If operating system cache is disabled differences in database query execution time according to file system storage can be perceived. Figure 2-4 confirms that older file system is the fastest file system due to code complexity (journal) of the newest file system [20]. ZFS is file system designed with different approach especially for Solaris operating system on which the performances were measured. Unfortunately when cache and no-cache graphs are compared favors goes to cache solution as it is significantly faster than no-cache solution. Finally, it could be concluded that there are no significant differences in file system storage speed performance in modern operating systems on modern database engines.

In future some other file systems could be measured to confirm this assumption. Also, it would be interesting to see differences in operating system cache performance between different operating systems.

Abstract – The peaks in energy consumption arise when a number of consumers start to run within a relatively short period of time. In the case of large consumers, this can lead to an overload of the electro-energetic system. In order to avoid such scenarios, the consumers have to pay peak load additionally. The share of this cost in overall costs for electricity can be significant, up to 50% for smaller production plants with discontinuous production. For large consumers, peak load costs usually do not exceed 30% of total costs for electricity. In order to reduce the peak load, it is necessary to provide consistent power consumption that is without major short-term peaks. The paper presents several examples of microcontroller based systems for peak load reduction.

I. INTRODUCTION

The rationalization of electricity consumption is an imperative nowadays. It is economically more justified than investment in the construction of new power generating capacities and associated facilities and services [1]. The overall electricity costs consist of two main components: the energy costs and the power costs (peak load). It can often be significantly reduced with minimal technical efforts. Decreased energy costs can be achieved by permanently diminishing excessive energy consumption, or by shifting the energy import from the high tariff periods to the less expensive low tariff periods.

The power costs imply the peak load, which is the maximum average power load over a designated interval of time (15 minutes). They can be significantly reduced by means of just a few short, targeted interventions at the right point in time. For example, postponing the energy import for only several minutes can lead to significant peak load reduction in some cases, whereas the effects on the production process are minimal. This short-term redistribution of imported energy is usually executed automatically using the peak load reduction systems.

Peak load reduction systems must be fully synchronized to the power utility's measuring period, i.e. 15 minutes interval. The redistribution of energy within the single measuring interval does not result in any savings, since the average peak load is charged, not the instantaneous power peaks. It also becomes apparent that, under certain circumstances, single 15 minute interval of unusually high energy import resulting from coincidental, concurrent start-up of specific equipment units may drastically increase power costs for an entire month.

The objective of peak load optimization is to avoid exceeding one or more specified chargeable demand set-points. This means that energy made available during any of the power utility's measuring periods must be limited to a fixed value. In this way, the optimization system actually limits the amount of imported energy during high demand measuring periods by shutting down certain power consumers, which is then compensated in the subsequent period. An extensive analysis must be conducted in order to determine which power consumers can be shut down at the specified point of time, so the production process is not disturbed.

The peak load reduction systems should provide accurate and timely energy import data in order to make correct decisions. Usually, these systems are realized as complex control systems, including software solutions that can present information about the energy and power consumption and utilization of production equipment to the end users in a user-friendly manner. With the help of menu-driven parameters configuration, user-specific control strategies (load, time or event dependent) can be conveniently selected and limit values can be specified and modified during operation.

Whether or not it makes sense or is economical to implement a peak load reduction system must be clarified in detail for each individual case. Potential savings in this area remain unexploited at many companies. In addition, the system to be utilized should be intelligent and adaptable to accept the future requirements, and should have adequate capacity in order to assure that potential savings can be taken advantage as long as possible.

II. MICROCONTROLLER BASED SYSTEMS FOR PEAK LOAD REDUCTION

A microcontroller is a single chip that contains the processor (CPU), non-volatile memory for the program (ROM or flash), volatile memory for input and output (RAM), a clock and an I/O control unit. Microcontrollers are designed for embedded applications, in contrast to the microprocessors used in personal computers or other general purpose applications.

Two different types of microcontroller based systems for peak load reduction will be described in this paper; one

based on MC68HC11 microcontroller [2], and the other one based on microcontroller PIC16F877A.

III. THE SYSTEM FOR PEAK LOAD REDUCTION BASED ON MC68HC11 MICROCONTROLLER

A. Hardware Setup

A distributed control system (DCS) was developed at the Department of Industrial Informatics, Mining and Metallurgy Institute in Bor, Serbia for the purpose of peak load reduction. The portable measuring station (PMS) designed as a typical compact mobile measuring device is used as a core of the DCS [3]. In functional point of view, it is an autonomous unit, which is used with the aim of data acquisition and command execution. The PMS overall block diagram is shown in Fig. 1. The CPU module is the one-board computer containing the MC68HC11 microcontroller shown in Fig. 2. Although the PMS can be an autonomous unit, it is more frequently used as a node in a simple network (forming an entity), which contains PMS and PC workstation (WS). The complex communication subsystem was developed on both sides for efficient entity functioning.

Main characteristics of the PMS are: microcontroller Motorola 68HC11E, internal eight channel, 8-bit A/D converter, 8 analog inputs, 4 + 4 digital state signals (input + output) with mutual point (or independent), RS232 communication port, 48 (56) KB for data (RAM), 16 (8) KB for software (EPROM), LC display and functional keyboard (shown in Fig. 3). The PMS motherboard with I/O modules connected is shown in Fig. 4.

B. Software Setup

Working as an autonomous data logger, the PMS can store over 3000 data messages in the local RAM, and transfer them to WS later. The source code of its control program is written in the symbolic Motorola language. For that purpose a special environment of ∏-assembler [4] was used. The EPROM of the PMS holds residential software, which acts as an executive system. It consists of executable versions of test, control, operational and communication software modules.

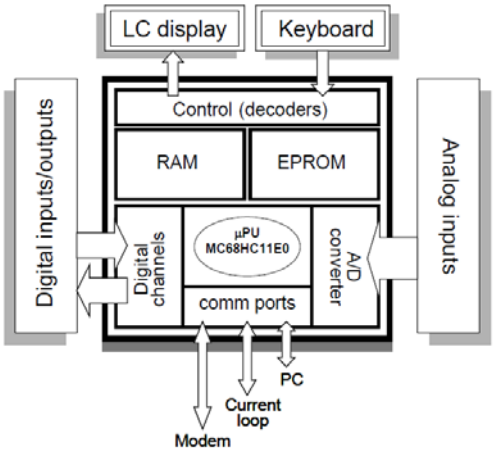

Figure 1. The PMS functional block scheme

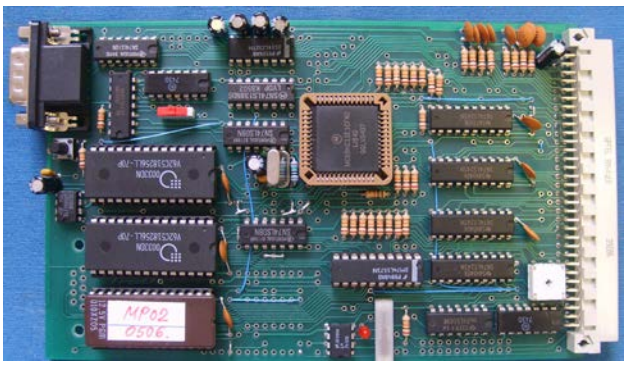

Figure 2. The PMS CPU board based on MC68HC11 microcontroller

Operational program module is responsible for measuring of analog channels and checking the states of digital inputs. The type of measuring, sampling rate and other parameters can be configured using local keyboard, or commanded from the supervising WS. The PMS status and measurement results are transferred to WS, or stored in local memory.

The PMS performs peak load limitations according to algorithm developed for this purpose. The output current signals (4-20 mA) from the power transducers (associated to large consumers that are of interest) are led to analog inputs of the PMS. In such a way it is possibly to monitor and control the energy consumption (based on the cumulative measurements of electrical power only). The PMS calculates average minute values of electrical power and forms cumulative, which are compared to limits given by the algorithm. Comparison is performed starting from the 7th up to 15th minute. The result of the comparison generates adequate action: “do nothing”, or (suggest) “switch off” the desired consumer.

C. Network setup

Special SCADA (Supervising Control and Data Acquisition) software named PLCP (Peak Load Control Program) is developed for the purpose of visualization and remote control of peak load reduction process. The PLCP enables the peak load reduction with large scale of facilities.

Figure 3. The PMS (front panel view)

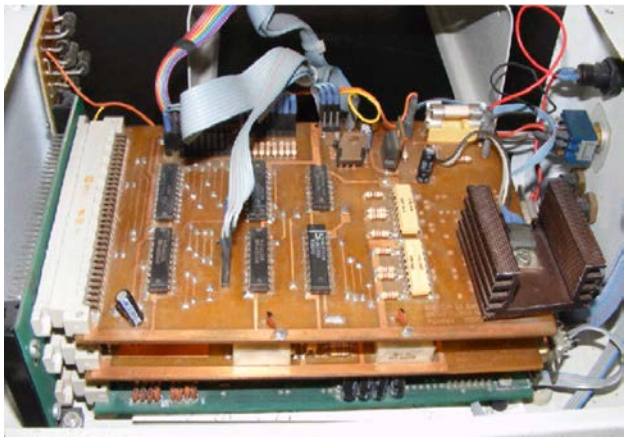

Figure 4. The PMS motherboard with I/O modules connected

It has client/server architecture and operates under Windows XP operating system. The PLCP was developed in the Microsoft Visual C++ development environment [5]. The PLCP communication module contains driver to support the networking with PMS. Communication protocol is ASP (Asynchronous Serial Protocol) [6]. It fulfills the following objectives: request for communications, connection establishment, data transfer and transfer quality control, network node status indication and examination. The communication on the PMS side is handled by its operational program. Communication module is one of the most important modules of the executive system. It is responsible for information transfer between PMS and PC workstation. The PMS is a slave node and the communication session starts as a stochastic event. This is the main reason why data transmission has the highest priority level compared to other PMS functions, provided by priority ordering mechanism [7]. The main step in communication initialization is programming of serial I/O for the desired operational regime. It is performed by execution of the procedure that prepares PMS to detect communication interrupt request. When the interrupt request is detected, current process stops running and communication service routine takes place instead. Actual command from WS can be received, and appropriate response sent back. The response can be the PMS status, remote command execution status, measured data, or all of them.

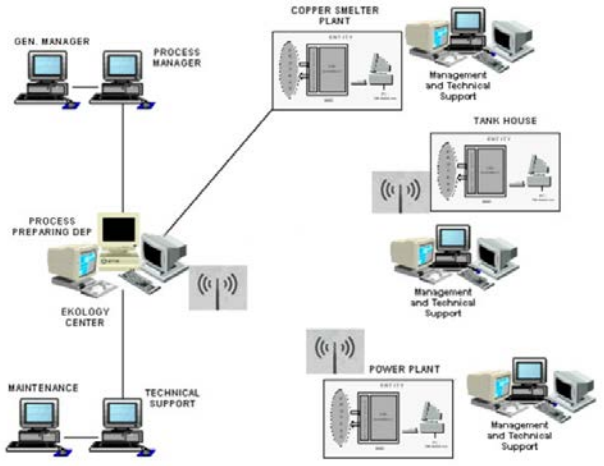

Figure 5. The block scheme of realized industrial network

During the data transfer (in both directions) the PMS operational program is busy and can not perform usual tasks such as measuring or process control. In some cases data transfer can take more then 50 ms per session. To increase the measuring and control efficiency the communication message can be shortened. In such cases the measuring performance of the PMS becomes more efficient and response time is improved. Data transfer can be performed in less then 5 ms, allowing PMS response time of 10 ms. The PMS working regime, the communications mode and frequency (polling rate) may be configured from the PLCP drop-down menu, or locally on the PMS. The PMS digital output channels are used to generate the command signals to activate some actuators (relays, contactors, solid state switches etc.) to switch off appropriate aggregates or to block switching on new consumers.

The realized PMS and PLCP are applied mainly in metallurgy industry. Production plants are often dislocated in a several kilometers wide area. To cover the main production plants and control peak load in the real-time, it is necessary to realize complex industrial network [8, 9]. The basic network nodes are entities consisted of the PMS and the WS. The configuration of a typical realized network is shown in Fig. 5. The WS is a server in network configuration, running the appropriate PLCP (shown in Fig. 6). The remaining network nodes (clients in network configuration) are running a passive version of the PLCP called Remote Peak Load Control Program (RPLCP). The RPLCP is used for distant monitoring only, without having the possibility of sending commands to PMS.

IV. THE SYSTEM FOR PEAK LOAD REDUCTION BASED ON PIC16F877A

The PIC16F877A CMOS FLASH-based 8-bit microcontroller [10] is upward compatible with the PIC16C5x, PIC12Cxxx and PIC16C7x devices. It features 200 ns instruction execution, FLASH program memory 8KB, 2 comparators, 8 channels of 10-bit A/D converter, a USART, and a parallel slave port as shown in Fig 7. All of these features make it ideal for more advanced level A/D applications in automotive, industrial, appliances or consumer applications. As it has most of the necessary peripherals on-chip it is suitable for applications on a single chip.

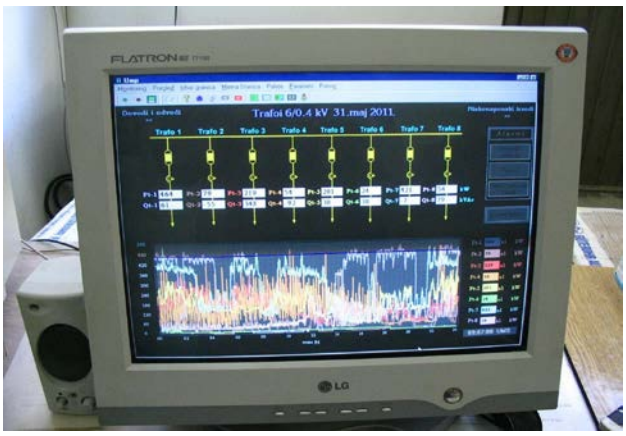

Figure 6. PLCP sinoptic screen

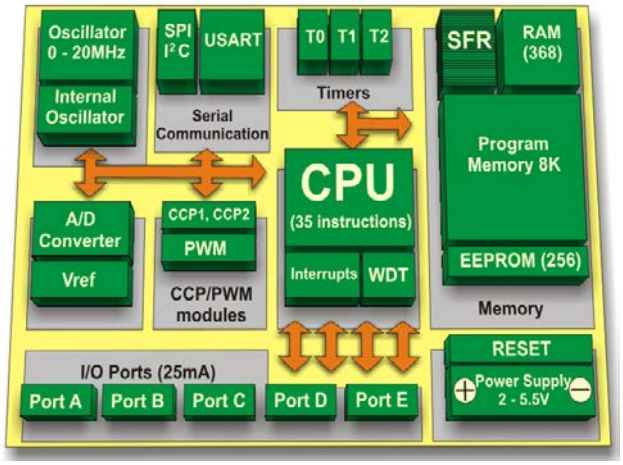

Figure 7. The PIC16F877A basic features

The special development board based on PIC16F877A microcontroller (shown in Fig. 8) was designed and realized containing electronic circuits for programming, communication, I/O drivers, switches and LC display. Part of the electric scheme with the connections of relay outputs, analog inputs, and communication with PC is shown in Fig. 9.

MPLAB Integrated Development Environment (IDE) is usually used for the development of embedded application for PIC microcontrollers. MPLAB IDE is the Microchip's application that runs under Microsoft Windows operating systems and includes code editor (supports assembler and C languages), simulator with the debugger, and project manager.

However, for the purpose of realization of system for peak load reduction a special development environment is realized for programming of PIC16F877A, named DLadder [11]. It is developed in Borland Delphi 7 and features programming using ladder logic and their compilation into PIC16 and PIC18 object (native) code. Ladder logic is a programming language that represents a program by a graphical diagram based on the circuit diagrams of relay logic hardware, and it is very convenient in industrial control applications. A library of logical functions is developed for this purpose. The debugger and the real-time simulation are also realized, which allows displaying the contents of a microcontroller ports and memory locations in the real-time.

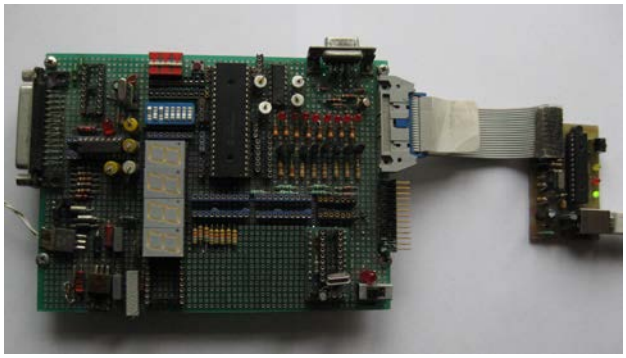

Figure 8. The development board based on PIC16F877A microcontroller with the programmer connected

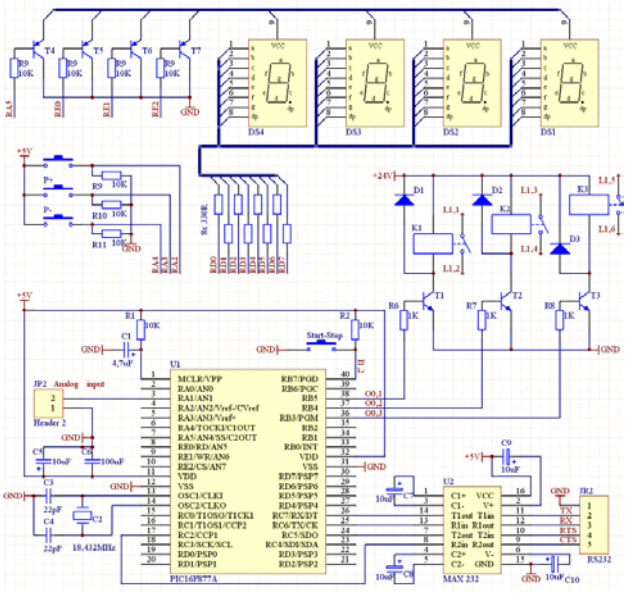

Figure 9. PIC16F877A development board electric scheme

The system for peak load reduction based on PIC16F877A can operate in the same manner as the previously described MC68HC11 based system. The algorithm is the same as described in section III B. The output current signals (4-20 mA) from the power transducers (associated to large consumers) are led to the analog inputs of PIC16F877A. The PIC16F877A digital outputs are used to generate the command signals to activate actuators to switch off the particular consumers. Special SCADA named PICCP (PIC Control Program) is developed in Borland Delphi 7 for the purpose of visualization and remote control of peak load reduction process. The PICCP contains driver to support the networking with PIC16F877A. PICCP enables configuration of operating parameters for peak load reduction and monitoring of consumption in real-time, as shown in Figs. 10 and 11. It also stores all relevant data in databases for later analyses.

V. CONLUSION

The objective of the peak load reduction is to avoid exceeding one or more specified chargeable demand setpoints. This means that energy consumption during measuring periods must be limited to a fixed value.

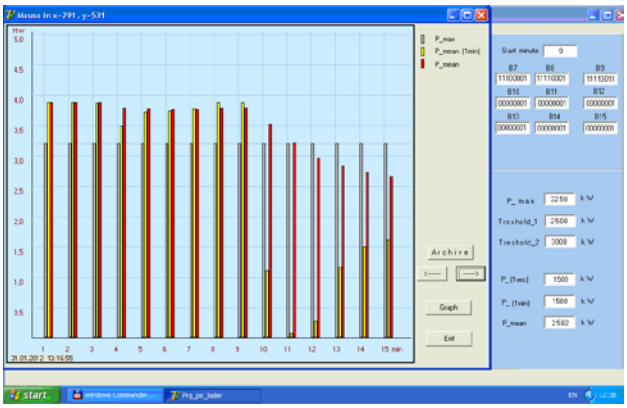

Figure 10. The real-time histogram during the measuring interval

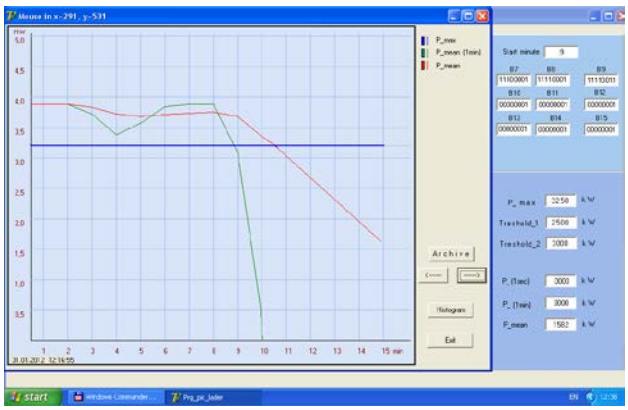

Figure 11. The real-time diagram during the measuring interval

The production process analysis must be conducted in order to determine which consumers can be shut down without disturbing the process. The examples presented here confirmed the applicability of the microcontroller based system in peak power reduction. Such systems can be used for local control, or as integral parts of the distributed control systems. The advantages of presented solutions are their modularity, ease of use, low price, and its applicability in different production processes. The described systems are applied mainly in metallurgy industry. They are equally present in the optimization of peak power of large consumers, as autonomous units, as well as an integral part of large scale systems. It is estimated that the achieved reduction in costs for the peak power, per application of such systems, is about 5-10% of total costs.

Protection relay software models in interaction with power system simulators

Ivan Goran Kuliš*, Ante Marušić** and Goran Leci *
* Končar-Power Plant and Electric Traction Engineering, Zagreb, Croatia
** Faculty of Electrical Engineering and Computing, Zagreb, Croatia
ivangoran.kulis@koncar-ket.hr

Abstract - Modelling and simulation software developed for analysing protective relaying applications and relay design concepts in power distribution is described in the paper. The intention was to develop an open system that is easy to use and allows simple future expansions. Easy to use presumes that the software should be suitable for teaching purposes. This is achieved by introducing new libraries of signal sources and relay elements developed in the MATLAB/SIMULINK environment. Combined with the SIMULINK/SimPowerSystems, the mentioned libraries enable a variety of studies aimed at better understanding protective relay design approaches and procedures and related applications in power system.

I. INTRODUCTION

In the MV networks in Croatia there are three ways of substation (transformer) neutral point grounding treatment: isolated, low-ohmic grounded and, from a couple of years ago, resonant grounded. Croatian MV distribution networks are mainly radially operated.

With an aim to define the criteria for appropriate neutral treatment selection depending on the substation and MV network type, an overview study has been conducted recently. Selection criteria in the study considered:

- Technical features of all three treatments concerning the earth-fault currents, overvoltages and network operation based on literature, measuring, computer analysis and operation experiences;
- Human safety requirements and rules (touch voltages), heath and voltage stresses and interferences with telecommunications lines;
- Network importance (number and type of connected customers), size (length of galvanic connected lines), type (cable to overhead lines ratio, type of poles and types of cable junctions and screens);
- Network reliability (SAIFI and SAIDI);
- Earth systems requirements concerning earthfault currents and soil resistivity.

Every criterion has been economically evaluated regarding capital and operation expenditure and then cost-benefit analyses have been made. The results of those analyses are criteria for adequate neutral treatment selection concerning mentioned features, requirements and rules.

The study also emphasized the need for rules renovation regarding a new way of operation and protection relay requirements as well as harmonization with European norms. The need for implementation of new protection methods and primary measuring equipment (current and voltage transformers) coordination have also been considered and analysed. The analysis performed and the results achieved are described in this article.

In the scope of the study, measurements of pre-fault and earth-fault currents and voltages were conducted in 10 kV and 20 kV distribution networks supplied from two HV/MV substations. Earth-faults were done with different fault resistances and types as well as by using different neutral point grounding methods: isolated, low-ohmic resistive and resonant.

II. CHARACTERISTICS OF SELECTIVE EARTH-FAULT PROTECTION IN DISTRIBUTION NETWORKS

Methods for selective detection of earth faults are based on measurements either of permanent or transient currents and voltages upon earth-faults occurrence. A special property of the isolated and resonant earthed networks is the rise in magnitude of the measured earth-fault current due to the contribution from healthy feeders, while feeder with the failure has no impact on it. Measurements of available currents and voltages in the event of an earth-fault, unless these values are not post processed, indicate the use of directional earth-fault protection. Because of compensation in resonant earthed networks, with reference to earth-fault current reduction, it is obvious that protective equipment, including transformers, must meet very high requirements. Most methods work under adverse conditions of the phase shift between current and voltage (~90°). Contrary to the measuring conditions during short-circuits, current transformers (CT) are often not adapted to deal with a small earth-fault currents. Adjustment is to be achieved by using ring-type (toroidal) transformers. These requirements are even greater in meshed than in radial networks because of earth fault currents spreading through branches.

Most commonly used numerical relays for selective earth-fault detection are:

- Neutral overcurrent relay (50/51N)
- Directional and sensitive directional neutral overcurrent relay (67N(S))

- Wattmetric and warmetric neutral relays (32P/QN)
- Neutral overcurrent relay based on higher (5th) harmonic
  This relay operation is based on the fact that in the resonant networks 5th harmonic is not compensated by Petersen coil. 5th harmonic is usually intentionally added upon earth-fault occurrence.
- Relay for static or dynamic comparison of neutral currents
  This relays operation is based on comparison of neutral currents or their changes. Neutral currents of different feeders connected on the same busbar are compared.
- Admittance and conductance neutral relays
  This relays operation is based on comparison of neutral admittances/conductance's changes.
- Transient relays
  This relays tracks and compares voltage and currants wave shapes at earth-fault occurrence.

III. RELAY MODELLING

Protective relays together with current and voltage transformers are a substantial part of the power system. Protective relays rapidly isolate faulted part of the system which allow system stability and undisturbed power supply for most customers. Incorrect operation of protective relays can have adverse consequences for continued power supply. Developing, using and teaching protective relay application and design concepts assumes multidisciplinary approach comprising among others power system physics, mathematical formulations and electronic devices. Majority of components that constitute a modern electrical power system have been successfully modelled for transient studies for more than forty years. The exception is protective relaying. Progress in modelling of power relays in transient analysis appeared in the last twenty years.

Electrical faults, switching actions and other power system disturbances, cause a redistribution of the electric and magnetic energy stored in capacitive and inductive elements and mechanic energy stored in rotational elements of the network. This redistribution of electric energy cannot occur instantaneously and the power system must undergo through a transient state before it reaches a new steady state. During the first few cycles following a power system fault, high-speed protective relays are expected to make a correct decision as to the presence and location of the fault in order to preserve system stability and to minimize the extent of equipment damage. The majority of protective relays make their decisions based on fundamental frequency (50 Hz or 60 Hz) voltage and current signals. However, it is precisely at this moment that the voltage and current signals are badly corrupted by fault-induced transients in the form of an exponentially decaying dc component, and with frequencies above and below the fundamental power system frequency. The dynamic performance of protective relays depends to a large extent on their design principle that addresses things such as selectivity, sensitivity, security, and dependability. In addition, the dynamic performance of high-speed protective relays depends to a large extent on the signals produced by instrument transformers, and these signals depend on the overall transient response of the instrument transformers, and the type of transients generated by the power system [1, 2, 3].

Relay software models are useful for relay manufacturers, utilities, customers and also for educational purposes. In general, manufacturers use more sophisticated models to support development and presentation. Representatives of manufacturers can explain the behaviour of the relays to their clients with the help of relay models using input from network simulation programs or from power system transient recorders.

Depending on the purpose they serve it is possible to create more or less sophisticated relay models. Simple models use only mathematical equations to describe the pick-up and tripping characteristics of the relays. These models can be used to make general decisions for the selection of relay types, and together with network calculation programs they can be used to derive relay settings.

More sophisticated relay models are much more comprehensive. They process voltage and current transient waveforms from emtp simulations, actual fault waveforms captured by numerical relays, or digital fault recorders. This way user can observe their response to these transients and reaffirm the protection behaviour during network disturbances.

IV. RELAY MODELLING IN MATLAB

Matlab has been selected as programming environment for protective relaying software modelling for the following reasons:

- Matlab is well recognized as one of standard tools for protective relay modelling in industry and in university environment [1, 2, 4].
- Matlab has powerful calculation and visualisation tools and enables fast and efficient software expansion without developing any extra programming tools.
- Matlab and its time domain solver Simulink create an open and user friendly system. They provide libraries, models and programs enabling integration of different model components. New models and libraries can be easily added.
- Simulink and SimPowerSystems allow fast development and closed-loop testing of protection and control systems used in power systems and drives. This is important since actual power systems and their protection systems operate in a closed-loop manner [2, 5]. SimPowerSystems enable modelling of power system components. It provides computations and analyses similar to other electromagnetic transient programs permitting modelling of the power systems and its controls in the same environment and thus, facilitating closed-loop simulation.

The (earth-fault) relays are modelled so that the general working principles of protection systems can be demonstrated. The interaction between network

calculation program and software protection system models is achieved. Closed-loop simulations of relay software models with an electromagnetic transient simulation enables evaluation of the transient behaviour of the protective relaying algorithms due to changes and switching in the network. Different protection settings and their consequences on the protection behaviour are possible as well as protection coordination analysis. In this manner the application of relay models can effectively support the education of students and engineers.

Intention is to develop relay software modelling for relevant testing prior the building of a prototype relays. This is essential in the development process because, it allows testing of various relaying algorithms, the relay logic, and to make necessary changes without the need to make changes in hardware or software modules of the actual device. Relay algorithm development enables use of relay software models to test different digital signal processing techniques, protection algorithms, the transient response of digital filters, phasor estimating methods, directional or distance element unit performance and evaluation of new measuring techniques.

Of course, all previously mentioned cannot completely replace tests with the actual protection devices in a real environment. Whatever degree of detail is used in a model, the engineer must be aware of the limitations of the model. Failure to bear this in mind is a well-known weakness in all design studies based on models [3].

V. DISTRIBUTION POWER SYSTEM MODEL

Within Matalabs Simulink environment, SimPowerSystems are selected as a design tool for modelling and simulating a distribution power system. In Simulink environment it is possible to model and simulate the total system by combining SimPowerSystem with control system tools. This allows optimisation of control parts of the model. Accurate and fast real-time simulations are possible by using variable step integrator and zero crossing detection capabilities.

The system is modelled according to the two real radial distribution networks in which earth-fault tests were done. Current and voltage measured records from tests are used for model calibration and also as a signal source for testing the relay models.

Earth-fault and resonant curve field tests have been conducted in the substations 110/20 kV Botinec and 110/10 kV Velika Gorica. Tests consisted of earth-faults over different fixed resistances (1÷5 Ω, 1, 4 and 10 kΩ) and in different conditions (phase wire fell on dry and wet ground, phase wire fell on trees, transient faults simulated with variable spark gap) at few places in the networks with ungrounded, low-ohmic grounded and resonant grounded neutral points. Earth-faults with resonant grounded neutral points have been done with different tuning of Petersen coils with and without shunt resistor (connected on secondary winding). Resonant curves were also measured and recorded.

MV networks supplied from these substations are mostly wide spread semi urban radially operated, with only a few meshed branches. This kind of network was considered as most interesting for resonant grounding method implementation. It is because these networks have 8 to 12 feeders on one bus-bar system, with total sum of 100 to 300 A capacitive currents, large numbers of short and long supply interruptions and a lot of households and small industries connected and with ~21 MVA of average peak load.

Modelled distribution network with wattmetric relay (red box) on feeder 1 is shown in Figure 1. Earth-fault is simulated on phase A of feeder 1.

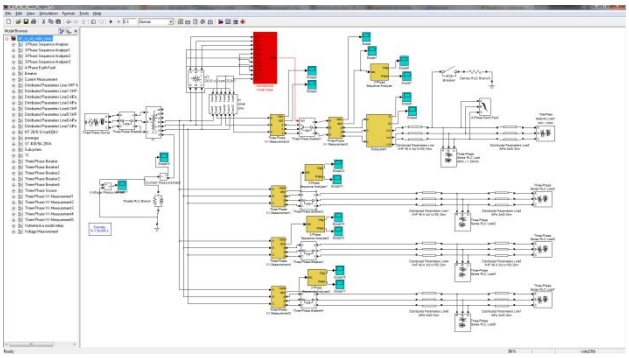

Figure 1: Radial distribution network modelled in Matlab

VI. RELAY MODELS

Erath-fault relays are modelled as generic numerical relays. In Matlab/Simulink environment, relays are modelled in the function blocks as it is shown in Figure 2.

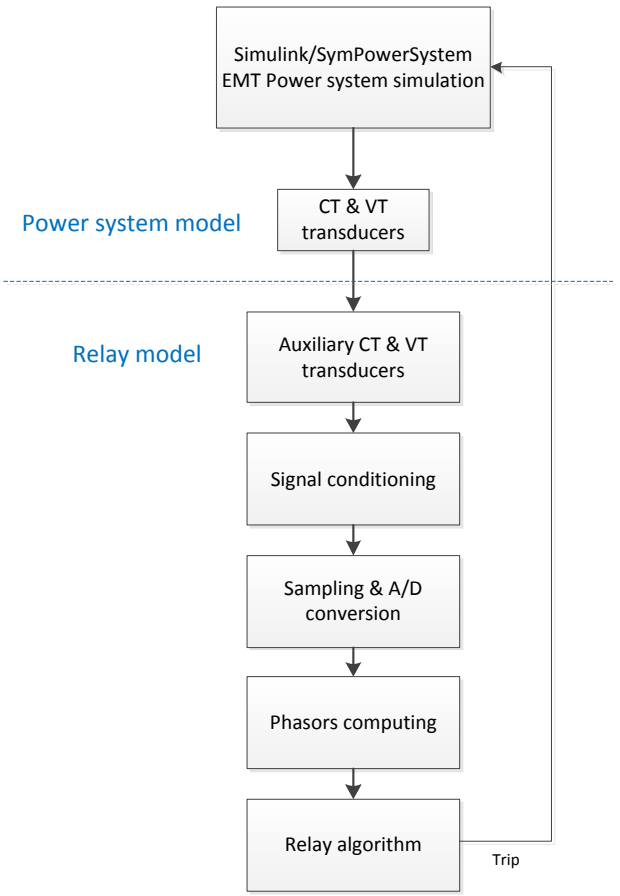

Figure 2: Power system and relay device model presented in the function blocks

Power system model

Power system is modelled in Simulink environment by use of SimPowerSystem and other Simulink library elements.

SimPowerSystem is a design tool for modelling and simulating electrical power systems within the Simulink, allowing a power system model to be built in an easy manner. It is a powerful solution for modelling the electrical power system, especially when designing associated control and protection systems. The library contains blocks that represent common components and devices found in electrical power networks. The blocks are based on well-known electro-magnetic and electro-mechanical equations. The libraries contain models of typical power equipment.

Distribution system is mostly modelled by common library elements with minor modifications where necessary, as for example with arc model. Even though to Matlab is inherent slower power system simulation (compared with EMTP (ATP) [1]), this drawback is negligible since the distribution model does not present large system.

Measuring (instrument) transformer models

Power system high voltages and currents cannot be directly applied to the relays. Therefore, voltage (VT) and current (CT) transformers reduce power system voltages and currents. In Croatia distribution system voltages are typically reduced to the nominal value of 100 V and currents are reduced to the nominal value of 5 A or 1 A.

Special attention has been paid to the CT modelling regarding the CTs DC saturation effect (noticed and recorded during the earth-fault tests with resonant grounding and small fault resistances, Figure 3) has a great impact on earth-fault protection. With increase of the fault resistance the time constant decreases and the saturation DC component is not so effective so the problem becomes less noticeable. Therefore, it has been recommended [8] that with resonant grounding ring type current transformers should be used in all bays for earth-fault protection. It is expected that the ring type CTs will not have the saturation problem as significant as phase CTs. In addition, a resistance can be added in a series with Petersen coil by adding a suitable resistor or by increasing the copper loses of the coil. With the series resistance the defined higher limit of time constant can be ensured.

Both types of CTs (phase and ring) have been modelled in appropriate detail.

Auxiliary transformer models

Numerical relays cannot process 100 V of nominal voltage during normal operation and currents of few tens of Amps during faults. The voltages are usually reduced to within 5 V to 10 V range so that the electronic components are not damaged. The voltage reduction is achieved by using either auxiliary VTs or resistance dividers. Since these devices operate in their linear range, proportionality factors are used in the relay models.

Auxiliary CTs are used to reduce the levels of currents applied to the relay. The outputs of the auxiliary CTs are passed through precision resistors. Voltage drops across the resistors are used to represent currents. If no saturation is expected, modelling the CT and its burden is an easy process.

In general, the relay input auxiliary CTs may saturate adding to the complexity of modelling and analysis. But, saturation of relay input auxiliary CTs may be neglected because: the secondary current is substantially reduced under severe saturation of main CTs. Moreover, saturation of the main CT makes the secondary current symmetrical eliminating the danger of exposing the relay input auxiliary CT to decaying DC components. The secondary current has a form of short lasting spikes and this limits the flux in the cores of auxiliary CTs. Therefore, auxiliary CTs are not modelled as saturable ones.

But, it is fair to mention that some authors recommend that saturation modelling of auxiliary CTs, including saturation due to low frequency signals, should be made in the relay models.

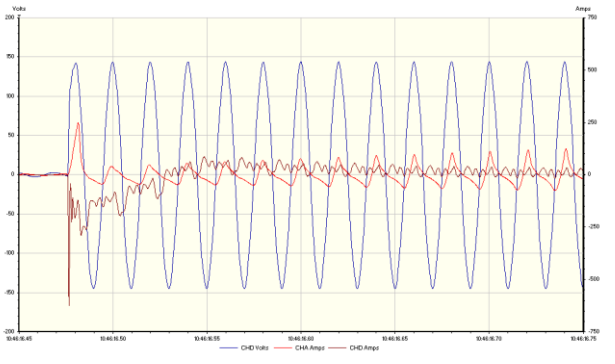

Figure 3: Neutral point voltage (blue), "faulted" line zero current (brown) and current trough Petersen coil (red) during earth-fault over 1 ohm

Signal conditioning

Currents and voltages applied to numerical relays during faults contain components of high frequencies. Most algorithms of numerical relays are adversely affected by signal components of high frequencies. Some high frequency components are also likely to seem to be of the fundamental frequency because of aliasing. Therefore, low pass filters are used in numerical relays. These filters are analog devices. Typically, a second order filter is used with a cut-off frequency about three times less than of the sampling rate. For modelling standard analog low-pass filter, Simulink low-pass filter block is used with parameters of method, order and edge frequency.

Sampling and A/D conversion

Numerical relays convert the analog information to numerical form using sampler and analog to digital (A/D) converters. A/D conversion process can be considered as a two-stage process consisting of a sampler and a quantizer.

At the first stage sampler creates the sequence s(n) by sampling the analog signal s(t) at regular intervals of ΔT seconds. This part of the process is usually considered accurate and without any addition of errors.

The second stage expresses each sample of the sequence s(n) by a finite number of bits giving the sequence $s_q(n)$. The difference between the elements of the sequence $s_q(n)$ and s(n) is the quantizing noise (it is also called A/D conversion noise). The quantizing process either could truncate the signal as it converts the analog information to numerical form or could round it.

The quantizer stage of a relay model may be skipped for some cases. Depending on the accuracy requirements of the relay model, the values obtained from the sampler may be directly used for phasor calculations and for modelling relay algorithm and relay dynamics.

A/D converters have a double impact. Any converter has a limited conversion range where signals above a certain level are cut off. The conversion range of the numerical relays is typically in the range of 10 to 50 times. For example, some relays cut off the inputs at 200 A secondary peaks while the rated current is 5 A.

The second aspect related to the A/D conversion is a limited sampling rate. Modern relays sample at rates up to 128 samples per cycle. As heavily saturated CTs produces signal pulses of short duration, location of A/D samples on the waveform plays an important role.

Phasors computing

Electromagnetic transient analysis programs calculate voltage and current waveforms as functions of time. So, it may be necessary to convert the sequences of the values of voltages and currents to their equivalent phasors as functions of time.

For example, if a transmission line model is used by a numerical relay for detecting line faults, it would not be necessary to convert the sequences to phasors. On the other hand, numerical distance relays that compute apparent impedance have to compute phasors. The same is with the majority of the distribution earth-fault relays.

Phasors computing can be done by using one of the several signal-processing techniques. Two commonly used techniques are Discrete Fourier Transform (DFT) algorithm and Least squares algorithm. In this project, phasors are computed by Simulink standard DFT element.

For example, overcurrent function calculates current magnitude from unpolished signal samples. Process of estimation prior Fourier RMS estimation can include digital filtering for DC offset removal. If the only fundamental frequency (50 Hz) is extracted from waveform through filtering process, this would result in a lower magnitude with heavily distorted waveforms than it is case when the total magnitude (true RMS) from entire signal spectrum is extracted.

Relay algorithm

In many cases, the modelling of numerical distribution relay algorithm is not a complicated procedure. For example, a trip command of an overcurrent relay has to be issued when the current is greater than the relay setting. In this case, the modelling is consisted of comparison of the calculated impedance with the set value and issues the trip command if the calculated value is greater than the setting. In addition, algorithm security can be realised requiring several consecutive checks for trip confirmation.

In some relays, an appropriate time delay has to be incorporated. For the definite time delays the modelling is an easy process. The procedure commonly consists of the following steps:
1. Start a timer when a trip command is indicated.
2. Check the trip criteria after the next iteration is performed by the analysis program.
3. Increment the timer if the trip criterion is satisfied.
4. If the trip criteria are not satisfied, either decrement the timer or reset it. The decision should be based on what the relay being modelled is designed to do.
5. Check if the desired time delay has elapsed or not.
6. If it has, model the tripping of the appropriate circuit breakers. Otherwise, revert to step 2.

The modelling of inverse-time delays, such as in inverse-time overcurrent relays is somewhat more complicated.

In Figure 4 an earth-fault overcurrent definite time (51N) relay model is shown. Model consists of:

- Input circuit comprising auxiliary CT and analog filter
- A/D converter with digital filter
- Discrete Fourier transformation module and
- Comparator with time delay component.

In Figure 5 output of this relay by components is shown. The picture shows from up to bottom respectively: three phase current waveforms, 3I0 earth-fault waveform, earth-fault waveform after filtering, earth-fault current RMS of base harmonic (50 Hz) and relay module pick-up and trip signals.

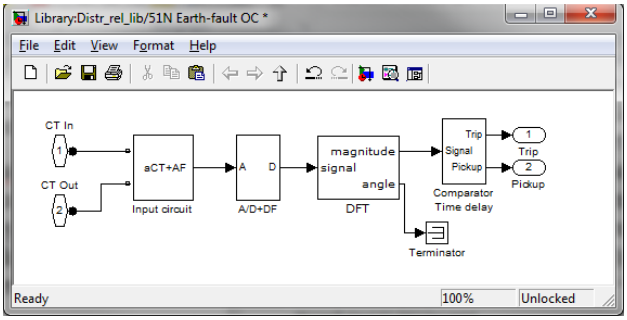

Figure 4: Definite time earth-fault relay model

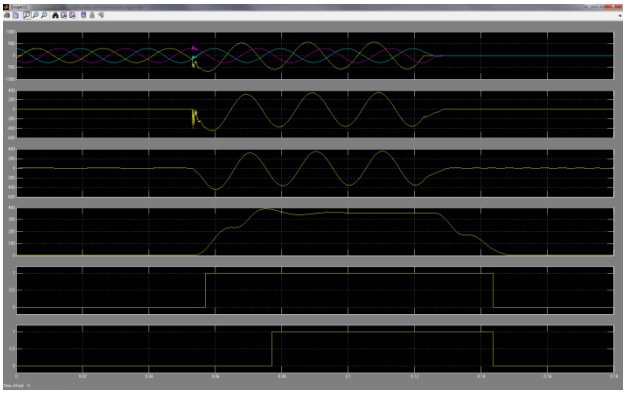

Figure 5: Earth-fault waveforms and earth-fault OC relay outputs of modelled system and relay

VII. RELAY LIBRARIES

As shawn in Figure 6, several models of earth-fault relays are modelled and stored in relay library.

Modelled earth-fault relays are: overcurrent (51N), directional voltage or current polarised directional (67N, 32U or 32I), directional sensitive or wattmetric/warmetric (67Ns, 32W) and admittance earth-fault relay.

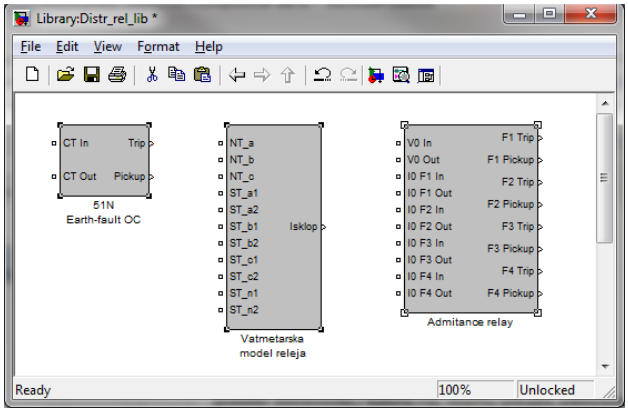

Figure 6: Earth-fault relay models library

Definite time earth-fault overcurrent relay is non-directional relay which compares measured or from phase currents derived earth-fault current with set constant value.

Inputs for traditional directional current polarised relay are $3I_0$ and I_{pol}, where I_{pol} is polarising current obtained from neutral point ground conductor [6]. So, this relay is only suitable for solidly or low impedance grounded distribution networks. It calculates torque (term derived from electro-mechanical relaying) based on magnitudes and relative angle of analog input quantities, Equation 1. Relay compares the result of calculated torque against set thresholds. If torque is positive and above the positive threshold, then relay determines a forward earth-fault. If torque is negative and below the negative threshold, then relay determines a reverse earth-fault.

$$T=|I_{pol}|\cdot|3I_0|\cdot\cos(\varphi_{Ipol}-\varphi_{3I0}) \qquad (1)$$

where:
$\mathbf{I}_{pol}$: Polarising current
$3\mathbf{I}_0$: = $\mathbf{I}_A+\mathbf{I}_B+\mathbf{I}_C$

Directional voltage polarised relay makes directional decision according to Equation 2. The relay compares calculated Z0 against Z0F and Z0R thresholds to determine the direction of the ground fault.

$$Z0 = \frac{Re[3V_0\cdot(1e^{j\theta_{L0}}\cdot 3I_0)^*]}{|3I_0|^2} \qquad (2)$$

where (* - complex conjugate):
$3\mathbf{V}_0$: = $\mathbf{V}_A+\mathbf{V}_B+\mathbf{V}_C$
$3\mathbf{I}_0$: = $\mathbf{I}_A+\mathbf{I}_B+\mathbf{I}_C$
Θ_{L0}: Line zero-sequence impedance angle

Directional wattmetric relay makes directional decision according to Equation 3. The relay compares calculated W against -w and +w thresholds to determine the direction of the ground fault. W < -w indicates a forward fault and W > +w indicates a reverse fault.

$$W = Re\left[\overrightarrow{V_o}\cdot\overrightarrow{I_0}^*\right] = V_0 I_0\cos\varphi_0 \qquad (3)$$

Earth-fault admittance relay algorithm is centralised and it simultaneously uses zero currents from all galvanic connected feeders (on the same busbar) and common zero voltage. It calculates zero asymmetry admittance for each feeder. Asymmetries occur as a consequence of asymmetries of feeder capacitances to the earth or of an earth-fault. Advantage is that it also calculates asymmetry admittance change d**Y**. This algorithm has two thresholds, an absolute Y_{as_max} and the sensitive one dY_{as_max}.

VIII. CONCLUSION

In this paper methodology for power system and relay modelling is described in accordance to the relevant literature. A distribution system and several earth-fault relay models are developed using user friendly open system environment Matlab and Simulink.

Developed comprehensive relay models process voltage and current transient waveforms obtained from electromagnetic transients simulations, actual fault waveforms captured by numerical relays, or from digital fault recorders. This way user can observe their response to these transients and reaffirm the protection behaviour during network disturbances.

In the future intention is to develop relay software modelling for relevant testing prior the building of a prototype relays. This is essential in the development process because, it allows testing of various relaying algorithms, the relay logic and to make necessary changes without the need to make changes in hardware or software modules of the actual device.

Abstract

Pipe rupture monitoring system on PSPP Velebit is the first installed microprocessor based protection and monitoring system of large diameteres penstocks in Croatia. It is based on high precision measurement method as well as on protection agorithm implemented in process controller. Paper describes system overview, mesurement method implemented in measurement units and protection algorithm implemented in process controllers. System implementation and future planned system integration are also shown.

I INTRODUCTION

Pipe rupture monitoring system is one of the most advanced methods of people and environment protection from water leakage from pipeline or from consequences of its rupture. System is based on ultrasonic flow measurement Rittmeyer Risonic2000 and two cubicles with automatization components connected by optic communication. Flowmeters are placed on the beginning (top) of the pipe section which is monitored and on its end (bottom). Data acquired by these measurements are compared and, in case they are unequal, alarms are sent or butterfly valve is shut. The thing which makes this system more interesting is the fact that it is installed on pumped storage power plant (PSPP). System needs to operate in both flow directions with high precision.

This paper is to pass experiences from system installation and system calibration, with special focus on integration in plant process information system and measurement data acquired during parameterization.

II FACILITY DESCRIPTION

PSPP Velebit is a facility which harnesses the water of the Ricica, Opsenica, Otuca and Krivak streams from the Gracac plateau in the south east part of the Lika region in Croatia. Lika region is located in the central part of Croatia at the altitude between 550 and 700m a.s.l. and is separated from the Adriatic Sea by the Mountain Velebit massif. The Velebit PSPP power house is located on elevation 11m a.s.l., by the Zrmanja River, in its downstream stretch, around 10km upstream the town Obrovac. The Velebit PSPP was constructed from 1978 to 1985, and it has been in regular operation since 1984. From the hydraulic and civil engineering aspect, the plant may be divided into three parts: upper reservoirs, pressure headrace structures and power house structures with auxiliaries and lower reservoir.

The entire capacity of upper reservoirs is $16{,}35 \times 10^6$ m^3 while the lower reservoir Razovac has a volume of $1{,}84 \times 10^6$ m^3. The water from upper reservoirs is conveyed to the power house through concrete pressure tunnel and steel penstock. The complete length of pressure tunnel is 8191m. The steel penstock, 3.9 to 3.3m in diameter, totalling in length 2108m has been routed between the valve chamber and the power house surmounting altitude difference of 549,15m. The penstock was made with no expansion joints, supported on friction bearings and 103 concrete supports with seven fixed anchored concrete points, so from the stress-strain aspect it behaves as the continuous girder. Upstream of the power house, the pipeline branches into two sections, each towards one turbine-pump.

Power house was fitted with two generating units which are designed for turbine, pump and compensation operating modes. Rating of each unit is 138MW in generation mode and 120MW in pump mode. Continuous state monitoring of steel penstock has a large importance due to fact that it has no pressure regulator at the end of the pipeline. When emergency shutdown in power house takes place, the pressure in penstock arises from 50 up to 120bars.

Possible damage of steel penstock can cause extremely dangerous situation for entire power plant as well as for local community. Due to these reasons investor has decided to install the last generation equipment for ultrasonic flow measurement and pipe rupture monitoring.

III PIPE RUPTURE MONITORING SYSTEM

Pipe rupture monitoring system has the function to alarm or react in cases of leakages or ruptures on protected penstocks. System consists of two flow measurements (one at the beginning of protected penstock section and the other one at the end) which are compared, and in case of reaching predefined set values for actions, an alarm is set or the butterfly is closed. Figure 1 shows block scheme of the system. Shown system is also connected to the power plant process information system and visualization of entire pipe rupture monitoring system is made on plant SCADA system. System shown in figure 1 is based on high technology equipment for measurement, monitoring and protection functions

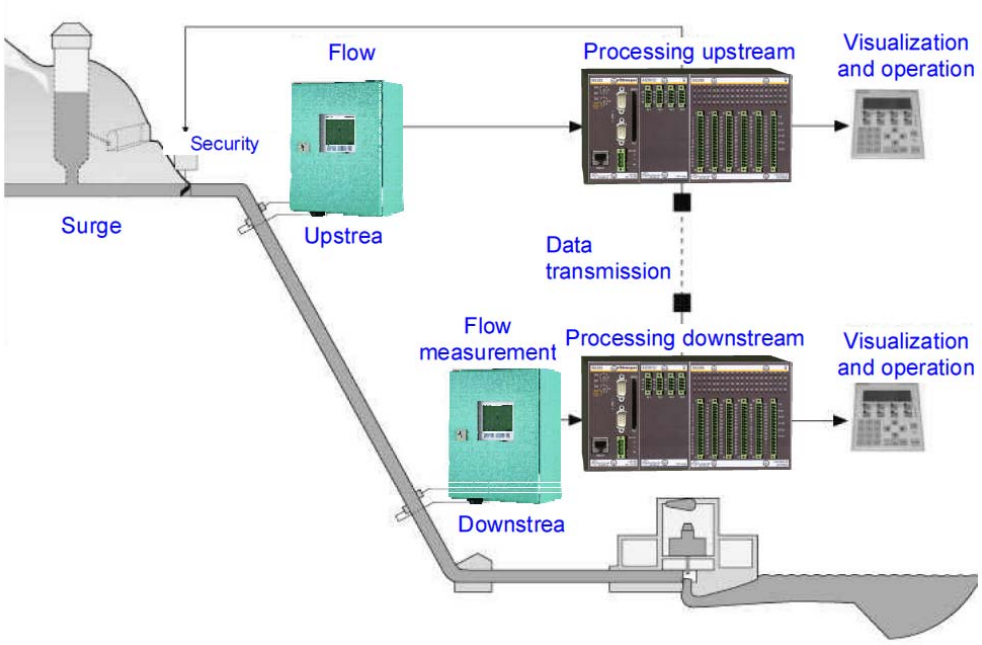

Fig. 1. System overview

The system itself can be divided in two functional units:

a) flow measurement
b) processing equipment

A Flow measurement

For flow measurement, Rittmeyer Risonic2000 ultrasonic flowmeter has been used. This measurement is based on time propagation for ultrasonic impulse sent in flow direction and in the reverse flow direction (Figure 2.).

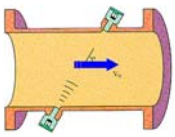

Fig. 2. Propagation measurement

Based on this information, combined with pipe geometry and ultrasonic sensors distance, flow velocity is calculated. For this calculation, the following relations are used:

$$t_{12} = \frac{D_i}{c + \overline{v_Q} \cdot \cos\alpha} \qquad (1)$$

$$t_{21} = \frac{D_i}{c - \overline{v_Q} \cdot \cos\alpha} \qquad (2)$$

$$\overline{v_Q} = \frac{D_i}{2\cos\alpha}\left(\frac{1}{t_{21}} - \frac{1}{t_{12}}\right) \quad (3),$$

where following is applied:

t_{12} – impulse time propagation in flow direction
t_{21} – impulse time propagation in reverse flow direction
D_i – distance between ultrasonic transducers
$\overline{v_Q}$ – mean velocity of the fluid
c – speed of light

Using information on fluid mean velocity, a flow is calculated (4):

$$Q = v_K \cdot A \qquad v_K = k \cdot v_Q \qquad k = \frac{1}{1.125 - 0.011 \cdot \log(\mathrm{Re})} \qquad \mathrm{Re} = \frac{v_Q \cdot D_i}{\nu(T)} \qquad (4)$$

where variables are:

Q – flow
$\nu(T)$ – kinematic viscosity
D_i – pipe diameter
k – Nikuradse hydraulic constant
A – cross section of a pipe

From above it is clearly visible that the precision of cross section measurement and calculation directly influences the precision of the whole flow measurement.

This fact was the trigger for development of OWICS (Optimal Weighted Integration for Circular Section) alghoritm, which reduces inegration error to a range of 0,1% to 0,2%.

In order to increase measurement accuracy, a multipath sensor configuration can be used, especially when the installation location has bad hydrodynamic conditions (near elbows, reductions, pumps, …). The picture 3 shows the most complex installation 8P2E (eight paths in two layers). On PSPP Velebit the 4P2E configuration was used.

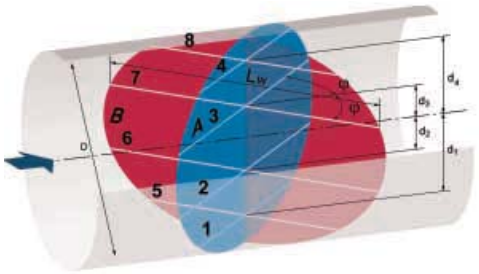

Fig. 3. Risonic2000 installation configuration 8P2E

With this configuration, and with installation according IEC41 norm, the precision of flow measurement less than 0,5% is achieved.

B Processing equipment

The processing equipment is built around Rittmeyer Riflex M1 PLC, which alarms in case of deviations in flow or triggers the butterfly valve closing in case of disaster. The cubicles are installed near measurement sections and are connected by optic modems and cables. All process information necessary for system operation (flow measurement, pressure switch status, power plant current operation status,…) is transferred to appropriate cubicle.

Each measured value is processed with the software macro "recording of measurement". The macro supervises the measured value on one minimum and maximum value each, as well as maximum rate of change. When responding to the wire break or the gradient monitoring the last valid measured value is frozen and an appropriate alarm is produced. With limit value monitoring the measured value is supervised on absolute limitation in case where the measured value exceeds or falls below the set value, then an appropriate signal is produced, which can be processed as a warning, disturbance or an alarm.

The macro contains a filter of the 1st order as well as a component with a sliding neutral zone. For the further processing the measured value with or alternatively without neutral zone can be used. The neutral zone-afflicted measured value changes its value only if the raw value of the input exceeds an adjustable change. Typically this value is used for remote transmission. In automatic control loops the neutral zone-afflicted measured value may not be used. All set values, delays and neutral zones can be parameterized.

The pipe rupture monitoring system compares information on flow from upper and lower measurement site and, based on predefined parameters, sends alarms or, in case of excess situations, triggers butterfly closing. Set values are defined during commissioning, but the customer has the option to change these settings on his own, using the Siemens operating panel installed on cubicle doors. This option is password protected.

Monitored parameters are:

dQ – differential flow between top and bottom
dQ_i – integrated differential flow between top and bottom
Q_{max} – maximum flow

If one of the above parameters exceeds a set value an appropriate process alarm will be triggered. System has self diagnostic module which monitors operational functionality of vital system components. In case of failure of a vital component, an adequate system alarm will be triggered.

IV PROGRAM PARAMETERS DETERMINATION

After successful installation and functionality examinations of single components, the system calibration has been accomplished. System calibration concerns monitoring of the flows on the upper and down measurement locations and the analysis of the collected data. During the process, the special focus had to be put on the characteristic transient conditions concerning operation of the plant. Those transient conditions appear when generation or a pump unit change mode of operation e.g. passes from generation mode to compensation mode of operation. Under those conditions variation of flow velocity in the penstock are the most intensive which may produce false tripping of differential protection. The graphs below show flows on UMP and DMP, and their difference for some of the transient conditions in the operation of the PSPP Velebit.

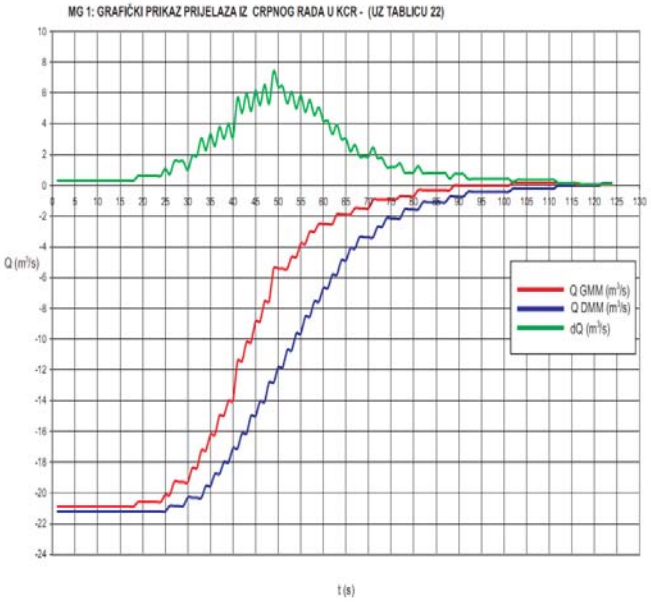

Fig. 4. Graph showing the variation of flow velocity due to transition from pump mode to compensating-pump mode of unit operation

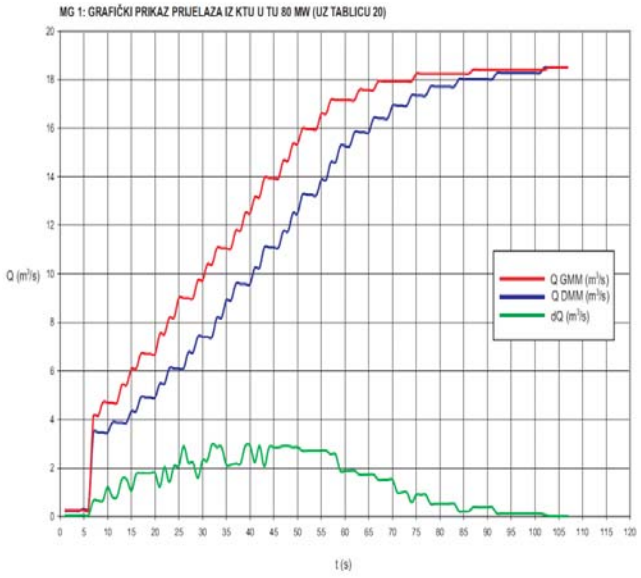

Fig. 5. Graph showing the variation of flow velocity due to transition from compensating-generation mode to generation mode of unit operation

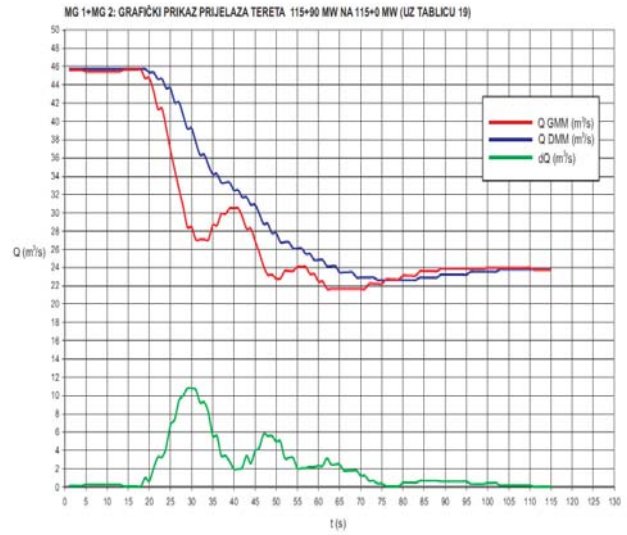

Fig. 6. Graph showing the load variation of 115+90MW to 115+0MW

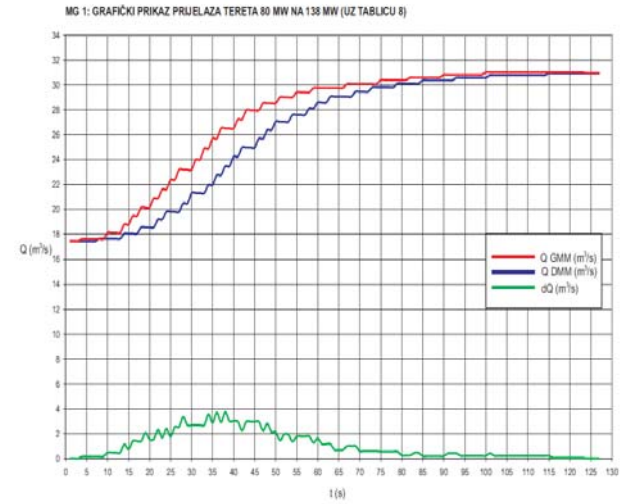

Fig. 7. Graph showing the load variation of one unit in generation mode (from 80MW to 138MW)

Setting Value	Flow $Q(m^3/s)$	Time delay t(s)
Q_{max}, alarm	66	20
Q_{max}, shut down	72	10
dQ_{max}, alarm	4	20
dQ_{max}, shut down	8	30
$dQ_{integrated}$/10min, alarm	3	30

Table I. Pipe Rupture Monitoring setting parameters

Shown parameters represent compromise between duration of transient conditions and requirements for faster closing of guide vanes. During the period of calibration of the ultrasonic monitoring system, it was recorded twenty experiments of loading and unloading with one and both units on the power grid, as well as functioning of one and both units in the pump mode. As a special experiment it was also recorded emergency shut down of each unit. During experiment the system remained stable and no unwanted shut down was activated.

Algorithm of differential protection represents exclusively calculated difference of flows on the down and upper measurement location while there is no special stabilisation parameter, and the calculated difference refers to optimisation of trip time value and flows value. Primary probes have, as expected, shown the highest oscillation of the flows during load rejection and transits shown on the pictures 4 and 5, which represent relatively usual operation mode. It would be interesting to present the results of the direct transition from pump into the generation mode probe, but such probe has never been performed since such transition is never used in the practice.

Due to the fact that the PSPP Velebit is derivation plant with particularities which refer to big length of the penstock, one of the criteria for the closing velocity of guide vanes is also the pressure growth in the penstock. Time values shown in the table I refer exclusively on the beginning of activation of guide vanes shut down and butterfly valve shut down after detection of failure i.e. detection of the trip setting value. Concerning the dynamics of complete hydrodynamic process, which is in the connection with the unit operation, mentioned time periods between 10 and 30 seconds represent satisfying tripping time velocity.

Of all the mentioned parameters it was the most difficult to determine dQ integrated which is extremely important, because in the case of appearance of the smaller ruptures, depending on the dynamics of its propagation, dQ integrated pick-up activate protection functions of the penstock. This would protect the penstock from complete destruction. The activation of function under other parameters would probably prevent catastrophic consequences of penstock destruction to the entire plant and local community.

V INTEGRATION IN PLANT PROCESS INFORMATION SYSTEM

Process information system of PSPP Velebit is based on 800xA information system according to [4] . The main references of process information system are:

- two process stations AC800M,
- redundant optical process network (Ethernet 100MB/s based on protocols TCP/IP i RNRP),
- two operator stations Connectivity/Aspect Servers,
- one process data Information Server,
- one business data Information Server fo asset management,
- swtch for connection to company Intranet.

Software platform for operator stations is Operate IT Process Portal ABB which operates on Windows XP. Each operator station has itself Operator Workplace Client.

Pipe rupture monitoring system on PSPP Velebit supposed to be an integral part of independent water management system as well as equipment described in [5]. Data exchange between plant process information system and pipe rupture monitoring system is temporary based on hard wire connections between input/output modules of Riflex controlers and process stations of generating units. Future plan is implementation of new process information station for water management purposes and fielbus connection between pipe rupture monitoring system and water management system. Water management system is important in facilities like PSPP Velebit for correct economic planing of generatig and pumping regimes. As shown before protection and monitoring functions are on first place.

VI CONCLUSION

Pipe rupture ultrasonic monitoring system of derivation penstock presented in this work has replaced the old system produced in analog technique which was not in the function. The new system is, thanks to the described method of flow measurement more precise than the old one, and at the same time it encompasses all the advantages of microprocessor technology. During the phase of project preparing and installation of the system, experiences of many machine engineers and electrical engineers from various fields were used. Analysing the transient conditions, using experience of operation staff and equipment deliverer, the system has been put into test operation for period of 6 months, and after that period it was enabled with executive trip functions (shut down of butterfly valve and shut down of unit guide vanes) and full functionality.

From the end of commissioning period, which was in December 2007, until today pipe rupture monitoring system of PSPP Velebit is in continuous operation without failures and false alarms. Described system represents the highest standard for monitoring and protecting large penstocks of derivation and reversible power plants.

A New Approach towards Visual Programming for the Blinds

Mario Konecki*
* Faculty of Organization and Informatics,
University of Zagreb, Pavlinska 2, 42000 Varaždin, Croatia
E-mail(s): mario.konecki@foi.hr

Abstract - Visual user interfaces have left blind programmers that were able to perform programming job for years in a challenging situation. This problem has especially been present in classical desktop programming due to the nature of technology used in this field. Efforts have been made to help blinds work with graphical interfaces but none of them gave a fully usable solution for blind programming professionals. To solve this issue several different approaches can be applied but only one of them can lead to generally usable solution. In this paper mentioned approaches are discussed and proposed solution is described in more detail in the form of GUIDL (Graphical User Interface Description Language) that represents a new system that would include a new description language and would enable blinds to make graphical interfaces as a part of their programs in a way that would be acceptable to not only professional programmers but also to designers and other blind computer hobbyists. The demands for this kind of system as a combination of initial ideas and results obtained by research among the blind programmers will also be presented. Finally, a formal description of proposed system and its parts including a description language as its core part will be given.

I. INTRODUCTION

Blinds have been the significant part of computer technology revolution since its very beginning. In 1970s computers have found its appliance in many business systems and other areas of life. Personal computer started to be something that is an essential part of people's life. This huge variety of possible computer users have made a huge difference in the way that blinds study, work and communicate with their colleagues. The main aiding technologies that made this possible were Braille typewriter and text-to-speech or speech-to-text synthesizers that made reading and using various computer programs accessible to the blinds.

These technological means have greatly supported a greater percentage of successful blinds that were able to study or work not only in the field of computer science but also in other areas. Text has become available and new information was no longer an issue for the blinds. The very same aiding technology has virtually enabled blinds to do the work of professional programmers. This was not a problem because all software was text based and developed speech synthesizers could support all necessary actions. Inclusion of blinds into the world of computer science and professional programming was done and the interest of the blinds for this area of work never faded [1].

The same aiding technology enabled blinds to become professional programmers and since all software was text based this wasn't a problem. Speech synthesizers were able to cope with all software and programming was brought to the blinds as an equal opportunity. The inclusion of blinds into programming was successful and this interest never faded [1].

Although inclusion of blinds in the world of programming was successful it wasn't long lasting. 1980s and development of Graphical User Interfaces (GUI) brought a number of problems for blind computer users and programming professionals. The prospect of existing technologies for aiding blinds was not bright and it was obvious that existing methods won't be sufficient in the very near future.

Several issues have emerged. Software development has become so rapid that it stopped being documented in the way that would be satisfied for the blind professionals. Existing aiding technologies weren't enough to support a huge variety of new concepts and different software. GUI adoption made the worst problem since speech synthesizers could not even cope with all graphical elements and were not able to visualize the graphical layout of the screen. These tools tried to read text from certain graphical controls with more or less success but the general context was in many cases lost. One of the things that called for a suitable solution was the problem of designing graphical elements that became a part of almost every piece of software. Point and click visual environments weren't suitable for the blinds and textual description of these environments became virtually impossible [2]. All this has left blind professionals in a very hard position.

Importance of blinds inclusion into the world of professional programming can be confirmed today by over 130 registered blind programming professionals listed at American Foundation of the blind programmers and also by some promising data that can be seen in other countries. Programming is listed as one of popular occupations for blinds in Czechs Republic, Finland, Poland and Spain [3] and it's also stated as one of promising new carrier opportunities for the blinds in Europe [4].

II. CURRENT EFFORTS AND ISSUES

Aiding tools today are mostly based on the same technology that was used from the very beginning and that is speech-to-text and text-to-speech converters. The existing converters and similar in nature and differ in details and some specialized functions. The most known and used speech synthesizers today are:

- JAWS [5]
- HAL Screen Reader [6]
- COBRA [7]
- Window Eyes [8]
- Easy Web Browsing [9]

All these tools have similar problems among which are problems with graphical representation of images and large amounts of tabular data and also the problem of robustness or inability to support new technologies and concepts in sufficient amount. There are also efforts aimed at learning of programming concepts rather than supporting professional activities. One of these efforts can be seen in development of Audio Programming Language (APL) tool [10] and JavaSpeak [11]. There are also some interesting conceptual attempts to visualize graphical shapes to the blinds like Audiograph [12] which uses different sounds and pitches of sounds to represent different shapes and coordinates. An approach that combines speech, music, tactile panels, Braille and other media to represent visual concepts and images to the blinds is called multimodal approach [13].

Another interesting area where the problem of visualization is present is World Wide Web. Web pages have become very graphically and multimedia oriented which also made their translating into text very difficult and sometimes impossible. The fact that makes this issue even worse is the fact that over 50% of web pages tend to be partially accessible on inaccessible to the blinds [14]. This shows that web developers don't know much about web pages accessibility or think that it is of no great importance. Tactile panels and tactical web browsing [15] are technological attempts to elevate this issue. Tactical web panels are multiline Braille panels that try to represent image by using a series of pins that can be lowered or elevated (Figure 1 [15]).

All these efforts offer some features and solve some issues but none of them offer a usable solution for blind programming professionals. If we look at the two main areas of computer programming it can be concluded that these issues are not so prominent in the area of web programming.

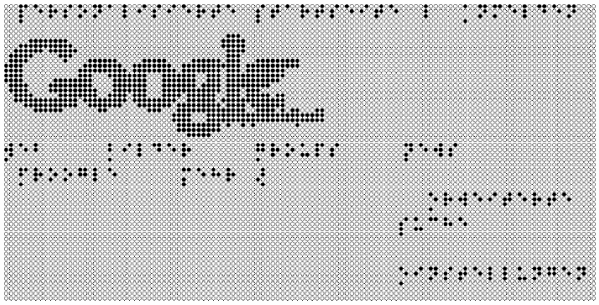

Figure 1. Tactical display

This is because of the nature of web technologies and the fact that blinds are still able to code web programs through pure text which is completely supported by existing speech synthesizer's software. There are some minor issues with color recognition and some other accessibility elements [16] but these are issues on the lower levels. Main issues arise in the area of GUI programming where almost all environments adopted graphical interfaces and complex environments that are not adequately supported by existing aiding tools. So, it can be concluded that the area of designing GUI is the area that needs to be focused on and addressed in order to provide blinds with means to be once again fully included in the world of professional programming.

III. TOWARDS SOLUTION OF BLINDS ISSUES

In order to address and solve mentioned issues of blind programmers several approaches can be undertaken.

- Interpreters that would support different types of controls and interpret different form elements and attributes could be developed.
- Programming environments could have built-in support for designing of graphical elements through speech.
- Specific scripting languages could be developed that would enable textual creation of specific elements in specific programming languages. An example of this kind of scripting language can be found for Visual Basic forms [17].

Finally in order to create a general solution a more abstract approach can be taken. A new description language can be developed would enable creation of different User Interface (UI) elements in a simple and understandable way. This kind of specification would then be translatable to a particular programming language GUI code using specific GUI generator. In this way the generally usable and extensible solution would be proposed that would be usable to programmers but also to pure blind designers. This kind of system with an new description language as its central part would be called Graphical User Interface Description Language (GUIDL). The benefits of this kind of solution would be in inclusion of blinds in the overall process of designing and exchanging ideas among the whole team and in enabling blinds to design their own final solutions as a equal part of development team.

IV. REQUIREMENTS FOR GUIDL SYSTEM

The first step in the development of the new GUIDL system is to define the requirements which such system would have to satisfy. Based on the literature analysis and research several requirements can be identified that this kind of system would have to include in order to be usable and sustainable.

Mentioned requirements are:

- Easiness of usage: system has to be easy to use for programmers but also to other interested professionals such as designers
- Intuitive, simple and easy to understand syntax: descriptive language that will be used for description of user interfaces graphical elements has to be intuitive and easily applicable to all that are in the business of programming classical GUI applications but also to other programmers and designers.
- Independence of descriptive language: descriptive language of UI definition has to be general and not programming language specific or programming environment specific.
- Extensibility of descriptive language: descriptive language has to be extensible in the way that it enables inclusion of new programming environments and languages and in ideal case inclusion of new graphical elements or controls.

In order to evaluate stated requirements and to find out about the interest of blind users for proposed solution a suitable research has been conducted. The research has been conducted through specifically designed questionnaire that included statements needed to assess the mentioned requirements but also questions regarding other aspects and elements that have been recognized as potentially relevant in the process of designing the questionnaire. Open type questions were also included so that blinds would have chance to make their own comments and state additional aspects that possibly were not included as initial requirements.

In order to conduct the research in the satisfying way it was necessary to find appropriate places where it would be possible to address the desired population. Several well known groups of blind programmers have been identified and included into research scope [18] [19] [20] [21] along with some less known lists. This population represented a convenience sample that was addressed with the e-mail request to participate in the research.

In the moment of research analysis the 37 answers were obtained and it can be expected that this number will be even higher in the future regarding that the research is still ongoing. Overall results showed that blind population is generally interested in this kind of solution. A part of research that was of great value was the part that included personal comments.

Respondents were given a possibility to apply with their e-mail for future testing of the system prototype which has been announced to be available in the near future. Respondents have also been instructed that additional research will be conducted to assess the usability of developed system prototype according to defined requirements and project goals. Most interesting question and their average values are given in Table 1. All answers were graded using Likert scale from 1 to 5 (1 - I disagree completely, 5 – I agree completely).

Table 1. Research results

Statement	Average reply value	Standard deviation
How old are you?	28,51	6,22
How long have you been programming?	7,64	4,64
Designing Graphical User Interfaces is one of the biggest issues for me as a programmer.	4,59	0,79
The issue of Graphical User Interfaces design is more prominent in the area of desktop programming than in the area of web programming.	3,91	1,11
I would like to have a solution to the issue of designing Graphical User Interfaces.	4,70	0,66
It is important to me to be able to create interfaces that can be included in standard programming environments (Visual Basic, C#, etc.).	4,35	0,78
It is important to me to be able to describe visual interfaces in simple and familiar way.	4,54	0,69
I would like a new programming environment and new programming environment rather than including my designs in existing programming environments.	1,43	0,76
I don't care how complicated is to describe visual interfaces, if it works.	1,78	0,85
I would like the language and system used to describe visual interfaces to be very easy to use with simple syntax.	4,51	0,60
I would like the language and system used to describe visual interfaces to have intuitive and recognizable syntax similar to some well known programming language.	4,16	0,72
I would like the language and system used to describe visual interfaces to be independent of particular programming environment and translatable to several well known programming languages environment's forms.	4,48	0,69
I would like the language and system used to describe visual interfaces to be extensible and have an ability to include new programming languages when needed.	4,02	0,86

Respondents were also asked about their experience in programming and whether they have more experience in web or classical desktop programming or both. There were 29 male and 8 female respondents and 11 respondents were primarily desktop oriented, 8 web oriented and 18 respondents stated that they have experience in both desktop and web programming.

From the comments of respondents along with other results can be concluded that they consider important the simplicity of the syntax and user interface along with proper documentation as one of very important aspects. All these results have been taken into consideration as requests for GUIDL system.

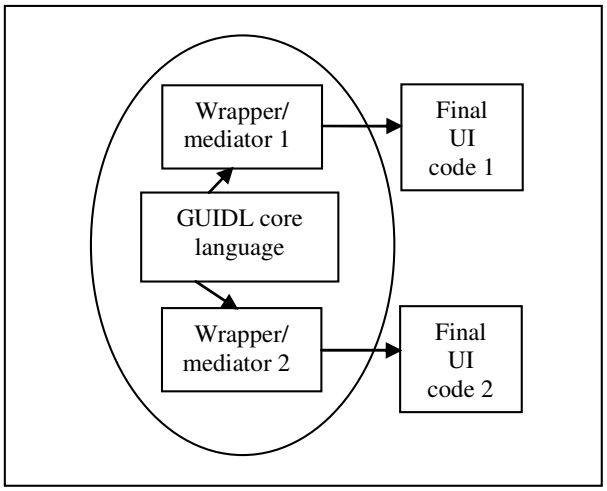

Figure 3. GUIDL conceptual model

V. GUIDL MODEL OF DEVELOPMENT

After defining the requests for the GUIDL system it is necessary to define the model and parameters of GUIDL development process. The conceptual model of GUIDL is shown in Figure 3.

GUIDL system consists of several elements. The core part is GUIDL central description language. GUIDL language serves for description of graphical interface and GUIDL source code is stored for future processing. GUIDL code is processed after UI description by one of specific mediators. Every mediator serves as a translator of GUIDL UI code to a programming language specific UI code. In this way the extensibility of the system is supported. The first step in the process of GUIDL language development is to define the parameters in the sense of scope and syntax of the language and to define other aspect of the language. In the language prototype some restrictions have been made in the sense of supported graphical controls. Selected graphical controls represent the most used controls in the applications development.

Selected controls are:

- Form
- Button
- Label
- TextBox
- CheckBox
- ComboBox
- PictureBox
- RadioButton

In the same way certain control properties were selected. This initial graphical control set will be expanded regarding future research results. Syntax of GUIDL language is designed in the way to be simple and of known form. The language that best fulfills these criteria is Beginner's All-purpose Symbolic Instruction Code (BASIC). GUIDL language is because of that inspired by BASIC but does not have any direct link to it and BASIC interpreter/compiler cannot understand GUIDL code. Syntax inspired by BASIC assures simplicity and easiness of usage that is important in order for GUIDL to be used not only by programmers but also by designer and other computer user.

Example of GUIDL code along with partial grammar in EBNF is given below.

```
Form 'form name'
  Size = 'width' 'height'
  Location = 'x coordinate' 'y coordinate'
  Caption = 'form title'
  WindowState = 'visual state of a form on
  runtime'
  ControlDeclaration
End
```

EBNF grammar:

```
form =  'Form ', formname, formattributes,
controldeclaration, 'End';
formname = alphabeticcharacter, {alphabeticcharacter
| digit}, eol;
formattributes =  sizeattribute, locationattribute,
captionattribute, windowstateattribute, eol;
sizeattribute = 'Size = ', width, ws, height, eol;
```

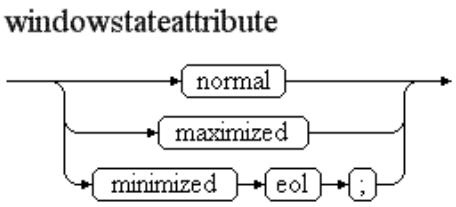

Figure 4. Syntax diagram of windowstate atribute

```
locationattribute = 'Location = ', xcoordinate, ws,
ycoordinate, eol;
caption = alphabeticcharacter, {alphabeticcharacter |
digit}, eol;
windowstateattribute = 'normal' | 'maximized' |
'minimized', eol;
controldeclaration = {controldeclaration}, eol;
alphabeticcharacter = "A" | "B" | ... | "W" | "X" | "Y" |
"Z" ;
digit = "0" | "1" | "2" | "3" | "4" | "5" | "6" | "7" | "8" |
"9" ;
ws = ? white space character ? ;
xcoordinate = digit, {digit}, eol;
ycoordinate = digit, {digit}, eol;
eol = ? CR (carriage return) character ? ;
```

Syntactical diagram of windowstate attribute is given in Figure 4.

After the grammar of GUIDL is defined the development of GUIDL language and system will be conducted according to defined structure of GUIDL which is given in Figure 5.

The GUIDL source code is processed by GUIDL lexer that conducts the lexical analysis of the code.

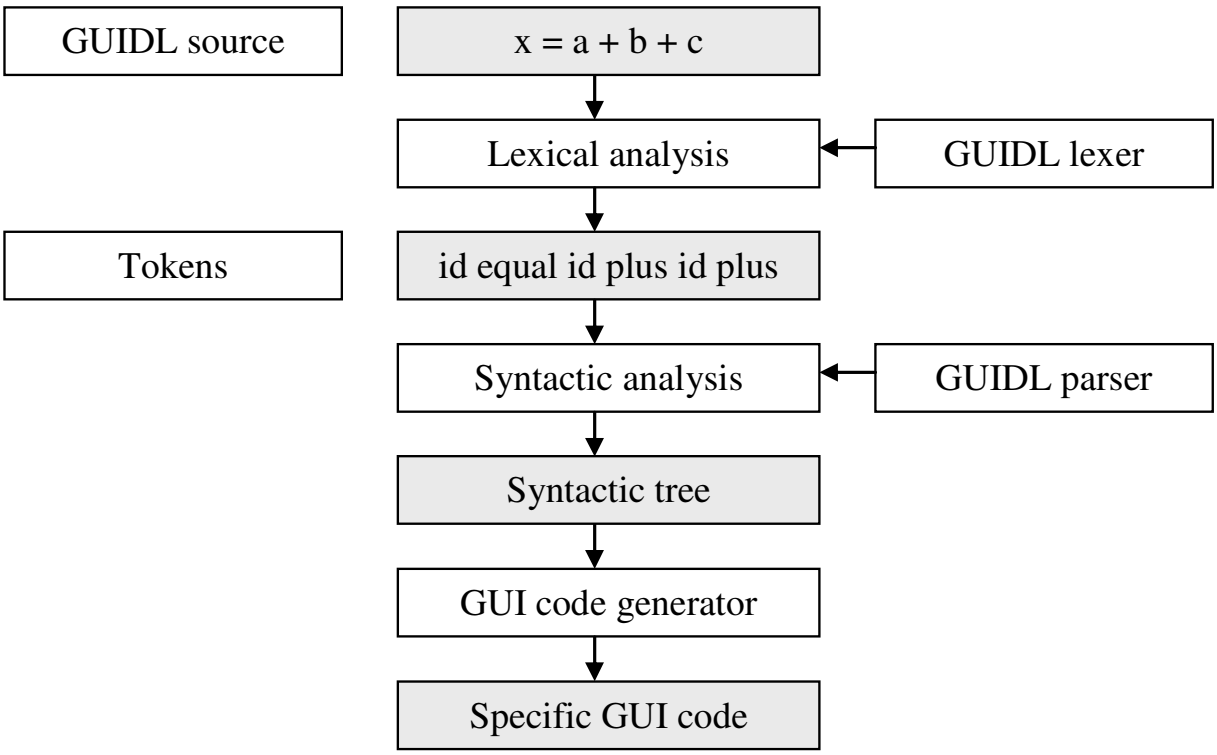

Figure 5. Structure of GUIDL

Constituent part of lexer is the scanner. Scanner reads the file with the GUIDL source code character by character and forwards it to lexer. Lexer accepts the signs and indentifies acceptable character strings as tokens. The set of possible tokens is defined inside of GUIDL parser form where it is included into lexer. GUIDL parser reads tokens recognized by lexer and conducts the syntactical analysis based on grammar rules of GUIDL. GUIDL parser creates syntactical trees that will serve as basis for specific GUI generator that will translate GUIDL code into programming language specific code.

After the development of initial prototype further testing and modification of GUIDL model will be conducted according to research results.

VI. CONCLUSION

Blinds have been using computers since the very beginning of computer era. They have performed programming jobs with great success using various aiding technologies available. Since GUI development took place blind programmers have found themselves in difficult position particularly regarding development of GUI. Existing aiding tools weren't able to support different GUI development environments in a way that would be generally usable to blind programmers and existing efforts didn't give conclusive results.

In order to solve this problem several approaches can be undertaken which include development of more sophisticated aiding tools, integration of different aiding technology to development environments and development of programming language specific scripting languages. In order to provide a generally usable solution a new model of GUIDL description language and system has been proposed based on defined requirements obtained by research that would provide simple and extensible solution for development of GUI. Testing and improving of GUIDL system will be a part of future research efforts.

Abstract – Due to the strong impact of the deregulation of the electricity sector there is a growing need for the correct and timely information from different parts of the system. The introduction of an increasing number of modern intelligent electronic devices enables the interaction between devices in the electric power facility. This enables vertical and horizontal multi-dimensional data exchange. Different generations of different devices with their proprietary communication solutions prevent the establishment of free data and information exchange. Need for standardization of communication within the power system has resulted in the emergence of new standards. The increasing emphasis on ecology and sustainable development lead to a continuous growth of renewable energy sources. With the growing number of distributed energy resources on the power grid there is a need to establish a new model for process information system. This paper gives an overview of new technological solutions and standards that enable more efficient utilization of all available resources. Basic building blocks for the modeling process are presented. Certain specifics of distributed energy resources that affect the modeling process of information system for modern electric power system are presented in this work.

I. INTRODUCTION

In recent years, there are several different impacts (carbon dioxide emission reduction, energy efficiency programs, deregulation and competition, diversification of energy sources) that have resulted in increased interest in distributed generation. Environmental impact is one of the most important factors in considering the connection of distributed energy resources to the power grid [1].

Another very important factor in the power system was the technological development of microprocessors in the second half of twentieth century. This has led to the introduction of a new generation of secondary equipment. A new intelligent electronic devices (IEDs) have led to significant changes in the process information system. Classical secondary equipment for protection, measurement and control wasn't equipped with communication unit. Communication was realized with remote terminal units and it enabled only vertical data exchange. New IEDs with embedded communication enabled vertical and horizontal data exchange between secondary devices and supervisory control and data acquisition system (SCADA) [2].

Due to the large number of different generation of devices from different vendors a growing problem arises, how to connect these devices. Multiple protocols existed for substation automation, which included many proprietary protocols with custom communication links. Interoperation of devices from different vendors would be an advantage for substation automation system. An international electrotechnical commission (IEC) project group created a standard.

Introduction of modern IEDs and modern standardized communication solutions lead to a change in the existing paradigm of process information modeling. Regarding to that, it is necessary to create a new process information model which will be based on a new concept of multidimensional data integration and information exchange [3].

This paper will give a detailed overview of the basic technological solutions and the basic properties of the used standards. Particular emphasis will be placed on the application of distributed energy resources and their impact on the process information model.

II. IMPACT OF DISTRIBUTED ENERGY RESOURCES ON PROCESS INFORMATION SYSTEM

Distributed energy resources (DER) are generally considered to include all forms of electricity generation and storage that are interconnected to the power system. The advent of decentralized electric power production is a reality in the majority of the power systems all over the world, driven by [4]:

- the increased demand for cost-effective, efficient and reliable electrical energy,
- the increasing need for renewable sources of energy to minimize carbon dioxide and other pollution emissions,
- the development of new and increasingly cost-effective technologies for small power generators,
- the development of new energy converters to reduce dependence on oil and other carbon-based fuels,
- the deregulation of energy market.

These pressures have greatly increased the demand for DER systems, particularly renewable DER systems, which are interconnected with the power systems. Electric power systems where developed based on the centralized production. In such a system distributed network is realized as a radial network that is used to deliver energy to the end user [5]. The distributed energy is designed for unidirectional flow of energy. Problems occur with monitoring and control of distribution network with lots of connected distributed energy resources. The main problem is the need for collection of process information from distributed energy resources.

A. *Monitoring and Control for DER Systems*

Managing the system with significant DER generation and storage requires the monitoring and control of the interconnected DER systems. No longer can these DER systems be viewed as just negative load. Some of the challenges for the various stakeholders in planning and managing the interconnected DER system include:

- connecting distributed energy resources to the power grid,
- management of power grid in normal conditions,
- management of power gird in abnormal conditions,
- scheduling DER generation, based on different criteria such as economic dispatch, peak shaving, backup power,
- monitoring and control of large DER plants in real-time as producers not only of electrical energy, but also for balancing energy, var support, peak demand, and emergency microgrid operations,
- monitoring and control the individual DER generators, storage units, excitation systems and inverters/converters,
- monitoring and control the energy conversion systems, such as hydrogen for fuel cells, methane for biomass, and other types of fuel,
- monitoring and control the auxiliary systems, such as revenue meters, fuel systems and batteries,
- monitoring the physical characteristics of equipment, such as temperature, pressure, heat, vibration, flow, emissions and meteorological information.

The wide varieties of information flows needed for managing DER plants and systems are illustrated in Fig. 1.

III. PROCESS INFORMATION MODELING CONCEPT

In order to properly model the complex system with distributed energy resources it is necessary to be familiar with an observed domain and the basic principles of modeling. It should also be kept in mind that we are talking about modeling for communication needs between distributed energy resources and electric power grid.

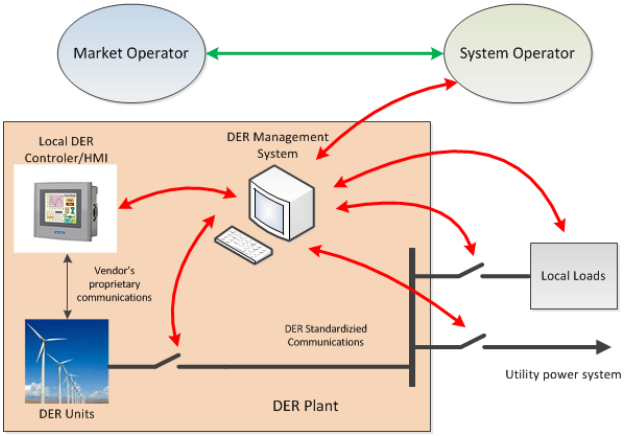

Figure 1. Process information flow for DER system

In fundamental ways, "communication" can be separated into four parts [6]:

- information modeling (the types of data to be exchanged – nouns),
- services modeling (the read, write, or other actions to take on the data – verbs),
- communication protocols (mapping the noun and verbs models to actual bits and bytes),
- telecommunication media (fiber optics, radio system, wireless systems, and other physical equipment).

The emphasis of observation in this paper is on information modeling. Information's on certain values in the primary system are obtained using equipment at the facility. Information modeling of secondary equipment creates a virtual model of the real system.

A. *Classic Process Information Model*

Electric power facility represents a technical system divided into several hierarchical levels [7]. By looking at the substation in terms of analysis from the standpoint of management, substation consists of high voltage part and low voltage part. Furthermore, these parts can be divided into individual substation parts, for example high voltage part is further divided according to voltage levels. Each section represents a separate entity that contains all the elements that belong to the observed voltage level. To truly understand substation operation it is necessary to broke down substation into smallest entities. These entities are referred as technological modules.

Technological modules do not present specific devices but represents logical units. Such formed structure proved to be sufficient for substation monitoring [8]. By observing the operation of individual modules the performance of complete substation can be monitored. To illustrate substation decomposition into smaller subsystems one classic transmission substation is presented (Fig. 2). Left side of the figure presents real power system and right side presents corresponding process information model.

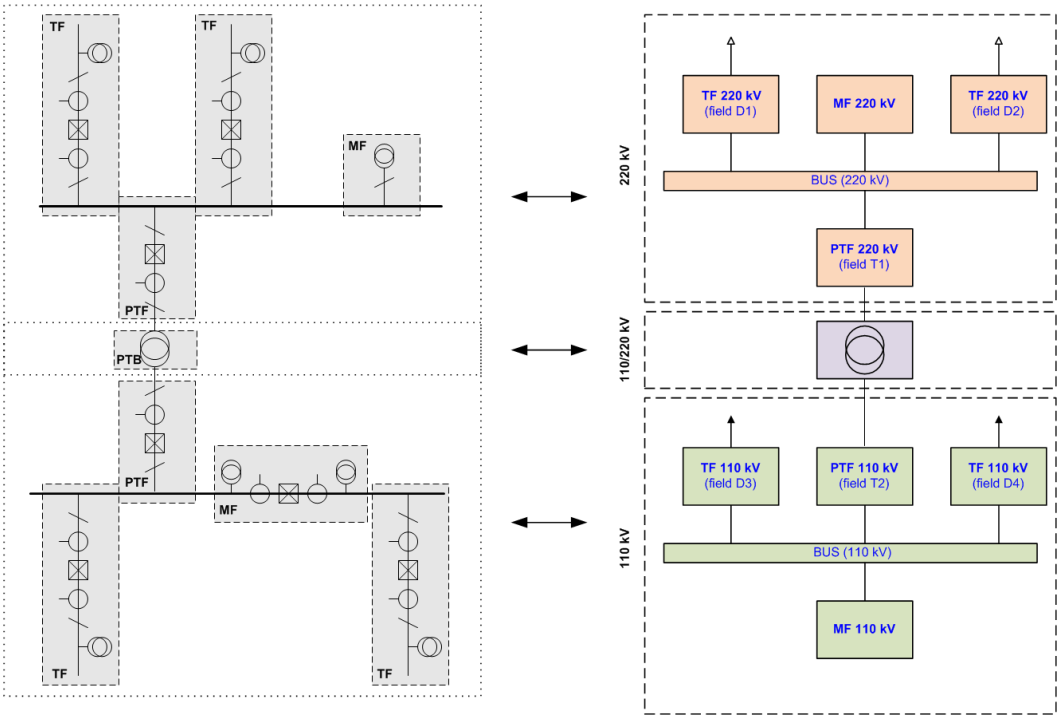

Figure 2. Substation decomposition

Substation is divided into technological modules, and technological modules consist of functional modules. Technological modules are considered to be sources and sinks of information. Some examples of technological modules are: transmission filed (TF), power transformer field (PTF), measuring field (MSF), merge field (MF), power transformer block (PTB. Each of the presented technological modules (TM) is described with a series of information that belong to different functional modules (FM). Functional module presents a simple function in substation. Some functional modules in substation are: protection (p), measurement (m), commands (c).

This process information model is named technological-functional model. This model has some specific limitation and drawbacks:

- process information are organized at the level of technological modules,
- entire modeling procedure must be repeated for each substation,
- the device, as the basic element of substation isn't separated as carrier of information,
- device states cannot be defined for the needs of modern process information design,
- links among devices cannot be determined,
- redundancy of the data entry is great.

This model was created during the use of remote terminal units for the purpose of communication. At that time communication capabilities were limited and therefore it was necessary to conduct the analysis. Today it is necessary to create a new process information model, while taking into account the possibilities of new intelligent electronic devices and possibilities of modern communication system. The second part of the paper will present the basic elements for creation on new process information model.

B. Information Models

With the development of new IEDs with integrated communication unit came the opportunity for easy data and information exchange. The main problem for seamless exchange was the proprietary communication protocols. Introduction of IEC 61850 standard solved this problem [9]. This standard defines a standardized information models, which provides unification of information and enables easy data exchange. Information models have a hierarchical structure which is shown in Fig. 3. Basic elements for creation of information model are presented [10]. Hierarchical structure will be explained from the bottom up:

- standard data types - common digital formats such

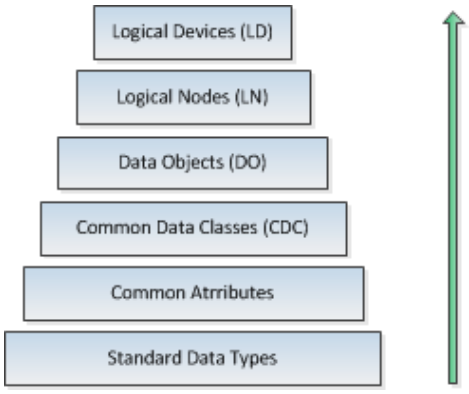

Figure 3. Information model hiearchy

as Boolean, integer and floating point,

- common attributes - predefined common attributes that can be reused by many different objects,
- common data classes (CDCs) - predefined groupings building on the standard data types and predefined common attributes, in essence, these CDCs are used to define the type or format of data objects,
- data objects (DO) - predefined names of objects associated with one or more logical nodes. Their type or format is defined by one of the CDCs. They are listed only within the logical nodes,
- logical nodes (LN) - predefined grouping of data objects that serve specific functions and can be used as "bricks" to build the complete device,
- logical devices (LD) - the device model composed of the relevant logical nodes for providing the information needed for a particular device.

Based on this new information model it is possible to create a new process information model for power energy system.

C. New Modeling Concept

A logical node is "the smallest part of a function that exchange data" [11]. It is an object that is defined by its data and methods. Multiple instances of different logical nodes become components of different protection, control, monitoring and other functions in automation system.

A multifunctional device has a complex functional hierarchy that needs to be modeled according to the definitions of the model which is presented in the previous section. This model can be used to represent both primary and secondary equipment in power energy system. For modeling the secondary equipment there are available several major groups of functions:

- protection,
- measurement,
- monitoring,
- control.

Each IED can be split in functional elements. Functional elements are defined as the smallest functional unit that can exist by itself and exchange signals or information with other elements within a device or a system. Functional hierarchy of modern IEDs depends largely on their application and main function. A simple low-end device has very limited functionality, while a device that supports IEC 61850 will typically have more complex functional hierarchy. In the following section emphasis is on process information modeling for systems with distributed energy resources.

IV. Function Modeling in Systems with Distributed Energy Resources

The fundamental concept that is necessary to understood at the beginning of modeling process associated with distributed energy resources is that the model includes only objects that are visible to the communications. If the function is represented to the outside world as a black box with certain inputs and outputs, these internal signals are not visible and as a result they should not be included in the model.

The modeling of complex distributed energy resources systems depends not only on their functionality, but also on the configuration of the substation where they are installed and connected to the electric power system.

General functions that are characteristic for distributed energy resources are presented with the corresponding logical nodes (Fig. 4). They can be grouped according to function and the specific type of distributed energy resource. Logical nodes for distributed energy resources can be grouped into the following categories:

- plant electrical connection point,
- unit controller,
- generation systems,
- specific types of distributed energy resources,
- auxiliary systems.

Logical nodes for the DER plant electrical connection point belong to a group D which is specific for distributed energy resources domain. Every DER has to be connected somehow to the electric power system. This group includes logical nodes that define the characteristics of the DER plant at the point of electrical connection. Usually there is a switch or circuit breaker (XFUS – electric fuse, XCBR – circuit breaker, CSWI – switch controller) at this point of connection. An example of a logical node that belongs to this subgroup is DPST which is used to model actual status at each electrical connection point, including DER plant connection status, alarms.

Variety of DER devices does not mean that they don't have some similarities, for example the existence of a different prime mover. Any DER needs to be controlled in order to perform its functions. Logical nodes for the DER device controller define the operational characteristics of a single DER device, regardless of the type of generator of prime mover. Some examples of logical nodes for this subgroup are DRCS - DER unit control actions, DRCT – DER unit controller characteristics, including type of DER unit, FSEQ – sequencer status if used in startup or shutdown of automated sequences.

DER units have different prime movers (hydro, wind, tidal, etc.) however the general operational characteristics of the generators are similar. Because of this, different DER types require only one DER generator model. The generator model is based on several groups of logical nodes: generator (DGEN – DER generator operations, DRAT – DER basic generator ratings, DRAZ – DER advanced generator features), excitation system (DREX – excitation ratings, DEXC – excitation operations),

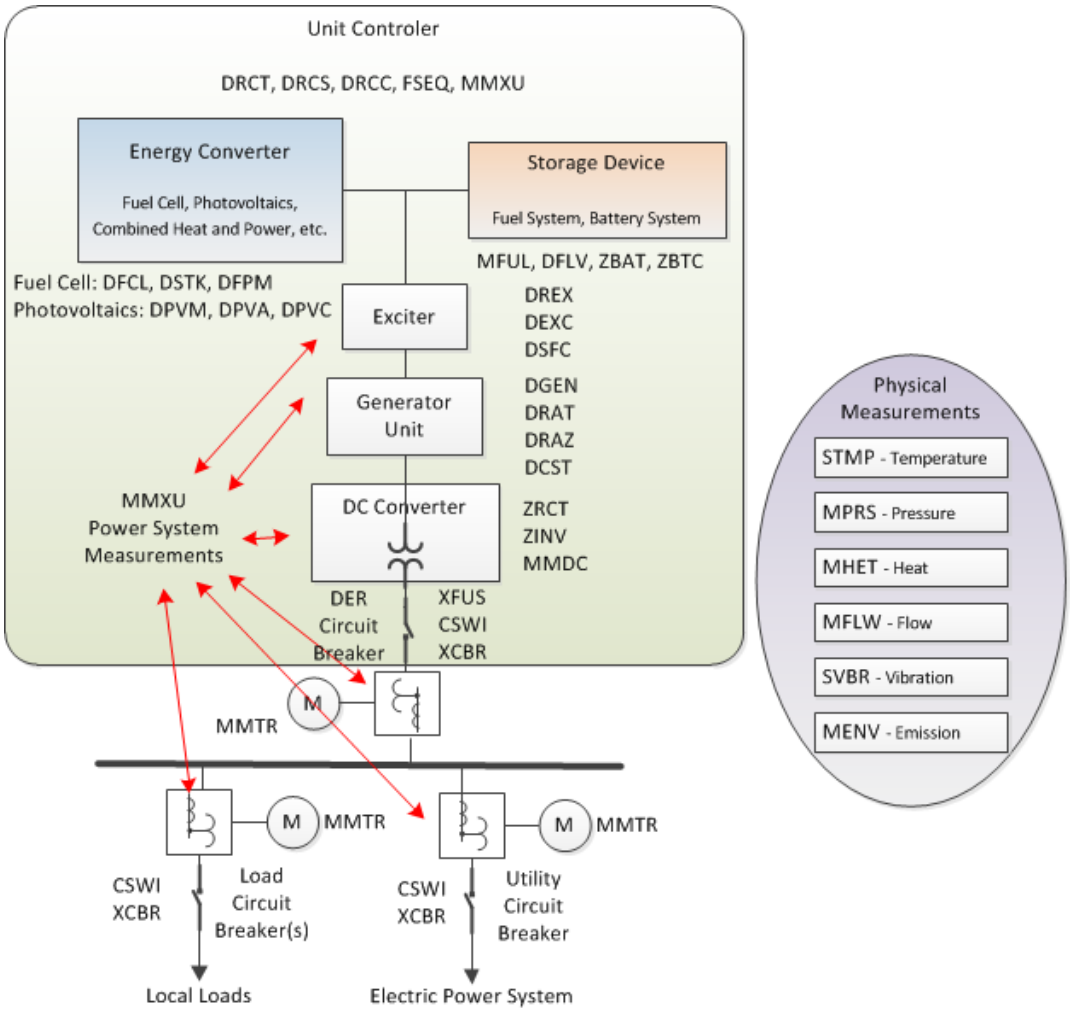

Figure 4. Conceptual distribution of logical nodes and logical devices for system with distributed energy resources

speed/frequency controller (DSFC – speed or frequency controller), an inverter/converter (ZRCT – rectifier for converting alternating current to continuous direct current, ZINV – inverter for converting direct current to alternating current, MMXU – measurements of input or output AC).

As mentioned earlier, different types of DERs require some specific logical nodes for their models. Some examples of those logical nodes are logical nodes that represent specifics of: reciprocating engine devices, fuel cells, photovoltaic systems. Below a detailed explanation of specific logical nodes for fuel cell distributed energy resource are presented.

A fuel cell is an electrochemical energy conversion device. It produces electricity from external supplies of fuel and oxidant. Over 20 different types of fuel cells have been developed. Logical nodes describe the information for the fuel cell as a prime mover. Some examples of logical nodes are below presented and explain:

- DFCL – fuel cell controller characteristics, presents information for remote monitoring of critical functions and states of the fuel cell itself. Detailed information is presented in Table I.,
- DFMP – fuel processing module of the fuel cell is used to extract hydrogen from other types of fuels. The hydrogen can then be used in the fuel cell to make electricity. For example this logical node combined with one of two MFLU logical nodes are used for complete picture of fuel processing. Data included in this logical node are those required for remote monitoring of the fuel processing module,
- MFLU – fuel characteristics, presents information to describe the type and nature of the fuel,
- DFLV – fuel delivery system, presents information to describe the delivery system for the fuel.

In Table I. it can be seen that each logical node contains information relating to the status values and measured values, but also can have some control values and setting values. Logical nodes consist of data objects which are defined by common data classes. Each common data class consists of specific attributes. For example common data class INS represents integer status common attributes like stVal (integer), q (quality), t (time stamp). Each logical node can be presented in the previous manner.

TABLE I. FUEL CELL CONTROLER

DFCL class		
Data object name	***CDC***	***Explanation***
Status information		
StrCnt	INS	Count of system starts since last reset
ConnGriCnt	INS	Count of reconnections to power system
OpTms	INS	Lifetime system run time
Settings		
Alim	ASG	Input current limit
Vlim	ASG	Input voltage limit
Control		
FuelShut	DPC	True = open, False = close fuel valve driver command
Measured values		
LifeWh	MV	Lifetime system run energy
InOxFlwRte	MV	Input air or oxygen flow rate
OutHydRte	MV	Output hydrogen flow rate

Each specific type of distributed generation has its own specifics that should be taken into account. Ultimately it can be concluded that the connection of distributed energy resources on electric power systems has a large impact on monitoring and control system.

V. CONLUSION

This paper presents the need for a unified modeling of distributed energy resources for data and information exchange between components in electric power systems. Due to increase in volume of distributed energy resources there is a need to connect them to electric power system monitoring and control system.

Use of open communication solutions enables the realization of power system automation. Applying this principle enables multidimensional insight into the information at all levels of electric power system. By applying the displayed solutions multiple benefits for monitoring and control system are realized.

In further work it is necessary to conduct specific simulations and tests to determine the optimal use of process information obtained from distributed energy resources.

ACKNOWLEDGMENT

This work was carried out on a project “Open market and new technologies in the process informatics of electric power systems” No. 069-0361557-1615 supported by Ministry of Science, Education and Sports of the Republic of Croatia.

Definicija efikasnog komunikacijskog protokola za bežične senzorske mreže

Martina Ašenbrener*, Boško Mrković **
* Sveučilište u Rijeci / Odjel za informatiku, Rijeka, Hrvatska
** Tehnoalarm d.o.o.Zagreb, Hrvatska
E-mail: masenbrener@inf.uniri.hr, bosko.mrkovic@kr.t-com.hr

Sažetak - Rad definira efikasan, pouzdan i konfigurabilan komunikacijski protokol za cluster-tree topologije bežičnih senzorskih mreža (Wireless Sensor Network, WSN). Podržane su bežične senzorske mreže s velikim brojem modula u dometu radija, sa slobodnim pridruživanjem mreži i odjavljivanjem iz mreže, sa self-healing-om na razini routera, a sve uz osiguranu visoku efikasnost (minimalni energetski zahtjevi, potrošnja modula) – minimalni komunikacijski overhead i izbjegavanje kolizija.

I. UVOD

Bežična senzorska mreža (Wireless Sensor Networks, WSN) je organizirani, komunikacijski povezani, prostorno distribuirani skup modula koji prikupljaju podatke iz okruženja, obavljaju (barem osnovnu) digitalnu obradu podataka i te podatke prosljeđuju centralnom modulu (u hijerarhijskom smislu).

U sklopu projekta ***„Sustav za lociranje i zaštitu plovila u marini“*** (eng. *Smart MARina TechnologY*, skraćeno SMARTY, Smarty) razvijena je sklopovska osnova za bežične senzorske mreže te razvijen i implementiran odgovarajući komunikacijski protokol, ***SmartyMAC***[1].

Važnije karakteristike senzorskog modula sustava Smarty:

- Sačinjavaju ga low-power mikrokontroler (omogućava svu potrebnu lokalnu digitalnu obradu i zaštitu podataka) i primopredajni radio modul (omogućava efikasnu komunikaciju radio prijenosom unutar licence-free ***ISM/SRD*** [2] SubGHz radiofrekvencijskih područja).
- Napaja se iz primarnih, ili iz dostupnih energy-harvesting izvora.
- Raspolaže većim brojem konfigurabilnih analognih i digitalnih ulaza i izlaza (moduli mogu imati i ulogu aktivatora te se Smarty može promatrati i kao specifični prostorno i hijerarhijski distribuirani sustav za nadzor i upravljanje u stvarnom vremenu).
- Module je moguće povezati s gotovo svim dostupnim senzorima/senzorskim podsustavima direktno, ili korištenjem uobičajenih komunikacijskih kanala (***I^2C*** [3]***, SPI*** [4]***, UART*** [5]).
- Integrirano mjerenje temperature i akceleracije po svim osima.

Osim mrežnog koordinatora, sustav Smarty sadrži dvije osnovne skupine modula:

- Prethodno opisani senzorski, pokretni moduli – moduli čija se pozicija u prostoru može mijenjati.
- Moduli sa zadanom pozicijom, lokalni koordinatori, ili router-i – moduli čija je pozicija u prostoru definirana i nepromjenjiva, s vlastitim podsustavom neprekidnog napajanja.

II. KOMUNIKACIJSKI PROTOKOL ZA WSN

Intenzivna testiranja i evaluacije obavljene su izgradnjom testne bežične senzorske mreže koja je korištena i za evaluacije raspoloživih ***mrežnih komunikacijskih protokola***[6]. Definirani su opći zahtjevi koje je potrebno ispuniti za značajno proširenje mogućnosti komercijalnih primjena bežičnih senzorskih mreža. Osim toga, uz kritičnu efikasnost definirani su i dodatni zahtjevi koji se postavljaju na željeni komunikacijski protokol WSN-a.

Prepoznati zahtjevi koji definiraju komunikacijski protokol:

- Efikasnost i maksimalna konfigurabilnost.
- Minimalna osjetljivost na kvarove, minimalna infrastruktura i minimalno održavanje.

[1] **Sloj kontrole pristupa mediju, Media Access Control (MAC)** je podsloj sloja veze podataka (2. razina OSI modela). Zadaća mu je adresiranje i kontrola pristupa mediju, što je posebno značajno kod mreža s dijeljenim medijem (primjer kojih su bežične mreže). Primjena može biti i šira.
OSI - Open Systems Interconnection, referentni model. OSI model je apstraktni opis dizajna protokola komunikacijskih i računalnih mreža koji dijeli komunikacijski sustav u slojeve.

[2] Industrial, Scientific and Medical / Short Range Device

[3] Inter-Integrated Circuit

[4] Serial peripheral interconnect

[5] Universal asynchronous receiver/transmitter

[6] **Mrežni komunikacijski protokol (Network Protocols)** je strukturirani programski stack, dizajniran da osigura efikasan (s minimalnim gubicima, odnosno minimalnim ponavljanjem prijenosa) prijenos podataka do odredišta. Struktura većine komunikacijskih protokola je usklađena s Open Systems Interconnection referentnim modelom (OSI, OSI model) koji predviđa sedam slojeva.

- Pouzdana detekcija kvara na svim mrežnim modulima. U slučaju kvara na fiksnom dijelu mreže automatski se redefiniraju komunikacijski putovi i grupe, ukoliko je potrebno.
- 8196 senzorskih modula u dometu radio primopredajnika.
- Konfigurabilna i fleksibilna prostorna distribucija bežične mreže, od koncentrirane sa svim modulima unutar dometa radia, do distribucije u prostoru do nekoliko desetaka kilometara.
- Automatsko pridruživanje i odjavljivanje senzorskih modula iz grupe/mreže.
- Razmjena podataka unutar sustava mora biti zaštićena (kriptirana).
- Mogućnost reprogramiranja svih modula unutar sustava.
- Mogućnost implementacije i na drugim sklopovskim platformama.

Zahtijevana efikasnost odnosi se na minimalnu potrošnju energije i minimalnu zauzetost komunikacijskog kanala. U vezi s potrošnjom energije potrebno je upozoriti na činjenicu da je potrošnja energije modula u prijemu značajna, u optimiranim sustavima kakvom težimo, uglavnom i veća od potrošnje u slanju. Potrošnja modula je prevelika da bi mogao biti potpuno aktivan cijelo vrijeme. Senzor se mora isključivati djelomično, ili u cijelosti s minimalnim duty-cycle-om (efektivnim vremenom aktivnosti).

III. SMARTYMAC

Komunikacijski protokol SmartyMAC namijenjen je malim i srednje velikim bežičnim senzorskim mrežama s jednostavnim mrežnim topologijama (peer-to-peer i star). S obzirom na OSI model, sadrži samo niže slojeve, fizički i podatkovni sloj.

Neka od svojstava SmartyMAC-a:

- U cijelosti je konfigurabilan.
- Kao i komunikacijski moduli, njima namijenjeni SmartyMAC podržava sva sub-GHz ISM/SRD frekvencijska područja dopuštena za korištenje u Europi. Podržane su brzine prijenosa (data rate) od 1.2 kbps do 256 kbps s odgovarajućim korištenjem frekvencijskog područja (bandwidth).
- Podržani su svi uobičajeni načini adresiranja i filtriranja paketa te odgovarajuće metode za detekciju grešaka koje su definirane formatom paketa.
- Implementiran je automatski acknowledgement (potvrda ispravnosti primljenog paketa) s programabilnim brojem ponavljanja nepotvrđenih paketa te automatsko prosljeđivanje paketa.
- Podržano je i dinamičko mijenjanje kanala odnosno mijenjanje radne frekvencije (frequency hopping) u skladu s ***ETSI***[7]) definiranih unutar ISM/SRD frekvencijskih područja. To čini komunikaciju robusnijom, manje osjetljivom na smetnje u frekvencijskom kanalu, ali značajno produljuje svaku pojedinačnu komunikacijsku sekvencu te u odgovarajućoj mjeri povećava zauzetost kanala i potrošnju.
- U SmartyMAC je implementiran vrlo efikasan i potpuno konfigurabilan mehanizam "slušaj prije nego šalješ" (Listen Before Talk, LBT).
- Kako idealni radio prijenos (obzirom na ujednačenost distribucije snage u korištenom frekvencijskom području i ovisnost regulacijskih petlji prijemnika o podacima) pretpostavlja slučajni serijski tok podataka, bez offset-a (jednak broj "nula" i "jedinica"), u SmartyMAC implementiran je i data whitening.

SmartyMAC je namijenjen komunikaciji koja zahtijeva prijenos male količine podataka korištenjem ISM/SRD radiofrekvencijskih područja. U cijelosti se odvija kao niz interrupt servisa u pozadini aplikacijskog sloja na mikrokontroleru, čime su pojednostavljene sve buduće nadogradnje.

Predviđeni maksimalni broj modula u mreži limitiran je 16-bitnim adresnim poljem što omogućava izgradnju vrlo velikih bežičnih senzorskih mreža te zahtijeva implementaciju nekih funkcija viših mrežnih slojeva (mrežnog i transportnog).

SmartyMAC je u cijelosti napisan u programskom jeziku C. Tijekom razvoja SmartyMAC-a, definiran je i implementiran odgovarajući Application Programming Interface (API) koji omogućuje jednostavniju implementaciju potrebnih viših mrežnih funkcija te proširenje funkcija aplikacijskog sloja (ako se za to ukaže potreba).

SmartyMAC je implementiran kao dvostruki konačni automat (state machine) čijim radom upravljaju time i external interrupt koje postavlja radio modul. Ponašanje stack-a definirano je parametrima spremljenim u konfiguracijskom polju registara. Osnovna stanja u kojima se stack može nalaziti su SLEEP, IDLE, TRANSMIT i RECEIVE.

IV. SMARTYNET

Kako je spomenuto, visoka efikasnost (kao i propisi koji definiraju korištenje europskih ISM/SRD radio područja) podrazumijeva rad s malim duty cycle-om, moduli su najveći dio vremena neaktivni, u SLEEP stanju, s minimalnom potrošnjom.

Iako SmartyMAC omogućava njihovu implementaciju, osnovni zahtjevi o efikasnosti komunikacije i velikim brojem modula u području prijema radija čine poznate i dostupne komunikacijske protokole (ZigBee, ipv4, ipv6 i sl.) te njihove izvedenice neprimjenjivima.

[7] European Telecommunications Standards Institute

Pouzdana komunikacija radiom zahtjeva određeni komunikacijski overhead, u slučaju WSN-a često i višestruko veći od podataka koji se razmjenjuju.

Minimalna komunikacijska sekvenca koja dopušta implementaciju SmartyNET-a se sastoji od:

- Preamble i sync: 6 byte-a,
- Transmit header (adrese, tip, varijabilna duljina poruke): 6 byte-a,
- Poruka, podaci (status senzora i nadzirano stanje): 4 byte-a,
- CRC: 2 byte-a.

U slučaju zahtijevane sekvence potvrde (ACK), kao odgovor slijedi jednako formatirana poruka sa 2 byte-a podataka (npr. dodijeljena grupa i vremenski interval).

Prijelaz između TRANSMIT i RECEIVE stanja nije trenutan, za odabranu brzinu prijenosa od 128 kbps ekvivalentan je vremenu potrebnom za slanje 4 byte-a.

Uz navedeno, aktiviranje senzora, prijelaz iz SLEEP stanja u TRANSMIT vremenski je ekvivalentno slanju čak 10 byte-a pri odabranih 128 kbps.

Znači, slanje 4 i prijem 2 byte-a zahtijeva razmjenu od čak 38 byte-a. Energetski, situacija je još nepovoljnija, potrebno je zbrojiti dodatno vrijeme aktiviranja, s nezanemarivom potrošnjom.

Potrebno je napomenuti da aktiviranje dinamičkog mijenjanja kanala (frequency hopping) značajno produljuje preamble dio sekvence te značajno smanjuje efikasnost komunikacije.

Kao optimalna, podržana je cluster-tree (stablo grupa) topologija sa senzorskim čvorovima grupiranim oko lokalnih centralnih čvorova, router-a. Veličina svake od dopuštenih 255 grupa limitirana je na 255 senzorskih čvorova. Takav odabir dopušta veliku fleksibilnost u izgradnji WSN-a, od prostorno koncentriranih do maksimalno distribuiranih, bez potrebe za povećanjem komunikacijskog overhead-a.

Komunikacija je vremenski sinkronizirana i obavlja se unutar konfigurabilnih vremenskih intervala (beacon). Router-i sekvencijalno generiraju sinkronizacijske sekvence s najvećim intervalom definiranim najvećom dopuštenom greškom ***RTC***[8] oscilatora senzorskih modula, odnosno, dopuštenom greškom duljine SLEEP stanja.

Sinkronizacijski interval je podijeljen na jednake podintervale čija je duljina konfigurabilna i definirana duljinom komunikacijske sekvence. Konfigurabilni broj početnih podintervala koristi se za pridruživanje senzorskih modula mreži, a od preostalih, svaki drugi se dodjeljuje senzorskim modulima tijekom ACK sekvence. Nedodijeljeni podintervali se, po potrebi, koriste za prijenos neregularnih stanja unutar sustava.

Komunikacija između router-a, unutar stabla, u cijelosti je upravljana od strane mrežnog koordinatora. U slučaju kvara koordinator redefinira grupe i komunikacijske putove ukoliko postoje te, u slučaju komunikacijskih smetnji, mijenja i frekvencijsko područje. Uz navedeno, mrežni koordinator dinamički dodjeljuje senzorske module grupama, osiguravajući optimalnu i neometanu komunikaciju.

[8] Real Time Clock

V. ZAKLJUČAK

Ukratko je opisan efikasan, pouzdan i konfigurabilan komunikacijski protokol za cluster-tree topologije bežičnih senzorskih mreža. Podržane su bežične senzorske mreže s velikim brojem modula u dometu radija, sa slobodnim pridruživanjem mreži i odjavljivanjem iz mreže, s osiguranom vrlo malom osjetljivosti na kvarove.

Opisani komunikacijski protokol implementiran je u sustav Smarty, kao komunikacijska osnova podsustava za određivanje pozicije senzorskih modula.

Razvoj i uvođenje informacijskog sustava za praćenje pokazatelja rada proizvodnih jedinica HEP Proizvodnje d.o.o.

Ivica Vukelić Prvi autor*
* Hep Proizvodnja d.o.o. , Sektor za termoelektrane, Zagreb, Hrvatska
ivica.vukelic@hep.hr

Sažetak – Za upravljanje, planiranje i donošenje poslovnih odluka u složenim poslovnim sustavima kao što je i HEP Proizvodnja d.o.o. potrebno je imati na raspolaganju bazu relevantnih i pravovremenih podataka. Danas je to moguće ostvariti jedino prikladnim informatičkim sustavom za prikupljanje i obradu podataka. Osim malih lokalnih sustava po pogonima, u HEP Proizvodnji d.o.o. nije postojao integralni sustav koji bi obuhvaćao sve pogone i proizvodne jedinice. Zbog toga je odlučeno da se takav sustav samostalno razvije i implementira. U radu su prikazana dosadašnja ostvarenja, funkcije i mogućnosti sustava, kao i daljnji planirani razvoj sustava.

I. UVOD

HEP Proizvodnja d.o.o. član je HEP Grupe, zadužena za proizvodnju električne i toplinske energije. Upravlja sa složenim i raznovrsnim skupom energetskih jedinica raspoređenih u 25 hidroelektrana i 7 termoelektrana, s ukupno, više od 80 generatora na mreži [2]. Tvrtka isporučuje također i energiju za grijanje u tri grada i tehnološku paru za industriju. Obzirom na raznovrsnost tehnologije proizvodnih jedinica i korišteni energent (ugljen, mazut, plin, voda) nije jednostavno planirati i voditi ukupnu proizvodnju tvrtke.

Zbog toga se od 2007. samostalno se razvija i uvodi informatički sustav - aplikacija: Pokazatelji Proizvodnje Elektrana (PPE). Sustav se uvodi postupno u koracima, a osnovna namjena mu je prikupljanje i prikaz relevantnih podataka svih energetskih jedinica za planiranje rada, njihovo optimalno vođenje, i donošenje dobrih poslovnih odluka. Osim toga sustav se koristi za direktno povezivanje i razmjenu podataka s drugim aplikacijama partnera unutar HEP grupe i izvan nje.

U aplikaciju su uvedeni, ili će biti uvedeni svi podaci relevantni za tehničko i komercijalno poslovanje tvrtke. To su: statusi jedinica (trenutna snaga, raspoloživost, planovi neraspoloživosti, pogonski događaji), proizvodi (električna energija, toplinska energija, tehnološka para), goriva/voda (potrošnja, nabava, zalihe/akumulacije, dotoci, preljevi), ekologija (emisije dimnih plinova, ostatni proizvodi izgaranja goriva, otpadne vode), elementi za plaćanje naknada i koncesija itd.

Aplikacija je izrađena na bazi METADATA relacijskog modela, koji dozvoljava gotovo neograničenu nadogradnju i fleksibilnost, pa nema granica pri praćenju i uvođenju novih podataka. Transakcijski sloj aplikacije izrađen je s Oracle Forms&Reports 10g alatima, dok je web portal napravljen Adobe Flex tehnologijom. Za veliku količinu podataka i zahtjeve aplikacije zadužena je Oracle 10g baza podataka.

Projekt je u potpunosti izrađen vlastitom idejom, znanjem i kadrovima. Pri tome su korišteni samo postojeći HEP-ovi tehnički resursi (hardware) i postojeći licencirani softveri. Na taj način je za tvrtku ostvarena značajna ušteda jer za razvoj i implementaciju aplikacije nije bilo nikakvih dodatnih troškova.

II. POLAZNI PRINCIPI I ZAHTIJEVI

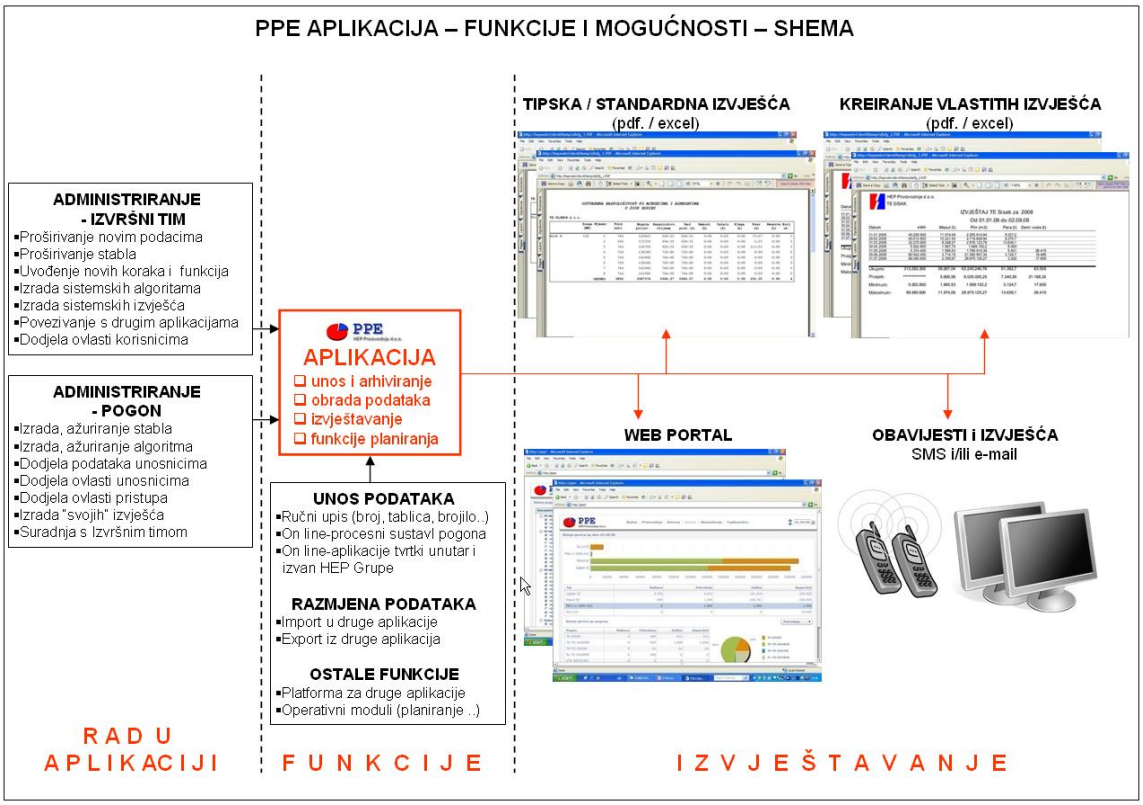
Aplikacija je razvijana i rađena isključivo za potrebe HEP Proizvodnje, prilagođena organizaciji i postojećoj tehnološkoj razini njenih jedinica, ne koristeći ni jednu postojeću aplikaciju s tržišta kao uzor. Također je prilagođena i postojećim odnosima među tvrtkama – kćerima u HEP Grupi. Uvažavajući ove početne postavke, kao i buduće potrebe u poslovanju tvrtke, na razvoj aplikacije postavljeni su slijedeći polazni principi i zahtjevi na njen rad:

A. Polazni principi

- jedan podatak jedan unos
- jedinstvena baza podataka čitave HEP Proizvodnje
- modularni razvoj i uvođenje u koracima
- strukturna, logička i korisnička fleksibilnost
- ispunjavanje trenutnih i budućih zahtjeva poslovanja

B. Zahtijevi na aplikaciju

- jednostavnost, jednoobraznost i brzina u prikupljanju, obradi i prikazu podataka
- hijerarhijsko administriranje i pristup podacima
- unos i pregled podatka sa svakog računala na internoj HEP-ovoj mreži (mrežni princip)
- osigurati aktivnim korisnicima mogućnost samostalnog konfiguriranja unutar aplikacije



Slika 1 Principjelna shema funkcija i mogućnosti PPE Aaplikacije

III. STRUKTURA APLIKACIJE

Osnovna struktura aplikacije zasniva se na kombinaciji podatka i mjesta na kojem je pridodan (grana, čvor), čime je moguće definirati sve veličine potrebne kao pokazatelje rada tvrtke [5]. Tako se jedan podatak npr. za radnu energiju može dodati na sva ona mjesta gdje se on pojavljuje i potrebno ga je pratiti. Od pojedinog uređaja u pogonu pa do sume za čitavu tvrtku. Time se osigurava i njegovo naknadno korištenje, za razne korisnike, na različitim razinama i različite potrebe. Osnovna struktura mjesta (stablo) prati organizacijsku strukturu tvrtke i izrađena je od strane Tima za razvoj aplikacije. Tako se ostvaruju ukupne potrebe i zahtjevi čitave tvrtke unificirano za sve pogone. No, korisnici mogu u dogovoru s Timom dodavati i svoje grane, čvorove i na njima podatke , prema specifičnostima i zahtjevima svog pogona, a koji su samo njima potrebni. Npr. u termoelektrani na ugljen dio ostatnih proizvoda izgaranja (pepeo, šljaka, gips) se prodaje a dio odlaže na deponiju. Omjer prodanog i deponiranog nije od interesa za čitavu tvrtku ali korisnici aplikacije mogu ove podatke voditi kao svoje interne podatke, za svoje potrebe.

IV. PODACI

U kontekstu aplikacije, "podatak" je svaka veličina ,tehnička, komercijalna ili bilo koja druga, za koju se žele unositi vrijednosti. Zahvaljujući META DATA relacijskom modelu, u katalog podataka vrlo jednostavno se uvode novi podaci koji se žele pratiti. Za njihov broj, vrstu i dinamiku unosa nema nikakvih ograničenja.

Kod uvođenja novog podatka u katalog svakome se definiraju parametri: ime, simbol, jedinica, grupa, tip pogona u kojem se primjenjuje. Kod pridodavanja čvoru definira se način njegovog unosa: broj, brojilo, tablica, formula, plan, a također i dinamika unosa: satno, dnevno, godišnje, jednokratno, po potrebi. Podaci su imenovani prema trenutnim potrebama s dodjeljenim internim simbolima, koji nisu sukladni ni jednom standardu, ali što se može po potrebi vrlo jednostavno uskladiti.

Za neke veličine uvedene su dvije kategorije istog podatka: dnevne-informativne i mjesečne-obračunske. Razlog tome je tehnička nemogućnost dnevnog očitanja određenih podataka na razini obračunske , knjigovodstvene, točnosti. Primjer za to su stanja goriva, u kojima se mora čekati dostava certifikata mjeriteljskih kuća za točne knjigovodstvene podatke. Do tada se koriste dnevni-informativni podaci, očitani s pogonskih brojila, sasvim dovoljne točnosti kao informacija za potrebe planiranja rada.

Unos podataka u aplikaciju omogućen je na sve načine: on-line iz procesnih sustava, preuzimanjem iz drugih aplikacija, upisom broja, upisom stanja brojila, upisom tablične vrijednosti.

U katalogu podataka trenutno postoje 82 podataka za koje se vrijednosti unose u aplikaciju. Broj podataka u katalogu sasvim sigurno će se povećavati daljnjim razvojem aplikacije. Također će se sve više prelaziti na on-line unos podataka kako se budu za to ostvarivali tehnički uvjeti u pogonima.

U tablici 1 prikazani su načelno trenutni podaci u katalogu aplikacije, razvrstani po tematskim grupama.

TABLICA I. NAČELNI POPIS PODATAKA U KATALOGU

STATUS JEDINICA:	
Status (rad, rezerva, kvar)	simbol
Trenutna snaga	(MW)
Trenutna raspoloživost/neraspoloživost	(MW)
PLANIRANA NERASPOLOŽIVOST:	
Godišnji plan neraspoloživosti	(hh/MW)
Tjedna planirana neraspoloživost	(hh/MW)
Neplanirana neraspoloživost	(hh/MW)
Raspoloživa snaga tijekom neraspoloživosti	(MW)
Snaga nakon prestanka neraspoloživosti	(MW)
Vrijeme do sinkronizacije nakon neraspol.	(hh)
POGONSKI DOGAĐAJI:	
Pogonski događaji	(dd.mm.yyyy hh:mm)
- trenutne obavijesti SMS/e-mail	
- statistike, kronologije, raspoloživosti..	(h), (%)
- raspoloživosti po VGB smjernicama	(h), (%)
GORIVA:	
Goriva; EL ulje, mazut, ugljen - zalihe	(t)
Goriva; EL ulje, mazut, ugljen - potrošnje	(t)
Goriva; mazut, ugljen - ulaz	(t)
Plin - potrošnja	(m3),(m3/h)
Plin - planirana potrošnja	(m3),(m3/h)
AKUMULACIJE:	
Akumulacije - stanje	(m3),(GWh)
Akumulacije - dotoci	(m3/s),(GWh)
Akumulacije - preljevi	(m3/s),(GWh)
ENERGIJE:	
Na generatoru	(kWh), (kVAr)
Na pragu	(kWh), (kVAr)
Vlastita potrošnja	(kWh), (kVAr)
Opća potrošnja	(kWh), (kVAr)
Isporučeno HEP OPS	(kWh), (kVAr)
Preuzeto od HEP OPS	(kWh), (kVAr)
Isporučeno/preuzeto HEP ODS	(kWh), (kVAr)
Preuzeto HEP ODS	(kWh), (kVAr)
Zelena energija	(kWh), (kVAr)
Isporučeno po mrežama 220/110/35 .. kV	(kWh), (kVAr)
TOPLINARSKI PODACI:	
Tehnološka para	(t)
Isporučena toplinska energija	(MWt)
Nadopuna vrelovoda	(t)
Ukupna potrošnja procesne vode u TE	(t)
EKOLOGIJA:	
CO, NOx, čestice, SO2 - satni prosjeci	(mg/Nm3)/h
mCO, mNOx, mčestice, mSO2 - mase	(kg/h)
CO2 - mjesečne emitirane količine (t)	(t)
OSTACI PROCESA PROIZVODNJE:	
Pepeo	(t)
Šljaka	(t)
Gips	(t)
Talog obrade otpadnih voda	(t)
ELEMENTI ZA IZRAČUN:	
Naknada za emitirani SO2, CO2, NOx - lp/t	(t)
Naknada za korištenje prostora - lp/kWh	(kWh)

V. POGONSKI DOGAĐAJI

Pogonski događaji posebna su kategorija podataka striktno vezana s vremenom njihove pojave koji se registriraju kroz posebni modul. Pogonskim događajem se smatra svaka izmjena statusa jedinice osim redovnih naloga dispečerske službe za promjenom opterećenja. Znači, pokretanje, zaustavljanje, ispad, prijava spremnosti nakon remonta, promjena raspoloživosti u radu ili stajanju itd.

Kod unosa događaja u formatu (dd.mm.yyyy hh:mm), osim vremena, unosi se još nekoliko podataka kojim je svaki događaj potpuno definiran. To su status jedinice nakon pojave događaja, podstatus, preostala raspoloživa snaga nakon događaja i tekstualni opis događaja. Također se bilježe i neke spacifične situacije, kao npr.: turbinski/pumpni rad kod reverzibilnih hidroelektrana , kompenzacijski rad .. i sl.

Iz tih podataka vidljivo je trenutno stanje raspoloživosti svake jedinice. Iz arhive događaja moguće je pregledavati i pretraživati događaje po raznim filtarima: kronološki, po statusima, podstatusima, samo rad, samo stajanje, samo remont itd. Osim toga, izračunavaju se i svi kumulativi vremena koja se prate za pojedinu jedinicu. To su sati rada, stajanja, rezerve, kvara, remonta raspoloživosti, neraspoloživosti. Moguće je također i izračunavati raspoloživost jedinica po određenim standardima (VGB) [1].

VI. IZVJEŠTAVANJE

Pristup podacima moguć je samo uz autorizaciju, koja se dodjeljuje na hijerahijskom principu. To znači da korisnici mogu pristupiti samo podacima onog dijela tvrtke za koji su ovlašteni.

Izvještajni modul omogućuje četri osnovna načina pristupa podacima:

A. Tipski izvještaji

Za sve korisnike kreiran je u određen broj tipskih izvještaja koji se najčešće koriste u svim pogonima i organizacijskim cjelinama. Za izvještaj se može izabrati željeni vremenski period i željena hijerarhijska razina, ovisno o autorizaciji korisnika.

Aplikacija omogućava korisnicima i samokreiranje izvještaja (Wizard). Korisnik sam određuje format i sadržaj željenih podataka u izvještaju, a po želji se svaki izvještaj može spremiti te ubuduće pozivati i izlistavati za neki drugi vremenski period. Tipski i Wizard izvještaji mogu se kreirati u PDF. ili xls. formtu, a mogu sadržavati sve podatke koji se nalaze u katalogu aplikacije.

Na slici 2 prikazan je jedan tipski izvještaj mjesečnog obračuna energije pogona. Na izvještaju je posebno izražena proizvodnja po čvorovima, isporuka/preuzeto od raznih tvrtki i dio koji otpada na zelenu energiju. Na slici 3 tipični je godišnji izvještaj raspoloživosti jedinice po mjesecima.

B. Web Portal

Za široki krug korisnika izrađen je web portal , s namjenom brzog pristupa željenom podatku. Portal je multimedijalno jedinstven, korisnički vrlo jednostavan za pregled i navigaciju. Stranice portala podijeljene su po funkcionalnim i sadržajnim cjelinama, a svaka sadrži svoje specifične podstranice.

Stranice web portal su dinamičke, potpuno prilagođene potrebama korisnika s najvažnijim informacijama i

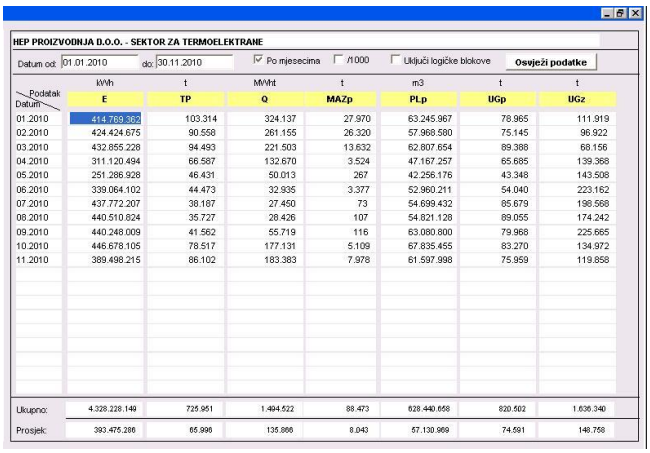
Slika 3 Tipsko izvješće – Godišnja raspoloživost pogona



Slika 4 Web Portal – Satna isporuka plina

korisnim funkcionalnim mogućnostima. Tako se npr. na stranici "status" (slika 5) prikazuju trenutni statusi svake jedinice na simbolički način, što objašnjava i legenda u kutu slike. Slika se može zumirati do razine svakog pogona kada se pojavljuje i prozor s podacima o zadnjem događaju i preostaloj raspoloživoj snazi. Korisnici mogu isključivati jedinice koje ne žele vidjeti, a također izabrati i samo statuse jedinica koje žele vidjeti; samo jedinice u radu , samo jedinice u kvaru.. itd.

Na slikama 6,7 i 8 prikazane su neke stranice web portala.

C. *Ekranski prikazi*

Ovaj način prikaza predviđen je za brzi pristup željenim podacima, i na jednostavan način osigurava pregled svih podataka u katalogu. Korisnik izabire željenu hijerarhijsku razinu i sam ih svrstava u željene kolone, izborom iz kataloga.

Na slici 4 prikazan je ekranski prikaz za izabranu razinu Sektora za termoelektrane, za prvih jedanaest mjeseci 2010. Pri tome su u kolone izabrani mjesečni, obračunski podaci: proizvedene električne energije, tehnološke pare, isporučene toplinske energije, potrošenog mazuta, potrošenog plina, potrošenog ugljena i zalihe ugljena na kraju mjeseca.

D. *Servis automatskih izvještaja i poruka*

Iz aplikacije se automatski kreiraju i dostavljaju u određeno vrijeme korisnicima koji to žele e-mail izvješća:

- Lista događaja prethodnog dana
- Lista događaja prethodnog tjedna
- Dnevni izvještaj goriva za prethodni dan
- Dnevni izvještaj akumulacija za prethodni dan
- Dnevni izvještaj potrošnje plina

Unosom pogonskog događaja automatski se kreira i šalje SMS i/ili e-mail obavijest korisnicima koji to žele. Pri tome korisnik može odabrati primanje opcije:

- Svi događaji
- Događaji koji utječu na raspoloživost jedinice

Ove opcije uvedene su radi velike razlike u broju događaja između termoelektrana i hidroelektrana.

VII. FLEKSIBILNOST APLIKACIJE

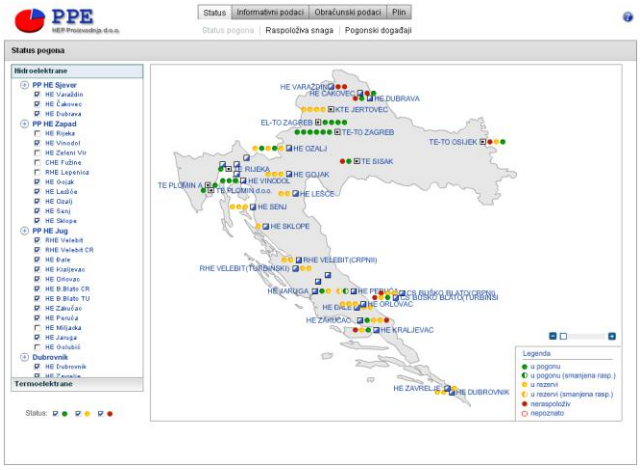
Od početne ideje i razvoja bilo je očigledno da će aplikacija morati biti izuzetno fleksibilna u svim pogledima. Razloga za to ima dosta, a uglavnom se svode na različitost tehnologija i tehnoloških razina jedinca u tvrtci te različitostima u postojećim procedurama i načinima rada. Značajan razlog ovakovom pristupu je također i priprema za buduće poslovanje u uvjetima otvorenog tržišta energije.

Osim već spomenutog neograničenog dodavanja novih podataka, aplikacija je fleksibilna i zbog sljedećih mogućnosti:

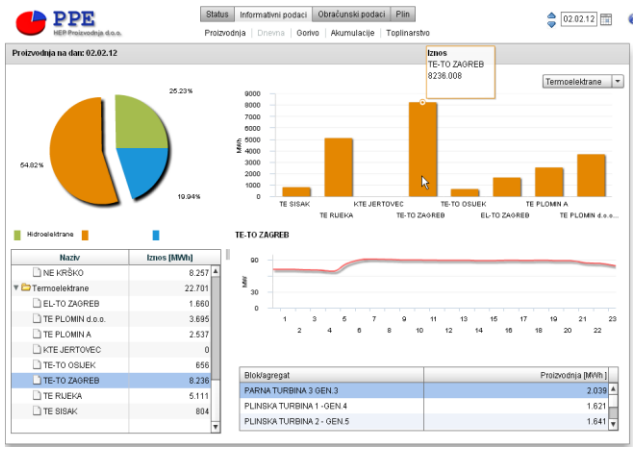
- Dodavanje novih grana, čvorova i novih jedinica
- Dodavanje/izmjena algoritama za obradu podataka
- Dodavanje novih aktivnih i pasivnih korisnika
- Dodavanje novih funkcionalnih modula
- Export/import podataka u druge aplikacije tvrtke
- Povezivanje s operativnim aplikacijama tvrtki partnera (HEP Trgovina, HEP OPS..)
- Prilagodba budućim zahtjevima poslovanja (EU)

Mogućnost exporta/imorta podataka i povezivanje s drugim aplikacijama unutar i izvan tvrtke, posebno je važna i korisna mogućnost za buduće poslovanje. To će doći naročito do izražaja kada zaživi otvoreno tržišta električne energije i tržište plina.

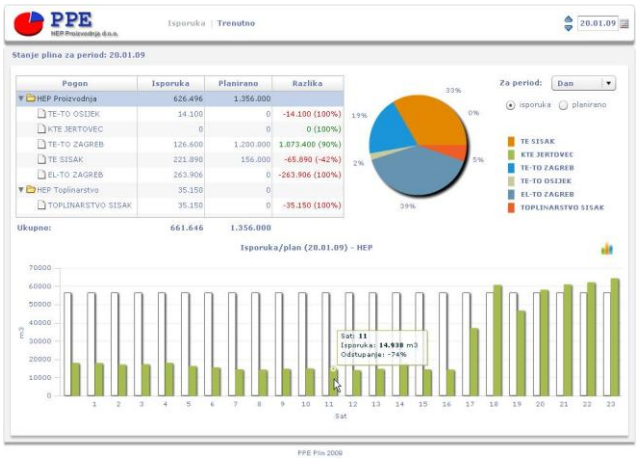
Tipičan primjer je buduće poslovanje na plinskom tržištu, u kojem će se operatoru tržišta nominirati potrebne satne potrošnje, pratiti realizacija i penalizirati odstupanja. U PPE aplikaciji već postoje podaci o satnim planiranim i ostvarenim potrošnjama, koji se mogu na



Slika 5 Web Portal – Status jedinica



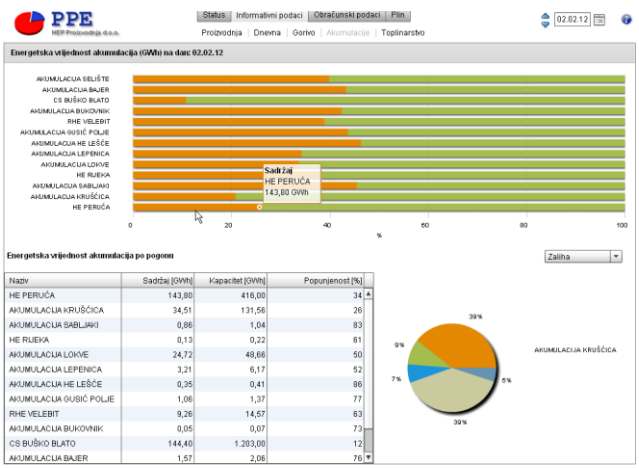
Slika 6 Web Portal – Dnevna proizvodnja električne energije



Slika 7 Web Portal – Satna isporuka plina

željeni način obrađivati unutar aplikacije, ili prenositi u neku drugu aplikaciju, posebno namjenjenu za to.

U dijelu tržišta električne energije važno je znati status raspoloživosti svih jedinica radi planiranja proizvodnje, isporuke, prodaje. Taj status u trenutno raspoloživoj snazi



Slika 8 Web Portal – Stanje akumulacija

već postoji u aplikaciji a u izrađen je i modul za tjedni plan neraspoloživosti. Kroz njega će se voditi kompletna operativa planiranja, zahtjevanja, odobravanja i realizacije obustava za potrebe održavanja. Pristup i aktivno učešće u modulu osim pogona i službi HEP Proizvodnje imat će i tvrtke partneri: HEP Trgovina i HEP Operator prijenosnog sustava. Podaci iz ovog modula mogu se po potrebi također exportirati u druge aplikacije.

U strukturiranju aplikacije razmišljalo se i o zahtjevima koji bi mogle biti od koristi u budućem poslovanja. Tako su npr. precizirane sve predane i preuzete energije po mjestu mjerenja: generator, odcjep, prag, vlastita potrošnja, opća potrošnja.. Osim toga energije su definirane i po naponskoj razini 10kV..400kV čime se može odrediti ukupna razmjena po mrežama. Također se iskazuje i ukupna razmijena po tvrtkama (isporučeno/preuzeto od HEP Operator prijenosnog sustava i HEP Oparetor distribucijskog sustava). Posebno se izražava i energija koja se tretira kao "zelena energija". .. itd. [2].

VIII. REALIZIRANI I PLANIRANI KORACI I MODULIE

Svaka logička grupa podataka tretirana je kao novi korak npr. energije, goriva, toplinarstvo, ekologija itd. Za neke grupe podataka ili neke funkcije aplikacije bilo je potrebno unutar aplikacije izraditi dodatni program, pa se to smatra novim modulom u aplikaciji. To su npr.: modul za slanje SMS/e-mail poruka, univerzalni modul za unos planskih veličina, modul za planiranje tjedne neraspoloživosti .. itd. Sadržajno i funkcionalno koraci i moduli se isprepliću pa ovu podjelu treba shvatiti uvjetno.

Koraci koji su do sada razvijeni i implementirani odnose se na glavne dijelove poslovanja tvrtke a općenito bi s e mogli prikazati kao:

- Pogonski događaji / statusi / raspoloživosti
- Električne energije, proizvodnje, potrošnje
- Goriva; potrošnje, nabave, zalihe
- Akumulacije, stanja, protoci, preljevi
- Toplinarstvo; toplinska energija / tehnološka para
- Ekologija – emisije dimnih plinova

Razvoj aplikacije kretat će se kao i do sada, u dva osnovna smjera. To su: koraci koje planira Tim za razvoj i implementaciju, uključujući i korake potaknute potrebama pogona, te koraci koje će nametnuti trenutne i buduće potrebe poslovanja tvrtke. Dobar primjer koraka kojeg su nametnule potrebe poslovanja je satna isporuka plina pogonima HEP Proizvodnje, što se pokazalo vrlo korisnim u upravljanju energetskim jedinicama. Spajanjem s procesnom aplikacijom Plinacra, direktno u PPE aplikaciju uvedeni su trenutni podaci isporuke plina za pogone HEP Proizvodnje [3]. Ovo preuzimanje podataka otpočelo je 2009. godine, a gotovo da se poklopilo s rusko-ukrajinskom krizom u isporuci plina Europi. Tako se na slici 7 vidi porast potrošnje nakon dogovorenog "puštanja" plina za HEP 20.01.2009. godine.

Koraci koji se planiraju razviti uvesti u aplikaciju u budućnosti :

- Izračun raspoloživosti po VGB standardu
- Uvođenje svih godišnjih planskih veličina poslovanja
- Uvođenje ostalih ekoloških parametara
- On-line unos podataka gdje se za to ostavare uvjeti
- Zamjena svih pogonskih izvještaja kreiranjem iz PPE
- Uvođenje komercijalnih pokazatelja rada
- Izračun naknada, koncesija
- On-line izračun trenutne cijene električne energije
- Simulacijski modul za izbor optimalnih jedinica u radu

Spomenuti on-line izračun cijene i simulacijski modul planirani su još od pojave ideje za razvoj ovog sustava, i trebali bi predstavljati najviše, završne korake aplikacije. Hoće li se oni razvijati u sklopu ove aplikacije ili će za to biti nabavljene gotove aplikacije s tržišta, ovisi o poslovnoj politici tvrtke i drugim okolnostima. No, sasvim sigurno je da će u budućnosti takve aplikacije biti neophodne, a ako budu i kupljene na tržištu, PPE aplikacija će im osiguravati nužne ulazne podatke !

IX. ZAKLJUČAK

Svojom širokom bazom podataka i drugim operativnim funkcijama, PPE aplikacija postaje sve više multi namjenski sustav za planiranje i praćenje rada svih jedinica i tvrtke u cjelini. U ovom segmentu poslovanja može zadovoljiti većinu trenutnih i budućih zahtjeva. Puna snaga i vrijednost aplikacije , zbog njenih mogućnosti, a naročito njene fleksibilnosti, doći će do izražaja tek u budućnosti, u uvjetima rada na otvorenom tržištu energije.

U aplikaciji se mogu razvijati i implementirati mnogi korisni koraci i moduli koje će zahtjevati nove, buduće okolnosti i zahtjevi poslovanja. No, aplikacija može služiti i kao široka baza i izvor podataka za druge specijalizirane aplikacije čija će se potreba eventualno pojaviti.

DISTRIBUIRANI SUSTAV DALJINSKOG VOĐENJA U RAFINERIJI NAFTE RIJEKA

B. Brestovec*, Maja Šlogar Brcko*, Predrag Domjan**, Željko Beljan**, Sanjin Jurešić**
* KONČAR – Inženjering za energetiku i transport d.d.
Falllerovo šetalište 22, 10 000 Zagreb, Hrvatska, Grad, Država
** INA Rafinerija Nafte Rijeka, Urinj bb
boris.brestovec@koncar-ket.hr

Sažetak – Elektroenergetski sustav u INA RNR izrazito je složen sustav čija je zadaće osigurati pouzdano i kontinuirano napajanje svih potrošača sustava. Razni ventilatori, pumpe, kompresori i motorni pogoni izrazito su važni kao izvršni elementi u procesu prerade nafte, te bi njihovom neplaniranom i iznenadnom obustavom rada moglo doći do naplaniranog zaustavljanja postrojenja i s time povezane ekonomske štete te nepovoljen utjecal na okoliš rafinerije.

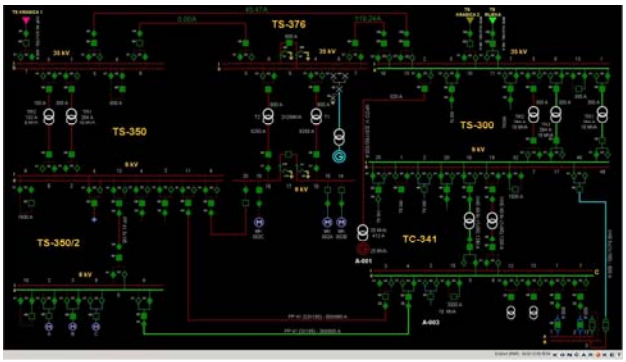
Kako bi se osigurao kvalitetan i efikasan nadzor i upravljanje samim EES u rafineriji početkom godine pušten je u pogon Distribuirani Sustava Daljinskog Vođenja (DSDV) elektroenergetskom mrežom u rafineriji. Sustav predstavlja moderan i otvoren sustav koji se temelji na sustavu SCADA i sustavu brzog rasterećenja potrošača. Oba sustava međusobno su komplementarna i nadopunjuju se omogućavajući operaterima daljinsko vođenje EE mreže uzimajući u obzir i napredne funkcije kao što su sinkronizacija postrojenja, automatsko preklapanje sekcija, praćenje smjera zemnih spojeva, optimizacija razmjene energije sa vanjskim izvorima, odvajanje EES-a u slučaju većih poremećaja na vanjskoj mreži.

Referat opisuje osnovne karakteristike i funkcije Distribuiranog Sustava Daljinskog Vođenja koji je već pola godine u radu, a isporučen je po principu ključ u ruke od strane KONČAR Inženjeringa za energetiku i transport d.d.

I. UVOD

Elektroenergetski sustav u INA Rafineriji Nafte Rijeka (INA RNR) velik je i složen sustav koji se sastoji od osnovnih dijelova: 35 kV prstena sa 6 glavnih TS i 3 turbogeneratora koji su sastavni dio parne termoelektrane. Osim vlastitih izvora napajanja (3 turbogeneratora) postoji mogućnost napajanja i iz vanjske distributivne mreže HEP ODS-a preko 2 dovodna polja. EES ima zadaću osigurati napajanje za sve potrošače u sustavu, a to su uglavnom razni elektromotorni pogoni (ventilatori, pumpe, kompresori) koji su nužni u procesu prerade nafte, a čiji se broj znatno povećao prilikom modernizacije i izgradnje novih postrojenja u zadnjih nekoliko godina.

Ovako složena EE mreža predstavlja u biti cjelokupan i zaseban EES u malom za koji postoji potreba za osiguranjem stabilnosti sustava i osiguranja pouzdanih izvora energije koji opskrbljuju potrošače na rafineriji. Slika 1. prikazuje modificiranu EE mrežu u INA RNR.



Slika 1. EES u INA RNR – prikaz SCADA sustava

Kako bi se operateru složenog energetskog sustava u INA RNR omogućio kompletan centralni nadzor i upravljanje kompletnom elektroenergetskom mrežom rafinerije, upravljanje turboagregatima i proizvodnjom električne energije, te razmjenu sa vanjskom distributivnom mrežom HEP-a nužno je bilo isporučiti suvremeni i složeni sustav daljinskog vođenja kompletnog EES-a u INA RNR.

Sustav je dizajnirao i isporučio KONČAR – Ineženjering za energetiku i transport d.d. u sklopu projekta po principu „ključ u ruke“ koji je započeo krajem 2009. , dok je puštanje u pogon sustava i završetak projekta početkom 2012.

Projekt se sastojao od projektiranja sustava, isporuka računalne i programske opreme DSDV, izradi telekomunikacijske infrastrukture i povezivanja dijelova sustava po postrojenjima, isporuka sekundarne opreme po postrojenjima, funkcionalnih ispitivanja svih cjelina, te uređenja Centra Daljinskog Upravljanja (CDU) sustava.

II. FUNKCIJE DSDV

Sigurno i pouzdano vođenje složenog EES rafinerije sastoji se od obavljanja određenih zadaća i funkcija koje je do sad ručno obavljao operater putem stare upravljačke ploče ili upravljačkog pulta, te direktno upravljajući aparatima tipkalima na poslužnim ormarićima ćelija.

Povećanjem broja pogona i postrojenja, za koje se mora osigurati pouzdano napajanje, nužno je bilo uvesti centralno mjesto sa kojega će operater moći efikasnije i ažurnije pratiti i upravljati stanjem kompletnog EES sa jednog mjesta.

Kako bi se operateru omogućilo vođenje EES prema novim uvjetima i zahtjevima koji su nastali kao posljedica modernizacije rafinerije, nužno je bilo osigurati slijedeće funkcionalnosti unutar DSDV-a:

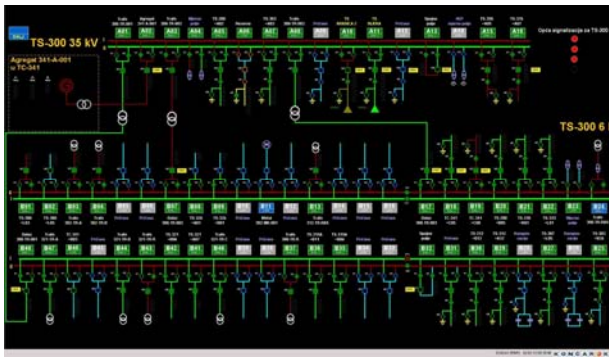
- Daljinski nadzor i upravljanje svim aparatima u glavnim TS sustava (35kV, 6kV, 0,4kV),
- Daljinski nadzor nad procesnim mjerenjima numeričkih uređaja na nivou postrojenja,
- Centralna obrada i pohranjivanje svih podataka na redundantnim SCADA poslužiteljima,
- Daljinski dohvat arhiva poremećaja sa pojedinog numeričkog uređaja,
- Brzo rasterećenje sustava (FLS engl. Fast Load Sheeding) u trenutku odvajanja distributivne mreže HEP-a,
- Zaštita i odvajanje energetskog sustava rafinerije na 2 kabelska voda HEP-ove distribucijske mreže,
- Sinkronizacija (automatska i ručna) pojedinih dijelova sustava obzirom na vlastitu proizvodnju električne energije na tri turbogeneratora,
- Optimizacija razmjene električne energije sa distribucijskom mrežom HEP-a,
- Automatski preklop na zdravu elektroenergetsku mrežu dijela koji je ostao bez napajanja,
- Automatski restart motora na ključnim postrojenjima za koja je to nužno,
- Analiza smjera zemnih spojeva na pojedinim poljima u mreži,
- Bojanje topologije mreže s obzirom na izvore u energetskom sustavu,
- Nadzor nad svim motorima u energetskom sustavu (6kV i 0,4kV).

Kako bi se osigurao veliki broj funkcija sustava nužno je bilo isporučiti suvremeni, fleksibilan i otvoren sustav koji bi omogućio distribuciju pojedinih funkcija na određene dijelove sustava.

Odlika distribuiranog sustava je da distribucijom funckija postiže efikasniji i brži odziv procesa, kao i rasterećenje i disperzija jednostavnijih zadaća u sustavu na njegove periferne komponente (uređaje na nivou postrojenja).

Prema zahtjevima pojedinih funkcija i specifičnosti izvođenja potrebno je bilo raspodijeliti zadaće na različite uređaje što na nivou samog postrojenja, a što na centralne poslužitelje podataka.

Prikupljanje podataka, izvršavanje komandi i neke automatske funkcije (automatski preklop, zaštita i odvajanje EES, sinkronizacija, automatski restart) distribuirane su na različite uređaje na nivou postrojenja. Njihov nadzor i upravljanje moguće je kako lokalno, tako i daljinski iz CDU. Slika 2. prikazuje modificiranu jednopolnu shemu koji operater vidi na radnim stanicama prilikom nadzora i upravljanja na DSDV-u.



Slika 2. Jednopolna shema na radnim stanicama SCADA sustava

Obrada, analiza i prikazivanje podataka, te razni proračuni obavljaju se na centralnim poslužiteljima podataka (SCADA obrada i prikaz podataka, proračuni algoritma brzog rasterećenja, optimizacija, analiza zemnih spojeva, topološko bojanje).

Funkcionalni zahtjevi na sustav uvelike diktira i samu arhitekturu sustava, u ovom slučaju izrazito distribuiranu.

III. ARHITEKTURA DSDV

Izrazito složenu arhitekturu DSDV moguće je hijerarhijski podijeliti na nekoliko razina [1]. Na najnižem hijerarhijskoj razini nalazi se oprema vodnih polja TS kao što su numerički terminali polja koji osim što imaju mjernu, zaštitnu i upravljačku zadaću polja, prikupljaju procesne podatke.

Tako prikupljeni procesni podaci šalju se u uređaje slijedeće razine, a to su koncentratori podataka i PLC kontroleri koji osim prikupljanja i proslijeđivanja podataka imaju i određene distribuirane automatske funkcije koje se izvrše zasebno od ostalih zadaća sustava na razini postrojenja.

Centralni poslužitelji podataka, na najvišoj razini, prikupljaju podatke iz koncentratora i PLC kontrolera i obrađuju ih i analiziraju. Tako obrađeni podaci se grafički prikazuju operateru i podloga su za izvođenje raznih složenih funkcija i proračuna. Svi kritični podaci, bilo procesni ili rezultati proračuna, adekvatno se pohranjuju u povijesnoj bazi podataka.

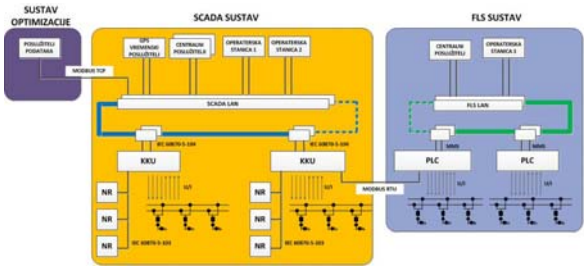
Imajući na umu hijerarhijsku podjelu sustava i distribuirano izvođenje glavnih funkcija moguće je izvršiti podjelu DSDV na:

- SCADA sustav ,
- FLS sustav,
- Sustav Optimizacije.

Slika 3. Prikazuje modificiranu arhitekturu DSDV isporučenog u INA RNR.

A. SCADA sustav

Osnovni dio cjelokupnog DSDV i najveći broj glavnih funkcija dio je SCADA sustava. SCADA sustav se sastoji od nekoliko dijelova koji se nalaze na različitim hijerarhijskim razinama unutar INA RNR.



Slika 3. Blok shema arhitekture DSDV-a

Na postrojenjima na razini polja TS nalaze se numerički terminali polja koji prikupljaju procesne podatke, upravljaju aparatima te štite postrojenje i njegove primarne dijelove. Numerički terminali polja omogućuju i lokalno upravljanje u slučaju prekida komunikacije sa CDU.

Koncentratori podataka komunikacijskim putem prikupljaju podatke iz numeričkih terminala polja putem iec 60870-5-103 standarda i šalju ih ka nadređenim centralnim poslužiteljima podataka u CDU koristeći IEC 60870-5-104 mrežni standard.

Osim komunikacijom, na ovoj se razini procesni podaci prikupljaju i putem U/I jedinice koncentratora. Na koncentratorima podataka se odvijaju i neke distribuirane automatske funkcije kao što su automatski preklop, odabir polja i upravljanje opremom za sinkronizaciju, automatski restart motora. Izvođenje automatskih funkcija omogućeno je PLC razvojnom okolinom (IEC 61131) koja je sastavni dio koncentratora podataka putem posebne centralne jedinice. Povezivanje sa centralnim poslužiteljima podataka odvija se prema mrežnom IEC 60870-5-104 standardu. Koncentratori podataka također se koriste kao čvorovi povezivanja i razmjene podataka preko MODBUS RTU ili TCP komunikacije sa postojećim procesnim sustavima EMERSON i HONEYWELL, te za komunikaciju sa posebnim postojećim PLC kontrolerima putem PROFIBUS protokola koji nadziru i upravljaju sa svim motorima na niskom naponu 0,4kV.

Za potrebe povezivanja postrojenja sa CDU izveden je optički komunikacijski sustav. Dvostruki (redundantni) optički prsten osigurava visoku pouzdanost i veliki kapacitet prijenosa podataka koji se zahtjeva u sustavima daljinskog vođenja složenih EES-a.

Centralni poslužitelji podataka nalaze se u CDU i prikupljaju procesne podatke te ih obrađuju i pohranjuju. Pouzdanost u radu osiguravaju dualni centralni poslužitelji od kojih je jedan vodeći aktivan, dok je drugi vruća pričuva i u stanju je pripravnosti. U slučaju kvara vodećeg računala, kompletno sve aktivnosti preuzima prateće računalo bez ikakvog ometanja operatera u radu. Centralni poslužitelji podataka ostvaruju i razmjenu podataka sa Sustavom optimizacije, čiji se rezultati opet obrađuju i pohranjuju na poslužiteljima. Razmjena podataka ostvarena je putem mrežnog MODBUS TCP protokola. Osim razmjene podataka sa Sustavom optimizacije, centralni poslužitelji razmjenjuju podatke i sa SCADA sustavom HEP ODS-a, ELEKTROPRIMORJE putem serijske komunikacije i IEC 60870-5-101 standarda.

Operaterske radne stanice i radna stanica sistem inženjera služe za grafički prikaz i sučelje prema čovjeku. Razni prikazi JS, te tablice alarma i grafički prikazi omogućuju operaterima nadzor na EE postrojenjima.

Da bi operater mogao daljinski nadzirati postrojenja i kompletni EES nužno je da je cjelokupan sustav vremenski sinkroniziran, što je zadaća posebnog vremenskog poslužitelja. Poslužitelj u sebi ima integriran GPS prijemnik koji osigurava sinkronizaciju svih uređaja na optičkom mreži na isto vrijeme korištenjem SNTP-a (engl. Simple Time Network Protocol). Slika 4. prikazuje upravljanje sustavom uzbude turboagregata koja je izvedena na SCADA operaterskim prikazima.

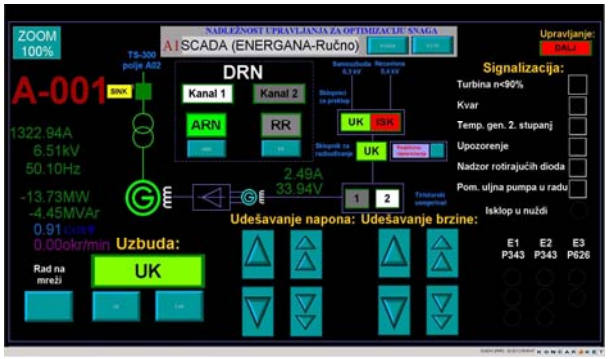
Funkcije SCADA sustava dijele se na osnovne i napredne i detaljno su opisane u [1].

B. FLS sustav

Sustav brzog rasterećenja ili FLS sustav ima za zadaću rasteretiti potrošače u trenutku odvajanja RNR sa vanjske distributivne mreže HEP-a. Proračun i algoritam rasterećenja temelji se na metodi proračuna bilance snage i na praćenju kretanja frekvencije EES u RNR.

U slučaju odvajanja sa distributivne mreže, koja je pored vlastitih parnih turboagregata nužna da bi se zadovoljio cjelokupni konzum, sustav prema tablicama prioriteta potrošača rasterećuje sustav kako bi održao i osigurao siguran rad turboagregata. U protivnome bi se manjak snage pokušao kompenzirati na račun turboagregata koji pak nisu dovoljni i oni bi se postupno zaustavili i na taj način neplanski zaustavili rad pojedinih pogona rafinerije te prouzročili financijsku i ekološku štetu [1].

Arhitektura FLS sustava slična je onoj SCADA sustava. Na razini postrojenja nalaze se PLC kontroleri koji prikupljaju podatke o stanjima aparata putem U/I jedinica ili komunikacijski preko koncentratora podataka SCADA sustava (MODBUS RTU). Upravljanje prekidačima kao rezultat proračuna algoritma brzog rasterećenja također se odvija putem U/I jedinica. Na centralnom PLC kontroleru u TS 300 izvodi se algoritam i cjelokupni proračun, te je taj kontroler izveden redundantno, dok na ostalim postrojenjima to nije slučaj. Međusobna komunikacija i razmjenu podataka između PLC kontrolera također se odvija preko dvostrukog (redundantnog) optičkog prstena, ali neovisnog od prstena SCADA sustava. Razmjena podataka između PLC



Slika 4. Upravljanje sustavom uzbude turboagregata

kontrolera odvija se korištenjem MMS standarda.

Centralni poslužitelj podataka nalazi se u CDU i prikuplja, obrađuje i pohranjuje podatke. Na poslužitelju se nalazi posebna PLC razvojna okolina koja omogućuje daljinsko uređivanje i rad na samom algoritmu.

Operaterska radna stanica služi za prikaz i grafičko sučelje prema operateru. Putem operaterske stanice moguće je definirati tablice prioriteta i pratiti raspored i tijek isključenja, te grafički pratiti snage i frekvencije EES.

C. Sustav optimizacije

Osnovna zadaća sustava optimizacije je automatsko praćenje razmjene količine energije sa distributivnom mrežom HEP ODS-a na 3 dovodna polja i praćenje proizvodnje električne energije na 3 turboagregata u sklopu parne termoelektrane. Slika 5. prikazuje modificirano sučelje prema operateru Sustava Optimizacije.

Radi velikog broja potrošača, nastalih u fazi modernizacije, neophodan je paralelan rad EES u RNR sa distributivnom mrežom HEP ODS-a.

Sustav zadavanjem količine energije koja se razmjenjuje (daje ili uzima) sa distributivnom mrežom omogućuje optimiranje proizvodnih i rafinerijskih procesa obzirom na ugovorene količine energije sa distributerom.

Ovaj sustav je u biti priprema za cjelokupnu optimizaciju proizvodnje i cjelokupnog rada rafinerije obzirom na kretanje treuntne cijene električne energije na tržištu. U skoroj budućnosti, radi liberalizacije tržišta energije, RNR će moći prema potrebi i prema financijskoj isplativosti ili kupovati ili prodavati električnu energiju u mreži optimirajući vlastitu proizvodnju električne energije putem vlastith turboagregata.

Sustav optimizacije koristi podatke sa dovodnih polja (distirbutivne mreže) i generatorskih polja o količini energije, radnoj i jalovoj snazi, te podacima o tarifi. Osim tih podataka sustavu bita su i stanja prekidača turbogeneratora i još nekih određenih prekidača na temelju kojih sustav može izračunati da li se radi o paralelenom ili otočnom režimu rada rafinerije.

Sam algoritam i proračun optimizacije izvodi se na zasebnom poslužitelju podataka koji komunikacijskim putem razmjenjuje potrebne podatke sa centralnim poslužiteljima SCADA sustava putem mrežnog MODBUS TCP standarda. Podaci se ciklički razmjenjuju i izvode se proračuni. Operater putem grafičkog sučelja zadaje količinu energije koja se želi razmjenjivati sa distributivnom mrežom.

Sustav na temelju ulaznih, prikupljenih podataka (sa centralnih poslužitelja SCADA sustava) izvodi proračune i kao izlaz daje upravljačke impulse za turboagregate, konkretno za sustav uzbude – upravljanje Q, i turbinski regulator – upravljanje P.

Upravljački impulsi se u biti preko centralnih poslužitelja podataka SCADA sustava, šalju na koncentratore koji preko U/I jedinica šalju komande prema postrojenju.

Slika 5. Grafički prikazi razmjene energije u sklopu Sustava Optimizacije

Imajući na umu rečeno, upravljanje turboagregatima moguće je automatski (preko sustava optimizacije) ili ručno (preko SCADA sustava).

IV. ZAKLJUČAK

Isporučeni sustav predstavlja izrazito složen sustav koji zadovoljava sve zahtjeve krajnjeg korisnika koji proizlaze iz zahtjeva za pouzdanim i sigurnim vođenjem EES. Specifičnost EES u rafineriji je ta da je sustav izrazito složen sa velikim brojem potrošača koji zahtjevaju pouzdano napajanja električnom energijom, čiji bi čak i kratkotrajni neplanirani ispad mogao prouzročiti materijalnu i financijsku štetu te ekološki incidednt.

Za osiguranje strogih zahtjeva napajanja nužno je da se osigura siguran paralelan rad RNR sa okolnom distirbutivnom mrežom HEP ODS-a.

Da bi se u današnje doba globalizacije tržišta, a posebno u ovo doba recesije uz liberalizaciju tržišta energije (plina, nafte, električne energije) moglo opstati i kvalitetno poslovati nužno je optimirati svaki dio osnovne djelatnosti, a posebno se to odnosi na potrošnju EE.

Uzevši u obzir sve te činjenice ispravno rješenje za vođenje pogona i kompletnog EES rafinerije jest bilo uvođenje centralnog sustava koji će automatizirati sve zadaće operatera i složene funkcije koje se zahtjevaju.

Distribuirani Sustav Daljinskog Vođenja EES u INA RNR predstavlja izrazito složen sustav koji distribucijom arhitekture i funkcija te njihovom automatizacijom olakšava izvođenje svih zadaća operatera te na taj način povećava efikasnost i ekonomičnost vođenja sustava.

Svi podaci izneseni u članku su informativni i ne odražavaju stvarno stanje u cilju očuvanja poslovnih tajni i informacija.

Modeliranje transportnih tokova obojenom Petrijevom mrežom

Marina Bagić Babac i Dragan Jevtić*
* Fakultet elektrotehnike i računarstva, Zagreb, Hrvatska
marina.bagic@fer.hr, dragan.jevtic@fer.hr

Sažetak – Obojena Petrijeva mreža kao jezik i programsko pomagalo za modeliranje složenih konkurentnih distribuiranih sustava omogućava simulaciju transportnih tokova. Mehanizmom analize prostora stanja ukazuje na nedostatke, zastoje i nepravilosti transportnih tokova čija uklanjanja odnosno modifikacije značajno doprinose porastu efikasnosti cjelokupnog procesa transporta. U ovome radu prikazano je modeliranje obojenom Petrijevom mreže na primjeru kontejnerskih transportnih tokova brodova u lučkim terminalima. Korištenjem ovakvih programskih pomagala u procesima optimizacije moguće je značajano smanjiti ukupno vrijeme boravka broda u luci što je i krajnji cilj transportnih tokova kontejnera.

I. UVOD

U lučkim terminalima cirkulira ogroman broj kontejnera. Kontejneri se moraju ukrcati i iskrcati s brodova te se pri tome transferiraju raznim modovima transporta. Pri tome se koristi čitav niz opreme i prometnih sredstava, od teretnih brodica do kamiona i željeznice. Razvojem tehnologije kapacitet brodova značajno je porastao u zadnjih nekoliko desetljeća pa su i zahtjevi na efikasno i optimalno korištenje takvih brodova značajno porasli. Procesi vezani uz transportne tokove teže smanjivanju boravka brodova u luci zbog minimizacije materijalnih troškova, ali i troškova ljudskog rada, te su izrazito važni u smislu strateškog razvoja luke kao i regije odnosno zemlje u kojoj se luka nalazi.

Uzmimo primjerice hrvatsku luku Rijeka. U razdoblju od 2002. do 2010. Luka Rijeka d.d. povećala je ukupni promet za 69%. Gledano po vrstama tereta moguće je uočiti pozitivan trend generalnog tereta čiji je promet povećan za 9% i nakon pada u 2009. u 2010. vraćen na razinu rekordne 2008. Pozitivan trend u odnosu na 2009. ostvaren je također u prometu drva, dok je negativan trend zabilježen samo u prometu nekih vrsta rasutog tereta [4].

Dakle, na promet lučkih terminala uvelike utječe unutrašnja organizacija odnosno funkcioniranje međusobno povezanih elemenata transporta. U tom smislu funkioniranje odnosno efikasnost prometa u luci određuju strateški, taktički i operacijski planovi luke. Strateški planovi podrazumijevaju materijalne resurse koji se dugoročno planiraju i nabavljaju (od jedne do više godina), poput potrebnih dizalica i teretnih vozila. Taktički planovi odnose se na odabir informacija i odluka o organizaciji rada luke. Primjerice, na koji način će se slagati kontejneri u skladištu. Ovakve odluke donose se na razdoblje od nekoliko dana do mjeseci. Na operacijskoj razini su svakodnevni problemi, poput pitanja gdje odložiti određeni pristigli kontejner.

Cjelokupni proces strateškog, taktičkog i operacijskog planiranja te unutarlučke procese prijenosa tereta između točaka utovara, istovara i pohrane tereta, moguće je optimizirati programskim pomagalima informacijsko komunikacijskih tehnologija. Konkretno, u ovome radu odabrana je obojena Petrijeva mreža kao pomagalo koji efikasno modelira složene i distribuirane konkurentne sustave. Obojena Petrijeva mreža (*Coloured Petri net*, u daljnjem tekstu CPN) odnosno CPN Tools kao pomagalo za modeliranje i simulaciju daje konkretne statističke podatke o modeliranoj CP-mreži. CP-mreža može predvidjeti, utvrditi i spriječiti probleme poput zastoja, začepljenja i blokade transportnih tokova. Simulacijom i metodom prostora stanja pomagalo daje konkretan uvid u eventualne manjkavosti modeliranog sustava te time podiže kvalitetu odnosno efikasnost modela što u konačnici omogućava ubrzavanje stvarnovremenskih procesa prisutnih kod transportnih tokova lučkih kontejnerskih terminala.

Rad se tematski sastoji od tri dijela. Prvi dio daje uvid u problematiku i složenost lučkih procesa transportnih kontejnerskih tokova. Drugi dio razlaže osnove obojene Petrijeve mreže kao jezika i pomagala za modeliranje navedene problematike. Treći dio daje konkretan primjer modela lučkog kontejnerskog terminala i rezultate simulacije odnosno analize prostora stanja obojene Petrijeve mreže.

II. LUČKI TRANSPORTNI TOKOVI

Lučki transportni tokovi uglavnom podrazumijevaju intermodalni transport tereta. Intermodalni transport je uzastopni prijenos jedinica tereta pomoću dvije ili više vrsta transporta bez potrebe prepakiravanja unutar kompleksnog transportnog lanca. U takvom kompleksnom transportnom lancu luka je posebna vrsta točke pretovara robe. Njezinu posebnu aktivnost određuje postojeća infrastruktura, hidrometeorološki uvjeti geografskog položaja te povezanost s nacionalnom infrastrukturom zemlje. Transportni lanac moguće je podijeliti u odvojene faze u svrhu detaljnije analize odnosno postizanja veće učinkovitosti i cjelokupne brzine transporta.

Ovaj rad podupire Ministarstvo znanosti, obrazovanja i sporta Republike Hrvatske u okviru znanstveno-istraživačkog projekta 036-0362027-1640 „Upravljanje mrežom i uslugama temeljeno na znanju“ .

Kad brod stigne u luku, potrebno je s broda skinuti pristigle kontejnere. To se radi pomoću obalnih dizalica (engl. *quay crane*) koje skidaju kontejnere s palube i sa skladišta broda. Zatim se kontejneri prenose posebnim vozilima do kontejnerskih složaja (engl. *stack*). Složaj je u pravilu podijeljen na nekoliko zona (engl. *lane*) u kojima kontejneri budu smješteni određeno vrijeme. Zonama pristupaju dizalice ili posebni nosači (engl. *straddle carrier*) koji mogu i voziti i pospremiti kontejner na složaj. Kad vozilo dođe do složaja, spusti teret na zemlju ili složajna dizalica uzme teret s vozila i pospremi ga na složaj. Nakon određenog vremena kontejneri se dizalicama uzimaju sa složaja i prevoze prometalima ovisno o sljedećem transportnom modu, teretnim čamcima, kamionima ili vlakovima.

Većina terminala ručno upravlja vozilima nosačima, dizalicama i prikolicama (engl. *multi-trailer-systems*), ali neki su i automatizirani poput terminala u Roterdamu [4]. U takvim terminalima za prijevoz kontejnera koriste se AGV-ovi (engl. *automated guided vehicle*). Koriste se i ASC-ovi (engl. *automated stacking cranes*) radi ubrzanja procesa oko kontejnerskih složaja.

A. Dolazak broda

Kad brod pristigne u luku, najprije se mora usidriti na nekom od raspoloživih sidrišta (engl. *berth*). Broj raspoloživih sidrišta u luci jedna je od strateških odluka u luci dok je pak operacijska odluka dodijeliti sidrište brodu na licu mjesta. Modeli sidrenja su raznoliki, od modela prvi dođe prvi ode (engl. *first in first one*) do alociranja prema vrsti tereta koju brod nosi.

B. Utovar i istovar broda

Broj dolaznih kontejnera nekog broda koji trebaju biti isotvareni u terminalu obično je poznat tek kratko vrijeme prije stizanja broda. Plan istovara precizira koje kontejnere treba istovariti i gdje se oni nalaze na brodu. Vrijeme istovara ovisi o položaju kontejnera na brodu tako da to vrijeme varira od broda do broda.

Za razliku od istovara puno je manje fleksibilnosti kod utovara broda. Za brz i efikasan utovar kontejnera potreban je kvalitetan distribucijski plan kontejnera koji ovisi o fizičkim karakteristikama broda i rasporedu posjeta lukama. Jedan od mogućih pristupa ovome planu je Monte Carlo metoda [4].

C. Prijenos kontejnera od broda do složaja i obrnuto

Jedna od strateških odluka mora biti dizajn terminala odnosno materijalni resursi koji upravljaju prijenosom kontejnera. Za prijenos jednog kontejnera na ručno upravljanim terminalima koriste se vozila poput viličara (engl. *forklift truck*), kamiona za transport (engl. *yard truck*) ili nosača (engl. *straddle carrier*). Dizalica pomaže ukrcati kontejner na kamion. Za prijenos više kontejnera koristi se višestruki prikoličar (engl. *multi-trailer system*). U automatiziranim sustavima za interni prijenos koriste se AVG-ovi (engl. *automated guided vehicle*) koji imaju kapacitet 1 ili 2 TEU tereta po kontejneru.

D. Interterminalni transport i drugi modovi transporta

Kontejnere je potrebno transportirati od složaja do drugih modova transporta poput teretnih brodica, željeznice i cesta. Očekuje se da će porastom terminala ovaj interterminalni transport dobiti na još većoj važnosti. Za takav promet potrebna su vozila poput višestrukog prikoličara ili AGV-ova. U nekim je terminalima moguće i da kontejneri idu direktno na, npr. vlakove bez korištenja transportnih vozila.

III. INFORMACIJSKI TOKOVI O TRANSPORTU

Opisane procese prisutne kod transportnih tokova kontejnera povezujemo s, tzv. informacijskim tokom. Informacijski tok podrazumijeva skup podataka koje koristi sustav, a služi pri obradi izvođenja transportne aktivnosti [2]. Potrebna je multilateralna veza između centra za obradu informacija i raznih izvora informacija za ritmično i sigurno funkcioniranje transportnog lanca. Ovu vezu osiguravaju računala lokalne mreže u centrima za prikupljanje, obradu i raspačavanje informacija. Ovakvi centri su najčešće u samim lukama koje su čvorovi različitih transportnih tokova i prometala. Postoje tri vrste informacija u ovakvim bazama podataka [2]:

- statički podaci – ovi podaci unose se u sustav najčešće samo jedanput jer su to, npr. informacije o brodovima (ime, identifikacijski broj, kapacitet, snaga motora, gorivo, brzina, itd.), zatim podaci o hidrometeorološkom režimu vodenih transportnih ruta (dimenzije, dubina, brzina, itd.), karakteristike luke (interni lučki transport, norme za pretovar tereta, nabava rezervnih dijelova, itd.)
- dinamički podaci duljeg trajanja – podaci o vrsti tereta, vrijeme utovara broda, vrijeme odlaska, vozarina, vrijeme i datum dolaska broda u različite luke, itd.
- dinamički podaci kraćeg trajanja – koordinate lokacije broda, hidrometeorološka prognoza, trenutne promjene u vodenim rutama, itd.

Sve dolazne informacije korisnika proslijeđuju se centru i obrađuju prema stupnju važnosti. Korisnici su brodovi, navigacijske kompanije, vlasnici brodova, pošiljatelji tereta, brodske agencije, primatelji tereta, luka, nadzornici navigacije, lučka policija, carinarnica, ekološke organizacije, spasilačke ekipe, motorni transportni centar, itd.

Podatke možemo podijeliti s obzirom na mjesto otkud se šalju, dakle podaci koji se šalju s broda i podaci koje sustav šalje brodu. Podaci koje brod šalje sustavu su: lokacija broda, brzina kretanja, vjerojatnost dodatnog utovara, potreba za dodatnim resursima (gorivo, voda, hrana, rezervni dijelovi), nužnost popravka, nužnost novih certifikata za tehničku opremu broda, nužnost medicinske pomoći, i slično. Podaci koje sustav šalje brodu su: redoslijed sidrenja u luci, vrijeme čekanja na pristaništu, način i redoslijed dobivanja rezervi, vjerojatnost popravaka, stanje otpuštanja i primanja tereta, trajanje istovara i utovara tereta, trajanje popravka, i slično.

Transportno lučko vozilo šalje podatke o lokaciji transportnog vozila, brzini kretanja, očekivanom vremenu

pristizanja u luku, načinu distribucije tereta, redoslijedu istovara, vjerojatnosti dodatnog utovara, nužnosti obnove rezervnog goriva, rezervnih dijelova te nužnosti popravka. Transportno lučko vozilo prima podatke o redoslijedu pristizanja u luku, vremenu čekanja u sidrištu, statusu otpuštanja i primanja tereta, trajanju istovara i utovara tereta te trajanju popravaka.

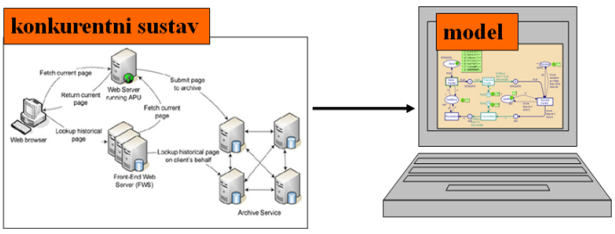
IV. MODELIRANJE KONKURENTNIH SUSTAVA

Pod modeliranjem se podrazumijeva proces oblikovanja, izrađivanja na temelju nekog uzorka. Rezultat tog procesa je određeni model. Model predstavlja apstraktni prikaz sustava i posjeduje barem osnovna svojstva originala. Modelima se omogućava opisivanje složenih fenomena. Upotrebom modela ti se fenomeni rješavaju, a modeli time postaju važno komunikacijsko sredstvo ljudi koji se bave tim fenomenom [1]. U ovome radu fokusirani smo na izradu modela prometa odnosno transportnih tokova unutar lučkog kontejnerskog terminala. Odabrani jezik za modeliranje je obojena Petrijeva mreža koja je izuzetno jaka formalna metoda (teorijski podržana matematičkim aparatom) u modeliranju posebno konkurentnih i distribuiranih sustava.

A. *Obojena Petrijeva mreža*

Konkurentni i distribuirani sustavi uglavnom su složeni i zahtjevni za dizajniranje i testiranje jer njihovo izvođenje može otići u različitim smjerova. Primjerice, poslana poruka može se izgubiti u prijenosu, mogu se mijenjati brzine pojedinih procesa sustava, te vrijeme u kojem stižu poticaji iz okoline, itd.

Obojene Petrijeve omogućavaju konstrukciju i analizu distribuiranih i konkurentnih sustava. CPN model nekog sustava opisuje stanja u kojima se sustav može nalaziti i moguće prijelaze između tih stanja. CPN primjenjuju se u velikom broju raznih područja, poput modeliranja komunikacijskih protokola, audio/video sustava, operacijskih sustava, u dizajniranju hardvera i softvera, itd.



Slika 1: CPN za modeliranje konkurentnih sustava

Obojene Petrijeve mreže razvile su se iz potrebe za industrijski jakim jezikom za modeliranje koji je istovremeno teorijski dobro potkovan i dovoljno svestran za praktičnu upotrebu. Ponašanje CPN sustava provjerava se simulacijom kojom se mogu uočiti te ukloniti pogreške u dizajnu sustava. Promatranje svakog koraka simulacije realnog cjelovitog sustava obično nije moguće, ali se zato može pratiti u većim koracima.

Ispravno funkcioniranje nekih sustava ovisi i o vremenu koje je potrebno za određene aktivnosti pa CPN uključuju koncept vremena. Vremenski CPN modeli i simulacija mogu se iskoristiti za analizu, npr. kvalitete usluge.

CPN model može se strukturirati kao hijerarhija više manjih elemenata. Takve elemente zovemo modulima. Novi moduli mogu se stvarati iz već postojećih modula, a mogu višestruko se upotrebljavati u više dijelova istog CPN modela. Budući da se radi o strukturiranom hijerarhijskom mehanizmu, mogu se razdvojiti različite razine sustava u istom CPN modelu.

Analizom, tzv. prostora stanja (engl. *state space*) CPN-a provjeravaju se funkcionalne ispravnosti odnosno slabosti sustava. Ovom metodom računaju se sva moguća stanja i promjene stanja sustava pa se mogu otkriti nedostaci poput zastoja, nemogućnosti da se uvijek može doći u neko stanje, itd. što je u konačnici i svrha CPN modela i programskog pomagala.

B. *Modeliranje mjesta i prijelaza*

CPN model uvijek se prikazuje kao grafički crtež. Stanja u CPN modelu predstavljena su pojmom mjesta (engl. *place*) koja su na slici nacrtana kao elipse. U pravilu se imena mjesta pišu unutar elipse. Imena nemaju toliko formalno značenje koliko pomažu čitljivosti CPN modela (slično kao mnemonička imena u programiranju). Isto se odnosi i na grafički položaj mjesta, debljinu linija, veličinu, boju, vrstu slova, poziciju, itd. Mjesta ne opisuju direktno moguća stanja sustava već samo doprinose opisu cjelokupnog stanja sustava.

Svako mjesto ima pridruženu boju ili, preciznije, skup boja (engl. *colour set*) koji određuje vrstu podataka koju mjesto može sadržavati. U pravilu se skup boja mjesta piše pored mjesta. Skup boja odnosno vrsta podataka slične su vrstama u programskim jezicima. Stanje sustava sadrži određeni broj oznaka (engl. *token*) pozicioniranih na svakom pojedinom mjestu mreže. Svaka oznaka nosi neku vrijednost koja pripada skupu boja mjesta kojemu oznaka pripada. Oznake koje se nalaze na nekom mjestu nazivaju se stanjem tog mjesta. Boja je inače metaforička slika kada promatramo oznake CPN-a koje se razlikuju jedna od druge, za razliku od običnih Petrijevih mreža koje imaju crne oznake koje se ne razlikuju.

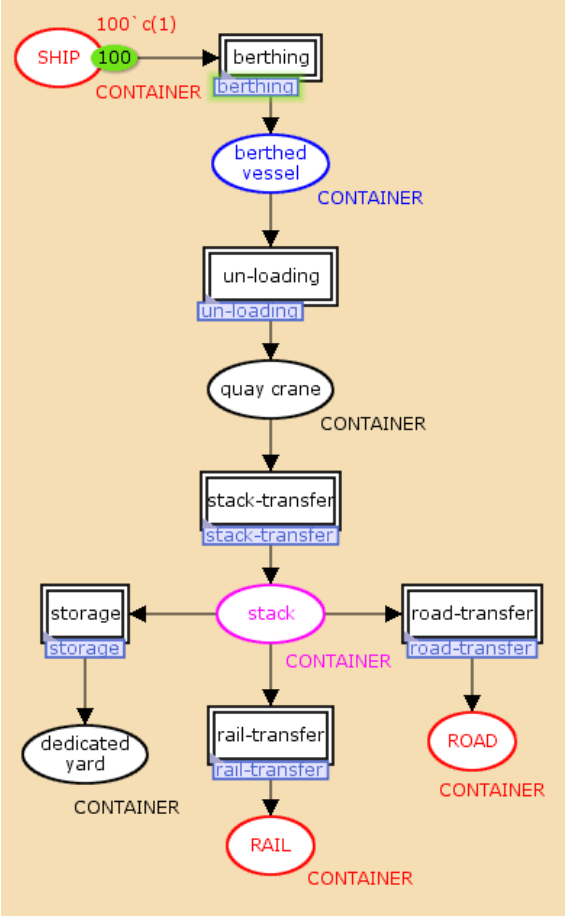
Promjene stanja CP-mreže događaju se izvođenjem prijelaza (engl. *transition*) koji se crtaju kao pravokutnici. Kao i kod stanja, imena prijelaza pišu se unutar pravokutnika.

Prijelazi i mjesta povezani su granama. Izvođenjem prijelaza pomiču se oznake sa mjesta iz kojeg grana izlazi (ulazna mjesta u prijelaz) i dodaju oznake na mjesta u koja grane ulaze (izlazna mjesta iz prijelaza), a pri tome se mijenja ukupna označenost odnosno stanje CPN-a.

Točan broj dodanih i pomaknutih oznaka izvođenjem prijelaza, i njihove vrijednosti su određeni *izrazima* na granama. Dvosmjerna grana je naprosto pojednostavljenje koje predstavlja dvije grane suprotnih smjerova sa istim izrazima. Promjena stanja CP-mreže sadrži jedan ili više prijelaza koji se izvode istovremeno.

C. *Hijerarhijska mreža transportnih tokova*

Obojena Petrijeva mreža omogućava simulaciju transportnih tokova kontejnera u lučkim kontejnerskim terminalima.



Slika 2: CPN model transporta kontejnera za lučke terminale

Na slici 2 izdvajamo pojednostavljeni prikaz procesa koji se odvijaju u lučkom transportnom terminalu pomoću CP-mreže. Mjesta *Ship*, *Road*, *Rail* odnose se na moguće transportne modove kroz koje prolaze kontejneri. Prijelazi *berthing*, *un-loading*, *stack-transfer*, *storage*, *road-transfer*, *rail-transfer* su redom složeni odnosno, tzv. zamjenski prijelazi (engl. *substitution transitions*). Za razliku od „običnih" prijelaza, zamjenski predstavljaju module odnosno zamjensku podmrežu koja se također sastoji od skupa mjesta i prijelaza. Uvođenjem modula postiže se efekt hijerarhije CP-mreže jer, primjerice, na slici 2 vidimo prijelaz *berthing*, ali ne vidimo detalje njegova izvođenja. Dakle, na ovoj višoj razini apstrakcije jasno je da se izvodi prijelaz *berthing*, ali se tek uvidom u nižu hijerarhijsku razinu apstrakcije može dobiti uvid u to kako točno radi prijelaz *berthing*. Moguće je i gniježđenje zamjenskih prijelaza radi prikrivanja detalja izvođenja na različitim razinama apstrakcije.

Nakon što se brod usidri, slijedi istovar kontejnera (prijelaz *un-loading*) pomoću lučkih dizalica (mjesto *quay crane*) te prijevoz do složaja (prijelaz *stack-transfer*). Nakon što određeno vrijeme budu na složaju kontejneri se dalje distribuiraju ovisno o narednom transportnom modu (ceste, željeznica, drugi brod).

Prostor stanja (engl. *state space*) CP-mreže predstavlja skup svih mogućih odnosno dohvatljivih stanja (ili označenosti) mreže kroz koja ona može proći tijekom izvođenjem protokola.

Uzme li se red veličine stotine kontejnera za CP-mrežu, dobije se prostor stanja sa 35429 čvorova i 143121 grana. SCC graf nije moguće postići u ovoj izvedbi CP-mreže jer nema zatvorenih petlji (kontejneri bespovratno odlaze iz sustava nakon što se pravilno usmjere). SCC elementi, koji sačinjavaju SCC graf (engl. *strongly connected component*), su maksimalni podgrafovi u kojima postoji put između bilo koja dva čvora (jedan čvor odgovara jednom stanju). Svaki čvor prostora stanja pripada točno jednom SCC elementu pa je analizom SCC grafa moguće brže dobiti ponašajna svojstva CP-mreže.

Svojstva o aktivnosti mreže pokazuju da nema *home* stanja, a inače je to ono stanje koje je dohvatljivo iz svih dohvatljivih stanja. Stanje u zastoju je pak ono u kojemu nema više omogućenih prijelaza za izvođenje. Prijelazi u zastoju (engl. *dead transition instances*) su oni koji niti u jednom dohvatljivom stanju nisu omogućeni, a ovdje se dakle svi izvedu barem jednom. Aktivni prijelazi (engl. *live transition instances*) su pak oni koji uvijek mogu biti ponovno omogućeni za izvođenje. U primjeru nema aktivnih prijelaza zbog postojanja stanja u zastoju.

Također ne postoje beskonačni slijedovi izvođenja.

V. ZAKLJUČAK

U radu je prikazano modeliranje obojenom Petrijevom mrežom na primjeru transpornih tokova kontejnera u lučkim terminalima. Rezultati izvođenja CP-mreže ovise o početnom rasporedu oznaka. Kritične točke naše CP-mreže su opterećenje i količina brojem kontejnera što ukazuje na potrebu iznalaženja algoritama za ravnomjerniji ulazak i raspored kontejnera u sustavu.

suad.ibrahimkadic@fds.ba; sead.kreso@etf.unsa.ba

This paper describes implementation of the project already presented at the 34th International Convention MIPRO 2011. A new control system for stem moisturizing line in Tobacco factory Sarajevo has been designed and implemented, including both PLC and SCADA applications. The aim of this paper is to investigate the benefits of control system design based on the recommendations from the international standard for batch control systems IEC 61512-1, through a practical example.

The paper describes one approach for development of a batch control system.

I. INTRODUCTION

THROUGH the continuous operation of the stem moisturizing line in Tobacco factory Sarajevo, numerous failings of the line control system have been recognized, to name just a few [1]:

1) No archiving of the key process variables
2) No batch traceability
3) No integration in the SCADA system existing in the remaining part of the Primary process
4) No analysis of the quality of production possible upon the completion of a batch

After the existing control system had been analyzed, two main suggestions were given:

1) Develop a new PLC program, according to the IEC 61512-1
2) Develop a new SCADA application and integrate it into the SCADA system existing in the remaining part of the Primary process

The idea was to try to solve the recognized failings without significant financial investments, by using the available potential of the existing equipment in a more extensive and efficient way.

Since the moisturizing line represents only the first of the three parts of the stem preparation process, each controlled by its own control cabinet, it was necessary to implement certain information exchange with the relevant control cabinets in order to have fully automated process. Furthermore, in order to have the SCADA application totally integrated into the SCADA system already present in the remaining Primary process, it was necessary to adopt the data structures and the screen organization in the same way, or as similar as possible.

The solution needed to be prepared in such a way that the user can define the number of recipes to work with, together with its structure, having the possibility also to make and track the modifications of these recipes over the time.

The solution needed to be prepared for possible future integration into a higher control system, through a supported remote control.

II. CONTROL SYSTEM DESIGN

Prior to writing the actual code, it is extremely important to deeply understand the process and all the required functionality of the control system.

In this section a short description of the steps taken in the control system design will be given.

A. Building the models

A good way to start to become familiar with the process is to build the three models, according to IEC 61512-1 [2]:

1) Process model
2) Physical model
3) Procedural control model

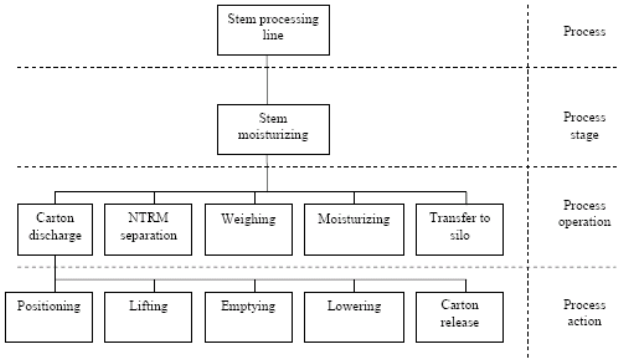

Figure 1: Example of the Process model

On the Fig. 1, an example of the Process model hierarchy is given, with only one Process stage shown in more details. On the left-hand side, there are elements of the model that

belongs to the same hierarchy level. On the right-hand side, the name of the level is stated, according to IEC 61512-1.

After creating the Process model, the same approach is applied to the Physical and Procedural control models.

Having all the three models known and relations between the same hierarchies defined, proves that the process to be controlled is well known.

B. *Defining possible states*

According to the IEC 61512-1, equipment entities and procedural elements may have states. After the three models have been created, the next step was definition of the possible states for equipment and for procedural elements as well.

This step required a detailed analysis of all the Equipment modules and Units from the Process model and definition of all the possible states for each of them. The information about the actual state is propagated through hierarchy levels up to the top, so the control system can react accordingly.

An example of possible states e.g. for moisturizing cylinder could be:

1) *Off* – the line is stopped and the batch is stopped also
2) *Preheating* – the line has started, but the cylinder has not warmed up
3) *Idle* – the line has started and the cylinder preheated
4) *Run In* – material present at the feed end and not at the delivery end of the cylinder
5) *Normal Run* – material at both sides of cylinder
6) *Run Out* – material only at the discharge side of the cylinder
7) *Washing* – washing operation in progress

In the same way, the possible states of the complete line and batch can be defined as well. Possible states of the complete line can include information like:

1) *Not permissive to run*
2) *Partially permissive to run*
3) *Totally permissive to run*
4) *Line running*
5) *Line partially running*
6) *Line stopped*

After defining the possible states, the conditions for transition from one to another must be clearly defined.

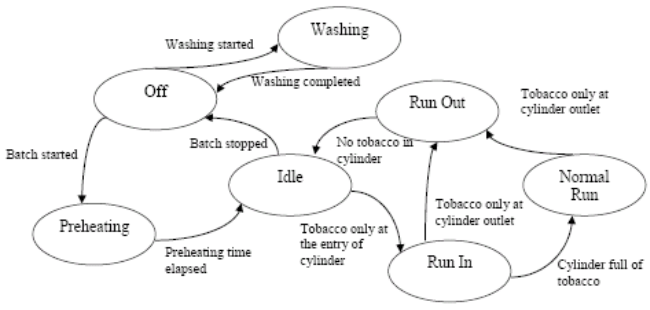

Figure 2: Example of unit state transitions

A sample diagram showing the possible states and conditions for transition for moisturizing cylinder is shown on Fig. 2.

C. *Equipment allocation and arbitration*

Depending on the processing activities required, available equipment and possibility to improve the efficiency by working with materials belonging to different batches at the same time, allocation of the equipment can be more or less demanding task. However, this is always a point that needs to be observed carefully.

In the mentioned project, just a few cases with possible allocation problems were found. In all these cases, the solution can be issuing "not available" signal to control system from the equipment in question. In other words, the algorithm works as "the first demand issued – first gets served"[5].

For example, moisturizing cylinder is a Unit that requires washing after every batch. When a batch is finished and the line is stopped, the washing operation can enter the state "Washing permissive". Once the washing has started, the complete line can be started only partially in the automatic mode, because all the motors an valves needed for washing have already been allocated to washing operation and can not be used for other purposes in automatic mode.

D. *Modes of operation*

As already mentioned, different modes of operation are possible. In this project, two modes are available:

1) *Manual*
2) *Automatic*

Manual mode is generally used for maintenance, cleaning or similar purpose. However, when in this mode, it is under the operator's responsibility to follow the regulations for operating the equipment, although the control system still takes care of the safety preconditions, wherever possible.

Automatic mode is used in normal operation of the equipment.

E. *Recipes*

It is very important at this stage of the control system development to define the way how the information from the recipe will be retrieved, used and stored by control system. Besides that, the control system needs to provide the user a possibility to modify the actual recipe parameters, automatically saving all the modification into a report, available for later analysis.

The structure of the recipe is also a part of the standard IEC 61512- 1. According to this, a recipe contains the following categories of information:

1) *Header*
2) *Formula*
3) *Equipment requirements*
4) *Procedure*
5) *Other information*

Together with the technologists engaged in this part of the process, the structure of the recipe is defined, in terms of quantity and type of information a recipe should contain.

III. CONTROL SYSTEM IMPLEMENTATION

In this section, due to the space requirement, only the most important stages of the control system implementation will be presented.

Implementation of a batch control system is a quite demanding and complex task. There is a huge amount of information that need to be built in a correct way, then structured and properly used. Many of these are potential source of a problem – "a bug", so programming and testing the code can be time-consuming job [4].

A. PLC program development

Since the original PLC used in the existing control cabinet had enough capacity to handle the estimated size of the program and computing complexity, there was no need to change the hardware. The intention of this project was to change only the software, so the hardware configuration [3] from the original project had been used.

Complete task was deeply analyzed and separated into lower-level tasks, to mention just a few:

1. Development of code for building general information used later in the project.
2. Development of code for Unit and Equipment modules logic.
3. Development of code for handling recipes.
4. Development of code for handling batches.

Once the physical equipment is defined, developing the code for preparation of all the status information can be a time-consuming task. All the data related to motors and valves, auxiliary functions, general working preconditions, actual alarms etc is programmed here.

The fact that all the equipment is physically connected in such a way that it fulfills only the dedicated task, significantly simplified the solution. A great deal of procedural control module is practically defined by the connection of the physical equipment. After the Unit and Equipment modules logic were created, these were simply connected one to another, following the physical connection. In this way, both the Procedural and the Physical model were finished.

B. Recipe handling

In order to have the Process model completed, it was necessary to implement also the recipe handling logic.

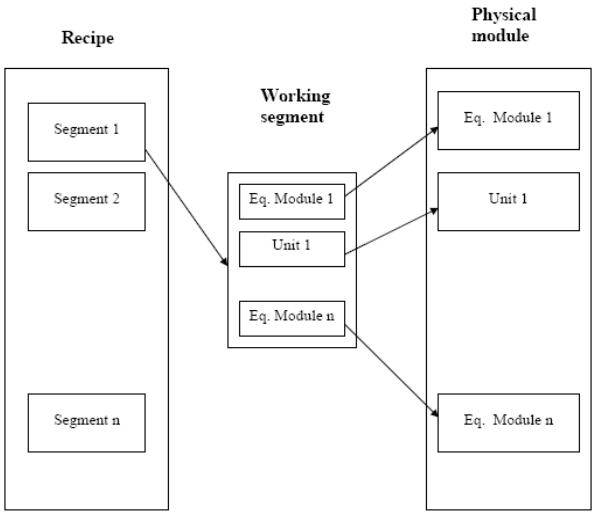

Figure 3: Handling recipes

Since the controlled process was about treating different types of tobacco stem under different conditions, recipe contained all the parameters needed to define these conditions. The number of recipes to be worked with was estimated, as well as maximum number of different types of tobacco stem that can be mixed in one recipe. After this, appropriate data structures were created and adequate space was reserved in the CPU memory.

Control program recognizes current type of tobacco stem and copy appropriate segment of current recipe into a dedicated area. Unit and Equipment modules logic continuously access this area and use the values read from there for normal operation, until the batch is completed.
The principle has been shown in Figure 3.

C. Control code hierarchy

When all the mentioned segments of code had been developed, it was necessary to connect it one to another in a correct way. In Fig.4 a short overview of the control code hierarchy is presented.

At the top level, the Batch control block is situated. This is where recipe handling, batch start/stop and code for preparation of reports data is programmed. From this block, necessary coordination control information is sent to the Equipment control block.

The Equipment control block contains all the Equipment modules and Units, programmed as separated blocks of code. In every single block of code, appropriate commands, statuses and/or setpoints for PID control loops are created, based on information supplied by Batch control block.

These commands are sent to executive blocks, like motor and valve blocks. As result, physical outputs signals are applied and correct status information are collected.

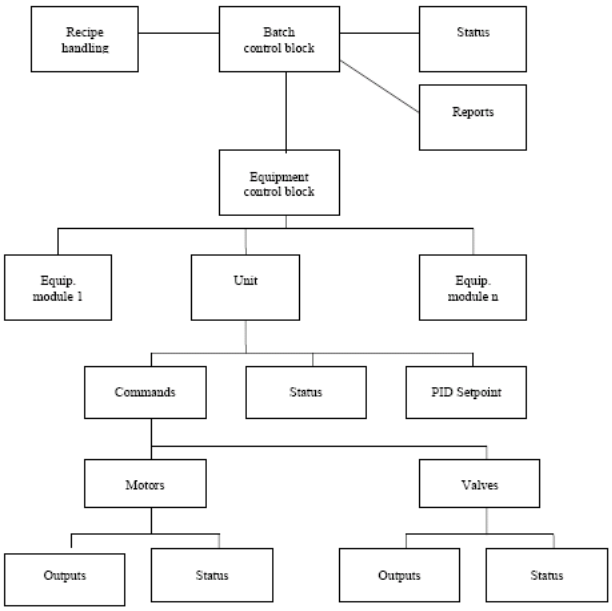

Figure 4: Control code hierarchy

D. SCADA application

Due to the requirement to integrate the SCADA application totally into the existing SCADA system, decision was made to actually extend the existing system by creating additional screens, data structures, alarm messages, process variables logging/archiving, automating functions and actions, reports etc. Naturally, the existing database had to be modified accordingly.

This approach saved some work, since already adopted philosophy of a screen organization could be used, as well as some data structures, screens, etc.

As the first step, communication to the target CPU over Ethernet network is configured. After this, all the process tags used in the visualization project was created and the relevant address configured.

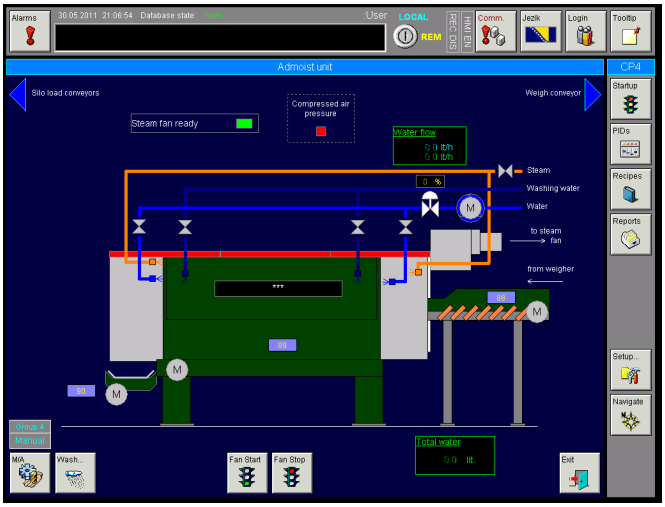

Figure 5: An example of a visualization screen

Fig. 5 shows the visualization screen for moisturizing cylinder. The screen organization can be recognized from the figure:

1) Main screen is located in the central area, showing the statuses of the variables related to the unit

2) Navigation buttons are located on the right-hand side

3) Some system information and global buttons are located on top of the screen

E. Testing the code

All the mentioned activities on batch control system design and implementation were tested on the actual equipment in Tobacco factory Sarajevo. In order to have the quantity of material out of specification minimized, thorough testing process of the new control system was conveyed.

The process of code testing started actually even before the code was downloaded to the CPU. As the second step in code testing, inputs and outputs addresses were checked. After this, all the safety-related functionalities were checked also.

Once the mentioned checks were successfully completed, the functional test of all the motors and valves in manual mode was conveyed. After this, a separate test of every unit with appropriate parameter setting was conveyed. At the same time, statuses of all the equipment in all the visualization screens were checked and corrected, if necessary.

At this point, automatic mode of line operation was tested, as well as the communication to the other control cabinets, required for fully automated work of this line.

Having these checks finished, the recipe handling and batch control code were tested.

Finally, the complete line and batch operation were tested, having the real material only simulated. After some acceptable results were achieved, as the final stage, the first batch with real materials and real recipe was operated.

IV. Results

In this section some results of the new control system design and implementation will be presented.

A. Volume of changes

In order to provide the user with all the information he/she may need, a significant effort has been made. This is equally true for PLC and SCADA systems.

At the PLC side, the complete automation task was repeatedly split to several simpler tasks, which resulted in the code organization with great code reusability.

Trough the whole project, 10 functional blocks, 58 functions, 57 data blocks and a few organization blocks have been programmed.

At the same time, at the SCADA system side, 29 new visualization screens in total have been created. The system uses 630 process variables, 4 of which are cyclically logged and archived in the system. 170 alarm messages have been configured, a database table has been created and many

different global script functions and actions have been programmed.

B. Benefits from the new control system

Just like expected, it turned out that a different code organization can make a difference in equipment operation.

The first recognizable benefits appeared even during the code testing, proving that the new code organization provides bigger code reusability. This made the code testing process significantly shorter. At the same time, a wider perspective when creating the models can make the equipment easily adjustable to different types of materials (tobacco stem) by offering the user a lot of parameters for every unit. Thanks to a number of status information, a diagnosis of a problem on the line also doesn't require the use of programming device or specialized knowledge and experience.

The archiving function of SCADA application opened a completely new perspective in line operation. The batch identification enabled full traceability of the batch processing and changed the approach to the product quality assurance in its roots.

With the new SCADA application totally integrated in the existing SCADA system, an instant check of the current quality of the process is possible even from a remote location, decreasing the number of employees required, having the same or even higher quality control possible.

Implementation of the user administration, together with parameter modification logging function, significantly improved the quality assurance of the process.

V. CONCLUSION

Design and implementation of a batch control system is a very complex and time-consuming job. Although the Standard IEC 61512-1 by its nature gives to designers just the recommendations for developing successful control system, it has been proved that the approach suggested there is really applicable for all batch processes, regardless of their level of complexity. Furthermore, the suggested approach can be used even for other types of processes.

Implementation of the control system according to the mentioned standard brings a number of benefits to the user:

1) The automation task is logically split to several simpler tasks, in an optimal way

2) It gives the user maximum from the available equipment in the available time

3) It provides the user with a possibility to track its own production process and constantly improve its quality

In the case described, the effects expected after making the analysis of the original control system have been completely proved and justified.

Abstract - As vehicle emission standards become more stringent, there is an increasing need for continual monitoring of benzene content in gasoline. Since the on-line analyzers are often unavailable, and laboratory analyses are infrequently obtained, soft sensors for the estimation of benzene content of light reformate are developed. Soft sensors are developed using system identification methods. Experimental data is acquired from the refinery distributed control system (DCS) and include continuously measured variables and analyzer assays available on-line. In the present work, the development of a Finite Impulse Response (FIR) model, an Output Error (OE) model and an Auto-Regressive Model with Exogenous Inputs (ARX) model are presented. To overcome the problem of selecting the best model parameters by trial and error, genetic algorithm was used. Based on developed soft sensors, it is possible to entirely replace on-line analyzers with soft sensors by embedding the model in a DCS on-site.

I. INTRODUCTION

In various process plants, there are variables which are either difficult to measure on-line (viscosity, odor, boiling point, color, etc.) or only obtainable through infrequent laboratory measurements. Those properties are often of great importance for the process industry, because they may greatly influence the final product quality. On-line analyzers are often out of service or under maintenance. Laboratory analyses are infrequent and can be time-consuming. This problem can be solved by the application of soft sensors. The soft sensing technique, developed in recent years, has become a widely used solution. It utilizes variables measurable on-line to predict the product quality variable through certain modeling approaches, such as mechanism modeling, statistical modeling, artificial intelligence modeling, etc. As distributed control system (DCS) is installed in most chemical plants, many process variables can be measured and stored in real time [1]. A database containing historical data enables engineers to build soft sensors with a goal of producing reliable estimates of unmeasured data.

Typical soft sensor design procedure is [2]:

1. Selection of historical data from the plant database
2. Outlier detection, data filtering
3. Model structure and regressor selection
4. Model estimation
5. Model validation

Choosing the optimal model structure and regressors is crucial for soft sensor performance [3]. Differently structured models can be used to model real systems. One possible approach is to start with a simple model structure and gradually increase its complexity. In the field of industrial applications, the focus of attention is on parametric (polynomial) model structures. To estimate polynomial models, the model order must be predetermined. Model order can be defined as a set of integers that represent the number of coefficients for each polynomial included in the selected model structure. Dead time – given by the number of samples before the output corresponds to the input – must also be specified. Depending on the model structure, mentioned and an additional set of parameters may need to be adjusted.

In a case of multiple input models, predetermining the set of parameters can become a very complex task. A cumbersome trial and error procedure is therefore commonly applied. To overcome the problem of selecting the best model order, as well as the delays of each input and other configurable parameters, genetic algorithms (GA) were used.

The primary application of soft sensors developed in this case study is a temporary substitution of measuring equipment, either during maintenance or other periods of unavailability.

In this work, Finite Impulse Response (FIR), Output Error (OE) and Auto-Regressive Model with Exogenous inputs (ARX) models were considered. FIR and OE models don't require past samples of the measured output (variable inferred by the soft sensor) when using validation data. Hence, FIR and OE model can be used for back-up of measuring devices. ARX model requires past samples of the measured output, thus can only be used for analyzer diagnostic or advance process control.

II. SOFT SENSOR MODEL IDENTIFICATION

Linear dynamical models are in many cases sufficient for real-life applications [4]. One of the most used linear parametric models is the FIR model:

$$\hat{y}(t) = \sum_{i=1}^{nu} \mathbf{B}_i(q) \cdot u_i(t - nk_i). \tag{1}$$

$$\begin{aligned} \hat{y}(t) &= \mathbf{B}_1(q) \cdot u_1(t - nk_1) + \ldots \\ \ldots &+ \mathbf{B}_2(q) \cdot u_2(t - nk_2) + \ldots + \mathbf{B}_{nu}(q) \cdot u_{nu}(t - nk_{nu}) \end{aligned} \tag{2}$$

where:

q – the time-shift operator,

$$\mathbf{B}_1(q) = b_{1,1} + b_{1,2}q^{-1} + \ldots + b_{1,nb_1}q^{-nb_1+1}\ , \quad (3)$$

$$\mathbf{B}_2(q) = b_{2,1} + b_{2,2}q^{-1} + \ldots + b_{2,nb_2}q^{-nb_2+1}\ , \quad (4)$$

…

$$\mathbf{B}_{nu}(q) = b_{nu,1} + b_{nu,2}q^{-1} + \ldots + b_{nu,nb_{nu}}q^{-nb_{nu}+1}\ , \quad (5)$$

nu – the number of system inputs,

$\hat{y}(t)$ – the predictor (predicted output) at time t,

ui(*t*) – *i*-th input at time *t*,

nk_i – the time delay for the i-th input,

nb_i is the maximum number of past input values.

Polynomial coefficients of $\mathbf{B}_i(q)$ can be determined using the least-square optimization method.

The block diagram shown on Figure 1 represents the FIR model structure.

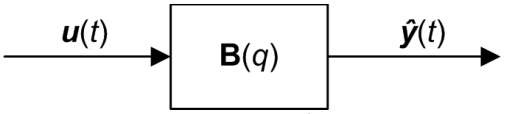

Figure 1. Block diagram of the FIR model

A somewhat extended variant of FIR model is the OE model. The OE model predictor is given by:

$$\hat{y}(t) = \mathbf{B}(q)u(t-nk) + \left[\mathbf{I} - \mathbf{F}(q)\right]\hat{y}(t)\,. \quad (6)$$

$$\mathbf{F}(q) = \mathbf{I} + \mathbf{F}_1 q^{-1} + \mathbf{F}_2 q^{-2} + \ \ldots\ + \mathbf{F}_{nf} q^{-nf}\ , \quad (7)$$

where *nf* is the maximum number of past predicted output.

The block diagram shown on Figure 2 represents the structure of OE model.

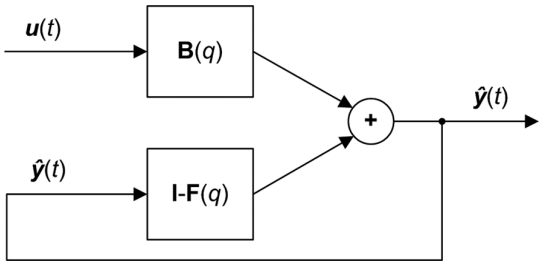

Figure 2. Block diagram of the OE model

Predictor of the ARX model is given by:

$$\hat{y}(t) = \left[\mathbf{I} - \mathbf{A}(q)\right]y(t) + \mathbf{B}_i(q)u_i(t-nk_i)\,. \quad (8)$$

$$\mathbf{A}(q) = \mathbf{I} + \mathbf{A}_1 q^{-1} + \mathbf{A}_2 q^{-2} + \ \ldots\ + \mathbf{A}_{na} q^{-na} \quad (9)$$

The block diagram shown on Figure 3 represents the structure of ARX model.

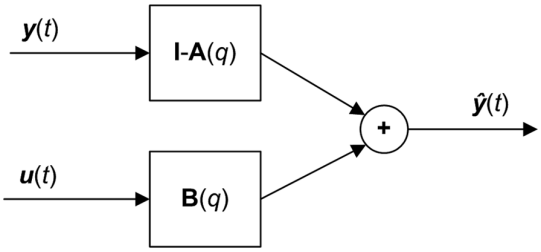

Figure 3. Block diagram of the ARX model

After choosing an appropriate model structure, model orders of the FIR, OE and ARX models are determined by GA.

GA is optimizing techniques with a high potential for finding the global optimum of the fitness (objective) function. GA's are implemented in a computer simulation in which a population of chromosomes of candidate solutions to an optimization problem evolves toward better solutions. The evolution starts from a population of randomly generated individuals. In each generation, the fitness of every individual is evaluated, individuals are stochastically selected from the current population based on their fitness and modified (recombined and mutated) to form a new population. The new population is used in the next iteration of the algorithm. The algorithm terminates when a maximum number of generations has been produced, or a satisfactory fitness level has been reached [5].

III. PROCESS DESCRIPTION

70-85% of the benzene in the refinery processes is contributed by reformate from catalytic reforming process. The catalytic reformate is fractioned into light and heavy reformate and the benzene-rich fraction in splitter columns. Although benzene has a high octane number and high calorific values, the benzene content in light reformate need to be reduced to 1%. This is due to the fact that benzene is a precursor for the formation of cyclohexane in the process of isomerization, and thus an undesirable component of gasoline (low octane number). Also, European emission standards (such as EURO IV and EURO V) for vehicle exhaust emission and MSAT (Mobile Source Air Toxics) regulations limit the amount of benzene in gasoline, due to the hazardous environmental impact.

Hence, the continuous measurement of benzene content in reformate is necessary, but the problem is that the benzene on-line chromatographic analyzer is frequently under maintenance.

An overview of a fractionation reformate plant with the variables used for soft sensor development is given in Figure 4. Fractionation of light reformate (top product) takes place in column C1. Fractionation of the benzene-rich fraction (top product) from heavy reformate (bottom product) takes place in column C2.

The following continuously measured variables have been chosen as key input variables of the soft sensor for the estimation of benzene content in light reformate:

- C1 inlet stream temperature, TC-001;
- C1 column bottom temperature, TC-018;
- C1 column temperature, TC-003;
- C1 column pressure, PI-009 and
- pumparound flowrate, FC-002.

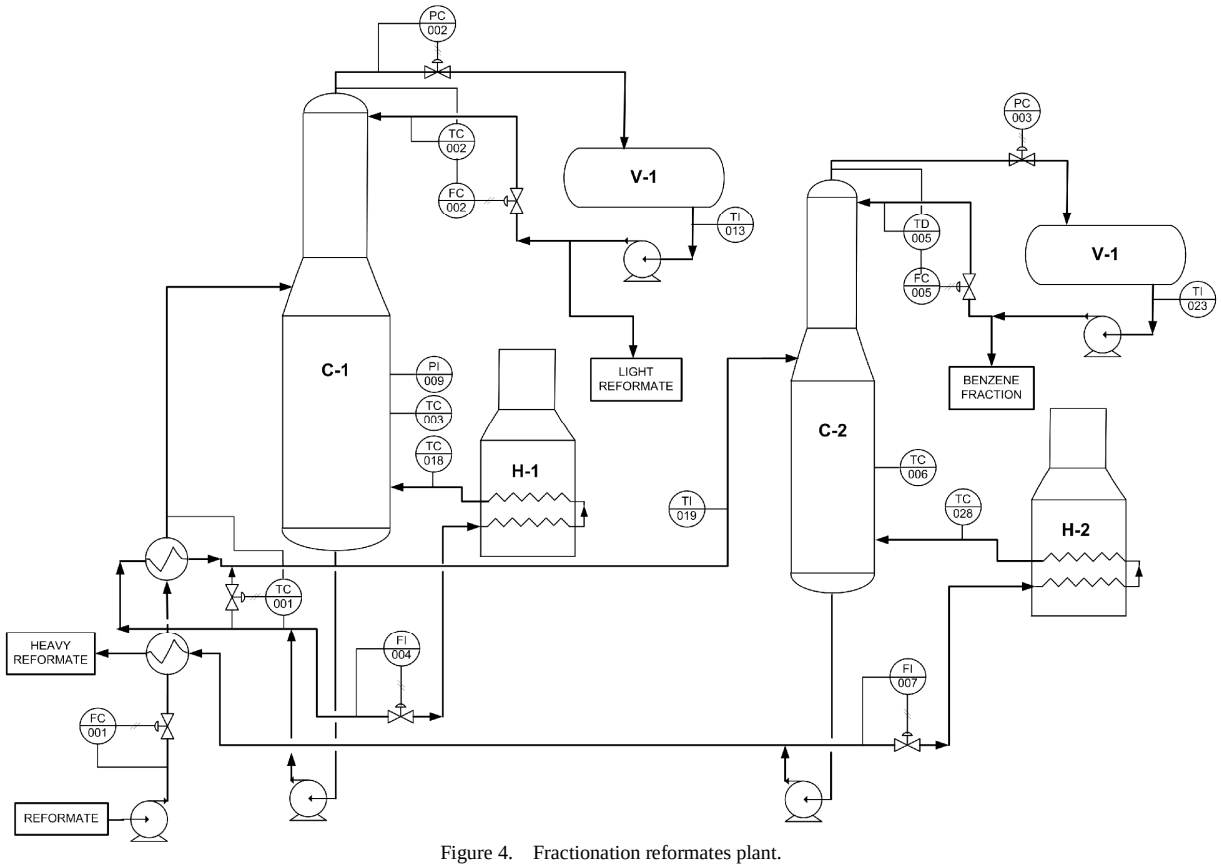

Figure 4. Fractionation reformates plant.

IV. SOFT SENSOR DEVELOPMENT

Offline process data was obtained from the plant database over a continuous period of three weeks, with a sampling time of five minutes according to the process dynamics. Data preprocessing included detecting missing data and outlier detection and removal (3 sigma rule). Output quantities (benzene content, v/v %) measured by the on-line analyzer, were sampled every twenty minutes. The number of each input data (sampled every five minutes) must correspond to the number of output data, thus requiring additional output data. This was generated by the Multivariate Adaptive Regression Splines algorithm. Data was also detrended and filtered. The modeling data set for the estimation and the independent validation data set included 4500 samples and 1500 samples respectively.

After data preprocessing, MATLAB System identification toolbox and Global Optimization toolbox were used for the development of soft sensor models.

A. Optimizing model parameters by GA

After the model structure is chosen, optimal model parameters need to be determined. Configurable parameters (of FIR, OE and ARX structure) and their ranges are shown in Table 1. Parameter ranges have been chosen based on operators' experience of observed process dynamics.

TABLE 1. CONFIGURABLE PARAMETERS OF FIR, OE AND ARX MODEL

Parameter	Parameter description	Minimum value	Maximum value
nb	No. of past input samples (there are five *nb* in each model according to five inputs).	1	8
na	No. of past measured output samples (there is one *na* according to one output).	1	8
nk	Input delay (there are five *nk* according to five inputs).	0	15
nf	No. of past predicted output.	1	5

There are 10, 15 and 11 configurable parameters of interest in FIR, OE and ARX models respectively, all positive integers.

Important GA parameters, presented in Table 2, have been chosen based on experience, as well as rational calculating time. In the GA evolution, each individual chromosome in the population represents a set of possible model orders. In the proposed GA for FIR, ARX and OE models, 34 individuals have been created in each generation by using a crossover procedure, 15 by using a mutation procedure, and 1 is an elite individual (i.e., with the lowest fitness function value from the previous generation). The algorithm terminated when 60 generations had been produced.

Search space of configurable parameters for the FIR model is equal to $8^5*16^5 = 3{,}4360*10^{10}$. For the OE model it is equal to $8^5*16^5*5^5 = 1{,}0737*10^{14}$, and for the ARX model is equal to $8^5*16^5*8^1 = 2{,}7488*10^{11}$. GA procedure found combinations of the parameters, among the billions of possibilities, which best (or nearly so) described the process dynamics.

TABLE 2. GA PARAMETERS

Parameter	**Value / property**
Population size	50
Number of generation	60
Function evaluation	3000
Selection	Stochastic uniform
Crossover	Scattered
Mutation	Uniform
Mutation probability rate	0,1
Fitness scaling	Rank
Number of elite individuals	1
Crossover fraction	0,7

B. Model evaluation criteria and Fitness Function Assignment

Models are primarily evaluated based on FIT, FPE and RMS value. The fitness function (FIT) of model is calculated as follows:

$$\mathrm{FIT} = \left(1 - \frac{\sqrt{\sum_{i=1}^{n}\left(\hat{y}_i - y_i\right)^2}}{\sqrt{\sum_{i=1}^{n}\left(y_i - y_m\right)^2}}\right)\cdot 100 \qquad (10)$$

y is the measured output, $\hat{y}$ is the simulated or predicted model output, and y_m is the mean of y. 100% corresponds to a perfect FIT.

Akaike's Final Prediction Error (FPE) criterion represents the compromise between model accuracy, expressed by the accuracy of estimated parameters, and model complexity. According to Akaike's theory, the most accurate model has the smallest FPE [6].

FPE is defined by the following equation:

$$\mathrm{FPE} = V\left(1 + {}^{2d}\!/_{n}\right), \qquad (11)$$

where V is the loss function, d is the number of estimated parameters, and n is the number of values in the estimation data set.

The loss function V is defined by the following equation:

$$V = \det\left(\frac{1}{n}\sum_{1}^{n}\varepsilon\left(t,\theta_n\right)\left(\varepsilon\left(t,\theta_n\right)\right)^T\right), \qquad (12)$$

where θ_n represents the estimated parameters and ε is output error.

Root mean square error (RMS) as frequently used criteria for model evaluation is also presented in the results:

$$\mathrm{RMS} = \sqrt{\frac{1}{n}\sum_{i=1}^{n}(\hat{y}_i - y_i)^2} \qquad (13)$$

FIT should be as high as possible, and FPE and RMS as low as possible.

The definition of chromosome fitness function is an important element of a GA [7]. Since preliminary investigation showed that FIT and FPE are not correlated, but both are frequently used criteria for model evaluation, they are integrated in the fitness function y, as follows:

$$y = (100 - \mathrm{FIT}) + 1000\cdot\mathrm{FPE} + 100\cdot\mathrm{RMS} \qquad (14)$$

The weighted sum method for multi-objective criteria is used for setting the fitness function. Each criterion is assigned a weighting value (estimated from the previous investigation), and fitness function is a linear combination of all weighted criteria [8,9].

Results also include the mean absolute error, e_{MAE} that is given by:

$$e_{\mathrm{MAE}} = \frac{1}{n}\cdot\sum_{i=1}^{n}\left|\hat{y}_i - y_i\right|. \qquad (15)$$

V. RESULTS AND DISCUSSION

All results were calculated for a new set of validation data. Parameters *nb*, *na*, *nf* and *nk* were estimated by minimizing the objective function (14) using the GA procedure, as was discussed earlier. Coefficients of polynomial $\mathbf{B}_i(q)$ and $\mathbf{F}(q)$ were estimated using the optimization methods integrated with the MATLAB System Identification Toolbox.

Model parameters of the best achieved models are presented in the following vector form (table 3):

TABLE 3. ESTIMATED MODEL ORDERS USING GA AS AN OPTIMIZATION TECHNIQUE

	FIR	**OE**	**ARX**
na	/	/	[2]
nb	[6 7 8 8 8]	[6 1 2 3 3]	[8 1 4 7 5]
nk	[5 3 15 5 15]	[1 8 7 9 13]	[0 5 5 6 11]
nf	/	[1 1 2 2 1]	/

Properties of the FIR, OE and ARX model are shown in Table 4.

TABLE 4. MODEL PROPERTIES

	FIT	**FPE**	**RMS**	e_{MAE}	**fitness function, *y***
FIR	78,895	0,0064	0,0517	0,0391	32,654
OE	90,267	0,0023	0,0239	0,0171	14.396
ARX	87,111	$7{,}71\cdot10^{-6}$	0,0316	0,0248	16,056

Since the FIR model has the simplest parametric structure among the proposed models, it gives the poorest results with a higher model order. Compared to the FIR model, the OE model gives better results, with a lower model order (lower *nb*) as was expected, since the past predicted output values are taken.

Figures 5, 6 and 7 show the comparison between model and measured output for the validation data set of FIR, OE and ARX model, respectively. It can be seen that all model outputs match very good for the validation data. As can be seen from Table 4 and Figure 7, ARX model performed somewhat poorer compared to the OE model. A graphical comparison and the corresponding FIT, FPE and RMS values show that experimental and model OE data are in accurate agreement.

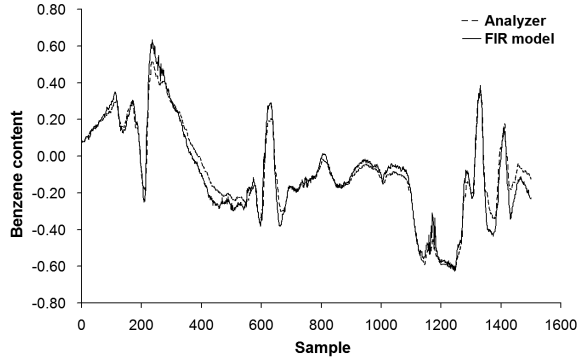

Figure 5. A comparison between measured and FIR model output data

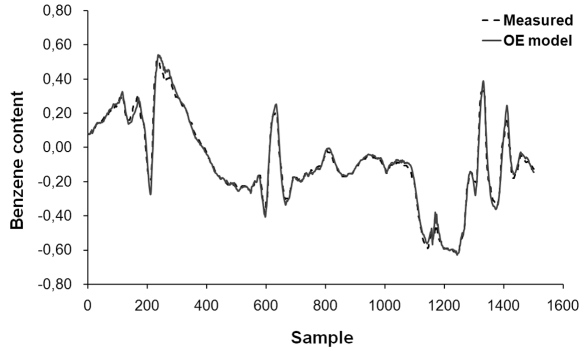

Figure 6. Comparison between measured and OE model output data

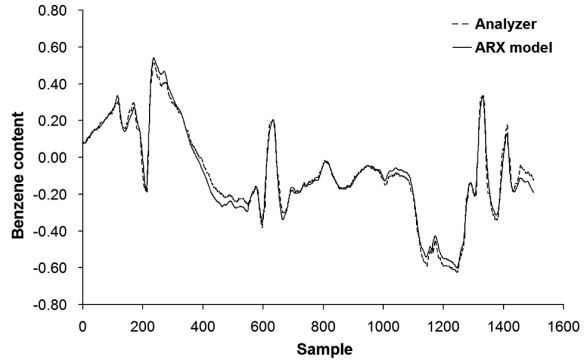

Figure 7. Comparison between measured and ARX model output data

Figures 8, 9 and 10 represent the histogram (residual plot) of FIR, OE and ARX model residuals, *e* (differences between predicted and measured output), respectively. As can be seen, all residual plots have a normal distribution, zero centered. OE model has a higher and narrower bell shape than the histogram of FIR and ARX model.

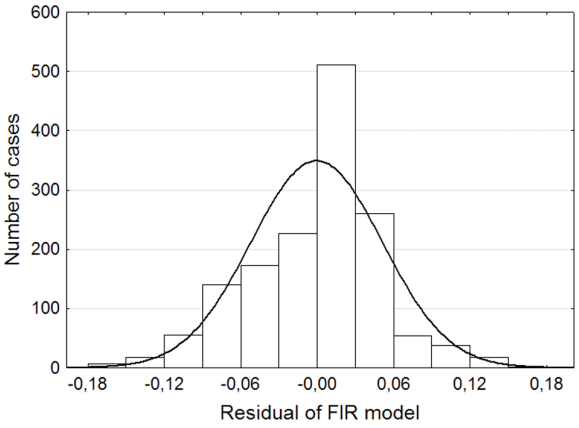

Figure 8. Distribution of FIR model residuals

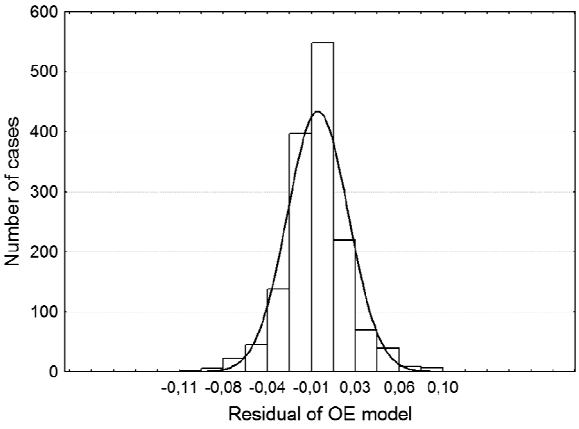

Figure 9. Distribution of OE model residuals

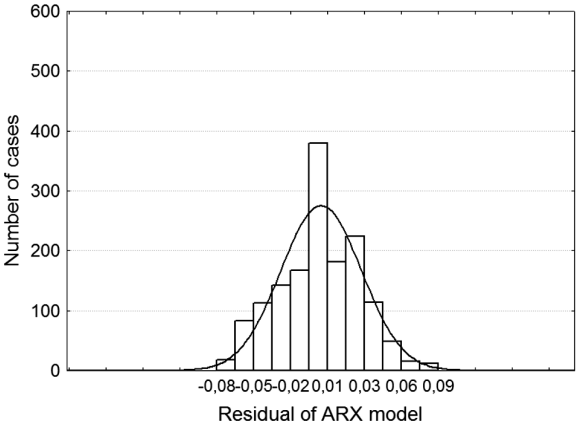

Figure 10. Distribution of ARX model residuals

The OE model is the right choice to embed on-site since that describes the process dynamics most accurately. But, OE model can become unstable for a while, when some of the inputs are not available, so in that period the FIR model can be used for approximate estimation of benzene content.

Developed code can be easily adapted for the development of other parametric models, such as auto-regressive moving average models, Box Jenkins, nonlinear ARX models or Hammerstein-Wiener models.

In the presented work, FIT, FPE and RMS are included in the fitness function. However, the fitness function can be some other measure used for model evaluation.

VI. CONCLUSION

Linear dynamic models for the estimation of benzene content of light reformate were developed. To avoid a trial and error procedure, GA method was proposed for model order selection, which makes the development of soft sensors more systematic. Chosen models show a satisfactory match with experimental data, thus proving their usefulness as soft sensors for the on-line estimation of benzene content in light reformate. Using the described procedure, it was shown that GA can be satisfactorily applied for optimizing configurable parameters of input-output polynomial models. OE model can be successfully employed as the soft sensor for the on-line prediction of benzene content. ARX model can be successfully used for the monitoring or advance process control. Implementation of the model itself was done on module for advanced applications inside Honeywell distributed control system. Execution is carried out using CL (Control Language) program which is based on internal and external variables, result is calculated value of the benzene content based on polynomial model. The validity of the models currently can not be fully tested at the plant because the process analyzer for benzene content (which is now done to the model) is a for a long time out of order. The results obtained by the model are compared with laboratory analyzes carried out 2-3 times a day

Primjena FPS metode raspoređivanja na sustavu automatizacije upravljanog PAC uređajem

Sažetak - Programirljivi automatizacijski kontroleri (PAC) su nova generacija industrijskih upravljačkih uređaja koji kombiniraju funkcionalnost PLC uređaja i PC računala. PAC uređaji slijede normu IEC 61131-3 koja između ostalog programeru daje punu kontrolu nad redoslijedom i dinamikom izvršavanja procesnih zadataka (*eng. task scheduling*). U većini slučajeva se koristi statičko raspoređivanje koje je tipično za upravljačke procese u industrijskim postrojenjima jer ono podrazumijeva prethodno poznavanje bitnih značajki procesnih zadataka kao što je učestalost zahtjeva za obradu. Iako se smatra nefleksibilnim jer se procesima dodjeljuju fiksni prioriteti (*eng. Fixed-Priority Scheduling, FPS)* ovo je najčešće korišteno raspoređivanje u takvim sustavima. Važna karakteristika ovako definiranog raspoređivanja je veća predvidljivost te mogućnost testiranja raspoređivosti koje se zasniva na ispitivanju iskorištenja procesa (metoda *Liu & Layland*). U ovom radu je uzet primjer upravljačkog programa gdje je primijenjen ISA S88 standard na sustavu distribucije cementa. Upravljački program ciklički izvodi programske module jedan iza drugoga što rezultira prevelikim ukupnim vremenom izvršavanja ciklusa od preko 260 ms. Kako program čita ulaze samo na početku ciklusa podaci se osvježavaju otprilike 4 puta u sekundi što je uzrok da se pojedina stanja periferije uopće ne registriraju. Rješenje ovog problema je da se kritične rutine izvršavaju periodički i osiguravaju neposredno ažuriranje stanja periferije.

I. UVOD

Proteklih desetak godina postavljaju se pitanja o prednostima i nedostacima programirljivih logičkih kontrolera (eng. ***P**rogrammable **L**ogic **C**ontrollers*, dalje *PLC*) u usporedbi s upravljačkim sustavima izvedenim pomoću PC računala (eng. *PC based control*). Analize su pokazale da je 80 % industrijskih aplikacija izvedeno tradicionalnim načinima upravljanja što na tržištu uzrokuje potrebu za jeftinim PLC uređajima [3]. To je potaknulo povećanu ponudu po cijeni pristupačnih mikro PLC uređaja koji sadrže samo digitalne U/I i osnovne instrukcije ladder logike. Jednako tako, došlo je do nesrazmjera u tehnologiji kontrolera jer 80 % aplikacija zahtijeva jednostavne i pristupačne PLC uređaje dok preostalih 20 % aplikacija uvelike premašuje mogućnosti klasičnih upravljačkih sustava. Projektantima modernih industrijskih aplikacija koje spadaju unutar tih 20 % postavljaju se zahtjevi za naprednim upravljačkim algoritmima i boljom integracijom sa poslovnim sustavima poduzeća. Vodeći proizvođači su povećanom opsegu zahtjeva modernih industrijskih aplikacija odgovorili razvojem industrijskih upravljačkih uređaja koji predstavljaju kombinaciju najboljih obilježja PLC uređaja i PC računala. Tako je nastala nova vrsta kontrolera koji su nazvani programirljivi automatizacijski kontroleri (eng. ***P**rogrammable **A**utomation **C**ontroller*, dalje *PAC)*. Skraćenicu PAC koriste kako proizvođači klasičnih PLC uređaja za opis svojih upravljačkih uređaja visoke klase (eng. *High end*) tako i proizvođači upravljačkih sustava izvedenih PC računalima za opis svojih industrijskih upravljačkih platformi. Time su spojene prednosti PLC uređaja u upravljanju procesima sa fleksibilnošću konfiguracije i sposobnošću integracije sa poslovnom razinom koje pružaju upravljački sustavi bazirani na PC računalima.

II. RASPOREĐIVANJE U RT SUSTAVIMA

U sustavima koji rade u realnom vremenu (*eng. **R**eal **T**ime*, dalje *RT*) raspoređivanje procesa (*eng. task*) može biti statičko i dinamičko. Statičko raspoređivanje je tipično za upravljačke procese u industrijskim postrojenjima jer ono podrazumijeva prethodno poznavanje bitnih značajki procesnih zadataka. To se u prvom redu odnosi na karakteristike kao što su učestalost (frekvencija) zahtjeva za obradom (procesiranjem) i računalna vremena (*eng. Computation times*). Raspored procesa kao rezultat ove metode je nepromijenjen tijekom izvođenja i omogućava procjenu mogućnosti izvođenja (*eng. Schedulability analysis*). Iako se smatra nefleksibilnom metodom jer se procesima dodjeljuju fiksni prioriteti (*eng. **F**ixed-**P**riority **S**cheduling*, dalje *FPS)* prije izvođenja ovo je najčešće korišteno raspoređivanje osobito u sustavima s tzv. „kritičnom sigurnošću“. Ovakvo raspoređivanje može biti izvedeno sa mogućnošću prekida (eng. *Preemptive*) i bez mogućnosti prekida (eng. *Non-preemptive*) koje predstavlja klasičan način izvođenja programa. Dakle, prvo spomenuto raspoređivanje karakterizira mogućnost prekidanja procesa i njihovo naknadno nastavljanje bez gubitka njihovih funkcionalnosti. Proces u trenutku izvođenja može biti prekinut samo od strane drugog procesa kojem je pridodjeljen viši prioritet. Prioritet procesa u takvom sustavu nije posljedica značaja dotičnog procesa nego vremenskih karakteristika. Metoda dodjeljivanja prioriteta procesima je veoma jednostavna i kaže da se prioriteti dodjeljuju monotono po učestalostima (*eng. **R**ate-*

***M**onotonic **P**riority **O**rdering*, dalje *RMPO*). To znači da se periodičnim procesima dodjeljuju jedinstveni prioriteti, monotono uređeni prema učestalosti procesa, tako da proces sa kraćom periodom ima viši prioritet.

Još jedna važna karakteristika ovako definiranog raspoređivanja je veća predvidljivost (*eng. Predictability*) te mogućnost testiranja rasporedivosti (*eng. Schedule Feasibility*). Kriterij provjere rasporedivosti skupa periodičnih procesa je zasnovan samo na ispitivanju iskorištenja procesora (*eng. Processor Utilization)*. Iako on nije egzaktan, jer predstavlja samo dovoljan, ali ne i potreban uvjet rasporedivosti, veoma je popularan zbog svoj jednostavnosti. Prema tome testu je skup periodičnih procesa rasporediv ako je ispunjen slijedeći uvjet:

$$\sum_{i=1}^{N}\left(\frac{C_i}{T_i}\right) \le N \cdot \left(2^{\frac{1}{N}} - 1\right) \qquad (1)$$

gdje je:

C_I - Vrijeme izvršavanja u najgorem slučaju (*eng. **W**orst-**C**ase **E**xecution **T**ime, WCET*)

T_i - Vrijeme između dvije susjedne aktivacije procesa (period procesa)

N - Ukupan broj procesa

Lijeva strana nejednadžbe predstavlja sumu svih iskorištenja procesora dok desna strana predstavlja graničnu vrijednost iskorištenja procesora za N procesa iznad koje uvjet više ne zadovoljava. Zbog toga što ova granična vrijednost teži brojci 69.3%, kada broj procesa teži beskonačnosti, zaključujemo da je svaki skup procesa koji ima ukupno iskorištenje manje od 69.3% sigurno rasporediv korištenjem ove metode.

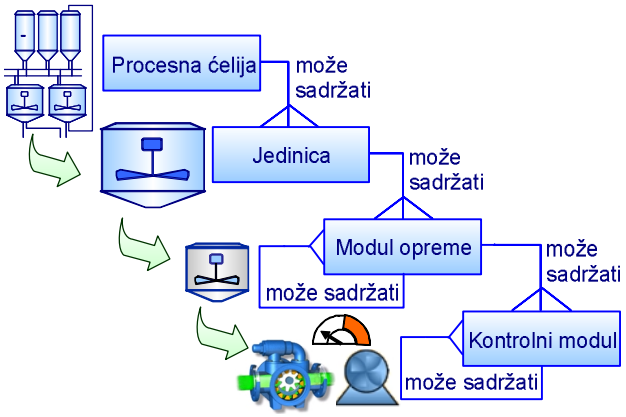
III. PRILAGODBA ISA-S88 STANDARDU

Industrijski procesi se definiraju kao slijed kemijskih, fizičkih i bioloških aktivnosti kojima se postiže pretvorba, prijenos ili pohrana materijala ili energije. Operacije u proizvodnji odnosno industrijski procesi se općenito mogu dijeliti na diskretne (eng. *Discrete*), kontinuirane (eng. *Continuous*) ili šaržne (eng. *Batch*).

Potreba za normizacijom i dugogodišnja iskustva mnogih stručnjaka u polju industrijske automatizacije, dovela su do razvoja ISA-S88 standarda za upravljanje šaržnim procesima, opće poznatijeg kao S88 standarda. Ovaj standard je svojim značajkama i sastavom uvelike priznat kao moćan alat u savladavanju prepreka prilikom planiranja, projektiranja, izvedbe i održavanja šaržnih procesa. Standard nudi precizno definiranu terminologiju i standardizirane modele koji su svim korisnicaima šaržnih procesa lako shvatljivi.

A. *Fizički model*

Oprema je podijeljena po modulima pomoću S88 alata koji se naziva fizički model (eng. *Physical model*). Koristi za opisivanje materijalnih sredstava poduzeća i hijerahrijskih odnosa između različite opreme uključenje u proizvodnju šarža. Fizički model je sredstvo kojim se organizira i definira oprema korištena za upravljanje šaržnim procesom. Sastoji se od četiri glavne hijerarhijske razine prikazane na slici 1.



Slika 1. Fizički model ISA-S88 standarda

B. *Kontrolni modul*

Kontrolni modul (eng. ***C**ontrol **M**odule*, dalje *CM*) je temeljni element fizičkog modela kojeg S88.01 standard ga definira kao: „*Kontrolni modul je u pravilu jedan ili grupa senzora, aktuatora, ostalih kontrolnih modula, i povezane procesne opreme, koji sa stajališta upravljanja djeluje kao zaseban uređaj*“ [4]. Dakle, svaki kontrolni modul osigurava izravnu "poveznicu" sa procesom preko aktuatora i senzora te tako izvršava neke osnovne upravljačke funkcije.

Ovakva podjela opreme omogućuje jednostavan razvoj i standardizaciju programskih komponenata za upravljanje radom pripadajuće opreme koja služi za obavljanje šaržnog procesa. Kontrolni moduli, odnosno programske komponente, se standardiziraju prema najčešćim tipovima uređaja korištenih u industrijskim postrojenjima. Na taj način se jednom isprogramirana programska komponenta (npr. dvosmjerni ventil sa potvrdom položaja) može kasnije neograničeno primjenjivati u izradi programske podrške za razne šaržne procese u kojima se taj dio opreme koristi.

IV. RAZVOJ UPRAVLJAČKOG PROGRAMA

Razvoj upravljačkog programa počinje razradom procesnih dijagrama (eng. ***P**iping and **I**nstrumentation **D**iagram*, skraćeno *P&ID*) i detaljnom tehničkom specifikacijom svih komponenti procesnog sustava (ventili, motori, digitalni i analogni senzori, PID regulatori, pretvarači napona i frekvencije, itd). Nakon razrade, u posebno izrađenom *MS Excel* predlošku se upisuju podaci za svaku komponentu zasebno, koji su bitni za rad te komponente u sustavu.

Tako spremljene podatke jednostavnim postupkom učitamo u programski editor *RS Logix 5000*[1], u kojem se piše upravljački program *PAC* sustava distribucije cementa. Isti nazivi komponenti i tag-ovi kreirani u *MS Excel* tablici koriste se i u izradi nadzornog programa, odnosno SCADA sustava (eng. ***S**upervisory **C**ontrol **A**nd*

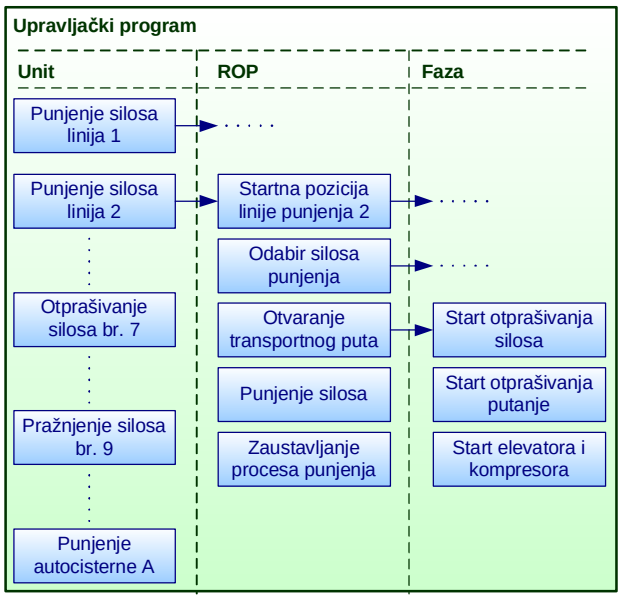
[1] Programsko okruženje za izradu programske podrške PAC uređaja serije *ControlLogix* tvrtke *Allen Bradley*

***D**ata **A**cquisition*, dalje *SCADA*), čime je postignuta apsolutna transparentnost u izradi programske podrške.

Nakon izrade liste komponenti, za svaku od komponenti postoji programski modul, odnosno gotov programski kod izrađen u jednom od jezika za programiranje PAC uređaja. Taj kod se konstantno ciklički izvodi za svaku komponentu koja je pozvana unutar upravljačkog programa. Na taj modularan način, nije potrebno pisati programsku podršku svaki put za pojedine komponente sustava, nego se programski kod prenosi iz projekta u projekt, a mijenja se samo tok programa i imena komponenti.

Tok programa određuju tehnolozi proizvodnog sustava, a opisuju ga tekstualno i tablično u tzv. *FDS* dokumentima (eng. ***F**unctionally **D**escription **S**oftware*, *FDS*). Prema njemu i prema procesu, programeri određuju najmanje samostalne programske cjeline (eng. *Unit*) za koje pojedinačno izrađuju potprograme i pozivaju prema potrebi (npr. punjenje silosa, kotao, filtar i sl.). Te cjeline, kao dijelovi procesa, sastoje se od jedne ili više komponenti, koje se u potprogramu pojedine cjeline pozivaju prema potrebi procesa. Više takovih cjelina koji se međusobno pozivaju i istovremeno i/ili zasebno izvode, čine upravljački program.

Slika 2. prikazuje blok shemu toka izrađenog upravljačkog programa sustava distribucije cementa primjenom S88 standarda.



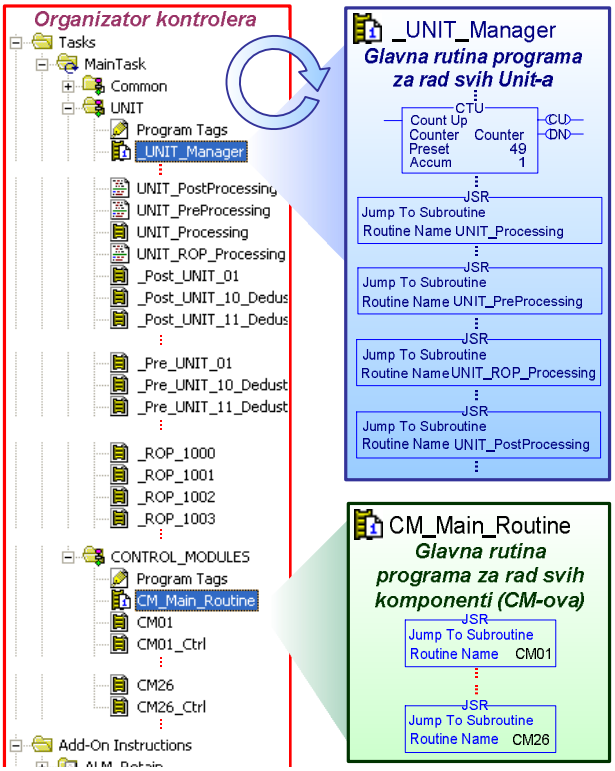
Slika 2. Blok shema toka izrađenog upravljačkog programa

Izrađeni upravljački program sustava distribucije cemeta ima ukupno 23 procesne cjeline koje su slične i ponavljaju se:

- *Punjenje silosa linija 1* te još takve dvije za liniju punjenja 2 i 3;
- *Otprašivanje silosa br. 6* i još takvih 7 po strukturi programskog koda identičnih za ostalih 7 silosa;
- *Pražnjenje silosa br. 6* i još takvih 7 identičnih strukturi programskog koda za ostalih 7 silosa;
- *Punjenje autocisterne A* i još 3 takva identična za punjenje autocisterni na utovarnim mjestima B, C i D.

Svaka cjelina ima svoju proceduru toka izvođenja koja se sastoji od jednog ili više *ROP*-ova (eng. ***R**ecipe **O**peration **P**rocedures*, *ROP*) koje se zasebno programiraju i izvode sekvencijalno prema receptu izvođenja danom od operatera nadzornog programa [5].

Upravljački program poziva zasebno svaki kontrolni modul i prema dobivenim statusnim varijablama upravlja izvršnim elementima procesa (Slika 3.).



Slika 3. Principna shema rada sustava na *Rockwell software* platformi prema S88 standardu

Problem koji je prisutan kod ovako napisanog upravljačkog programa je ukupno vrijeme izvršavanja cijelog ciklusa preko 260 ms. Iz razloga što upravljački program čita svoje ulaze samo na početku ciklusa ispada da se ulazi osježavaju samo 4 puta u sekundi što je izuzetno sporo. Teoretski se može dogoditi da pojedini signal traje npr. 200 ms, a vrijeme između dva čitanja ulaza je 260 ms, te je moguće da sustav uopće ne registrira taj signal.

V. PRIJEDLOG RJEŠENJA

Kao što je na početku spomenuto, PAC koji se koristi kao procesno računalo podržava IEC 61131-3 standard što znači da omogućava izvršavanje programskog koda kako u kontinuiranom vremenskom procesu tako i od korisnika definiranim procesima.

Postoje dvije vrste takvih procesa: periodički (eng. *Periodic*) koji se izvršavaju u zadanim vremenskim intervalima i procesi potaknuti događajem (eng. *Event*) koji se aktiviraju na promjenu stanja sklopovske opreme ili programskih varijabli.

Prijedlog rješenja opisanih nedostataka uključuje definiranje nove strukture programa gdje se upravo u

periodičkim procesima pokreću kritične rutine. Samo periodično pokretanje odabranih CM-ova nije dovoljno jer u polju ulazno-izlazne memorijske procesne mape *AB_I[]* i *AB_Q[]* u tom trenutku nisu ažurni podaci pa je njih potrebno osvježiti. Da bi se zadovoljili ovi uvjeti napisane su nove rutine koje osvježavaju polje procesne mape prije pokretanje kritičnih CM-ova.

A. *Rutine*

Za svaki CM napisana je vlastita rutinu za osvježavanje podataka nazvana *CMxx_RefreshData* koja je prikazana slikom 4. Ona provjerava sve upotrijebljene CM-ove koristeći status *CMxx_CONFIG[n].CM_Enable* te čita ulazne signale i zapisuje izlazne.

Ulazni parametar rutine *CMxx_RefreshData* je modus rada *_RefreshMode* koji određuje što će se odraditi:

- 1 – čitanje podataka sa periferije PAC i spremanje u *AB_I[x,y]*
- 2 – čitanje iz *AB_Q[x,y]* i zapisivanje na periferiju PAC-a
- 3 – obadvije navedene operacije u jednom prolazu

Sva svojstva CM-a imaju filtar upotrebljenosti *IOpar_<name>Exist* i ne osvježavaju se ako se ne upotrebljavaju da bi se maksimalno smanjilo vrijeme potrebno za izvršavanje rutine. Za čitanje sa perifernog sklopovlja procesnog računala koriste se rutine *Get_BitFromSlot* i *Get_AnalogFromSlot*.

Za digitalne signale koristi se rutina *Get_BitFromSlot* a njezini ulazni parametri su sljedeći:

- *_SlotNumber* – definira s kojega će se slota čitati signal
- *_ByteNumber* – definira se adresa kartice ako se koristi distribuirana periferija
- *_BitNumber* – definira koji bit predstavlja željeni signal

Za analogne signale koristi se rutina *Get_AnalogFromSlot* a njezini ulazni parametri su sljedeći:

- *_SlotNumber* – definira s kojega će se slota čitati signal
- *_ByteNumber* – definira se kanal analoge kartice

Analogno tome za zapis na izlazno sklopovlje PAC-a koriste se rutine *Set_BitOnSlot* i *Set_AnalogOnSlot* koje imaju identične ulazne parametre kao i rutine za čitanje.

TABLICA I. POPIS NAPISANIH PROGRAMSKIH RUTINA

Red. br.	Rutina	CM tip
1	*CM01_RefreshData*	Valve On/Off (air/spring)
2	*CM02_RefreshData*	Motor/pump
3	*CM04_RefreshData*	Motor variable speed
4	*CM05_RefreshData*	Proportional valve
5	*CM06_RefreshData*	Digital Switch
6	*CM07_RefreshData*	Motor 2 speed
7	*CM08_RefreshData*	Motor 2 directions
8	*CM09_RefreshData*	Analog measurement
9	*CM13_RefreshData*	Valve double solenoid (air/air)
10	*CM14_RefreshData*	Motor Variable Speed 2 dir
11	*CM15_RefreshData*	Two way flap
12	*CM16_RefreshData*	Totalizer
13	*CM17_RefreshData*	Digital output
14	*CM25_RefreshData*	Motorized 2 way flap
15	*CM26_RefreshData*	Two way flap with middle position

Gore opisane rutine su univerzalne i mogu se koristi u svim projektima ne narušavajući opisani način generiranja programskog koda. Rutine za pristup sklopovskoj opremi *Get_BitFromSlot*, *SetBitOnSlot*, *GetAnalogFromSlot* i *SetAnalogOnSlot* moraju se pisati posebno za svaku sklopovsku konfiguraciju. Ovo je zbog toga što razvojno okruženje *RSLogix 5000* ne dopušta simbolično adresiranje periferije nego se ono mora egzaktno pozivati u kodu.

B. *Izbor kritičnih zadataka i definiranje procesa*

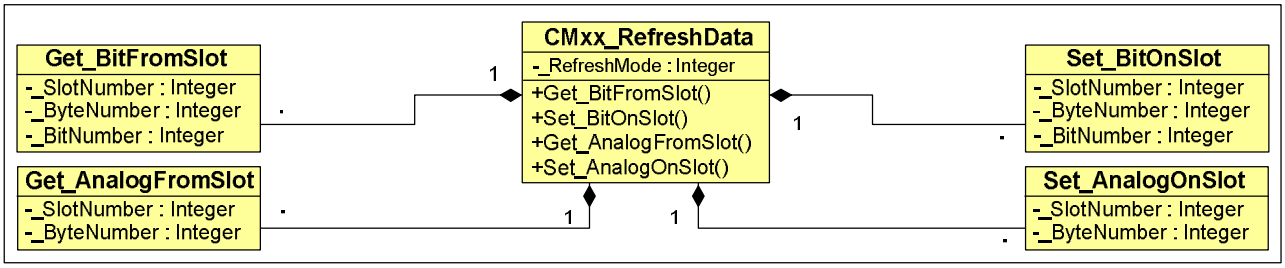
1. Isklop u nuždi

Jedan od kritičnih zadataka je detekcija zahtjeva za isklop u nuždi koji se obrađuje s kontrolnim modulom *CM06:Digital Switch*. Kako bi se zaštitili životi i imovina, a u skladu s IEC normama trajanja napona dodira, sustav u najgorem slučaju mora reagirati 70ms nakon što je stisnut taster isklopa u nuždi (eng. *Safety switch*). Iz tog zahtjeva proizlazi da se CM06 mora aktivirati najmanje svakih 70ms pa slijedi:

$$C = C_{CM06_Re} + C_{CM06} = 889 + 35140 = 36029$$

$$T = 70000\mu s$$

$$U = \frac{C}{T} = \frac{36029}{70000} = 0{,}5147$$



Slika 4. Blok shema *CMxx_RefreshData* rutine

2. Klapna sa srednjim položajem

Tijekom rada postrojenja kritične su se pokazale klapne sa srednjim položajem. Radi se o elektromehaničkom sustavu pokretanom elektromotorom čiji se radni status dojavljuje pomoću tri senzora položaja (početni, srednji i krajnji). Kako bi se osigurala sigurna detekcija položaja klapne period procesa koji čita njezin status mora biti manji od vremena prolaska preko senzora položaja. Na taj način osiguravamo da dva puta detektiramo aktivan senzor položaja. Iz mehaničkih karakteristika sustava smo izračunali da je vrijeme kada je klapna na senzorima položaja 110ms. Iz ovoga proizlazi da se očitanje položaja kontrolnim modulom *CM26 - Two way flap with middle position* mora periodično izvršavati svakih 100 ms pa slijedi:

$$C = C_{CM\,26_\mathrm{Re}} + C_{CM\,26} = 1950 + 7144 = 9094$$

$$T = 100000$$

$$U = \frac{C}{T} = \frac{9094}{100000} = 0{,}09094$$

3. Provjera raporedivosti po Liu & Layland

Nakon što smo definirani zahtjeve za periodične procese provjeriti ćemo njihovu rasporedivost odnosno mogućnost da se procesi korektno izvršavaju.

$$\sum_{i=1}^{N}\left(\frac{C_i}{T_i}\right) \le N \cdot \left(2^{\frac{1}{N}} - 1\right)$$

$$\sum_{i=1}^{2}\left(\frac{36029}{70000}, \frac{09094}{100000}\right) \le 2 \cdot \left(2^{\frac{1}{2}} - 1\right)$$

$$0{,}5147 + 0{,}09094 \le 2 \cdot (1{,}41421 - 1)$$

$$0{,}60564 \le 82842$$

Test je pozitivan što znači da ova dva kritična zadatka možemo potjerati u periodičkim procesima a prioritete ćemo odrediti monotono po učestalosti:

- Proces 1: CM06 svakih 70ms, prioritet 5
- Proces 2: CM26 svakih 100ms , prioritet 6

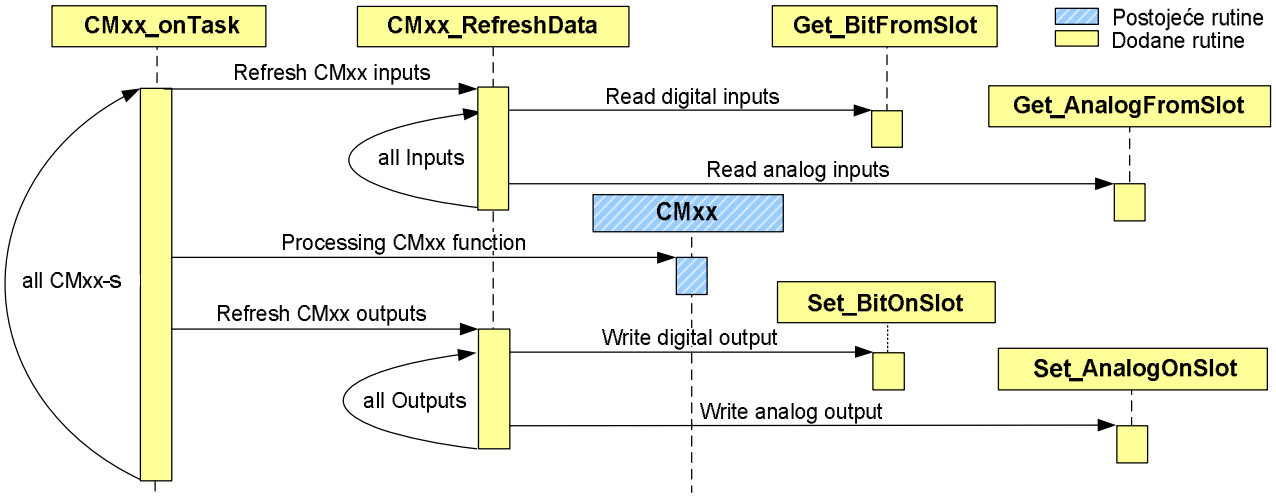
C. Implementacija

Implementacija opisanih rutina u program je relativno jednostavna. U početku u stablastu strukturu *Tasks* dodamo nove periodičke procese *PeriodicalTask_70ms i PeriodicalTask_100ms* te im dodijelimo prioritete. U njima su rutine *CM_OnTaskMain* za poziv kritičnih CM-ova. U njemu pozivam odabrane kritične rutine *CM06_onTask i CM26_onTask* na isti način kao i u kontinuiranom tasku *CONTROL_MODULES/ CM_Main_Routine*. Spomenute rutine osvježavaju podatke prije i nakon poziva originalnog CM-a i tako osiguravaju aktualna ulazna i izlazna stanja industrijskog postrojenja (Slika 5.). Ovdje pozvane odabrane komponente ne pozivamo u kontinuiranom procesu.

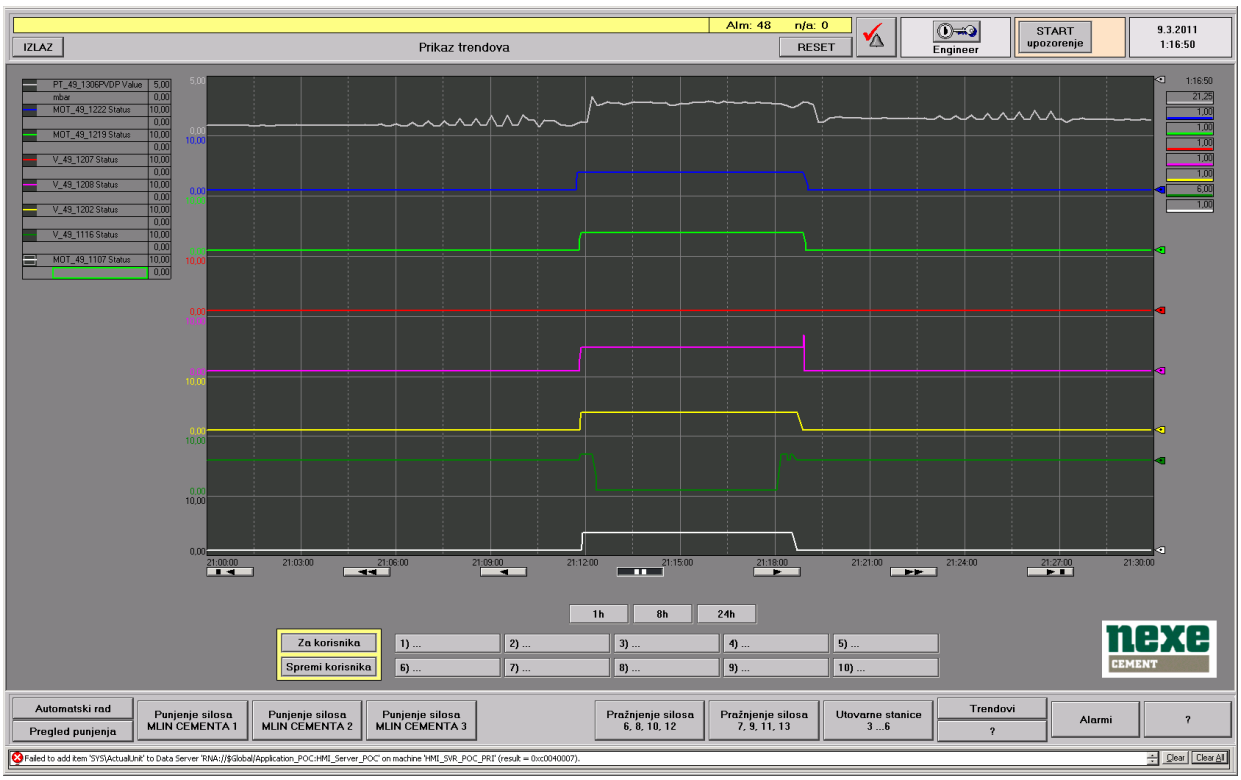
VI. EKSPLOATACIJSKE KARATKERISTIKE

Kao primjer eksploatacijskih karakteristika dan je trend koji prikazuje postupak pokretanja i zaustavljanja komponenti transportnog sustava kod punjenja autocistene preko mobilnog punjača (Slika 6.). Uvjet da se autocisterna počne puniti je da u silosu ima dovoljno cementa prema količini cementa koja je na vagi zadana za istovar i da sustav razrahljivanja cementa silosa iz kojega vršimo punjenje radi. Kako se količina utovarenoga cementa približava zadanoj, zadnjih 700 kg pneumatska zaklopka se ponovo zatvara na 50% tako da se tok cementa uspori. Kada vaga pokaže da preostaje još 200kg, pneumatska zaklopka se potpuno zatvara i preostala količina isteče u autocisternu. Točnost sa kojom se računa je ±40 kg.

Ključno kod ovoga dijela procesa je da se pokretanje pojedinih motora za uzdužno, poprečno i vertikalno gibanje punjača autocisterni vrši preko kutije sa tipkalima. Između ostaloga, do rješavanja ove problematike je upravo došlo iz razloga što sustav nije svaki puta mogao ustanoviti i pravovremeno reagirati na pritisak tipkala, te je u najgorem slučaju radnik na punjaču morao držati tipkalo pritisnuto dulje od pola sekunde. Naravno, takva situacija je nedopustiva. Kasnije se iz tog problema pokazalo da je sustav manjkav u pogledu brzine izvršavanja i u radu sa ostalim komponentama koje su vremenski kritične. Primjenom periodičkog izvršavanja pojedinih komponenata ova se problematika u potpunosti uklonila.



Slika 5. Dijagram izvršavanja *CMxx_onTask* rutine



Slika 6. Pokretanje i zaustavljanje komponenti transportnog sustava kod punjenja autocistene preko mobilnog punjača

VII. ZAKLJUČAK

Uvođenjem i razvojem ISA-88.01-1995 standarda za izradu programske podrške šaržnih procesa dobila se ujednačena struktura upravljačkih programa koja je standardizacijom pružila mogućnost jednoznačnog opisa i izrade. Možda najvažniji dio za inženjere u praksi je vrlo jednostavno prepravljanje postojećeg upravljačkog programa i njegova nadogradnja prema jasnom obrascu koji je uvjetovan S88 standardom. Prikazani sustav je temeljen na unaprijed isprogramiranim komponentama koje se nalaze u upravljačkom programu i unaprijed izvedenim komponentama *SCADA* sustava koje se prilikom izgradnje aplikacije za zadani proces povezuju u cjelinu.

Zbog sporosti rada računalnog sustava, koji nije bio u stanju registrirati pojedine kritične signale u trajanju i do pola sekunde, pristupilo se promjeni upravljačkog programa tako da se se pojedine vremenski kritične komponente izvode u posebno definiranim cikličkim procesima. Pri tome su se prije primjene definirali zahtjevi te izabrale frekvencije procesa kritičnih zadataka. Ograničenja primjene ovakvih rješenja je mogućnost raspoređivanja pa je neophodno testiranje istoga. Nakon izvršene provjere rasporedivosti (metoda *Liu & Layland*) zaključeno je da je ona moguća. Potom su napisane nove programske rutine koje su se uspješno implementirale u postojeće programsko rješenje i tako riješile problem.

Naravno, ovdje se može postaviti i teoretsko pitanje što ako je veća količina komponenti kritična u pogledu vremena izvršavanja tako da procesor ne može izvršiti kod u zadanom periodu odnosno ciklusu pozivanja. Ukoliko bi došlo do toga, moralo bi se nabaviti brži procesor, što je opet relativno loš odabir ukoliko se sustav planira proširivati, ili bi se nabavila dva procesora koji bi djelili komponente. Svakako, uvijek ostaje mogućnost optimiranja koda na uštrb gubljenja pojedinih mogućnosti komponente (simulacijski mod rada, testni mod rada).

Izrada ovakvih aplikacija pokazuje kako je za automatizaciju procesa potrebno poznavati i upotrijebiti znanja iz raznih područja tehničke struke.

danijel.marsic@tvz.hr

Sažetak - Izgradnjom plinskog transportnog sustava u Republici Hrvatskoj između ostalih su postavljeni visoki zahtjevi u pogledu održavanja sustava katodne zaštite plinovoda. Ovaj rad prikazuje razvoj uređaja za prikupljanje podataka u katodnoj zaštiti koji podatke mjeri i pohranjuje na *SD* memorijsku karticu. Samim time podatke je moguće jednostavno prenijeti na računalo, a korištenjem programa *MS Excel* podaci se mogu grafički obrađivati. Uređajem se upravlja preko ugrađene tipkovnice, a na ugrađenom zaslonu mogu se vidjeti podaci iz procesa kao i trenutne vrijednosti koji se mjere.

I. UVOD

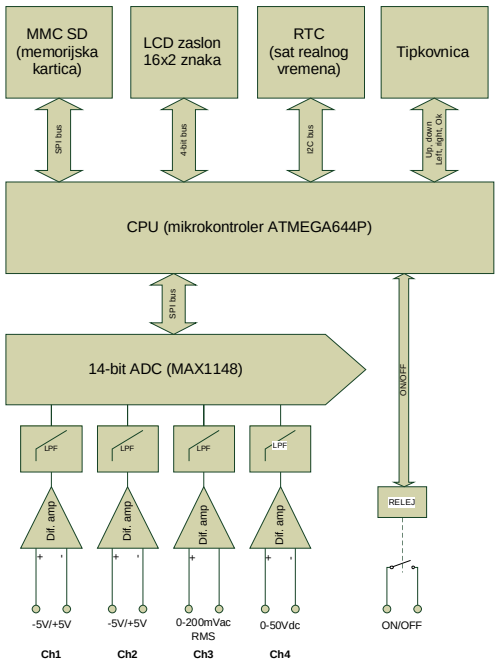
Korozija je nenamjerno odnošenje materijala sa površine metalnih konstrukcija. Nastaje zbog prirodne tendencije metala da se vrati u termodinamički stabilno početno stanje oksida. Sam proces korozije odvija se preko lokalnih katoda i anoda na površini metala. Uslijed anodne reakcije oksidacije metal u obliku iona napušta konstrukciju i time metal korodira.

Katodna zaštita u kombinaciji s premazima ili prevlakama učinkovita je tehnika zaštite od korozije za uronjene ili ukopane metalne konstrukcije, a zasniva se na tome da sva anodna područja na površini materijala dovedemo na potencijal najmanje katodnog područja. Kad nema razlike potencijala na površini metalne konstrukcije nema niti struje iona – tj. nema korozije. Kako bi se u tlima uspostavila dostatna razina zaštitnih struja na svaki dio ukopanog plinovoda (spremnika), primjenjuju se sustavi sa vanjskim izvorima struje [9]. Vanjski izvori struje osiguravaju dostatnu razinu napona za svladavanje otpora tla i omogućuju distribuciju struje od anodnih ležišta na mnogo veće duljine plinovoda od sustava sa žrtvenim anodama [2]. Sustavi katodne zaštite sa vanjskim izvorima struje uz uporabu automatske regulacije i uz dopunu sa sklopovima za zaštitu od interferencija i utjecaja *EE* postrojenja, daju veoma visoku sigurnost potpune zaštite ukopanog plinovoda (čelične konstrukcije) od korozije. Kao izvor zaštitne struje koristi se jednofazno upravljivi tiristorski most koji je sastavni dio uređaja katodne zaštite. Razvoj automatike i informatike omogućio je da sustavi katodnih zaštita budu i daljinski nadzirani i upravljani [3].

Osnovna ideja kod izrade uređaja za prikupljanje podataka u katodnoj zaštiti je da bude prenosiv, da ima mogućnost pohrane velike količine podataka (> 2GB), da omogućava tehnike mjerenja i skupljanja podataka prema *HRN EN 13509:2004* (Mjerne metode u katodnoj zaštiti), da prikupljene podatke na jednostavan način možemo prenijeti na osobno računalo i da korištenjem standardnih *MS Office* programa (*MS Excel*) podatke možemo editirati te izraditi izvještaje. U radu je prikazan razvoj programske podrške uređaja za mjerenje i prikupljanje podataka u katodnoj zaštiti izvedenog pomoću mikroprocesora *ATtmega644P*.

II. IDEJNO RJEŠENJE UREĐAJA

Uređaj za prikupljanje podataka u katodnoj zaštiti je mikroprocesorski uređaj koji prema zadanom algoritmu (programu) komunicira s periferijom (*AD* pretvarač, tipkovnica, zaslon), te na osnovu zadanih parametara (brzina uzorkovanja, tip mjerenja) prikupljene podatke sprema na *SD* (eng. ***S**ecure **D**igital, SD*) memorijsku karticu u obliku datoteke s ekstenzijom *.csv* (eng. *Microsoft Excel **C**omma **S**eparated **V**alues File*). Takva datoteka se jednostavno prenosi na osobno računalo gdje se radi daljnja obrada podataka. Principna shema uređaja za prikupljanje podataka u katodnoj zaštiti prikazana je na Slici 1.



Slika 1. Principna shema uređaja za prikupljanje podataka u katodnoj zaštiti

Sastoji se od sljedećih međusobno povezanih cjelina:

*1) Alfanumerički LCD (eng. **L**iquid **C**rystal **D**isplay) zaslon* za prikaz sljedećih trenutnih procesnih veličina:

- prikaz trenutnih izmjerenih vrijednosti za pojedini kanal (Ch1, Ch2, Ch3, Ch4);
- izbornik za odabir brzine snimanja (1 do 100 puta u sekundi);
- izbornik za odabir tipa mjerne metode. U slučaju *On/Off* mjerenja odabire se vrijeme *On*, vrijeme *Off* i broj perioda snimanja;
- izbornik za podešavanje sata realnog vremena.

2) Tipkala: za podešavanje i očitavanje trenutnih parametara

3) Sat realnog vremena RTC (eng. ***R**eal **T**ime **C**lock, RTC)* potreban da se odredi vrijeme i datum snimanja, a isto radi dodjele ekstenzije napravljene datoteke prilikom pohrane na karticu. Uređaj ima ugrađenu dodatnu bateriju za napajanje sata realnog vremena tako da u slučaju prekida napajanja ili prilikom zamjene baterije uređaja podaci o vremenu ostaju sačuvani.

4) 14-bitni AD (eng. ***A**nalog to **D**igital) pretvarač:* Jedan od najvažnijih dijelova uređaja. Podatke u katodnoj zaštiti potrebno je prikupiti s rezolucijom od 1 mV na cijelom mjernom opsegu od -5/+5V. Budući da ugrađeni AD pretvarač u mikrokontroleru *ATMEGA 644P* ima rezoluciju od 10 bita (rezolucija 9,7mV na mjernom opsegu -5V/+5V), to nije zadovoljavajuća preciznost za mjerenja u katodnoj zaštiti. U uređaju je korišten 14-bitni AD pretvarač *MAX 1148* koji na navedenom mjernom opsegu od -5V/+5V ima rezoluciju od 0,61mV. *AD* pretvarač s mikrokontrolerom komunicira preko *SPI* (eng. ***S**erial **P**eripheral **I**nterface, SPI*) sabirnice.

5) Analogni ulazi: Ulazna impedancija analognih ulaza i diferencijalnih pojačala za mjerenja u katodnoj zaštiti mora biti jako velika (*>10MΩ*). Tako prikupljene signale potrebno je odvojiti od smetnji tj. filtrirati. Za tu namjenu na svakom kanalu korišteni su niskopropusni aktivni filteri s donjom graničnom frekvencijom 5 Hz. Kod odabira naponskih granica (mjernih opsega) analognih ulaza korištena su iskustva u mjerenjima iz dosadašnje prakse. U uređaj su implementirana četiri analogna kanala. *Kanal 1* i *Kanal 2* (*Ch1* i *Ch2*) imaju mjerni opseg od -5V do +5V. Oni su namijenjeni snimanju elektrokemijskog potencijala cjevovoda ili drugih uronjenih ili ugrađenih podzemnih metalnih konstrukcija. *Kanal 3* (*Ch3*) ima mjerni opseg od 0-200mVAC RMS. On mjeri čistu efektivnu vrijednost izmjeničnog signala. Predviđen je za mjerenje izmjeničnih struja na čeličnoj mjernoj sondi. Mjerenje struje omogućeno je dodavanjem vanjskog otpornika 10Ω klase točnosti +/-1%. Na taj način moguće je mjeriti jakost izmjenične struje do 20 mA. Promjenom otpornika možemo podesiti mjerni opseg za mjerenje struje. *Kanal 4* (*Ch4*) ima mjerni opseg od -50V do +50V i namijenjen je snimanju izlaznog napona uređaja katodne zaštite.

6) Sklop za inicijalizaciju i snimanje krivulje depolarizacije na mjernoj sondi: Uređaj za prikupljanje podataka u katodnoj zaštiti mora imati ugrađen relej spojen sa izvodima na mjernom mjestu katodne zaštite koji programski upravljan prekida i uspostavlja galvansku vezu između mjerne sonde i mjernog izvoda sa cjevovoda. Na taj način moguće je izmjeriti tzv. krivulju depolarizacije potencijala na mjernoj sondi. Iz te krivulje nadalje se mogu očitati svi relevantni podaci: Uključni potencijal E_{on}, Isključni potencijal E_{off}, Količina depolarizacije ΔE, te *IR* pad napona u strujnim krugovima. Svi ti podaci potrebni su za određivanje ispravnosti rada i analizu sustava katodne zaštite.

7) Centralna procesorska jedinica (eng. ***C**entral **P**rocessing **U**nit, CPU*) je glavni dio uređaja za prikupljanje podataka u katodnoj zaštiti. Sastoji se od 8-bitnog mikroprocesora *ATMEGA644P* sklopovske arhitekture *AVR*, proizvođača *ATMEL*. Mikroprocesor brine o sljedećim funkcijama:

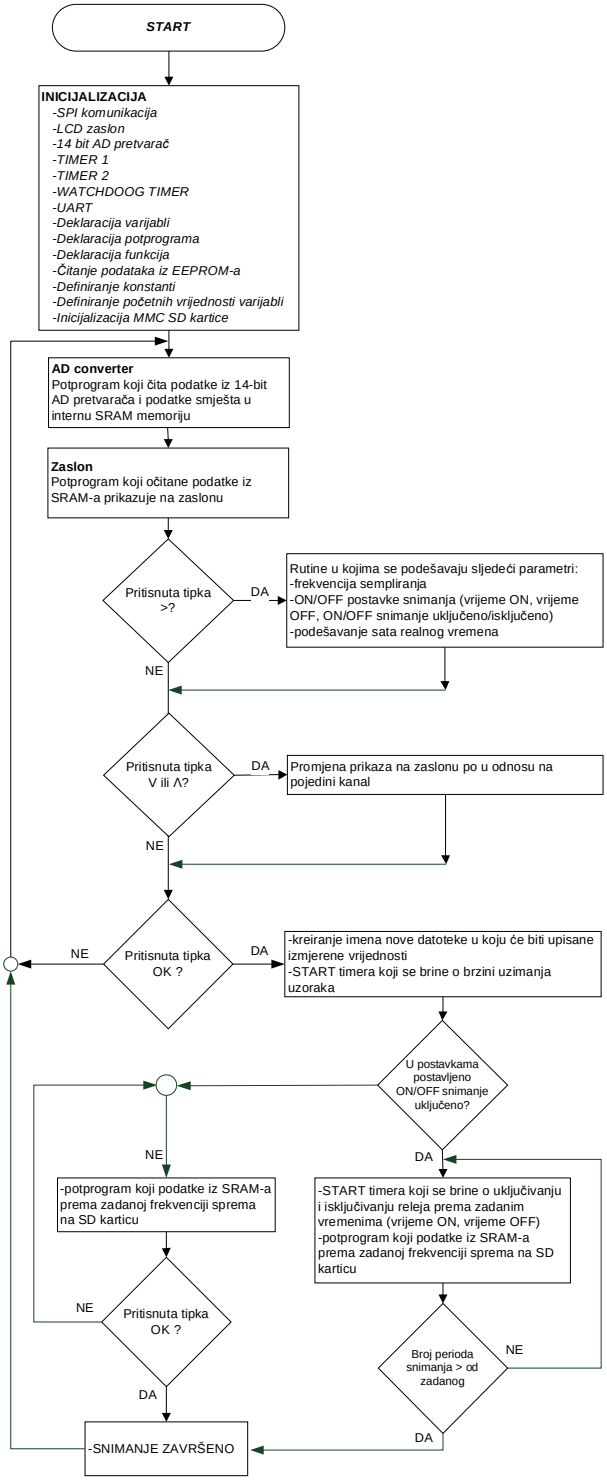
- Na osnovu algoritma i podešenih parametara (brzina uzimanja uzoraka, tip mjerenja) mikrokontroler preko *SPI* sabirnice komunicira sa *AD* pretvaračem te izmjerene podatke iz *AD* pretvarača sprema u svoju *SRAM* (eng. ***S**tatic **R**andom **A**ccess **M**emory, SRAM*) memoriju.
- Preko *SPI* sabirnice komunicira sa *SD* karticom te podatke iz *SRAM* memorije mikrokontrolera sprema na *SD* memorijsku karticu.
- Omogućava prikaz izmjerenih vrijednosti na *LCD* zaslonu.
- Preko *I2C* (eng. ***I**nter-**I**ntegrated **C**ircuit*) sabirnice komunicira sa satom realnog vremena te na osnovu vremena određuje ime datoteke.

8) Napajanje uređaja. Kućište u koje je uređaj ugrađen ima predviđeno mjesto za ugradnju jedne baterije od 9V, tipa *6R61-R22*. Uređaj se napaja iz punjive baterija NiMh 8,4V i kapaciteta 200 mAh. Potrošnja uređaja ograničava njegov rad s navedenim kapacitetom baterije na cca jedan sat. Iz navedenog razloga uređaj je moguće preko ugrađenog konektora priključiti na vanjski izvor napajanja ili bateriju od 9-15 VDC. Priključak na vanjsku bateriju od 12 V koristi se za tzv. 24 satna snimanja, dok auto-priključak 12 V koristimo za punjenje baterije uređaja u pauzama između pojedinih snimanja.

Slika 2. Uređaj za prikupljanje podataka u katodnoj zaštiti

III. PROGRAMSKO RJEŠENJE

Za izradu programskog rješenja uređaja za prikupljanje podataka u katodnoj zaštiti korištena je razvojna okolina *BASCOM* i istoimeni programski jezik. "Podloga" tog jezika je klasični *Basic*, na čiju je strukturu nadograđena podrška za rad s mikroprocesorima arhitekture *AVR*, odnosno naredbe ili funkcije koje konfiguriraju i aktiviraju pojedine sklopove mikroprocesora [2]. Prijenos podataka sa računala u programsku memoriju mikroprocesora se izvodi preko programatora *AVRISP mkII*.



Slika 3. Principni dijagram toka programa

Programsko rješenje za uređaj sastoji se od tri cjeline:

- Inicijalizacija
- Glavna petlja programa
- Prekidni potprogrami (eng. *Interrupt routine*)

A. *Inicijalizacija*

Inicijalizacijski dio programa služi za pripremu uređaja za ispravan rad punjenjem pripadajućih registara u mikroprocesoru određenim vrijednostima. U inicijalno konfiguriranje prije svega spada:

- Definiranje osnovnih parametara *SPI* komunikacije
- Definiranje osnovnih parametra za povezivanje sa *LCD* zaslonom.
- Definiranje parametara rada 14-bitnog AD (eng. ***A**nalog to **D**igital*) pretvarača.
- Konfiguracija *TIMERA1*.
- Definiranje načina rada *TIMERA2* (skok u prekidnu rutinu svaku sekundu – *On/Off* mjerenje).
- Konfiguracija *Watchdog* timera (napravi generalni reset ukoliko postoji zastoj u programu veći od 2048 ms).
- Deklaracija varijabli, potprograma i funkcija (u memoriji mikroprocesora definiramo memorijski prostor za varijable potrebne za izvršavanje programa).
- Čitanje spremljenih podataka iz *EEPROM* (eng. ***E**lectricaly **E**rasable **P**rogrammable **R**ead-**O**nly **M**emory*) memorije, definiranje konstanti i dodjeljivanje početnih vrijednosti varijabli.
- Inicijalizacija memorijske *MMC SD* kartice. Prilikom inicijalizacije program provjerava da li je kartica umetnuta u uređaj. U slučaju da *MMC SD* kartica nije umetnuta, program na zaslonu ispisuje grešku, a uređaj nastavlja s radom kao običan digitalni instrument s četiri kanala bez mogućnošću snimanja podataka na *MMC CD* karticu. Nakon provjere program provjerava da li na memorijskoj kartici ima memorijskog prostora za spremanje podataka. Ukoliko nema prostora na zaslonu se prikaže obavijest da je memorija puna.

B. *Glavna petlja programa*

Nakon inicijalizacije mikroprocesor počinje izvršavati zadaće koje su mu dodijeljene i to u zatvorenoj "*do-loop*" petlji. U glavnoj petlji programa izvršavaju se sljedeće zadaće:

1) AD pretvorba: Nakon inicijalizacije *SPI* sabirnice program u glavnom programu stalno čita podatke iz četverokanalnog 14-bitnog *AD* pretvarača i podatke smješta unutra *SRAM* memorije mikrokontrolera. Podaci se osvježavaju velikom brzinom tako da je moguće snimanje i spremanje na memorijsku karticu svih četiri kanala i do 100 puta u sekundi (100 Hz) što je više nego dovoljno za procese koji se događaju u katodnoj zaštiti.

2) Zaslon: Podaci očitani od strane AD pretvarača spremljeni u SRAM u zavisnosti od odabranog kanala (prikaz pojedinog kanala odabire se tipkama „▲“ i „▼“) prikazuju se na zaslonu.

3) Podešavanje parametara snimanja: Pritiskom na tipku „► “ program ulazi u rutinu u kojoj je moguće

podesiti frekvenciju snimanja i spremanja podataka na *MMC SD* karticu. U toj rutini se tipkama „▲“ i „▼“ na jednostavan način podesi frekvencija. Iz rutine podešavanja frekvencije u glavni izbornik se vraćamo pritiskom na tipku „◄“. Sljedećim pritiskom na tipku „►“ ulazimo u izbornik za podešavanje ON/OFF mjerenja. U toj rutini možemo tipkama „▲“ i „▼“ na jednostavan način podesiti vrijeme koliko dugo (prilikom ON/OFF mjerenja) želimo da je relej uključen (vrijeme *On*), vrijeme koliko dugo želimo da je relej isključen (vrijeme *Off*), broj perioda snimanja (vrijeme jedne periode = vrijeme *On* + vrijeme *Off*) i naravno želimo li uopće *On/Off* mjerenje (*On/Off* je uključeno ili isključeno). Nakon povratka u glavni izbornik na sličan način možemo u izborniku za podešavanje vremena podesiti sekunde, minute, sate, dane, mjesece i godinu. U glavni izbornik vraćamo se pritkom na tipku „◄“ više puta.

4) Komanda za snimanje: Pritiskom na tipku „OK “ program ulazi u rutinu u kojoj se odvija snimanje podataka na *MMC SD* karticu. Odmah na početku program kreira ime datoteke na način: dan, mjesec-redni dnevni broj snimke (1-999). Primjer *0504-001.csv* znači ime datoteke je napravljeno petog travnja i to je prva snimka po redu u tekućem danu. Redni dnevni broj snimke ograničen je na 999 snimki u jednom danu, što je više nego dovoljno dnevno potrebnih snimki za potrebe u katodnoj zaštiti. Nakon kreiranja datoteke program pokreće *TIMER 1* i dalje se izvodi prekidna rutina pod kontrolom *TIMERA 1*. U slučaju da smo u postavkama pod *On/Off* mjerenjem odabrali *On/Off uključeno* tada se u trenutku pokreće *timer 1*, pokrene se i interni brojač koji je odgovoran za kontrolu *On/Off* mjerenja. Tada interni brojač prema postavkama *On/Off* mjerenja uključuje i isključuje izlazni pin koji upravlja radom releja. Ukoliko smo odabrali *On/Off* mjerenje u postavkama *On/Off* mjerenja tada program nakon završenih unaprijed zadanih broja perioda mjerenja sam završava snimku, a u slučaju da imamo normalno mjerenje tada korisnik može završiti snimanje u trenutku kad mu to odgovara. Snimanje se tada završava ponovnim pritiskom na tipku „OK“.

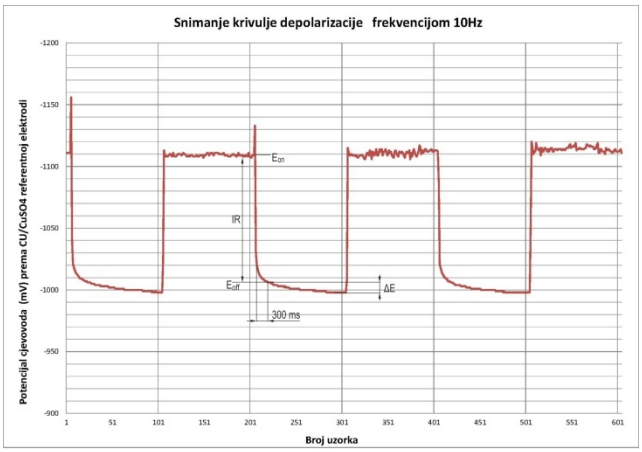
C. Prekidni potprogram

U njemu se u točno određenim vremenskim razmacima uzimaju uzorci sa *A/D* pretvarača iz *SRAM* memorije za sva četiri kanala i spremaju na *MMC SD* memorijsku karticu. Izvršava se pod nadzorom TIMERA1 kojeg konfiguriramo kada podesimo frekvenciju uzimanja uzoraka. Podešavanjem frekvencije uzimanja uzoraka moguće je podesiti da se prekidni potprogram izvršava od 10ms (100Hz) do 1s (1Hz).

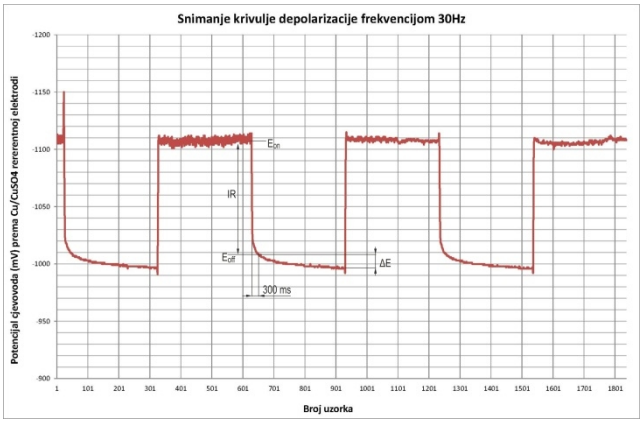
IV. REZULTATI MJERENJA

Nakon završetka „demo“ verzije uređaja napravljena su testna mjerenja na *Kanalu 1* (*Ch1*). Mjerenja su provođena kod normalnih meteoroloških uvjeta na testnom mjernom mjestu unutar kompanije *PA-EL d.o.o.* Napravljene su četiri snimke na različitim frekvencijama snimanja. Određene su vrijednosti frekvencija uzorkovanja 10 Hz, 30 Hz, 50 Hz i 100 Hz. Na slikama 4. do 7. prikazani su podaci snimljeni uređajem na spomenutim frekvencijama. Iz sva četiri grafa možemo očitati podatke potrebne za analizu stanja katodne zaštite.

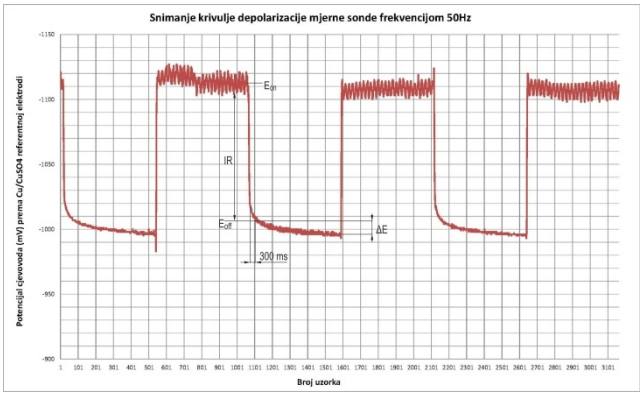
Porastom frekvencije uzorkovanja grafovi prikazuju „gušće“ krivulje jer uređaj mjeri signal koji u sebi sadrži više frekvencije. Na taj način moguće je mjeriti i snimiti čak i najmanju smetnju koja se javlja na cjevovodu što prikazuje i slika 7. Ipak, za potrebe katodne zaštite i za određivanje kriterija dostatnosti prema *HRN EN 12954*, inženjerska praksa je pokazala kako je mjerenje sa 10 uzoraka u sekundi (10 Hz) sasvim dovoljno.



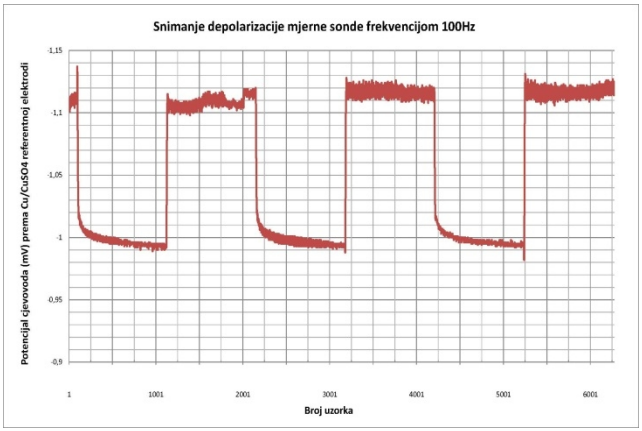
Slika 4. Snimanje krivulje depolarizacije frekvencijom 10 Hz



Slika 5. Snimanje krivulje depolarizacije frekvencijom 30 Hz



Slika 6. Snimanje krivulje depolarizacije frekvencijom 50 Hz



Slika 7. Snimanje krivulje depolarizacije frekvencijom 100 Hz

V. ZAKLJUČAK

Primjenom mikroprocesora, te dugogodišnje iskustvo u mjerenjima na sustavima katodne zaštite, poštivanje normi za katodnu zaštitu otvorilo je put prema razvoju uređaja za prikupljanje podataka u katodnoj zaštiti.

Prikazani uređaj za mjerenje i prikupljanje podataka u katodnoj zaštiti u potpunosti je zadovoljio zahtjeve iz projektnog zadatka da bude prenosiv, da ima mogućnost pohrane velike količine podataka (> 2GB), da omogućava tehnike mjerenja i skupljanja podataka prema *HRN EN 13509:2004* (Mjerne metode u katodnoj zaštiti) te na taj način postao konkurentan proizvod na domaćem i svjetskom tržištu. Pored svega opisanog bitno je navesti da je prikazani uređaj potpuno nezavisan u svom radu, jer podatke sprema na medij koji je prenosiv, a datoteke koje stvara moguće je direktno importitrati u *MS Excel*. Na taj način nije potrebna izrada dodatnog softvera za prikaz i obradu podatka te izradu izvještaja, čime uređaj još više dobiva na konkurentnosti.

Ovim radom je dokazano da se korištenjem mikrokontrolera može proizvesti uređaj koji zadovoljavaja i najzahtjevnije zahtjeve korisnika, ubrzava postupak analize stanja cjevovoda te omogućuje kvalitetnije održavanje sustava katodne zaštite. Samim time, poštivajući norme i standarde, uređajem za mjerenje i snimanje podataka u katodnoj zaštiti dovodimo sigurnost naftnog i plinskog transportnog sustava na zavidni nivo pouzdanosti i sigurnosti.

Idejno rješenje kalibracije industrijskog kompaktnog termometra

Lj. Cvitaš
Tehničko veleučilište u Zagrebu, Zagreb, Hrvatska
lcvitas@tvz.hr

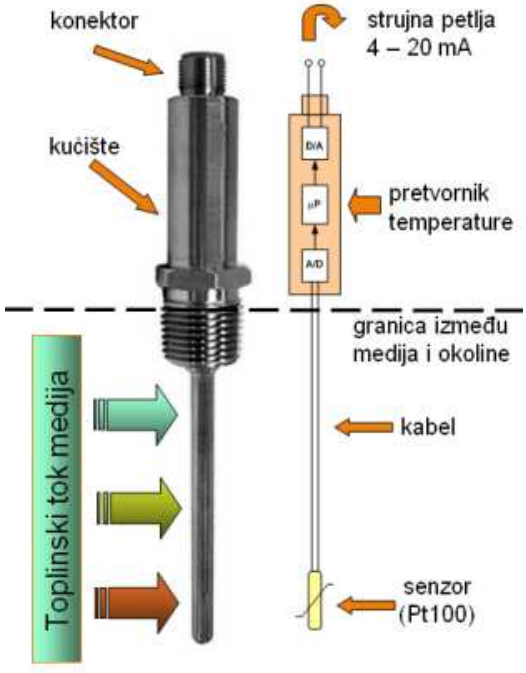
Sažetak – Kompaktne izvedbe mjernih senzora i mjernih pretvornika pružaju dodatni komfor korisniku; jednostavnost montaže i primjene te bolja otpornost na elektromagnetske i druge smetnje iz okoliša. Gledano pogledom proizvođača, ali i servisera te evidentne prednosti imaju i svoju cijenu: primarna veličina koju senzor daje nije dostupna niti naknadno direktno mjerljiva, te otpada standardni postupak kalibracije gdje se u mjernom području posebno kalibrira senzor , a odvojeno mjerni pretvornik. Naročito je problem izražen kod kompaktnih pretvornika temperature, gdje se uz sve prednosti koju pruža digitalni uređaj želi ostvariti i vrhunska apsolutna točnost mjerenja upotrebom platinskog senzora. Kalibracija ugrađenog mjernog pretvornika nije provediva kao kod samostalnog uređaja. Direktna simulacija senzora otpornom dekadom na ulazu nije moguća. Zbog svega navedenog u radu se obrazlaže idejno rješenje posebne kalibracije predložene izvedbe industrijskog kompaktnog termometra. Rješenje je osigurano usklađenom interakcijom programske podrške mikroupravljača mjernog pretvornika te same kalibracione metode koja se provodi u uvjetima serijske proizvodnje.

I. UVOD

Kompaktni pretvornik temperature je sklop mjernog senzora i mjernog pretvornika zatvoren u jedinstvenom kućištu od čelika ili sličnog čvrstog materijala (slika 1). U principu tu bi sa dalo govoriti i o kompaktnom mjernom pretvorniku temperature sa ugrađenim senzorom, ali naglasak je kod mjerenja temperature ipak na senzoru koji dolazi na direktan ili indirektan način u doticaj s medijem čija se temperatura mjeri, a što je izlazna veličina tog mjerenja, nije od kapitalnog značaja [1,2]. Termometar, u širem značenju, je termometar imao on ili nemao ugrađeni mjerni pretvornik temperature. Korisnik takav uređaj na lak način može montirati u industrijsko postrojenje ili drugu napravu ili stroj, te predviđene izvode tog termometra (naponski, strujni ili pak digitalni signal) spojiti na upravljački, nadgledani ili ini sustav gdje se informacija o izmjerenoj temperaturi koristi.

U slučaju korištenja kompaktnog termometra, korisnik se ne mora brinuti o načinu spajanja samog senzora sa mjernim pretvornikom temperature (dvožično, trožično, četverožično), pa u krajnjoj liniji ne mora ga niti zanimati koje je vrste sam senzor (otporni, naponski ili neki drugi), već ga zapravo samo zanima predviđeno mjerno područje takvog kompaktnog termometra, točnost mjerenja, te vrsta izlaznog signala. Naravno da upotreba mikroupravljača unutar takvog sklopa omogućuje korisniku i druge pogodnosti kao npr. naknadno podešavanje mjernog područja mjerenja, vrijeme odziva odnosno njegovo usporenje, te razne vrste dijagnostičkih, sigurnosnih i drugih funkcija.

Za razliku od "temperaturnog mjernog mjesta" koje se sastoji od više sastavnica, npr. zaštitne cijevi ugrađene u cjevovod, mjernog uloška gdje je smješten senzor te mjernog pretvornika temperature koji može biti ugrađen u glavu termometra ili pak kabelom povezan sa mjernim uloškom i smješten u upravljačkom ormaru postrojenja, kompaktni termometar je cjelovito mjerno mjesto koje se ne da rastaviti na rečene sastavnice. Za primjenu i montažu svakako jednostavno, ali glede kalibracije (tvorničke ili naknadne) svakako zahtjevno. Naime primarna veličina koju senzor daje (otpor u konkretnom slučaju kad imamo platinski senzor) nije dostupna niti naknadno direktno mjerljiva, te otpada standardni postupak kalibracije gdje se u mjernom području kalibrira sam senzor (mjereći vrijednost otpora u više referentnih točaka temperature), da bi se izračunati Calendar van Dusen (dalje CvD) koeficijenti prenijeli u mjerni pretvornik temperature [3].



Slika 1. Kocept kompaktnog pretvornika temperature

II. STRUKTURA SKLOPA

A. Blokovska shema

Na slici 2 prikazana je blokovska shema prototipa kompaktnog termometra koji će se koristiti kao osnova za razvoj cijele serije sličnih proizvoda. Paralelno blokovskoj shemi prikazan je fizički izgled prototipa položenog tako da smještaj elemenata blokovske sheme otprilike odgovara položaju u unutrašnjosti termometra. Tako je platinski senzor smješten krajnje u samom vrhu zaštitne cijevi te spojen četverožično sa štampanom pločicom elektroničkog modula. Kabel, odnosno žice koje povezuju elektronički modul sa senzorom imaju silikonsku izolaciju kako bi mogli biti izloženi temperaturama medija u mjernom području od -50°C do 200°C. Elektronički modul, odnosno sam mjerni pretvornik temperature smješten je u cijevi koja se nastavlja na procesni priključak namijenjen za uvrtanje termometra u mjerno mjesto. Električni priključak kompaktnog termometra su izvodi ”1” i ”2” na konektoru tipa M12 koji je integriran u kućištu termometra.

Mjerni dio kompaktnog termometra sastoji se od diferencijalne strujne petlje i dvokanalnog analogno-digitalnog pretvornika [4]. Strujna petlja sastoji se od izvora te serijski spojenih otpornika od kojih je jedan otpor senzora temperature (vanjski izvodi) te jedan je precizni i što je još važnije temperaturno stabilni referentni otpornik [5]. Otpornici R1 i R2 služe za ograničenje struje petlje te za dizanje diferencijalnih napona petlje u zonu definicije A/D pretvornika. Idealni spoj trebao bi imati regulirani izvor konstantne struje, a mjerenje diferencijalnih napona na Pt100 senzoru i R_{ref} trebalo bi biti sinkrono [6]. Spoj na prototipu ne koristi izvor konstantne struje već stabilizirani naponski izvor (3,5VDC). Pri tom se polazi od pretpostavke da je struja

$$I_{sens} = Vcc / (R1 + Pt100 + R_{ref} + R2) \qquad (1)$$

konstantna za vrijeme trajanja mjerenja diferencijalnih napona ΔU_{Pt100} i ΔU_{Rref}. Pretpostavka je plauzibilna ako znamo koliki je maksimalni porast temperature koja djeluje na senzor u odnosu na vrijeme trajanja mjerenja dva napona na ulazu A/D pretvornika. Uzmimo dakle da koristimo keramički Pt100 senzor sa vremenom odziva cca $t_{0,9}$ = 0,5 s [7][8]. To vrijeme je pet puta duže od vremena analogno digitalne pretvorbe potrebnog da se izmjere naponi U_{Pt100} ili U_{ref}.

. Vrijeme analogno digitalne pretvorbe može biti i kraće, ali zbog potrebe da se potisne negativni utjecaj smetnji od mrežnog napona (50/60 Hz) preporuča se koristiti vrijeme A/D pretvorbe koje potiskuje taj utjecaj. To pravilo vrijedi za mjerne pretvornike kod kojih se signal sa senzora temperature spaja dužim kabelom gdje je očekivani utjecaj izmjeničnog mrežnog napona veći. U slučaju kompaktnog termometra, koji ima metalno kompaktno kućište, ne očekuje se utjecaj mrežne frekvencije, međutim to se mora potvrditi na prototipu.

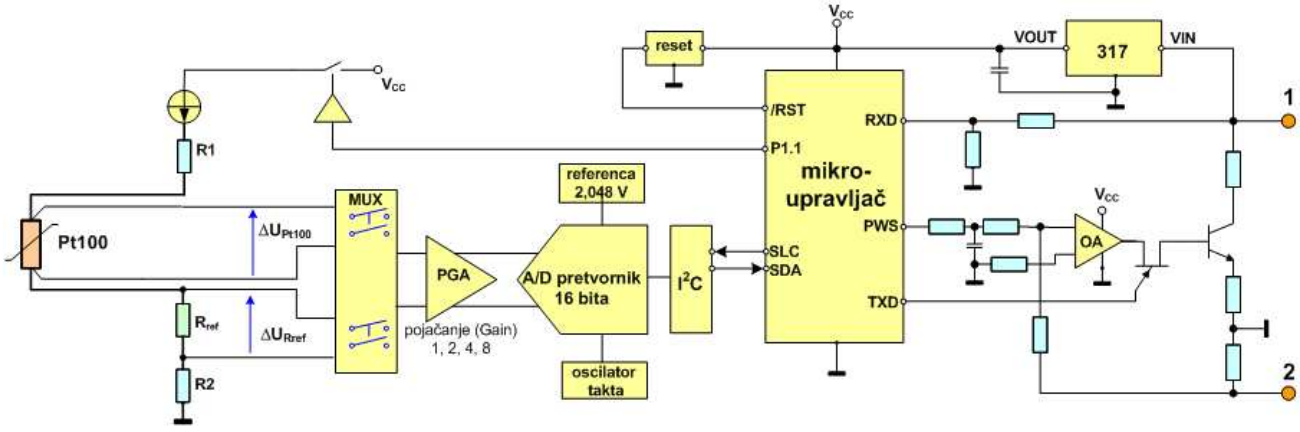
Mikroupravljač vrlo niske vlastite potrošnje ugrađen je kao središnji element pretvornika temperature [9]. Preko sučelja izvor je modulacije struje strujne petlje 4-20mA te digitalne komunikacije ostvarene amplitudnom modulacijom na napajačkom krugu petlje. Asinkrona serijska komunikacija, jednostavnog vlastitog protokola koristi se u modu programiranja i kalibracije kompaktnog termometra.

B. Proračun

Proračun ulaznog sklopa kompaktnog termometra bazira na sljedećim pretpostavkama:

- mjerno područje termometra je od -50°C do +200°C
- vrijednost otpora senzora u granicama od 80Ω do 176Ω.
- ugrađeni senzor je tip Pt100 klase A
- maksimalna vrijednost otpora senzora (kod 850°C) je 390Ω
- referentni napon A/D pretvornika 2,048V
- vrijednost referentnog otpornika je 130Ω
- maksimalno pojačanje programibilnog pojačala u ADS1112 je 8.
- ulazna dinamička impedancija A/D pretvornika je 350kΩ
- vrijednost senzorske struje o granicama od 0,2mA do 0,8mA
- stabilizirani napon pretvornika Vcc= 3,5V

Uzmimo kao granični slučaj da se kod maksimalne vrijednost otpora senzora ulaz A/D pretvornika još ne ulazi u zasićenje:



Slika 2. Blokovska shema industrijskog kompaktnog termometra

$$U_x = I_{sens} * Pt100_{max} * Gain = 2{,}000V \quad (2)$$

Iz (2) proizlazi struja kroz senzor:

$$Isens = 2{,}000 / (390 * 8) = 0{,}641\ mA \quad (3)$$

Ako pak izraz (1) riješimo po R1+R2 = R_{uk} dobivamo:

$$R_{uk} = (V_{cc}*Pt100_{max}*Gain)/2 - (Pt100_{max} + R_{ref}) \quad (4)$$

odnosno R_{uk} = 4940 Ω.

Time dobivamo mogući izbor za R1= 2200Ω i R2 = 2700Ω. Ulazna impedancija diferencijalnog ulaza A/D pretvornika nije zanemariva i kod pojačanja 8 iznosi oko 350kΩ. To znači da kod mjerenja ΔU_{Pt100} mjerimo napon na paraleli senzorskog otpora i otpora ulazne impedancije. Isti je slučaj i kod mjerenja ΔU_{Rref} , ali je tu vrijednost paralele otpora konstantna. Razlika u mjerenju otpora senzora kod minimalne i maksimalne očekivane vrijednosti u mjernom području (između 80Ω i 176Ω) iznosi 0,07Ω i može se kompenzirati u programskom kodu mikroupravljača.

Osim ulazne impedancije A/D pretvornika kod mjerenja se mora uzeti u obzir i pomak koji se dobiva mjerenjem kratko-spojenog ulaza A/D pretvornika. Ta mala vrijednost ipak utječe na točnost mjerenja i mora se uzeti u obzir:

$$R_{izm} = R_{ref} * (U_x - U_{off}) / (U_{ref} - U_{off}) \quad (5)$$

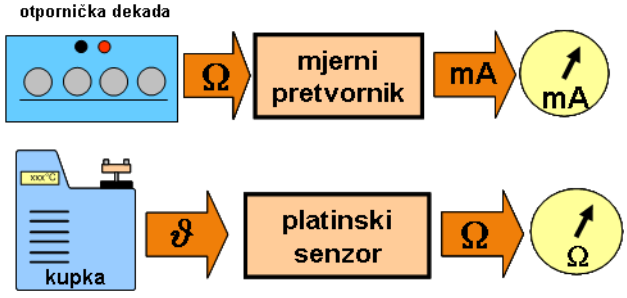
Mjerenje U_{off} moguće je provesti uz uvjet I_k =0 , obzirom da su vrijednosti otpora Pt100 i Rref male u odnosu na ulaznu impedanciju A/D pretvornika. Da bi se poništio utjecaj *common mode* efekta dobro je izmjeriti posebno pomak na svakom od dva ulaza A/D pretvornika tako da je preciznije određivanje otpora Pt100 senzora određeno izrazom:

$$R_{izm} = R_{ref} * (U_x - U_{offx}) / (U_{ref} - U_{offref}) \quad (6))$$

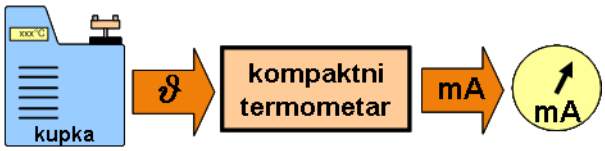
III. KALIBRACIJA

A. Osnovne postavke

Kalibracija kompaktnog termometra može se obaviti



Slika 4. Nezavisna kalibracija senzora i mjernog pretvornika



Slika 3. Kalibracija kompaktnog termometra

na dva načina:

- posebno kalibrirati senzor, a posebno pretvornik temperature
- kalibrirati u istom procesu kompletni uređaj

Prvi način provodi se kod standardnog temperaturnog mjernog mjesta koje se sastoji od termometra i odvojenog pretvornika (slika 3). Postupak je vremenski duži, naravno i skuplji, a zahtjeva i prenošenje podataka o izračunatim CvD koeficijentima sa senzora na mjerni pretvornik. Pri tom se mora paziti da i serijskoj proizvodnji ne dođe do zamjene spojenih parova senzor-pretvornik.

Taj način kalibracije je s druge strane opet „jednostavan“ jer ne zahtjeva promjenu metodologije kalibracije ili promjene u softveru mjernog pretvornika ili softvera kalibracijskog sustava. Senzor se uranja u medij poznate temperature, a otpor senzora se mjeri preciznim instrumentom. Na ulaz mjernog pretvornika se pak spaja precizna otpornička dekada, a izmjereni otpor ili pak izračunata temperatura očitava se digitalno na izlazu mjernog pretvornika [10][11].

Drugi način kalibracije pretpostavlja da kompletni uređaj u kojem je senzor fiksno spojen u četvorožičnom spoju na ulaz pretvornika i nije moguće izmjeriti „međuvrijednost“ odnosno otpor koji ima senzor na nekoj od referentnoj temperatura. Ulazna vrijednost je temperatura kojoj je izložen senzor kompaktnog termometra, a izlazna vrijednost je digitalni iznos temperature, otpora ili neke druge interne varijable pretvornika temperature (slika 4).

U mjerni pretvornik je ugrađen referentni otpornik Rref vrlo malog temperaturnog koeficijenta (Tk < 50ppm/°C). Nazivna vrijednost tog otpornika je upisana kao početni parametar (130Ω) u memoriju kao vrijednost R_{ref}, ali stvarna vrijednost referentnog otpornika može odstupati od te nominalne vrijednosti. Taj parametar se koristi u izrazu (6) kao konstanta koja svojom vrijednošću direktno utječe na točnost izračuna otpora senzora.

Pošto se vrijednost tog otpora ne da direktno izmjeriti uspoređujući njegovu vrijednost sa vrijednosti nekog poznatog vanjskog otpornika (npr. otporničke dekade), jedina preostala opcija je usporedba otpora ugrađenog Pt100 senzora sa referentnim otpornikom.

Platinski vodič u formi vrlo tanke žice ili metaliziranog sloja na keramičkoj čip-bazi prvi je izbor za linearne i stabilne senzore u industrijskoj primjeni [12]. Ugrađeni Pt100 otpornik klase A ima po normi IEC 60751 najmanju grešku u točki 0°C i to ±0,06Ω [13]. Znači da ako kompaktni termometar uronimo u temperaturnu kupku (mješavinu leda i vode) vrijednost otpora Pt100 senzora nalazit će se u granicama od 99,94 do 100,06Ω pa to stanje možemo koristiti kao „okidač“ za točno određivanje parametra R_{ref}:

$$R_{ref} = (100\pm0{,}06)^* (U_{ref} - U_{offref})/ (U_x-U_{off}) \quad (7)$$

Ako se želi postići veća točnost mjerenja paralelno sa termometrom koji se umjerava, u kupku se treba uroniti standardni platinski termometar veće klase točnosti, ali vremena odziva koje je slično ili barem red veličine kao i kompaktni termometar koji se umjerava. Kontrolom temperature koji mjeri taj referentni termometar, odnosno mjerenjem njegovog otpora R_{std}, postiže se da je u trenutku „okidanja“ tj. uzimanja mjernih podataka u pretvorniku temperature određena vrijednost otpora R_{ref} još točnija:

$$R_{ref} = R_{std} * (U_{ref} - U_{offref})/ (U_x-U_{off}) \quad (8)$$

B. Izračun koeficijenata CvD

Otpor senzora i temperaturu u temperaturnom području od −200°C do 0° C povezuje polinom četvrtog stupnja:

$$R_T = R_0*(1+A*T+B*T^2+C*(T-100)*T^3), \quad (9)$$

a za temperaturno područje od 0°C do 850 °C vrijedi polinom drugog stupnja:

$$R_T = R_0*(1+A*T+B*T^2). \quad (10)$$

Obzirom da je mjerno područje kompaktnog termometra ograničeno na raspon od -50°C do +200°C, za postizanje povećane točnosti mjerenja senzor i mjerni pretvornik uskladit će se preko CvD koeficijenata A i B (odnosno α i δ) [14]. Koeficijent C (odnosno β) neće se računati nego će se uzeti kao konstanta

$$C = -4,183 \cdot 10^{-12} \ °C^{-4} . \quad (11)$$

Naime pokazalo se da je utjecaj koeficijenta C u negativnom području temperatura vidljiv tek u području ispod -50°C, odnosno da koeficijenti A i B bolje korigiraju grešku mjerenja u području od -50°C do 0°C nego sam koeficijent C [14].

Iz toga proizlazi da za kalibraciju kompaktnog termometra dostaju tri referentne temperature točke:

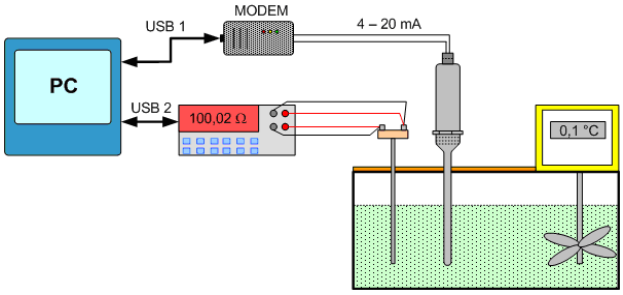
$T_0 = 0°C$ ($R_{izm}= 100\Omega$)
$T_{100} = 100°C$ ($R_{izm}= R100$)
$T_{high} = 200°C$ ($R_{izm}= R200$)

Prema tablici 7.1 [14] možemo izračunati vrijednosti za koeficijente alfa i delta:

$$\alpha = (R100-100) / 10^4 \quad (12)$$

$$\delta = 100 - 50*(R200-100) / (R100-100) \quad (13)$$

Prema izrazu (3-29) [14] imamo priliku izračunati I srediti izraz za koeficijent A:



Slika 5. Postupak kalibracije referentnog otpornika R_{ref}

$$A = 2* (R100-100)/10^5 - 50*(R200-100)/10^6 \quad (14)$$

Koeficijent B računamo prema izrazu (3-30) iz [14] te sređivanjem dobijemo:

$$B = - (R100-100)/10^4 + 50*(R200-100)/10^8 \quad (15)$$

Uočimo sljedeće elemente u računanju koeficijenata A odnosno B:

$$PRVI = (R100-100) / 10^4 \quad (16)$$

$$DRUGI = 50 * (R200-100) / 10^6 \quad (17)$$

Pojednostavljeno koeficijente A i B možemo prikazati kao:

$$A = 2 * PRVI - DRUGI \quad (18)$$

$$B = - PRVI / 100 + DRUGI / 100 \quad (19)$$

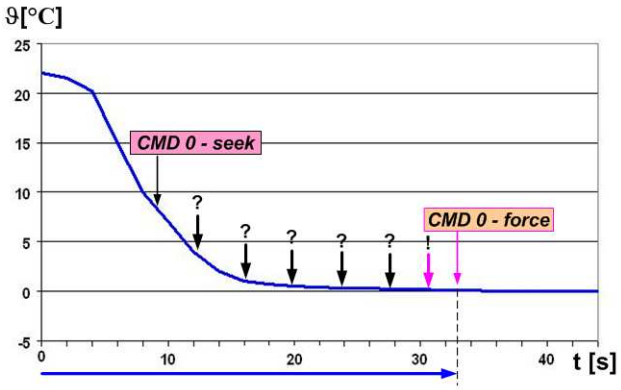
Izračun varijabli *PRVI* i *DRUGI* može obaviti program mikroupravljača u pretvorniku u trenutku kada se inicira kalibracija u temperaturnoj točki T=100°C (dobiva se vrijednost otpora senzora R_{100} te se računa izraz *PRVI*), odnosno u temperaturnoj točki T=200°C (dobiva se vrijednost otpora senzora R_{200} te se računa izraz *DRUGI*).

C. Kalibracija u temperaturnim kupkama

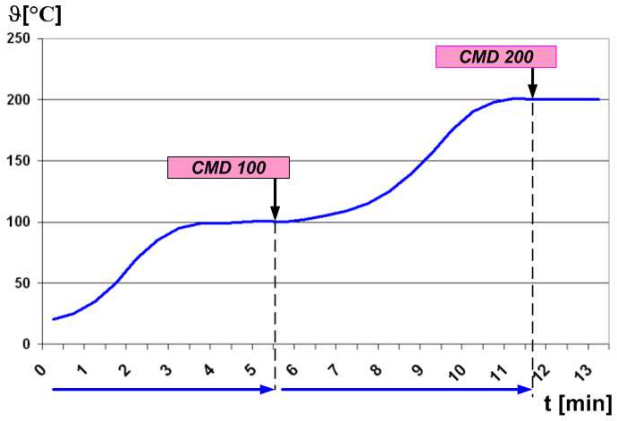
Temperaturna točka T=0°C koristi se za rekalibraciju referentnog otpora prema izrazu (8) što opet direktno utječe na ukupnu točnost kompaktnog termometra. Na slici 5 prikazan je postupak kalibracije uz upotrebu standardnog (etalonskog) termometra visoke točnosti. U tom slučaju moguće su dvije varijante umjeravanja:

- preko modema daje se komanda pretvorniku temperature da izvrši mjerenje Ux u trenutku kada je R_{std} =100Ω
- preko modema se prenosi izmjerena vrijednost R_{std} (ohmometar spojen na računalo) koja se koristi u izrazu (8) za proračun.

-



Slika 6. Temperaturni odziv prilikom uranjanja kompaktnog termometra u ledenu kupku



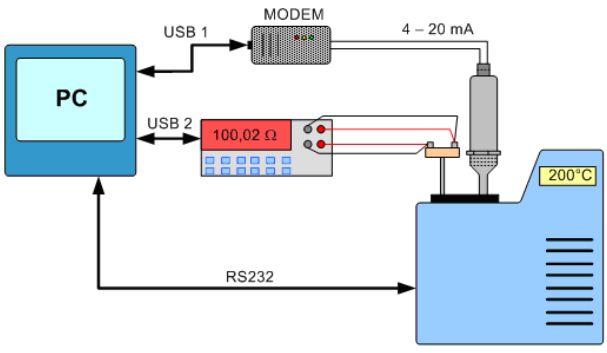
Slika 7. Temperaturni odziv suhog bloka prilikom kalibracije na 100°C i 200°C

Pojednostavljeni oblik kalibracije (servis i održavanje) koristio bi samo ledenu kupku bez etalonskog termometra tako da bi se modemskom komandom forsirala upotreba izraza (7).

Na slici 6 prikazan je graf ovisnosti izmjerene temperature o vremenu nakon uranjanja kontrolnog (standardnog) ili pak kompaktnog termometra u mješavinu leda i vode. Obzirom na mali toplinski otpor i zbog male mase malen toplinski kapacitet, odziv termometra je relativno brz. Vidljivo je da je ciljna (referentna) temperatura dostignuta nakon cca 30 sekundi pa se u tom momentu preko komande *CMD0-force* pretvorniku temperature signalizira da izvrši sekvencu mjerenja otpora platinskog senzora te izračuna novu vrijednost R_{ref}.

Prilikom kalibracije u kupki treba obratiti pažnju na dubinu uranjanja mjernog dijela termometra kako bi se osigurala točna očekivana vrijednost referentne temperature od 0,1°C. U varijanti kad se kalibracija obavlja uz pomoć kontrolnog termometra, dubine uranjanja moraju biti istovjetne pa će se uz pretpostavku istog vremena odziva kontrolna i mjerena temperatura podudarati [15].

U varijanti kada se ne koristi kontrolni termometar, okidanje komandom *CMD0-seek* može pokrenuti postupak u mikroupravljaču termometra koji nadgleda dostignuto područje temperature te mjeri razliku temperature u nekoliko uzastopnih koraka. Nakon konačnog usporenja pada temperaturne krivulje (npr. $\Delta\vartheta \leq 0{,}2$°C) uzima se vrijednost senzora i računa aktualni R_{ref}.



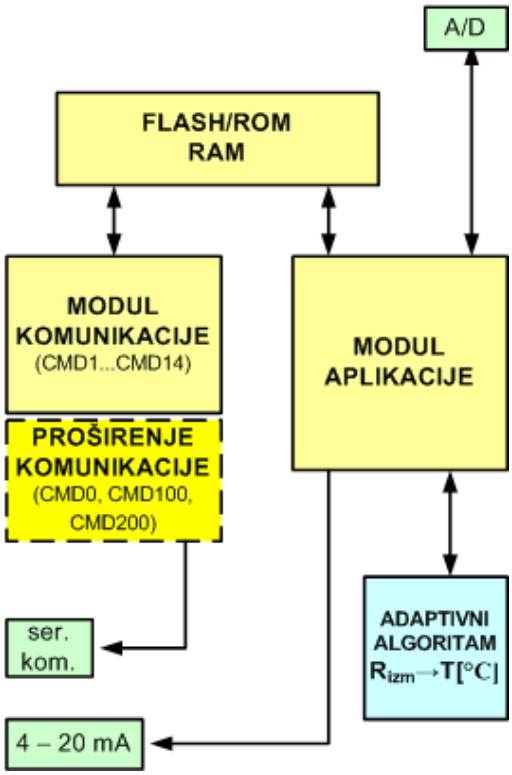
Slika 8. Postupak kalibracije na višim temperaturama

Na slici 7 prikazan je postupak kalibracije na referentnim temperaturama od 100°C odnosno 200°C. Kontrolni termometar i mjereni kompaktni termometar umetnuti su u otvore bloka „suhe“ kupke na podjednakim dubinama te po mogućnosti istim promjerima mjernog uloška odnosno zaštitne cijevi. Računalo kontrolira postavljanje zadane temperature regulatora suhog bloka te mjeri vrijednost otpora senzora kontrolnog termometra. U trenutku dostizanja prve referentne temperature (graf temperaturnog odziva na slici 8) preko modema daje se komanda mikroupravljaču *CMD100* što je okidač za uzimanje vrijednosti sa senzora kompaktnog termometra te pohranjivanje aktualne vrijednosti *R100*. Vrijeme dostizanja postavljene temperature je otprilike 6 minuta / 100°C i ovisi o performansama suhe kupke. Pri kontinuiranom postupku kalibracije moguće je preko regulatora postaviti kao sljedeću željenu vrijednost 200°C te postizanjem te vrijednosti komandom *CMD200* prema mikroupravljaču pohraniti aktualnu vrijednost *R200*.

Nakon posljednje kalibracione točke aktivira se algoritam za računanje izraza *PRVI* i *DRUGI* što je osnova za proračun CvD koeficijenata *A* i *B* te njihov upis u memoriju mikroupravljača. Uparivanjem podataka o krivulji platinskog senzora sa ugrađenim pretvornikom temperature moguće je smanjiti mjernu nesigurnost minimalno za tri puta [16].

IV. PROGRAMSKA PODRŠKA MIKROUPRAVLJAČA

Postojeća programska podrška mikroupravljača realizirana je za standardni pretvornik temperature. Komunikacijski modul podržava privatni protokol za potrebe parametriranja pretvornika (mjerno područje, usporenje, podešavanje parametara strujne petlje, itd.), a aplikacijski modul obrađuje sve poslove vezane uz dohvat podataka sa A/D pretvornika te kontrole struje na strujnoj petlji 4-20mA. Posebni programski blok obavlja proračun temperature na temelju izmjerenog otpora platinskog senzora. Proračun se bazira na adaptivnom algoritmu [14] uz primjenu jednadžbe (10).



Slika 9. Blokovska shema modula programske podrške s proširenjem u modulu komunikacije

Blokovska shema programske arhitekture prikazana je na slici 9. Prijenos podataka između programskih blokova ostvaren je preko FLASH/RAM memorije mikroupravljača (RAM, FLASH). Proširenje vezano za novo idejno rješenje kalibracije kompaktnog termometra odnosi se isključivo na komunikacijski modul. Dodane su komande *CMD0-seek*, *CMD-force*, *CMD100* i *CMD200* te aritmetički blokovi za izračun CvD koeficijenata *A* i *B*. Realizacija proširenja ovisi naravno o raspoloživim memorijskim resursima mikroupravljača te moguć scenarij zamjene mikroupravljača drugim, pin-kompatibilnim, ali sa većom FLASH/RAM memorijom. Naime, koliko god bio optimiran postupak kalibracije sa stajališta redukcije izvedbenog koda, opet se me može zanijekati činjenica da izračun jednadžbi (16), (17), (18) i (19) „košta“ prostora na složaju u RAM-u te dodatnog koda u FLASH memoriji.

V. ZAKLJUČAK

Predloženo idejno rješenje kalibracije industrijskog kompaktnog termometra bazira se na tri pretpostavke:

- sklopovsko rješenje garantira stabilnost i točnost mjerenja otpora platinskog senzora primjenom diferencijalne strujne petlje i temperaturno stabilnog referentnog otpornika
- kalibracija se provodi u tri referentne temperature primjenom računalom vođenog sustava koristeći usporedbu sa etalonskim (standardnim) termometrom u mokroj i suhim kupkama
- resursi primijenjenog mikroupravljača dozvoljavaju proširenje programske podrške u komunikacijskom modulu, odnosno proširenje postojećeg privatnog komunikacijskog protokola sa komandama povezanih sa postupkom kalibracije

Rješenje kalibracije omogućuje relativno brzi i pouzdan postupak u uvjetima serijske proizvodnje kompaktnih termometara. Za potrebe naknadne rekalibracije odnosnog servisa dovoljan je postupak autokalibracije (bez vanjskog standardnog termometra) primjenom mokre kupke na temperaturi od 0,1°C (mješavina leda i vode).

Abstract - This paper shows how to classify the medical ultrasound images by using artificial intelligence with experimental software with MATLAB. The main goal is a classification of ROI substantia nigra in midbrain. This classification of the images is useful to detection Parkinson´s disease. This work is based on image processing and is realized with the help of artificial intelligence which has been experimentally simulated in MATLAB software environment. This method is well applicable with Neural Network Toolbox in MATLAB.

I. INTRODUCTION

Modern medical imaging methods helps to diagnoses in different branches in medicine. This paper is focused on processing of transcranial (TCS) ultrasound images. It is useful to potential Parkinson´s disease diagnosis. We developed a computer program in MATLAB to area measurement of substantia nigra which is described in next part. This application is based on image processing and neural network approach for artificial intelligence elements. The main goal of designed approach is to measure area of substantia nigra for all levels of echogenicity. The purpose of neural network approach is a positioning of needed ROI in substantia to area computing. Input files are in DICOM format, see chapter II.

A. Role of SN and Parkinson´s disease

The following part brings some information about role of substantia nigra (SN) in brain stem and Parkinson´s disease diagnosis and features. Parkinson's disease (PD) is caused by the death of dopaminergic neurons. It is a degenerative disease of basal ganglias inside the brain, described by James Parkinson in 19th century. The main symptoms of PD include muscle rigidity, tremors and changes in speech and gait, bradykinesia, sleep disorders and more.[1] This type of tremor is typical for PD. It is a chronicle disease and initial features sometimes are insignificant for diagnosis.[2]

Substantia nigra (SN; in English "black substance") is a brain structure which is located in the mesencephalon (midbrain) that plays an important role in reward, addiction, and movement. SN produces important dopamine for correct function of CNS (Central nervous system). The CNS is one of the two major divisions of the nervous system. SN is our ROI for processing and searching pathological defects to Parkinson ´s disease diagnosis. SN is very important part of midbrain and is well recognizable by ultrasound. Ultrasound imaging in neurology is also important for detection of another diagnoses. Detailed information about substantia nigra and echogenicity are available in [1], [2] and [3]. The following figure shows the position of basal ganglias where is located SN.

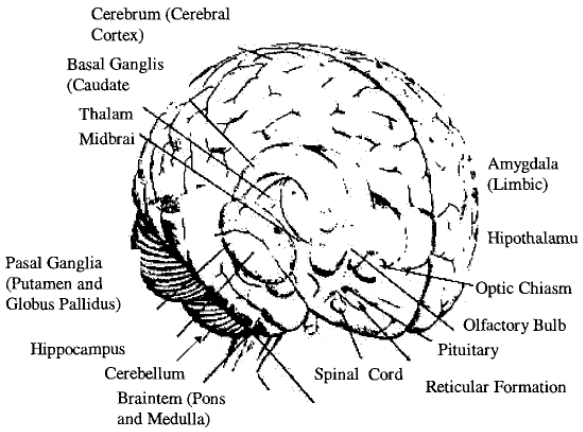

Fig. 1 – Position of basal ganglias where is situated SN

II. THE GOAL OF PROCESSING

In this section we will describe the goal of this processing and used methods. The following flow-chart shows how to work our designed method.

[1] http://www.mdvu.org/library/disease/pd/
[2] http://www2.parkinson.org/Document.Doc?id=618

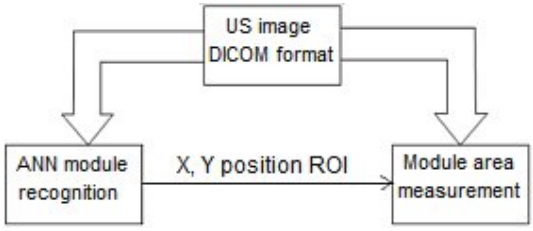

Fig. 2 – Flow-chart of whole processing

In the following parts we will describe in details each module of processing.

A. *Input and pre-processing*

As input files we have a set of TCS images in native DICOM (Digital Imaging and Communications in Medicine) [3] format, which is worldwide standard for medical imaging and each image contains metadata about image acquisition, used modality, bit depth and more. MATLAB with Image Processing Toolbox was selected because provides strong tools for image processing and also supports DICOM files.

We used ultrasound images. Generally we use diagnostic ultrasound for soft tissues. General benefits for ultrasound in neurology are:

- no radiation; exposition can be repeated and correlated - repeatability for examiners
- US is well applicable for soft tissues (brain stem density is 34.7 HU)[4]
- B-mode scanning is advisable in form brightness differentation to select ROI SN
  applicable for small areas such as SN

The following figure shows an input TCS image with highlighted SN area 50x50 mm loaded into MATLAB Figure.

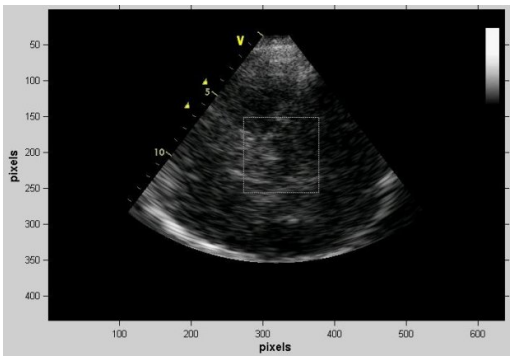

Fig. 3 – Input TCS image with position of ROI window

For the main processing we will used these windows 50x50 mm measured from native US axis.

[3] http://www.rsna.org/Technology/DICOM/index.cfm

[4] http://www.fpnotebook.com/Rad/CT/HnsfldUnt.htm

For whole processing we need all input images in grayscale, therefore R=G=B. If input image is in 24-bit depth (RGB), rgb2gray function converts this input by the following formula into grayscale image:

$$I = 0{,}299 \times R + 0{,}587 \times G + 0{,}114 \times B. \quad (1)$$

Thus, each pixel p_i in image has an intensity value from range $\langle 0; 255 \rangle$, it is a real matrix with these matrix elements. It is necessary for area measuring which is

based on monitoring of decreasing area for all intensities, thus echogenicity from range $\langle 0; 255 \rangle$ and relative. It is main goal of this processing to classify PD and non-PD cases, we search regions inside SN which can be critical to PD diagnosis.

B. *Main processing with ANN*

The main processing is based on artificial neural network (ANN) approach and measurement of area inside ROI SN which has been described in previous part. The image recognition is well applicable problem for artificial neural network (ANN) using. The idea of ANN is motivated by biological neural networks in brain. It is very interesting trend not only for image processing, ANN are used for prediction, matching, clustering, etc. The basic element of ANN is artificial neuron also called as processing element (PE). These neurons are connected to network. We will not describe ANN theory; it is available in [7], [10] and [13].

Firstly, we can divide whole processing:

- ANN module
- area measurement

In the next parts we will describe both of these parts, ANN more detailed.

For this processing we assume that input images were cut to 50x50 mm ROI with SN (Fig. 3). This dimension of window with ROI has been appointed by neurologist, for details see (2) where this operation was presented.

We require an elliptical ROI with initial area $A = 50$ mm^2 with 60° angle, which is applicable for this goal. Thus, we need the ellipse how shows the following figure.

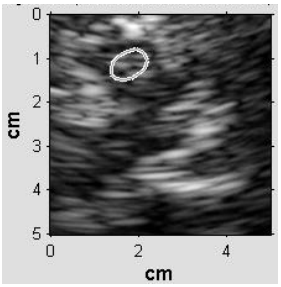

Fig. 4 – An example of applicable elliptical ROI

In this part we need to locale this ellipse inside SN in appropriate position, see example on Fig. 4. The aim of our problem is to applicably locate this ellipse inside SN with ANN.

1) *ANN module recognition*

Now we will discuss an ANN module to described problem of position elliptical ROI. The following figure shows the block diagram of ANN processing.

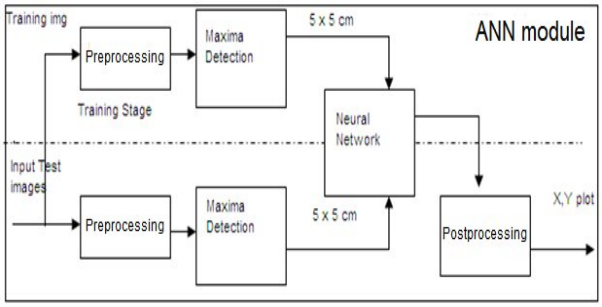

Fig. 5 – ANN processing

Preprocessing part indicates cut images 50×50 mm. Maxima detection denotes the recognizing of light regions inside ROI for lesion detection and ellipse will be a training sample, see Fig. 2. Simply we can describe used ANN:

- multilayer ANN with supervised learning
- patternnet ANN in MATLAB
- learning with backpropagation (EBP) algorithm[5]
- MSE error for checking

In MATLAB we create this MLP topology with patternnet function with inputs and targets

```
patternnet(hiddenSizes,trainFcn)
```

with parameters of number of hidden layer and training function. In our case `hiddenSizes`=3 and `trainFcn` is `traingdx`[6] with momentum and adaptive learning rate backpropagation. This function is one of used modified EBP algorithm for optimal MSE (better convergent to global minimum).

Training set S for supervised learning is given by inputs and desired response (targets).

$$S=\{(I_1, D_1), (I_2, D_2),\ldots, (I_n, D_n)\} \tag{2}$$

In our case as input are vectors with optimal position of ellipses for different input images, The desired responses are given as positions of correct coordinates for ellipse. The goal of ANN module is a learning of position for different images which is based on correct SN position in input image (Fig. 3). Designed ANN is 3-layer MLP where hidden layer computes the positions. As output we get the correct ellipse to consecutive area measurement inside ROI. Activation function for this case is used logical sigmoid expressed by:

$$f(x) = \frac{1}{1+e^{-\lambda x}}, \tag{3}$$

where λ is gain of sigmoid $0 \le \lambda \le 1$, standardly λ=1.

ANN compares after each epoch of leasing an error which is define as difference between targets and output from network. We can stop learn if this error is minimal. We will use MSE (Minimal Square Error), usually used for this model. The MSE is expressed as sum of partial differences between real results and desired response. Formally we can express

$$MSE = \frac{1}{N}\sum_{j=1}^{N}(D_i - I_i)^2 \tag{4}$$

Total error is defined by summation of partial errors for each training sample. Partial error for j-th training sample is defined as the difference $D_j - I_j$. This error is computed for each sample from *S*. The goal of ANN training is to minimize MSE. It is iterative process based on gradient method and we need to reach a global minimum of this error. MSE is graphically interpreted as learning curve. MSE < 0.01 (we set this threshold) is reached after 100 epochs of learning.

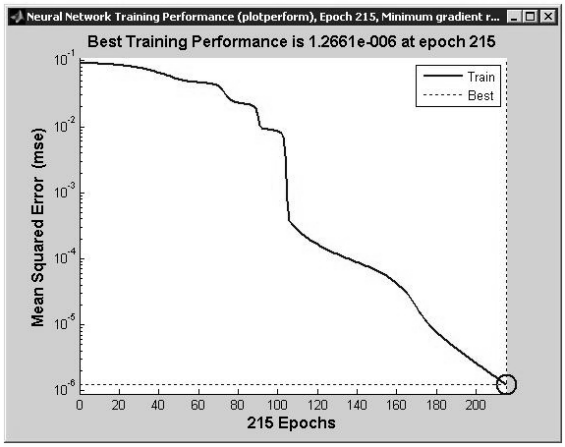

Fig. 6 – MSE error decreases with epochs

The learning is based on comparison of *x*, *y* coordinates of located ellipse with input samples. Output of ANN is 2-D vector of *x*, *y* coordinates which were acquired by training. User can set a new coordinates as

[5] http://www.learnartificialneuralnetworks.com/backpropagation.html

[6] http://www.mathworks.com/help/toolbox/nnet/ref/traingdx.html

applicable input followed by re-train of ANN with new coordinates. These coordinates ANN inserts as a new training sample, thus we have more correct samples. Furthermore, we observe descending tendency of MSE (Fig. 5). We set the threshold value for *MSE*=0.01, thus

if $T_{MSE} \leq 0.01$ ***then*** stop_learning ***else*** next_epoch.

Practical testing of this method showed that designed ANN is useful for positioning of ellipse in correct position in ROI window. Accuracy of this method is approximately 70% for 50 tested images. Re-training allows reach higher accuracy for manually set of coordinates and more images as input position. GUI of designed application is presented below. It was implemented with GUIDE in MATLAB.

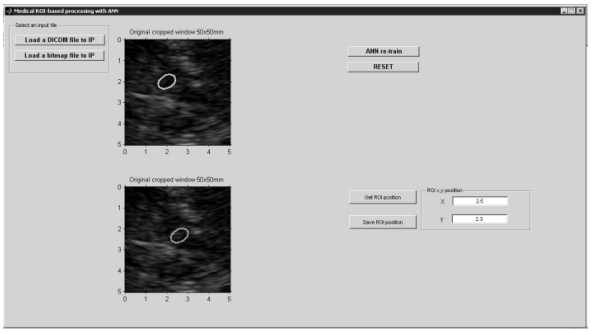

Fig. 7 – GUI of designed application

We can see output position ellipse and re-trained position from new coordinates.

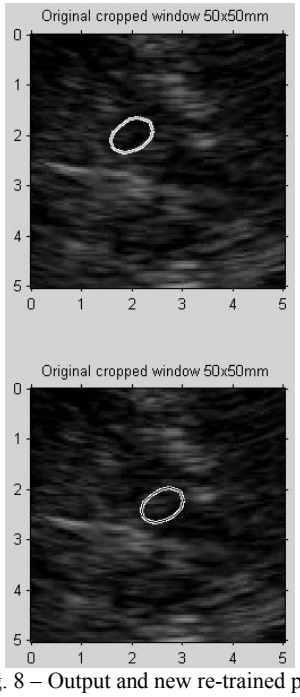

Fig. 8 – Output and new re-trained position

If we have more examples, we should reach higher accuracy, because ANN will be better trained for more input samples. Application also provides get and set coordinates for re-training.

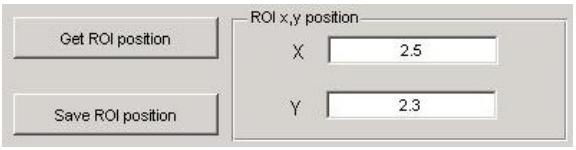

Fig. 9 – Get and set coordinates X, Y for training samples

2) Module area measurement

After this processing with ANN module for correct positioning of ROI inside SN, we need to compute the area of lesions (regions) for all intensities as we described in Chapter I. The result of this module is decreasing area depend on level of echogenicity (intensity) to distinction of PD and non-PD cases, it is based on binary thresholding and using masks as ROI objects. For details about processing and statistics, see [2] and [3]. Details about reproducibility for PD diagnosis in [14]. The following figure shows the result of measurement of area. More about used statistical characteristics in medicine is available in [8].

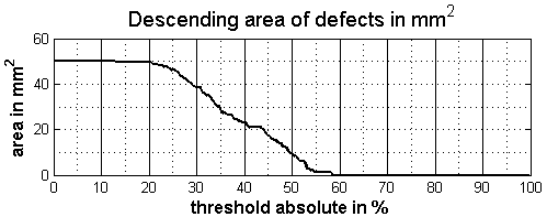

Fig. 5 – Measurement module and result of measuring

III. CONCLUSION

The goal of presented method is to show the image processing of ultrasound images with approach of ANN. Method is based on supervised learning of MLP and positioning of elliptical ROI inside examined SN in midbrain. Precise positioning helps to automatic recognition of ROI for different images. We detect that method is useful with relative good results, but results may be better with accuracy with more training samples and more images. Processing with MATLAB is effective because MATLAB provides wide range of tools for image processing and neural networks.

Designed ANN MLP has been tested with different settings such the training algorithm, number of hidden layers, etc. Training with momentum and sigmoid gain adaptation were found as useful for this case. MSE < 0.01 were reached after approximately 90 epochs of training (Fig. 6). User can manually set coordinates and add it to new training sample for re-train of ANN for better accuracy for a priori unknown images. Measurement module provides final measuring of area inside ROI SN to distinction PD and non-PD cases.

The future work will base on better accuracy of ANN to automatic positioning. It will be tested on larger

dataset than 100 images and will be examined other ANN topologies with different learning approach.

ACKNOWLEDGMENT

We would like to thank to Fakultní nemocnice v Ostravě (Czech Republic) and Klinik für Neurologie und Poliklinik in Rostock (Germany) to supplying input TCS DICOM images to processing.

Abstract - The paper describes the first version of the digital map detection and extraction mechanism. This approach is targeted to be applied in content-based image retrieval systems. The algorithm is based on a multilayer perceptron classifier, used to separate two kinds of objects: maps and non-maps. The classifier accepts image histograms, computed for each colour layer as an input. We show that these histograms are characteristic features of the map images compared to other images. The proposed algorithm is able to detect maps that constitute a part of larger images. Due to proposed optimization techniques the algorithm is fast and has low memory requirements. We also outline potential improvements and future research directions in this area.

I. Introduction

Humans use images from ancient times. An image is the most easy and informative means of perception of the world. The natural development of human mind has led to creation of complex images, depicting not only visible objects, but also imaginary ones such as maps, charts, diagrams etc. Today one can find images everywhere, their number is huge.

Nowadays, due to the development of computer and internet technologies, the task of content based image retrieval (CBIR) is quite common [1]. This task is common in such activities as advertisement creation, articles preparation and copyright protection since many images are objects of intellectual property. With ever-increasing quantity of existing images, the problem of image retrieval becomes more challenging.

Moreover, the area of content-based image retrieval attracts considerable research interest as such technologies are demanded in many professions**.** Historians search ancient cities plans, engineers look for technical diagrams, and journalists trace images of celebrities and politicians.

The aim of this paper is to suggest one of possible solutions to the following specific task: within an arbitrary set of images to find those that contain geographical maps.

We proceed as follows: Section II and III outline the main idea of this method that is to identify the right kind of image features for a standard set. Section IV describes neural network training strategy based on negative practice. The chosen arbitration mechanism is given in section V. The results are described in sections VI. Section VII concludes and outlines future research directions.

II. Map Detection Mechanism

The proposed map detection mechanism (see Fig.1) is similar to the face detection approach proposed by Rowley et al in [2]. Every input image is scaled to form an input image pyramid. Each image in the pyramid is then processed with a fixed size sliding window, which is passed as an input to the map classifier. Online maps services (e.g. maps.google.com) compose a map in browser from a set of tiles each having size of 256×256 pixels. In documents and images map objects usually consists of several tiles. Therefore, to increase probability for sliding window to be placed on a map inside the document, images are scanned with 150×150 window shifting by 30 pixels in both directions. Image pyramid contains 1-3 layers depending on the initial image size.

All sub-windows in the pyramid are divided into maps and non-maps by neural-network classifier. The arbitration mechanism is used to take the final decision based on the information collected in the previous steps. Each step of the developed algorithm is described in the following sections.

III. Map Features

A man can easily distinguish a map from a general image, with the help of the semantic information which is present on a map. Such semantics includes roads, fields, forests, human settlements and other objects, that depend on the type of the map. The great number and the variety of such objects on maps make it impossible to use that knowledge in order to recognize an image as a map. Thus, the map can be characterized as an image containing a relatively small number of regions separated by clear boundaries, with a predominance of one colour in each area.

The first step of CBIR systems is feature extraction stage. A feature represents either a global or local visual property of a particular image. Global properties are obtained from the entire image, while local ones from a small group of pixels. The most commonly used features include those reflecting colour, texture, shape, and salient points in an image [3].

The average color can be used as a map feature. Consider an (R, G, B) color space. Let p_{ij} be a pixel on an image, where $i = \overline{1, \mathrm{n}}$ and $j = \overline{1, \mathrm{m}}$.

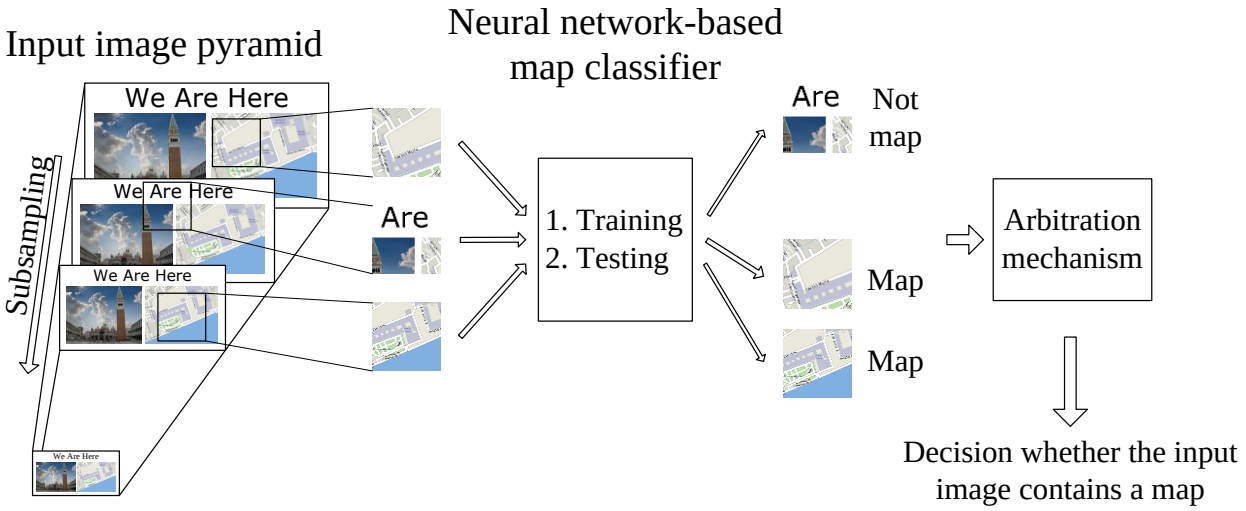

Figure 1. Neural network-based digital map extraction mechanism scheme

The amount of red, green and blue is reflected in the vector $p_{ij} = (r_{ij}, g_{ij}, b_{ij})$, and then an average color can be computed as following:

$$(r, g, b) = \frac{\sum r_{ij}}{mn}, \frac{\sum g_{ij}}{mn}, \frac{\sum b_{ij}}{mn}. \quad (1)$$

Thereby each image is assigned a vector of three elements. Let S be an arbitrary part of an image. If the color in S area changes, it will lead to the following change in the mean color (r', g', b'):

$$(r', g', b') = r + \frac{\sum_S \Delta r_{ij}}{mn}, g + \frac{\sum_S \Delta g_{ij}}{mn}, b + \frac{\sum_S \Delta b_{ij}}{mn}, \quad (2)$$

where Δr_{ij}, Δg_{ij}, and Δb_{ij} represent changes in each colour. It is easily seen that the change in the mean color depends on the number of pixels inside S, that were changed, and the size of that change. Since neighbouring map fragments have almost the same background colour and symbols, the value of the average colour of the image will vary within a small range, which can be defined experimentally. That is, if the picture is a map, then its average colour should satisfy:

$$(r_{min} \le r \le r_{max}, g_{min} \le g \le g_{max}, b_{min}, \le b \le b_{max}) \quad (3)$$

where the values of $\Delta r = r_{max} - r_{min}$, $\Delta g = g_{max} - g_{min}$, $\Delta b = b_{max} - b_{min}$ are rather small. However, this estimate is rather rough and there can be many non-map images that can satisfy this condition.

Histograms are more appropriate map characteristics. They can be treated as a generalization of the average color. Let $N(k, C)$ be an amount of pixels on the image, with color $C \in R, G, B$ equal to $k = \overline{0,255}$. Now we can form vector with $3 \cdot 256 = 768$ elements, containing the quantity of the red, green and blue in the image. Apparently that this histogram contains information about average color:

$$(r, g, b) = \left[\frac{\sum_{k=0}^{255} kN(k, R)}{mn}\right], \left[\frac{\sum_{k=0}^{255} kN(k, G)}{mn}\right], \left[\frac{\sum_{k=0}^{255} kN(k, B)}{mn}\right] \quad (4)$$

However, the histogram contains more information, than average colour. We use normalized histograms, where each bin is divided by the maximum bin value, to make all histogram values fit the interval [0, 1].

Fig. 2 shows histograms computed from different images. Two upper rows of the figure show histograms computed from maps belonging to different vendors. These two rows show robustness of histograms across different locations and vendors. The last two rows show histograms computed from different general images. It is easy to see that histograms differ from maps histograms which contain expressive pikes. This is due to the fact that general map can be characterized as an image with prevailing amount of background with comparatively low variety of colour, having no colour gradients. This is very different from general images, which contain significantly greater color range (Fig. 2). The histogram creation method is robust enough to rotation and size of the scanning window (Fig. 3) shows six sub-windows obtained from the bigger image. It is easy to see that the general shapes of the histograms quite resemble, all pikes are placing on the same position on axes. This is yet evidence that histograms are suitable for neural-network map recognition.

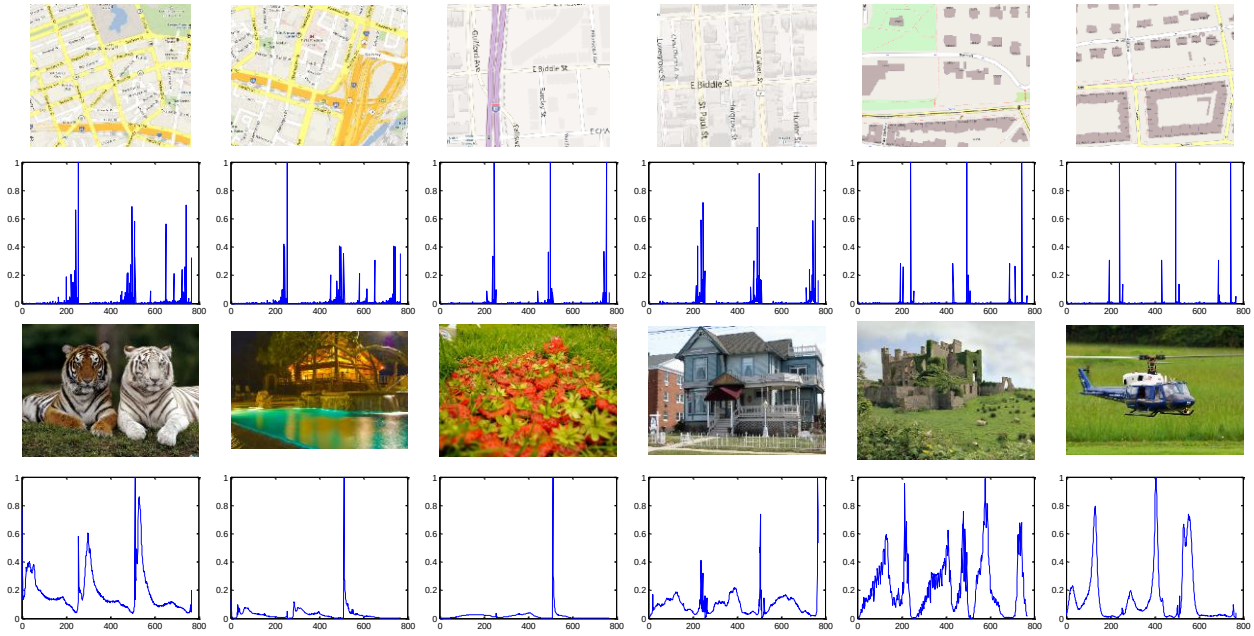

Figure 2. Comparison of histogram computed from maps and regular images

The algorithm of histogram computation is quite effective. Initially image pyramid is calculated for each image, the results of all levels of the pyramid are placed in one collection. When cutting out is done, no image data is copied. Instead, pointers to the first element of the cropping region, as well as the size of the fragment are stored. This approach reduces the amount of necessary memory up to 12MB.

IV. NEURAL NETWORK TRAINING

In order to improve the accuracy of the neural network one should carefully prepare training examples. This means to include in training set typical examples for each class [3][4]. In case of map detection we have only two classes of objects on images: maps and non-maps.

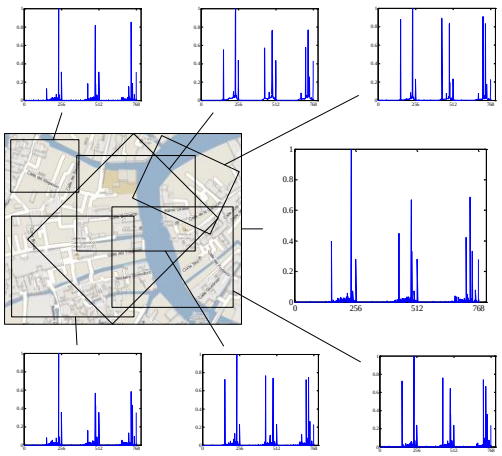

Figure 3. Histogram robustness to scale, place and rotation. The right diagram in the middle row shows the whole images histogram

It is quite easy to define a map image, while the definition of a typical non-map is not trivial. Rowley et al [2] used partially trained neural network to determine negative examples for face detection. In the first iteration of the training process network is trained with the use of manually collected positive examples (face images) and random set of images not containing faces. Next, great number of images without faces is passed through the network, and those that are recognized as faces are used as negative examples in the second iteration of training process.

We follow this approach in selection of negative examples. However, there is one subtlety. Some images have histograms similar to maps histograms. Several examples of such images are given in the Fig. 4.

If we remind a map definition given earlier, we will see that these images fit given definition, because they have regions filled with a certain colour and have clear borders between these regions.

One should ensure that a share of such images in whole set of negative examples is rather small. Otherwise, this can affect the ability of neural network to recognize true positive images.

Figure 4. Examples of images that have histograms similar to map histograms

We used the same positive training set for both training iterations. Negative training set differs across iterations. We have collected more than one million various images from the internet, as well as manually chosen images, so that their quantity is equal to the quantity of positive examples. We use Vapnik-Chervonekis measure es-

timate to choose neural network topology [6][7]. As a training algorithm we use back propagation.

After training, each image from initial one million size set is passed through neural network and the images marked as positive are used as negative example set for the second stage of training process.

The total quantity of examples used in training is 544917 including negatives and positives in approximately equal proportions.

V. ARBITRATION MECHANISM

As discussed in the previous section, images may contain parts with histograms similar to maps. This can lead to increased quantity of false positive hits. Arbitration mechanism is intended to reduce the number of such false detections.

At this stage of development, the system uses a simple arbitration mechanism based on a parameter computed as a sum of the square of the areas recognised as map divided by the total image square in pixels. If this parameter is greater than some threshold Θ the image is marked the one containing a map.

VI. RESULTS

We have collected on the Internet a huge number of various images containing nature, animals, faces, places of interest, chart and diagrams, buildings, textures, cars, posters etc. The set of negatives consists of 73 451 images. To test the ability of the system to recognize positive images we used 5308 maps, that were not present in training set. The number of false positives is 4573 images representing 6.2 % of the total quantity of negatives. The number of false negatives is 43 that is 0.8%. That suggests that the probability of missing a map by the system is very low.

VII. CONCLUSION AND FURTHER RESEARCHES

The described system was implemented on C++ programming language with the use of Open Source Computer Vision Library.

The system scans image on different scales, allowing detecting map of various size. Histogram's robustness to size, rotation, and location makes the system insensitive to initial image transformations, which is essential when working with scanned images. Moreover, computation of histograms take little time, which along with memory consumption optimizations yields in fast processing speed.

There are several future research directions that we think are promising. Maps usually contain text, while other images don't. The researches in the field of text extraction [8] can speed up the process of selecting map-like regions on the image.

The proposed system can be extended to coarse-to-fine approach. The neural network-based filter can be used as coarse detector, allowing most of map-like images pass through it. The accurate selection can be performed by extracting some scale invariant features [9] from map-like regions and comparing them with known map features.

At this point stage the system uses a simple and efficient arbitration mechanism. The results show a fairly low error rate of this approach. However, the use of a more complex approach, based on the number of neighbours of the area, recognized as a map will reduce the false positive rate.

E-mail:slobodan.ribaric@fer.hr

***Abstract*—In this paper a personal recognition system based on the Gabor features of colour palmprint images is described. The features are extracted by a bank of Gabor filters from the palmprint region represented by three primary spectral components: R, G and B. The system, based on fusion at the matching-score level, is used to improve the recognition accuracy. The recognition results of the system are compared with the results of a grey-level-based palmprint-recognition system for the same database.**

I. Introduction

A Gabor-based approach is widely used for the feature extraction in biometric applications, such as iris [1], face [2], fingerprint [3] and palmprint recognition [4], [5], [6]. Zhang et al. [5] describe an online palmprint-recognition system that is based on a 2D Gabor phase-encoding scheme for palmprint-feature extraction. By applying the tuning process to a training set consisting of grey-level palmprint images (384 × 284, 75 dpi), the optimal three parameters (θ, u, σ) of a 35×35 Gabor filter were selected. The verification test was made on grey-level palmprint images from 193 people, with 20 images of the left and right palms. The results of the verification showed a 98% genuine acceptance rate and a 0.04% false acceptance rate for a threshold value of 0.3425. The EER was 0.6%. The identification tests with three registration databases for $N = 50, 100$ and 200 users were performed. The best recognition rate was achieved for a 1-to-50 identification, where the system operated at about a 99.5% genuine acceptance rate; for a 1-to-100 identification, at a 0.1% false acceptance rate and a 97% genuine acceptance rate; and for a 1-to-200 identification, at a 0.1% false acceptance rate and a 95% genuine acceptance rate.

In [6] a bank of twelve Gabor filters was tested for verification on a database consisting of 4647 palmprint images (about 40 images from 120 people from the PolyU database [7]). The regions of interest, cropped from grey-level palmar images, were represented by two resolutions, i.e., 128×128 and 64×64 pixels. The test showed that three Gabor filters, size 35 x 35, with parameters $u = 0.0916, \sigma = 5.6179, \theta = 0, \pi/4$ and $3\pi/4$ achieved the best results for the region of interest (ROI) with size 128×128: for a false acceptance rate smaller than 10^{-2}, the false rejection rates were 5.6% (for $\theta = 0$), 2.9% (for $\theta = \pi/4$) and 6.4% (for $\theta = 3\pi/4$). A verification test for ROI of 64×64 showed that the best filter parameters were: size 17×17, $\theta = \pi/4$, $u = 0.1833$, and $\sigma = 1.8090$. The result was a 2.5% false rejection rate at a smaller than 10^{-2} false acceptance rate.

Pan and Ruan proposed a novel approach to Gabor feature-based palmprint recognition, which combines a Gabor filter bank and an improved two-dimensional PCA ((2D)^{2}PCA) for dimensionality reduction [4]. The (2D)^{2}PCA reduces the dimension of the feature space in both row and column directions resulting in fewer coefficients for feature matching. The main steps involved in the system are:

1) The Gabor features of different scales and orientations are extracted (there were 30 different Gabor filters);
2) The (2D)^{2}PCA is then applied for the dimensionality reduction of the feature space in both row and column directions;
3) The Euclidian distance is used for 1-NN classification.

The database consists of 800 left-hand images from 80 people. A Gabor feature-based (2D)^{2}PCA gives the best recognition rate of 99% when five training samples per class were used. Also, the genuine acceptance rate (GAR) is higher than the Gabor feature-based 2DPCA at the same false acceptance rate (FAR).

II. Description of the System

The proposed system (Fig. 1) consists of six parts: acquisition unit, pre-processing, feature extraction, thresholding, matching and decision based on fusion. The colour RGB images of the right hand are scanned at 180 dpi / 256 grey levels in the acquisition unit. In the pre-processing module the following steps are performed: conversion to grey-scale image, binarization of the grey-scale image with thresholding, border following of the contour of the hand, detection of the stable points, rotation of the hand in the normal position and finally, a determination of the region of interest (ROI). After that, the ROIs are cropped separately from the colour-palmprint image R, G, B and resized to 64×64 pixels. The primary spectral components R, G and B of each ROI are processed independently. The feature extraction is based on a 2D Gabor filter. The binarization of the features is made with a zero threshold. The palmprint matching is based on a generalised

Hamming distance. Fusion at the matching-score levels for all three primary spectral components is made.

A block-scheme of the personal recognition system based on the Gabor features for colour ROIs of palmprint images is shown in Fig. 1.

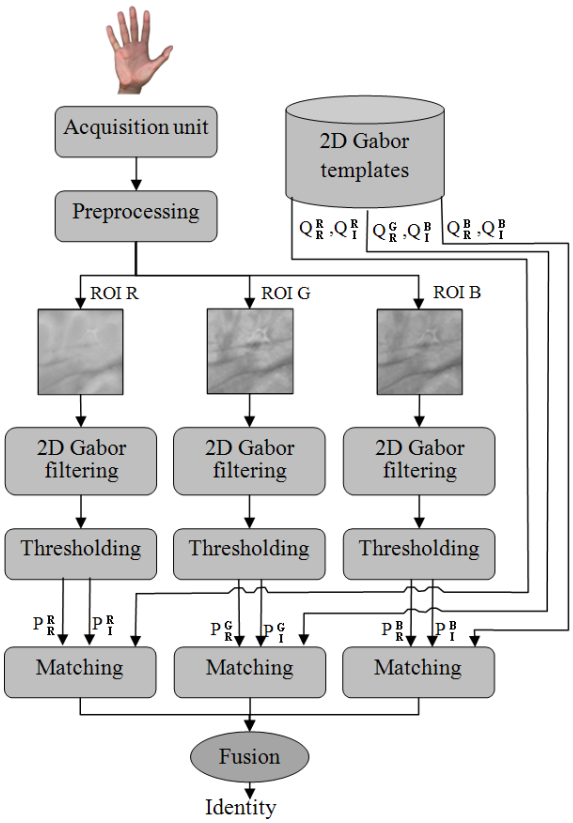

Fig. 1: Architecture of our colour-based palmprint-recognition system based on 2D Gabor filtering

A. Acquisition

Colour RGB images of the right hand are scanned at 180 dots per inch (dpi) / 256 levels. The user puts his/her hand on the scanner surface with the fingers spread naturally; there are no pegs or any other hand-position constrainers. An example of an image acquired with this method is shown in Fig. 2.

Fig. 2: Acquired palmprint image

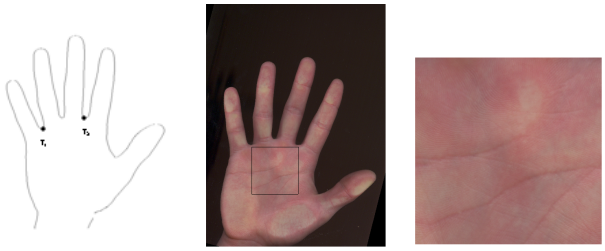
B. Pre-processing

In the first step of pre-processing a palmprint image is extracted from the background. For that we use a grey-scale image whose values of image intensities are obtained as

$$I = \frac{r+g+b}{3}$$

where r, g and b are the R, G and B primary spectral values. The obtained image has grey intensities set in the interval from 0 to 255 (8 bits). Because of the good impose of the lightning conditions during the image acquisition in the segmentation of the grey-scale image, simple global thresholding is used. With the use of the border-following algorithm [8] in the binary image, the contour of the hand is obtained. On the contour of the hand the stable points are searched for, which will then be used as reference points for determining the region of interest (ROI). Previous research [5], [9] has determined determined that these are the points (T_1 and T_2) that lie on the tangent of the gaps between the ring finger and the little finger and between the index finger and the middle finger (see Fig. 3(a)). The connecting of the points T_1 and T_2 will be used for determining the image ROI and for the geometric normalization of the palmprint image. The geometric normalization is carried out by rotating the palmprint image so that a line connecting T_1 and T_2 has the angle 0° with the x coordinate axis of the image. The coordinates of the ROI that are obtained on the grey-scale image are used for cropping the ROI on primary spectral images (R, G, B) to acquire ROIs for the R, G and B image. The position of the ROI is defined by a $d \times d$ square that is moved $d/10$ pixels below the line that connects the stable points T_1 and T_2 (Fig. 3(b)). In such a way the determined ROI is cropped from the corresponding colour images of the palm (R, G and B). After that, all the regions (in images R, G and B) are resized to 64×64 pixels with the use of bicubic interpolation (Fig. 3(c)).

The above-described procedure is used for modeling two experimental databases that are composed of 64×64 pixel ROIs. The first database Database B_1 contains 648 ROIs from 81 people (eight ROIs per person). The second database Database B_2 contains 787 ROIs of the right palm of 80 people (about 10 ROIs per person).



(a) (b) (c)

Fig. 3: (a) Stable points on the border, (b) ROI cropping, (c) ROI

C. Feature extraction based on a 2D-Gabor filter

Palmprint authentication is usually based on texture analysis. Gabor filters and Gabor filter banks are widely applied for feature extraction from texture images [5], [6]. A circular Gabor filter, in general, has the following form:

$$G(x, y, \theta, u, \sigma) = \frac{1}{2\pi\sigma^2} e^{-\frac{x^2+y^2}{2\sigma^2}} e^{2\pi i(ux\cos\theta + uy\sin\theta)}$$

where $i = \sqrt{-1}$; u is the frequency of the sinusoidal wave; θ controls the orientation of the function and σ is the standard deviation of the Gaussian envelope. The σ and u are dependent on the size of the filter with $\sigma \cdot u = const$. To make it more robust against brightness, a discrete Gabor filter, $G[x, y, \theta, u, \sigma]$, is produced and the filter values are grouped around zero, so that the average filter value is 0, while the obtained filter is called the zero DC Gabor filter $\tilde{G}$

$$\tilde{G}[x, y, \theta, u, \sigma] = G[x, y, \theta, u, \sigma] - \frac{\sum_{i=-n}^{n}\sum_{j=-n}^{n} G[i,j,\theta,u,\sigma]}{(2n+1)^2},$$

where $2n + 1$ is the filter size.

Convolution in the spatial domain of each primary spectral ROI with the selected Gabor filter $\tilde{G}$ is performed. For each primary colour ROI image the convolution gives the real part of the texture image and the imaginary part of the texture image.

The real and imaginary parts of the texture image are binarized using a zero threshold. The binary pixel value of the real part b_r or of the imaginary part b_i of the filtered image is obtained as follows:

$b_r = 1$, $Re[\tilde{G}[x, y, \theta, u, \sigma] * I] \geq 0$

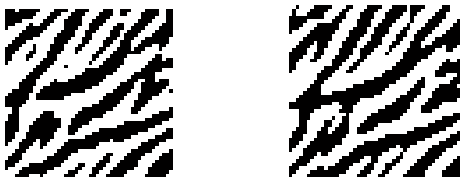
$b_r = 0$, $Re[\tilde{G}[x, y, \theta, u, \sigma] * I] < 0$

for the real part of the filtered texture image P_R, and

$b_i = 1$, $Im[\tilde{G}[x, y, \theta, u, \sigma] * I] \geq 0$

$b_i = 0$, $Im[\tilde{G}[x, y, \theta, u, \sigma] * I] < 0$

for the imaginary part of the filtered texture image P_I, where '$*$' denotes the 2D convolution in the spatial domain and $I \in \{I^R, I^G, I^B\}$ is the primary spectral ROI image. An example of the appearance of the real and imaginary textures obtained for a red colour ROI palmprint image is given in Fig. 4.



(a) (b)

Fig. 4: (a) Real part of the filtered texture image, P_R and (b) the imaginary part of the filtered texture image, P_I

D. Feature matching

Let $\{P_1, ..., P_n\}$ be the live templates that will be tested and $\{Q_1, ..., Q_m\}$ be the templates from the database, where n is the number of live templates and m is the number of templates in the database, $n > m$. For the matching the generalised Hamming distance is utilized. It is carried out from the normal Hamming distance, which has the form

$$D_0(P, Q) = \frac{1}{2N^2} \cdot \sum_{i=1}^{N}\sum_{j=1}^{N}(P_R(i,j) \otimes Q_R(i,j) + P_I(i,j) \otimes Q_I(i,j))$$

where N is the size of the filtered image, P_R and P_I are the real part and the imaginary part of the live template P, and Q_R and Q_I are the real part and the imaginary part of the database template Q, respectively, and $\otimes$ is the exclusive OR operator. In order to provide translation invariance matching in both directions, the generalised Hamming distance is used [6]

$$D_{\min}(P, Q) = \min_{|s|<S, |t|<T} \frac{1}{2H(s)H(t)} \cdot \sum_{i=\max(1,1+s)}^{\min(N,N+s)} \sum_{j=\max(1,1+t)}^{\min(N,N+t)} (P_R(i+s, j+t) \otimes Q_R(i,j) + P_I(i+s, j+t) \otimes Q_I(i,j))$$

where the shifting parameter in the horizontal direction is $s <| S |$, and in the vertical direction it is $t <| T |$, where $S = 6$ and $T = 6$ are the parameters that control the range of the horizontal and vertical translations of a feature in the matching process, respectively. $H(s)$ and $H(t)$ are defined as

$$H(q) = min(N, N + q) - max(1, 1 + q) + 1$$

where q is s or t.

E. Fusion at the matching-score level

Fusion is based on the total similarity measure (TSM) that is obtained as a weighted sum of the similarity measures S_R, S_G and S_B:

$$TSM(P_k, Q_l) = w_R \cdot S_R + w_G \cdot S_G + w_B \cdot S_B$$

where $S_i = e^{-D^i_{min}}$, $i \in \{R, G, B\}$, D^i_{min} is the minimum generalised Hamming distance for the corresponding primary spectral components, the live template is P_k, the current template from the database is Q_l, and w_R, w_G, w_B are the weights of the corresponding primary spectral ROI images. The weights are obtained on the basis of the first two experiments (see Experiment 1, and Experiment 2). The parameters w_R, w_G, w_B for the R, G and B primary spectral components are empirically calculated:

$$w_i = \frac{\mu_i}{\mu_R + \mu_G + \mu_B}$$

where μ_i is the mean recognition rate in Experiment 2 for the best filter (filter no. 10; Table II) for i primary spectral components, $i \in \{R, G, B\}$. μ_R, μ_G, μ_B are the corresponding mean recognition rates for the same filter. The weights are found to

be $w_R = 0.33430$, $w_G = 0.33305$ and $w_B = 0.33265$, and $w_R + w_G + w_B = 1$. The classification rule is based on the maximum total similarity measure (TSM) by using the 1-NN rule.

III. Experiments and Results

In this section, four experiments are described. The first experiment evaluates the information content of the Gabor-based features of the primary spectral components R, G and B. The second experiment selects the best filter parameters for the recognition performed on the primary spectral components R, G and B. The third experiment checks if whether fusion at the matching-score level of the primary spectral components improves the recognition accuracy. Finally, we perform an open-set identification with fusion.

Two palmprint databases are utilized for the experiments. The first database, B_1, contains 648 palmprint images of 81 people. From each person 8 images of the right palm are taken. The second database, B_2, contains 787 palmprint images of 80 people (10 images of the right palm from 71 people, 9 images from 6 people, 8 images from 2 people, and 7 palmprint images from 1 person).

A. Experiment 1

In the first experiment, Filters 5-8 from Table I are used. They are chosen according to the Gabor filters used in [6]. From the database B_1 80 palmprint images of 10 people (8 images per person) are taken.

TABLE I. GABOR FILTER BANK

Filter no	Sizes	θ	u	σ
1	9×9	0	0.3666	1.4045
2	9×9	45	0.3666	1.4045
3	9×9	90	0.3666	1.4045
4	9×9	135	0.3666	1.4045
5	13×13	0	0.2444	2.1067
6	13×13	45	0.2444	2.1067
7	13×13	90	0.2444	2.1067
8	13×13	135	0.2444	2.1067
9	17×17	0	0.1833	2.8090
10	17×17	45	0.1833	2.8090
11	17×17	90	0.1833	2.8090
12	17×17	135	0.1833	2.8090

1) Experiment 1a: We want to show that the information content of each of the three primary spectral components of the same ROI image, even though they are correlated, is different. We determine the normal Hamming distances of the binary Gabor features of the primary spectral components R, G and B, taken from the same image ROIs of the same person for Filters 5-8. We take the minimum distance of these four filters. Experiment 1a is repeated for ten people from database B_1 where there were 8 images for each person.

Fig. 5 shows the mean and the standard deviation of the normal Hamming distances for each of ten people and for the pairs RG, RB and GB. From Fig. 5 we can see that the normal Hamming distances vary, and they are the smallest for the GB pair. We can conclude that there exists a difference in the information for different primary spectral components of the same image ROIs.

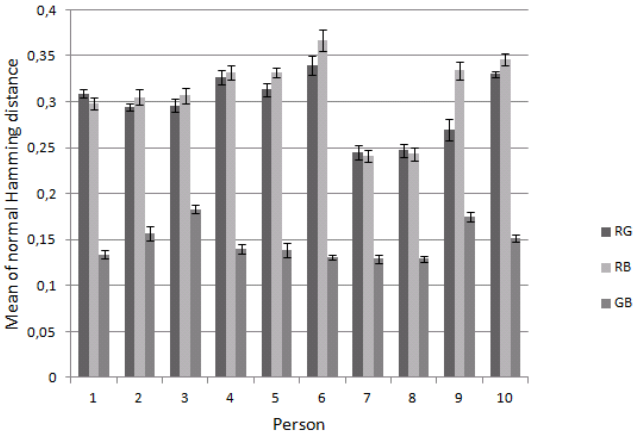


Fig. 5: Mean and standard deviation of the minimal normal Hamming distances that come from the same ROI images of the same person

In the following two experiments (1b, 1c) we want to show that the generalised Hamming distances of the image ROIs of the same person are smaller than the generalised Hamming distances of the image ROIs of different people.

2) Experiment 1b: We take 8 palmprint images from one person and compute the generalised Hamming distance for the binary Gabor features of different image ROIs of the same person. We have 28 combinations for RR, GG, BB, RG, RB, and GB. Experiment 1b was repeated for ten people from database B_1.

Fig. 6 shows the mean and the standard deviation of the generalised Hamming distances for six pairs of combinations.

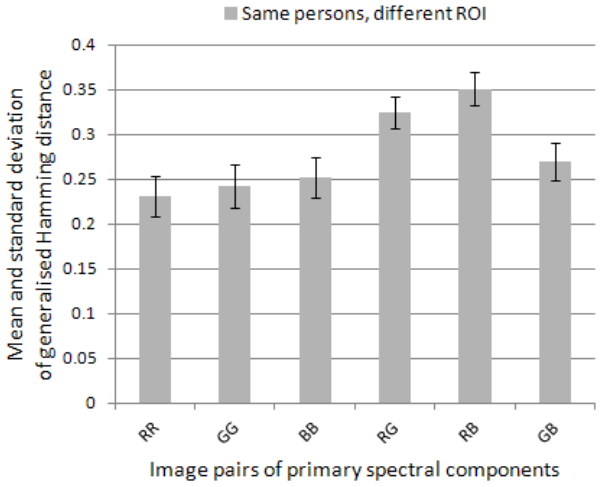

Fig. 6: Mean and standard deviation of the generalised Hamming distances that come from the different ROI images of the same person

3) Experiment 1c: We compute the generalised Hamming distances of the binary Gabor features of the image ROIs of

ten different people. We have 2880 image combinations for the RR, GG, BB, RG, RB and GB primary spectral components.

Fig. 7 shows the mean and the standard deviation of the generalised Hamming distances for six combinations of pairs. From Fig. 7 we can see that the generalised Hamming distances of the image ROIs from different people are greater than the generalised Hamming distances from Experiment 1a and Experiment 1b.

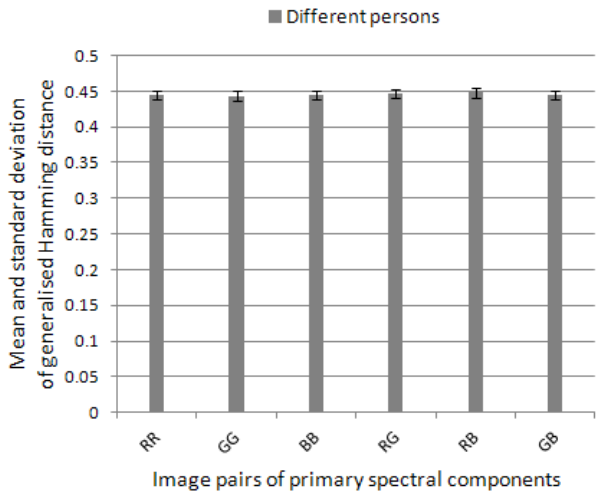

Fig. 7: Mean and standard deviation of the generalised Hamming distances that come from the ROI images of different people

B. Experiment 2

The experiment selects the best filter from a bank of Gabor filters for the R, G and B primary spectral component. The parameters of the bank of Gabor filters coincide with the parameters in [6]. They are displayed in Table I. The filter sizes are 9×9, 13×13 and 17×17. The orientations θ are $0, \pi/4, \pi/2, 3\pi/4$. After the best filter is found, it will be used in the last two experiments.

For the experiment the whole database B_1 is used: three palmprints are used as templates in the user database, and the remaining five are used for testing. The experiments are repeated ten times, and in each experiment three samples are randomly selected as the templates in the database. The classification of an unknown sample is based on the minimum generalised Hamming distance between the unknown template and the templates stored in the template database.

The results of the recognition are presented with the mean and the standard deviation for 10 experiments (Table II). From Table II it can be seen that the best recognition accuracy is 99.23±0.45 for the primary spectral component R, 98.86±0.63 for G and 98.74±0.78 for B, and this is achieved for Filter 10, size 17x17, with the parameters $\theta = \pi/4, u = 0.1833, \sigma = 2.8090$.

TABLE II MEAN PERCENTAGE AND STANDARD DEVIATION OF CORRECT CLASSIFICATION

Filter no	R	G	B
1	94.40 ± 2.04	94.37 ± 2.19	94.03 ± 1.83
2	97.24 ± 1.30	96.15 ± 1.34	95.58 ± 1.28
3	88.25 ± 2.14	90.25 ± 2.62	88.26 ± 2.77
4	88.37 ± 3.13	89.90 ± 3.13	89.24 ± 3.03
5	98.32 ± 0.91	97.63 ± 1.51	97.26 ± 1.18
6	99.16 ± 0.65	98.27 ± 1.14	98.32 ± 0.90
7	98.03 ± 1.21	96.30 ± 1.35	95.80 ± 2.34
8	96.69 ± 1.81	95.98 ± 2.15	95.53 ± 2.18
9	98.77 ± 0.72	97.85 ± 0.71	98.03 ± 0.78
10	99.23 ± 0.45	98.86 ± 0.63	98.74 ± 0.78
11	98.92 ± 0.63	97.73 ± 1.21	97.31 ± 1.18
12	98.12 ± 0.94	96.99 ± 1.18	96.79 ± 1.14

C. Experiment 3

The goal of this experiment is to see how fusion based on primary spectral components at the matching-score level affects the result of the recognition in accordance with the grey image for the best filter.

The experiment utilizes the whole database B_2: three palmprints of a person are used for the enrolment, and the remaining images are used for testing. The experiment is repeated ten times, and in each experiment three samples for the enrolment are randomly selected.

The recognition results of the colour palmprint image, the grey image and the fusion based on the primary spectral components are given with the mean and the standard deviation for ten experiments. The recognition accuracy for the R primary spectral component is 98.51 ± 0.37, for G it is 98.29 ± 0.43, for B it is 98.37 ± 0.54, and for grey it is 98.31 ± 0.52, and finally for the fusion based on primary spectral components the best recognition accuracy is achieved, i.e., 98.71 ± 0.37.

D. Experiment 4

This experiment will show how our personal identification system works with open-set identification. Fusion is based on the total similarity measure at the matching-score level of primary spectral component features obtained with the best filter.

From the B_2 database all 80 people are selected as genuine users, and from the B_1 database all 81 people are labelled as imposters. For 80 genuine users 3 out of about 10 palmprint images are used as templates for the extracting features to be stored in the biometric database and the other part called the test samples is used for testing the performance of the system. For 81 imposters, all 8 palmprint images are used for testing the performance of the system.

The detection rate (DR) and the false-alarm rate (FAR) as a function of the threshold for the open-set identification are evaluated for the following outcomes:

i) A live template of the user has the maximum TSM with respect to the database template(s), which corresponds to the same user, and this measure exceeds the threshold value. The user is correctly identified.

ii) A live template of the user has the maximum TSM with respect to the database template(s) and this value exceeds the

given threshold but these templates do not correspond to the correct user. The user is misclassified.
iii) A live template of the user has the maximum TSM with respect to the arbitrary database template, but this value measure does not exceed the threshold value. The user is incorrectly rejected as an imposter.
iv) A live template of the imposter has the maximum TSM with respect to the arbitrary database template and this measure exceeds the given threshold. In this case an imposter is incorrectly identified as a user.
v) A live template of the imposter has the maximum TSM with respect to an arbitrary database template and the measure does not exceed the threshold. An imposter is correctly rejected.

The DR and FAR depicted in Fig. 8 are evaluated as follows:

$$DR(T) = \frac{\text{number of templates for case i)}}{\text{the total number of templates of users}}$$

$$FAR(T) = \frac{\text{number of templates case ii) and iv)}}{\text{the total number of templates of users and imposters}}$$

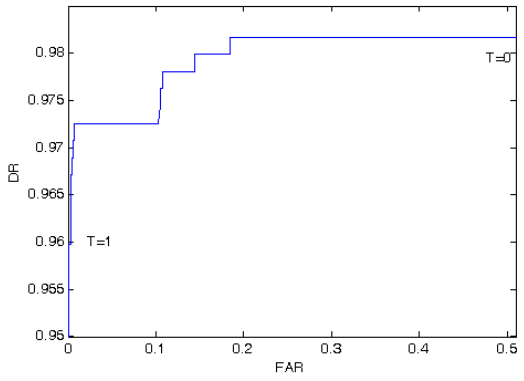

Fig. 8: Detection rate plotted against the False Alarm Rate

IV. Conclusion

We have developed a colour-based palmprint personal identification system. A pre-processing algorithm extracts the central area from a palmprint image size 64x64 for feature extraction. We use 2D Gabor phase coding to represent a palmprint image using its texture feature, and apply a generalised Hamming distance for the matching measurement. We achieve a recognition accuracy of 98.71 ± 0.37 for fusion of the colour palmprint images, while the best recognition accuracy for a grey palmprint image is 98.31 ± 0.52 for the same database.

In summary, we conclude that our colour-based palmprint-identification system has achieved a slightly better performance in comparison with the grey-scale system.

Abstract - In the previous years there has been a lot of research done in the field of Computer Vision and its application in Natural Interaction. Based on the fact that communication using gestures is one of the primary methods of communication between people, this discipline has seen a lot of advancement. In this paper we present a comparative study of curve representation and similarity measurement algorithms with the purpose of using them for gesture detection and interpretation. Of special interest are algorithms that will be able to detect and track different types of gestures. Therefore, a thorough discussion of gesture classification has been an important part of this research.

I. INTRODUCTION

Among the main purposes of this paper is to detect and recognize gestures. It is known that Haar classifiers can be used in real-time scenarios to recognize and correctly classify a gesture (such as a palm, pointing gestures, grab etc). Since we are dealing with video frames, one gesture can be detected in multiple consequent frames, but with a different recorded location. Based on that, one can record such gesture trajectories as time dependant structures, known as time-series data.

Additionally, one needs to be able to compare a gesture trajectory captured in real-time, with a set of gestures existing on a database. Beyond the accuracy of this comparison, a special focus must be dedicated to the performance of such algorithms which also must operate in real time. A great resource that covers in depth the aspects of time series data analysis can be found in [1].

By dealing with time series data, one must consider two problems:

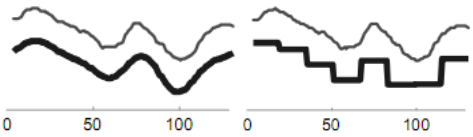
- Data representation algorithms
- Querying time-series data

There are many ways one can represent time series data and many representations are tightly related with the context of their usage. Since time-series analysis has been targeted increasingly by the data mining community, especially in analyzing streaming data most representations aim to reduce the dimensionality of the data. Since dimensionality reduction algorithms (PCA, LDA etc) have been thoroughly researched in the context of data mining and data representation they will not be subject of discussion in this paper.

Time-series analysis is especially evident in the analysis of large amounts of data, especially in the fields of bioinformatics (genetics, DNA sequences etc) in which these structures have very large lengths. Due to this, there is a tendency among researchers to transform these datasets in a more discrete form. In that regard, [2] propose the usage of Discrete Fourier Transformation (DFT) to convert time series data from a continuous representation to a spectral (discrete) representation. Effectively, this transformation gives a smoother shape to our data.

Another approach proposed by [3], aims to use wavelets for time series data representation. The proposed method is to use Discrete Wavelet Transforms (DWT), similar to Haar wavelets in which time series data is scaled down to a discrete representation so it can fit in memory and also represented / indexed in databases.

Finally, [4] propose the usage of Singular Value Decomposition (SVD) method to represent time series data. The research proposed in that article is biased by the use case scenario, in which databases are dynamic in structure and as a consequence are subject of change.



a). Discrete Fourier Transform (DFW) b). Discrete Wavelet Transform (DWT)

Figure 1 - Representation of time series data

The above mentioned data representation methods share the same purpose: they are designed to support queries against large databases. They can also be qualified as dimensionality reduction algorithms which consequently result with some data loss. However, one must consider that the above mentioned methods aim to represent very large sequences, which is not a case of the sequences discussed in this paper. Based on this, we propose a lossless method of data representation, which aims to preserve the shape, order and the length of our sequences. Same as in the above mentioned examples, of special interest for us is that these representations can be indexed properly for the purpose of querying a database of such sequences.

Since gestures occur in relatively small time intervals (usually takes less than a second for a gesture) we only need to represent curves with no more than 24 edges (if we use a 24 fps camera). This gives us the advantage of having much simpler data structures, and our only requirement is to preserve the order of recorded points. Based on that our representation in memory resembles acyclic directed graphs (ADG), and we use adjacency lists to represent them in memory.

In its simplest form, the second problem (querying time series data) aims to answer the following question: given an input curve (time series data) return the most similar sequences that exist in the database. However, this problem definition does not satisfy all the requirements of a gesture recognition system.

Since gestures are captured using digital cameras, one cannot expect that the same gesture when repeated will represent the exact same curve. For this purpose, all the algorithms evaluated here, aim to determine a similarity between two gestures, where a threshold will determine whether one gesture resembles the other.

One of the concerns arisen is that a gesture will not have a starting and ending point on the same location as another time series representation. Another requirement of a gesture recognition system is to be able to detect gestures that have been executed with different speeds. Also the similarity matching algorithm should be scale invariant. Finally, the order of data observations must be preserved. This problem can be simplified by representing detected gestures as two curves, and in order to define the problem in the simplest matter we will use the visual representation of two curves (*P* and *Q*) as shown in **Figure 2**. The distance between these curves will be defined as *d(P,Q)*.

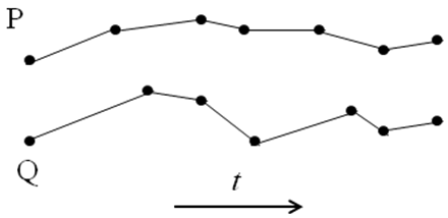


Figure 2 - Two curves represented with P and Q. The problem is to find out how similar they are

There has been a lot of research done in data mining with the purpose of calculating the similarity between two curves. However, before covering these methods, it would be helpful to approach solving the problem using a naïve approach. Since the anticipated outcome is to evaluate the distance between two curves, one can try to evaluate the distance between every point in one curve against appropriate points in the second curve:

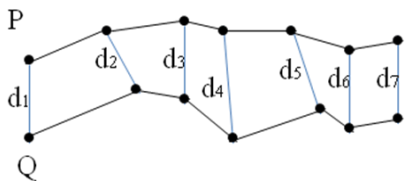

Figure 3 - A naive approach in curve matching

The distance between two points can be calculated using a simple Euclidian distance metric. Therefore, one can use a one-to-one relationship between points in *P* against points in *Q* (see **Figure 3**). Assuming that two points have the same length (i.e. number of observations in our case), one can use the following equation to calculate the distance between them:

$$d(P,Q) = \frac{\sum_{i=0}^{N} d_i}{N} \qquad (1)$$

Where *N* represents the number of points in a curve, and d_i represents the distance between two points at location *i*. As mentioned previously, the distance can be Euclidian distance between points in a two dimensional space:

$$d_i = \sqrt{(x_i - x_j)^2 + (y_i - y_j)^2} \qquad (2)$$

This method is known as the *linear matching model*, and obviously it fails in the assumption that two curves have the same length. When two curves have different lengths the similarity methods should be able to detect sub sections of the lengthier curve that are similar to the second curve. An extension of the previous method would be to use a windowing function, which will represent the smaller curve and after each calculated distance the window would move forward and compare with another section of the lengthier curve. This way, the section that minimizes the equation in (1) would be the matching subsection. This introduces a new problem though; what if there is a subsequence in *P* that is similar to a subsequence in *Q*?

A solution to this problem has been given by [5]; in a paper that introduces the Longest Common Subsequence (LCS) method. This method aims to find the longest subsequence present in two curves. By giving a threshold, the algorithm works as a similarity measurement method, solving for the assumption that two subsequences will rarely be exactly the same. While designed to be used for substring matching, this method is suitable for analyzing time series data as well.

Another commonly used algorithm is the Frechet method [6], which aims to compare two paths and determine the maximal distance between them. This is why the algorithm is famously known as the dog-man method, because it associates with the paths walked by a man and his leashed dog. The algorithm aims to find the maximum length of the leash to be used. The Frechet distance lacks the capability of comparing closed curves. A modified version of this method is applied a lot in handwritten recognition [7] and solves the closed curve problem but can only be applied to offline handwritten recognition, due to performance considerations. Also, since it aims to find the maximal distance, the algorithm is not suitable in situations where one aims to find two closest points (the minimal distance).

Finally there is a subset of curve matching algorithms which falls in the family of elastic matching methods. In [8], the authors propose the usage of directed acyclic graphs for the purpose of representing time-series data. Their method, known as Minimal Variance Matching

(MVM), uses the method of shortest path in acyclic graphs to determine the distance between two paths. It will be shown later, that the method of using acyclic graphs has also found application in our own implementation of time-series data mining.

Finally, a method that has shown a lot of success and has seen much research lately is the Dynamic Time Warping (DTW) method [9]. With roots in speech recognition, it has recently found a lot of application in time-series analysis and handwriting recognition systems. The algorithm is not only rather simple to implement, but it has also shown great results in comparing time series data, and it is also flexible enough to be configured using various thresholds. Based on this, we have chosen this algorithm for comparing gestures, and the algorithm is discussed in detail further in this paper.

Finally before building a gesture recognition system one must be able to differentiate between various types of gestures. Based on how gestures are used for interaction, the following gesture classes can be determined:

- **Deictic gestures** – used to point in order to determine the spatial location of an object.
- **Manipulative gestures** – used to manipulate with objects. E.g., moving an object on a 2D screen.
- **Semaphoric gestures** – used for signaling purposes. E.g., traffic controllers use gestures to manage the traffic.
- **Gesticulation** – commonly used by people while speaking.
- **Language gestures** – gestures used to substitute speech. E.g., sign languages.

A detailed classification of gestures can be found in [11], and since many fields can influence how gestures are classified (linguistics, cognitive sciences, psychology etc) this research does not aim to propose a detailed classification of gesture types. Instead, this research will focus mainly in detecting manipulative and semaphoric gestures, since we anticipate that these types of gestures are more suitable for a human-computer interaction system.

II. Gesture Trajectory Recognition Using Dynamic Time Warping

No matter what algorithm is used for shape extraction, whether one is using blobs or by tracking changes in images via background subtraction, the trajectory (movement) of the retrieved objects can be treated as curves. These curves can be represented as time dependant functions, where each point of the curve is represented with its coordinates and the exact moment of being recorded (retrieved):

$$c = \begin{bmatrix} t_1(x_1, y_1) \\ t_2(x_2, y_2) \\ t_3(x_3, y_3) \\ \cdots \\ t_n(x_n, y_n) \end{bmatrix} \quad (3)$$

Many algorithms exist for comparing curves with each other, but for the purpose of this research, we have investigated the possibility to apply the Dynamic Time Warping (DTW) [10] algorithm, which has been widely used in speech recognition and has found application in handwriting recognition systems. This algorithm is widely known for being very effective when applied to time-series data, and proven to be useful in many data mining tasks that need to analyze and compare similarities of time series data.

In essence, DTW is a method to calculate the similarity between two curves. Two are the anticipated benefits of using this algorithm: time is *warped* so gestures made with different speeds are the same and gestures with different lengths share similarities as well. The algorithm extends the well known *linear matching* method.

The linear matching method, assumes that two curves have the same length. Matching is done by calculating a distance for each point from one curve with its corresponding point on the other curve (a 1:1 relationship). A sum of all these distances is later divided by the total number of combinations. The end result will determine how similar these two curves are, a result equal to zero means that these curves are exactly the same.

However, the above mentioned approach fails in the assumption that curves have equal lengths. One cannot assume that two gestures will have equal lengths, and a gesture recognition system might safely assume the opposite: two curves (gestures) will never have the same length. What one needs to determine in this case is whether one curve is a subset of another lengthier curve. Algorithms that solve such problems are the Longest Common Subsequence, and the DTW algorithm.

The Longest Common Subsequence (LCS) method aims to find the longest subsequence present in two curves. By giving a threshold, the algorithm works as a similarity measurement method, solving for the assumption that two subsequences will rarely be exactly the same. While designed to be used for substring matching, this method is suitable for analyzing time series data as well.

As mentioned previously, DTW relies on the linear matching algorithm, but extends this algorithm by applying two [1] important criteria: *continuity condition*, *boundary condition*.

Continuity condition is the most important condition, which makes the algorithm different from its linear matching counterpart. The condition relies on two coefficients: the first one ensures that all data points are matched once taking into account the time function; the second coefficient regulates how much the matching

[1] In some cases in literature (also in the original paper) there is a third monotonicity condition, which makes sure that both *i* and *j* are being increased by the same value at the same time. This is not a concern in our case due to the fact that the comparison is made with curves being formed in real-time. Therefore it is not discussed in this paper.

differs from linear matching (noted with *c*). More formally, if we assume that we have two curves C_1 and C_2, and the total number of points in them is noted with N_1 and N_2 respectively. Then, point *i* from the first curve can be matched with point *j* from the second curve only if:

$$\frac{N_2}{N_1} i - cN_2 \leq j \leq \frac{N_2}{N_1} i + cN_2 \qquad (4)$$

Important to mention in the above equation is that the coefficient *c* (where $0 \leq c \leq 1$) determines how different DWT is from linear matching. If $c = 0$ then we are dealing with linear matching, and on the other hand if $c=1$ then the continuity condition does not apply since all points in the C_1 will be matched to all points in C_2.

The **boundary condition** ensures that the first two points of both curves are the starting matching points. The end point of the first curve also must match the end point of the second curve.

III. Experimental results

For the purpose of evaluating the effectiveness and feasibility of using the methods proposed above, we have conducted experiments aiming to evaluate:

- Accuracy of the algorithm – determined by the number of correctly predicted instances.
- Performance – defined as time required to recognize a gesture.

Another criteria in the decision making process was to be able to use as simple data structures as possible that would represent our curves. This was important because we wanted to be able to save certain curves for future retrieval.

Tests were done on a closed system, in which every input query was known to be found on our database. The database was trained to recognize 30 gestures, such as swipe left, swipe right, top-down, bottom-up etc. Table 1 depicts the accuracy of algorithms we used.

Gestures were extracted using a webcam that would record video sequences. A custom trained Haar classifier would detect hand gestures and track them on each frame of the video sequence. By using empirical studies it was determined that gestures do not last for more than one second, therefore the Haar classifier would track a gesture for a total of 24 frames. Gestures that were recorded on our database were extracted using the same method.

Each gesture was tested manually ten times against the database and both the correctness of the result as well as the response time would be recorded. To have consistent results all the experiments were conducted on the same machine.

In conclusion we have seen that DTW has the potential of being used in gesture recognition systems. Even though this algorithm has mostly been applied to signal processing tasks, the results presented on this paper show that the algorithm has two big advantages: low error rate and quick execution time. It also relies on simple data structures, represented in the form of adjacency lists in memory. With this in mind, we were able to implement a system that will record multiple gestures and be able to quickly query them.

TABLE I. Experimental results

Algorithm	Accuracy	Average Time
LMM	83.7 %	33.1 ms
DTW	97.3 %	123.6 ms
Frechet	89.0 %	473.4 ms

IV. Conclusion

This paper compares different methods used in time series analysis with the purpose of searching subsequences. The purpose of using these algorithms is to evaluate the feasibility their usage in gesture recognition systems. Experiments are conducted aiming to evaluate these methods by analyzing both their performance and accuracy. The experiments show that the Dynamic Time Warping algorithm excels when compared to other similar methods.

***Abstract*—This paper presents a pilot study towards estimating complex traffic flow parameters in airborne video. The study presents two prototype software systems attempting to solve intermediate tasks in recovering microscopic OD (origin-destination) matrices at complex road intersections. The first system employs background modelling in order to estimate the OD matrix of an intersection imaged by a fixed camera. The second system explores the feasibility of applying such approach to input video acquired from a hovering aircraft by pre-warping the whole video towards the coordinates of the first frame. The experimental part presents performance evaluation of the two prototype systems on real traffic videos acquired from a tall building and a non-rigid airship. The paper is concluded by discussing the achieved baseline performance and proposing suitable directions for future research.**

I. Introduction

Modern transportation systems are designed by optimizing traffic flow models which are parameterized by actual demands estimated from empirical measurements. Typical traffic flow parameters include frequency, density, headway, etc. of the vehicles at relevant sections of the transportation network. There are many suitable commercial technologies for estimating these parameters at straight sections of the network. However, none of them provides satisfactory performance at intersections where one needs to establish temporal correspondence between the detected vehicles in order to estimate microscopic OD (origin-destination) matrices [1], [2]. The most general approach for estimating intersection parameters corresponds to manual vehicle counting. However, that approach is hampered by organizational and financial difficulties, since measuring complex intersections usually requires many trained human operators. Encouraging results have been achieved by computer vision based approaches [3], [4] in video acquired from viaducts or telescopic cranes, but this is not applicable at many intersections. Airplane imagery [5] has a broader scope but is often infeasible due to the high costs involved. Acquisition from a helicopter [6] is more accessible, but the costs are still significant. Additionally, if affordable standard resolution cameras are employed, one has to address the problem of small-sized vehicles in images which makes it difficult to count them automatically.

This paper presents introductory research towards estimating intersection parameters in video acquired from an unmanned aerial vehicle (UAV) hovering at the heights of about 50 m. The main commercial advantages of such approach include lower acquisition costs and better performance with standard resolution images. In particular, the paper evaluates performance of the following two intermediate tasks. In the first task we assess the accuracy of OD matrices estimated in video acquired by a fixed camera from a tall building, based on a straight forward background modelling technique. The second task involves stabilizing video from a hovering airship, in the ambition to extend the applicability of fixed-camera approaches to UAV-based applications.

In the rest of the paper, we first present a short review of the related work in Section II. Subsequently, in Section III we explain the broad significance of airborne video for estimating parameters of a transportation system. We detail the theoretical backgrounds for the considered intermediate tasks in Sections IV and V. Subsequently we present experimental results obtained on videos of real intersections acquired from a tall building and a hovering airship in VI. Finally, in Section VII we present conclusions and directions for future work.

II. Related work

Extraction of complex intersection features such as OD matrices and headway from airborne imagery has many advantages over ground-based approaches [5], [6], however the involved costs have been very high. Recent development of low-cost UAV technology encourages new research on airborne traffic flow feature collection [4].

A large body of previous work addresses videos acquired with fixed cameras. These approaches have been mostly based on image motion detection [7] and background modelling [3], [8]. In both cases, the transition towards a moving airborne camera [6], [9] is not straightforward and requires further research. More versatile approaches build on generic object detection [10], however most of them address images in which the street scene is viewed from an orthogonal direction. This would not be the case in images acquired from low-height howering UAVs where we observe both appearance variety (due to different relative poses of the object with respect to the camera), and the variety of object categories (cars, trams, buses, pedestrians, cyclists, etc). This variability would have to be addressed by a multi-class detection approach based on feature sharing such as [11], however the performance of such approaches still appears insufficient for our purpose.

Stabilization of the acquired video is an important issue in airborne surveillance. Camera orientation can often be stabilized within some limits by suitable gyroscope platforms. Medium to high frequency vibrations generated from UAV's motors and wind can also be problematic and can be addressed by suitable absorbing materials. Unfortunately, many of the UAVs considered suitable for traffic surveillance have significant payload weight limitations,

which greatly reduce the possibility of utilising hardware stabilization setups. This accentuates the importance of software based stabilization [6], such as the approach presented in V and VI-C.

An additional concern specific to UAV operation is automatic control. Autonomous UAV capabilities would be interesting in order to i) relax the human operator involvement, ii) ensure optimal acquisition in bad weather through UAV stabilization, and iii) minimize the risks of damage during take-off and landing. A recent study [12] confirmed the potential of visual control, even when sophisticated alternatives are present such as inertial sensors and GNSS (GPS, Galileo).

III. Measuring traffic flow parameters at the microscopic scale

The most critical part of every transport system are its nodes or intersections. Design, throughput and capacity of a single intersection can affect even very distant parts of the transport network. Therefore studies leading to appropriate intersection design and traffic control are the most important factors in transport network optimisation. An important category of these studies is performed at the microscopic scale, where traffic flow parameters are measured by considering each vehicle as an individual. In this paper we are especially interested in measuring OD matrices and time headway at complex intersections.

OD matrix is also know as a trip table. It contains the number of vehicles going from each intersection entry to each intersection exit during the considered time interval. OD matrices are especially hard to recover at complex intersections and interrelated junctions where comprehending and accurately counting the entries is highly impractical and expensive both for human operators and commercial sensor technologies.

Time headway [13] corresponds to the elapsed time between the front of the first vehicle passing a road cross-section and the front of the subsequent vehicle. Headway is the most essential microscopic traffic flow parameter. Interaction between headway and vehicle speed is responsible for the overall traffic flow performance. Precise measurements of headway in relation to speed provide a detailed insight in the capacity limitations and design flaws at observed intersections. Unfortunately, most existing studies focus on average headway within a limited period of time, mostly due to imperfections of various sensors used for vehicle counting and traffic parameter measurement. Headway-to-speed ratio is particularly difficult to recover at intersections since it is not constant during intersection passing [14]. Therefore, there is a strong need for future sensor technologies which would be able to map this parameter over the intersection area.

IV. Vehicle detection by fixed cameras

When viewing a rigid scene from a fixed viewpoint, each pixel is always projected from the same part of the scene. By analyzing the changes of a pixel in time, a model can be constructed to determine whether a current realization of that pixel is more likely to belong to a moving foreground object or to the background scenery [8]. An object detection system based on such model would need to include the following processing steps.

- Creation of a per-pixel background model for the desired scene.
- Comparing the current video frame against the background model to identify foreground pixels.
- Grouping the foreground pixels into high-level objects.

The background model is often built and updated concurrently with the object detection process. The main advantage of such approach is the ability to make an adaptive model which would be able to tollerate small changes due to different time of day. However, we do not need that feature, since the traffic parameters are estimated in limited time intervals (less than one hour), usually at the time of peak traffic. Therefore we build the background model in an off-line fashion, by employing all available frames of the input video. The object detection is consequently performed on the same video, after having rewound it back to the start, as described in Figure 1.

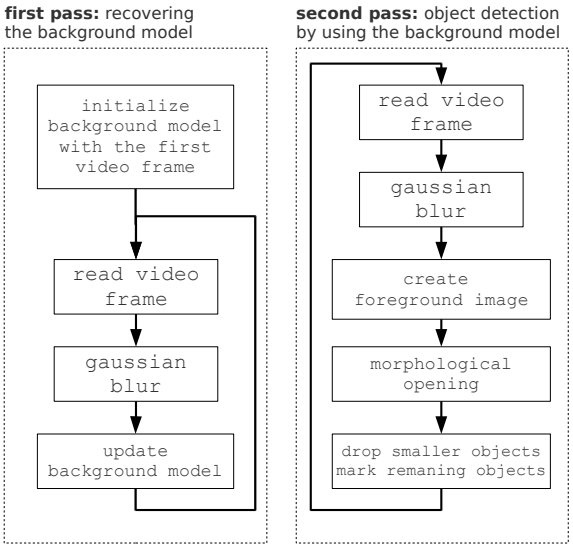

Fig. 1. Flow chart of the proposed procedure

The first step in both processing phases is to apply Gaussian filtering to the current frame. Doing so greatly reduces the noise and the undesired effects of minute camera vibrations. This technique therefore improves both the accuracy of the background model and the reliability of foreground object detection.

A background model of an intersection tries to mimic how an image of the intersection would look like without any moving objects (vehicles, pedestrians, etc.) on it. Two different approaches were considered for creating a background model of the intersection. The first approach was to calculate the moving average for each pixel on the picture. Due to the fact that vehicles often differ in color and keep a safety distance from other vehicles the average of each pixel converges to the color of the underlying intersection in that position. The second approach was to keep a histogram for each pixel and choose the most frequent color for the background model. An another option for creating a background model would

be based on Mixtures of Gaussians [15], however preliminary results did not show dramatic improvement over unimodal approaches and so we preferred to invest our time elsewhere.

After the background model converges, the current frame is compared against it in order to form a binary (1 bit black and white) image showing whether a pixel differs from the background or not. A white pixel indicates that the corresponding pixel from the current frame differs significantly from the background model. A black pixel indicates that the current value is very similar or identical to the background model. Vehicles are detected by growing a region around each unvisited white pixel. Coordinates of each pixel of the current region are stored in a vector. When there are no more unvisited white pixel neighbors, vertical and horizontal extremes are found in the vector and a rectangle is drawn so that it encloses the detected group.

Sometimes a vehicle has parts that do not differ significantly from the background. The most common case is the gray reflection of the sky on the windshield that can be very similar to the gray background of the asphalt. This can cause a single vehicle to be detected as two separate groups of foreground pixels. To address this problem, morphological opening [16] is applied to the binary image, by successively applying dilation and erosion. Dilation widens the groups of white pixels causing their melting with neighbouring groups. By applying erosion the groups regain their initial size, but remain connected to their neigbours. In the last step, objects greater than a specific size are detected as vehicles while smaller objects are ignored since they're likely due to pedestrians or noise.

V. Stabilization of Video Acquired from Hovering Aircraft

In the case of acquisition from hovering aircraft, the acquired video is often unsuitable for background modelling due to 6 DOF motion of the attached camera. We wish to stabilize the video in a way that the image plane remains in consistent relation with the starting video frame (or any other reference frame).

The developed system consists of two main parts: feature tracker and homography estimator. In the first part, a large number of features are tracked throughout the video sequence from the reference frame to the current frame, by using Kanade-Lucas-Tomasi (KLT) feature tracking algorithm. The KLT tracker selects only those features that can be reliably tracked [17].

Before estimating the transformation between the reference frame and the current frame, it is neccessary to remove features whose movement deviates from other features, i.e. outliers. In our case, most of outlying features are projected from moving vehicles, which deviate from the desired transformation of the ground plane in two images. The removal of outliers is done by a Random Sample Consensus (RANSAC) algorithm [18].

Coordinates of every tracked feature are then used to estimate the desired transformation. We assume that aircraft is high above the ground so that the transformation can be fairly well-approximated by a homography. To estimate homography, we need to solve equation of the form:

$$\mathbf{A}_{2n\times 9} \cdot \begin{bmatrix} \mathbf{H}_1^\top \\ \mathbf{H}_2^\top \\ \mathbf{H}_3^\top \end{bmatrix} = \mathbf{0}_{2n} \ . \qquad (1)$$

Every corresponding pair of coordinates participates with two linearly independent equations to the overconstrained linear system (1). Each independent equation contributes one row of the matrix $\mathbf{A}_{2n\times 9}$, where n is the number of such corresponding pairs. Matrix $\mathbf{H}_{3\times 3}$ is a solution which we are searching for, and it contains the coefficients of the desired homography (note: $\mathbf{H}_i$ is i-th row of matrix $\mathbf{H}$). In our system, the linear system (1) is estimated by SVD matrix decomposition. Since this estimation does not maximize likelihood, the solution is additionally improved by using gradient optimization – Levenberg-Marquardt algorithm.

The estimated transformation is applied to current video frame as follows:

$$\begin{bmatrix} x' & y' & 1 \end{bmatrix}^\top = \mathbf{H}_{3\times 3} \cdot \begin{bmatrix} x & y & 1 \end{bmatrix}^\top \ . \qquad (2)$$

In the above equation, (x, y) is point in current frame, (x', y') is (x, y) put into the reference image plane and $\mathbf{H}_{3\times 3}$ is a homography matrix. An example of video stabilization is shown in Figure 2.

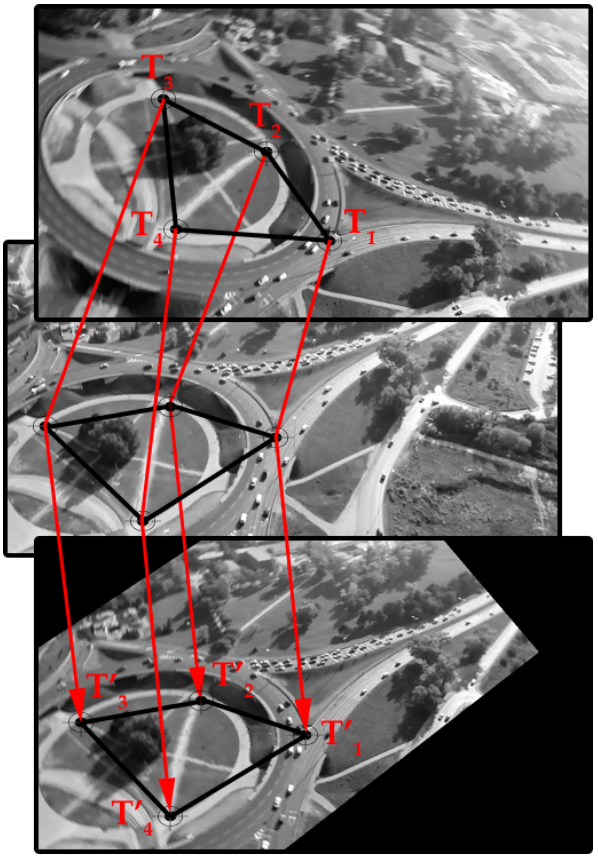

Fig. 2. Stabilization of video acquired from hovering aircraft. The figure shows the current frame (top), the reference frame (middle), and the transformed current frame (bottom). Points T_i in the current frame are transformed to the points T_i' by the homography between the current frame and the reference frame.

During the tracking of point features through image sequence, error is accumulated. To improve results, as

a final step we check consistency of features. For each feature, the similarity between the intensity of tracking window in current frame and the intensity of tracking window in reference frame is calculated. If the two tracking windows are not similar, the feature is inconsistent and can be rejected as a bad feature.

VI. Experimental results

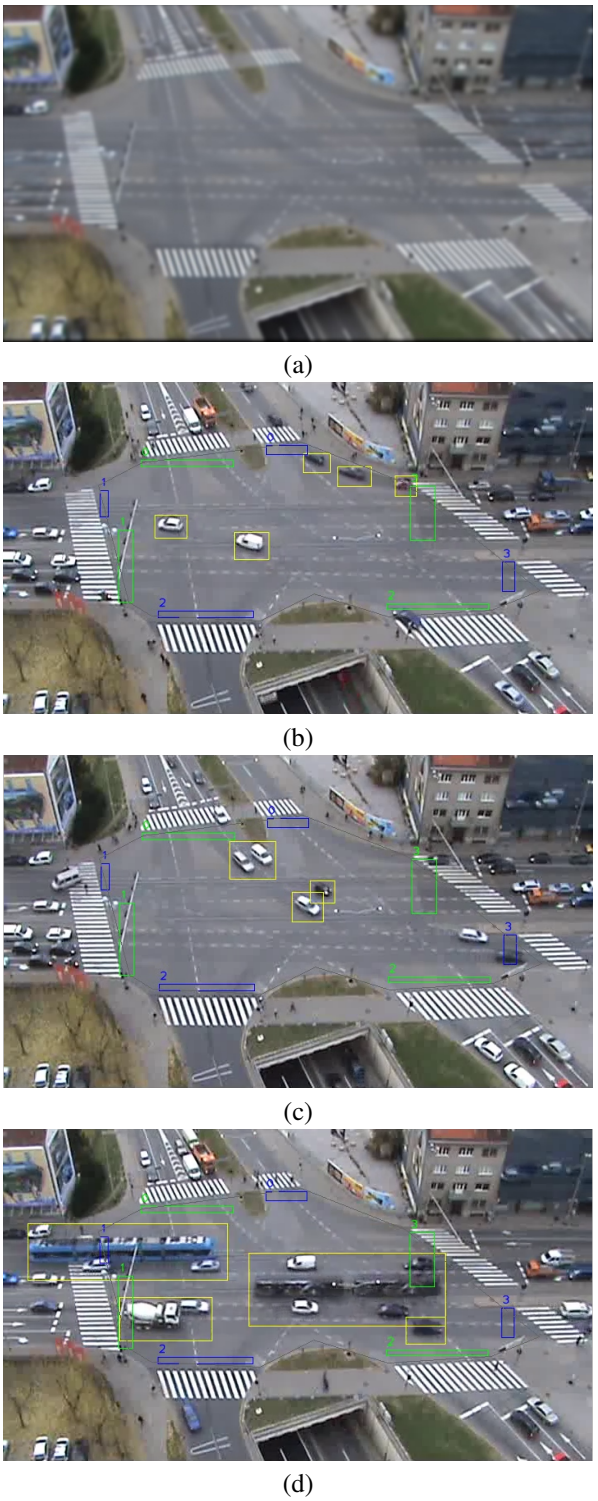
A. Vehicle detection based on background modelling

Gaussian filtering was performed by convolving an image with a Gaussian filter kernel. A good quality/performance ratio was obtained by applying a 7×7 Gaussian kernel with a standard deviation σ=3.5. Due to its symmetry the Gaussian kernel can be applied separately to each dimension. Separating the filtering process in vertical and horizontal directions and using OpenMP for parallelization resulted in a faster implementation of the filtering algorithm.

Creating the background model by computing a moving average uses less memory but requires more time to converge. Histogram-based background models converge faster but, on the downside, require considerable memory for storing histograms in each image pixel. In order to save space, our approach stores only marginal RGB histograms (we assume unimodal distributions) and therefore requires a total of 3 × 256 × width × height bytes for an 8 bit RGB image. Besides the differences in memory usage and convergence speed no other relevant performance differences were noticed between these two approaches. Both approaches can be precomputed or used in real time. We chose the precomputed approach in order to i) avoid having to wait for model convergence, and ii) being able to focus on object detection instead of on background modeling. The main drawback of precomputed background models is their inability to adapt to changes, however this is not a problem in our context since traffic analyses are typically carried out in limited time intervals. The foreground image is determined by comparing the current image to the previously recovered background model. For simplicity, the comparison is implemented by comparing absolute RGB differences with a fixed threshold. In all experiments the threshold was set to 20.

Before further processing, the binary foreground image is subjected to morphological opening implemented as three dilations followed by three erosions, by using the structuring element 1×1. This procedure sometimes causes neighbouring vehicles to be detected as one. However, empirical analysis has shown that these losses are outweighed by the gains from having fewer fragmented objects. The obtained results have been illustrated in Figure 3.

Experimental evaluation revealed two major problems. The biggest problem is the tram entrance to the scene during which our system detects a large object which predates all vehicles moving near the tram. Therefore, all experimental results which we show here have been obtained in parts of the video in which trams are not present at the intersection. The most common problem is detecting multiple neighbouring vehicles as only one object. Additionally, some vehicles are detected as two objecs. This may occur either when a car is similar to the background or due to the reflections of the gray sky on the windshield.



(a) (b) (c) (d)

Fig. 3. Results of object detection: background model (a), successful detection of multiple objects (b), two vehicles detected as one (c), problems with big vehicles (d).

B. Estimating the intersection OD matrix

The developed prototype system allows the user to define regions that represent origins and destinations in the intersection and to count the number of objects that pass from each origin to each destination. The OD matrix is displayed as an overlay in the video and saved to a file

for further analysis.

Figure 4 shows the intersection with marked origins (green) and destinations (blue). All objects detected outside of the red polygon are discarded. This had to be done due to reflections on the building windows and due to groups of pedestrians which may be large enough to be detected as vehicles.

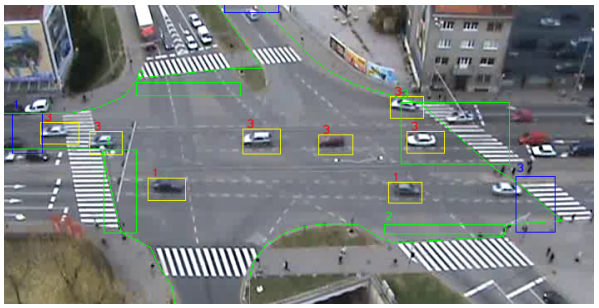


Fig. 4. The regions employed in the process of estimating the OD matrix are defined manually as green (source) and blue (destination) rectangles. The employed background model is shown in the background. A demonstration video can be viewed at http://www.zemris.fer.hr/~ssegvic/pubs/braut12ok.avi.

The recovered OD matrices have been evaluated with respect to the groundtruth. In the evaluation we have omitted frames in which the tramways are passing through the intersection. The obtained results have been summarized in Table I. The table entries show the number of estimated vehicles compared to the groundtruth.

TABLE I
THE ESTIMATED OD MATRIX COMPARED TO THE GROUNDTRUTH.

	destinations			
origins	0	1	2	3
0	0:0	9:9	15:17	42:44
1	14:14	0:0	8:8	24:17
2	22:27	20:23	1:1	0:0
3	28:30	32:32	26:24	3:3

C. Video stabilization

The developed prototype for video stabilization uses the library for KLT feature tracking[1], and the OpenCV library "Camera Calibration and 3d Reconstruction" [19] for homography estimation. The system tracks 3000 features in windows of 7×7 pixels. Large number of features and large tracking window improve stabilization but negatively affect the processing speed. The original video resolution is 1920×1080, however it has been downsampled to 960×540 in order to make the computation more tractable. Typically the system succeeds to maintain a fair correspondence with the reference frame for a few seconds. After that the results deteriorate due to the excessive number of lost features. Demonstration videos can be viewed at http://www.zemris.fer.hr/~ssegvic/pubs/culjak12original.mp4 and http://www.zemris.fer.hr/~ssegvic/pubs/culjak12stable.mp4.

The quality of results can be expressed as an average displacement of transformed image pixels in relation to corresponding pixels in the reference image, i.e. jitter. To calculate jitter, five suitable control points are manually chosen in the reference image. These control points are consequently located in 13 transformed images. The average displacement in each image is calculated as an average difference of control point coordinates between reference image and transformed images:

$$\bar{x} = \left\lceil \sum_{j=1}^{k} \sum_{i=1}^{n} \frac{|xc_i - x_{i,j}|}{nk} \right\rceil , \quad (3)$$

$$\bar{y} = \left\lceil \sum_{j=1}^{k} \sum_{i=1}^{n} \frac{|yc_i - y_{i,j}|}{nk} \right\rceil . \quad (4)$$

In the above equation $k = 13$, $n = 5$, $\bar{x}$ and $\bar{y}$ are average displacements on abscissa and ordinate, (xc_i, yc_i) are coordinates of i-th control point in the reference image and $(x_{i,j}, y_{i,j})$ are coordinates of i-th control point in the j-th transformed image. The results of evaluation are shown in Figure 5.

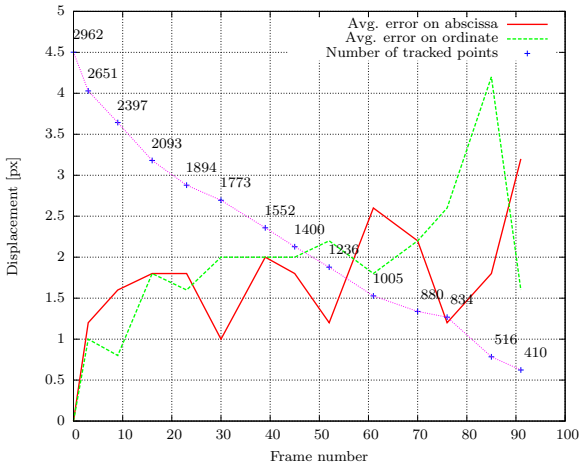

Fig. 5. Average displacement of the current image with respect to the reference image, as a function the frame distance.

VII. CONCLUSION AND FUTURE WORK

This paper considered the feasibility of estimating microscopic OD (origin-destination) matrices at complex road intersections in airborne video. Encouraging results have been obtained even with straight-forward computer vision techniques. The main problems identified by performance evaluation in the fixed-camera context include aggregated detections of nearby vehicles and occlusion by large vehicles such as tramways. The main problem identified in the hovering-camera context is the starvation of the tracked features.

The identified problems shall be addressed in our future work. In particular, advanced object detection approaches shall be tried out which would assign high-level objects to foreground pixels not only by looking at their proximity, but also by considering at their colour histograms and their image motion. Long-term stabilization of the hovering aircraft video shall be attempted by creating a map of suitable ground plane points in a SLAM fashion. The map shall be employed to restart the tracking of lost points

[1]URL http://www.ces.clemson.edu/~stb/klt/

which shall enable us to maintain an accurate relation towards the reference frame throughout the whole video.

Our future work shall also address estimating speed and headway at all points of the vehicle trajectory. These important parameters can not be reliably estimated by existing sensor technologies, since their values typically vary across the intersection. It is therefore expected that the future developments might provide significant insight into opportunities for improving the efficiency of our transportation systems.

Abstract – In this paper, the methods for the estimation of the printed text skew are explored. Initail skew rate and moment based method are presented. They are tested with single and multi line document image samples in different resolutions. Furthermore, the results are evaluated by common measures. Moment based method proved its advantage in the domain of accuracy and robustness over the initial skew rate method.

I. INTRODUCTION

The printed text represents a well-formed text type. It means that it has a strong regularity in shape. The letters are the similar size. The distance between text lines is sufficient. This leads that spacing between text lines is decent. Furthermore, the different text line orientation is quite similar. Hence, the text has a uniform text skew. From all above, the printed text can be characterized as relatively predictable.

The goal of the optical character recognition (OCR) system is the transformation of the printed documentation into the computer editing form. During the first step in this process i.e. digitization, the text skew occurrence is unavoidable. However, the existence of this phenomena could cause the OCR failing. Hence, the skew estimation represents one of the important steps in the OCR [1].

Existing methods for the estimation of the text skew can be classified in the following groups [1]: projection profiles method, k-nearest neighbor clustering method, Hough transforms method, Fourier transformation method, cross-correlation method, and other methods.

The techniques classified as other methods are based mostly on morphological and geometrical transformation. These algorithms are characterized commonly as computationally inexpensive. Hence, in this paper two methods of this group have been exploited. They are moment based and boundary growing method.

The moments define a measure of the pixel distribution in the image [2]. They can be used for the extraction of some important image features like the skew estimation. Hence, it can be used for the skew estimation of the printed text [2].

Boundary growing method estimates the text skew based on a straight-line fitting [3]. In this method, the gravity centers of the bounding boxes of the connected components are used as an eigen-points. They are extracted as sample points which represent the inputs for the least squares method. It calculates the estimated baseline.

The main contribution of this paper is the critical analysis and comparison of different methods for the text skew estimation. They include moment based and boundary growing method, i.e. initial skew rate. These methods are tested with the set of printed text samples in standard and low resolutions. The proposed algorithm shows a good skew estimation in standard and low resolutions. Hence, it contributes to theirs robustness.

Organization of this paper is as follows. Section 2 describes the proposed algorithms for the estimation of the text skew. Section 3 defines text experiments. Section 4 compares and discusses obtained results. Section 5 makes conclusions.

II. PROPOSED ALGORITHMS

Document text image is a product of the image scanning. It is a digital gray-level image, which is represented by matrix **D**. It consists of M rows, N columns, and contains the elements which intensity has L discrete levels of gray. L is the integer from $\{0, \ldots, 255\}$, $D(i, j) \in \{0, \ldots, 255\}$, where $i = 1, \ldots, M$ and $j = 1, \ldots, N$. After performing the binarization procedure the image represented by matrix **D** is transformed into binary image $B(i, j)$. Its elements are equal to 1 if $D(i, j) \geq D_{th}(i, j)$, or to 0 if $D(i, j) < D_{th}(i, j)$, where D_{th} is given by any local binarization method [4-5]. D_{th} represents local threshold sensitivity decision value. Currently, document image is given as binary matrix **B** featuring M rows and N columns.

A. Moment Based Method

Moment defines the measure of the pixel distribution in the image. It identifies global image information concerning its contour. The $(p+q)$-th order geometric moment m_{pq} of a gray-level image $D(i, j)$ is defined as:

$$m_{pq} = \sum_{i=1}^{N} \sum_{j=1}^{M} i^p j^q D(i,j) \,. \quad (1)$$

In eq. (1) p and q = 0, 1, 2, 3, ..., n, and n represent the order of the moment. Accordingly, for the binary image $B(i, j)$ geometric moments m_{pq} are defined as [6]:

$$m_{pq} = \sum_{i=1}^{N} \sum_{j=1}^{M} i^p j^q \,. \quad (2)$$

From eq. (2) central moments μ_{pq} for the binary image $B(i, j)$ can be calculated as:

$$m_{pq} = \sum_{i=1}^{N} \sum_{j=1}^{M} (i-\bar{i})^p (j-\bar{j})^q \,. \quad (3)$$

In eq. (3) $\bar{i}$ and $\bar{j}$ represent the coordinates of the centre of mass (gravity center) given as:

$$\bar{i} = \frac{m_{10}}{m_{00}}, \quad \bar{j} = \frac{m_{01}}{m_{00}} \quad , \quad (4)$$

where m_{00} is the area of the object in binary image $B(i, j)$.

Some of the important image features can be obtained from the moments. The second order moments $\{\mu_{02}, \mu_{11}, \mu_{20}\}$ known as the moments of intertia may be used to determine an important image feature orientation [6]. In general the orientation of an image describes how the image lies in the field of view, or the directions of the principal axes. In terms of moments the orientations of the principal axes are given by angle θ [6-8]:

$$q = \frac{1}{2} \arctan\left(\frac{2m_{11}}{m_{20} - m_{02}} \right). \quad (5)$$

All these features represent the characteristics of the separate object. Hence, this method can be used for the printed text skew evaluation. In that case, the skew estimation of the each text object is similar or equal to others.

B. Initial Skew Rate Method

The initial skew rate method is based on the boundary growing area method. It extracts the bounding box gravity centers of the connected components. The gravity center coordinates represent the inputs for the linear approximation made by the least square method [9]. As the results, the calculated baseline gives the estimated text skew angle.

Firstly, the algorithm creates a bounding box around each character or text object called connected component (*CC*). The bounding box is defined by its endpoints $x_{\min}$, $y_{\min}$, $x_{\max}$, and $y_{\max}$. Each pixel $B(i, j)$ that belongs to the bounding box is given by [10]:

$$B(i,j) \big| (x_{\min} \le i \le x_{\max}) \wedge (y_{\min} \le j \le y_{\max}) \,. \quad (6)$$

Furthermore, they are filled with black pixels. To separate every text line, each connected component is growing in all directions. They are growing up to 10% of typical character height in each direction [11]. It is made by morphological dilatation. As the structuring element $\mathbf{L}_v$, the simple line with variable width according to the [10] has been used.

$$\mathbf{B}_v = \mathbf{B} \oplus \mathbf{L}_v \,, \quad (7)$$

where v = 1, …, U, and U = 3. It means that three variable width lines are used. Experimental results show that extending the number of structuring elements above U = 3 is not necessary [11].

Furthermore, the longest connected components CC_l has been captured by longest common subsequence (LCS) [11].

$$CC_l = \bigcap_{v=1}^{U} B_v \,. \quad (8)$$

Currently, CC_l consists of the set of bounding boxes. Furthermore, each of them has its gravity center. Gravity center points are determined with its endpoints $x_{\max}$, $x_{\min}$, $y_{\max}$ and $y_{\min}$. They are given as:

$$GC(x,y) = \left(\frac{x_{\min} + x_{\max}}{2}, \frac{y_{\min} + y_{\max}}{2} \right). \quad (9)$$

The array of gravity center points GC_K for the longest connected component CC_l is given as:

$$\begin{aligned} GC_K &= \{GC_1(x,y), \mathbf{K}, GC_R(x,y)\} = \\ &= \{(x_1,y_1), \mathbf{K}, (x_R,y_R)\} \quad , \end{aligned} \quad (10)$$

where K = 1, ..., R, and R represent the number of bounding boxes included in the longest connected component CC_l. These pixels are the input for the calculation of the printed text baseline.

Text baseline in printed text is a linear one. That's why its identification is simplified. It can be calculated using the least square method. The approximation of the first degree polynomial function is given by:

$$y = a_l x + b_l \,, \quad (11)$$

where a_l is the slope and b_l is y-intercept for the longest connected component CC_l. Furthermore, the slope a_l and y-intercept b_l are calculated as [9]:

$$a_l = \frac{(\sum y_{K,l})*(\sum x_{K,l}\cdot y_{K,l}) - m_L * (\sum x_{K,l}\cdot y_{K,l})}{(\sum x_{K,l})^2 - m_l * (\sum x_{K,l}^2)}, \quad (12)$$

$$b_l = \frac{(\sum x_{K,l})*(\sum x_{K,l}\cdot y_{K,l}) - (\sum y_{K,l})*(\sum x_{K,l}^2)}{(\sum x_{K,l})^2 - m_l*(\sum x_{K,l}^2)}, \quad (13)$$

where m_l is the data point number for the array $GC_K(x, y)$ of the longest connected component CC_l, and $x_{K,l}$, $y_{K,l}$ are gravity center coordinates of the each bounding box GC_K, $K = 1, ..., R$, included in the longest connected component CC_l. Hence for CC_l, calculated i.e. estimated text line has been represented by the group of pixels $GC_{K,l}(x_{K,l}, y_{K,l})$. Furthermore, initial text skew (for CC_l) is given as:

$$b_l = \arctan(a_l). \quad (14)$$

Currently, document text image is rotating for the calculated angle β_l. Real text skew is close to that estimated initial text skew. However, a final adjustment is needed which is made by repeating the method.

III. EXPERIMENTS

The goal of the experiments is the evaluation of the algorithm for the text skew estimation. It evaluates the algorithm's performance in the skew tracking domain. Experiments were performed mostly on the synthetic datasets which represents the single line of the printed text sample [12].

The test consists of the single line printed text rotated for the angle β from 0° to 85° in the steps of 5° around x-axis [12]. Text sample is shown in Figure 1.

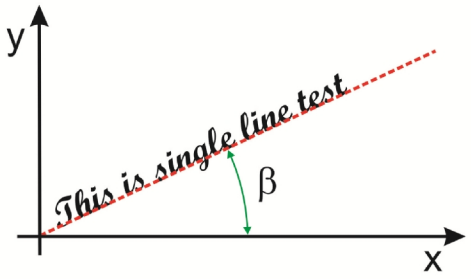

Figure 1. A printed text sample which is rotated up to 85° in 5° steps

Furthermore, all text samples are given in the standard resolution of 300 dpi and in the low resolution of 25 and 50 dpi. The results are evaluated by the absolute deviation, i.e. error. Absolute deviation is given as:

$$\Delta b_A = |b_{REF} - b_A|, \quad (15)$$

where β_{REF} is the referent skew of the input text sample and β_A is the skew of the text sample obtained with tested algorithm.

IV. RESULTS

Firstly, both methods are tested with the printed text sample in the resolution of 300 dpi. Figure 2 shows the absolute skew deviation of the initial skew rate and moment based method for the text samples in 300 dpi resolution.

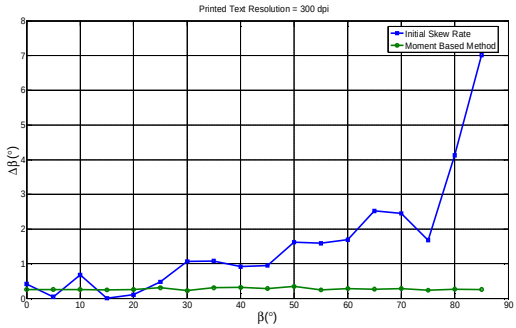

Figure 2. Absolute deviation of the initial skew rate and moment based method for the text sample in 300 dpi resolution

For the image resolution of 300 dpi, the results for both methods are similar for the skew angle up to 25°. However, the moment based method has a uniform absolute deviation in the whole examined range. The most important is its level of the absolute deviation of 0.2° to 0.3° in the examined range. For the bigger skew angles the moment based method has clear benefits. Obviously, the moment based method has a better skew estimation ability. Hence, it shows clear advantages for the bigger text angles compared those obtained by initial skew rate. In contrast, the initial skew rate can not follow correctly the increased skew angles.

Further, the obtained results are linked with the binary images in low resolution. Figure 3 shows the absolute skew deviation of the initial skew rate and moment based method for the text samples in 50 dpi resolution.

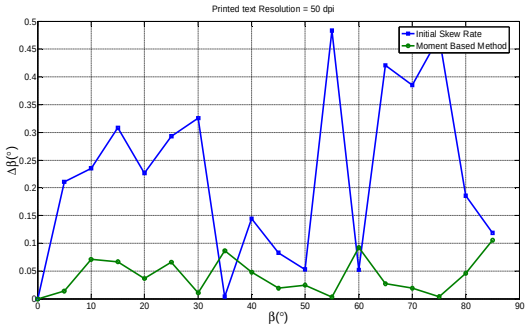

Figure 3. Absolute deviation of the initial skew rate and moment based method for the text sample in 50 dpi resolution

For the complete range of testing skew angles, the moment based method has a level of absolute skew deviation up to 0.1°. Again, this level of deviation is a pretty uniform. The initial skew rate method has the level of absolute skew deviation up to 0.5°. It is about five times higher compared to the moment based method. Hence, the moment based method has clear benefits.

Figure 4 shows the absolute skew deviation of the initial skew rate and moment based method for the text samples in 25 dpi resolution.

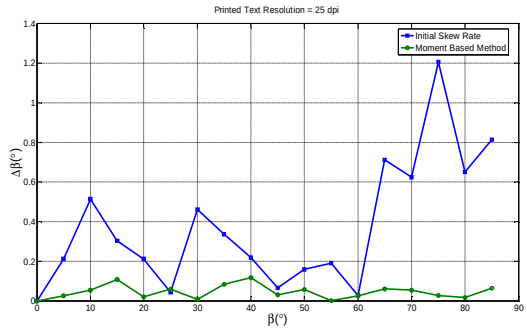

Figure 4. Absolute deviation of the initial skew rate and moment based method for the text sample in 25 dpi resolution

The moment based method has a level of absolute skew deviation up to 0.1°. This level of deviation is a uniform, as in previous examples. On the contrary, the initial skew rate method is raising the levels of the absolute skew deviation to the peak of 1.2°. Hence, it is five to ten times higher compared to the moment based method. Again, the moment based method is a more accurate method for the text skew estimation.

At the end, a summary of the presented results is given in TABLE I.

TABLE I. TESTING RESULTS SUMMARY

$0° \le \beta \le 85°$	Text skew estimation method	
Res. 300 dpi	***Moment based method***	***Initial skew rate***
$\Delta\beta$	$< 0.02°$	$< 0.09°$
Res. 50 dpi	***Moment based method***	***Initial skew rate***
$\Delta\beta$	$< 0.1°$	$< 0.48°$
Res. 25 dpi	***Moment based method***	***Initial skew rate***
$\Delta\beta$	$< 0.11°$	$< 1.2°$

V. CONCLUSION

This paper gives the critical analysis and comparison between two text skew estimation techniques: moment based and initial skew rate method. Both methods are tested with the document image samples in the standard resolution of 300 dpi and in lower resolutions of 25 and 50 dpi. The analyzed algorithms show different skew accuracy for the standard and low resolution document images. Initial skew rate proved to be a correct method for the skew estimation at the resolution of 300 dpi. However, the method has a higher level of error in the low resolution images. On the contrary, the moment based method has a lower accuracy deviation for different text image resolutions. Hence, it proves its correctness and robustness in the standard as well as the low resolution of text images. However, it should be mentioned that both methods are promising due to their computationally inexpensiveness.

Croatian visual speech synthesis

M. Pobar, I. Ipšić
University of Rijeka/Department of Informatics, Rijeka, Croatia
{mpobar, ipsic}@inf.uniri.hr

Abstract - Virtual human characters are being used in a variety of applications, such as computer games, movies, tutoring software and virtual guides. Virtual characters interact with persons using speech and gestures. In some applications speech can be pre-recorded and synchronized with animation to produce a believable virtual character. However in many cases an ability to produce synthesized speech synchronized with facial animation is necessary or desireable, for example in cases the output text is not known in advance, for ability to choose among various voices, or because recording natural speech is too time consuming and expensive for a given application. This paper presents the effort to integrate and extend existing text-to-speech system for Croatian language and a face and body animation system to produce a system capable of real-time visual text-to-speech synthesis for Croatian language.

I. INTRODUCTION

Addition of visual mode to speech synthesis can be important in many applications, such as tutoring software for language learning [1], where seeing the articulators may help distinguishing and learning non-native phonemes, or in noisy acoustic conditions where lip reading can help with intelligibility of speech [2,3]. The improvement of intelligibility can only be achieved when the visual representation or animation of vocal tract is coherent with speech sounds. Mismatched or conflicting visual and acoustic message can even decrease intelligibility, for example a /ba/ sound played over a visual representation of /va/ causes the perceived sound to be /va/, a phenomenon known as McGurk effect [4]. It is thus essential that visual and auditory modes of speech synthesis are synchronized.

Visual text-to-speech (TTS) systems have been developed for English [1], French [2] Arabic [5] and Italian [6,7].

Often text-to-speech systems and facial animation systems are developed independently and to get a system that allows visual text-to-speech synthesis in a new language several requirements need to be met. First, the TTS system for the language must be available, and it must output not only the synthesiszed audio, but also phoneme sequence and precise timings, to enable synchronization with the visual mode. Most commercial TTS systems (at least for the Windows platform) use Microsoft SAPI interface, which outputs events with phoneme identities in realtime and could be used for this purpuse. Open-source Festival [8] TTS system is also suitable for this purpuse, as it is able to provide precise time alignment of phonemes in advance. Several Croatian voices have been developed using the Festival system [9,10].On the visual side, the facial animation must support the visual representation of phonemes in the target language (i.e. visemes), or must allow definition of new visemes. ISO/IEC standard MPEG-4 Face and Body Animation (MPEG4-FBA) compliant facial animation models support the visemes for English language. The standard also provides low level parameters that can be used to define new complex facial movements and visemes for other languages.

In this article we present the system for Croatian visual text-to-speech synthesis that integrates the open source Festival speech synthesis engine with Croatian voices and MPEG4-FBA compliant visage|SDK[1] toolkit for virtual character animation. The proposed system uses a client/server architecture where the server handles auditory modality of TTS and the client handles the visual aspect. The system requires no change in the existing Croatian voices for Festival TTS, and existing applications that rely on visage|SDK and SAPI-5 for English visual TTS can be adapted very easily in order to use the new Croatian visual TTS.

The paper is organized as follows: in the next section the Croatian speech synthesis system is briefly described. An overview of visual speech synthesis is given in Section III. Details of the client/server architecture that enables Croatian visual text-to-speech synthesis are described in Section IV. Finally, we conclude with a summary and future work.

II. SPEECH SYNTHESIS

For this work two Croatian voices for the Festival text-to-speech systems were used. Festival is an open-source speech synthesis system, with facilities that allow custom voices for different languages to be built [8]. It supports a server mode which allows clients to access a Scheme command interface using TCP/IP sockets, which is used in this work to establish connection between the speech synthesis and character animation subsystems.

Our voices were built from the same corpus of recorded speech, and share between them the high-level text analysis features such as phoneset, text normalization procedures, dictionary and grapheme-to-phoneme conversion rules, but use different low-level synthesis techniques (concatenative unit selection and statistical

Support for this work was provided by the Ministry of Science, Education and Sports of the Republic of Croatia (project number 318-0361935-0852).

[1] The visage|SDK software was developed at the Human-Oriented Technologies Laboratory (HOTLab), Department of telecommunications, Faculty of electrical engineering and computing, University of Zagreb (http://hotlab.fer.hr).

parametric synthesis). The phoneset consists of 30 standard phonemes of the Croatian language, accented forms of vowels (5), the syllable forming phoneme /r/, and the silence phoneme (37 phonemes in total).

The first voice is based on concatenative unit selection method, where synthetic speech is produced by concatenating segments (units) of recorded natural speech. Specifically it is based on the clustering unit selection method [11] which restricts the search space by off-line clustering of similar speech units and searching only promising clusters at runtime. In this implementation of unit selection, the basic units of speech are phonemes. Linguistic (phonetic and prosodic) features that can be derived from text are used for clustering acoustically similar units of the same type. For each phoneme type, a classification and regression tree (CART) is built. The nodes are split according to questions pertaining to linguistic features, minimizing the mean acoustic distance between units in the resulting clusters. For example, a question may be "is the next phoneme voiced?", or "is the current phoneme the first one in a syllable?". At synthesis time, linguistic features are extracted from input text and for each phoneme the corresponding decision tree is queried to select the cluster of candidate units. The Viterbi algorithm is then used to find the optimal path through the network of candidate units. For each phoneme linguistic features that are used in CART questions were defined, such as whether the phone is a vowel or a consonant, its place of articulation, length, voicing etc.

The second voice is created using the statistical parametric synthesis technique and was built using the Festival and Festvox tools, with the clustergen [12] statistical parametric synthesis module. The higher level modules like the phoneset, lexicon and grapheme to phoneme rules were kept the same as in the previously described unit selection voice. To train the context-dependent HMMs, acoustic features (MFCCs, voicing information and log F0) were first extracted from the data. Each context dependent phoneme is modeled using a three state HMM with the set of parameters consisting of 24 MFCCs and log F0, extracted at 5 ms intervals. Duration of each HMM state is predicted using a separate CART tree. The HMM training stage requires HMM state level segmentation of speech, whereas the unit selection voice required phone level segmentation, so the data needed to be segmented again. The state segment labels were generated using the Festvox scripts and the EHMM recognizer. Finally, the HMM parameters and duration CART trees were estimated from the aligned utterances and extracted features. The resulting voice takes up 10.2 MB. Full details of the voices can be found in [10].

III. FACIAL ANIMATION

Facial animation for use in visual text-to-speech can be based on pre-recorded key-frame images of faces uttering various sounds, which are played back in sequence determined by the phoneme sequence of the speech synthesizer output. This is a similar approach as in concatenative speech synthesis, described in Section II.

Smoother transitions between lip gestures and coarticulation effects are more easily achieved with parametric models of faces. Such models, 2D or 3D, have a mathematical representation of relevant facial features, and sets of parameters that allow those features to be controlled. The parametric model allows generation of nearly infinite facial and lip configurations and easy interpolation between configurations, which allows continuous and smooth animation of a talking face without abrupt jumps that may occur in the non-parametric key-frame based animation.

Additionally, it is shown that certain amount of stylization or even cartoonish or non-human apperance of virtual characters, which is enabled by paramtric models, is preferable to faces that strive to be photo-realistic [3].

The models may differ in the chosen parameters that can be controlled as well as in the mathematical representation of the model. The model proposed in [13]is based on face muscles and strives to be anatomically correct and produce natural and realistic facial movement. Other models such as [1] rely on surface characteristics of the skin and do not attempt to model the underlying causes of possible facial actions, with the goal of duplicating the visible articulation of speech production. A 3D polygon mesh of the face and tongue is used, and most of the parameters in this case move the vertices of the wireframe mesh model, either by rotation or translation, or perform scaling and interpolation of different facial regions.

ISO/IEC standard MPEG-4 FBA (ISO14496) specifies a set of parameters for facial and body animation of virtual characters. A group of parameters define the shape (mesh) and texture of the model itself (the Face Definition Parameters – FDPs and Body Definition Parameters, BDPs). Other group of parameters is used to drive the animation of virutal character's body and face. These are the *face animation parameters* (FAPs) which control specific facial feature points and *body animation parameters*, or BAPs, corresponding to degrees of freedom in the skeleton model of the body. The standard defines 66 low level FAPs corresponding to distances between key facial features and each controls a specific feature point. The MPEG4-FBA standard additionally defines also two high level FAPs, expression and viseme, with six predefined expressions and 14 predefined visemes. The expressions have intensity values that can be set, and visemes can be formed as a cross between two of the predefined visemes with a blending factor between them that sets how much influence each viseme has [14]. The facial animation is controlled by specifying the values of FAPs for each frame of animation. Sometimes a mapping between parameters specific to one system and MPEG4-FBA parameters can be established, thus making the system MPEG4 – FBA compliant.

A number of software tools include facial models which are compliant with MPEG-4 FBA specification, e.g. visage|SDK [15] or open-source Greta [16]. In this work the visage|SDK system is used for the facial animation component.

Visage|SDK is a set of software libraries with a C++ API covering a range of character animation and computer vision applications, such as face and body animation, lip sync, facial motion tracking and cloning. It also includes tools for offline creation of face models and morph target

cloning [15]. Different sources of FBAPs like files, procedural animation or tracking can be used simultaneously to drive the caracter animation. This is enabled by the system's layered modular architecture where low level components provide interface to the character model and play FBA actions. The high level components that generate the FBAPs are in separate modules and communicate with lower layers through a common interface. An example of such high-level module is the visual speech synthesis module driven by Microsoft SAPI-5 speech synthesis. This module, implemented as a C++ class, converts the SAPI-5 output to a sequence of FBA visemes which can be applied to a face model for animation. Our system should provide the same facilities as the SAPI-5 system, but for Croatian speech synthesis which uses the Festival speech synthesis system. One of the goals for our system was to develop a system which is compatible with the visage|SDK SAPI-5 visual speech synthesis, so that a user who wishes to use Croatian voices in Festival instead of SAPI-5 can do it with minimal changes in the application code. The client part of the system is thus implemented as a C++ class that can be used as a drop-in replacement for the SAPI-5 based module.

IV. INTEGRATION

The proposed system integrates speech synthesis component realized using Festival and facial animation from visage|SDK. The architecture of the proposed system is shown in Figure 1. The system consists of two main parts: the speech synthesis server, and a client application that accesses it. The two parts of the system communicate via TCP/IP sockets, typically on a local machine. The synthesis is initiated by the client application that uses visage|SDK for facial animation. Input text is encapsulated in a Scheme command and passed via TCP to the Festival server. The server synthesizes the requested utterance, signals the client that it is ready to play back the generated speech and returns the phoneme sequence and their timings relative to the beginning of the utterance. From this information the viseme timings are calculated. After visage|SDK receives the phoneme timings, it requests the Festival server to play the utterance and starts playing the facial animation at the same time, thus achieving synchronization of facial animation and speech.

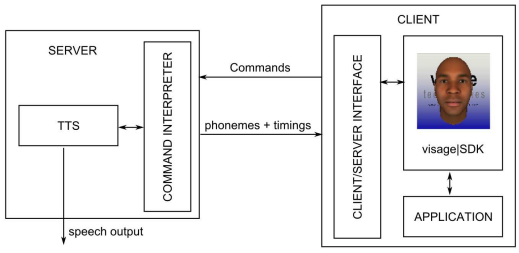

Figure 1. Architecture of the visual speech synthesis system.

The client part is implemented as a C++ class that has the same interface as the existing visage|SDK visual text-to-speech class which uses SAPI-5 synthesis. Existing applications that use visage|SDK for English visual TTS can thus be easily adapted to use Croatian synthesis by simply changing the class of the synthesis object.

The usage of Festival system may offer an advantage over SAPI-5 based synthesis, as it provides phoneme timings information before the speech is output. This should in future enable easier synchronization of gestures that last more than the duration of one phoneme (e.g. hand waving, head tilting, etc.). Knowledge of exact phoneme timings before the speech is heard allows such actions to be planned in advance from the same data the speech synthsizer uses. In contrast, SAPI-5 based synthesizer outputs viseme, sentence and word boundaries in real time, requiring the phoneme durations to be separately approximated [17].

The 14 visemes defined by the MPEG-4 FBA standard and implemented in visage|SDK provide coverage for all English phonemes, but do not provide full coverage for all languages. It was necessary to see if a mapping from Croatian phonemes to MPEG-4 FBA visemes could be established. The English phoneme set only partially overlaps with Croatian phoneme set used in our speech synthesis system, and importantly not all Croatian phonemes exist in English, e.g. /ts/ or /ɲ/. First the correspondence between matching English phonemes/visemes and Croatian ones were found, then the remaining Croatian phonemes were mapped to the closest viseme. In some cases, like /ts/ and /dʒ/ the corresponding English viseme matches the Croatian phoneme even though those phonemes do not occur in English. For others, like /ɲ/ (nj) and /ʎ/ (lj) the mapping is to the closest available English viseme. If found necessary by further testing, these missing visemes could be defined in terms of low level FAPs described in Section III. The proposed mapping is shown in Table 1 where for all Croatian phonemes used by the TTS their corresponding visemes are given as well as examples of words in Croatian and English where these phonemes occur, with their phonetic transcriptions.

V. CONCLUSION AND FUTURE WORK

We have presented our system for visual speech synthesis for Croatian. The system integrates Festival speech synthesis system with MPEG4-FBA compatible face and body animation component visage|SDK using a client/server architecture. To enable the synchronization of speech with lip movements a mapping from phonemes used in Croatian TTS to English visemes defined in MPEG-4 FBA standard is proposed. Some phonemes in Croatian do not appear in English and mappings for those phonemes is approximate. Further work should be done to verify if the mapping is adequate, or if custom visemes synthesiszed from low level FAPs should be provided instead.

***Abstract*—In this work, a mathematical structure based on the functional analysis for studying the existence of fuzzy optimal control, which the feedback is evaluated through approximate reasoning using the center of sums defuzzification method on IF-THEN fuzzy rules. The framework consists of two propositions: To guarantee the convergence of optimal solution, a set of fuzzy membership functions (admissible fuzzy controller) which are selected out of continuous function space is compact metrizable. And assuming approximate reasoning to be a functional on the set of membership functions, its continuity is proved. Then, we show the existence of a fuzzy controller which minimize (maximize) the integral performance function of the nonlinear feedback fuzzy system.**

I. Introduction

In the beginning, the fuzzy membership functions (fuzzy sets), which represent input and output states in optimal control system, were decided on the basis of the experience of experts in each peculiar plant. Recently many acquisition techniques and turning methods of them have been proposed [5] [6].

The authors have been studying to establish the automatic and computational determination of fuzzy membership functions, which give optimal controls in fuzzy control system. We also have been studying to find algorithms that compute optimal solutions. The optimization of fuzzy control discussed in this paper is different from conventional method such as classical control and modern control [4]. We consider fuzzy optimal control problems as problems of finding the minimum (maximum) value of the performance function with feedback law constructed by approximate reasoning with the way of functional analysis [7]. The author discussed various approximate reasoning, Mamdani method [1], the product sum gravity method [3] and TSK method etc., in previous work. Although these methods use the center of gravity defuzzification method which is the most prevalent, many defuzzification methods are proposed in recent years. The center of sums method among the many methods is focused in this study. This method is similar to the weighted average method (Nakamori model) and the height method which the authors analysed in the previous work [10] [11]. However, the weighted average method and the height method need the membership function to be symmetric, and the area of the membership function is not particularly important.

This work is organized in the following way: A nonlinear feedback control using approximate reasoning is presented. Then, the approach to the control based on functional analysis is discussed, and some propositions are obtained. Finally, the mathematical properties are applied to optimal control problem.

II. Fuzzy Control

A. Feedback System

In this paper we assume that the feedback part in this system is calculated by approximate reasoning through the center of sums defuzzification method. Using an idea and framework mentioned in the following section III and IV, the existence of optimal control based on fuzzy rules is designed.

$\mathbb{R}^n$ denotes the n-dimensional Euclidean space with the usual norm $\|\cdot\|$. Let $f(v_1, v_2) : \mathbb{R}^n \times \mathbb{R} \to \mathbb{R}^n$ be a (nonlinear) vector valued function which is Lipschitz continuous. In addition, assume that there exists a constant $M_f > 0$ such that

$$\|f(v_1, v_2)\| \leq M_f \left(\|v_1\| + |v_2| + 1\right)$$

for all $(v_1, v_2) \in \mathbb{R}^n \times \mathbb{R}$. Consider a system given by the following state equation:

$$\dot{x}(t) = f(x(t), u(t)),$$

where $x(t)$ is the state and the control input $u(t)$ of the system is given by the state feedback

$$u(t) = \rho(x(t)).$$

For a sufficiently large $r > 0$, $B_r = \{x \in \mathbb{R}^n : \|x\| \leq r\}$ denotes a bounded set containing all possible initial states x_0 of the system. Let T be a sufficiently large final time. Then, we have

Proposition 1: Let $\rho : \mathbb{R}^n \to \mathbb{R}$ be a Lipschitz continuous function and $x_0 \in B_r$. Then, the state equation

$$\dot{x}(t) = f(x(t), \rho(x(t))) \tag{1}$$

has a unique solution $x(t, x_0, \rho)$ on $[0, T]$ with the initial condition $x(0) = x_0$ such that the mapping

$$(t, x_0) \in [0, T] \times B_r \mapsto x(t, x_0, \rho)$$

is continuous.

For any $r_2 > 0$, denote by Φ the set of Lipschitz continuous functions $\rho : \mathbb{R}^n \to \mathbb{R}$ satisfying

$$\sup_{u \in \mathbb{R}^n} |\rho(u)| \leq r_2.$$

Then, the following a) and b) hold.

a) For any $t \in [0,T], x_0 \in B_r$ and $\rho \in \Phi$, $\|x(t,x_0,\rho)\| \le r_1$, where

$$r_1 = e^{M_f T} r + (e^{M_f T} - 1)(r_2 + 1). \tag{2}$$

b) Let $\rho_1, \rho_2 \in \Phi$. Then, for any $t \in [0,T]$ and $x_0 \in B_r$,

$$\|x(t,x_0,\rho_1) - x(t,x_0,\rho_2)\| \le \frac{e^{L_f\,(1+L_{\rho_1})t} - 1}{1 + L_{\rho_1}} \sup_{u \in [-r_1,r_1]^n} |\rho_1(u) - \rho_2(u)|, \tag{3}$$

where L_f and L_{ρ_1} are the Lipschitz constants of f and ρ_1 [9].

B. Approximate Reasoning Using Center of Sums Method

In this section we briefly explain the approximate reasoning using the center of sums method [15] which decides feedback output in the previous nonlinear system for the convenience of the reader.

Assume the feedback law ρ consists of the following m IF-THEN type fuzzy control rules.

$$\text{RULE } i\text{:} \quad IF\ x_1\ is\ A_{i1}\ and\ \dots\ and\ x_n\ is\ A_{in}$$
$$THEN\ y\ is\ B_i \quad (i = 1,2,\dots,m) \tag{4}$$

Here, m is the number of fuzzy production rules, and n is the number of premise variables $x_1, x_2, \dots, x_n$. Let $\mu_{A_{ij}}$ $(i = 1,2,\dots,m;\ j = 1,2,\dots,n)$ be membership functions defined on a certain closed interval of the fuzzy set A_{ij}. Let μ_{B_i} $(i = 1,2,\dots,m)$ be membership functions defined on a certain closed interval of the fuzzy set B_i. For simplicity, we write "IF" and "THEN" parts in the rules by the following notation:

$$\mathcal{A}_i = (\mu_{A_{i1}}, \dots, \mu_{A_{in}}) \quad (i = 1, \dots, m),$$
$$\mathcal{A} = (\mathcal{A}_1, \dots, \mathcal{A}_m), \quad \mathcal{B} = (\mu_{B_1}, \dots, \mu_{B_m}).$$

Then, the IF-THEN type fuzzy control rules (4) is called a fuzzy controller, and is denoted by $(\mathcal{A}, \mathcal{B})$. In the rules, the tuple of premise variable $x = (x_1, x_2, \dots, x_n)$ is called an input information given to the fuzzy controller $(\mathcal{A}, \mathcal{B})$, and y is called an control variable.

Mamdani method [1] is widely used in fuzzy controls because of its simplicity and comprehensibility. Nakamori fuzzy model (the weighted average method) [2] does not infer each rule, and defines the inference result of all rules as a weighted average of agreement degree. The following center of sums method is similar to the weighted average method except that the weight is the area instead of the agreement degree of premise part. This method is faster than many defuzzification methods and not restricted to symmetrical membership functions.

In this study, when an input information $x = (x_1, x_2, \dots, x_n) \in \mathbb{R}^n$ is given to the fuzzy controller $(\mathcal{A}, \mathcal{B})$ in other words, the IF-THEN rules (4), then one can obtain the amount of operation from the controller through the following procedures:

Procedure 1: The degree of each rule i is calculated by

$$\alpha_{\mathcal{A}_i}(x) = \bigotimes_{j=1}^{n} \mu_{A_{ij}}(x_j) \quad (i = 1,2,\dots,m).$$

Here, $\otimes$ means scaling down calculation "product $\prod$" or clipping calculation "minimum $\bigwedge$".

Procedure 2: The inference result of i-th rule is calculated by

$$\beta_{\mathcal{A}_i B_i}(x,y) = \alpha_{\mathcal{A}_i}(x) \otimes \mu_{B_i}(y) \quad (i = 1,2,\dots,m).$$

Procedure 3: The center of sums method.

$$\rho_{\mathcal{AB}}(x) = \frac{\sum_{i=1}^{m} \bar{y}_i \int \beta_{\mathcal{A}_i B_i}(x,y)dy}{\sum_{i=1}^{m} \int \beta_{\mathcal{A}_i B_i}(x,y)dy}.$$

Here, $\bar{y}_i$ is the defuzzified value of individual fuzzy set in consequent part of i-th rule given by

$$\bar{y}_i = \frac{\int y \mu_{B_i}(y)dy}{\int \mu_{B_i}(y)dy} \quad (i = 1,2,\dots,m).$$

This is the centroid of the membership function.

III. Compactness of a Set of Membership Functions

In this section, we introduce two sets of fuzzy membership functions and study their topological properties. Then we can show that a set of admissible fuzzy controllers is compact and metrizable with respect to an appropriate topology on fuzzy membership functions.

In the following fix $r > 0$, a sufficiently large $r_2 > 0$ and a final time T of the control (1). Put r_1 be the positive constant determined by (2). We also fix $\Delta_{ij} > 0$ $(i = 1,2,\dots,m;\ j = 1,2,\dots,n)$. Let $C[-r_1, r_1]$ and $C[-r_2, r_2]$ be the Banach space of all continuous real functions on $[-r_1, r_1]$ and $[-r_2, r_2]$ respectively. We consider the following two sets of fuzzy membership functions.

$$F_{\Delta_{ij}} = \{\mu \in C[-r_1,r_1] : 0 \le \mu(x) \le 1 \text{ for } \forall x \in [-r_1,r_1],$$
$$|\mu(x) - \mu(x')| \le \Delta_{ij}|x - x'| \text{ for } \forall x, x' \in [-r_1,r_1]\}$$

and

$$G = \{\mu \in C[-r_2,r_2] : 0 \le \mu(y) \le 1 \text{ for } \forall y \in [-r_2,r_2]\}.$$

The set $F_{\Delta_{ij}}$, which is more restrictive than G, contains asymmetric triangular, trapezoidal and bell-shaped fuzzy membership functions with gradients less than positive value Δ_{ij}. Consequently, if $\Delta_{ij} > 0$ is taken large enough, $F_{\Delta_{ij}}$ contains almost all fuzzy membership functions which are used in practical applications. We assume that the fuzzy membership function $\mu_{A_{ij}}$ in "IF" parts of the rules (4) belongs to the set $F_{\Delta_{ij}}$. On the other hand, we also assume that the fuzzy membership function μ_{B_i} in "THEN" parts of the rules (4) belongs to the set G. In the following, we endow the space $F_{\Delta_{ij}}$ and G with the norm topology on $C[-r_1, r_1]$ and $C[-r_2, r_2]$ respectively. Then for all $i = 1,2,\dots,m$ and

$j = 1, 2, \ldots, n$, $F_{\Delta_{ij}}$ is a compact subset of $C[-r_1, r_1]$, and G is also compact [8]. Put

$$\mathcal{F} = \prod_{i=1}^{m} \left\{ \prod_{j=1}^{n} F_{\Delta_{ij}} \right\} \times G^m,$$

where G^m denotes the m times Cartesian product of G. Then, every element $(\mathcal{A}, \mathcal{B})$ of $\mathcal{F}$ is a fuzzy controller given by the IF-THEN type fuzzy control rules (4). By the Tychonoff theorem we can have readily:

Proposition 2: $\mathcal{F}$ is compact and metrizable with respect to the product topology on $C[-r_1, r_1]^{mn} \times C[-r_2, r_2]^m$.

To avoid making the denominator of the fractional expressions in the procedure 3 in the previous section equal to 0, for any $\delta > 0$, $\sigma > 0$, we consider the set:

$$\mathcal{F}_{\delta\sigma} = \Bigg\{ (\mathcal{A}, \mathcal{B}) \in \mathcal{F} : \forall i = 1, 2, \ldots, m, \int_{-r_2}^{r_2} \mu_{B_i}(y) dy \geq \delta$$

$$\forall x \in [-r_1, r_1]^n, \sum_{i=1}^{m} \int_{-r_2}^{r_2} \beta_{\mathcal{A}_i B_i}(x, y) dy \geq \sigma, \Bigg\}, \quad (5)$$

which is a slight modification of $\mathcal{F}$. If δ and σ are taken small enough, it is possible to consider $\mathcal{F} = \mathcal{F}_{\delta\sigma}$ for practical applications. We say that an element $(\mathcal{A}, \mathcal{B})$ of $\mathcal{F}_{\delta\sigma}$ is an admissible fuzzy controller. Then, we have the following

Proposition 3: The set $\mathcal{F}_{\delta\sigma}$ of all admissible fuzzy controllers is compact and metrizable with respect to the product topology on $C[-r_1, r_1]^{mn} \times C[-r_2, r_2]^m$.

Proof: We first note that a sequence $\{(\mathcal{A}^k, \mathcal{B}^k)\} \subset \mathcal{F}$ converges to $(\mathcal{A}, \mathcal{B})$ in $\mathcal{F}$ for the product topology if and only if, for each $(i = 1, 2, \ldots, m)$,

$$\|\alpha_{\mathcal{A}_i^k} - \alpha_{\mathcal{A}_i}\|_\infty = \sup_{x \in [-r_1, r_1]^n} |\alpha_{\mathcal{A}_i^k}(x) - \alpha_{\mathcal{A}_i}(x)| \to 0$$

and

$$\|\mu_{B_i^k} - \mu_{B_i}\|_\infty = \sup_{y \in [-r_2, r_2]} |\mu_{B_i^k}(y) - \mu_{B_i}(y)| \to 0$$

Assume that a sequence $\{(\mathcal{A}^k, \mathcal{B}^k)\}$ in $\mathcal{F}_{\delta\sigma}$ converges to $(\mathcal{A}, \mathcal{B}) \in \mathcal{F}$. Fix $x \in [-r_1, r_1]^n$. Then, it is easy to show that

$$\forall i = 1, 2, \ldots, m, \ \int_{-r_2}^{r_2} \mu_{B_i}(y) dy = \lim_{k \to \infty} \int_{-r_2}^{r_2} \mu_{B_i^k}(y) dy \geq \delta$$

and

$$\sum_{i=1}^{m} \int_{-r_2}^{r_2} \beta_{\mathcal{A}_i B_i}(x, y) dy = \lim_{k \to 0} \sum_{i=1}^{m} \int_{-r_2}^{r_2} \beta_{\mathcal{A}_i^k B_i^k}(x, y) dy \geq \sigma.$$

And this implies $(\mathcal{A}, \mathcal{B}) \in \mathcal{F}_{\delta\sigma}$. Therefore, $\mathcal{F}_{\delta\sigma}$ is a closed subset of $\mathcal{F}$, and hence it is compact metrizable. ■

IV. Lipschitz Continuity of Approximate Reasoning

In this paper, for any tuple $(\mathcal{A}, \mathcal{B}) \in \mathcal{F}_{\delta\sigma}$, we define the feedback function $\rho_{\mathcal{AB}}$ in section II on the basis of the rules using the center of sums method.

$$\rho_{\mathcal{AB}}(x) = \frac{\sum_{i=1}^{m} \bar{y}_i \int_{-r_2}^{r_2} \beta_{\mathcal{A}_i B_i}(x, y) dy}{\sum_{i=1}^{m} \int_{-r_2}^{r_2} \beta_{\mathcal{A}_i B_i}(x, y) dy}.$$

where

$$\bar{y}_i = \frac{\int_{-r_2}^{r_2} y \mu_{B_i}(y) dy}{\int_{-r_2}^{r_2} \mu_{B_i}(y) dy}$$

and

$$\beta_{\mathcal{A}_i B_i}(x, y) = \bigotimes_{j=1}^{n} \mu_{A_{ij}}(x_j) \otimes \mu_{B_i}(y) \quad (i = 1, 2, \ldots, m).$$

Proposition 4: Let $(\mathcal{A}, \mathcal{B}) \in \mathcal{F}_{\delta\sigma}$. Then, the following 1) and 2) hold.

1) $\rho_{\mathcal{AB}}$ is Lipschitz continuous on $[-r_1, r_1]^n$.

2) $|\rho_{\mathcal{AB}}(x)| \leq r_2$ for all $x \in [-r_1, r_1]^n$.

Proof: 1) The mapping $\alpha_{\mathcal{A}_i}$ $(i = 1, 2, \ldots, m)$ is Lipschitz continuous on $[-r_1, r_1]^n$ [8] [10]. For any $x, x' \in [-r_1, r_1]^n$, we have

$$|\rho_{\mathcal{AB}}(x) - \rho_{\mathcal{AB}}(x')|$$

$$\leq \frac{4m{r_2}^2}{\sigma^2} \sum_{i=1}^{m} \int_{-r_2}^{r_2} |\alpha_{\mathcal{A}_i}(x) \otimes \mu_{B_i}(y) - \alpha_{\mathcal{A}_i}(x') \otimes \mu_{B_i}(y)| dy$$

$$\leq \frac{8m^2 {r_2}^3 \Delta_\alpha}{\sigma^2} \|x - x'\|$$

where

$$\Delta_\alpha = n \sum_{i=1}^{m} \max_{j=1,2,\ldots,n} \Delta_{ij}.$$

Then Lipschitz continuity of $\rho_{\mathcal{AB}}$ on $[-r_1, r_1]^n$ is proved.

2) The proof is omitted ■

Let $(\mathcal{A}, \mathcal{B})$ be a fuzzy controller given by the IF-THEN type fuzzy control rules (4). We say that the system (1) is a fuzzy feedback system if the control function $u(t)$ is given by the state feedback $u(t) = \rho_{\mathcal{AB}}(x(t))$, where $\rho_{\mathcal{AB}}(x(t))$ is the amount of operation from the fuzzy controller $(\mathcal{A}, \mathcal{B})$ for an input information $x(t)$.

It needs that the domain of bounded Lipschitz function $\rho_{\mathcal{AB}}$ is expanded from $[-r_1, r_1]^n$ to $\mathbb{R}^n$ to adopt the previous proposition 4 to the proposition 1. It is possible without increasing its Lipschitz constant and bound though details are omitted. Then the state equation (1) for the feedback law $\rho_{\mathcal{AB}}$ has a unique solution $x(t, x_0, \rho_{\mathcal{AB}})$ with the initial condition $x(0) = x_0$ [12]. Consequently, in the following the extension Lipschitz function is written as $\rho_{\mathcal{AB}}$ without confusion.

V. Minimize the Performance Function

The performance index of this fuzzy feedback control system is evaluated with the following integral performance function:

$$J = \int_{B_r} \int_0^T w(x(t,\zeta,\rho_{\mathcal{AB}}), \rho_{\mathcal{AB}}(x(t,\zeta,\rho_{\mathcal{AB}})))dtd\zeta, \quad (7)$$

where $w : \mathbb{R}^n \times \mathbb{R} \to \mathbb{R}$ is a positive continuous function. The following theorem guarantees the existence of a fuzzy controller $(\mathcal{A}, \mathcal{B})$ (IF-THEN type fuzzy control rules) which minimizes the previous performance function (7).

Theorem 1: The mapping

$$(\mathcal{A}, \mathcal{B}) \mapsto \int_{B_r} \int_0^T w(x(t,\zeta,\rho_{\mathcal{AB}}), \rho_{\mathcal{AB}}(x(t,\zeta,\rho_{\mathcal{AB}})))dtd\zeta$$

has a minimum (maximum) value on the compact metric space $\mathcal{F}_{\delta\sigma}$ defined by (5).

Proof: Since compactness of $\mathcal{F}_{\delta\sigma}$ is already derived by proposition 3, it is sufficient to prove that the performance function is continuous on $\mathcal{F}_{\delta\sigma}$. Routine calculation gives the estimate

$$\sup_{x\in[-r_1,r_1]^n} |\rho_{\mathcal{A}^k\mathcal{B}^k}(x) - \rho_{\mathcal{AB}}(x)|$$

$$\leq \frac{4mr_2{}^2}{\sigma^2} \sum_{i=1}^{m} \Big\{ 2r_2 \big(\|\alpha_{\mathcal{A}_i^k} - \alpha_{\mathcal{A}_i}\|_\infty + \|\mu_{B_i^k} - \mu_{B_i}\|_\infty \big)$$

$$+ |\bar{y_i}^k - \bar{y_i}| \Big\}.$$

Assume that $(\mathcal{A}^k, \mathcal{B}^k) \to (\mathcal{A}, \mathcal{B})$ in $\mathcal{F}_{\delta\sigma}$ and fix $(t, \zeta) \in [0, T] \times B_r$. For all $i = 1, 2, \ldots, m$, the mapping $\alpha_{\mathcal{A}_i}$ and the defuzzified value $\bar{y_i}$ are continuous on $\mathcal{F}_{\delta\sigma}$ [8] [11]. Then it follows from the estimate above that

$$\lim_{k\to\infty} \sup_{x\in[-r_1,r_1]^n} |\rho_{\mathcal{A}^k\mathcal{B}^k}(x) - \rho_{\mathcal{AB}}(x)| = 0. \quad (8)$$

Hence, by 2) of proposition 1, we have

$$\lim_{k\to\infty} \|x(t,\zeta,\rho_{\mathcal{A}^k\mathcal{B}^k}) - x(t,\zeta,\rho_{\mathcal{AB}})\| = 0. \quad (9)$$

Further, it follows from (8), (9) and 1) of proposition 1 that

$$\lim_{k\to\infty} \rho_{\mathcal{A}^k\mathcal{B}^k}(x(t,\zeta,\rho_{\mathcal{A}^k\mathcal{B}^k})) = \rho_{\mathcal{AB}}(x(t,\zeta,\rho_{\mathcal{AB}})). \quad (10)$$

Noting that $w : \mathbb{R}^n \times \mathbb{R} \to \mathbb{R}$ is positive and continuous, it follows from (9), (10) and the Lebesgue's dominated convergence theorem [14] that the mapping is continuous on the compact metric space $\mathcal{F}_{\delta\sigma}$. Thus it has a minimum (maximum) value on $\mathcal{F}_{\delta\sigma}$, and the proof is complete. ■

VI. Conclusion

This paper presents the analysis of the center of sums defuzzification model. Lipschitz continuity on the premise variables and the continuity on the set of membership functions of its approximate reasoning are proved. Lipschitz continuity is one of the sufficient conditions for the existence of the unique solution of the state equation in the nonlinear feedback control. On the other, the continuity on the set of membership functions guarantees the existence of a rule set, in other words a tuple of membership functions, which minimize the integral cost function with compactness of the set of membership functions. The compact membership function set $\mathcal{F}_{\delta\sigma}$ in this paper includes the class of triangular, trapezoidal, and bell-shaped functions used in an application generally. It is recognized that in various applications it could be a useful tool in analyzing the convergence of fuzzy control rules modified recursively.

Abstract - Ever increasing number of patents makes impossible to find and analyze relevant documents manually. Various software tools have been developed in the patent field. They could analyze individual patents as well as patent portfolios; retrieve patents and make basic statistics as well as visualize, map and landscape the same data. The essential function any tool should provide is patent clustering. There have been many different clustering approaches. In this paper we compare performances of k-means, the neural-gas, fuzzy c-means and ronn clustering technique when used on patent data set that was also clustered by the experts.

I. INTRODUCTION

Besides being a way to protect IP, patents are an extremely valuable source of technical information. Approximately 80% of all scientific and technical information can be found only in patent documents [1]. In addition to technical data, patent document provides legal as well as business and public policy relevant information. In order to completely utilise the potential of patent documents and extract valuable content from them, it is necessary to analyse structured as well as unstructured data. This means to collect and analyse basic statistics for patent documents, based on information from the front page (bibliographic data, data in a structured form), but also to analyse free text (unstructured text data) in the body of the document and provide meaningful feedback to users. The former task is easier to complete. It is based on availability of patent databases and application of well developed routines for statistical analyses. However, the possibility to automatically analyse unstructured text data would offer much more value to users and potential to save huge resources (time and money). This fact motivated design of numerous software tools in this field. The majority of them follow standard sequence of steps: text mining, multidimensional data scaling, clustering and visualisation.

Text mining is used as a data-processing and information-extracting tool. It transforms raw data (unstructured text) into structured data. In order to extract useful information from collection of documents, text mining algorithms identify and extract keyword and explore patterns among them. The term frequency – inverse document frequency (tf-idf) is often used as a weighting scheme for keyword extraction in text mining. Based on extracted keywords the high dimensional matrix is formed. Using the multidimensional scaling (MDS) to explore the similarities or dissimilarities in data, high-dimensional data contained in the patent documents are transformed into much lower dimensionality space (2D or 3D) maintaining the most similar structure to the original. After multidimensional scaling, clustering is performed in order to find undetected or unexpected patterns of concentrations embedded in data sets. The clustering task consists in grouping the given unlabelled collection of patent documents into meaningful clusters without any prior information. The clustered patent data space can be presented and visualized with respect to various contexts in order to allow the human better understanding of and interaction with the data. This process is presented at Fig. 1.

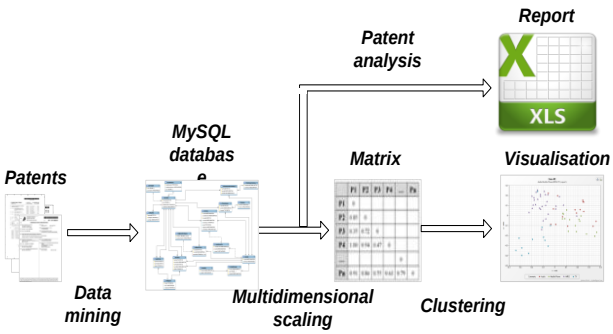

Figure 1. Analyzes of unstructured patent data

The focus of our paper is on clustering issue. Patent clustering is essential function any tool for patent data visualisation should provide. The task of clustering is to assign objects into similar groups and reveal conceptual, spatial and/or temporal, and representational aggregations. There have been many different clustering approaches. Most of them are application-dependent, and each clustering method has its own strengths and weaknesses. In this paper we compare performances of k-means, the neural-gas, fuzzy c-means and ronn clustering technique when used on patent data set that was also clustered by the experts.

The remainder of the paper is organized as follows. In Section 2, we briefly introduce clustering techniques. Section 3 describes dataset and methodology used in experiment, while Section 4 presents results and

discussion. Finally, in Section 5 we conclude with a summary of our results and a discussion of further research.

II. CLUSTERING

Clustering is to partition a set $O = \{O_1, O_2, \ldots, O_n\}$ of objects into homogenous clusters maximizing intra-cluster similarity while minimizing inter-cluster similarity. Clusters are formed without any prior information about objects that are grouped. Any labels associated with objects are obtained solely from the data. Clustering helps identify important topics or concepts from a set of documents and helps bring out undetected or unexpected patterns of concentrations embedded in databases. It is one of the most popular and frequently used approaches for forming meaningful groups from unlabeled objects. Clustering is a core technique in many disciplines including machine learning and AI. It has been widely used in various decision making processes.

As the number of patents increases and volume of data grows it is impossible to successfully analyze any set of patents without clustering. Therefore, clustering is the essential function any patent analysis tool should provide. The following section briefly presents four unsupervised learning algorithms that have been analyzed in this paper: k-means, fuzzy c-means, neural gas and re-organizing neural network (ronn).

A. K-means Clustering

The k-partitioning attempts to detect k optimal clusters by an iterative relocation method based on an optimization function. The most popular k-clustering is k-means clustering [2]. K-means clustering segments the n observations into k clusters in which each observation belongs to the cluster with the nearest mean. It uses the mean (centroid) as the representative of a cluster. One of main strengths of k-means clustering is its scalability. K-means clustering problem is regarding complexity NP-hard [14] however there are efficient approximate solutions [15].

B. Fuzzy c-means Clustering (fcm)

Based Fuzzy clustering is very similar to k-means, difference is that each object has a degree of belonging to clusters, rather that belonging to just one cluster. Thus, objects on the edges of the cluster are in the cluster in somewhat lesser degree than objects inside the cluster. Fuzzy c-means is an important algorithm for image processing used for clustering of objects inside the image [3]. Complete overview and comparison of fuzzy clustering is presented in [4].

C. Re-Organising Neural Network (ronn)

The algorithm proposed for learning is called Re-Organising Neural Network (ronn). The ronn algorithm is an iterative learning procedure, which performs iterative adjustments of node-coordinates, in the manner of k-means algorithm, until the nodes stabilise relatively in their current positions, and simultaneously shifting of those nodes that turn out to be dead-nodes into better positions. Complete overview of ronn algorithm is presented in [5].

D. Neural Gas

The Neural Gas is an unsupervised learning technique that allows the uniform placement of representative prototypes in the vector space. This algorithm determines prototypes in such a way that the Euclidean distance between data vectors and the prototype vectors is minimal. The neural gas is a relatively simple algorithm for finding optimal data representations and represents robust alternative for the k-means clustering. It is widely used where compression is a problem, like image processing or pattern recognition [6]. A more detailed description of the algorithm is given in [7].

III. DATASET AND METHODOLOGY

A. Methodology

In order to compare performances of k-means, the neural-gas, fuzzy c-means and ronn clustering technique, we compared their results with experts created clusters. Although artificial intelligence and machine learning significantly improved over last few years, patent analysis and clustering by human experts has remained the safest and the most accurate [8]. Therefore, we decided to compare results of clustering techniques to experts' results. In order to do that, we developed methodology for both mathematical and visual comparison of clustering techniques using Matlab.

Matlab code consists of four functions, one for each technique (k-means, fuzzy c-means, ronn, neural gas). For mathematical comparison Matlab code loads array from MySQL base and compares output of each function.

Beside mathematical comparison we used Matlab code for visual comparison. Output of each function is array clustered in accordance with clustering algorithm. These arrays were used as input for visualisation and they allowed visual comparison.

B. Dataset

In this study we use 72 US patents. All patents have been invented by the same company and cover field of consumer electronics. Five experienced engineers, first separately and after that by round table discussion, clustered by consensus these patents in the following four groups: Audio (16 patents), Mobile phone (15 patents), Video (29 patents) and TV set (12 patents).

IV. RESULTS AND DISCUSSION

This section presents results for both visual and mathematical comparison of clustering technique.

Visual comparison offer opportunity to compare two or more landscape patents maps. This is done by overlapping them and finding differences in patent location on the maps.

To visually compare results of experts and clustering algorithms we first created patent landscape maps. Each cluster is presented with different symbol. Audio group is presented by rhomb, mobile phone cluster by square, video by triangle, and TV set by reverse triangle. After patent landscapes are created for each clustering technique they were overlapped by patent landscape map created from experts' results. In this way it was easy to find

differences in patent location on the maps. Results are shown on Fig 2 for honn algorithm and on Fig 3 for k-means algorithm. Bolded marks represent mismatch between clusters made by experts and clusters made by specific clustering algorithm.

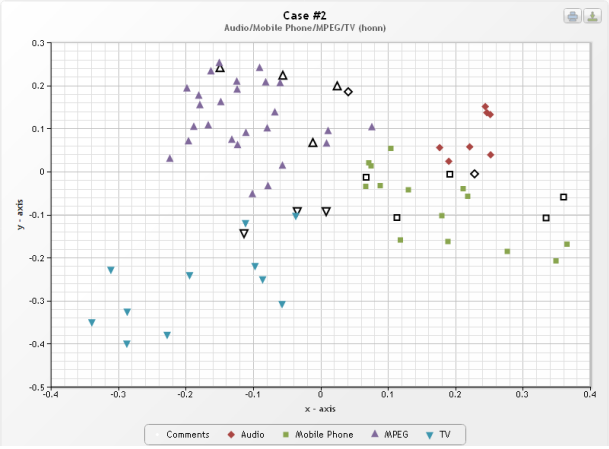

Figure 2. Overlap: expert and ronn algorithm landscape maps

Similarly, the others clustering techniques were compared. The graphical results are not presented here but were very similar.

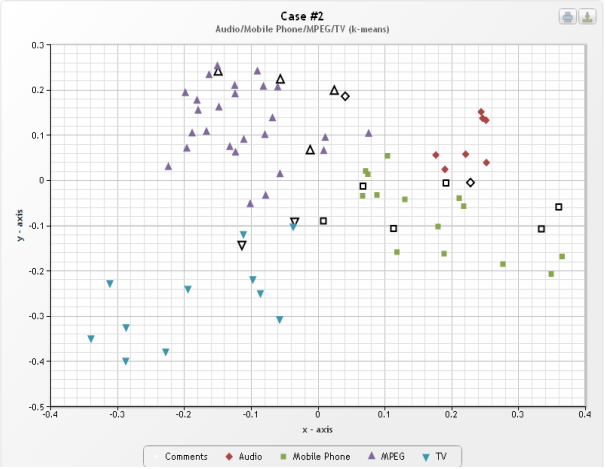

Figure 3. Overlap: expert and k-means algorithm landscape maps

Classification accuracy for four different algorithms is calculated by Matlab code and results are presented in Table I and Table II.

TABLE I CLASSIFICATION ACCURACY FOR FOUR CLUSTERING ALGORITHMS IN FOUR TECHNOLOGY GROUPS

	Classification accuracy [%]			
	Audio	Mobile Phone	Video	TV set
k-means	**47.88**	74.80	89.72	90.50
neural-gas	43.87	89.60	90.14	**91.67**
fcm	43.75	**93.33**	89.66	**91.67**
ronn	46.25	66.00	**90.41**	**91.67**

Table I presents classification accuracy for each of four clustering algorithms in every cluster, while Table II present's performances of clustering algorithms. Results demonstrate similar performances for all 4 tested clustering techniques. The audio group is clustered with less than 50 percent accuracy which is very poor accuracy. Main problem does not lie in clustering but in data mining phase.

TABLE II PERFORMANCES OF CLUSTERING ALGORITHMS

Algorithm	Performances	
	Average MSE ($x10^{-4}$)	DB index
k-means	85	0.717
neural-gas	**74**	0.709
fcm	**74**	0.719
ronn	75	0.706

V. CONLUSION

This paper compares the performances of four unsupervised learning algorithms: k-means, the neural-gas, fuzzy c-means and ronn. They clustering results are compared on data set of 72 US patents that were previously clustered by the experts. Clustering algorithms are realised in Matlab programming environment and their results are visualised. Final results, mathematical and visual, have shown that all considered clustering technique have similar clustering performances and classification accuracy and thus could be used in practical realisations of patent data analyzing tools. Future improvements of the clustering results will be achieved by enhancement of data mining phase.

Deep learning architecture for data mining from surgical data

I. Nikolova
Technical University of Sofia, Sofia, Bulgaria
cs_irina@abv.bg

Abstract - The paper addresses issues about data mining from surgical data. Surgical data has several distinguishing features – it is voluminous, heterogeneous, noise-prone, has low level of formalization due to lack of standardization in domain and highly correlated features. Architecture for data mining from surgical data, which deals with described features, is proposed. It is related to deep learning architectures as it consists of several hierarchical levels. Context-wise input layer modules process heterogeneous data. Results from these modules are calibrated before being passed to the next layer. At the last layer inference model for classification and prediction is derived.

I. INTRODUCTION

Modern medicine produces large amounts of data every day. There is however a widening gap between data collection and data comprehension. Data mining techniques are needed to help people address this problem and use that data to provide better healthcare.

Building a model of the domain would allow clinicians to execute various data mining tasks like associations, classification and rules extraction. Association refers to finding correlated patterns. Particular task in the domain is to identify treatment that was successful for specific group of cases. Classification is grouping related cases given some criteria. Example task is to identify group of patients prone to particular complication. Rules often concern casual connection between events – both predictive and explanatory. Example task in the domain is to analyze what could happen if particular operation is done given patient's health condition.

An extensive study on activities of Clinic of Pediatric Surgery in St. George University Hospital - Plovdiv had been conducted. As a result the electronic health record, which is required to produce a detailed description of a medical case, had been identified.

The electronic health record is heterogeneous as it includes data from different sources and with different data type. That diversity suggests various error source and level.

Essential part of the electronic health record is the free-text information, entered by the clinicians about the condition of the patient during all stages of his treatment. Although this is a convenient way to express concepts and events, it is hard for data mining purposes to use these notes for searching, summarization or statistical analysis.

TABLE I. PARTS OF THE ELECTRONIC HEALTH RECORD

Medical record		
Part	***Data Source***	***Error source***
Text	Clinicians	Human
Numeric	Laboratory tests	Measurement
Image	Image diagnostic instruments	Measurement, instrumental
Nomenclatures	Nomenclature codes, lists of predefined values	Human

That piece of information is prone to correlated and uncorrelated errors. Correlated errors may be caused by inaccurate observations for example, while uncorrelated errors are usually caused by misspelling. Information in that section of the electronic health record is weak-structured as only a few nomenclature codes are used.

Important part of the record is image diagnostic information provided by Magnetic Resonance Imaging (MRI) or X-Ray. That data is often affected by random noise, arising in the image acquisition process. The presence of noise not only produces undesirable visual quality, but also lowers the visibility of low contrast objects.

Another part of the record is results from laboratory tests. It usually consists of numeric values from analogous range. That part of the record is prone mainly to measurement errors, although conducting tests on patients in inappropriate condition also may lead to misleading results.

The best formalized part from the electronic health record is the one with values, chosen from predefined datasets. Examples from the domain include medical diagnose code, chosen from International Statistical Classification of Diseases and Related Health Problems, 10th Revision, (known as "ICD-10") list, or general condition of the patient, which is chosen from one of five values, defined from clinicians.

Different parts of the record should be preprocessed in different manner. In the same time, information from different parts should be combined in single model, as information is highly correlated.

An electronic medical record often contains lots of unnecessary data, related to the recorded case, so the

National Science Fund of Bulgaria. Grant Number:"DVU-10-0100/2010"

problem of choosing relevant features exists. Another issue is that the record is sparse since only few fields are filled with data as usually only a few of all possible diagnostics are prescribed and performed by the medical staff, so inference on missing data should be done. Robustness of the architecture is another issue of great importance as the data is noise-prone to different error types. Since electronic health records are large and numerous, efficient processing of vast amounts of data is another great concern.

II. RELATED WORK

Clinical data mining is a very active area of research [5]. In [6], Hahn et al. presented ontology-driven data mining system for information extraction from free-text medical data, combining syntactic and semantic parsing approaches in one step. Delen et al. explore three data mining methods on medical data – decision trees, artificial neuron networks and logistic regression in [7]. Pakhomov et al. use two complementary approaches in [8] – natural language processing and Naïve Bayes. Their approach is multi-pass and certainty-based. Roberts et al. use support vector machines and conditional random fields in [9] both for feature extraction and classification.

III. ARCHITECTURE FOR DATA MINING IN CLINIC OF PEDIATRIC SURGERY

Architecture for data mining database of Clinic of Pediatric Surgery in St. George University Hospital – Plovdiv is designed. In contrast with the majority of existing architectures for data mining of electronic health records, it is based on deep learning concepts and methods. Another feature is that preprocessing is fully separated from knowledge extraction which enables easily system upgrade and module reusability.

An exhaustive description of a medical case requires vast number of correlated features. It could be described with highly varying functions that depict high-dimensional problem. Most machine learning and signal processing techniques discussed so far had exploited shallow-structured architectures. These architectures typically contain a single layer of nonlinear feature transformations and they lack multiple layers of adaptive non-linear features. Examples of the shallow architectures are conventional hidden Markov models, linear or nonlinear dynamical systems, conditional random fields, maximum entropy models, support vector machines, logistic regression, kernel regression, and multi-layer perceptron neural network with a single hidden layer. A property, common to these shallow learning models, is the simple architecture that consists of only one layer responsible for transforming the raw input signals or features into a problem-specific feature space, which may be unobservable. Shallow architectures have been shown effective in solving many simple or well-constrained problems, but their limited modeling and representational power can cause difficulties when dealing with more complicated real-world applications as surgery. We refer the problem of learning a proper model to learning deep learning architectures as they are suitable for learning in high-dimensional spaces as some empirical results suggest [1, 4]. There are also theoretical results showing that architecture with insufficient depth can require many more computational elements than architectures whose depth is matched to the task [1].

Deep architectures are composed of multiple levels of non-linear computational units. The output from each level is used as input for the next one. Each level produces a representation of the input pattern that is more abstract than the previous level's, because it is obtained by composing more operations. Auto Encoders and Restricted Boltzman Machines are used as building blocks most often. We had chosen to use auto-encoder networks because their activation function is more flexible.

Although great breakthrough of deep architectures is related to unsupervised learning mode, they could also be learned in supervised mode. Both approaches are adopted in the designed system since there is supervised validation, provided by clinicians, but new features are extracted from the raw data.

The architecture has five layers differentiated:

- storage layer
- preprocessing layer
- dimensionality reduction layer
- calibration and combination layer
- inference layer.

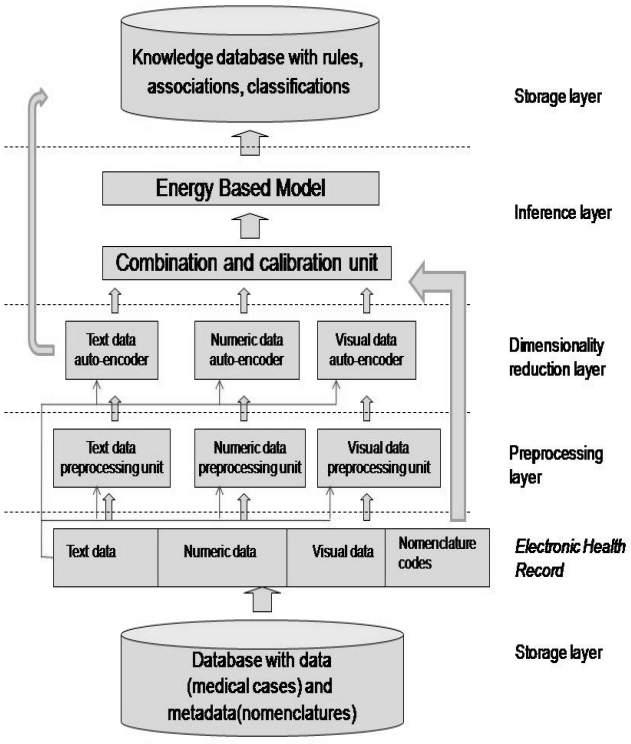

Figure1. Architecture for data mining in Clinic of Pediatric Surgery

A. Storage layer

Storage layer contains the database and the knowledge base of the system. All medical cases are stored in the database, altogether with metadata – nomenclatures, vocabulary with medical terms used in the clinic and table with synonyms and acronyms, used when text part of medical cases is processed, referential bounds for laboratory tests. Knowledge base stores extracted rules, classifications and associations.

Electronic health records are derived from the database in specific xml format, suitable for later processing. Different data types are in separate parts of the ERP.

B. Preprocessing layer

Preprocessing layer has two functions. First one is to detect and remove as much of noise in data as possible. Second one is to convert data to format, which is appropriate for further processing.

Preprocessing layer contains three input modules for the three raw data types – text, numeric and image. Due to the diversity of Electronic health record's data types and error sources different preprocessing is necessary. Nomenclature codes are not preprocessed.

Input module for text data involves techniques, borrowed from natural language preprocessing like tokenization, removing particles, word stemming. A dictionary of synonyms and abbreviations, created by medical staff of the Clinic of Pediatric Surgery, is used for synonym replacement. Other useful technique is identifiers removing (like personal names and places). Spell checking is executed, because according to work of Ruch in [10], misspelling in medical text is 10% more than in ordinary text.

Input module for image data includes application of algorithms for noise removal. It is important to notice that noise arising in these images is not Gaussian, but Rician, so general-purpose denoising algorithms are not applicable [11, 12].

For numeric data it is important the outliers to be examined, because they are usually caused by poor measurements. Referential bounds, defined in the Clinic of Pediatric Surgery, are used.

C. Dimensionality reduction layer

Electronic health record, used in the system, has large size – it is not unusual the description of a single medical case ten to be twelve thousand symbols. That size disables most learning algorithms to produce results in reasonable time. Dimensionality reduction techniques should be applied for efficient inference.

Traditionally, dimensionality reduction was performed using linear techniques such as Principal Components Analysis and factor analysis. However, these linear techniques cannot adequately handle complex nonlinear data [14] like the one contained in the Electronic health records of the Clinic.

We had chosen to use auto-encoder networks for solving dimensionality reduction task. It is a global dimensionality

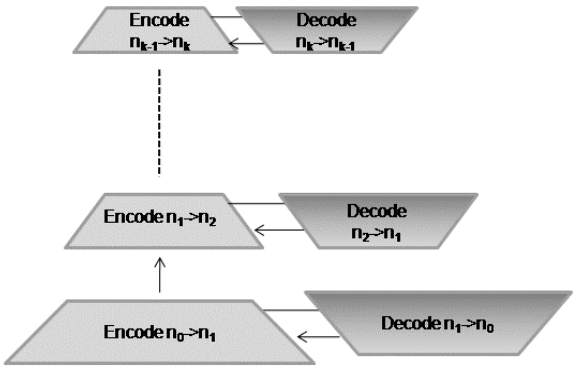

Figure2. Auto-encoder network

reduction technique as it tries to preserve global properties of data. It is known as feature-extraction technique because it constructs new features in contrast to feature-selection, which select the most important ones.

The aim of an auto-encoder is to learn a compressed representation (encoding) for a set of data. An auto-encoder network uses a set of weights to convert an input vector into a code vector. It then uses a set of generative weights to convert the code vector into an approximate reconstruction of the input vector.

Auto-encoders use three or more layers - an input layer, a number of considerably smaller hidden layers, which will form the encoding and an output layer, where each neuron has the same meaning as in the input layer.

For our auto-encoder network activation function is:

$$y = f_0(x) = s(Wx + b) \tag{1}$$

S(x) is the nonlinearity function. It is sigmoid function for regular auto-encoders (2), and (3) for sparsifying auto-encoders, as proposed in [2]:

$$s(x) = \frac{1}{1+e^{-x}}, \tag{2}$$

$$s(x) = \frac{x^2}{x^3 + Q}. \tag{3}$$

W is weight matrix with size $d_0 \times d$ and b is bias vector. W is result from addition of initial weight matrix W_i and rules matrix W_r, which contains rules from the domain:

$$W = W_i + W_r \tag{4}$$

Reconstruction vector z is:

$$z = g_Q(y) = s(W^{'} y + b^{'}), \tag{5}$$

W^i and b^i are decoder parameters.

Loss function, which measures reconstruction error, is computed as cross-entropy:

$$L_H(x,z) = H(B_{x_m} \| B_{z_m}) = \\ = -\sum [x_k \log z_k + (1-x_k)\log(1-z_k)] \quad (6)$$

Loss function defines the energy of the configuration.

Weight matrix is updated so that loss is decreasing until desired loss threshold is reached.

To ensure noise robustness, auto-encoders are learned to reconstruct partially corrupted input as described in [3]. Different corruption functions are used for the three modules according to noise level and distribution.

After the process of learning model is finished, decoder units are not used.

TABLE II. AUTO-ENCODER NETWORKS

Auto-encoder units			
Part	*Input element count - representative value*	*Output element count*	*Layer count*
Text	1500	50	8
Numeric	130	200	4
Image	250000	20	6

Electronic health record's parts with different data type need to be processed separately in that layer, too. Text information has complex structure that leads to greatest number of auto-encoder network layers, compared to numeric and image information. Text and image information should be aggregated in order to extract features, while numeric data should be sparsified.

Text auto-encoder unit has number of units corresponding to number of distinct words in the corpus, image unit – pixel count (there are several different images types), for numeric module – different laboratory test parameters. Reference intervals, defined in the Clinic are used to represent input for numeric unit.

Some results from that layer are useful associations, which are written to knowledge base.

D. Combination and calibration unit

Calibration and combination module's task is to combine results from different dimensionality reduction modules and the nomenclature codes in single model, because all parts of the electronic patient record are strongly related to each other. They should be used together in order to obtain correct and rich model for data mining.

Cross control by rules, provided by the medical staff, should be executed between learned concepts from different input modules. It ensures model noise robustness. Cross control is also used to measure noise level for different electronic patient record's parts.

Different probability distributions, produced by the auto-encoder networks from the previous layer, are used. The distributions to be combined are called "experts". Several algorithms for probability distributions combination are used recently – mixture of experts, product of experts, averaging. Product of experts algorithm is selected because it would return sharper distributions than the other ones [13]. That means that even though evidence from two modules is weak, if evidence from the third one is very strong match could occur.

First step to execute is to obtain probabilities from energies, derived from auto-encoder networks:

$$P(d_m \mid Q_m) = \frac{e^{-E(d_m|Q_m)}}{\sum_c e^{-E(d_c|Q_c)}} \quad (7)$$

Result is calculated with following formula:

$$P(d \mid Q_1, Q_2, Q_3, Q_0) = \frac{\prod_{m=1}^{4} \prod_m P_m(d \mid Q_m)}{\sum_c \prod_m P_m(c \mid Q_m)}$$

Maximization of that probability density provides model parameters.

E. Inference unit

When the model is learned, various inference algorithms are applied. Most applicable is belief propagation algorithm, which allows efficient marginalization of variables of interest over other variables in the model.

Data mining already could be executed. Structure of the model reveals casual dependencies between medical facts. It is the base for explanatory and predictive analysis. Functions, associated with model's nodes, provide quantity measure how often particular event (with particular predecessors) occurs, so that risk alerts could be raised when a risky situation is registered.

IV. CONCLUSIONS AND FUTURE WORK

Architecture for data mining electronic health records from Clinic of Pediatric Surgery in St. George University Hospital – Plovdiv is proposed. It is based on deep learning approach. It could deal properly with the features of the domain. The architecture is capable of processing voluminous data. It is aware that data is heterogeneous and has different data source and noise level. After proper preprocessing, architecture combines that data in single model. Architecture is able to identify important features and deal with sparse datasets. We believe it will be starting point for exuberant data mining process in the Clinic.

Next steps include model evaluation and calibration. Analytical and empirical evaluation of the results, produced by the model, is essential. The analytical evaluation will include execution of a sensitivity analysis

on the model. Throughout the empirical evaluation experiments, exhaustive case study will be conducted.

ACKNOWLEDGMENTS

This work was supported by National Science Research Fund of Bulgaria, project “Modern approaches in the design of clinical information systems (CIS) for observation of pediatric surgery diseases”, under grant number “DVU-10-0100/2010”.

Abstract - Emotionally annotated databases are repositories of multimedia documents with annotated affective content that elicit emotional responses in exposed human subjects. They are primarily used in research of human emotions, attention and development of stress-related mental disorders. This can be successfully exploited in larger processes like selection, evaluation and training of personnel for occupations involving high stress levels. Emotionally annotated databases are also used in multimodal affective user interfaces to facilitate richer and more intuitive human-computer interaction. Multimedia documents in emotionally annotated databases must have maximum personal ego relevance to be the most effective in all these applications. For this reason flexible construction of subject-specific of emotionally annotated databases is imperative. But current construction process is lengthy and labor intensive because it inherently includes an elaborate tagging experiment involving a team of human experts. This is unacceptable since the creation of new databases or modification of the existing ones becomes slow and difficult. We identify a positive correlation between the affect and semantics in the existing emotionally annotated databases and propose to exploit this feature with an interactive relevance feedback for a more efficient construction of emotionally annotated databases. Automatic estimation of affective annotations from existing semantics enhanced with information refinement processes may lead to an efficient construction of high-quality emotionally annotated databases.

I. INTRODUCTION

Coupling of semantics and affect in multimedia documents is an interaction between description of object and events represented in a document and affect which they are eliciting. In other words, coupling refers to how the content of a multimedia document, and its perceived meaning, is related to emotions, sentiments and moods a human subject is experiencing when exposed to the document (i.e. multimedia stimulus). The underlying assumption is that similar semantics will provoke similar emotions in standard subjects [1][2]. The function describing functional dependency between semantics and emotion is surjective because two or more distinct semantics may trigger the same emotion.

We postulate the semantics-affect coupling rule in emotionally annotated databases and apply the coupling to a construction process of these databases. The coupling must be used with a premise of statistically uniform population of subjects which server as an annotation baseline. Although limiting in terms of experimentation this is necessary and also sufficient to define the coupling rule in its minimal form. In our work we rely on International Affective Picture System (IAPS) [3]. This multimedia database with almost 1000 different images is constructed on a statistically significant number of affective responses from a controlled population of subjects. The database has so far been used in a wide range of research (examples [4][5][6]) and as such provides an adequate source of quality data for identification of semantics-emotion pairs and their mutual coupling.

Determinate dependency between semantics and emotions can be pragmatically exploited in construction of emotionally annotated databases. This is very important since all contemporary emotionally annotated databases have been constructed manually. The coupling enables faster and less job-intensive identification of emotion present in multimedia based on known semantics, which in turn allows algorithms for semi-automatic annotations of stimuli and supported construction of emotionally annotated databases.

The layout of the papers is as follows: the next chapter describes emotionally annotated databases, their format and content. The third chapter deals with the functional definition of the semantic-affective coupling. The fourth chapter gives two examples of the coupling in IAPS. The fifth chapters explains how emotionally annotated databases can be constructed using information refinement with the coupling. Since all contemporary emotionally annotated databases have been constructed manually by different groups of experts, this chapter is important in clarifying why the coupling is a useful feature in construction of emotionally annotated databases and how it can be exploited to make the construction process simpler, faster and less work intensive. Finally, the conclusion is given in the final chapter.

II. EMOTIONALLY ANNOTATED DATABASES

Emotionally annotated database or more precisely affective annotated multimedia database is a repository of semantically and affectively indexed multimedia documents such as [3][7][8][9][10][11][12]. Apart from

This research has been partially supported by the Croatian Ministry of Science, Education and Sports.

still images, sounds, video-clips some emotionally annotated databases may contain text in a form of individual words or short sentences [9][10]. Emotionally annotated databases contain information about affect and semantics of every stored document. This specific trait distinguishes them from other multimedia repositories. Specifically, emotionally annotated databases contain information about affective values of multimedia documents, i.e. the expected emotion or affect which will be induced in a human subject when exposed to the document. Because affectively annotated multimedia induces or stimulates emotional response the multimedia documents are also called multimedia stimuli or just stimuli.

Multimedia documents may provoke not just one but several emotional responses with different intensity [2]. In computer systems structure of emotion is categorized in two models: discrete and dimensional [13]. Although there is still some controversy on which approach is the best, in terms of computer systems implementation both models are simple and easy-to-use. Additionally, several other ad-hoc approaches in emotion state categorization exist such as those for expression of sentiment [11] and description of emotions' taxonomy [14].

Affective annotation of multimedia is a lengthy and laborious task that always includes a psychological experiment conducted with a statistically relevant group of participants. These experiments vary from the simple, such as the validation of a universal facial expression in a picture [8], to the elaborated which may include hundreds of participants [3]. To establish a baseline response all answers in the experiment are aggregated and statistically processed. Since they follow Gaussian distribution the affective annotations are described with the mean value and standard deviation. The mean represents the baseline and standard deviation the level of confidence in the aggregated baseline.

In the current form all emotionally annotated databases have very simple structures usually consisting of a file repository and a manifesto file that describes the content of the belonging repository [15]. The manifesto is comma-separated values (CSV) formatted textual file with attributes such as unique identifier, semantic descriptor and eliciting affect for each multimedia document in the repository. In the case of IAPS the unique identifier is the name of the stimulus file, e.g. 5200.jpg, 5201.jpg, etc. Through the combination of unique folder paths and unique file names within them the stimuli obtain their URIs (Uniform Resource Identificator) which allows their retrieval.

Some emotionally annotated databases like Geneva Affective PicturE Database (GAPED) [12], NimStim Face Stimulus Set [8] or Karolinska Directed Emotional Faces (KDEF) [16] use named files to describe stimuli valence and semantic content. These databases do not have a manifesto file but rather their affect and semantics are simple enough to be implicitly described with unique names of pictures or folders they are stored in. This is the simplest database structure and only minimally sufficient in conveying meaning of stimuli. In these cases it is expected that database user must look over all stimuli and selected them manually before using them. If the database does not contain many stimuli per single level of semantic taxonomy manual document retrieval from these databases is still manageable. For example, GAPED – currently the latest emotionally annotated database developed – has 730 negative, neutral and positive pictures but only up to 159 stimuli in a single named folder.

Figure 1. Several representative picture stimuli from GAPED and IAPS databases. Emotion and semantics are specified for each stimulus.

In terms of knowledge management emotionally annotated databases only specify data about the stimuli themselves, but do not describe knowledge stored in the stimuli. Therefore, they should not be confused with databases and taxonomies of knowledge. Also, emotionally annotated databases always contain multimedia documents while knowledge databases do not. On the other hand, knowledge databases describe semantic concepts in detail while emotionally annotated databases only reference semantic labels present in stimuli. The full expression of semantic labels is never found in these databases. It is up to the user to find the most appropriate knowledge database and reasoning engine to deduce the meaning of multimedia semantic descriptors.

All this clearly demonstrates diversification and content variability of currently available emotionally annotated databases. Today these databases are described loosely and informally, they are domain dependant and with arbitrary custom structures, new stimuli cannot be simply added in a database but require a separate set of affective ratings to be acquired through experimentation; existing stimuli must be extracted manually which is frequently tiresome and work-intensive; etc. In light of these drawbacks much can be done to improve functionality and usefulness of existing emotionally annotated databases. One of the most pressing tasks is automatization of stimuli insertion. Exploitation of semantic and affective coupling may greatly contribute in this process.

III. DEFINING SEMANTIC AND AFFECTIVE COUPLING

Multimedia stimuli have semantics, affect and context. Any semantics will induce an emotion, or affect, in an exposed subject. We are interested in interaction of semantics and emotions since their relationship is not random but subjected to personal knowledge, personal experience, cultural conditioning, collective memory and other similar factors which cumulatively direct articulation of particular semantics towards a specific set of emotions. Difference in articulation of images through pixel-defined content and semantic content is known as semantic gap [17][18]. Here we use the phenomena of semantic gap and broaden its scope on emotional content within the context of affective computing. We define coupling of semantics and affect in emotionally annotated multimedia documents as a deterministic interaction between semantics of a document and affect which its semantics is inducing.

Dimensional model of emotion [13] describes each emotion as a tuple $e_i = \{val, ar, dom\}$ where *val*, *ar*, *dom* are continuous variables representing valence, arousal and dominance emotional dimensions: $val \in [1,9] \in Val$, $ar \in [1,9] \in Ar$, $dom \in [1,9] \in Dom$. Dominance is frequently omitted from description of emotion space because it was shown to be the least informative measure of the elicited affect [3]. Therefore, for all practical purposes a single multimedia document from an emotionally annotated database can be represented as a coordinate in a two-dimensional emotion space $\Omega_{Emo} = Val \times Ar$. Semantics represents a list of document's objects and events, as well as constraints and functional dependencies between objects and events. These are generally described with free-text keywords (i.e. tags), but more expressive methods may be used such as WordNet synsets or ontology concepts (example [19]). Regardless of representation method we define semantics s_i as a set of descriptors d_n in semantics space Ω_{Sem}

$$s_i = (d_1, d_2, \dots \quad , \; s_i \in \Omega_{Sem} \tag{1}$$

Then a surjective functions f_{se} maps elements in semantics space to elements in emotion space $f_{se} : \Omega_{Sem} \to \Omega_{Emo}$ (Fig. 2).

We introduce semantic distance operator d_{Sem} and emotion distance operator d_{Emo}

$$\begin{aligned} d_{Sem} &: \Omega_{Sem} \times \Omega_{Sem} \to \mathbb{R} \\ d_{Emo} &: \Omega_{Emo} \times \Omega_{Emo} \to \mathbb{R} \end{aligned} \tag{2}$$

Since Ω_{Emo} is Euclidian space we can write $d_{Emo} = \sqrt{(val_i - val_j)^2 + (ar_i - ar_j)^2}$ for any two emotions $e_i = (val_i, ar_i)$, $e_j = (val_j, ar_j)$.

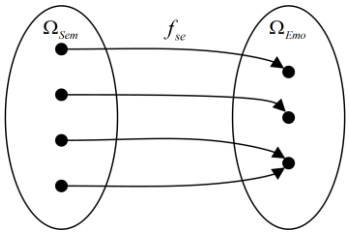

Figure 2. Surjective function f_{se} mapping semantics space domain Ω_{Sem} to emotion space codomain Ω_{Emo}.

Distance between semantic descriptors can be calculated if they are represented as nodes in a graph or semantic network like WordNet. Indeed, many measures of term similarity exits and can be applied to assess the semantic distance (as example see Semantic Similarity Retrieval Model[20]). Both distance operators have symmetry and can be defined with emotional similarity sim_{Emo} and semantic similarity sim_{Sem}.

$$\begin{aligned} d_{Emo}(e_i, e_j) &= d_{Emo}(e_j, e_i), \; e_i, e_j \in \Omega_{Emo} \\ d_{Sem}(s_i, s_j) &= d_{Sem}(s_j, s_i), \; s_i, s_j \in \Omega_{Sem} \\ d_{Emo} &= 1/sim_{Emo} \\ d_{Sem} &= 1/sim_{Sem} \end{aligned} \tag{3}$$

The semantic-affective coupling tells us that similar semantics in Ω_{Sem} induces similar emotion in Ω_{Emo}. Formally the coupling exists between multimedia documents $doc_i = \{e_i, s_i\}$, $doc_j = \{e_j, s_j\}$ with different semantics $s_i \neq s_j$ if e_i in a neighborhood ε_{Emo} of e_j and s_i is in a neighborhood ε_{Sim} of s_j

$$\begin{aligned} d_{Emo}(e_i, e_j) &\leq \varepsilon_{Emo}, \; e_i, e_j \in \Omega_{Emo} \\ d_{Sem}(s_i, s_j) &\leq \varepsilon_{Sim}, s_i \neq s_j \quad s_i, s_j \in \Omega_{Sem} \end{aligned} \tag{4}$$

For example, if we have three distinct images $doc_1 = \{e_1, s_1\}$, $doc_2 = \{e_2, s_2\}$, $doc_3 = \{e_3, s_3\}$, the coupling will exist between doc_1 and doc_2 only if

$$\begin{aligned} d_{Sem}(s_1, s_2) &\leq \varepsilon_{Sim} \\ d_{Sem}(s_1, s_2) < d_{Sem}(s_1, s_3) &\leq d_{Sem}(s_2, s_3) \end{aligned} \tag{5}$$

and

$$\begin{aligned} d_{Emo}(e_1, e_2) &\leq \varepsilon_{Emo} \\ d_{Emo}(e_1, e_2) < d_{Emo}(e_1, e_3) &\leq d_{Emo}(e_2, e_3) \end{aligned} \tag{6}$$

If (5) is true but (6) is not then doc_1 and doc_2 are not coupled. This is illustrated in the next figure.

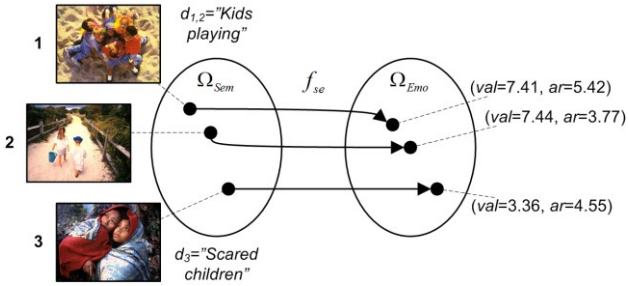

Figure 3. Semantic and affective coupling between images 1 and 2. Image 3 is not coupled with the other two images.

As can be seen in the example multimedia documents doc_1 and doc_2 are semantically and affectively coupled since their semantic and emotional distance falls within the defined neighborhoods in Ω_{Emo} and Ω_{Sem}.

IV. COUPLING EXAMPLES IN EMOTIONALLY ANNOTATED IMAGES

We present two unequivocal examples of semantic and affective coupling in image stimuli from IAPS. Since IAPS semantic descriptors (i.e. keywords) are not interconnected or supervised [15] we had to develop our own software tool Stimulus Generator (StimGen) for research in emotionally annotated databases and construction of well-defined personalized stimuli sequences [21][22][23]. In StimGen we have expanded IAPS and IADS databases to include tags clouds. We use tag clouds in these examples to retrieve stimuli with identical or sufficiently similar semantics as defined in the previous chapter.

The first example analyzes different images of animals in IAPS. We have extracted 40 images with 26 keywords and grouped them into six distinct sets: Dead animals, Dangerous animals, Revolting animals, Neutral animals, Wild animals and Miscellaneous animals. (Fig. 4).

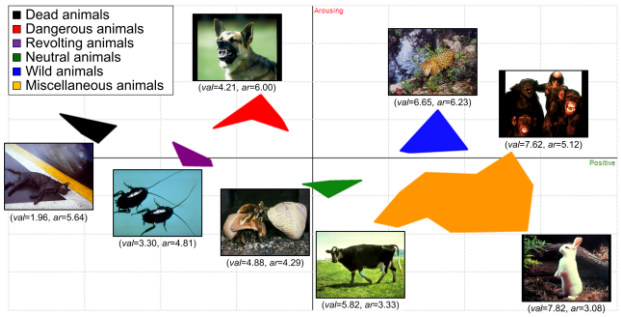

Figure 4. First example of semantic and affective coupling with IAPS images of various animals.

Since IAPS keywords are inadequate in relying true image semantics we had to construct our own specific tag clouds. Sets contain semantically similar images and sets' different semantics do not overlap in the emotion plane. It is immediately apparent that the tag clouds have well-defined boundaries and that they induce distinct sets of emotions. Since each of this emotion sets is elicited with images of similar semantics, we can say that the sets are semantically and affectively coupled.

In the second example (Fig. 5) we select total of 72 stimuli from IAPS tagged with food-related keywords (Beer, Brownie, Cake, Candy, Cheeseburger, Chicken, Desserts, Food …) annotating 35 stimuli, 24 nature-related stimuli (Cave, Desert, Farmland, Mountain, Mountains, Nature, Sunset, Waterfall, …) and 13 stimuli representing various high-action sports (CliffDivers, Motorcyclist, Rafting, SkyDivers, Skysurfer, WaterSkier, Windsurfers, …). These stimuli groups also outline distinctive areas in $Val \times Ar$ plane. From group dispositions it is immediately apparent that their semantics and affect are coupled; groups are small, closed and well-defined.

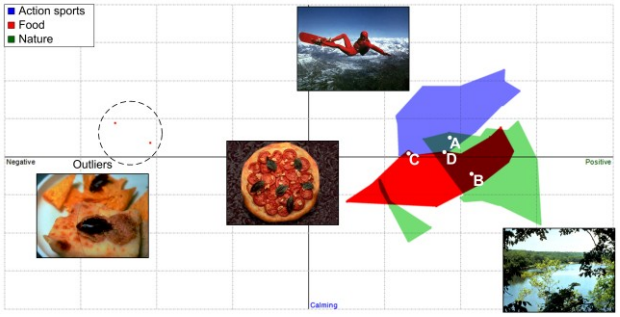

Figure 5. Second example of semantic and affective coupling with IAPS images of food, nature and action sports.

Emotions in points A, B and C in Fig. 5 can be induced with actions sports or nature, food or nature and action sports and food semantics, respectively. The point D emotion (val~6.82, ar~5.12) can be elicited with all three semantics groups (i.e. IAPS tag clods) in this example: food, actions sports and nature. We also note two outlier images with semantics of revolting food. In IAPS these images are tagged with "food" keyword like other non-repugnant images of food. This is another example of how semantically insufficient IAPS tags are and a clear indicator how this emotionally annotated database should be improved.

These examples clearly demonstrate the existence of semantic and affective coupling in emotionally annotated databases' multimedia stimuli. While emotional similarity can be easily established in the dimensional model of emotion which is essentially a simple geometric 2-D/3-D model, this is not also true for the semantics. Our continuing research is focused on using lexical ontologies like WordNet [24], and more formal and expressive upper ontologies such as SUMO [25] to better describe stimuli content and to measure semantic similarity of concepts describing stimuli content.

V. COUPLING IN SUPPORTED CONSTRUCTION OF EMOTIONALLY ANNOTATED DATABASES

Supported construction of emotionally annotated databases is a much needed feature leading to their more frequent everyday utilization. Since current construction processes require assessment of a large number of individual ratings collected in stimuli annotation experiments, the amount of time, resources and workload required to perform these tasks hider database deployment. Therefore, any type of automatization in stimuli annotation is needed to facilitate the development

of emotionally annotated databases and intensify their subsequent use.

The coupling of semantics and affect enables a priori knowledge of stimulus semantics to derive stimulus emotion using semantics and emotion information of stimuli already in the emotionally annotated database. The database construction algorithm may use the coupling to retrieve a set of the most probable emotion annotations for a new stimulus. The results are estimated, sorted by estimation likelihood and displayed to the user. Through interactive user feedback the classification may be optimized in a sequence of question-answer sessions between the stimulus annotation system and human annotation expert. An algorithm for supported and iterative construction of emotionally annotated databases using semantic and affective coupling is given in the figure below.

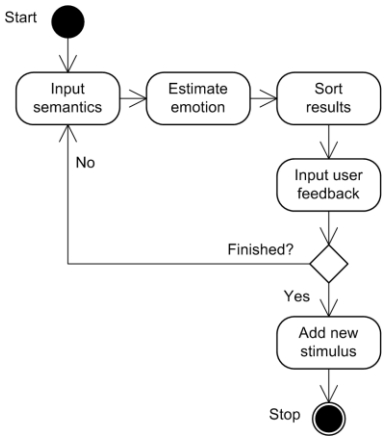

Figure 6. Algorith for supported construction of emotionally annotated databases using semantic and affective coupling.

For each new multimedia stimulus $doc_n = \{e_n, s_n\}$ that is being added to an emotionally annotated database the algorithm's input is $doc_1, doc_2, \ldots \wedge s_n$ and output $e_n = \{val, ar\}$. In other words, the algorithm based on the semantic-affective coupling uses new stimulus' semantics and existing knowledge about semantics and emotion of stimuli already in the emotionally annotated database to assess the most likely classification of new stimulus' emotion.

The proposed algorithm could substantially accelerate creation of new emotionally annotated databases or modification of the existing ones because semantics is more easily defined than emotion. Also a number of content-based or concept-based image recognition procedures could be used to automatically identify, at least partially, the semantics of an image stimulus.

VI. CONLUSION

We have shown that despite semantic gap semantic-affective coupling is a real phenomenon in emotionally annotated multimedia databases and proposed the algorithm for its utilization. The coupling can fill missing stimuli annotation data using existing information on semantics and emotion. As such it may be envisioned as a method for faster and simpler construction of emotionally annotated databases.

The biggest obstacle in implementation of an efficient coupling estimation algorithm is ambiguous and insufficient description of stimuli semantics in existing emotionally annotated databases. To address this problem our research focuses on applying formal knowledge representation methods for description of image content.

In the continuation of our work we are building core Stimulus Ontology for formal presentation and integration of semantics, affect and context information in multimedia stimuli. We will use WordNet lexical ontology and SUMO upper ontology to reach an optimal description of stimuli content and explore benefits of the coupling.

I. Abstract

In the last decade, the technology of multitouch displays has reached a level of maturity that has given new life to virtual reality environments and has introduced in the mass market Graphical User Interfaces previously depicted in SCI-FI literature. Three dimensional and stereoscopic displays are moving into mass market and users are getting accustomed to such concepts. This has sparked a new wave of interest in the public and we are now surrounded by several devices that allow the user to experience visuals that were not even thinkable a few years ago. On the other side, devices that allow users to actively interact with the environment are still cumbersome and expensive and not on a par with the evolution of display technologies. In this paper, we introduce a virtual reality application allowing users to stream and share multimedia contents like TV channels, web radio an others. Furthermore we introduce a wireless, light and small vibrotactile haptic device that allows users to interact with the various objects in the virtual scene, increasing the interaction feeling resulting in a more involving experience.

II. Introduction

Art, especially cinema, quite often influences the evolution of technology. In several recent movies, the protagonist interacts with a screen with his/her hands, freely moving in the space and interacting with 3D displayed objects. This type of interaction inspired a completely new type of environments called Spatial Operating Environment (SOE), where users can perform gestures to interact with the interface. Technological examples of this are rapidly coming out. The g-Speak from Oblong Company[1] is the most clear example of such a system where the user is introduced to a completely new type of interaction, where old paradigms like mice, keyboards and monitors, may be replaced by natural movements of the users. Another interesting application was defined by Han [9] and then carried on by Perceptive Pixel[2], and it proofed how the user can interact with the system adopting a new Graphical User Interface (GUI) concept. This allows multitouch/multiusers interactions, where objects can be moved around, zoomed, selected and so on.

These new kinds of interfaces have several improvements in comparison to previous systems, but they still have limitations. In current examples of a SOE, a very important missing aspect is haptic information feedback during the interaction itself. However, the work by Han limits the user to operate touching a screen no matter what the size is. We strongly believe that the combinations of the results of the previously cited works together with the information stream provided by haptic feedback may take to a completely new generation of interfaces, capable of improving the user's overall experience. We argue that these kinds of interfaces can be used both in Virtual Reality (VR) and, in large scale, with stereoscopic TVs. To demonstrate this, we leverage the currently growing interest of users in real time communication with friends to share multimedia contents. Our work implements a 3D virtual environment where users can share their multimedia experience and they can join other users on the same TV channel or other content streams. We then show how the introduction of a portable lightweight and low-cost vibrotactile device, connected by wireless with the host computer, enhances the user experience.

In the following sections, we describe the related works and the objectives of our study. Then we describe the experimental setup, the multimedia sharing system and the haptic device, developed for our purpose. Finally, we provide analysis of the data and considerations on the results.

III. Related Works

Many current researchers in human computer interaction field are investigating the big phenomena constituted by social networks and social communication. Websites like Facebook[3] and Twitter[4] are just examples of the large scale distributed concept of interaction between users over the Internet, with possibilities of sharing ideas and media contents. But this

[1] http://oblong.com/
[2] http://www.perceptivepixel.com/
[3] http://www.facebook.com
[4] http://www.twitter.com

is still limited. Our intention is to improve this concept and give new possibilities to the user, sharing a media content in real time, improving the perception of presence of other user experiencing the same application.

Human interaction in a 3D world is nowadays a big research topic. As outlined in Section II, many different ways of interaction are now possible. Despite of these new possibilities and improvements from the visual point of view, there is still a lack of feedback information: the need of multimodal feedback to improve the user experience was outlined since the late nineties in [2].

Visual information is mandatory in a virtual reality application but to improve the overall realistic experience other types of feedback are necessary. This is the case of the haptic feedback. Haptic, composed of proprioception and skin sensation, is a field where the user comes in contact with a virtual object. Vibro-tactile devices are an important part of the haptic devices family. Haptic devices are human computer interfaces that allow users to interact with computer applications where natural characteristics are simulated. The goodness of such devices is proportional to the freedom given to the user in his/her movements and to the realism reached in reproducing natural characteristics such as contact, vibration and many others, and where a direct stimulation of the human sensory system is achieved. In research field like VR, haptic devices dramatically improve the user experience, but an important issue is the freedom of movement still allowed to the user, considering cables and overall reduced weight. Despite these considerations, haptic devices are still cumbersome and they may have considerable weight [1]. Since the beginning of the exploration of the haptic field, big effort has been used to develop kinaestetic feedback, via large exoskeletons used to reproduce force feedback [6].

In the last decade, many studies have been dedicated to design highly integrated systems, giving the possibility to have different types of feedback such as force, vibration and thermal. Commercially, the market has seen the commercialization of many different haptic interfaces either fixed to a desktop like Phantom[5] either wearable like Cyberglove[6]. Even if these devices well achieve the use they were meant for, they still have high costs. Our aim was to develop a vibrotactile haptic device to reproduce contact, contact depth and vibration, using simple design and keeping costs as low as possible, also reducing the dimensions.

IV. Virtual Reality Application

A. Objectives

Nowadays, the way users think and consider computer applications is significantly different from the past, regardless the physical interface they are operating with. User Interfaces (UI) are moving toward 3D interaction both in virtual environments systems and desktops. The third dimension provides a completely new set of possibilities from a GUI point of view. Combining new graphical interfaces with Internet, users can greatly improve their perception of the application and achieve a better level of immersion into the interface. Internet is now the standard for worldwide communication and its pervasiveness is growing, with the advent of network applications and shared resources. As a consequence, also classical paradigms like mouse and keyboard may be reviewed and adapted to the evolving type of interaction requested. Tangible User Interfaces (TUI) frameworks are quite diffused and used in many different research fields to augment user reality [8]. As explained in [4], we should move to the *"task-centred design"*, understanding the key to allocate and perform interactions in the relationship between users and machines to improve their digital experience. When people watch television, listen to the radio, go to the cinema or do similar activities, they can share their experience with others. At the moment this aspect is limited to the sharing of the visual and audio environment and not to the sharing of the actual experience. This constitutes an interesting research field capable, in the next few years, of allowing a better involvement of the users' emotional aspects. Following these considerations, we propose a virtual reality application where a user can experience multimedia streaming and share it with others.

B. Experimental Setup

The VR environment is presented to the user by two Christie Mirage S+ 4000 projectors,synchronised with StereoGraphicsCrystalEyesactive shutter glasses. We used a $4x2m^2$ powerwall, and an Intersense IS-900 inertial-ultrasonic motion tracking system to monitor the area in front of the screen; in this way the user's head is always tracked. The main 3D application was developed with VRMedia XVR[7] which handles OpenGL graphics, scene behavior and input/output data sending. Finger tracking is instead achieved using a set of 12 Optitrack FLEX:100 infrared cameras; passive markers were placed on two fingers, thumb and index, for tracking the manipulation.

C. System Architecture

The system is based on a client-server architecture, and it allows playing streaming contents over the web in a multiuser interactive environment. The idea is to design and develop a cross platform application, that can exploit all the communication capabilities offered by Internet. Many hardware independent applications make strong use of Common Object Request Broker Architecture(CORBA) [10] to communicate between server and clients. This technology allows applications to be independent from the location, the I/O, the language and the scaling of the whole environment. In this way, in a near future the same application could be used both in desktop 3D and completely different systems, like TV, complex VR systems or mobiles. Our implementation consists of a bidirectional command strings communication system between the server and clients. The server application manages the interaction

[5]http://www.sensable.com/

[6]http://www.cyberglovesystems.com/

[7]http://www.vrmedia.it/

communication between users and available streaming media contents. User generated interaction messages can be point-to-point or broadcast to every connected client. The multimedia streaming is not performed by the server but by the client itself on the local machine, and the server only sends a string to the client with the embedded streaming media link.

The client application is composed by a cross-platform OpenGL application that runs inside an Internet browser. The user is able to perform several interactions moving around the space. An important and difficult goal to achieve is to stream multimedia inside a virtual world, in fact this operation may take to poor system performances. Thus, instead of mapping a target running multimedia streaming via OpenGL functions, we preferred, for this first prototype, to have a 2D content layer for streaming functions. Inside this layer we have embodied a VLC[8] plugin to manage streaming visualization. The communication between the 3D application and VLC is granted by a simple and lightweight Javascript framework. The Figure 1 shows the communication diagram. In this way, the client application receives from the Server a streaming command string, that is passed to VLC plugin via Javascript and finally the streaming begins. As VLC supports many different formats, the application therefore does as well. Supported streaming protocols are http, rtp, rtsp and mms.

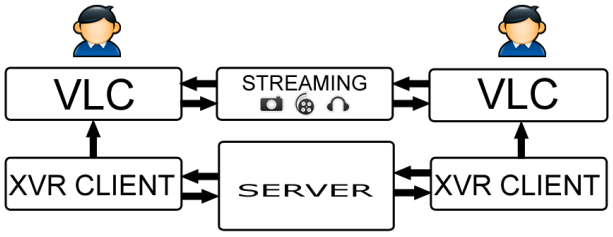

Fig. 1. Representation of the communication scheme for what concern the multimedia streaming. The Server is not responsible for the streaming but only for generating streaming string for the VLC plugin on the client application.

This means that it is possible to stream contents such as TV channels, web radios and all the streaming fluxes supported by VLC. Other functionalities, such as the streaming of local sources running on the users' machines, are already supported by VLC, but not yet implemented in our prototype.

D. Graphical User Interface

A quite common and well established habit in the design of GUIs for virtual environments is to use virtual widgets [7]. The presented client GUI is mainly based upon spheres and cubes widgets and is presented in figure 3. We took inspiration from [5] where a new kind of TV controller interaction is proposed. Our idea is to have the stream flux country related, where the user can choose between channels coming from different geographical areas. The main virtual object is a three dimensional representation of the world map and a texture of the world map is applied to a sphere of 30cm diameter: this is starting point element for the whole application. In correspondence to the 2D shape of each continent a 3D generated mesh is applied representing that particular continent. Each continent contains a list of server generated streaming channels. Selecting a continent, a streaming channel list is displayed. From the list, that is server side generated, the user can select the desired streaming and a new panel is opened. This is a stream control panel where users can be dragged into and join the streaming after acceptance, by clicking an upcoming message placed on the top part of the screen. If the user accepts his corresponding stream panel opens. At the stream panel is attached the previously explained layer containing the VLC plugin. The user can move the streaming panel around the space and the 2D streaming layer will move as well. This is achieved using an OpenGl function. Indeed using the *gluProject* function we find a vector representing the position that the panel has in the 2D world as briefly represented in Figure 2.

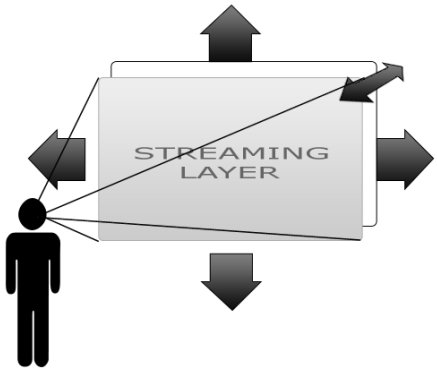

Fig. 2. Stream layer position depends from the position of the stream panel behind it. The 2D position is calculated on the resulting vector of the *gluProject* function upon the stream panel coordinates.

With a frequency of 1 Khz, position and scale of the streaming layer is updated depending from the position of the panel in the 3D space. This allows the object to be moved and scaled around depending on the user operation. Classic movie control buttons like play, stop, back and forward are located in the lower part of the panel All these widgets are monitored and when a 3D marker get in touch with one of them, it generates a contact command string useful for haptic implementation or other purposes, and a particular javascript function is called to manage the streaming layer.

E. User Interaction

In [14], referring to the ISO/DP 7942, a set of generic interactions is proposed. We followed that simple model and extended it for our needs. We have implemented in our applications the following object interactions:

- **Single Touch**
  Used to push buttons.

[8]http://www.videolan.org/vlc/

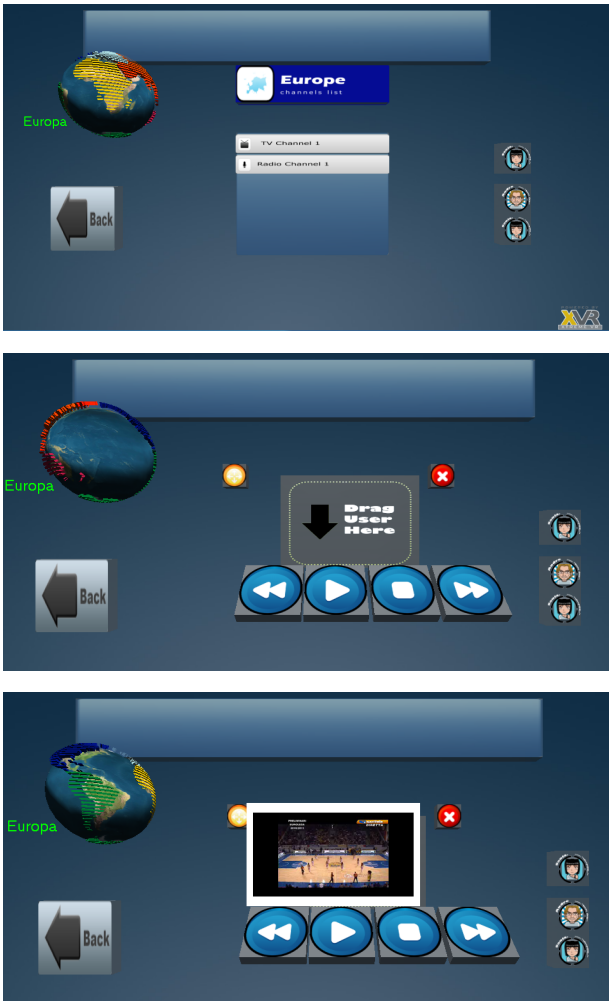

Fig. 3. The virtual application in its different states. After selecting a continent a corresponding channel list is shown. In the middle is visible the stream panel after the channel selection. The last image shows the streaming of that particular channel.

- **Double Touch**
  Used to make selections i.e. of a continent on the world sphere.
- **Drag and Drop**
  Used to drag and drop the streaming panel and users.
- **Rotation**
  Used to rotate the world.
- **Zoom**
  Moving the panel zoom in/zoom out operation are possible.

User interaction is mainly focused on moving and dragging objects around the space. Monitoring the marker position in the 3D space, when the users' finger touches a virtual object an event is generated. Every object is defined having specific behavior properties. In particular, the event is generated when the marker position collides with the bounding box of an object and it provokes a consequent behavior.

If the user touches an object defined as single click button, this will cause a specific action. Furthermore, to select a geographic continent the user has to touch the object twice. Rotating objects like the world widget need a previously achieved single touch event, if this is true, the rotation of the object is a function of the user finger position and it will stop if the finger is no longer in contact with the object. To operate in a virtual environment and give to the user a perception of freedom, we need to implement the drag and drop feature. In [11] they outlined the need to have common user interface elements with a 2D desktop computer. On this direction we implemented the drag and drop behavior when two markers are inside the bounding box of the same object.

F. User Feedbacks

The described application has been tested by different users. The reaction to the application was generally enthusiastic and they all were extremely positive about the idea of having a multimedia streaming system inside a virtual environment. Nonetheless, all the users were also extremely coherent in reporting that the lack of any feedback sensation from the user interface was a severely limiting factor to the immersion in the environment. Figure 4 represents a user operating in the virtual environment.

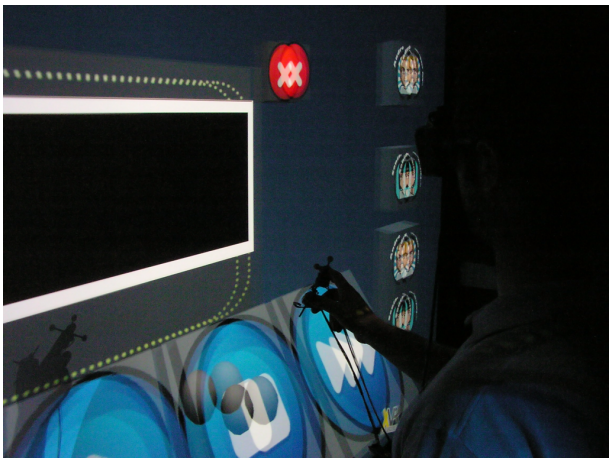

Fig. 4. Subject wearing the haptic interface during the use of the application.

V. Haptic Device

Starting from users' reports about the lack of feedback from the UI, we decided to introduce such a feedback to improve the user experience. Commonly used interface devices, such as a mouse, are not apt to the task and we do not want to adopt big exoskeleton-like structures to provide actual force feedback. Reproducing feedback sensation is an important aspect to give the final user a better perception experience of the environment where he is operating, whether the environment is real or virtual. As already outlined, demand of three dimensions ready displays is increasing and it is our opinion that systems allowing users to operate in fully immersing three

dimensional environments need multimodal smart actuators that are lightweight and easy to use. Thus we have investigated which are the possibilities offered by technology to achieve a full sensory interaction. The aim of this work is to realise a simple and low-cost cutaneous tactile interface for the finger, the most sensitive part of the human body [12], to be used in a virtual environment. The idea is to build a device simple to use, fast to integrate and lightweight. The interface has to reproduce the sensation of object surface depth of penetration through vibration. The following sections describe the haptic interface from simulation to different control techniques and the final implementation.

A. Simulation

Nowadays many different simulation programs are available on the market. We have chosen 20Sim from Controllab Products[9] due to its simplicity in modeling dynamic models. In fact,it allows having a mixed system of bondgraphs, iconic diagrams and components. The model in Figure 5 is composed of a DC motor, whose shaft is connected to a gear. The chain is then connected to a bondgraph 1-junction, that receives as input also an ideal effort source, used to simulate a mechanical stop when reaching the bottom side. As an output, the 1-junction is connected to a spindle where rotational motion is translated into translational movement and the output of this component is then connected to the 3D representation of the whole system, useful for understanding the behavior of the system. The 3D model is composed by two block connected via a translational joint: the first is fixed to the world and the second can move along the vertical axis whose movement is generated by the spindle. The desired maximum travel is 3mm. Different motor input sources allow different motion profiles of the moving cursor.

Contact with the finger skin is modeled as compliant and not rigid because of the finger elasticity, therefore contact is simulated as penetration of the cursor inside another object. At the contact point the reaction force of the skin against the cursor is obtained using a spring-damper model. Figure 6 shows the representation of the compliant contact between two generic objects. Table I shows the parameters that have been chosen to simulate the system. Motor torque value is from the company data sheet, the others are simulation parameters for a 5mm diameter cursor made in plastic.

The simulation in Figure 7 shows that for a maximum traveling distance of 3mm, the frequency achieved by the actuator is 2.25 Hz. From simulation, we have seen that a motor torque

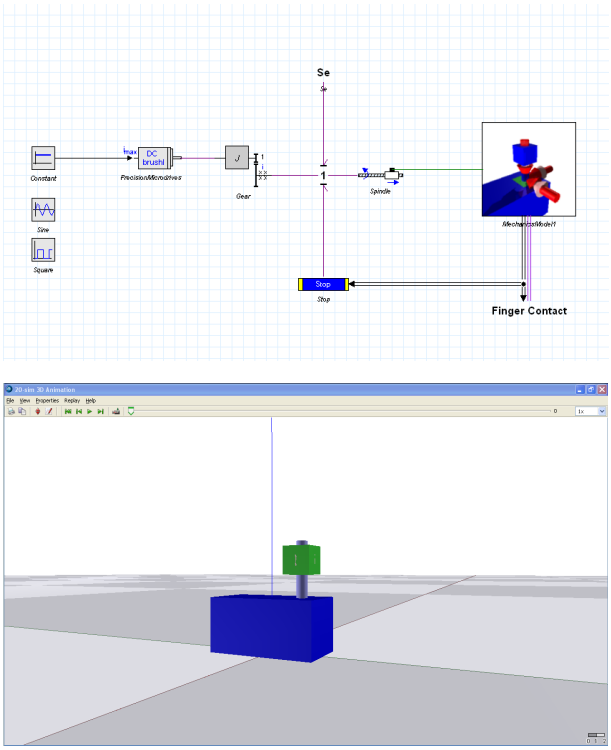

Fig. 5. The 20sim editor, where the system has been modeled. The system is a mix of bond graph components and iconic diagram to control the 3D mechanical system.

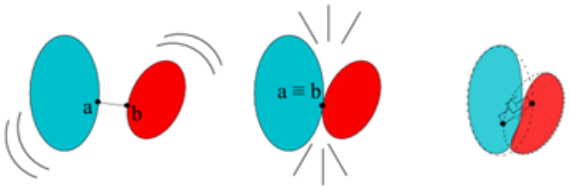

Fig. 6. Representation of compliant contact between two objects.

of 2.65 mNm is enough to implement the simulated system. The maximum output vertical force is 1.23N. This value is useful in low elasticity finger skin and big finger dimensions to achieve good contact sensation.

B. Implementation

Simulation results have been considered during the implementation of the haptic prototype in Figure 8. The lightweight ABS plastic chassis is a parallelepiped of (21x11x15)mm. The actuator itself is a single DC motor from Precisionmicrodrives[10] whose motion is translated ninety degrees via a couple of bevelled gears. The planetary gearbox mounted on the motor shaft, creates a reduction of 255:1 with an output peak torque of 20 gr*cm and a speed value of 1440 rpm

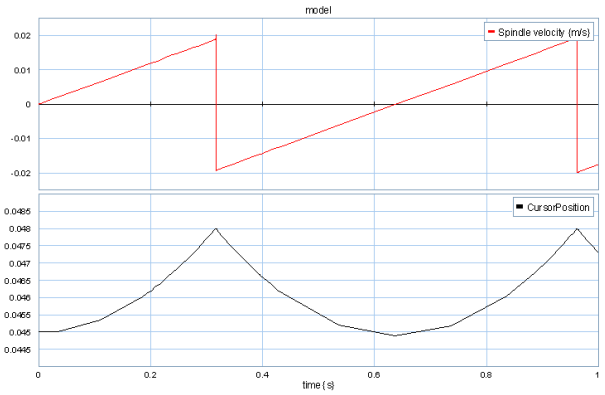

Fig. 7. Cursor Position and spindle velocity along the vertical axis.

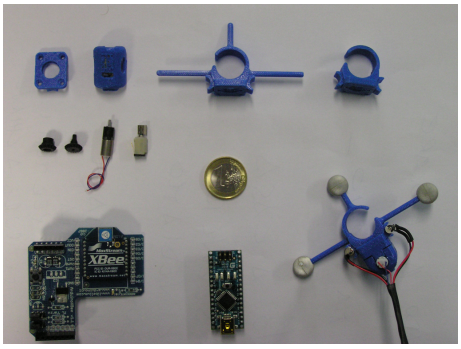

Fig. 8. The hardware architecture. Disassembled part of the haptic device compared to a fully assembled.

with no load. The final gear is internally threaded to allow a cursor to go up and down, like a worm gear mechanism. With the system in Figure 8 we can achieve contact with the finger and generate a touching sensation of virtual objects with a heterogeneous variety of skin elasticity. This mechanism is then connected to a curved plastic ring to permit finger insertion. The cursor is fixed to move vertically using two plastic edges.

This solution has been chosen for its simplicity and to avoid the usage of additional external gears, typically used for providing the needed vertical force. The presented worm-gear system can generate up to 1,25 N with a speed value up to 5.1 mm/s. In this way a full and proportional deep contact can be achieved. The maximum height reachable is 3mm, but the system can be tuned to travel less space due to big finger dimension or to increase the system frequency. In this way we also avoid the gears of the planetary box from breaking. An external electronic board, the commercially distributed Arduino Nano[11], is used to generate PWM signals and to communicate with the Virtual Environment. This board sends signals, wireless using a ZigBee interface, to a second Arduino board that generates PWM signals for an H-bridge to drive the motor and have motion in both directions.

[11] http://arduino.cc/

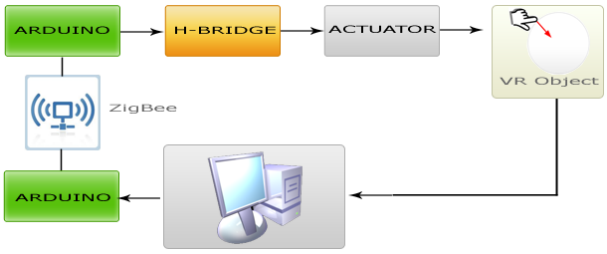

Fig. 9. Communication schema. The application environment generates a command string that a desktop computer send wireless to the haptic device.

The communication protocol abstracted in Figure 9 is based upon simple command strings, generated by the application environment. To keep the device as simple and low-cost as possible, the motor is controlled in open loop where the only control variable is time. The simple control system is based on shifting time of the cursor and features two different operating modalities: boolean operation and stepping movement. In the boolean modality, the cursor is forced to move from the bottom position to the top one: this allows an on/off contact. The stepping movement allows a gradually insertion sensation. With this option the entire path is split into three 1 mm steps, that can be customize by the programmer. The cursor can therefore move in accordance with the desired step, reaching the top only with the last step. These two different modalities allow the differentiation of the contact sensation. Regardless of where the marker position is, with the boolean contact, the cursor will go up in one step, whereas in the stepping mode, three different pressure sensations on the fingertip give better sensation to the user, during the insertion of the finger in the virtual object. Phong in [13], demonstrated how simple vibrating motors can be useful for path recognition and hand pointing. Using this concept, on both sides of the actuator two vibrating motors have been placed to reproduce vibrating sensations useful to give more information to the user on the action he is performing. This can be applied for example in a drag and drop operation or rotating an object.

C. Experiment

In [3], a simple and low cost vibrating tactile device has been tested in a virtual application showing how those kinds of actuators could help to be more precise and remain nearer to object boundaries. To test the haptic device we have carried out a simple experiment application. Twelve subjects from 20 to 35 years participated in the experiment. They were asked to grab and move up spheres along the vertical axis first wearing only two passive markers and later using two haptic actuators on index finger and on the thumb. Three different sphere diameters were chosen: 10 cm, 20 cm, 30 cm. These spheres were placed at 1.1 m from the ground and 0.2 m far away from the screen. Users were free to move around the virtual environments and they had to perform 5 repetitions of 6 spheres each, grasping each sphere with both of the markers inside the sphere boundaries and moving it vertically until

the sphere would changes his color from black to blue. This point was at 1.5 m from the ground. In Figure 10 a subject performing the experiment is visible.

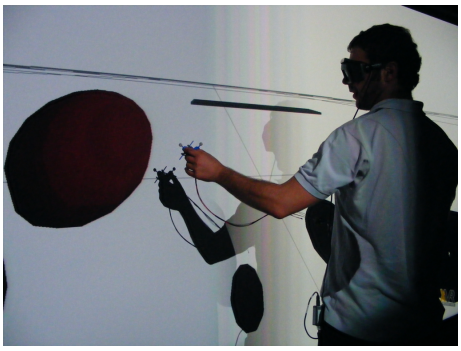

Fig. 10. User haptic session during one of the experimental session.

1) Statistical Analysis: We ran a ttest analysis, at an overall 1% level, in the group of the three different diameters and grouping the data in with/without haptic feedback. We evaluated the means of the distance between the markers from the moment the volunteer grabbed the sphere for the whole lifting action, all over the trials. We considered the distance between the two markers on the fingers as variable for the analysis. The idea was to consider this distance as grasping position during the lifting. This distance was recorded during the whole experiment, and for each subject, the has maximum possible distance between his two fingers was normalized. The analysis was then made on the mean values of the ten trials done by the subjects for each sphere, so the values are from zero (fingers in contact and closed) to 1 (max opening of the hand and max distance between the fingers).

Considering the diameter groups, the results didn't show significant differences between haptic and non haptic condition, as shown in the Figures 11 and 12. The medians are listed in Table II. The box plots show anyway the tendency by the volunteers to close the fingers more when they were without the haptic feedback. In particular, with the 10 cm and 30 cm diameters spheres, this effect was more evident. An important consideration could be done related to the standard deviation. The haptic condition has a smaller deviation from the median than the non haptic one, and this could indicate that the subjects tended to keep the position of the fingers during the lifting more stable with haptic feedback. This warrants a better and deeper analysis and a wider and more comprehensive study, because it could mean that the haptic feedback, even if just on the finger tip, could increase the perception of virtual environment.

The analysis between the feedback conditions show similar results, but with more significant differences between them. In Figures 13 and 14, the graphs show the significant difference in the distance between haptic and non haptic, for all the spheres. Only the pValue for the ttest between 20 and 30 cm was above 0.01, while the rest was well below.

The ttest analysis confirms that the approach of the subject

Diameter	Haptic	Not Haptic

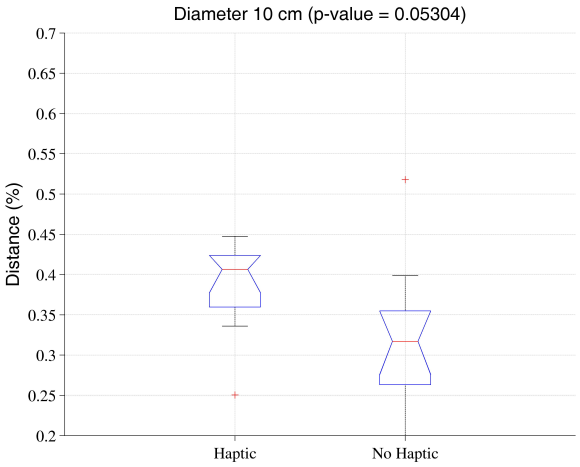

Fig. 11. Boxplots for the sphere with 10 cm diameter.

was different whether or not he had haptic feedback. Once he grabbed the sphere and started the lifting, having haptic feedback on the fingers induced the subject to keep the position, even if the feedback was only on the finger tip, and no force feedback on the whole finger was active. The subject was free to close the hand, but he tended not to do it, because of the feedback.

VI. Conclusion and Future Works

A new virtual social streaming application has been implemented. The application allows different users to participate at the same time to a real-time streaming content. Connected users participate in the vision of the same media content such as TV channels or web radios. This characteristic improves the level of interaction possibilities between users. Indeed, sharing the same stream content increases the level of perception of communication with other users and it could be the starting point for several studies toward social streaming contents sharing. In this application, different interaction mechanisms have been implemented to touch an object, like making a selection or dragging and dropping objects. The interactions implemented have been introduced to let the user feel as comfortable as possible and for reducing the gap between a virtual reality application and a real electronic application.

The application needs to be improved integrating other social characteristics like a chat system and microphone. To improve the user experience inside the virtual environment, a novel haptic device has been designed, implemented and introduced in the application. Its main characteristics are lightweight and portability, low cost and wireless connectivity. Tests with the environment enhanced with the haptic device show an increase in user satisfaction and experiments with the device itself suggest a new way in developing simple haptic interfaces.

Novel Approaches to Automated Personality Classification: Ideas and Their Potentials

Aleksandar Kartelj*, Vladimir Filipović* and Veljko Milutinović**
* School of Mathematics, University of Belgrade, Serbia
** School of Electrical Engineering, University of Belgrade, Serbia
aleksandar.kartelj@gmail.com

Abstract - In this paper, we propose several new research directions regarding the problem of Automated Personality Classification (APC). Firstly, we investigate possible improvements of the existing solutions to the problem of APC, for which we use different combinations of the APC corpora, psychological trait measurements, and learning algorithms. Afterwards, we consider extensions of the APC problem and the related tasks, such as dynamical APC and detecting personality inconsistency in a text. This entire research was performed in the context of social networks and the related datamining mechanisms.

I. INTRODUCTION

Personality classification is one of the problems considered by personality psychology, a branch of psychology. The focus of this field is the study of personality and individual differences. According to that study, personality can be defined as a dynamic and organized set of characteristics of a person, which have a unique influence on cognition, motivation and behavior of that person. In this paper the problem of automated personality classification is considered based on information from the following content: textual content that the person wrote and meta information about a person received on request, through social networks or other means. There are studies that also include speech, analysis of facial characteristics, gestures and other aspects of behavior, but they are not the subjects of our study. The standard approach to solving the APC problem based on the aforementioned content is described in the following steps: A. Gathering the corpus data, B. Determination of the personality characteristics of the participants, and C. Building the model.

A. Gathering the corpus data

The corpus includes a collection of content (both text and meta) from the participants on whom the building of the model is based. In previous research, this base usually consisted of student essays and accompanying meta information ([1], [16], [17] and [31]), originally collected and described in [24] and [23]. Other studies have considered Internet blogs ([9], [10], [11], [13], [18], [19], [20], [21], [34] and [36]). There were some efforts described in [22] and [27] that used emails and SMS, while the latest researches [3], [25] and [26] used information available on social networks, Twitter and Facebook.

B. Determination of the personality characteristics

Determination of personality characteristics is traditionally performed by subjecting participants to a personality test. The most common implementation of a personality test is The Big Five Model of traits that classifies the personalities to five separate characteristics, where each is evaluated on the real scale. Considered characteristics are: 1) openness to experience, 2) conscientiousness, 3) extraversion, 4) agreeableness and 5) neuroticism. Certain questionnaire based implementations of this model are described in [2], [7] and [14].

C. Building a model

After collecting the corpus and determining the personality characteristics for each of the participants, it is necessary to develop an appropriate classification model. This procedure involves the selection of independent variables, i.e. a set of relevant attributes that determine the dependent variable, where the dependent variable represents one or more personality traits. In [4] and [23] two sets of features were identified, LIWC and MRC, which turned out to be correlated with certain personality characteristics. The LIWC (Linguistic Inquiry and Word Count) represents a database of several hundred words, which have been found to contribute to the determination of personality characteristics. For example, words *hate* and *kill* are quite important in determining the level of neuroticism. The MRC is a psycholinguistic database consisted of words classified by various measures, such as, imagery, concreteness, frequency of usage, etc. For example, the word *ship* is highly rated on the scale of concreteness, whereas the word patience is very poorly rated. After a set of relevant attributes (features) is established, an appropriate classification model is built on top of it. These classification models are usually based on different linguistic, stylistic and statistical techniques.

In the next section we describe general ideas for the improvement of the solutions to the problem of APC. In the third section of the paper we give brief overview of a several solutions to the problem of APC, and ideas for

their improvement. The fourth section will hold the conclusions of our research.

II. General Ideas For Improvement

In this section we present several ideas for the improvement of APC. For clarity, the ideas are categorized as follows: A. New types of corpora, B. New ways of measuring the personality, C. New models and algorithms, and D. Extensions and related problems.

A. New types of corpora

A considerable number of researches on the topic of APC considered Internet blogs and student essays. In [28] user reviews from *tripadvisor.com* system for proposing tourist destinations are taken into account, but only to the extent of evaluation of the model formed based on the student essays corpus from [24]. Our view is that the user reviews and comments should be used, not only for the testing of the quality of the model, but also for its creation. News portals and comments made by the general population could be utilized for solving the problem of determination of certain personality traits, such as extroversion, neuroticism, and openness to experience. Comments from the Internet site *youtube*.com could be used in a similar way. The analysis of public data flows from social networks is yet another resource that is currently not used for solving the APC problem. In the following paragraph we consider the alternative, primarily indirect ways of measuring the personality traits, based on these new corpora.

B. New ways of measuring the personality

Measurement of personality traits of participants is a difficult task because it requires cooperation of persons who are the authors of the content. Our idea is to simplify this aspect of the research, which is usually based on the use of complex questionnaires, by simplifying the problem of the APC. In the context of news portals and Youtube, this would require labeling (tagging) of articles and video content with certain pervasive personality trait or combination of traits, for example, scientific content would clearly indicate towards openness to experience, extreme sports content towards a combination of extraversion and neuroticism, etc. In this way we would simultaneously get both the corpus of content and a set of information on certain personality traits of the authors of those contents. In the context of measurement of personality traits on social networks, such as *Facebook*, the idea would be to create an application, which would be appealing to the users. At the same time it should have a hidden function for the measurement of personality traits.

C. New models and algorithms

There are several potential algorithms that could be applied to solve the problem of the APC. Combining, or hybridization, of the existing methods is one of the ways of achieving better results. In [29] a regression model is considered, whose evaluation is based on ranking, instead of the standard approach, which is based on residuals. Reducing the problem of the APC to the problem of clustering is also one of the alternatives. That would require analysis of several personality traits simultaneously, as opposed to analysis of each trait separately. In our opinion, this approach would be more natural, as we believe that the traits are mutually conditioned, i.e. that they cannot be combined in a completely arbitrary way. In addition to the support vector machine (SVM), the use of other methods from the class of soft computing algorithms, such as neural networks and fuzzy logic methods could also provide valid results.

D. Extensions and related problems

The dynamical APC system refers to the system that is capable to adapt to the users and the input data, and to "learn" through use. It has been shown that psychological traits follow a normal distribution. However, the moments of distribution differ in terms of various age groups, demographic characteristics, level of education, and other information about the author of the content. The dynamical APC system would also learn the parameters of the distribution through use and this could be achieved by applying the Bayesian learning.

Algorithms that solve the problem of automated plagiarism detection ([6] and [15]) represent an interesting scientific and practical topic. A personality classification could be used to catch some inconsistency in texts. The idea is to pass different fragments of the same text through the algorithm that performs the APC and compare the resulting personality scores. If deviations are too high, then we could conclude that more than one person wrote the text. There are some issues related to this idea, for example, what if the observed text was legally written by more than one person (scientific papers usually have more than one author)?

III. Improvement Of The Existing Solutions

In this section we will give brief overview of several research papers that considered the problem of APC. After each overview we will propose one, the most prominent, idea for the improvement of the existing solution. This idea will be represented with a short description, diagram, and mathematical considerations. Note that in the previous section we proposed general ideas, which are applicable to almost every existing solution. Therefore, in this section, we will concentrate only on the specific aspects of ideas.

A. Using Linguistic Cues for the Automatic Recognition of Personality in Conversation and Text

In [17] three different statistical models are applied on the corpus composed of text and speech. The classification of traits was based on the five-factor model, where each of the five traits represented a binary variable (low or high). Apart from the classification algorithms, authors considered the regression and the ranking based models. The textual part of the corpus consisted of student essays previously collected and discussed in [24]. Beside the LIWC and the MRC features, authors utilized ratios between the usages of different types of sentences: commands, prompts, questions, and assertions. Testing was performed on the Weka statistical tool. The ranking model outperformed other two models in overall. The

results also suggested that the evaluation of openness to experience was the most accurate.

We think that utilization of a ranking based model combined with clustering algorithm is the right direction for improvement. In [17] the authors used the RankBoost ranking algorithm ([8] and [30]). This algorithm uses a set of training pairs $T_i = \{(x,y) \mid p_i(x) > p_i(y)\}$, where *x* and *y* are vectors of linguistic features associated with content of an author, and p_i corresponds to the score on the personality trait i $(i = 1..5)$ for that author. Each vector *x* is composed of *m* indicator functions $h_s(x)$ *for* $1 \le s \le m$, where each indicator takes value 0 or 1, depending on whether the feature at position *s* of vector *x* is lower or greater than some threshold value (in the case of binary classification, the threshold may be represented with the median). Ranking score is afterwards calculated as $F(x) = \sum_s \alpha_s h_s(x)$. The training process is then used to adjust values of vector α, such that the following loss function (1) is minimized:

$$Loss = \frac{1}{|T|} \sum_{(x,y) \in T} eval(F(x) \le F(y)), \qquad (1)$$

where the *eval* function returns 1 if the ranking scores of (*x, y*) pair are not ordered, 0 otherwise. In [32] authors propose a novel clustering framework called RankClus that directly generates clusters integrated with ranking. Based on the initial K clusters, ranking is applied separately, which serves as a good measure for each cluster. Their experiment results show that RankClus can generate more accurate clusters and in a more efficient way than the state-of-the-art link-based clustering methods. In Fig. 1, a schema of this new hybrid approach is represented. We believe that this approach could improve the existing solution to the problem of APC in qualitative manner, mainly because clustering may be a more appropriate class of algorithms for solving the problem of APC. On the other hand, the complexity of the implementation of such a hybrid algorithm would increase drastically.

B. Personality Based Latent Friendship Mining

In [34] authors proposed a method that solves the problem of finding compatible friends within community of web bloggers. Unlike other methods that considered this problem, where the main hypothesis was that compatible bloggers write about related topics, authors here assume that compatible bloggers have similar personality characteristics. This way, the problem of APC is considered as a subproblem of the main problem. The logistic regression model for binary classification was utilized in this research. The feature vector consisted of 20 elements: the number of comments, the number of images, readability, average size of sentence, open text, represented as a vector of the used words, and others.

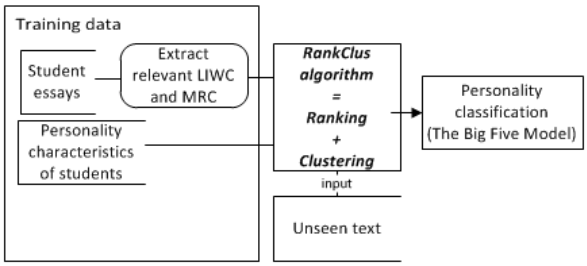

Figure 1. Ranking + clustering based algorithm

Let θ represent a similarity vector between a pair of bloggers w_i and w_j. The logistic function is defined as $Y = e^A / (1 + e^A)$, where the variable A is defined as $A = \lambda_0 + \lambda_1 X_1 + ... + \lambda_{20} X_{20}$. X_i is the ith element of vector θ. Output *Y* ranges between 0 and 1. The threshold value of 0.5 is used to distinguish between two classes: non-potential friends (0) and potential friends (1). Articles of the bloggers, randomly selected from the MSN live space, were considered as an input in the regression. After that, based on their blogger friend lists, their friend's blogs were also downloaded. This way, blogger friends' relations were established. After that, the previously described regression model was trained and tested (80% of data for training and 20% for testing). Out of 20 features, those which proved to be significant are: plain text similarity, average number of comments, special symbols, font changes, words, hyperlinks, adjectives, nouns, average lexical density and readability. Authors concluded that the full-feature model gives solid precision and recall measures, 80% and 75%, respectively.

Our idea for improvement of this solution is based on the usage of a more sophisticated binary classifier, support vector machines ([5] and [33]). It would be interesting to check whether the SVM would give better results. Additionally, we suggest resizing of the 20th feature, which represents the vector of all words occurring in text. Keeping in mind the results of previous researches, mainly [23] and [24], non-LIWC words should be removed from this feature. This modification (Fig. 2) would ensure stronger implementation of author's hypothesis, that compatible bloggers have similar personality characteristics.

C. Lexical Predictors of Personality Type

In [31] authors consider the problem of binary classification of neuroticism and extraversion. They used four different sets of features: function word list, conjunctive phrases, modality indicators, and appraisal adjectives and modifiers. Support vector machine is used as a binary classifier. This study is based on language psychology and computational stylistic. Computational stylistic is a discipline that threats the meaning of text through the following aspects: affect (what feeling is conveyed by the text?), genre (in what community of discourse does the text function?), register (what is the function of the text as a whole?), and personality (what sort of person, or who specifically wrote the text?). This discipline suggests that all these aspects can be extracted from the text's style of writing.

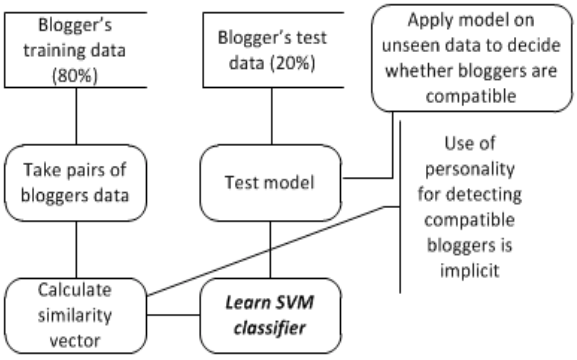

Figure 2. The SVM classifier instead of the logistic regression

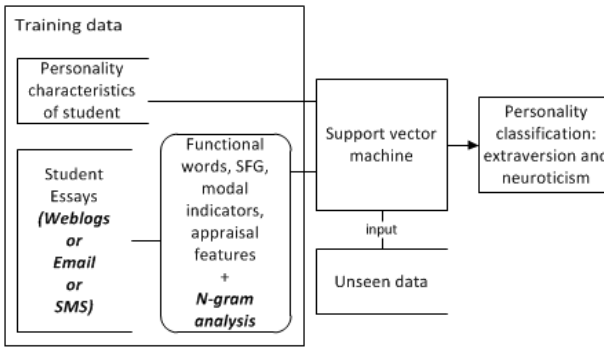

Figure 3. Utilization of the n-gram analysis and different types of corpora

Function words are frequent words that have a primarily grammatical function in the language (such as *and*, *for*, and *the*). The motivation behind using them as features is that they are not likely to be consciously controlled by the author of the text. Therefore, their frequencies can be useful in detecting author's style. Conjunctive phrases represent a concept in the theory of Systemic Functional Grammar (SFG), a functional approach to linguistic analysis ([12]). Modality indicators qualify events or entities in text to be classified according to their likelihood, typicality or necessity (modal verbs, adverbial adjunct, etc.). Finally, appraisal considers two attributes: attitude and orientation. Authors used corpus of essays written by students at the University of Texas at Austin between 1997 and 2003 ([23] and [24]). Appraisal features gave the highest accuracy when the neuroticism was in question. When extraversion was in question, only function words improved accuracy. Moreover, usage of other three types of features reduced the overall accuracy when they were added to function words.

Future research should consider different types of corpora. We are not convinced whether the approach that the authors proposed here would work for some less formal types of text, such as weblogs (web blogs), emails, as well as social networks feeds and conversations. Hybridization of this approach with some data-driven approaches, such as, the n-gram analysis should also be considered (Fig. 3).

D. Comparative Evaluation of Personality Estimation Algorithms for the TWIN Recommender System

In [28], a comparative evaluation of several algorithms for APC is presented. The goal of this research was finding the most adequate algorithm for use within the TWIN ("Tell me What I Need") system. The TWIN is a tourist recommender system used on the website *tripadvisor.com*. Recommender systems are usually based on evolutionary user profiling. The initial amount of profile information is collected during the user registration process. Afterwards, information is collected through surveillance of user activities. The key hypothesis of this research is that groups of people that share similar personality characteristics usually prefer to choose similar tourist destination and hotels.

Within TWIN systems, user reviews are gathered, and then a personality profile of user is constructed based on them. Finally, user profile is used to decide which destinations are suitable. Authors used previously formed corpus of student essays and their personality characteristics ([23] and [24]). Personality characteristics were measured using the five-factor model. The LIWC and the MRC were used as input features. Four models were utilized: linear regression, M5' classification tree, M5' regression tree, and support vector machine. Testing of quality was performed on reviews of 15 randomly chosen users of the TWIN system that had at least 30 reviews. For each personality trait and for each of the four models, a personality score was determined. Hypothesis is that a model is good if it gives similar scores to all reviews, written by the same user (standard deviation is as little as possible). M5' regression tree has been shown as the most prominent model, with respect to this criterion. Therefore, it was implemented inside the TWIN system.

In this work, authors used quality metric that is similar to one of those used in cluster analysis, the so-called intra-cluster distance. There are several ways to model this distance, but the essential common intuition behind all of them is that, if this distance is minimized, then elements inside clusters are more similar. Beside the intra-cluster distance, there is also inter-cluster distance, which measures the distance between centroids of different clusters. Note that this metric should be maximized. Our recommendation regarding this research is to use composite similarity metric that combines intra-cluster and inter-cluster distance (Fig. 4). David-Bouldin (2) and Dunn index (3) are examples of two such metrics:

$$DB = \frac{1}{n}\sum_{i=1}^{n}\max_{i\neq j}\left(\frac{\sigma_i+\sigma_j}{d(c_i,c_j)}\right), \tag{2}$$

$$D = \min_{1\le i\le n}\left\{\min_{1\le j\le n, i\neq j}\left\{\frac{d(c_i,c_j)}{\max_{1\le k\le n} d'(k)}\right\}\right\}. \tag{3}$$

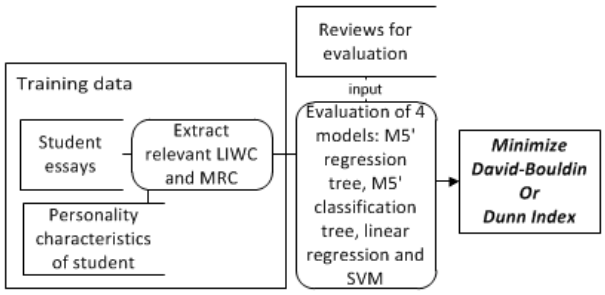

Figure 4. Composite cluster quaility metrics

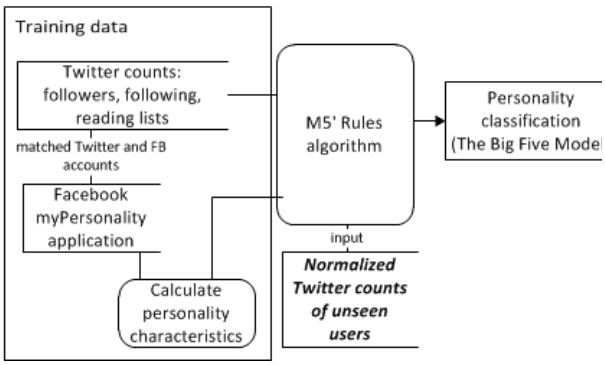

Figure 5. Normalization of Twitter stats

n represents the number of clusters, c_x is the centroid of cluster x, σ_x is the standard deviation of elements inside cluster c_x and $d(c_i, c_j)$ is the distance between centroids.

E. *Our Twitter Profiles, Our Selves: Predicting Personality with Twitter*

In [25] authors analyze the relation between personality characteristics, based on the five-factor model and three publicly available Twitter stats. They used a corpus that consisted of 335 user's information. Proposed predictor of personality characteristics is based on the usage of: "following", "followers", and "listed" counts. Personality characteristics measurement was performed indirectly, through a Facebook application called *myPersonality*. Authors considered all users who specified their Twitter accounts on their Facebook profiles, and ended up having 335 Twitter users who took *myPersonality* questionnaire. The authors performed regression analysis based on the M5' Rules algorithm [35] for each of the five characteristics separately (Weka toolbox). Prediction error was 0.88 according to RMSE scale (root-mean-square error, takes values from interval [0, 5]). Authors claim that this error is low, and the main argument is the fact that the best collaborative filter algorithm for prediction of user movie ratings had RMSE of 0.8567 (company Netflix awarded the authors of this algorithm with the prize of $1M).

Regarding the possible improvement of personality prediction, we suggest two changes. First, the three aforementioned accounts should be normalized. We think that the usage of absolute figures could lead to obtainment of biased results. Given that all Twitter accounts used in this research are mapped with Facebook, $1/n_{facebook}$ could be utilized as a normalization factor, where $n_{facebook}$ represents the number of Facebook contacts. Another possibility for dealing with this problem would be to use ratios between Twitter counts. Second, implementation of some other regression-based algorithms should be considered. Keeping in mind that support vector machines had shown to be a high-quality solution for various classification and regression tasks, we would suggest the usage of support vector machine regression model (Fig. 5).

IV. CONLUSION

In this paper, new ideas regarding the problem of automated personality classification are presented. We proposed some general directions for improvement of all existing solutions. Afterwards, we gave a brief overview of some selected existing solutions and discussed about their possible specific enchantments. We also acknowledged extensions of APC and possible usages of APC for solving related problems. Solutions to the problem of APC could be used to solve other problems, whenever solving the problem of APC can draw some conclusions regarding those problems.

In our future work we will consider actual implementations of some of the proposed ideas. We also want to put efforts in finding and implementing new ideas related to the social network algorithms.

Our opinion is that, in the near future, the APC is going to be heavily exploited, directly or indirectly inside recommender systems, social networks and expert systems. Therefore, this paper, conceived as an initial analysis research, could announce new scientific and practical work related to the problem of APC.

ACKNOWLEDGMENT

***Abstract*— In the most intrusion detection systems (IDS), a system tries to learn characteristics of different type of attacks by analyzing packets that sent or received in network. These packets have a lot of features. But not all of them is required to be analyzed to detect that specific type of attack. Detection speed and computational cost is another vital matter here, because in these types of problems, datasets are very huge regularly. In this paper we tried to propose a very simple and fast feature selection method to eliminate features with no helpful information on them. Result faster learning in process of redundant feature omission. We compared our proposed method with three most successful similarity based feature selection algorithm including *Correlation Coefficient, Least Square Regression Error* and *Maximal Information Compression Index*. After that we used recommended features by each of these algorithms in two popular classifiers including: Bayes and KNN classifier to measure the quality of the recommendations. Experimental result shows that although the proposed method can't outperform evaluated algorithms with high differences in accuracy, but in computational cost it has huge superiority over them.**

I. INTRODUCTION

As the time passes the internet breaches more and more in human life and merge itself in all aspect it. Despite the benefit of internet in making life easier as well as doing varies of works faster than ever, it made the whole new ways to do illicit behavior. These behaviors vary from infiltration to anything that is connected to it illegally to making a resource so busy that it can't service to legitimate users. There are two type of defense mechanism against these attacks: static and dynamics. Security update and firewalls is some example of static defense mechanism. A very popular dynamic defense is *Intrusion Detection Systems* (IDS). In definition, "intrusion means violation of security policy"[1]. With this definition intrusion detection express the concept of finding a way to detect any illegal behavior that is performing in the network or more accurately in transmitting packets. Process of finding these illegal activities assume that normal packets are different from packets that doing intrusive behavior. Intrusion detection is not an alternative to prevention-based techniques (for ex. authentication and access control), instead, it is used to complete the security measures and recognition of actions that tries to bypass the security sections and monitoring of the system. There for Intrusion detection stand in the next level of security component of the system[1]. In short IDS are used as a dynamic methodology to supplement static defense and make it more powerful and accurate. An example of these systems is represented in figure.1. Some specific examples of intrusions that concern system administrators include[2]:

- "Unauthorized modifications of system files so as to facilitate illegal access to either system or user information.
- Unauthorized access or modification of user files or information.
- Unauthorized modifications of tables or other system information in network components (e.g. modifications of router tables in an internet to deny use of the network).
- Unauthorized use of computing resources (perhaps through the creation of unauthorized accounts or perhaps through the unauthorized use of existing accounts)".

Some of the important features an intrusion detection system should possess include[1]:

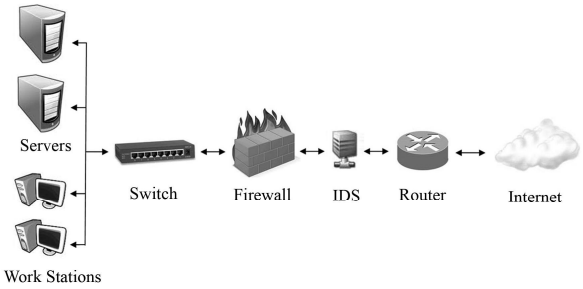

Figure1. Location of an intrusion detection system (IDS) in a network and utilization of it as second line of defense.

- "Be fault tolerant and run continually with minimal human supervision. The IDS must be able to recover from system crashes, either accidental or caused by malicious activity.
- Possess the ability to resist subversion so that an attacker cannot disable or modify the IDS easily. Furthermore, the IDS must be able to detect any modifications forced on the IDS by an attacker.
- Impose minimal overhead on the system to avoid interfering with the normal operation of the system.
- Be configurable so as to accurately implement the security policies of the systems that are being monitored. The IDS must be adaptable to changes in system and user behavior over time.
- Be easy to deploy: this can be achieved through portability to different architectures and operating systems, through simple installation mechanisms, and by being easy to use by the operator.
- Be general enough to detect different types of attacks and must not recognize any legitimate activity as an attack (false positives). At the same time, the IDS must not fail to recognize any real attacks (false negatives)".

There are varieties of attacks that IDS tries to detect. Some of these can be detected by scanning the packets to find signature of specific attacks. Other types of attacks are very much like normal packet pattern with slight difference in packet content. So there is two type of intrusion detection algorithm. They are called Misuse Detection and Anomaly Detection respectively.

A. Anomaly Detection

Anomaly detection is based on assumption that an attack will always similar to normal pattern with a slight difference. With this assumption a classifier first trained with normal and abnormal samples. It should predict whatever a future coming data should be placed in normal class or abnormal class. The training process is performed with finding characteristics of normal class and definition of rules and heuristics depend on observations. A very popular method for doing this is *Support Vector Data Description* (SVDD)[3]. Experimental result shows a very high detection rate and accuracy using SVDD [4-8]. Another approach is Neural Networks[9-10]. Hybrid methods also used to utilize the positive aspects of these two approaches while reducing negative aspects of them as much as possible. SVDD maximizes the margin but it can't handle missing values correctly. Neural networks have O(1) in prediction and ability of handling missing values but it's not obvious what is the optimal weight or how many level is required to achieve the best result. An example of hybrid method is proposed in [11].

B. Misuse detection

Misuse detection is based on searching for signature of known attacks in packets that are transmitted on the network. In the other word, misuse detection tries to find intruder who is trying to breach in the system using some known attack type. Although in real world, system administrators should be familiar with all known vulnerability of the system and fix them. In this methodology a term *intrusion scenario* is widely used. For any attack to be performed, there are a certain steps that an intruder will do to make that attack, these steps is called intrusion scenario. Misuse intrusion detection persistently scans recent activities and looking for known intrusion scenario to ensure no one is trying to attack the system. For intrusion detector to be able to detect known attack types, every attack should be represented or modeled in specific ways that the system can recognize it. This is the point where different methodologies for misuse detection are varying[1].

II. PREPROCESSING AND DATA PROVISION

A. Preparing Raw Network Data

To performing learning process packets from network are collected and fed to the learning algorithm. Regularly these networks transmits huge amount of data every second. So that, datasets for intrusion detection are very populated and extensive amount of data should be analyzed. Also packets transmitting on the network have a lot of overhead on them that is not related to the content of the packet. Because of this a preprocessing is performed for raw network data. In the other word raw network packets is converted to structures that have closer level to meaning of that connection, for example connection records. Any of these structures have set of features describing them. Deciding which of these features can represent more knowledge is a critical decision and one should have very wide and accurate knowledge about the domain to do that. Because of this, there are not a lot of dataset for intrusion detection. As far as the authors know there are only two dataset for intrusion detection: KDD 99[12] and IDEval[13], while the former is only a refinement version of the later one.

B. KDD 99

The KDD 99 is an intrusion detection dataset that is build upon about four gigabytes of compressed binary TCP dump data from seven weeks of network traffic. This was processed into about five million connection records. Similarly, the two weeks of test data yielded around two million connection records. The network was a simulation of military network which had three servers with rule of victim computers that exposure a lot of attacks and normal network traffic. All attacks were consisted on four main categories:

- Denial of Service (dos): Intruder tries to consume server resources as much as possible, so that normal users can't get resources they need.
- Remote to Local (r2l): Intruder has no legitimate access to victim machine but tries to gain access.
- User to Root (u2r): Intruder has limited privilege access to victim machine but tries to get root privilege.
- Probe: Intruder tries to gain some information about victim machine.

The original raw dump network traffic were preprocessed for International Knowledge Discovery and Data Mining Tools

Competition[14]. For this, all the raw data is converted into connection. A connection means "a sequence of TCP packets starting and ending at some well defined times, between which data flows from a source IP address to a target IP address under some well defined protocol"[15]. This conversion is performed by Paxson algorithm[16]. Result of this algorithm has 41 features. Each of features is member of these four categories[17]:

- Basic Features: These features are captured from packet headers only and without analyzing payload. Features 1 to 6 are in this category.
- Content Features: In this category original tcp packets analyzed with assistance of domain knowledge. An example of this category is number of "hot" indicators.
- Time-based Traffic Features: for capturing these types of features a window of 2 second interval is defined. In this interval, some properties of packets is measured. For example number of connections to the same service as the current connection in the past two seconds.
- Host-based Traffic Features: In this category instead of a time based window, a number of connections are used for building the window. This category is designed so that attacks longer than 2 second can be detected.

The KDD 99 is distributed in three versions which are described in table.1. "10% KDD" has 22 attack types and is a synopsis version of "Whole KDD" dataset. These datasets has more attack samples than normal samples. Because of specific attribute of DoS attacks, it has more frequency in dataset than other types. In the "Corrected KDD" dataset distribution of data is changed also it has more 14 additional attacks. The list of subcategories of "10% KDD" is represented in table.2. This version of dataset is used for wide variety of studies and more importantly it is used in the contest. So for evaluation result, we used this version. This version of dataset is used for wide variety of studies and more importantly it is used in the contest. So for evaluation result, we used this version. Feature values for each sample in this dataset have a very unbalanced range in compare of other features. For example feature #1 has range between 0 and 42448 and feature #10 has range between 0 and 28. Because of this performing normalization on dataset before training phase seems reasonable although this process can be done in preprocessing phase too.

III. SIMILARITY MEASURES

In this section we introduce some of most successful similarity measures. These successful similarity measures includes: *Correlation Coefficient[18], Least Square Regression Error[19-22] and Maximal Information Compression Index[23].*

A. Correlation Coefficient[18]:

One of the most popular and known measures of similarity between two random variable is correlation coefficient. It also called cross-correlation coefficient. We can use (1) to measure how much random variable x is similar to random variable y.

$$Relation(x,y) = \frac{cov(x,y)}{\sqrt{var(x) \times var(y)}} \quad (1)$$

Where $var(x)$ correspond to variance of variable x and $cov(x,y)$ correspond to covariance of random variable x and y. Covariance of two variables shows strength of relation between those variables. If x grow when y rises with exact linear relation, covariance of these two variable will be $+1$ and if x shrink when y rises covariance will be -1. If two variables are unrelated at all covariance will be 0. We can use this as a similarity measure. This measure have following properties[23]:

1. $0 \leq 1 - |Relation(x,y)| \leq 1$.
2. $1 - |Relation(x,y)| = 0$ If and only if x and y are linearly related.

3. This measure is symmetric. Meaning that always $Relation(x,y) = Relation(y,x)$.
4. Assume $u = \frac{x-a}{c}$ and $v = \frac{y-b}{d}$. For any arbitrary value for a, b, c, d we have:
$$|Relation(x,y)| = |Relation(u,v)|$$
5. $Relation(x,y)$ Is *sensitive to rotation* of the scatter diagram in (x,y) plane.

As Mitra[23] discussed correlation coefficient have a lot of convenient specifications but because of having properties of 4 and 5 mentioned above it is invariant to scale. Because of this, it's possible that two variables have same similarity measure although they have very different variances. It is not preferable because variance always gives high information about content.

B. Least Square Regression Error:

Another similarity measure that is used regularly is least square regression error or *residual variance*. It is the error of predicating y from $y = bx + a$. Where a and b are the regression coefficients which can be calculated by minimizing $e(x,y)^2$ in (2):

$$e(x,y)^2 = \frac{1}{n}\sum e(x,y)_i^2 \quad (2)$$

Where $e(x,y)_i$ can be calculated with (3):

$$e(x,y)^2 = y_i - a - bx_i \quad (3)$$

So we have (4), (5):

$$a = \overline{y} \quad (4)$$

$$b = \frac{cov(x,y)}{var(x)} \quad (5)$$

Having a and b we can calculate mean square error $e(x,y)$ by (6):

$$e(x,y) = var(y) \times (1 - Relation(x,y)^2) \quad (6)$$

With this new measure if x and y have linear relation $e(x,y)$ will be 0 and if x and y have no relation at all $e(x,y)$ will equal to $var(x)$. Mitra also argues about properties of this measure[23]:

1. $0 \le e(x,y) \le var(y)$.
2. $e(x,y)$ Is equal to 0 if and only if x and y have perfect linear relation.
3. This measure is not symmetric.
4. Assume $u = \frac{x}{c}$ and $v = \frac{y}{d}$. For any arbitrary value for c, d we have $e(x,y) = d^2 e(u,v)$. With this property we can conclude that *e* is *sensitive to scaling* of the variables. It's obvious that *e* is not *sensitive to translation.*
5. *e* Is *sensitive to rotation* of scatter diagram in $x - y$ plane.

C. Maximal Information Compresseion Index[23]:

This measure fixed some defects of two previous described measures. We refer to it by MICI and use λ_2 for simplicity. MICI can be calculated using (7):

$$\lambda_2(x,y) = \min(eigv(\sum)) \quad (7)$$

Where $\sum$ correspond to covariance of x and y and $eigv$ is a vector of eigen values of that covariance.

The λ_2 will equal to 0 when the feature have linear relation and as much as the relation fade away, the value of λ_2 increase. As the formula represent λ_2 is only an eigenvalue for a direction where data have the most elongation. In the other word it is the main idea behind *Principle Component Analysis* (PCA)[20, 24]. PCA is based on the fact that if a data be projected along its principal component direction, it yields maximum information compaction. If we reconstruct the data, the amount of lost information is related to eigenvectors that is not considered in PCA calculation. In PCA we always use k eigenvectors that have maximum corresponding eigenvalues. So the amount of lost information will be minimal. The λ_2 have following properties[23]:

1. $0 \le \lambda_2(x,y) \le 0.5(\mathrm{var(x)} + \mathrm{var(y)})$.
2. $\lambda_2(x,y)$ Will equal to 0 if and only if x and y is linearly related.
3. $\lambda_2(x,y) = \lambda_2(y,x)$, so it's a symmetric measure.
4. Assume $u = \frac{x}{c}$ and $v = \frac{y}{d}$. For any arbitrary value for c, d we have $\lambda_2(x,y) \neq \lambda_2(u,v)$ so it is *sensitive to scaling* and is not related to *translation.*
5. $\lambda_2(x,y)$ Is not related to rotation.

To detect which feature should be removed from dataset using discussed similarity measures, a simple general algorithm based on *K-Nearest Neighbor* (KNN) algorithm[25] is used. It has two phases. In the first phase, all of features partitioned using the similarity measure as a distance in KNN algorithm. In the second phase a feature that describes its cluster more accurately is selected as a candidate of that group.

IV. Proposed Method

As discussed earlier, variance of a random variable has very high information inside. Intuitively, we used this measure to find features with low quality to be eliminated from dataset while preserving others. In the other word we used variance to discover if any feature has no class dependent information included. Features with low information should be removed. Also because of nature of intrusion detection datasets, they are very populated by samples and even a linear order for computational cost is very slow. So we tried to make our approach to be simple as possible while preserving its accuracy.

If we look precisely at a simple two class dataset with separate classes, we can clearly see that if there is any feature in dataset that have separate range of values in each class, we can classify all of samples in the dataset with 100% accuracy

with a linear classifier. An example of such a situation is shown in figure.2. Now let's assume a more general but still simple dataset shown in figure.3. In this dataset it is clearly obvious that if we remove any features from dataset, the accuracy of classification will not be 100% although the classes are separated with high distance. In real world dataset usually we have a very mixed dataset but we can still use this fact to detect if any feature can have more roles on separation of classes than other features. We developed this fact and built our algorithm upon it.

Let $X = \{\boldsymbol{x}_i\}_{i=1}^{N}$ be our intrusion detection dataset, containing N network connection samples containing all attack and normal connections. Each $\boldsymbol{x}_i$ is a vector with D dimension and $\boldsymbol{x}_i \in \mathbb{R}^D$. Let $L = \{l_i\}_{i=1}^{N}$ be our class labels for each sample. Also we have $l_i \in k$ where $k = \{1, \dots, K\}$. With this definition we have K class in our dataset and $K = 5$ because we used "KDD 10%" as our dataset. $\boldsymbol{x}_{id}$ Represent the value of feature $d = \{1, \dots, D\}$ in connection sample i. For each class first we add all data point $\boldsymbol{x}_i$ which are in same class, feature by feature (8):

$$S_{cd} = \left\{ for\ all\ \boldsymbol{x}_i\ where\ \ l_i = c \middle| \frac{\sum \boldsymbol{x}_{id}}{n_c} \right\} \qquad (8)$$

Where n_c is number of samples in class c and S_{cd} is mean of connection sample $\boldsymbol{x}_i$ along feature d whose class is c and $c \in k$. We put all S_{cd} in a vector and call it FS(9):

$$S_d = [S_{1d}\ \ S_{2d}\ \dots\ S_{Kd}] \qquad (9)$$

After that we need to calculate how much S_d is scattered along each feature. In the other word we need to measure confusion of S_d for each feature. For this reason we used variance of S_d(10):

$$V_d = Var(S_d) = E[(S_d - \mu_d)^2] \qquad (10)$$

Where μ_d is mean of all values in S_d and V_d is variance of S_d. Items in $V = \{V_d\}_{d=1}^{D}$ with high value represent degree of turbulence in feature d among all classes. High turbulence represents power of corresponding feature in class separation. Now we can sort V with ascending order and select t feature index for classification where t is number of desired feature that user defined to be selected.

V. EVALUATION

In this section we used KDD 99 dataset to evaluate these three similarity measure and compare them with our proposed method. To survey the effectiveness of these feature selection algorithm in classification, we used two popular classification algorithms including: Bayesian Network Classifier[26-27] and K-nearest neighbor classifier[25] and measured their accuracy.

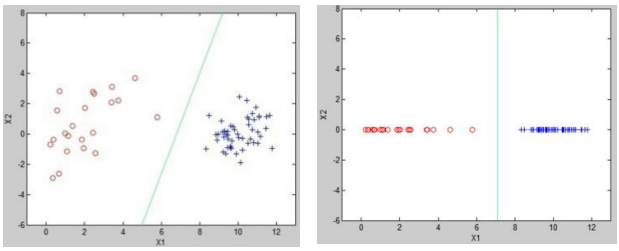

Figure 2. Demonstration of the fact that we can still classify data with 100% accuracy with only one feature when we have separate range of data on that feature corresponds to its class.

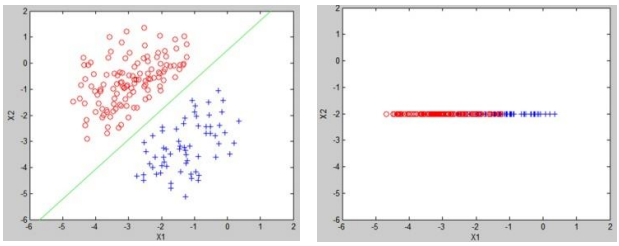

Figure 3. Demonstration of the fact that we can't classify the data with 100% accuracy when there is no feature with separate range corresponds to its class.

Evaluation is done with 10-fold algorithm to ensure the result is as authentic as possible. So the goal for these feature selection algorithm is to keep the class separability of the dataset as much as possible while reducing its size to lower dimension. Also selection algorithm should be very fast because in real world problem we encounter very large datasets and slow algorithm is not applicable.

First of all we classified the original "10% KDD" dataset with KNN and Bayes classifiers, result of this process is represented in first main column of table.3 and table.4. After that, dataset is fed to three discussed methodology also to our proposed method. Then the original dataset is reduced to features recommended by each of these similarity measure based algorithms and FFR (Fast Feature Reduction). At last the reduced dataset is again fed to KNN and Bayes classifier and result of this classification measured.

In this research speed of feature selection was our main goal. Because of this consumed time of each algorithm with different reject threshold measured and shown in table.3. The evaluated result for each algorithm is represented in its respective column of table.4 and table.5. As evaluation result shows, although FFR cannot defeat other methodologies in accuracy of classification and accuracy didn't changed very much, but in speed FFR outperformed all other feature selection method with great differences.

Abstract - Survey of probabilistc topic models is presented with emphasis on fundamentally different approaches used in modeling. Introduced classification differs from earlier efforts, providing a complementary view of the field. Purpose of this survey is to provide a brief overview of the current probailistic topic models as well as an inspiration for future research.

I. INTRODUCTION

Probabilistic topic models are a group of machine learning algorithms for discovering latent topical structures in data. Although many applications are found in various data mining areas such as image annotation, audio and video analysis, they are primarily invented for use in finding topics in textual data. Profiling and modeling knowledge from scientific papers is one area of research that benefits most.

Few surveys of topic models already exist; among most significant are [1], [2] and [3]. Most notable one [1], presents a classificaion of directed probabilistic topic models and a broader view on graphical models in general, and can serve as a great starting point for venture in the field of topic modeling. In [2] and [3] a gentle introduction is made to the field.

Main criterion of classification in [1] is functionality, and models are presented in a chronological order in a systematic evolution-based fashion. This is not the purpose of this survey; functionality is not of a primary interest for us. Criteria of presented classification are chosen as to highlight fundamental approaches and assumptions used in topic modeling. Also, [1] focuses on directed probabilistic topic models while we impose no such restriction. Introducing general ideas and formal definition has also been done in [2] and [3] so this is not our primary goal either. In [1] models are also classified acording to their original problem domain. As many of those problems, such as topic discovery, topic evolution, document classification and many others, present a subproblem to the modeling and profiling of the knowledge from scientific papers, such distinction is not made in this survey.

Survey of topic models is presented with emphasis on different approaches used.

II. CLASSIFICATION

Topic models are classified according to three orthogonal critera. First criterion is based on word ordering and a document representation. Two distinct approaches are posible. Simpler and very often more usefull solution is commonly known as bag of words. In this document representation the word ordering is neglected which enables focus on a global semantic structures without need to model local word order dependencies. Other approach, that doesn't neglect word ordering will be referred to as a sequence of words. Although first approach is appreciated for its simplicity and is often sufficient, second approach bear more information which can supposedly lead to better results in some problem domains. Second criterion is taking external knowledge into consideration. First approach where no such knowledge is provided is simpler and for many purposes sufficient. Second approach is based on using in-domain knowledge for the target problem, yielding more specific and human interpretable topics. Third and final criterion is dependability on labeled data. Main idea behind topic models is unsupervised clustering of topics which renders them applicable to a broad range of real life problems where there are no data labels and cannot be provided. Most of the topic models are fully unsupervised. Some models can be used in a supervised or semi-supervised manner in order to be applicable to classification tasks or simply to yield better results if labeled data for domain is already present. Classification tree with corresponding models at the leaves can be seen on Figure 1.

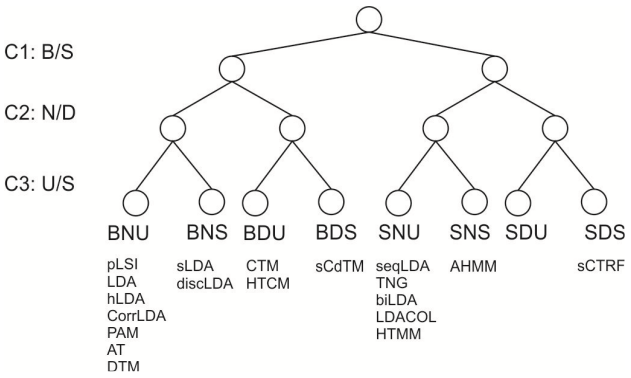

Figure 1. The classification three of probabilistic topic models. **Legend**: B/S – bag of words vs sequence of words; N/D – no in-domain vs in-domain; U/S – unsupervised vs supervised. **Description:** The classification three obtained by successive application of the chosen criteria. **Implication:** The class of unsupervised sequence of word models with in-domain knowledge requirements have no known implementations.

III. EXISTING SOLUTIONS

For each class defined in previous section most prominent examples are presented, if such solutions exist.

A. Unsupervised bag of words topic models with no in-domain knowledge requirements

This class of models reside on word exchangeability assumption, i.e. discards information on word position within documents. Such models are often used regarding problems such as information retrieval, document clustering and summarization due to their simplicity introduced with bag of words approach and greater real-world problem applicability based on their unsupervised nature. Most of the probabilistic topic models, including the earliest ones, fall into this category. There are numerous extensions from the baseline approach (Latent Dirichlet Allocation) that introduce additional abilities beside modeling word-topic and document-topic distributions, some of which are presented here.

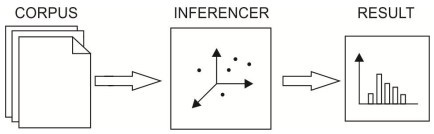

Figure 2. Outline of the unsupervised bag of words topic model with no in-domain knowledge requirements. **Description**: Appropriate inference equations stipulated by the particular model are applied to the textual corpus after tokenizing and preprocessing. Word ordering is neglected.

A.1. Probabilistic Latent Semantic Indexing

Probabilistic Latent Semantic Indexing (pLSI) was invented by T. Hoffman and was first published in Proceedings of the Twenty-Second Annual International SIGIR Conference on Research and Development in Information Retrieval in 1999 as a probabilistic variant of Latent Semantic Analysis that has a sound statistical foundation and defines a proper generative data model [15].

pLSI models generative process responsible for creating each document in corpus, where each word in a document is sampled from a mixture of multinomial distributions that can be interpreted as topics, and proportions corresponding to mixture weights are sampled from a separate multinomial distribution for each document. Based on generative model, an inference algorithm is defined as a method for infering topic-word distributions, as well as document-topic distributions, from textual corpora.

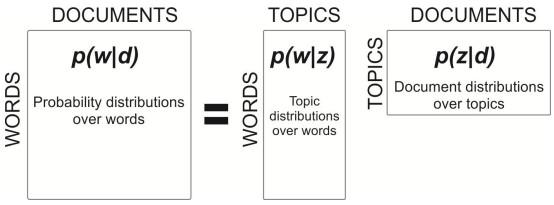

Figure 3. Probabilistic Latent Semantic Indexing, viewed as a matrix factorization

There are several methods for computing word-topic and topic-document distributions, one videly accepted is Expectation Maximization algorithm. Equations for E and M steps are inferred directly from the generative model (Fig. 4).

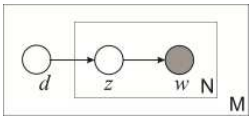

Figure 4. Plate notation of pLSI model. **Description**: Graphical presentation of a bayesian network corresponding to pLSI model. For interpretation of this as well as other graphical models presented in the survey, reader is encouraged to read [1] and [2].

pLSI efficiently resolve several issues of Latent Semantic Analysis (LSA) [16], it's non-probabilistic predecessor, such as capturing polysemy. Also, as opposed to LSA, this generative model has a strong theoretical justification. Problem that pLSI is often confronted to is large number of estimation parameters that depends on corpus size which can create problems with overfiting as number of documents increases, as well as inability to be applied incrementally to unseen documents due to its offline nature.

A.2. Latent Dirichlet Allocation

Latent Dirichlet Allocation (LDA) is a generative probabilistic model that represents a bayesian upgrade to pLSI by introducing priors on document-topic distributions and is published in Journal of Machine Learning Research by D. Blei, A. Ng, and M. Jordan in 2003 [9] creating a foundation for numerous latent structure discovery algorithms collectively known as Probabilistic topic models.

LDA resolves problematic issues of pLSI such as increasing number of estimation parameters by placing a Dirichlet prior distribution, effectively considering them as a random variables on their own. By introducing such a prior not only the number of estimation parameters was reduced (and made independant of the number of documents), but inability of model to be applied incrementally to unseen documents was also surpassed.

Because of it's increased complexity in comparison to pLSI, exact inference is intractable from the generative model (Figure 5. **LDA model in plate notation**). To efficiently cope with this problem, several approximate inference algorithms are derived such as Variational Inference, and various Markov Chain Monte Carlo algorithms, such as Gibbs Sampling[8].

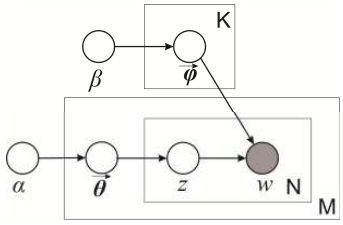

Figure 5. LDA model in plate notation

One of main advantages of LDA over earlier probabilistic methods such as pLSI, beside ability to be incrementally applied to unseen documents, i.e. online property, lies in its expandability. LDA serves as a basis for many topic models, some of which are presented in further text. LDA is computationally more expensive than earlier models such as pLSI and LSA, but also lacks some of the features of later more complex models such as modeling relationships between topics [13][14][23], modeling evolution of topics over time based on document metadata [11][12], modeling autorship [19], modeling arbitrary document metadata [18] and others. As a attempt to address the computational time requirements, several implementations exploiting potentional parallelism are made [22].

B. Supervised bag of words models with no in-domain knowledge requirements

This class of models stems from unsupervised bag of words models with no in-domain knowledge requirements, as a group of models used for classification instead of clustering. Due to their supervised nature, on some tasks these models can exibit better modeling results.

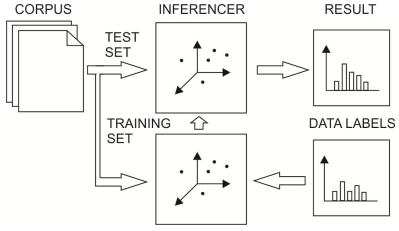

Figure 6. Outline of the supervised bag of words topic model with no in-domain knowledge requirements. **Description**: Textual corpus is divided into training and test set (to be evaluated on) and tokenizing and preprocessing is applied. Appropriate inference equations stipulated by the particular model are applied to training set given appropriate set of data labels effectively learning latent parameters. Finally, model with inferred parameters can be used for evaluation on test set or completly new set of unknown, unlabeled data. Word ordering is neglected.

B.1. Supervised LDA

Supervised Latent Dirichlet Allocation is first introduced by Blei and McAuliffe in 2007 as a supervised extension to LDA [17].

As opposed to other probabilistic topic models that work in purely unupervised fashion, sLDA extends on LDA by introducing a observable response variable in the model for each document. This extension enables sLDA to fit latent topics that will best predict future unlabeled documents.

Most appropriate aproximate inference method used for estimating the uknown parameters is Mean Field variational inference and can be derived from graphical model in Figure 7.

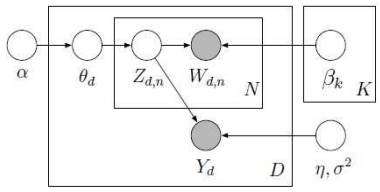

Figure 7. Supervised Topic Model

C. Unsupervised bag of words models with in-domain knowledge requirements

Models that belong to this category make abundant use of in-domain knowledge while retaining unsupervised learning strategy. This approach is used to increase the human interpretability of topics. For instance, if modeling of a biology corpus is required, additional constraints induced by a biological ontology are expected to yield better resutls.

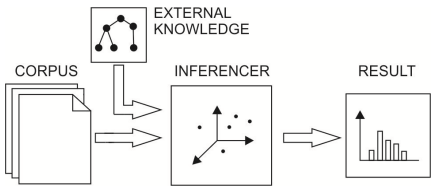

Figure 8. Outline of the unsupervised bag of words topic model with in-domain knowledge requirements. **Description**: Appropriate inference equations stipulated by the particular model are applied to the textual corpus after tokenizing and preprocessing. Additional in-domain knowledge is supplied, usually in form of ontolgy or thesaurus. Word ordering is neglected.

C.1. Concept Topic Model

Concept Topic Model was conceived by M. Steyvers et al. in 2009. as an attempt to introduce semantically rich concepts into the probabilistic model.

CTM is an extension to LDA where beside ordinary learned topics also exists a number of constrained topics where non-zero probabilities can be assigned only to words representing human defined concepts that are provided along textual data.

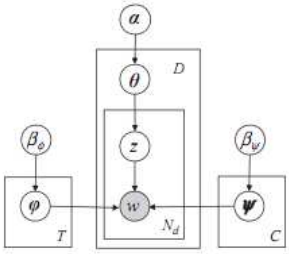

Figure 9. Concept Topic Model

D. Supervised bag of words models with in-domain knowledge requirements

This group of topic models attempt to employ additional constraints from domain of interest in classification tasks, while retaining simplicity of the bag of words assumption.

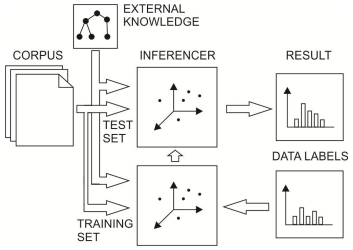

Figure 9. Outline of the supervised bag of words topic model with in-domain knowledge requirements. **Description**: Textual corpus is divided into training and test set (to be evaluated on) and tokenizing and preprocessing is applied. Appropriate inference equations stipulated by the particular model are applied to training set given appropriate set of data labels effectively learning latent parameters. Additional in-domain knowledge is supplied, usually in form of ontolgy or thesaurus. Finally, model with inferred parameters can be used for evaluation on test set or completly new set of unknown, unlabeled data. Word ordering is neglected.

D.1. *Supervised Conditional Topic Model*

Supervised Conditional Topic Model (sCdTM) is proposed by J.Xu and E.Xing in 2010. as an attempt to utilize nontrivial input features in order to improve performance.

As opposed to Dirichlet Multinomial Regression [18], that can utilize arbitrary document-level metadata, Supervised Conditional Topic Model can utilze metadata at word level which enables use of ritch feature such as POS taggs and ontologies in modeling. This is accomplished through conditioning on metadata insted of a generative approach.

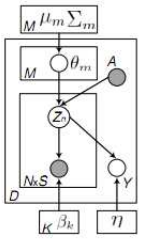

Figure 10. Conditional Topic Model in plate notation

E. Unsupervised sequence of words models with no in-domain knowledge requirements

Models belonging to this group go beyond bag of words model and account for sequential nature of textual data. Unsupervised nature of these models make them applicable to many real-world problems where data labels aren't at disposal. Lack of in-domain knowledge requirements makes them simpler and more appicable to some problems with presumably less domain-specific and humanly intepretable results.

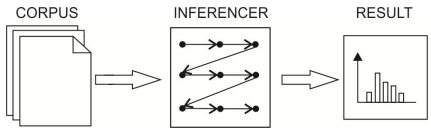

Figure 11. Outline of the unsupervised sequence of words topic model with no in-domain knowledge requirements. **Description**: Appropriate inference equations stipulated by the particular model are applied to the textual corpus after tokenizing and preprocessing. Word order is not neglected.

E.1. Topical N-Grams

Topical N-Grams (TNG) is defined by X. Wang et al in 2007. and published in Proceeding of the seventh IEEE International Conference On Data Mining, as a generative probabilistic model that attempts to relieve bag of words assumption made by Latent Dirichlet Allocation [10].

As opposed to LDA, which relies on bag of words assumption and models only unigrams, TNG also models Ngrams up to arbitrary N. Using this approach, although still relying on bag of words assumption, TNG attempts to account for sequential nature of text and enable modeling of complex phrases as well as unigrams.

Inference is slightly more complicated than in LDA, but similar aproximate inference algorithms are still applicable. Structure of TNG generative model is given in Figure 12.

Benefits of Topical NGrams model are semantically richer topic representations, enabling modeling of concepts made of multiple words which was impossible by earlier probabilistic topic models, but such benefits come at a greater computational costs.

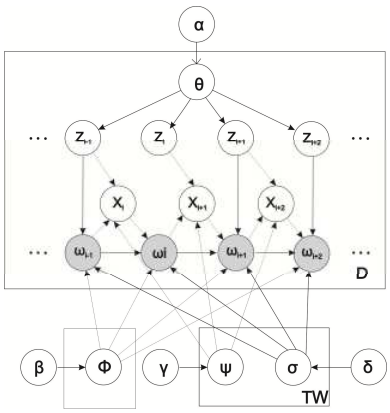

Figure 12. Plate notation of Topical NGrams model

F. Supervised sequence of words models with no in-domain knowledge requirements

Analog to supervised variants of bag of words models, these models are intended for use in classification tasks, i.e. tasks where labels corresponding to training data are provided. These models pose no in-domain knowledge requirements.

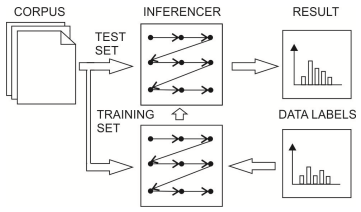

Figure 13. Outline of the supervised sequence of words topic model with no in-domain knowledge requirements. **Description**: Textual corpus is divided into training and test set (to be evaluated on) and tokenizing and preprocessing is applied. Appropriate inference equations stipulated by the particular model are applied to training set given appropriate set of data labels effectively learning latent parameters. Finally, model with inferred parameters can be used for evaluation on test set or completly new set of unknown, unlabeled data. Word order is not neglected.

F.1. Aspect Hidden Markov Model

Aspect Hidden Markov Model (AHMM) is invented by D.Blei and P. Moreno in 2001. as an attempt to use Hidden Markov Models for topic modeling.

AHMM is based on segmenting Hidden Markov Model and providing intuitive topical dependency between words and cohesive segmentation model.

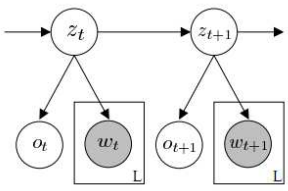

Figure 14. Plate notation of Aspect Hidden Markov Model

G. Supervised sequence of words models with in-domain knowledge requirements

This category of models account for sequential nature of textual data in supervised manner, using preassigned labels for training set while seeking to increase result specificality for domain of interest using some sort of in-domain knowledge .

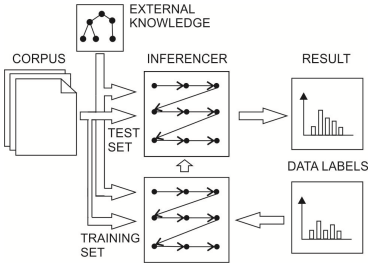

Figure 15. Outline of the supervised sequence of words topic model with in-domain knowledge requirements.

G.1. Supervised Conditional Topic Random Field Model

Supervised Conditional Topic Random Field Model is created by J. Xu and E. Xing in 2010. as an attempt to utilize nontrivial input features in order to improve performance and to incorporate Markov dependency between topics assigned to neighbouring words .

This model presents further enhancement over Dirichlet Multinomial Regression and Conditional Topic Models in modeling using feature rich metadata, by employing a Markov dependency between topics thus accounting for sequential nature of textual data. This is accomplished through use of Conditional Random Field, a type of undirected graphical model.

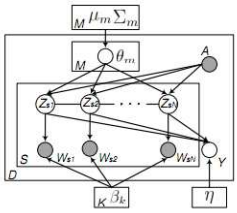

Figure 16. Plate notation of Conditional Random Field Model

H. Unsupervised sequence of words models with in-domain knowledge requirements

This class of topic models make use of word-order information, while attempting to increase applicability and interpretability of results to domain of interest with additionally supplied in-domain knowledge. This class is especially interesting because of lack of instances; there are few if any models that fall into this category. Authors are non-aware of such solutions.

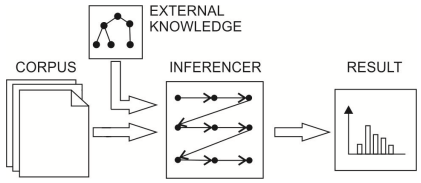

Figure 17. Outline of the unsupervised sequence of words topic model with in-domain knowledge requirements. **Description**: Appropriate inference equations stipulated by the particular model are applied to the textual corpus after tokenizing and preprocessing. Additional in-domain knowledge is supplied, usually in form of ontolgy or thesaurus. Word order is not neglected.

IV. CONCLUSION

A survey of most prominent probabilistic models is presented and a novel classification is proposed in order to emphasize fundamental approaches to probabilistic topic modeling. Motivation for such a survey rests in finding a new, possibly prospective direction of research. It is a fact that there are more models with simpler assumptions (bag of words models that do not use in-domain knowledge) than others. Bag of word models induce increased interest over sequence based ever since Latent Dirichlet Allocation was introduced. Models introducing in-domain knowlegde are sparse comparing to others, but with increasing need for semantically richer topics and applications, incorporating in-domain knowledge is gaining on popularity. Unsupervised models have generally precedence over supervised because of their applicability to large unlabeled corpora, but in problem domain where data labels exist, supervised models are presumably more reliant.

Perhaps the most notable contribution of this survey lies in observing the SDU class where none of the models are found. This observation may turn out to be the most valuable for doing further research.

Abstract - This paper presents an automated etalon-based integrated microchip inspection system, aimed to minimize manual quality control tasks, by analyzing images of integrated microchips taken by electronic microscope. To perform inspection the system requires three to five images of the analyzed region to average them into etalon image; no other a priori information is needed. The system uses rule-based approach, that assigns each defect to one of three groups: 1) shorting of two or more adjacent conductors; 2) islet or pin hole, representing defect contained within conductor’s boundaries or in metallization layer; 3) group type of defect including conductor’s breakups, mousebites and spurs. The paper proposes two algorithms to tackle two major problems of reference-based systems: slope and alignment correction. To detect topological elements affected by the defect, the algorithm of random polygon intersection is introduced. The decision whether a particular defect is significant is based on the comparison of the defect and affected conductor dimensions.

I. Introduction

The reliability is an indispensable component of the competitive advantage in the microchip manufacturing industry. Quality control test might be conducted through electrical/contact methods and non-electrical/non-contact ones[1]. Although electrical or functional testing performs badly in identifying mousebite- and spur-defects, it is very effective in locating shorts or opens in microchips. Non-contact methods use automated or manual inspection of optical, x-ray or ultrasonic images. Since manual quality assurance is slow and expensive, the area of automated microchip inspection attracts considerable research interest.

Visual inspection systems can be divided into three main groups: referential approaches, non-referential approaches, and hybrid approaches [1]. Referential approaches require manually selected etalon images free of any defects. These etalons must be created before the inspection stage. Non-reference approaches test whether the testing fragment conforms to the standard specification. As a prerequisite non-reference methods require some design-verification rules, which might not be available. Hybrid inspection combines the aforementioned methods, sharing their strengths and weaknesses. However, both initial conditions must be satisfied.

We propose a reference-based algorithm that uses an etalon created by averaging several images of the same microchip. Fig. 1 shows three types of defects the system can recognize.

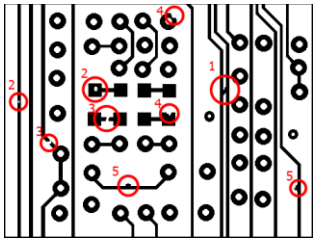

Figure 1. The system recognizes three types of defects: shorting of two or more adjanced conductors (1), islet or a pin hole (2), group of defects including conductor’s breakups (3), mousebites (4) and spurs (5).

Although accurate alignment and the same slope of the etalon and testing fragment are the key requirements of the reference-based approaches, we propose a simple algorithm for slope correction of an arbitrary image, based on vertical and horizontal lines detection. Moreover, to ensure precise image alignment we introduce an efficient projection-based method.

The rest of the paper is organized as follows: section II identifies the problem and describes the microchip inspection workflow. Section III discusses slope correction, image alignment and detection of defect-containing regions in detail. Defects analysis that includes faulty topological elements determination and identification of the defects’ type is looked at in section 0. Some preliminary results are given in section IV and conclusions are disclosed in section V.

II. The System Overview

The electronic microscope scans the microchip’s area and takes overlapping photos (θ is a given overlapping distance, see Fig. 2). Prior to recognition stage the system requires scanning several defect-free microchips to create an etalon by averaging them into one image.

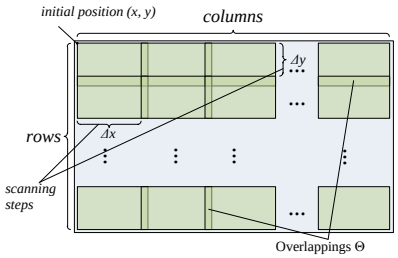

Figure 2. Example of a scanning session. A microchip is scanned subsequently by frames of the same dimension.

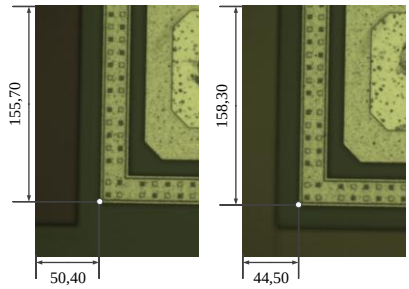

Figure 3. The white dot has different coordinates on these two images.

We will use term analyzed fragment to define the fragment that needs to be verified. Fragment containing zero defects is called etalon or reference fragment. The analysis of each fragment is divided into the following steps:

- Correspondent etalon fragment is retrieved from the database.
- The slope of the analyzed fragment is aligned so that the majority of the conductors' borders have strait horizontal or vertical orientation (see section III.A for details).
- The etalon and analyzed fragments are aligned so that they have exact match between pixels (see section III.B for details). The example of different alignment is shown in the Fig. 3. The coordinates of the corner marked with white dot differ on both images.
- Defect-containing regions are detected. Since both the etalon and the analyzed fragment are properly aligned, difference regions can be found by subtracting one image from another (see section III.C for details).
- Each defect is contained in a conductor or other topological element. Before proceeding further, all affected elements are determined (see section III.D for details).
- Each difference region is labeled as belonging to a specific defect type, allowing different dimensions analysis for every type. For example, mousebites or spurs must not exceed the half of the minimum size of the topological element in which they are present (see section III.E for details).

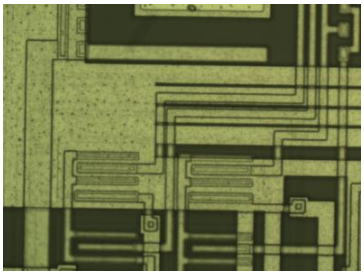

Figure 4. An image of arbitrary fragment of the microchip consisting mostly of vertical and horizontal lines.

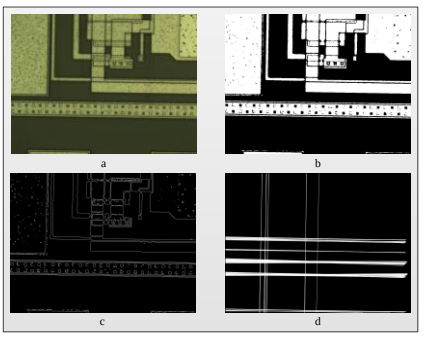

Figure 5. Lines detection steps: a) Initial image; b) Otsu threshold is applied; c) Canny edges extraction is performed; d) Standard Hough Transform is applied to detect lines.

III. DEFECTS DETECTION

A. *Fragment Slope Correction*

Each microchip is placed onto the positioning table by quality control specialist. Given the impossibility of fixing the microchip precisely, the electronic microscope's images will be of different albeit small slope. This slope will be constant for one capturing session, while it will vary from session to session.

Each fragment can be represented as a set of horizontal and vertical elements (Fig. 4). Let $h_i \in H, i = \overline{1,n}$, $n = |H|$, and $v_j \in V, j = \overline{1,m}$, $m = |V|$, where H, V are sets of vertical and horizontal lines in the image correspondingly. Let α_i and β_j be the angles between h_j and Xaxis, v_i and Yaxis correspondingly. We define an extended vector of all the angles as $\Gamma = [\alpha_1, \alpha_2, .., \alpha_n, \beta_1, \beta_2, .., \beta_m]$. Zero-slope condition can be defined with the following way:

$$M(\Gamma) = 0, \tag{1}$$

where $M(\cdot)$ is mode operator. This means that the majority of lines will have zero slopes. To find all slopes of the borders of the topological elements, well-known Standard Hough Transform (SHT) is used [2][3]. SHT uses the parametric representation of a line:

$$\rho = x \cdot \cos(\theta) + y \cdot \sin(\theta), \tag{2}$$

where ρ is the distance from the origin to the line, and θ is the angle of the perpendicular projection from the origin to the line.

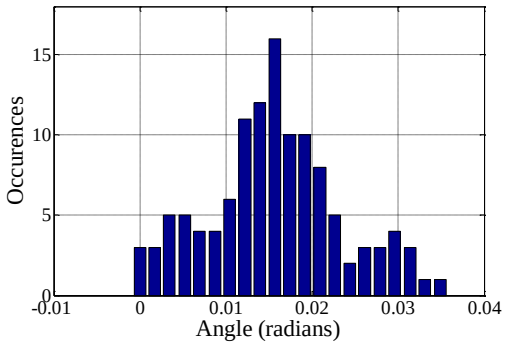

Figure 6. This diagram shows the density distribution of the slopes of the fragment in Fig. 4. The mode of this distribution is easily determined.

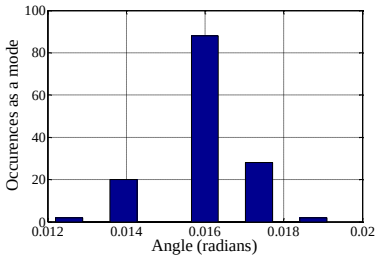

Figure 7. Histogram of the $M(\mathbf{\Gamma})$ of a session containing 140 fragments

As a preprocessing step, Otsu [4][5] and Canny [6] methods are used (Fig. 5). The histogram of Γ is given in Fig. 6**.** In this particular case $M(\Gamma) = 0.0157$ radians, meaning that source image should be rotated by -0.0157. Given that each microchip is placed on the positioning table only once, $M(\Gamma)$ should be the same within each session.

The condition that the slope of the microchip remains unchanged during one capturing session is used to choose the most probable slope angle. The resulting slope is determined with majority voting among the angles of every fragment. We have tested this approach on 20 sessions with 140 fragments in each and the results are almost the same: approximately 65% of all images have $M(\mathbf{\Gamma})$ equal to their real slope, others 35% have slightly different $M(\mathbf{\Gamma})$ (see Fig. 7).

B. Image Alignment

As it is seen from Fig. 2 the electronics microscope scans a microchip starting from some initial position (x, y) and shifting in both directions with some step $(\Delta x, \Delta y)$. For the two subsequent scanning sessions starting positions $(x_1, y_1) \neq (x_2, y_2)$ and $(\Delta x_1, \Delta y_1) \neq (\Delta x_2, \Delta y_2)$. The difference can be as small as several microns only. Images are perfectly aligned when the displacement of the elements is compensated.

Let us define horizontal (HI) and vertical (VI) profiles as follows:

$$HI(x) = \sum_{x=1}^{n} I(x, y), \qquad VI(x) = \sum_{y=1}^{m} I(x, y), \tag{3}$$

where I is an image. Similar profiles are used in [7][8][9] for face and facial features location.

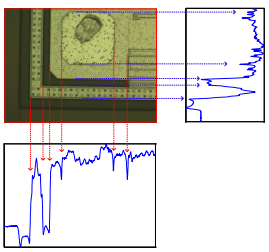

Figure 8. The structure of horizontal and vertical profiles reflect the structure of the analyzed fragment.

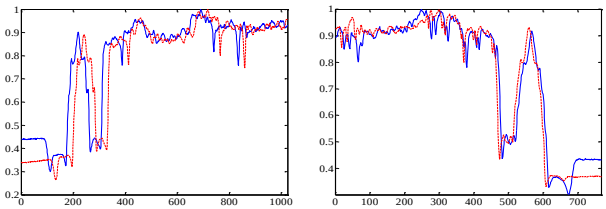

Figure 9. Horizontal (left) and Vertical (right) profiles of the similar fragments before alignment

Since microchip fragments consist mostly of vertical and horizontal lines, these profiles will have characteristic structure (Fig. 8).

Horizontal and vertical profiles of two fragments shown in Fig. 3 are given in Fig. 9. The left diagram shows projections on the horizontal axis, the right one – on the vertical axis. It is easy to see that these projections have very much in common, with corresponding pikes shifted by some pixels. To determine the best correspondence we slide one projection along the other and calculate correlation coefficient:

$$r = \frac{\sum_i (a_i - \bar{a})\,(b_i - \bar{b})}{\sqrt{\sum_i (a_i - \bar{a})^2}\sqrt{\sum_i (b_i - \bar{b})^2}}, \tag{3}$$

where a and b represent the profiles calculated from similar fragments. The best-fit position will have maximum r value. Having determined the most aligned regions of the two images we extract them and use in further processing.

C. Detection of Defect-Containing Regions

Defect-containing regions are determined with the use of the etalon fragment, aligned with the analyzed fragment. We calculate the sum of two differences:

$$D = (E - I) + (I - E), \tag{4}$$

where E is the etalon, I is current image, $\pm$ are elementwise operations. D will contain mostly black pixels, except regions that differ in the etalon and current fragment. These regions are most likely to be defective.

In Fig. 10 the left image shows the etalon based on 3 fragments. Image on the right contains three defects highlighted with white circles. We calculate **D** and apply connected components extraction [10] to find the defects. Fig. 11a shows calculated difference, Fig. 11b shows defect-containing regions.

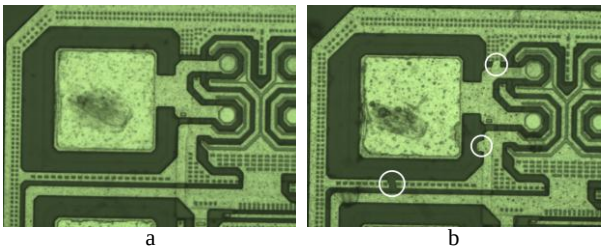

Figure 10. Etalon image (a) will be used to check image with defects (b).

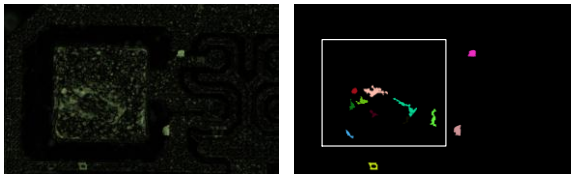

a b

Figure 11. Difference shows most probable regions containing defects (a). Connected components extraction is used to localize the defects (b).

Defects inside white rectangle correspond to the contact pad, which was used in functional testing of the microchip on the previous stages of quality assurance process. The spot inside the contact pad was made by the probe and therefore is not a defect. So contact pads should be removed from visual analysis.

We apply simple and efficient template-matching algorithm to identify contact pads: a sliding patch containing the cropped pad image is placed on every position inside the analyzed image, and correlation is calculated. The position with highest correlation coefficient is considered to be the pad location. Defect Analysis

During this step each defect is classified and defect-significance test is performed. We use a simple rule-based approach to classify defect as belonging to one of three types:

- Short of two or more neighboring conductors. A defect is classified as a short if it affects two or more topological elements.
- An islet or a pin hole, representing defect fully contained by the conductor or metallization layer.
- Group of defects including breaks of the conductor into several parts, mousebites and spurs. A defect is classified as belonging to this group when it partially intersects with the topological element. All these defects are grouped together because in some cases it is impossible to distinguish between conductor and metallization layer in the image without design specification. In Fig. 12 it is almost impossible to distinguish whether the defects are located on conductors or on the metallization layer.

Short-type defects are considered significant by default given that regardless of the size, they affect the microchip topology. Defects of last two types can have insignificant dimensions compared with the dimensions of the conductor.

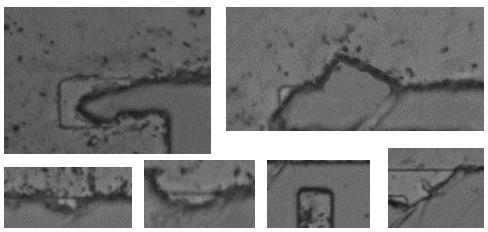

Figure 12. Sometimes it is impossible to accurately distinguish topological elements from metallization layer without any a priori information, such as design specification.

Moreover, small jaggies on the bound of the conductor can be also recognized as defects. Therefore, defect significance must depend on the size of the affected conductor. This requires size-measuring algorithm with considerable degree of accuracy.

We solve this task using the following steps:

- Determine a conductor or a group of conductors bordering or intersecting with the defect.
- Classify defect type using rule-based approach.
- Measure the size of the conductor and defect in the neighborhood of their intersection and compare these dimensions.

D. Determining Affected Conductors

At this step we know defects' blob, its' border, bounding rectangle, and the gravity center. We extract the region having the same boundaries and coordinates from the etalon image and apply connected component approach the same way as we did in section C. So the task to find defect and element intersection can be treated as well-known random polygons intersection problem. There exist a number of methods to solve such a problem [11]:

- Ray-tracing algorithm that identifies a point inside a polygon if, for any ray from this point, there is an odd number of crossings of the ray with the polygon's edges.
- Angle-summation test that calculates the sum of the signed angles formed at the point by each edge's endpoints. If the sum is close to zero, the point is outside; if not, it's inside.
- Grid method. The idea is to impose a grid inside the bounding box containing the polygon. Each grid cell is categorized as being fully inside, fully outside, or indeterminate. The indeterminate cells also have a list of edges which overlap the cell, and also one corner (or more) is determined to be inside or outside using a traditional test. It is quick to determine the state of these corners by dealing with those on each latitude line by flipping the state of each corner to the right of the edge's crossing point.

Although all these methods solve the problem, they all share the same drawbacks:

- The real bound can have different coordinates than the shape of the bounding box since image processing is performed prior to blob extraction. So the actual problem can be formulated as: Do the polygons lay within some distance?
- To calculate the intersection these algorithms need to run test for every point resulting in lack of performance.

To solve these tasks we propose a more efficient algorithm that also allows to measure distance in pixels between two polygons. Suppose we are analyzing a region around the center of defect.

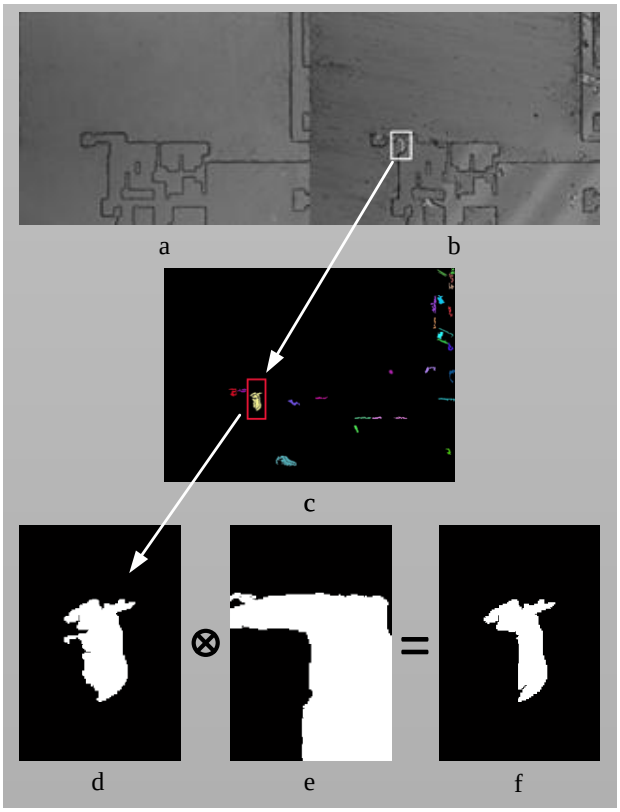

Figure 13. Affected element determination: etalon image (a) is subtracted from the testing fragment (b), defects regions are detected (c), and intersection area is found (d, e, f).

This region has dimension of the defects' bounding box extended by some coefficient $n \cdot w \times n \cdot h$. Our algorithm consists of the following steps:

- Create two matrices E, D filled with zeros having the same size as analyzed region.
- Fill with ones defect's regions inside matrix D (Fig. 13, d).
- Fill with ones the area of blobs extracted from the etalon region inside matrix E (Fig. 13, e).
- Calculate matrix $I = E \otimes D$, where $\otimes$ is binary AND operation (Fig. 13, f).
- If matrix I will contain non-zero elements the shapes intersect. Non-zero regions represent intersection areas.

This algorithm can be applied to measure the distance between the nearest points of the random shapes. On the step 2 we can apply dilatation operation [10] to one of the two matrices thereby increasing the filled area. We can continue to perform dilatation with the same structuring element until the shapes will intersect. The total amount of dilatation will give the distance between shapes in pixels.

E. Defect Significance Determination

After we found affected regions we measure conductor dimensions by using a cross-profile (see Fig. 14), centered in the middle of the intersection area.

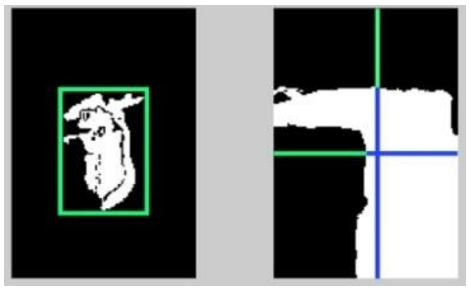

Figure 14. Defect size is measured with cross-profile centered on the gravity center of defect and conductor intersection region.

The defect in Fig. 14 has width more than a half of the width of the cross-profile, and therefore is considered to be significant.

IV. Preliminary Results

The system now is under extensive beta-testing stage. Experiments to determine false positives and false negatives rates are yet to be performed. Some preliminary results are given in Table I.

V. Conclusions

In this paper we present a reference-based system of visual microchip inspection. We propose two algorithms to overcome two major difficulties of reference-based approaches: slope and alignment correction. The slope correction is based on the well-known Standard Hough Transform. The alignment correction algorithm uses image to axes projections, also known as horizontal and vertical profiles, to minimize the displacement error. The paper introduces a simple and efficient algorithm of random polygons intersection. The proposed algorithm can be used to measure the distance between two shapes. One of the future improvements is to use design specification on the defect classification stage to expand the number of recognizable defects.

***Abstract* - Spectral analysis and wavelet analysis of successive flood waves on the basis of measured water levels help to understand hydrological processes and to improve hydrological modeling. In this paper, we compare Fourier transform, short time Fourier transform and continuous wavelet transforms to describe behavior of River Sava. Urban, agricultural and nature protected areas in the Republic of Croatia are under considerable influence of floods caused by the River Sava. Better understanding of the temporal patterns of the hydrological signals (discharge, water - level) is an important contribution to the water management of the River Sava.**

I. INTRODUCTION

The River Sava is one of the most important rivers for water management in Republic of Croatia. Its total length is 947 km and the river basin area covers 97,713 km^2 from witch 25,373 km^2 (26%) belongs to Croatia. With its average discharge of 1564 m^3/s, the River Sava represents the most important Danube tributary. In spring, after the snow melts, and in autumn, after the heavy rainfall, the middle part of the River Sava valley is prone to floods. Better describing and understanding of the hydrological regime is very important in the process of undertaking measures to prevent or limit flood hazards. This paper is focused on better description of water level regime in the middle reaches of the River Sava.

Natural processes and signals, such as discharge and water levels are characterized with significant departures from stationary and time–varying autocorrelation properties. These hydrological time series consist of intermittent processes where extreme events do not occur evenly. Fourier analyses have severe limitations for that kind of processes. Main shortcoming is that it identifies the frequencies present in the signal but not their moment of occurrence. Wavelet analysis gives a possible solution by time–frequency or time-scale localization of the process. An application of the wavelet analysis (WA) for the geophysical seismic signals was first introduced by Grossmann and Morlet [1]. WA founds its application in hydrology for different types of applications such as: identification of seasonal and interannual variability in temperature, precipitation and discharge [2][3]; identification of impact of climate variability on the river discharge and karst springs discharges [4][5][6]; rainfall-runoff model calibration and performance [7][8] and comparing temporal patterns of water quality [9].

In this paper, water levels from six gauging stations (GS) on the River Sava are qualitatively analyzed and compared to different spectral methods. Several advantages of the wavelet analysis are shown in this application. After wavelet decomposition, annual period is extracted and delays of the high water level between stations are obtained.

II. SIGNAL PROCESSING BACKGROUND

A. *Fourier transform, short time Fourier transform and continuous wavelet transform*

Discrete time Fourier transform is given by:

$$X(e^{j\omega}) = \sum_{n=-\infty}^{\infty} x(n)e^{-j\omega n}, \tag{1}$$

where $x(n)$ is a time domain signal (i.e. the observed water-level time series) and $X(e^{j\omega})$ is its frequency domain spectrum. $X(e^{j\omega})$ is periodic with the period 2π and is observed on the range $\langle -\pi, \pi]$. In order to observe time and frequency components of the signal simultaneously, short time Fourier transform is introduced:

$$X(\tau, \omega) = \sum_{n=-\infty}^{\infty} x(n)w(n-\tau)e^{-j\omega n}, \tag{2}$$

where $w(n-\tau)$ is a window function (Hann, Gaussian, rectangular,…) and τ is a time shift. The resulting two-indexed transform $X(\tau, \omega)$ is plotted in a time-frequency plane [10]. Time and frequency resolution in the time-frequency plane is constant. Due to the uncertainty principle, better localization in the time domain can be traded off for the worse localization in the frequency domain, using either longer or shorter window lengths. In some applications, the size of the window should be adjusted, i.e. wide window is better for low frequency components (provides for good frequency resolution), and shorter window is better for higher frequencies (good time resolution). For that purpose, wavelet transform is defined as follows:

$$X(\tau, a) = \frac{1}{\sqrt{|a|}} \int_{-\infty}^{\infty} x(t)\psi^*\left(\frac{t-\tau}{a}\right) dt, \tag{3}$$

where $\frac{1}{\sqrt{|a|}}\psi\left(\frac{t-\tau}{a}\right)$ is a wavelet function, ψ^* is a complex conjugate of the wavelet function, τ is a time shift and a is

a scale parameter. There are plenty different wavelet functions: Haar, Daubechies, Morlet, Shannon, Meyer,… and several of them will be considered in this paper and compared with the Fourier transform and the short time Fourier transform [10][11].

B. *Synthetic water level wave analysis*

A synthetic water-level wave is created for better understanding of obtained real world results:

$$x_1(t) = 400 + 100 \cdot \cos(2\pi \cdot 1/T \cdot t) + 150 \cdot \cos(2\pi \cdot 2/T \cdot t - T/6) + 200 \cdot \cos(2\pi \cdot 12/T \cdot t), \text{for } t \in \langle 0, 2T]$$

$$x_2(t) = 400 + 100 \cdot \cos(2\pi \cdot 1/T \cdot t) + 150 \cdot \cos(2\pi \cdot 2/T \cdot t - T/6) + 200 \cdot \cos(2\pi \cdot 4/T \cdot t), \text{for } t \in \langle 2T, 4T] \quad (4)$$

where $T = 365$ number of days in one year. The whole signal has the duration of four years, with half-year component and another one-year component. An extra wave with a month period is added to the first two years, and a wave with three months period to the second two years (Figure 1a). Corresponding frequency components using $\omega = 2\pi/T$ are: 0.0172 (for a year period), 0.0344 (for a half year period), 0.0689 (for three months period) and 0.2066 (for a month period).

Fourier transform is applied on the synthetic signal and all of the already mentioned frequency components are found (Figure 1b and c). However, it cannot be explicitly seen when the frequency components occurred. Therefore, the short time Fourier transform is calculated and plotted (Figure 1d). For better visibility, the interesting part is magnified and shown in Figure 1e. Obviously, short time Fourier transform is not the best possible representation for this kind of signals.

In hydrological sense, waves with long periods must be visible (one year, half year, one month), and short periods are not that important. Therefore, an analysis using wavelet transform is conducted. The wavelet transforms of the synthetic signal using several wavelet functions are compared and the results are shown on Figure 1f - 1g and are summarized in TABLE 1. Haar and Mexican hat give the least acceptable results. Most of the real wavelet functions (biorthogonal, coiflets, symlets) result in a good time resolution, except for long periods (i.e. period of one year). Complex wavelets give good frequency resolution; but still do not provide information of occurrence of events in the time domain (Figure 1h). If only real part of the transform is observed, the complex wavelets give very precise results (Figure 1i). However, real Morlet wavelet gave the best result; hence it was our choice to represent the water levels of the River Sava (Figure 1g).

III. ANALYSIS OF THE WATER LEVEL OF THE RIVER SAVA

The signal for the analysis was obtained as a hydrological time series of hourly water levels from six gauging stations (GS) on the River Sava (Figure 2). They are located in the middle reaches of the River Sava and the total distance between first and last GS is 184.5 km (TABLE 2) [12].

A. Preparation of the signal

The daily water level data were taken in the period of 25 years, between 1982 and 2007. Samples of the signal were taken every day at 2 PM. Therefore, signal consists of 9496 observations. It was checked and cleared of the possible measurement errors and was not statistically preprocessed (Figure 3). The records were incomplete on the five GS because of the war in the 1990s, which interrupted the measuring process. Data gaps were from one year on the GS Crnac, and up to ten years on the GS Gradiška (TABLE 2). Therefore, for five GS with data gaps, years 1982-1990 and 2001-2007 were considered separately.

B. Analysis of the temporal pattern of the water levels

First, the examination of detailed temporal pattern is conducted on GS Kobaš, using the STFT and the WT, since the data set is complete for the observed period (1982-2008). Magnified part of its STFT is shown on the Figure 4a. Longer periods are almost invisible due to pure frequency resolution and it can be clearly seen that the WT is a better representation for this type of hydrological signals (Figure 4b). The River Sava is characterized by the minimum water levels in the summer and maximum water levels in the spring and autumn. Annual scale has the highest amplitudes and its impact is the strongest. If its amplitudes are lower, the observed year is drier (1988-1991). On the other hand, if its amplitudes are higher, the year is more humid (1994). Except for annual scale impact, semiannual scale is also very strong, especially visible in dry years. When semiannual impact is lower, seasonal or monthly impacts are higher. Their influences change over the years, so the signal is evidently nonstationary.

Analysis of temporal patterns for the five remaining GS is conducted for the shorter time spans that are common for all six GS, i.e. for 1982-1990 and 2001-2008 (Figure 3). For all six GS, temporal patterns are almost identical. Information obtained using wavelet spectrogram is considered spatially consistent along all six GS (Figure 5).

This fact offers a possibility for drawing some conclusions on the missing data for the remaining five GS from the GS Kobaš data. Observed data for the remaining five GS is not stationary in time, too, because of high and low patterns in different years and seasons. For example, GS Kobaš has annual scale high water levels that occurred in years 1982-1987 and 1993-2005, but years 1988-1992 did not have expressed such annual highs. From 1995 to 1999, mentioned temporal peaks are less significant. Large variations in the wavelet transform domain are visible in years 1988-1993, and correspond to the high variation of the water levels in that period (Figure 3).

It can be concluded that there is a considerate change in stability of temporal pattern from 2001 to 2007 for almost all scales, because dominant peaks are intermittent. They are spread from seasonal scale, across semiannual and annual scales, and up to the 1.5-year and 2-year scales.

C. Propagation of annual scales flood wave between gauging stations

To clearly see the differences between the stations, one row from the wavelet transform for years 1982-1990 is extracted and shown in Figure 6a. The waves represent one year period. They have different amplitudes depending on the GS. Magnified parts of the waves are shown in Figure 6b and are delayed to each others. All the delays are measured and mean and median average values are calculated for years 1982-1990 and 2001-2007, separately and all together. The results are presented in TABLE 3. The average values tell how many days the annual high water level needs to come from one to another GS. It is about 3.8 days between Crnac – Jasenovac and 0.9 days between Mačkovac and Davor. As expected, the delay of flood wave propagation between gauging stations is in relation to their mutual distance. But, the annual wave shows the shortest delay between Davor and Kobaš, despite the fact they are not the closest GS. Explanation of this is in different geometrical and hydraulic characteristics of the river bed in that river section.

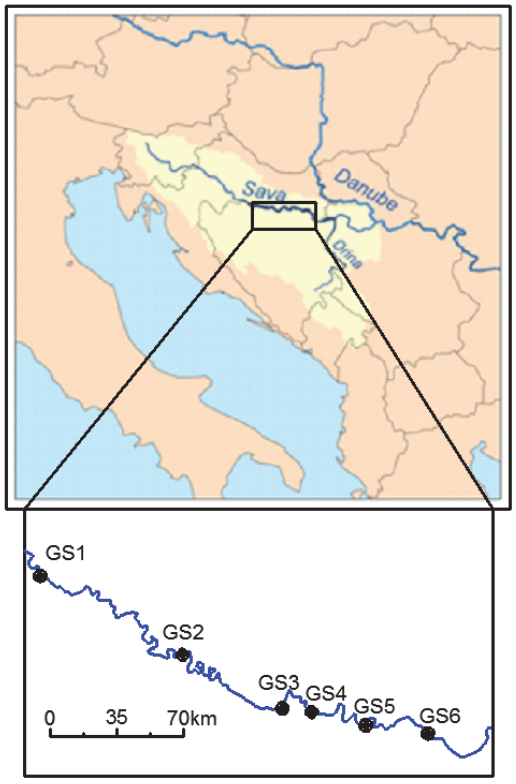

Figure 2. Sava and the analyzed gauging stations. GS1 is Crnac, GS2 is Jasenovac, GS3 is Stara Gradiška, GS4 is Mačkovac, GS5 is Davor and GS6 is Kobaš.

TABLE 2. DESCRIPTION OF THE ANALYZED GAUGING STATIONS.

	Years of missing data	Distance from river mouth [km]	Distance from previous GS [km]	GS vertical reference point [m]	Statistical characteristics [cm]			
					Mean	Std. dev.	Min	Max

IV. CONCLUSION

The wavelet transform is a powerful tool for hydrology analysis. We obtained the best results when applying Morlet wavelet function. It gives better balance between time and frequency localization of hydrological signals than the other examined wavelet functions. Morlet wavelet was applied to water level signals from six gauging stations in the middle reaches of the River Sava. Nonstationary patterns in flood waves were examined and dominant peaks were detected: for one year, one half year, three months and one month periods. In addition, flood wave propagation time between neighboring gauging station was determined as well.

Wavelet analysis and understanding of temporal patterns in water levels has its application in improving actions for considering flood defense, e.g. early warning and conducting flood defense measures. Data used in this study is taken for the River Sava, where detailed physical hydraulic models have already existed. These hydraulic models enable precise forecasting of the flood wave amplitude and of the propagation time and

velocity. Wavelet (black-box) analysis in this study is offered as an alternative to the hydraulic models. Hence, wavelet analysis could be used for other watercourses for which hydraulic models are not available.

For further research, it could be possible to define the stationary flood waves with the constant averaged water level amplitudes over all six gauging stations and for all dominant scales. This information could improve the derivation of the realistic synthetic flood waves, needed for testing of the hydraulic models of the River Sava and of the other watercourses in Croatia.

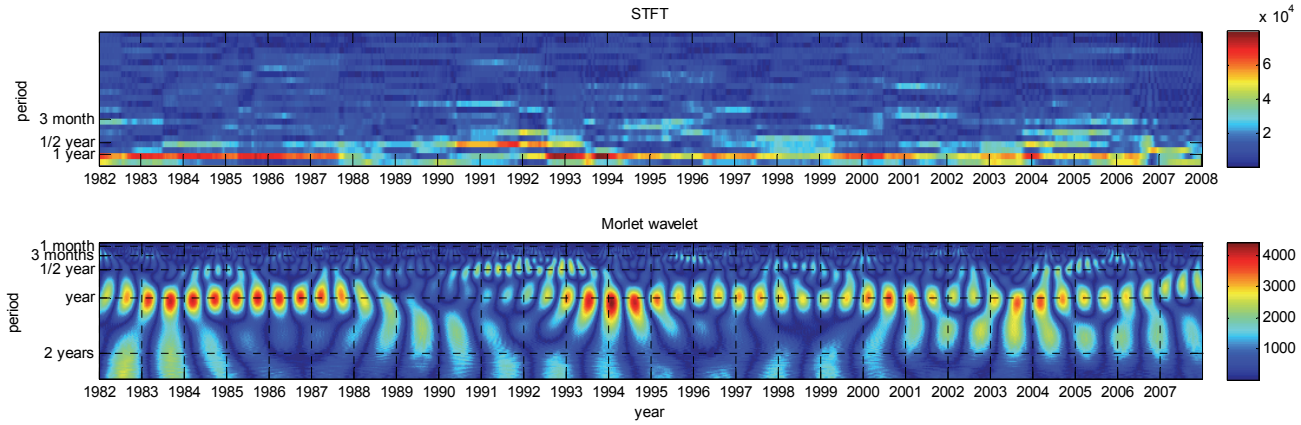

Figure 4. (a) Magnified part of the STFT for gauging station Kobaš. 1 year and 1/2 year period (scale) are clearly visible, (b) Real Morlet wavelet analysis for the same gauging station. One year period has the strongest peak, but 2 years, 1/2 year, and 3 months periods are visible, too.

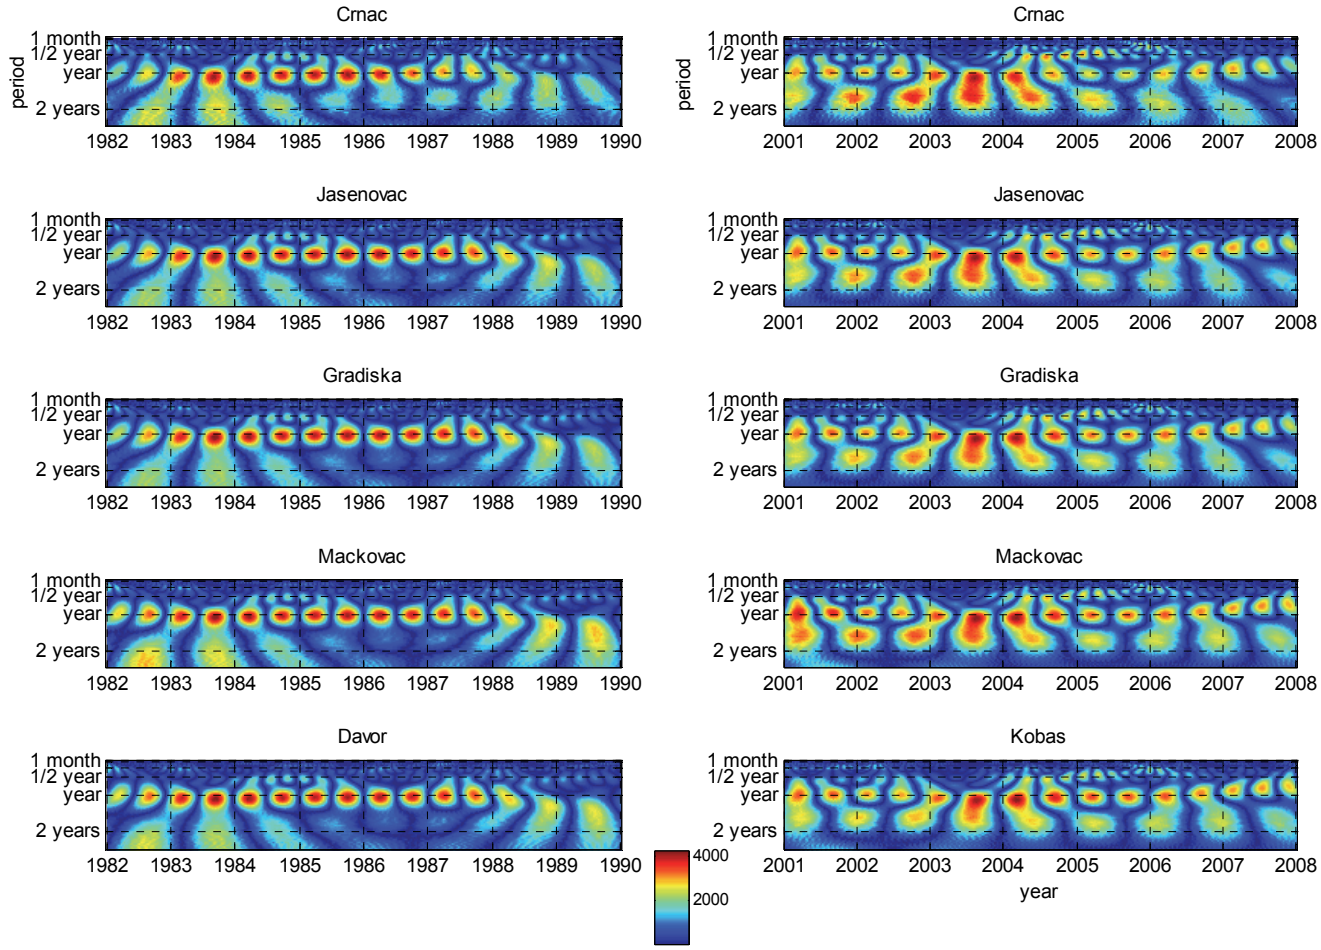

Figure 5. Apsolute value of the real Morlet wavelet analysis for the gauging stations: Crnac, Jasenovac, Stara Gradiška, Mačkovac and Davor. Because of the missing years, it is shown separately for years 1982-1990 and 2001-2008. The results in wavelet domain are similar, but with different amplitudes and delays. One year period (scale) is the strongest one, with the highest amplitudes.

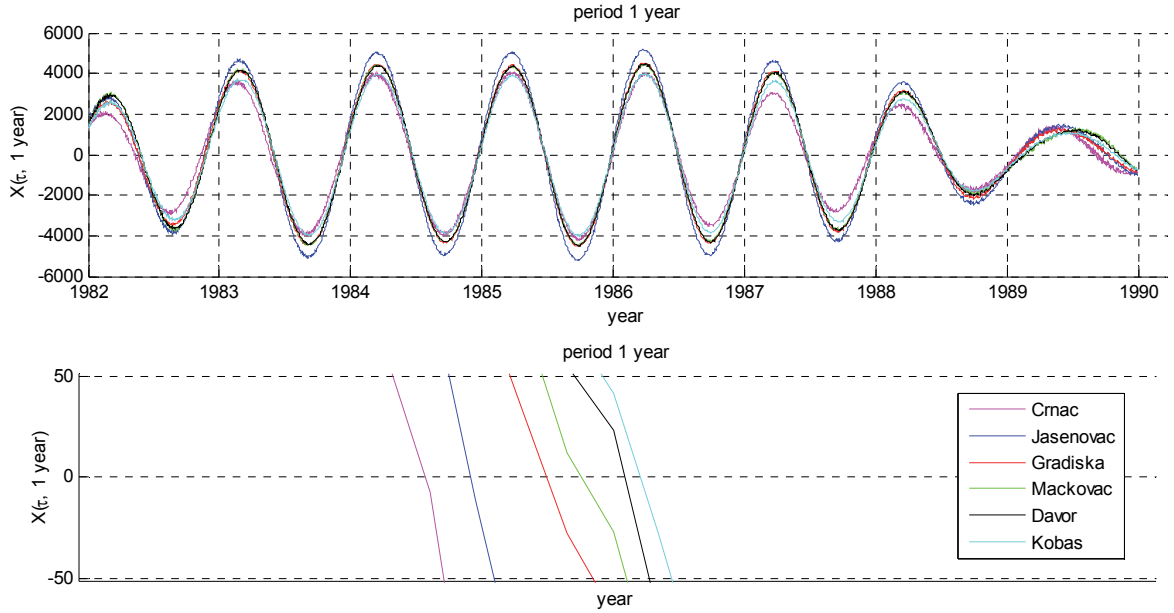

Figure 6. (a) A wave from one year period after the real Morlet wavelet transform. The waves have different amplitudes and delays when they pass through zero; (b) Magnified part of the passing through zero in the middle of year 1984.

Abstract

Hot or even boiling water is often used in the household. During the process of heating the water, molecules become more and more active. Intensity of their movement depends on the temperature. Moving molecules are bumping into the container and causing audible noise. This audible noise can be regarded as a useful and functional signal on one hand, but some people find it as a disturbing noise.
A MSX technology was developed. MSX technology is presented in this article, together with some results of applied active noise control. MSX technology uses a sound sensor for determination of temperature of the water and even more important, the state of boiling itself. Microphone is placed in the base of the kettle and is recording sound. A microcontroller regulates the power of kettle according to calculated algorithm, which is based on the sound signal. The boiling point of the water is the main regulation point and by monitoring the sound, we can detect it much better then by monitoring the thermal sensor, which is commonly used in digital kettles. A new step forward in MSX technology is integration of Active Noise Control algorithm. Such algorithm enables the use of generated noise for control purposes and it attenuates the very same signal with additional loudspeaker. Audible noise is attenuated and almost silent performance of the kettle is achieved.

I.INTRODUCTION

The acronym MSX, which stands for Multi Sensor Approach, is trademark, and the method used is patented**.** MSX technology uses a sound sensor for determination of temperature of the water and even more important, the state of boiling itself. Regular kettle on the market have only 360 grad connector and bimetal switch for disconnecting electricity from the heater. Vapor from water surface produce steam that travels true the pipes to the bimetal switch and after it reaches the temperature it disconnect the power. The experiments show that the time of disconnecting power is not precise and the result is unnecessary use of energy after water boils. These kettles are not energy efficient because on heating bimetal switch needs time after boiling point is reached. There are two different types of digital kettle on the market. First system is with electronic in the base and Thermometer sensor is in the kettle and second system is with electronic in the kettles body. In the first case the connector is different and also base is complicated with user interface. The second case is made with electronic in the kettle. All these kettles are very expensive.
The MSX regulation is simple and very efficient. Only single microphone is placed in the base of the kettle the sound is used in simple electronic to obtain the temperature / sound connected algorithm. On top of MSX base each regular kettle can be used Figure 1. The regulation has also an important possibility to regulate the process on different level of boiling.

Figure 1: Regular kettle on MSX base

A microcontroller regulates the power of kettle according to calculated algorithm, which is based on the sound signal. The boiling point of the water is the main regulation point and by monitoring the sound, the regulation of boiling is much better than by monitoring the thermal sensor commonly used in digital kettles. The kettle electronic is ready for market and the price of electronic is lower the today PCB in kettles. We achieve

the goal to produce the technology that can be build in all kettles bringing minimum 10% energy saving.

II. BOILLING PROCESS

The boiling phase is monitored. The boiling phase starts when individually isolated bubbles start to appear, denoted with nucleate boiling in Figure 2. During the boiling phase, bubbles appear in jets creating the effect commonly referred to as simmering. Finally, in the fully developed boiling phase (denoted with film boiling in Figure 2), the bubbling of the liquid is generalized, resulting in the familiar turbulence of a boiling liquid. Transition from nucleate boiling to film boiling is not discrete, but uniform as depicted in Figure 2.

The formation and collapse of the bubbles during the phases create an acoustic signature, which changes with the size and number of the bubbles, the rate of their formation, their collapse, and the temperature gradient in the liquid. The response includes an audible component, which can be easily observed when cooking, and it has distinctive frequency band [1].[2]

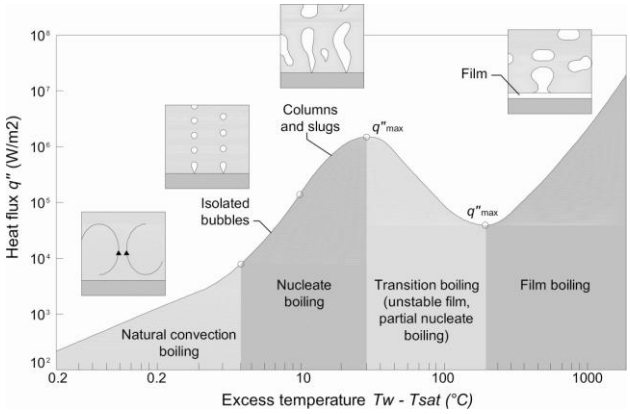

Figure 2: Boiling phases of water

A microphone with an integrated preamplifier is fitted to the base of the kettle. Typical Sound produced by heat is depicted in Figure 3 and Figure 4. In Figure 3 the sound pressure signal is presented. Increasing sound pressure amplitude at 75 seconds can be easily observed. Frequency analysis is presented in Figure 4. This frequency range was also found in all our experiments and they are correlated with the formation of end implosions of bubbles. Sound signature of kettle is very good for regulating boiling in shown on Figure 5.

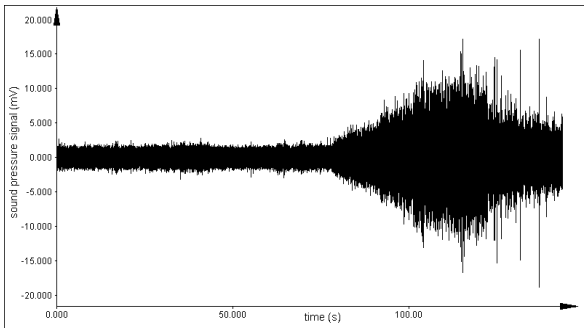

Figure 3: Sound pressure signal of cooking process

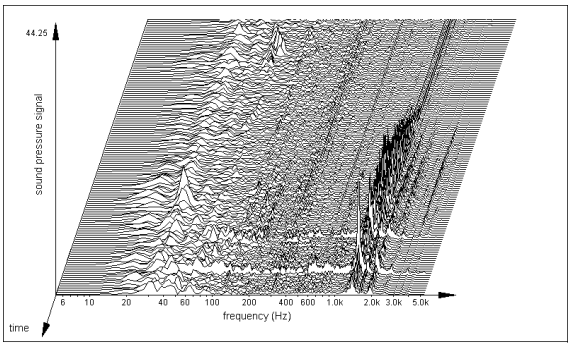

Figure 4: Waterfall diagram of cooking process

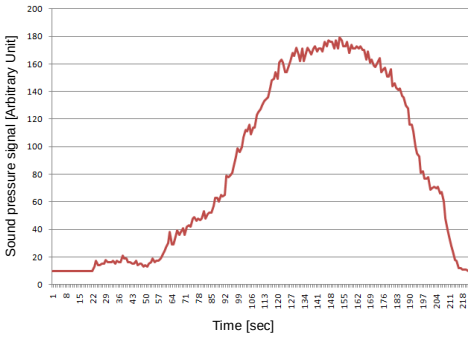

Figure 5: Sound signature of kettle is very good for regulating boiling

3. MEASUREMENT RESULTS AND DISCUSION

Experimentally, it was determined that various phases of boiling have distinctive acoustic signatures and that the acoustic signatures are repeatable and robust to many commonly occurring disturbances.

Microphone in the base is taking sound samples and microcontroller is regulating the power of kettle according to calculated algorithm settings. The boiling point of the water is the main regulation point. One Example of Heating water in kettle 0,7 lit is depicted on Figure 6.

MSX software algorithm for definition of temperature derived from sound signature uses for different temperature settings different parameter.

Boiling point is defined with P1 and P2. In regular kettle BM is time where bimetal switch turn OFF the electricity.

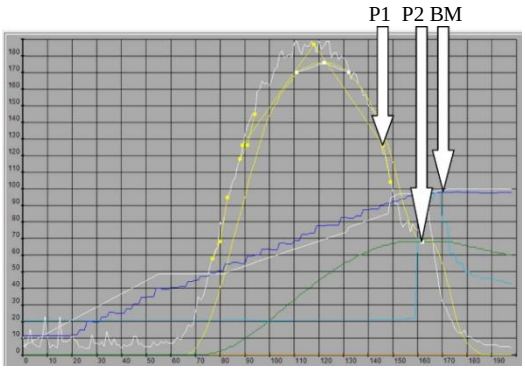

Figure 6: measured and calculated data – x axis is time y axis is temperature

Time: P1 = 146 s P2 = 162 s BM = 170 s

In case if we choose to regulate on P1 we have 24 s saving what is 14%. The percentage depends on BM switch that is not repeatable defined.

On the marked and standard of kettles there is no definition of level of boiling [3]. This makes the presentation of MSX kettle on the market more difficult because boiling is determined under big influence of user's habits.

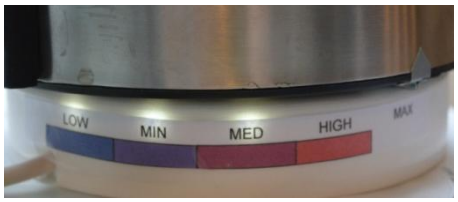
For the producer of kettles MSX offers:

- Special constructions on interactive interface

For demonstrating technology to companies that produce kettles we built MSX technology in different kettles. MSX have his own hardware profile based on MSX algorithms. The PCB Figure 7 Printed electronic board is placed in the base of kettle. The price power performance is all the time present so we have not expensive electronic board.

Figure 7 MSX PCB

The base is modified with holder and white plate on the bottom to cover the bottom of the base and to prevent possible touch with electricity. Single magnet on the housing of the kettles and reed relees in the base make it possible. Figure 8. The level of boiling can be defined from industries. We choose possibility to set up different levels of boiling. LOW .. MIN ..MED.. HIGH ..MAX. Saving of energy is minimum 10%. [4]



[1] Figure 8 MSX base with LED user interface

- MSX kettle development kit

For easy application of MSX technology in the industry we prepare development kit. MSX development kit is based on measuring data, analyzing data, defining parameter, producing software for microprocessor, programming hardware MSX kettle. Included is all hardware for developing, samples of hardware for kettle, programming tools and software for PC.

A new step forward in MSX technology is integration of Active Noise Control algorithm. Such algorithm enables the use of generated noise for control purposes and it attenuates the very same signal with additional loudspeaker. Audible noise is attenuated and almost silent performance of the kettle is achieved.

4. ACTIVE NOISE CONTROL SYSTEM IN KETTLES

Figure 9 indicates changes in noise amplitude during different phases of heating the water. Higher frequency noise above 1000 Hz is correlated to formation of small bubbles, which can be correlated to formation of isolated bubbles, which are composed of dissolved gasses in the water.

Sound of water heating with frequencies above 2000 Hz has god signal to noise ratio and can be used as for controlling the cooking process. Sound signal in this frequency range can be directly correlated to the temperature of water during the heating process

Lowest frequency range around 125 Hz increases with temperature. Lower frequency noise is associated film boiling, and with big bubbles dynamics.

Minimum of noise level wit 250 Hz, at 110 sec indicates start of film boiling. High values after 110 sec indicate to strong bubbling in the liquid with big bubbles.

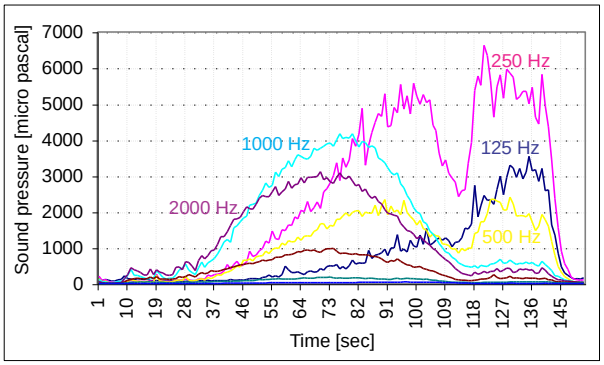


Figure 9: Time chart of different frequency ranges

Noise of water heating is around 5000 mPa (70 dBA) at a distance 4 cm away from the kettle. Majority of noise after 80 sec can be assigned to frequency range around 250 Hz.

This frequency range can be controlled with active systems. For this purpose a shaker was attached to the bottom of the kettle. In such a way the kettle itself become a sound-generating device.

With signal processing, kettle can produce anti noise. Anti noise is noise with the same form as noise, only its phase is inverted. In order to analyze if the idea of integrating the active noise control in the kettle is feasible simulations were performed.

Simulations are based on the measured impulse response of the kettle with attached shaker as a sound source. Frequency response of the kettle working as a sound-generating device is presented in Figure 10.

Results indicate that kettle can produce anti noise levels, which are comparable to noise levels produced by the heating and boiling process. From this point of view it can be used as a controlled noise source. However, its impulse response should be suitable as well. Impulse response of the active noise cancellation system in the kettle is presented in Figure 11.

Impulse response of the control system is relatively very long, and it clearly indicates towards a resonant frequency. This is because the microphone was attached directly on the metal housing.

Simulation results of feedback active noise control system in the kettle are presented in Figure 12.

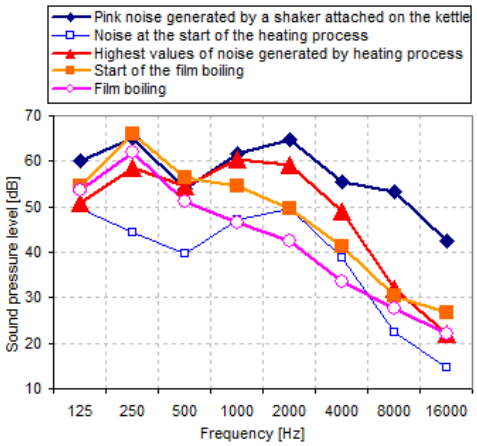

Figure 10. Frequency response of the kettle as a controlled noise source in comparison to noise spectra generated during the heating and boiling process.

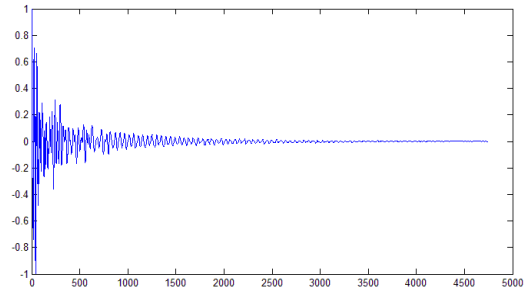

Figure 11: Impulse response of the active noise cancellation system in the kettle

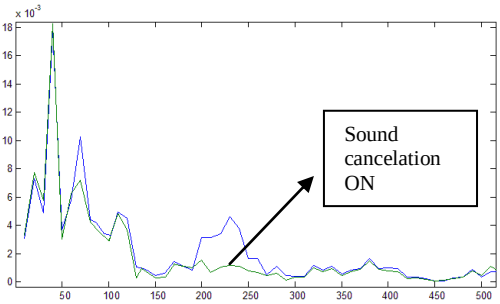

Figure 12: Simulation results of feedback active noise control system in the kettle

Frequency range noise, after the noise cancellation system is switched on, is presented in figure 12. We can see, that even with a very long impulse response of control element and with distinguished resonant frequency of the control element, some positive effect was achieved in desired frequency range.

In order to improve the performance of the ANC system in the kettle some additional work has to be done. First of all, the impulse response of the control element should be improved by using some vibration absorbing material. Efficiency of the kettle, as sound generating device in low frequency range should be improved by using stronger shaker.

5. CONCLUSION

Energy conservation achieved by new designs of kettle will have an effect on global energy consumption. Preliminary data shows that decreasing the consumption of energy is possible in the design of cooking consumer appliances. The quality of energy regulation can be improved if the boiling states are identified. Audible sound is a parameter, which has proven to be very helpful in obtaining exact data in identifying the different boiling states. The pattern signature in the sound signal can be easily detected and analyzed to find the algorithm for identifying boiling states. With application of the new proposed methods, we expect savings higher then 20%. Regular kettle becomes all the benefits off the best digital kettle on the market and the production price is only little part of the temperature regulated digital kettle with following Advantages:

- MSX technology uses sound sensor for determination of temperature of the water and state of boiling.
- MSX can be located in base without connection to the kettle and the production cost is much cheaper
- MSX regulation is the only technology in world concentrated on boiling process and only technology that can bring so high savings in comparison with bimetal switch.
- MSX technology can be used for simple regulation of "normal" kettle where it replace the bimetal switch and also for most sophisticated definition of different temperature levels and MSX is market ready
- MSX kettle with active noise system is the most quite kettle

Parallel Neural Network Training with OpenCL

***Abstract*—This paper describes the parallelization of neural network training algorithms on heterogeneous architectures with graphical processing units (GPU). The algorithms used for training are particle swarm optimization and backpropagation. Parallel versions of both methods are presented and speedup results are given as compared to the sequential version. The efficiency of parallel training is investigated in regards to various neural network and training parameters.**

I. Introduction

The application of neural networks can greatly benefit from implementations that take advantage of parallelism, i.e. where the neural network output is computed in parallel [1], [2], [3]. However, the neural network learning process also requires much time and needs high-performance machines for industrial applications. This is especially true for networks with numerous neurons and synaptic connections and for training sets with large number of examples.

This paper discusses the parallelization of neural network training process on heterogeneous architectures using OpenCL. We present parallel implementations of two training algorithms: the backpropagation algorithm and training with particle swarm optimization (PSO). Backpropagation is probably the most used algorithm for training, whereas PSO is increasingly gaining popularity for this purpose in recent years. The parallel versions are compared to their serial counterparts and speedup and efficiency measures are reported.

A special care is given to the influence that neural network and learning parameters, such as the number of layers, neurons and learning samples, have on parallel algorithm performance. Furthermore, the specifics of the OpenCL architecture are taken into account so as to carefully devise the parallelization method that would be efficient in different conditions and thus usable to potential researchers. The results show that parallel implementations have a clear advantage over original algorithms, which can be obtained with widely available hardware.

The remainder of this paper is organized as follows: Section II describes the neural network training process with the two algorithms. Section III presents parallel models of the training algorithms for the target OpenCL platform. Section IV gives experimental results and efficiency analysis, and short conclusions are given in Section V.

II. Training Neural Networks

Training neural networks includes finding a suitable set of neuron weights, given a network structure, that best describe the given set of examples (learning test cases, learning samples). Neural networks can be trained with almost any optimization method, but several algorithms have proven especially efficient for this purpose. Among those, the backpropagation algorithm and particle swarm optimization may well be the most prominent ones in recent years.

A. Backpropagation

The main goal of network training is to reduce the amount of difference between the actual and the desired network output. The backpropagation algorithm uses the output error to adapt the weights of the output layer, hidden layers and finally the input layer. The update scheme uses the derivative of the activation function and thus requires the function to be differentiable. After the procedure is performed for each training sample, the process is repeated until a predefined rate of convergence is attained [4], [5], [6].

The error of a single output neuron j is defined as $e_j = d_j - y_j$, where d_j is the desired and y_j the actual output. The local derivative of an output neuron is defined as

$$\delta_j = e_j \cdot \varphi'_j \ , \tag{1}$$

where φ'_j is the derivative of the activation function, and the local derivative of a neuron j in the hidden layer is

$$\delta_j = \varphi'_j \sum_k \delta_k \cdot w_{jk} \ , \tag{2}$$

where k indicates all the output neurons the neuron j is connected to. The neuron weights are then updated with the predefined learning rate η by

$$\Delta w_{ji} = \eta \cdot \delta_j \cdot y_i. \tag{3}$$

B. Particle Swarm Optimization

PSO is an optimization algorithm (a metaheuristic) inspired by the flocking of birds and similar representations of organisms in large groups [7], [5], [8]. It is an example of a larger group of algorithms implementing *swarm intelligence* to solve non-linear optimization problems. PSO simulates the movement of a group of potential solutions, or particles, in problem domain according to simple rules governing their relative velocity.

In each iteration, the algorithm updates the position of every particle (its value in problem domain) and its speed taking into account:

- previous speed of the particle;
- previous best position found by this particle;
- best position found by all particles so far.

These components are combined in such a way to maintain the exploratory nature of the algorithm on one hand, and to preserve convergence properties on the other.

The dimensionality of the problem domain (the space the particles move in) is equal to the number of weights in the neural network. Each particle represents a potential solution, i.e. a complete set of weights and biases (if included) of the neural network. Particle fitness f is usually obtained by evaluating the corresponding network on a number of test cases and calculating the mean squared error as:

$$f = \frac{1}{N \cdot O} \sum_{i=1}^{N} \sum_{j=1}^{O} (y_{ij} - d_{ij})^2 \tag{4}$$

where N represents the number of learning samples, O is the number of neurons in the output layer, whereas y_ij and d_ij is the actual and the desired output of j-th output neuron for i-th learning sample. After the evolution process, the best evolved particle is used to define the weights for the resulting neural network.

III. Parallelization using OpenCL

A. OpenCL programming model

OpenCL [9], [10], [11] is an open standard which defines a parallel programming framework for programs that execute across heterogeneous platforms. Programs that conform to the standard may be executed on CPU, graphical processing units (GPU) and other devices that have interfaces to the standard specification. Processing elements in OpenCL are the *compute device* (such as GPU), which may have one or more *compute units* (e.g. a GPU multiprocessor), which in turn may consist of one or more *processing elements* (e.g. a GPU scalar processor). The processing elements are accessed by a *host*, which may be a computer system where OpenCL programs are initiated.

The programming elements in OpenCL are based on *work items* or *kernels*, which are equivalent to tasks in parallel programming model, and which execute on a processing element. A set of multiple work items that are processed (in parallel) by a compute unit is called a *workgroup*.

OpenCL memory model distinguishes different levels of memory:

- *global memory* is a multipurpose memory on the compute device that is the largest and the slowest one;
- *constant memory* is a part of the global memory that remains unchanged during the kernel execution;
- *local memory* is assigned to a compute unit and is smaller and faster than the global memory;
- *private memory* is the smallest and the fastest (e.g. registers), and is accessible only from the processing element it belongs to.

The global memory is the only way of communication between the host and the compute device, whereas the other types of memory may be used for internal computation. In case more private memory is requested than physically available, global memory will be used instead.

B. Training with parallel Backpropagation

The neural network structure in this work is presumed to match the multilayered perceptron. The algorithms can also be used for different models, but possibly with different performance results.

In our parallel backpropagation variant, first the network output is computed layer by layer at a time. Each layer is handled with a set of work items, where each work item computes the output of a single neuron. The computation of the output of the next layer is possible only when the previous layer has been computed, so this is done sequentially for each layer.

The same mechanism is used when local derivatives are calculated in the opposite direction - layer by layer are processed in parallel, and finally a single kernel is executed which updates the weights of all neurons. The number of times N_k that the kernel execution is started in each backpropagation iteration is thus

$$N_k = S \cdot (2 \cdot (L - 1) + 1), \tag{5}$$

where L is the number of layers and S the number of samples. Since every kernel execution induces a slight overhead, this technique is not expected to be efficient for small networks.

C. Training with parallel PSO

In parallel PSO implementation, the task of calculating the network output for every learning sample and every particle is represented as an individual OpenCL kernel function (unlike in the backpropagation algorithm). In the training process there are S samples and N particles, where each particle contains a set of all weights in a network (a particle is equivalent to a single network). In each iteration of the algorithm $N \cdot S$ work items can be executed in parallel (for all the particles and all the samples). The algorithm is briefly presented as follows:

```
copy samples from host to device;
repeat
  copy weights to device;
  compute outputs for all particles;
  compute MSE of all particles;
  copy MSEs to host;
  update particle positions and speeds;
until termination criterion is satisfied;
```

The samples are copied onto the computing device (the GPU) only once in the beginning as they remain unchanged during the learning. The network weights (particles) are modified in each iteration and thus have to be transferred to the device each time. The MSEs of all particles are also calculated on the device and are then copied to the host machine. The host machine maintains and updates the current speed and position of every particle, since the complexity of this operation is negligible compared to the rest of the algorithm.

When calculating network output on the device, a single work item determines the output values of a single network layer in parallel, based on the previous layer output. From this

it follows that every work item has to allocate the amount of memory twice the size of the largest network layer.

Based on this approach, we developed and tested two variants of parallel training algorithm: the first variant uses the *private memory* for calculation, which can only be allocated statically inside the kernel. Since OpenCL program requires compilation before every kernel execution, the exact amount of memory doesn't need to be predefined.

The second variant uses the *local memory* for output calculation. Work items are organized in workgroups so that every work item in the same group computes outputs for the same particle, but for different input sample. The total amount L of local memory per workgroup (in bytes) can thus be determined by

$$L = 4 \cdot (N_w + 2 \cdot G \cdot W_{Lmax}) \tag{6}$$

where N_w is the number of weights, G is the number of work items in a group and W_{Lmax} is the size of the largest network layer. This number must be taken into account beforehand, and this approach cannot be used for very large networks.

IV. Results and Analysis

In this section the performance analysis for both presented methods is reported. The target platform for maximum performance is the GPU, but since the OpenCL programming model allows portability to different platforms, this allows the same OpenCL program to be executed on a CPU as a computing device. Beside the GPU results we also include measurements of the same program executed on a central processor with multiple cores.

The tested GPU platform is NVIDIA GeForce GTS 250 and the CPU is AMD Phenom II x6 1055T (6 cores). Regardless of the target platform, for speedup measurement all OpenCL execution times are compared to the serial algorithm implementation on a single CPU core.

A. Parallel backpropagation algorithm

For the backpropagation algorithm the following annotations for tested platforms are used in the results:

- **CPU**: sequential algorithm, executed on CPU (on a single core);
- **OpenCL GPU**: OpenCL implementation on GPU;
- **OpenCL CPU**: OpenCL implementation on CPU.

The parallel BP algorithm was tested on a network with 9 input neurons, 3 hidden layers and a single output. The algorithm efficiency proved to be very low for smaller networks; only when the number of neurons in a hidden layer is larger than 400, the algorithm is faster than the serial version. The runtimes of single algorithm iteration are shown in Fig. 1 and the corresponding speedup is given in Fig. 2. If the number of neurons is even more increased, the algorithm exhibits useful speedups, as shown in Fig. 3.

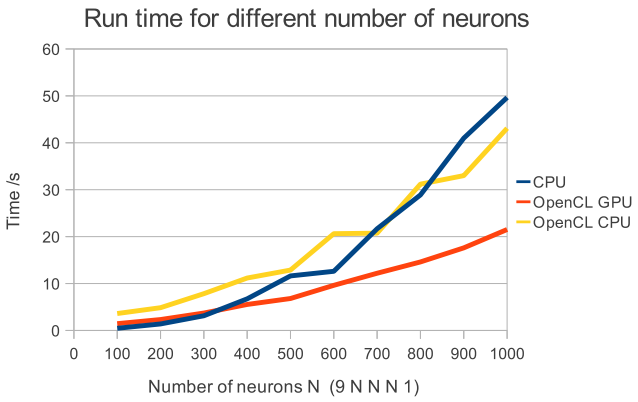

Fig. 1. Parallel BP, run time for different number of neurons

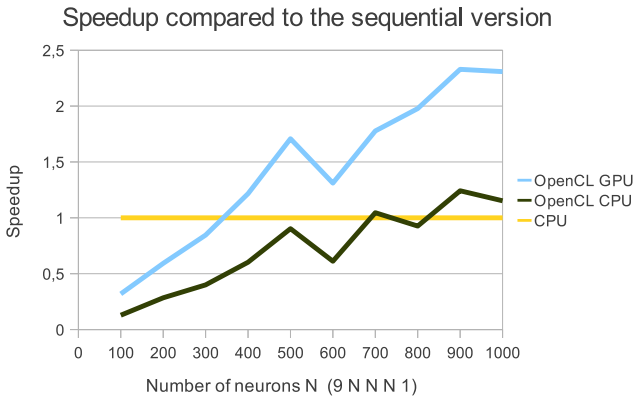

Fig. 2. Parallel BP, speedup for different number of neurons

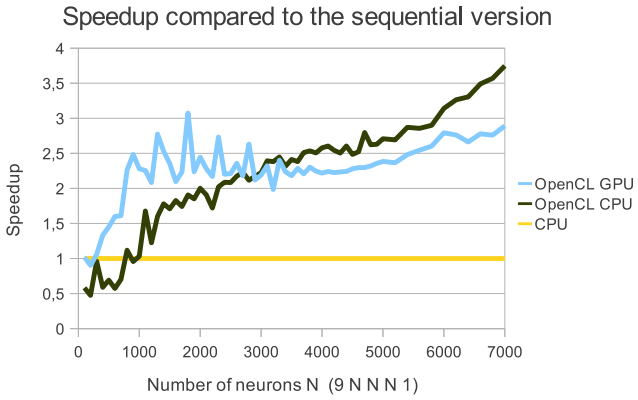

Fig. 3. Parallel BP, speedup for larger number of neurons

B. Parallel PSO algorithm

The parallel PSO algorithm performance is reported with the following annotations:

- **CPU**: sequential PSO, executed on CPU (on a single core);
- **local GPU**: OpenCL implementation on GPU, variant with local memory;
- **private GPU**: OpenCL implementation on GPU, variant with private memory;
- **local CPU**: OpenCL implementation on CPU, variant with local memory;
- **private CPU**: OpenCL implementation on CPU, variant with private memory.

Note that the OpenCL 'local memory', when deployed on a CPU, actually represents the RAM and is equivalent to the OpenCL global memory. This may be implementation dependent, but in practice both local and private memory can be expected to be implemented as global memory on CPU devices. The population size in PSO algorithm is 64 particles.

We found the parallel PSO implementation much more adaptive to different network sizes; the initial results are obtained on a network with number of neurons 9-15-6-1 in 4 layers. The following experiments were performed to test the algorithm efficiency when changing the number of samples, the number of neurons and the number of layers.

The influence of the number of samples is measured by executing a single PSO iteration and averaging over 10 repetitions. The runtimes are given in Fig. 4 and the speedup in Fig. 5. When both the network and the number of samples is relatively small, the parallel GPU implementation is faster than sequential PSO for more than 30 samples, and OpenCL CPU version for more than 120 samples. If the number of samples is even larger, the speedup is clearly visible in Fig. 6. It can be seen from the results that the speedup of the CPU variant of parallel PSO is close to ideal, since the tested CPU contains 6 cores. At about 30000 samples (not shown here) the GPU variant with local memory reaches the maximum speedup value of 32, which does not increase with additional samples.

In the next experiment the number of samples was set to 10000 and the number of neurons in a single hidden layer was varied. The speedup results for this experiment are shown in Fig. 7 and Fig. 8. These results show great variability in speedup for parallel PSO with local GPU memory; remember that this version requires the amount of memory that is equal to twice the number of neurons in the largest layer. With the increase of the layer size, the number of available work units that can be executed in parallel decreases, which causes this version to be slower than other OpenCL variants for more than 90 neurons in the largest layer (this value of course depends on the GPU characteristics).

The last experiment included 10000 learning samples, variable number of hidden layers and 10 neurons per layer. The speedup results for this case are given in Fig. 9. All the OpenCL variants except the GPU local memory maintain a

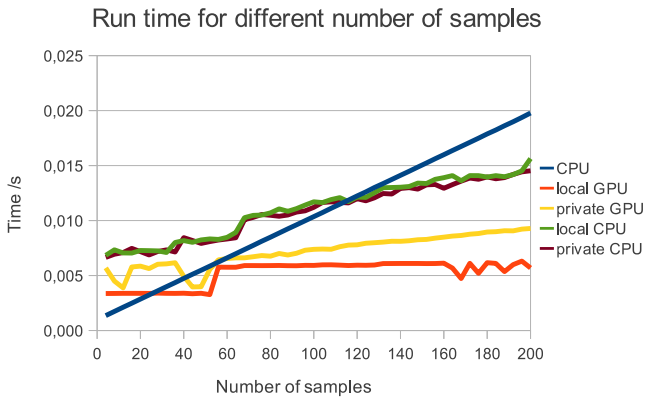

Fig. 4. Parallel PSO, run time for different number of samples

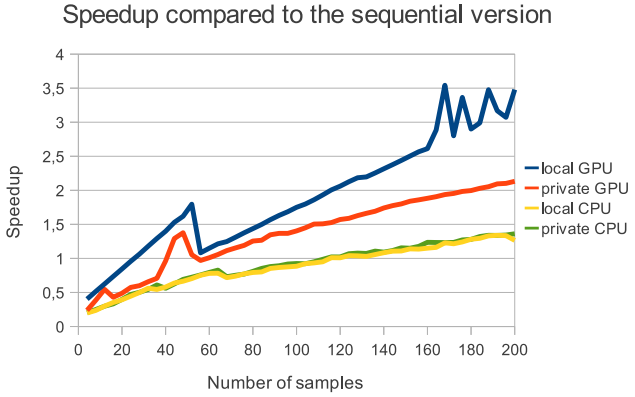

Fig. 5. Parallel PSO, speedup for different number of samples

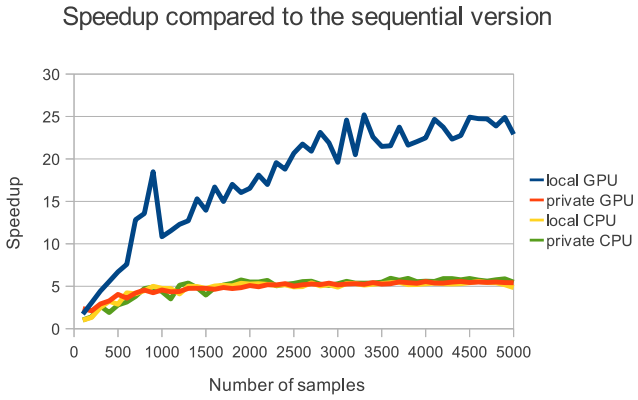

Fig. 6. Parallel PSO, speedup for larger number of samples

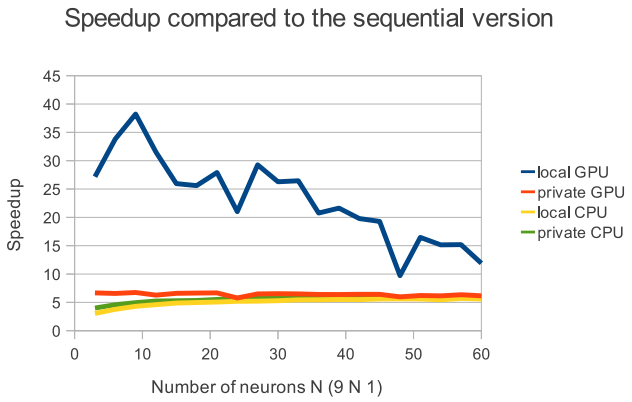

Fig. 7. Parallel PSO, speedup for different number of neurons

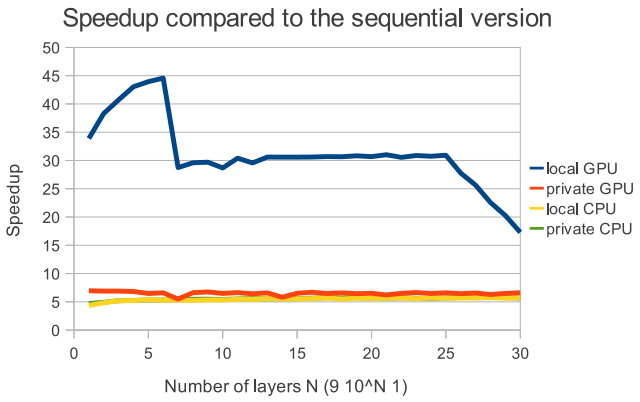

Fig. 9. Parallel PSO, speedup for different number of hidden layers

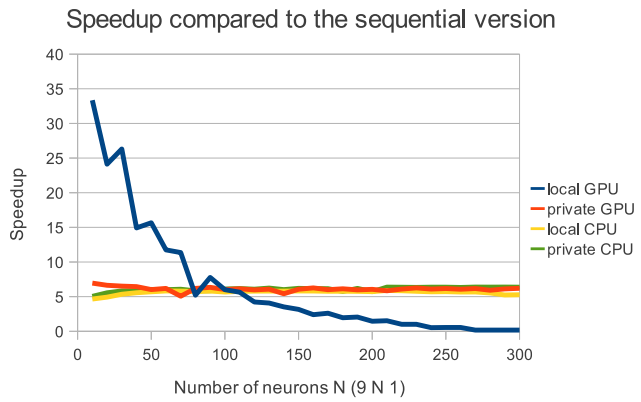

Fig. 8. Parallel PSO, speedup for larger number of neurons

stable speedup of about 6. The version with local memory, on the other hand, shows great variability depending on the number of layers and the required amount of memory. As the memory footprint is increased, less work groups can fit in a compute unit at the same time, thus lowering the parallelism. Finally, with more than 25 layers the needed amount of memory causes the decrease in the number of available work items per workgroup, which is visible as a speedup decrease.

V. Conclusions

This paper describes two implementations of parallel neural network training algorithms with OpenCL. The programming model allows the implementations to be deployed on different platforms; although the maximum efficiency is obtained on a GPU device, the program can also be executed on a general purpose CPU.

Training with parallel backpropagation proved to be efficient only with large networks and is not recommended for smaller networks and smaller number of samples. Parallel training with PSO, on the other hand, is much more applicable in various conditions regarding the number of samples and network size and structure. Two versions of parallel PSO are described, which differ by the type of memory primarily used for calculation. The local memory version shows the best overall speedup results, but may be highly dependent on the network parameters. The version with private memory exhibits a smaller speedup, but is less sensitive to parameter changes.

APPLICATION OF GENETIC ALGORITHMS IN WIRE BUSBARS DESIGN

Davor Petranović
Energy Institute Inc.
Ulica grada Vukovara 37, 10000 Zagreb, Croatia
E-mail: davor.petranovic@ie-zagreb.hr

Abstract - This work shows how a substation wire busbar design can be achieved by means of genetic algorithms (GA). Major parameters of busbars are mapped into a chromosome like a string. This includes insulators and wire types and geometry, thrust requirements and operating parameters. GA operators are performed on a population of such strings and natural selection is expected to occur. The design performance is obtained by using the busbar price as the fitness function.

I. INTRODUCTION

The wire busbars in outdoor switchgear are used for transfer of the electrical power between incoming and outcoming feeder bays and transformer bays. The main two designs are: tube and wire busbars. This paper deals with wire busbars, which are presented at Figure 1.

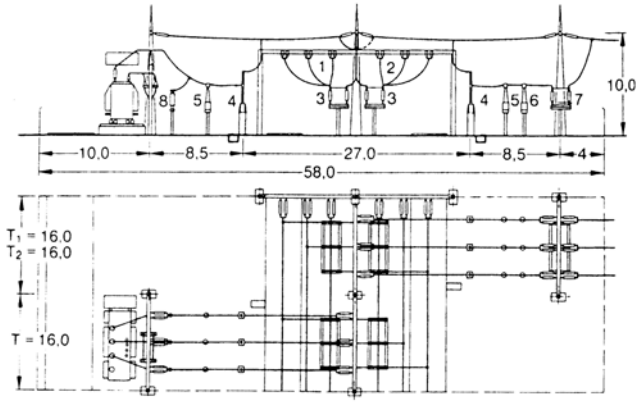

Figure 1. Typical wire busbars

The main part of wire busbars are: wire conductor, insulator strings and portals.

Steel reinforced, aluminum conductors (ACSR) and aluminum alloy conductors (AAC) are usually used for flexible conductors. Conductor cross-section ranges from 200 to 1600 mm^2. The span length is usually from 10 to 60 m. The full span length between supports must be distinguished from the conductor span length between end points of insulator strings. Bundled conductors (for high nominal current) are composed of two to four conductors placed within the distance between subconductors, ranging from 0.08 to 0.6 m. This distance is maintained by spacers placed at intervals along the bundle, and the distance between spacers, ranges from 2 to 30 m. Strained conductors are usually designed with an initial static stress of a relatively low value (in relation to overhead lines) in the order of 10-20 N/mm^2. This is only a small percentage (less than 10%) of the nominal rupture conductor strength. The total sag (the sum of the conductor sag and the insulator string sag) under this tension amounts to about 3% of the span length. For the maximum permissible conductors temperature (for example 80 °C), the sag is about 30% greater than the initial sag.

Strained flexible conductors are connected to the steel supporting structures (usually portals) with insulator strings or chains. These consist of cap and pin porcelain or glass insulators or long rod porcelain insulators. Insulators chains may be single or doubled in parallel arrangements.

Steel supporting structures are typically portals, usually made of latticed or solid webbed steel and erected on concrete foundations. Their design is typically carried out by civil engineers. The mechanical behaviour of such structures is characterized by their spring constant and their mechanical frequency.

Wire busbars are one of two types of busbars in the switchyard. The other one is tube busbar. Their characteristic is the tensioned wire conductor connected to portals. Wire conductor under the influence of short-circuit currents starts to swing out and swing in. The choice of parameters of the wire busbar system is complex, since they must be taken into account, except on busbar parts, and steel portals with its foundations. The increase in static stress caused by wire conductors increases the cost of steel structures and foundations. Also intermediate conductor spacing causes the change in the cost of steel structures and foundations.

Because of the complex interrelationship between the bus parameters, we tried to develop a method based on the application of genetic algorithms. At the end of the paper the application of the developed program to test example has been presented, with the display of optimization process flow.

No available published papers on optimization of wire busbars. In relation to author's previously published paper [12], portals are described by I-beams instead of typical portals. The basis for the development of the described GA method are general works in the field of GA [4,5,6,10,11] and works in the field of optimization of steel structures [8,9]. For programming has been used Genetic Algorithm Toolbox for use with MATLAB [7].

II. OPTIMAL WIRE BUSBARS DESIGN

Optimal wire busbars depend upon nominal and short-circuit current effects [1, 2, 3]. The short-circuit current passing through conductor makes the conductor swing with lower phase clearances and higher tension forces. Three main ways to solve this problem are: a greater static tension force, a greater conductor unit mass or a greater phase distance. The first and the third solution on the opposite give more expensive steel supporting structures with their foundations.

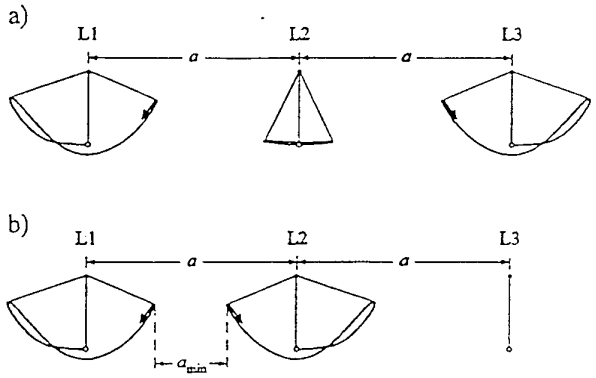

Figure 2. Conductor movement due to short-circuit current
a) three phase short-circuit
b) two phase short-circuit

The optimization task is to give a solution with all criterions satisfied and with a lower overall price. A typical optimization problem involves the search for the minimum of the stated objective function subject to various constraints and also restricted by practical minimum sizes, or dimensions of components. If the design variables may be continuously varied between practical extremes, the problem is termed continuous, while if the design variables represent a selection from a set of parts, the problem is considered discrete.

Finally, the wire busbar design must satisfy:

- load current in continuous operation,
- load current in short circuit,
- reduction of the corona,
- limitation of stresses in the conductors,
- limit the forces on the insulator strings,
- limit deflection of steel structure,
- limit the pressure on the foundation soil,
- restrictions on conductor deflection.

The goal is to optimize the cost of all components of the wire busbar system that meet all technical requirements.

$$C = C_1 + C_2 + C_3 + C_4 + C_5 \qquad (1)$$

Wire busbar system price consists of the following prices:

C_1 - conductors cost,
C_2 - insulator strings cost,
C_3 - spacers cost,
C_4 - portal (steel construction) cost (according to portal mass),
C_5 - concrete foundations cost (according to foundation volume).

Input data for the optimization process are database components, data related to the specific case and set parameters for the optimization process.

The typical components database consists of the following:

- wire conductor data,
- string insulator data,
- spacers data,
- I-beam data,
- concrete foundation data.

The specific case values are the following:

- continuous current,
- ambient temperature (minimum, maximum and temperature with the occurrence of ice),
- other parameters to determine the allowable continuous load,
- short-circuit current,
- short-circuit duration,
- additional load,
- minimum and maximum phase distance,
- span length,
- allowable conductor distance during the short-circuit.

The results of the optimization process are discrete (integer) and continuous (real) values:

Discrete values are the following:

- conductor type,
- number of conductors,
- insulator string type,
- spacers type,
- number of spacers,
- conductor distance (depending on the type of spacers)
- I-beam type,
- concrete foundation type.

Continuous values are the following:

- maximum static conductor horizontal stress,
- phase distance.

The described optimization problem is a mixed "discrete-continuous" model, where some variables take values from countable group of values and the other variables have real values.

Optimization methods are based on the search space and try to facilitate the search process or speed up (reduced) during the search.

There are three main categories of methods of search for the optimum:

- countable,
- calculation based, and
- stochastic.

Countable methods include search of all possible solutions within the searched space. Disadvantages of this method are the lack of efficiency and lack of use of the results of preceding tests. The advantage of this method is the ease of use.

Calculation based methods are divided into two main classes: direct and indirect. Both methods are treated as a continuous search space of multi-dimensional function and search a maximum or a minimum using its derivatives. In the indirect method, the idea is to seek local optimum by solving a group of equations for finding the point where the derivative equals zero. The function should be smooth and number of points where the derivative equals zero are small. In the direct search, a common technique as Newton's method requires a local optimum function and moving in the direction of the local gradient. These methods are known as the hill climbing method starting from the current point estimates, they tend to increase function in the steepest direction to the next point. This method is difficult to apply if the search space is filled by noise or discontinuities.

Stochastic methods use information from previous tests to determine the probable choice of the following points. Evolutionary algorithms are based on the Darwinian theory of evolution where the fitted survive. In evolutionary strategies, the typical search space consists of vectors with real values. Adding random noise in these vectors points creates a new item. Search continues from the new points, if they are better than old ones, and if not, then the old items are kept. Finally, in the genetic algorithms, the search space is characterized by bit vector codes. The new vectors, which can potentially lead to the solution, are created from parents bits. This is analogous to the manner in which the DNA chromosomes travel to a new generation from parents.

Because of the mixed type of variables (integer and real) for process of wire busbars optimization the method of genetic algorithms is selected.

III. GENETIC ALGORITHMS

The MATLAB Genetic Algorithm Toolbox [7] aims to make the GAs accessible to the design engineer within the framework of a calculation/simulation package. This allows the retention of existing modeling and simulation tools for building objective functions and allows the user to make direct comparisons between genetic methods and traditional procedures.

- GAs search a population of points in parallel, not a single point,
- GAs do not require derivative information or other auxiliary knowledge; only the objective function and corresponding fitness levels influence the directions of search,
- GAs use probabilistic transition rules, not deterministic ones,
- GAs work on encoding of the parameter set rather than the parameter set itself (except in the case where real-valued individuals are used).

Basic concept of a GA is based on the following:

Population - current set of solutions coded in a manner suitable for the treatment of a genetic algorithm,
Chromosome - an individual in a population that represents a coded solution,
Gene - part of a chromosome, represents a certain property, that is part of the solution,
Generation - one step in an iterative process of measuring fitness solutions and creating a new population by applying reproduction operators,
Selection - the mapping of chromosomes to the next step in the development of population,
Recombination - crossover of two chromosomes, i.e. their genetic content,
Mutations - random changes to the process values of genes in the chromosome.

The procedure method of genetic algorithms:

1. Generation of an initial population
2. Calculating the initial population fitness
3. Selection of the most appropriate individuals
4. Creating a new population by genetic crossover procedures
5. Creating a new population by genetic mutation process
6. Calculate the current population fitness
7. Selection of the most appropriate individuals
8. Checking the condition of convergence (maximum number of generations reached, stall fitness, operating time maximum reached, ...) YES – jump to 9 or NO - jump to 4
9. Print Solutions
10. Completion of proceedings

The description of the wire busbar system is defined by the values of design variables. The allowable range for each of the design variables, are given in Table I. Table II shows the tableau for the wire busbar design.

TABLE I. RANGE OF DESIGN VARIABLES

Design variable	Admissible values	Type
Conductor type	database	discrete
Conductor number	integer	discrete
Insulator string type	database	discrete
Spacer type	database	discrete
Spacer number	integer	discrete
Conductor stress	10 -30 N/mm^2	continuous
Phase distance	2 - 4 m	continuous
I-beam	database	discrete
Foundation	database	discrete

TABLE II. TABLEAU FOR THE WIRE BUSBAR DESIGN

Objective	Find the globally optimum combination of nine wire busbar parameters
Representation scheme	Structure: fixed length Alphabet size: real values String length: 9
Fitness cases	Only one
Fitness	Wire busbar price (1), with penalty for constraint violations. Less is better.
Parameters	Population size: 100 Maximum number of generations: 30
Termination criteria	The genetic algorithm has run maximum number of generations
Result designation	The best so far individual in the population.

The constraint violations were taken into consideration by penalizing the fitness value (10^6 HRK).

IV. TEST EXAMPLE

A. Input data

To illustrate the application of genetic algorithms for optimization of the wire busbar system, we have calculated the bus system with the following data:

Span length (m): 30
Portal height (m): 9
Continuous current (A): 1400
Short-circuit current (A): 16000
Short-circuit duration (s): 0.3
Factor kappa: 1.70
Conductor static stress (N/mm^2): from 4 to 20
Phase conductor centerline spacing (m): from 1.5 to 4 m

The parameters of the database of the wire busbar components:

Number of conductors: 3
Number of insulator strings: 2
Number of spacers: 2
Number of steel I-beams: 28
Number of foundations: 19

Parameters of genetic algorithm

Generation gap: 0.80
The ratio of the crossing: 0.80
The ratio of mutation: 0.09
The ratio of insert: 0.40

B. Results

In Table III are presented results for 5 runs of GA program.

TABLE III. RESULTS OF GA PROGRAM

Run	Fitness (HRK)
1	102.218,48
2	94.678,75
3	93.466,00
4	93.403,03
5	108.513,39
Average	98.455,93
Standard deviation	6.708,35

The parameters of optimal, or the best obtained, busbar system (4th run) are:

Conductor: AAC400
Number of conductors: 2
Insulator string: 1Z2-330
Number of spacers: 0
I-beam: IPB200
Foundation: T1400
Conductor stress (N/m^2): 5.83
Phase spacing (m): 1.92
Price (HRK): 93.403,03

Prices of individual components are (1):

$$C_1 = 171{,}6m \cdot 29HRK/m = 4.975HRK$$
$$C_2 = 6pcs \cdot 3.870HRK/pcs = 23.220HRK$$
$$C_3 = 0HRK \quad \text{no spacers}$$
$$C_4 = 3.139{,}7kg \cdot 15HRK/kg = 47.098HRK$$
$$C_5 = 8{,}232m^3 \cdot 2200HRK/m^3 = 18.110HRK$$

The main task is to reduce costs of steele structure (C_4) and foundation (C_5).

The flow of the optimization procedure for 4th run is shown at Figures 3 to 7.

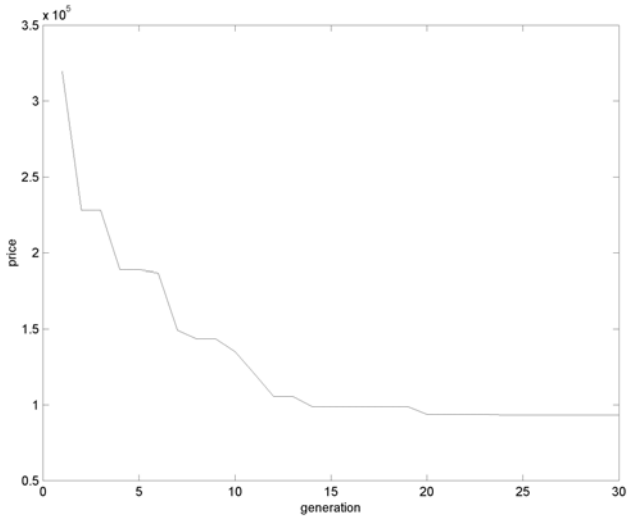

Figure 3. Price vs. Generations

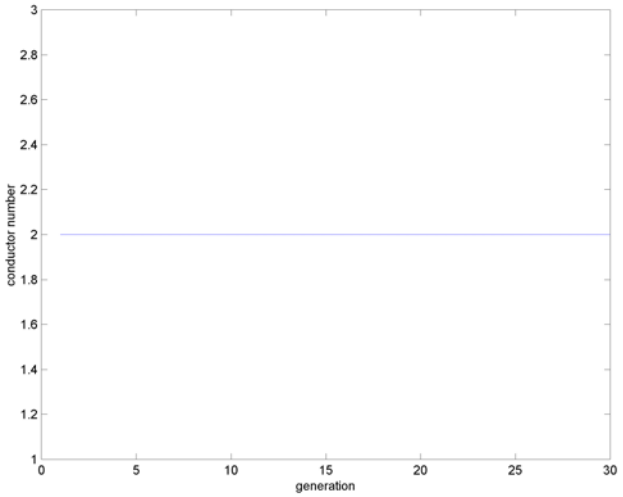

Figure 4. Number of Conductors vs. Generations

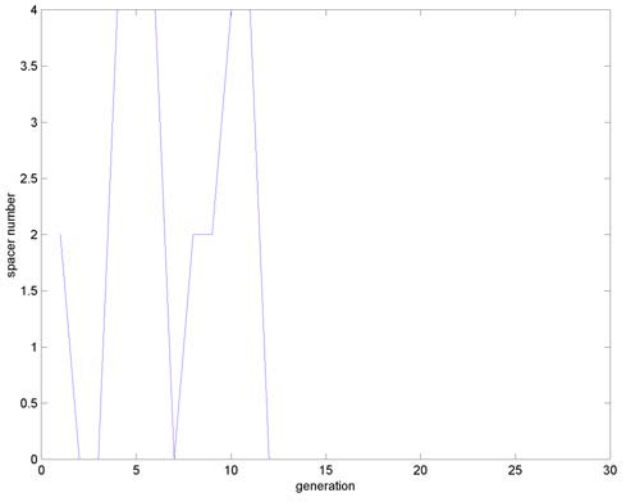

Figure 5. Number of Spacers vs. Generations

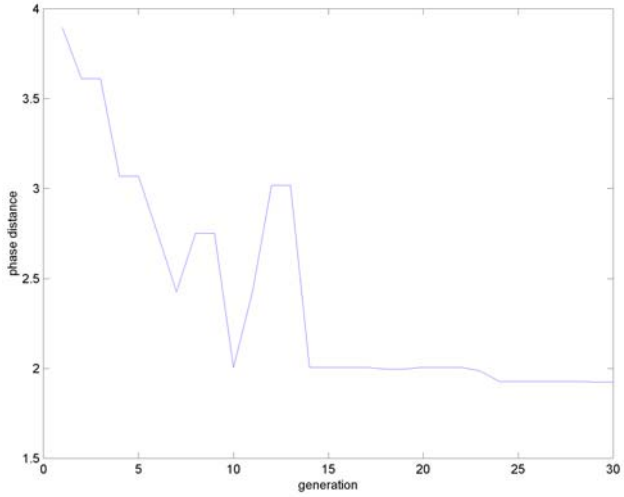

Figure 6. Phase Distance vs. Generations

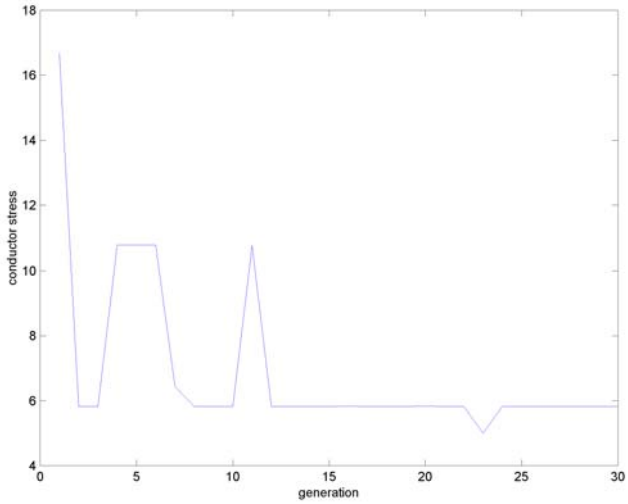

Figure 7. Conductor Stress vs. Generations

V. CONCLUSION

In this paper is described the method for wire busbar design by implementing GA with real-value chromosomes. Some of the design variables have discrete values and the others have continuous values. The reason for choice of GA method is the simplicity of description of the stated problem - optimum wire busbars. The fitness (objective) function is a sum of the wire busbars components prices. For violating of constraints the wire busbar system receives a huge total wire busbars price (10^6 HRK) and in this way this case is excluded from possible solutions.

The future work can be divided into two distinct tasks - improvement of the GA efficiency and implementation of more accurate wire busbars model. GA efficiency can be improved by choice of optimal GA parameters (selection procedure, crossover rate and mutation rates). The ultimate goal is to minimize the number of fitness evaluations (population size times number of generations) necessary to obtain the solution. The more accurate wire busbars model can be based on modelling of real portals (3D wire frame instead of portal with I-beams).

Optimization of the bus system by using methods of genetic algorithms is demonstrated on test examples. The attached images present the gradual approaching to the optimal solution.

ACKNOWLEDGMENT

I would like to state thanks to the staff of The Polytechnic of Zagreb, where I am a part time lecturer, for the use of mentioned program tools.

***Abstract*—Evolutionary computation methods are successfully applied in solving of combinatorial optimization problems. Since the "No Free Lunch" theorem states that there is no single best algorithm to solve all possible problems, throughout the years many algorithms and their modifications have emerged. When a new algorithm is developed, one question that naturally arises is how it compares to other algorithms, whether for some specific problem or in general performance. Because of the stochastic nature of systems involved, usually the only possible way of deriving the answer is to perform extensive experimental analysis. In this paper we provide an overview of possible approaches in the experimental analysis, and describe statistical methods that could be used. Furthermore, we outline similarities and differences between these methods, which lead to a discussion of important issues that need to be resolved when using these methods.**

I. Introduction

Evolutionary computation forms a subfield of computational intelligence that involves combinatorial optimization problems. Even broadly speaking, this field has a multitude of methods and their variations. Among those algorithms and theirs modifications it is often hard to single out the more successful ones. To single out the best overall algorithm would be impossible as is stated in the "No Free Lunch" theorem. Wolpert stated that, when averaged over all test problems, all search algorithms perform equally. This means that if algorithm A is better than algorithm B on some problems, then the algorithm B will be better than the algorithm A in exactly as many different problems [1]. However, it is important to state that"No Free Lunch" theorem assumes no knowledge of the problems. Since almost always we have at least partial knowledge of the problems at hand, it is possible to sort out the better algorithms for particular classes of problems.

If it is possible to find better, more suitable algorithms for a particular problem, the next question is how to recognize which of those algorithms are better. Due to the fact that the theory of evolutionary computation is often not developed enough, one way to do it is to perform an experimental analysis.

It is necessary to realize that the experimental analysis is usually not a trivial task. When we have algorithms that we want to compare, then it is first necessary to decide on the test problems that should be used. Deciding about the test problems is often more difficult then it seems. If the problems are too easy, then the algorithms will always find the global optimum. From the other side, if the problems are too hard, algorithms will typically get stuck in local optima. Optimal parameters must also be found for those problems (this alone can be a very difficult task where approaches range from guessing to complex parameter tuning methods). After these preparation steps have been done, the experiments can be made.

The next step is the analysis of experimental results which requires the usage of statistical methods. However, there are different possibilities regarding statistical procedures that can be used. Although often different statistical methods can reach the same or very similar results, the wrong choice of a method can lead to a misleading result [2]. Even if the analysis is properly conducted, there is still the question whether the results are more depending on the algorithm design or the problem design.

Our aim is to discuss statistical methods, with an accent on the nonparametric statistical procedures since those methods are rarely used, but are often a needed tool for conducting a proper statistical analysis.
In Section 2 we present relevant theory needed for the understanding of the experimental models and the statistics employed in the analysis of the results. In Section 3 a review of nonparametric statistical methods is done, in Section 4 we give a hypothetical test case where nonparametric statistic procedures should be used, and finally, in Section 5 a conclusion is given.

II. Preliminary

A. Experimental Analysis Models

When performing experiments, several options exist regarding the algorithms and problems choice. Regarding the chosen model, the appropriate statistical analysis should be chosen as well.

1) Single Algorithm Single Problem analysis: This approach is best when some real-world setting is investigated. It also brings the benefit of thorough investigation of dedicated algorithm on some particular problem which is often not possible when there are more algorithms or problems.

2) Single Algorithm Multiple Problem analysis: Main benefit of this approach is that it can help in better understanding of the algorithm and its parameters.

3) Multiple Algorithm Single Problem analysis: This approach can help in understanding of the algorithms and their similarities.

4) Multiple Algorithm Multiple Problem analysis: This approach usually gives the biggest mass of data but smallest actual insight in the inner mechanisms of algorithms or understanding of problems. This is because of the complexity of this approach.

Among the approaches mentioned above, the last one is the most common one, since that approach usually suggests (although that is not necessarily true) a serious research paper.

When the model of the analysis is a single problem scenario, it should be safe to use parametric statistical tests, however, when the model has a multiple problem scenario, an analysis should be done regarding the choice of appropriate statistical methods.

B. Statistical Analysis

1) Descriptive Statistics: Descriptive statistics represents statistics that allows us to present data in a way that is easier when interpreting the results. This kind of statistics does not allow making any conclusions beyond the data that have been analyzed.

2) Inferential Statistics: Inferential statistics represents techniques that allow us to make generalizations about the populations on the basis of the samples that are evaluated. Inferential statistics employs two methodologies: hypothesis testing, and estimation of population parameters.

a) Hypothesis Testing: Hypothesis represents a prediction about a population or relationship between two or more populations. Hypothesis testing is a procedure in which sample data is employed to evaluate a hypothesis. There is also a research hypothesis which represents a statement of what the research predicts, and statistical hypotheses which represent restatement of the research hypothesis.

Statistical hypotheses are null hypothesis which is a statement of no difference, e.g. a hypothesis that researcher expects to be rejected. Second statistical hypothesis is alternative hypothesis and it represents a statement of difference, e.g. a hypothesis that researcher expects to be supported [3].

The more conventional hypothesis testing model used in inferential statistics assumes *a priori* stating at what level of significance , the null hypothesis will be evaluated. Other approach is that instead of *a priori* setting of a level of significance, one calculates the smallest level of significance that results in rejection of null hypothesis where that is represented by p-value [3]. P-value is the probability of obtaining a test statistic at least as extreme as the one that was observed, assuming that the null hypothesis is true.

b) Estimation of Population Parameters: This framework is employed for estimating the value of one or more population parameters. There can be point estimation where a value is estimated from the computed value of statistics, and interval estimation where a range of values are computed and in which a true value of a parameter falls with a high degree of certainty [3].

C. Parametric and Nonparametric Statistics

Statistical procedure employed in inferential statistics can be divided in parametric statistical methods and nonparametric statistical methods. The distinction between parametric and nonparametric statistical methods can be on the basis that parametric tests make specific assumptions regarding population parameters that characterize the underlying distribution whereas nonparametric tests make no such assumptions. Because of that, the nonparametric statistical tests are also sometimes called distribution free statistical methods.

The second distinction that can be used is that parametric statistical methods work with categorical/nominal data and nonparametric methods work with ordinal/rank-order data [3].

In an analysis, it is necessary to decide whether to use parametric or nonparametric tests. Parametric tests present a more powerful option when testing alternative hypothesis than nonparametric tests, but if some assumptions for using parametric tests are violated then that advantage can be lost. If no assumptions of a parametric tests have been violated, and when the level of measurement for a set of data is interval or ratio then the data should be evaluated with parametric tests. If one or more assumptions are violated then it could be prudent to transform the data into format that is compatible with nonparametric tests. However, not all researchers agree on this approach because in the transformation of the data from interval/ratio data to the ordinal/rank-order format some of the information is lost. This is due to the fact that interval/ratio data contain more information. Because of that, some researchers advocate the usage of parametric test with some adjustments when assumptions for parametric test are violated [3]. Finally, usual conclusion is that in the end, parametric or nonparametric tests give the same or very similar results and so there is no real consequence in choosing the wrong tests. When there are conflicting results between these two approaches, often it could be enough to conduct multiple experiments [3].

However, as displayed in [2], it can be seen that wrong choice of statistical tests can lead to a misleading conclusion. Additionally, conducting multiple experiments may not be

always possible due to the complexity of the problems and often limited time frame on disposal.

To decide on the choice of nonparametric or parametric statistical tests, it is necessary to check all the conditions to see if it is allowed to use parametric tests. These conditions are independence, normality, and homoscedasticity. For details about the necessary conditions or tests check [2] [3].

1) Independence
   Two events are independent if the occurrence of one of the events gives no information about whether or not the other event will occur.
2) Normality
   Normal or Gaussian distribution is a continuous probability distribution that has a bell-shaped probability density function. An observation is normal if it follows normal distribution. Tests that can be used to indicate the presence of normality in a sample are:
   - Kolmogorov-Smirnov test
   - Shapiro-Wilk test
   - D'Agostino-Pearson test
3) Homoscedasticity
   Homoscedasticity is also called homogeneity of variance. It is a property which shows that all of the samples have the same variances. The tests that can be used to check homoscedasticity are:
   - Bartlett test
   - Levene test

For every parametric statistical test, there exists a nonparametric statistical equivalent as shown in Table IV.

TABLE I
PARAMETRIC VERSUS NONPARAMETRIC TESTS

	Parametric test	Nonparametric test
Pairwise	t-test	Sign test Wilcoxon signed rank test
Multiple	ANOVA Tukey, Tamhane	Friedman Holm, Hochberg, Rom, Li,...

III. NONPARAMETRIC STATISTICAL PROCEDURES

Once we decide to use nonparametric statistical methods, the first step is to decide whether to use pairwise or multiple comparison tests. Pairwise tests are a good option when two methods are compared. If more than two methods are compared, multiple comparison tests should be used because pairwise tests do not control error propagation of making more than one comparison.

As we stated before, since most of the research work today compare more than two methods (multiple algorithms multiple problem scenario), we will put an emphasis on the use of multiple comparison tests.

A. Discovering Global Differences

The simplest tests for multiple comparisons are Friedman test and its extension Iman-Davenport test. The purpose of those tests is to answer whether there are global differences between related samples obtained.

These tests do not give the answer which algorithm is better: they only show if the null hypothesis is rejected, i.e. if there are differences between algorithms. More details about Friedman and Iman-Davenport tests can be found in [3] [4] . The Friedman two-way analysis of variances by ranks test is a nonparametric analogue of the parametric two-way analysis of variance. Ranking of the data is the transformation that enables the usage of nonparametric statistical methods on the real data. There are several possibilities how to conduct that transformation, and depending on that, it is possible to improve the standard Friedman test.

B. Post-hoc Procedures

When we determine that the null hypothesis is rejected through the use of tests mentioned above, then we can use post-hoc procedures to find where those differences exactly are. Those tests can be done in the way that control method (usually one that is suggested by researchers) is tested against other methods (1 x N comparison) or to conduct multiple comparisons (N x N comparisons) among all methods.

With the post-hoc procedures we can obtain the p-values which determine the degree of rejection of each hypothesis. P-value gives information whether some statistical hypothesis is significant, and if it is, then how significant it is. The smaller the p-value is, the more strongly the null hypothesis is rejected. However, p-values obtained directly from the formulas are not suitable for multiple comparisons case. When a p-value is considered in a multiple comparison test, it reflects the probability error of a certain comparison, but it does not take into account the remaining comparisons.

This problem is possible to solve with the usage of adjusted p-values. Adjusted p-values can solve that problem since they take into account the accumulated error [3]. When a p-value is found, then it can be compared with desired level of significance α to see if the null hypothesis is rejected. In regards how the level of significance α can be adjusted to compensate for multiple comparisons there are following procedures and examples of tests:

- One-step: Bonferroni-Dunn test
- Step-down: Holm, Holland, Finner tests
- Step-up: Hochberg, Hommel, Rom tests
- Two-step: Li test

C. Contrast Estimation Procedure

A contrast estimation procedure based on medians can be used to estimate the differences between each two crossover operators. In this test the performance of the algorithms is reflected by the magnitudes of the differences in error rates [4].

TABLE II
BENCHMARK FUNCTIONS

Test function	Abbreviation
$f(x) = \sum_{i=1}^{D} x_i^2$	P_1
$f(x) = \sum_{i=1}^{D} i \cdot x_i^2$	P_2
$f(x) = \sum_{i=1}^{D} 5 \cdot i \cdot x_i^2$	P_3
$f(x) = \sum_{i=1}^{D} \left(\sum_{j=1}^{i} x_j^2 \right)$	P_4
$f(x) = \sum_{i=1}^{D-1} 100 \cdot \left(x_{i+1} - x_i^2 \right)^2 + (1 - x_i)^2$	P_5
$f(x) = 10 \cdot D + \sum_{i=1}^{D} \left(x_i^2 - 10 \cdot \cos(2 \cdot \Pi \cdot x_i) \right)$	P_6
$f(x) = \sum_{i=1}^{D} -x_i \cdot \sin\left(\sqrt{\lvert x_i \rvert} \right)$	P_7
$f(x) = \sum_{i=1}^{D} x_i^2/4000 - \prod_{i=1}^{D} \cos\left(x_i/\sqrt{i} \right) + 1$	P_8
$f(x) = -20 \cdot e^{-0.2\sqrt{\sum_{i=1}^{D} x_i^2/D}} - e^{\sum_{i=1}^{D} \cos(2\Pi x_i)/D} + 20 + e$	P_9
$f(x) = -\sum_{i=1}^{D} \sin(x_i) \cdot \left(\sin\left(i \cdot x_i^2/\Pi \right) \right)^{20}$	P_{10}

IV. AN EXAMPLE APPLICATION OF NONPARAMETRIC STATISTICAL ANALYSIS

The purpose of this section is to go through one simple example of statistical analysis for a genetic algorithm (GA) case (of course, these steps are valid in general case). We compare four different crossover operators (single-point crossover - Alg. 1, uniform crossover - Alg. 2, shuffle crossover - Alg. 3, non-geometric crossover - Alg. 4) in a binary-coded genetic algorithm with a roulette-wheel selection. GAs with different crossover operators can be regarded as different algorithms. The comparison is made on a set of 10 standard benchmark functions. The formulas for these benchmark functions are given in Table II.

More details on the benchmark functions and the algorithms can be found in [5]. As a performance measure the error rate obtained for every operator (algorithm) is used. For all the test functions, the objective is to find global minimum. For each algorithm 30 independent runs are made.
From the each run of the algorithm, the individual with the smallest error rate is chosen as the best one from that run. Then, the mean value is taken from those 30 values for each algorithm and problem. Those mean values for all the algorithms and problems are displayed in Table III.

TABLE III
MEAN ERROR RATES FOR EVERY ALGORITHM AND PROBLEM

Problem	Alg. 1	Alg. 2	Alg. 3	Alg. 4
P_1	0.056	0.065	0.112	0.139
P_2	233.41	434.133	1197.863	1799.66

P_{10}	2.243	2.230	2.349	2.365

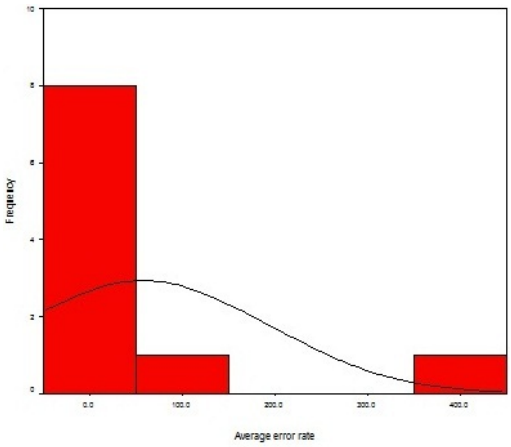

Fig. 1. Histogram for the uniform crossover case

First it is necessary to decide whether to use parametric or nonparametric tests so we test indenpendence, normality and homoscedasticity assumptions. Independence condition is easily checked since there are independent runs of the algorithms.

Normality and homoscedasticity conditions are estimated at the level of significance α of 0.01.
For normality condition we use Shapiro-Wilk test that can be easily conducted in SPSS tool [6]. Shapiro-Wilk is used instead of Kolmogorov-Smirnov because the number of samples is smaller than 50. The obtained values are smaller than 0.01, so we can conclude that normality condition is not satisfied. In Fig. 1 a histogram is displayed for the uniform crossover case where it can be seen that the solutions do not follow normal distribution.

For the homoscedasticity test we can use Levene test that can also be done in SPSS tool. However, since the normality assumption is not satisfied we do not need to conduct the homoscedasticity test.

Next, we can start with the nonparametric statistical tests. We use KEEL tool for conducting nonparametric statistical analysis [7]. There are many possible choices of the statistical packages that can be used, but we decided on KEEL since it is very easy to use and free. First we conduct Friedman and Iman-Davenport test. Table V gives the results for a Friedman two-way analysis of variances by ranks.

The transformation to rank data is done in the following way: for each row in Table III a rank of 1 is assigned to the lowest score in that row, a rank of 2 is assigned to the second smallest value in that row and so on until the rank 4. If two algorithms have the same value for a problem (row), then the average value of the ranks that are involved is assigned to all algorithms tied for a given rank. In Table IV are displayed all the ranked values and the scores for the each column.

To compute the chi-square approximation of the Friedman

TABLE IV
RANKED VALUES FOR ALL THE ALGORITHMS AND PROBLEMS

Problem	Alg. 1	Alg. 2	Alg. 3	Alg. 4
P1	1	2	3	4
P2	1	2	3	4
P3	3	2	1	4
P4	1.5	1.5	3	4
P5	1.5	1.5	4	3
P6	2	1	4	3
P7	2	1	3	4
P8	2	1	3	4
P9	2	1	3	4
P10	2	1	3	4
	$R_1 = 18$	$R_2 = 14$	$R_3 = 30$	$R_4 = 38$

TABLE V
AVERAGE RANKINGS OF THE ALGORITHMS (FRIEDMAN)

Algorithm	Ranking
Single-point	1.8
Uniform	1.4
Shuffle	3
Non-geometric	3.8

test statistic we use 1:

$$\chi_r^2 = \frac{12}{n * k(k+1)} \left[\sum_{j=1}^{k} \left(\frac{R_j}{n} \right)^2 \right] - 3 * n\,(k+1) \qquad (1)$$

Here *n* represents the number of problems, *k* the number of algorithms, and R_j are column scores from the Table IV.

With the level of significance α of 0.01 both the Friedman and Iman-Davenport statistic show significant differences on operators with test values of 21.84 and 24.08, respectively, and $p < 0.001$.

The next test that can be done is the Bonferroni-Dunn test. This procedure does not have a great resolution in distinguishing differences but is appropriate for graphical display. For the Bonferroni-Dunn test, first the critical difference (CD) must be found [2]. The equation for calculating critical difference is as follows:

$$CD = q_\alpha \sqrt{\frac{k * (k+1)}{6 * n}} \qquad (2)$$

where q_α is the critical value for two-tailed Bonferroni-Dunn test.
Critical difference computed according to 2 has a value of 1.38. The interpretation of this measure is that the performance of two algorithms is significantly different only if the corresponding mean ranks differ by at least a critical difference, which is depicted in Fig. 2. A cut line is drawn at height equal to the sum of critical difference and ranking of the control algorithm. The bars that exceed this line are associated with the algorithms that have worse performance than the control algorithm.

Now, post-hoc procedures can be applied. We use one procedure from every class mentioned previously: Bonferroni-Dunn, Holm, Hochberg, and Li test. For the control algorithm,

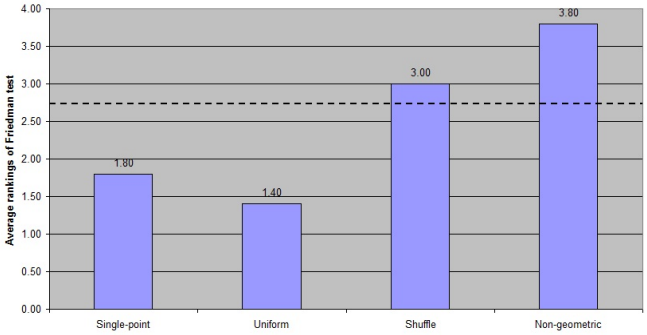

Fig. 2. Bonferroni-Dunn's test, critical difference = 1.38, control operator: uniform crossover

uniform crossover is selected as the best one from Friedman test. Results obtained from the post-hoc analysis are presented in Table VI.

TABLE VI
POST-HOC COMPARISON (CONTROL OPERATOR: UNIFORM CROSSOVER)

Algorithm	p_{Li}	p_{Bonf}	p_{Holm}	$p_{Hochberg}$
Non-geometric	0.000063	0.000097	0.000097	0.000097
Shuffle	0.010797	0.016751	0.011167	0.011167
Single-point	0.488422	1.465267	0.488422	0.488422

From the Table VI it is obvious that the Bonferroni-Dunn results are confirmed; and that the uniform crossover is better than the shuffle and the non-geometric crossover. However, we still can not answer the question whether the uniform or single-point crossover are better. Because of that, now we use the contrast estimation method.

TABLE VII
CONTRAST ESTIMATION

	Single-point	Uniform	Shuffle	Non-geometric
Single-point	0	0.026	-0.138	-0.258
Uniform	-0.026	0	-0.164	-0.284
Shuffle	0.138	0.164	0	-0.12
Non-geometric	0.258	0.284	0.12	0

A negative value for the operator in a given row indicates that the operator performs better than the operator in a given column. From the Table VII we can see that uniform crossover is the best operator for the selected benchmark functions.

This simple example should be regarded just as a roadmap through the nonparametric statistical tests, and not as some representative case. Often, we can not get the definitive answer which algorithm is the best one, but a set of better algorithms.

V. CONCLUSION

Experimental analysis often represents the only method of evaluating the performance in evolutionary computation. Because of that, it is important to use as appropriate statistical methods as possible. It may also be advisable to perform parametric statistical tests together with nonparametric statistical

tests.

Only by applying a rigorous statistical analysis on a set of well defined benchmark functions a proper performance evaluation can be made.

Only then can we properly evaluate not only existing algorithms but also the future ones. Some of those algorithms proved to be very successful and now are widely used. Some other algorithms were presented as successful (even better than the more common ones) but they soon disappeared from usage.

Stadium Reflector Aiming Using Genetic Algorithms

Davor Petranović
Energy Institute Inc., Zagreb, Croatia
davor.petranovic@ie-zagreb.hr

Abstract - When designing football stadium lighting, the longest job is to aim reflectors which should ensure a high enough horizontal and vertical illuminance with the required uniformity. The present paper deals with methods of applying genetic algorithms to this activity. The results are demonstrated on real football stadium lighting.

I. INTRODUCTION

Football pitches lighting must allow playing and monitoring the game (directly at stadium and indirectly via the TV broadcast). Requirements regarding lighting are given in the relevant standard. Aiming of the football stadium reflectors is the longest job which should ensure a high enough horizontal and vertical illuminance with the required uniformity. The development of genetic algorithms methods provides the possibility that this part of the project is left to the computer. The paper will deal with methods of applying genetic algorithms to this activity. The results are demonstrated on a real football stadium and will include numerical and graphical results of the optimal design for a variety of criteria.

Several papers have been already published in this field [5, 6, 8, 9].

Paper [5] deals with genetic algorithm technique that is developed for the optimal design of a supplemental lighting system for greenhouse crop production. The approach uses the evolutionary parallel search capabilities of genetic algorithms to design the pattern layout of the lamps luminaries, their mounting heights and their wattage. The total number and the exact positions of luminaries are not predefined (even though possible positions lay on a fixed grid layout), thus the genetic algorithm system has a large degree of freedom in the designing process. The possibilities of mounting heights and luminaire wattages are limited to four different values for each luminaire in this study.

Paper [6] deals with football stadium lighting optimization by GA methods. The calculation method is based on discrete points on rectangular grid. The reflector data are not included.

Paper [8] proposes a Genetic Algorithm to optimize lighting design parameters integrated with a Computer Aided Design (CAD) application. Genetic Algorithm offers an optimization approach to perform a search to achieve better design solutions, and proposed CAD tool uses innovative concepts of Information Visualization within virtual environments.

Paper [9] deals with american football stadium lighting optimization using nonlinear least squares optimization (MINPACK routine). Calculated example is based on 6 towers.

Author uses the possibility to connect the early developed lighting program VRAS [7] to Matlab GA Toolbox. In this way Matlab optimization program GAVRAS, based on genetic algorithms, calls external program VRAS for illuminance calculations as bases for fitness function calculation. In comparison with paper [6] program GAVRAS does not use discrete aiming points. The results can not be compared with early publish results because of luck of reflector intensity data in published papers.

II. FOOTBALL STADIUM LIGHTING

Lighting requirements are defined by EN 12193 [1]. Additional requirements may be defined by sports governing bodies such as FIFA [3], Olympic Delivery Authorities, etc. and by television authorities, such as Sky.

Each sport has a playing area that is the principal playing area (the area inside the line marking for tennis or football for example) and the total area which is defined as the principal playing area, plus an additional safety area outside the principal playing area.

Lighting levels for sports are normally defined in terms of the minimum average horizontal illuminance on a reference plane, and the illuminance uniformity. In some instances the illumination plane will be relevant to the sport and the spectator viewing distance, or TV camera-viewing plane. Here, the normal to camera illuminance and vertical illuminance will be relevant.

As some sporting areas are large, they have the need for high illuminance levels, or if they are used for long periods during the day, highly efficient lighting systems are required to keep the energy consumption low. Maintenance is also important to ensure system efficiency and functionality and therefore all lighting equipment should be safely accessible and maintainable throughout its life.

Average maintained horizontal illuminance (E_{hav}) is the average quantity of lux to be achieved over the agreed maintenance cycle period for an installation. Maintenance includes replacement of lamps and cleaning of luminaries. Where there is television coverage, it has become increasingly common for minimum lighting levels to be specified in the regulations. This is also true for the vertical illuminance described below.

This is the amount of light (measured in lux) that is required for the relevant sport to be played. The faster the sport and the smaller the playing object, the higher is the lighting level required. Normally, several different settings or 'switching modes' are recommended so that the lighting system can be used efficiently at all levels, from 'training mode' (non-televised) right through to 'international TV' mode (televised).

Average maintained vertical illuminance (E_{vav}) or camera illuminance is the quantity of light that shines in the direction of a fixed camera position. Calculations should be carried out using the actual angles perpendicular to the camera positions. The side of a player forms the reference for the television camera. The camera illuminance should ideally also be considered for the ball in flight, as this reading will differ from the camera illuminance at ground level. This is generally defined as being 1.5m from the ground.

TABLE1 ILLUMINANCE REQUIREMENTS [1]

Lighting class	Horizontal average illuminance (lx)	Uniformity of horizontal illuminance $U_2=E_{hmin}/E_{hav}$
Training & recreation	75	0,5
Leagues & clubs	200	0,6
National league	500	0,7

The required vertical illuminance for the TV broadcasting of a football game can be found in Figure 1 at curve B depending on the shooting distance.

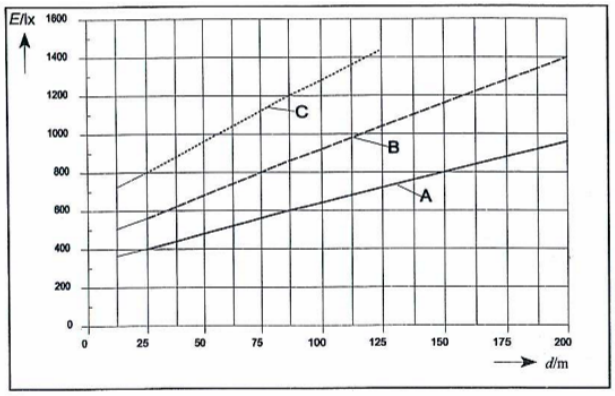

Figure 1. Required vertical illuminance

For shooting distance around 120 m the required vertical illuminance equals to 1000 lx.

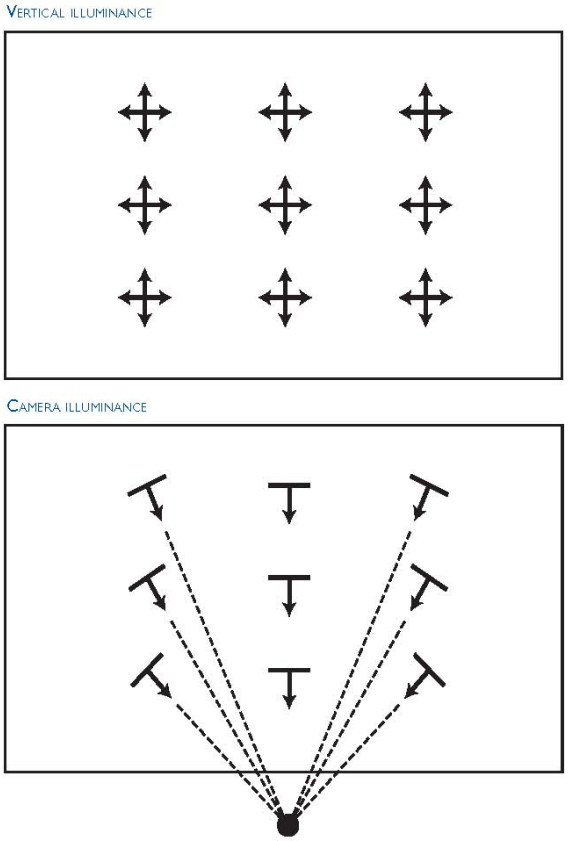

Figure 2. Vertical and Camera Illuminance

Requirements for horizontal and vertical illuminance with TV broadcast are stated in following equations:

$$\frac{E_{v\min}}{E_{v\max}} \geq 0.4 \tag{1}$$

$$0.5 \leq \frac{E_{hav}}{E_{vav}} \leq 2 \tag{2}$$

$$\frac{E_{h\min}}{E_{h\max}} \geq 0.5 \tag{3}$$

where:

E_{vmin} - minimal value of vertical illuminance (lx),
E_{vmax} - maximum value of vertical illuminance (lx),
E_{vav} - average value of vertical illuminance (lx),
E_{hmin} - minimal value of horizontal illuminance (lx),
E_{hmax} - maximum value of horizontal illuminance (lx),
E_{hav} - average value of horizontal illuminance (lx).

Equations for illuminance calculations are:

$$E_h = \frac{I_\alpha}{h^2} \cdot \cos^3 \alpha \tag{4}$$

$$E_v = \frac{I_\alpha}{h^2} \cdot \cos^2 \alpha \cdot \sin \alpha \cdot \cos \beta \tag{5}$$

$$E_{TV} = \frac{I_\alpha}{h^2} \cdot \cos^2 \alpha \cdot \cos \gamma \qquad (6)$$

where:

E_h - horizontal illuminance (lx),
E_v - vertical illuminance (lx),
E_{TV} - camera illuminance (towards TV camera) (lx),
I_α - lumens per lamp (intensity) in the direction towards calculation point (cd),
h - height of reflector (m),
α - angle between reflector normal vector and reflector distance vector (°),
β - angle between reflector x-axes and horizontal projection of reflector distance vector (°),
γ - angle between reflector distance vector and TV camera distance vector (°).

Calculation points are placed on rectangular grid with maximum distances p between nodes:

$$p = 0.2 \cdot 5^{\log d} \qquad (7)$$

where d equals the longest side of football field. For length of 105 m d equals 5 m.

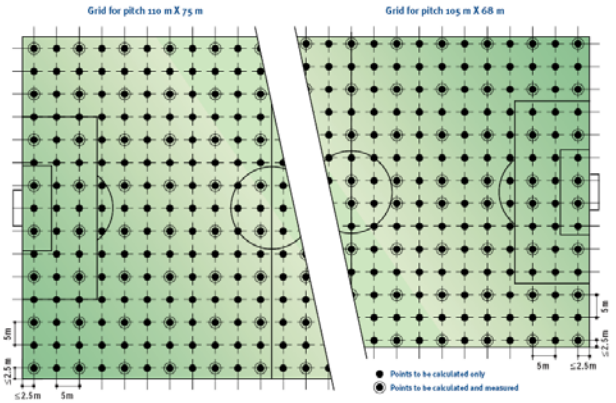

Figure 3. Calculation Grid Points

One of the popular ways of the reflectors placement is arrangement with 4 towers in the corners of the football stadium. Aiming of reflectors is than mirrored over x and y axes.

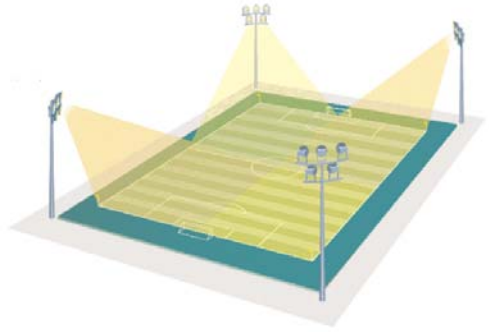

Figure 4. Four Lighting Tower Arrangement

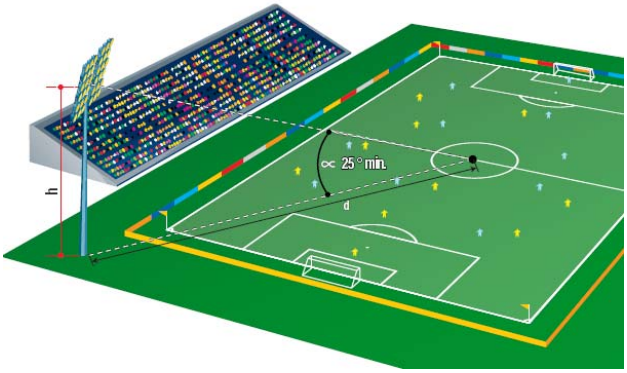

Figure 5. Minimum Lighting Tower Height

Figure 6. Lighting Tower Sitting

III. IMPLEMENTATION OF THE GA METHOD

A genetic algorithm technique is developed for aiming of the optimal design of a football stadium lighting system. The approach uses the evolutionary parallel search capabilities of genetic algorithms.

The real-value chromosomes were used representing the x and y coordinates of aiming points on the football field.

Program GAVRAS (written in MATLAB) randomly selects aiming points on a playing area and call VRAS lighting program [7] for calculation of illuminance as base for fitness function calculation.

Fitness (objective) functions were a mix of illuminance level and uniformity requirements. Huge penalties are implemented for violation of constraints (required illuminance level or uniformity).

Fitness function, for levels I, II and III, must correspond to the requirements in Chapter II (E_{hav} and U_2) and their values:

$$f_1 = k_1 \cdot \left(E_{hav} - E'_{hav}\right) + k_2 \cdot \frac{E_{hav}}{U_2} \cdot \left(U_2 - U'_2\right) \qquad (8)$$

where:

f_1 - fitness function,
k_1,k_2 - factors of satisfying requirements,
E_{hav} - required horizontal illuminance (lx),

E'_{hav} - current average horizontal illuminance (lx),
U_2 - required uniformity factor,
U'_2 - current uniformity factor.

Factor k_1 and k_2 equal 1 if requirements are satisfied or 1000 if requirements are not satisfied. In such a way the optimization (minimization) process is moved to the satisfactory solution. For unsatisfied aiming points fitness function is positive and for satisfied aiming points negative.

For TV transmission of a football game the requirements in Chapter II must be satisfied in the similar way as in equation (8) but simultaneously the horizontal and vertical illuminance must be tracked as well as their uniformity factors in equations (1), (2) and (3).

IV. EXAMPLE

GA method shall be presented on a football stadium with the playing field (or principal area) equal to 105 m x 68 m. Longer size is parallel with x-axes. Central point of playing area is at point (0; 0), towers with reflectors are at points (70; 45), (70; -45), (-70; 45) and (-70; -45). Towers height equals 40 m.

Check of towers sitting:

$$\alpha_B = arctg\frac{45-34}{70} = 8{,}9° > 5°$$

$$\alpha_A = arctg\frac{70-52{,}5}{45} = 21{,}5° > 15°$$

Check for towers height:

$$\alpha = arctg\frac{40}{\sqrt{70^2+45^2}} = 26° > 25°$$

Calculation grid:

$$p = 0{,}2\cdot 5^{\log d} = 0{,}2\cdot 5^{\log 105} = 5m$$

Calculation grid has 21x14 calculation points.

Reflector type is MAGNUM LVR-10 2000 TS, TEP with lighting source HQI 2000 W, 183.000 lm. Photo of reflector is given at Figure 7 and Cartesian intensity diagram is given at Figure 8. Cartesian intensity diagram is also given in datasheet view in Table 2.

Average	**-37,952**	**92,79**	**0,648**
Standard deviation	**6,043**	**10,84**	**0,101**

Stochastic behaviour of GA results is shown at Table 7 by calculations of average values and standard deviations for 10 runs for level I.

V. CONCLUSION

The paper describes the method for football stadium reflector aiming by means of GA implementation. The real-value chromosomes were used representing the coordinates of aiming points on the football field. The reason for the GA choice is the description simplicity of the stated problem and easy connection to the VRAS lighting program. Value of fitness (objective) function depends on satisfying of illuminance level and illuminance uniformity requirements. Penalties are implemented for violation of constraints (required illuminance level or uniformity).

The future work might be divided into several tasks - connection of the GA model to the professional lighting programs (i.e. RELUX, CALCULUX, SiSport,..), simultaneous usage of several reflector types, selection of reflector quantity and sequential optimization (i.e. during optimization at second illuminance level, the reflector aiming points at first level are fixed).

ACKNOWLEDGMENT

I would like to state thanks to the staff of The Polytechnic of Zagreb, where I am a part time lecturer, for the use of the mentioned program tools.

Towards Software Autogeneration

D. Radosevic, T. Orehovacki and I. Magdalenic

{danijel.radosevic, tihomir.orehovacki, ivan.magdalenic}@foi.hr

Abstract - Program generators are usually aimed for the generation of program source code. This paper introduces the idea of software source code generation and its execution on demand that we refer to as Autogeneration. Autogeneration avoids the generation of program files by using the possibility of scripting languages to evaluate program code from variables. There are several features that could be achieved by Autogeneration. Some of them are program update during its execution, optimized code without temporarily unnecessary instructions and introspection of the generation process for development purposes. An example of a web application for database content management that is implemented as an autogeneration process is presented and discussed.

I. INTRODUCTION

Program code is usually observed as a set of program files. It could be written manually or generated by usage of a software generator. Although usage of files is a usual way of storing program code scripting languages like JavaScript, Perl or Python have an alternate option, which is to evaluate program code from variables. This is a relatively scarcely researched possibility, which is mostly used for limited purposes like testing program code or generation of small program pieces.

In this paper we introduce Autogeneration, which we refer to as the automatic generation of program code and its execution on demand. In our approach, Autogeneration avoids the generation of program files in favor of using possibilities of scripting languages to evaluate program code from variables.

It is worthwhile considering possible benefits of Autogeneration. So far we have identified several possibilities enabled by such an approach. The most obvious one is the possibility to change a program specification and, consequently, its execution 'on the fly', i.e. during program execution. In addition, some program instructions, e.g. changing the database structure, are rarely used. In this case, according to our approach, the imperative statement (e.g. alter table) should be performed, and the program specification updated to the obtained new state. The code is generated in accordance with a service requested from the user, so there is no need for the regeneration of the entire application. Furthermore, there is a possibility of some introspection of the generation process. The generator can easily find the corresponding parts of the program specification, configuration and used code templates for achieving a particular user action. This could be used in the development of autogenerated software.

There are also some prerequisites and limitations of Autogeneration. Firstly, the autogenerated software has to be organized as a set of clearly distinguished services that are requested by users. This is easier to achieve in web applications, where users demand services via HTML links. Secondly, autogenerated code should be written in a scripting language (preferably the same as the generator) to work effectively. Finally, some security and performance issues need to be observed.

An example of an autogenerated web application is presented in this paper that is also available online for testing. The generator used for Autogeneration is based on our previously introduced SCT generator model [1].

The remainder of paper is organized as follows. Background to the research is described in Section 2. Basics of the SCT generation model are discussed in Section 3. An introduction to the autogeneration process is provided in Section 4. Section 5 illustrates an application example. Concluding remarks are given in the last section.

II. BACKGROUND TO THE RESEARCH

In this section we will provide a brief overview of the software development paradigms in order to create a theoretical background of the software auto-generation approach.

Software Product Line Engineering (SPLE) is a methodology of software product lines development based on the reuse of artifacts, that is, core assets. A Software Product Line (SPL) or Product Family (PF) is a group of software intensive systems sharing common set of features that meet specific needs of particular stakeholders [11]. The aim of SPLE is to reduce development time, effort, cost, and complexity, increase productivity and quality of software, and achieve higher end-user satisfaction. Rather than developing software from scratch, an existing SPL can be reconfigured and reused across projects. SPLE consists of two processes: domain engineering (in which the core assets are designed), and application engineering (in which core assets are reused during the development of a target product).

Feature Oriented Software Development (FOSD) is a common technique for representing variabilities and commonalities of a SPL. A feature is a property of a system relevant to some stakeholder used to capture

variabilities or discriminate among products in the same family [36]. Features are hierarchically organized in a diagram with a concept as a tree root. A feature model is a feature diagram that contains feature descriptions, information about stakeholders, priorities, etc. Feature modeling was proposed as a part of Feature-Oriented Domain Analysis (FODA) method for performing a domain analysis [7]. FODA provides a comprehensive description of the domain features, but neglects design and implementation phases. Therefore it has been extended to the Feature-Oriented Reuse Method (FORM), thus providing support to the object-oriented component development and architecture design [8].

Model Driven Software Development (MDSD) is a paradigm that captures essential features of a system through appropriate models [12]. In MDSD, models represent first class entities that are combined and transformed as the system is created. A modeling notation commonly referred to as Domain-Specific Language (DSL) plays the central role in MDSD [16]. DSL encompasses a meta-model that defines the abstract syntax for building models, concrete syntax description, mappings between abstract and concrete syntax, and semantics description. Former research efforts on the relationship between MDSD and SPL were mainly focused on specifying PF members by using DSLs [18]. Although MDSD has a number of benefits, a gap between specifications and their software implementations still exists [15]. With an aim to overcome the problem of having annotations scattered all over the model template, the use of Object Constraint Language (OCL) [14] notation was proposed [13].

Aspect Oriented Software Development (AOSD) aims at improving the software development process by providing modularization and composition techniques to handle crosscutting concerns [37].In general, concern is anything that is of interest to a certain stakeholder. A concern that affects multiple classes or one that is triggered in multiple situations is called a crosscutting concern. Separate modules, known as aspects, encapsulate crosscutting concerns and are subsequently composed with the rest of the system using an aspect weaver. Automatic composition of aspects with other software artifacts is either static during compilation, or dynamic at loading or runtime. There are two types of AOSD approaches. In asymmetric approaches such as AspectJ [3] there is a difference between the aspects and entities that compose the base system. Accordingly, they provide language extensions, thus declaring aspects as first class entities. On the other hand, symmetric approaches such as Hyper/J [4] assume that all concerns in a system are created equal and consequently can serve as an aspect or base in different compositions.

Frame Based Software Development (FBSD) advocates creating generalized, adapted, and thus configured components based on Frame Technology (FT). The concept of a frame as a data-structure for representing a stereotyped situations was introduced by Marvin Minsky in 1975 [19]. FT is a language independent textual pre-processor for creating systems that can be easily adapted or modified to different reuse contexts [5]. The key elements of FT are code templates organized into a hierarchy of modules known as frames, and a specification that contains particular features written by the developer. In the SPLE context, such an infrastructure embodies architectures from which SPLs are derived and evolved [6].According to an independent audit [9], FT has reduced large software project costs by over 84% and their times-to-market by 70%,concurrently reaching the reuse levels of up to 90%. The aforementioned productivity improvements motivated Jarzabek and Zhang [10] to implement XML-based Variant Configuration Language (XVCL). It is a meta-programming technique based on Basset's frames [20] to manage variabilities in SPLs. To facilitate effective reuse, XVCL enables the partitioning of programs into generic and adaptable meta-components called x-frames. An x-frame is an XML file that represents domain knowledge in the form of SPL assets. X-frames form a layered hierarchical structure called an x-framework, enabling handling variants at all granularity levels. A configuration of variants in SPL assets is recorded in a specification x-frame (SPC). Starting from the call of SPC, the XVCL Processor interprets an x-framework, performs the composition and adaptation of visited x-frames by executing XVCL commands (XML tags), and generates specific SPL members that meet specific requirements. Owing to its status as a public domain meta-language for enhancing reusability, the principles of XVCL have been thoroughly tested in practice [21][22][23].

Generative Software Development (GSD) is a widely accepted software development approach focused on the automatic generation of PF members [24]. The key concept of GSD is a generative domain model which refers to a mapping between problem space and solution space [17]. Problem space is a set of features of a PF member that are described by a DSL. On the other hand, solution space refers to implementation-based abstractions that are contained in the specification of a PF member. The mapping between the spaces is performed by means of a generator which calls a specification and results in a corresponding implementation. Apart from XVCL [10], techniques such as GenVoca [26], XFramer [25], and openArchitectureWare [27] are used for generating different types of artifacts. There are three types of generators. The ones belonging to the first type are aimed to generate code artifacts in programming languages such as PHP [28], Java [29], or Python [2]. The generators in the second type are focused on generating non-code artifacts like text [34], graphical interface [33], or students' exercises [31]. The ones in the third type are meant for building new scripting languages such as Open PROMOL [30] or CodeWorker [32], whose purpose is generator design.

Given that the afore-discussed paradigms are different but rather complementary, a number of authors (e.g. [35], [38]) have proposed the integration of two or more approaches with the aim of attaining significant synergy effects.

With a research objective of contributing to the body of knowledge on SPLE we initiated a research into the autogeneration of software. Our approach is mostly based on Generative Programming and Frame Technology with

some adjustments like the usage of dynamic frames generation [1].

III. BASICS OF THE SCT GENERATOR MODEL

The autogeneration system proposed in this paper is based on our SCT generator model [1]. For the autogeneration purpose, it is important that a generator in the base of such a system fulfills some prerequisites. Firstly, such a generator has to produce full executable program code, not only a code skeleton. Otherwise, it would not be possible to re-generate the code and execute it on each user's demand. Furthermore, the generator should be fully configurable, i.e. the configuration has to be separated from the generator code so it can be changed 'on the fly', just like in changing a program specification. Finally, the autogeneration system should use the same program specification and configuration as the 'plain' generator that generates program files. Code templates could be adapted automatically (e.g. some internal links in web applications have to be adapted for Autogeneration).

A. SCT Frame

The SCT generator model defines the source code generator on the basis of three kinds of elements [1]: Specification (S), Configuration (C) and Templates (T). All the three model elements together make the SCT frame (Fig. 1):

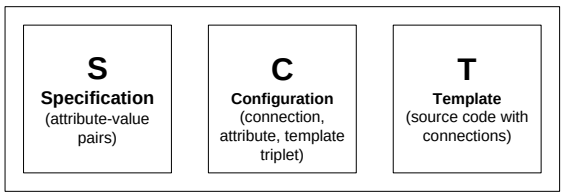

Figure 1. SCT frame [2]

Specification contains the features of a generated application in form of attribute-value pairs. Template contains the source code in a target programming language together with connections (tags for insertion of variable code parts). Configuration defines the connection rules between Specification and Templates.

B. The Generation Tree

The generation process starts from the starting, top-level SCT frame that is defined by the developer [1]. It contains the whole Specification, the whole Configuration, but only the base template from the set of all Templates. Other SCT frames are produced dynamically, during the generation process, forming the generation tree (Fig. 2).

The depth of the generation tree depends on Configuration. Configuration manages the generation process by using a set of simple rules that connect the attributes from Specification with connections (insertion tags) in Templates [1].

C. Handler

The role of Handler [2] in the original SCT model is to make the generator scalable in a way that it could produce more pieces of program code (e.g. program files) from the same set of Specification, Configuration and Templates. For the purpose of Autogeneration, Handler has been modified, as described in the next section.

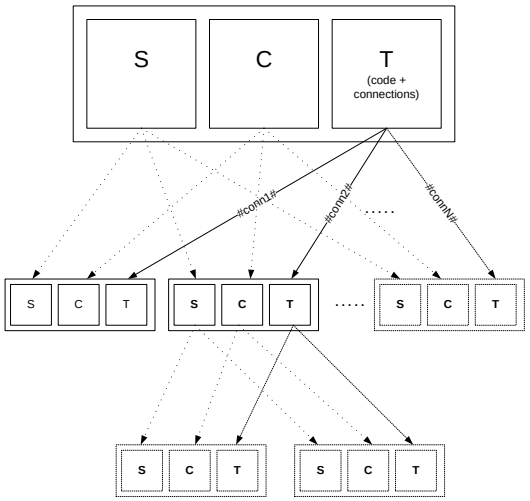

Figure 2. The generation tree [2]

IV. THE AUTOGENERATION PROCESS

The autogeneration process is described in Fig. 3. A user request is accepted by a request handler, whose task is to decompose the request and to determine what action should be taken. The request handler has to build an initial SCT frame and call the source code generator to produce the appropriate source code. It should be noted that in the autogeneration process only the source code that is needed to fulfill the user request is generated. This is the main difference in comparison with the usual use of generative programming, where the source code of a complete application is generated. This is achieved by taking a subset of Specification. Usually, the Specification contains the information needed for generating the source code of the complete application. By taking only a subset of the Specification it is possible to generate the source code needed for certain actions. Fig. 4 shows one possible subset of Specification whose purpose is to generate html templates and *cgi* scripts that deal with particular database table management.

After the request handler has built the initial SCT frame with the Specification subset, the source code generator is called to generate the program source code. The generated source code is stored in a variable, where scripting languages like JavaScript, Perl or Python can evaluate it. The Execution unit presented in Fig. 3 has the task to execute the generated source code together with arguments obtained from the request handler. Those arguments are presented in Fig. 3 as Application context and are usually obtained from user request. For example, they can include information about the user who is performing a certain action or information about a table and a record in a database that is being updated. The result of the Execution unit is sent to the user as a response to their request. In the case of a web application, the response is a web page that will be presented in the user's browser.

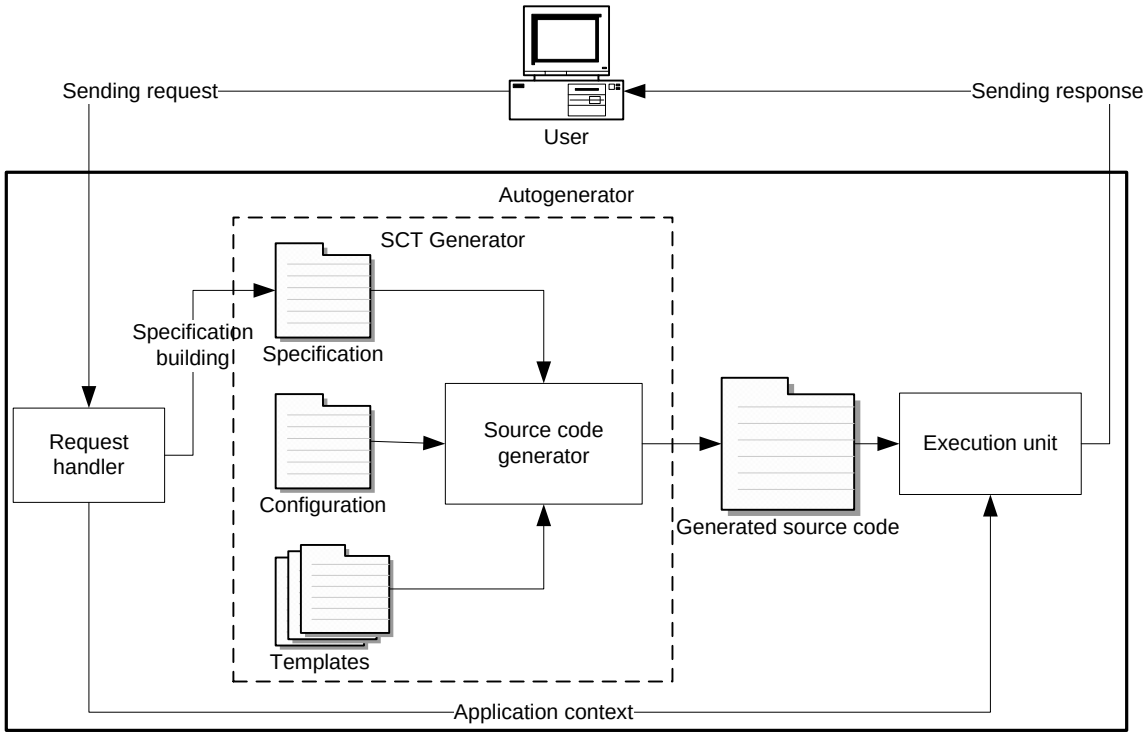

Figure 3. The autogeneration process

The autogeneration process uses two parameters (that, in case of a web autogeneration system, could be sent using the get method): the piece of code to be generated (file) and the action that should be performed (action). Specifying the file is inherited from the 'plain' generator, to maintain compatibility. As shown in Fig. 4., depending on the file, the appropriate part of Specification will be used, while depending on the action, the appropriate action will be performed (e.g. data display, data entry, data correction etc).

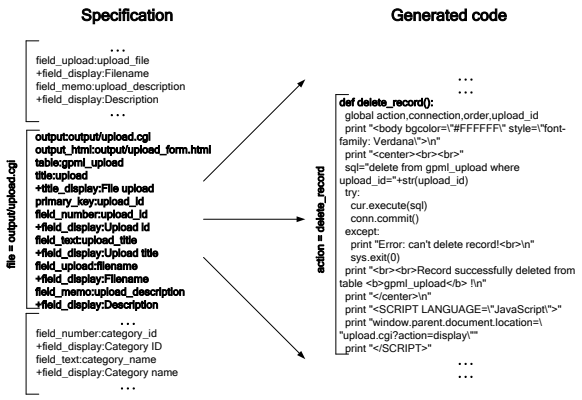

Figure 4. Specification subset

V. AN EXAMPLE

The example of the autogeneration system is a web application for database administration via web forms[1]. Basic model elements of the SCT generator model (Specification, Configuration and Templates) are available in the same way as with a conventional generator that produces program files (Fig. 5).

Figure 5. Basic model element in *html* form

Specification still contains some filenames, e.g.:

out1:output/index.html

The file 'output/index.html' is not generated, but the filename is used internally to denote the generated piece of code. Also, filenames are retained to keep the same specification that is used in a conventional generator.

[1]An example is available at:
http://gpml.foi.hr/SCT_Autogenerator_Example/

The generator is integrated with application execution, so that starting the generator also starts the autogenerated application (Fig. 6).

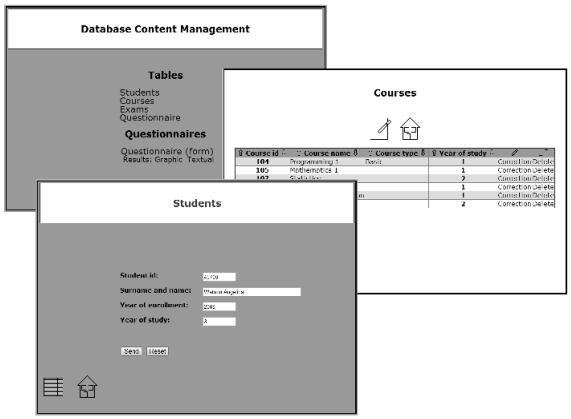

Figure 6. The autogenerated application

The example shows basic features of an autogeneration system: changing the application 'on the fly', imperative statements and code introspection.

A. *Changing the application 'on the fly'*

The code to be generated is defined by a parameter file (submitted via the get method). Any change in Specification is updated each time the user requests the re-generation and execution of the appropriatepiece of code. Configuration and Templates can also be modified 'on the fly', enabling even a substantial change in the application structure.

B. *Imperative statements*

Imperative statements in Specification are used to perform rarely used instructions, usually connected with some program dependencies, like databases. A typical example of usage of such statements is changing a database table structure, along with the change in program code. For example, the Specification statement:

ADD_field_int:new_column

will cause the generation of the appropriate ALTER TABLE statement in the generated code. After the instruction is executed, the specification will be updated by removing the imperative statement (here: ADD):

field_int:new_column

So, the imperative statement is intended to be performed once, establishing a new state.

C. *Code introspection*

Introspection in an autogeneration system enables application developers to see exactly which part of Specification, Configuration and Templates was used in the generation of acurrently executing part of an application. In the example application, introspection is implemented in form of an introspection pane, as shown in Fig. 7.

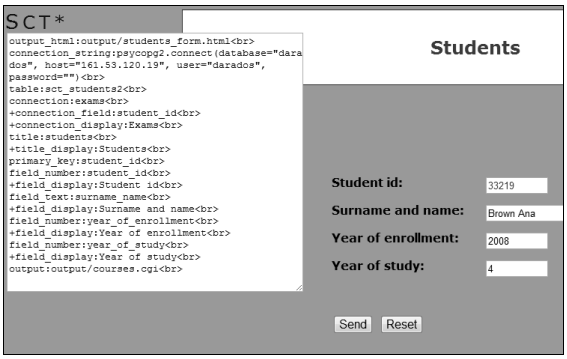

Figure 7. The introspection pane

The introspection starts from the generator' 'knowledge' of how something was generated, helping developers to find possible errors or possibilities for application improvement.

VI. CONCLUSION

The paper introduces the idea of software source code generation and its execution on demand that we refer to as Autogeneration. The presented example of a web application that works as an autogeneration system shows that such a concept is possible and could have some advantages in comparison with the usual way of code generation (into program files). Some of the possible benefits of such an autogeneration system include changing the application 'on the fly', imperative statements and code introspection. All these three concepts are included in the example application.

In addition to the benefits of using Autogeneration, there are some limitations – and even disadvantages – of such a concept. Firstly, the concept is closely connected to scripting languages (we used Python) that contain the possibility of code evaluation from variables. Furthermore, the autogenerated application also needs to be in a scripting language, preferably the same one as the generator.

The performances of such systems could therefore be slightly degraded in relation to applications generated/written in a usual way.

In our future work, we plan to define a formal model of Autogeneration and test the concept in the development of different kinds of applications.

Abstract - The software development process is represented as propagation of the differences (modifications) within a set of models representing the software under development. The theory of system of complexes (configurations) is used to represent the model set of the software under development. The target of the research is to construct an approach to describe the process of the difference propagation as a basis of a corresponding instrumental environment for software development. The work extends the present MDA (Model Driven Architecture) approach.

I. INTRODUCTION

Any software development life cycle consists of distinct stages and involves various formal and informal models, agents (designers, software developers, users, etc.) and technologies. Various combinations of stages form a number of software development life cycle schemes, such as waterfall and spiral models, 'V'-model, agile and extreme approaches, iterative and incremental development, and various improvement models [1]. All the approaches make use of models of various degrees of abstraction and formalization. We consider a general case of the life cycles as a process of adaptation of new ideas, requirements and specifications, where each adaptation event is a model change. The adaptation implies modification of all the affected models due to the event. Thus, the software development process is represented as propagation of the differences (modifications) within a set of models representing the software under development. The target of the research is to construct an approach to describe the process of the difference propagation as a basis of a corresponding instrumental environment for software development.

The difference propagation in our approach is interpreted in terms of model transformation of Model Driven Architecture (MDA) [2]. In the ideal case the transformation is automatic. MDA is aimed at automation of creative activity of designers and programmers and implemented in some instrumental software. The software development technique of MDA is based on multistage transformation of Platform Independent Model (PIM) into a number of Platform Specific Models (PSM). PIM is a model of the software reflecting most of the structural and some semantic aspects of the software, but the model contains no information about implementation of the structures on the target program architecture. The software development tools having a model at input generate a model or source code, which is also considered as a software model.

The transformation of the PIM into PSMs is carried out under control of a Platform Model (PM) and a transformation scenario. PM contains information and algorithms of PIM's structure analysis and generation of corresponding structures in PSMs. The main idea of MDA is to allow developer to modify PM according programmers' preferences and task properties. Our experience shows that usage of present expressive logical languages and PMs based on formalized knowledge [3] allows us to affect the transformation in an efficient way by means of refinement of the rule set content.

MDA is successfully used in development complex software, but it has following significant disadvantages:

- Usage of MDA in simple projects usually extends time of software construction;
- MDA is of little use in already constructed and implemented systems and systems based on stored data manipulation;
- Modification of PIM and source code is ignored by the procedures of transformations.

To deal with these disadvantages we consider application of the theory of systems of complexes (configurations), successfully used in geography research [4], to software life cycle, implying that the software development is a natural process. The life cycle is represented as system of models and morphisms between them.

In the paper we show how the theory can be applied to the software life cycle. As a result of the application it appears that the difference propagation does not require extension of the expressive power of the models. The differences are represented as morphisms between changing parts of the software model by means of the same informational models. The morphisms are translated by the existing transformational rules and merging algorithms into corresponding morphisms for lower layer model of the software, e.g., source code.

The proposed approach to the MDA technologies extension allows us not only to cope with the above mentioned disadvantages, but to develop MDA further to support automatic PM knowledge mining and software development process based on logical inference on the analogy of a previously constructed history of differences of the model set.

II. THEORY OF COMPLEX SYSTEMS AND COMPLEXES [4]

Complexes (compositions) and systems of compositions (configurations) X_i are formed from combinations of various elements, components, systems, complexes, systems-complexes. Configurations X_i are different kinds of complex system's polymorphism. The universal structure X contains all X_i, and in this case it is analogous to notion of set of all subsets or category of all the subcategories. The connections between compositions are represented by means of mapping (morphism) $F_{ij} : X_i \to X_j$. The composition connected with morphisms (represented a category in the mathematical sense) form a complex. The comparison of the two compositions X_i and X_j, namely $\Delta X_{ij} = X_j \setminus X_i$, shows the dissimilarity between *j*-th composition and *i*-th one. For example, let X_i and X_j be different UML (Unified Modeling Language) models of software before and after adding a new structure, so ΔX_{ij} reflects a complex of the current development step. If X_i and X_j are two UML models of different software systems, then ΔX_{ij} fixes, in particular, their structural dissimilarity, and F_{ij} is a comparison relation. The structure ΔX_{ij} is also a composition and belongs to the set of all the comparisons ΔX. The set F is a set of all possible mappings F_{ij}.

There are also a reference set of comparison I; it is the interval [0, 1], which is a metric linearly ordered inductive continuous bounded above and below set of points. The one-to-one correspondence of compositions and reference set points is denoted by relation ($\leftrightarrow$), for example, $I \leftrightarrow I$ means that each point I turns into itself; $X \leftrightarrow I$ means that any composition from set X is one-to-one corresponded to a definite point of the interval [0, 1]. In the latter case I is a bundle (fibration) basis of X, in other words the differentiation X into compositions is conducted by means of comparing them with points (numbers) from the interval [0, 1].

The axioms of complex systems' theory are to compare compositions and their connection functions with an identification index of an order and together.

$$1)\ X \leftrightarrow I;\ 2)\ F \leftrightarrow I;\ 3)\ \Delta X_{ij} \leftrightarrow F_{ij}. \qquad (1)$$

The axioms 1 and 2 transfer all the order properties of the set I to the sets of all compositions $X_i \subset X$, their comparisons $\Delta X_i \subset X$, and mappings $F_{ij} \subset F$. This also implies that all the combinations are toposes, i.e. they are linearly ordered structures with the individual measure from I. By means of I the structures, their comparisons and mappings are one-to-one connected to each other.

$$X \leftrightarrow F \leftrightarrow \Delta X \leftrightarrow I.$$

This emphasize a necessary moment of complexing, the complexes, their comparisons and mappings are equivalent (identical in the sense of dialectical logics), and have the single identification index in I. The complexes are self developing systems, where each alteration is based on its structure $\Delta X \leftrightarrow X$. Complexes are static formations, the transitional states with partially formed connections cannot be related to them.

Complexes are linear sequences of morphisms (categories)

$$\cdots \to X_i \to X_j \to X_k \to \cdots;$$

the contained compositions form homologous series of comparison, as each composition has a measure from I, this series is also homotopic. Homologo- homotopic series form comparisons and mappings. All the elements of the series are functionally similar, that's why they can be considered as series of analogs.

Any fragment of a homological series $X_i \to X_j$ is a complex, which corresponds to a complex of comparison of the dissimilarities $\Delta X_i \to \Delta X_j$. Consequently, a similarity of the structure implies similarity of differences and vice-versa. Therefore, observed similarity in the structure must be caused by similarities of the processes and their models. The search of structural and dynamical similarity is the main subject of the theory of complexes.

III. APPLICATION TO SOFTWARE LIFE CYCLE

In the field of software development the theory could be implemented in various aspects. If we choose the reference set I as detail level of software model representation, then 0 could mean a completely abstract level (just an idea), and 1 denotes completely realized software complex. Further, X_i will correspond to informational models of various abstraction levels. For example, X_0 is the original idea, X_1 is a textual representation of the requirements, X_2 is an UML model, …, and at the end of the interval, e.g., X_9 is a completely realized software system. The configurations X_0, X_1, …, X_9 correspond to points $I = \{i_0, i_1, \ldots i_9\}$ of the interval [0, 1], where $i_0 = 0,\ i_9 = 1,\ i_k < i_{k+1},$ for each $k = 0,1,\ldots,8.$

The idea X_0 is explained by means of its terminological basis of formalization and references to the software domain and problem stated. The reference could be an existing ontology or a textual representation of the problem. The dissimilarity ΔX_{01} denotes the additional information about requirements to the software under development. This is a result of the problem and domain decomposition. As X_1 one can understand as IDEF0 model extended with formal or informal specification of its structural elements. The morphism F_{01} is a creative function realized by system engineer under restriction of some technique, e.g., SADT [5]. The dissimilarity ΔX_{12} denotes the result of system designer's activity F_{12} of conversion IDEF0 model with the requirements into set of

UML diagrams. All ΔX_{ij} have their corresponding interpretations.

Theory's axiomatic basis here is realized as follows:

- Axiom 1 in (1) denotes, that any software system can be considered (modeled) at various abstraction levels denoted by I, and the inverse direction means, that for the bundle basis denoted by I a set of models could be devised;
- Axiom 2 means that it is possible to develop software as model transformations and refinements, as well as having developed a sound in some sense software, then it has sound model set representation (formalized or just implied);
- Axiom 3 for each model specialization or transformation a set of methods (techniques, tools) to carry out the development could be found or developed, as well as methods and instrumental software are used to develop software by means transformation of the structures of corresponding models describing the software.

The interpretation of the identity $X \leftrightarrow \Delta X$ means that the process of software development is based on its structure, ΔX results from testing and exploitation, and the software development is an improvement of the set of the models. The complex in this example also form a homologous (homotopic, analog) series, in other words, one can make advantage of the same steps as in an early project using the same set of models X to develop new software.

There are various approaches to automatic transformation of the models in the field of software development, such as IBM Rational Unified Process, Model Driven Architecture (MDA) [2] and formal methods [1]. The approaches are aimed at automation of creative activity of designers and programmers and implemented in instrumental software. The software development tools having a model at input generate a model or source code, which also we consider as a model. Most of the transformations are formal and deductive; the MDA approach requires a Platform Model and a scenario to specify a variant of a transformation.

A translation of the properties of the theory of complexes to the processes of MDA-transformations results in following conclusions:

- In developing software any state of X, including ΔX should be stored for later usage in transformation
- The stored results of the transformations should be analyzed to extract new knowledge about the transformation specific of the current task and also general templates about designing software.
- Complex ΔX is of especial interest and subject of analysis. Namely, as transformation $X_i \to X_j$ corresponds to the dissimilarities $\Delta X_i \to \Delta X_j$, then the instrumental software should correct all the models in X as soon as some ΔX_{ij} has been fixed by a developer.

Thus, it is of purpose to construct instrumental software based on analysis of analogy and propagation of the differences ΔX.

IV. Transformation of the Configurations

Since 2001 OMG exploits Model Driven Architecture (MDA) of software development. MDA [2] is a part of the model considered in the section III. MDA exploits three levels of abstractions to represent software: CIM, PIM and PSM. The Computation Independent Model (CIM) reflects software's external requirements – its interfaces. CIM hides structural elements, and can be used for define specifications and checking requirements.

The software designing technique of MDA is based on multistage transformation of Platform Independent Model (PIM) into a number of Platform Specific Models (PSM). PIM is a model of the software reflecting most of the structural and some semantic aspects of the software, but the model contains no information about implementation of the structures on the target program architecture. UML Class Diagram extended with some tag values and additional stereotypes is an example of PIM [3]. The extension allows one to denote implementation variants and hints for structures. PSM is a model, which can be implemented as source code of the subsystems, e.g., it could be a physical structure of a rational database, which is directly (deductively or by means of code templates) translated into DDL SQL-requests.

The transformation of the PIM into PSMs is carried out under control of a Platform Model (PM) and a transformation scenario. PM contains information and algorithms of PIM's structure analysis and generation of corresponding structures in PSMs. Sometimes PSM is understood as specified variant of PIM. The tag values and stereotypes are used to direct the transformation of a structure into desired frame.

Main advantages of MDA usage in the software development are as follows:

- Design stage independence of the implementation platform; capability to replace the platform without redesigning PIM.
- Formal definition of PM: programmers' knowledge is represented as rules and algorithms.
- Raising the automation level of the life cycle: early stage modifications (design stages) are less expensive to implement in PSMs.

MDA is a great approach and successfully used in development complex software, but it has significant disadvantage, which we are to overcome:

- Using the MDA in simple projects usually extends time of software construction, although obtained formal PIM and PM models when analyzed could be used in other projects;

- Currently MDA is of little use in already constructed and implemented systems and systems based on stored data manipulation, e.g., existing informational systems, as modification of information data model results in database structure modification like adaptation to new data structures;
- Modification of PIM and source code is ignored by the procedures of transformations.

The support of the above mentioned propagation of dissimilarities ΔX_{ij} and modeling whole life cycle's homology should overcome the disadvantages, and it means, in particular, that the instrumentation software should support the transformation in both directions.

At present PMs in most of commercial MDA systems have been implemented on the basis of algorithmic approach. They are not far from CASE systems translating UML diagrams into a source code by various plug-ins. The main idea of MDA is to allow developer to modify PM according his/her preferences and task properties. Our experience shows that usage of present logical languages and PMs based on formalized knowledge [3] allows us to affect the transformation in an efficient way by means of changing a rule set content. Moreover, declarative paradigm of the logical languages naturally forces programmer to create rules processing only small parts of PIM in a multistage fashion with a number of intermediate decisions. This results in dividing the transformation process on stages, where each next stage deals with more concrete structures, which are nearer to PSM. Such approach looks naturally similar to above described application of the theory.

Further extension of the present approach to transformation of the MDA models is a realization of the transformation as propagation of differences ΔX_{ij} between models of various abstraction levels. This allows one, in particular, to deviate from accent on whole software model development and transformation to development of its logically connected subsystem, and track the development of the subsystem in a context of whole software system in some sense more independently. From other hand side the concentration on local neighborhood of a model structure during development is more natural for programmers and designers during implementation.

Let us consider how the difference propagation can be implemented.

A. *Data structures for representing ΔX_{ij} and their transformation rules F_{ij}*

The results of the application of the theory of systems of complexes show as both $X_i \subset X$ and $\Delta X_{ij} \subset X$, then the data structures representing X_i can be used to represent ΔX_{ij}; the same holds for $F_{ij} \subset F$, where F_{ij} can represent mapping for both of the structures $X_i \to X_j$ and $\Delta X_i \to \Delta X_j$. Therefore, the data structures and algorithms, as well as the principles of their construction and implementation, are inherited from known MDA techniques. Consider existing programmers' technologies reflecting the idea.

The first example is `diffutils` package of any Unix distribution. The package allows programmer figuring out the differences between two versions of a source code text file – a patch file – and apply the patch file to the sources. The package contains two main utilities `diff` and `patch`. The first utility compares two ASCII or Unicode texts and produces a new text file with a representation of the difference between input files.

```
--- t1.cpp 2012-02-12 11:50:42.668030039 +0900
+++ t2.cpp 2012-02-12 11:52:44.944957992 +0900
@@ -2,6 +2,7 @@
     char * name;
 };

-class Pupil:Person {
-    Class * cls;
+class Student:Person {
+    char * stud_no;
+    Group * group;
 }
```

This example shows that the difference is expressed with the same ASCII or Unicode characters: the text is shifted by one character left so the first column became control column, where control characters define the elements of ΔX_{ij}. Space character denotes a context of the text part under change. Minus character denotes part that to be removed and plus character denotes the new text composition to be added into the context. As in one patch file the whole project change set can be stored, special format substrings "---" and "+++" are used to denote the particular files, and "@@" is used to denote general relative position of the first line of the context in the files.

The second example of the difference representation principle is XMI standard of UML-model representation [6], which is used for "transmitting metadata differences" to achieve some level of real-time collaboration between developers. XMI is XML-based format and no define difference special tag `<difference xmi:type="…">` is introduced. Consider an example from the standard's specification version 2.4.1.

```
<xmi:XMI xmlns:uml="http://www.omg.org/spec/
    UML/20110701"
    xmlns:xmi="http://www.omg.org/spec/
    UML/20110701">
<difference xmi:type="xmi:Delete">
    <target href="original.xml#ccc"/>
</difference/>
<difference xmi:type="xmi:Add"
    addition="Class_1 Class_2">
    <target href="original.xml#ppp"/>
</difference>
<packagedElement xmi:type="uml:Class"
    xmi:id="Class_1" name="c2">
<packagedElement xmi:type="uml:Class"
    xmi:id="Class_2" name="c3">
<difference xmi:type="xmi:Replace"
    position="0" replacement="c4">
    <target href="original.xml#Class_2"/>
</difference>
<packagedElement xmi:type="uml:Class"
    xmi:id="Class_3" name="c4">
</xmi:XMI>
```

Here, three operations defined on previously existing model file referred to as `original.xml`. The operations defined by attribute `xmi:type` value are

`"xmi:Delete"`, `"xmi:Add"`, `"xmi:Replace"`. In the contexts of the `difference` tag the operands are defined as `href`-references to identifiers of the original model entities and to new elements, which are included in the difference file. The operations are performed on `original.xml` in the order of their appearance in the difference file producing new versions of model.

As we can see the formats of difference representation ΔX_{ij} are structural extensions of the original formats. The main format addition is operations, i.e., morphisms with the special semantics.

In the context of MDA transformation generated source code usually has special additional features.

1. It is not just a flat file, but a partially ordered set of definitions, and when nondeterministic procedures are used the variant of the set representation can alter. So the diffutils format should be modified, and absolute offsets "@@" should be removed or adapted.
2. The transformation procedures can markup the generated source code with high-level semantics of PIM's structures, from which the code was generated. The markup is denoted in comments or by means of "background" code. The markup forms additional context for the difference construction.

Consider transformation UML PIM ΔX_i to source code ΔX_j. The model entities to be replaced are represented either with objects or their identifier references into PIM X_i. The removed objects are transformed by MDA transformation procedures and form source code part to be removed ("-"), new objects are also translated and form new source code parts ("+"). The context is defined by corresponding tag markup of the source codes. Now we need to correct new part of ΔX_j to the changes made in source code by programmer. Here we can use known 3-way merging methods [7]. The result is applied to ΔX_j under construction.

The opposite way – from source code to UML PIM – can be made on the base of source code comparison driven by the tag markup. If we have detail markup, showing identifiers of original structures, then most of trivial changes, like identifier name or type, can be figured out from analysis of PIM. Nontrivial changes are either stored as patches for further 3-way merging, or can be revealed by analysis of comparison of abstract syntax trees of the versions, or programmer is forced to reconstruct the high level model to reflect the source code.

We adapt a logical approach [3] of transformations implementation. The source PIM is represented as XMI-file version 1.2. As it is a variant of XML, its file is parsed by means of `libxml` XML parsers into a tree. The tree encapsulated inside a LogTalk module, which processes queries to PIM structure. Thus, the transformation procedures and PM is represented as set of LogTalk modules connected with messages. Each module contains a knowledge base to recognize an aspect in the PIM and its derivate structures. The results of recognition form new facts about PSM and stored in the module working memory. Thus, the generated PSM is represented as set of facts consisting of the subset describing the original PIM and the subset describing the implementation aspects of the software under development.

The transformation scenario is a set (sequence) of the leave modules, which generate source code and other data structures. The resulting source code is generated by means of templates, i.e., the templates play the similar role as CSS in web; it represents PSM as texts of source codes.

V. Another Example of Difference Propagation Based Software

To investigate other possibilities of the software development approach based on difference propagation we started another pilot project of notarial office automation. The development of the notarial software is deeply depended on users' desire to change, namely, creating instances of documents, correcting errors, forming new document classes, composing new document workflows, as well as refinement of user interface aimed at raising the office productivity.

From the functional point of view the notarial office is primarily an organization for document preparation, storage, and retrieval; tracking of the individual's data is the secondary aim that allows producing the document more agile. There exist four user roles in the office; they are "secretary", who fills in the templates, "template modifier", who is an experienced user allowed to construct forms and describe new regular structures found in documents, "programmer", who understands information modeling and implements the routine tasks as program modules, and "notary", who validates and signs the documents. As usual the roles define the set of activities and responsibilities for corresponding users. During the exploitation of the information system secretaries gain experience and can evolve in template modifiers. Shifting a user from first role to another can be done as a result of his/her qualification assessment. The assessment can be performed by notary and programmer or by means of testing, for example, answering a set of tests and/or doing test exercises.

Each instantiation of a template can be considered as a copying a document in the storage and its refill with new data or even just an edition of the copy. Modification of the second kind can be interpreted in several ways. Firstly, as mentioned before, it is just refill of the template. Secondly, it is a template body text error correction or a further improvement of the document. Thirdly, the modification could touch the form structure giving rise a new template of existing kind (class) or form even a new class of templates, e.g., fixing some parameter or substructure.

The difference propagation process is based on a number of document models. Secretaries will fill in documents as HTML forms and edit the generated instances in a WYSIWIG HTML editor. HTML supports a necessary level of the notarial document representation. There are many useful methods of HTML generation and modifications. The difference between documents of

various versions is to be propagated to other models. Such models represent the document layout and presentation (CSS), structure of the document class (what parts should be presented in the document and in which order), structure of the form of the template, fixed data structures stored in a rational database, and so on. The structural models are based on corresponding ontologies, e.g., ontology of structure elements of a document, ontology for expression individual's data, etc.

The system should control the process of the document designing in a dialog with user, acquiring the additional information on user's intention and acting in concordance. Complex problems are described by users as texts for programmers, who implements new features of the software after confirmation of the requirements.

VI. CONCLUSION

Software development life cycle has been considered as subject of the theory of complex systems and complexes [4] implying that the software development is a natural process. The life cycle is represented as system of models and morphisms between them. Analysis of the theory's properties realization in the model shown, that the present instrumental software productivity could be extended by means of developing techniques for analysis of the passed life cycle stages, analysis and difference propagation of the models.

To support the propagation of the differences existing examples of the present source code development technologies should be adapted. Namely, known patchfile format is considered and some its modification is suggested to account properties of generated source code. An approach to realization of the difference propagation is also briefly considered. It is shown, that the transformation technique and file formats are closed with respect to original formats of the software models representation.

One of the aims of the research is to construct a software development tools based on analogy. For example, having stores in a revision control systems all the states, models and stages of MDA software development as the differences, it probably be possible to construct new sequence of differences for new original model.

To gain some new experience about the topic a pilot project started to automate document preparation in a notarial office, where users have a dominant role in developing the software function set.

Abstract – The paper deals with the problem of automatic extraction of a software project structure and its ontology from revision control system network of the project source code. The aim of the investigation is to determine the correlation between the project structure and ontology terms of the project domain, i.e., to answer the question about possibility to describe the structure of the project with terms of the ontology. If it will be true then a modification of the ontology can be interpreted as modification of the project structure.

I. INTRODUCTION

The evolution of instrumental software development technologies is aimed at shifting the programmer's creative activity to the higher level of abstraction, raising the productivity. The programming technologies like UML, CASE, MDA (Model Driven Architecture) [1] allow programmer to consider (to model) the software systems under development on the higher level of abstraction as compared to the source code of subsystems; all of them usually generate parts of the source code from their abstract models. Ontological models are abstract models which usually denote only the terminological basis of the developed software. The ontological models reflect a set of terms used by programmers to describe software artifacts, various technical documentation and other texts related to the software. We consider a problem of ontology models construction and use them in the development automation within the software life cycle.

The ontology model (hereafter "ontology") can be extracted from the texts as thesaurus [2] and be further developed in the life cycle of the software. From other hand side the ontology modification implies also the texts and the software modifications, thus, the ontology controls in some degree the software development process. To support the statement above we try to construct a thesaurus used in the Linux kernel project, and investigate the correlation between the thesaurus terms structure used by programmers in their commit messages and the branching structure of the project.

In order to compare the thesaurus and the project structure a tree of project structure is extracted from GIT-tree of Linux kernel source code. The project structure tree reflects the division of the project to inferior subprojects and kernel to its subsystems. To represent the tree a theory of system of complexes (configurations) is used [3]. The theory allows us to represent the tree in a number of dimensions to take advantage of additional information of the source code tree, such as timelines, branching and merging structure.

The source information for the investigation is the network graph structure representing all development, branching, and merging modes of the Linux kernel sources. Each new branching node can be interpreted as starting or continuation point of a subproject generally and particularly, but many of the branches are devoted to fixing errors. Merge points can be interpreted as finishing or committing points of a subproject. So the analysis of the Linux sources tree structure is in general is a pattern recognition problem.

To describe the project structure we use the theory of complex systems and complexes, it represents compound (complex) objects as compositions of other objects and morphisms (mapping) between objects.

II. THE THEORY OF COMPLEX SYSTEMS AND COMPLEXES [3]

Complexes (compositions) and systems of compositions (configurations) X_i are formed from combinations of various elements, components, systems, complexes, systems-complexes. Configurations X_i are different kinds of complex system's polymorphism. The universal structure X contains all X_i, and in this case it is analogous to notion of set of all subsets or category of all the subcategories. The connections between compositions are represented by means of mapping (morphism) $F_{ij} : X_i \to X_j$. The composition connected with morphisms (represented a category in the mathematical sense) form a complex. The comparison of the two compositions X_i and X_j, namely $\Delta X_{ij} = X_j \setminus X_i$, shows the dissimilarity between j-th composition and i-th one. For example, let X_i and X_j be different UML models of software before and after adding a new structure, so ΔX_{ij} reflects a complex of the current development step. If X_i and X_j are two UML models of different software systems, then ΔX_{ij} fixes, in particular, their structural dissimilarity, and F_{ij} is a comparison relation. The structure ΔX_{ij} is also a composition and

belongs to the set of all the comparisons ΔX. The set F is a set of all possible mappings F_{ij}.

There are also a reference set of comparison I; it is the interval [0, 1], which is a metric linearly ordered inductive continuous bounded above and below set of points. The one-to-one correspondence of compositions and reference set points is denoted by relation ($\leftrightarrow$), for example, $I \leftrightarrow I$ means that each point I turns into itself; $X \leftrightarrow I$ means that any composition from set X is one-to-one corresponded to a definite point of the interval [0, 1]. In the latter case I is a bundle (fibration) basis of X, in other words the differentiation X into compositions is conducted by means of comparing them with points (numbers) from the interval [0, 1].

The axioms of complex systems' theory are to compare compositions and their connection functions with an identification index of an order and together.

$$1)\ X \leftrightarrow I;\ 2)\ F \leftrightarrow I;\ 3)\ \Delta X_{ij} \leftrightarrow F_{ij}. \qquad (1)$$

The axioms 1 and 2 transfer all the order properties of the set I to the sets of all compositions $X_i \subset X$, their comparisons $\Delta X_i \subset X$, and mappings $F_{ij} \subset F$. This also implies that all the combinations are toposes, i.e. they are linearly ordered structures with the individual measure from I. By means of I the structures, their comparisons and mappings are one-to-one connected to each other.

$$X \leftrightarrow F \leftrightarrow \Delta X \leftrightarrow I.$$

This emphasize a necessary moment of complexing, the complexes, their comparisons and mappings are equivalent (identical in the sense of dialectical logics), and have the single identification index in I. The complexes are self developing systems, where each alteration is based on its structure $\Delta X \leftrightarrow X$. Complexes are static formations, the transitional states with partially formed connections cannot be related to them.

Complexes are linear sequences of morphisms (categories)

$$\cdots \rightarrow X_i \rightarrow X_j \rightarrow X_k \rightarrow \cdots;$$

the contained compositions form homologous series of comparison, as each composition has a measure from I, this series is also homotopic. Homologo- homotopic series form comparisons and mappings. All the elements of the series are functionally similar, that's why they can be considered as series of analogs.

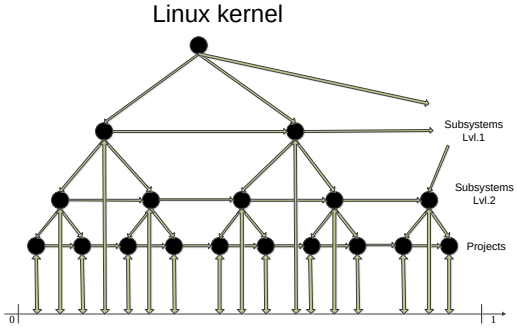

Figure 1. The project division tree as a composition

Any fragment of a homological series $X_i \rightarrow X_j$ is a complex, which corresponds to a complex of comparison of the dissimilarities $\Delta X_i \rightarrow \Delta X_j$. Consequently, a similarity of the structure implies similarity of modifications and vice-versa. Therefore, observed similarity in the structure must be caused by similarities of the processes and their models. The search of structural and dynamical similarity is the main subject of the theory of complexes.

III. A 2-D Representation of the Source Code Development Network

Most of present distributed revision control systems represent the source development process as a network graph, where each node is a version of the source code. The network reflects a time line of the project development process with various branching and merging nodes. This network can be represented as 2-D structure, and the structure being projected on an axis will reflect the desired project structure. Let us consider how to define two axes bundle basis for the object under investigation.

The topic we are interesting in is the project structure, namely, most of the present complex software systems are subdivided on subprojects so that individual groups of programmers can develop the subsystems in some degree of independence. The project division is represented naturally as a tree (Fig. 1).

The tree representation is a variant of application of the described above Theory of complex systems and complexes, where each complex is combinations of subsystems of one level. The horizontal morphisms map the elements between subprojects: system objects have their representations in subsystems. Vertical mappings reflect each subproject to a positional index in I. The similar index is used in [3] for description of the geographical formations such as landscapes. Other morphisms describe connections in projects-subprojects and system-subsystem relationships.

The second axe of the network graph is timeline of development. In this case I denotes time moments, where commits were made. For each complex a sequence of commits is associated. Moreover, this axis also reflects versioning of the software. Namely, tag values usually used to mark a special commits, which correspond, e.g., a stable version of the project. Examples of the marks are as follows: "v2.6.14", "v3.0.6-rc1". The version tags have linear order.

Now we can describe the commit network in the defined 2-D space.

IV. The Project Structure Analysis

In order to compare the thesaurus and the project structure, a tree of project structure should be extracted from GIT-network of Linux kernel source code. GIT is a distributed version control system developed by Linus Torvalds – who is the main developer of Linux kernel –

especially to manage the development of the kernel [4]. GIT supports rapid split and merge versions of the source code, includes tools for visualization and navigation, and GIT also gives each developer a local copy of the entire history of the development. The changes made locally can be propagated from one repository to another. In addition, this system allows representing the history of the changes (the network) graphically.

Nodes of GIT-network – versions of the source codes – are the SHA1-hashed commits. Every commit is a fixation of changes made in a working copy of the main repository of the project, as well as a description of the changes made. In the GIT representation the nodes are connected to each other, each combination of the connections form linear intervals of the development, splitting (branching) subprojects, merging of the subprojects and their results in a superior subproject. Linear intervals reflect a logical sequence of the project development events related to the same subproject. The same is true for a merging sequence of the results from an auxiliary branch to a subproject branch. But most necessary, branching and merging combinations denote subprojects.

The branching and merging in GIT can mean two different kind of programmer activity. The first activity is cloning a repository, e.g., creating local copy of the main project repository, and incorporating the changes made in the main repository. The second case, which is of our interest, is the project development itself. In this case according to developer recommendation of GIT programmer should create a lightweight branch of the local repository, develop of the feature or correct an error, and then merge the results to a superior branch of development, in particular in the main branch. The simplified graphical representation of the software development served by GIT is given in Fig. 2. Results of development in cloned repository when pushed on the server will create corresponding branches in the main project.

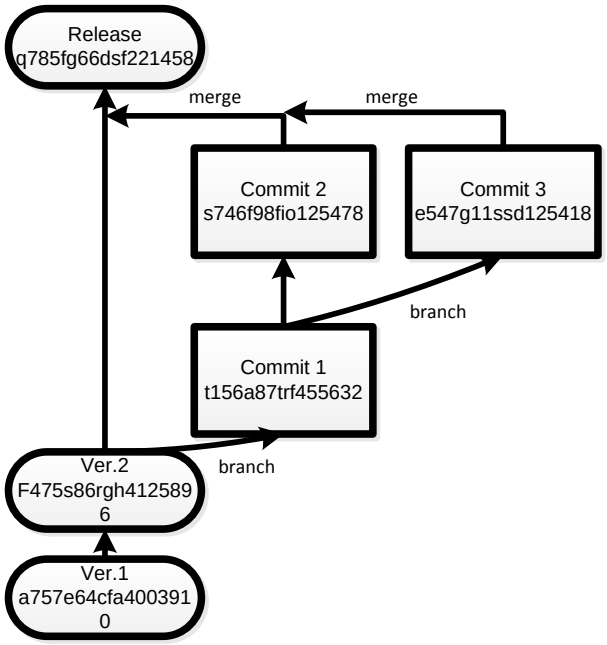

Figure 2. An exmple diagram of a GIT -network

To recognize the 2-D coordinate of each commit of GIT-network an analytical program is being developed in the programming environment GnuProlog. The idea is to develop a set of the Prolog rules which will recognize template subgraphs in the main GIT-network and construct markup structure denoting for each node its coordinate and role. The source data for the analysis is a set of facts about GIT-network obtained by translation of the network structure.

The translation subsystem is developed using the programming language Python, as well as its libraries GitPython. GitPython is a Python library used to interact with GIT repositories at various levels of abstraction. GitPython provides object model access to a GIT repository. It allows traverse the repository to find parent commits, trees, source code objects, binary blobs, etc. It provides abstractions of GIT objects for easy access of repository data, and additionally allows one to access the GIT repository more directly using either a pure python implementation, or the faster, but more resource intensive GIT command implementation. The object database implementation is optimized for handling large quantities of objects and large datasets, which is achieved by using low-level structures and data streaming.

The translation subsystem transforms the structure of the project represented in a GIT repository into a text format, which can be loaded by GnuProlog, i.e., into a collection of facts (Fig. 3). The facts establish parent-child relationship between nodes. Furthermore, this structure reflects the order versions of the project source code. The versions in a GIT repository can be represented with tags, which are labels assigned to a specific commit of the source code. The tag label as a compound string value can express a symbolic name for a group of committed files, and a common version of each file in the group in some general versioning principle. This property of tags gives us a possibility to consider the inheritance of the individual parts of the project, and different versions of the project as well.

The following prolog phrases are examples of a GIT-network translation:

```
node('df145gt6984tgh1254fr').
node('4684dsf457fesae4452').
node('qw78er96ty54ui12opo').
node('as558df74g110hyu058').

parent('df145gt6984tgh1254fr',
    '4684dsf457fesae4452').
parent('df145gt6984tgh1254fr',
    'qw78er96ty54ui12opo').
parent('4684dsf457fesae4452',
    'as558df74g110hyu058').
parent('qw78er96ty54ui12opo',
    'as558df74g110hyu058').

branch(Z,X,Y):-
   parent(Z, X), parent(Z, Y).

merge(X,Y,Z):-
   parent(X, Z), parent(Y, Z).

tag('v3.3-rc2', '4564dfgert84tgdre4gs').

recent('v3.3-rc2', 'v3.3-rc1').
```

```
tagged(T,R):-tag(T,R),!.
tagged(T,R):-parent(P,R), tagged(T,P).
```

Here, the facts of the structure `node/1` denote existence of the nodes in the GIT network. Facts `parent/2` denote inheritance relation between existing nodes. Facts `tag/2` associates a tag value with a node, and `recent/2` defines a versioning order between tags. Rules `branch/3` and `merge/3` are base rules for recognition of branching and merging; rule `tagged/2` reveals the linear intervals belonging to a tagged set of commits.

Project structure recognition rules differentiate branches, which are error corrections and feature implementation. The first part of the rules figure out the main trunk of the development: it is marked by version tagging and specific name of the pointing branch name "master". Then for all the branch names first branching node is detected. These will be main subprojects. Then for all the subprojects long lasting branches are recognized: the longer a branch is, the more probably it corresponds to a subproject and the more general subproject it is. The subprojects, whose length is less than a predefined length are considered inessential, which are supposed to be the error correction or a small feature developing branch.

Linear intervals also can be constructed as a sequence of subprojects. The subprojects can be recognized by analyzing the programmer's activity pattern in time. A project task is given for a programmer or a group of programmers, they develop the task solution, and at the merge point coordinator of the superior project merges their results. The recognition is based on analysis of time intervals and programmer's roles. A programmer who mostly (according to statistics) does the merge is supposed to belong to the superior project, and intervals between the merging points are supposed to be subprojects.

In order to extract the project structure it is necessary to run all recognition rules and write down all combinations of variable values obtained as a result of Prolog's logical inference.

V. THESAURUS EXTRACTION SOFTWARE

As the project structure is deduced from the GIT-network of Linux kernel source repository the nodes of the structure should be labeled by a terms, the labeling will denote the semantic information for the project structure tree nodes. The labeling terms can be obtained from texts associated with the commit nodes – commit messages. In the same time parent-child relationship between project

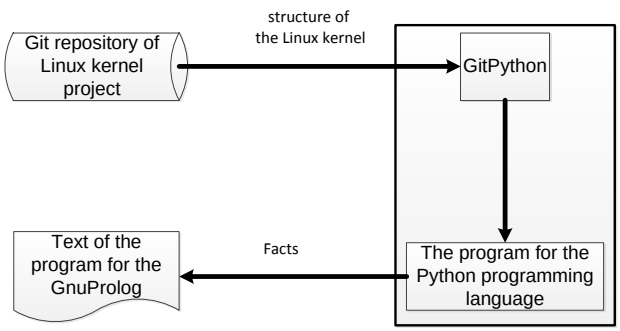

Figure 3. An exmple diagram of a GIT -network

structure nodes can reflect a thesaurus of the project domain. In this section we consider how this thesaurus and the labeling can be deduced from the commit messages. The thesaurus extraction subsystem is based on technique described in [2].

Thesaurus is a way of formalizing object domains of software under development, it is kind of ontology [5]. Ontology is a object domain model consisting of a set of concepts and a set of assertions about these concepts, based on which one can describe classes, relations, functions and individuals, but usually it denote only the terminological basis of the developed software. Ontologies are intuitively used by programmers when they name objects and describe relationships to be implemented. Hypothetically, using of ontologies allows one automating the development some parts of the source code, reducing the cost of software development and also managing the development process.

Let us briefly consider a general scheme of the thesaurus deduction technique.

At the first stage a set of independent texts are constructed, e.g., the elements of the set can be a books in a public library or articles of a journal issue(s). The texts are stored in fast access database. At the second step a full text index of the stemmed words of the texts is produced. The index should contain positions of the stemmed worlds in the texts. At the next step a terminological basis is constructed.

The terminological basis construction algorithm looks through the texts and tries to join adjacent words in a compound term. The full text index frequency for the compound term is figured out. The join succeeds if the frequency of the term decreases not more than in 0.7 times (the coefficient is arbitrary). If an original stemmed word is used at lest once as first word of a compound term, then it is removed from the terminological basis.

At the fourth step the full text index is transformed into terminological index, where the terms are mapped into their frequencies of appearances in the texts. Now the texts are represented as points in property space, where each of the property is a term of the terminological basis. If term appearances probabilities are similar for two texts then the texts are similar and located near to each other in the property space. The set of texts are processed by some hierarchical clustering algorithm, which induced the hierarchy of classes of semantically similar texts. For big amounts of texts it is of purpose to use divisive clustering as it allows one to restrict the depth of the hierarchy.

On this fourth step on the each step of clustering the terminological index is recalculated for the texts for the cluster each node. The most frequent term is selected among the terms used in the node's texts. This term denotes the semantic of the node's text content. Also among most frequent terms a set can be chosen, the set will also describe the semantic of the texts subset.

The resulting hierarchy clustering also denotes class-subclass (term-subterm) relationship between terms, which can be thought as thesaurus, a kind of ontology of the domain presented by the original texts. Now consider our Linux kernel development domain.

At the first glance each commit message can be considered to be an independent text characterizing a corresponding stated or solved task. But as we interesting in description of programmers' activity in developing a software project and, at this stage of investigation, in description of Linux project structure, it will be of purpose to merge all commit messages at least in all linear intervals of the each branch of the project. Developing this idea further we can project the commit messages on the structural axe of GIT-network representation.

The merged commits stored in a fast indexed accessed warehouse constructed with a MySQL database engine. The stemmed word index is generated by means of slightly modified Sphinx search server engine (http://www.sphinxsearch.com). Sphinx is an open source full text search server, designed from the ground up with performance, relevance (i.e., search quality), and integration simplicity in mind. It lets programmer either batch index and search data stored in an SQL database, NoSQL storage, or just files or index and search data on the fly, working with Sphinx pretty much as with a database server. The engine closely bound to the MySQL API and protocols. The modification allows relating the engines' CRC32 coding of the stemmed words with the original worlds. Also some API modifications made to unload the index in a Python language dictionary-like structure.

A terminological basis is induced by a Python program according to the above described scheme using a library for the hierarchical cluster construction. The main role of the Python program is to calculate indexes for the subsets and convert data structures before and after processing with the external and library modules.

A. Project tree labelling

Similar to above mentioned technique an approach can be used to deduce semantic information about project tree nodes from the commit messages. The first steps including the terminological basis construction are the same. After that we will not construct the hierarchy clustering, as we have already constructed the project structure tree. For each node set of commit messages is analyzed on the base of the terminological basis and by analogy of the step four; the most frequent term is chosen to denote the semantic of the node.

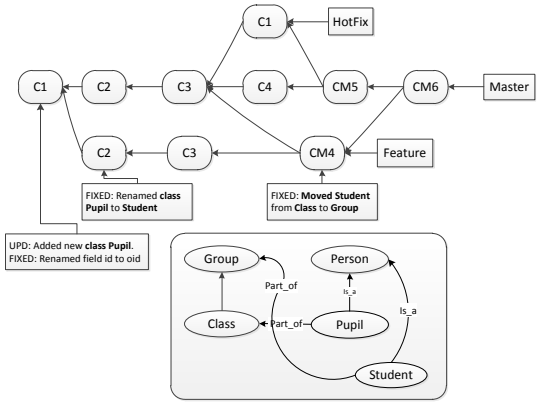

Figure 4. Ontology extraction from commit messages

VI. CONCLUSION

In this paper we considered a theory and software for a project structure extraction on the base of analysis of project revision control system commit network. Linux kernel project and its GIT-network are used as testing ground and objects under investigation. The GIT-network is represented as 2-D structure, where the first dimension is a structural index of a subproject, the second dimension is a time moments of the commits of each of subproject. Logic recognition procedures have been developed and implemented as Prolog program to recognize the space coordinate of each commit. In the same time procedures for ontology extraction and labeling the project tree from the commit messages has been implemented. The ontology and the labeling will carry semantic information for each of the project tree nodes.

In the essence we are interested in investigation of the possibility to describe the software development process in terms of a higher order model, which is in between the ontological model and source code representation, i.e., some kind of functional relations between structures. From other hand side the source code modification commit messages describe the ontology change (Fig. 4). More over, some messages can be interpreted in a constructive fashion by means of description the source code changes.

At present state of the investigation we developed the recognition software, labeling subsystem and thesaurus extraction modules. Now we need to develop a technique for project structure and thesaurus trees comparison. If a correlation between the thesaurus and Linux kernel project structure will be found then it will be possible to predict the set of programming artifacts to be modified in case of the thesaurus modification.

The results of the investigations supposed to be used as an advisory or a project planning subsystem in a new generation of MDA-based instrumental software. For example, having modified a formalized ontology, the instrumental software can suggest a modification of an UML Class Diagram or advice designers to implement new software function on the base of the new feature textual description analysis.

***Abstract*—The iterated prisoner's dilemma game is a widely used tool for modelling and formalization of complex interactions within groups. Every player tries to find the best strategy which would maximize long-term payoffs. Tournaments were organized to determine whether there is a single best stable strategy.**

This paper presents a summary of tournaments held in 1980, 2004 and 2005, reviews strategies which were presented during the last 30 years, both in tournaments and in scientific literature and outlines current issues and trends.

I. Introduction

Game theory and more specifically prisoner's dilemma allow the formalization of the interaction within the group. The prisoner's dilemma is an elegant way of modelling the problem of cooperation between participants who have opposing interests. Modelling the interaction with the prisoners dilemma is applied to many fields, in politics [1], biology [2], economy [3] etc. There are applications in computer systems in determining the best route for packets that traverse the network [4], or better allocation of network resources with BitTorrent protocol [5].

The basic form of the game takes place in Chicago, where the district attorney knows that the two gangsters are guilty of some major crime, but he can not convict anybody without a confession. Both individuals are arrested and brought to interrogation separately and offered the following deal: each has a possibility to confess the crime to obtain a minor sentence, or accuse the other gangster to get away without a sentence [6]:

> If the first suspect accuses the other prisoner and the other suspect confesses his guilt, the first suspect is free (his reward is usually denoted by T - the temptation) and the other suspect gets the maximum sentence (marked with S - suckers payoff). In case that both suspects confess their guilt, they both get minor prison sentence (marked with R - reward for cooperation). If both suspects accuse each other, then both receive a major prison sentence (marked with P - punishment - the punishment for mutual defection).

The game is defined by $T > R > P > S$ and $R < (S + T)/2$ so that the continuous cooperation is better than the alternating cooperation and defection [7].

In a single prisoner's dilemma game, the dominant strategy is defection (accusing the other) because it carries the highest reward regardless of the opponent's strategy [6]. In games that have multiple iterations and where is a high probability that opponents will meet again, cooperative strategies achieve better results, as proved through competitions that were organized by Axelrod (1979) based on strategies of experts in game theory from the field of economics, sociology, political science and mathematics [7]. Similar results were gathered on competitions that were held in years 2004 and 2005.

This paper analyses the strategies that have emerged in competitions. Chapter 2 gives a brief overview of the first competition and chapter 3 summarizes the results of the first competition. Chapter 4 outlines the important strategies that appeared in between the competitions (1979-2004). Chapter 5 summarizes the results of the competitions in years 2004 and 2005. Chapter 6 analyses the open questions on the subject and chapter 7 concludes the paper.

II. First competition

The first competition was organized by Axelrod in the year 1979. It was based on the strategies by experts in game theory from the field of economics, sociology, political science and mathematics. It was a contest of mean 200 rounds with the following values: $S = 0, P = 1, R = 3, T = 5$, as shown in Table 1.

TABLE I Result matrix

Player A \ Player B	Cooperation	Defection
Cooperation	$R = 3$ Reward for mutual cooperation	$S = 0$ Suckers payoff
Defection	$T = 5$ Temptation for defection	$P = 1$ Punishment for mutual defection

The surprising result was that the simplest strategy won the competition. It was sent by professor Anatol Rappoport, called Tit for Tat (TFT) which is based on attempt of cooperation and later on reciprocity - copying the opponent's last move. In the second round of the first competition conducted after the announcement of the results of the first round, the same strategy won again between 63 other strategies including random strategy. The third round was simulating the evolution in a way that successful strategies passed descendants to the next generation based on their success in the previous generation. The same strategy won again.

The main characteristic of strategies that have achieved good results is the tendency to cooperate - nice strategies are the ones that never defect first, or at least not until the last few rounds. The results of the first competition showed that the first 8 strategies were nice strategies and none of the others were nice and there was even a gap in the score between nice strategies and the others [8].

Axelrod [8] analyses the strategies and recognizes the importance of "kingmaker" strategies, which did not have good results themselves but because of them nice strategies had better results and other strategies were punished for defecting (this will be especially important in later competitions with possibility of sending multiple strategies). Two such strategies are DOWNING and GRAASKAMP (in the original paper all strategies except TFT are called by the authors).

DOWNING begins with two defections and later at every step computes the probability of opponent's cooperation after its cooperation and also the probability of opponent's cooperation after its defection. After each move those estimates are updated and strategy chooses the choice that will bring the best long term payoff. If the probability of cooperation and defection is close enough, the strategy concludes that the opponent does not respond and the strategy defects afterwards. The downside is that the first two moves are defections so it automatically loses the possibility of further cooperation with some strategies that severely retaliate on any defection.

Another similar strategy is GRAASKAMP which plays TFT the first 50 moves and then it defects once. The following 5 moves it continues with the TFT, and then it analyses the current development of the game. Defection at 51st round serves to identify whether the strategy is playing against its own twin, TFT or any other known strategy and then it adjusts its moves depending on the opponent. The problem with this strategy is that when it meets an unknown strategy, it assumes that this is a RANDOM strategy and it defects for the rest of the game. This strategy was not nice itself, it did not have good results but it was lowering the results of other strategies that were not nice and TFT had very good results with this strategy.

RANDOM strategy that randomly selects an action had even better results than nice strategies in the individual games, but in the end, nice strategies prevailed. If some strategy wants to get good results against RANDOM, it needs to start with complete defection early on, but the question is whether it really is a RANDOM strategy or is it some unknown strategy that it can not recognize. Complete defection in the beginning of the game may prevent establishment of cooperation later on.

An extreme example of this strategy is the strategy called FRIEDMAN (also known as the GRIM [6], grudger [2], spite [9], spiteful[10]) that cooperates until the first defection and after that it defects until the end of the game. This strategy is very good against RANDOM strategy and against all nice strategies but it had bad results against strategies that defected, especially early on, because there is no way to re-establish cooperation after a defection.

III. Conclusions of the first competition

The first competitions brought a few surprises [8]:

1) Tit for Tat as the simplest rule won the competition
2) Most strategies that tried to improve on TFT had worse results because they attempted to slip occasional unexpected defections which then resulted in chains of mutual defections: "they were too clever"
3) The clearest success factor was a "niceness" - the first 8 strategies were nice which means that they were never the first to defect.
4) It pays to forgive: a strategies that had some mechanism of forgiving defection and restoration of cooperation had better results. Those that forgave earlier and tried to cooperate had better results.
5) Existence of "kingmaker" strategies - the ultimate success of the best strategies is the result of their cooperation with "kingmaker" strategies.
6) Despite that the complicated strategies did not have better results than TFT, it is easy to find a better strategies, for example TFTT - retaliate after two defections or the use of artificial intelligence methods.

Axelrod gives a detailed analysis of the strategies and sets out basic rules for successful strategies [11]:

1) The strategy should not be jealous, it must not attempt to gain more points than the opponent by defection
2) The strategy should not be the first to defect.
3) The strategy must clearly and *quickly* respond on cooperation or defection in a way that consequences are clear and that opponent strategy can adapt
4) The strategy must be simple and clear - it should not be too smart and make assumptions too soon about its opponent. If the strategy is "too smart" it can prematurely declare that the opponent is a

RANDOM strategy and move on with defections that lower the scores of both strategies.

Competitions have given new perspectives on the social and biological developments, especially the results that are related to the evolutionary experiments which showed that cooperation is the only stable option (interpretation of the relationship between figs and wasps or between hydras and algae [7], or the interpretation of sudden and spontaneous truces during the World War I [2]). One of the conclusions is that there is no single evolutionary stable strategy which is proven in [12], stated in [9] - nice strategies always cooperate with each other so that for instance, strategy that only cooperates (ALLC) can penetrate into population that is consisted only of TFT and then become easy prey for any defecting strategy.

Some of the strategies that have emerged in the early competitions were taken as standard and they continue to appear in the literature as a measure of the success of new strategies and those new strategies are often based on existing ones, especially TFT, with modifications to facilitate the establishment of cooperation or exploitation of RANDOM or ALLC opponents.

IV. Strategies that have emerged in between competitions

One of the most famous and later most upgraded strategies that had better results than the TFT is Pavlov [13] or win-stay, lose-shift strategy. Strategy cooperates if and only if both strategies in the previous round had the same action. The name comes from the fact that the strategy exhibits almost a reflex-like adjustment to the result of previous round - repeat previous move if it was rewarded with R or T points and change behaviour if the result was just P or S points. Deficiency of strategy is that is has bad results with the strategies that constantly do defections because every second move tries to cooperate but it has much better results with the strategies that do only cooperation. There is no problem with constant defection if it turns out that the opponent does not reciprocate.

Beaufils and some other researchers reject the last conclusion that Axelrod gave in the book - simplicity. They provide a view where complexity plays a major role [9]. They bring strategy *gradual* which at first behaves like TFT but after each defection reciprocates with another defection: after the first defection it will respond with one defection, after the second defection it will respond with two defections etc. By using genetic algorithms they reached even better strategy that has even better results against predetermined strategies and strategies from the first competition but in the subsequent competitions they didn not show such good results as in their own laboratory [14].

Other strategies are mostly based on aforementioned approaches - the base is always TFT or Pavlov. Examples are adaptable strategy [15], forgiving strategy [10] and winning strategies in subsequent competitions.

There is also interesting research of teams of strategies that collude to increase one member's score. One strategy is set as master and others as slaves, who then work towards the unconditional cooperation with master strategy and unconditional defection towards other strategies so they lower results of other strategies and in that way help their master [16], [17], cited in [18].

Some authors see the simplicity of the original prisoner's dilemma as a limitation and extend the payoff matrix with additional fields [19]. There is also the concept of noise in the communication channel which means that the opponent's response can only be interpreted with certain probability, altering the experiment results and expected behaviour of strategies [20]. In order to take into account these ideas, competitions were repeated in 2004 and 2005. Those competitions included several variants of competition. In the literature, the prisoner's dilemma that was studied by Axelrod in called classical iterated prisoner's dilemma [9] or traditional iterated prisoner's dilemma [21], [22], [23].

V. 2004 and 2005 competitions

Competitions had four variants [24]:

1) Repetition of original Axelrod experiment, to determine whether the TFT is still dominating strategy or there has been found a new better strategy during the period of 25 years in between the competitions.
2) The competition is identical to the previous except the addition of the noise - there is a small probability that the cooperation or defection might be misinterpreted.
3) The competition that allows sending strategies with more players and more choices.
4) The competition that copies the original Axelrod experiment but has the following additional rules:
   - Only one strategy is permitted per competitor, collaboration is prohibited
   - Organizers of the competition will add only a RANDOM strategy as a default strategy
   - Each strategy also competes against its own copy
   - Each competition consists of the same number of moves that is unknown to the authors of the strategies - every event is performed five times using different number of moves
   - Payoff matrix is the same as in the original events (shown in Table 1)
   - Each strategy has to play a move in less than two seconds (the difference from the original competition, added to avoid infinite loops)
   - Each strategy must be accompanied by a description and source code in order to reduce the possibility of collusion

In these competitions, strategies were received via e-mail. It was possible to send a strategy written in the Java programming language using provided ipdlx package, or one could determine the behaviour of the strategy through the web interface. Strategies could use external resources over the internet but they had a time limit to give response which disabled some more complicated approaches such as using genetic algorithms.

The competition in year 2004 consisted of 223 strategies, including 9 default strategies shown in Table 2 (RAND - a random selection, NEG - denies the last action of the opponent, ALLC - always cooperate, ALLD - always defect, TFT, STFT - TFT beginning with defection, TFTT - retaliates only after two defections, GRIM and Pavlov). In the end the winners were the strategies submitted by the University of Southampton who worked in teams. One strategy was team leader and the rest were members of the team. All members cooperated with their leader and they constantly defected to all strategies outside of their team. Strategies that were team leaders had 13% more points than the others, they also won in the competition with the noise because they implemented a way to resolve mistakes [18].

Slany and Kienreich disputed the results of the first competition since from 223 strategies, 112 were sent by the winner and they were not allowed to send as many strategies as they wanted which would make them the winners [25]. The basic approach they had was the same as the winning strategies - team strategies, but the team leader from University of Southampton played defection towards team members and towards others it played standard TFT. Slany and Kienreich modified TFT to deal with the chains of mutual defections which is the main problem of TFT, especially in cases where the noise simulation was added. They also added the ability to recognize and exploit the RANDOM strategy in a way that after an opponent strategy crosses a certain randomness threshold they conclude that the opponent is a RANDOM strategy and change the behavour to act as ALLD. They called their strategy OmegaTFT [25].

TABLE II DEFAULT TYPES OF STRATEGIES

Designation	Description
ALLC	Strategy always plays cooperation
ALLD	Strategy always plays defection
RAND	Strategy has a 50% probability to play cooperation or defection
GRIM	It starts with cooperation, but after the first defection of its opponent continues with defection
TFT	It starts with cooperation and then it copies the moves of the opponent
TFTT	As TFT but defects after two consecutive defections
STFT	As TFT but starts with defection
TTFT	As TFT but for each defection retaliates with two defections
Pavlov	Action results are divided into 2 groups, positive actions are T and R and negative actions are P and S - if the result of previous action belonged to the first group, action is repeated and if the result was in the second group, then the action was changed, it is also called win-stay, lose shift

Competition held in 2005 took into account the results and criticisms and introduced additional restrictions so that each institution could send only one team of 20 strategies in the first two contests. This time there were many more teams and first four places came from different institutions. The winners of the first competition were Slany and Kienreich with their Cosa Nostra Godfather / hitman strategy. In the second competition, which included noise in the data transfer, the winner was again team from University of Southampton with their team of Greek gods [26].

The rules of fourth competition allowed only one strategy per participant and the winning strategy was Adaptive Pavlov (APavlov) that was sent by Jiawei Li. It is based on Pavlov strategy with addition of recognition of the opponent and its classification into one of the default strategy types. Then, the strategy responds to each opponent in an optimal way. If a strategy is unknown to APavlov, it is classified as a RANDOM strategy and it behaves accordingly - it responds with constant defection [27].

VI. CONCLUSIONS OF 2004. AND 2005. COMPETITIONS

Since it has been shown that the collaboration of strategies that work as a team has a key role in the success of individual strategies, one of the major new issues is how to detect and prevent collusion of strategies. Slany and Kienreich showed that it is possible to deceive the organizers. They invented a person, wrote a mail with broken English and submitted strategies that were matched with their main strategies. The results showed that some other completely unrelated strategies accidentally met the conditions so that their main strategy recognized them as their own team member strategies and began to exploit them with unconditional defections [25].

Team from the University of Southampton had focused on communication and coordination between agents in the environment with noise. They implemented their strategies by using Hamming codes that are usually used in information theory in order to eliminate errors, for example, to send teletext via analogue signal [28]. Their strategies have been very successful in competition with noise, while their good result in year 2004 was probably based on great number of strategies that they had sent to work in their favour.

APavlov heuristic strategy that won the 2005 competition, presented by Li in his paper, also had some advantages and disadvantages. It is always a problem if some strategy is too early classified as RANDOM strategy, because there is no way of establishing cooperation later on. It is necessary to constantly develop new rules for new strategies that will appear. The crucial problem is to balance between the need to recognize any possible

rival strategy and the need that the strategy remains as simple as possible [27].

VII. Conclusion

Prisoner's dilemma is still a current research area with nearly 15000 papers during the past two years (Source: Google Scholar). New strategies are developed and old ones are reused in new areas. But basic rules for cooperation that were recognized by Axelrod in the first competition are still valid: kindness, provocability, forgiveness and simplicity. Most of new successful strategies are based on principles that were set up 20 or 30 years ago (from 223 strategies at the competition 1 in the year 2004 there were 73 based on TFT principle).

New approaches upgrade known ideas through genetic algorithms and heuristic approaches to successfully recognize opponents, to anticipate their moves and try to achieve better results. But there is always a problem of possibility to misjudge opponent which will bring worse results in the end. However, the information carries the key role in any sort of intelligent activities and strategies. Individuals with more information will have advantage in most of situations so the strategies that learn about the opponents and adjust their own behaviour will certainly have an increasingly important role in the future.

A Model of Software System for Parking Using Search Algorithms

Dražen Drašković*, Sanja Vukićević **

Abstract - In this paper a model of software system for parking using search algorithms has been described. The basic idea is to provide a system user with a fast and simplified way to find the nearest empty place while entering the parking lot of large surface. During the searching procedure, modified branch and bound method is used.

On entering the parking lot, a system user is connected to a server by means of the Bluetooth. Then, the server sends the parking lot schema in a predefined XML format to a smart phone, as well as the identifier of the entrance where the user is currently located. Then, a parking schema is being created on the phone and a route to the closest parking space is being displayed. This software system has been developed to be used as an educational system for teaching the academic course 'Expert Systems', but it could be improved and used in real-life applications as well.

Keywords - Branch and Bound Search Algorithm, Educational System, Expert Systems, Parking System, Wireless Sensor Network (WSN)

I. INTRODUCTION

With the development of contemporary technologies, people very often do not show understanding of everyday activities, which may waste lot of time. However, with the help of modern technologies such activities may be accelerated to a great extent. Generally speaking, large parking lots with lots of parking space are used more worldwide. Usually, users see the number of empty parking places at the very entrance, but they are not able to notice the location of the nearest parking place. The situation, in which a user moving through the parking lot may find himself at the spot where he should turn left or right not knowing where he would find the parking place faster and more easily, represents a real problem. The borderline case may occur in which a user cruises endlessly within the parking lot while some parking places are being emptied, and then filled by other users who have been faster. According to the study by IBM in 20 cities worldwide drivers usually spend daily 20 minutes on average in order to find an empty parking place [1]. This time, spent by users trying to find a place, increases the petrol consumption, and the harmful gases release pollutes the environment.

The idea of this paper is to create the system that would enable the users to find the first empty parking place more easily. At the entrance a user would obtain the schema of the whole parking lot via his mobile phone. Sending the parking lot schema may be fulfilled by means of some data transfer wireless technologies. Thus, on the basis of the obtained parking lot schema, a mobile phone would draw a path to the nearest parking place whereby a user reach the first empty place quickly and easily by following the drawn path. In addition to this, all empty places within the parking lot would be marked, which enables a user to select another empty place at his own will. This system would lead to minimizing the number of vehicles circulating around the parking lot in search of an empty place at parking with high level of congestion. The vehicle movement time at the parking lot would thus be significantly minimized, and the entering parking time would not be maximized, mainly because a user must wait for the entrance ramp to be lifted during which time a parking lot schema will be received via a mobile phone.

In section II, the technical requirements for the creation of this software system have been given, while Section III provides the problem description with the model parking lot description together with the search algorithm. Section IV provides the conclusion of this paper.

II. TECHNICAL REQUIREMENTS

Certain parking lot technical requirements are needed for the proper functioning of the designed system. Figure 1 displays the technical requirements diagram for a parking lot and for a user, as well as their interconnection. The displayed devices on the technical requirements diagram are the following: (1) the central server, (2) the distributed terminal, (3) a Bluetooth terminal adaptor, (4) a user's mobile phone, and (5) parking place status sensors, respectively.

The central server and a user's mobile phone are connected by means of the distributed terminal and the Bluetooth terminal adaptor that represent intermediaries in communication. On the other hand, parking place status sensors have one-way connection with the server.

The central server represents a processing unit which keeps a record on all the parking places and their current

This project is supported by the Ministry of Education and Science of the Republic of Serbia.

availability for a user (a place is either empty or occupied). At a given moment, on the central server there is up-to-date status of parking spaces. In case that a parking lot has a great number of parking places, the parking place availability check-up may be a complex time consuming operation. At the same time, the central server is also a server of a distributed system, which is accessed by the terminals using a predefined protocol. Terminals send requirements for the parking schema to the central server. If a great number of terminals exist, then the central server must provide the parallel requirements processing in order to prevent the slowing down of the terminals in cases of great traffic jam. The system performances heavily depend on the central server performances.

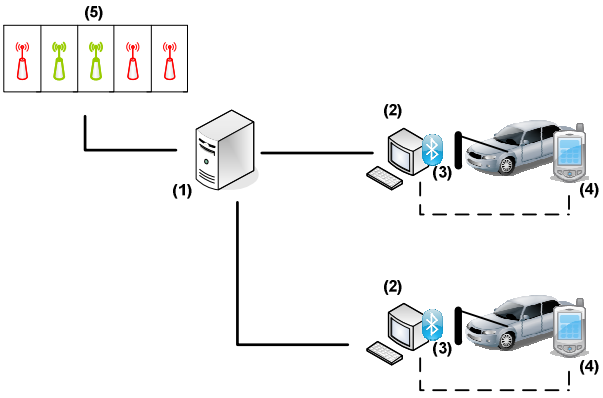

Figure 1. Parking Lot System Model

The distributed terminals represent the devices located at every entrance of a parking lot. A terminal serves as an intermediary in communication between a user and the central server. The need for terminal existence has arisen due to a reason that there are several entrances within the larger parking lots. In case of the central server non-existence, it would be necessary for the terminals to communicate between each other concerning the parking place availability, which renders the communication protocol of the whole system more complex and demanding, while simultaneously increasing the data synchronization time and leads to the terminal response delay. The central server and terminal connection must be carried out via fast connections. In the borderline case, the information flow up to the central server will be equal to the speed of terminal requests multiplied by the number of terminals. For this reason, a terminal should possess appropriate resources so that these pieces of information are being processed timely, and the response would be then sent back to the terminal.

A parking place status sensor is a device that enables the automatic detection of parking place availability. The sensor detects the presence of an object having vehicle dimensions whereby the oscillation between occupied and empty state is evaded too often. It could be a problem, if sensor detects a person who is passing past the sensor. This problem was solved by using two sensors on each parking place [2]. Status sensors are connected to the sensor network which communicates with the central server. For system implementation in real-life, we suggest using sensors explained in [3].

The communication between the sensor network and the central server must be stable and fast, because the parking place state update frequency will be proportional to the vehicle circulation at the parking lot [4]. If the vehicles circulation at the parking lot is extremely frequent, it might be the case that a great number of sensors would then send the parking place status information too frequently, thus making the central server overloaded and unable to process other requests coming from the terminal. The parking place status sensor request which is sent to the central server has the higher priority during the processing, because it is essential that all the terminals should be provided with the updated parking lot situation picture.

The Bluetooth adaptor is a device that has to exist at each terminal. The Bluetooth adaptor represents an intermediary at the physical level of communication between users, that is, between a mobile phone and a terminal, which passes the requests to the central server. The predefined protocol for the exchange of messages and other objects is being used. At each terminal an adaptor must be adjusted to be visible so that a user might connect by means of his mobile phone to the terminal he moves towards.

A user must possess a mobile phone with the application able to display a parking lot schema obtained by the Bluetooth communication with the terminal. A mobile phone must also support the Bluetooth protocol so that the mobile phone should be visible to the terminal with the Bluetooth adaptor. The application should be enabled to establish a device visibility so that an adapter can find it and approve the Bluetooth communication with other devices. The mobile phone must have empty memory space in order to permit the application to save the parking lot terminal information and display it to the user. Accordingly, the application should be allowed to enter data into the memory card and allowed to read data from that card too.

The new Android phones support Bluetooth Core version 2.0 with Enhanced Data Rate (EDR), for fast data transfer. The practical data transfer rate of EDR is 2.1 Mbit/s [5]. Considering the schema which is transferred via Bluetooth is in XML format, it does not require faster connection.

Users, who do not have smart phones, may also use this system but with modification of the proposed solution. The whole parking lot should possess the system of the Bluetooth transmitter and the Bluetooth receiver, and a mobile phone would be constantly connected with only one receiver/transmitter. In the ideal case it would always be the nearest one, because the signal of such a receiver/transmitter is the strongest one. The empty parking place notice would be sent to users in the format of a text message.

III. THE PROBLEM DESCRIPTION

Parking lot schema defining ought to be carried out before the system installation. By parking lot schema

defining the system is being provided with the information concerning the parking spaces set up, the parking lot shape, the entrance/exit system, and the possibility of passing from one part of the parking lot to another one, and the like. XML files have been used for the parking lot schema description, and the system has been realized in the Java programming language, using the Android libraries.

A. The Parking Lot Model

The basic elements which represent a parking lot are the following:

- The parking block,
- The parking place,
- The parking entrance,
- The transition between the two parking blocks.

Every parking element has a unique ID for a group of elements to which it belongs. Parking places, entrances to the parking block, as well as the transitions between two parking blocks might be located only at the edge of a parking block. If the need arises for parking places in the middle of the rectangular parking lot, this would be achieved by merging several parking blocks. Parking blocks constitute the tree structure. The block which contains the entrance at which the user is located represents the tree root. The simplest way to write down this model is in the XML files format. The XML file possesses the main tag entitled <ParkingLotSchema> within which the other tags, described in the remaining part of the paper, are contained. The parking block represents a block within which parking places are located, and which may be accessed by using the parking entrance and from which one might move to the neighboring parking block by means of the transition between the two parking blocks. The parking block may be of any shape. At this moment, there exists a support only for the rectangular parking block. The rectangular parking block is described through its height, width, parent block, merge place in relation to the parent block and the merge side in relation to the parent block. If the parent block does not contain the data on the place of merging with the parent block and the side of merging in relation to the parent block, the data become irrelevant. The parking block contains the list of parking places which are located within it, the list of parking block entrances, as well as the list of transitions to the parent parking block. An example of one parking block, described in the XML file is provided in Figure 2.

```
<ParkingBlock ID='1'>
      <Type>Rectangular</Type>
      <Width>15</Width>
      <Height>14</Height>
      <OffsetX>0</OffsetX>
      <OffsetY>15</OffsetY>
      <ParentBlock>3</ParentBlock>
      <MergingPoint>10</MergingPoint>
      <MergingSide>right</MergingSide>
      <ParkingSpots>
        <ParkingSpot>...</ParkingSpot>
      </ParkingSpots>
      <Gateways>
        <Gateway>...</Gateway>
      </Gateways>
      <Entries>
        <Entry>...</Entry>
      </Entries>
</ParkingBlock>
```

Figure 2. XML code for a parking block

The type of a given parking block is rectangular. The displayed block in the parking blocks tree has a parent block with ID=3, located at the parent right side, starting from the tenth meter of the parent right side (viewed from above downwards). Only the name of a new block should be added in case of introducing new shapes of parking blocks. The move absolute values change along the appropriate axes, even though they are given in the block structure. Equally, these values might be calculated in the application itself.

The parking place represents space aimed for one vehicle. The parking place is described by its height, width, position in the given block, the side at which it is located within the parking block and the status, which might be either empty or occupied. An example of a parking place, described in the XML file, is given in Figure 3. A parking place located at the lower part of the given parking block is displayed, as well as the initial point of parking place branching which is on the coordinate 0, and the block is extended 3 meters to the right and 5 meters upwards. The current status of this parking place is „occupied".

```
<ParkingSpot>
      <BlockSide>Bottom</BlockSide>
      <StartPoint>0</StartPoint>
      <Width>3</Width>
      <Height>5</Height>
      <Status>Occupied</Status>
</ParkingSpot>
```

Figure 3. XML code for a parking places

The parking block entrance is described in terms of its width, position and side at which it is located within the appropriate parking block. An example of one such parking entrance, described in the XML file, is given in Figure 4. The displayed example represents the parking block entrance located on the left side of the given parking block, being 3 meter wide and the branching point from which it begins is located on the left side of the block, 5 meters from its upper point. Since the entrance is located on the left side of the block, or more precisely on one of the vertical sides, the block entrance is extended according to the height, so the final extension point is at the eighth meter from the upper side of the block on its left side.

```
<Entry>
      <EntrySide>left</EntrySide>
      <Width>3</Width>
      <StartPoint>5</StartPoint>
</Entry>
```

Figure 4. XML code for entry point

The transition between two parking blocks represents the place to which one might move from one to parking block to another. The transition between the two parking blocks is described in terms of the width, position in an appropriate parking block, as well as the side on which it is located in an appropriate parking block. Currently, every transition is a two-way one. Nevertheless, it might be introduced in the subsequent versions of the system that the transition type is one-way or two-way transition. An example of one transition between the two parking blocks, described in the XML file, is given in Figure 5.

```
<Gateway>
      <GatewaySide>Top</GatewaySide>
      <Width>5</Width>
      <StartPoint>10</StartPoint>
</Gateway>
```

Figure 5. XML code for gateway

This system supports all sorts of parking that may be described by a sequence of mutually perpendicular and parallel rectangles which are mutually in the contact. The most basic shape is a rectangular parking lot, which contains parking places along its edge. Such a parking lot is described by only one block at which parking places are located. If a parking lot shape is a rectangular and has parking places not only along the edge, but also within the block, a need would arise for the existence of several parking blocks, which are lined up one upon the other.

Figure 6 illustrates two blocks. Block 1 represents the root block in the parking tree. Block 2 immediately follows the first one. The merge side for block 2 is the lower one, because it is viewed in relation to the parents block. The place of merging equals 0 and blocks have the same width (merge side). Block 2 contains two transitions to the parent block. Both transitions are located at its bottom side, one begins at the beginning and the other one at the end of the bottom side. The first two rows of parking places belong to the upper block, and the other two to the lower block. Each block contains two parking

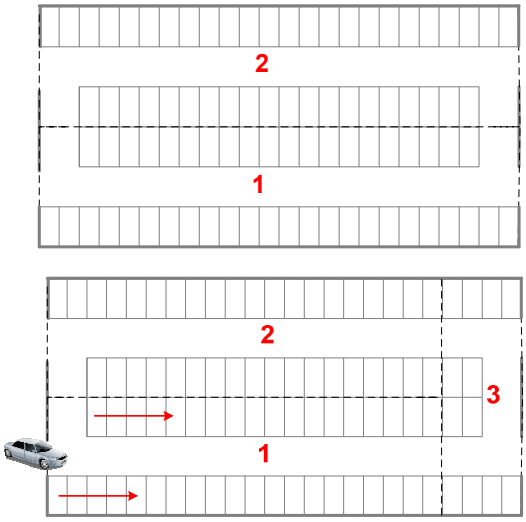

Figure 6. The different block schema for the same parking lot

entrances, from its left and right side. Provided that a vehicle enters through the left entrance, and the first empty place is in block 2, the schema by which it would move is a schema through the left transition to the second block to the parking place.

The implementation of the system itself is divided into classes for parking structure realization and the specific Android classes. The classes comprising the parking structure are the classes describing the block, the rectangular block, parking place, parking entrance, the transition between the parking blocks and the search for the nearest parking place on the given side of the parking block. Android classes realize the very appearance of the application, as well as the communication with the parking server.

B. The Implemented Algorithm

The XML scheme will serve the purpose of dynamic tree formation depending on the vehicle position. Figure 7 displays an example of the Faculty of Electrical Engineering parking lot schema. Graph in Figure 7 displays every schema block by node, while each transition between the blocks is represented by relationship. If two or more rectangular blocks meet, connections towards all the blocks will be defined.

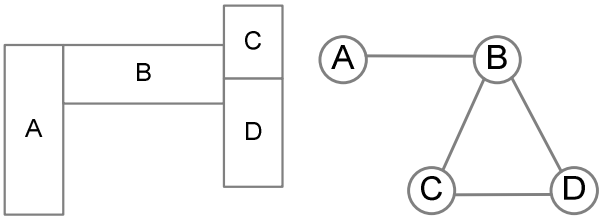

Figure 7. Blok schema and graph for parking of the Faculty of Electrical Engineering

The algorithm starts by locating the block in which the vehicle is situated (block A). Having detected the belonging to a particular block, a search in that block is being initiated as well as a search in all the neighboring blocks (block B). A search is performed in such a way that the shortest distance between the located vehicle coordinates and the parking place coordinates are searched for. The algorithm forms the search tree and memorizes the nodes which are visited during the search so that they do not move the same direction several times.

The search may be simultaneously performed in the observed and in the neighboring blocks. If an empty place has not been found in the neighboring place, it is being checked whether any block has already found the nearest parking place. If this is the case, the search is being finalized and stopped, and the nearest place is selected from among the found ones. If this is not the case, the search continues in its neighboring blocks, which have not been searched through. We initialize four threads, one for each block side, for the rectangular shape that is being searched through. On finishing all the search threads, each search thread reports on one parking place if there is one existent. Having received the report on four parking places, one is being selected that is the nearest one. The

search for neighboring blocks is performed likewise. Whether an algorithm would find a better place in the neighboring blocks also depends on the transition distance between the observed block and its neighbor. If the nearest transition to the neighboring block is placed farther from the place we have found in the observed block, the search in the neighboring block is not necessary. As it is presented in Figure 6, blocks could be the same size but it is not usual in real life, as it can be seen in Figure 7. Each block contains information how many parking spots it consists. Therefore, time for block searching is different.

When a user enters the block 1 parking entrance displayed in Figure 6, the algorithm initiates the threads for both sides of the block. It is being inspected whether the parking places are empty or occupied in each thread for all the parking places. Then, the empty parking places, if there are such, sorts ascending in relation to the entrance distance. The thread execution result is the first empty parking place nearest to the entrance. When both threads finish the search, the empty parking places are compared and the one nearest to the entrance is selected, but the obtained parking place does not represent the ultimate result. Namely, it might be the case that in block 2 there is a parking place which is nearer from the one found in the block 1. Therefore, parallel with the block 1 threads, all the neighboring blocks of the block one are searched through, i.e. blocks 2 and 3. They are searched through in the same way as block 1. When the search in all three blocks is finished, the found parking places are compared and then the parking place nearest to the entrance is being proclaimed. Optimization may be performed in the algorithm, so that the search is not carried out in the block which is more distanced from the last parking place in the block within which a car is located. In this example, this would mean that the empty parking places search would not be performed in block 3, unless there is no empty place in blocks 1 and 2. In specific case, if driver isn't able to occupy empty parking spot, because another driver has occupied an empty parking spot at this time, the driver will require an empty parking spot again, through a Bluetooth adaptor.

IV. FUTURE WORK

Possible improvement of the selected model are support for other types of parking blocks, one-way transition between parking blocks, more levels parking support, and the nearest parking exit search. Other shapes of parking blocks may be added to the system, in such a way as to define the block description and the new types of sides on condition that the edges are neither horizontal nor vertical. The block is being currently described only by its height and width, which is not sufficient enough when we describe, for example a triangularly-shaped parking lot. One-way transitions between the blocks are possible with addition of the additional data which would define whether the transition from one block to another is unidirectional, and if this is the case, which direction movement is permitted. Also, during the parking place search, the algorithm might include the direction transition check up. Modifications for parking with several levels is simple, because the transition from one block of the lower level to the higher level block would be regarded as ascending or descending. It would be also useful to add the information to the blocks concerning the level to which they belong, so that the system user can follow the movement on the drawn schema. The calculation of movements along the coordinates would be more complicated for parking lots with several levels than in the case of one level parking lot. Similarly, as there is a search for the nearest parking place from the entrance, it is possible to implement the nearest exit of the parking block. The search algorithm remains the same as in the case of empty parking place search, with the exception of finding the exit, which must be defined in the XML schema.

Defining the parking structure is possible also in the form of the weighted graph, in which case, instead of searching according to the branch and bound algorithm, algorithm A* would be implemented, taking into consideration also the schema weight, which would represent heuristics in searching [6]. This graph is useful in case when one transition is more passable than the other, so the former should be used, even though it is somewhat placed farther.

V. CONCLUSION

Our research is based on the standard parking analysis, represented by the structure of mutually perpendicular or parallel rectangles with two-way transition points between the blocks, and then, on building a software system model and defining the search algorithm.

The described system enables its users to save time in the course of finding the nearest available parking place. The existing parking system is not complicated to be upgraded. On the contrary, it is necessary to add the wireless infrastructure, in such a way as to place and adjust the terminal with the Bluetooth adaptor connected to the central server at every entrance ramp. Also, it is necessary to define the parking lot schema with the division into blocks. This might be complex depending on the parking size and complexity, but should be done only once. Finally, the most demanding process of parking updating represents installing parking sensors at every parking place. The complexity of parking installation is directly dependent on the parking lot size and the number of parking places.

Due to its modified search algorithm, this system is also used as an educational system in teaching process within the subject 'Expert Systems' for undergraduate academic studies.

***Abstract*—With significant advances in computing power during recent years, increasingly complex variants of the vehicle routing problem (VRP) with added constraints are coming into focus. VRP is a combination of the classical traveling salesman and bin packing problems, with many real world applications in various fields – from physical resource manipulation planning to virtual resource management in the ever more popular cloud computing domain. In this paper, we consider large-scale VRP problem instances with time window constraints. Due to their complexity, we propose a solution approach based on the divide and conquer paradigm, decomposing problem instances into smaller, mutually independent sub-problems which can be solved using traditional algorithms and integrated into a global solution of reasonably good quality. Numerical results indicate the efficiency and scalability of the proposed approach, making it highly applicable to large-scale realistic VRP problem instances.**

***Index Terms*—vehicle routing problem, time windows, large-scale, greedy search, decomposition, scalability, optimization**

I. Introduction

Travel logistics have always been important to minimize expenses (be it raw materials such as fuels or the manpower behind it) and mantain a good quality of service. Today, they have become even more so, when we know that the environment is at stake as well – in 2010 the transport sector was responsible for 23% of all the CO_2 emissions in the EU [1]. A good formal representation of real-life transportation and service delivery problems is the capacitated vehicle routing problem with time windows (VRPTW). It is a problem of having to minimize the distance that vehicles need to travel in order to deliver a service with multiple realistic constraints regarding space, time and capacity. It was shown that solutions for this problem could be applied to real-life domains and significantly improve their efficiency – up to 30% in some cases [2]. Consequently, in this paper we propose improvements to existing solutions of the VRPTW.

VRPTW is an NP-hard problem [3], so the aim is to find an approximate solution of high-enough quality. There are many solutions to the VRPTW and the most promising ones, such as [4], [5] apply the so-called optimization decomposition technique to divide the search into separate constraint dimensions. The method we propose here applies a decomposition based on separate vehicles and then uses parallel local search for optimisation within each decomposed dimension.

The main *contribution* of this paper is an efficient decomposition heuristic comprised of an initial greedy step followed by parallel local search.

The rest of the paper is organised as follows. Section II lists the related work in the field. Section III gives a formal problem statement and introduces the considered model. In Section IV we present our decomposition method and parallel local search algorithm. An evaluation method and the numerical results are described in Section V. Section VI gives possible future research directions and finally, section VII concludes the paper.

II. Related work

A lot of work has been invested in creating efficient solvers for the vehicle routing problem.

A constraint decomposition approach, where a possible solution is optimized for each of the constraints in turn and then combined, was proposed in [4], [5]. The problem space is decomposed to spatial, time and vehicle dimensions. In our proposed solution we also decompose the problem space based on the vehicle dimension.

As for the optimization techniques inside the VRP domain [6], various algorithms are used. A simulated-annealing-like local search was proposed in [7]. In [8] a tabu search optimisation is used. The naive ejection chain method for local neighbourhood searching is proposed in [9] with a high potential for solution diversification and total vehicle number reduction. Models for evolutionary methods were presented in [10], [11]. Ant-colony optimisation was used in [12]. Our optimisation approach is based on a parallel local search algorithm once the solution space is decomposed into small-enough instances.

III. Problem and model statement

The vehicle routing problem with time windows is an extension of the well-known vehicle routing problem (VRP,

defined in [13]). The VRP is described as follows: "A set of n customers must be serviced from a central office using vehicles of equal given capacity". Each customer must be served from exaclty one vehicle. Usually two objective criteria are used, the primary to minimize the number of vehicles and the secondary to minimize the total travel distance. An additional constraint associated with the time windows extension is that every customer must be serviced within a given time frame. If a vehicle arrives earlier it must wait for the window opening time. If the vehicle arrives after the end of the time window, the solution is not valid. Every customer has the following parameters defined:

- readyTime - window opening time
- dueDate - window closing time
- serviceTime - time needed for the customer to be serviced
- geographical data

Other parameters:

- distance - geographical distance between two customers
- timeDistance - time needed to travel from one customer to another
- windowTime - difference between dueDate and readyTime

In the algorithm we propose here to solve the VRP, we consider a single objective criterion which is to minimize the total number of vehicles. Generally, a smaller vehicle number implies a smaller travel distance. Thus, to simplify the algorithm without loss of generality, the secondary criterion will not be considered here.

IV. A TWO-PHASE VEHICLE BASED DECOMPOSITION ALGORITHM

The presented algorithm is divided in two major parts. Firstly, an initial solution is generated using a fast greedy algorithm. Then the number of vehicles is reduced using parallel customer insertion. One of the most important advantages of the implemented parallel method is easy patching of subresults into a global result which fully meets the defined constraints.

The proposed algorithm is illustrated in Fig. 1, resembling a state-transition diagram. It can be seen that our algorithm consist of 5 states and 5 transitions. The start and end states differ from the middle states because they represent the initial points (customers) and the final points (vehicle routes). The second state is an abstraction for selecting a route which will be removed. The center state expresses parallel insertion of customers from the removed route (second state). In the fourth state we decide which of the existing vehicles (routes) will accept customers from the deleted route. The central states presents vehicles as lines and customers as points on those lines. Transitions are intuitive and describe what will be done in the next state. A special type of transition is a backward transition which allows removing routes, one by one, if the current route is not removed or if the current vehicle number has been reduced.

A. Greedy initial solution creation

To create an initial solution, a greedy algorithm is used that creates a list of customers for each vehicle. The input parameters are the initial customer, the vehicle capacity and a list of unvisited customers (that still need to be visited). The pseudocode of phase 1 of the algorithm follows:

```
function GREEDY
    while unvisitedCustomer exists do
        start newRoute
        set newRoute.first(home depot)
        nextCustomer ← greedy.getNextCustomer
        while nextCustomer exists do
            newRoute.add(nextCustomer)
            nextCustomer ← greedy.getNextCustomer
        end while
        set newRoute.last(home depot)
        add newRoute to result[route]
    end while
end function
function GETNEXTCUSTOMER
    get unvisited customers which meets route capacity limitation
    get customers which carry out time restrictions
    customer ← select customer with minimal OBJ value
    if customer selected then
        return customer
    else
        return null
    end if
end function
```

In the algorithm, we basically build a list of customers to visit by first taking into consideration the minimization criterion expressed with the getNextCustomer function. Many optimization criteria were tested, including OBJ=

- Distance
- ReadyTime
- DueDate
- VisitedTime
- WindowTime
- fun1: $fun1 = x * distance + y * waitTime + z * (dueTime - visitedTime)$

We focused on a custom function fun1, which combines three main criteria: distance, wait time and urgency. Once the vehicle is full ($current_load \geq capacity$) the vector of customers is taken as a sub-problem and a new vector is created for the next vehicle, for as long as there are unvisited customers.

B. Vehicle reduction

Once an initial solution is created, the parallel optimisation algorithm (phase 2) starts. The main idea is to divide the current result among independent units. This is possible by assigning every vehicle to a separate parallel job. Iterating through the appointed vehicles list, the current vehicle is deleted and its customers are sequentially redirected to the

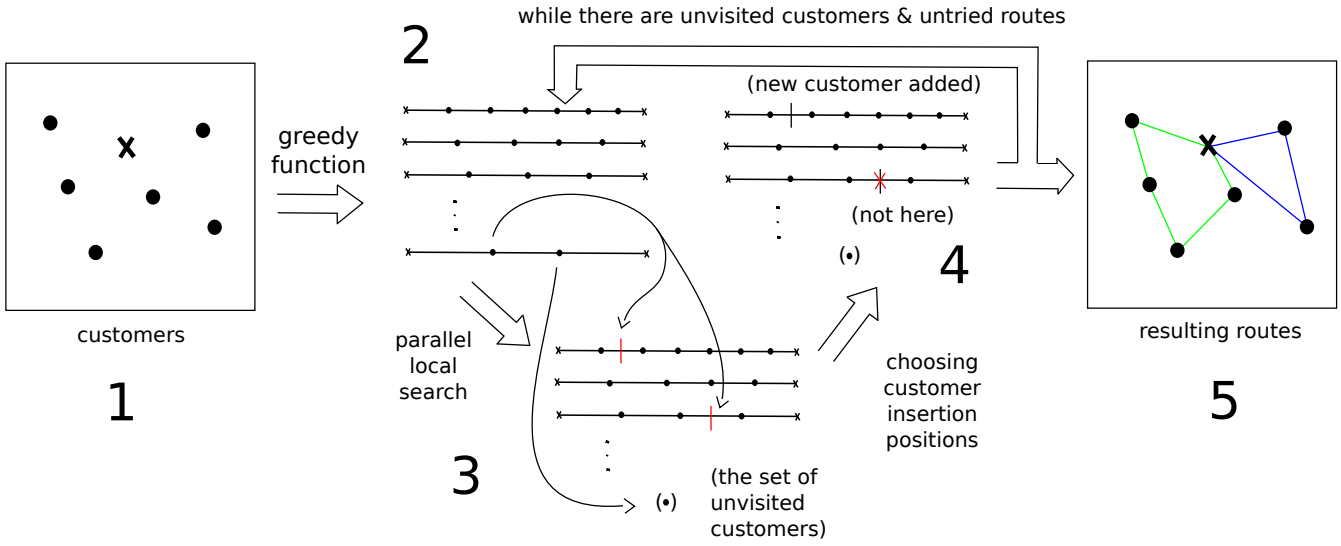

Fig. 1. A diagram illustrating the steps that comprise vehicle based decomposition

remaining vehicle routes. If there are customers which do not fit into any available vehicle route, they are added to a new vehicle, which means that vehicle reduction did not succeed in this scenario. Fitting customers into other vehicle routes is performed in a parallel. The insertion function considers fitting customers into every possible position in the current customer list, as long as the capacity and time constraints have been met. After customer fitting is finished, it is necessary to decide to which new vehicle (route) will each of the customers be assigned. The vehicle which has the least spare capacity is selected in the vehicle route selection process.

```
function VehicleReduction
    order routes ascending by customers count
    for route in 50% smallest routes do
        currCustomers ← route.Customers
        remove route from routes
        for customer in currCustomers do
            StartParallelInsertion(customer)
            if a customer is not inserted then
                create newRoute
                add uninserted customers to newRoute
                add newRoute to Routes
            end if
        end for
    end for
end function
function StartParallelInsertion(customer)
    send customer to all routes
    start parallel insertion in each route
    wait for all routes to finish
    select which route will accept customer
end function
```

The algorithm always starts from routes which have the smallest customer count, as it is generally easier to redirect fewer customers.

V. Evaluation

Experiments were conducted on Solomon's 56 benchmark problems [14] and Gehring and Homberger 300 benchmark problems [15]. The Solomon benchmark problems consist of 100 customers, while the Gehring and Homberger problems consist of 200, 400, 600, 800 and 1000 customers. Both of the benchmark sets are divided into 6 groups (C1, C2, R1, R2, RC1, RC2). Groups named Cx contain problems in which geographical data is clustered, those named Rx have randomly generated geographical data and RCx contain problems with a combination of both. Problems in groups x1 have a short scheduling horizon and allow only a small number of customers per route. In contrast, groups x2 have a long scheduling horizon and the number of customers per route is significantly bigger. For all problems, the travel time and distance is equal to the corresponding euclidian distance [16]. All problems have a central depot, as well as capacity and time window constraints.

Each of reported results is the average of 3 runs on an Intel Pentium Dual CPU T3200 (2 cores). The parameters used for function fun1 were set to x=0.8 , y=0.4 and z=0.1, determined experimentally.

Table I shows results obtained by our 2-VD (two-phase Vehicle based Decomposition) algorithm on all 356 test instances. The sum of the best known results is 10702 vehicles [17], this result is obtained by combining many different algorithms which provide the best know solutions for only part of the test instances. To the best of our knowledge there is no algorithm that was tested on all instances. The calculated best result

obtained using the objective fun1 in our algorithm is only 5.51% worse than the sum of the best known solutions.

The results presented in the continuation of this section were all obtained using a greedy initial solution with the objective criterion OBJ=fun1.

Fig. 2 presents the influence of the number of customers on the algorithm execution time. For 60 test instances with 1000 customers, the algorithm runs 2 minutes and 14 seconds, which is approximately 2.23 seconds per problem instance.

Tables II and III report the execution time and vehicle count for the 2-VD algorithm for problems with 1000 customers for each specific test group. Results for group C2 are very poor both with respect to run time and vehicle count. Group R1, which is the most complementary to group C2, gives very good results. Evaluated instances with randomly generated geographical data and fewer customers per route provide better results than instances with clustered geographical data and a larger number of customers per route. The percentages in Table II gives a comparison of our results and best known results. For group combination Rx our results are only 1.71% worse than the best know solution combining several algorithms.

TABLE II
RESULTS BASED ON BENCHMARK PROBLEMS GROUP COMBINATIONS

Group	Vehicles Count best known	VC (fun1)	%	VC after VR	%
x1	2760	3008	8.99	2826	2.39
x2	661	773	16.94	731	10.59
Cx	1230	1318	7.16	1310	6.5
Rx	1109	1269	14.43	1128	1.71
RCx	1082	1194	10.35	1119	3.42

Figure 3 shows the number of cores influence on the vehicle reduction execution time. Vehicle reduction execution time is a major part of the whole algorithm execution time. Results are evaluated for problem instances with 1000 customers. As can be seen, parallel jobs scale well and multiplying cores provides the expected results of improving speed.

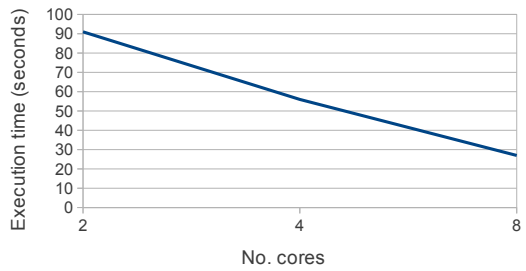

Fig. 3. Cores count and vehicle reduction execution time

VI. FUTURE WORK

Future work will primary focus on exploring additional customer-to-route insertion methods. According to the obtained results, using more cores gives additional time for insertion exploration. Some possible methods are the 2-opt heristic, ruin and recreate tehnique [10], CROSS-exchange operator and GENIUS-exchange operator [8].

One of our aims is to apply the proposed algorithm to the domain of cloud computing. Scheduling resources in cloud computing is a problem where constraints in a multiple-dimensioned solution space have to be satisfied (energy wastage minimization, service level agreement fullfilment). Given that the 2-VD algorithm has shown to be good for this problem with constraints in various solution space dimensions (time, space, capacity), it is our belief that it would be well suited for the domain of cloud computing as well. By using user resource demand forecasting (based on time series forecasting), we could obtain information regarding customer time windows and could look at physical machines as capacitated vehicles that need to visit these customers.

VII. CONCLUSION

A 2-phase Vehicle based Decomposition algorithm has been proposed. First, the initial solution is obtained using a customized greedy algorithm, followed by a vehicle reducing method. Vehicle reduction consist of removing vehicles with less customers and parallel insertion of customers from the removed vehicles to the available ones. Parallel insertion is implemented using multi-threading. After insertion, only one vehicle is selected for each customer. The obtained results (vehicle count) are within 5.51% of the sum of the best known results obtained by a diverse algorithm set. Experimental results show that parallel jobs scale well and the program's execution time decreases linearly with the increase in CPU cores.

ACKNOWLEDGEMENTS

The authors wish to express their gratitude to Ivan Fabek for his valuable contribution in implementing the result visualization program.

Implementation of Tracking Mobile Application and Analysis of Spatial Data

D.Donko and A.Alispahic
Faculty of Electrical Engineering, University of Sarajevo, Bosnia and Herzegovina
ddonko@etf.unsa.ba

Abstract - The paper presents utilization of existing aspects of global navigation and global position system (GPS), and visualization of Earth using satellite images, in order to gather and store particular data. The analyzed GPS data are related to the position and tracking of important person, vehicle or device. The described model of developed monitoring application allows more comprehensive and detailed analysis and insight in the traffic congested areas on the map in the specific amount of time, which is achieved by creation and manipulating of multidimensional data model presented in the paper. The paper also describes practical aspects of implemented monitoring center for GPS devices and possible future improvements.

I. INTRODUCTION

Visualization of the Earth is a relatively new idea, which also has created requirements for tracking and navigation. Technological support came to the level that was once considered impossible: enabled global navigation as the ability to define own position in the absolute coordinate system; developed global positioning system (GPS) [1][2]; implemented a virtual view with a satellite recordings as part of Google Earth. All this changes the way in which spatial data are acquired, assessed, organized and visualized. The question is how to use all theoretical concepts in order to monitor and detect GPS devices assigned to important person, or installed in the vehicle that has a special purpose, and how to store certain data for further statistics and analysis [3][4][5].

In this paper we use system for tracking of GPS devices, virtual view of the Earth and knowledge about the spatial data in order to develop applications for the monitoring of GPS device. Monitoring includes tracking of GPS devices, access to certain spatial data and their analysis. Spatial data analysis provides insight into the area with traffic congestions on the map in a certain period of time. This is achieved by creating and manipulating multidimensional data model.

The next section of this paper gives a detailed explanation of the problem. The third section presents the requirements for implementation of the monitoring center of the GPS devices. The fourth section presents the implementation of solutions and fifth section gives data analysis of stored spatial data and their usage for data mining algorithms. Ideas about the possibilities of improving the monitoring center for GPS devices are given in the final section of the paper.

Figure 1. Detection and archiving of the current position of GPS devices

II. PROBLEM DESCRIPTION

In the business world there is a need for tracking and locating employees and vehicles. Using the ability to determine the global position, many GPS systems have been developed, and their purpose is navigation and orientation in space. One of the optional solutions to this problem is presented in this paper

Conceptual realization of monitoring center of GPS devices described in this paper requires implementation of tracking of GPS devices, archiving, and review and statistic estimate of spatial data related to detection.

GPS tracking devices requires implementation of the following options:

- detection of the current location (Fig.1)
- archiving of detected locations (Fig.1)
- access and visualization of current spatial data

In order to utilize archived spatial data, it is necessary to:

- pull statistical data
- provide insight into the location with the highest traffic congestion in a particular time (slow move of the tracked vehicle).

Queries on stored data are called spatial queries. They include spatial selection query, spatial join query, nearest

neighbor query, etc. These queries are sometimes very time consuming and there are many research efforts to improve response time [6][7].

III. REQUIREMENTS FOR SYSTEM DEPLOYMENT

This section gives preliminary concept of problem solution. Monitoring center must have dedicated set of devices with GPS and Internet access.

The device with the GPS has to have:

- option for detection of current GPS device position
- option for sending that information to the monitoring control centers. (Fig. 2)

Monitoring center has to have:

- visualization of the current position, which precedes the functionality of receiving information from a device with GPS,
- options for review of additional information regarding the current position of the device with GPS
- options for review of the global information related to the movement of the device with GPS
- option of reviewing the information regarding traffic congestion (Fig. 2)

A prerequisite of successful implementation of functional requirements and the application involves knowledge of theoretical concepts:

- presentation, storage, manipulation and visualization of spatial data,
- manipulation of spatial databases and the use of Google Earth program,
- operation of the GPS
- basics knowledge about data warehousing, data mining and On-Line Analytical Processing (OLAP)

IV. IMPLEMENTATION

The application is developed using two separate databases: database called the Sarajevo streets - Online database and the database on the location of GPS devices - GPSdb database and the multidimensional data model.

The application consists of two main parts:

• Mobile (Android) application - to detect the position
• Web applications - to view and manipulate stored spatial data

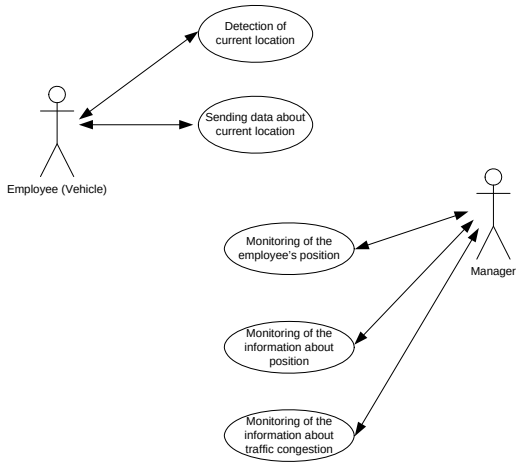

Figure 2. Use case diagram of monitoring center

A. *Implementation of mobile application*

The purpose of this part of the application is to detect the current position of the GPS device, and to store this information in the corresponding database.

Connect of the GPS device to the data warehouse is performed using mobile devices. Android application that primarily requires tracking based on current GPS integrated into device is installed on mobile device. After detection of the coordinates, they have to be stored in a database, which is located on the server. Android application allows the connection to the Internet, access to the server and stores the detected information in the database.

In order to protect data in the database, database access from client application is implemented using the service. Implemented service enters the corresponding GPS coordinates, which are forwarded to the Android-based applications. In this way the database is protected from possible accidental or deliberate client's intrusions.

Android mobile application allows location of the GPS, and a visual map display of the location, the name of the place where it is located, as well as coordinates of the current position. The application is associated with a service that forwards the data on the current coordinate position, followed by service insertion of data into GPSdb database.

Figure 3. Arhitecture of link between Android application and database

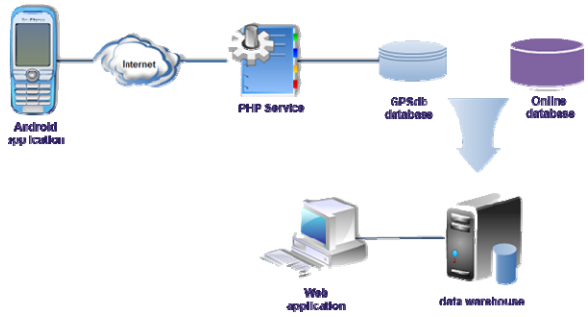

Figure 4. Arhitecture of implemented application for tracking GPS devices

B. *Implementation of web application*

This part of the application is implemented in order to monitor devices, that have the option of tracking the devices with desktop computers connected to the WLAN.

During the deployment three connections are created:

- Connection to GPSdb database - in order to access detection data of a GPS position
- Connection to Spatial Database - access to information about street names
- Connection to the created cube - in order to access data about traffic congestion at the certain locations

Created web application has the task of representing spatial data retrieved from the database on Google maps. There is enabled display of the icon above a certain GPS coordinates, display of the balloon with corresponding data over the icon, which is activated by clicking on the icon, as well as creation of polylines and polygons. Creation of a series of pole-points and their integration into polyline, create the display of all-day route that is made by device.

V. DATA ANALYSIS

Database created in this implementation is the basis for implementation of data warehousing.

One of the classifications of warehouse depends on the number of layers that comprise the architecture. Accordingly, there is single, two and three-tier architecture [8]. In this application is used two-layers architecture in order to minimize amount of stored data and to delete surplus data. In this architecture there are two physical and one virtual layer. Part of warehouse is virtualized, which means that warehouse is implemented as multidimensional view on cleaned and integrated database, which is created in specific middle layer or at the middle layer of processing.

This architecture is used according to requirements for limited analysis and the large amount of data.

Architecture has following elements:

Source Layer – it contains heterogeneous data source, such as spatial databases in organization (GPSdb database), or data that are external for organization (Spatial database)

Data Preparation Layer – data from these heterogeneous data source are extracted, cleaned (deleting non-consistent data) and linked into one common scheme using Extraction, Transformation and Loading (ETL) tools. This layer is related to creation of consistent database of streets and other important geographical location and creation of internal database of devices that are tracked with additional data that are required for analysis - driver, type of the vehicle, etc.

Cleaned and integrated database layer – information is stored in one logical centralized single-layer repository that can be accessed directly.

Data warehouse view – view on cleaned and integrated database.

Analysis layer – it enables efficient and flexible access to data in order to create reports, dynamic data analysis and simulate business scenario.

Analysis of archived data is enabled by creation and manipulation of multidimensional models and it is performed within the web application. Multidimensional view allows data to be modeled and viewed in multiple dimensions. It is defined by the dimensions (street, time, date) and fact (statistic).

Multidimensional data model is organized around delays and slow moves of the vehicles and it is created to obtain information about the most traffic congested area in a given time interval. This topic was presented with a table of facts (fact table). An example of the fact of retention includes a number of detection devices with the same GPS coordinates.

One of the possible multidimensional view and corresponding star schema in database from which are taken out data about congested traffic in a predefined period of time is shown in Fig. 5. Multidimensional view is created using Business Intelligence System tool, which is integrated into the MSSQL Server Enterprise and Visual Studio.

It is possible to get lot of information from created scheme, such as information on congested areas in the city at a certain time interval. In order to obtain any information from multidimensional data model, the specific multi-dimensional expressions (MDX) query language for multidimensional OLAP is used [9].

Multidimensional view from the Fig. 5 was created in order to allow access to the data about traffic congestion, so it was necessary to keep record of vehicle routes (with a GPS device) with respect to the dimensions time, date and streets. These dimensions allow us to take into account facts such as the time interval of slow move of the GPS device in a particular street.

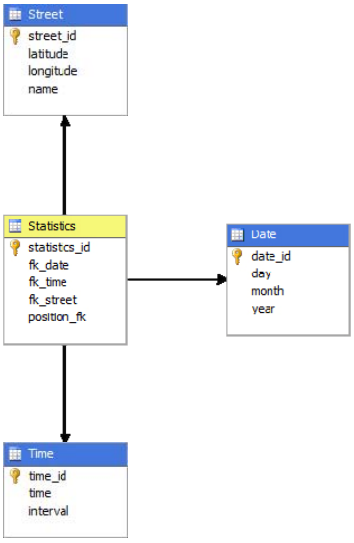

Figure 5. Multidimensional data model

Further improvements can be achieved using data mining algorithms.

Data mining is the extraction and "mining" of knowledge from large amounts of data. In this paper data mining is partly realized by determining delays in particular locations. However, data mining typically uses complex algorithms to handle much larger amounts of data. This processing could be one of the steps to improve the application in the future.

Using data mining algorithms could be possible to process data to predict which route vehicles or employees should use on a certain day, to predict the position at which should be on a specific vehicle (employee) in a given time, determining the fuel consumption in relation to time and particular vehicle etc.

VI. CONLUSION

This paper presents implementation of tracking mobile application. The data are stored and analyzed in monitoring center within the web application. Analysis of archived data is enabled by creation and manipulation of multidimensional data model. One of the implemented multidimensional views described in paper is corresponding star schema in database from which data about congested traffic can be extracted. This allows real time identification of areas that should be avoided by vehicle and to advise alternative route. The platform is flexible and reusable and its true value could be detrmined after collection and archiving data over a longer time preiod.

In addition to data on the position of the vehicle, the overall system can be expanded in terms that data send to the application includes state of the car engine, the sensor data from the vehicle, etc. Data mining algorithms can be deployed on gathered data for further analysis.

Abstract - This paper presents the set of laboratory exercises developed for the embedded engineering learning platform. The platform used is based on FPGA device which is programmed by students. The laboratory exercises cover the fundamental topics in digital design: (1) design of combinational circuits, (2) design of sequential circuits, (3) design of finite state machines, (4) design of complex digital systems, (5) processor design – components, arithmetic logic unit and control unit and (6) programming of the designed processor. The designed set of laboratory exercises was used in Digital Systems Design Principles course. At the end of the semester the students were asked to fill the survey about the laboratory exercises and they gave positive feedback. The new laboratory exercises demand more effort than the previous version, but the end result was increased percentage of students who passed the course, even though the exercises are more challenging.

I. INTRODUCTION

Electrical and computer engineering education depends on laboratory work. The students are faced with problems in a laboratory-based course, including too much time needed to learn the new tool and finish projects, lack of support for design tools and a hard maintenance of the lab. In order to overcome these and other problems, a cross-curriculum embedded engineering learning platform has been proposed (Fig. 1) [1]. The platform is based on Field Programmable Gate Array (FPGA) which students configure with their digital design. It is intended to cover a complete process of embedded systems learning, considering modular approaches for unifying education in relevant embedded system technologies. It offers a unique platform for learning process within education system (one platform for the complete curriculum), which main aim is to efficiently educate future engineers capable of coping with current challenges in real-time embedded computer engineering.

Students gave positive feedback when the embedded engineering learning platform was introduced in the laboratory work in several courses at the University of Novi Sad, as reported in [2]. The students of the digital design principles course were asked to give feedback in the following questions, among others: usability of the embedded engineering learning platform and the influence platform left in making the course more comprehensible, less frustrating and easier to pass. The students' feedback showed that the platform has met its goals and made the digital design principles course easier to understand, more interesting to students and increased the percentage of students who passed the course without lowering the difficulty of the tasks.

Digital design courses are constantly tried to be improved by many universities around the world. University in Tampere, Finland, also tried to establish a unified platform based on FPGA for teaching digital systems [3]. They carried a reform in order to streamline the learning towards core content instead of studying multiple complex design software and hardware environments.

Amaral, Berube and Mehta [4] proposed a set of laboratory exercises which would teach digital systems to computer science majors in a single term. They needed to overcome time issues and present the whole introduction to digital systems design in a single term, but also to overcome possible loss of interest to the course, because the course is not a typical computer science course.

Adamo, Guturu and Varanasi [5] presented a method of teaching digital system design in an undergraduate electrical and computer engineering curriculum. They proposed a project-based approach to teaching digital system design as opposed to the traditional method that uses conventional classroom lectures with short laboratory exercises. In their approach, students are exposed to a series of industrial-like, semester-long projects that cover fundamental topics in digital system design such as combinational circuit design, sequential circuit design, state machine design, etc. These projects are carried out in groups, thereby developing the students' abilities to work in teams.

Even though we agree with the need to develop teamwork, we believe that such an approach is not applicable under the circumstances we have in our digital design principles course, because it is early in the curriculum and it is taken by almost 200 students each year. With such a large number of students and limited resources, we find project-based course hard to establish and maintain. Therefore, we aimed to develop a better set of laboratory exercises, which would have some elements of projects (e.g. the last three exercises are interconnected and represent a small project). With this approach we tried to increase students understanding of the digital design and by allowing collaboration during laboratory exercises, we also incorporated some elements of teamwork.

This work was partially supported by the Ministry of Education and Science of Republic of Serbia, under the project No. 32030, year 2011.

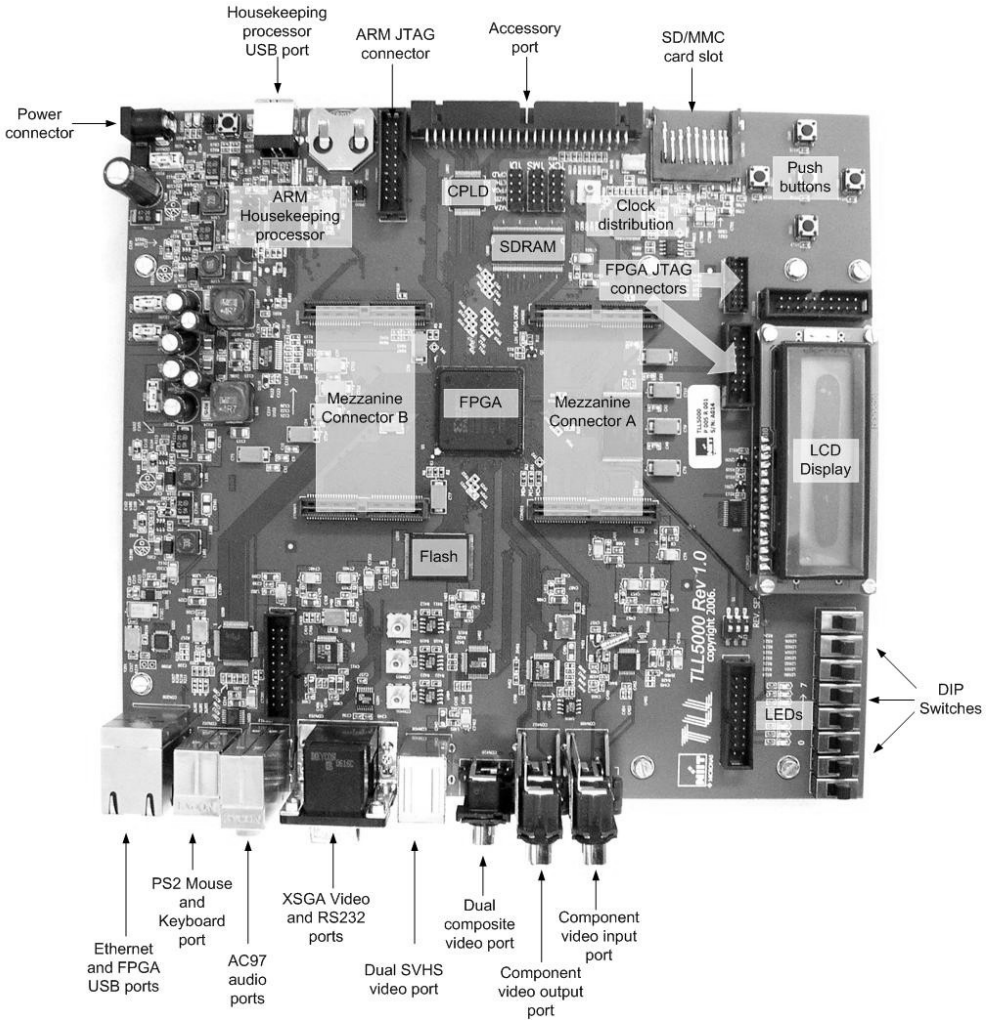

Figure 1. Board layout of the cross-curriculum embedded engineering learning platform

As a result, a new set of laboratory exercises was developed for the embedded engineering learning platform and it is presented in this paper. The rest of the paper is organized as follows: section 2 gives the digital design principles course overview, for which the new set of lab exercises was developed. Section 3 explains the new set of lab exercises in full detail. Section 4 gives the results of the survey which asked students to give feedback on the new set of lab exercises. Finally, section 5 gives some concluding remarks.

II. COURSE OVERVIEW

The Digital Systems Design Principles course is an introductory course in the design of digital systems. It teaches students fundamental topics in digital systems. The laboratory exercises for this course cover the following topics:

- Design of combinational circuits,
- Design of sequential circuits,
- Design of finite state machines,
- Design of complex digital systems,
- Processor design,
- Programming of the designed processor.

Students verify their digital designs by downloading them on FPGA on the learning platform (Fig. 1).

The grading system has been changed a little from the previous edition of the course [2], in order to stress even higher importance of the laboratory exercises. The new grading system is presented in table 1. The students now receive bonus points only for the exceptional laboratory work. Lecture attendance points are not bonus points anymore. Laboratory exercises now carry 39.25% of the total points, opposed to 37.5% from the previous version.

TABLE I. POINT DISTRIBUTION IN THE COURSE

No	Point distribution in the Digital Design Principles Course		
	Exam	***Points***	***Minimum to pass***
1	Laboratory exercises	35	10
2	Exam 1	20	10
3	Exam 2	20	10
4	Exam 3	20	10
5	Lecture attendance	5	-
6	Bonus problems in labs	7	-

III. LABORATORY EXERCISES

This section presents the new set of laboratory exercises developed for the course. It covers all fundamentals of digital design, from simple combinational and sequential circuits to the design of a simple processor. The language used for design is Very-high-speed integrated circuit Hardware Description Language (VHDL).

A. Design of Combinational Circuits

The first laboratory exercise starts by asking students to design a two-bit and a four-bit adder on the gate level. They design a two-bit adder by using the schematic design. A four-bit adder is designed using gate-level VHDL. After that students are asked to use VHDL IF and CASE statements to implement a more complex combinational logic which turns Light Emitting Diodes (LED) on the board on/off, depending on the current state of switches.

The goal of this exercise is to give students a promising start by not being hard and in the meantime prepare them for combinational circuit design which they will use throughout the course.

B. Design of Sequential Circuits

The second laboratory exercise introduces the design and VHDL descriptions of sequential circuits. The students are asked to design a stopwatch which counts only seconds and presents the number of seconds as a state on LED's. Since the board oscillator has frequency of 24 MHz, students need to design two counters – one for counting until one second has passed and the other for counting the number of seconds. Simple modifications are later performed on this stopwatch – introduction of start/stop control with switches and the changes in the counting step and interval.

In this exercise, the students get the chance to use their knowledge of combinational circuits from the previous exercise and extend it by adding sequential components, registers, to their system.

C. Design of Finite State Machines (FSM)

Lab 3 asks students to design a simple headlights system based on FSM [6]. They control the direction of the lights by changing the state of the switches. Modifications of the system include setting different priorities to the switch inputs and introducing a special "hazard" state in which all headlights are turned on and off periodically.

In this exercise, the students get the chance to use their stopwatch from the previous exercise in order to define the interval for state changes in FSM. This exercise extends the students' knowledge by teaching them to design a special type of sequential systems – finite state machines.

Transition diagram of the headlights FSM is given in Fig. 2.

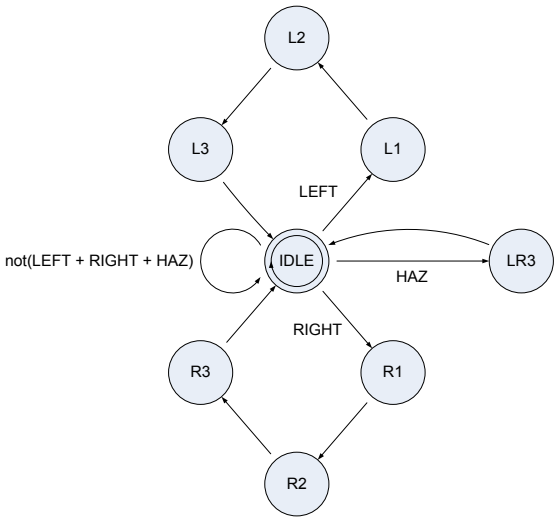

Figure 2. FSM transition diagram

D. Design of Complex Digital Systems

After completing the three introductory exercises which introduced fundamental elements of digital design – combinational circuits, sequential circuits and finite state machines, the students get the chance to design their first complex digital system. In this exercise, they are taught how to design a system made of several components and how to describe interconnections between these components in VHDL.

This exercise asks students to design an LCD banner. It is based on FSM, which allows them to use the knowledge on FSM's they acquired in the previous exercise. A new element in this exercise, besides system complexity, is the design of FSM which needs to communicate with another component and follow a communication protocol. A simple protocol exists between the LCD driver and students' LCD banner which involves three signals and it is a good way for students to learn the design of digital systems which must adhere to some timing protocols.

End result of this exercise is the system presented in Fig. 3. Students design one component (LCD banner) and the top level, using the finished LCD driver and clock generator. This LCD system communicates with the LCD controller on the board to write the first and last name of the student on LCD screen. The students also make modifications which include rotating the name and displaying the current state of the switches as a hexadecimal number on the screen.

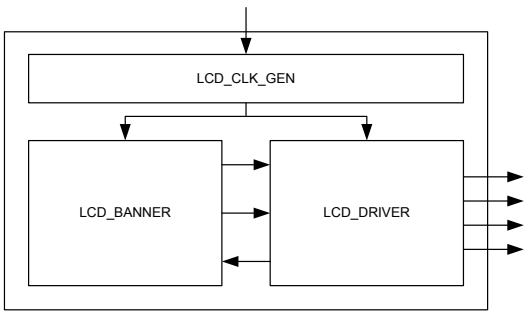

Figure 3. A complex digital system

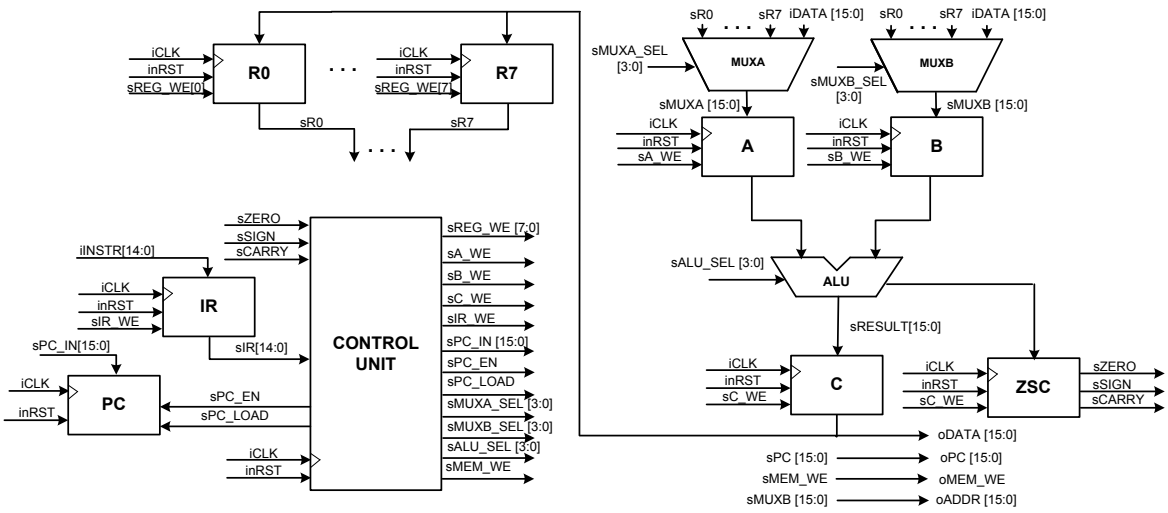

Figure 4. A simple processor

E. Processor design

The final three laboratory exercises comprise a small project of processor design. The architecture of the processor is given in Fig. 4. The students design this processor from scratch, which has an added educational value compared to extending some finished processors.

In the first lab, students design processor components: registers, program counter, multiplexers and the arithmetic-logic unit (ALU). They also prepare "the ground" for the design of control unit and connect the components in the design top-level. Memories with which the processor communicates - instruction Read Only Memory (ROM) and data Random Access Memory (RAM) are also designed here.

The second lab asks students to design a control unit for the processor. The control unit executes instructions in four phases:

1. Instruction Fetch – in which the instruction is loaded from instruction ROM to the instruction register inside the processor,
2. Instruction Decode – in which the operands are loaded in registers A and B (Fig. 4), either from registers R0-R7 or from data RAM,
3. Instruction Execute – in which ALU performs the operation, the result is written in register C and status bits (zero, sign and carry) are written in register ZSC,
4. Write Back – in which the results is written to registers R0-R7 or data RAM and program counter is changed to the next address.

At the end of the second processor lab, students finish design of the control unit which executes arithmetic and logic instructions using ALU as well as unconditional and conditional jumps.

The third lab asks students to extend the control unit in order to execute load and store instructions. After that, students can program the processor which they do in the rest of the lab.

Table 2 summarizes the instructions which are supported by this processor.

TABLE II. PROCESSOR INSTRUCTIONS

No	Processor instructions		
	Assembler mnemonic	*Function*	*Code*

IV. SURVEY RESULTS

At the end of the first semester in which the new set of laboratory exercises was introduced, the students were asked to complete the survey which covered a similar set of questions like in the previous years [2]. While developing the new set of lab exercises, survey results from previous years were taken into account. We made the start slower, i.e. with more introductory exercises and tutorials in the beginning of the course, and we eliminated SDRAM lab from the course, because it was constantly perceived as the most difficult and the least interesting one. Instead, the final part of the course concentrates on CPU design, which is designed from scratch as opposed to extending a given design like in the previous years [2]. Students were asked to give each laboratory exercise a grade between 5 and 10, which is summarized in table 3.

Besides the seven laboratory exercises explained in the section 3, students attended four tutorial sessions which prepared them for the laboratory tasks. Grades that students gave to these sessions are also included in table 3, numbered T1 to T4. The students were also asked to select the most and the least interesting lab. Results of this selection are summarized on the histograms in Fig. 5.

Comparing the grades from table 3 with the grades given to laboratory exercises in the previous years, presented in [2], it can be seen that the new set was positively accepted by the students. The new set has an average grade which is higher than the grades given to the labs in the previous generations. Another positive side of the new set is the similarity in grades among the labs – all grades fall between 8.32 and 9.10, while in the previous year, grades fluctuated between 6.79 and 8.56 [2]. This means that there is no lab which students particularly dislike, like it was the case with the SDRAM lab in [2].

Students found the headlights lab to be the most interesting, based on both the grades in table 3 and selection in Fig. 5. The least interesting lab is the design of components of the processor.

TABLE III. LAB GRADES GIVEN BY STUDENTS IN ACADEMIC YEAR 2011/2012

No	Lab grades given by students	
	Lab	*2011/2012*
T1	Tutorial – Gate-level digital design	8.50
T2	Tutorial – Gate-level VHDL descriptions	8.46
T3	Tutorial – VHDL for sequential circuits	8.50
T4	Tutorial – FSM, complex digital systems	8.65
1	Design of combinational circuits - adders	8.61
2	Design of sequential circuits - stopwatch	8.55
3	Design of finite-state machines - headlights	9.10
4	Design of complex digital systems - LCD	8.43
5	Processor design - components	8.39
6	Processor design – control unit	8.35
7	Processor design – programming	8.32

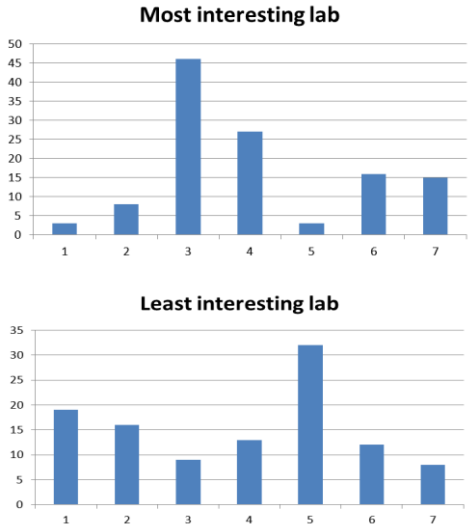

Figure 5. The most and the least interesting labs in 2011/2012

The possible reason for this is the simplicity of the components and the amount of coding which wasn't challenging – mostly interconnecting the components. This shows that the students prefer more challenging, but faster labs to the longer and easy ones.

V. CONCLUSION

This paper presented the new set of laboratory exercises developed for the embedded engineering learning platform. The new set of laboratory exercises was positively accepted by students. It brought improvements to the Digital Design Principles course, making it better perceived and easier to understand by students. The end result was an increase in the students who successfully passed the course, even though the new set of labs required more work than the previous set.

Abstract: In the past years we have discovered that aesthetic principles need to be one of priority topics for successful e-learning material design projects. Aesthetic items can be identified but since it is a subjective term no absolute measure can be applied to produce undisputable values that would grade e-learning materials. Aesthetic is influenced by users' age, social preference, previous knowledge and technical development. We have also discovered that assessment of aesthetic can be influenced by reposition of materials in the assessment process. In the article we propose the optimal evaluation method for aesthetic assessment to eliminate the external influences and achieve better results. Results of different testing methods are also presented in the article.

I. INTRODUCTION

In previous researches [1] [2] [3] [4] we have discovered that aesthetic design is a very important part of e-learning materials. This is especially true for e-learning materials for younger primary school students where a said truth is always present that users do not always experience the same kind of impression that designers intended to convey through their web pages.

Today's e-learning materials connect textual and non-textual elements. Students receive high percentages of information through visual materials where multimedia and interactive elements complement text and vice versa. The aim of e-learning materials is also the use of multiple senses to reduce the amount of text compared with traditional textbooks. Researches of e-learning design produced the following findings and recommendations of the ways in which digital technologies could be designed and used to support creative collaboration in the classroom: [5]

1. well designed digital technologies enable children to externalize their ideas;
2. multiple means of representing ideas through sound, image, color, movement and simulation;
3. in order to support creativity and collaboration;
4. digital technologies should be developed that allow children to work in a non-linear fashion;
5. the ability to personalize creations encourages a commitment from children to working through an idea;
6. digital tools can only support creativity and collaboration within classrooms in which these processes are valued.

In reality we have seen that too little time is available for e-learning materials research in order to satisfy more important sociological topics. These topics are:

- role of e-learning materials in education process;
- performance analysis of e-learning materials efficiency based on official knowledge and inherit curriculum; and
- aesthetic analysis of e-learning materials.

In accordance with previous topics we also need to address the level of qualification of decision makers who approve e-learning materials; and those who decide in the process of preparation, assessment, evaluation and confirmation of e-learning materials. This is especially important at the last stage of approval [6]. It is a legitimate question about the expertise level of decision makers who approve e-learning materials. Are they capable to autonomously assess and defend the most suitable e-learning materials for students to achieve the best results – received knowledge, educational goals, and educational standards?

Despite the serious implications of decisions this topic is neither assessed nor addressed in the aesthetic evaluation of e-learning materials. Even in the publication "Baselines for the Preparation of Electronic Textbooks" published by The national education institute of the Republic of Slovenia the quality of visual appearance of e-learning materials are neglected. The descriptions of requirements that represent the report of the reviewer include technical/user and content/didactical aspect of evaluation. The addition of the report is also an in-class evaluation of e-learning materials prepared by the teacher that used these materials. This addition therefore represents the experience aspect that numerically grades e-learning materials from technical/user and content/ didactical aspect and feedback from students [7].

Aesthetic of web sites can be divided into classical aesthetic (classical notion of aesthetic) and expressive aesthetic (designers creativity and originality) [8] while the combination of both create a satisfactory feeling. But the e-learning materials assessments have a subjective and an objective part. Objective assessment is easier than subjective since we can define a set of rules and values that apply to those rules. In one of our assessment researches where we compare e-learning materials we have set the following rules for readability and legibility. Categories are defined but the values are still debatable and we will require some additional work to get the right weights for categories. In the beginning we use +, 0, and -

for assessment but we still know that there are some categories that have greater value than others.

Similar complications are shown in the assessment of aesthetical aspect of e-learning materials. Even in the publication "Baselines for the Preparation of Electronic Textbooks" that suppose to be the guidelines for assessment the text only states that quality assessment of multimedia elements should be assessed by the quality of images from the viewpoints of size (the possibility of seeing the image in full screen), quality of colors, gradation of resized images, vibrancy, and composition. Only in the assessment of animation and simulations a question of quality of illustrations and appropriateness (how appropriate is the presentation of animated or simulated topics) is present [7]. It is evident that the assessments of aesthetic of e-learning materials need to be developed.

II. AESTHETIC ASSESSMENT STRATEGIES

When we want to conduct a broad assessment of e-learning materials we thought this was easy. Armed with the previous knowledge and experiences in fine art assessment we wanted to do this the same way. But the problem is reversed in this enterprise and transformation is not trivial. When we wanted to prepare a web assessment to address bigger population of users we started to prepare a to-do list and list of possible problems. Soon we discovered that the list of potential problems increased beyond previous assessments and produced controversial situations. Research should be such that we can claim that it is optimal, good and everyone who reads it would generally agree with our procedures. Then we have found that we don't share the same understanding of how to conduct the process of evaluation and how to interpret outcomes.

We decide to prepare a list of different assessment types that could be applied and prepare benefits and drawbacks of those assessment types.

III. LINEAR ASSESSMENT

Linear assessment means that reviewers assess items one by one. The assessment process finishes when we assess the last item. In our research this means that we grade screens of e-learning materials. Linear assessment type is used extensively in sport for assessment of sportsmen aesthetic assessment. In general we have more highly trained viewers that perform assessments and their grades combined make an items grade. Screen assessment could be contextual, didactical, technical and aesthetic. The grades represent the state of a screen. Benefits of linear assessment type are individuality, transparency, and integrity of grades. But there are also weaknesses in linear assessment type. These are opacity and inability of comparability when a large number of computer screens are assessed. Impression on active computer screen can differ in quality in both directions (positive and negative) based on halo effect. Whole assessment set can be influenced by the current computer screen. From aesthetical viewpoint where assessment criteria are flexible linear assessment type is therefore less appropriate. This type of assessment requires a clear set of quality criteria and a trained assessment specialist.

Suppose that we have already assessed and sorted items that need to be assessed. If we sort them in ascending or descending order we get significant assessment difference on untrained viewers (see Figure 1 and Figure 2). Images in the article are small and dimed since we want to explore visual expressions and position of visual elements and not what is written on them.

Figure 1: Reviewing the 2nd screen and feedback to the reviewer that he is on the second screen

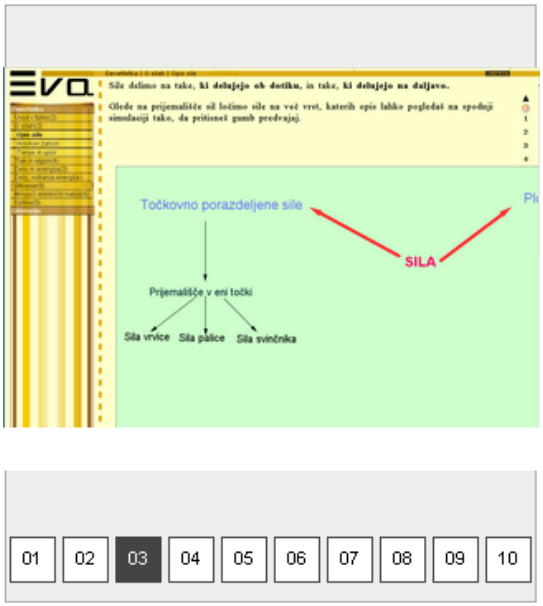

Figure 2: Reviewing the 3rd screen in the "Linear assessment" type

IV. MAP ASSESSMENT

We defined map assessment as the type of assessment where a viewer has all items in front of their eyes (see Figure 3) and can compare them. As if all paintings would be put on the wall. This assessment type resembles painting exhibition and viewers have the ability to check each item as long as they want (see Figure 4). In general this gives better assessment results but at the cost of longer assessment time. If we have time this type of assessment would be the best for our purpose but we encounter some technical difficulties. If we assess web pages then we cannot see all pages at once. Small screen shots do not represent the web page. On the other hand switching between multiple web pages requires mental discipline that untrained viewers do not have. We have to know that the small size of computer screen presented in the "map panel" for assessment raise the reduced reliability topic of assessment process. Even if we present multiple different screens from the same e-learning materials we can have assessment errors that are described in "docimology" sciences (*eng. educational assessment*) as adaptation of criteria [9]. A reviewer unconsciously changes the criteria and adjusts them to the specific e-learning materials. Error in assessment can lead to the equality of worse assessment of actually better designed screens because of the poorly designed entrance screen.

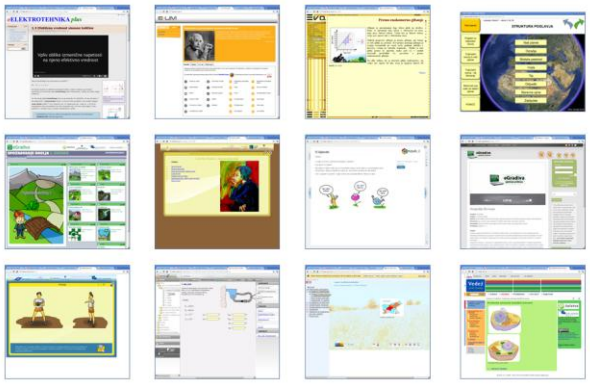

Figure 3: Map panel for assessment of aesthetics of e-learning materials based on computer screens of e-learning materials.

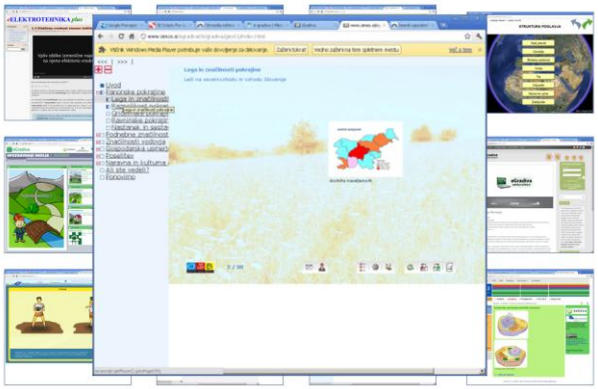

Figure 4: The zoom of selected image from the map panel that enables preview inspection (image is not crisp since we want to explore position of elements on the screen and this is sufficient for our purpose).

V. SORT ASSESSMENT

Sort assessment emerges from computer sort algorithms. Viewer decides between two items and selects the one which he thinks is better. In general we need to make many comparisons and then we get results. Sort algorithms work good in electronic environment but are not suitable for environment where decision may be wrong. It is known in many programs that you have to verify your decision (like when closing a program and the program asks the user if he really wants to discard changes). If we apply this type of checking than users get irritated since they actually decide twice between two web pages and pick the one that they think is better. From analysis of user behavior we see that many of them do pick default values (like when a program is installed they pick next, yes, I agree … until it is over). If we do not apply default values then we also need to change the position of confirm button so that it would not be accidentally clicked after previous pick. This type of assessment is not suitable from educational assessment viewpoint. At the assessment of two screens from the same e-learning materials or different e-learning materials and picking the better of the two the error of contrast can occur. This is a subjective error of the reviewer who is under impression of previously assessed computer screens (see Figure 5, Figure 6 and Figure 7). High quality computer screen can therefore cause the unfair assessment of next screen. Under impression of good screen reviewer assess all successive screens worse than their actual aesthetical value.

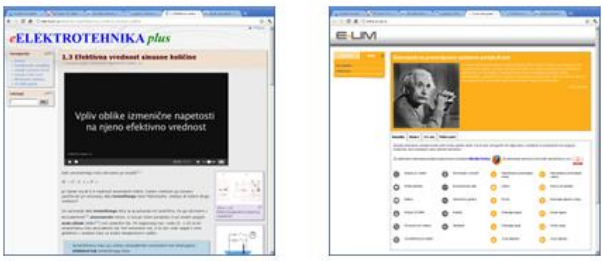

Figure 5: Comparison of first two pages in sort assessment

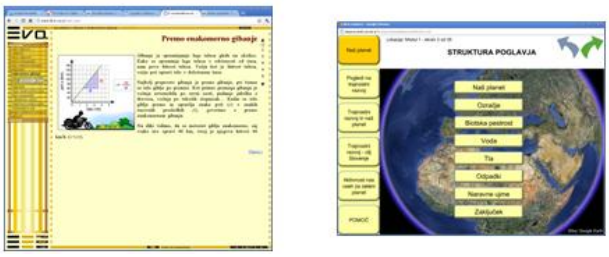

Figure 6: Comparison of second two pages in sort assessment

Figure 7: This comparisson is influenced by the second comparison where right screen was assessed lower then its actual aesthetic value is.

VI. PILOT RESEARCH RESULTS AND PLANS FOR THE FUTURE

We have tested all types of assessment on a limited number of test subjects and gained valuable insight for future research. In the pilot research we prepared tests on all topics we have described in this article. We conducted the tests with trained professionals who have done many assessments and also with untrained and reviewed the results. It is evident and expected that we received different results.

The purpose of preliminary research was to find an assessment type that we could apply to an untrained reviewer in order to acquire reliable results. Even though we want to use the assessment as a group assessment in primary and secondary schools we did not use kids as pilot test subjects. Feasibility of assessment, logistical problems, and time constraints were rather tested on university students for start. Therefore we have used 4th year students of elementary education studies and 3rd year students of fine arts at the Faculty of Education in Maribor.

Research was conducted on 24 random screen selections. Some e-learning materials were presented with more then one screen but majority were from different e-learning materials and different developers (authors). Students from each of the two study disciplines were divided into four groups of four to five students. Each group assessed 24 computer screens using their unique assessment type. The first group used linear assessment type, the second used map assessment type, the third used sort assessment type and the fourth used mix assessment type. The goal for each team was to sort computer screens into more and less visually appropriate from the aesthetic coherence perspective. In the instructions they were instructed to make even distribution.

Linear assessment type was very time consuming (see Figure 1 and Figure 2). We allowed students to move forward and backward between screens during the assessment to get more reliable results. But this movement between screens took a lot of coordination effort between team members who make individual marks for each screen. Similar results were observed in students from both study disciplines.

Twelve computer screen images were presented at once (see Figure 3) for map assessment type. Students that were assessing these screens stated that the method is opaque and slow. Picking one image to display it bigger for analysis was time consuming since they needed to coordinate for each image. Bigger images were displayed for longer time and reviewers inevitably changed the content of computer screens and their didactical values. High discrepancies were observed in the assessment of computer screens between members of the assessment team and validity was therefore reduced. Students did not assess only what we want them to but also other aspects. We skipped the assessment errors where reviewers made their own criteria and coordinate them with other members of the team because we used only twelve images in two successions. Because of the reviewers feedback we decided that this assessment type is not suitable for our purposes.

Pilot study also conducted that two groups of students from different study disciplines (elementary education and fine arts) assessed computer screens from e-learning materials in sort assessment type. Sort assessment type uses process of elimination and produces a ranking list for computer screens but requires highly trained reviewers. In the group assessment this approach was completely useless since different reviewers preferred some screens and any further steps were problematic. Individual assessment was not feasible since coordination was needed at every step. Coordination influenced the objectivity of assessment and graded values of screens were highly questionable. From the first confrontation onward the system falls apart and is not suitable for group work for individual assessment.

VII. MIX ASSESSMENT

Mix assessment is a combination of the previous assessment types. We recommend mix assessment that provides better results than previous assessment types. Based on facts that we measure users' subjective response from e-learning materials computer screens this assessment approach has the least impact on the evaluation results.

In the mix assessment approach we used six sets of computer screen images. In each set we have 5 images which make a sum of 30 images out of 24 different images. For controlling the process of assessment we repeat 6 images in different sets. We prepared the slideshow of 5 images in 12 second succession therefore all 5 images were observed for a sum of 1 minute. Despite the fact that same research shows that we need 50 milliseconds to make good first impression [8] in classroom we need a longer period which is about 5 images per minute [10]. Reviewers have enough time for aesthetic impression of observed screen unrelated to the content and didactical structure. On every 6th screen all five previous images were displayed for reviewers to assess each individual image. This approach was time economical and practical since they all managed to process five images in succession.

This approach was tested in two ways. In the first way the reviewers used a scale from 1 to 5 to grade images in the sequence of 5 images. Grade 1 was used for images that were most convincing and 5 for least convincing from aesthetical viewpoint. This 5 level scale has some weaknesses since control images in different sets were assessed with different grades. For example computer

screen 1B and 3C (see Figure 8) were the same but were graded differently because of the quality of their surrounding images. Reliability of assessment was therefore not sufficient. But when we reverse the order of grades (second way) where 1 means the least convincing and 5 the most convincing from aesthetic viewpoint we receive much better results – lower dispersion of grades in control images. Therefore in our environment we need to use traditional grading principle that is used in schools. With enlargement of the reviewers and average grades objectivity rise. Comparison between students from two different study disciplines shows small deviations. In general students from elementary education give a bit higher grades then students of fine arts who apparently have higher aesthetics standards.

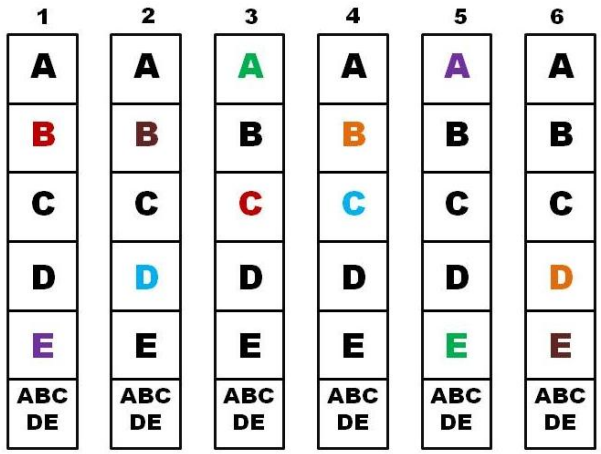

Figure 8: Evaluation scheme for mix assessment type

We have concluded that mix assessment has fulfilled our basic criteria we have expected from e-learning materials assessment. We believe that this assessment type ensures the validity of the results since we reduce the side effects of previous basic assessment types. With this approach we have achieved satisfactory objectivity. Assessments of the same computer screen from different reviewers give least deviation and more homogenous values. During the assessment process reviewers sometimes assessed the previously assessed computer screen and the matching of values of these screens in consecutive assessments were high. With tests of multiple assessment of the same screen we improved reliability of assessment process. This model proved high reliability of assessed values. The last demand that would confirm efficiency of this approach would be sensitivity. Since we used five level grades for evaluation (1-5) we could not achieve high sensitivity of the assessment. In the future the finer gradation level could provide better sensitivity. On the other hand the finer gradation can have negative impact on objectivity. All dilemmas can be solved with the evaluation committee of e-learning materials that gives the most objective results.

For an overview of all assessment methods we prepared a table (Table 1) of pluses, minuses and suitability in the classroom.

Table 1: Overview of assessment methods

	plus	minus	suitability in class	comment
Linear assessment	good time control, good progress control	dynamic sensibility, poor overview, suitable for skilled reviewers	no	finished in 35 minutes but poor results
Map assessment	good overview, ability to compare	poor time control, computer screen resolution, unconscious changes of criteria	conditionally	not finished in 35 minutes, each student has its own pace of assessment
Sort assessment	good time control, good progress control	dynamic sensibility, poor overview, unfair results	conditionally	finished in 35 minutes but questionable results
Mixed assessment	good time control, good progress control	adequate fairnes, adequate overview, self control	yes	finished in 35 minutes with adequate results

VIII. CONCLUSION

Pilot research study tested a small sample of e-learning materials on two homogenous groups of reviewers without any necessary experiences. Results of this study should therefore not be generalized and are not part of this paper. But the research was still valid since we wanted to prove a concept of how to assess the e-learning materials aesthetics and get objective results. At the end we discovered that mix assessment type was the optimal approach. E-learning materials are grouped into small enough sets that enable systematic assessment. Approach is suitable for inexperienced reviewers. Time frame of 5 images per minute used in this approach enables only aesthetic assessment and the overview image at the end of slideshow enables them to grade each previously shown screen. Using this approach we satisfy basic criteria of validity, objectivity, reliability, and sensitivity. We are aware of the problem of subjective grades that can be solved only with more reviewers from different study disciplines and at the end with the students from primary or secondary school that are going to use these e-learning materials.

** Faculty of Electrical Engineering and Computing, University of Zagreb, Zagreb, Croatia
{goran.molnar | vjera.omrcen}@asseco-see.hr, marko.cupic@fer.hr

Abstract - Formal logic topics are typical parts of the introductory faculty level artificial intelligence courses. An important part of each faculty course are student quizzes and exams. Despite the fact that the propositional logic is a formal system, in many institutions exams are prepared and graded manually. This process is labour intensive and error prone. In this paper, we present two tools for automating a part of this process: the random propositional logic formula generator and the propositional logic formula parser. The random logical formula generator is used to create logical formulae with desired content and complexity and the formula parser can be used to automatically evaluate the well formedness of formulae entered by students. Together, they are used as a part of the integrated artificial intelligence course management system at the Faculty of Electrical Engineering and Computing, University of Zagreb, Croatia. Computer aided quiz assembly enables teaching staff to easily assign each student their own, unique questions in order to discourage cheating. Aside from the aforementioned purposes, they are used as a support for the mutual development of both components, using test driven development paradigm.

I. Introduction

Throughout the history of philosophy and science, logic has been both an interesting research subject as well as the foundational tool for most intellectual activities. Nowadays, it is studied in various disciplines such as philosophy, mathematics, linguistics, and computer science. Introductory courses with topics related to logic are common in a diverse set of educational institutions, even at a high-school level. At a higher education level, logic is widely present, as it is closely related to natural sciences as well as law and humanities [1].

Teaching students topics dealing with logic may be a demanding task. Since it inherently deals with highly abstract concepts, communicating them effectively can pose a challenge. Instruments such as Venn diagrams and truth tables are commonly used to present various complex facts simply and easy to understand. Additionally, various computer based teaching aids are increasingly used to teach logic [4, 5]. Aside from benefits for students, computer based teaching systems can also unburden teaching staff and provide them more time to focus on other aspects of their work while students are performing their e-learning activities.

Propositional logic is a very simple formal system, usually introduced to students as one of the basic types of formal logic. While limited in its expressiveness, it still provides a solid ground for understanding more complex formal logic systems. Due to its simplicity it enables teaching staff to easily present important notions shared with the more complex logical systems.

Teaching propositional logic also includes evaluating students' knowledge, usually through some type of quizzes or exams. Traditionally, this process involves manually assembling a number of questions, printing the exams on paper sheets, supervising the students during the exam to discourage cheating and finally, evaluating the students' answers and grading the exams. Each of these four stages involves a large amount of manual work This work flow is time consuming and error prone.

In this paper, we present two utilities that provide a basis for creating a comprehensive suite for propositional logic e-learning. The first tool, *random propositional formula generator* is used to generate random formulae with desired complexity. It can be used to quickly generate arbitrary number of formulae with random structure, operators and variables. The second utility, the *propositional logic formula parser* is used to check the formula well formedness and build syntax trees of entered formulae. Using the formula parser, applications that use it can check the formula syntax and use the syntax tree to perform further checks and analyses of the formula entered by a student.

These tools enable teaching staff to automate exam assembly, evaluation and grading. They can easily be integrated with any Java application that needs to generate random logical formulae or parse formulae entered by human or some other application. For example, they are used as a basis for an interactive educational applets used to teach students propositional logic as a part of the Ferko system [3], devised at the Faculty of Electrical Engineering and Computing, University of Zagreb, Croatia. These applet quizzes are dealing with various topics, for example formula evaluation, converting formulae to conjunctive normal form, syntax checking and others. They support distance education, since they can be accessed from any web browser that can run Java applets.

The remainder of this paper is organised as follows: Section 2 gives a brief introduction to propositional logic, Section 3 brings the overview of the random formula generator and the formula parser is described in Section 4. The results of our work are presented in Section 5 and Section 6 concludes the paper.

II. PROPOSITIONAL LOGIC

Propositional logic or calculus is a formal system consisting of:

- *Alphabet*: a finite set of symbols used for constructing formulae,
- *Syntax*: a set of rules which defines how a *well formed formula* (WFF) is constructed using the symbols in the alphabet,
- *Semantics*: systematic constraints on how sentences relate to states of affairs and
- *Proof theory*: a set of rules for deducing the entailments of a set of formulae.

The *alphabet* contains four kinds of symbols defined as follows:

- *Logical variables* (propositional symbols, propositions) denoted by the Latin alphabet letters $\{a, b, \ldots, z\}$,
- *Logical operators:*
  - *not (*denoted ~),
  - *and* (denoted $\wedge$),
  - *or* (denoted $\vee$),
  - *implication* (denoted $\rightarrow$)
  - *equivalence* (denoted $\leftrightarrow$),
- *Logical constants* $\{true, false\}$,
- *parentheses* { (,) }.

The syntax rules for deriving well formed formulae of propositional logic by putting the alphabet symbols together are given recursively:

- Logical variable is a WFF,
- Logical constant is a WFF,
- If F is a WFF, then (~F) is a WFF as well,
- If F and G are both WFFs, then the following formulae are also well formed:
  – (F $\wedge$ G) ,
  – (F $\vee$ G),
  – (F $\rightarrow$ G),
  – (F $\leftrightarrow$ G).

Each logical formula can be represented using a syntax tree. The syntax tree consists of variable nodes connected by the operator nodes. For example, the formula

$$(a \wedge b) \rightarrow \sim (c \vee (\sim(d)))$$

is well formed, and its syntax tree is given in Figure 1, drawn using an educational applet implemented as a part of this work.

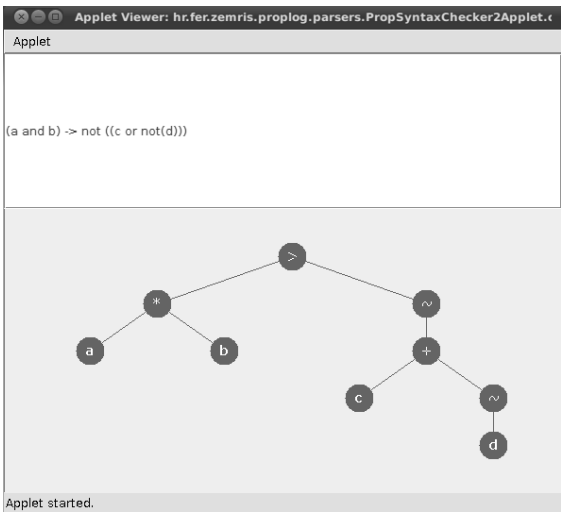

Figure 1: Propositional logic syntax tree example

Seen from the graph theory point of view, the leaf nodes (terminal vertices) of the well formed formula syntax tree are either variables or constants. All other nodes can represent only the operator nodes. In the simplest case, (only one node), the single and only node in the formula can be either a variable or a constant. For all other formulae, at least one node needs to represent a logical operator.

Propositional logic formula operators can be either unary (operator *not*), or binary (conjunction, disjunction, implication and equivalence operators). Binary operators have exactly two child nodes, while the *not* operator has exactly one child node. Each child node can be an another operator, a variable or a constant. Variables and constants do not have children nodes.

The root node is always an operator unless the formula is the simplest type of formula consisting of a single constant or a single variable.

A. Logical formula semantics

Let V denote the set of proposition symbols in a well formed formula F. Any function

$$i: \quad V \rightarrow \{true, false\}$$

is called an interpretation of the formula F. Proposition symbols have an arbitrary meaning, but their truth values are stipulated by defining an interpretation function.

Evaluating the truth value of a complex logical formula F with regards to a particular interpretation is accomplished in two steps:

1. Replace the value of each proposition symbol $v \in V$ with $i(v)$,
2. Decompose the formula using the truth tables which define the operator functions.

III. Random Formula Generator

Random value generating systems such as random number generators are widely used for purposes varying from games to cryptography. The random formula generator described in this paper is primarily intended for use in logic quizzes assembly, but it can as well be used wherever large number of logical formulae is needed. Let us assume that we want to deliver a completely personalized quiz to each of the students enrolled in the course related to propositional logic. Even for the courses with moderate number of enrolled students, manually assembling tens or hundreds of formulae would take too long and require too many staff members to be feasible for most education institutions.

Thus, we wanted to automate the aforementioned process. A few experiments with the simple random formula generator that directly generated the formula's string representation were conducted. However the results of such generator were not good enough. Most of the formulae generated using this tool could be reduced to a tautology or a contradiction, which are therefore not enough random and complex for general purpose use.

Therefore, the random propositional logic formula generator we devised generates formula syntax trees. The formula syntax tree provides easy access to the formula elements and the formula evaluation can be determined using a simple recursive algorithm. Furthermore, when the formula needs to be displayed in a format readable by human, the syntax trees can be easily transformed into a textual or graphical representation.

The first issue that needed to be solved during the implementation was to decide which parameters to use to describe the *complexity* of the formulae in a way that corresponds to the difficulty of the exam questions. Another task was to provide an implementation of such system that randomizes all of the formula elements and yet produces results within the constraints imposed by these parameters.

A. Configuring the formula generator

The main design goal for the formula generator is to provide users an easy to understand and easy to use way to set up the desired complexity of logical formulae. We use the following parameters:

- minimum and maximum operator number,
- number of variables,
- allowing or disallowing constants.

For example, it is clear that the task of writing down the truth table for a formula with two variables and just one operator is significantly easier than doing the same task for the formula with 7 variables and 12 operators. By combining various settings of the above parameters, the generator can be set up to generate formulae whose complexity is appropriate for the the quiz question and the students' level. The above parameters define what we call "feasible formulae", i.e. formulae that satisfy the complexity needed for a particular application.

Along with the above, simplified way of configuring the generator, more advanced set-up is also available, such as determining the total number of nodes (includes operators, variables and constants) in the graph, number of leaf nodes etc.

B. Implementation details

When designing a random value generating system, the usual goal is to ensure that the output values have a certain type of distribution, usually uniform distribution. Most common random value generators are random number generators that generate pseudorandom floating point number values in the interval [0, 1>. It is intuitively clear that a good random formula generator will likewise, generate any of the formulae in the feasible formula space with approximately same probability.

A naive approach – building all possible formulae, ordering them by some criteria and using a random integer generator to choose one of them would work. However, the task of generating all of the formulae for each of the possible settings has prohibitively large memory and time requirements. Therefore, we decided to use another approach.

We implemented a generator that can randomize most important elements of logical formulae: variables, constants, their relative number, number of multiple uses for the same variable and the formula structure. Randomizing the formula structure has shown to be the most challenging task, since randomising variable names and constants can successfully be solved using the aforementioned approach of constructing a list of all possible variable names/constants and randomly choosing one of them.

However, the task of randomizing the structure of a syntax tree is not so straightforward. The number of operators and the number of leaf nodes are mutually dependant. Let us define *tree width* as a number of leaf nodes in a tree. Adding a binary operator to a formula according to the rules in Section 2 increases the tree width for 1, while adding the unary not operator retains the tree width constant. Therefore, the inequality

$$tree\ width \leq operator\ number + 1 \quad (1)$$

is always satisfied.

In a special case when all of the operator nodes are binary, e.g.

$$(a \wedge b) \rightarrow (c \vee d)$$

(Figure 2a), the above inequality degenerates to the equation

$$tree\ width = operator\ number + 1.$$

In another special case, when all of the operators are instances of the unary operator *not*, e.g. for the formula

$$\sim\sim\sim\sim b$$

(Figure 2b), the tree width will be equal to 1 and the tree will degenerate to a chain of not operators and a single constant or variable.

The formula generator needs to ensure that the number of leaf nodes satisfies the constraints given by the user. Since the user can also define the desired number of operators, the formula generation starts by verifying that the inequality (1) is satisfied in the user's input.

After that, the number of leaf nodes is calculated. Note that the number of leaf nodes will be greater than the number of different variables, since the same variable can occur more than once in a formula. Along with the variables, the formulas can also have constants as leaf nodes. To simplify the design, the number of leaf nodes is currently calculated to be 1.5 greater than the number of different variables. However, the system can be easily extended to take more precise input parameters describing the leaf nodes. After the number of leaf nodes has been determined using the above simple rule, number of operators needs to be selected, as a random integer in between the minimum and maximum operator number given by the user. This is accomplished using a simple interval mapping formula and a random integer generator.

Finally, the tree structure with a given number of operator nodes and a given number of leaf nodes needs to be constructed. This is possible using a recursive algorithm (Figure 3) that creates operator nodes based on a number of operators to add and a randomly initialized *growth pattern*. The key method is called *random*, and it returns a complete, pseudorandom formula syntax tree. The number of operator nodes is decreased as the recursion goes further, until it reaches value of zero. After zero has been reached, no new operators need to be added and a single or two leaf nodes (variables or constants) are added to the current operator.

The growth pattern is a list of boolean variables in which the total number of elements is equal to the required number of nodes, and the number of true values is equal to the desired tree width. In that manner, the growth pattern is analogous to choosing whether a binary or a unary node needs to be added during the tree construction. The growth pattern needs to be initialized prior to the tree construction, and in each step, the recursive function retrieves and removes the first element of the pattern. Since the number of true values is equal

```
random (Node current, int operatorsToAdd) {

       if(operatorsToAdd == 0) {
          // add random leaf nodes
       }

       if(operatorsToAdd == 1) {
          if(isBinary(current) {
               // add a random operator and
               // random leaf nodes
          } else {
              // add a random operator and
              // random leaf nodes
          }
       }

       if(operatorsToAdd >= 2) {
          if(isBinary(current)) {
            // add two operators
            Node operator1 = getOperator();
            Node operator2 = getOperator();
            operatorsToAdd -= 2;
            int limit1 =
               randomInt(operatorsToAdd);
            int limit2 =
               operatorsToAdd - limit1;
            add(current, operator1, operator2);
            random(operator1, limit1);
            random(operator2, limit2);
          } else {
            // add a single operator
            Node operator = getOperator();
            add(current, operator);
            random(operator, operatorsToAdd-1);
          }
       }
    }

getOperator() {
       // get and remove growth pattern's
       // first element
       boolean binary = growthPattern.get(0);
       growthPattern.remove(0);

       // generate a new operator
       // according to the growth pattern
       if(binary) {
            return getRandomBinaryOperator();
       } else {
            return getNotOperator();
       }

    }
```

Figure 3: Random tree generator pseudo code

to the needed number of binary nodes, each generated formula contains the precise number of leaf nodes. Additionally, since the growth pattern is initialized using random boolean variable generator before the tree construction, each of the generated formulae will have a pseudorandom structure.

IV. Propositional Formula Parser

Propositional logic formula parser is primarily used to verify student input for syntax errors, and give the student a warning when he or she tries to enter an invalid formula. In this way, students are not penalized for miswrites like

unresolved parentheses problem or using the incorrect operator symbol.

The parser utility is implemented in such manner that in case of a valid formula input it returns the syntax parse tree instead of the boolean value indicating parse success or failure. Because of this, the utility can be used by any application in the automated testing framework to build and manipulate propositional logic syntax trees or to easily evaluate the formula. One example of possible syntax tree manipulation would be constructing the propositional logic substitution instance by replacing the correct nodes of the syntax tree with the substituting well formed formula subtree.

In order to implement a propositional logic parser, we first define the formal grammar according to the recursive set of rules describing the syntax of propositional logic (see section II). Formal grammar is defined as a four tuple G = (*V*, *T*, *P*, *S*) where:

- *V* is a set of symbols called variables
- *T* is a set of terminal symbols
- S is the starting or goal variable from *V*
- *P* is a set of grammar productions

For the propositional logic grammar we define the tuple elements as follows:

V = {S0, S, O, A , E , I , E},

T = {[‘A’ – ‘Z’], [‘a’ – ‘z’], &, | , ~, (,),→, ⇔ },

S = S0.

The production set *P* is defined in Table I. Note that the production set is constructed in such a way that the given grammar is left recursion free.

In order to construct a more robust parser the student input is preprocessed with a simple lexical analysis utility, which allows flexibility of the formula operator input format. Regular expressions with tokens representing logical operators are given in Table 2. Both international and Croatian tokens (*ne*, *i*, *ili*) are supported.

It is also important to note that the proposed grammar allows the student to use the associativity property of *and*, *or* and *equivalence* operators, while the priority and evaluation order of compound formulae must be explicitly specified by enclosing the subexpressions in parentheses. For example, the expression

$$a \vee b \vee c$$

has correct syntax, while the expression

$$a \vee b \wedge c$$

does not. The student must use the parentheses to group the expression in one of the two possible ways:

- $(a \vee b) \wedge c$,
- $a \vee (b \wedge c)$.

With grammar specified in this way a recursive descent parser with backup can be constructed. Recursive descent parser performs a depth-first exhaustive search of the derivation tree for the string being parsed and is guaranteed to terminate for LL(k) grammars. In other words, the implemented parser attempts to verify the syntax of the input stream by reading it from left to right, hence finding the leftmost derivation of the string being parsed.

Generally, the recursive descent parsers for LL(k) grammars may require exponential time to finish. However, in the simplistic case of propositional logic it does not pose a performance issue, as confirmed in practice.

TABLE I. PROPOSITIONAL LOGIC PRODUCTION SET

S0 → S	(S0 is the starting non-terminal symbol)
S → O	
S → A	
S → E	
S → I	
O → T | O	
O → T	
E → T ↔ E	
E → T	
I → T → I0	
I → T	
I0 → (T → I0)	
I0 → T	
A → T & A	
A → T	
T → (T)	
T → ~ T	
T → [‘A’-‘Z’,’a’-‘z’]	

V. RESULTS

The result of our efforts are two software libraries implemented in Java programming language. They can be used wherever generating a large number of formulae with desired complexity is needed and wherever their parsing into syntax trees can be useful. The programming interfaces used by the implemented tools are simple and

false	`(false) | (FALSE)`

```
// initialise the generator to
// generate formulas with 3 to 10 operators,
// 4 variables and include constants
   RandomPLFunctionGenerator generator =
    new RandomPLFunctionGenerator(
                  3, 10, 4, true);

// generate a random formula syntax tree
   ProplogFormula foo = generator.getNext();

// Convert the syntax tree to the formula text
   String fooText = foo.toString();

// print the formula
   System.out.println(fooText);

// Parse a formula using parser's static
// parsing method
   NodeGeneric<PropNode> fooParse =
   PropSyntax.parse("a and (b -> c)");
```

Figure 4: Parser and generator use snippet

easy to learn. An actual code snippet that illustrates how to use the parser and the generator is shown in Figure 4.

The primary goal of our work was to build a foundation for an integrated propositional logic teaching suite. The formula parser and generator have been successfully used in the Ferko course management suite.

Using the formula generator and parser, other authors created a number of different educational applets used to automatically create a unique problem for each student, evaluate the students' answer, and store the students' score in a database. In that manner, each of the students can have a different formula of a similar complexity in their exercise problems, which encourages individual work instead of cheating, while still ensuring that the tasks are approximately equally difficult for students.

Additionally, we propose a simple model for measuring complexity of the logical formulae, suitable for use in education. The devised generator is an efficient tool capable of producing large number of formulae in a short time. For example, our tests have shown that the generator can produce more than 10.000 formulae (with the complexity defined in Figure 4) in one second. The tests were performed on the AMD Turion™ 64 X2 Dual-Core Mobile Technology TL-52 processor (1.6-GHz, 2 x 512-KB L2 cache) processor that runs Oracle Java 1.6 on Ubuntu Linux v10.4.

Likewise, the formula parser is used in many educational applets within the Ferko system to warn the students about the syntax errors in their input, evaluate their input and provide the applets the syntax tree of the entered formula to enable additional checks and manipulation, depending on the problem type. For example, it is used in a utility for syntax tree drawing that was used to draw all of the syntax tree images in this paper. As a part of our work, we also defined a formal grammar suitable for parsing propositional logic formulae using top-down recursive descent parsing with backup.

Finally, the parser and the generator are used to mutually test each other. Assembling large number of logical formulae for the needs of parser testing can be easily achieved using the formula generator, ensuring greater scope of the automated tests than would be possible by using manually entered formulae. Conversely, the propositional formula parser is used to ensure that all of the generated formulae are well formed, giving assurance of the generator's proper work.

VI. Conclusion

In this paper, we present two software libraries that help teaching staff to automate part of their work, and are used as a basis for an interactive formal logic e-learning system. While these libraries have already been used in the Ferko course management system, their modular design also enables other authors to easily integrate them in their Java based projects. Although the project started as a response to a particular educational need, their use is not limited to educational purposes.

Acknowledgement

We would also like to thank Prof. Bojana Dalbelo Bašić for inviting us to participate in the JAPAIC project organised at the Faculty of Electrical Engineering and Computing, University of Zagreb, Croatia. We would also like to thank Prof. Jan Šnajder for his helpful comments and guidelines during the course of this research, as well as other members of the project for creating various useful utilities used in this work.

Abstract - This research focused on examining the library wall activity and the content Croatian libraries made available through their Facebook representations. First part of research analyzed the Facebook wall activity of 91 libraries during a period of 14 days in May/June 2011. In the second phase a detailed content analysis was undertaken on libraries that had at least one wall post in the observed period. The results of wall activity analysis showed that a small number of libraries are responsible for generating a large portion of content, and most of the libraries are not very active. The content analysis has shown that libraries mostly use their Facebook representations as a platform for marketing and posting links potentially interesting to subscribers. Also, a significant number of library posts falls into the "spam" category, which can show the lack of knowledge on potential threats when using the Facebook platform.

I. INTRODUCTION

Social networking today has become an everyday activity for many Internet users. Between many currently existing services that provide the possibilities for users to create and maintain their online social network, Facebook (http://www.facebook.com) has emerged as the most popular one. Some key statistics from different researches can help in gaining some insight into the impact of social networking and Facebook on today Internet users:

- Over 80% of all Americans use a social network; nearly 23% of online time is spent on social networks [1]
- There are now more than 750 million active Facebook users [2]
- 98% of 18- to 24-year-olds access social accounts monthly; college population logs on to Facebook the most [3]

Those numbers are confirmed by another research, undertaken by the Pew Internet Project [4], where 2255 adult Americans answered questions about their online activities. It was found that 59% of them have an account on at least one of the existing social network services, and 92% of them chose Facebook as their preferred service. A follow-up research [5] found that a single Facebook user can reach an average of more than 150,000 Facebook users through their Facebook friends; the median user can reach about 31,000 others.

As far as Croatia goes, latest numbers [6] show that from a total of 2,5 million Internet users, around 1,5 million of them use Facebook, which makes over 67% of the total online population. Demographic data show that around 60% of users are from 18-34 years old, and around 20% of them are under 18.

Considering the vast usage between Internet users, Facebook has quickly become a desirable marketing channel for many businesses: it's free, simple to use and has a very large user base. Apart from the business sector, the non-profit institutions have also begun exploring the possibilities that Facebook offers. As King [7] notes: "What if there was a way for your library to get the attention of 51% of your local community? For free? Would you do it? I'm guessing so. Guess what? There *is* a way to potentially do that – by using Facebook!"

By creating a Facebook representation, libraries can actively take part in the everyday online activities of its users by communicating with them through less formal channels. Besides the marketing possibilities in making the library more visible in the online environment, Facebook can also provide a platform for offering new library services or reaching new and existing users. One report [8] found that 50% of small business owners reported gaining new customers through social media; 51% of Facebook users are more likely to buy from the brands they follow.

Taking these trends in perspective, Facebook can give new options to libraries in enhancing their online presence, as well as reaching their potential users. In a world where information is easily accessible, but its value is often dubious, library can act as an educator inside the Facebook environment and warn users on the potential threats and problems of information integrity. By actively participating inside their chosen social network, libraries can improve their image and gain many benefits, but the lack of proper strategy can often produce more damage than good. As Farkas [9] puts it: „A lot of libraries have started building presence in MySpace and Facebook by creating profiles. And I honestly think this is a really good idea though unfortunately most libraries are doing it *really* badly. When you decide to put up a library profile on MySpace or Facebook, what is your goal? If it's to look cool or to make students more aware of the library, don't bother…I think there is a big difference between "being where our patrons are" and being *useful* to our patrons where they are."

This opinion highlights the main problem libraries are facing when creating their representation in social networks – the lack of strategy. The process of creating and maintaining library representations often isn't thoroughly planned and depends on a single librarian and his/her knowledge and preferences. That can often lead to inconsistencies in types of posts and frequency of posting.

II. PREVIOUS RESEARCH

In the area of non-profit institutions, libraries were among the first in searching the possibilities that social networking could bring to their services. Considerable amount of research was undertaken from different perspectives, but most of the research can be categorized into three main categories: library perspective (exploring how social networking could be integrated into the existing library services), user perspective (what users expect from libraries inside the social network environment) and content perspective (what kind of information libraries post inside their chosen social network).

Library perspective

One of the first researches was undertaken by Charnigo and Barnett-Ellis [10] where 126 academic librarians were surveyed on their attitudes towards integrating Facebook as a part of library service. Although most of the librarians were familiar with the notion of social networking, most of them did not see its role in library services, with only 2 out of 74 libraries having a Facebook profile. Authors have concluded that with the emerging presence and popularity of social networking services, a new channel of communication is opened for libraries that shouldn't be rejected in advance. A similar research conducted by Bejune and Ronan [11] on the sample of 64 libraries members of the ARL has shown that 44 libraries (70%) have a social network representation, and that 33 of them actively maintain it.

As social networking was given more coverage in academic papers, a series of researches has emerged covering the use of social software in academic libraries. Chua and Goh [12] surveyed 120 web sites of academic and public libraries and concluded that only 24 of them use some kind of social networking service. In a similar research, Xu, Ouyang and Chu [13] have surveyed web sites of 81 academic libraries in the state of New York, where only 4 of them had a representation inside a chosen social networking service.

These researches show that, although a growing number of libraries are starting to participate in the social networking wave, they still don't perceive social networking as an area in which they should extend their library services. The majority of libraries are still considering the notion of social networking as too unstable and „unprofessional" for traditional library services. Furthermore, Facebook is still mainly perceived as fun (not suitable for business purposes), private (users do not want professional services inside their private social network), too commercial or even dangerous (known problems with data privacy).

On the other hand, some researches, such as one undertaken by Secker [14] have shown that Facebook has great potential in the area of enhancing library online presence, and especially in the educational segment of information integrity.

User perspective

User studies exploring social networking and libraries have often included student population as a representative sample. One of the first user studies was undertaken by Mathews [15], trying to explore the usefulness of Facebook in promoting library services. The author concludes that Facebook can be of great help in the area of library marketing and encourages colleagues in exploring the service further.

Chu and Meulemans [16] explored the willingness of students to communicate with faculty staff through Facebook, as well as the potential use of Facebook platform in extending library services. It was shown that the library could use Facebook for promoting new services, providing reference services and teaching information literacy. As far as communication with students goes, students were more willing to contact the library as an organization than the individual library or faculty staff.

One of the most elaborate researches was conducted by Bietilla, Bloechl and Edwards [17] from the Gellman library from the University of Washington. The research team consisted from two librarians and an anthropologist who created an extensive methodological apparatus focused on determining how to plan services grounded in real user needs. During the first phase the anthropologist examined all the existing social network representations that the Gellman library created and formed an online image of the library. In the second phase, 105 students were surveyed on the current and potential library services. The last phase consisted of semi-structured interviews with 15 students on their habits of learning, using technology, Facebook and library services. In the end, authors concluded that Facebook is, for students, primarily a place of relaxation and informal communication. It is not used as a collaboration tool, and the presence of faculty staff is generally considered as an intrusion to their private spaces.

One of the latest user studies on college students and libraries conducted by OCLC [18] shows a steep decline in the use of library web sites, stating that almost all researches today start with Internet search engines (84%) and none of the participants stated that he/she started their research on the library web site. Social networking plays a vital role in the online lives of people with 66% of Americans using social networking. Local research [19] on Croatian student population has confirmed those results and found that Croatian students see a role for the library inside their social network, and would like to use some of the library services in that environment, such as searching the catalogue or receiving useful and relevant notifications from the library.

User studies have shown that a large number of students have a profile on at least one of the social networking services, with Facebook being the preferred

one. In the area of library participation inside social networks, opinions differ: some librarians and students do not see a role for the library inside their social network, while others can see the benefits of extending library services in these new areas. Although the opinions are divided, authors agree that the emerging role of social networking services in the everyday life of library users will inevitably change library services in the future.

Content perspective

The third category of researches deals with analyzing the content that libraries post inside their chosen social networking service.

One of the first content analysis studies [20] surveyed 72 medical libraries and the content they post on their Facebook wall. It was shown that only 9 libraries use Facebook, mostly to promote library services and post photographs. Although the libraries using Facebook had positive experiences, small sample has limited the value of the conclusions.

Another research [21] analyzed 12 libraries and the content they post on their Facebook representations. It was shown that libraries mostly use Facebook as a marketing tool, while the area of communication with the library users was not that widely used.

A similar research undertaken by Calvi, Cassella and Nuijten [22] analyzed the Facebook content that 12 libraries posted in the period of 8 days. It was shown that libraries post only a few posts a day, mostly about library activities. Users were not that active on the library wall. Authors have concluded that further development of social networking services will enable more efficient ways of extending library services.

III. SAMPLE AND METHODOLOGY

The initial data was collected during July 2011 using several methods: a) examination of the Facebook page "Croatian Libraries on Facebook", b) entering the keyword "library" in Facebook search, and c) browsing all the gained results as well as browsing the libraries' "friend lists" and activities in order to discover new libraries. The collected data consisted of 91 libraries and their Facebook representations (profile/group/page).

First part of research analyzed library wall activity on the sample of 91 libraries, during the selected period of 14 days (May 30 – June 12 2011). This analysis included recording the number of new posts on individual page, profile or group opened by library.

The second phase of the content analysis attempted to organize the data according to specified content categories. From the original sample of 91 libraries, 27 libraries were excluded from further research due to their total wall inactivity in the selected period of 14 days. The overall sample for content analysis consisted of 64 libraries with the total of 402 individual posts, as shown in Table 1.

TABLE I. SAMPLE

Library type	# of libraries	# of posts
SCHOOL LIBRARIES	14	77
ACADEMIC LIBRARIES	14	50
PUBLIC LIBRARIES	36	275
TOTAL	**64**	**402**

The content analysis consisted of two types of data: the type of post and the post content. As for the type of post goes, the categories for analysis included library posts, user posts, pictures posted, user comments, library comments and the number of user "likes". Based on previous similar researches [21] [22], the probable content categories for published posts were defined in advance, but during the analyses some new categories were added. The final categories were: activities in the library, culture news, notifications about library services, useful/interesting links, new book arrivals, calls for cooperation, spam and "other". The results were collected and statistically processed in Microsoft Excel 2010.

IV. RESULTS AND DISCUSSION

First part of the content analysis recorded the types of posts libraries posted on Facebook. In a period of 14 days, the data on library posts, user posts, pictures, user comments, library comments and the number of user "likes" were collected. The aggregated data for all 3 groups of libraries are presented in Table 2.

TABLE II. TYPES OF CONTENT PUBLISHED

Library type	Posts	Photographs	Comments	Likes
SCHOOL LIBRARIES	77	127	53	204
ACADEMIC LIBRARIES	50	55	6	214
PUBLIC LIBRARIES	275	286	98	950
TOTAL	**402**	**468**	**157**	**1368**
STDEV	**6,52**	**18,65**	**5,61**	**38,14**

Statistical analysis of the data showed unequal distribution of some analyzed categories. Table 2 shows that the largest dispersion (standard deviation) of values was present in the number of photos and the number of "likes". These inequalities were also confirmed in a detailed overview of the results where it was shown that only one library was responsible for posting 125 out of total of 468 (26%) photos, and only 4 libraries with the biggest number of "likes" were responsible for over 40% of the total number of "likes". Also, the overall results show that 39 libraries (61%) didn't post any photos and 33 libraries (51%) didn't have a single comment on their posts.

Detailed analysis of post frequency shown in Figure 1 indicates that the majority of the libraries (58%) have a very small number of posts (0-3), and only a small number of libraries have more than 10 posts published in a selected period of 14 days (14%). It should also be noted that one library is solely responsible for 16% of posts in the sample of public libraries and 10% in the overall sample of 402 posts.

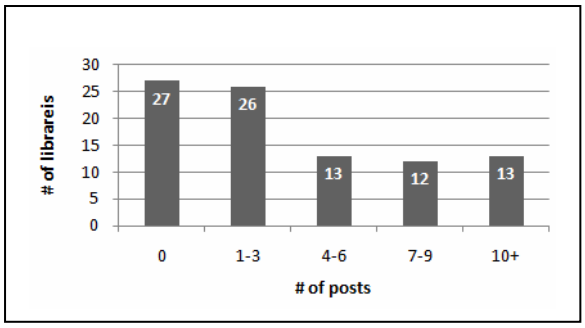

Figure 1. Library post frequency in a selected period of 14 days

When examining detailed data on total number of posts, this inequality becomes even more obvious. The results showed that 13 libraries with the biggest number of posts published (10-44) in a critical period were responsible for producing 50% of all the content. The other 50% was distributed on 51 other libraries. This clearly indicates that a small number of libraries are responsible for publishing a large amount of content, while majority of libraries only occasionally maintain their Facebook representations.

Next, posts and comments were analyzed regarding on the source – whether the posts and comments were published by the users or by the library. Figure 2 shows that the vast majority of posts (83%) are published by the library, while the most of the comments are published by the users (77%).

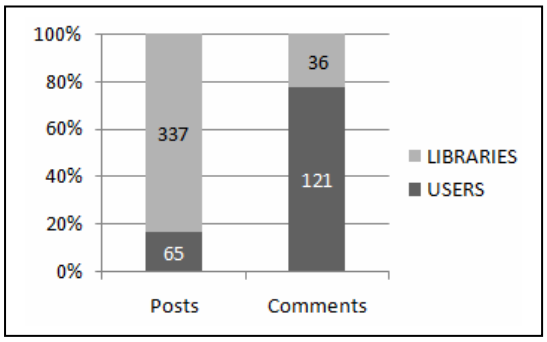

Figure 2. Comments and posts – library or users

The second phase of the content analysis attempted to organize the data according to specified content categories. In this part of the analysis, only library posts were examined except when user post would belong to the "spam" category, so the total sample included 375 posts. The total data for all 3 library categories are shown in the Table 3.

TABLE III. TYPES OF CONTENT PUBLISHED

Library type	Posts	%
Activities in the library	157	42%
Useful/interesting links	79	21%
Spam	44	12%
Notifications (working hours, etc.)	34	9%
Book arrivals	31	8%
Culture news	18	5%
Calls for cooperation	7	2%
Other	5	1%
TOTAL	**375**	**100%**

Overall results show that almost half of all posts fall into the category "activities in the library" (42%), followed by "useful/interesting links" (21%) and "spam (12%).

Detailed analysis showed some differences in content libraries publish regarding on the library type. In the group of school libraries, the majority of posts were equally divided between "activities in the library" (35%) and "useful/interesting links" (28%). In group of academic libraries the dominant content category was "useful/interesting links" with 51% of the overall posts. The third group, public libraries, had the most posts published in the category "activities in the library" (47%).

These differences between post content may indicate a more "social" dimension of Facebook representations of school and public libraries, achieved by posting more content on library activities. On the other hand, academic libraries are more oriented in providing useful content in the form of links potentially interesting to their users, maintaining a more "professional" approach to their Facebook users.

V. CONCLUSION

Although a fairly large number of Croatian libraries have a Facebook representation, only a small number of them are using it to its full potential. The analysis has shown that a small number of libraries are responsible for publishing majority of the content. Most of the libraries only publish one or two times a month, making their Facebook representations very inactive. On the other hand, those few libraries that post often, have managed to achieve an active communication dynamics with the users inside the Facebook environment. In exploring how this dynamics is created, a content analysis of library posts was undertaken to group the content in adequate categories and show what kind of content libraries publish. Libraries mainly used Facebook as a marketing tool, publishing content related to activities in the library. A significant number of library posts (especially by academic libraries) were aimed to foster user activity in the form of comments or likes, by posting interesting/useful links. In those cases, library would post content potentially interesting to users hoping it would foster user activity. This communication dynamics follows a simple pattern: library posts content, and users comment

on it, or "like" it. This is supported by research results where the vast majority of posts (83%) were published by the library, while the most of the comments were published by the users (77%). If the library manages to create this pattern of communication, their Facebook representation becomes very active and can generate a lot of content. This pattern is the model of success for those few libraries that have managed to use Facebook as a useful communication platform.

But, the need to carefully select and monitor the published content becomes obvious when we see that 12% of all posts fall in the "spam" category. Spam can be created by the library (mainly by playing Facebook games) or users (by using different Facebook applications). While the process of removing spam posts is fairly easy and quick, a large number of spam posts show a lack of knowledge about the Facebook platform and its potential threats.

The analysis showed that Croatian libraries still have a lot of space for improvement when it comes to integrating social networking into their services. Except from a few good examples, Facebook representations of libraries are often inactive, lack content and can generate spam posts. Also, using Facebook as a platform for extending library services (for example, searching the library catalogue or reference services) wasn't used by any of the libraries. Most of the Facebook representations are trying "to be where the users are", but a lack of proper strategy hinders them from using Facebook platform in its full potential.

Abstract - The main goal of this paper is to discuss the impact of personal learning environment (PLEs) on the process of e-learning. PLEs bring the radical shift on e-learning process not only how the educational technology is used but also on the organization of the learning process. Paper exhibits: the background of personal learning environments; the impact of PLEs on learning process especially when informal learning is in question; changes on learning process according to the implementation of Web 2.0 services; changes on accessing ways to Internet services and Web 2.0 services involved in social connecting, information sharing, discussing, knowledge collecting etc.; implementation of PLEs on personal learning management (PKM). This paper presents some of the results of a survey carried out at the Faculty of Economics and Business Zagreb about student's inclination for PLEs services.

I. INTRODUCTION

Personal Learning Environments (PLEs) help individuals to take s control of the learning and manage their own way of learning. That include support in determine individuals' own learning goals, in managing their learning processes and contents, in organizing ways of communication between individuals involved in learning process. The term PLE describes the tools, community and services that presents individual learning platform. Permanent necessity of new skills and knowledge brings changes on individuals' perception of learning and on the whole educational system. Individuals become more and more oriented on lifelong learning and at the same time the role of informal learning arises. In the context of new learning orientation, PLEs present a useful system or platform that should help people to organize their own learning process. Using new technologies, especially Web 2.0 tools, individuals become active participants in the process of learning and they create their personal knowledge and they developed their personal skills. They collect, classify, store, search, retrieve information, share knowledge; communicate, cooperate and discuss with other individuals of the same interests. New possibilities of mobile communication systems and mobile software applications allow individuals simple communication with members of learning community whenever they want as well as simple collection of information wherever they are. Personal knowledge management as a conceptual framework for knowledge managing, has to help individuals to recognize, organize and integrate accessible information in their own personal knowledge bases.. As information is fundamental part of knowledge, the main aim of personal knowledge management together with PLEs is to help individuals to select proper web 2.0 tools and apply it on the best way developing new knowledge and skills.

Paper is divided into six sections. After the introduction, in the second section the background of PLEs is described. The third section presents the reflection of PLEs on educational process analyzing it from three aspects: social software, Web 2.0 services and devices involved in PLEs. The forth section points out the relationship between PLEs and PKM. In fifth section the results of a survey carried out at Faculty of Economics and Business are presented. Conclusion follows in sixth section.

II. BACKGROUND OF PLEs

PLEs are systems that help learners take control of and manage their own learning supporting learners to set their own goals; manage their learning, both content and process; and communicate with the others in the process of learning [12]. The term personal learning environment describes the tools, communities, and services that constitute the individual educational platforms learners use to direct their own learning and pursue educational goals [11]. A PLE is characterized by the freedom use of a set of lightweight services and tools that belongs to and are controlled by individual learners [13]. From the mentioned definitions should be concluded that the main purpose of PLEs is to help individuals (learners and students) in learning process organization and in the realization of goals of education. As education is very multifunction system, the individuals during their lifelong learning pass through different types of learning (formal, non formal and informal learning), using information and internet technology (tools, services …). This points out that the role of PLEs is very important. The new educational imperative is to involve students to manage

their own learning in a variety of contexts building their own personal learning environments according to recent goals and interests [4]. PLEs should be accepted as the instrument that makes the process of learning easier to individual. At the same time, PLE is learner-centric system that supports self-oriented learning access or user-centric learning approach [9]. In that case the focus of learning process is the person itself. A PLE could allow a learner to configure and develop a learning environment to suit and enable their own style of learning [1] . It also put students in charge of their own learning processes challenging them to reflect on the tools and resources that help them learn the best [11]. Every learning environment is going to possess differing goals, differing resources and differing set of values. Although PLE helps student to create his own way of learning, student is self oriented in the moment when he has to decided when, where and how he will learn. The process of self-directed learning requires a degree of self-awareness, and it must be given a time to mature [11]. A student is involved in ongoing decision making process, but he also has to maintain, organize and grow his learning environment.

The interest for PLEs is increased together with the interest for e-learning. However, in the earlier phases of learning process the particular environments have already existed but were aligned to technological maturity of that time.

Schaffert and Hilzensauers [9] describe "seven crucial aspects of PLE". These aspects are: role of learner; personalization; content; social involvement; ownership; educational and organizational culture; and technological aspects. Student's or learner's role is changed mostly as a result of impact of Web 2.0 services on learning process. They become not only the consumers of learning materials (as they were before - using "read only" or Web 1.0 services), but active participants in learning content development (using "read/write" or Web 2.0 services). In that context, student's role is changed from the role of consumer to the role of "prosumer" [9]. Personalization, content and social involvement aspects are closely connected with self-directed learning concept where student is responsible for all his activities based on learning process. He has to decide what kind of software tools or web services he intend to use, how he will communicate with other students in the community, what information, knowledge and skills will share with the rest of the community, when and where will learn etc. Students prefer to develop and share learning materials with the community then to take care about the ownership of the materials they produced. Educational and organizational culture based on the usage of PLEs is characterized as "self-directed, decentralized, dynamic, communicative and situated within community of practice" [9]. Technological aspect of PLEs is closely connected with the characteristics of social software and web 2.0 services.

Blees and Rittberger point out on a trend in contemporary learning. Contemporary learning is based on more activities, self-productivity and self governing of involved students and the character of learning is shift from the product towards to process [2]. New students' generations have various PLEs resources on disposal that able them not to be restricted only on learning materials published on web (products) then that they can independently develop their own learning materials, cooperate and collaborate with students developing and sharing common learning materials (processes). These new trends are expressed by the learning theories of constructivism and connectivism [2].

III. REFLECTIONS OF PLEs ON EDUCATIONAL PROCESS

The reflections of PLEs on the learning process will be discussed from two points of view. First is the impact of Web 2.0, social software and devices (environments), on learning process and the second one is based on the influence of PLEs on the types of learning (formal and informal learning).

A. The impact of Web 2.0, social software and devices on learning process

The implementation of Internet and web services opened up the new possibilities in educational process management. Developing the new way of learning (e-learning), web becomes the central place for learning materials storage. Students should access to stored materials whenever they want, how many times they need and download materials on their computers. Although, at the beginning of web implementation, it made possible only an asynchrony or "Read only" communication, the access to web stored materials was easy and fast. But, the most important changes for e-learning process appeared with Web 2.0. One of most significant aspects of Web 2.0 for e-learning is the social aspect that can be summarized using 4C's [3]: Communication, Cooperation, Collaboration and Connection. Each of these activities contributes to the acquisition of knowledge in its own course while implemented through Web 2.0 services. The services themselves are mostly multifunctional, so while providing its intended functionality they provide additional functionalities and advantages. This means that an individual focused on improving his or her knowledge on a particular subject can do this either by (1) communicating with other individuals with similar interests, (2) cooperating with other individuals through sharing and exchanging content of mutual interest, (3) collaborating with others so that the mutual issue is being solved, developed and comprehended by adding new facts in a shared digital working environment, or (4) building contacts with individuals belonging to the same interest or social community. For all these activities (collaboration, cooperation, communication, connection), individuals use social software. The term social software

can be use for describing a wide range of social applications like wikis, weblogs, instant messaging social bookmarking, media sharing, social networking systems [9]. Social networking systems, in the context of personal learning, should be defined as Personal Learning Networks (PLNs). PLN presents an informal learning network where a person makes a connection with another person with specific intent that some type of learning will occur because of that connection [14].

Writing about attitudes of proponents of PLEs implementation, Sclater [10] diverge proponents in three different groups: first group argues that client software have to mediate between the learner, resources and facilitates on the Internet. The second group thinks that learners do not need any additional software and that they can reach resources and facilities they need from web servers using their web browsers. The third group argues that PLEs essentially already exist and that online learners use a range of online facilities.

Students feel computer as their primary learning tool, a base of PLE. In this content computer is a synonym for all digital devices, as well for desktop devices as for mobile devices, like laptops, tablets, PDAs, even mobiles. The presumption for all these devices is that they have access to internet and to main web 2.0 services. Students' mobility asks for same mobility of PLEs.

B. The influence of PLEs on the types of learning

It is unnecessary to argument about the necessity of lifelong education because lifelong learning becomes the style of life. Talking about lifelong learning we often refer to formal education, i.e. a basic education system, or to non-formal education through specific organized forms of acquiring knowledge via specialized courses. What is usually neglected and not mentioned is informal education. Studies have shown that informal education is the dominant one in a person's life, a person acquiring 70-75% of total knowledge through it [6]. It is estimated that 80% of all knowledge and skills is attained through informal types of learning [8], and that 70% to 90% of all learning activities have some informal properties [5]. Informal education is acquired through everyday activities, when a person freely chooses what knowledge and skills they want to master and the ways in which they want to accomplish it. A person has control over learning process and its results [6].

Connecting learning resources and types of learning, learning management system (LMS) plays an important role in formal educational, while the same roll belongs to PLEs in informal education. Using LMS students are consumers of pre-defined learning materials developed by teachers or domain experts. From the other side, using PLEs, students are active participants in learning content creating, self-directed according to all learning activities, opened for cooperation in community. LMS platform is formal, class-centric; PLEs platform is informal, student-centric.

IV. PLEs AND PKM

Personal Knowledge management (PKM) as a sub-domain of knowledge management proposes a model of knowledge management focused on individuals. PKM refers to collection of processes that an individual carries out to gather, classify, store, search, retrieve and share knowledge in his/her daily activities [15]. Initially, PKM was approached as a framework to organize the knowledge of individuals that is important for individuals. PKM as a conceptual framework for knowledge managing has to help individuals to recognize, organize and integrate accessible information in their own personal knowledge bases. From the other point of view, personal knowledge management is a theoretical frame that brings together technology, personal skills, practice and methods [7]. Analyzing presented above, the main task of PKM is to recognize and systemize technologies, software, skills and methodology, and according to students' requirements and PKM best practices and suggests students how to implement PLEs in learning materials collecting, developing, storing and sharing with community. PLEs are instruments of PKM strongly related in the process of knowledge acquirement needed for student's education.

V. RESEARCH METHODOLOGY AND RESULTS

A survey was carried out at the Faculty of Economics and Business, University of Zagreb, Croatia, at the course of Informatics, on first-year students, during the first semester of academic year 2011/2012. The survey covered themes specified in Informatics course syllabus. Students were polled five times during the semester. We gather students' attitudes about various themes like hardware devices, software applications, social software and social networking, e-business, e-learning, knowledge management etc. Students' attitudes relevant for the paper's topics will be presented in continuation. In this section we present students' attitude towards: (1) prerequisites for PLEs using, (2) social software, Web 2.0 services and mobile devices, (3) personal knowledge perception. First set of attitudes are focused on the time when students have started to use computers, do they have computers, how much time they spend using computer per week and what are the sources of their everyday's information. Second set of attitudes is concerned on the role of social software, Web 2.0 services and mobile devices in the process of learning materials collecting, educational contents development, knowledge sharing etc. Third set points out on the relationship between PLEs and personal knowledge management and on their influence on individual knowledge as the whole.

The relevant hypotheses that form the research are the following: (1) students' computer literacy and knowledge about information and internet technologies enable them to use PLEs in the process of learning; (2) students have high interest for Web 2.0 services and social networks but they use it more for leisure then for learning; (3) PLEs should help students in managing their personal knowledge.

The survey was carried out five times per semester and the sample of pooled students varied from 80 to 95 persons. The majority of students were female (average value is 53 or 59%) and the rest were male students (average value is 37 or 41%).

A. Prerequisites for PLEs using

Two main prerequisites for PLEs using are: (1) have a personal computer or device with the same functionality and (2) be enough computer literate to use information and internet technology.

Our first question (Table I) was concerned on the time when students started to use computers. Most students (76 of them or 80 %) started to use computer in primary school; even 16 students (16.84%) do it before the school.

TABLE I. TIME WHEN STUDENTS STARTED TO USE COMPUTER (Sample: 95 students)

Usage of computer	n	%
Before school	16	16.84
In primary school	76	80.00
In secondary school	2	2.11
At the faculty	1	1.05
Total	95	100.00

Results show that nearly the whole generation of polled students have reached their first experiences in manipulation of computers either in the childhood or as young teenagers. We should conclude that they have had enough time to develop their computer's skills and get used computers in everyday life.

As we have mentioned before, computer is the main environment within PLEs. Our next question was about possess or dispose of computer. Multiple-choice question was used. Table II shows that about 47% of polled students have their own mobile computer, nearly 40% of them have their own desk computer, 13% of them have a computer at home and share it with the members of the family.

TABLE II. OWNERSHIP OF THE COMPUTER (Sample: 95 students)

Ownership of computer	n	%
Own mobile computer	63	47.01
Own desk computer	53	39.55
Household computer	17	12.69
Have no computer, but use it	1	0.75
Have no computer and don't use it	0	0.00
Total	134	100.00

Only one student has no computer but he can use it. Further analyze shows that more than half polled students have two types of computer devices at disposal. Mostly it is a combination of mobile and desk computer or mobile computer and computer in students' household.

Further in our survey we wanted to know how much time do students spend using computer. Data shows that more than half polled students (nearly 60%) spend from one to two hours per day in average on a weekly basis; 24 of them (27%) spend up to two hours per day per week. It would be interesting to know how much time they spend being online because of learning or being there for fun enjoying on social networks or somewhere in virtual world. Unfortunately, we have no data about it.

B. The role of social software and social networking in the process of learning

In this part of the survey we were concentrated on the media as the source of knowledge needed for exams preparation; social software students used; social networks students used for connection and collaboration and the reasons for social networking. Also, we wanted to know student's attitude about mobile devices as the instruments of personal learning.

Next question was applied on the sources (media) where information needed for exam preparation is stored. Selected sources are in correspondence to the organizational concept of the course of Informatics. Students have at disposal: paper textbook and shortcuts of lesson's slides at faculty's intranet and notes made down during the lessons. Multiple-choice question brought 219 responses (Table III).

TABLE III. SOURCES OF KNOWLEDGE (Sample: 87 students)

Media	n	%
Classical paper sources (books, articles)	72	32.87
Own paper sources (notes)	42	19.28
Digital sources circulated around students	26	11.87
Sources on Intranet	65	29.68
Sources on Internet	14	6.39
Other	0	0.00
Total	219	100.00

Learning for the exam of Informatics students are oriented on the classical paper sources, (32.87%), lesson slides' shortcuts (29.68%) and paper notes(19.28%).. Unfortunately, from our experiences, learning for exams students are in general more oriented on lesson slides' shortcuts and their own notes than on paper sources like book.

We were interested to know students' attitudes about Web 2.0 services and social networks they prefer. For the next three surveys' sample were 94 students.

Next question offered six types of Web 2.0 services (social networking services were excluded) for which we

estimated that they should be more interested for students than others. Multiple-choice question was used and we have got 128 responses (Table IV).

TABLE IV. USE OF WEB 2.0 SERVICES AMONG STUDENTS

Services	n	%
Wiki	26	20.31
Blog	2	1.56
YouTube, Google! Video Yahoo! Video	93	72.66
Flickr	3	2.34
Delicious	0	0.00
Podcast	4	3.13
Other services	0	0.00
Total	128	100.00

The results show that nearly 73% of responses belong to YouTube and similar services, only about 22% of responses to Wiki and blog. It is hard to say for what these services are used because selected services should be used for fun or for serious learning. As, informal learning (learning from everyday situations) is dominate type of learning in person's education, students have used these services to master new knowledge and skills.

Only one student from the polled group has no profile on social network (Table V). All others have a profile on Facebook, some of them on other networks too. It means that they are social connected using network for various purposes sometimes for informal communication but also for collaboration and cooperation according to educational subjects.

TABLE V. STUDENTS WITH REGISTERED PROFILES BY SOCIAL NETWORKING SERVICE

Profile on social network	n	%
Facebook	93	80.87
MySpace	3	2.61
Twitter	9	7.83
Hi5	1	0.87
Linkedln	1	0.87
Other	7	6.08
No profile	1	0.87
Total	115	100.00

Next question was applied on the reasons of using social networks (Table VI). As the social networking is the most popular way of communication between young people, collected data are responded to the real situation.

TABLE VI. REASONS FOR SOCIAL NETWORK USING

Reasons	n	%
Communication with friends	85	43.37
Meet new people	18	9.18
Taking off contents for fun	31	15.82
Discussing about themes about study	58	29.59
Possibility to earn extra money	4	2.04
Other	0	0.00
Total	196	100.00

The top reason for social networking is, as it was expected, communication with friends. The second position belongs to discussion about themes about study. Social network offer users some sub-services like mailing, putting information on the "wall", discussing and commenting responsible contents, all in one place. As students used to be daily on line, social network should be an acceptable way of communication and appropriate source of information.

Mobility in everyday's life is not possible if persons are not able to have particular devices at disposal. It means that only mobile devices with functionality like classical on line computers would be able to insure accessing or storing information when it is needed. Students were asked to express the agreement or disagreement with the statement of that thesis. Creating this question a Likert scale was used ranging the answers on a scale 1(totally disagree) to 5 (strongly agree). Presented data show (Table VII) that 57 students (or more that 65%) were strongly or partly agree with that statement. But 7 students (or 8%) were mostly or totally disagree with the same statement.

TABLE VII: STUDENTS' ATITUDES ABOUT THE POSIBILITY THAT MOBILE DEVICES SHOULD BE ABLE TO SUBSTITUE CLASICAL COMPUTERS (Sample: 87 students)

Opinion	n	%
Strongly agree	22	25.29
Mostly agree	35	40.23
Partly agree	23	26.43
Mostly disagree	4	4.60
Totally disagree	3	3.45
Total	87	100.00

C Personal knowledge perception

In the next question, the perception of personal knowledge was oriented on the level of knowledge that individuals could reach during the education. As in the previous question, we have used same type of the question. The aim was to collect students' attitudes about the thesis that individuals are responsible by themselves for the level of knowledge they disposed.

TABLE VIII. STUDENTS' ATITUDE ABOUT THE POSIBILITY THAT INDIVIDUALS ARE RESPONSIBLE FOR THE LEVEL OF THEIR KNOWLEDGE

Opinion	n	%
Strongly agree	43	49.43
Mostly agree	36	41.38
Partly agree	7	8.04
Mostly disagree	1	1.15
Totally disagree	0	0.00
Total	87	100.00

Nearly 90% of polled students (or 79 of them) were strongly or mostly agree with this thesis. These attitudes confirm the fact that we learn the whole life but the dominate way of learning is changing over the life, and that we are personally responsible for all knowledge and skills we have collected during the life.

VI. CONCLUSION

In this paper the authors present the implementation and implication of PLEs on e-learning process. The paper is divided into two parts. In the first, theoretical part of the paper, authors introduce some definitions and the background of PLEs pointing on seven crucial aspects of PLE's. The reflection of PLEs on learning process is discussed from two points of view: from the impact of Web 2.0, social software and particular devices and from the influence of PLEs on the types of learning. The connection between PKM and PLEs in the process of learning is also discussed. Second part of the paper is applied to the results of the survey carried out at the Faculty of Economics and Business Zagreb.

Hypotheses defined in the study are proven by students' opinions and attitudes presented in the survey. Students' knowledge about internet technology and web services allows them to use PLEs (questions about the time when students started to use computers, about the computers they used and about the time spending on computers). Students have high interest for Web 2.0 services and social networking but they still use it more for leisure then for real learning (questions about the sources of knowledge, preferences about the usage of web 2.0 services, participations on social networking and reasons about social networks usage). Students' willingness to use PLEs in covering new information, knowledge and skills indicates that they are also ready to use PLEs in managing their personal knowledge.

Possible limitations of the study are based on the small sample of polled students used in the survey and on the fact that the survey was carried out not at once then at five times per semester. It implicate that students covered by the survey were not always but mainly the same persons.

Developing the course Database systems to respond to market requirements

P. Poščić*, D. Subotić*, M. Ivašić-Kos*
*University of Rijeka/ Department of informatics, Rijeka, Croatia
patrizia@inf.uniri.hr, dsubotic@inf.uniri.hr, marinai@inf.uniri.hr

Abstract - With a development of the information technology companies worldwide have been using database systems to store and retreive data about their customers, employees, business partners or products. This paper describes content and implementation of a Database systems course developed for undergraduate students at the Department of Informatics, University of Rijeka. Research was conducted on complexity and innovation of student projects (their own databases) and students' ability to recognize and respond to potential market requirements. Results will be presented in the paper.

I. INTRODUCTION

The database is a collection of permanent data used by a business application systems [1]. It contains data of different objects of the business system, such as business partners, products, services, orders, invoices, etc. The organization and development of a database is a fundamental activity performed during the development of a business information system.

The concept of a database starts from the point of creating a single set of data so that there are certain relationships between that data. This data set is used by multiple users or applications. Foundation of well-designed database is a comprehensive, non redundant and consistent conceptual, logical and physical data model. Thus, the database can be defined as a regulated, non redundant set of interrelated data.

The introduction of a database in an enterprise or institution is a complex task that requires team work of experts of various profiles. It can be divided into five phases: requirement analysis, data modeling, implementation, testing and maintenance [2].

First we must examine the information flows within the company. We observe data to be stored and connections between that data. Then, different views of data found in the requirement analysis phase, are synthesized into a single unit. Also, data types are defined precisely. The scheme is further "polished" (normalized) and adjusted to the limitations, set by the default data model. The scheme is also further modified to better respond to the requirements. From the scheme we then derive different views for specific applications or user groups. Based on the scheme and specific views and also with the help of available database management system (DBMS) the database is physically implemented on a computer. The database is then initially filled with the data. Users do test work with the database to check whether it satisfies all requirements. We try to detect errors that could have appeared in every phase of development: in the requirement analysis, data modeling or implementation. Maintaining the database takes place at a time when the database is already in a regular use. It requires constant monitoring of the database, in a way that it does not interfere with users and their work.

II. ABOUT THE COURSE

The course Database systems is a mandatory course on the second year of undergraduate study of computer science. The main objective of the course is to train students to work independently with relational databases. Emphasis is on lab exercises where students learn how to design their own database in the selected programming tool. At the end of the semester, students are required to develop their own application based on a relational database. A tool that is used for application development is called Clarion.

A. About Clarion

Clarion is a programming tool for fast and efficient way of developing applications based on relational database model. It belongs to the fourth generation systems (4GL), and it's developed by the American company SoftVelocity. Clarion is a tool independent of the type of database, which means it can work with virtually all databases. Also, Clarion offers tools to create data dictionary with all the necessary elements (tables, relationships, keys, constraints, etc.). It has its own database called Top Speed and an application generator that is directly related to the data dictionary. From an application generator Clarion derives the necessary information in order to generate parts of or the entire application. Application is generated in the source code of Clarion programming language, but we can also insert our own code in order to modify the application to better suit our needs. Exactly this ease of creating applications is the reason to continue using this software tool. Clarion allows us to select a level of programming that we need in order to build a database application, but in the same time monitors the development of database technology.

B. An example of data model and database

The organization and development of a database is a fundamental activity performed during the development of a business information system. This includes the creation of high quality data models. One of the main goals of good data modeling is to build a database that has a minimum redundancy, maximum integrity and consistency of data, adequate stability, adaptability, safety

and efficiency [3]. Therefore, the data model forms the basis for conceiving, designing and implementing databases.

For the purpose of the course, we use the entity-relationship model (conceptual model) and the relational data model (logical model). The great advantage of entity-relationship model is the ability to do a good graphical representation. Entity-relationship diagram greatly facilitates understanding of data models. In Figure 1. is an example used in the course; entity-relationship diagram for a company order forms. Entity-relationship model is then translated into a relational data model, which we can see in Figure 2.

Based on previous exemplar data models, students' task was to design a business application that will operate

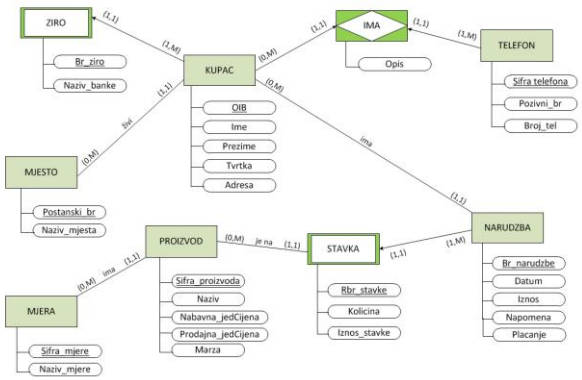

Figure 1. Entity-relationship diagram

KUPAC (OIB, IME, PREZIME, TVRTKA, ADRESA, POSTANSKI_BR)
ZIRO (OIB, BR_ZIRO, NAZIV_BANKE)
MJESTO (POSTANSKI_BR, NAZIV_MJESTA)
PROIZVOD (SIFRA_PROIZVODA, NAZIV, NABAVNA_jedCIJENA, PRODAJNA_jedCIJENA, MARZA, SIFRA_MJERE)
MJERA (SIFRA_MJERE, NAZIV_MJERE)
NARUDZBA (BR_NARUDZBE, DATUM, IZNOS, NAPOMENA, PLACANJE, OIB)
STAVKA (BR_NARUDZBE, RBR_STAVKE, KOLICINA, IZNOS_STAVKE, SIFRA_PROIZVODA)
TELEFON (SIFRA_TELEFONA, POZIVNI_BR, BROJ_TEL)
IMA (OIB, SIFRA_TELEFONA, OPIS)

Figure 2. Relational data model

on the database by entering data into the database and using them in different views. To define the architecture of a software product (application) we use method for modeling the architecture of the software product (APP). The structure of a software product is graphically represented in a software product diagram (DPP) [4]. An example is shown in Figure 3. In Figure 4. we can see an example of application screen.

III. RESEARCH

In the academic year 2011./2012. we plan to introduce into the course a correlation between the development of database technology and the current market situation. In this way students could develop an awareness of market demands. Also, students could identify successful industries and get more insight into business operations of those industries, to which they could then direct the development of their own applications.

Figure 3. Software product diagram

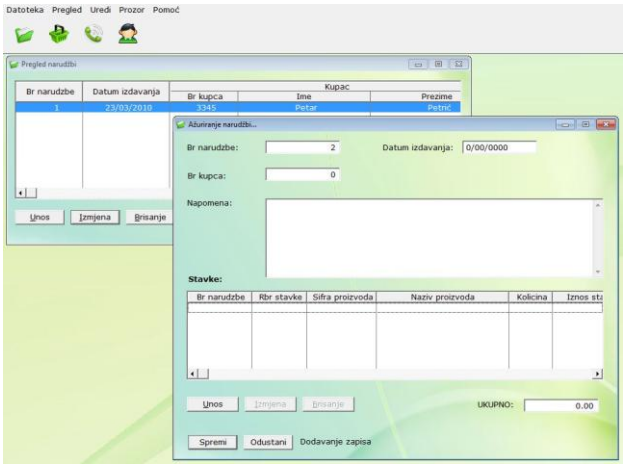

Figure 4. Example of an application screen

We know that the productivity and quality of application increases, if the software engineer is familiar with the business area for which application is made [5]. Last academic year, at the end of the course, students filled out an informal questionnaire about their applications. They were asked what they think might improve the results (score on the course and quality of their own applications) and facilitate the process of building applications. 81% of students think it would help if they knew more about the business area (domain) and business operations of companies for which they were building applications.

It is for this reason we plan to introduce into the course the annual analysis of market requirements, in order to demonstrate development of business applications for currently leading business areas. The content of exercises will change depending on the annual leading business areas; we will include modeling of business applications for several major business areas in the lectures, while in the lab exercises we plan to build application for only one chosen business area. In this way, students will gain knowledge and better understanding of business processes in the selected business areas, in order to successfully pass the course, and better prepare for the labor market.

To check the quality of student applications so far, we conducted a research on a sample of 52 second-year undergraduate students. The research included all students

who enrolled Database systems course in academic year 2010./2011. The goal of the research was to discover a way of enhancing the quality of student applications and to find a way to make a connection between Database systems course and current state of the market. We believe that students can produce better applications if they have (pre)knowledge of a business area for which the applications are built (and thus have a greater motivation for work). That was the general research hypothesis. We gathered 52 student applications and categorized them by business area (domain), complexity of data models, complexity of applications and innovation. The quality of an application (and a final grade in the course) was measured through these elements. Also, we examined data on employment and the state of the market taken from the Croatian Employment Service and the Central Bureau of Statistics.

A. State of the market

According to the Croatian Employment Bureau in March 2010 the number of employees decreased by 6.6% compared to same period in the year 2009. Number of persons in paid employment decreased by 5.9%, while the number of employed in crafts and free lances decreased by 9.5%. For paid employment, business areas in which there is a rise in the number of employees are the real estate business (8.7%), education (2.3%), administrative and support activities (1.9%) and arts, entertainment and recreation (0.2%) [6].

According to the Central Bureau of Statistics, in the year 2010, most people were employed in construction and mining, water supply and electric power, transport and storage, education and health and social care [7]. According to this data, we can choose several major business areas to process in the course (e.g., construction, education, transport and storage, health and social care or arts, entertainment and recreation).

B. Research results

Figure 5. represents a division of student applications by business domain. We can see that most students (23% of the total number of submitted applications) decided to go with topics in art, entertainment and recreation. These were mostly business applications for fitness centers, cinemas, theaters, concerts, amusement parks, etc. 13% of students decided to go with the topic in health and social care (hospitals, the general practice of medicine and dentistry, pharmacy, retirement homes, etc.), 11% of students decided to go with the topic in the education (university, school, kindergarten, libraries, etc.) and transport (rail operations, airports, highways, parking lots, etc.), while the smallest number of students (4%) chose the topic in the finance, sports and real estate. As the reason for the selection of topics in these areas, students state the fact that these are business areas with which they are most familiar and have the best understanding of their business processes.

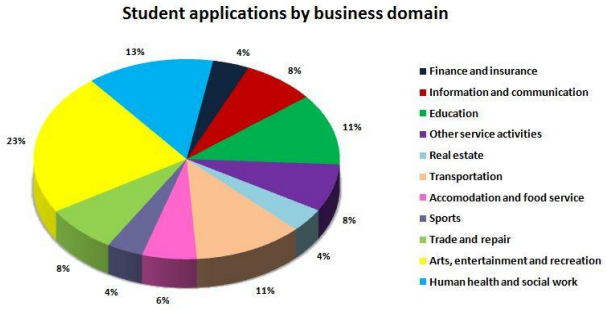

Figure 5. Student applications by business domain

Figure 6. shows the complexity of student data models. We measured complexity of data models by the number of entities, attributes, aggregations and weak (child) entities. The more of these elements a data model has, the more it is complex. Data model with a greater level of detail shows that student has knowledge and comprehension of selected business area. We can see that the largest number of entities (100) and associated attributes (411) have data models in the business area of arts, entertainment and recreation. The share of weak entities in the total number of entities is here 18% and of aggregation is 11%. This result is not surprising, given that most students (23%) chose the theme in that business area. The biggest number of weak (child) entities is used in the business area of real estate (28%), and the biggest number of aggregations is used in business areas of trade and services, and information and communications (19%). However, we can conclude that the most complex data models belong to the business areas of sports (complexity coefficient 0.39) and finance (complexity coefficient 0.37), while the simplest data models can be found in the areas of health (0.11) and the arts, entertainment and recreation (0.06). The complexity coefficient is calculated by the formula

$$K_s = [1-(S+A)]/N_m,$$

where K_s is the complexity coefficient, S is the number of weak (child) entities in the total number of entities in the data model, A is the number of aggregations in the total number of entities in the data model and N_m is an amount of data models within the business domain.

Figure 7. shows the complexity of student applications. We measured complexity by the number of browse and lookup procedures, number of reports and amount of student embedded code, within each business domain. More complex applications (with a larger number of procedures and reports, and a significant quantity of embedded code) show that students are more familiar with the business processes of the selected business area. Therefore, they can better customize the functionality of

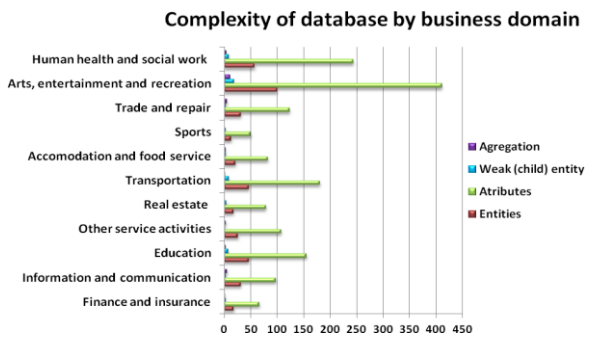

Figure 6. Complexity of student databases by business domain

the application to the requirements of specific business area. In this way, applications with a greater level of detail are built. Students can devote more time to researching the features and options of a programming tool with which the application is built, rather than learning about business processes (they already know and understand them). By understanding the business processes of a selected business area, students become better prepared for future work and market requirements. Based on the research, the biggest number of browse and lookup procedures and reports has applications in the business area of arts, entertainment and recreation. However, the amount of student embedded code, in relation to the number of browse procedures, is here 45%. Interestingly, student applications in the business area of trade and services (chosen by only 8% of students) have the highest ratio of browse procedures and student embedded code (52%). This may be due to peculiarity of this business area and opportunity for different ways of modeling and building business applications.

Figure 8. shows the level of innovation in student applications, within each business domain. We measured innovation by the number of new elements presented in the application, which were not shown or processed during the course lab exercises. By measuring the innovation we can also get an insight into the student's knowledge of the selected business area and level of motivation for an additional (optional) work in the programming tool, Clarion. If the student knows and understands the business processes and can easily and quickly build high-quality data model, he/she can focus on exploring and researching the features and options of the programming tool. With a better knowledge of the tool, student can build an application with various new elements which were not demonstrated in the classroom and which he/she added into the application on the basis of his/her own research. These new elements can be various accessories and business area-specific functions and add-ons, such as original calculators, unit converters, custom reports, etc. Therefore, by measuring the innovation we can estimate how the quality of applications (also, final grade in the course) depends on knowledge and understanding of business areas for which applications are built. Based on the research, the highest level of innovation has applications in the business area of information and communications (36%). These were mostly business applications for television stations, radio stations, telecoms, forums, internet business, etc. This is not surprising, considering that the students of this new information age may be most familiar with the area and therefore can generate the most ideas.

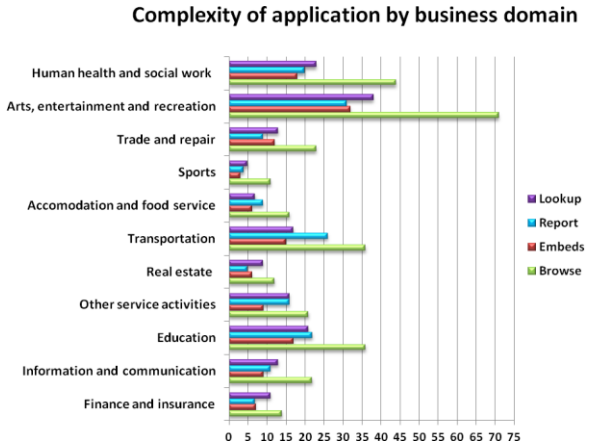

Figure 7. Complexity of student applications by business domain

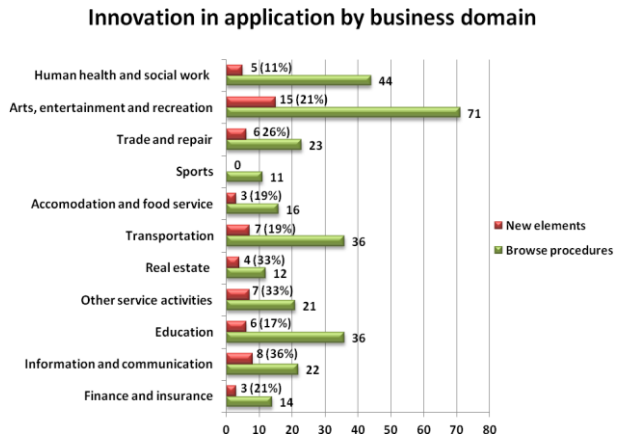

Figure 8. Innovation in student applications by business domain

These results are important to us to be able to choose the best future direction of teaching the course. With the insight into the business areas that have positive employment growth and development, we can more easily focus education and students' interest in that direction. This could have positive consequences for individual students and for industry. The changes will be introduced into the course this academic year, but also we plan to compare the number of passing students and quality of student applications from last academic year with the results from this academic year.

IV. CONCLUSION

Information technology is now an integral part of business. Huge amounts of data and complex business processes condition a fact that without information technology business is almost impossible. Due to the rapid development of information technology, what once was the culmination of innovation, has become of-date. There are new tools and software products that modernize, accelerate and optimize business generally, so it would still remain competitive. These solutions are based on the collection, processing, storage and availability of information that gives us insight into business knowledge and state of the entire business. That's why we believe it is important in the educational system already to make the connection between development and use of technology and market requirements. For the future designers and developers of business applications certainly is a useful skill to recognize, predict and follow market trends, and be able to understand the business processes of various business areas, so they could meet the demands of industry properly.

The results of the research conducted at the Department of Informatics are showing exactly that. We

got an insight into the business areas that are of most interest to students and whose business operations they mostly understand. Also, we measured the level of complexity and innovation of their applications and data models in these business areas. We noticed that students, when building an application, are already intuitively oriented towards the business areas whose business processes they understand and with which they are most familiar. Students who are more familiar with the selected business area (they have pre-knowledge of a business area and its processes), have better applications and higher grades. Therefore, modeling a business system and setting up the basic structure of application is not a problem for them. Also, they can focus more on design, research of the programming tool's features and options and working in the tool. These students have a greater motivation for learning how the programming tool works and for creating a higher number of additional elements and functionalities specific for the business area for which an application is built. In this way, applications have higher quality and students are becoming more qualified and better prepared for the market requirements. We believe it is definitely worth to introduce changes to the course, associate it with an assessment of market requirements and introduce further exploring of the business processes of several leading business areas. Our goal is to achieve a high level of complexity and innovation in student applications. In this way, students will have sufficient knowledge of the current major business areas and their business processes. Therefore, they would be able to focus on various ways to enhance the quality of an application, rather than on understanding the business processes. We plan to continue research in the academic year 2011/2012 and make a comparison with data on the complexity and innovation of student data models and applications presented in this paper.

ViSA: Visualization of Sorting Algorithms

I. Reif and T. Orehovacki
University of Zagreb, Faculty of Organization and Informatics, Varazdin, Croatia
{ivan.reif, tihomir.orehovacki}@foi.hr

Abstract - Algorithm analysis and design is a great challenge for both computer and information science students. Fear of programming, lack of interest and the abstract nature of programming concepts are main causes of the high dropout and failure rates in introductory programming courses. With an aim to motivate and help students, a number of researchers have proposed various tools. Although it has been reported that some of these tools have a positive impact on acquiring programming skills, the problem still remains essentially unresolved. This paper describes ViSA, a tool for visualization of sorting algorithms. ViSA is an easy-to-set-up and fully automatic visualization system with step-by-step explanations and comparison of sorting algorithms. Design principles and technical structure of the visualization system as well as its practical implications and educational benefits are presented and discussed.

I. INTRODUCTION

Programming courses are a fundamental part of both computer and information science curricula. Their purpose is to introduce basic programming concepts (e.g. control structures, aggregation mechanisms, sorting algorithms, etc.) to students, thus helping them to acquire programming skills. This goal is often very difficult to achieve and according to some studies (e.g. [28]), introductory programming courses have relatively high dropout and failure rates. Nevertheless, a tremendous variation in pass, fail, abort and skip rates were reported by Bennedsen and Caspersen [2]. It should be noted that the higher average passing rate was established at colleges (88%) than at universities (66%). The most common reason for failing a course was the abstract nature of programming concepts since this was the first course where students were confronted with programming. According to Radošević et al. [1], the main problems in learning programming are: lack of previous knowledge, problem-solving algorithms, fear of programming, and the perception of difficulty of programming language syntax. They also discovered that problem-solving algorithms are perceived as a much greater obstacle than programming language syntax itself. Regarding the problems related to the C++, programming language syntax, research on compilation behavior [20] has reported that most common mistakes made by novice programmers are: use of undeclared variable, defining variable within iteration, wrong operator in the logical expression, etc.

The objective of novice programmers is to implement the abstract process of algorithm execution in a way or language that will be understandable to the computer. However, if a programmer wants to 'explain' something to the computer, he or she first has to understand it perfectly. Namely, it is very difficult to understand and learn complex algorithms such as iterations, recursions or sorting algorithms only by watching code lines or a flow chart. On the contrary, if students can control their own data sets and see the whole process of algorithm execution, they are able to draw conclusions from the resulting data or in course of the algorithm visualization.

The aforementioned claims have motivated researchers to develop tools that will simplify and facilitate the learning of programming concepts, thus helping students to acquire both programming knowledge and skills. With an aim to engage students in learning activities, the implementation of a visualization technology within educational process has been proposed [8][27]. The earliest examples were slideshow presentations or simple web interfaces with basic structures and operations [3], [5]. Later, more advanced tools such as DrScheme [29] or Robolab [30] were introduced. However, a mere development and deployment of visualization tools is not enough to attain an objective of learning complex algorithms. Hansen et al. [6] suggested that visualization technology should involve students in activities such as the construction of their own input data sets and interaction with animation, which will eventually result in their own predictions and logical conclusions.

With an aim to facilitate the understanding, analysis and design of sorting algorithms, a tool for their visualization called ViSA is presented in this paper. Using ViSA, students are guided in the learning process by a detailed step-by-step explanation. The remainder of the paper is structured as follows. Section 2 provides a brief literature review. In section 3, specific features and examples of ViSA use are described. Section 4 presents the results of a pilot study on perceived usefulness, perceived ease of use, behavioral intention, and attitude towards use of ViSA. Concluding remarks and future work directions are provided in the last section.

II. RELATED WORK

A gap between the way in which algorithms are taught and the students' learning style is one of the main reasons why introductory programming courses are perceived as hard. Namely, while the majority of people are visual types [7], teaching, to a great extent, is verbal. Visual learning is a type of learning where people prefer using images, pictures, colors, and maps to organize information in order to comprehend complex concepts. This is the main reason why algorithm visualization (AV) tools are implemented in learning process. In literature there are a lot of AV tools such as Alice [9], Software Visualization

System [7], Jcat [10], Guido von Robot [11], Samba Algorithm Animation System [12], JHAVÉ [4], etc. Most of them contain a set of control options for the user and can run in a step-by-step mode. On the other hand, only some of them allow the user to adjust the speed of animation (e.g. Samba [12]). Moreover, the feature allowing the user to going backwards a certain number of steps as in DDD [13] is relatively uncommon.

There are two types of AV: animation and simulation tools. Algorithma 99 [14] is an animation tool that enables the user to enter algorithms in a predefined pseudo-code language which can then be visualized. Such a method of animation requires the knowledge of setting up the pseudo code and linking it with control elements which then execute the animation. Systems like JAWAA [15] and JSamba [4] simulate the algorithm provided in a special syntax that needs to be learned prior to starting using the tools.

There are several animation tools based on interpreting source code, such as Zstep95 [16]. However, without precognition related to system expressions and their contribution to the animation, user cannot make the decision whether to use the details (animation controls) or an expression. On the other hand, if all elements are enabled and shown during animation, some key parts needed for the understanding of algorithm could be overlooked.

The KAMI system [17] is an animation tool that relies on debugging data and generates a slide-by-slide display illustrating the code execution. Slide by slide animations are not controlled by the user or reviewed by the instructor so they might present excessive additional information. Jeliot [18] reads Java source code and automatically generates visualizations. This tool does not offer the explanation of any step executed during animation and is limited only to java source code.

BlueJ [19] is one of the first systems developed to teach introductory object oriented programming. The key feature of the system is the static visualization of a class structure as a UML diagram. Furthermore, it allows the learner to interact with the objects by creating them, calling their methods, and inspecting their state with easy-to-use menus and dialogs. However, it does not provide any dynamic visualization of the program.

Simulation tools are more user-friendly and useful in teaching programming. One of them is Alice [9], a general purpose simulation tool aimed for teaching any kind of programming concepts. However, before it can be used for teaching specific algorithms, the user has to learn its specific syntax. In addition, it does not allow any interaction with animation during programming. According to Hansen et al. [6] the use of Alice produces a great deal of time wasted on learning a new syntax instead of learning the algorithms at hand. For example, to create a simple iteration, a user would have to know how to use the syntax, set up 3D models, and implement the triggers that interact with the models. Setting up a tool like Alice would also require intense preparations on the host computer such as 3D driver installation, etc.

A similar tool aimed for teaching programming and algorithms is Guido von Robot. It is not 3D based, but instead uses its own programming syntax which is entirely written in Python. When working with Guido von Robot [11], similar problems occur. Although the knowledge of triggers and animation is not required here, a more complex syntax is still used. Guido von Robot is a simulation tool made of two basic parts: pointer, and array of dots. The pointer represents the current position of data in the algorithm while the array of dots represents the path which the data take. This is why the user has to integrate the pointer move commands inside the code itself. The user also needs to know what the code does in order to integrate the data for moving the cursor correctly, which makes the process of learning a new algorithm much more difficult than necessary.

While the aforementioned tools are aimed for learning programming in general, the tools described below are intended for sorting algorithms visualization. Jcat [10] is a web based simulation tool developed in the Java programming language. Unlike the afore-mentioned tools, it enables sorting algorithm visualization and provides information related to the steps taken during simulation. However, it has a number of drawbacks. Users are not allowed to customize the array size or elements value, which constrains interaction. Furthermore, users cannot control the speed or flow of animation and the information that is shown during the animation does not explain why certain elements are swapped or compared. Executing web based applications also implies several potential problems such as missing add-ons that are required for code execution.

Animal [21] animations include a linked sequence of animation steps operated by the pause, stop, play and rewind buttons just like any other visualization tool. The main window is sectionalized in three segments. A control tool bar at the top of the windows allows adjusting the display speed and magnification. A tool bar at the bottom contains control elements for triggering the animation display and the last part is the pseudo-code area. Animal provides several different control mechanisms for selecting the current animation step: a control tool bar, a list of labeled animation steps, a slide ruler, and text field for direct input. The main advantage of this tool is its support to rewinding an animation or skipping to a certain step. However, it has serious problems with screen resolution. Namely, data containers, graphs, and pseudo-code will change their positions or completely cover the animation control if the screen resolution is changed. Additionally, this tool does not provide any information about the steps that are taken during the animation.

Software Visualization System [7] is very similar to ViSA. It allows users to select one of the sorting algorithms and, subsequently, to fill in the array data and run the animation. The main window is made of four panels. The first panel presents the execution of the algorithm in an array. Along with the execution panel, the interface also contains a pseudo-code panel, where users can learn the algorithm during code creation. Beneath the pseudo-code panel the execution status messages panel is located which shows the steps during the animation. Next to it is a panel which shows variables in use. Although this

kind of window organization does not explain steps in which specific elements are swapped or compared, it shows the user full algorithm information. Nevertheless, it does not support more than seven elements in the array. We believe that customization of the numbers of elements in an array is very important because some algorithms work better with larger arrays than small ones. Given that Software Visualization System does not support changing the size of an array, it is not really possible to compare two different sorting algorithms. Finally, the lack of multi-threading, which means that only one algorithm can be executed at the same time, presents the greatest disadvantage of this tool.

III. VISUALIZATION OF SORTING ALGORITHMS (VISA)

The purpose of ViSA is to provide an easy to use learning interface with as much as possible feedback information presented to the user through explanation. As mentioned earlier, a good AV tool has to allow a quick integration, where one-click setup is enough to have the software ready for use and enable users to construct their own input data sets and interact with the visualization. ViSA installation is powered by the Microsoft click-one install method [22], where the software automatically downloads all the necessary drivers and after the installation it runs entirely by itself.

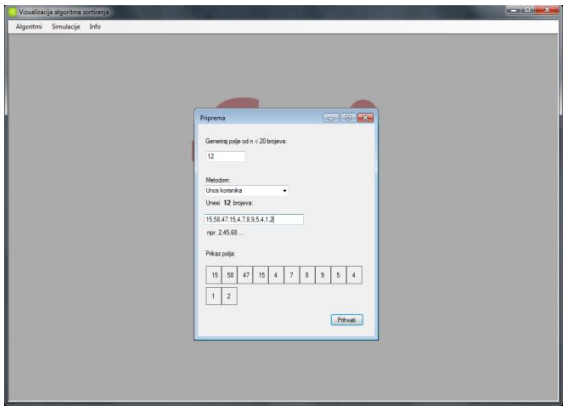

Figure 1. ViSA data set construction

ViSA supports well known sorting algorithms such as Cocktail Sort, Comb Sort, Heap Sort, Insertion Sort, Merge Sort, Quick Sort, Selection Sort, and Shell Sort. After choosing an algorithm, the user is prompted with the data set construction form. The form elements (textboxes, labels, array preview) are dynamic, thus allowing the user to make changes at any time without preventing the software to receive the correct data input. In case of an error committed by the user, he or she will receive a warning about the wrongly entered or inaccurately formatted data. The user can select among a range of methods for generating random numbers such as pure random, big values at the end, small values at the end, or almost sorted. If the user wants to enter specific values, he or she will simply enter the numbers in the empty textbox delimited with a coma and an array preview will be generated. When the user has finished with setting up the data set, ViSA runs a final data format test and allows the user to proceed. This form of input generation is constructed in a way to be forwarded to the visualization, allowing the students to learn whether their data set drives the animation in the anticipated manner. The animation sequence is generated dynamically, as presented in the code block 1. After each comparison or swap, the information about the elements is added to the Listbox queue.

```
    Do

        blnSwapped = False

        For i = iMin To iMax

        ListBox1.Items.Add((i.ToString + "|" + (i
+ 1).ToString).ToString())

              If Array(i) > Array(i + 1) Then

        ListBox1.Items.Add((i.ToString + ">" + (i
+ 1).ToString).ToString())

                           varSwap = Array(i)

                           Array(i) = Array(i + 1)

                           Array(i + 1) = varSwap

                           blnSwapped = True

                      End If

                Next

     ListBox1.Items.Add(((iMax  +  1).ToString  +
"+" + (iMax).ToString).ToString())

                iMax = iMax - 1

    Loop Until Not blnSwapped
```

Code block 1. Bubble Sort

After the algorithm is finished, the actions for the visualization are executed from the Listbox one by one. This is the reason why it is very easy to add more algorithm examples to the ViSA repository. If an algorithm is added, any of the control elements can be activated by inserting the appropriate syntax, as shown in code block 2.

```
ListBox1.Items.Add((i.ToString + ">" + (i +
1).ToString).ToString())
```

Code block 2. Control elements syntax

The function Listbox1.Items.add receives three parameters: (i) *i* that represents the first element, (ii) string ">" that represents a comparison action, and (iii) *i+1*, a variable that contains the second element.

Figure 2. ViSA main window

The ViSA main animation (presented in Figure 2) window is composed of several standard controls: (i) oval shapes that represent elements in an array, (ii) slider for controlling the animation speed, (iii) start and stop button, (iv) information about complexity of the algorithm including the number of swaps and comparisons that are executed during the animation, and (v) the panel on the right side that contains explanations of each step that is taken during the visualization. The animation flow can be controlled by the user with the next button that will either execute one step at the time or fully automatically. Additional controls are added to each sorting algorithm for better understanding of the algorithm (e.g. a data structure-max tree for Heap sort or a divided sub-array in Merge Sort). After each action (swap, comparison, interval readjustment or pivot update) an appropriate explanation is shown in the bottom right area. The animation playback has two modes: automatic and step-by-step mode. In any of these two modes the user can pause the animation and read the description of the current action. The most appropriate mode for novice programmers is the step-by-step mode, where the user is able to see every action during the visualization and read the corresponding explanation.

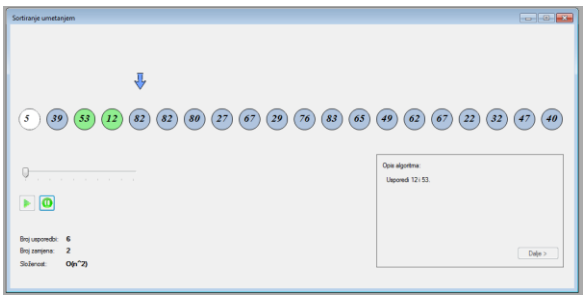

Figure 3. Array controls

For easier understanding of the actions that are happening inside the array, additional controls (shown in Figure 3) have been implemented. Controls like pointer (arrow) represent the end of the sorted part of the array (in the case of Insertion sort) or pivot (in the case of Quick sort). If necessary, each control can be used for any other algorithm, to either provide a more detailed explanation or support the visualization. Colors like green and white are used to flag the status of the element in the array. Green informs the user that two elements are being compared or swapped, while white notifies the user that the element has been sorted and is positioned at its final place inside the array. The last control is the interval marker. With the interval marker we can visualize the size of a sub-array in Shell Sort or intervals that are being sorted in Quick Sort. All the controls are dynamically created, which means that one or more controls can be used at the same time. Using the aforementioned controls provides the user with a full visualization of actions that are happening inside the array, making them easy to remember.

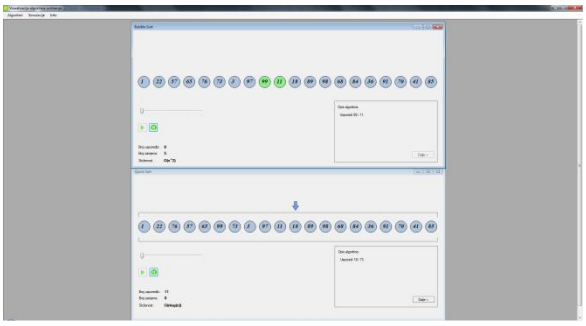

Figure 4. Simultaneous animation

Figure 4 illustrates one of ViSA's special features – simultaneous visualization of selected sorting algorithms. This feature allows the user to compare the speed and complexity of the sorting algorithms that have been selected. The user can sort the same array with any algorithm from the list or choose a new data set for a particular algorithm. If all algorithms are executed for the same initial array, it is possible to run a real time speed test. In that case, the visualization window is minimized to the bottom part of the form container, enabling the user to access any of the running algorithms. Given that some algorithms perform more comparisons at the beginning and finish with a quick series of swap actions, users can compare the number of actions for each algorithm in real time. In order to enable as much user interaction as possible and stimulate users' logical conclusions, ViSA is supplemented with algorithm analysis (Figure 5).

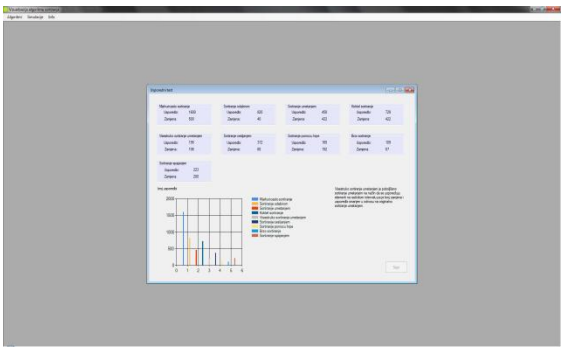

Figure 5. Algorithm analysis

Algorithm analysis allows the user to select a data set, executes all the sorting algorithms for the same array, resulting in a simple benchmark of sorting algorithms shown as a graph. The columns in such a graph represent the efficiency of sorting algorithms. By observing analysis results, the user can easily make a conclusion on the complexity of the compared sorting algorithms. The benchmark test can be run to a maximum of the integer array size, thus providing a very accurate method of comparing algorithms. The input data set can be constructed in the same manner as the visualization, but by using different array setups algorithm methods can be fully analyzed since some algorithms work faster or perform fewer element swaps if the array is formed in a certain way. For example, the Quick Sort algorithm will

not be executed in the same manner every time since the pivot element is randomly selected and the algorithm has to go through the whole array even though the array might already have been sorted. On the other hand, Bubble Sort is quite an old and slow algorithm that will still perform very well on an almost sorted array. An additional feature of algorithm analysis is that when the user drags a mouse pointer over a particular algorithm, a detailed explanation of the algorithm as well as its comparison with similar algorithms is provided.

IV. MODELLING THE ACCEPTANCE OF VISA

With an aim to investigate the perceived ease of use, perceived usefulness, behavioral intention, and attitude towards using ViSA, a pilot study was conducted. A total of 76 information science students participated in the study. The sample was composed of 65 male (85.5%) and 11 female (14.5%) students. The majority of them (94.7%) were enrolled in the second year of study. Data were collected with an online questionnaire survey. The average age of students was 20.39 (SD = 0.994). Before taking part in the survey, students had used ViSA during one lab-based session. The responses were modulated on a five point Likert scale (1-strongly agree, 5-strongly disagree). The Cronbach's alpha values ranged from .668 to .808, thus indicating sufficient reliability of the scale for exploratory research [23][26]. In order to ensure content validity, the questionnaire items were adopted from previous research on this topic [24][25].

As can be observed from the responses to survey items which are presented in Table 1 (Appendix A.), the majority of students perceived ViSA as a useful and easy to use tool aimed for learning sorting algorithms. For instance, in case of the survey item "Using ViSA would enable me to learn sorting algorithms much faster than learning from textbooks." 90.8% of the students responded with "Strongly agree" or "Mostly agree". Furthermore, 82.9% of the participants responded in the same way to the survey item "Using ViSA would help me to understand sorting algorithms much easier than during classes." Also, in case of the survey item "My interaction with ViSA would be clear and understandable." 98.7% of the students responded with "Strongly agree" or "Mostly agree". Finally, as many as 96.1% of the participants responded positively to the following statement: "It would be easy for me to become skillful at using ViSA." The aforementioned results indicate a positive attitude towards ViSA as well as the behavioral intention regarding its use.

V. CONLUSION

The purpose of our research was to develop an educational tool that would engage students in the learning process, helping them to acquire knowledge about well-known sorting algorithms. Visualization of sorting algorithms (ViSA) offers a full range of functionalities such as data set entry and animation control as well as the explanation and detailed algorithm analysis. Using ViSA, the learning curve and time spent learning and understanding should be significantly reduced. ViSA creates a bridge between students and algorithms in a manner that removes the need for writing the programming code, thus reducing the fear of programming. Once they have familiarized themselves with the algorithm, students would access programming with much more confidence. According to the results of our pilot study, ViSA is perceived as an educational tool whose usefulness and ease of use contribute to a positive attitude and behavioral intention regarding its use.

In our future work, we plan to extend ViSA with additional pedagogical features such as a pop-up form that would prompt the user with a question regarding a specific algorithm. Supplementing ViSA with such features may enhance its pedagogical usability and stimulate students' creative and logical thinking. Given that all forms and controls are created dynamically, we intend to supplement ViSA with visualization of other programming concepts such as data structures. Finally, we will also expand our research efforts related to the acceptance of ViSA.

APPENDIX A.

TABLE I. SUMMARY OF MEASUREMENT SCALES

Items	**Mean**	**SD**
Perceived Usefulness (Cronbach's α = 0.668)		
Using ViSA would enhance my efficiency in understanding of sorting algorithms.	1.41	0.570
Using ViSA would enhance my effectiveness in understanding of sorting algorithms.	1.55	0.551
Using ViSA would enable me to learn sorting algorithms much faster than learning from textbooks.	1.61	0.750
Using ViSA would help me to understand sorting algorithms much more easily than during classes.	1.89	0.741
I would find ViSA useful for learning sorting algorithms.	1.37	0.538
Perceived Ease of Use (Cronbach's α = 0.808)		
Learning to operate ViSA would be easy for me.	1.36	0.534
I would find it easy to get ViSA to do what I want it to do.	1.64	0.725
My interaction with ViSA would be clear and understandable.	1.37	0.512
I would find ViSA to be flexible to interact with.	1.96	0.720
It would be easy for me to become skillful at using ViSA.	1.45	0.575
I would find ViSA easy to use	1.39	0.591
Attitude Towards Use (Cronbach's α = 0.777)		
I think it would be very useful to use ViSA in programming related courses.	1.43	0.574
In my opinion, it would be very desirable to use ViSA in programming related courses.	1.42	0.572
I think it would be very wise if students used ViSA for learning sorting algorithms.	1.43	0.618
Behavioral Intention (Cronbach's α = 0.807)		
I would recommend ViSA to my colleagues.	1.49	0.702
I would recommend ViSA to novice programmers.	1.33	0.661
I intend to use ViSA for learning and recapitulation of sorting algorithms.	2.16	0.994
To the extent possible, I would use ViSA as part of courses related to the programming.	1.67	0.806
When I need to make a comparison and analysis of sorting algorithms, I intend to use ViSA.	1.96	0.855

An Innovative Industrial Automation System Showcase for Quality Management and Statistical Process Control Lectures

ABSTRACT

This paper describes the R&D Project FlexZell. FlexZell is an industrial automation showcase including hardware and software as well as mechanical components. The objective of the project is on the one hand the implementation of a flexible, fully automated production line with special emphasis on quality aspects, on the other hand the possibility of sharing this knowledge with pupils, students and SMC (small- and medium- sized companies). It combines various disciplines of industrial automation, like robotics, image processing and analysis, and CNC-based manufacturing.

The FlexZell is organized into different process modules, which can be used independently or integrated into an automated industrial manufacturing process. The first process step determines the kind and orientation of the raw material. It communicates the results via PROFIBUS to the KUKA industrial robot module of FlexZell. The industrial robot will handle the part into the CNC-based milling-machine, which is mechanically coupled to the FlexZell. After the milling process is complete, the robot will handle the part into an optical inspection system module. There, the serial number as well as the dimensions of the part will be measured and transmitted into a database system. Finally, the robot will sort the part into the corresponding output tray of FlexZell, according to the quality results. The collected measurement data, together with different process related data is used as the basis for Quality Management and Statistical Process Control.

The FlexZell can be used stand-alone in the class-room as well as together with the CNC milling machine in the lab. Students will be able to test the influence of different setups on the resulting quality of the parts manufactured.

I. OVERVIEW

Automated production processes play a major role in today's modern industrial society. A high degree of flexibility, automation and excellent quality are necessary to stay competitive. The project FlexZell covers all aspects: flexibility, automation and quality management. The objective of the project is on the one hand the implementation of a flexible, fully automated production line with special emphasis on quality aspects, on the other hand the possibility of sharing this knowledge with pupils, students and SMC (small- and medium- sized companies).
Therefore a system was constructed which especially fulfills the didactic demands on teaching and learning. It consists of a transportable part (see Figure 1), which can be also used separately in a lecture room and easily decoupled from the production CNC-machine and the CNC-tool.

The main components of the transportable part are:

1.) robot
2.) optical inspection system
3.) automatic data acquisition and evaluation system

The coaction of all units is described in section Industrial Automation.

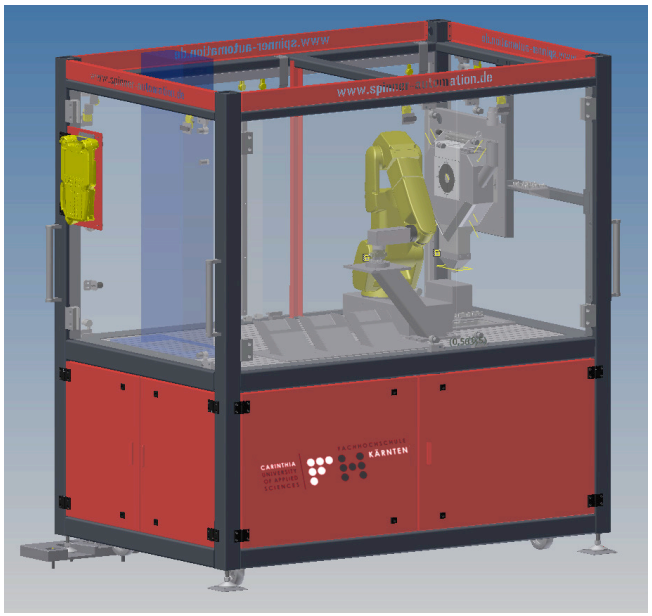

Figure 1: FlexZell

II. INDUSTRIAL AUTOMATION

As common in most small and medium sized industrial automation systems [1], the industrial robot controller (IRC) comprises the central unit for process automation. The interconnection between the IRC and the CNC milling machine as well as the optical inspection system is realized by

PROFIBUS. PROcess FIeld Bus (PROFIBUS) is a standardized (IEC 61158) communication system, which is widely used in process automation and industrial control. The specific communication protocol used is PROFIBUS/DP (decentralized peripherals), which assumes a system structure consisting of one or more master controllers and one to many slave units [2].

The master controller at FlexZell is the IRC, the slave units are the CNC milling machine and the optical inspection system. The IRC master uses the Cyclic Send and Receive Data (CSRD) service to communicate with its slaves on a regular timely basis. The CSRD telegram consists of several outgoing bytes (from the master to the slave) and several incoming bytes (from the slave to the master).

Figure 2 depicts the communication structure within FlexZell on a physical level. One possible extension to the PROFIBUS setup could be a passive bus-analyzer, which captures the bus traffic and allows for offline analysis of the data flow. This will be used as a demo or lab-exercise for bus-system lectures.

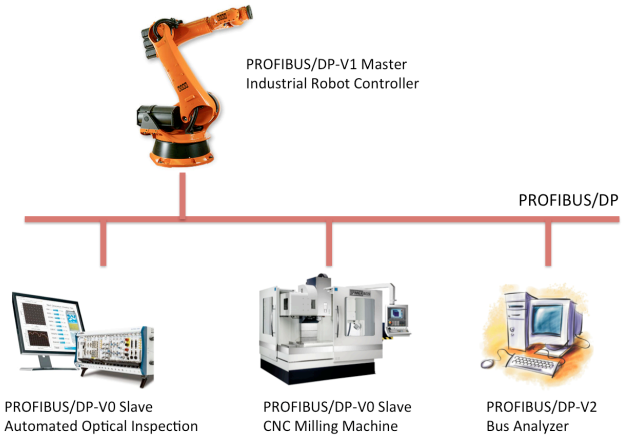

Figure 2: PROFIBUS Communication Structure

Figure 3 shows the entire process automation. The process starts with the manual loading of the unprocessed part into the system. In *S1a*, the first optical inspection system determines the position, the size, and the orientation of the part and communicates this information to the IRC. The robot handles the part into the milling machine (*S2*) where they get processed and labeled. After the processing is done, the robot handles the part to *S3* (cleaning station) and *S4* (drying station).

Next, the robot handles the part into *S1b* where a second optical inspection system reads the labeling. After this step is complete, the robot handles the part to *S5*, where a third optical inspection system does detailed measurements. The measured data from all optical inspection systems is stored in a central database for offline statistical analysis. This data communication does not involve the PROFIBUS/DP but used a regular TCP/IP Ethernet connection instead. Finally, the robot handles the part to *S6* where, depending upon the measurement result from *S5*, the part is classified as OK, NOK or scrap. Currently, FlexZell is intended to process one part at a time, future changes might allow the simultaneous processing of many parts (up to the number of independent stations). The process automation also allows for a classroom mode, where the CNC milling machine is absent. Instead, a placement area is present where the teacher can exchange an unprocessed part against a processed part.

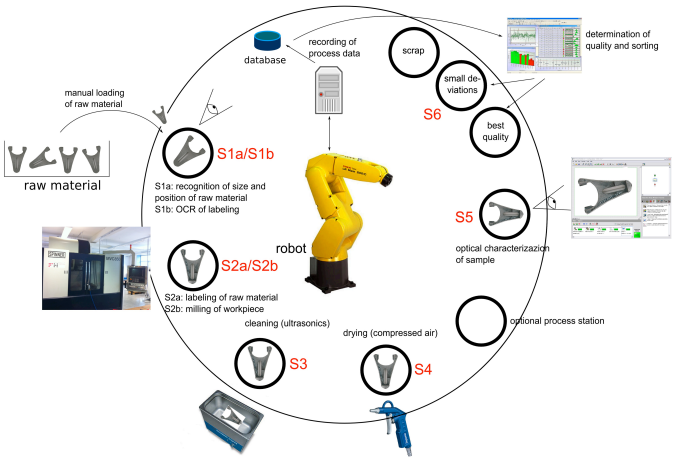

Figure 3: FlexZell Process Automation Overview

III. Quality Management

Quality Management Topics in FlexZell are performed by measuring characteristic values of the machined parts, such as diameter of drill holes, distances or surface parameters. For these tasks, image processing and analysis methods, using National Instruments' hard- and software [3], were defined. Basically, the tasks can be divided into three groups: part identification, high precision measurements, and miscellaneous (e.g. character reading).

Part identification: This first step is performed by pattern matching techniques including texture feature extraction and normalized cross-correlation. With this information, the part can be identified and linked to its corresponding quality data, which is gathered in the following steps (see Figure 4).

High precision measurements: In order to obtain measurement data with sufficient accuracy and resolution, a special hardware set up had to be realized. The combination of a telecentric lens together with an 8.000 pixel line scan camera and a linear drive for moving the machined part perpendicular to the camera's pixel line enables a length resolution in the area of some 10^{-3} millimeters.

The telecentric lens itself in combination with backlight illumination ensures a reduction of a possible error caused by reflection or diffraction of light rays, which may cause wrong distance measurements. Moreover, positioning of the part to be measured, the number of movement steps of the linear drive, or the camera resolution itself are potential error sources.

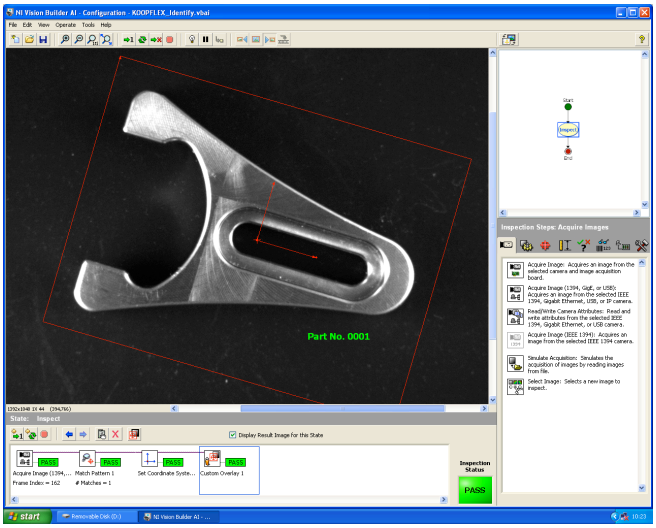

Figure 4: Part identification

Character reading: This step can be used for the final identification and classification of a machined part with respect to part number, and machining date and time (see Figure 5). This information can be used to identify trends in differences of measurement results by assigning them to specific production dates and/or times.

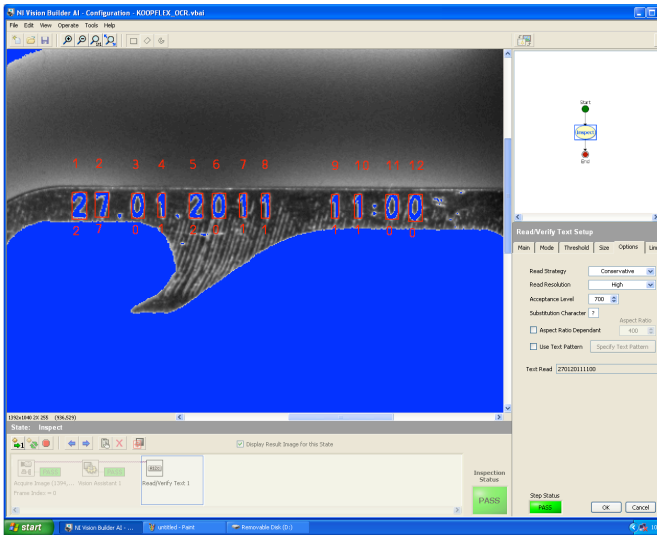

Figure 5: Character reading

The optical measurement methods were realized using National Instrument's software "Vision Builder for Automated Inspection". Prior to any training or reading process, the characters have to be separated from the background by means of image pre-processing techniques such as thresholding and particle separation. To ensure proper functioning, non-perpendicular lighting was applied for this step. Furthermore, the characters have to be segmented, so that each character to be read forms one specific object or particle.

The OCR (Optical Character Recognition) step itself extracts features for each possible character. Therefore, a training process has to be performed, in which a character value is provided for each trained object; all trained objects together form a character set for this specific application. The reading procedure compares the features of the segments in the new image with those of the characters in the trained character set file and returns the best match together with a nonzero classification score.

IV. Statistical Process Control

Statistical process control (SPC) is the application of statistical methods to the monitoring and control of a process to ensure that it operates at its full potential to produce conforming products. Under SPC, a process behaves predictably to produce as much conforming products as possible with the least possible waste. While SPC has been applied most frequently to controlling manufacturing lines, it applies equally well to any process with a measurable output. Key tools in SPC are control charts, a focus on continuous improvement and designed experiments.

In FlexZell, after generating a lot of measurement and production data it is necessary to uncover the relevant information in order to get a high quality product. Main task of the FlexZell Statistical Process Control (SPC) is to detect, if the process line runs stable or if there are significant deviations. By using so called "control-charts" (see Figure 6) it is possible to answer these questions. The idea of control charts is based on the fact that the process data or at least the mean values for a stable production are Gaussian distributed in a good approximation. This can be mathematically shown [4].

The limits of control charts can be adapted over the course of time depending on any process changes. In a first approach several WER (western electric rules) are considered.

The calculation of a cp/cpk-value for the process line is made to characterize the stability of the production cell quantitatively [5]. Additionally in-situ CNC-machine data can be used to detect problems with the equipment, e.g. wear of material or other difficulties. For this reason the implementation of an adaptive program code is done.

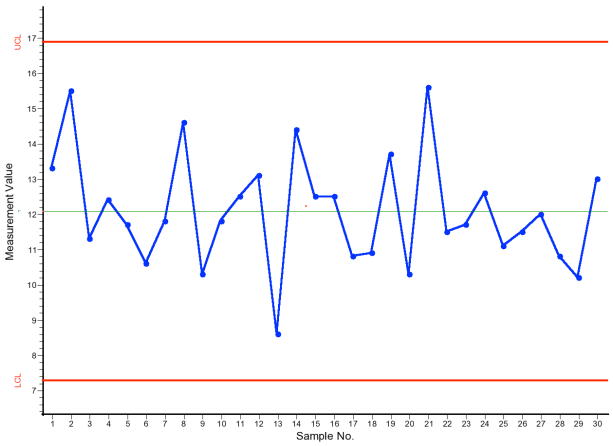

Figure 6: Example Control Chart

V. Discussion and Outlook

In this paper the project FlexZell, which combines various disciplines of industrial automation, like robotics [6], image processing and analysis and CNC-based manufacturing has been described in details.

FlexZell was designed to guide students of different levels in education into the field of process automation. This is done by a very practical approach. Furthermore the process will help technical staff of small and medium-sized companies to create a modern solution for their own process automation tasks. An industrial robot represents the central part of the construction. Therefore robot handling and programming is of particular importance in the training modules. Furthermore the great relevance of quality management in any industrial process is clearly manifested in the training program of the project.

FlexZell will be used both in our mechatronic program of studies and for training courses offered to companies. The manufacturing process is of course not limited to the considered items described in the paper. It can be used to build and to analyze different CNC-based production lines, especially for small-batch production. Furthermore the proposed process device can easily be extended for additional tasks that have to be considered in an adapted or even new automation process.

Abstract - **Looking back for the last months it can be noted that the cases of the intellectual fraud and academic dishonesty become a sad truth in Germany as well as in Croatia. If one compares the trend of the named countries with the trend towards the intellectual deception or to the level of the intellectual honesty and fairness at the universities of the some anglo-saxon countries, so one can find out that in particular in the university area, a difference is recognizably in the favour of intellectual honesty and fairness of some anglo-saxon countries. This work investigates the cultural differences and similarities of Germany and Croatia comparing them with the Australia as representative of one anglo-saxon country in regard to an intellectual fraud and examines the possibilities of avoidance of academic dishonesty. The limitations of the plagiarism software often used at the colleges or universities are mentioned. In addition, the applications of further possible means against intellectual deception cases are discussed.**

I. INTRODUCTION

During the last few months in the German as well as in the Croatian society, several cases of the academic dishonesty have been discovered. Those cases of the intellectual fraud may wouldn't be discovered at all, if those persons wouldn't be related to the general public. In many cases those people concerned have been individuals which serve as a role model in the general public. So in Germany for example more than a few public persons have been concerned with the problem of the plagiarism of their doctoral dissertations. Some of the famous plagiarists are Karl-Theodor zu Guttenberg, Germans former Minister for Defense, followed by the Silvana Koch-Mehrin, former politician former Vice President of the European Parliament but still the Member of the European Parliament or Jorgo Chatzimarkakis, still Member of the European Parliament and president of German-Greek Industrial Association. All named persons have been or still are with Free Democratic Party of Germany. Despite of massive criticism on their current positions, they remained to be present in the general public and have try as much as possible, to defend their academic dishonesty. Even for Silvana Koch-Mehrin or Jorgo Chatzimarkakis, these haven't had any consequences regarding their work in the European Parliament. Surprisingly Silvana Koch-Mehrin, despite of the proved massive plagiarism and official rescindment of her doctorate title by the University of Heidelberg, only 4 days later she announced that she is promoted and hat had become a full member of the European Committee on Industry, Research and Energy in Brussels. With it, is she responsible for the research politics in Europe [1,2,3]. It effected the substantial negative reaction in the general public and especially by the Alliance of the German Science Organizations which includes Fraunhofer-Gesellschaft, Helmholtz-Gemeinschaft Deutscher Forschungszentren (Helmholtz Association of German Research Centres) , Hochschulrektorenkonferenz (German Rectors' Conference), Leibniz-Gemeinschaft (Leibniz- Association), Max-Planck-Gesellschaft (Max-Planck-Association) and many more, but at the beginning without any result. At least, because of the massive criticism she left the Committee on Industry, Research and Energy in Brussels in June 2011 but she is still a Member of the European Parliament [4]. In the case of Germans former Minister for Defense, Karl Guttenberg, even German chancellor, Mr. Angela Merkel wanted to keep him as Minister despite of the plagiarism affair. It was accompanied with the massive criticism, and numerous open letters, as one know signed by 23000 German doctorates which massively criticize statements of chancellor [5]. After it former Minister announced his resignation, and removed to live in USA. Few weeks ago, Karl Guttenberg came back to the German public with his book, where he handle with the topic of plagiarism, but without observable remorse and regret. Similar is in the case of Jorgo Chatzimarkakis, who even accused the University of Oxford for learning him to write plagiarism because they do not use quotation marks when quote. University of Oxford reacted hefty on this statement [6]. There are also other examples from Germany, which will be here, because of the limitation of the paper length here not presented. Similar situation could have been observed in Croatia a few mounts ago. Croatian Institute for development of the education has in Mai 2010 dealt with the question of the plagiarism and academic dishonesty in Croatia [7]. They state that in Croatia, where also in the general public many cases of plagiarism in the recent time are known [cf.8,9,10], is the main issue the process after plagiarism and not the avoidance of the plagiarism itself like for example in the United Stated where plagiarism is an marginal incident. So for instance, during the year 2011 accused by plagiarism are first rector of the university in Pula Marčelo Dujanić or e.g. Anto Đapić member of Croatian parliament, president of the political party and mayor of the Osijek town. Similar as at the European level, instead that Croatian executives react promptly, journalist

which has discovered Đapi's plagiarism was get into a real trouble, because of his critical comment about the Split's judge, who has trivialized the problem of plagiarism and has stated "why to accuse Đapić , when whole Croatian academic society makes permanently plagiarism"[10,p.1]. This statement of one Croatian's judge but has not sufficient reaction of the Croatian general public. Croatian Ministry for Science, Education and Sports has on its web-page for the case of application for scientific programs announced with the Ministry publicized the necessary documentation as for example the declaration about the scientific honesty and integrity [11]. It is only one official document found, with still unclear information how the scientific honesty and integrity becomes assessed by the institution. So as it seems to be in Croatia like in Germany, there has been in the last time not sufficient interests to deal with the question of academic dishonesty. Summarized for the German and Croatian case, it can be observed, that with the persons accused for plagiarism a real regret for it wrongdoing regarding the question of the intellectual honesty or an academic dishonesty can't be observed. Even European institutions are not really concerned with this question and have not reacted as expected. Only massive criticism has led to change in academically accepted direction.

II. DEFINITION OF THE ACADEMIC DISHONESTY AN MEANS HOW TO AVOID IT

In different sources academic dishonesty is defined in different manner. A relative clear definition of the term plagiarism is given in [19]. Some sources use mostly the term "plagiarism", some of them the term "academic dishonesty" (mostly in the English literature). Academic dishonesty is but more general terminology for defining many different types of intellectual fraud and types of dishonest in relation to the academic work. According to [7,12, p.1] it can take following main known forms:

-Plagiarism (non academically acknowledged presentation of another person's work as the own one), Collusion (collaborative plagiarism)

-Falsification (presentation of the untrue data)

-Cheating (not allowed obtaining or giving the support and assistance or information)

-Deceit (resubmitting of the own previously assessed work)

-Personation (supposition of the characteristics of another person with intent to mislead or gain inequitable benefit). Furthermore also having a ghostwriter, paraphrasing or translation of the text out of foreign language are in different literature defined as an academic dishonesty. Today, different types of software (plagiarism-software) can be used to detect plagiarism. The software made by some companies is in-between very good developed but the not all cases of the plagiarism can be detected [24]. Maximal 60-70% of the cases of plagiarism only, can even be found with the best rated software. It means there is a lot of potential for improvement. Furthermore, translation of the text out of the foreign language, collusion, using of the ghostwriter or pseudo-references etc., can't still be detected. Also direct use of the software does not immediately raise the fair-mindedness and honesty of the user. Academic dishonesty is according to the [13, p.1] closely linked with "a commitment to five fundamental values: honesty, trust, fairness, respect, and responsibility". Also according to the same source [13, p.1], "defining cheating is much more complicated, given that the term cheating carries distinctive meaning depending on one's background, personal beliefs, culture, and even gender". Analysis shows that academic dishonesty can have different sources or even motivators to exist. Some can be a lack of regulations or of sufficient and consequent penalty policy. Considering the academic institutions it is a lack of so called "honor code", anchored within the organizational culture, which broadly used at Anglo-Saxon universities, in USA since 1779 [13, 14] and defines main rules related to ethnical academic behavior which is directly and substantially at the beginning of the studies , explained to the students or scholars. Sometimes but academic dishonesty can be result of stress in form of time pressure, or because of the triviality and irrelevance of the material which needs to be studied, or because of "believe that cheating is simply acquiring a skill that will help them in the future in the real world" [13, p.1]. Academic dishonesty is widely supported by the general public behavior, clarity of the definition of the law and of the culture. In Germany compared to Croatia there is excising the clear judicative regulation and even one norm (DIN 1505) where is clearly explained how to cite, quote and reference. But as experience of the last month showed, regulations are not sufficient to avoid it. Moreover, steady vigilance of the public, media and institutions closely related with the question of the academic dishonesty have to be present in order to avoid academic dishonesty. Also the variety of the different regulations how to reference (APA Style, Harvard Style, DIN 1505, IEEE Style etc.) may bring difficulties to understand how correctly to reference academy text without to make, willingly or unwillingly plagiarism. Better transparency and simpler rules are necessary. In some cultures as for instance in the Far and Middle people are more tending to keep in helping others to take advantage by using of any kind of information like to copy other's thoughts and products because to help a needily friends is an significant cultural ritual and belief and it is not considered to be something wrong. In the following part Croatian and German culture becomes compared by using of means of cross cultural comparison.

III. GERMAN VERSUS CROATIAN CULTURE AND POSSIBLE IMPLICATIONS ON THE PUBLIC INTEREST FOR ACADEMIC DISHONESTY

Kroeber and Kluckhohn [30] identified "more than 160 different" definitions of the term culture. In this work we define culture according to [31] as "collective mental programming; it is part of our conditioning that we share with other members of our nation, region, or group but not with members of other nations, regions or groups."There are different studies which tried to make a link between cross-cultural theory and academic dishonesty [cf. 13, 15, 16,17]. As stated by [17, p.15] "the studies revealed that plagiarism is deeply rooted in the academic environment of some European universities". The authors claim the acceptance of the plagiarism by the students even in the case that awareness about the intellectual fraud is existing. Authors argue that cultural environment and political

system have a great impact on the occurrence and positions toward plagiarism. So according to [17,p.16] "the results of the studies presented, revealing that almost 20% of students in Bulgaria and Croatia vs.7% in the UK find cheating on exams acceptable behavior". The authors explain it with the study done by [18,20] according to open-mindedness in the direction of educational and intellectual misbehavior was more obvious in post-communist countries because educational and intellectual situation of post-communist countries, where a high level of criminal and dishonesty is assumed, is typified by a high rank of open-mindedness in the direction of unethical behavior, cheating or plagiarisms, which consecutively creates unsuitable manners in the direction of intellectual and methodical honesty. As stated by [16, p.277-278] refereeing to other studies , "students in the United Kingdom were more tolerant of cheating … and were more cynical but tended to cheat less (40%) than students in the United States (56%)", or "a smaller percentage of Australian students admitted that had ever cheated compared with the U.S. students, who were more likely than Australian students to perceive cheating as improving their examination scores", or "Japanese students reported a higher incidence rate of cheating on exams, a greater tendency to neutralize (i.e., justify) cheating, and a greater passivity in their reactions to the observed cheating of other", or "55% percent of U.S. students reported they had cheated in college compared with 84% of Polish students". By using the cross-cultural methods to analyze it, mostly Hofstede's cultural dimensions [20,21,22], authors find out that business students coming from the country with higher rated Collectivism dimension "will participate and collaborate in unilateral, independent questionable behaviors more than individualist business… will participate in delaying questionable behaviors more than individualist business students", furthermore "attitude toward teamwork will mediate the effect between collectivism and collaborative questionable behaviors" [18,p.281-289]. On the other side according to [15,p.1-3] " collectivist students may be less likely to engage in questionable practices than more achievement-oriented, individualistic students", higher "Masculinity score index is a positive determinant of academic dishonesty", higher score on "Power distance is a positive determinant of academic dishonesty" and higher scored "Uncertainty avoidance is a negative determinant of academic dishonesty". By using of that information we compare German and Croatian Culture related to the Australian culture, regarded to as country with less academic dishonesty behavior. According to [23] following Hofstede's cultural dimensions exist:

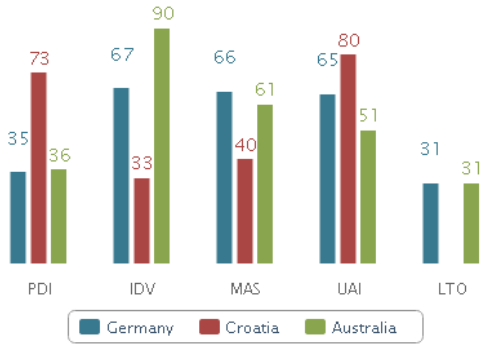

Fig.1 Cross-Cultural Comparison

If considering the Power distance score (PDI) and its definition [23,p.1] "as the extent to which the less powerful members of institutions and organizations within a country expect and accept that power is distributed unequally", we argue that high acceptance of the hierarchically distributed power can in some cases lead to acceptance of questionable academic activities, because commonly accepted. It means that in Croatia compared to Germany the tendency is higher that students more tolerate doubtful academic activities. Further, Croatia is higher rated on Collectivism score, and has therefore lesser degree "of interdependence a society maintains among its members". Explained implications of the dimension are different in different studies. However, based on studies as [15,16] it can be assumed that collectivists are more ethical as individualists and that there is negative relationship between collectivism and the inclination to break rules but that collectivist students "tend to value in-group membership and tend to be less likely to have esteem for the individual work of someone else, whether or not it is copyrighted" [16,p.281]. Therefore we argue that high individualism is positively oriented toward academic honesty as in the case in Australia. Thus Croatian students are also more inclined to acceptance of questionable academic activities as German students. High Uncertainty Avoidance index (UAI) is defined as "extent to which the members of a culture feel threatened by ambiguous or unknown situations and have created beliefs and institutions that try to avoid these" [23, p.2] and is according to the mentioned study [15]an indicator for less tendency for academic dishonesty because "individuals who are low in uncertainty avoidance are more likely to take risks " and "from an ethical perspective the tendency to take risks is highly correlated with unethical behavior" [15,p.3]. Looking on those scores Croatian students tend more to be less risky and should therefore more likely reject the doubtful academic activities as German students. Nevertheless the difference on this score is not as significant as in the case of the IDV and PDI. Also high masculinity index seems to be positive indicator for academic dishonesty because of the aggressive, dollar-driven behavior of countries ranged high on masculinity score [15]. We doubt this definition, because "feminine dimension "means that the dominant values in society are caring for others and quality of life" and high masculine "indicates that the society will be driven by competition, achievement and success, with success being defined by the winner / best in field – a value system that starts in school and continues throughout organisational behavior" [23,p.2]. Therefore caring for others may mean to allow others to write off in order to save positive relationship and to "stand in the crowd" as admirable sign of those societies. Countries compared have similar MAS index, where Croatian is a bit lower as German and Australian one.

IV. LIMITATION OF THE STUDY

For in-depth investigation of the relevant societal and cultural factors, further studies made have to be analyses and compared. Also primary data analysis regarding the cultural behavior between Croatian and German students in relation to the Australian students is necessary to underpin the secondary data statements. Also organizational culture of the institutions investigated, needs to be taken into consideration in order to gain reliable indicators. Cross-cultural models have experienced diverse critics.

Regarding the critics of the model of the social psychologists we refer i.e. to the work of Fang [25], Williamson [26] and McSweeney [27,28] as well as the Hofstede's replay to McSweeney's criticism [29].

V. CONCLUSION

In this study we compared recent cases of plagiarism in Germany and Croatia and how the general public has reacted on it. We found out that awareness at the level of European institutions on the problem of the academic dishonesty is not sufficed and needs to be more and frequently debated in the media in order to raise the public awareness. The roots of the academic dishonesty are closely linked with the values of individual definition of the honesty, trust, fairness, respect, and responsibility and have roots in individual and organizational culture. Only using the national cultural dimensions is not sufficient to explain tendencies to academic dishonesty but are well-built indicators in order to make tailored concepts for avoidance of the cases of intellectual fraud. To answer arising questions, further research will be carried on by the authors.

Education via Modeling and Simulation

L. Révészová
Department of Applied Mathematics and Business Informatics,
Faculty of Economics, Technical University of Košice, Slovakia
libusa.reveszova@tuke.sk

Abstract - In this paper we present our approach to establishing modeling and simulation as an important part of the managers' education at the Faculty of Economics, Technical University of Košice. The paper deals with experience in teaching and it also discusses the body of knowledge and methods which have been implemented into the subjects – Informatics II and Economic Information System.

I. INTRODUCTION

Modeling and simulation (M&S) and their implementation are now very important for industrial companies, organizations, e-government, e-health, educational institutions, etc. [5]. We believe in the necessity, role and importance of educating and training of people in this field. However, there does not exist a consensus on what, how, and why to educate students - non-professional analysts/modelers in this field.

At present, in the incoming knowledge society, it is very important for all university students to be familiar with the basic terms from areas of modeling, simulation and getting accessible information from different sources. They should understand functions and possibilities of the Information and Communication Technology (ICT), Internet and advantages of modeling. They will use all these terms in their professional and common life because many social, political, and technological changes have taken place in all fields of the global society. Organizations and companies are looking for ways to optimize their processes in order to create a competitive advantage. The application of modeling and simulation techniques represents opportunities for improvement of abilities to design, develop, manufacture and operate. Modeling of business processes will be a challenge in the near future. There are many languages and tools for modeling business processes as the result of development in the information technology (IT) field and changes in the enterprises demands. Applying new adequate technologies and knowledge in the right place at the right time depends on the proper education and capability of graduates.

Why modeling and simulation? M&S technologies represent tremendous opportunities for radical improvement of our ability to design, develop, manufacture, operate, and support complex products [3].

The development and growth of Modeling and Simulation – as a discipline, a profession, and an industry – is strongly bound up with the growth of education and training. M&S has become a technical field that pervades a wide cross-section of science, business and engineering applications and projections for growth in the future. It indicates an exponentially increasing curve. Unlike some software related tasks, education and training in M&S is essential to enable people to carry out tasks involving M&S with a competence that is not otherwise possible. At this time, the offerings in education and training are not capable of meeting the current and future requirements and demand and there must be significant developments in this regard [8].

Universities need to characterize the M&S discipline requirements for their study programs and thus they must work with recent research results and knowledge in M&S field. Companies using M&S should cooperate with universities to characterize the current requirements for graduates and what their educational background should be in the M&S field.

Why enterprise modeling? Enterprise Modeling (EM) is the art of externalizing and formalizing structural and behavioral knowledge about how a company or an organization is organized, how it works and to some extent how it performs. EM equally applies to a single organization, a networked organization, or a part of those. The aim is to build models to represent, analyze, design and simulate various facets of an organization (e.g. functional, information, resource or decisional aspects) as well as various flows (e.g. control, information or material flows). Depending on their level of details and precision, these models can serve as the basis for enterprise/business reengineering; they can be shared among users as a means of communication or can support systems interoperability. They can even be used to control enterprise operations. EM is at the crossroads of several disciplines including systems engineering, organization management, information systems engineering, control theory or enterprise sociology, only to name a few [9].

Why processes? Processes are very important for the success within many business fields. They define the proper application of methods, technologies and company structures in order to reach business goals. Not only manufacturing processes have to be defined from the start point to their end, also other processes like product development processes need a proper description to achieve success. Over the last decades several product modeling languages have been developed moving to object oriented modeling languages, such as Unified Modeling Language (UML), but the used process modeling languages are still procedural. The paradigm

shift caused by object oriented description within product modeling languages has to be transferred to process modeling languages [1].

For many companies, the competitive field has been reshaped significantly during the past years. The globalization of markets, the current economic recession, new customer requirements for product and service quality, and the rapid development of ICT require new strategies for successful enterprising, as well as new methodologies and tools for system analysis and design in dynamic environments. Many leading companies have therefore launched large-scale efforts to deliver greater customer value by "reengineering" their businesses, "customerizing" their business processes and using IT as an enabler for gaining competitive advantage [7]. Reengineering or the redesign of business processes has been the least understood science and art. Specifically, research has shown that business and technology people need to work together in synergy to make reengineering a success. However, there is a conceptual and communication gap between the two groups of people [4].

II. IMPLEMENTATION OF M&S INTO THE INFORMATICS COURSE

In order to prepare our graduates for challenges of knowledge economy, we have decided to include aspects concerning M&S into the basic informatics course [6]. Because, at present, informatics is a very extensive field for studying within one semester, we divided the course into two parts: Informatics I (first semester) and Informatics II (second semester). Informatics I is focused on the practical skills in the scope defined by ECDL standard [2]. During the study of this subject, students become familiar with the operating system, Internet and its services and MS Office package. Teaching these basics is necessary because of various knowledge levels of high school graduates in this area.

Informatics II builds on the knowledge obtained by the study of the previous subject - Informatics I. The content of the Informatics II is primarily focused on tools which help to facilitate the processing and presentation of information. Except the traditional content and methods of teaching (lectures and practices focused on handling with advanced functions of MS Excel and MS Access), we use also e-learning, learning-by-doing and project method.

To the subject Informatics II we included a chapter called Information Systems. We started from the basic theoretical concepts in the Theory of Systems and modeling in general, business processes modeling using ARIS and UML. By solving practical problems, students become familiar with available features helping them to work with a lot of available information. We simulate a situation in which students are in positions of responsible executive managers of a little company and they take part in projects of building/developing information systems (IS). All students have to create projects of user requirements of IS in some virtual modern companies/firms/institutions. The project is divided into four parts, in a close relation to information system:

1. **Short description of company and its main business process or processes.**

It includes the definition of business field of the company, usage of IS. Based on the previous lectures, practical exercises and provided study materials students form a model of the main business process using the Business Process Modeling Notation (BPMN), ARIS Express, UML or similar notation. The aim is to make students think about the main processes realized within the company/firm/institution and their connection to particular sub-processes represented by real activities. The expected outcome is a description of the main processes and a model of chosen process or sub-process realized within the company.

2. **Short description of required IS.**

This part is based on following: model of the main process, IS main aims specification, definition of groups of users, schedule of the most important parts and functions of IS, required infrastructure (hardware, software), presumed dates of realization and approximation of costs, way of IS implementation, requirements of documentation and training, IS prospect, expectation, expansion, maintenance and service. The required IS must reflect the processes described and modeled in the first part. The students have to realize connections between processes of the company and the information system. In this part we expect the definition of user requirements in a text form.

3. **Specification of the basic proposed IS functionality.**

Specification of IS functionality requires using simple form of UML Use-Case diagram, which consists of a list of actors and their brief descriptions, a list and a brief description of Use-Cases, a scenario of every individual Use-Case. Students are led to create one or two simple Use-Case diagrams of the required IS, which can be used as a “translator” between the user and IT professionals.

4. **Simple database design.**

This part is based on the UML Class diagram for selected classes with their attributes in relation with the previous parts. The small part of required and analyzed IS is converted into “something real” – relational database designed in MS Access and its tools. This step is crucial for the students, because within this phase their own requirements and system descriptions are put through test of valiability. The outcome of this part is a small relational database containing at minimum three tables with relations, 50 records and realized filters, queries, etc.

In Figure 1 we present a typical example of such a student project.

The great benefit of the mentioned approach is students´ active participation in the learning process. They not only test their understanding of the subject matter of the course, but they also further develop their analytical and communication skills. They have a chance to solve problems and to create “something new” on their own. Using e-learning and electronic communication via Learning Management System (LMS) Moodle and applying learning-by-doing we make learning process more effective.

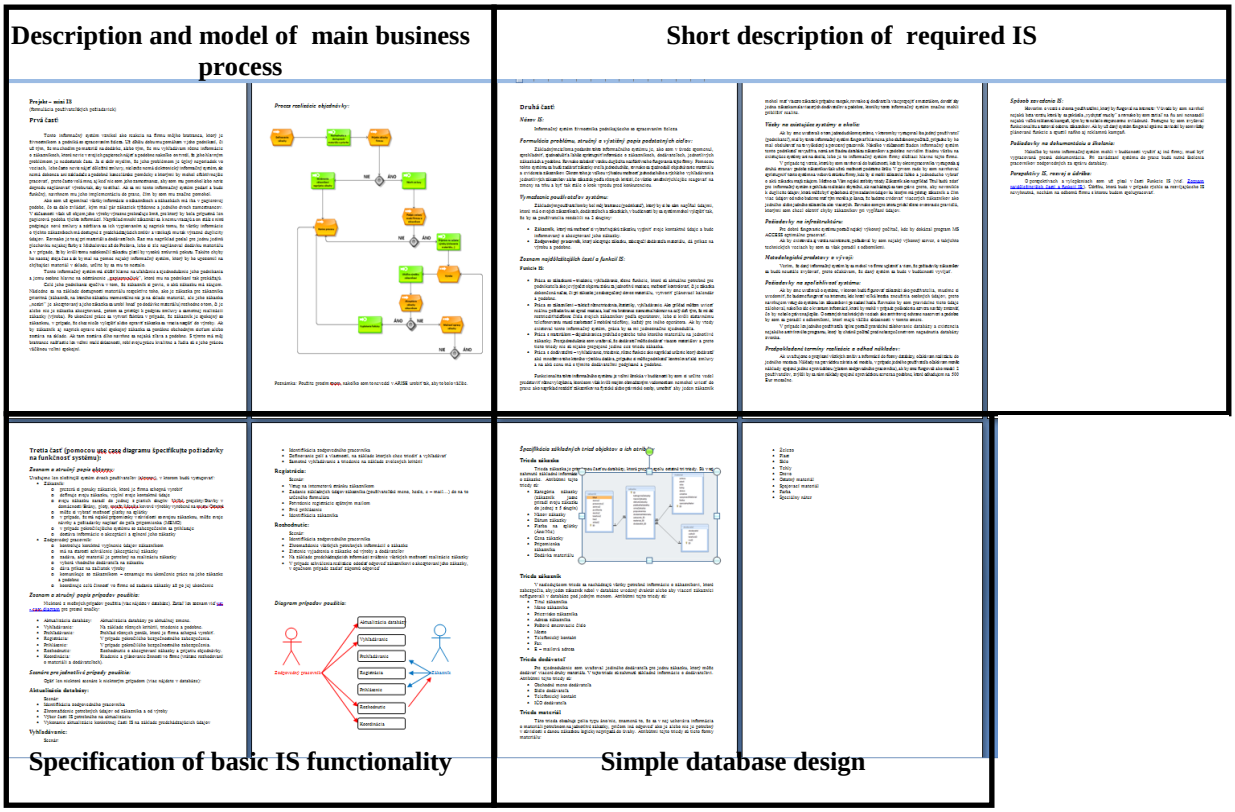

Figure 1. Example of a student´s project

III. TEACHING OF THE SUBJECT ECONOMICS INFORMATION SYSTEMS VIA M&S

In this part we describe another example of the implementation of M&S into the education - the way of teaching „Economic Information Systems" (EIS) subject. It is an optional subject in the third year. The main aim of this subject is to simulate the small company life cycle from the beginning (establishment) to the financial statement at its end. The education of the EIS is realized by usage of on-line bank system UNICOM and by using the bookkeeping software POHODA, which were presented to the Faculty of Economics of Technical University for the education and science.

The students should be taught how to establish a small company and how to do e-business with other small companies. The realization of the EIS is based on the students' knowledge of the previous subjects, e.g. Informatics I, Informatics II, Marketing, Management, Civil and Industrial Law, Accounting, Information System and Taxation Policy.

The education via modeling and simulation of the company life cycle includes:

- establishment of the company and creation of the business plan,
- creation, temporary placement, maintenance and updating of the company website,
- trading of goods with other students´ companies through the Central company,
- bookkeeping of all items by using the bookkeeping software,
- evaluating of the business work in the marketing case studies,
- analyzing of the used IS, writing of users´ requirements, creation of simple IS model using the UML or similar notation,
- writing of requirements and suggestions for the learning system exchanges - providing feedback.

The bases of the education are the websites of the EIS. The main website: "The virtual lab of e-business" is available at http://www3.ekf.tuke.sk/ and it is shown at Figure 2. Further follow-up website available at, http://elab.ekf.tuke.sk/Eisweb/index.html provides a space for presentation of students´ virtual companies. Figure 3 depicts the website of students´ companies.

These websites are prepared and updated by cooperating teachers from different departments according to the required tasks. There are included: the Central company (created and managed by teachers) as a distributor of the goods for the business, the (virtual) Trade Office, the (virtual) Tax Office, the (virtual) Business Register, etc. as shown in Figure 2.

Figure 2. The main website of EISsubject:The virtual lab of e-business

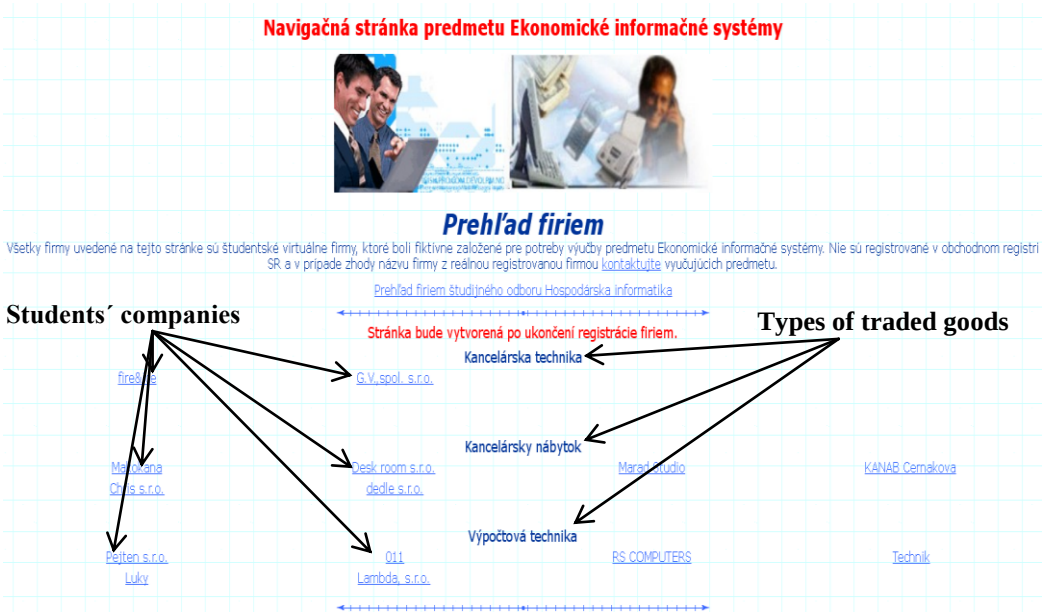

Figure 3. Students´companies website

The main aim of the EIS course is to achieve practical experiences with doing e-business that is why the main strength of the EIS is in the practical exercises for students. They must fill up all forms and documents for the establishment of small business and send it to the competent office on website by e-mail. The students have to prepare (gradually, according to the timetable) a pattern form, a business plan, a marketing case study, a database of the bookkeeping, UML diagrams, etc. When the virtual offices (administered by teachers) obtain students demands, they assign accounts on the bank with allotted amount of money. Students should be rented a space on the website of the EIS for the presentation of their virtual companies. The same space is used for e-business.

The students' virtual companies are trading goods and services with other companies or the Central company by e-business. They must book and keep the files by the bookkeeping system POHODA. It includes personal files and wages keeping. When the appointed time runs out, the students have to have the balance and the tax return of the company prepared. At the end of this subject, students prepare the strategy study "Analyzing of the managing of the business within budget".

This manner of the education has many advantages. Students do not need to be at school, when the teacher divides the task for the students, they can do the tasks at home or at school using e-mail or a reference to a subject website. Education and communication are more effective by using LMS Moodle. There are all learning materials, information, tables of tasks and dates required for successful completion of this course.

These days, in times of student oriented education, we are interested in students' satisfaction with subject that they absolved. It is also important to know their opinions, suggestions, expectations and ideas - their point of view. At the end of the semester the students are annually asked to evaluate the education of the subject EIS. Students´ remarks, perceptions and proposals can be summarized as follows:

- Pros: It is a very interesting experience. It is very good for our practical skills and it could include the possibility to work with the e-bank, e-business and to create the business plan.
- Cons: This subject is time demanding. There were sometimes technical problems.
- Proposals: The subject should be divided into two terms and there should be preferred seminars more than lectures.

As teachers we can conclude that this way of education has positives: the manner of the education is interesting for both – students and teachers. There is a possibility of real usage of e-learning and learning-by-doing. It is necessary to build connections between different fields of e-business. We see in practice how important it is to build better inter-subject connections between all subjects at the faculty, e.g. Informatics, Management, Accounting, Civil and Industrial Law, Marketing, Finance of the Firms, Taxation Policy, etc. However the preparation for education is more demanding, it takes a lot of time and sometimes there occur organizational problems. The effective realization of the EIS is also based on involvement of a team of enthusiastic teachers from different departments of the Faculty and interdisciplinary character of this subject.

IV. CONCLUSION

We are sure, that no kind of education can replace the "personal experience". Combining "classical" methods – lectures, seminars, discussions with a learning process via M&S is giving a new point of view. Referring to the words of a Canadian expert on education technology Brenda Pfaus: "A man can memorize 10% of what he reads, 50% of what he sees and more than 90% information he is reaching by an interactive work" it is trustworthy to say that M&S and ICT-based learning within a virtual e-business environment is much more effective than the classical "Face to Face" teaching.

We can summarize our experience in education of both Informatics II and EIS via M&S as follows:

- students accept it very well, many examples of common life can be used,
- students do not need much theoretical knowledge to work out simple projects themselves,
- students can use their own point of view, their creativity, knowledge and logical thinking to solve problems,
- teaching can be realized on different levels of difficulty, basic terms and examples in obligate subject like Informatics II, or extended level in optional subject EIS,
- teaching Informatics II via M&S doesn't depend on the technical equipment.

The future positions of our graduates in enterprises and organizations require the best qualification and a lot of skills and experience with the modern technologies.

Role of ICT in learning and knowledge acquisition

How much students know about their research skills?

J. Lovrinčević*, D. Kovačević** i M. Erl Šafar***

Summary- purpose: The paper analyses self-study processes, with the emphasis on the assistance provided to students by ICT. In Republic of Croatia the availability of ICT for study assistance is comprehensive at all relevant levels (at the universities: lecture theatres, ICT booths, libraries, dormitories, but also at home) which should facilitate high learning standards. That very fact sets the expectation that for the information acquisition students utilise all resources that are (can be) made available to them through the ICT. It is important to find out if that is really the case and if the learning process employed by the students is most effective possible.

The method: The paper is oriented towards the research into some of the ways of student's self-study. Their learning process is analysed in the context of the universal access to information, and correlations established between effectiveness, quality and competencies.

Results: The survey conducted is based on student interviews regarding the methods of self-study used, the role of ICT and the ways it is employed. The research will lessen the ambiguities about the ways students nowadays acquire the necessary knowledge for the chosen curriculum. It is hoped that the results will demonstrate a significant improvement compared with the pre-ICT era. On the other hand, it just might happen that student interviews will evidence poor utilisation of ICT capabilities.

Practical application: ascertaining if the use of ICT for self-study is optimal. If that is not the case, it is necessary to recommend and/or devise additional training in ICT literacy as to fully utilise ICT capabilities for increased study effectiveness.

Keywords: ICT, learning, students, self-study and knowledge acquisition

I. INTRODUCTION

The educational system, which appears and is understood differently than before, determines the changed and by now established ways of knowledge acquisition, whether formally or informally, as the constituents of lifelong learning, up to and including the ever more present e-learning or distance learning. Taking into account all the listed and unlisted modes of knowledge acquisition, very different from pre-ICT constraints, it could be reasoned that the knowledge today is not only different but also richer, it is acquired faster and more simply, therefore it is larger, more widely applicable and has a deeper quality.

The fundamental and evident difference between the students then and now is their behaviour, in the way they perceive themselves, their capabilities and the totality of the acquired knowledge. In the context of these conclusions [1], and of the research and reading of scientific and professional material, the modern learning approach is often bound to a term "critical reading".
It is this observation of different students' behaviour during the formal education and comprehension of tasks that have been set, make us want to follow, challenge and analyse knowledge acquired, and to try tell causes from consequences between the learning processes and the ultimate knowledge quality.

The formal educational process is constantly being adjusted to the needs and demands of the students so its methods and teaching forms are well known, but there is also that part of learning that is created and applied by the student herself. In spite of the greater ability to access the necessary information, it cannot be simply concluded that all recommended and „correct“ methods are being

employed. To get an understanding of how much, how much and how serious do the students study, it has been necessary to research into customs and habits, and hopefully new patterns of self-study. The initial research included a small participant sample and it is a basis for a voluminous survey which will be later carried out on several Universities.

II. KNOWLEDGE AND INTELLECTUAL CAPITAL

It is everyones' desire to be, survive and make a quality contribution in what is now commonly known as the knowledge society. This implies having, with regard to the educational input, the totality of cognitive knowledge at a level adequate for functioning in work and social eco-sphere.
Knowledge indeed is necessary for functioning, but it is also an intellectual category that at various levels participates in shaping life, from personal to general. Ultimately, it determines the quantity and quality of the transfer to others, how the social eco-system will be shaped, up to the economic and political determination of a country.
The sum total quality of life or development in a country can be viewed from the viewpoint of knowledge, which should reflect a particular educational system.

There is very little doubt that all the above is the case considering the supplied and obvious facts. However, and especially today, the researchers are increasingly and from a multitude of viewpoints, analysing the processes of knowledge acquisition and application. The reason for that is the unquestionable change in the quantity, quality, speciality, shapes and forms of knowledge application, compared to the pre-ICT era. From the logical viewpoint that had to be the case – the computer has had to and had brought about immeasurable benefits, especially with regard to information access and study self-reliance.

Until the ICT era studying was primarily based on the knowledge transfer through teaching process and the self studying was mainly limited to the printed sources of information and knowledge, so that the learning process has had a well established pattern. Nowadays, in dramatically different circumstances, it is necessary to reconsider the learning process, and the satisfaction experienced both by teachers and students alike.

III. THE SURVEY

The secondary and tertiary education syllabuses promote the reading and information literacy to a higher level. During the study years the learning demands are increasing; in the context of information comprehension this includes assessment thereof from viewpoint the content, relevance, structuring and reshaping to recorded and applicable knowledge.

IV. RESEARCH OBJECTIVES

The objective of this project was to find out how much are the students self-reliant in their study, which methods and shapes thereof the employ to comprehend the subject matter, how satisfied are they with the results i.e. learning outcomes.
Until recently there was very little understanding of the „reading psychology“, i.e. the processes for acquiring and exercising that skill because the pool of knowledge about reading is constantly being extended and modified in line with new discoveries and new ways of research into the reading process and the associated mental activities [2].
The central theme is the learning process, specifically the knowledge acquisition and selection of information from a variety of sources. The key question was about the form and extent of the role ICT plays in the learning process.

V. HYPOTHESIS

Nowadays students belong, by and large, to the online generation, which would suggest a level of information literacy. However, the information deluge and rapid changes to the visual and audio content make it difficult to successfully search for the required information, The objectives and activities of our research have determined the hypotheses:

- That there is a need for a better alignment of information literacy with the learning process developments in the higher education;
- That it is of interest to establish the students' level of (dis)satisfaction with their processes of comprehension, extension and knowledge structuring and presentation;
- That there is an inadequate understanding of the role of ICT in promoting the learning process quality.

VI. RESEARCH METHODS

The set objectives and hypotheses by and large determine the research methods, activities and instruments. The project being undertaken is directed towards the research into some of the modes of student self-study. Their learning process is being analysed within today’s universal information access and establishes a link between effectiveness, quality and competencies.
The project is primarily based on the descriptive research method. That method was also used to analyse and compare the pre-existent knowledge about the learning processes with the data obtained from the survey participants. The stratified sample method consisting of 12 questions and analysis of answers have been used to

establish the relevant survey indicators. The activities undertaken were reasoning and judgment, besides the paperwork.

Participant sample

The research was focused on the undergraduate students of the Culturology Department of Josip Juraj Strossmayer University in Osijek. Surveyed were 80 students of the Year 1, majoring in Librarianship, Media Culture and Cultural Management with the aim of establishing the true forms, habits and skills of self-study so to use the established indicators, even during the university attendance, to direct and if necessary correct the learning process with the goal of acquiring a quality 'final' result. Why Year 1 students of Culturology Department? Exactly because they are at the first rung of their academic education and to climb further rungs they will have to master two or four more rungs (two at the graduate level). Questions 1,2,4,5 and 6 have been posed as "open" question and they are not of exclusive character in order to get more reliable answers. The analysis below shows how students articulated their answers.

Survey analysis

1. On average, how many hours you spend preparing to take exam in one of the mandatory subject?

1 hour	3
2 hours	12
2 – 3 hours	5
3 hours	11
4 hours	8
5 hours	2
5 – 6 hours	3
6 hours	3
7 hours	5
8 hours	9
8 – 10 hours	1
10 hours	8
11 hours	1
10 – 15 hours	1
Depends, never the same	4
Insufficient	4

2. In your opinion, how many hours do take other students?

1 hour	5
2 hours	10
2-3 hours	3
3 hours	10
4 hours	7
5 hours	6
5-6 hours	8
6 hours	3
7 hours	2
8 hours	7
10 hours	10
12 hours	1
20 hours	1
100 hours	1
Don't know	6

The key question was to determine the hours spent preparing to take exams in the mandatory subjects that for the profession basis. According to the survey, a majority (36 students) spend only 2-4 hours, and a significant minority of 18 students spend 8-10 hours. Below the 2 hours was the response of 3 students, and more than 10 for 10 students.

When asked about their colleagues, the answers differed slightly (30 students thought their colleagues spend 2-4 hours, and 17 students opted for 8-10 hours) ; so that comparison suggests that the answers may have been truthful. (The difference in the 5-7 brackets (13 versus 19) was not considered to be significant.

3. In your opinion, is your self-study - - - ?

a) sufficient 66,25 %
b) over the top 7,5 %
c) insufficient 26,25 %

According to this self-assessment, the majority of students (66,25%) thought their self-study was sufficient, which might indicate they concur with the marks obtained, or that they are complacent regarding the marks.

4. Which techniques you use to memorise the subject matter?

No technique	1
Writing bulletpoints and repeatedly going over them	3
Repeating and reciting	18
Reciting and reading	18
Writing notes	13
Learning with understanding	5
Memorising	2
Underlying key facts	4
Associating with real life examples	2
Learning by heart	3
Reading aloud	9
Self-quizzing	2
Photographic memory	2
Have own technique	1
Associations	3
Sitting	1
Learning like mad	2

For years our pupils have been taught the information literacy, primarily "learning how to learn", through the Library programme of information literacy in school libraries. This makes the answers, showing that by and large (36) students practise reading and reciting, even more interesting. (The second preference was for reading aloud). It must be mentioned that these answers are directly connected with the lack of appreciation for the role of school libraries in Croatia.
All other techniques that have been under introduction into the educational system for years, such as learning with understanding, making notes, research, mind maps etc. seem to be applied only seldom.

5. What role does internet play in studying the subject?

Printouts	5
MS PowerPoint presentations	8
It distracts me	3
Reading the teaching material on Internet	4
No big role	12
Major role	2
Reading essays	1
No role	6
Significant role	23
Downloading the material for exam	12
Resolving queries	2
Depends on the subject	2
Big, I learn based on it	1
It helps find additional info	6
Communication with other students	1
Serves as an intermediary	1

The answers to this key question and the starting point for other questions and answers is not a surprise. As was to be expected, a big number (23) opted for a "Significant role". The problem remains that they were unable to precisely name that role.
When they did go into specifics, they mainly opted for "Downloading the material for exam". Together with a more detailed answer "Reading the teaching material on Internet" this was by and large about access to the lecture notes which, for many, was the beginning and the end of research, with insufficient access of other relevant sources.
There is little doubt that nowadays the personal computer is a great help to the contemporary students because they do not have to make (important) notes during the lecture itself. On the minus side this does not make them focused on the content, the lecture topic. Active listening helps all of the understanding, memorising and questioning on the spot. That means clarifying ambiguities there and then, debating, asking questions about the topic which needs memorising. Everyday practice and teachers' experience suggests that student avoid two-way communication because they seem to excessively relay on the availability of the electronic material.

6. If the material is voluminous and complex, how do you reduce it and repeat it to make sure you understood it and memorised it all?

Reading again	1
Writing bulletpoints and notes	12
Repeatedly reciting	9
Learning from lecture notes	5
Reading with understanding	1
Communicating with other students	3
Reading over the most important parts	4
Shortening the text	15
Cheating	2
Writing down what I have learned	2
Underlying the most important parts	7
Re-reading lecture notes	4
Mind maps	1
Associations	2
I learn only one half	1
I simplify to an extreme	1
If I knew I wouldn't fail	1
I start learning sooner rather than later	1

The desired answer was not obtained because the students still do not recognise ICT as a source of multiple variations to the theme; thus simplifying, through images, video, animations etc, the voluminous and complex material, and at the same time making texts more comprehensible and interesting. In the information and communication context that means that [3] quantitative dimension is expressed as an information overflow, and qualitative dimension is expressed as difference in quality, authenticity, validity and reliability of information.
It follows that students tend to opt for well established and outdated learning form, according to them that is the reduction (of material) with making notes, which are then firmed up by repetition.

7. How would you mark, one average, your knowledge acquired through study?

1	2	3	4	5
1,25 %	7,5 %	6,5%	30,0%	1,25%

After the self-study, 56,25% students thought they have acquired, on average, good knowledge, and 30% consider it to be very good. Taking into account all previous answers regarding the learning process, it may be concluded that the students are complacent and have a great amout of self-confidence, which cannot be fully justified by the day-to-day teaching practice and lecturer experience.

8. What proportion of your acquired knowledge is down to info gained during the lectures?

1	2	3	4	5
7,5 %	23,75%	45,00%	21,25%	2,5%

Of particular interest to lecturers and of significant importance is the fact that 45% of students claim only a medium role (3 on the 1-5 scale) played by the info gained at the lectures. In fact, more than 50% consider it to be less than very important. Those answers suggest that students believe they knowledge primarily originates in the self-study. This should be a hint to the lecturers when planning further lecture activities.

9. What proportion of your acquired knowledge is down to info gained through ICT?

1	2	3	4	5
5,00 %	7,5%	46,25%	35,00%	6,25%

46,25% of students report a medium role having been played by the ICT.

10. What proportion of your acquired knowledge is down to your own learning style, e.g. to info gained through from other sources of information?

Much - 11,25 %	Barely – 11,25 %
Most - 13,75 %	Enough – 10,00 %

Students seem divided on this question. 25% claim to have their own, presumably successful, learning methods; whilst 21.25% are unhappy with the approach they are taking.

11. Do you believe you would be able to master the subject matter without ICT?

Yes – 36,25 %	Maybe – 7,5 %
No – 43,7 %	Hardly - 25%

The students (43,75%) were negative about mastering the subject without ICT. Only 36,25% believed they could do without ICT. These answers confirm how learning with ICT assistance is becoming an everyday requirement, which would suggest there is today a good balance between the teaching methods and information literacy.

12. Percentagewise, how much has ICT in all shapes and forms contributed to your exam success?

0%	2,5%
10%	2,5%
20%	5,0%
30%	11%
40%	6,25%
50%	20%
60%	10%
70%	10%
80%	10%
90%	8,75%
100%	7,5%

20% of students chose 50% contribution of ICT. To remain objective, to that number we would add only 60-80% answers (90-100% seems rather excessive); put together it would appear that ICT has played a very positive role.

VII. RESEARCH RESULTS

In everyday teaching and planning the most important aspect is enabling students' progress in learning and competency acquisition,. Because of the new approach to students and learning, in line with Bologna, the content and methods of teaching and covering the syllabus are being challenged and evaluated just like any other part of the syllabus.

The results of this research should be significant indicators to teachers, in line with the commonly accepted view that increasing the capabilities of utilising information sources and knowledge therein will improve

educational standards across the board and therefore in higher education too. After analysing all answers in the group sampled it can be concluded that students use ICT in self-study, as required, in a balanced mix with other knowledge sources, but the role of ICT seems more pronounced in self-study. Further monitoring and evaluation of learning outcomes, through new research and subsequently innovated methods and forms of reading and information literacy will result in better competencies as the learning outcomes.

The wider context of the value and the role of information is about helping students to develop to fully fledged members of the educational system, linked through research, and about understanding and responding to the ever evolving information needs. In that process teaching information skills increases the literacy standards [4] through:

- Development of critical-reading skills (reading with a purpose i.e. reading for learning, utilising varied information sources)
- Linking varied reading strategies (skimming, scanning, intensive reading)
- The development of individual capabilities, so that the students can select an appropriate strategy other learning situations
- The capability and skills that enable students to effectively utilise information on various media and in different forms.

VIII. CONCLUSION

The learning in the new circumstances is largely based on the constructivist paradigm of active encounters with the eco-system, starting from experience and moving towards new knowledge, In that way the new knowledge is purposeful and aligned to the everyday life situations. It follows that students should no longer be passive recipients but, instead, active and competent researchers and information users, and would have to be continuously motivated for reading and research activities.

The purpose of the work with students is not merely solving the problems set (analysis) and articulating research results (synthesis) but also the development of a myriad of capabilities and the personal value system. By self-study and writing essays the first year students don't need to and typically cannot demonstrate research accomplishments, but have to evidence the ability of applying a theory, through researching information in different media and the analytical reading ability.

The key question, and sometimes a problem, linked with the higher education online generation is where to start, whereas the starts of teachers' educational effort is in a well thought out motivation. In that context the written essay is a constituent that is written up with the purpose of getting more widely and deeply acquainted with the subject matter and with the scientific research methodology. An important part of this learning process is mastering the rules of scientific expression and the theme presentation, including correctly presenting quotations and listing the sources used.

E-learning as a tool for improving ICT knowledge of university teachers

Dana Paľová
Department of Applied Mathematics and Business Informatics
Faculty of Economics, Technical university of Košice, Slovakia
dana.palova@tuke.sk

Abstract - It is indisputable, that Information and communication technologies (ICT) have influenced all areas of our lives. In recent years, to the universities come the students from a generation of "digital natives", who surpass their teachers in the knowledge of ICT in many ways. The main objective of any education institution is to provide that kind and quality of study that could prepare the best graduates for the work market. These institutions (including universities) have to face many important changes – stay competitive in providing the study by implementation the newest information for the students by ICT supported and more eye-catching ways. Trends in education indicate ongoing changes of learning styles to learner-centred education, which currently means for the teacher a change not only in the traditional methods of teaching, but also the usage of new technologies to increasing student involvement in the learning process. This process of transformation is very intensive and covers several areas of teachers' life.

Within the proposed paper there will be shortly described the fundamental aspects of this transformation process and demands on today's teacher as well as activities that were already done and currently underway at our faculty to support our teachers.

I. INTRODUCTION

Knowledge, the major-creating factor in modern society is closely linked to innovation, one of the main engines of long-term economic growth [17]. Nowadays innovation doesn't refer only to R&D-based technological inventions but also to non-technological and social innovations in public and private services [1]. The revised Lisbon agenda for growth and jobs defined "knowledge triangle" – education, research and innovation. Education provides the appropriate skills and competences for innovation and creates new knowledge and at the same time stated, that "the modern economy requires a broad creative skills base, involving the whole population" [5]. Following that idea it is necessary to support and cultivate creativity and skills, which seem to be harder task than improving the knowledge base and in final consequences, need a new pedagogical concept with innovative didactics. As knowledge can flow through people moving between organizations, labour mobility enables or even forces enterprises to open up their innovation processes [6].

The current global economic crisis is also simultaneously affecting the education sector as well as other sectors in society across Europe. Knowledge, innovation and technology remain key elements in the future strategies. [5]

II. CHANGES/CHALLENGES IN THE WORLD OF EDUCATION

The requirements on education changes are continuously evoked by changes gone over the world of ICT and also by all around society changes (for example transformation from industry to information and after that to knowledge society). These changes need to be really dynamic – the education is become more and the more diverse, colorful and versatile. Today no one could be sufficient with the only one qualification for the life, what is the reason for transformation the education of students (in terms to provide them education ensuring employability in the labor market) or adults (in terms of lifelong learning). In the following, there will be listed several changes, respectively challenges the education is exposed (as can be seen, they are connected and all influenced by each other).

- *New approach / new educational methods*
  - *Learning to learn* – only classical providing information to students by the teacher does not become to relevant aspects of education, but it is important to change the approach of the students to their learning. It is necessary to lead people to self-learning habits, because today within the companies operating in the labour market is a standard practice to favourite persons who have been constantly searching for new information, studying and outside working hours, and are able to contribute to problem solving in practice by creative and innovative way. And also as not least aspect can be considered the developing of strategic and methodological knowledge in order to be able to select and use relevant information.
  - *Learner centred education* – no unique information have to be forwarded to students, and the education must be adapted to their needs, learning methods and study opportunities, making also disadvantaged people easier to study.
  - *eLearning* – computer supported learning is already a common part of education at all levels of study. The problem of this method is its strong

dependence on ICT skills of both sides of education process – teachers and also students. However, it cannot be disclaimed its advantage for modern education, for example for education of many part-time students, possibility of study materials "recycling" (which can save time not only to the teacher), 24/7 availability of education at a time when it is most convenient for students, etc.). The success of eLearning introduction to the institution is strongly dependent on understanding the technology and specialised pedagogical aspects and their common interaction and integration [18].

- *New technologies* - Information and Communications Technologies (ICT) are already a daily part of our lives. Each of EU Member States has developed various programmes concerned especially on the integration of ICT into education. At present, could be concluded that the available ICT infrastructure is already available, but it is high time to work out its use in learning itself. The most recent tools usable/utilizable in the field of education are:
  - LMS – systems designed to publishing various information sources, learning management by many available tools (like communication with the students (messages, forums), design and evaluation of students' activities, etc.).
  - Videogames - becomes a motivating tool (mostly for younger students/pupils) by which could they be seduced to use new technologies and incorporate themselves into the digital world through a more entertaining way [18].
  - Web2.0 tools – can be described as a tool for developing the user generated content. A range of software tools which allow users to interact and share data with others users, primarily via the web can be covered also by the term 'social software'. Blogs, wikis, social networking websites and social bookmarking sites are examples of some of the tools that are being used to share and collaborate in educational, social, and business contexts. The key characteristic of a social software tool is that it involves wider participation in the creation of information which is shared [14], [8].
- *New skills needed* – especially digital literacy and ability to monitor the rapidly developing world of technologies, and apply the acquired knowledge into education, by using new technology as a tool for increasing interest of students in the object of education. ICT is everywhere in society and everybody needs digital competencies that is why the digital competences turned into a key priority in teacher education & training. However, it can also be the core bottleneck to the embedding of learning digital competence in education and training. The ICT should be successfully used both as a learning tool within subject teaching and a tool used by learners for their coursework outside school settings.
- *Creativity and Innovativeness* - Creativity is the prerequisite of innovation and it should be treated in education with the same respect as literacy [17]. The educational process may be focused also on creativity of students – for example the teacher needs to motivate them to put their own contribution to almost every assignment and not just create the compilation of the information published on the Internet. This requires a creative teacher, because such a change in the subject is more complicated and complex in terms of various tasks design and their evaluation. As was shortly described, the creative learning needs transformation on the both sides of the educational process.

To share and improve education in context of all above mentioned facts could help co called OpenInnovation approach defined in [2] as "*the use of purposive inflows and outflows of knowledge to accelerate internal innovation, and expand the markets for external use of innovation, respectively. It assumes that firms can and should use external ideas as well as internal ideas, and internal and external paths to market, as they look to advance their technology*". This approach can be well applied also in education as the approach of communication and exchange of information among EU teachers. Learners and facilitators need to have a strong self-esteem and trust that they will be accepted with their new ideas, not to be afraid of introducing new solutions. This way they will be able to use new ICT-enhanced solutions effectively for collaborative learning. Innovative social networks can enhance learning in formal and informal education [9].

III. IMPROVEMENTS IN THE FIELD OF USING ELEARNING AT THE FACULTY OF ECONOMICS, TECHNICAL UNIVERSITY OF KOŠICE

Faculty of Economics was established 20 years ago. Currently belongs among the best educational institution in the field of economics in the Slovak republic, as evidenced by the evaluation of ARRA the Academic Ranking and Rating Agency in the last 4 years in the category of Faculties of Economics (#1 in 2010, 2008, 2007 and in #2 2009). Education at the faculty is provided and supervised by 51 academic staff (professor, associate professors and assistant professors). In the academic year 2011/2012 attend the Faculty of total 1160 students at bachelor and master level and 56 at PhD. level.

In order to stay one of the best Slovakian faculties faculty management defined the main mission of the Faculty - *To develop knowledge and provide high-quality, professional education in the field of economic sciences and to contribute to the development of society and shaping of the regional economy through the provision of research and consultancy activity, continuing education and services for the local and regional communities.*

In order to fulfil this mission, the Faculty fosters the spirit of democracy, tolerance and humanism, and supports critical and creative thinking among students. Innovation, quality, accountability, critical thinking and freedom of speech are the values which are shared by the Faculty staff and also represent main requirements on high education graduates by the labour market. Besides all mentioned skills it is important for the graduates to be well oriented in the field of ICT [10], [15].

Current students could be considered as representatives of the so called digital native generation. To support them the staff of the faculty besides the classical publishing of actual information about life at the faculty on the web-pages, provide also LMS Moodle, where they can find almost everything they need for their studying. Students of face-to-face learning have available many specialized software for business process modeling [16], accounting, financial decisions, portfolio analysis and many others [13], [7].

A. Distance learning institutional project

In the year 2003, the experiences obtained by participating on various projects concerned on the use of eLearning [10], [19] led to the institutional project "*Preparation and realization of the distance learning bachelor study in the field of Finance, Banking and Investment*."

In terms of management of the project can be implementation of distance education described by the following phases of this process life cycle (Fig. 1):

- Preparation of organization the project (year 2003):
  - definition of the project objectives and target groups,
  - determination of persons responsible for managing the implementation of distance learning at the faculty,
  - preparation of detailed activity plan (overview of the necessary activities and available human and technological resources, finding a suitable LMS),
  - pedagogical, technical and administration staff training,
- Design of specialized materials for particular subjects and on-line courses (year 2004 – up to now),
- Distance learning Bachelor study realization (2005 – up to now). Currently there are at the faculty provided two bachelor study programmes (Finance, Banking and Investments and Public Administration and Regional Development) and one master study programme (Finance, Banking and Investment). Master study programme Public Administration and Regional Development is in preparation and its start is assumed to next academic year.
- Execution of students 'feedback concerning on evaluation particular subject with emphasis on pros and cons of subjects thought by distance learning method.
- Improvement provided materials and extension of proposed information and activities based on feedback results.

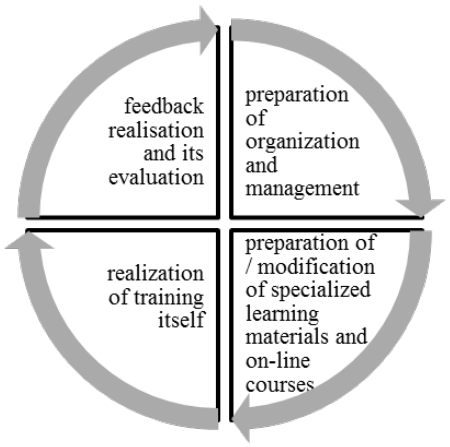

Figure 1. Life cycle of the education process

In [11], [12], [13] is the ICT supported education at the Faculty of Economics described in more details.

As it was pointed out in chapter "Changes/Challenges in the world of education", is there a high need to implement the convenience of modern technology into education independently of the content and focus of the subject.

Introduction of distance learning and necessity of use the LMS for the mediation the necessary information unfortunately wasn't sufficient motivation for using most of available tools that LMS Moodle provides. The detailed analysis of the existing courses content and students` feedback evaluation showed that most of involved teachers consider the courses in Moodle just a place for information publishing not a tool for eLearning. Given the tingling situation, the project management decided to find out what causes that problem. Therefore they decided to verify Moodle working skills among all teachers who are involved in this form of education.

Verification of teachers LMS Moodle working skill was done through evaluation of the performance of particular practical tasks and personal interviewing the teachers. The test tasks were designed mainly to check their knowledge and experience in:

- modification the course settings,
- publication and setting up the various information sources (titles, files, web pages, text, notifications, links to external resources),
- creating students activities and their setting up (on-line, off-line, blog, poll, forum, online test, ...),
- adding information to the calendar,
- send messages, search in their history,
- setting up marks reports and course backup.

To the distance learning at the faculty was involved 41 teachers, who are responsible for setting up the course, publication of necessary information and working with students in LMS Moodle environment. In order to provide the possible best quality and effective usage of available technical background the management decided to be very strict in final evaluation of demonstrated skills. Only those who reached the 90% within the test could continue to provide learning in LMS Moodle. Teachers with fewer percent are able to repeat the test again after a period of time (approximately 6 month), and have available a specialized course in LMS Moodle, where is provided the manuals for this system, case studies, examples, a sample

course and specialised course they can “play” with the course settings.

As is shown in the chart below (Fig. 2):

- 57% of the test tested teachers was able to pass through the test tasks well (20% of them need help in various activities – mostly in setting up assignment and test tools, 37% of all teachers reached the 100% value),
- 2% of them failed and need other IT staff to assist during realization of the on-line learning,
- 7% of them were not taken a part on the test because of various reasons (for example - they are not involved to distance learning previously and there were provided some time for become familiar with the system environment).

The most surprising result was that 57% of teachers who have used the system for eLearning in previous years reached the critical value 90%. It follows, that the weak further development of the on-line courses is not caused exactly by low level of digital literacy of teachers. After practical test was every participant interviewed in order to get the reasons of this surprising situation. Most of them (approximately 80%) agreed that they had low level of motivation to find out and use tools provided by LMS Moodle within education. But after the decision of top management that everyone must be tested in work with Moodle they were forced to study closer the available tool and their options. With this initiative they discovered a number of tools that they will also be used in teaching their subjects.

After the above mentioned testing phase and achieved results coordinator of that form of study and faculty’s top management were interested in real situation within already running on-line courses. The test was done before this year winter semester so there are available for evaluation only courses realized in last semester what means 48 courses in all study programmes and levels. As can be seen on the Fig. 3, before test most of the courses contained only obligatory information and base study materials, calendar with the information about face-to-face consultations, but after test the situation markedly changed. Within 34 courses were been created many other supporting and interesting materials (doc, xls, ppt and pdf files, web-pages and link to external sources) and various types of students’ assignments with on-line evaluation.

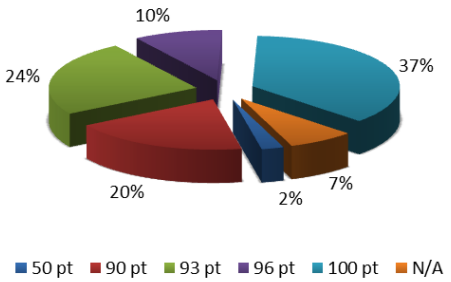

Figure 2. Results of testing the ICT skill of pedagogical staff

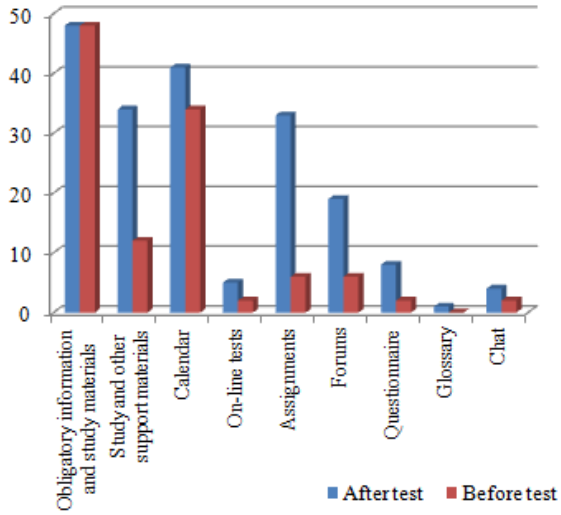

Figure 3. Summary of the usage of particular LMS tools in provided on-line courses

B. OpenInn project

Besides institutional activities concerned on the continuous improvement of provided education, staff of the faculty of Economics also participates on the various international projects dealing problems the same field – field of modern education. Actually it is done in following projects:

- Leonardo da Vinci programme:
  - OpenInn2.0: A Knowledge generating House and e-Assessment (OpenInn),
  - 50+ Citizens’ Participation in Creation of their Lives - SAGE+
  - Stress Prevention Activities Training (SPAT)
- Erasmus/Socrates/Grundvig programme:
  - Turning the silver Challenge into Golden Opportunity (SIGOLD)
  - Policy and Policy making at the local level,
  - ESTIA – EARTH - To Sustain the Women’s Careers as Academics, Researchers and Professionals in Engineering, Computers and Science.

Concerning the problem of innovation and improvement of provided education (as well as a distance education) at the faculty, the outcomes of the project OpenInn [9] seem to be very interesting in way of enhancement creativity and innovation in education.

The expected outcomes of the project are:

- Pedagogical and organizational model for communities and individuals to explore their innovative potentials by the use of ICT tools,

- Knowledge Generating House (KGH) a collaborative learning environment based on the web2.0 elements containing:
  - Innovation eLearning Rooms (IeLR) - a collection of web-based tools to support collaborative and distributed innovation exercises. The participants of the IeLR are connected together for brainstorming and mind-mapping in a specific topic and a level of difficulty.
  - an eLearning material on all subjects along the innovation process from how to develop innovative ideas, as well as how to evaluate, implement, protect, finance & market innovative products & services.
  - resource library – documents and links oriented to innovation management.
  - guide for Informal Learning - case studies and best practices on the use of the portal and tools for informal and cooperative learning scenarios.
- e-Assessment model – the theoretical concept and didactics for creativity, with topics including: ways to support the learner to introduce new ideas, evaluating and rewarding creative results, methods for giving instructions to reach innovative solutions, providing autonomy for creative expression both for not-yet ICT users and advanced level users in their specific sectors.

These results are designed in 9 languages (EN, DE, SK, PT, IT, HU, ES, DA, BG), languages of participants of the project and target to:

- talented youth in higher and secondary education,
- groups at risk of falling out from the educational system in secondary, higher education, vocational training and adults wanting or needing to further explore their capabilities,
- students with a specific research or scientific interest: experts, SMEs, managers of large enterprises, non-profit organizations, groups that need more support in order to be able to use the portal for enhancing creativity.

The KGH will have following positive impacts to education process:

- teachers could look for ideas expressed by others and by exploiting their own inner potentials as well. This innovative approach generates a new learning experience, where users can be actively engaged in creating and inventing,
- teachers in various level of digital literacy could find the materials helping their effort to use of ICT in the learning process,
- students and young researchers will be more motivated to explore the utilization possibilities of their ideas as a self-realization process, contribute to the actual real work or find mentors among the experts,

C. General summary, remarks and proposals for the future

As is stated also in the publication [4], despite the availability of technologies for improving education at modern slovak universities, there is a significant gap between availability of technologies and their exploitation if it is just voluntary activity of academic staff. The situation rapidly changes, when the use of ICT is defined by directive or some regulation specified by top management of the institution or by the introduction of distance education, which is mostly based on their use. Miscellaneous training will not help in that case. At the universities in Slovak Republic there is expected rather separate personal involvement of teachers in the implementation of ICT. Introduction of new tools in education requires constant provocation in terms of promoting a genuine interest and understanding of the environment that is in their everyday resistant and naturally resists any change. Therefore that is the one of reasons, that there are only slow changes in educational methods and continual improvement the quality of higher education [3]. Teacher attitudes towards ICT is a challenge – 20% of teachers are still reluctant to make use of ICT and believe that the use of computers in class does not have significant learning benefits for students. In Slovakia education system pedagogical support for the field of eLearning is still missing. There is not enough support for teachers – in the form of maintenance, and ICT advisers, for example [4]. From that point of view it is necessary:

- to implement the eLearning into institutional strategic documents and design, disseminate and support a tool like KGH where teachers can collaborate with their colleagues engaged the same area from other education institutions,
- to change of attitude to the changes of education in the highest places - as can be stated, mentioned (not very common) activity of management faculty has led to not only increase the quality of courses, but also of study teacher and opened new areas and ways to improve provided education. These tools allow developing the engagement of students in their own studies, and at the same time focusing on the creativity and innovativeness of the graduates. A creative approach and innovativeness is a strong asset of the life in practice when solving real problems.

IV. CONCLUSION

In terms of implementation of innovations, educational institutions can be inspired by other companies operating on the labour market. In present days, many of modern universities undertake change their view on the education – institutional management defines the education process as a service/product provided to clients/students. And in order to remain competitive and to guarantee success of their graduates on the labour market it is necessary continuously innovate the education. Nowadays it means among other things, change the thinking of teachers, the necessity to exploit the available ICT tools in the innovation process.

The OpenInn project outputs may help in increasing the quality of education on both sides - to support engagement students in the study and increase their confidence and show the teacher what kinds and how broad are the available possibilities for modern education.

ACKNOWLEDGMENT

This work has been kindly funded by the European Commission through the LLP Project OpenInn2.0: A Knowledge Generating House and e-Assessment Model (No. 511583-LLP-1-SK-KA3-KA3MP). I also wish to acknowledge my gratitude and appreciation to all the OpenInn2.0 project partners for their contribution during the development of research presented in this paper.

Students' Perceptions of Scrum Practices

V. Mahnic and I.Rozanc
Faculty of Computer and Information Science, University of Ljubljana, Trzaska 25, SI-1000 Ljubljana, Slovenia
viljan.mahnic@fri.uni-lj.si, igor.rozanc@fri.uni-lj.si

Abstract - In order to prepare students for increasing use of agile methods in industry, teaching these methods is becoming an important part of the Software Engineering curricula. At the University of Ljubljana Scrum has been systematically taught since 2009 in the framework of the software engineering capstone course. The paper describes the course content and analyzes results of the survey that was performed among students with the aim of identifying those practices that students perceive most important for the success of Scrum-based software projects. Students' opinions on 12 typical practices representing possible success factors are described and compared to opinions of professional developers in order to find out similarities and differences in their perceptions. Both groups of respondents identified team-work and communication among team members, as well as good communication with the Product Owner, most important. Students also stressed the importance of strict adherence to the notion of "done", while professional developers ranked third Sprint Planning Meetings and maintenance of Sprint Backlog. Accuracy of user stories and velocity estimation was rated least important by both groups of respondents.

I. INTRODUCTION

Numerous agile software development methods [1] have appeared in the last 15 years that – in contrast to disciplined plan-driven approach advocated by the quality models – "value individuals and interactions over processes and tools, working software over comprehensive documentation, customer collaboration over contract negotiation, and responding to change over following a plan" [2]. According to the Agile Adoption Rate Survey [3] performed by Dr. Dobb's Journal in 2008, agile teams report significant improvements in productivity, quality, and stakeholder satisfaction, and reasonable improvements in cost. A similar survey conducted by VersionOne [4] additionally reports an enhanced ability to manage changing priorities and significantly improved project visibility. On the other hand, the same survey has revealed that the lack of experience with agile methods, and the conflict between the company's culture and core agile values are the leading causes of failed agile projects.

Due to the increasing use of agile methods in industry in the last few years, the teaching of agile methods for software development has become an important issue [5]. Although some universities are starting to teach courses on agile methods, these are still rather new [6]. Since core software engineering courses mainly teach the traditional plan-driven approach, the capstone course seems to be an appropriate place for the introduction of agile software development.

An extensive study of 49 capstone projects [7] using different software processes (ad hoc, MIL-STD-498, IEEE 1074, Team Software Process, and Extreme Programming (XP)) reports several benefits of introducing the agile approach in place of the traditional plan-driven processes. The agile approach is more appealing to student teams, and project success, measured by how well the finished software met customers' expectations, surpassed that of previous projects using non-agile software processes. Coupal and Boechler [8] report a similar experience comparing student projects developed following an agile approach to their previous projects developed in a traditional way. Successful introduction of agile methods in capstone courses is also reported in several other studies, for example [6], [9]–[11].

State of agile surveys conducted by VersionOne since 2006 indicate that Scrum [12, 13] is the most widespread agile method and its share is permanently increasing (see Fig. 1). In light of the above, a new software engineering capstone course was designed at the University of Ljubljana, Slovenia, that introduces Scrum as a framework for the planning and management of students' projects. The course ran for the first time in the Academic Year 2008/2009, and as well as teaching students agile software development through team-work on two industry-relevant projects, also paid special attention to students' perceptions about the learnability and usability of Scrum. An empirical evaluation [14] has shown that students enjoyed learning Scrum and successfully grasped its main strengths. Their perceptions of Scrum improved from Sprint to Sprint and were in statistically significant agreement with anecdotal evidence about Scrum's benefits reported in the literature.

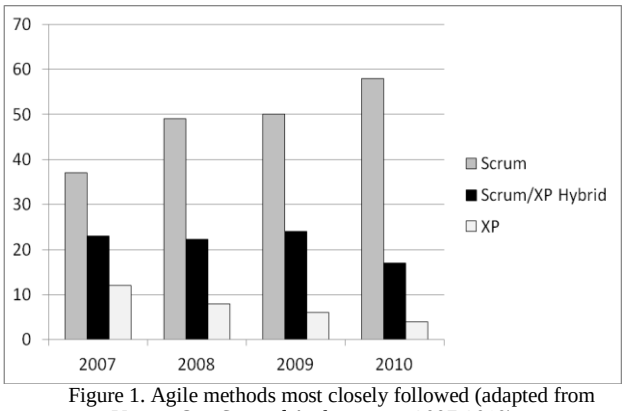

Figure 1. Agile methods most closely followed (adapted from VersionOne State of Agile surveys 2007-2010)

In order to help students to better understand the problem of agile estimation and planning, and to improve

their skills, the course was upgraded in the Academic Year 2009/2010, with the project work being designed as an observational study providing data for empirical evaluation of students' skills with special emphasis on user stories estimation, release planning, fulfillment of scope, and velocity tracking [15, 16]. The course was conducted in a similar way in the Academic Year 2010/2011, further emphasizing the use of user stories as a means for requirements specification [17], and agile project planning and management [18].

In order to obtain students' opinions, several surveys were preformed during the last three years. An important part of the survey that was conducted at the end of Academic Years 2009/10 and 2010/11 was focused on students' perceptions of 12 typical Scrum practices in view of their impact on the success of Scrum projects. Proper execution of each practice was treated as a possible success factor and students were asked to evaluate its importance using a 5-point Likert scale. The same survey was later conducted among a group of developers at the largest Slovenian media house, which used Scrum in a project of rebuilding the web site of its daily newspaper with the highest circulation. This paper presents the results of both surveys and compares opinions of students with those of professional developers.

The remainder of the paper is organized as follows: Section II contains a brief description of the capstone course. Section III describes 12 typical Scrum practices the respondents had to rate. The results are presented in Section IV and discussed in Section V. Section VI provides a conclusion.

II. COURSE DESIGN

The course is designed to teach Scrum in a near real-world environment, augmenting the Scrum method with user stories, release planning, and velocity tracking. Students are required to work in groups in order to develop a quasi-real project on the basis of user requirements provided by a domain expert playing the role of the Product Owner. The course lasts 15 weeks and is taken by Computer Science students in their last (eighth) semester. It is allocated 7 ECTS [1] points; therefore, the expected workload of each student (including contact hours) is between 175 and 210 hours.

The first three weeks serve as a preparatory Sprint (Sprint 0) before the start of the project. During Sprint 0 students are given 12 hours of formal lectures on agile principles, Scrum, and the use of user stories for requirements specification and iteration planning. These three weeks are also used to prepare the development environment and acquaint students with the initial Product Backlog, containing a set of prioritized user stories for the project they are going to develop. Each story contains a short description and a set of acceptance tests that must be used to demonstrate that the story is correctly and fully coded. Students are grouped into teams of four, responsible for the development of the required functionality. Each team estimates the stories using planning poker [19] and prepares the release plan.

The rest of the course is divided into three Sprints, each lasting four weeks. Strictly following the Scrum method, each Sprint starts with a Sprint planning meeting at which student teams negotiate the contents of the next iteration with the Product Owner, and develop the initial version of the Sprint Backlog. During the Sprint the teams have to meet regularly at the Daily Scrum meetings and maintain their Sprint Backlogs, adding new tasks if required and updating data on work spent and work remaining.

At the end of each Sprint, the Sprint review and Sprint retrospective meetings take place. At the review the students present their results to the instructors, while at the retrospective meeting students and instructors meet to review the work done in the previous Sprint, giving suggestions for improvements in the next. After three Sprints the first release should be complete and delivered to the customer.

Since user stories provide only a rough description of required functionality all teams are strongly encouraged to communicate with the Product Owner in order to resolve possible disagreements over the implementation as soon as possible. When a team finishes a story the Product Owner is asked to evaluate its implementation. The Product Owner strictly enforces the concept of "done", rejecting all stories that do not conform to user requirements. If the shortcomings are not removed by the end of the Sprint a new story must be defined in the Product Backlog requiring the completion of missing features in one of the remaining Sprints.

The course is conducted as a case study; therefore, students are required to provide data on their initial effort estimates, the amount of work spent and the amount of work remaining. At the beginning of each Sprint they are encouraged to re-estimate their velocity and the remaining user stories in order to obtain a more realistic plan for future iterations. Instructors compare students' plans with actual achievement and analyze whether students' estimation and planning abilities improve as they gain more knowledge of Scrum and a better understanding of the user requirements. An upgraded version of the Agilo for Scrum project management tool [20] is used to support the collection of all required data.

There is no formal final exam, and the students' grades are determined on the basis of the amount of Product Backlog accomplished, the quality of software and documentation developed, the fulfillment of release and Sprint plans, and the instructor's judgment on how well the team worked together, maintained the Sprint Backlog, and kept to schedule.

In the Academic Year 2009/10 the course was attended by 52 students, while in the Academic Year 2010/11 the number of students was 51. Both times 13 student teams were formed that were required to develop a Web-based student records information system covering enrollment, examination applications, examination records, some statistical surveys, and a special module for the maintenance of all data required

[1] European Credit Transfer and Accumulation System

for the proper functioning of the system (i.e., the maintenance of various code tables, lists of required and optional courses, data about teachers of each course, etc.). Strictly following Scrum rules, each team acted as a self-organizing and self-managing Scrum team collectively responsible for the implementation of the required functionality.

The initial Product Backlog consisted of 60 user stories. 55 stories described the required functionality for four different user roles (student records administrative staff, students, teachers, and data administrator), whereas five stories described constraints that had to be obeyed (e.g., the system had to enable remote access to data through the Internet, all outputs should also be printable, and so on).

The initial Product Backlog was prepared by a teacher who had considerable experience in developing university information systems, thus being able to provide realistic user requirements and play the role of Product Owner. The stories were divided into four groups on the basis of priority. Among the 55 stories describing the required functionality there were 21 "must have", 4 "should have", 3 "could have", and 27 "won't have this time" stories. The teams were asked to implement at least all "must have" and as many as possible "should have" stories for the first release. If they planned to be more productive they could also include the "could have" and even some of the "won't have this time" stories. However, the "won't have this time" stories were specified merely to illustrate the desired functionality for the next release.

III. SCRUM PRACTICES AS SUCCESS FACTORS

After attending the course students were asked to evaluate how much the proper execution of each Scrum practice contributes to the success of a Scrum project. In order to identify the most important success factors they had to rate the following items:

Quality of requirements specified in the Product Backlog: Scrum requires the maintenance of the Product Backlog. Product Backlog consists of a set of user stories describing the required functionality and constraints of the new system. Each user story must contain a short description and a list of acceptance tests to confirm that it has been developed with the functionality the customer had in mind when he/she wrote the story. The Product Owner is responsible for the contents, prioritization, and availability of the Product Backlog. The quality of Product Backlog can significantly affect the success of a Scrum project.

Good communication with the Product Owner: Scrum requires all details regarding a user story implementation to be clarified through conversations between the Product Owner and developers. At the end of each Sprint, the Product Owner also decides whether a story has been fully implemented or not. It is important that the Product Owner provides timely answers to questions on user stories details, and makes quick evaluations of work being done.

Good ScrumMaster: Scrum prescribes the role of ScrumMaster instead of the traditional project manager. The ScrumMaster is responsible for managing the Scrum process so that it fits within an organization's culture and still delivers the expected benefits, and for ensuring that everyone follows Scrum rules and practices. He must protect the team by making sure they do not over-commit themselves to what they can achieve during a Sprint, and resolve impediments brought up by the team during Daily Scrum meetings.

Team-work and communication among team members: Scrum requires self-organizing, self-managing, and cross-functional teams that are collectively responsible for implementation of the committed functionality. Therefore, it is important to establish team-work and good communication among team members.

Accurate user story estimations: Scrum requires development teams to estimate the effort required for the implementation of each user story. Stories are usually estimated in story points using the planning poker technique. Estimates are owned by the team and serve for preparation of release and iteration plans. Inaccurate estimations can cause cost overruns, delayed projects, improper resource allocation and/or lost contracts.

Release Planning: Scrum requires the Release Plan to be created by allocating stories to Sprints strictly considering their priority. The total number of story points allocated to each Sprint must not exceed the team's planned velocity. The Release Plan helps the Product Owner and the whole team decide how much must be developed and provides an estimate of the approximate duration of a project. It serves as a guidepost toward which the project team can progress. Without the concept of a release, teams move endlessly from one iteration to the next [21].

Accurate velocity estimation at the beginning of each Sprint: Scrum requires Scrum teams to estimate their expected velocity at the beginning of each Sprint. Accurate velocity estimates enable Scrum teams to take the right decision about the amount of work they can accomplish. Measuring and monitoring velocity through several iterations improves the accuracy of estimates, thus contributing to better Sprint planning and smooth running of a project.

Sprint Planning Meetings and maintenance of the Sprint Backlog: Scrum requires each Sprint to start with a Sprint planning meeting. At the Sprint planning meeting the Product Owner and team get together to agree upon user stories to be implemented over the next Sprint. The Product Owner presents the highest priority Product Backlog and the team selects how much of what is desired it can implement. Then the team develops the Sprint Backlog, i.e., a list of tasks that must be performed to deliver committed functionality by the end of the Sprint. The tasks in the list emerge as the Sprint evolves and should be divided so that each takes roughly 4 to 16 hours to finish.

Daily Scrum Meetings: Scrum requires that the development team meets every day for a 15-minute Daily Scrum meeting. Daily Scrum meetings serve as a means

of empirical process control in order to assure visibility, inspection, and adaptation. Each team member must report what he has done since the last meeting, what he will do till the next meeting, and what impedes him from performing his work as effectively as possible. Daily Scrum meetings must not be for reporting to the ScrumMaster, but for the team members to inform each other about the current state of the project.

Concept "done": Scrum requires that at the end of each Sprint the Product owner accepts only those stories that are potentially shippable. It is preferable to have a small number of completed stories than to have a slightly larger number of stories all incomplete. Strict enforcement of the concept of "done" contributes to the awareness that the code must be fully tested, integrated, and resistant to user errors in order to be used in practice.

Sprint Review Meetings: Scrum requires a Sprint review meeting to be held at the end of each Sprint. At the Sprint review meeting the team presents what was developed during the Sprint to the Product Owner and any other stakeholders who want to attend. This meeting is intended to review the work completed and provide directions for the next Sprint. Through Sprint review meetings customers see on-time delivery of increments, and obtain frequent feedback on how the product actually works.

Sprint Retrospective Meetings: In order to assure continuous improvement of the development process, Scrum requires a Sprint retrospective meeting to take place at the end of each Sprint, i.e., after the Sprint review meeting and prior to the next Sprint planning meeting. At this meeting, the ScrumMaster encourages the team to revise its development proces to make it more effective for the next Sprint.

IV. RESULTS

Students rated the aforementioned practices using a 5-point Likert scale. Grade 1 indicated that the practice was not important at all, and grade 5 indicated the highest importance. Grade 3 represented a neutral opinion, indicating that the practice was considered neither important nor unimportant. In total the authors obtained 94 answers (51 in the Academic Year 2009/10 and 43 in the Academic Year 2010/11).

Since the authors wanted to compare students' opinions with opinions of professional developers, the same survey was also conducted among 6 developers at the media house working on the project of rebuilding the website of their major daily newspaper. The aim of the project was to introduce completely new design using Drupal content management system [22] as the base for implementation. Developers at the media house were surveyed at the end of the fourth Sprint of their project. Both, students and the media house developers used Scrum for the first time, thus having approximately the same amount of experience with agile methods. The only exception was one of the media house developers who attended the capstone course in the Academic Year 2008/09 and proposed the media house management to use Scrum in their project.

Results of both surveys are presented in Table I (students) and Table II (professional developers).

V. DISCUSSION

Comparison of Tables I and II reveals several similarities, but also some differences between the students and professional developers. Both groups of respondents

- agreed on the two most important success factors, i.e., team-work and communication among team members, and good communication with the Product Owner;
- stressed the high importance of the concept "done";
- had similar opinions about the role of the ScrumMaster, Sprint review and Sprint retrospective meetings, and Release planning;
- rated accurate user story estimation and accurate velocity estimation least important.

On the other hand, the students and professional developers had different opinions about

- the importance of the clarity of requirements specified in the Product Backlog;
- Sprint planning and Daily Scrum meetings.

A. Two most important success factors

The survey has shown that the two most important factors affecting the success of Scrum projects are: (1) team-work and communication among team members, and (2) good communication with the Product Owner.

TABLE I. STUDENTS' OPINIONS REGARDING THE IMPORTANCE OF SCRUM PRACTICIES (N=93)

Rank	Factor	Mean	Std. dev.
1	Team-work and communication among team members	4.80	0.43
2	Good communication with the Product Owner	4.79	0.44
3	Concept "done"	4.33	0.88
4	Clarity of requirements specified in the Product Backlog	4.29	0.68
5	Sprint Review Meetings	4.24	0.71
6	Good ScrumMaster	3.99	0.92
7	Sprint Planning Meetings and maintenance of Sprint Backlog	3.87	0.82
8	Daily Scrum Meetings	3.83	0.98
9	Release planning	3.81	0.85
10	Sprint Retrospective Meetings	3.76	0.89
11	Accurate velocity estimation	3.61	0.88
12	Accurate user story estimation	3.60	0.85

TABLE II. PROFESSIONAL DEVELOPERS' OPINIONS REGARDING THE IMPORTANCE OF SCRUM PRACTICIES (N=6)

Rank	Factor	Mean	Std. dev.
1	Team-work and communication among team members	4.67	0.52
2-3	Good communication with the Product Owner	4.33	0.82
2-3	Sprint Planning Meetings and maintenance of Sprint Backlog	4.33	0.52
4-5	Concept "done"	4.00	0.63
4-5	Sprint Review Meetings	4.00	0.89
6	Good ScrumMaster	3.83	0.75
7	Clarity of requirements specified in the Product Backlog	3.67	1.03
8	Sprint Retrospective Meetings	3.50	1.05
9	Release planning	3.33	1.21
10-11	Daily Scrum Meetings	3.17	0.75
10-11	Accurate user story estimation	3.17	0.75
12	Accurate velocity estimation	3.00	0.63

This is in line with agile principles that (1) the most efficient and effective method of conveying information to and within a development team is face-to-face conversation, and that (2) business people and developers must work together daily through the project. These principles emphasize synchronous human communication rather than communicating through documents, and require a customer representative to be available in order to provide feedback and to answer the questions of the development team [1]. Authors' experience with the capstone course [15] has shown that the role of the Product Owner is crucial for the success of a Scrum project. He/she communicates the vision of what is to be developed and defines the criteria by which it will be judged. A nonresponsive Product Owner can cause unproductive work periods, which make iteration planning more difficult or even impossible. Additionally, the Product Owner must be knowledgeable enough about Scrum to be able to write, maintain, and prioritize user stories. On the other hand, the Product Owner must not interfere in the management of teams, redefining the scope or goals of a Sprint, or trying to add new requirements once a Sprint has started.

B. Concept "done"

The notion of "done" was also rated very high by both groups of respondents, especially students. Although it was their first Scrum project, it seems that they immediately accepted one of the most important agile values, i.e., that the progress of the team is measured in working software. Producing large paper documents and reporting that the code is 80% complete give a false impression of project progress; therefore, the developers should "rely on the honesty that comes with running code" [21]. Only those stories that are brought up to the useful, real-world level which can survive an encounter with users can be considered "done" by the Product Owner and contribute to the velocity calculation.

C. The role of ScrumMaster

The importance of having a good ScrumMaster was ranked sixth by both groups of respondents obtaining average rates 3.99 and 3.83, respectively. Although still considered important, it seems that this role is less exposed than the role of the Product Owner. Strictly following the Scrum principles of self-organizing and self-managing teams, the ScrumMaster acts merely as a facilitator, thus giving an impression of less importance. He is not the team leader, but acts as a buffer between the team and any distracting influences. A key part of the ScrumMaster's role is to protect the team and keep them focused on the tasks at hand.

D. The role of Scrum meetings

Both groups of respondents had similar opinions regarding the importance of Sprint review meetings and Sprint retrospective meetings, but differed quite a lot in their ratings of Sprint planning meetings and Daily Scrum meetings.

Students rated Sprint review meetings to be very important (rank 5, mean 4.24), while the other meetings received average grades between 3.76 and 3.87, which means that these meetings are also considered important, but less than other Scrum practices. While the authors agree that Sprint review meetings are important for reviewing the work completed and providing directions for next Sprints, they attribute a slightly lower grade of other meetings to the fact that Computer Science students prefer technical activities and often perceive meetings as an unproductive waste of time. Nevertheless, it is worth noting that students rated all meetings except Sprint planning higher than professional developers.

Professional developers attributed most importance to Sprint planning meetings, which were rated as high as the good communication with the Product Owner (rank 2-3, mean 4.33). It seems that the professional developers are more aware of the fact that a well prepared and maintained Sprint Backlog is a prerequisite for smooth running of a Sprint. The rates and ranks of Sprint review and Sprint retrospective meetings are similar to those of students, while the rate and rank of Daily Scrum meetings are much lower.

Quite surprisingly, the importance of Daily Scrum meetings was rated higher by students (rank 8, mean 3.83) than by professional developers (rank 10-11, mean 3.17). It seems that students better grasped the fact that Daily Scrum meetings represent one of the most important Scrum practices providing continuous insight into project activities and serving as a means for immediate detection and resolution of possible impediments. Nevertheless, both groups of respondents ranked this practice quite low, which is in conflict with the widespread use of Daily Scrum meetings in industrial environment. According to survey [4], daily standup meetings are used by 82% of respondents, thus being the second most used agile technique (iteration planning is used by 83% of respondents).

E. Release planning

In spite of the fact that a release plan provides a context that allows iterations to combine into a satisfying whole, the importance of such a plan was rated rather low especially by the developers working at the media house. The low rate can be partly justified by Cohn's warning [17] "not to put too much faith in the release plan" since it only represents an approximate duration of a project. Nevertheless, the Scrum users should bear in mind that without a release plan they do not have a clear picture about what is likely to be developed and in what timeframe.

F. Accuracy of estimates

Accurate user story estimation and accurate velocity estimation were rated least important by both groups of respondents. Although agile methods advise not to put too much effort into plans, but to apply an ongoing iterative approach to planning (putting too much effort into plans can lead to the common misbelief that the plans must be right), the authors think that both groups of respondents underestimated the impact of accurate user story and velocity estimates on iteration and release plans.

G. Clarity of requirements specified in the Product Backlog

The students attributed much more importance to the clarity of requirements specified in the Product Backlog than professional developers. During the capstone course many of them were suspicious of the use of user stories for requirements specification finding user stories not precise enough to adequately describe the desired functionality. It seems that the students were less aware of the fact that the essence of the agile approach is not in writing detailed requirements specification, but in acquiring missing details through conversations with the Product Owner and end users.

VI. CONLUSION

Agile software development methods represent an important teaching challenge. Authors' experience has shown that the capstone course is an appropriate place for the introduction of these methods. Such a course can provide students with a realistic simulation of professional experience enabling them to better grasp the most important agile concepts. The survey that was conducted among students at the end of Academic Years 2009/2010 and 2010/11 showed that they mastered the most important practices, and that their perceptions are mostly in line with those of professional developers. In some cases (e.g., with regard to importance of Daily Scrum meetings) the authors found their opinions even more appropriate.

The authors agree with students' opinions that team-work and communication among team members, as well as good communication with the Product Owner are most important. On the other hand, the survey revealed some practices that were underestimated (e.g., Sprint retrospective meetings, velocity estimation and user stories estimation) and should deserve more attention when teaching forthcoming generations.

Abstract - **The unstoppable growth of market demand for good knowledge workers is an imperative for educational institutions to continuosly improve their programmes and equip young people with skills that will give them the best possible access to the business world. As higher education institutions strive to provide the best possible educational programmes, the importance of the logistic pillar of IT and its continuous development is self-evident. The new century in the European Union countries has highlighted the importance of high quality knowledge, lifelong learning, and common dimensions of the knowledge base. Knowledge is today one of the fundamental levers of development. Knowledge management is the capability of active formation and creation of one's immediate and wider environment. Information and communication technologies (ICT), particularly the Internet and its applications, increase the volume, speed and accessibility of information, while eliminating the obstacles of space and time. In today's world, companies demand applicable solutions to the problems in their environment. The central goal of university reform in the Republic of Croatia is the transition towards an integrated, competent, research-orientated and efficient higher education, with accredited programmes and institutions. The Bologna process in the new education structure for economists (undergraduate and graduate studies, specialist graduate studies, doctoral studies) requires continuous monitoring, adapting, updating, innovation and transparency of the devised model of education.**

I. INTRODUCTION

The processes of globalization and internationalization are inevitably recognized in the economy, with its ever more noticeable division of labour, increasing competition, changes in professional structure, as well as in required knowledge and skills. One of the consequences of globalization is increased student mobility.[1] All these changes will have an impact on the education system.

Considering the growing possibility of student mobility (ERASMUS PROGRAMME), educational and training institutions must strive to retain the users of educational services by offering to provide applicable knowledge accompanied with high quality teaching.

In the last few years, the European Union has intensified activities in the area of education and research, although the responsibility still lies with the particular member states. Through exchanges of good practices in education, e.g. referring to teacher training, developing foreign language skills, acquiring skills with information and communication technology (ICT), funding, management, consultancy, informal learning and teaching, results monitoring using the agreed indicators and measures, there is an interconnected education and research area emerging in Europe. It is in this area that the Republic of Croatia will also define its profile in key knowledge areas.

II. KNOWLEDGE MANAGEMENT MODEL IN CROATIAN HIGHER EDUCATION

The principles outlined in the Bologna Declaration have defined the goals that are of primary importance in establishing the common European Higher Education Area and its promotion.

The goal is to construct recognizable and comparable education levels, and to introduce a Diploma Supplement. This should promote the possibility for employment of EU citizens all over Europe, as well as improve the competitiveness of the European higher education system.

The stated overall goal subsumes its specific sub-goals:

- Higher education system is based on two cycles, undergraduate and graduate. In order to access the second cycle, a student needs to graduate from the first cycle lasting at least three years. The degree attained after the three years (baccalaureus) is considered to be the required level of qualification on the European labour market. The second cycle leads to specialization and/or doctoral studies, in line with the majority of European countries.

- Introducing the ECTS is a desirable means of promoting wide-ranging student mobility. ECTS points can be acquired also outside the higher education system, for example in lifelong learning programmes, provided they are recognized by the

university where a student wishes to continue his/her studies.

- Overcoming the obstacles to free student mobility in the education process promotes the mobility of students, teachers and researchers, which enables them to gain a new access to studies, and provides continuous training. The time spent in other countries researching, teaching, or studying is recognized and acknowledged, without prejudice to their statutory rights.

- Promoting European cooperation in quality assurance, with the aim of developing comparable criteria and methodologies.

- Promoting the required European dimension in higher education, especially in the development of study programmes, inter-institutional cooperation, mobility schemes and integrated study programmes, further training and research.

The stated structural principles of the Bologna process are defined through the following development goals[2]:

- Adapt the adult education system to labour market requirements and adult capacity for learning. This refers in particular to underprivileged target groups.
- Reduce illiteracy rates and provide everybody with the possibility to finish primary and secondary education in order to increase their employability.

III. KNOWLEDGE TRANSFER THROUGH QUALITY ASSURANCE MODEL IN HIGHER EDUCATION

Interactive approach in the dialogue between Croatian universities and their socio-political environment aims to develop a sustainable regional research programme, which would contribute to the knowledge transfer model. Investment in science and higher education is considered to be a highly productive government spending, since it contributes directly to the economic growth of a country.

The basic responsibility and purpose of higher education institutions is the transfer of advanced knowledge and skills to individuals who will be able to apply them in practice and thus contribute to continuous growth. This in fact is the essence of knowledge transfer. Scientific institutions have a major role in this, as they gain and create new scientific and technical knowledge through research and advanced scholarship, as well as through sharing and implementing the latest European and world achievements in Croatian economy. [3]

Since higher education is a crucial part of the whole system – starting with pre-school, primary and secondary schools, to polytechnic (vocational) and university studies, to different lifelong learning programmes – the quality assurance model at Josip Juraj Strossmayer University in Osijek aims to redesign the position of this university in the overall education process in the knowledge society.

The function of all the universities in Europe, as well as in Croatia, has always been to create knowledge and transfer it to new generations. In this way universities contribute to social continuity. Due to the critical nature of new knowledge, they are frequently also initiators of social change.

Every society needs a quality higher education in order to ensure continuous 'training of trainers', educate experts in all scholarly fields and promote critical thinking at all levels. The functioning of any university, including Josip Juraj Strossmayer University in Osijek, presupposes its autonomy in research work and teaching. All the representatives of political, ideological and economic power in the society traditionally acknowledge and support this role of the university.

The quality of education has always been a crucial aspect in overall success of any nation. It is important to note here the examples of 'small' countries such as Switzerland, Finland or the Netherlands.

The changes summarized in the notion of evolving into the 'knowledge society' have underpinned some already existent features of universities. They will continue to influence the role of universities in the society. This refers primarily to the increased importance of knowledge for the processes of social production, as well as for personal success, increased density of interactions between people around the world, and finally, increased speed of replacing existing knowledge with new knowledge.

The rate of knowledge substitution is steadily increasing. Knowledge creates more knowledge, thus the whole knowledge generation process, its technological implementation, and innovations in knowledge transfer through teaching have been continuously accelerating. All these factors contribute to interdisciplinarity, meaning that new combinations of knowledge from different scholarly disciplines emerge, trying to analyze and solve the issues from a different angle.

Josip Juraj Strossmayer University in Osijek has a very important role in implementing the processes discussed above. Everybody is striving for improved research and teaching practices, thus 'excellence centres' should be established wherever possible, and the University in Osijek has accomplished this. Furthermore, international student and teacher exchanges should be stimulated, and joint transnational specializations, postgraduate and

doctoral studies established. When we compare the science and education system in Croatia with these systems in neighbouring countries, one question looms large – how to significantly increase the number of students, and at the same time achieve high quality of studies and knowledge transfer. Planning a feasible pace and preconditions for such growth is one of the key tasks of Josip Juraj Strossmayer University in Osijek and the Faculty of Economics in Osijek, which is the biggest and oldest constituent of this university. [4]

Economic operators are increasingly aware that their performance in the global market depends on the extent to which they have managed to incorporate scientific results into their business. They are capable of spending more and more funds on research within their organizations, but also support universities and faculties, and finance the education of professionals they will need, binding them with a contract. Companies play an important role in further transfer of knowledge from universities, and influence higher education in a way to contribute to forming well-educated, flexible experts, who are capable to quickly start functioning in their jobs after graduating from their faculty.

The goal of quality assurance system at Josip Juraj Strossmayer University in Osijek is to improve overall student experience – from applying and enrolling into faculty, through classes, exams, graduation, to employment and lifelong learning. [5]

The quality of the whole teaching process represents the university's ability – of teachers, management and services – to meet the needs of students, and achieve knowledge transfer through teaching methods and technologies. The student is at the centre of quality monitoring, assurance and improvement system at Josip Juraj Strossmayer University in Osijek. The student is an actor in the system, which is used to follow, assess and improve the quality of student experience during time spent at the university.

The development of global information society has increased the demand for learning, i.e. education in all areas needs to become lifelong education. This is a process of continuous training which does not end when an individual exits the education system; rather, it continues in various forms till the end of his/her career. Lifelong learning is defined as the activity of learning and studying throughout one's life, in order to improve knowledge, skills and abilities within personal, civic, social and business perspectives.

"The knowledge acquired in childhood or youth will not be valid for long. Active continuation of learning is an important form of applying lifelong learning. Motivation and the diversity of education options is a basic condition for successful lifelong learning. It is necessary to increase the demand for education, and in this way also the supply. So far, formal education was the form that determined the policies and mode of acquiring education. The continuity of lifelong learning puts more emphasis on non-formal and informal education and learning. Non-formal learning is an integral part of the concept of lifelong learning and one of the key orientations of education for the 21st century, as well as a response to challenges posed by quick changes in the world. The idea of lifelong learning has arisen from the belief that people are the most valuable asset of any society and therefore merit investment." [6]

Non-formal learning promotes personal growth. This is a framework for developing one's potentials, interests and talents. Furthermore, it promotes employability and encourages people to recognize their interest in a certain profession or to choose an appropriate job. Lifelong learning promotes active citizenship, civil society and democracy, peace and the integrated Europe. It is an instrument for attaining a higher level of social equality and justice. [7]

Today's dynamic trends of volatile economic conditions in the world require lifelong learning. Figure 1 below gives an overview of the Croatian education system from primary school to lifelong learning.

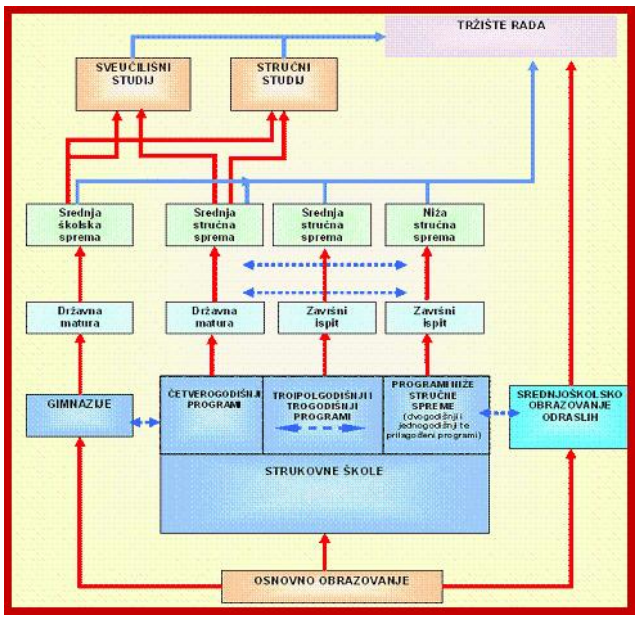

Figure 1. Croatian education system from primary school to lifelong learning (From primary education to labour market)

IV. HIGHER EDUCATION SYSTEM AND THE LABOUR MARKET

Quality assurance is an important aspect in the implementation of the Bologna process as well. It emphasizes the important need to conduct a coherent policy based on the proposition that institutional autonomy creates and requires accountability, and that

universities are responsible for developing the internal quality assurance system.

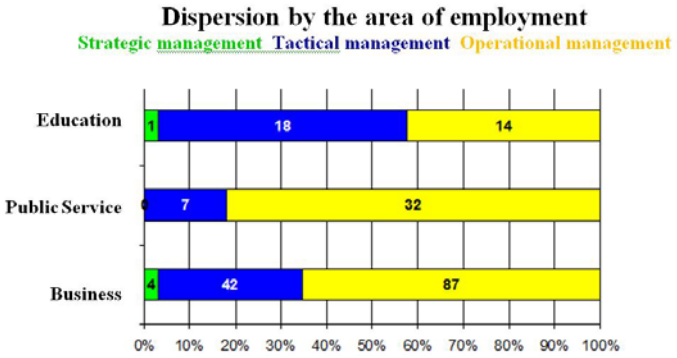

Figure 2. Dispersion by the area of employment

It has been observed that five Slavonian counties are lagging behind modern trends of strategic management when human resources are concerned. If a country or a region is to gain a better position on the global market, increase competitiveness and economic growth, it is necessary to examine its labour market, i.e. the structure and quality of its work force. As for the counties in Eastern Croatia, they are characterized by aging population, negative birth rate, but also strong migratory trends. Despite high unemployment, some industries already suffer from lack of appropriate labour, and they have to supplement this with foreign workers. This indicates that in the near future Croatia might face difficulties in terms of insufficient labour supply. The need for life long learning should be explained and promoted. It is advisable to motivate and encourage employees, and particularly long-time unemployed, to participate in training programmes in order to regain lost skills or acquire some new ones.

The world has long realized that human capital is the main tool in achieving competitive advantage on a global market. An efficient society, which bases its competitive advantage on knowledge, needs to have a flexible labour market, an adequate level of worker security and protection, but it also needs a system which continuously promotes and rewards investment into knowledge. Company people, their needs, motivation and satisfaction are the focus of interest for human resources management. [8]

The University in Osijek strives to synchronize the relations between the labour market and higher education system. As one of its oldest constituents, the Faculty of Economics in Osijek keeps track of the employment of its former students after graduation, through a system of the Alumni association according to European standards (Figure 2).

The system of following the employment area of students that graduated from the Faculty of Economics in Osijek is connected with the internal quality assessment system, i.e. evaluation of education provided by this particular institution.

V. CONLUSION

Modern ICT technologies, especially the Internet and its services, make it very easy to bypass space and time. Today we are faced with previously unconceivable problem: it is no longer scarcity, but the overload of information. A newly designed knowledge structure is required also by the much-sought economic knowledge.

Applying knowledge in economics is nowadays taken not only as a product, or a new business opportunity. In addition, it creates a critical framework for the development of scientific information. Companies are now looking for predominantly applicative solutions to the problems perceived and identified in their operation.

Awareness that investment into education brings excellent returns, a growing need for life-long learning and continuous expansion of knowledge through interdisciplinary approach is also a foundation for improved social accountability. The acquired knowledge can quickly become obsolete. It is therefore necessary to learn how to quickly acquire new knowledge.

The process of bringing the higher education system at the University in Osijek in line with the Bologna process is accompanied with the regional development model based on social accountability. In this way, the Bologna process has assumed the mentor role for the initiatives in regional development.

Interactive approach in the dialogue between university and its environment aims to develop a sustainable regional research programme, which would contribute to the knowledge transfer model.

Abstract - At the beginning of the academic year 2011-2012 the Central Library of Faculty of Electrical Engineering and Computing (FER) set foot in the world of Web 2.0 expanding to social networks: Facebook, Twitter, YouTube and Google+. The necessity to integrate social networks into library management occurred due to the presence of a large number of patrons on the Web. It also turned out that besides being a learning and resource centre, the essential concept of a modern library refers to its active participation in teaching. For the purpose of this study we have isolated the Central Library Facebook Page, as the most significant in social networking. This paper will review and analyze the reactions of users/patrons to the content offered by the Central Library FER and the interaction over a certain time period. In the long run, it is expected that the Facebook Page will allow a form of maintaining users/patrons database, close communication, development of interactive services, breaking the conventional stereotypes of libraries and librarians, in other words, opening the door to the "living-room library" concept.

I. INTRODUCTION

The fundamental idea and its associated research on community management in informal e-learning environment through Facebook page, like a hybrid between personal profiles and groups (available in late 2007) [1], arose as the final result of a research conducted on functionality of the "Dobrodošli@FER" portal (eng. "Welcome@FER"), a service introduced by the Central Library of the Faculty of Electrical Engineering and Computing. The portal was created during the summer, and it served as a source of information for freshmen (and their parents) on enrollment, study programs and studies at the Faculty. SMS, Instant messaging (Meebo), Facebook profile, e-mail, telephone and cell phone were presented as communication tools on the portal. Preliminary concept was to connect with freshmen during the summer and give them crucial information about their college. At the end of September, with the beginning of a new 2011-2012 academic year, the portal was shut down and the research about its functionality and cooperativeness had been narrowed down to a target group, the freshmen. The study included 183 students. When asked "Have you seen our profile on Facebook?" as many as 59,3% answered positively, while 40,7% answered negatively (also including those who did not provide an answer). On the second question, "Are you a student of the Faculty of Electrical Engineering and Computing?", which was set to a Facebook version of the survey (n=175), 94,5% of students answered affirmatively, furthermore declaring themselves as freshmen, while 2,3% were seniors and 2,9% were not the Faculty students. The results showed a large number of freshmen using Facebook Profile, the fact which initiated further steps in the launching of a Facebook Page.

While devising a strategy for future development of Central Library services, we decided to use an informal approach to patrons, primarily students of the Faculty, through social networks. Initially, the existing official Central Library web page (http://www.fer.unizg.hr/knjiznica) was conceived as a place where users can find all the necessary information regarding activities and services provided by the academic library, whereas communication through social networks was purely for informal socializing and e-learning. In fact, one of the major premises, set to evaluate the situation of the Central Library, was the idea that it is necessary to change its entire image and transform it from a rigid state, so to speak, to a more unconventional library, which would resist challenges of the 21st century and the coming generations of critical, challenging and open-minded students not used to barriers.

Moving from a Facebook Profile to a Facebook Page was prompted by the limitations of a Profile. The Profile represents a kind of intrusion into the privacy of library users, and students may be hesitant to make such a personal connection with librarians, [2] but this problem could be avoided by the use of Facebook Groups (and Pages later on), which Xia perceived as a way to market library services [3]. The attitude of the library as an institution which promotes academic integrity cannot afford an invasion of privacy of its users. Therefore, it was

decided to deactivate the Facebook Profile and activate the Facebook Page in the form of a profile usually used by businesses, products, services, or created for pets and even public figures. Such a page allows entities or individuals to have a real presence in social networks and is designed just like a personal profile [4]. In this way, the Library does not require that librarians establish a personal (and possibly unpleasant) connection with users [3]. Also, having such a Page, the Library becomes an extension of e-learning platforms with intention to encourage research, desire for knowledge and better communication with patrons and secondary (extramural) users. At the same time, with the activation of a Facebook Page, profiles were created on Twitter and YouTube - the leaders of "The big 4" (Facebook, Twitter, LinkedIn, YouTube). The social media, referring to sharing information, experiences and perspectives throughout community-oriented web sites, is becoming increasingly significant in our online world, and "social media marketing" has become more than just a buzzword. It is the way of life and means of survival in contemporary Internet lifestyle [4]. We also established rules on content publishing and community management. Bearing in mind the results of the survey, it was decided that the management of the Central Library community would be based primarily on the Facebook platform. Facebook is a social utility that helps people communicate more efficiently with their friends, family and coworkers [5], and also in the academic area, Facebook is a primarily - and often exclusively recreational space, and is heavily used by students for social [6] and e-learning purposes.

In order to achieve a better performance as a medium of knowledge transfer, it is necessary to become a community manager, who is often the voice of the public of a company or an institution, or an academic library in this particular case, and who also connects with patrons at a personal level. At the same time, the community manager is responsible for conveying the feelings of patrons to internal departments, so he or she needs to be able to communicate both in person and online, and this should be someone who loves working with people, who is approachable, has a sense of humor, and who enjoys challenges. After all, the community manager has the key responsibility of humanizing the academic library. Using feedback given by constituents, the manager analyzes anomalies, patterns and trends that may be of concern [4].

II. METHODOLOGY

On 26 September 2011 Facebook Page was officially launched as an upgrade of Facebook Profile from the web site "Dobrodošli@FER". Guided by the Facebook Insights analysis of the user activity on the Central Library Facebook Page between 26 September and 31 December 2011, we want to show the necessity to introduce the Page and reach out to patrons/users through proactive community management. The target user population refers to demographic structure [7] that covers age group of 18-24 years, which is also structurally identical to undergraduate and graduate students. According to Facebook Page, 69% of fans are just a part of the group, which is also the largest category represented according to Social Bakers [8] research about Croatia Facebook statistics in which the largest age group is currently 18–24 with the total of 467 127 users or 31% of total users (1 506 860).

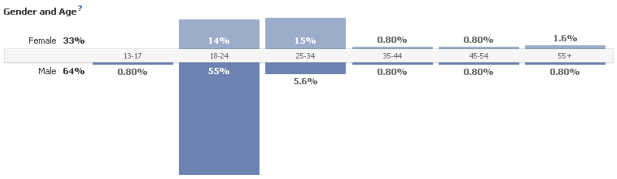

FIGURE I. People who like your page (Demographics)

Since this is an analysis of activities, we as community managers had to introduce some new applications in addition to default ones on the Facebook Page. By implementing and developing additional applications we aimed to be more proactive and outgoing towards our patrons and extramural users of social networks. Our intention was to achieve this with following applications: Ask a librarian, Instant messaging, and Invite a colleague. These applications are adjusted following users' needs. *Ask a librarian* is an online reference service that allows researchers to submit reference questions (especially when it comes to essays) to librarians. It was evident that this service is very popular on official Central Library web page, so it was decided to implement it in the Facebook environment. *Instant messaging* was also taken from the portal, as a necessity in present imperatives of community management. Instant messaging, as the most frequently adopted Web 2.0 tool in academic libraries, is typically used as an alternate communication channel in reference services between librarians and users. Libraries either choose commercial programs or free platforms for incorporating IM in reference services. Users can ask librarians various questions in real time regardless of their location [9]. Meebo chat widget was chosen because it is lightweight, easily accessible, supports multiple IM services and is optimized for embedding on Web and Facebook interface. With *Invite a colleague* application we intended to allow all patrons/extramural users (fans) of Facebook Page to invite everyone whom they believe may be interested in the Page; this is another aspect of connecting with new patrons.

III. RESEARCH AND RESULTS

The best way to get your audience to take interest into your content and share it with friends is to be fully aware of the interests of your target group. Page insights give you the data required for gathering patrons' insights, and through that deep insight we can change/modify parameters of communication. To properly asses the performance of Facebook Page we need to look at the "total number of fans" and understand that posting regularly with engaging content gets more people talking about our institution, which will eventually result in reaching to a growing number of people. "Friends" (Facebook Profile) or "fans" (Facebook Group or Page) represent the total number of people we could potentially reach if all our fans were talking about our institution to their friends.

The metric "People talking about this", indicates how many people are actually talking about our institution to their friends. This metric includes everyone who liked our page; liked, commented on or shared our Page post,

answered a question we asked, responded to our event, mentioned our Page, tagged our Page in a photo or checked in or recommended our Place. Getting more people to talk about our institution allows us to reach to more people. We can see that by looking at the "Total reach" metric, which represents the unique number of people who have seen our post.

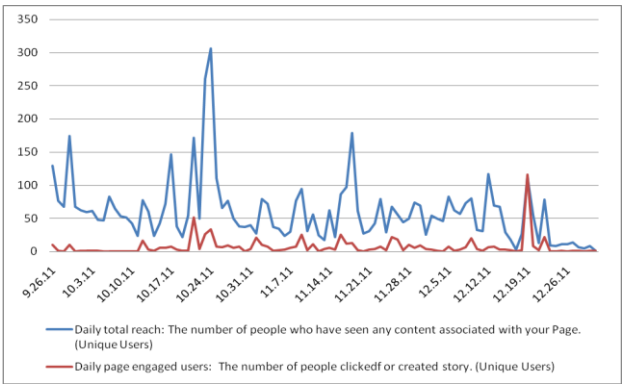

FIGURE II. Comparison of daily engaged users and number of people who have seen any content associated with Page

Anyone clicking anywhere on our post is considered an "Engaged user". The types of engagement include all the ways people can consume our post (clicking on a link, viewing a picture, watching a video etc.), spread it to friends (by linking it, commenting on it, answering a question, RSVP-ing to an event etc.) or simply click on some other area of the post.

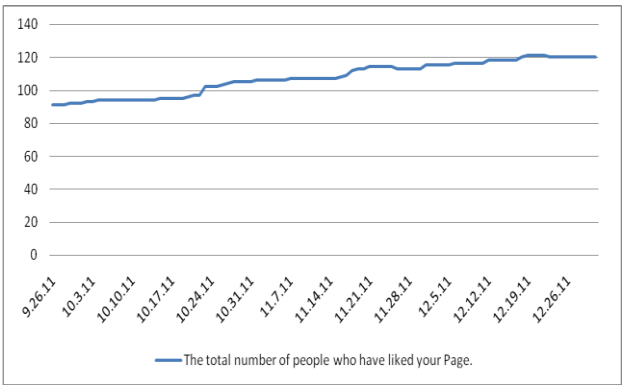

FIGURE III. Lifetime Total likes Lifetime The total number of people who have liked your Page

The content of posts on the wall was a very colorful representation of fun, educational information, students associations, exhibition, and activities of the Central Library to attract and interest students, fans. But the activity of comments and likes can be merged into one where the Like button lets a user share the content with friends on Facebook. When the user clicks the Like button on a site, a story appears in the user's friends' News Feed with a link back to this specific web site [10]. Our results of the Like/comment activity is highly variable and very active (see Figure IV.), containing humorous posts (for example, the picture of the Christmas book tree in the lobby of the Central Library). In his study, Michalis Gerolimos shows user modified participation in communication with librarians through Library Facebook Page where users rarely create content (comments) or participate ("likes") Facebook library content. Facing the truth about the usage of comments, there was a very high percentage of posts that contained no comments at all and often there was not even a feedback [11]. Number of vital posts on our Page is identical to the number of posts in the previous study. The first interaction was a post by a user triggered by the amount of noise in the Library providing us with a "full contact"/interaction realized through: *comment + like* merged interaction. On the other end, as a comment to the article dealing with the abovesaid Gerolimos' study, and Facebook activities of libraries in general, one user wrote: "I'm a facebook fan of a couple of libraries but the reason isn't so much that I want to show my support – and I don't really want to be engaged either – I just use it as a sort of RSS feed. A feed with a content I like but don't consider vital (if it was I would RSS it, if possible)" [12]. Although this user's opinion reflects the status of this particular web page (after all, this particular user was the one and only commenting at a given time), it may as well, we firmly believe, reflect the real status of every other Facebook page of an academic library, given the content of the article.

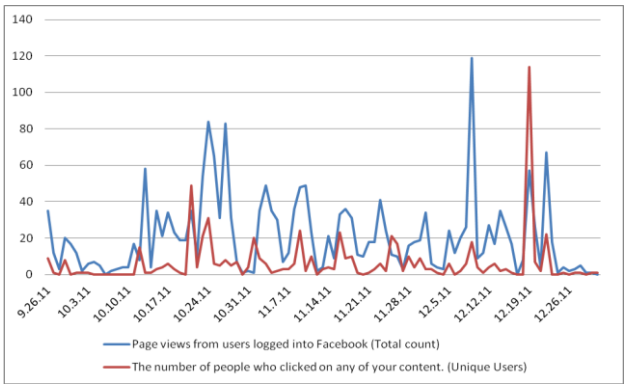

FIGURE IV. Logged-in page views vs. the total number of people who clicked on any content

IV. CONCLUSION AND STRATEGY FOR THE FUTURE

Implementation of the Facebook Page into library management is a new step in developing a new kind of approach to students, e-learning, and information literacy education. With this media we can encourage students to interact (through comments, likes, and other posts) with the Central Library, and we can also stimulate communication and discussions among students themselves, as well as with librarians as representatives of the learning and resource centre.

In this study we encountered a potential problem of low interaction between fans and the Central Library. The time of publishing any content is crucial. It is not the same to publish content, for example at 8 a.m. or 1 p.m, because the post(s) will not appear on users' News feed (the center column of your home page — which is a constantly updated list of stories from people and Pages that you follow on Facebook).

When we think about the future of Web 2.0 library we need to understand that it does not matter how many members we have in our community, but more importantly how we interact with them. We also consider the Web 2.0 a tool for engaging business intelligence and e-learning in the concept of creating-developing-adopting

unique communication channel(s) with recognizable characteristics of new (*Y, Homo Zappiens, IT*) generations of students.

Students' Perception of Institutional Affect towards Minorities: Case-Study of European, American and Australian Universities

Alen Delić*, Katarina Pažur * and Violeta Vidaček-Hainš*
* University of Zagreb, Faculty of Organization and Informatics, Varaždin, Croatia
alen.delic@foi.hr

Abstract - As we are facing many differences between education systems around the world, as well as high mobility among university students, it is of particular importance to examine how students perceive institution affect on their education regarding minorities. The purpose of our research was to observe how students from different countries perceive the above mentioned. In order to execute the research project, an online questionnaire was designed and administrated among students from three countries (Croatia, Australia and USA). Our results showed differences between respondents from Croatia, Australia and USA. Statistically, significant differences were found between answers to questions regarding support programs, financial support and faculty members' attitudes towards students and minorities.

Our research results and conclusions can be used for planning student mobility activities, as well as for organizing minority students support programs. Questionnaire can also be implemented in other researches, especially those that will be encompass a larger number of countries than this one did.

I. INTRODUCTION

Nowadays student's population is becoming more diverse in the sector of higher education. Higher educational institutions provide access for student's from different underrepresented groups regarding to nationality, ethnics, age, disability, gender reassignment, race, religion or belief, sexual orientation [1]. Student's mobility is increasing. Regarding to big amount of social independency in traveling among university students, some Universities developed models for stimulating students travel behavior [2]. Other factors, like E-learning and computer mediated communication also enhance the access, retention and learning outcomes of students of equality groups [3]. Besides that, on line communication may affect the change in experiences with multiculturalism [4]. Specifically, Web 2.0 tools are promoting multiculturalism and multicultural education through changing student's beliefs, perception and attitudes towards others [5].

II. UNIVERSITY STAFF IMPACT

There is also great impact of University staff and mentors on student's self efficacy and confidence [6], as well as the impact of race and family background to the student's expectations towards studying and knowledge achievement [7]. The multicultural component of training programs for staff and teachers is very important. Very often teachers are not prepared enough for coming in contact with different cultures and multicultural students or student from minorities [8]. Increasing trainees' multicultural counseling competence becomes an important topic in training counseling. Research results [9] indicate a significant positive interaction effect of attitudes towards multiculturalism on multicultural awareness. Research results show that academic programs are perceived as less multicultural than internship programs and that sector needs to be developed [10].

Positive attitudes among minority students towards the effectiveness of their college can be one of the indicators of college success [11]. It is significant that students who participated in study abroad programs, reported the increase of confidence, self-reliance and improvement of their professional knowledge and skills [12]. Those competences could be helpful in their further academic achievement and profession. Psychological dimensions and science self-efficacy appear as to be a strong predictor of commitment and academic achievement for undergraduate, graduate and postdoctoral minority students. But, there are also slightly lower scores in academic engagement, pass rates and course grades for students from different underrepresented ethnic groups and those factors needs to be taken into account [13]. Multicultural issue in curriculum ensures better achievement for the minority students and that is a reason why multicultural issue needs to be integrated in the curriculum [14].

Regarding the aforementioned, there are many factors related to student's success and achievement. Effective learning environment factors in higher education institutions are a whole range of variables in the area of psychological, pedagogical, technical,

cultural, and pragmatic research [15]. The importance of effective learning environment factors was confirmed through research conducted with a group of Croatian students. Factor analysis showed that learning techniques, communication skills and availability of state-of-the-art technology are important factors of students' college success [16]. Results of comparative studies show that there are more similarities than differences between students from different universities in Europe, America and Asia with regard to the students' perception of the importance of usage adequate learning style as well as oral and writing communication skills [17]. This research also showed that American students have slightly higher self-efficacy and more strongly believe that they can perform difficult tasks, manage to solve difficult problems and act efficiently in unexpected circumstances in comparison to their Croatian peers [18]. The important factor of student's learning and communication process is the usage of information and communication technology, this was the presumption of all sample groups of university students in Albania, USA, Austria, Croatia and Japan [19]. When speaking about the perception of problems that multicultural students have during their pre-college education, college education and in their endeavors later on, it is interesting that non-multicultural college students in USA, Australia and Croatia perceive these problems to be larger than the extent of these problems perceived by actual multicultural students about themselves [20].

Regarding the previous results of comparative study, the overall objective of this research was to examine how students perceive the affect of government, faculty members, scholarship opportunities and special support programs on their education regarding minorities. The specific objective was to find similarities and differences in perceptions of USA, Australian and Croatian students related to those variables, as well as the similarities and differences between respondents according their gender.

III. METHODOLOGY

A. Measurement

The study called for an online questionnaire; on the whole it consisted of 30 items, generally divided into four parts. A secured online questionnaire was distributed via email. The reason for using an online form of questionnaire, instead of paper form, is the possibility to contact a larger number of respondents, who make an appropriate sample, from geographically remote areas. This method has some limitations that should be taken into account when interpreting data. Respondents were divided in two groups already with the first question; namely depending on whether they identified themselves as multicultural or non-multicultural. Student's personal experiences related to multiculturalism represented the second part of the survey, i.e. 6 items in total. The second part was adapted depending on the response to the first question (whether or not a student identifies him- or herself as "multicultural"). This part was connected to the educational system (three items), while the third part related to the common perceptions about multiculturalism and education (12 items). Demographic questions (8 items) were put together to make part 4. Items related to minorities from the third part were based on [21]. A Likert-type scale was utilized in parts two and three. Survey estimates ranged from "1 = strongly disagree" to "5 = strongly agree". The alpha coefficient of reliability (α) amounted to 0.53 for 15 Likert-type items of the survey.

B. Respondents

University students between 18 and 25 years of age made the target group with snowball sampling used as sampling method. 600 university students/recent university graduates (within one year of graduation) were the recipients of the survey with the response rate of 377 (62.83%) - students from Australia (N=124), Croatia (N=108) and USA (N=145). 45.00% of Croatian respondents were male and 55.00% female. 38.00% of USA respondents were male, while 62.00% were female. Finally, in Australia, respondents' gender ratio was 34.00% male and 66.00% female. Average age was approx. 21 in all countries). Most of the student respondents were undergraduates (Croatia 79.60%, USA 73.80%, Australia 88.70%), while the others were in the graduate level of study (Croatia 20.40%, USA 26.20% and Australia 11.30%). Most of the respondents in Croatia (99.00%) and in Australia (96.00%) are White/European Americans, while great mixture of racial/ethnic backgrounds were seen in the USA respondents: 67.60% White/European Americans, 13.80 % Latino/as, 12.40% Blacks/African Americans, 1.40% Asian-American and 4.8% multiracial.

IV. RESULTS AND INTERPRETATION

According to Shapiro-Wilk test (Sig.<0.05), distribution was not normal for all of the observed variables, so non-parametric chi-square test was used to determine whether significant differences existed in student's perception of some questions with regards to the gender and country of living. As already mentioned within the "Measurement" part, there was a certain limitation in data collection. Given the impossibility of equalizing sample of respondents according to the age, gender, cultural differences etc., the results can be interpreted only with the respect to those limitations.

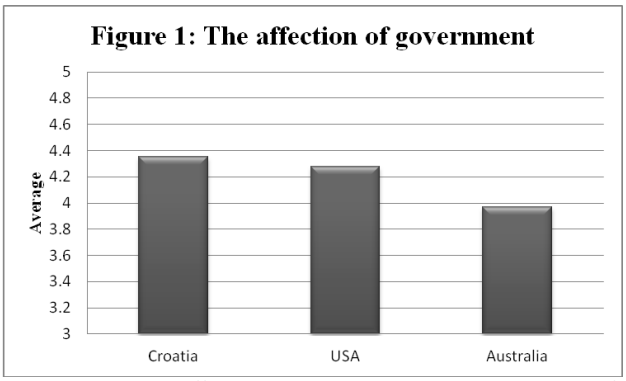
A. Results according to gender

Chi-square test showed that statistically significant differences are not attributed to gender in all the observed questions: „My government should implement the objectives and make assignment plans which would make all schools available to all students in an equitable way" (χ^2 = 2.142, p=0.713), „Most faculty members show the same amount of interest in students regardless of their cultural background" (χ^2 = 7.264, P=0.123), „Minority

students should have an opportunity to get scholarships or financial support." (χ^2 = 2.908, P=0.573) and „Special support programs should be designed for minority students." (χ^2 = 1.780, P=0.776). In general, students perceive the governments and their role in education, and minorities in particular, as the most important among this four factors (M=4.19, sd=0.90). From the students' assessment of the statement about the faculty members, it can be concluded that students would not agree that all the faculty members show the same level of respect to all the students, regardless of their cultural background (M=3.82, sd=0.89). When talking about scholarship opportunities (M=3.77, sd=0.96) and special support programs (M=3.51, sd=0.98) for minority students, respondents are a bit more neutral.

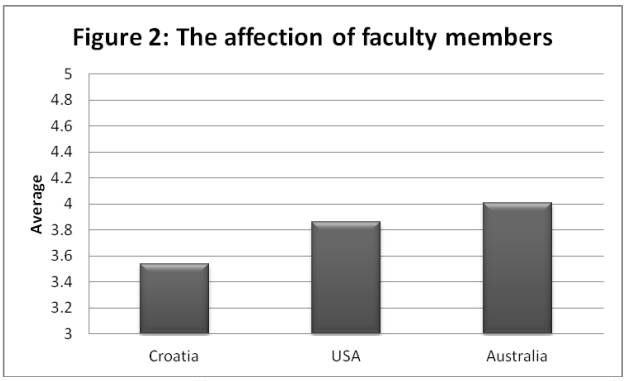
B. Results according to the country of living

According to the country of living, results are slightly different, with the obvious statistically significant difference for all the observed questions. For the statement: „My government should implement the objectives and make assignment plans which would make all schools available to all students in an equitable way" (χ^2 = 79.600, P=0.000), Croatian (M=4.35, sd=0.67) and USA (M=4.28, sd=1.13) students have higher assessments than their Australian (M=3.97, sd=0.67) peers, as can be seen from the Figure 1.



Legend: Access X: different countries; Access Y = mean values (M) of estimates

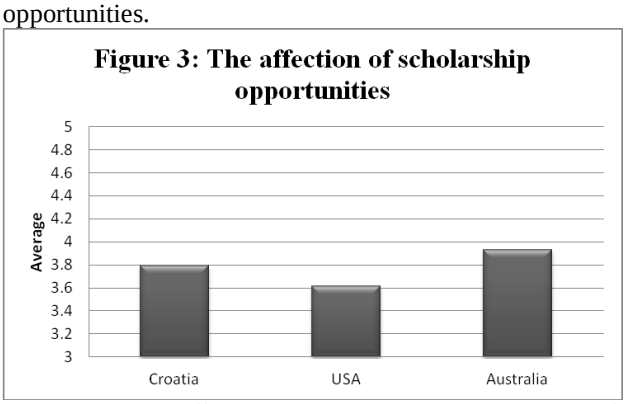
Figure 2 shows a different situation in the perception of faculty members and their interest in students regardless of their cultural background (χ^2 = 43.579, P=0.000).



Legend: Access X: different countries; Access Y = mean values (M) of estimates

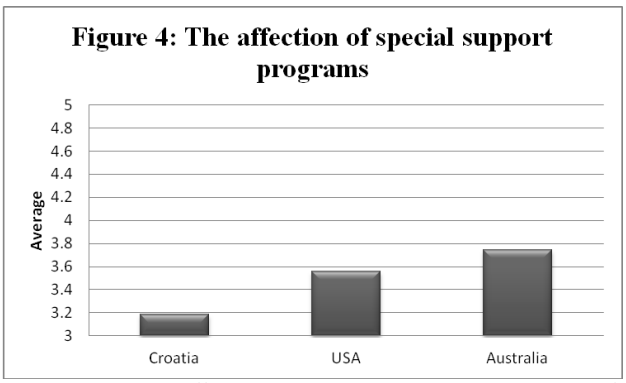
Australian students (M=4.01, sd=0.83) agree to a greater extent that faculty members show the same amount of interest for students of different cultural background that USA (M=3.86, sd=0.97) and Croatian students (M=3.54, sd=0.79).

Students' opinion about the scholarship opportunities for minority students vary from country to country (χ^2 = 26.505, P=0.001), but with a smaller differences in assessments – Australia (M=3.93, sd=0.94), Croatia (M=3.80, sd=0.99) and USA (M=3.61, sd=0.93). Figure 3 presents student's perceptions about the scholarship opportunities.



Legend: Access X: different countries; Access Y = mean values (M) of estimates

The lowest assessment was obtained from all the respondents for the statement about the special support programs for minority students, but again with the statistically significant difference according to the country of living (χ^2 = 43.058, P=0.000). Again, Australian students gave the highest assessment (M=3.74, sd=0.82) and Croatian the lowest (M=3.19, sd=1.07), while the USA students were in the middle (M=3.56, sd=0.98), as shown in the Figure 4.



Legend: Access X: different countries; Access Y = mean values (M) of estimates

This led us to the conclusion that Australian and USA students show greater awareness about the minorities and their needs than Croatian students.

V. CONCLUSION

We have, in this research, managed to fulfill the objectives we had set. Two specific objectives were set. One was to find similarities and differences in perceptions of USA, Australian and Croatian students related to the affect of government, faculty members, scholarship

opportunities and special support programs on their education regarding minorities. The other was to find the similarities and differences between same variables and respondents, but according their gender.

After comparing the results between the answers from the questionnaire that we have conducted, we could set two main conclusions. First, no differences were found when comparing results according to gender, which leads us to a conclusion that both female and male students perceive the institutional affect (regarding minorities) on the education in the same way. Second, statistically significant differences were found between responses from USA, Croatian and Australian students.

According to all the observed variables, Australian and USA students show greater awareness about minorities and their needs while talking about institution affect towards mentioned (throughout special programs and scholarships). The reported differences in a sample from Croatia may be due to their different definition of minorities and their experiences based on the regional diversity and not just necessary on the ethnicity, which is usually the case in USA and Australia.

While the results from this research can be used to prepare different programs and study models for students, further researches are as well planed in terms of defining a new sample in order to found similarities and/or differences between more countries, especially within a narrow geographical area. In order to improve the quality of sampling and increase the control of conditions during data collection, a combination of on-line and paper form of questionnaire will be used in further research.

Abstract: Introduction of any new technology in education is a hard job. It takes years to embed LMS to study processes. At present we have lectures for different scientific disciplines that use LMSs. LMSs have far more functions than general lecturer generally use. In the beginning they started to use LMS as data warehouse for learning material and communication. Nowadays, a question arises about the next phase. Naturally one would think about improving and enhancing learning materials. But the feedbacks from lecturers are different and the next phase should be achieving efficient (self)-testing and (self)-assessment, commonly jointly named as e-testing. Limitations of existing tools are well known; usually question types like true/false, single/multi-choice correct answer, matching, and limited open texts are used. Paper discuss the advantages and weaknesses of traditional electronic question types and gives reader good overview of potential benefits and hazards on its implementation. Traditional questions types are springboard to more elaborate CATs (Computer Adaptive Tests) which will be used when authoring tools will be available. Our approach presents a simple enough technique that can be used as software requirements for CAT authoring tools. Such authoring tool would enable teachers to produce their own CATs and overcome current e-testing constraints.

Distance education, electronic testing, learning management system, knowledge assessment

I INTRODUCTION

First attempts toward electronic learning (e-learning) started in the early 1960s and boosted up around fifteen years ago. Following some disappointment phases (according to Gartner, http://www.gartner.com), more parties including almost all higher level education institutions are involved into e-learning and now we have more than a decade of valuable experiences. Since information-communication technology (ICT) changes rapidly, a decade represents a short and a long period of time. One can observe that every now and then old ideas are reinvented in new or more polished manner, e.g. latest "invention" of the Apple iBook application. Recently we showed that the common believe that Web 2.0 in "modern education" is mandatory has no solid roots, since some old fashioned (i.e. non-interactive) e-resources serve the purpose and students frequently use them [1]. Important observation is also about the meaning of "contemporary ICT". What was once contemporary is not contemporary any more. It seems that in education field this time gap is even bigger. Partly this is due to amount of funds available for education but mostly due to the fear and the unwillingness to rush into new and educationally not yet proven technology. The latter is unfortunately also a common excuse not to use the technology that is proven and successful since users fear that when they start to use it, it will be outdated.

Conducting a digital augmented, blended, assisted, collaborative, etc. learning requires a significant amount of effort. Teachers (i.e. lecturers, assistants, tutors, etc.) should use contemporary approaches and technology, and prepare high quality eye candy e-learning materials. In general, it is expected that they would teach themselves how to produce them. Another fact is that teachers' payment regulations and related quality and quantity demands have not considerably changed for at least two decades yielding not enough motivated teachers to switch to new learning approaches and technology. Even more, researches about usage of computer technology in education show that computer is mostly used for writing text and web browsing [1]. Clearly, changes in the education are not sufficiently quick to satisfy young generations (digi-kids or digital natives; generations Y and Z).

In the last couple of years we have established several learning management systems (LMSs) on our institutions. Additionally we have organized workshops about their usage, and teachers are now reasonably familiar with this technology (the same applies for students). In general these LMSs are now mostly used for learning material distribution, messaging and data warehouse for students' assignments. Recently several lecturers expressed their demands for additional training in LMS usage. Although we expected that teachers would like to upgrade their learning materials or use advanced types of communication, it was a surprise that their most desirable demand was how to efficiently use electronic testing (e-testing) within or outside their LMSs. In e-learning community e-testing has its history, benefits and also drawbacks. In order to prepare next workshops regarding the e-testing, we have researched the possibilities how to upgrade e-testing and enhance its usage to better evaluate students' knowledge by using traditional electronic tests

(e-tests). Computerized adaptive testing is not a new idea. It was used in psychology more than twenty years ago [2]. Teachers prefer to use oral examination (adaptive testing principles) as long as their amount of student is manageable. Sub-questions always depend on answers to the main question. But transition from the human adaptive testing to electronic adaptive testing is not that simple. Electronic implementation of traditional question types' tests is easier even though some question type needs special graphics environment to work properly (drag-and-drop types). Computer adaptive testing (CAT) is still not widely used in education despite that early attempts were made in nineties of last century [3] [4] [5], and also at the end of the century [6]; probably because we are missing suitable authoring tools to prepare adaptive tests. It looks like adaptive tests were prepared, tested, evaluated, used and forgotten. Today adaptive testing principles are primarily used in psychology, medicine, industry and communication technology (protocols) and slowly become more involved in education with recent ICT development [7].

Authoring tools for traditional e-tests are available and easy to use. Traditional e-tests are also suitable for students since they can review answers before submission. LMS Moodle have even question bank and tests can be created randomly. But efficient CAT should provide better knowledge evaluation than traditional e-tests. In the article we are going to present our evaluation of e-tests and suggestions for CAT preparation.

II TRADITIONAL TESTING

Assessing knowledge, competences and skills may be performed during different parts of learning process and for different purposes. Assessments can be performed for diagnostics reasons, commonly at the beginning of the learning process, in formative form during the learning process or in summative and formative form at the end of the learning process [8]. Traditional assessment can be written (i.e. paper-and-pencil testing) or oral. Teachers are believed to be good evaluators for assessment of student's knowledge, competences and skills. Experienced teachers can use small amount of questions and based on answers and observation of students can make reasonable accurate assessments. Sometimes oral examinations are not feasible and written assignments are used, e.g. for large population of students. Teachers are still the best in the understanding and evaluation of written text answers, drawings and schematics answers, and can evaluate partially correct answers.

To assess the level of knowledge, competences and skills desired testing instruments are required. They may differ regarding the purpose of the assessment. The assessment methods oriented exclusively to assess the level of knowledge are certainly different from those assessing competences and skills. But not always, since in pedagogical science and education the skills and knowledge are described as competences [9]. More precisely the competences can be defined as a combination of knowledge, understanding, skills, capabilities and values [10], or divided into knowledge, skills and wider competences [11]. In the continuation, only assessing the knowledge is taken into the consideration.

A. *Important factors of testing*

For efficient and reliable testing reliable instruments are required. Such instruments should meet certain requirements or characteristics. Particularly this is important when grading is taken into consideration. General and empirical characteristics are: reliability, discrimination, and difficulty. Rationales and also important characteristics are validity, objectivity and sensitivity.

The *reliability index* expressed as the Chronbach's alpha (α) indicates the reliability of the instrument in measuring the values of desired variable. By applying α to assessment of knowledge level, α represents the assessment's ability to interpret the level of knowledge being measured. The lowest acceptable value of Chronbach's alpha is 0.7 but in many cases lower values are also accepted [12].

In general, the assessment comprehends of several questions which together influence the quality of the assessment. When the correct answer to the particular question is given by the majority of the best students in total assessment the question has an acceptable level of discrimination. The *level of discrimination* is expressed by using the point-biserial correlation coefficient [13]. The acceptable discrimination of the particular question is achieved by the value higher than 0.30 [14].

The *difficulty index* of the assessment's particular question is the proportion of students answered the question correctly. The index is expressed as p-value percent (p%). The value between 50% and 80% is considered as the acceptable difficulty level of the particular question [15].

Validity of the assessment is the rational measure to determine if the assessment is measuring the desired characteristic. The validity can be verified by the comparison of the theoretical and operational definitions. More exact, it is the comparison of the achieved results with the results of similar assessments. To enhance the validity of the assessments the questions can be leveled according to widely adopted taxonomies like Bloom's taxonomy or other appropriate ones. *Objectivity* of the assessment is achieved if the assessment result is the consequence of the assessed characteristic without the influence of assessors. The *sensitivity* of the assessment is the characteristic that enables distinguishing small differences between the results which allows setting the minimal standards for students with lower level of knowledge [8].

When preparing the assessment the purpose and the goals should be defined first. Some experts recommend that questions should be prepared simultaneously during the learning process. The questions have to be clearly expressed, with unambiguous meaning, and enough attractive and interesting. The choices in all questions should be randomly sorted. The questions should be presented in ascending difficulty order. In traditional

testing two main types of questions are used: filling-in type and short answers type. The latter can be implemented as three different versions: as single or multiple choices, alternative questions and matching items [16].

All mentioned rules, recommendations and examples in this Section are applicable in e-testing, with or without some reasonable modifications. Some of them may be omitted in future development of e-testing and certainly some new principles will arise.

III COMPUTER BASED TESTING

Computer based testing (CBT) [17] and technology-based assessment (TBA) is fast. Students get feedback as soon as they finish the test (submit all answers to the system). It has many types of questions and can be used in most of situations. Traditional e-tests enable students to answer questions at random order until they submit results or run out of time. But as was stated previously there are some areas where computer cannot evaluate student's work. Electronic testing system is also unable to evaluate the way the students answer the tests. Teacher instinctively knows that a student is deciding based on random answer pick or based on knowledge.

A. Types of e-tests

There are two major types of electronic tests: programs or browser based tests. If we create program then we have better control over the test subject and more custom made test questions. On the other hand if we prepare browser based tests then we are limited with the browsers capability to display graphical elements and manipulate with them (Table 1).

TABLE 1:
Benefits and weaknesses of program vs. browser based tests

	Benefits	Weaknesses
Program based tests	• Ability to prepare non-traditional test questions • Can be used offline • Better control over user actions	• Require specific software platform • Custom build tests • Closed tests with limited ability to modification
Browsers based tests	• Works on any operation system • Many authoring tools are readily available • Easy to learn	• Different browser behavior and capability • Sufficient security cannot be achieved • Reliability depends on internet connection

B. Types of questions for e-tests

There are many authoring tool to prepare electronic tests. From freeware to commercial software all have common types of questions: Yes/No (True/False) questions; Multiple choices; Matching; Short answer; Numerical; and Text or Essay (Table 2).

Some authoring tools may have additional questions types that can be described as subtypes of these general types. If we take a look at tests in LMS Moodle we see additional types as Description, Embedded answers (Cloze), and Random Short-Answer Matching.

TABLE 2:
Benefits and weaknesses of different question types

	Benefits	Weaknesses
Yes/No (True/False) questions	• Simple questions • Question and statements covered. • Can be used in different way (positive, negative and combined)	• Question design • Tests with only this type of question are hard
Multiple choice	• Use in different way (one right answer, multiple correct answers) • Most common type of questions	• Require additional design consideration since not all answers can have the same weight • It is not always easy to prepare the answers that are not trivial to dismiss
Matching	• Dynamic questions • Require more than just clicking • Can be used for matching or categorizing	• Not all authoring tool enables the classification (multiple answers to put into the same category) • Not all browsers are capable to handle moving objects
Short answer	• Appropriate in language learning	• Not all authoring tools enable multiple correct answers. • Sometimes correct answer can be lost.
Numerical	• More suitable for numerical answer then text • Type checking	• Sometimes when the result is real number true answers can be lost because of rounding
Essay	• Enables creativity of student	• Cannot be electronically evaluated • Post processing is required • Response is delayed • Due to technical limitation sometimes special characters can corrupt data

In test environments we usually prepare test that is used for all students. But in the electronic testing we have ability to randomly prepare tests and each student can have its unique test. Randomly created unique test can only be done in LMS environment and not all authoring tools are able to cope with the specifications.

LMS Moodle has basic test and can incorporate test from other authoring tools like HotPotatoe or files format like Aiken, Blackboard, Course Test manager, Examview, GIFT, Learnwise, Missing word, Moodle XML and WebCT. Despite the apparent vast array of supported format we still have only traditional types of questions. One difference we have discovered in Moodle is the behavior of "multiple choice" when used with multiple answers. These types of questions behave different in different authoring tool. In some authoring tools all correct answers need to be checked to receive points but on other (Moodle included) each correct answer brings points. Both behaviors can be treated as correct depending on situation. For example 1 (Fig. 1) a student should receive points for any right answer he/she pick but for example 2 (Fig. 2) only all correct answers enable him/her to finish the job. In these types of questions we also need to give penalty factors for wrong answers and gross count of all points if all were checked can be 0. However, there

are still debates about this and some said that positive points should not cover negative and each correct answers could give for example 1 point and wrong answer -2 points. This would prevent students to answer questions at random since they would know for sure they could not pass.

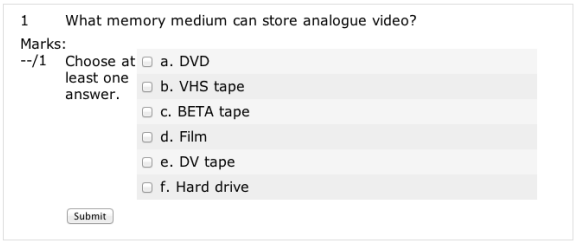

Fig. 1: Multiple choices question that can be partially correct since answers are not related.

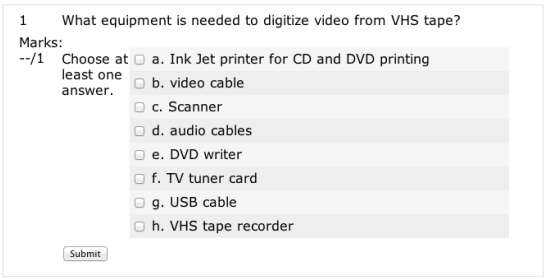

Fig. 2: Multiple choice questions that need all correct answers because digitalization cannot be achieved if one answers is missing

IV COMPUTER ADAPTIVE TESTS

Traditional e-tests are linear, and with the fixed or slightly random questions in the specified or randomized order usually do not imitate teacher's personalized approach in oral assessment. It is easy for teachers to discover student's knowledge recall and ability of applying and using skills and wider competencies in different situations. Namely, students are individuals and process information in different ways (application of the brain, senses and physical movement) to enable them to learn a given domain topic area [18] and consequently, teachers adapt their assessments.

Adaptability is the ability to "tailor the difficulty level of each question based on the correctness of the previously answered question" [19]. Adaptive techniques were developed for local systems before the advent of WWW [20], first computerized adaptive testing was proposed by Lord in 1980, and lately adaptive technology is more and more used also in CBT. In the literature different naming and abbreviations can be found for adaptive CBT, such as computer-adaptive assessment (CAA) and computer adaptive testing (CAT). Adaptive e-tests are e-tests in which the number and sequence of test items are adjusted during the test in response to the performance of the person being tested [21] [22]. Such tests are being quicker to administer, reduce costs in administering tests, can significantly reduce number of questions (even for 50% [23]), are student friendly the student and not less precise than non-adaptive tests [21] [19]. Their main disadvantage is that questions paths are modeled with probabilistic functions [24]. In addition, they still do not solve concerns as in CBT: cost of technology, technology malfunction, administrator training, and a student's computer skill, but these concerns are usually easy to deal with. The theories behind adaptive e-tests are Student Model (SM) [25] of modeling student behavior and characteristics, and Item Response Theory (IRT) [22] [25] [24] which is a robust well-founded psychometric theory in education assessment. The latter is responsible for estimating student knowledge, determining the next question that must be posed at each moment, and deciding test finalization [24]. Some authors name combination of SM and IRT as Computer Adaptive Test Theory (CAT theory) [26].

From ICT point of view imitation of teachers in oral exams in CAT is done with methods of artificial intelligence (AI) and expert educational systems (see Fig. 3). Since not a lot of systems are developed and generally used, adaptive assessment is still "*an innovative, online form of assessment in which items are presented in a sequence that is dependent on the correctness of the examinee's response to the preceding item*" [19]. Some products that reader can find in the literature are: system called Test++ that bases on playing game methodology [20], SIETTE for creating tests for self-assessment [24], AITS that uses AI techniques [27], system that uses AI agent technology [28], while some testing system are compared in [26].

The using of CAT is apparent; our purpose of using it is to provide valid assessment and teach student if needed. If adaptive e-test system recognizes some misunderstandings, weaknesses or pitfalls in student's answers then it selects new path of next questions where student will be challenged to improve or correct his/her answers – learning by assessment paradigm. It usually starts with a question of medium difficulty, while the questions path can be determined on-the-fly or can be predetermined, e.g. with tree structure [23]. Final grading is determined based on the answers in the questions path. CAT theory ensures that the obtained student knowledge estimations do not vary in terms of items used in the estimation process [26].

In the nineties we have created "Model of application of computer in education" [29] and one of the topics was Expert educational systems (Fig. 3). CATs use similar techniques as the expert educational systems; only the aim is different. But when we observe intelligent computer aided education in details (Fig. 4) we can see that differences in the tests and education are actually blurred. If we present knowledge with the network in the education we want students to visit all paths but in test we want students to find individual paths in limited amount of time.

V DESIGNING COMPUTER ADAPTIVE TESTS

To prepare adaptive test teacher needs to prepare a blueprint of possible questions/answers and state transition diagram. We have modified a state transition

diagram from UML (Unified Modeling Language) to be more friendly for general users - teachers. Therefore we omit start sign and stop sign and leave this to the reader to comprehend. We have used grey rounded rectangular to indicate meta-questions and the rounded rectangular real questions. Rectangular is used for condition for transition. The rectangular with multiple questions represent the questions' set. Questions from the set can be chosen arbitrary and can be of any traditional e-test type.

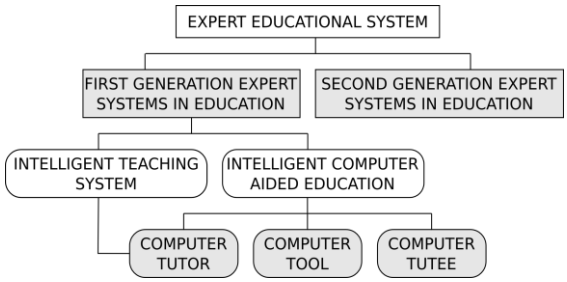

Fig. 3: Expert educational system

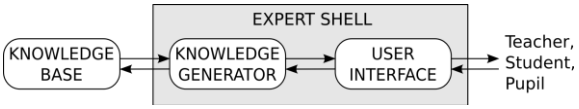

Fig. 4: Intelligent computer aided education

In the continuation we represent two hypothetical situations to show the simplicity of design of our approach. One example is in ICT and the other is from physics.

Example 1: "How to upgrade your computer?" is something that requires student to know his/her hardware and its' potential. In general there are three ways to improve computer. We have dismissed the option to buy another computer since this would not get us any valuable results. Students can pick three answers in the first question: either he/she decides to upgrade RAM, hard drive, or processor. If he/she decides to upgrade RAM then we test his/her decision with the questions How much RAM he/she wants to add, What operation system he/she has, What is his/her current RAM configuration and what is his/her RAM speed. We do not need to ask all the questions but we can cascade question to check student's understanding (e.g. it is useless to upgrade RAM over 4 gigabytes if computer has 32 bit operating system). If desired we can subdivide questions into higher level of understanding.

The second option, upgrading disk, can be fulfilled with two types of disk (magnetic or SSD - solid state disk). If student decides to change magnetic disk in his/her computer he/she is going to get three questions: what size of disk he/she wants to have, what speed of new disk he/she has in mind, and which technology (referred to type PATA and DMA types or SATA and subtypes) is on his/her mind. Each question can have right and wrong answers and the combination of answers from all three questions can be valid or not. It therefore may happen that answers to each question are true but combinations are not. On the other hand if he/she decides to use SSD disk only two additional questions will be asked: the size of SSD, and why he/she will use this disk. For example, it is known that Windows XP can be squeezed on 10 GB disk but Windows 7 requires around 20 GB. We could also add another question in this topic about the price.

The third option to upgrade processor has also a set of questions. On any existing motherboard only certain type of processor can be used. Processors can be upgraded in desktop computers and rarely in laptop. Modern power hungry **i7** processors require stronger power supply and cannot be picked on any computers. For those who know chipset background even technology question can apply.

The schema of example 1 is presented in the Fig. 5 and corresponds to previous description.

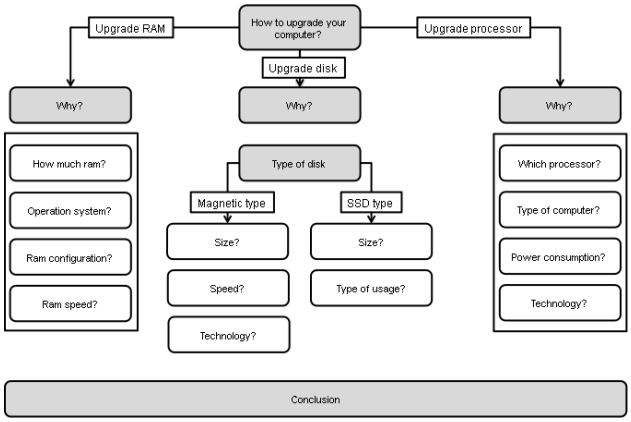

Fig. 5: Schema - example 1 - computer upgrade

Example 2: "Cartesian diver" [30] [31] is from physics and is the fundamental for understanding how fish swim in the water and how submarine works. Any physics teachers should know to explain this phenomenon on multiple different ways [32]. Schema of experiment with the Cartesian diver is presented in Fig. 6.

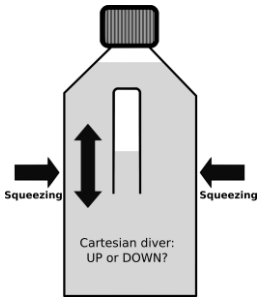

Fig. 6: Cartesian diver

The initial question "How the Cartesian diver works?" gives student five different options. Each option has its own explanation (Fig. 7 at the end of the paper).

Gravity force theory: Squeezing the bottle forces water into the diver. More water makes the diver heavier and causes it to sink. Releasing the bottle allows the

compressed air trapped in the diver to push the excess water out. The diver becomes light enough to float again.

The air theory: Air makes things float. When the air by volume of an object is reduced to a certain point, there's not enough air to hold the object up and the object sinks. The diver works because squeezing the bottle compresses the air to the point where it cannot hold up the diver. When the bottle is released, the air expands again to the point where it can hold the diver up.

The pressure-flow theory: Squeezing the bottle puts pressure on the water inside. The water tries to go up out of the mouth of the bottle. This can be seen when squeezing the bottle without a lid. When the lid is on, the water rebounds and carries the diver down. Releasing the bottle reverses this current.

The pressure-force theory: Squeezing the bottle puts pressure on the water inside. Because the force of squeezing cannot move the water since it is enclosed, the force is transmitted to the diver and pushes it down. This transmitted force disappears when the squeezing stops and the diver returns to a floating position.

The volume-displacement theory: Floating and sinking involves a relationship between the weight of an object and the weight of the water it displaces. For floaters, the weight of the floating object is equal to the weight of the water displaced. For sinkers, the weight of the sinking object is greater than the weight of the water displaced. The diver uses the pressure to cause different amounts of water to be displaced and thus change back and forth from being a floater to a sinker. The different amounts of displaced water seem to go in and out of the diver.

Despite the fact that the equal questions can be used for each theory some theories require different mandatory question (out of the box questions in Fig. 7). Those mandatory questions are also easiest for the selected theory. With the depth of the question the difficulty raises.

VI Conclusion

Computer adaptive testing is not new invention but it is not widely used in our schools. We cannot say that teachers do not use it because they have insufficient knowledge how to prepare adaptive tests. Teachers' oral knowledge assessments are adaptive "per se". Problem is somewhere else. There are no simple authoring tools that would enable teachers to prepare their own computer adaptive tests. We have shown that traditional tests can be used successfully in the evaluation process and we expect they will be used in the future. But in pedagogy the same educational problems can usually be solved using different approach and therefore a test could allow students to choose their own approach. In the process of finding the simple and effective way to prepare a scheme for adaptive tests the solution is evident. We have shown that there is the need for simple authoring tool to enable CAT for LMSs. Software requirements are known and task is feasible. In the next few years we will probably see more CATs used in education even on lower levels of education. The side effect of CATs design is also the blueprint for better e-learning material structure. Observing the schemas for CAT we see that they could be used for education too. Only differences between using CAT or education is that in CAT we seek one way through the maze but in the education we want student to follow more or all of paths through the maze of educational topics.
