This section shows measurements on data storage requirements and protocol completion times for certificates generated by OpenSSL, in connection to number of supported terminal and functions.

A. Data storage capacity

According to Table V, most demanding data to store on card are LEN_{X509} and LEN_{SCDK}. LEN_{X509} size is dictated by the size of certificate extension or LEN_{EXT_TAG}. In cases when N_F and N_T are of approximately same size, or when N_F is of several orders of magnitude greater then N_T (first eight rows), LEN_{X509} data is the limiting factor. On the other hand, when N_T value is much greater than N_F (last three rows), LEN_{SCDK} quickly reaches maximum array size limit, closely followed by LEN_{X509}. Also, results in rows 9, 10, and 11 are very close to the maximum EEPROM storage limit.

TABLE VI. MEMORY SIZE OF DATA ELEMENTS

	$N_T * N_F$	Size in Bytes		
		$LENX_{509}$	LEN_{SCDK}	LEN_{IS}
1.	10 * 10	1042	240	120
2.	30 * 30	2862	720	360
3.	70 * 70	11302	1680	840
4.	90 * 90	17922	2160	1080
5.	120 * 120	30852	2880	1440
6.	1 * 15000	30743	24	12
7.	2 * 10000	40754	48	24
8.	3 * 5000	30765	72	36
9.	1300 * 1	17632	31200	15600
10.	1300 * 2	20232	31200	15600
11.	1300 * 3	22832	31200	15600

a. Memory size of data elements for several combinations of N_T and N_F

B. Protocol completion time

Measurements of the time elapsed for each of the protocol messages is shown in Table VI. Various combinations of N_T and N_F values have been tested; each test case was repeated five times and middle value was calculated based on those repeated measurements. Additionally, a number of Application Protocol Data Unit (APDU) packets required for transmission of M.2 is included inside parenthesis, since digital certificate constitutes largest amount of data exchanged between card and terminal.

TABLE V. PROTOCOL COMPLETION TIMES

$N_T * N_F$	Time measured in microseconds			
	M.1 + M.2 (APDU-M.2)	*M.3 + M.4a*	*M.5 + E_{sk}*	
			First in Order	Last in Order
10 * 10	581 (5)	257	141	144
30 * 30	885 (12)	256	140	149
70 * 70	2405 (46)	259	139	163
120 * 120	5850 (123)	255	140	181
1 * 15000	5793 (122)	258	139	4019

An important factor to consider when interpreting results is the sequential order of TID tag stored in IS and MFCID tag stored in restriction tags inside certificate extension. Therefore, each test case has two additional sub-tests dubbed as “First in order” and “Last in order”. “First in order” is activation of the sequentially first ordered maintenance function on sequentially first ordered terminal, while “Last in order” is the activation of sequentially last maintenance function on sequentially last terminal. A visible departure in results for these two sub tests can be observed due to the use of linear search algorithm.

C. Discussion

Based on shown data, most significant factors in protocol completion times are the size of digital certificate (larger certificates require more time and more APDUs for transmission to terminal) and the sequential order of function and terminal tags in their respective structures. Therefore, it can be said that the bottlenecks in this protocol implementation is neither the speed of cryptographic functions nor issues related to read/write memory operations. As tests have demonstrated, card-terminal interface speed and linear search algorithm have much greater impact on protocol performance.

Another thing to consider is the possibility of hash collisions when creating restriction tags by Formulas (1), (2), (3) and (4). SHA-1 hash output is 20 bytes long so truncation is needed in order to get to 2 or 4 bytes needed for tag size. A more thorough security analysis regarding this issue is recommended.

In terms of practicality, having an identity certificate fused together with its attributes (restriction tags) could be a cumbersome solution in situations where large number

of terminals and functions are supported. Even if the size of certificate is not an issue, adding or removing support for single terminal or function is not a simple task. A complex process needs to be initiated: revocation of current certificate, updating Certificate Revocation List in terminal, followed by issuance of new certificate with updated set of restriction tags. A better alternative would be to separate attributes from user identity through use of attribute certificates. This could result in a more flexible approach since attribute certificates could be created to have much shorter life span and thus not requiring explicit revocation process.

Regarding future implementations, there are several directions of improvement. More advanced search algorithm should result in acceptable protocol completion times in scenarios when large number of terminals and maintenance functions are supported. Another significant improvement would be introduction of attribute certificates.

V. CONCLUSION

In this paper, a smart card implementation of a complex authentication protocol is presented and analyzed. A brief survey of available technologies was done in order to determine desired features of implementing platform. This is followed by selection of technologies and review of other works since JavaCard technology is limiting in certain aspects. Finally, results of measurements are displayed followed by discussion on performance bottlenecks and possible future improvements.

Abstract - XML signature is form of digital signature designed for use in XML transactions. The XML Digital Signature standard defines a schema that is used for storing the result of a digital signature operation applied to (in most cases) XML data. Like non-XML digital signatures, XML signatures add authentication, data integrity, and support for non-repudiation to the data that is object of XML digital signing process. However, unlike non-XML digital signature standards, XML signature has been designed to both account for and take advantage of the Internet and XML.
A fundamental feature of XML Signature is the ability to sign only specific portions of the XML content rather than the complete document. This is relevant when a single XML document may have a long history in which the different components are authored at different times by different parties, each signing only those elements relevant to it. This flexibility will also be critical in situations where it is important to ensure the integrity of certain portions of an XML document, while leaving open the possibility for other portions of the document to change. Since data security – in form of data verification and authorization - represents an important part of information system security paradigm this article is addressing the questions and possibilities of XMLDigSig usage in everyday information system security procedures.

I. INTRODUCTION

The trends in ICT development and the way the ICT supports business processes are clearly focused on use of web based technologies and web services in the last decade. Web services, as a programming technology, enable companies to use and integrate different application modules (e.g. developed by them or third parties) into one unique information system infrastructure that can be present in form of *real*, but also *virtual*, or *on-demand* information system. In case of web services based information system infrastructure it is important to achieve a desired and demanded level of security, just like in any other form of information system infrastructure. Therefore this article addresses the evolution of web services based architectures and it's focused on deployment and implementation of secure web services.

Just like in other forms of information systems architectures, in web services based information systems the question of reliability and security can be addresses in many different ways – from organizational security measures, technical, program, legislative, etc. But one form of security measures that characterizes web services based information systems is the use of different forms of digital signatures to ensure the integrity of content and to authenticate the author (person, company, application component) of specific content (data, information, service component, application component). One form of digital signature specifically design for the use in web content is XML digital signature, and in this article we will try to determine if the security level of web services messaging mechanisms can be improved through the introduction of XML digital signatures. Namely, the web service's technology and the way web services are "working" is based on exchange of XML messages defined by specific WSDL format unique to each web service.

II. WEB SERVICES AS AN FORM OF INFORMATION SYSTEM INFRASTRUCTURE

The history of information system's architectures development was, and still is, motivated with desire for higher program code re-usability. In that manner different types of information systems architectures were developed with time, and each evolutional step used the current and state-of-the-art technologies. The important step in this process was emergence of Object Oriented paradigm, which introduced concepts like inheritance, polymorphism and data abstraction. Those concepts introduced by Object Oriented (OO) design provided developers with new level of code re-usability. But, despite the positive trends in application development affected in OO design there are some limitations. One of the most important limitation is the fact that the classes used in program code have to be included in it, in other words they have to be accessible in the application framework. To achieve that it is necessary to redesign the application structure, to use and store Application Programming Interface in the class path or to correctly reference compiled DLL (2) To achieve this all parts and program components of an application have to be (physically) stored on one computer, and in the world of business-to-business integration processes and cross-organizational information systems this is serious problem.
The next evolutional step in information system's architectures development was a set of architectures that are based on OO concepts, but more focused on distribution of program components and their interoperability. The architectures like component based architecture (CBA), distributed computing emerged to

response of OO limitations. Component-based development allows developers to create more complex, high quality systems, because it provides better means of managing complexities and dependencies within an application. A software component is defined as a unit of composition with contractually specified interfaces and explicit context dependencies. It can be deployed independently and is subject to composition by third parties It is a group of objects with has a specified interface, working together to provide an application function (9). Similarly to this the idea of distributed computing was to set up a communication between two distributed programs directly on the basic physical network protocol and to use distributed information system resources (8). As the next evolutionary step, in this process a communication middleware framework enables to access a remote application without knowledge of technical details such as operating systems, lower-level information of the network protocol, and the physical network address. As distributed computing technologies evolve, it becomes increasingly necessary to provide multiple network implementations to satisfy various quality-of-service requirements. These requirements may include timeliness of message delivery, performance, throughput, reliability, security and other nonfunctional requirements. (4)

The end of nineties and the evolution of network based resources and web services defined a new step in information system architecture evolution that is characterized with use of network based resources and technologies. The programming technology that lays behind architectures like Service-oriented architecture (SOA), Cloud computing, Software-as-a-Service architecture is web service technology. Web services can be implemented using various programming languages and are therefore heterogeneous from point of their implementation. In order to work and to connect web services implemented in different programming languages each web service (as a program component) has defined an unique and specific web service interface based on web service description language (WSDL). WSDL interface describes all parameters that are necessary for use of specific web service, like XML message format, procedure/ method/ function calls, ports, etc. Since web service exists in network environment a XML based messaging system is used for their communication and control. Therefore, even IBM defines web services as programs that accept requests in XML format from other systems across the Internet or Intranet via lightweight and vendor-neutral communications protocols (IBM developersWorks, 2003a).

The implementation of web service usually consists of following processes. Firstly, the web service that requires access to the another program has to send a method with its arguments (defined by WSDL interface) through a Remote Procedure Call (RPC). This is done using Simple Object Access Protocol (SOAP) (Champion, Ferris, Newcomer and Orchard, 2002). that is developed and used specifically for communication between different web services. Each RPC call is stored in a SOAP message that is constructed using XML specification and structure defined by web service WSDL. That way XML document structure contains all information necessary to start an activity in web service. After the remote application has received the SOAP message it will begin to process the content of the message (it will start to perform a specific operation or activity defined by message) and after the operation is finalized it will send the response back to the caller in XML format (2)

III. SECURITY ISSUES IN MODERN INFORMATION SYSTEM'S ARCHITECTURES

Information system's architectures based on use of web services are widely spread today. They offer many advantages compared to "traditional" form of IS architectures, but also have some concerns, specially from information system security point of view. Modern IS architectures usually consist from more than one services (e.g. web services) that are produced and developed by different organizations and individuals, that are developed under different platforms, and operate in different conditions and under different security management systems. All those components are connected into one information system that has to provide its users with the same level of security as classical IS. And that leads to the mayor security challenges that can be grouped in four main categories (5):

- *Data security and data control,*
- *Development and use,*
- *Authentication,*
- *Requirement for "off-the-shelf" components.*

The focus of this article is on first category – data security and data control. One of the oldest security mechanisms that is used for securing data in context of network based resources, and that has a great popularity in securing electronic transactions is Secure Socket Layer (SSL). SSL is used for securing communication path between two points (user side and server side), and it provides a sufficient level of security during the transport but it leaves data unprotected on origin (user) or destination (server) side.

Although some authors (7) suggest that it is not likely that data would be tempered during transmission; moreover identity management and non-repudiation issues have been looked over in the deployed version of SSL. This has been a concerning issue for companies wanting to deploy web services solutions to perform high value business transactions. (1, 7, 9)

This resulted with a development of a solution that will secure the data all over their transportation path, and not only during the process of transport, and that will be optimized for securing communication between web services, in other words that will be optimized for securing XML based transmission. The result was a new form of digital signature for XML documents developed by W3C and IETS that provides authentication, data integrity, and support for non-repudiation of the signed. It is based on similar algorithms and mechanisms like "standard" forms of digital signatures, but it has a unique characteristic that can be used for signing a specific element of XML

structure, rather than complete document. Just like a "standard" form of digital signature it defines a verification algorithm that indicates the originator of the XML document and thereby revealing the sender's identity. (1)

IV. XML SIGNATURES

XML Digital Signature (XMLDigSig) is a form of digital signature that is optimized for signing of XML data. What differ the XML digital signature mechanism from "standard" digital signatures is possibility of *partial signature* which allows that XML digital signature is used only on specific tags in XML structure. Beside partial signature, XML digital signature also has the possibility of *multiple signatures* that enables signing of multiple tags in XML structure.

The XMLDigSig was developed to solve specific security issues concerning data security and control in electronic transactions, and later in messaging mechanisms used in web services. Primarily, it is used to solve problems like falsification, spoofing, and repudiation.

Comparing with the "standard" digital signatures, the result of XMLDigSig is stored in **<*Signature*>** element expression, and the result of "standard" digital signature is represented by a string of code calculated based on input data. XMLDigSig are suitable for use in the network environment. Standard digital signature mechanism is relaying on Certificate Authority, as a third party used for verifying digital signature certificates and signature itself. In order to do this an extensive network communication had to be conducted what in some cases affected the efficiency of signature confirmation process. The XMLDigSig is using URI modeling that is incorporated into network resources, so the entire process of XMLDigSig verification is more networks efficient.

The result of XMLDigSig is stored in form of XML syntax that uses **<*Signature*>** element. Beside the signature value, this syntax stores all other information relevant to XMLDigSig verification. The syntax is defined by W3C organization, and it's available through web link: http://www.w3.org/TR/xmldsig-core/.

The main element of XMLDigSig specification is **<*Signature*>** element. Its child elements are used to store all information regarding the signature and its verification. **<*SignedInfo*>** element defines references of the algorithm used for the XML signature creation and points out the targeted XML data. It is also used to store digest value and other information. **<*SignatureValue*>** element is used for storing the signature value, and a **<*KeyInfo*>** element contains information about XMLDigSig certificates, like the public key certificate information that are used during XMLDigSig verification process.

It was already stated that XMLDigSig can be used to sign specific elements, specific set of data. To specify the data that are going to be sign by XMLDigSig mechanism **<*Reference*>** element is used. It specifies the location of data or XML element that is signed.

XML SIGNATURE FORMAT (11, 12)

```
<Signature ID ?>
        <SignedInfo>
                <CanonicalizationMethod/>
                <SignatureMethod/>
                (<Reference URI ?>
                (<Transforms/>) ?
                <DigestMethod>
                <DigestValue/>
                </DigestMethod>
                </Reference >) +
        </SignedInfo>
        <SignatureValue/>
        (<KeyInfo/>) ?
        (<Object ID ? />) *
</Signature>
```

The mechanism of XMLDigSig is based on several steps:

1. To define the URI that will be signed;
2. To calculate the hash value;
3. To write the hash value into the **<*Reference*>** element, with additional information regarding the algorithms and other information;
4. To standardize the whole **<*SignedInfo*>** element, and calculate its hash and the signature value;
5. To write the signature value to the **<*SignatureValue*>** element;
6. To add certificate/ key information;
7. To combine **<*SignedInfo*>, <*SignatureValue*>** and **<*KeyInfo*>** into the **<*Signature*>** element.

XMLDigSig mechanism can be described on the following example. The goal is to sign 3 sets of data, which are stored on the folowing URL adresses:

"http://www.foi.hr/index.html" - HTML web page
"http://www.foi.hr/slika.jpg" – file in GIF format
"http://www.foi.hr/xml/popis.xml#JMBAG" – JMBAG field in popis.xml file

The first step is to calculate the hash values for specified content stored at *http://www.foi.hr/index.html* location. The adresses of content that will be signed are stored in **<*Reference*>** element, and calculated hash value in **<*DigestValue*>** element. Beside that in **<*DigestMethod Algorithm*>** element is written information about used algorithm (sha1 in this case).

```
<Reference URI="http://www.foi.hr">
 <DigestMethod
Algorithm="http://www.w3.org/2000/09/xmldsig#sha1
" />
<DigestValue>j6lwx3rvEPO0vKtMup4NbeVu8nk=</
DigestValue>
</Reference>
```

The same is done for other two data sets, and then is all combined into **<*SignedInfo*>** element.

```
<SignedInfo Id="Primjer">
 <CanonicalizationMethod
   Algorithm="http://www.w3.org/TR/2001/REC-xml-c14n-20010315"/>
 <SignatureMethod
Algorithm="http://www.w3.org/2000/09/xmldsig#dsa-sha1" />
 < Reference URI="http://www.foi.hr/index.html">
  <DigestMethod
Algorithm="http://www.w3.org/2000/09/xmldsig#sha1" />
<DigestValue>j6lwx3rvEPO0vKtMup4NbeVu8nk=</DigestValue>
 </Reference>
< Reference URI=" http://www.foi.hr/slika.jpg ">
  <DigestMethod
Algorithm="http://www.w3.org/2000/09/xmldsig#sha1" />
<DigestValue>j6lwx3rvEPO0v123454NbeVu8nk=</DigestValue>
 </Reference>
 <Reference URI="
http://www.foi.hr/xml/popis.xml#JMBAG">
  <DigestMethod
Algorithm="http://www.w3.org/2000/09/xmldsig#sha1"/>
<DigestValue>85214LBIta6skoV5qA8Q38GEw44=</DigestValue>
 </Reference>
</SignedInfo>
```

Based on digest values a digital signtaure is formed, and its value is stored into **<*SignatureValue*>** element.

```
<SignatureValue>PqLeN7E</SignatureValue>
```

All links and information regarding keys, certificates and verification process are stored into **<*KeyInfo*>** element.

```
<KeyInfo>
 <X509Data>
  <X509SubjectName>CN=Sandro Geric,O=FOI,ST=Varazdin,C=Croatia</X509SubjectName>
<X509Certificate>125478LkmNHJuzt...KLO9</X509Certificate>
 </X509Data>
</KeyInfo>
```

The final step is to combine all previously mentioned elements of XMLDigSig specification into root **<*Signature*>** element. The result is as follows:

```
<?xml version="1.0" encoding="UTF-8"?>
<Signature
xmlns="http://www.w3.org/2000/09/xmldsig#">
<SignedInfo Id="Primjer">
 <CanonicalizationMethod
   Algorithm="http://www.w3.org/TR/2001/REC-xml-c14n-20010315"/>
 <SignatureMethod
Algorithm="http://www.w3.org/2000/09/xmldsig#dsa-sha1" />
 < Reference URI="http://www.foi.hr/index.html">
  <DigestMethod
Algorithm="http://www.w3.org/2000/09/xmldsig#sha1" />
<DigestValue>j6lwx3rvEPO0vKtMup4NbeVu8nk=</DigestValue>
 </Reference>
< Reference URI=" http://www.foi.hr/slika.jpg ">
  <DigestMethod
Algorithm="http://www.w3.org/2000/09/xmldsig#sha1" />
<DigestValue>j6lwx3rvEPO0v123454NbeVu8nk=</DigestValue>
 </Reference>
 <Reference URI="
http://www.foi.hr/xml/popis.xml#JMBAG">
  <DigestMethod
Algorithm="http://www.w3.org/2000/09/xmldsig#sha1"/>
<DigestValue>85214LBIta6skoV5qA8Q38GEw44=</DigestValue>
 </Reference>
</SignedInfo>
<SignatureValue>PqLeN7E</SignatureValue>
<KeyInfo>
 <X509Data>
  <X509SubjectName>CN=Sandro Geric,O=FOI,ST=Varazdin,C=Croatia</X509SubjectName>
<X509Certificate>125478LkmNHJuzt...KLO9</X509Certificate>
 </X509Data>
</KeyInfo>
</Signature>
```

The verification of XMLDigSig is based on two main steps:

1. The signature confirmation – the receiver side is calculating their own hash values (digest) based on received content (signed data) and information about used algorithms. The result is calculated **<*SignatureValue*>** that is compared with received **<*SignatureValue*>** content. If they match, signature confirmation is positive.
2. The reference validation – comparing the calculated hash value with that stored in the **<*DigestValue*>** element. If they match then the original data set wasn't changed

Verification of the XML signature passes, only when all of the two steps above succeed.

V. IMPLEMENTATION OF XML DIGITAL SIGNATURE

An example of application modules that can be used for XMLDigSig implementation and verification is shown below (9).

1) Creating a signature

```
KeyStore keystore=KeyStore.getInstance("JKS");
keystore.load(new
FileInputStream(keystorepath),storepass)
X509Certificate cert=
(X509Certificate)keystore.getCertificate(usrdata);
Key key= keystore.getKey(usrdata,keypass);
If (key==null) {System.err.println("Could not get a
key,"+usrdata);System.exit();}
KeyInfo eyinfo=dsig.SignatureUtil.createKeyInfo(cert);
Element signatureElement=
signatureGen.getSignatureElement();
keyinfo.insertTo(signatureElement,prefix);
signatureContext sigContext=new SignatureContext();
sigContext.setIDResolver(sig);
sigContext.sign(signatureElement,key);
doc.appendchild(signatureElement);
dsig.SignatureUtil.printDocum(do,System.out);
```

2) Verification of signature

```
XmlDocument xdoc=new XmlDocument();
xdoc.PreserveWhitespace=true;
XmlTextReader xfile=new XmlTextReader(filename);
xdoc.Load(xfile);
xfile.Close();
SignedXml sx=new SignedXml(xdoc);
XmlNodeList nl=
xdoc.GetElementsByTagName("Signature",
"http://www.w3.org/2000/09/xmldsig#");
sx.LoadXml((XmlElement) nl[0]);
if (sx.CheckSignture())
{Console.Writeline("Sign check Pass !");}
else
{ Console.Writeline("Sign check Fail !");}
```

VI. XML ENCRYPTIONS

XMLDig Sig has a possibility to protect the confidentiality of documents as well. For that purpose XML encryption technology is used. It is a form of encryption mechanism optimized for encrypting XML data. Just like XMLDigSig it enable partial encryption which encrypts specific tags in XML structure, and multiple encryption which encrypts multiple tags in XML structure, or parts of XML document, or entire XML document. It has a possibility to define specific segments of encrypted data that can be decrypted by receiver, meaning that it is possible to determine which part of encrypted data a receiver can decrypt and which cannot. The use of XML Encryption prevents some security issues, like XML data eavesdropping, and it adds an additional level of functionality and protection to XMLDigSig.

XML Encription is defined by XML specification available at: http://www.w3.org/TR/xmlenc-core/#sec-Overview, and it defines following structure that is used for XML Encryption files.

XML Encryption format (11, 12)

```
<EncryptedData Id? Type? MimeType?
Encoding?>
  <EncryptionMethod/>?
  <ds:KeyInfo>
   <EncryptedKey>?
   <AgreementMethod>?
   <ds:KeyName>?
   <ds:RetrievalMethod>?
   <ds:*>?
  </ds:KeyInfo>?
  <CipherData>
   <CipherValue>?
   <CipherReference URI?>?
  </CipherData>
  <EncryptionProperties>?
 </EncryptedData>
```

The root element of XML Encryption is **<*EncryptedData*>** element that is used to store all information regarding encryption process, divided into previousely shown XML Schema elements. The **<*EncryptedData*>** element is the core element in the syntax. Not only does its **<*CipherData*>** child contain the encrypted data, but it's also the element that replaces the encrypted element, or serves as the new document root. **<*EncryptionMethod*>** is an optional element that describes the encryption algorithm applied to the cipher data. If the element is absent, the encryption algorithm must be known by the recipient or the decryption will fail. The **<*EncryptedKey*>** element is used to transport encryption keys from the originator to a known recipient(s). It may be used as a stand-alone XML document, be placed within an application document, or appear inside an **<*EncryptedData*>** element as a child of a **<*ds:KeyInfo*>** element. The key value is always encrypted to the recipient(s). When **<*EncryptedKey*>** is decrypted the resulting octets are made available to the **<*EncryptionMethod*>** algorithm without any additional processing. The **<*CipherData*>** is a mandatory element that provides the encrypted data. It must either contain the encrypted octet sequence as base64 encoded text of the **<*CipherValue*>** element, or provide a reference to an external location containing the encrypted octet sequence via the **<*CipherReference*>** element (1, 6).

The process of XML Encryption consists of several steps:

1. *to define an encryption algorithm that will be used* – XML encryption can use both symmetrical encryption and the asymmetrical encryption. Considering this for symmetrical algorithm DES and AES algorithms are mostly used, and RSA is mostly used in the domain of asymmetrical algorithms.

2. *to choose a key transmission method* – to ensure that both sides have a necessary encryption and decryption keys in case of symmetrical encryption a trusted third party is

used for key exchange. In case of asymmetrical encryption a public key infrastructure is used to distribute the necessary keys, and relations to them are ensured using X.509 certificates.

3. *to encrypt the primary data* – using defined encryption algorithms defined XML data are being encrypted. The results of encryption are stored into XML Encryption schema form.

VII. IMPLEMENTATION OF XML ENCRYPTION

An example of application modules that can be used for XML Encryption (encrypting and decrypting process) is shown below (1, 9).

1. Encryption process

First it is necessary to create a <***XmlDocument***> object, and load it into the XML file that will be encrypted:

```
XmlDocument xdoc=new XmlDocument();
xdoc.Load("encrypting.xml");
```

The next step is to create an <***EncryptedXml***> object, and transmit the object of previous step to it as a parameter:

```
EncryptedXml exml=new EncryptedXml(xdoc);
```

The function GetNumberingKey() will provide us with key:

```
RSA numberingKey=GetNumberingKey();
exml.AddKeyNameMapping("id",
numberingKey);
```

The element that will be encrypted is being captured, and data are being encrypted using encrypt method:

```
XmlNodeList xnode=
xdoc.GetElementsByTagName('cardid');
XmlElement xelement = XmlElement(xnode[0]);
EncryptedData encryptedNeedEncrypt =
exml.Encrypt(xelement,"id");
```

Finally, it is necessary to replace the unencrypted part of the original XML file with the new encrypted data:

```
exml.ReplaceElement(xelement,encryptedNeedEn
crypt,true);
```

2) Decryption process

First it is necessary to load the encrypted XML file with necessary keys and information:

```
XmlDocument xdoc = new
XmlDocument("encrypted.xml");
EncryptedXml exml = new
EncryptedXml(xdoc,documentEvidence);
RSA numberingKey = GetNumberingKey();
exml.AddKeyNameMapping("numbering",
numberingKey);
```

The second step is to decrypt the file using decrypt method:

```
exml.DecryptDocument();
```

VIII. CONCLUSION

XML signature is form of digital signature designed for use in XML transactions. The XML Digital Signature standard defines a schema that is used for storing the result of a digital signature operation applied to (in most cases) XML data. Like non-XML digital signatures, XML signatures add authentication, data integrity, and support for non-repudiation to the data that is object of XML digital signing process. However, unlike non-XML digital signature standards, XML signature has been designed to both account for and take advantage of the Internet and XML. A fundamental feature of XML Signature is the ability to sign only specific portions of the XML content rather than the complete document. This is relevant when a single XML document may have a long history in which the different components are authored at different times by different parties, each signing only those elements relevant to it. This flexibility will also be critical in situations where it is important to ensure the integrity of certain portions of an XML document, while leaving open the possibility for other portions of the document to change. Since data security – in form of data verification and authorization - represents an important part of information system security paradigm this article is addressing the questions and possibilities of XMLDigSig usage in everyday information system security procedures. Regarding all this XMLDigSig presents a valuable mechanism in security of electronic transactions that are mostly based on exchange of XML data.

Determining Autonomous Systems Reputation based on DNS measurements

Stjepan Groš, Mislav Stublić and Leonardo Jelenović

***Abstract*—Security on the Internet is a serious problem without satisfactory solution. One problem is at the level of Internet service providers and autonomous systems. This space is highly distributed and without central control, driven primarily by the economic factors. Many solutions have been proposed, with moderate success, concentrating mainly on the Internet routing protocol BGP. We approached this problem with an observation that there is a certain similarity between the Internet's organization at the level of autonomous systems and peer-to-peer networks and thus certain similarity with respect to security issues. In peer-to-peer networks reputation mechanisms are the primary means of protection. We propose similar reputation mechanisms to be applied to autonomous systems. There are many factors that could be used for reputation calculation per autonomous systems, like spam, worms, DoS attacks. In this paper we concentrate only on DNS traffic and propose reputation calculation based on it. Our results show that it is possible to make judgements about entities on the Internet based on the errors found in their traffic.**

***Index Terms*—reputation, security, ISP, autonomous systems, Internet, peer-to-peer networks, DNS**

I. Introduction

It is a fact that today's Internet is plagued with all kinds of security problems. This is evidenced by large quantities of malware, constant attacks, hijacking of network addresses, etc. [1]. The majority of those problems is caused by the Internet's decentralized nature consisting mainly of mutually equal and competitive Autonomous Systems (AS). Within this architecture there is no common oversight body and there are no mechanisms that would punish misbehaving ASes or force them to better control their customers and their own resources in order not to "harm" Internet as the whole. In other words, anything done by any AS has to be justified by an appropriate return on investment (ROI) for the same AS. This explicitly rules out any change done for a common cause as the *common cause* usually doesn't yield direct ROI. Even worse, any network setup and configuration that doesn't affect local customers is acceptable, even if it has negative affects on the rest of the Internet (e.g. [2]). This situation can occur either intentionally, or unintentionally due to the lack of knowledge or carelessness of a person in charge.

In order to solve some of the security problems on the Internet we base our thinking on the premise that the problems are the primary consequence of the decentralized nature of the Internet. This is very similar, though not identical, to a peer-to-peer network. We note that the Internet's architecture at the level of the autonomous systems can be viewed as a form of a peer-to-peer network. An inherent characteristic of the peer-to-peer network is a lack of central authority, just like on the Internet, and this is regarded as a feature, not a bug. Thus, this will not be changed. In a peer-to-peer network similar problems to those on the Internet are being solved using reputation [3]. This analogy suggests that the security measures from peer-to-peer networks might be used by autonomous systems in order to enhance their protection and improve their behavior. This is not the first paper that suggests reputation approach (e.g. [1], [4]), but our view differs significantly as we do not seek to find some absolute values or truths about the Internet as a whole, instead we acknowledge that each entity on Internet see the Internet differently and has a different view about it.

The next premise of our work, and difference from the existing work, is that it would be hard to expect that all, or even majority, of ASes introduce reputation system at once. Thus, there should be some benefit for early adopters. In other words, single autonomous system can measure and monitor other autonomous systems it communicates with and based on those measurements it can determine how good they are. Once significant number of other autonomous systems introduces similar measurements, all those measurements could be combined to form even better reputation value of other ASes.

Once that reputation of ASes is available, ISPs can use this information to better protect themselves and to provide better service to their customers. For example, when there are multiple available AS paths to certain destination ISP can take into account reputation of paths to make better selection. Or, traffic entering ISP can be assigned a different Differentiated Services Code Point (DSCP) [5]. At the moment congestion occurs, traffic can be dropped based on this information. This, in effect, will punish misbehaving ASes. Finally, this information can be made available to different services, like SPAM detection.

To implement this reputation system we hypothesize that the goodness of other ASes could be determined by monitoring what comes from those other ASes to us. Analyzing the incoming traffic (e.g. error packets) the quality of ASes on the path through which this traffic comes can be inferred. In this paper we present preliminary results obtained by monitoring DNS traffic. We also tried to correlate, as best as we could, the obtained results about ASes with the available information on the Internet.

II. Building reputation from DNS traffic

DNS [6] is a well-known and a well-studied protocol. But all the studies done so far tried to gain a global picture about DNS state, and none, that we are aware of, tried to infer anything about the goodness of ASes from which this traffic originates or through which it passes. So, we started by enumerating known DNS errors and analyzed them in order to select only those that we think can tell us something about the quality of the network they come from. Furthermore, we quantified each error by severity. Table I shows the results of that analysis.

TABLE I
DNS errors with estimated severity

Error	Client	Server
Response to erroneous requests	-40	-10
Refused requests	-20	-5
Failed responses (SERVFAIL)	-10	-20
Requests for non-existant domains (NXDOMAIN)	-15	-5
Not implemented RRs	-30	-20
Requests for private addresses (RFC1918)	-50	0
Non-existent TLDs	-60	0
A requests for IP address (A for A)	-60	0
Using port in request 0	-30	-20
Requests with invalid (forbidden) characters	-30	0
Unknown query class	-40	0
Obsoleted and experimental requests	-30	-30

Severity quantifications are based upon the study of what causes them, the amount of occurrences of a particular error found during our own study and also as observed by other authors [7][8]. Also, we note that the client and server side are not equally responsible for a given error so they are not equally punished. For example, when we see *Refused request* then we punish the client (-20) more than a server (-5) since the error is more likely client's fault even though there is a small possibility that it is also on a server side. On the other hand *Using port 0 in request* is more severe when it occurs on a client (value -30) then on a server (value -20).

It should be noted that erroneous packet doesn't mean that the error is on, e.g., server side. For example, when we receive a *Refused requests* packet it could be completely legitimate for a server to send such a response. But we still add a small penalty and count on the scale, i.e. for large number of requests small number of wrongly attributed penalties will go unnoticed.

Reputation itself is calculated in discrete steps of equal and predetermined duration. During each step, n, we collect DNS traffic. Each packet received is classified by AS from which it came from (based on the source address). DNS packets with error in one group (i.e. coming from a single autonomous system) are used to calculate reputation value for the group in the given interval. This value is denoted as R_w. We experimented with several formulas for R_w to study their behavior and to find one which shows the best characteristics. Some of the formulas used include the following representative ones:

$$R_{w1} = \sum r_i \times \beta_i, \tag{1}$$

$$R_{w2} = \frac{\sum r_i \times \beta_i}{A_n}, \tag{2}$$

$$R_{w3} = r_i \times \frac{\sum r_i \times \beta_i}{A_n}, \tag{3}$$

where β_i represents severity quantifications of an error i (as given in the Table I), r_i is the number of occurrences of that error in collected DNS traffic for a given AS in the nth time interval, and A_n is the total number of observed DNS packets (for the same AS and time interval).

Reputation value R_{w1} represents unnormalized reputation (moderated by severity), while R_{w2} represents reputation normalized with the total number of DNS packets in a given time interval. Third reputation value R_{w3} is somewhere between the first two: ASes with more unwanted traffic are more penalized with R_{w3} than with R_{w2} but less than with R_{w1}. In other words, R_{w1} and R_{w3} will point out ASes with lots of DNS traffic with DNS errors, while R_{w2} will highlight ASes with worst ratio of DNS error packets within DNS packets.

In order to determine cumulative reputation in the next time interval, R_{n+1}, that will be used to make judgments about ASes, we were using the following formula:

$$R_{n+1} = \alpha \times R_n + (1 - \alpha) \times R_w, \tag{4}$$

where R_w is one of the R_{w1}, R_{w2} or R_{w3} and parameter α is decay factor, e.g. how fast old reputation is forgotten.

III. Experimental results and discussion

To verify our reputation system and hypotheses from introduction we performed several experiments. Data used in analysis was collected from three points all in different ASes. Some statistics about used data are shown in the Table II.

TABLE II
Basic data about DNS traffic used for experiments

AS	Monitoring period	Packets
AS2108	3-12 Oct 2010	2.53×10^6
AS2108	20-30 Oct 2010	3.68×10^6
AS35549	14-27 Oct 2010	1.12×10^6
AS49788	6-16 Oct 2010	10^5

Within given data we found that appropriate value for α is 0.7 and appropriate time interval is one day. Smaller values have more erratic behaviour, while larger tend to be constant.

Fig. 1 shows cumulative reputations for AS10297 as viewed from AS2108 using all three formulas to determine reputation in current interval, i.e. R_{w1}, R_{w2} and R_{w3}. Since the formulas produce very different numbers, we can only compare them by their behaviour through time, not by absolute values. Initial fall for all formulas is due to initial reputation being set to zero. By the end of the measurement period formulas reach more constant values. Formula R_{w1} has a tipping point at the end of the work week (day 8), and starts rising during the weekend due to lower amount of traffic. As R_{w2} produces reputation values relative to total traffic, the change in total traffic (i.e. during weekends) doesn't change it's behaviour since relative number of errors stays the same.

Using equations (1), (2), and (3) we also determined the worst ASes as seen from each monitoring point. As every equation has it's strengths and weaknesses and tells us different information about AS behaviour all three equations

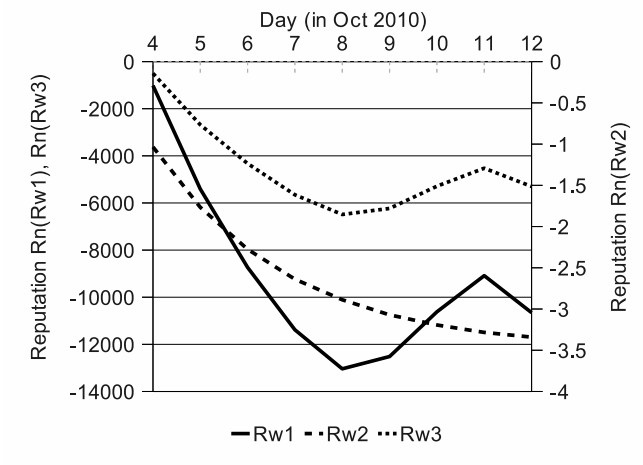

Fig. 1. Reputation of AS10297 as seen from AS2108 calculate from the first data set (3-12.Oct.2010)

are taken into account. Three separate average reputations are calculated for each AS, one for every equation. Average reputations are calculated over a whole measurement period. As we compare average reputations we get three separate worst AS rankings, again, one for every equation. To get worst absolute ASes, all three rankings are taken into account. The final ranking for each AS is created by adding rank as given by every average reputation. For example, if certain AS is 2nd by R_{w1}, 4th by R_{w2}, and 3rd by R_{w3} then it's total score is $2 + 4 + 3 = 7$ and it is ranked by number 7.

Using this method we can find worst ASes for every node where traffic was collected. Table III shows ten worst ASes as seen from different nodes.

TABLE III
WORST 10 ASES BY REPUTATION

AS:	2108	2108	35549	47988
Date:	3-12 Oct	20-30 Oct	14-17 Oct	6-16 Oct
1.	10297	10297	15083	6939
2.	15083	45899	29550	14618
3.	45899	15083	3676	47955
4.	29550	29550	10297	112
5.	14618	22927	3599	15083
6.	3599	8358	5388	10297
7.	5391	14618	7754	3599
8.	17974	17974	17370	22576
9.	6478	45595	8069	4323
10.	9829	4134	21788	29550

AS10297 is the worst AS from the point of view of the AS2108 node. It is Columbus network access point, a company from Columbus, Ohio. Now the AS number belongs to eNET Inc. based in the same town. According to *hostexploit.com*, and *sitevet.com* it is still one of the worst ASes. Among the worst ASes are also AS15083 or Infolink an IT company from Miami, and AS45899 or the VNPT Corp. a telecommunications company from Vietnam.

Data gathering on different nodes was not performed simultaneously on all nodes, although there is a bit of overlapping. However, reputation calculated for two different time periods on the same node within AS2108 suggests that behavior of peer ASes (i.e. ASes from which we receive traffic) is fairly constant, at least over the span of a month. Based on this we can assume similar behavior on other nodes for the same time span. With this assumption we can compare reputations of ASes calculated on different nodes as if they are measured simultaneously. As expected, the reputation picture of the Internet differs based on the measurement point. Still, several of the worst ASes appear throughout all measurement points.

Even though the preliminary results show promise, there is a severe problem of spoofed source IP addresses and attacks on the reputation system itself. This was not taken into account in these measurements and it seems, based on the correlation with available information on the Internet about bad ASes, that it didn't influence results much. Still, we believe that the problem of spoofed addresses can be solved using information available in the BGP. In other words, currently we are punishing apparent source of the erroneous traffic. For future work we left the cases when we are not certain on the source address. In those cases, we could, using BGP, punish path through which the packets had to pass.

IV. CONCLUSION AND FUTURE WORK

In this paper we propose application of reputation system in autonomous systems, as used in peer-to-peer networks, in order to make the actions on the Internet accountable. Presented reputation gathering method is only an example since it is solely based on erroneous DNS traffic. Used methodology for DNS traffic analysis and reputation calculation are promising since ASes with worst reputations are already recognized by other sources. We are aware that the change we propose with reputation system is both very ambitious and demanding in terms of the development resources required. In order to make this more realistic we expect feedback from collogues and, particularly, network operators.

How secure is quantum cryptography ?

M. Stipčević*

Rudjer Bošković Institute, Division of Experimental Physics, Zagreb, Croatia
mstipcev@physics.ucsb.edu

Abstract – In 1991 scientists have for the first time demonstrated practical quantum cryptography (QC) and given a proof of its unconditional security against two most obvious attacking strategies. In the next decade several groups of scientists have made more stringent security proofs and it was soon widely accepted that quantum cryptographic protocol BB84 and its variants are the only known protocols that allow unconditionally secure key growth. Moreover, QC was able to offer unique possibility that any eavesdropping activity could be detected by legitimate parties. In 2004 Swiss spin-off IdQuantique has shown the world's first commercial quantum key distribution system Clavis, followed soon by the QPN system of American start-up Magiq. For almost 7 years nobody suspected that there might be something terribly wrong with these systems. Then, at the end of 2010, a group of Norwegian scientists experimenting with attacks on photon detectors constructed tailored attacks to both commercial systems which were so successful that the plaintext was recovered in full (100%) and moreover the legitimate parties could not detect any suspicious activity ! This raised the question: where does it leave us with quantum cryptography, is it secure or not ? What about the security proofs, were they wrong ? Our conclusion is that security proofs were correct except that they proved security of something else - not the machines that were cracked. At present state of the art it is not clear how or is it even possible to build a provable QC machine.

I. INTRODUCTION

Quantum cryptography or more precise quantum key distribution (QKD) has been proposed by Bennett and Brassard in 1984 [1] and latter experimentally realized in 1991 [2]. This, so called BB84 protocol enables two parties (usually referred to as Alice and Bob) who initially share a short common secret key (binary number), to establish a common secret key of any length. This cryptographic function is also known as "secret key growing". The ultimate goal of establishing a long secret key is to use it as a one time pad and thus obtain transfer of data in absolute secrecy. A small part of the long key may be left unused and kept for future communication. The unconditional security of BB84 relies upon laws of quantum physics namely no-cloning theorem [3,4] and Heisenberg uncertainty principle and has been subsequently rigorously proven [5]. Another unique and somewhat surprising characteristic of QKD is that Alice and Bob can detect any attempt of eavesdropping – a goodie that is utterly impossible in any other kind of cryptography. The paper published in 1992 [2] contains detailed description of protocol and basic security proof against two most obvious attack strategies: beam splitting and intercept/resend.

For quite some time QKD was ignored by cryptographic engineers as something useless and hard to understand, a mere academic peculiarity of no practical use. Indeed, QKD apparatus demonstrated in 1991 was made of extremely exclusive (and expensive) scientific equipment only to enable Alice and Bob to exchange secret messages across the table, over the distance of bare 30cm and in total darkness (because they had to exchange *single* photons!). Unfortunately for QKD, at that time, cryptography itself was an obscure science mostly perceived as something interesting only to secret services and spies.

However, with proliferation of secure smart cashless payment cards, cash dispensers, points of sale and especially dawn of computer age and Internet in early 1990's and finally recent explosion of mobile communications, cryptography flourished as an indispensable ingredient of modern life. Now, suddenly, everyone has willingly or unwillingly, knowingly or unknowingly became a user of cryptographic products. This also gave boost to QKD research resulting in several more protocols that were subsequently proven secure, like: B92 [7], BBM92 [8,9] and the protocol with squeezed states [10]. Eventually QKD moved from scientific laboratories to the market. In 2004 Swiss spin-off company IdQuantique presented world's first QKD system capable of growing the secret key between two legitimate parties at a rate of 1kbps and at the distances up to 69km, while the newest model Clavis2 has extended the range to 100km. Soon after that USA based company MagiQ Technologies presented its QPN system followed latter by SmartQuantum (France) and Quintessence Labs (Australia). Several big companies such as Toshiba, NEC, IBM and HP are experimenting with their own QKD systems.

II. QUANTUM KEY DISTRIBUTION

In the BB84 scenario of quantum key distribution, Alice and Bob are connected via two different channels: the quantum channel (usually well shielded optic fiber) capable of conducting single photons of light and an un-secured "classical" channel such as a telephone line, radio link or internet (which can also be realized through the same fiber by using strong light pulses). These two channels differ fundamentally. The information sent over the classical channel between Alice and Bob can be copied by a third party (such as an eavesdropper) without introducing any noticeable loss of information. On the other hand, quantum channel is characterized by transmission of a fundamentally smallest, single quantum level of energy per bit (in our case one photon), such that any attempt of eavesdropping introduces irreducible

disturbance to the information according to uncertainty relations of quantum physics.

Fig. 1. illustrates how the protocol works. Alice is able to prepare photons in any of four different linear polarization states: 0°, 45°, 90°, 135°. In order to establish a secret key, Alice chooses randomly one of the four states and sends it to Bob.

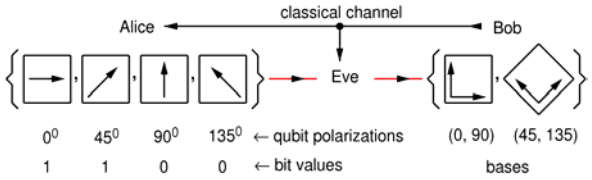

Fig. 1. Illustration of BB84 QKD protocol. Alice sends a randomly chosen qubit to Bob who detects it in a randomly chosen base. An eavesdropper (Eve) may intervene in the quantum line and can passively listen unencrypted but authenticated classical communication line.

By definition of the protocol, states 0° or 45^0 encode binary value "1", while states 90^0 or 135^0 encode "0". Laws of quantum physics allow Bob to measure polarization in only one orthogonal basis and he clearly has two optimal choices: (0,90) base or (45,135) base. So the protocol starts by Alice choosing one of the 4 polarizations *at random*, preparing a single photon (qubit) in that polarization state and sending it to Bob. Bob chooses one of the two bases *at random* and measures with it the qubit received from Alice. If, by chance, Bob has chosen the "right" base he will receive 0 or 1 as sent by Alice. For example, if Alice sent 45^0 and Bob happened to choose the second base he would receive "1", just as sent by Alice. If Bob has chosen "wrong" (first) base, by uncertainly principle of quantum physics he would obtain a random outcome, that is 0 or 1 with equal probability, regardless of what Alice has sent. Obviously, Alice and Bob should be able to figure out which bit has been received correctly and which is just a noise. So, after receiving a photon from Alice, Bob announces (over authenticated but not secret public channel) which base he has just used (first or second). Note that this says nothing to potential eavesdropper about the value of the bit Bob has got because, regardless of the chosen basis, Bob has an equal probability of receiving "0" or "1". According to Bobs announcement Alice responds with "Keep the bit!" or "Discard it!". Repeating this procedure the two of them can build their common secret key, bit by bit. Since Alice sends only one qubit at the time, an eavesdropper (Eve) tries to learn as much as possible from it. Laws of quantum physics do not permit her faithful multiplication of the qubit (no cloning theorem) while a single measurement in any basis of her choice destroys the qubit. A single measurement is not enough to figure out which qubit was sent so Eve can only obtain partial information. In order to keep the protocol going, Eve has to reproduce the destroyed qubit and send it to Bob, but because her information is imperfect she is bound to introduce errors. Alice and Bob can detect eavesdropping simply by comparing the bit error rate (BER) during communication to the "calibrated" BER of the communication channel at an earlier time when Eve was not present. They can also compensate for leakage of information to Eve by additional protocol (so called privacy amplification) which allows them to make Eve's knowledge about their secret key arbitrarily small at expense of sacrificing a small portion of it. (Some researchers dispute both detection and privacy amplification arguments by noting that Eve could have been present also at calibration time and intentionally elevate BER to mask her later eavesdropping [13]. This is especially problematic in case Eve is the owner of the communication equipment which is a realistic scenario.)

III. ATTACKS ON QKD

Cryptography is a matter of trust. Although vast majority of contemporary mathematical cryptographic primitives (ciphers, key protocols, secure hash functions etc.) have never been information theoretically proven secure and indeed from time to time cracks and problems appear (but also fixes and warnings) [30-33], most people trust it because it stood the tests of time, numerous public challenges and cryptanalytic research.

Quantum cryptography on the other hand is proven secure but it is much less used, less challenged and is much newer (younger). Finally, in recent years research in quantum cryptography gave more weight to study of security proofs and attacks rather than to invention of new protocols signaling maturing of the field. Numerous attack strategies have been proposed and studied: side-channel attacks [11,12], time-shift attack [13], intercept-resend attack [14], channel-loss attacks [15,16], untrusted source attacks [17,18], Trojan horse attack [19,20], man-in-the-middle attack [21] dense coding attack [22], phase remapping attack [23]. detector blinding attacks [24-29] etc.

In 2007 a group of scientists from MIT presented an "energy-momentum co-entanglement" attack on BB84 that that gave Eve as much as 100% of information about the key albeit at an expense of elevated bit error rate (BER) [30], but the attack was reassuringly classified as "simulation only" because it assumed that Eve has a specific information about Bob's receiver that she apparently could not get. The information Eve needed for the successful attack was to know which base settings Bob is going to use, *before* he makes his measurement.

First partially successful realistic attack on QKD was time-shift attack made on commercial system ID-500 (Clavis) manufactured by IdQuantique in 2008 [13]. The attack exploited loophole enabled by low efficiency of gated single photon detectors used in the system. Surprisingly, this attack made entirely by the current technology was successful in 4% of cases – more than would be expected from Quantum Nondemolition (QND) attack that is still far from being feasible in any foreseeable future.

But how an attack can be mounted against a system that has been information theoretically proven secure ? To paraphrase H.K. Lo of MagiQ, that is because systems that we build do not necessarily behave as the one that we have proven. Indeed, there are many imperfections that potentially allow yet unknown loopholes.

Then in 2010 a shock came. A truly remarkable experimental demonstration of complete breakdown of a QKD system based on BB84 protocol has been conceived and experimentally carried out by V. Makarov and collaborators [27,38]. Soon after that the demonstration of the same technique has been successfully carried out against two most trusted commercial QKD systems: Clavis2 (IdQuantique) and QPN5505 (MagiQ) [26]. In all cases the attackers were able to recover 100% of the secret key without being discovered! Improvements that would make QKD resistant to those attacks are possible and have been proposed soon after [35,37], but the lesson learned from this is that even quantum cryptographic protocols whose *theoretical* base is proven secure, may not to be automatically assumed immune to all practical attacks. The difficulty in achieving the security of practical QKD is the huge number of imperfections which deviate from idealized theoretical model and may hide loopholes for security.

IV. Role of Random Number Generator in Security of QKD

We will now illustrate importance of local random number generators used in every QKD system to the security and give a simple remedy to blinding attacks. We refer to the paper [38] of Makarov et al. where they explain a 100% successful eavesdropping without living a trace on a version of BB84 protocol which on the receiving station (Bob) contains passive optical random path chooser shown in Fig 2a.

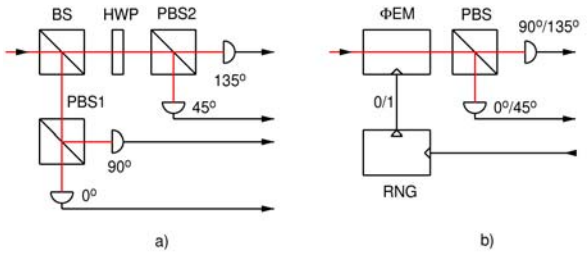

Fig. 2. a) Receiver with a passive random number generator: measurement basis is chosen randomly by means of a first, polarization insensitive beamsplitter; b) receiver with active random number generator: basis is determined by the random bit which controls the phase electro-modulator (ΦEM), for example a Pockels cell.

This passive receiving scheme works exactly as required by BB84 protocol. A photon incoming on the polarization insensitive beam splitter (BS), being the smallest quanta of light which cannot be split, either reflects towards PBS1 or passes towards PBS2. By careful construction of the BS, the qubit will have the same probability to go either way thus effectively choosing the measurement base at random. PBS1 and PBS2 are polarizing beam splitters which enable measuring polarization in (0,90) base and half wave plate (HWP) is used to rotate polarization of a qubit by 45° thus enabling the PBS2 to measure in (45,135) base.

In the scenario of faked-state attack [38], Eve cuts the optic fiber that links Alice and Bob and uses a copy of Bob to receive all qubits (single photons) from Alice. In order to be 100% successful and undetected she must ensure that Bob receives exactly the same bits in exactly the same measurement bases that she used and with near 100% efficiency. How can she achieve this ? By applying strong continuous illumination of circular polarization she blinds all four detectors such that they operate in classical regime meaning they are only sensitive to strong pulses of light and with near unity efficiency. It is then straightforward for Eve to activate any of the 4 detectors of her choosing by sending a strong light pulse of appropriate polarization (0°, 45°, 90°, 135°) into the end of the fiber that leads towards Bob, thus choosing both bit value and basis of Bob at her will. She follows the rest of the protocol by passively listening to the unencrypted classical communication between Alice and Bob (which is made over a separate channel) and doing exactly what they do. She ends up with the same key as Alice and Bob without her presence being detected.

Although authors in [38] claim that Eve exploits technological weaknesses in detectors, that is their blind-ability, our finding is that Eve's success relies entirely on the fact that she is able to manipulate Bob's local random number generator which determines Bob's detection base.

To illustrate this let us assume that Bob's receiver utilizes actively selectable detection bases by means of electronically controllable phase modulator, as shown in Fig 2b. Pockels cell is an electrically controlled wave plate which can be used to rotate polarization of the qubit, for example by either 0^0 or 45°. A binary value (0 or 1) from the local binary random number generator (RNG) determines the measurement base. Crucial assumption for the security is that the RNG must be local and private therefore unpredictable and random to Eve. In that case her blinding technique cannot help her to choose Bob's base. Instead Eve must rely on 50% chance to have chosen the same base as Bob did, in which case she can send him the correct bit value, but this would result in a very high BER and her wrongdoing would be easily detected.

But if she would be able to perfectly guess in advance the random bit which determines Bob's base, she then could swiftly choose the same base, generate qubit corresponding to whichever bit value she got from Alice and send it to Bob. She would probably generate not one but several of qubits to make sure that Bob detects it. In that way she would be able to run the same attack as described in [38] but now she would not need to use detector blinding technique nor to send strong pulses that would alarm potential blinding attack guard. This shows that guessability of random numbers in receiving station can be devastating for QKD. It is easy to see that the same holds for the sending station: if Eve would know the

random numbers in Eve's station perfectly she wouldn't even need to bother measuring the qubits, while if she could guess Alice's random numbers only with certain probability she could use that information to improve results of imperfect masurements of qubits.

From this we conclude that key to Eve's success in the faked-state attack [38] was not blindability itself but the fact that she was able to manipulate Bob's random number generator and thus choose his measurement bases such at will. Indeed the "faked-state attack" is actually an attack to the RNG of the receiving station. Blindability is merely a technique suitable to break the unfortunate passive construction of the RNG. In that respect a private, electronic quantum random number generator would significantly enhance security of the described QKD system, even if no countermeasure is undertaken to prevent the blindability of detectors.

Let us now describe one possible realization of information-theoretically perfect electronic random number generator which produces one random bit at a request, shown in Fig. 3. It consists of a single photon source, beam splitter and two detectors. When a request is sent through the Rq. line, a photon emitted by the photon source PS incoming to the beamsplitter BS either reflects towards detector D0 thus producing "0" or passes through towards detector D1 thus producing "1". Photon emission and detection do not happen with 100% efficiency, but this problem can be easily overcame by use of a small buffer memory.

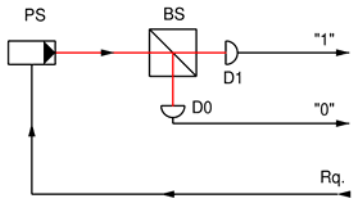

Fig. 3. Beam-splitter based random number generator

Although passive (Fig. 3a) and active (Fig. 3b) receiving schemes are seemingly functionally equivalent, the scheme with explicit, electronic random number generator is secure against random number attacks. Namely, even though an information-theoretically perfect random number generator shown can be made in exactly the same way as a part of the Bob's receiving station, namely using a photon source, a beam splitter and two detectors (Fig . 3), a subtle difference between passive and active schemes is that electronic RNG internally collapses wave function and outputs only classical information (random bits) in one (outward) direction. Such generator does not receive any information from communication channels and consequently cannot be manipulated by Eve. Contrary to that, the passive scheme utilized in the broken QKD system(s) uses very same photons, beam splitters and detectors for both random number generation and communication, which has proven to be an expensive way to make apparatus cheaper. Quantum random number generators suitable for QKD are of course well known in the art [39-41] and can readily be implemented as suggested here. The irony is that both companies whose QKD systems have been broken actually manufacture electronic random number generators which could have been used therein to achieve resilience to attacks on random number generators.

The active scheme in Fig. 2b is not new: it is actually the scheme used in the very first realization of QKD [2]. What is new in the present work is realization that passive receiving scheme permits attacks on the local RNG because it is directly linked to the communication line – a notion that obviously eluded constructors of the two commercial crypto systems. Furthermore, in this work we emphasize paramount importance of both local random number generators to security of the QKD protocol and that breaking either of them may lead to silent failure of the whole system.

Finally, we note that by using the detector blinding technique on a setup with passive RNG, the earlier mentioned "simulated" MIT attack [30] becomes a viable realistic possibility, not only a simulation, thus adding one more item to the list of 100% efficient attacks on QKD.

V. CONCLUSION

Recently, a strong attack called "faked state attack" has been demonstrated that was successful in completely breaking two commercial quantum cryptographic systems by exploiting overlooked technological loophole. Once loophole has been found it was relatively easy to close it. In this work we gave one original contribution to closing this most devastating loophole found so far by noting that the reason why it worked was that it enabled attack on the random number generator in the receiving station. We propose to use an active basis selection scheme and electronic random number generator to avoid this kind of attack. Even though the proposed scheme is not new, the understanding why it is better has eluded researchers so far. We further conclude that, no matter what technique may be used in future, it is sufficient to break either of the two RNGs in the QKD system and the system will fail. All this shows that, nevertheless, and in spite of the fact that information-theoretic security proofs still hold, it has become clear that more research is needed in studying connection between technical imperfections and possible security loopholes.

Quantum key distribution, QKD, is the only known practical information theoretic proven cryptographic system for secure key growth. We therefore believe that it is worth of effort to explore ways to make it secure also against implementation loopholes.

Probably a new approach to security proofs will be needed to accomplish that task.

Sažetak - U današnje vrijeme sve je važnije poslovne procese čim više automatizirati što se obavlja elektroničkim poslovanjem. Vrlo važan poslovni proces razmjena je elektroničkih računa (e-računa). Na FER-u je razvijen sustav za razmjenu elektroničkih računa *FER e-račun*. Sigurnost informacijskih sustava općenito pa tako i sigurnost sustava *FER e-račun* vrlo je važna. U ovom je članku opisano kako je u sustavu *FER e-račun* implementirana sigurnost. Ona je u ovom sustavu implementirana u pet osnovnih koraka: za pristup korisnika bilo kojoj od aplikacija od kojih se sustav sastoji potrebno je proći proces autentifikacije i autorizacije; sav korisnički unos provjerava se s ciljem zaštite od unosa zlonamjernog koda; veza između klijentskih računala i poslužitelja informacijskih posrednika provodi se korištenjem sigurnosne nadgradnje protokola HTTP, protokolom HTTPS koji koristi sigurnosni protokol SSL/TLS; komunikacija između informacijskih posrednika odvija se korištenjem *web*-usluga čija je sigurnost osigurana sigurnosnim proširenjem *WS-Security*; računi koji se kroz sustav razmjenjuju digitalno se potpisuju korištenjem FINA-ine pametne kartice.

I. UVOD

Elektroničko poslovanje (e-poslovanje) oblik je organizacije poslovanja koji obuhvaća poslovne transakcije i razmjenu informacija što se izvode uporabom informacijske i komunikacijske tehnologije u poduzeću, između poduzeća i njihovih kupaca ili između poduzeća i javne administracije [1]. Osnovna karika elektroničkog poslovanja dobavni je lanac, a osnovni poslovni procesi koje uključuje jesu: katalog, natjecanje, ugovor, narudžba, vremensko terminiranje isporuke, izdavanje računa, plaćanje te obavještavanje o plaćanju. Kako bi navedeni dobavni lanac te cjelokupni proces e-poslovanja bili ostvarivi, potrebno je ostvariti određene elektroničke isprave i postupke poput e-kataloga, e-narudžbenice, e-računa, registra korisnika e-računa, e-plaćanja, e-potpisa, e-identiteta te semantičke i tehničke interoperabilnosti. Cilj je elektroničkog poslovanja automatizirati (nužno i digitalizirati) poslovne procese u najvećoj mogućoj mjeri. Primjerice, u svijetu u kojem se ne koriste elektroničke isprave kupac bi napisao papirnatu narudžbu te je poštom, faksom ili elektroničkom poštom poslao prodavatelju. Prodavatelj bi ručno analizirao narudžbu te bi je, ako može isporučiti proizvode ili izvršiti usluge iz narudžbe, odobrio. Potom bi elemente iz narudžbe ručno prepisao na račun te bi istim medijem kojim je primio narudžbu izdao i račun. U svijetu koji koristi elektroničko poslovanje taj bi se isti postupak izveo slanjem računalno čitljive narudžbe (uobičajeno u formatu XML). Iz te narudžbe, nakon što je prodavatelj odobri, bilo bi moguće preuzeti elemente koje i račun sadrži te automatski (bez prepisivanja) generirati račun. Na opisani se način štedi vrijeme, papir (ekološka osviještenost), uklanja mogućnost pogrješaka pri prepisivanju što na koncu zajedno rezultira financijskim uštedama (prema [2], samo bi se u Hrvatskoj uštedjelo 6 milijardi kuna godišnje, od čega oko 350 milijuna kuna samo u državnoj upravi).

U današnje vrijeme elektroničko poslovanje sve više uzima maha. Mnogi procesi koji su se ranije vodili ručno danas se digitaliziraju i automatiziraju. U tom se procesu osim problema vezanih za funkcionalnost sustava javljaju i problemi vezani za sigurnosti sustava. Novi način organizacije poslovanja traži i provođenje novih sigurnosnih mjera. Bitno je omogućiti povjerljivu komunikaciju što se ostvaruje šifriranjem komunikacije, ali također i osigurati nadomjestak za vlastoručni potpis i pečat u papirnatom poslovanju. U tu je svrhu osmišljen digitalni potpis, tj. postupak kojim se dokumentu dodaje dodatak šifriran korištenjem podataka dostupnih samo osobi koja dokument potpisuje. Takav dodatak u potpunosti zamjenjuje vlastoručni potpis i pečat jer kao i spomenuti ima svojstvo da pripada samo jednoj osobi.

Ostatak članka organiziran je na sljedeći način: u poglavlju II opisan je sustav za razmjenu e-računa *FER e-račun*; u poglavlju III definirana je sigurnost mreža, usluga i aplikacija, pobrojani su osnovni sigurnosni zahtjevi te su opisane najvažnije sigurnosne norme za sustav *FER e-račun*; u poglavlju IV objašnjeno je kako je korištenjem ranije opisanih normi implementirana sigurnost u sustav *FER e-račun*; u poglavlju V ukratko je prikazana implementacija sigurnosti u sličnim sustavima; u poglavlju VI iznesene su smjernice za budući rad, a u poglavlju VII dan je zaključak.

II. OPIS SUSTAVA *FER E-RAČUN*

Na Fakultetu elektrotehnike i računarstva Sveučilišta u Zagrebu (FER) razvijen je pilotski sustav za razmjenu elektroničkih računa. Razmjena e-računa podrazumijeva oblikovanje, slanje, primanje, pohranjivanje i pretraživanje e-računa. Kao potpora sustavu za razmjenu e-računa razvijen je i prijedlog sustava registra korisnika e-računa. Korisnici koriste sustav kroz dvije osnovne pripremljene aplikacije: aplikaciju za razmjenu e-računa, sastavljenu od aplikacije za slanje e-računa i aplikacije za pristup arhivi e-računa, te aplikaciju za pristup registru

korisnika e-računa. Za registraciju novih korisnika koristi se posebna aplikacija (obrazac).

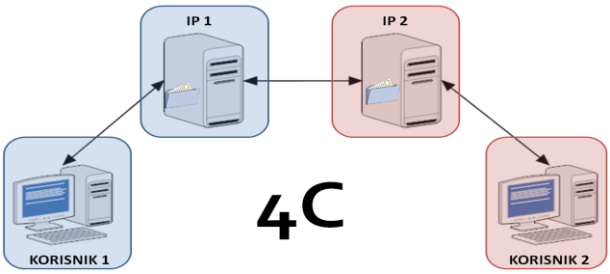
A. *Arhitektura sustava*

Arhitektura sustava *FER e-račun* temelji se na modelu 4 *corner* (4C – četiri kuta). Kao što i samo ime sugerira, sustav ima 4 osnovne komponente: korisnika pošiljatelja računa, informacijskog posrednika pošiljatelja, informacijskog posrednika primatelja te korisnika primatelja računa. Slika 1 prikazuje skicu modela 4C (korisnik 1 i 2 – primatelji/pošiljatelj računa, IP – informacijski posrednik).

Računi se šalju na način da korisnik-pošiljatelj oblikuje (ručno ili kroz aplikaciju) e-račun te ga proslijedi svom informacijskom posredniku. Informacijski posrednik pošiljatelja taj račun prosljeđuje informacijskom posredniku primatelja. Primatelj računa dobiva račune od svog informacijskog posrednika.

Podatke o korisnicima potrebno je negdje pohraniti zbog čega na svakom informacijskom posredniku postoji registar korisnika e-računa u kojem se pohranjuju svi važni podatci vezani za korisnike, klijente određenog informacijskog posrednika.

Bitna značajka ovakve arhitekture sustava jest činjenica da je središnji dio sustava potpuno decentraliziran. Središnji dio sustava sastoji se od skupa (moguće beskonačno mnogo) informacijskih posrednika. Međutim, što je veći broj informacijskih posrednika, teže je znati kojem informacijskom posredniku poslati račun kako bi on stigao do primatelja. Zbog toga je u sustav uveden središnji registar korisnika e-računa u kojem se pohranjuju osnovni podatci potrebni za usmjeravanje e-računa. Nakon što korisnik pošiljatelj računa preda račun koji želi poslati svom informacijskom posredniku, informacijski će posrednik iz računa dohvatiti OIB primatelja računa te od središnjeg registra zatražiti informaciju o tome kojem informacijskom posredniku treba proslijediti račun kako bi on stigao do primatelja. Skicu razvijenog sustava za razmjenu elektroničkih računa prikazuje Slika 2. Na slici su naznačene sastavnice sustava te *web*-usluge kojima te sastavnice komuniciraju.



Slika 1. Skica modela 4C

Sustav *FER e-račun* sastoji se od:

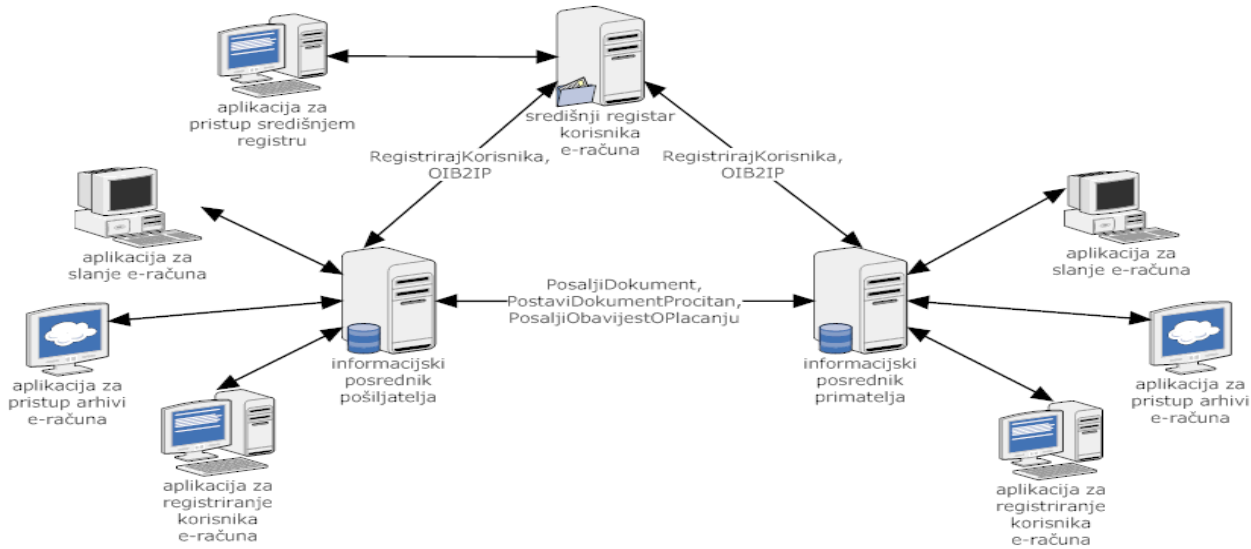
1. aplikacija koje omogućuju oblikovanje i slanje e-računa, pregledavanje arhive primljenih i poslanih e-računa te registriranje novih korisnika i pregledavanje podataka o postojećim korisnicima
2. informacijskih posrednika (s lokalnim registrima korisnika e-računa) koji omogućuju razmjenu oblikovanih računa
3. središnjeg registra korisnika e-računa
4. *web*-usluga korištenjem kojih se e-računi razmjenjuju.

III. PREGLED KORIŠTENIH SIGURNOSNIH NORMI

Nakon što je u prethodnom poglavlju opisan sustav *FER e-račun*, u ovom će poglavlju biti objašnjeno što je to sigurnost mreža, usluga i aplikacija te će biti opisane za taj sustav najvažnije sigurnosne norme, a sve s ciljem da se u sljedećem poglavlju objasni kako je korištenjem tih normi implementirana sigurnost u sustavu *FER e-račun*.

Sigurnost mreža, usluga i aplikacija može se promatrati kao sposobnost mreže i informacijskog sustava da se suprotstavi neočekivanim slučajnim događajima i neprijateljski usmjerenim akcijama [1]. Prema [1] osnovni sigurnosni zahtjevi svrstani su u sljedeće osnovne skupine:

1. **autentifikacija** – potvrda identiteta korisnika
2. **cjelovitost (integritet)** – jamstvo da su informacije poslane, primljene ili pohranjene u izvornom i nepromijenjenom obliku
3. **povjerljivost** – zaštita komunikacije ili pohranjenih podataka od presretanja i stavljanja na uvid neovlaštenim osobama



Slika 2. Skica sustava FER e-račun

4. **neporecivost** – sudionici ne mogu odbiti ili poreći akciju u kojoj su sudjelovali

5. **kontrola pristupa** – ograničenje pristupa informacijama i ograničenje provođenja akcija

6. **raspoloživost** – informacije moraju biti raspoložive, a sustavi i usluge u operativnom stanju, usprkos mogućim neočekivanim i nepredvidljivim događajima.

U nastavku ovog poglavlja dan je pregled sigurnosnih normi koje se u sustavu *FER e-račun* koriste za implementaciju sigurnosti, a u poglavlju IV objašnjeno je kako je korištenjem tih normi sigurnost sustava u konačnici i implementirana.

A. SSL/TLS

Protokol TLS (*Transport Layer Security*) [3] i SSL (*Secure Sockets Layer*) [4] kriptografski su protokoli koji osiguravaju sigurnu komunikaciju kroz nesigurnu komunikacijsku mrežu. Radi se o implementaciji sigurnosti povrh transportnog sloja komunikacijske mreže (internetski model komunikacijske mreže poznatiji i kao model TCP/IP opisan je u [5]). Za kriptiranje podataka koristi se simetrična kriptografija. Osnovna razlika između spomenuta dva protokola jest u tome što je SSL vlasnički protokol, dok je TLS otvoreni protokol.

Protokol TLS omogućuje aplikacijama zasnovanim na arhitekturi klijent – poslužitelj komuniciranje kroz mrežu na način da se onemogući prisluškivanje.

Prije no što se uspostavi sigurna veza koja čuva stanje komunikacije, klijent i poslužitelj pregovaraju o parametrima veze. Proces uspostave sigurne veze sljedeći je:

1. Postupak uspostavljanja sigurne veze započinje spajanjem klijenta na poslužitelj koji podržava protokol TLS i zahtjevom za uspostavom sigurne veze. Pri tome klijent poslužitelju predočava listu podržanih algoritama za šifriranje i računanje *hash*-koda.
2. Iz ponuđene liste algoritama poslužitelj odabire najjači algoritam šifriranja i računanja *hash*-koda koji ujedno i on podržava.
3. Poslužitelj se identificira prema klijentu slanjem svog digitalnog certifikata.
4. Klijent može kontaktirati izdavatelja digitalnog certifikata i provjeriti mu ispravnost.
5. Kako bi stvorio sjedničke (engl. *session*) ključeve koji se koriste za sigurnu komunikaciju, klijent šifrira slučajno odabrani broj s javnim ključem poslužitelja te ga šalje poslužitelju.
6. Iz slučajno odabranog broja koji je klijent poslao poslužitelju obje strane (klijent i poslužitelj) generiraju podatke potrebne za šifriranje i dešifriranje.

B. XML Signature

Današnje elektroničko poslovanje uglavnom se temelji na razmjeni XML-dokumenata. Zbog toga su razvijene posebne norme za sigurnost XML-dokumenata, tj. sigurnosne norme ugrađene u XML. Dakako, sigurnost XML-dokumenata može biti implementirana i korištenjem standardnih sigurnosnih protokola, ali u tom je slučaju problem što ti algoritmi koriste binarne datoteke koje onda mogu biti interpretirane samo korištenjem posebnih alata. U slučaju posebnih normi za sigurnost XML-a, sigurnosne mjere dodaju se dokumentu bez kršenja pravila XML-a. Takvi se dokumenti tada mogu pregledavati korištenjem standardnih alata za XML. Također, valja biti svjestan i razlike između implementiranja sigurnosti na razini dokumenta i na razini komunikacijske mreže. Primjerice, protokolima SSL i TLS moguće je osigurati povjerljivost prijenosa informacije kroz komunikacijsku mrežu. To znači da je dokument zaštićen samo dok putuje kroz mrežu. Povjerljivost dokumenta na računalu pošiljatelja kao ni povjerljivost dokumenta na računalu primatelja nije osigurana. Implementiranje sigurnosti na razini dokumenta osigurava povjerljivost dokumenta i nakon što stigne na odredište.

XML Signature [6] jest norma za digitalno potpisivanje korištenjem XML-a. Jednim potpisom moguće je potpisati više dokumenata. Dokumenti koji se potpisuju ne trebaju nužno biti u formatu XML, a onda kada jesu nije nužno potpisati cijeli XML-dokument. Moguće je potpisati samo dio XML-dokumenta. Na taj se način omogućuje da različite dijelove jednog XML-dokumenta potpisuju različiti ljudi. Norma *XML Signature* definira način na koji se digitalni potpis i informacije o njemu pohranjuju tako da su zadovoljena pravila XML-a. Standardom se ne definira algoritam za digitalno potpisivanje, ali se definira kako ugraditi digitalni potpis u XML.

XML-potpis može se pojaviti u tri različita osnova oblika:

1. **Omotani potpis** – potpis se nalazi unutar dokumenta koji se potpisuje
2. **Omotavajući potpis** – potpis omata dokument koji se potpisuje
3. **Odvojeni potpis** – potpis se nalazi u odvojenom dokumentu (dokument koji se potpisuje identificira se URI-jem).

XML-potpis ne mora nužno uvijek biti u osnovnom obliku. Moguće su različite kombinacije osnovna tri oblika, tj. hibridni oblik. Slika 3 prikazuje primjer omotanog potpisa u koji je dodana referenca na vanjski dokument koji se potpisuje. U ovom se slučaju jednim potpisom potpisuje dokument unutar kojeg je potpis (tamnije na slici) te dokument identificiran URI-jem (svjetlije na slici).

C. WS-Security

Norma za sigurnosno proširenje *web*-usluga *WS-Security* [7] zasnovana je na već postojećim tehnologijama kao što su to, primjerice, *XML-Signature* i *XML-Encryption* koje rješavaju problem šifriranja i digitalnog potpisivanja XML-poruka. Autentifikacija se rješava protokolima X.509 i Kerberos. *XML Canonicalization* [8] opisuje način pripreme XML-sadržaja za šifriranje i digitalno potpisivanje. Norma *WS-Security* postojećim specifikacijama dodaje mogućnost ugradnje spomenutih mehanizama u SOAP-poruke. Bitno je napomenuti da je sigurnost SOAP-poruka posve neovisna o sigurnosti transportnog sloja.

WS-Security definira element SOAP-zaglavlja koji nosi podatke vezane za sigurnost pri čemu format digitalnog potpisa ili format šifriranja nisu definirani.

Slika 3. Primjer hibridnog oblika XML-ovskog digitalnog potpisa

Specificira se kako se format, opisan nekom drugom specifikacijom, može ugraditi u SOAP-poruku. Slika 4 prikazuje na koji se način podatci vezani za sigurnost ugrađuju u SOAP-poruku.

IV. IMPLEMENTACIJA SIGURNOSTI U SUSTAVU *FER E-RAČUN*

U sustavu *FER e-račun* sigurnost je implementirana na način da je osigurana autentifikacija i autorizacija korisnika, podatci dobiveni od korisnika provjeravaju se radi zaštite od SQL-upada (engl. *SQL Injection*) i XSS-napada (engl. *Cross-Site Scripting*), aplikacijama koje su uključene u sustav pristupa se preko sigurnog protokola HTTP (HTTPS) korištenjem protokola SSL/TLS, a komunikacija između informacijskih posrednika odvija se korištenjem sigurnih *web*-usluga (*WS-Security*). Sustav omogućuje i digitalno potpisivanje izdanih računa, tj. cijelih XML-datoteka koje se kroz sustav *FER e-račun* razmjenjuju, a koje između ostalog sadrže i e-račun. XML-datoteke koje sadrže e-račune ne

Slika 4. Struktura sigurnosnih informacija u SOAP-poruci prema normi WS-Security [9]

šifriraju se prije arhiviranja jer se smatra da je njihovo pohranjivanje u bazu podataka kojoj se ne može pristupiti bez odgovarajućih korisničkih podataka dovoljna zaštita. Na taj način sustav ispunjava sljedeće sigurnosne zahtjeve: povjerljivost, cjelovitost, autentifikacija, neporecivost i kontrola pristupa. Zahtjev za raspoloživošću sustava nije razmatran, a njegova implementacija u značajnoj mjeri uvjetovana je i brojem korisnika realnog sustava koji će onda definirati potrebne performanse sustava. U svrhu bolje raspoloživosti, u sustavu treba implementirati redundantne ključne točke i usluge sustava.

U nastavku će po stavkama detaljnije biti opisano kako je implementirana sigurnost.

A. *Sigurnost aplikacija*

1) *Autentifikacija i autorizacija korisnika*

U postupku registracije u sustav korisniku se dodjeljuju podatci za pristup aplikacijama. Dodijeljeni pristupni podatci pohranjuju se u lokalnom registru korisnika e-računa koji održava svaki informacijski posrednik za sebe. Autentifikacija i autorizacija korisnika obavlja se korištenjem korisničkog imena i lozinke. Na taj se način određuje o kojem se korisniku radi te koje su njegove ovlasti u aplikaciji.

U bazi podataka bilježi se točno korisničko ime te *hash*-kod (SHA1 [10]) lozinke. Na taj se način osigurava njezina tajnost. Pri autentificiranju korisnika u bazi podataka traži se zapis koji sadrži uneseno korisničko ime. Za unesenu lozinku računa se njezin *hash*-kod i uspoređuje s onim koji je pohranjen u bazi podataka. Pronađe li se u bazi podataka korisnik s unesenim korisničkim imenom i odgovarajućim *hash*-kodom lozinke, autentifikacija je uspješno provedena, provjeravaju se ovlasti korisnika te se korisniku omogućuje korištenje sustava.

Tajnost lozinke temelji se na činjenici da iz *hash*-koda lozinke nije moguće rekonstruirati samu lozinku.

2) *Provjera ulaznih podataka, SQL-upadi i Cross-Site Scripting (XSS)*

Provjera ulaznih podataka temelj je sigurnosti *web*-aplikacija. Svaki podatak koji je dobiven od strane korisnika prije no što uđe u sustav mora biti provjeren na način da se eliminira mogućnost da se radi o zlonamjernom programskom kodu. Korisnik sustavu *FER e-račun* predaje podatke na način da ih unosi u odgovarajuća polja u HTML-obrascima ili ih prenosi kao parametre u upitnom dijelu URI-ja.

a) *SQL-upadi*

SQL-upadi [11] jesu način napada u kojem napadač unošenjem odgovarajućih podataka – SQL-koda umjesto traženih podataka (bilo kroz HTML-obrasce, bilo kroz parametre URI-ja) mijenja početni SQL-upit na način da dobije upit kakav on želi (naime, podatci dobiveni od korisnika uobičajeno se ugrađuju u SQL-upit). Za zaštitu od SQL-upada valja provjeriti sadrži li korisnički unos SQL-kod. Vrlo učinkovito rješenje jest i onemogućavanje istodobnog slanja više od jednog upita bazi podataka. Naime, SQL-upad često se izvodi na način da se na korisni SQL-upit zalijepi još jedan (zlonamjerni) upit.

Recimo, na SELECT-upit zalijepi se upit DELETE i obrišu se podatci iz baze podataka.

b) Cross-Site Scripting (XSS)

XSS-napadi [12] jesu napadi u kojima zlonamjerni korisnici umjesto regularnih podataka unose programski kod. Ovakvi napadi na *web*-aplikacije opasni su kada, primjerice, zlonamjerni korisnik unese zlonamjerni JavaScript-kod. Ako se unos ne provjerava, takav se zlonamjerni kod pohranjuje u bazu podataka i izvršava na računalu onih korisnika kojima se prikazuju podatci uneseni u bazu podataka. Na njihovim će se računalima izvršiti zlonamjerni kod umjesto da se prikažu podatci. Primjer takvog zlonamjernog koda može biti skripta koja napadaču šalje korisnička imena i lozinke pohranjena u korisničkom internetskom pregledniku.

Zaštita od ovakvih napada u funkcijama je koje programski kod pretvaraju u običan tekst. Primjerice, takve će funkcije znak „<“ pretvoriti u „&lt“. Naime, znak „<“ u HTML-u tretira se kao dio programskog koda, a za zapis „&lt“ na zaslonu će se ispisati znak „<“.

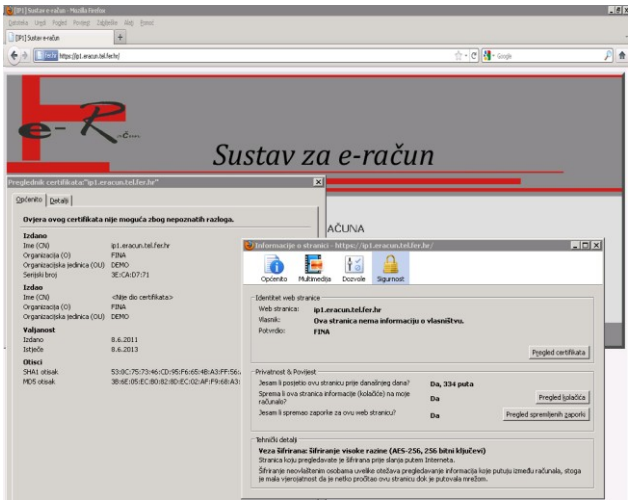
c) Zaštita skripti i konfiguracijskih datoteka od neovlaštenog pregledavanja i pokretanja

Datoteke unutar *web*-sjedišta bitno je organizirati tako da su javno dostupne (imaju globalni URL) samo one datoteke koje su za to pripremljene. Skripte koje se pišu da bi se na nekom mjestu uključile (engl. *include*) u postojeći kod, a same za sebe ne smiju se izvršiti valja smjestiti u posebne poslužiteljske mape koje nisu „izvana“ dostupne. Isto vrijedi i za konfiguracijske datoteke. Konfiguracijske datoteke ili ne smiju imati globalni URL ili treba biti osigurano da se uz poznavanje njihova URL-a ne može dohvatiti njihov sadržaj. Primjerice, ako se radi o jeziku PHP, na kraj naziva konfiguracijske datoteke može se staviti nastavak PHP. Na taj će način biti osigurano da će korisnik koji će pokušati dohvatiti konfiguracijsku datoteku vidjeti rezultat izvršavanja koda konfiguracijske datoteke (uglavnom bijeli ekran – konfiguracijske datoteke uglavnom su niz naredbi kojima se u određene varijable pohranjuju određene vrijednosti), a ne sam kod što mogu, primjerice, biti (tajni) pristupni podatci za bazu podataka.

B. *Pristup aplikacijama korištenjem HTTPS-a*

Aplikacijama sustava sigurno se pristupa korištenjem HTTPS-a [13], sigurnosne nadogradnje protokola HTTP. HTTPS koristi protokol SSL/TLS za šifriranje prometa povrh transportnog sloja. Informacije koje se korištenjem aplikacije razmjenjuju između klijenta i poslužitelja šifrirane su.

Za uspostavu sigurne sjednice koriste se demo poslužiteljski certifikati dobiveni od FINA-e. Certifikatima se također korisnicima jamči i da je sustav (*web*-aplikacija na koju se spajaju) onaj za kojeg se predstavlja. Slika 5 prikazuje pristup *web*-aplikacijama jednog od informacijskih posrednika uključenih u sustav *FER e-račun* preko HTTPS-a. Budući da se radi u demo-certifikatu, u certifikatu se ne nalaze točni podatci o sustavu *FER e-račun*, ali tehnički gledano demo-certifikat jednak je pravom certifikatu.



Slika 5. Pristup *web*-aplikaciji jednog od informacijskih posrednika preko HTTPS-a

C. *Sigurne web-usluge*

Sigurnost *web*-usluga osigurana je implementiranjem standarda *WS-Security*. Koriste se mehanizmi za autentifikaciju korisnika i šifriranje poruka.

Autentifikacija se obavlja uključivanjem korisničkog imena i lozinke u zaglavlje SOAP-zahtjeva. *Web*-usluge moguće je koristiti tek nakon uspješno provedenog procesa autentifikacije.

Poruke se šifriraju korištenjem asimetričnog kriptografskog algoritma DES [14].

D. *Digitalno potpisivanje*

Oblikovani sustav omogućuje digitalno potpisivanje datoteka koje se kroz njega razmjenjuju. Digitalni potpis pohranjuje se unutar posebnog elementa XML-datoteke koja se kroz sustav šalje. Za pohranjivanje digitalnog potpisa koristi se standard *XML Signature*. Digitalno potpisivanje e-računa nije obavezno, ali je omogućeno korisnicima koji žele jamčiti: autentičnost, cjelovitost i neporecivost u procesu razmjene e-računa.

Nakon što korisnik kroz aplikaciju popuni sve potrebne podatke i na taj način oblikuje novi račun ili preda gotov račun u formatu XML, taj se e-račun zajedno s možebitnim prilogom ugrađuje u XML-datoteku koja se šalje. Takvu datoteku korisnik može potpisati korištenjem korisničkog digitalnog certifikata koji je izdala FINA (jedini hrvatski CA – certifikacijsko tijelo, engl. *Certification Authority*). Digitalni certifikat pohranjen je na pametnoj kartici. Zahtjev za potpisivanjem šalje se pametnoj kartici iz JavaScripta korištenjem funkcija gotovog programskog međusloja koji je izradila FINA. Kao odgovor dobiva se digitalni potpis dokumenta koji se tada ugrađuje u spomenutu XML-datoteku.

Slika 6 prikazuje dio XML-datoteke koja se kroz sustav razmjenjuje, a prikazuje strukturu opisanog digitalnog potpisa dokumenta.

V. SIGURNOST U SLIČNIM SUSTAVIMA

U svrhu što bolje implementacije sigurnosti u sustav *FER e-račun* proučeni su još neki domaći i strani sustavi za razmjenu e-računa. U nastavku će biti objašnjeno kako je sigurnost implementirana u projektu Europske unije za elektroničku nabavu nazvanom e-Prior [15].

U projektu e-Prior za prenošenje poruka koristi se mreža PEPPOL. Sigurnost *web*-usluga u sustavu PEPPOL implementirana je korištenjem standarda *WS-Security*, *WS-Reliability*, *WS-Addressing* te *WS-Transfer*. Za prenošenje sigurnosnih informacija kroz mrežu koristi se protokol SAML 2.0. U sustavu e-Prior sigurnost se temelji na definiranim sigurnosnim procedurama te nadzoru (sva interakcija između korisnika i sustava bilježi se u *log*-datotekama). Sigurnost je implementirana na transportnom i aplikacijskom sloju te na razini poruke. Za zaštitu sigurnosti na transportnom sloju koristi se protokol SSL. Zaštita sigurnosti na aplikacijskom sloju implementirana je kroz pridjeljivanje korisničkih profila korisnicima. Na taj se način definiraju ovlasti pojedinog korisnika nad sustavom. Autentifikacija korisnika ostvarena je korištenjem običnih lozinki umjesto korištenjem klijentskih certifikata.

VI. BUDUĆI RAD

U budućem radu razmotrit će se implementacija normi *WS-Reliability*, *WS-Addressing* te *WS-Transfer* po uzoru na projekt PEPPOL, a sve s ciljem povećanja razine sigurnosti *web*-usluga. Također, po uzoru na projekt e-Prior valja omogućiti bilježenje informacija o svoj komunikaciji između korisnika i sustava u *log*-datoteke.

Kada bi se sustav *FER e-račun* počeo koristiti u praksi, bilo bi potrebno pomno analizirati raspoloživost sustava što do sada zbog nedostupnosti dovoljno kvalitetne računalne opreme nije učinjeno.

Spomenuto je da se za digitalno potpisivanje računa pametnim karticama koristi FINA-in programski međusloj za pristup pametnoj kartici. Programski međusloj koji se trenutno koristi radi isključivo u internetskom pregledniku Internet Explorer te samo na 32-bitnim računalima. Potrebno je kroz suradnju s FINA-om nabaviti noviju i fleksibilniju inačicu spomenutog međusloja ili izvesti vlastiti međusloj za pristup FINA-inoj pametnoj kartici.

U budućem radu razmotrit će se moguće ranjivosti sustava koje u dosadašnjem radu nisu uočene i razmatrane. Bitno je imati u vidu činjenicu da je sigurnost mjera, a ne karakteristika. Sigurnost sustava treba kontinuirano preispitivati i unaprjeđivati.

VII. ZAKLJUČAK

U članku je ukratko predstavljen sustav za razmjenu elektroničkih računa *FER e-račun*. Predstavljene su i opisane za sustav važne sigurnosne norme. Objašnjeno je kako je korištenjem tih normi implementirana sigurnost u sustavu *FER e-račun*. Na koncu je na primjeru europskog projekta e-Prior prikazano kako je problem sigurnosti riješen u tim sustavima te su dane smjernice za daljnji razvoj sustava *FER e-račun*a u domeni sigurnosti sustava.

LITERATURA

INFORMACIJSKA SIGURNOST U PODRUČJU PRAVNIH ZNANOSTI

prof. dr. sc. Slavko Šimundić i Danijel Barbarić, mag. iur.
Sveučilište u Splitu, Pravni fakultet Split, Katedra za informacijske znanosti i statistiku, Split, Croatia
slavko.simundic@pravst.hr

SAŽETAK:

Novo vrijeme donosi i nova kaznena djela. Čovječanstvo danas proživljava vrijeme koje je u tehnološko-znanstvenom smislu već sutra zastarjelo. Revolucionarna informacijska dostignuća i u isto vrijeme njihova domišljata zlouporaba prožima gotovo sve sfere ljudskog života i rada. Ljudi su postali svjesni činjenice da su samo informacije preduvjet širenja znanja, a da je znanje glavni čimbenik, odnosno preduvjet svakog daljnjeg razvoja i prosperiteta svakog razvijenog društva, odnosno države. Suzbijanje učinaka i samih djela iz područja računalnog kriminala zadaća je s kojom se ponajprije moraju suočiti zakonodavna tijela, kako u represivnom tako i u preventivnom smislu. Utjecaj informacijske tehnologije na strukturu i funkcioniranje nacionalnih gospodarstava i čitave svjetske ekonomije ogleda se na makroplanu u stvaranju, burnom razvoju i sve većem značenju novih privrednih grana, što usmjerava ekonomske aktivnosti čovječanstva. Promatra li se informacija kao resurs, uviđa se da su njezina obilježja sasvim iznimna. Ukoliko se informacija dijeli s drugima ili prenosi, ona ne gubi na vrijednosti. Informacija se ne pokorava zakonu o očuvanju materije i energije. Svi ostali resursi postali su ovisni o informacijskim, jer bez posjedovanja informacija o stanju, mjestu i načinu njihova korištenja, oni postaju beskorisni u području pravnih znanosti.

KLJUČNE RIJEČI: informacijska, sigurnost, računalni kriminalitet, pravna znanost

1. UVOD – ŠTO JE TO INFORMACIJA?

Prema Općem pravnom rječniku[1] informacijom se smatra obavijest, saopćenje, izvješće, podatak o nečemu. Javna informacija je podatak čije je korištenje dopušteno svakome, dakle i onima koji se bave objavljivanjem i širenjem informacija. Javne su informacije vijesti, podatci, mišljenja i saopćenja objavljena putem tiska i drugih sredstava javnog priopćavanja.

Pravni leksikon[2] pod informacijom podrazumijeva bilo koju vrstu saznanja o faktima, konceptima ili instrukcijama koji mogu biti predmet komunikacije; podatak u kontekstu, krajnji produkt interpretacije podataka iz konteksta; pravni podatak, tekst, fotografija, crtež, karikatura, film, usmeno izvješće, vrijednosni sud ili drugi prilog objavljen u mediju.

Pravo na pristup informacijama danas se smatra općim pravom koje proizlazi iz temeljnih odredbi Opće deklaracije Ujedinjenih Naroda o ljudskim pravima, Međunarodnog pakta o građanskim i političkim pravima, Europske konvencije o zaštiti ljudskih prava i temeljnih sloboda Vijeća Europe, Američke konvencije o ljudskim pravima Organizacije Američkih država i drugih dokumenata.[3]

U području informacijske sigurnosti možemo promatrati informaciju kao resurs, zato jer uviđamo da su njezina obilježja sasvim iznimna.Ukoliko se informacija dijeli s drugima ili prenosi, ona ne gubi na vrijednosti. Informacija se ne pokorava zakonu o očuvanju materije i energije. Svi ostali resursi postali su ovisni o informacijskim, jer bez posjedovanja informacija o stanju, mjestu i načinu njihova korištenja, oni postaju beskorisni. Utjecaj informacija i prateće tehnologije na strukturu i funkcioniranje nacionalnih gospodarstava, pa i čitave svjetske ekonomije, ogleda se na makroplanu u stvaranju, brzom razvoju i sve većem značaju novih privrednih grana, što usmjerava ekonomske aktivnosti čovječanstva i koncentrira ih oko djelatnosti na različite načine vezanih za informacije. Na mikroplanu, u okviru poduzeća, intenzivnom primjenom informacijskih tehnologija, dolazi do strukturnih promjena koje se najviše odražavaju na poslovne procese i aktivnosti.[4]

2. RAČUNALA U SVAKODNEVNOM ŽIVOTU SUVREMENOG ČOVJEKA

[2] Pravni leksikon, Lektikografski zavod Miroslav Krleža, 2007. god. str. 445.

[3] Rječnik, str. 859.

[4] Šimundić, Slavko; Pravna informatika, Sveučilište u Splitu, Pravni fakultet Split, Split, 2007. god. (u daljnjem tekstu: Šimundić, Informatika), str. 97.-98.

Današnje je doba svakako doba vladavine računala. Ona su u našim domovima, na radnim mjestima, automobilima, doslovno na svakom koraku. Shodno tome, danas zasigurno ne postoji ni jedna organizacija koja je uspjela izbjeći interes počinitelja, koji se bave računalnim kriminalom. Taj se interes može definirati kao napad, iako se vrlo često koriste termini poput provale ili upada. Vrlo je teško povući granicu koja bi odredila kada je određeno djelo provala, a kada upad. Iako izgledaju kao sinonimi, radi se o pojmovima koji se u kontekstu bavljenja računalnim kriminalom mogu razdvojiti i barem malo razlikovati. Naime, kada počinitelj uspije probiti sustave računalne sigurnosti s ciljem ostvarivanja materijalne koristi ili počinjenja štete, moguće je govoriti o provali, a u slučajevima kada se radi o proboju računalne sigurnosti bez cilja ostvarivanja materijalne koristi ili počinjenja štete, možemo govoriti o upadu. Napad na računalne sustave u kontekstu računalnog kriminala moguće je promatrati iz aspekta uspješnog napada i napada u pokušaju. Uspješan napad je napad koji je u konačnici rezultirao slamanjem sustava računalne sigurnosti, dok je napad u pokušaju napad, koji je računalni sigurnosni sustav detektirao i uspješno otklonio.

Općenito se napadi mogu klasificirati i na taj način opisati u nekoliko skupina. Mi ćemo ih klasificirati prema ciljevima, odnosno prema šteti koju napad može prouzročiti i po posljedicama koje mogu nastati na:

- računalni sustav u vlasništvu državnih institucija (ministarstva obrane, unutarnjih poslova te zakonodavnih tijela....),
- računalni sustav u vlasništvu velikih gospodarskih subjekata (međunarodnih korporacija, velikih društvenih organizacija, ...),
- računalni sustav u vlasništvu financijskih institucija (banke, burze, štedionice, ...),
- računalni sustav u državnim institucijama i organizacijama (vlada, ministarstva, elektroenergetski sustav...),
- računalni sustav u vlasništvu drugih organizacija i osoba.[5]

2.1. RAČUNALA U DRŽAVNIM INSTITUCIJAMA I ORGANIZACIJAMA

Računalni sustavi u državnim institucijama i organizacijama mete su terorističkih napada. Može se postaviti pitanje kakva je veza terorista i računalnog kriminala. Počinitelji terorističkih i saboterskih djela u skladu s informacijskom revolucijom postaju isto tako informacijski pismeni, te uvelike koriste blagodati informacijske tehnologije za svoja nedjela. Računalne se sabotaže sastoje u uništenju ili oštećenju računala, računalne opreme i drugih uređaja za obradu podataka, ili u brisanju ili mijenjanju, odnosno sprječavanju korištenja informacija sadržanih u memoriji računala i računalne oprema. Računala i računalna oprema može se uništavati ili oštećivati na klasičan način, kao i bilo koji drugi uređaj iz sasvim različitih motiva. Napadi na računalnu opremu ovog pa čak i terorističkog karaktera ne spadaju striktno u domenu računalnog kriminala.[6]

2.1.1. TEMELJI MODERNOG INFORMACIJSKOG SUSTAVA DRŽAVNIH INSTITUCIJA I ORGANIZACIJA

Cilj funkcijske informatike je tranformiranje općih teorijskih znanja relevantnih za informiranje u praktičku djelatnost usmjerenu k izgradnji informacijskih sustava određenih osobina i odgovarajuće informacijske tehnologije. Rezultati funkcijske informatike metode su za: utvrđivanje svrhovitosti automatizacije pojedinih segmenata informiranja i identifikaciju parametara odgovarajućih informacijskih sustava; projektiranje suvremenih informacijskih sustava kao elemenata automatiziranih upravljačkih sustava; uvođenje, odnosno aktiviranje izgrađenih informacijskih sustava; optimizaciju interakcije subjekata upravljanja i informacijskog sustava i dr.[7]

Funkcijska informatika nudi nam metode za izgradnju i korištenje suvremenih informacijskih sustava i odgovarajuće informacijske tehnologije. Na tim temeljima izgrađen je i informacijski sustav Republike Hrvatske.

Sadašnji sustavni i aplikativni software informacijskog sustava državnih institucija i organizacija čine:

- Operacijski sustav
- Aplikativni software
- Evidencija i poslovi suvremenog informacijskog sustava
- Centralizirani poslovi i evidencije
- Distribuirane obrade
- Kombinirani poslovi i obrade

2.2. PREVENCIJA RAČUNALNOG KRIMINALITETA

Prevencija računalnog kriminala može se promatrati s aspekta aktivne i pasivne prevencije. U aktivnu prevenciju

[5] Šimundić, Informatika, str. 93.

[6] ibid. str. 94.

[7] Šimundić, Slakvo; Funkcijska informatika u društvenim sustavima, Sveučilište u Splitu, Pravni fakultet Split, Split, 2000. god. (u daljnjem tekstu: Šimundić, Funkcijska), str. 25.

moguće je ubrojiti procjenu rizika računalnog sustava i njegove vrijednosti, dok se pod pasivnom prevencijom smatra permanentno obučavanje zaposlenika. Računalna se sigurnost može smatrati trgovinom, a s obzirom na cijenu te sigurnosti samo si najbogatije tvrtke mogu priuštiti zaštitu od svih rizika (ako je to uopće i moguće). Umjesto plaćanja visoke cijene potpune sigurnosti, većina tvrtki balansira s cijenom zaštite i rizikom od moguće posljedice. Proces analize računalnog sustava i donošenja odluke o načinu zaštite naziva se analiza rizika, a nivo prihvatljivosti sigurnosnog rizika tvrtke naziva se prihvatljivi rizik. Svaki proces analize rizika moguće je opisati trima pojmovima, to su: prijetnja, ranjivost i protumjere. Prijetnja je moguća šteta na računalnom sustavu. Šteta može biti posljedica djelovanja osobe, stvari ili događaja koji može napasti računalni sustav. Ranjivost je točka gdje je računalni sustav podložan napadu. Prijetnja je konkretna namjera ispitivanja ranjivosti računalnog sustava. Protumjere su tehnike zaštite računalnog sustava.[8]

Provjere fizičke sigurnosti provodi osoblje koje je zaposleno u samoj organizaciji ili u nekoj drugoj organizaciji koja se bavi fizičkom sigurnošću, koristeći unaprijed pripremljene ispitne liste. Ispitne liste pomažu kako bi se provjerile sve potencijalne ranjivosti. Nije dobro da fizičku sigurnost provjeravaju osobe koje u njoj rade, jer nisu u stanju dovoljno kvalitetno sagledati sve potencijalne opasnosti, već samo one koje su njima poznate. Izvještaji koje načine osobe koje se bave provjerom fizičke sigurnosti, odnosno ispitne liste, u pravilu su tehnički detaljne i opsežne, te se koriste u kratkoročnim ili dugoročnim poboljšanjima fizičke sigurnosti. Nakon obavljene provjere, ona se uspoređuje s prijašnjom, te se rješavaju sigurnosni problemi koji prije nisu bili riješeni. Počinitelji bi vrlo rado došli u posjed tih ispitnih lista, kako bi bez puno muke dobili ranjive točke fizičke zaštite objekta. Stoga je vrlo važno ove informacije tretirati kao vrlo povjerljive. Kakve god bile sigurnosne provjere, one su predvidljive. Povremene provjere unose element slučajnosti u program zaštite fizičke sigurnosti. Uz pomoć ovakvog načina provjere moguće je saznati pridržava li se i na koji način osoblje sigurnosnih mjera u području pravnih znanosti.[9]

Za prevenciju upada potrebno je kontinuirano voditi računa kako bi se postavile posebne prepreke na vratima i prozorima prostorija u kojima su smještena računala i računalna oprema, mediji za pohranu podataka i priručnici. Potrebno je, također, izvršiti provjeru i utvrditi da potencijalni počinitelj ne može preskočiti ili na neki drugi način ući preko zaštitnog zida, prokopati rupu i provući se ispod zaštitnog zida, te provjeriti jesu li odvodi za zrak dovoljno mali kako se počinitelj ne bi mogao kroz njih provući. Računala je potrebno držati podalje od prozora jer se prozorska stakla lako lome i mogu prouzročiti veliku štetu. Osim toga, potencijalni počinitelji mogu promatrati što se događa, posebno ako se radi o staklenim zidovima između ureda. Radi što učinkovitije zaštite potrebno je neovlaštene osobe udaljiti i u potpunosti zabraniti pristup telefonskim ormarićima, razdjelnim kutijama i drugim komunikacijskim uređajima. Važno je osigurati sigurno odvoz i uništavanje smeća, kako bi se počinitelje spriječilo da ga iskoriste. Da bi se što kvalitetnije spriječili upadi, nužno je osigurati fizičku zaštitu na kritičnim pozicijama, osigurati kvalitetnu zaštitu računalnog sustava, odnosno prostorije na pametnim karticama, ključevima ili nekom biometrijskom karakteristikom, a uz standardni protuprovalni sustav bilo bi poželjno instalirati i videonadzor.[10]

2.3. KOMUNIKACIJSKA ZAŠTITA

Komunikacijska zaštita temeljna je metoda zaštite koja se koristi za zaštitu podataka koji se prenose komunikacijskom linijom.

Kriptografija se danas sve više koristi i za zaštitu podataka u datotekama i bazama podataka i informacija. U svakom računalnom centru postoji znantna količina podataka i informacija koja zahtijeva visoku razinu zaštite, a ona se može osigurati u prvom redu upotrebom kriptografske tehnike. Kritptografija je postupak zaštite tajnosti podataka primjenom algoritama koji transformiraju razumljiv oblik teksta (čitlji) šifriran u tekst, nerazumljiv osobama koje ne poznaju algoritme transformacije.

Danas se uglavnom koriste četiri kriptografske metode:

- transformacija – preuređuje poruku preraspodjelom znakova razumljive poruke
- supstitucija – preuređuje poruku zamjenom znakova razumljivog teksta znakovima izabranim iz neke druge abecede
- aditivno kodiranje – preuređuje poruku kombiniranjem bitova razumljivog teksta s bitovima šifriranog niza s pomoću logičke operacije „ili“
- multiplikativno kodiranje – preuređuje poruku kombiniranjem bitova razumljivog teksta s bitovima šifriranog niza s pomoću logičke operacije „ili“ ponovnom logičkog operacijom „ili“ te kombiniranjem djelomičkog rezultata s nizom bitova koji je proizveden prethodnim parcijalnim operacijama.[11]

[8] Šimundić, Informatika, str. 103.
[9] Šimundić, Informatika, str. 106.
[10] Šimundić, Informatika, str. 107.
[11] Šimundić, Funkcijska, str. 27.

Ima više različitih načina zaštite mrežnih komunikacija, a koje uključuju, kontrolu pristupa, kriptografiju, firewall tehnologiju te ostale mjere fizičke zaštite. Kontrola pristupa je bitan čimbenik u ostvarivanju računalne sigurnosti u mrežnom okružju. Mnogi računalni sustavi koriste zaporke u smislu osiguravanja kontrole pristupa. Taj model je jednostavan - svatko tko poznaje ispravnu zaporku, ima dopušten pristup računalnom sustavu. Zbog toga je bitno da zaporku poznaju isključivo ovlašteni korisnici u području pravnih znanosti.

Osnovna pravila pri čuvanju zaporke:

- nikada zaporku čuvati napisanu u blizini računala ili terminala,
- zaporka ne smije biti ime korisnika ili neki pojam koji je lako pogoditi,
- ne koristiti istu zaporku koju već posjeduje neki drugi korisnik,
- ne spremati zaporku u datoteku na računalu.

Ako se korisnici pridržavaju navedenih pravila, kontrola pristupa će dobro obaviti svoj posao. Nažalost, samo nekolicina korisnika vodi brigu o odabiru zaporke koju nije lako pogoditi, i njenu čuvanju. Mnogi računalni sustavi ostavljaju korisnicima mogućnost samostalnog odabira zaporke, dok drugi uvode dodatne mjere kontrole zaporki.[12]

Pet je osnovnih načina kojima počinitelji računalnog kriminala pribavljaju informacije koje su im potrebne da počine zločin u području pravnih znanosti:

- promatranjem opreme i događaja,
- korištenjem lako dostupnih informacija,
- kopanjem po smeću,
- kompromitiranjem sustava,
- kompromitiranjem zaposlenika.

Poznato je, počinitelji računalnog kriminala jednostavno prolaze kroz radne prostore, obraćajući pažnju na zaporke koje su zalijepljene na stranama stolova iii zaslonima monitora, lokacije računala ili terminala koji nisu pod nadzorom, te procedurama ili protokolima koji se koriste za pristup različitoj programskoj podršci. Ponekad se počinitelj može pretvarati da je iz odjela za održavanje ili servisa ili se jednostavno može pretvarati da dostavlja paket u ured. Moguće je da netko dvogledom iz nasuprotne zgrade promatra što se događa u uredu. Dva su načina u sprječavanju ovakve prijetnje. U prvom redu, potrebno je promatrati i provjeriti što bi sve uljez mogao vidjeti te što bolje zaštititi opremu i informacije. Pobrinuti se da korisnici sustava ne ostavljaju zaporke, brojeve telefona i druge informacije na mjestima na kojima su lako uočljivi.[13]

[13] Šimundić, Informatika, str. 116.-117.

3. ZAKLJUČAK

Informatika i sigurnosno pravo relativno široko je obrađeno. Informatika će u budućnosti predstavljati temeljne radne postupke, a sigurnosno pravo u budućnosti, suglasno razvoju društva, činit će temelje društvene funkcionalnosti. Zbog toga smo obradili vrste mogućih napada na funkcije pravnih institucija, model ekonomskog rasta, informacije kao resurs razvoja, problem globalizacije itd. Posebno su obrađeni problemi: fizička sigurnost građana, sigurnosne mjere za osoblje u društvu, sigurnost komunikacija, računalni kriminal, činioci računalnog kriminala, postupci eliminiranja, prevencija zaštite i trajno postupanje s računalnim kriminalitetom.

Data ownership model for a telecom company

Žaklina Šupica, Tomislav Pavić
Croatian Telecom Inc./Information Systems Planning and Architecture Department, Zagreb, Croatia
zaklina.supica@t.ht.hr, tomislav.pavic@t.ht.hr

Abstract - Having in mind that data constitute the key asset of every company, it is necessary to define the owners of that asset. This paper proposes a model for clear determination of data ownership in information systems. Our intention is to show that there is an utmost need and practical possibility for formal definition of data ownership, including the clear definition of owners' responsibilities which are acceptable by all data owners. Model is based on enterprise architecture units called domains and smaller units called functional components. Applied domain model divide the complete business of a telecommunication company in to 12 domains where each domain represents a "natural" unit with clear responsibilities and competencies structured according to the business aspects. Although data ownership comprises several important responsibilities, approach taken in this paper is manly in respect to authorization of user access to data and validation of approved access. We propose to determine of which functional components information or network system is consistent of and that each functional component has to have an owner assigned. Owner of functional components becomes data owner of the applications which implements that functionality due to the fact that each functional component has its own data.

I. INTRODUCTION

In telecom environment, various organizational units use the same set of data in performing of their everyday business. Having in mind that data, and especially customer data, constitute one of the key asset for any telecom company, it is necessary to define the owners of that asset.

We started with assumption that every company has some sort of framework within which data ownership is organized but which are usually not fully formalized or not simply detailed enough to be implemented in practice. Therefore, our intention is to show that there is an utmost need and practical possibility for formal definition of ownership of data, including the clear definition of owners' responsibilities which can be accepted by all data owners and implemented in information security management systems.

Data owner's responsibilities can be divided in several categories: definition of data, data quality, maintenance of data, authorization of access, support the user community, etc. [1]. Approach taken in this paper is manly in respect to authorization of user access to data and validation of approved access category. Basically, we are driving data ownership through information security management system [2].

The essence of our approach lies in the control of information as an enterprise asset. That control includes not just the ability to access, create, modify, derive benefit from, or remove data but also the right to assign access privileges to others [1].

The problem that we were facing in the Croatian Telecom (HT) was the problem of no acceptance of data ownership due to unclear defined responsibilities of data owners and especially inability to clearly assign a person responsible for user access approval process for particular information or network system (IT/NT system). When one IT/NT system supports one business process with clear ownership of the process, meaning that one organisational unit is responsible for business process and uses IT/NT system alone, data ownership was accepted. But, more often we had situation where one IT/NT system was supporting several business processes and it was shared between two or more organisational units. Question guiding us was is there a model of data ownership dealing with this kind of situation that could be successfully implemented in practice?

Finding the answer to this question is not simple. It involves a process of identifying the interested parties associated with all data sets, determining each party's interest, identifying the different roles associated with all data sets, and assigning roles and responsibilities to the right parties [1].

Approach that we took for answering this question came from enterprise architecture units called domains and functional components that were already used for IT architecture and for business processes analysis. We recognized the usage of enterprise architecture is already known by business so we decided to adapt it to authorization of user access process as one of the security processes.

II. ENTERPRISE ARCHITECTURE

Enterprise architecture is the description of the current and future structure and behaviour of organization's processes, information systems, personnel and organizational units, aligned with the organization's core goals and strategic directions [3].

The analogy of city planning is very useful to provide a ground for what enterprise architecture is and to illustrate why it is important. A city plan describes the architectural constructs of policies and standards that direct individual building initiatives and define standards for shared and common services such as traffic, road and transportation, utilities and open space. City planning provides the framework within which multiple individual projects and architectures exists. The goal of city planning

is to ensure that buildings and shared services will work together to meet the goals of safety, efficiency, aesthetic quality and liability established by members of community.

Enterprise architecture is created and adopted to meet analogue goals for the enterprise. The multitude of systems in an organization need to work together, share data, provide information security, scale and adapt to change and growth, reduce overall costs, and allow the organization to meet its strategic goals. Enterprises need guiding and constraining architectural designs and standards with policies and processes for approval and enforcement of these standards for individual initiatives. This aspect of enterprise architecture helps companies to bridge conflicting priorities [4].

Enterprise architecture can be further described in terms of major architectural and process layers used to categorize broad areas of IT and business activities. The four-layer enterprise architecture based on [6] is accepted within DT Group (and in HT as a part of DT Group) as a model for IT standardization. It comprises the following layers: business, logical, application and technology architecture. In the following paragraphs we will define business and application architecture and describe in more detail logical architecture which is foundation for proposed Data Ownership Model for a telecom company while we will omit completely technology architecture which is not relevant for this model.

Business architecture describes the enterprise's structural, high-level business processes, service areas, and delivery channels. It defines the functional roadmap for the organization and describes processes like order management, complaint management and product lifecycle management. eTOM process framework [7] is used as a basis for description of business processes in HT.

Logical architecture layer describes the technology-independent logical architecture of applications. Typical objectives of logical architecture are to document major functions, data component and their relationships. Domain model, called Group Domain Model (GDM), has been developed in DT Group for the logical architecture layer to represent a cluster of confined, stable business functions. This approach enables decoupling business functions and IT applications and supporting infrastructure [7]. The basic components of DT Group common GDM are shown in the Figure 1.

GDM divides the complete business of the telecommunication company, in this case aligned with the DT Group specifics, to 12 domains: Customer Relationship Management (CRM), Billing, Partner Management, Service Management, Resource Management, Production, Supply Management, Strategic Management, Product Life Cycle Management, Service and Resource Lifecycle Management, Unified Communication and Enterprise Support. Each domain represents a "natural" unit with clear responsibilities and competencies structured according to the business aspects. Also, these domains represent first level of GDM.

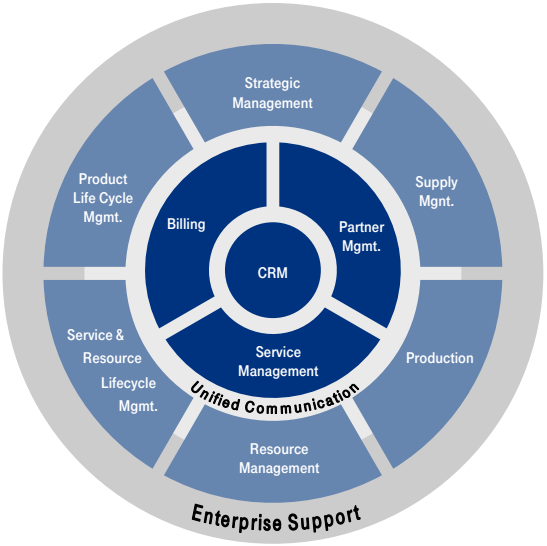

Figure 1: DT Group Domain Model (GDM)

At the second level, each domain consists of the functional components (FCs). In this sense FC is a sub-domain which structure domains that are complex from a business viewpoint. For example, CRM domain has following sub-domains: Customer Management, Contact Management, Customer Order Management, Sales & Acquisition, etc. Basically, FC is describing domains in more detail. Functional components of CRM domain are shown in Figure 2 [8]. This second level of granularity represents basis for our data ownership model and will be explained into more detail in the next section.

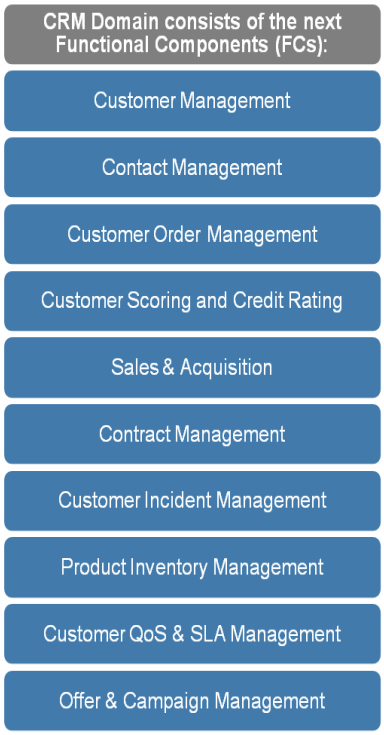

Figure 2: Functional components of CRM domain

The third level of this model is represented by capabilities. Capabilities describe the potential need for the realization of certain business activities, meaning the possibility of a company to successfully carry out certain business activity (e.g. creation of the order to connect the customer). This third level is used only in cases where it is hard to distinguish responsibilities of owners according to second level – FC, but they will not be explained in this paper because they are not important for this description of the model.

Finally, application architecture describes which applications are used to deliver certain FC or functionality, their interactions and their relationships to the core business functions of the organization. Described level of granularity of GDM enables consistent way of mapping existing and planned applications into functional components.

III. DATA OWNERSHIP MODEL

Between several data ownership models looked at from the perspective of the distribution of ownership [1] we have chosen a decentralized model where the ownership roles are allocated to separate areas of interest.

By following described GDM model, we changed approach and mind set of all stakeholders and instead of using IT/NT system as basis for data ownership we use functional components (FC) also known as functionalities. Reasoning for that is based on the fact that enterprise architecture helps to identify which IT/NT system is consistent of which FCs. In practice we mapped each IT/NT system to the relevant FC. We assigned an owner to each FC and that owner of FC is called data owner. In that way what we have got is an IT system (e.g. CRM system) mapped with ten FCs from CRM domain. Those ten FCs had six owners assigned. Owners were assigned to FC according to business activities. This mapping is later explained into more details. We were able to create this kind of connections due to the fact that every FC has been consistent of a data called Aggregated Business Entity (ABE). ABE are data which describe some business object in unique way, e.g. table with customer data (Customer). Data ownership is executed through FC in which data are produced. This kind of ownership is called "Master Data Ownership", and those data are called "Master Data".

Master data owner has an ultimate accountability and responsibility for data in his/hers area of responsibility. Data owner is establishing rules of data usage and rules of their availability to the Company. If Master data are needed in other FC, than owner of second FC has to have permission of the owner of the first FC for the usage of data and must accept rules made by Master Data Owner in written. Owner of second FC will be responsible for implementation of rules while using such data in his FC. Example of this data ownership is if data warehouse (DWH) systems need to copy data from billing system. Owner of billing data has to give permission to the owner of DWH functionality. Any changes of the data can be done only on master data.

In our example of CRM domain and 10 FCs from which this domains in consistent of (Figure 2), we have done several mappings to be able to define data owner of this one of the most complex domains. First mapping was necessary to define which IT/NT system is supporting identified 10 FCs. That mapping resulted with list of several IT/NT systems. Second mapping was done between FC and our internal organisational document describing what organisational unit is doing what in everyday business.

TABLE I. EXAMPLE OF DATA OWNERS IN CRM DOMAIN

FC	**IT/NT system supporting FC**	**Data (FC) owner**
Customer Management	IT/NT system 1	Organisation unit 1
	IT/NT system …	Organisation unit 2
	IT/NT system …	Organisation unit 3
	IT/NT system …	Organisation unit 4
Sales and Acquisition		Organisation unit 3
		Organisation unit 4
Offer and Campaign Management		Organisation unit 5
	IT/NT system n	Organisation unit 6

That way we got organisational units responsible for particular FC and manager of distinguished organisational unit has automatically become a data owner. This approach allowed us to get one of several data owners for one FC and we got data owner for IT/NT system supporting that FC. Table 1 is showing an example for CRM domain. When this case was put into practice we have got six data owners of several IT/NT systems with responsibilities to approve user access to data. In some ITNT systems few of them will have to give their approval (e.g. Customer Management FC has four data owners). Of course, we also have cases where one FC is supported by one IT/NT system and we have one data owner. Those are very clear cases with no necessity for further actions in implementation process.

TABLE II. EXAMPLE OF ROLES IN CRM DOMAIN

FC	**IT/NT system supporting FC**	**Role in the IT/NT system**	**Data (FC) owner**
Customer Management	IT/NT system 1	Incident administration	Organisation unit 1
	IT/NT system …	Administrative data correction	Organisation unit 2
	IT/NT system …	Administrative data correction	Organisation unit 3
	IT/NT system …		Organisation unit 4
Sales and Acquisition		Key-account users	Organisation unit 3
			Organisation unit 4
	IT/NT system n		

When we look at the authorization of user access to data, from this point of view it looks like several managers have to sign approval for user access. At the beginning that will be the case very often in complex domains. In FC where we have just one IT/NT system and one owner there is no problems. In FC where there is few IT/NT systems and several data owners we have to map each role in the IT/NT system to the right FC and owners of that FC will be signing approval for those roles. Each role in the system has access to certain ABE inside of its customer segment.

Table 2 is showing an example where some roles are added for CRM domain.

An explanation of the table 2 is this: IT/NT system 1 supports functional components called Customer management. That IT/NT system is having several roles which users have to have approval to use according to their business activities. Role called Incident administration also belongs into Customer Management FC. Organisational unit 1 is the owner of Customer Management FC therefore, manager of organisational unit 1 has to approve user request for role Incident Management. In a case of a role called Administrative data correction, two organisational units share ownership and therefore, two managers have to approve user access.

This model was presented to recognized data owners responsible for CRM domain and we tried the model on some practical examples of approval process just to show them that this model is applicable in practice. They responded positively to this model and after CRM domain (which was considered as pilot project) we applied this model to all domains from Figure 1.

Main advantage of proposed model is clearly divided responsibilities of data owners according to FC and data that they are really using in everyday business and they can easily accept responsibility of approving user access to it.

Main disadvantage of this model is a fact that this is a custom made model applicable to one company only. If some other telecom company wants to use it, it can be used just as baseline model that has to be customized to the real IT/NT systems and organisational units in a company.

IV. DATA OWNERSHIP RESPONSIBILITIES

Beside this data ownership model, we have defined data owner responsibilities based on international standards ISO 27001 [2], HT and DT Group security policies and standards. One of the responsibilities is to follow up legal and internal regulation during data collection and processing so he/she can be sure that data processed in their FC are processed in a way that is compliant with regulations (e.g. period of usage).

In a tight connection with regulations is also responsibility to define data lifecycle so that every IT/NT system has defined period of data processing (e.g. data can be archived for 1 year only).

Data owners also have to participate in data risk assessment and that is a process which is necessary when some security controls have to be implemented according to level of risk (e.g. if a risk of data theft is very high, than some security controls will be implemented, and if that risk is low or on acceptable level, security controls can be unnecessary). In that respect, when some security control or measure has to be implemented, data owner also have to approve this implementation due to accountability of the data security in IT/NT systems.

All data in IT/NT systems should be classified according to levels of data classification (e.g. internal, confidential, and strictly confidential) so data owners have responsibility to defined data classification.

One of the important responsibilities is approval of data usage rights and data user access and additionally periodically check of data access lists (e.g. one a year they get list of all active users in IT/NT systems and they have to check is list of users is correct in terms of early proved user access).

In development activities of IT/NT systems, data owners have to approve any change requests related to systems development where there is impact on data under his/hers ownership (e.g. new functionality added to IT/NT systems).

When we are talking about personal data, described data owner's responsibilities can be formulated in a way that responsibilities are related only to personal data processing. Those responsibilities are collection/further processing in line with lawful purposes known to data subject; collection/further processing exclusively on need to know principles; ensuring accurate, complete and up-to-date personal data; issuing authorization to access personal data; ensuring that personal data are not available to unauthorized persons; defining data retention period in line with applicable regulations; ensuring other technical, organizational and personnel data protection measures to protect personal data from accidental or deliberate abuse, destruction, loss unauthorized alteration or access.

All of these activities are embedded in an HT's data ownership concept, which incorporates all governance rules regarding data ownership and usage within the Company.

V. CONCLUSION

In Croatian Telecom (HT) IT/NT systems usually contains data that is in any way sensitive, whether it is confidential information, customer data, human resource data, or corporate intelligence. In all these cases it is necessary to define formal data ownership model and a security and authorization policy and to provide for its enforcement.

Situation with no acceptance of data ownership and not defined clear responsibilities was no longer sustainable in HT. We decided to use internally well-known GDM model used in enterprise architecture and adopt it to information security management system, more precisely to authorisation of user access process. The approach to data ownership was changed due to the change where we introduced functional components as one of the most important parts of IT/NT systems and defined that each functional component has its owner and

owner of one functional components becomes owner of all data produced in that functional component. GDM provided us the possibility of mapping every IT/NT systems to each FC.

ICT services development process with security as its integral part

Ivan Sedinić, Zrinka Lovrić
T-Hrvatski Telekom d.d., Zagreb, Croatia
ivan.sedinic@t.ht.hr, zrinka.lovric@t.ht.hr

Abstract – ICT services are under competitive pressure being launched daily. Because of that, security dimension in ICT services is often overlooked. To assure that security is integral part of such services, an organization needs to establish security infrastructure which will support it. Such infrastructure should consist of security documentation (policies, requirements, procedures…), established processes and appropriate organizational measures. Model and related process for ICT service development or modification, with security as its integral part from the initial phase will be described in this paper.

I. INTRODUCTION

The usage of different applications and services which store our personal data and valuable information, with or without our consent, keeps growing rapidly on a daily basis. So, in decision process to choose ICT service provider, facts of how secure are information and provided services, will have more and more influence. Data and information security became important component of each ICT service, same as delivery of the service itself. One of the major problems of organizations is the perception, where management and employees perceive ICT security as a technical problem and not a business problem. The meaning and the importance of security failures are better understood through economic losses than through a technical analysis. This situation leads to a misunderstanding of the nature of the security issues and constantly ends up with addressing the wrong problem [1]. The approach to security matter should be proactive from the very beginning of ICT service development. Giving insufficient relevance to security component when developing new service could cause great losses for the company after the service is launched. In this paper model and related process for ICT service development or modification, with security as its integral part from the initial phase will be shown.

II. RESEARCH PROBLEM

Today's telecommunication / ICT companies offer different services and products, from the basic ones like mobile & fix voice, mobile & fix data, internet to those which follow ultimate ICT trends in the given industry like IPTV, services in the cloud, location services etc. To keep up with extremely fast changing trends, continuous investment and development of new services and products are a must. ICT security is often treated as an add-on or as a separate issue, with its own budget and personnel to manage it. From an ICT industry point of view this is more convenient way of producing the new services – why bother much with security when there is a whole industry which fixes security issues and makes the products usable, relying on the fact that most products on the market are very weak from a security point of view. In the meantime, the developers can concentrate on features, time-to-market and prices of their service. They depend on the existence of the ICT security market in order to sell their products [3].

We could say that there is almost no service that functions without dealing with customer's personal data, whether it's about personal or traffic data used for marketing or invoicing purposes or location data used in different applications. Customer personal data are very sensitive category of company's asset that needs to be properly protected. It is extremely important to identify the potential threats and risks, to control it and to minimize the impact of uncertain events to an acceptable level. Budget constraints and the need to release new products within time-lines fixed by management, coupled with trying to provide the maximum numbers of features at a lower price are often reasons strong enough to cause this protection's oversight. Reasons like "we didn't have a security problem in the past, so there is no worry" or "security is just additional cost without real benefits" lead to secure disaster. Postponing the implementation of security measures for later, better times is not the solution of the problem. Such approach, even if very attractive at the moment, later usually has significantly bigger price as:

- Implementation of security measures in already running service is more expensive than such implementation during initial development
- Running system with security omission is increasing risk to be exploited
- Not fixed security issues have tendency to be forgotten through the time.

Losses from security breaches can be caused by a poor organization of security measures, human failures or fraud, technical failures or external events [2]. Those can be of financial, technical, ecological, social, psychological or similar nature.

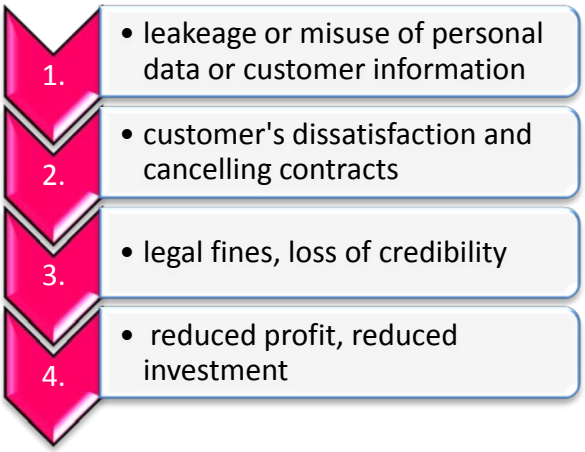
Security problems in ICT can be divided into two broad types [3]:

- Problems, bugs or mistakes in the design or implementation of ICT products
- Incorrect usage of ICT products by humans

Even though these types overlap, drawing the distinction helps to understand the kind of problems. The first type involves problems of a primarily technical nature

within ICT and the second type involves problems that arise from human usage of technology. The second type represents the most common security issues which can be solved only by continuous raise of security awareness level of each employee [3].

In the end, unrecognized need or insufficient security awareness level when developing a service or a product can have huge repercussions on business, services and operations like in bellow scenario:



III. INFORMATION SECURITY INFRASTRUCTURE

When dealing with security, there are two indispensable conditions that need to be fulfilled for a company to do a quality work:

- Management's support
- Security aware employees.

Strong ICT security management cannot be put in place without significant attention being given to human resources, the weakest link in any security chain, even where the best technical security controls are in place, which also extends to contractors, consultants and other individuals working on the organization's premises or using the organization's assets [2].

To be able to process customer data in a secure way and to declare a service or product as a secure one, the company needs to have certain security infrastructure.

Such infrastructure is prerequisite for company to manage its information security system in a quality manner and it usually consists of:

1. Security documentation [4]
   - Security policies
   - Security requirements
   - Security procedures
   - Security instructions
2. Organization

   Organizational unit in charge for security needs to be clearly defined, together with responsible person. Roles with description of tasks and responsibilities must be set, both in the security organizational unit and on the company level. Some basic security principles like "need to know" principle should be implemented. Established organization, set roles with descriptions of tasks and responsibilities and implemented "need to know" principle are a good preventive basis of security infrastructure.
3. Processes and procedures

   Processes and procedures how to implement mentioned security documentation, how to interact with different organizational unit in the company during such implementation also need to be defined and communicated to all relevant employees.
4. Personnel

   Employees who will perform all this tasks are crucial for success. Such people need to be constantly educated in security matters through different channels. It could be e-learning systems, awareness campaigns, workshops, seminars and all other ways to keep their awareness and knowledge on acceptable level.

By implementing the mentioned infrastructure, company has already started with upgrade of its security level from (almost) non existing to the preferable one. There is no such thing as 100% security, it is all about the risk which company is ready to accept as best balance between costs and potential damage. Main security goal that every company should tend to achieve is to have acceptable security level of all its services, based on mentioned security infrastructure and using it constantly in developing and upgrading the services.

IV. ICT SERVICES DEVELOPMENT PROCESS WITH SECURITY AS ITS INTEGRAL PART

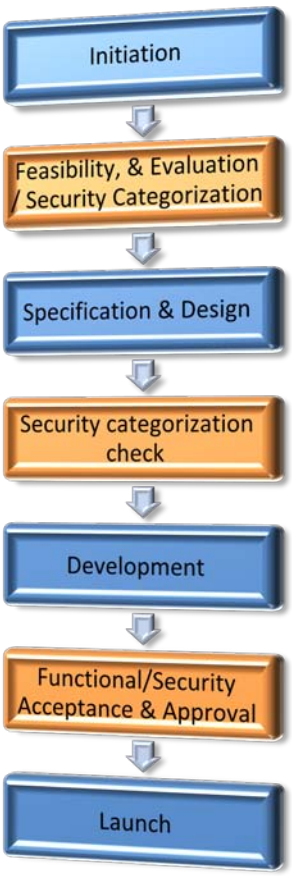
Each ICT service development project has its lifecycle which starts with collecting inputs and making their ideation after what follows the initiation of project

and all other steps, including technical design, realization and testing. Every ICT service development project should finish with the launch of new or modified product or service (Chart 1).

It is extremely important that the security is integrated in a service from its initial phase for different reasons mentioned in paragraph 2. To assure such approach it is necessary for security to become an integral part of Product development process. Such approach will guarantee that company in the future will not launch product or services which are not checked for eventual security issues.

But, not all services and products have equal security relevance. Different security relevancies are asking for different approach and engagement of experts. For some projects it will be necessary to engage security expert to solve security issues. For some other, regular project team members with adequate security awareness will be able to solve it and for third type of project security will not be relevant at all. Additionally, each project is running in changing environment and these changes could affect security relevance of project, so certain control points are necessary to monitor if project is still on same level of security relevance as it was at the beginning.

New Product development process with security as its integral part will look like:



First security related step after Project Initiation will be Security Categorization of Project. Such categorization will be performed by project responsible person from business side (Project Manager) and responsible person for technical part of project (Technical Project Manager) together. Security categorization of project could be based on the next criteria:

- budget,
- number of targeted users of service,
- type of data (personal, traffic or location data),
- whether new system will be implemented or existing modified, etc.

Due to provided answers, we are proposing projects classification in three categories:

- security critical
- security relevant
- security irrelevant.

Security critical projects are very complex project, with high budget and significant number of the users dealing with sensitive data. Because of new technology implementation it could be case that clear security requirements, which could be implemented as regular task in the project, does not exists. For such projects a security expert need to be nominated as member of the project team and he is responsible for all security issues in project.

Security relevant projects are “regular” projects for which we have already defined all necessary security requirements, and main task during project is to implement them in the proper way. Responsibility for such implementation is on the Technical Project Manager and accountability on the Project Manager.

Third type of the projects, security irrelevant, are simple projects in which we are not changing way of data processing and are not dealing with personal and sensitive data.

After security categorization of project, during project lifecycle, circumstances could change. To be on the safe side, it is recommended that after specification and design are finished, security category of project is checked once more. This way we are mitigating the risk which eventual changes in the project could have on security aspect. If security category of project is changed than we proceed according rules valid for new category.

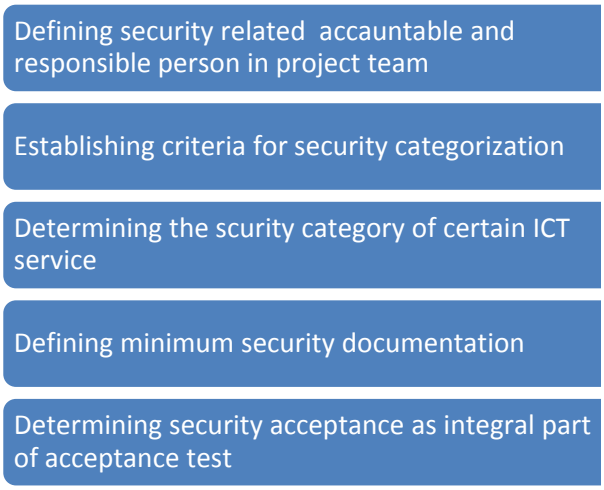
At the end of the project, we need to assure that security acceptance is the part of functional acceptance and approval for new service or product. Part of such acceptance needs to be obliged security documentation which consists of:

- system description
- authorization concept
- proof of security categorization
- list of relevant security requirements
- action plan

For security acceptance Project Manager is accountable, same as for functional acceptance. Security expert in security critical projects or Technical Project Manager in security relevant projects are responsible for

security acceptance. Acceptance could be granted unconditional, conditional or refused. If acceptance is granted conditional, than action plan need to be presented with described measures and timeline in which vulnerabilities will be fixed.

In an overview of proposed model we could point out few important aspects which improve security:



To assure quality of proposed model and process, organizational unit responsible for security needs to perform regular controls of process. In such controls, checking of security categorization on projects sample need to be done, same as checking of security acceptance process and documentation.

V. CONCLUSION

By implementation of this model, an adequate security level could be achieved. Security component will be integrated in the new ICT service at the same level as all other functions. Important feature of application of our proposed model is the security documentation as one of the project's outputs. Such documentation gives a complete overview of how and where security requirements were implemented, providing in that way the opportunity for speed up the future projects. This will also reduce the costs of future projects. With exclusive use of presented model and process, all systems and services in the company will pass through such process in certain time. Result will be adequate level of security of all company's systems, products or services.

Abstract – In last decade information security standards became well documented starting with ISO 27001:2005 which defines requirements for a organisation's Information Security Management System (ISMS). Other standards such as ISO 27004:2009, 27003, and 27005 are published later too. Organisational ISMS can be certifies for ISO 27001:2005 certificate and it adopts Plan-Do-Check-Act (PDCA) life cycle of constant system improvements. To be able to improve operations and information security ISO 27004:2009 standard has to be used to create useful Key Performance Indicators (KPI) in order to achieve constant improvements of the ISMS. During phase of maintenance every system needs infrastructure to collect data, analyse data and then to create KPI for constant improvements. In this paper is presented information security measurement infrastructure for KPI visualisation based on practical experience from production system in financial surrounding.

I. INTRODUCTION

For every business it is important to secure their operations and manage information security risk by using available data to create information and analyse that information to acquire new knowledge and improve operations. Probably the easiest way is to do it, is to use already available standardized methods such as implementing information security standards in order to manage information security risk. To manage Information security risk in terms of ISO 27001:2005 [1, 14, 15] standard is to manage risk connected to vulnerabilities and associated threats and impacts on Confidentiality, Integrity and Availability (CIA) of organisation or company information assets. Information assets are usually classified as: people, services, hardware, software, intangibles, utilities [1]. Information security is important for every person and organisation because today there are many activities which involve usage of secret or private information. For persons that might be social ID, PIN number for credit and mobile phone SIM cards, or personal biometric information such as fingerprint or retina readings, and even personal dairy. On the other hand, for any organisation or company all data related to a particular person mentioned above, and for all data and other organisation's or information assets CIA has to be provided there where it is necessary. To be able to provide reasonable assurance that risk management is working and that system is improved in every PDCA cycle, Key Performance Indicators (KPI) have to be collected and presented for making meaningful decisions. Here KPI represent information (similar to car dashboard with speed meter) which are used to make decisions that will correct future actions what can be used to accomplish specific goal. KPI might be compared to autopilot of organisation which responsible to keep business activities on right path.

Presentation of specific KPI is a result of information security measurement process [17, 18, 19, 20]. Organisation's information security goals and objectives can be reached with appropriate decisions created using exact system information by constant monitoring and measuring system KPIs [21, 22,]. Information security measurements are used to make easier process of making decisions helping in better accountability and performance management by collecting, analysing and reporting relevant KPIs [2]. The main reason to monitor KPIs is to provide information of status for specific activity or monitored process which will be used for improvements of those activities related to information security by implementing corrective and preventive actions based on objective results of measurements as it is presented in literature [16, 23, 24].

As it is already announced in abstract, below is presented holistic approach for data collection, data mining and KPI visualisation, rather then presenting only one aspect of measuring and managing performance and compatibility with information security standard such as 27001:2005 [1]. All results and proposals are done as a result of more than five years (preparation, implementation, and maintenance) of practical experience (of authors referenced above - Governor[3] member of Security Forum of Central Bank of Bosnia and Herzegovina (CBBH) and Information

Security Manager[1]) from Information Security Management System (ISMS) of CBBH which is certified for ISO 27001:2005 by authorised certification authority, started in 2009. In the specific ISMS implementation presented in this paper is used name of the organisational body role called Security Forum which represents top management responsible for making strategic decisions. Second important role is Information Security Manager which is responsible to coordinate and report all information security related activities and acts as information / action bus between Security Forum and organisation departments, divisions and sections and external / internal auditors. Practical experience from the real system could help for better understanding real situation and could help in developing better simulation tools for different business surroundings. Simulation tool for industrial surrounding such as power plant infrastructure is presented in the paper [8] for simulating security assessment of computer and network infrastructure targeted by malware attacks. This approach [8] is good to test potential risk and impacts in specific situations such as malicious – malware attacks, where specific and relevant data can be better recognized which will, be used as data for metrics and creation of useful KPIs.

II. Architecture Model for Data Collection, Calculation, Combination and KPI Visualisation

We grouped all ISO 27001:2005 controls in five groups related to area of application starting from number 2 (shown in Figure 3. Below) to Physical and Technical Security(2), IT or logical security (3), Common Affairs Security (4), Human Resources Security(5), and Legal Security (6). Presented grouping was done based on conducted risk assessment process and GAP analysis. Architecture model for data collection, combination and visualisation presented in Figure 3. is based on model [12] already used for Service Oriented Architecture (SOA) business model. In architecture model presented here are incorporated enhancements and customisation for ISMS managing purposes. This model proposes central point of data collection from five presented areas of information security.

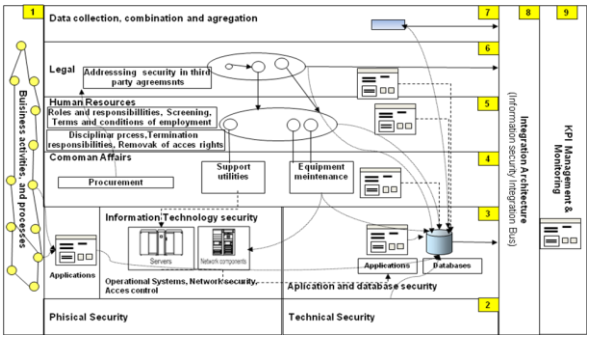

Figure 3. ISMS Architecture model based on [12]

III. Infrastructure for Data Collection, Calculation, Combination and KPI Visualisation

As a sample, for data collection point was used incident management system for reporting information security incidents.

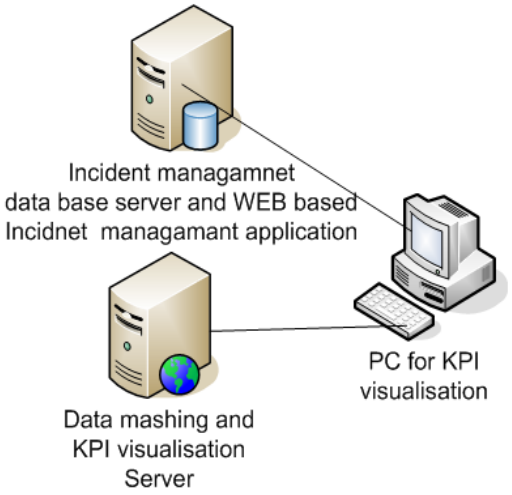

Figure 1. Infrastructure for data collection and KPI visualisation

These incidents are related to hardware and software information assets such as virus occurrences as result of removable media usage, Internet site browsing etc. General security incidents other than related to hardware and software are reported on incident management system. All data are stored in Microsoft SQL database.

In this database are created tables which contains data such as type of incident, location of incident, time of incident, time when incident is resolved, name of person who resolve and incident, source of infection and other relevant data. For the testing purposes was used ARIS MashZone software [10] able to read data and visualized them.

IV. Choosing Relevant Data for KPI Metrics

In order to successfully and constantly improve (PDCA) information security of the organization or company it is necessary to chose right processes, activities, and metrics to measure. There are number of ways which was used in past in order to standardize security metrics and measurement processes such as [4] and to propose research directions directions in security metrics [5]. One method which is accepted as the standard is ISO 27004:2009 [6] or NIST guide [2] for determining meaningful KPIs. This standard [6] provides guidance how to produce effective measurements and it gives examples in documented standard appendices how to create metrics for specific controls and how to measure results for specific controls from ISO 27001:2005[1]. Written sources

such as [7] provide details on how to measure effectiveness of security control implementations for managing application design, application implementation and their maintenance. Relevant data can be obtained and collected at different levels of organisation and can be used together, aggregated and rolled up to the higher levels of the organisation to create appropriate reports.

V. Relevant Data Collection Process

The most suitable way to collect relevant data is to automate this process where metrics have to be presented as number or percentage to present more objective results [7]. As an example of ISO 27001:2005 [1] metric for control *10.1.4* with the title "*Separation of development, test and operational facilities"* is percentage of critical applications that have a separate test environment. Using this simple but effective metric it is possible in objective way asses current risk that critical applications do not have surrounding for testing purposes. Critical application without test environment could create risk to test new system features on production system what can create unpredictable production system behavior.

VI. Data Calculation Formulas

We are not aware that it is already presented architecture model and infrastructure for data collection, data mining and presentation KPIs in intuitive and easy way as we trying to propose in this paper. In this paper is presented architecture and infrastructure to collect data, data mining and as a result to present KPIs in easy and meaningful way ready to be used for decision making.

We decided to present two examples with complete cycle of data collection and data mining for ISO 27001:2005 controls *7.1.3 Acceptable usage of assets* (MA713) and *10.4.1 Protection against malicious code*.

To decide how KPIs have to be created ISO 27001:2005 [1], 27004:2009 [6], [7] were used and risks assessment was performed. As a result for the control *7.1.3 Acceptable usage of assets* is chosen number of security malware incidents (MIN) occurred as a result of unacceptable way of assets usage such as bringing infected removable media (MIRM) with malware or browsing malware infected Internet sites (MIS). And having current system information it is set below acceptable values or goals where:

$$MIN = MIRM + MIS$$

MA713 = MIN <10 acceptable; MIN <10 not acceptable

And for the control *10.4.1 Protection against malicious code* (MA1041) is used ratio of malware incidents number (MIN) of recognised by internal protection system (anti-virus software) and malwares stopped (MS) at the system gate using following formula:

$$MA1041 = (MIN/MS)*100$$

MA1041 ≤ 0,1 acceptable; MA1041> 0,1 not acceptable

In similar way it is possible to initiate data collection for any other control. It is necessary for data collection that data are stored in one or more databases or tables so that they can be used for data mining and producing reports.

VII. Data Operations - Feeds, Calculations and Mashing Data

Recent research results show how [9] data presentation might be hard to monitor and manage since human information security manager might be overwhelmed with level of information that system produce shown in Figure 2 [9].

This is important since decision makers for information security are usually members of top management (Security Forum) which do not want large quantity of information to handle because it can prolong time for making decisions. It is to management decision to allow new funding or resources to support implementation of new controls, proposed in preventive and corrective actions as result of monitoring KPIs. Instead of having more levels of reporting [9] as it is shown in Figure 2. see below, where 8 levels of reporting is shown (details in Figure 2. are not important for this purpose which can be find in referenced paper but level of reporting), in this paper is proposed two level reporting approach.

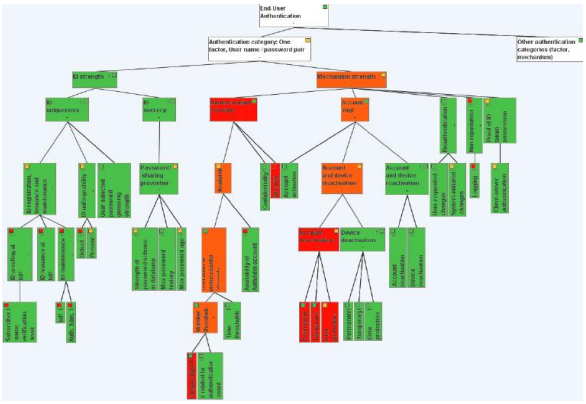

Figure 2. Visualisation Tool [9]

First level, or highest level of reporting where it is reported if control satisfies desired goals or not is intended for reporting top management (Security Forum).

Second level of reporting gives more details where reasons of specific problems can be marked and find reasons for not complying with goals previously set. This level of reporting is intended for Information

Security Manager and is used for making proposals for corrective and preventive actions in order to propose them to top management – Security Forum.
Commercial software such as ARIS MashZone [10] can be used search through data (data mining) and interpret KPIs by feeding data from databases such as Microsoft, Oracle, or Excel, CSV, or XML files, HTML web sites, or it can allows manual data feeds. ARIS MashZone [10] is primarily intended to be used for generic process monitoring and KPI management. By meshing data (meshing here means: to use data from different sources by combing, converting them, and to perform other operation to extract useful data) from different sources (databases, files and manual entries) it is possible to discovery knowledge not only from data bases, but from other sources too, especially by combining different sources together. Above presented solution for searching knowledge allows to read specific columns from tables of different sources. Different operation can be done with data from columns such as calculation (aggregation, arithmetic, average, round, etc.), change data type, insert, duplicate, delete, rename, manage different operations with date and time and other possibilities too.

For the presented control *7.1.3 Acceptable usage of assets* (MA713) in section *6. Data collection formulas* are taken columns which contains data: occurrence of the event, type of event (MIRM and MIS – see section *6. Data collection formulas*), time of finishing report for each event, open or closed status for each report of event which is monitored dynamically through the time having (see section *6. Data collection formulas*):

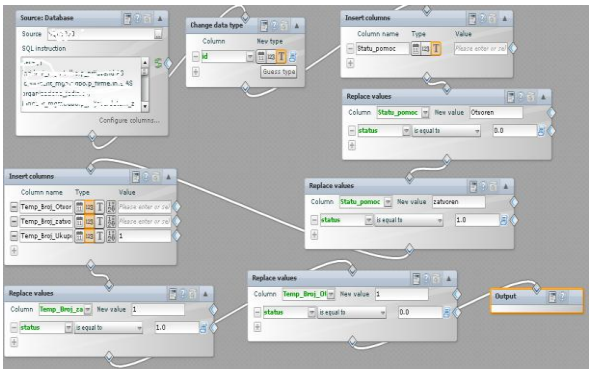
$$MIN = MIRM + MIS$$

For the presented *10.4.1 Protection against malicious code* (MA1041) in section 4, Data collection - are taken columns from tables from different Excel files. These files contains data: number of stopped viruses and trojans on network gates with Internet and value of MIN from control *7.1.3 Acceptable usage of assets* (MA713) to be used in this relation:

$$MA1041 = (MIN/MS)*100$$

Below in Figure 2. - Mashup data feeds is shown one mashup (here mashup means representation of relations and operation on data taken from different data sources) screen shot. In this mashup are incorporated above formulas which create results in two-dimensional table. This table is ready to be used for data filtering and presentation – visualisation.

This approach to collect data from different sources allows infrastructure to combine, and aggregate data from different levels of organisation and to create joint reports.



3. Mashup data feeds

VIII. KPI VISUALISATION

Purpose for all data collection and later for data mining is to visualize KPI results in time window. For testing KPI visualisation purposes was used ARIS MashZone [10] software.

According to specific time frames for PDCA cycles specific time window resolution can be chosen such as Yearly, Quarterly, Monthly, weekly, daily, or other KPI result representation for all or specific categories.

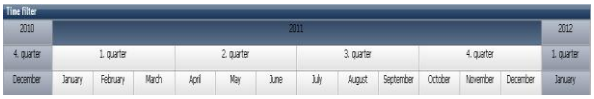


Figure 4. Yearly, Quarterly, monthly data

Top infected units, with names of responsible employees, locations of misused computer equipment, and other information assets.

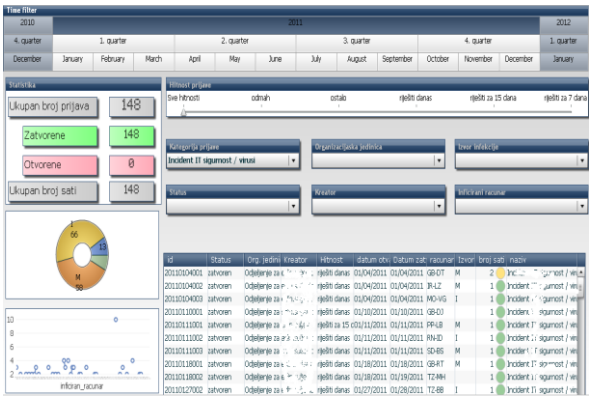

Figure 5. KPI visualisation window

By visualising and tracing KPI through the time is possible to adjust metric settings for tracking specific problems and avoid their future and possible occurrences. Process of information security improvements starting with base measurement

performed and by implementing corrective and preventive actions and monitoring trends and their effects with goal to reduce information security risk on information assets.

IX. CONCLUSIONS

While in other papers and documents [7], [8], [9] are presented partial solutions to crate and monitor information security KPIs, in this paper is presented architecture and infrastructure for whole solution for data collection, mining and KPI presentation. For monitoring information security KPIs in production or research environment infrastructure environment is needed to collect and present data. Presented environment might seems as already seen but presented approach show experienced knowledge and building blocks for researchers which would like to establish their own infrastructure environment for KPI visualisation. Best research results and experience could come from real world situations generated on production systems.

Reports and KPIs can be created with open source tools such as ReportManager [11] not only with commercial software like MashZone [10] used here only for test purposes, or HP Executive scorecard. Other available commercial solutions offer holistic solutions for data collection, mining and reporting too.

The role of perceived privacy and perceived security in online market

R. Mekovec*and Ž. Hutinski*
*University of Zagreb, Faculty of organization and informatics, Varaždin, Croatia
renata.mekovec@foi.hr and zeljko.hutinski@foi.hr

Abstract - Individuals mostly hesitate to use services offered via Internet due to their suspicions regarding the level of offered (1) protection of their privacy and (2) security of performing online transactions. Privacy is mostly concerned with the identifiable user data and users' rights to have control over their data. On the other hand, security provides the physical, logical, and procedural safeguards that are needed to keep the data private. Privacy cannot be achieved without obtaining security practice, nor will the usage of security mechanisms guarantee protection of privacy. Despite being closely linked in practice, privacy and security are perceived as separate issues by online users. Therefore, in this article the relationship between various privacy factors (factors that influence users' privacy concerns) and the perception of security protection during users' online activities is discussed. The role that perceived privacy and perceived security have in the e-service users' evaluation of a service is investigated.

I. INTRODUCTION

In the past decade we have witnessed extensive growth of electronic commerce. Internet has become a key communication media between companies and their customers. Accordingly, various web services provide "support" for individuals' daily activities, e.g. online shopping, e-banking or for communication with the government, doctors or professors (using e-government, e-health or e-learning services). Hence, more and more data about individuals' online behaviour are being collected. This causes concerns over the security of the transaction (and collected data) as well as concerns over the privacy protection of the individuals. Eurostat's data [1] shows that 35% of respondents (included in research in 2010) do not use online services due to their concerns regarding security of transactions, and 30% of respondents do not use online services due to issues related to privacy concerns, e.g. loss of personal data.

Thus, in order to increase the online users' confidence in the security of their data, companies (online service providers) should have various mechanisms that control access to the stored data [2]. On the other hand, the risk of online users' loss of control over their personal information should be reduced. Online users should have control (1) over disclosure of their personal information to others, as well as (2) over future usage of the disclosed information [3].

This article is focused on online users' perception of privacy and perception of security during their online activities. The research was performed to measure concerns of online shopping and e-banking users regarding their privacy perception. Various privacy factors were included to measure online users' overall privacy concerns. Perception of security was also measured. Relationship between perceived privacy and perceived security was investigated. In addition, the relationship between perceived privacy and security on one hand, and perceived quality of e-service on the other hand, was examined.

There are several important reasons to investigate online users' perception of privacy and security issues: (1) technology has great impact on privacy by making it easy to digitalise information, so it is easy to collect and search for information about anybody, (2) digitalised information usually cannot be deleted so every individuals' activity in the digital world exists in perpetuity, (3) there is evident growth of online users' awareness of their lack of privacy protection and possibility of their privacy invasion.

Online users are more and more familiar with Internet usage, as well as with their privacy rights. The role of information security is to implement the mechanisms that will grant one's rights to privacy [4]. Accordingly, online users' awareness of possible security mechanisms is rising. Therefore, they can define their requirements regarding the privacy and security protection. In addition, this can result in their resistance to use an e-service from a service provider which doesn't meet their needs. Online service with the best (lowest) price isn't always a good ground for the service provider to build competence. Online users will include various issues in an evaluation of a service and overall service quality, as well as benefits that they will gain.

II. ONLINE PRIVACY AND SECURITY

As the Internet is becoming a crucial part of people's lives, more companies use the Internet for business. This resulted with the transmission of large amounts of data where the capacity for storing, retrieving and monitoring data evidently rises. Obviously, Internet has two different faces [5]. One enables exciting opportunities for individuals to work, network and spread their ideas

online. The other makes people vulnerable and prevents them from participating equally in online environment.

Online users' behaviour is influenced by the trade-offs between what one gives up (like disclosure of some kind of information) and what one gains from it (benefits like 24/7 availability of service, time-saving or other conveniences). Meanwhile, increased risk in online scenarios is now recognized in a wide range of threats that seek to specifically target online users and exploit information about them.

Several studies suggest that Internet users have serious privacy and security concerns, and that their trust has the primary role in growth of e-commerce. Reference [6] has investigated the importance of four trust indices which influence Internet users purchase intention and willingness to provide personal information. The included trust indices were: (1) third party privacy seal, (2) privacy statement, (3) third party security seal, and (4) security features. The results indicate that respondents value security features the most.

Reference [7] investigated how perceived credibility influences the users acceptance of e-banking. Perceived credibility encompassed two dimensions: security and privacy concerns. Security referred to a level of assurance that a particular transaction will be performed without any security breach. Privacy referred to protection from the collection of various data during users' interaction with a bank. Results of the performed investigation indicate that perceived credibility (e.g. to conclude that transactions are secured and are protecting their privacy) had a significant positive effect on users' behaviour intentions. Authors in [8] identified sixteen e-business risks. In the study participants were asked to rate their perceptions of 16 risks. Three top concerns for 200 included participants were profitability risk, security risk and privacy risk. The relationships between three trust considerations (vendor, Internet and third parties) and customers' attitudes towards online purchasing were examined [9]. The authors found that the relationship between trust in a vendor and attitude towards online purchasing becomes more important when people have higher privacy and security concerns. In addition, they found that when people have higher privacy and security concerns the relationship between trust in Internet and attitude towards online purchasing weakens.

Managing risk related to e-business is an important issue. The lessons to be learnt include identifying e-business risks and using appropriate mechanisms to manage them. The study presented in this article is focused on risks identified as critical – privacy and security risks.

A. Online privacy

Privacy can be seen as a boundary control process where an individual defines with whom he will communicate and what type of communication (and how much) will occur [10]. Boundary control enables the particular individual to achieve the desired level of contact with others, at a particular time and according to stated conditions. Two types of factors have an impact on the process of boundary control: (1) situational factors and (2) personal factors. Situational factors encompass social and physical elements. Social elements refer to the existence of others with whom the individual can communicate, others' characteristics, and willingness to communicate. Physical elements refer to physical barriers, location and distance. Personal factors are related to individuals' characteristics, like their need for privacy.

Online privacy is accordingly defined as an exchange of Internet users' personal information for some benefits [11]. On the other hand, the term online privacy is usually connected with information privacy and therefore is described as Internet users' concerns regarding their ability to control the collection of their personal information, as well as to control the future usage of the collected information or the information that were generated based on their online activities [12].

According to their concerns regarding information privacy individuals can be grouped in three groups [13]: (1) privacy guardians, (2) information sellers and (3) convenience seekers. Privacy guardians are individuals who are very concerned about their information privacy. Information sellers are individuals who will trade their personal information for a small award. Finally, convenience seekers are individuals who are primarily focused on benefits that can be gained from the disclosure of their personal information.

The information about online users collected during their online activities can be arranged in three groups [14]: (1) anonymous information (e.g. information about IP address of the computer that has been used, type of web browser), (2) personally non-identifying information (e.g. information about age, gender, education, interests) and (3) personally identifying information (e.g. name, e-mail address, postal address, telephone number, credit card number).

Online privacy data can be categorized according to operations performed on data [15]: (1) data collection and (2) data use. Data collection process can be divided in four categories: (1) volunteered data collection for public use, (2) volunteered data collection for private use, (3) un-volunteered but noticed data collection, and (4) un-volunteered but unnoticed data collection. In category volunteered data collection for public use following data can be distinguished: (1) online registration data, (2) online administrative data, and (3) online facilitation data. On the other hand, volunteered data collection for private use includes (1) online survey data (e.g. online market survey, opinion research) and (2) online purchaser data (e.g. age, gender, credit card number, e-mail address). Category un-volunteered but noticed data collection includes online transaction data collected via interactive online shopping or online mail catalogue. During un-volunteered but unnoticed data collection click-streams data on Internet usage are collected. Data use process includes the following data operations: marketing, data disclosure to third parties and data sale to third parties.

B. Online security

First step of privacy related management is the identification and classification of data that need to be protected. When it is known what should be protected, the next question is how should it be protected. Information security can be defined as a discipline that uses the concepts of confidentiality, integrity, and availability to answer the question of how data should be protected. This CIA triad is enforced using various protective mechanisms like encryption, authentication, intrusion detection and etc. Questions that should be answered when dealing with the protection of information security are [16]:

1. Are the data protected from being disclosed to individuals that should not access them?
2. Are the data protected from being created, changed or deleted by individuals that do not have permission for these activities?
3. Are the data available to those who need them?

If a company cannot maintain the security of the data that it has collected from its customers through online channels, then it is evident that the company isn't meeting the demanded level of corporate responsibility [17].

Online users are increasingly finding themselves exposed to security risks during their online activities. Security risks include the threats like manipulation with information and/or networks (e.g. destruction, selling or modification of data) or various types of fraud and misuse [18]. Perceived online security is defined as online users' perception of how they are protected from risks related to security. Reference [19] used the term Perceived Security Protection (PSP) to describe consumers' perception that the Internet vendor will fulfil security requirements (such as authentication, integrity, and encryption).

Two main factors concerning perceived security in e-commerce can be distinguished [20]: (1) perceived operational factor and (2) perceived policy-related factor.

Perceived operational factor includes actions that a website can take to ensure that the users feel secure during the online interaction. On one hand, perceived operational factor includes: the site's blocking of unauthorized access; emphasis on login name and password authentication; funding and budget spent on security; monitoring of user compliance with security procedures; integration of state-of-the-art systems; distribution of security items within the site; website's encryption strategy; and consolidation with network security vendors. On the other hand, perceived policy-related factor includes the following items: the website's emphasis on network security; top management commitment; effort to make users aware of security procedures; the website's keeping up-to-date with product standards; the website's emphasis on security in file transfers; and issues concerning the web browser.

III. RESEARCH

The research was performed in order to investigate the level of Internet users' perception of online privacy and overall e-service quality. In addition, Internet users' perception of online security was measured. Finally, the relationship between perceived privacy, perceived security and perceived service quality was examined.

A. Respondents

Included participants were individuals who had been using online shopping and e-banking service (for at least a year). The research included 185 respondents of whom 63% were men and 37 % were female.

B. Measurement and results

Fourteen privacy factors were included in the investigation of Internet users' privacy perception. Privacy factors are factors that influence the overall perception of privacy in online environment. Detailed overview, systematisation and categorisation of proposed privacy factors, as well as a detailed research model of online shopping/e-banking users' privacy perception was reported elsewhere [21].

Research was performed using a written and an online questionnaire. Questionnaire consisted of 94 items. Respondents were using five-point Likert scale (5 = strongly agree, 1 = strongly disagree) to mark their agreement or disagreement with a particular item. Privacy factors included in research were labelled as follows: Control over information collection – CIC, Control over information usage – CUI, General information sensitivity – ISG (in general, during daily online activities), Legislation and government privacy protection – LPG, Service e-tailer's reputation – STR, Personal Internet interest – PII, Control – COL, Improper access – IA, Information sensitivity – ISS (when using online shop or bank service), Perceived Internet privacy risks – PIPR, Unauthorised secondary usage – USU, Perceived credibility – PC, Perceived integrity – PI, and Perceived benevolence - PB.

Perceived security (PS) was measured using five-item scale (items PS1-PS5). Security perceived by respondents referred to their judgment regarding security of transaction and security of collected data when using online shopping and e-banking service. Descriptive statistics regarding the items used to measure perceived security are presented in Table I. According to the presented results it can be concluded that perceived security is quite high with average score 4.01 (mean). Respondents are satisfied with security provided by online company or bank (whose service they were using). Minimum (average) score is marked for item PS2 (3.83) which is related with respondents' estimation if the data are secured during their usage of online shopping and e-banking service. Maximum (average) score is marked for item PS3 (4.14). This item is connected with respondents' judgment regarding the confidentiality of online transaction (online shopping and e-banking transaction).

TABLE I. DESCRIPTIVE STATISTICS FOR SCALE PERCEIVED SECURITY AND PERCEIVED PRIVACY

	Minimum	Maximum	Mean	Standard deviation	Variance
PS1 – security of transactions	2	5	4.11	0.675	0.456
PS2 – security of data	1	5	3.83	0.820	0.673
PS3 – transaction are confidential	2	5	4.14	0.822	0.676
PS4 – awareness of usage of security measures	1	5	4.07	0.828	0.685
PS5 – security of data transfer	1	5	3.92	0.820	0.673
Average perceived security	2.20	5.00	4.01	0.631	0.399
GPBC1 – uncertainty regarding paying with credit card online	1	5	3.44	1.127	1.269
GPBC2 – uncertainty regarding shopping online	1	5	3.24	1.263	1.595
GPBC3 – insecurity regarding privacy of data	1	5	3.21	1.207	1.458
GPBC4 – data privacy protection	1	5	3.69	1.137	1.292
Average perceived privacy	1.00	5.00	3.39	0.984	0.969

Overall online privacy perception (GPBC) was measured using four-item scale. Overall online privacy perception referred to online shopping and e-banking service users' anxiety about how an online company or bank (which is providing the e-service) will handle information that they collect about users during their online interaction. Results of the research shows that overall online privacy perception is 3.39 (mean). On proposed five-point scale this result is placed in the middle of the scale. This is a neutral result, neither are respondents concerned nor are they satisfied with the ways how information about them are handled by online companies or banks (whose service they used).

Overall service quality (PQual) was measured using two-item scale.

In order to explore relationships between perceived quality of service, perceived security and perceived privacy (and privacy factors) a correlation analysis was performed using Pearson coefficient. Table II. presents the results of the performed analysis (N=185, *p<0.05, **p<0.01).

Figure 1. illustrates the correlation between perceived privacy, perceived security and perceived service quality. In addition, the correlation between privacy factors and perceived (1) privacy, (2) security and (3) service quality are presented (where correlation coefficient is equal or greater than 0.350).

Perceived security is negatively correlated with perceived privacy (r= -0.182, p<0.05) and positively correlated with perceived service quality (r= 0.430, p<0.01). Respondents who perceived higher level of provided security were less concerned about their privacy protection. In addition, respondents who perceived higher level of security were also more satisfied with the quality of a provided service.

TABLE II. RESULTS OF CORRELATION ANALYSIS, n=185, ** p<0.01, * p<0.05

	PS	GPBC	PQual
CIC	-0.160*	0.352**	-0.129
CUI	0.207**	0.020	0.064
ISG	-0.141	0.443**	-0.179*
LPG	-0.059	0.210**	-0.138
STR	0.183*	0.139	0.145*
PII	0.045	0.064	-0.019
COL	-0.035	0.339**	-0.192**
IA	0.101	0.149*	0.026
ISS	-0.043	0.400**	-0.126
PIPR	-0.185*	0.363**	-0.140
USU	0.209**	0.064	0.044
PC	0.683**	-0.117	0.348**
PI	0.620**	-0.077	0.366**
PB	0.531**	0.009	0.243**
PS	1	-0.182*	0.430**
GPBC	-0.182*	1	-.290**
PQaul	0.430**	-0.290**	1

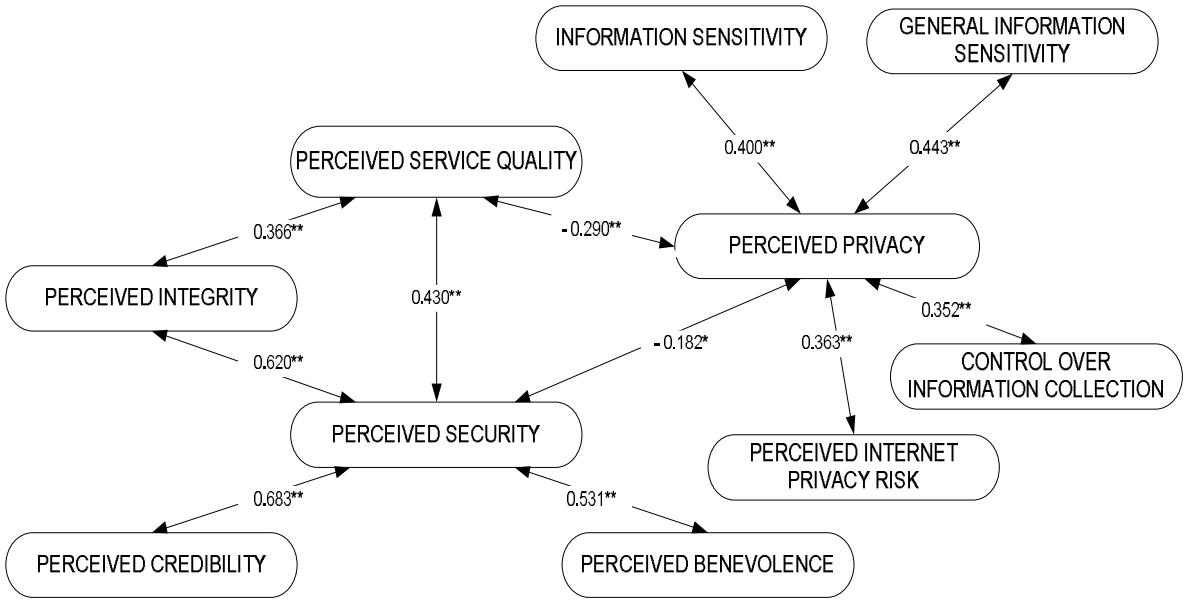

Figure 1. Correlation between (1) perceived service quality, (2) perceived security, (3) preceived privacy, and (4) privacy factors, n=185, ** p<0.01, * p<0.05

Further on, there is a negative correlation between perceived privacy and perceived quality (r= -0.290, p<0.01). Respondents who were less concerned about privacy protection perceived higher level of service quality.

Regarding the correlations between proposed privacy factors and perceived security the results of the correlation analysis indicate as follows. There is a significant correlation between perceived security and: (1) Control over information collection – CIC (r= -0.160, p<0.05), (2) Control over usage of information – CUI (r= 0.207, p<0.01), (3) Service e-tailer's reputation – STR (r= 0.183, p<0.05), (4) Perceived Internet privacy risk – PIPR (r= -0.185, p<0.05), (5) Unauthorized secondary usage – USU (r= 0.209, p<0.01), (6) Perceived credibility – PC (r= 0.683, p<0.01), (7) Perceived integrity – PI (r= 0.620, p<0.01), and (8) Perceived benevolence – PB (r= 0.531, p<0.01)

There is a significant correlation between perceived service quality and: (1) General information sensitivity – ISG (r= -0.179, p<0.05), (2) Service e-tailer reputation – STR (r=0.145, p<0.05), (3) Control – COL (r= -0.192, p<0.01), (4) Perceived credibility – PC (r= 0.348, p<0.01), (5) Perceived integrity – PI (r= 0.366, p<0.01), and (6) Perceived benevolence – PB (r= 0.243, p<0.01).

IV. CONCLUSION

Perception of privacy and perception of security are factors that affect costumers' trust in electronic commerce. Therefore companies that offer and sell their products or services online should put more efforts to positively influence costumers' perceptions of privacy and security [22]. Computer system security is a global problem that is affecting private as well as corporate users of information technology. Information technology users should be informed and should take responsibility for the security of resources that they are using. Accordingly, they should play an active role in protecting their privacy (in the use of computer or in the use of Internet) [23].

From a practical standpoint, the results highlight several issues that may guide the successful completion in electronic market. Specifically, we identified a significant relationship between perceived security and perceived privacy. If the online users are more convinced that a particular web site provides security of transaction and data they will be less concerned about their privacy protection. The relationship between (1) perceived security and (2) perceived privacy on one hand, and overall e-service quality (on the other hand) was confirmed. When online users are more satisfied with security protection they will be more satisfied with overall service quality. If online users are less concerned about their privacy protection, they will be more satisfied with overall service quality.

The role of a stress model in the development of information security culture

Goran Božić
Orešković-B.K./Zagreb, Croatia
goran@oreskovic-bk.hr

Abstract – The process of building information security is based on three controls. Technical and formal control ensures relatively quick results but its life cycle isn't very long. Informal control focuses on the person resulting in rather long implementation periods. Successful implementation should lead to the information security culture. In this process, the user is expected to change his behavior according to specified rules and in order to achieve this the user must invest significant efforts. In order to ease this effort, one should find some motivating factors, which influence positively such situations. Moreover, a better understanding of the process occurring during the interaction of the user and the environment is important. If one takes into consideration the fact that the user in his everyday activities uses certain processes which facilitate the performance of his tasks, then the demand to change his attitudes will not be seen positively. Such a situation is very stressful for the user and will be explained using the stress model. The attitude the user adopts in such situations will finally influence the development of the information security culture. In order for this process to be successful, the user should see (or have the attitude) the demands as challenges rather than threats. This attitude depends on the personal characteristics of the user. One of them is self-efficiency. By using the methods which increase confidence in self-efficiency, one is helping the user in his efforts to modify his behaviors.

I. INTRODUCTION

People are witnessing the increasing use of computer and telecommunication technologies in various fields of human activity. It is necessary to ensure security for the data, which is processed at the same time. Part of the insurance relates to the protection and safety of the systems and data. One way to ensure this is through the implementation and management of information security. It is a challenge for many organizations [1] which have started this process, because many of them are still at an early stage of implementation. One reason for this situation lies in the fact that information security is complex and depends on many components [2]. With the complexity of the system, the situation is also more difficult, because of the fact that some components change frequently [3]. The reasons which eventually force the organization to move forward with the process of implementation of information system security are primarily security incidents that occur in the organization, followed by legal provisions and requirements of the business (e.g. new models of remote access of information systems) [4]. Controls that are used in the process of building an information security system are divided into technical, formal, and informal. Although all three controls are equally important, the situation is such that a greater importance is given to the technical and formal controls in relation to informal control. Informal controls, with users as the center of interest, set out requirements for users to use statutory regulations and recommendations. Ultimately, this leads to a security culture in which the user's everyday behavior coincides with the prescribed rules. In order to achieve this, the user's effort is required to correct his behavior, as well as for the organization to present those requirements in a proper way. The question, for which an answer is required is which way can one facilitate the user's effort. A part of useful information can be found in previous studies related to the motivating factors that have had a positive effect on the acceptance of applications for change of behavior. One way is to better explore the user's behavior in situations where he needs to correct his behavior. Therefore, the situation will be explained using the model of stress. Namely, the stress model could explain why some requests are accepted by users, and some are not. What affects this behavior are the personal characteristics that lead users into a situation where such experiences are viewed as challenges rather than as a threat. Among the few features that are mentioned in the literature, self-efficacy was elected, so by increasing the belief in efficiency, one will see requirements as a challenge.

II. SAFETY CULTURE

Information culture is an integral part of the overall organizational culture, and it is developing for the same reasons as an organizational culture [4]. It is a culture that promotes safety behavior and thus contributes to achieving the overall goals of the organization. One speaks about safety culture when users in their daily activities take into account the security of information resources. One of the basic components in building a corporate safety culture is a process of education and awareness of users. The result of this process is visible through a change in user behavior. The safety culture in every organization develops differently depending on the type of organizational culture and implemented security components [6]. Safety culture can be seen as a stage in the development of information security [7]. The previous stages were related to the resolution of technical

and standardization issues. These questions are current today and present in the form of technical (technological) and formal (procedural) controls.

III. INFORMAL METHODS

Problems arising from the vulnerability of business processes and human behavior could not be ignored, so the way of solving the security of information systems has been revised over time.

And in a way that through the aforementioned control the informal (human) control was also introduced. The controls are interdependent as well as classes contained within these controls. Vulnerability in any of these controls can be used to compromise security. There should be a proper approach to the process of implementation and management of information systems' security and neither of them should be more favored or have attached greater importance. Unfortunately, technical control of information systems security is still in favor. The attitude of the scientific community towards these areas is indicative. The results of an analysis of scientific articles [8] (p.84) shows, among other things, that the number of articles covering the informal control is small and there is no indication that this trend will change. The research community that deals with security comes from the natural sciences, especially mathematics. Informal controls are related to human behavior and this area is much more present in the sociological and psychological research, so here one needs to look for reasons for the small number of articles.

Informal controls include user training in order to increase motivation and commitment to user safety [9]. Under the informal controls the introduction of information security in the workplace implies, i.e. the creation of a corporate safety culture. If one analyzes the time required for the implementation of individual control, then it is clear that technical controls are implemented relatively quickly as one would quickly see the result (e.g. installing a firewall). For the implementation and effects of formal control (a measure of the effectiveness of security controls) more time is needed, but that is the reason why they have a much longer lifetime than technical controls. The longest period of time is needed for the implementation of informal control, because it is about building a safety culture, but because of that it will have the longest life cycle. Therefore, it is important that resources are used in this process in a most appropriate and optimal way as possible.

A. The process of education and awareness

While information security focuses on protecting the confidentiality, integrity and availability of information, an education and awareness program on information security aims to establish and maintain proper security [10]. An adequate training process is required if one wants to create and enhance user awareness and behavior in informatics. It can be said that information security awareness is the degree or level of importance of information security that every user understands and operates in accordance with. The results of the process of education and awareness are evident in the change in consciousness and behavior of users in their daily activities, where they use prescribed policies and recommendations. The procedure of measurement is not easy, as well as interpretation of results. If the measurement is performed using the survey results, then it would be interpreted as a change only in their minds. Studies have shown that it takes a certain period of time for the conscious user to start to also change his/her behavior [11].

The current study was aimed to find those methods which give desired results in the educational process. Models were investigated that would explain the behavior of users who are expected to use the prescribed rules of information security [12]. The following will briefly expose the role of factors so far detected that positively influence the user's behavior when confronted with a request to amend his/her behavior.

IV. MOTIVATION FACTORS

User behavior is under various influences in the environment in which they work [13]. Some of the factors that affect the construction or change of the behavior are;

- What user sees in his/her environment;
  - The behavior of immediate associates and managers,
  - Consistency between the prescribed rules and obvious user‘s behavior,
  - The behavior of other departments
  - The existence of mechanisms for rewarding good behavior and punishing bad behavior
- Documents that management provides. By this it is meant various policies, procedures, prescribed modes of conduct and standards. Depending on clarity and simplicity of these documents, users will more readily accept the recommendations and adjust their behavior.
- User's habits and what they learn during the employment. It is not practical to prescribe behavior for all situations in which the user can find himself/herself in, so that he/she during daily activities has to make certain decisions regarding the security of information systems. If there is a mechanism of feedback on those decisions made, based upon them users will create a pattern that they will apply in all similar situations.

Attitude and behavior of the environment (colleagues and managers) that it demonstrates towards IT security has a significant impact on user's behavior. Fairness and consistency in behavior is also an important component of this factor.

One should be aware of the fact that the prescribed documents are a kind of psychological pressure on users, because they are expected to adjust their behavior. Because of that users are sensitive to the correctness in behavior. Users and organizations enter into a kind of psychological contract in which they define the

framework in which the users are willing to modify their behavior to the expectations of the organization. The process of harmonization should be taken into account, in which the controls that are introduced should not be difficult, and as such strongly interfere with normal activities. Positive effects of these processes will have a positive impact on the user's behavior. A positive effect will be affected with the mechanism of punishment for those who do not participate in this process in the prescribed manner.

When it comes to decision making in situations that are not required by documents, they will be influenced by several factors. The first factor relates to built-in personal values and standards. They can come into conflict with the values and standards of the organization, so a user has to adapt to the demands or leave. Another factor, which is highlighted by its influence, is the user's position on the safety and behavior pattern that is created by making independent decisions. An important component of this factor is proper informing about well made decisions, so in this way one helps a user to build the desired form of behavior.

V. STRESS AND COPING

According to everything mentioned so far, it can be said that the users and the environment are in close mutual interaction. Usually it happens when prescribing rules of conduct. The user's reaction is to take a stand that will result in a failure of prescribed rules. The education process will not have much effect on this type of attitude. The current findings indicate the factors that positively affect behavioral change, but the situation which the user is in needs to be better understood and explained. Through the focus on men and the environment's interest it should be considered appropriate to seek help in other areas of science. Primarily this refers to the sociological and psychological field that deeply explores human behavior, in a situation where he/she finds himself/herself in the same situation as the user. In psychology this process of the interaction of man and the environment is well researched, so there are a number of theories that were developed at the same time. One of them, the observed process, is defined as stress. It should be emphasized that stress is not a subject of interest in psychological studies only, but other scientific disciplines such as sociology and biology. In each of those areas the term "stress" refers to something else. Stress in psychology is defined in several ways.

The one which is interesting is the one that talks about the process involving the interaction of people and their environment, and particularly those interactions in which there is a mismatch between personal resources and the demands of the environment [14]. Richard Lazarus proposed a model of stress, which defines stress as a process that always means a harmful transaction between the person and the environment. In Lazarus's model, two processes of assessment and dealing are the ones that largely determine what will be the consequence of a stressful situation. The process of assessing the situation consists of a primary part, where an estimation of the value and meaning of the situation needs to be considered, and secondary the assessment of the impact on the event. If the situation is assessed as stressful, that might mean following for a person;

- Loss (damage that occurred due to stress)
- Threat (threat and potential damage)
- Challenge (possible positive consequences, gain)

Secondary assessment includes evaluation of own competence and opportunities to find appropriate ways of coping with stressful situations.

Secondary and primary estimates are mutually dependent, so that the threat could turn into a challenge if a person estimates that he/she can cope with the resulting situation. Terms which could make an event more challenging and less stressful are confidence in own abilities to cope, self-efficiency, high degree of positive emotions, and belief in the existence of resources and skills for coping.

Facing as a second process of Lazarus's model refers to the constant efforts to overcome and reduce internal and / or external demands that are assessed as excessive in relation to a person's ability. The model has the characteristics of reactive coping. Effort is invested in reactive coping in order to gather resources and to take precautions against various threatening events that might happen in the future. This confrontation can be seen as risk management.

This model has been developed over time through the inclusion of the positive efforts and motivational factors, and the relationship between man and the environment. The model was developed that has the characteristics of proactive coping [15]. The model is the result of progress that has been made in psychology when the focus shifted from helplessness to a positive and optimistic approach. In it a man acquires resources in order to realize gains and by collecting those resources he/she will be able to use these for the defense against future risks. Resources are collected with the aim to develop their skills. The new theory of proactive coping focuses on improving lives and taking initiatives to achieve the set goals. In this new theory, coping depends on the time perspective of stress application and the likelihood of these claims. Because of the time perspective the following differentiates can be present;

- Reactive coping (a loss that occurred in the past)
- Anticipated confrontation (safe threat that will happen in the near future)
- Preventive coping (uncertain threat that may happen in the distant future),
- Proactive coping (the upcoming challenges that are perceived as an opportunity for personal growth)

Proactive coping is not based on negative assessments such as the loss or threat. Effort is invested in the construction of general resources that facilitate the way to set goals and develop skills. This confrontation can be seen as management of objectives.

According to this theory, one can assume that the user, when he is in a situation that something is required

from him will use one of these four types of coping; furthermore, the focus will be restricted to the two types which are reactive and proactive. The assumption is that the different characteristics of the individual have an impact on the position he/she will take when he/she is in such a situation. The individual's characteristics, which could have an effect on it are self-efficiency, emotional intelligence, self-regulation, personal goals of courage, hope, optimism, perseverance, and ability to control.

In seeking answers to how to help the user to more easily accept the demands that are placed before him, one of the models explains how he/she behaves in such a situation. Behavior depends on personal characteristics, and if the user is required to change his/her behavior the characteristics one can influence in current situations must be taken into account.

From these specified types of coping, it is certain that it will be good for information security if users have a proactive attitude. A user with this attitude believes he/she has enough resources (internal or external) which he/she can use to achieve goals. Resource includes the use of information, advice, and practical help from others. With a proactive attitude, it is more likely that the user will accept the proposed action and start changing his/her behavior as expected.

In the event that it is about a user with a reactive attitude, then the user recognizes that there is a problem in front of him/her. After that, he/she judges which capacities he/she needs in order to solve the problem. Stress is a result of the assessment in which there is a discrepancy between the demands of the particular situation, and the ability of people to meet those requirements. It occurs as a negative feeling of belief when people estimate that they cannot deal with the demands of their environment.

Both models so far mentioned state that personal characteristics positively influence the user, so he/she perceives the situation as a challenge rather than a loss. Some features are not easily affected if the situation is viewed in the context of the implementation of security policy or the construction of safety culture. One feature could be purposeful by the way it increases or builds up in the user. It's about self-efficiency.

VI. SELF-EFFICIENCY

Self-efficiency is the belief that one has control over events that affect one's life or that are able to act on events [16]. This belief allows people to experience difficult tasks as challenges to be solved and not as a threat that should be avoided. In the literature one can find ways to develop self-efficiency [17]. Here a few will be mentioned; direct experience; evaluation of the behavior of others; and verbal persuasion. In the direct experience the outcome or the result of a personal decision that was made in a situation for which the organization did not prescribe instruction will be analyzed. If the outcome is assessed as successful, confidence and increased belief in their efficiency will increase. The other way is relating to the evaluation of the results of others in the area. This method has no such effect on the increase as a direct experience of belief, but it is important in such cases where a person is not sure in their own abilities.

As part of a group, the user is confronted with the results of his/her decisions and also witnesses the outcome of decisions made by its neighbors. What will be the sign of belief in their effectiveness depends on how they will evaluate their performance relative to the observed person. It is positive in the case when their abilities are assessed as greater than the observed person who has experienced a failure. And at the end the third way is related to verbal persuasion. This method has the least significance of the aforementioned. Competencies of the person who participates in this process are important for the user participating in a process of persuasion (education, some form of awareness).

For the user to be able to have a proactive stand when he is in a stressful situation, he/she should have the opportunity to build his/her faith in self-efficiency. According to these three ways of increase, it is clear what should be done. Users should be informed about the outcome of their behavior in the system, taking into account that a good decision should be publicly announced. Since through the policies and recommendations one cannot prescribe all the situations, the user will often be able to make decisions. A good outcome should be informed to all. Although with the least impact on increasing the belief, one should not ignore the fact that people who carry out information security should at least have competent person status.

VII. CONCLUSION

One should be aware of the fact that the user in the organization is primarily there to perform in some of the business processes. Daily routines create certain habits of behavior, which helps the user to do his/her job more efficiently. In this situation, information security does not help the user, but because of its demands to change behavior leads to a state that can be defined as stress. Previous studies have defined the motivating factors, which helped the user to change his/her habits. The stress model provides a little more light on the actual process or situation in which user is in. The views that a user has in this situation show that the requirements which are sometimes too easily prescribed are not seen as something easy by the user. Some effort needs to be invested in order to facilitate the change of habits in this process. It should be aimed at better preparation of the education process, at least through more competent teachers. The very process of awakening along with the standard components should have a section that would help to increase the user's faith in his/her efficiency. The influence of the environment should not be ignored, especially superiors' views towards information security. Just as the ordinary user's education is essential so it is as important that senior management is aware that they have a dual obligation, to change their behavior in everyday work and clearly show a positive attitude towards information security.

When it comes to information security and the role of man in it then it is justified to look for answers for some questions in other scientific fields. The stress model in psychology has helped to more clearly see one situation

in which user is. And if one is aware of it, then one can prepare processes better and understand why one has to wait for some results even longer.

kresimir@mefos.hr, btovjanin@mefos.hr, vilakov@mefos.hr

Abstract

The ICT system's users can significantly affect overall security level of the system, but problem is that most security solutions do not take into consideration user as possible critical security component of the system.

In this work assessment methodology is proposed to evaluate users' awareness regarding security issues. For purpose of collecting data on ICT system user's awareness special questionnaire was developed based on previously defined ontology domain regarding e-mail users' behavior.

The cluster analysis method was applied in order to group users into categories regarding level of their awareness about security issues. Cluster analysis gave six clusters of users on which Chi-square analysis was applied in order to detect potential relationship between level of awareness and gender, age, professional qualification and number of e-mail addresses used. The variables used to predict group membership were identified by applying discriminant analysis.

The evaluation and categorization of users' awareness should help in developing new concepts of security solutions with taking into consideration user as component of the ICT system.

I. INTRODUCTION

As ICT system evolves so the new security issues arise and new security technical solutions are going to be developed. This cycle seems to be hard to disassemble and many technical solutions are applicable only for definite period of time. Problem can be that these solutions do not focus on the user as critical security component of the ICT system.

User can significantly affect security level of the system [1] and should be taken in consideration and maybe even as starting point for proposition on a new possible concept of (global) security. Some solutions are proposed in some resent studies with subject of security in information and communication systems, with special emphasis on Internet security. One solution proposes concept *"trust on Internet"* [2], while the other proposes *"neighborhood watch"* organized as social network [3]. Both solutions target users and their awareness of security issues.

Also users are rarely taken into consideration in security guidelines. The *German national IT security guideline* takes user into consideration but it points out only user's usage of e-mail communication system as potential security critical issue and recommends that every user has to have basic understanding/awareness of system's security issues [4].

In this work assessment procedure is proposed to evaluate users' awareness regarding security issues. The evaluation and categorization of users' awareness should help with development of new concepts of security solutions with taking into consideration user as component of the ICT system.

II. ASSESMENT METHODOLOGY

In order to begin evaluation over some object first step should be to define and describe that object. Proposition is to use ontology, because in recent years ontology structure is mostly used do define domain(s) in area of information technologies [5]. *OWL ontology* has been chosen to formally define knowledge about some domain of interest by defining concepts and relations between them [6]. If ontologies that define particular domain already exist, one can choose among them.

Questionnaire was developed with questions mapping particular classes in ontology structure in order to gather data for evaluation.

Cluster analysis procedure was chosen in order to categorize ICT system's user's awareness regarding security issues. This procedure is frequently used for example in economic field related to marketing for categorization of customers [7]. Cluster analysis seeks to identify homogeneous groups of cases or individuals in a population, where the optimal number of groups, the properties of segments and group membership are unknown in advance. This means that a cluster analysis is used as exploratory technique.

Drawing *dendogram*, also known as *tree diagram*, is a common way to visualize the cluster analysis's progress by displaying the distance level at which there was a combination of objects and clusters. It is possible to define number of clusters by tracking differences between distance levels in previous and next step of algorithm [8].

Discriminant analysis was applied on groups and grouping variables in order to evaluate quality of clustering and to identify variables that have significant influence on group membership.

For detailed analysis of each identified group external variables can be defined. Those several additional

variables can identify gender, age, working place, professional qualification, technical background, etc.

III. CASE ANALYSIS

For purpose of collecting data on ICT system user's awareness special questionnaire was developed that was based on previously defined ontology domain regarding e-mail users' behavior. There are several ontologies defined regarding domain of ICT system or its parts, but even most detailed ontology fails to cover ICT system's users and their behavior [9]. Hence in this work ontology from previous research that formally defines behavior of e-mail system's user was used.

The organization of ontology's classes is presented in Fig.1. Instances in ontology are values representing grades from poor to excellent; some subclasses that represent questions have all five possible entities and some only two or three depending on associated answers. The questionnaire has few basic questions about gender, age, working place, number of e-mail addresses used; and questions regarding e-mail user's behavior which maps each case in the ontology and comprise following topics:

- quality of password
- criticism towards collocutor
- way of usage of e-mail address
- security issues regarding e-mail system
- way of access to e-mail system

Free, open source software tool, ontology editor Protégé 4.1 (Stanford, California, USA) was used for definition and description of the ontology.

Data variables collected by questionnaire were divided on external variables and dependent variables. External variables were gender, age, professional qualification and number of e-mail addresses in usage; and were used to analyze groups after categorization. Dependent variables were collected from answers regarding ICT system users' awareness of security issues and were used for categorization. Answers on those questions were ordinal data in scale from one to five (poor, indifferent, average, good and excellent), but some questions had only two or three possible answers.

From 18 questions 12 were discarded for the cluster analysis because of several reasons: questions with binary data are meaningless for cluster analysis; questions that correlate had to be reduced before cluster analysis and also relatively small size of dataset (n=306) was additional reason for discarding questions [8].

In total six questions with possible answers were selected (Fig.1, Tab.1):

1. Do you use free e-mail services (like gmail, yahoo and hotmail) and if yes in what manner?
   a) for professional communication
   b) for private purposes
   c) only for periodical usage

If answer is "No" grade equals *indifferent* meaning very secure, and for the rest of answers grades are as follows: "a" equals *average*, "b" equals *good* and "c" equals *excellent*.

2. Do you use web browser for accessing e-mail system and if answer is **sometimes** or **yes**, do you take care of the place where from you make connection?
   a) only from home or office PC
   b) sometimes from public places as well

Five possible answers give all five possible grades. Answer "No" equals *excellent*, because it is more secure to use e-mail client software tool. Combination of answers "Yes + a" equals *good*, combination of answers "sometimes + a" equals *average* and combination

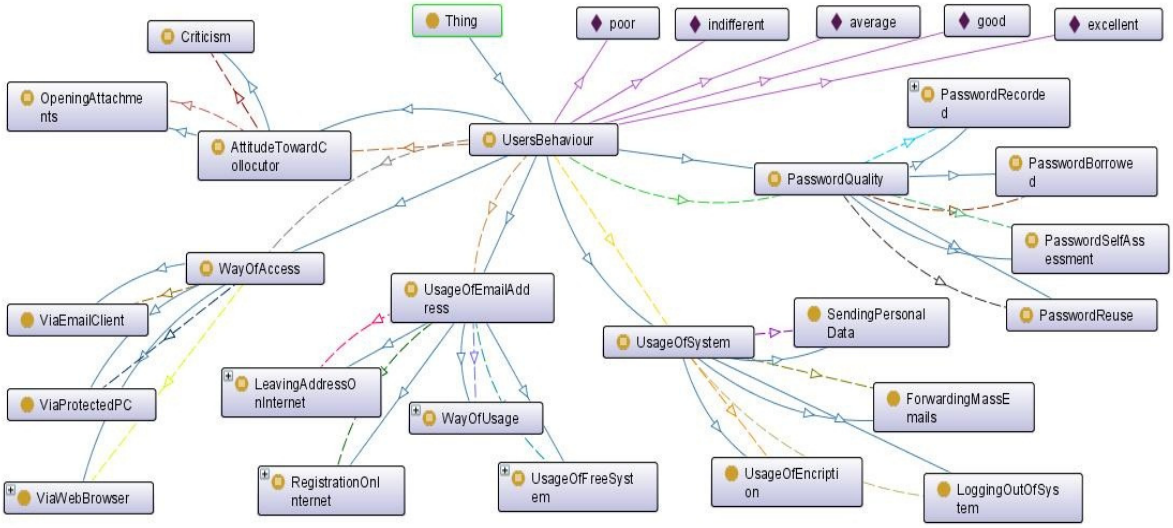

Figure 1. Formaly defined domain of knowledge in ontology editor Protégé 4.1

TABLE I. AVERAGE ANSWER GRADES PER GROUP

Selected questions with covered subjects	Group 1 /n=45	Group 2 /n=42	Group 3 /n=63	Group 4 /n=46	Group 5 /n=63	Group 6 /n=47	*p***
Q2 (usage of free e-mail services) /mean±SD	3.11±0.78	3.07±0.64	3.21±0.77	3.20±0.72	3.30±0.85	3.09±0.62	0.578
Q5 (way of access) /mean±SD	1.09±0.29*	3.26±0.59	3.24±0.53	2.50±1.28	2.49±1.15	2.60±1.14	<0.001
Q10 (attachments from unknown senders) /mean±SD	5.00±0.00	4.95±0.22	4.98±0.13	5.00±0.00	1.86±0.35*	4.96±0.20	<0.001
Q12 (sending private/sensitive data) /mean±SD	4.27±0.45	4.33±0.48	4.48±0.50	4.50±0.51	3.27±1.58	1.02±0.15*	<0.001
Q14 (logging off the system) /mean±SD	5.00±0.00	5.00±0.00	5.00±0.00	2.43±0.78*	4.41±1.01	4.49±1.04	<0.001
Q15 (quality of password) /mean±SD	3.80±1.08	5.00±0.00*	2.65±0.77	3.30±1.46	3.35±1.32	3.40±1.46	<0.001

*significant influence from particular question on particular group

**One Way ANOVA test; *p* is significant at level <0.05

"sometimes + b" equals *indifferent*. Combination of questions "Yes + b" equals grade *poor*, because it is the most unsecure combination.

3. Are you opening e-mail attachments sent to you from unknown persons?

With possible answers "No", "Sometimes" and "Yes" the examinee can get grades equal to *excellent, indifferent* or *poor*.

4. Are you sending your personal or sensitive data over e-mail?

Possible answers were: "Yes", "On an exceptional basis", "No" and "Don't know" and matching grades are equal to *poor, average, excellent,* and *indifferent*.

5. Do you log of from the e-mail system after finishing your work?

Possible answers for this question were "Yes", "Mostly yes", "No" and "Don't know" with matching grades *excellent, good, poor* and *indifferent*.

6. Please self-assess your password quality?
   a) excellent (combination of small letters, capital letters and numbers)
   b) average
   c) poor
   d) don't know

Grades for questions "a", "b" and "c" are the same as given answers and grade for answer "d" is *indifferent*.

The examinee would get the lowest possible grade if he/she gave multiple answers.

Hierarchical method was used as the most common approach to cluster analysis [8]. Also Euclidean distance measure of (dis)similarity was chosen because of ordinally scaled data and Ward's method was chosen algorithm because there are no outliers and the aim was to have

TABLE II. DISTRIBUTION OF GENDER, AGE, PROFESSIONAL QUALIFICATION AND NUMBER OF ADDRESSES

	Group 1 /n(%)	Group 2 /n(%)	Group 3 /n(%)	Group 4 /n(%)	Group 5 /n(%)	Group 6 /n(%)	*p**
gender							
male	19 (42)	19 (45)	18 (29)	14 (30)	24 (38)	21 (45)	
female	26 (58)	23 (55)	45 (71)	32 (70)	39 (62)	26 (55)	**0.341**
age							
<=25	27 (60)	18 (43)	29 (46)	28 (61)	39 (62)	22 (47)	
30<>45	16 (36)	20 (48)	24 (38)	12 (26)	21 (33)	23 (49)	
>=45	2 (4)	4 (9)	10 (16)	6 (13)	3 (5)	2 (4)	**0.099**
professional qualification							
secondary school	24 (53)	21 (50)	38 (60)	27 (59)	41 (65)	26 (55)	
university education	21 (47)	21 (50)	25 (40)	19 (41)	22 (35)	21 (45)	**0.687**
number of e-mail addresses in usage							
one	12 (27)	11 (26)	23 (36)	16 (35)	28 (44)	16 (34)	
two	20 (44)	20 (48)	31 (49)	20 (43)	30 (48)	19 (41)	
three	7 (16)	10 (24)	6 (10)	9 (20)	4 (6)	10 (21)	
> 3	6 (13)	1 (2)	3 (5)	1 (2)	1 (2)	2 (4)	**0.099**
total	**45 (100)**	**42 (100)**	**63 (100)**	**46 (100)**	**63 (100)**	**47 (100)**	

*Chi-square Test; *p* is significant at level <0.05

similarly sized clusters [7]. Standardization of variables is needed when values are in different scales or variance differs significantly, which is not the case in this example [8].

After the categorization and evaluation of clusters each group of users was analyzed regarding awareness of security issues in combination with additional variables (gender, age, professional qualification and number of e-mail addresses used).

Clustering and statistical calculations were done with software tool Statistica 10.0 (StatSoft, Tulsa, OK, USA).

IV. RESULTS

The number of clusters is defined when examining dendogram (Fig.2) which graphically presents result of the cluster analysis. The steps in which Ward's algorithm can be stopped should be detected from resulted dendogram, depending on number of clusters and distance between then. In this analysis algorithm was stopped between 26% and 41% of the whole clustering procedure because it presents quite big distance between groups and results in similarly sized clusters. Bigger distance in dendogram presents difference between groups and it is presented graphically as higher jump. This procedure results in six clusters representing six groups of users.

Classification of discriminant analysis showed that a 98.7% of originaly grouped cases were correctly classified and canonical discriminant functions gave variables that significantly influenced on group membership (Tab.1). Overlapping between groups was only 1.3%.

None of the questions had significantly influenced on the Group 3 and also question Q2 has equally influenced on all six groups (p=0.578).

Only Group 2 has value "excellent" for variable that has significant influence on clustering analysis and can be called *"excellent password quality group"*. Groups 1, 4, 5 and 6 are "poor" or "indifferent" in related variable with significant influence while group 3 is "average" in a way regarding all six variables.

Users that belong to the *"excellent password quality group"* have their password graded as excellent which is significantly different from the grades of passwords of users of the other five groups.

In the first group that can be called *"less secure access group"* users prefer less secure way of access to the e-mail system, which significantly differs comparing them to the other users.

While the users of the *"group of average awareness"* are average regarding answers to the all six questions, users that belong to the forth group, "*forgettable group*" do not log off the system after finishing working with it.

Fifth group can be called *"naive group"* because these users are not critical to unknown collocutors and sixth group can be called similarly, for example *"security critical group"* because users from that group are sending personal and sensitive data by e-mail as plain text.

Distributions of external variables were not significantly different between categorized groups. However sample size is relatively small and *p* value is close to level of significance for external variables: *age* and *number of e-mail addresses used* (Tab.2).

V. CONLUSION

According to results it seems that cluster analysis, in combination with ontology and associated questionnaire, can be applicable method for categorization of the ICT

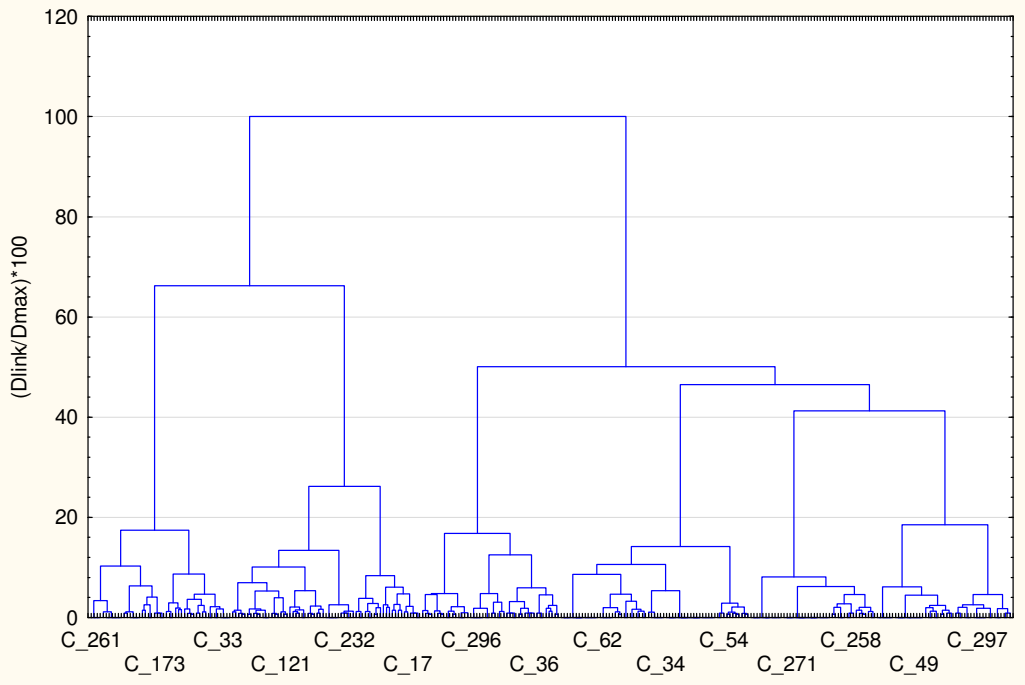

Figure 2. Tree diagram graphically presents result of the cluster analysis

system's users' awareness regarding security issues.

Formalizing domain of interest by using OWL ontology concept allows high level of flexibility (upgrade and update) and reuse of domain with possible coupling with other ontologies.

For upgraded or newly defined ontology new questionnaire can be easily made by mapping questions to the subclasses and answers to the possible instances.

Clustering analysis is flexible exploratory method and allows repetition of categorization on bigger sample size of either general or specific types of users (e.g. users of particular organization's ICT system). The evaluation and categorization of users' awareness should help in developing new concepts of security solutions.

Drawback of this study is in cluster analysis. As it is exploratory method researchers do not know what results to expect and if the resulting groups will differentiate enough for further statistical analysis.

Specific solutions can target different groups of users regarding results of the cluster analysis. For example specific solution can be developed for specific company after categorization and analysis of its employees and depending on company's security requirements which differs from bank, hospital, ICT company or some hotel.

From example analysis in this work *"naive group"* and *"security critical group"* need urgent attention and development of some solution in order to influence on security awareness level of these users.

Possible future work may be in applying this assessment methodology on students from different faculties. Analysis may identify what are differences in security awareness between students of different study fields and possible differences between students at the start and at the end of their studying period.

Upravljanje rizicima IT-projekata u državnoj i javnoj upravi

doc. dr. sc. Goran Vojković i Biljana Cerin, dipl.ing.

Sažetak – Državna i javna uprava jedan su od najvećih naručitelja projekata iz područja informacijskih tehnologija u Republici Hrvatskoj. Prema podacima državnog proračuna, na takve projekte se godišnje troši oko milijardu kuna. Međutim, sustav nadzora nad takvim projektima, a koji neminovno uključuje sustav upravljanja rizicima, nije na odgovarajući način ni propisan ni razvijen u praksi. Postojeći oblici nadzora nad projektima u javnom sektoru, formalizirani putem sustava unutarnjih financijskih kontrola te poslova koje obavlja Državna ured za reviziju, primarno se usmjeravaju na financijske aspekte projekta, a velikim dijelom su i oblik naknadne kontrole projekta, dakle kada su rizici projekta već ostvareni. U ovom radu želimo pokazati kako bi formaliziranje i propisivanje obveznim upravljanja rizika u IT-projektima u državnoj i javnoj upravi, sukladno uobičajenoj metodologiji (identifikacija rizika, ocjena rizika, tretiranje rizika te monitoriranje i kontrola rizika) povećalo kvalitetu i brzinu realizacije IT-projekata, a u konačnici i smanjilo troškove takvih projekata u državnom i javnom sektoru Republike Hrvatske.

I. UVOD

Neposredan povod pisanja ovog članka bilo je donošenje novog *Zakona o javnoj nabavi* [1] koji se u Republici Hrvatskoj primjenjuje od 1. siječnja 2012. godine, a koji u čl. 105. st. 3. propisuje: „Javni naručitelj obvezan je kontrolirati je li izvršenje ugovora o javnoj nabavi u skladu s uvjetima određenima u dokumentaciji za nadmetanje i odabranom ponudom."

S obzirom da se na postupke informatizacije u sustavu državne i javne uprave godišnje troše ogromna sredstva (Prema dokumentu „Pregled ulaganja ICT Državni proračun 2007-2013" iznos je između 800 milijuna i milijardu kuna po godini! [2]), jasno je da pitanje nadzora nad provođenjem projekata postaje sve važnije.

Pitanje nadzora nad projektima iz područja informacijskih tehnologija danas nije samo pitanje provođenja suvremene i svjetski raširene metodologije. Ono je postalo iznimno važno i radi potrebnih i nužnih ušteda u državnom proračunu (Državni proračun za 2012. godinu po prvi puta u povijesti neovisne Republike Hrvatske je i nominalno i stvarno manji nego u prethodnoj godini). Također, kako smo naveli, po prvi puta kontrola izvršenja ugovora postaje zakonska obveza. Tko i na koji način treba obavljati takvu kontrolu?

II. POSLOVI DRŽAVNE REVIZIJE

Kada se govori u nadzoru u sustavu državne i javne uprave, prva asocijacija je svakako Državni ured za reviziju (donedavno Državna revizija), čije ovlasti i zadaće su uređene novim *Zakonom o državnom uredu za reviziju* [3]. Prema tom Zakonu, reviziji podliježu državni prihodi i rashodi, financijski izvještaji i financijske transakcije jedinica državnog sektora, jedinica lokalne i područne (regionalne) samouprave, pravnih osoba koje se financiraju iz proračuna, pravnih osoba kojima je osnivač Republika Hrvatska ili jedinica lokalne i područne (regionalne) samouprave, društava i drugih pravnih osoba u kojima Republika Hrvatska, odnosno jedinice lokalne i područne (regionalne) samouprave imaju većinsko vlasništvo nad dionicama, odnosno udjelima te korištenje sredstava Europske unije i drugih međunarodnih organizacija ili institucija za financiranje javnih potreba.

Revizija je, u smislu Zakona o državnom uredu za reviziju, ispitivanje dokumenata, isprava, izvješća, sustava unutarnje kontrole i unutarnje revizije, računovodstvenih i financijskih postupaka te drugih evidencija radi utvrđivanja iskazuju li financijski izvještaji istinit financijski položaj i rezultate financijskih aktivnosti u skladu s prihvaćenim računovodstvenim načelima i računovodstvenim standardima. Revizija je i postupak ispitivanja financijskih transakcija u smislu zakonskog korištenja sredstava.

Prema izričitoj odredbi Zakona, revizija obuhvaća i davanje ocjene o djelotvornosti i ekonomičnosti obavljanja djelatnosti, te davanje ocjene o učinkovitosti ostvarenja ciljeva poslovanja ili ciljeva pojedinih financijskih transakcija, programa i projekata.

Državni ured za reviziju planira i obavlja reviziju u opsegu predviđenom godišnjim programom i planom rada, kao i prema zahtjevu Hrvatskog sabora ako glavni državni revizor ocijeni da je taj zahtjev opravdan.

Opseg godišnjeg programa i plana rada utvrđuje se na temelju: odredbi Zakona, procjene rizika, financijske značajnosti subjekta revizije, rezultata prethodne revizije, prikupljenih informacija o poslovanju subjekata revizije i

drugih kriterija koji se utvrđuju unutarnjim aktom Državnog ureda za reviziju.

Prema svemu gore navedenom Državni ured za reviziju ovlašten je za davanje ocjene o djelotvornosti i ekonomičnosti obavljanja djelatnosti te davanja ocjene o učinkovitosti ostvarenja poslovanja. Međutim, kada se uzmu u obzir odredbe prema kojima se revizija u pravilu obavlja temeljem godišnjeg plana, a i stvarna praksa kako i kada se ona u državnim tijelima obavlja – u pitanju je primarno naknadni nadzor nad projektima, kada je dobar dio projekta ili čak i čitav projekt dovršen (ili, u gorem slučaju, uvelike kasni s izvedbom).

III. SUSTAV UNUTARNJIH FINANCIJSKIH KONTROLA U JAVNOM SEKTORU

Godine 2006. godine donesen je *Zakon o sustavu unutarnjih financijskih kontrola u javnom sektoru* [4]. Tim Zakonom se obuhvaćaju financijsko upravljanje i kontrole te unutarnja revizija u javnom sektoru Republike Hrvatske.

Važno je spomenuti kako ovaj Zakon uređuje i upravljanje rizicima, u čl. 11. st. 1 se navodi: „Upravljanje rizicima cjelokupan je proces utvrđivanja, procjenjivanja i praćenja rizika, uzimajući u obzir ciljeve korisnika proračuna, te poduzimanja potrebnih radnji, posebice kroz promjenu sustava financijskog upravljanja i kontrola, a u svrhu smanjenja rizika.“ Dalje se u st. 2. istog članka navodi kako čelnik korisnika proračuna donosi strategiju upravljanja rizicima kojom se svake godine ažuriraju rizici značajni za cjelokupno poslovanje.

Dalje se navodi (čl. 12.) kako se kontrolne aktivnosti temelje na pisanim pravilima i načelima, postupcima i drugim mjerama koje se uspostavljaju radi ostvarenja ciljeva korisnika proračuna smanjenjem rizika na prihvatljivu razinu. Potom se u st. 3. navedenog članka primjerično navodi kako se kontrolne aktivnosti među ostalim odnose na (navodimo par tipičnih kategorija): postupke prijenosa ovlasti i odgovornosti; sustav dvostrukog potpisa; pravila koja osiguravaju zaštitu imovine i informacija; postupke potpunog, točnog, pravilnog i ažurnog evidentiranja svih poslovnih transakcija; postupke upravljanja ljudskim potencijalima; postupke praćenja financijskog upravljanja i kontrola i drugo. O rizicima se kratko govori i u dijelu Zakona koji regulira pitanja unutarnje revizije, tako među ostalim unutarnja revizija pruža podršku korisniku proračuna u ostvarivanju ciljeva izradom strateških i godišnjih planova unutarnje revizije temeljenih na objektivnoj procjeni rizika.

Za razliku od Državnog ureda za reviziju, koji u pravilu nastupa naknadno (*ex post*), sustav unutarnjih financijskih kontrola poznaje i izričito propisuje i prethodne (*ex ante*) kontrole, što svakako treba pozdraviti.

Uostalom, ukoliko promatramo funkcionalno – unutarnja kontrola je svo vrijeme unutar državnog tijela i može kontinuirano raditi na rizicima, dok Državni ured za reviziju u pravilu radi naknadnu kontrolu.

IV. SADAŠNJA KONTROLA – PRETEŽITO FINANCIJSKA

Općenito možemo reći da Republika Hrvatska ima razvijen sustav kontrola i revizije u javnom sektoru, a koji naravno obuhvaća kontrole i revizije svih projekata, uključujući i one iz područja informacijskih tehnologija. Osim nadzora, regulira se i procjena rizika.

Međutim, ono što smatramo bitnim naglasiti je da su kontrole, revizije i procjene rizika predviđene Zakonom o državnom uredu za reviziju i Zakon o sustavu unutarnjih financijskih kontrola u javnom sektoru primarno financijske. U tim propisima bi se tek uz vrlo prošireno tumačenje mogla naći osnova za IT-reviziju, ali opet bez propisane metodologije, postupaka te preporuka najboljih praksi.

IT-projekti u državnoj i javnoj upravi se iz više razloga mogu smatrati relativno rizičnim projektima: vezani su uz složene sustave javnih nabava (primjerice poništavanje natječaja za nabavku hardvera može ugroziti softverski projekt, koji se do tada provodio sukladno planu), uključuju velik broj procesa, prilagodbe obično inertnih organizacija, potrebu za intenzivnim školovanjem kadra, često i velik broj lokacija… Financijska kontrola neće pomoći smanjenju i otklanjaju navedenih i brojnih drugih specifičnih rizika. Financijska kontrola je potrebna, procjena financijskih rizika je također potrebna, ali bez kvalitetne procjene rizika i postupanja sukladno preporukama za izbjegavanje rizika, skupi projekt može doći u kašnjenje ili biti ugrožen čak i kada je financijska komponenta u potpunosti uredna.

Stoga smatramo potrebnim razviti, formalizirati i učiniti obveznim upravljanje rizicima IT-projekata u državnoj i javnoj upravi. Smatramo da bi takvo propisivanje povećalo kvalitetu, te postotak uspješnosti IT-projekata.

V. ČIMBENICI USPJEŠNOSTI IT-PROJEKATA U JAVNOM SEKTORU

IT-projekti u državnoj i javnoj upravi, kao i ostalim sektorima, općenito za cilj imaju poboljšati i automatizirati izvršavanje poslovnih procesa primjenom informatičke tehnologije. U velikoj mjeri, zbog nedostatka internih kadrova, povjerenje za izvršavanje ovih projekata ustupa se specijaliziranim tvrtkama za razvoj softvera i integraciju informacijskih sustava. Ove se tvrtke odabiru u postupku javne nabave temeljem ispunjenja uvjeta istaknutih u natječajnoj dokumentaciji. Sa stajališta procjene rizika, već u pripremi natječajne dokumentacije organizacija koja želi pokrenuti projekt izložena je brojnim rizicima:

- nemogućnost izrade kvalitetne tehničke specifikacije radi nedostatka stručnog kadra,
- nedovoljno jasan opseg projekta radi nemogućnosti definiranja jasnih granica opsega i količine potrebnog posla za izvršenje projekta, te
- nedovoljno kvalitetni kriteriji za odabir dobavljača radi zakonskih ograničenja.

Jednom kad je najpovoljniji, što ponekad ne znači i najkvalitetniji, dobavljač odabran, pokreće se projekt.

Prema istraživanju Standish group [5] za 2011. godinu, 66% IT-projekata su ili u problemima ili neuspješni, što

ostavlja samo 34% IT-projekata koji se smatraju uspješnima.

U ocjenjivanju IT-projekta uspješnim, nužno je procijeniti kvalitetu integracije izvedenog IT-rješenja u poslovne procese organizacije. Integracija IT-rješenja mora obuhvaćati identifikaciju postojećih poslovnih, sigurnosnih i regulatornih zahtjeva poslovnih procesa.

Osnovni uzroci neuspjeha IT-projekata mogu se svesti u sljedećih nekoliko kategorija:

- nerealni ili nedovoljno jasni ciljevi projekta,
- pogrešne procjene potrebnih resursa,
- loše definirani zahtjevi,
- nepotpuno izvještavanje o statusu projekta,
- nedovoljno upravljanje rizicima projekta,
- nedostatna komunikacija između naručitelja, izvođača i korisnika IT rješenja,
- korištenje nezrelih tehnologija,
- nemogućnost upravljanja kompleksnošću projekta,
- nemarne prakse u razvoju softvera,
- loše upravljanje projektom,
- politički utjecaji ključnih sudionika projekta,
- komercijalni pritisci.

U javnom sektoru najčešći problemi su: nerealno ili nedovoljno jasni ciljevi projekta (za projekt postoji samo opća politička volja, bez ulaženja u bit onoga što se želi riješiti), loše definirani zahtjevi (nedostatak procesnog upravljanja u javnom sektoru), a tu je često i općenito loše upravljanje projektom (zbog nedostatka kvalitetnih stručnjaka unutar sustava).

Dodajmo ovome da se zbog složenog sustava javne nabave korektivne radnje provode bitno teže nego u realnom sektoru, čak i ako se propusti uoče na vrijeme.

VI. PROCJENA RIZIKA IT-PROJEKATA U DRŽAVNOM I JAVNOM SEKTORU

Kako bismo uspješno proveli projektne aktivnosti i doveli projekt do kraja, nužno je na vrijeme prepoznati i procijeniti rizike kojima je projekt izložen, te odlučiti na koji ćemo način tretirati one projektne rizike koji su nam neprihvatljivi u odnosu na prethodno uspostavljene kriterije.

Projektne rizike razmatramo u nekoliko područja njihovog utjecaja na opseg, kvalitetu, trajanje i troškove projekta te zadovoljstvo uključenih strana [6]:

- tehnički rizici, rizici vezani uz kvalitetu ili performanse,
- rizici vezani uz upravljanje projektom,
- rizici vezani uz organizaciju u kojoj se projekt izvršava,
- vanjski rizici.

Gledano kroz faze izvođenja IT projekata, glavni rizici s kojima se projekt susreće u pojedinim fazama su prikazani u sljedećoj tablici:

TABLICA I. RIZICI IT-PROJEKATA PREMA FAZAMA IZVOĐENJA

Redni broj	Faza	Rizici
1	Inicijacija	Rizici koji mogu utjecati na izradu terminskog plana i upravljanje procesom implementacije informacijskog sustava
2	Specifikacija	Rizici povezani s utvrđivanjem postojeće hardverske infrastrukture, sigurnosti informacijskog sustava kao i specifikacije i dizajna korisničkih zahtjeva
3	Implementacija	Rizici povezani s procjenom implementacije korisničkih zahtjeva
4	Uvođenje u rad	Rizici povezani s prihvaćanjem informatiziranih poslovnih procesa kao i integracija sa sustavima trećih strana
5	Održavanje	Rizici u izmjeni postojeće hardverske i softverske infrastrukture potrebne za uspješno funkcioniranje informacijskog sustava kao i s mogućim izmjenama na informacijskom sustavu

Proces procjene i upravljanja rizicima u bilo kojem dijelu poslovanja organizacije [7], tako i na IT-projektu, odvija se kroz nekoliko glavnih faza:

1. utvrđivanje konteksta, odnosno okruženja u kojem rizike promatramo,
2. identifikacija rizika, odnosno identifikacija prijetnji i ranjivosti koje te prijetnje mogu iskoristiti te posljedica ostvarenja rizika,
3. utvrđivanje razine rizika i kriterija za njihovo upravljanje,
4. planiranje odgovora na neprihvatljive rizike,
5. kontinuirani nadzor nad rizicima i kontrola njihovog upravljanja.

Uzmimo za primjer projekt koji se oslanja na ključnog eksperta za neko stručno područje. Područje u kojem je potrebno znanje i iskustvo eksperta vrlo je važno područje u ukupnom opsegu projekta. Kojima je sve prijetnjama izložen ključni ekspert? Jedan od mogućih izvora rizika je nedostupnost ključnog eksperta, bilo uslijed opterećenja drugim obavezama, bilo uslijed bolesti, ili zbog odlaska na drugu funkciju. Kolike su vjerojatnosti ostvarenja svakog od identificiranih scenarija? Za određivanje vjerojatnosti moramo saznati više informacija o kontekstu u kojem se rizik promatra. Je li ključni ekspert dugogodišnji zaposlenik tvrtke i adekvatno plaćen? Je li raspoređen na razumnu količinu projekata ili, upravo zbog toga što je „ključni“, rastegnut je na nekoliko projekata istovremeno? Je li iskreno voljan sudjelovati u projektu ili se osjeća kao da mu je sudjelovanje nametnuto? Kakvo je njegovo zdravstveno stanje? Izostaje li često s posla? Pokazuje li interes za skorom promjenom pozicije, prelaskom na drugo radno mjesto u organizaciji, ili možda izvan organizacije? Sve su to parametri koji utječu na konačno određivanje vjerojatnosti ostvarenja rizika vezanih uz našeg ključnog eksperta.

Za razmatrani primjer ključnog eksperta, nakon što smo odredili vjerojatnost ostvarenja rizičnog događaja na temelju prikupljenih informacija, potrebno je odrediti kako ti događaji, u slučaju da se realiziraju, utječu na tijek i izvršenje projekta odnosno ispunjavanje projektnih ciljeva u cjelini. U ovom razmatranju moramo biti svjesni svih

ranjivosti kojima smo izloženi. Za ilustraciju, pretpostavimo da nemamo alternativnog stručnjaka koji je upoznat sa područjem koje u projektu pokriva naš ključni ekspert. U tom slučaju odsustvo ključnog eksperta može rezultirati zastojem u projektu, pogreškama u izvršavanju pojedinih projektnih aktivnosti, ili u slučaju njegovog dužeg odsustva i nemogućnosti pronalaska adekvatne zamjene, čak i odgađanjem/obustavom projekta. U slučaju da imamo alternativnog stručnjaka, posljedice odsustva ključnog eksperta i utjecaj ostvarenja takvog rizika na projekt bili bi znatno manji.

Kada smo ustanovili kako utjecaj ostvarenja rizika ovisi o razmatranim scenarijima, gdje god je to moguće nastojimo pobliže procijeniti štetu u financijskim pokazateljima. Kao izlaz iz ove faze procjene dobivamo parametre prihvatljivog gubitka i prihvatljivu razinu ulaganja u odziv na rizik. Za razmatrani primjer, mogući odzivi bili bi uključivanje adekvatnih zamjenskih stručnjaka u projekt, edukacija dodatnih stručnjaka, outsourcing aktivnosti dodijeljenih ključnom ekspertu itd., ovisno o rezultatima obavljenih procjena, razini rizika, visini procijenjenih šteta i mogućnostima ulaganja u upravljanje razmatranim rizikom.

Kako bismo što bolje procijenili utjecaje mogućeg ostvarenja rizika na projekt te na taj način dobili i konkretnu razinu i s njom povezane financijske pokazatelje, moramo imati kvalitetne informacije na raspolaganju. Izvori kvalitetnih informacija su redovito ključni sudionici projekta, podaci o prethodnim projektima, nalazi internih i vanjskih revizija ili relevantni izvori informacija o nekom stručnom području.

U državnom i javnom sektoru imamo i neke dodatne poteškoće za dobivanje podataka temeljem kojih se može obaviti procjena rizika IT-projekata. Navesti ćemo najvažnije.

Procesi unutar državnog i javnog sektora su specifični i vrlo složeni. Konzultanti i ostali sudionici projekta trebaju znati područje u koje ulaze, što u praksi uvijek nije slučaj.

Poseban problem uvijek predstavlja postojeća praksa u konkretnoj organizaciji – koju je potrebno provjeriti snimanjem stanja na terenu, a to je postupak koji košta, i za koji naručitelj često nema razumijevanja. Zbog toga se procjena najćešće radi temeljem formalno objavljene strukture organizacije, i temeljem pretpostavljenih procesa – što u ne mora odgovarati praksi. Praksa može biti lošija (npr. postoje samo sistematizirana radna mjesta, ali ne i službenici koji obavljaju poslove), ali može biti i bolja od pretpostavljene (službenici obavljaju poslove složenosti bitno iznad njihove sistematizirane razine i formalnog opisa posla).

Ponekad, dio poslovnog/upravnog postupaka se zna kriti od izvođača – makar za to ne postoje formalni razlozi tajnosti i slično.

U praksi čak i uobičajena upravna hijerarhija može predstavljati problem – konzultanta primaju i s njime razgovaraju više rangirani upravni službenici, a izbjegava se omogućiti konzultantu razgovor s neposrednim izvršiteljima, tipično službenicima koji imaju neposredni kontakt s vanjskim korisnicima i neposredno koriste informacijske sustave. Upravo takvi službenici mogu svojim znanjem i informacijama biti vrlo dragocjeni u procjeni rizika.

VII. UPRAVLJANJE RIZICIMA IT-PROJEKATA U DRŽAVNOM I JAVNOM SEKTORU

Pojam „prihvatljiva razina rizika“ je često nejasno definiran i na neki način izgubljen u samom izražavanju razine rizika, gdje se uzima za gotovo da je neprihvatljivo sve što je „visok rizik“ i „srednji rizik“ – ovakav pristup dobar je za inicijalnu procjenu i upravljanje rizikom, ali razrađenija metodologija i konzistentna primjena kulture upravljanja projektnim rizikom zahtijeva posvećivanje više pažnje upravo određivanju granice do koje je u projektu neki rizik prihvatljiv, a iznad koje više nije. Razlog tome je jednostavno ušteda u potrebnim sredstvima (bilo financijskim, ljudskim, tehnološkim) za kvalitetan odziv na neprihvatljiv rizik – što točnije odredimo posljedice ostvarenja rizika i samim time razinu potencijalne štete, to ćemo konkretnije moći odrediti i kolika je šteta nama prihvatljiva i pametnije investirati u potrebne mjere odziva. Pri tome ne smijemo zaboraviti na tzv. rezidualni rizik, tj. onaj projektni rizik koji nam preostaje nakon što smo primijenili sve poslovno prihvatljive mjere, kojeg je nužno nadzirati i periodički ponovo procijeniti.

Posljednja aktivnost u procesu upravljanja projektnim rizicima je nadzor i kontrola nad rizicima, koja se postiže praćenjem provođenja svih definiranih akcija upravljanja rizikom te aktivnim praćenjem okruženja u kojem se projekt odvija i svih relevantnih promjena u tom okruženju. Upravo za kvalitetan nadzor i kontrolu nad rizicima potrebno je stvoriti tzv. „risk awareness“ kulturu na projektu, odnosno sve članove projektnog tima potaknuti na prepoznavanje potencijalnih prijetnji i ranjivosti i pravovremeno informiranje voditelja projekta o njima, kako bi se rizik što je moguće ranije prepoznao i time omogućilo lakše (i jeftinije) ovladavanje njime.

Općenito, potrebne su složene promjene kako bi procjena rizika uvela kao „način razmišljanja“ u državni i javni sektor, kako je danas već uvedena u uspješnim kompanijama realnog sektora. Naravno, bilo bi najlakše „školski“ navesti sve potrebne reforme, ali time bismo zanemarili da se u doba recesije i smanjenja državnog financiranja ne mogu očekivati rješenja tipa zapošljavanja dovoljnog broja kvalitetnih kadrova. Moramo naime uzeti u obzir slijedeće:

a) obrazovna struktura državnog i javnog sektora uglavnom nije dovoljno visoka, no neće se u skorije vrijeme mijenjati,
b) veća nova sredstva neće biti dostupna,
c) osnivanje posebne organizacije unutar javnog sektora, koja bi se bavila ovim pitanjima (primjerice državnog ureda) gotovo je nemoguće u realnosti.

Stoga, rješenje treba nalaziti u okviru potencijala koji unutar državne i javne uprave postoje, naravno uz moguće i realne prilagodbe, a koje bismo podijeliti na tri cjeline:

a) temeljna edukacija voditelja projekata u državnoj i javnoj upravi o osnovama upravljanja rizika;
b) šira edukacija službenika koji već obavljaju poslove iz opsega sustava unutarnjih financijskih kontrola vezano za upravljanje rizicima – oni bi trebali biti osobe koje će neposredno obavljati ove poslove na „živim“ projektima koji se odvijaju u njihovoj organizaciji;
c) osposobljavanje službenika Državnog ureda za reviziju za najsloženije poslove nadzora upravljanja

rizicima, te omogućavanja njihovog angažiranja ne samo *ex post facto*, na godišnjim provjerama rada organizacije, već i na provjerama planova upravljanja rizicima prije nego što je operativni dio projekta počeo (npr. obveznim slanjem ovih planova Državnom uredu za reviziju iznad određene vrijednosti projekta).

Ovo sve naravno ne isključuje ni angažiranje profesionalaca iz područja upravljanja rizicima u projektima koji to uloženim sredstvima i složenošću opravdavaju.

VIII. ZAKLJUČAK

Novi pravni okvir javne nabave u Republici Hrvatskoj, a koji traži da javni naručitelj nadzire i izvršenje ugovora, svakako je poticaj u traženju boljih rješenja za upravljanje projektima u državnom i javnom sektoru. Taj sektor jest i biti će veliki naručitelj IT orijentiranih projekata.

Postojeći sustavi kontrole, putem unutarnje kontrole i Državnog ureda za reviziju, po postojećoj pravnoj regulativi primarno se odnose na financijsku kontrolu, koja je velikim dijelom (Državni ured za reviziju) i naknadna kontrola.

Ono što je potrebno, kako bi se ispunili zahtjevi Zakona o javnoj nabavi, a i povećala svrhovitost trošenja proračunskih sredstava, jest proširenje ovlasti sadašnjih nadzornih tijela i na rizike koji nisu samo financijske prirode. Također, dio naknadne kontrole, koji obavlja Državni ured za reviziju, posebno kada se radi o velikim, milijunskim projektima, potrebno je vezati za faze projekta, a ne samo za protok kalendarske godine.

Na kraju, potrebno je propisati i primjerenu metodologiju procjene rizika (odnosno propisati promjenu neke od postojećih svjetskih metodologija).

Korištenje postojećih ljudskih resursa, uz odgovarajuću edukaciju, a i neophodnu prilagodbu pravnog okvira, moglo bi znatno povećati kvalitetu upravljanja rizicima u državnom i javnom sektoru, uz razumna financijska ulaganja, koja bi se brzo vratila u obliku kvalitetnijih i na vrijeme dovršenih projekata u svom punom obimu.

Abstract - Application of biometric tools today is a major challenge for developers of biometric systems and for users of those systems. A specific application can be seen in systems requiring a certain accuracy in person authentication. A large number of systems is created in a way that the algorithms used are not verified as standardized, thus causing uncertainty in their results and application of those tools in processes which need to confirm obtained results. This paper will describe the basic model necessary to build a framework for the construction of a biometric system applicable in forensics for person authentication in court of law.

I. INTRODUCTION

Forensic science is broadly defined as the application of scientific knowledge to the legal system. It includes disciplines like pathology, biometrics, serology, molecular biology, trace evidence and weapons identification[1]. From this definition, it can be seen that one important discipline is biometrics.

Biometrics can be defined as field of technology using automated methods for person authentication using their physiological and behavioral characteristics[2,5]. It can be fingerprint analysis, voice recognition or signature recognition as more common techniques or face recognition, infrared image analysis, palmprint recognition, ear recognition, walk recognition as uncommon techniques.

The use of biometrics in forensics and law enforcement has become common and is used mainly to determine the identity of offenders which is acceptable in court.

This paper will give an introduction to usage of biometrics in forensics and law enforcement. Next, some problems related to biometrics in forensics will be presented and an idea for solution of those problems along with the future research on this topic, will be stated.

II. BIOMETRICS IN FORENSIC SCIENCE

At the time crime is commited, the perpretrator is typically unknown and the investigation has to be conducted in order to find suspects. Biometrics is very usefull in such situations. Especially automated systems for person comparison or identification.

These systems work well for biometric identification or verification, where characteristics are taken in controled conditions, and failure of those systems doesn't have severe consequences. Forensic recognition has severe consequences, because if a systems makes the wrong decision, a person could be convicted and spend time nad jail but be completely innocente.

There are three rules which forensic science must abide[1]:

- Forensic science must apply only those procedures that are solidly grounded through experimentation.
- Standards for qualifying tehnicians and scientists must be followed.
- Standard procedures must be adhered to during evidence collection and analysis.

The more evidence are scientifically grounded, the stronger the case is in court. If methods and technologies are untested, if no standardization exists, if algorithms are misapplied, the case won't stand in court and it is the same as evidence wasn't collected at all.

To this day, a vast number of biometric tools has been developed. The use of those tools in forensic investigations would improve the efficiency of forensic work and standardize the comparison process[3].

Problems with those systems are:

- Results are not robust to changes in, for example, pose or illumination
- Quality of images is usualy bad (taken from a far, low resolution, compression)
- A score based biometric recognition system is not suitable to judicial system where the objective is to give a probability or degree of support for one hypothesis against the other[4]

What makes things easier is that forensic recognition doesn't have to be in real time, so it doesn't have a time constraint.

The most important thing is that the technology in use must be thoroughly tested and evaluated. In European judicial system, there are no admissibility rules regarding scientific evidence[3].

III. BIOMETRIC SYSTEM CHARACTERISTICS

Biometric systems in general have a number of characteristics. Geradts and Ruifrok [6] describe important factors necessary for an effective biometric system:

- Accuracy
- Speed and throughput rate
- Acceptability to users
- Uniqueness
- Resistance to counterfeiting
- Reliability
- Data storage requirements
- Enrollment time
- Intrusiveness of data collection

These characteristics will be described below.

A. Accuracy

Accuracy is the most important characteristic of a biometric system. If the system is not accurate, there is no point to it at all. If a system is for verification (comparison one-to-one) purposes, Geradts and Ruifrok [6] define:

- False Reject Rate (FRR) – percentage at which enrolled person are rejected as unidentified or unverified
- False Acceptance Rate (FAR) – percentage at which impostor persones are accepted as authentic (enrolled) person
- Equal Error Rate (EER) – cross over error rate, stated as a percentage at which false rejection rate and the false acceptance rate are equal (Fig. 1)

For a biometric recognition system Bromba [7] diferentiates between four possibilities:

- Correct match – if two samples of the feature of the same subject match
- False match – If two features of two diferent subjects match
- False non-match – If two samples of the feature of the same subject do not match
- Correct non-match – if two features of two different subjects do not match

B. Speed and throughput rate

Another characteristic important when choosing a biometric system is the speed and throughput rate. The speed of a biometric system is not solely related to the speed or power of the data processing aspect of the system, it relates to the process flow in its entirety - the speed from beginning to end needs to be considered[8]. For example, this means that everything from taking a pen to sign your name to opening and closing the door, if required, should be considered when calculating the speed of the system.

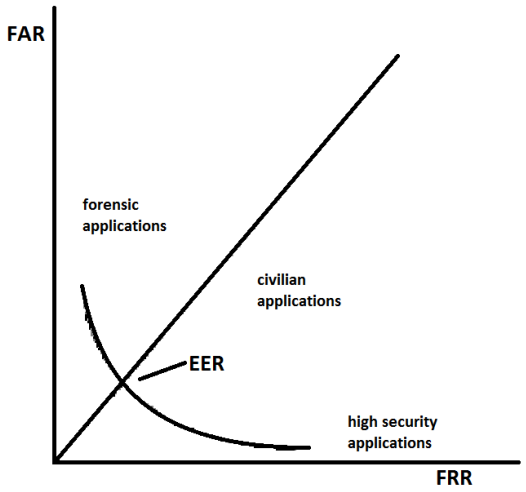

Figure 1. Receiver's Operating Curve: FAR versus FRR[6]

C. Acceptability to users

This is the main concern for users, next to performance. The biometric systems should be intuitive and easy to use. It shouldn't pose any problems to collect characteristics, and users should feel comfortable using it.

User acceptability can be increased in some degree by education and information.

D. Uniqueness of biometric characteristic

The key of every biometric system is the uniqueness of biometric characteristic employed. The most unique are fingerprints which, by now are most commonly used, and iris and retinal scans [8]. Uniqueness does not mean that these characteristics can not be replicated, it just means that they have a sufficient number of complex patterns or traits that can be used to build a strong template for authentication[8].

E. Resistance to counterfeiting

Resistance to counterfeiting is just the question how easily can a characteristic be replicated by an intruder. This is very different from uniqueness. Some characterisics can be very unique, but easily counterfeited.

F. Reliability

Reliability regards downtime of a system. It would be ideal, but impossible, that a system has no downtime. Next demand is for the downtime to be minimal, and when it happens, to be as short as possible. Getting the system back up should be easy with minimal losses of both productivity and data.

G. Data storage requirements

This characteristic may directly influence on speed of the system. If templates used in a biometric systems require are large, speed of processing will be smaller. Also, new hardware may be required[8].

H. Enrollment time

Enrollment is the proces of inputing users in the system. For organizations, it is enrollment of employees. From forensic and law enforcement standpoint, it is enrollment of suspects in the system, or whole country.

Enrollment time may take from several hours to couple of years.

I. Intrusiveness of data collection

Term data collection from this aspect means collection of peoples biometric characteristics (fingerprints, facial images, retina images, iris scans, palmprints, footprints...). Biometric characteristics used in a system should be easy to collect and non-intrusive.

IV. Evaluation Criteria

Simoens [9] in his work on Security and Privacy Challenges with Biometric Solutions gives evaluation criteria for template protection:

- Technical performance
  - Accuracy
  - Accuracy degradation
  - Throughput
    - PI encoding time
    - PI recoding time
    - PI comparison time
  - Storage requirements
    - Protected template size
    - Code size
  - Diversification capacity
- Security and privacy performance
  - Full-leakage irreversibility
  - Authorized-leakage irreversibility
  - Pseudo-authorized-leakage irreversibility
  - Unlinkability
- Operational preformance
  - Modality independence
  - Interoperability
  - Quality of performance
    - Granularity of performance
    - Stability of performance

It is visible that these two different approaches have a lot in common. Accuracy, throughput and storage requirements are visible in both approaches.

Also, in both of those algorithms, two thing important for forensics are missing. Biometric methods and algorithms need to be verifiable and repeatable. Every result obtained by any method must be able to be obtained in the same way, by the same method any time. And if someone knows the result and the method used, this person must be able to verify the given result.

V. Conclusion

Biometric methods are more and more popular in access restriction, but also in forensics and law enforcement. For their proper usage, apropriate standards need to be developed.

This paper points to problems which exist in using biometrics for forensic recognition of individuals in court of law. It describes the characteristics of biometric systems which should be taken into consideration when creating a framework for standardization of biometric methods for forensics purpose esspecially in the court of law. Future work will concentrate on creating a detailed framework for standardization of biometric methods for usage in forensics.

INVITED PAPERS

Using Ontologies and Requirements for Constructing and Optimizing Data Warehouses

Abstract - Developing database (DB) and data warehouse (DW) applications pass through three main phrases imposed by the ANSI/SPARC architecture: conceptual modeling, logical modeling and physical modeling. Some research efforts add a new ontological level above the conceptual one. This architecture has created two main actors whose presence is mandatory to ensure the success of applications: "*conceptual designer*" for conceptual and logical levels and "*database administrators*" (DBA) for physical level. Note that some administration tasks need some inputs from conceptual phase. Unfortunately, interaction between these two actors is negligible. Recently, some research and industrial efforts identify a highest cost of DBA and propose tools (advisors) to replace them, in order to ensure what we call zero-administration. The main limitation of these tools is their robustness. In this paper, we propose a new human resource management for database applications. Instead of replacing DBA, we claim to delegate some DBA tasks to conceptual designers. These tasks are usually those having inputs user requirements that may be translated to SQL queries. First, we propose a user make user requirements persistent into DWs. An analysis of requirements is given to identify SQL queries that may be used for physical design phase. Finally, a selection of indexes based on user requirements is presented and evaluated using star schema benchmark.

I. INTRODUCTION

DBs and DWs usually follow the ANSI/SPARC architecture, where three different levels of schemas exist: (i) external schemas describing the different external views of the data, (ii) the conceptual schema describe all data items and relationships between them and (iii) the internal schema contain definitions of the stored records, access methods and indexes, etc. This architecture creates two types of actors: conceptual designers and administrators. The first actors generally act based on user requirements. The analysis of these requirements allows designers to generate conceptual models including entities, attributes and cardinalities. Another aspect of this analysis is the identification of treatments needed for the target application. By analyzing these treatments, we can identify three main categories: (i) treatments that can be easily answered by SQL queries, (ii) treatments that may be answered by programming languages and (iii) treatments that may be partially answered by SQL queries. Database administrators (DBA) otherwise, need to select relevant optimization structures (e.g., partitioning, indexing, materialized views, etc.) during the physical design. This selection is usually based on the most frequently asked queries that can be identified from the conceptual modeling phase. Recently, we are moving towards truly zero-administration of database systems in which there is not the possibility for a DBA to check the recommendations of physical design tools before applying them. These tools are developed to reduce the *cost* of administrators. Developing such tools may suffer from robustness of the proposing recommendations. Reference [4] shows the risk of using such tools. Our vision is that, instead of replacing the task of administrators, we propose to delegate some administration tasks (such as selection of optimization structures) to conceptual designers. To do so, user requirements analysis needs to be well established.

On the other hand, a new extension of ANSI/SPARC architecture has been proposed introducing an ontological layer. Ontologies are actually seen as conceptual models defining a whole domain via a logical theory. We propose in this paper to revise this extended architecture by giving designers a more important role and by making user requirements persistent in the BD/DW structure. We focus in this paper on DW design as a case study. The paper is structured as follows. Section 2 presents the related work. Section 3 presents the background needed. Section 4 presents our methodology for designing DWs following the revisited version of ANSI/SPARC. Section 5 validates our proposal by performing new type of optimization: *requirements*-driven optimization. Section 6 concludes the paper.

II. RELATED WORK

Requirements engineering (RE) plays a crucial role in information systems development to reduce the risk of failure. Requirements for a DW system determine its functional behavior and all needed enterprise information. Requirements analysis in DW design literature can differ according to the object analyzed. We distinguish: *Process* driven analysis that analyzes requirements by identifying business processes of the organization, *User* driven analysis that identifies requirements of each target user and unifies them in a global model, and *Goal* driven analysis [8] that identifies goals and objectives that guide decisions of the organization at different levels. It is recognized by different authors that goal-driven analysis provides a suitable definition of user requirements especially for decisional applications. These requirements are either functional or non functional. Non-functional requirements are defined as constraints of the system (such as security, performance, flexibility, etc).

In addition to requirements, DW systems must integrate the set of available sources of the organization. Most of current DW design methods follow a mixed

design defining the DW model from both data sources and user requirements. As for traditional information system, these methods design DW systems following ANSI/SPARC specification (Fig. 1). This vision assumes that the conceptual model does not exist and have to be defined. With the emergence of domain ontologies, many DB and DW design methods used existing ontologies models as a first level of specification. Reference [12] proposed a method similar to Chen methodology for designing DBs by adding a semantic layer using linguistic ontologies. Reference [6] proposed an extension of ANSI/X3/SPARC architecture, illustrated in figure Fig.2.(a), giving ontologies their place during design process of DB/DW. The conceptual model in this architecture is just a view of an ontological model. Ontologies have been used in DW methods for providing an integrated and unified view of data sources [11], and also for identifying, formalizing, and reasoning on user requirements as we proposed in [9, 10].

In the first version of ANSI/X3/SPARC, and also in the revisited version with ontologies, two main actors are present. Requirements specification and conceptual design step are supervised by ***designers***. Logical design step generally relies on defined translation rules that are supported by many case tools (like Power AMC of Sybase or Rational Rose). Physical design step is supervised by the **DBA**. As for the logical design step, physical step is being automated by administration tools like Oracle SQL Tuning Advisor or SQL Server Advisor. These tools are provided to assist the DBA and sometimes to replace it. In this case, robustness of administration tools must be proven [4]. In this situation, the role of designers is strengthened while the role DBA is weakened. Designers rely for their work only on user requirements. They represent the most important information for the final system. For the case of DW systems for example: (i) requirements are saved a posteriori as queries in most DBMS (like Oracle or Sql Server) for optimization purposes, (ii) user's preferences, which are considered as non-functional requirements, are exploited for personalization and recommendation processes like in [7], (iii) quality of the DW can be measured according to its capacity to fulfill the different requirements and goals like in [13]. Unfortunately no trace of requirements is currently saved in DBs or DWs systems once developed.

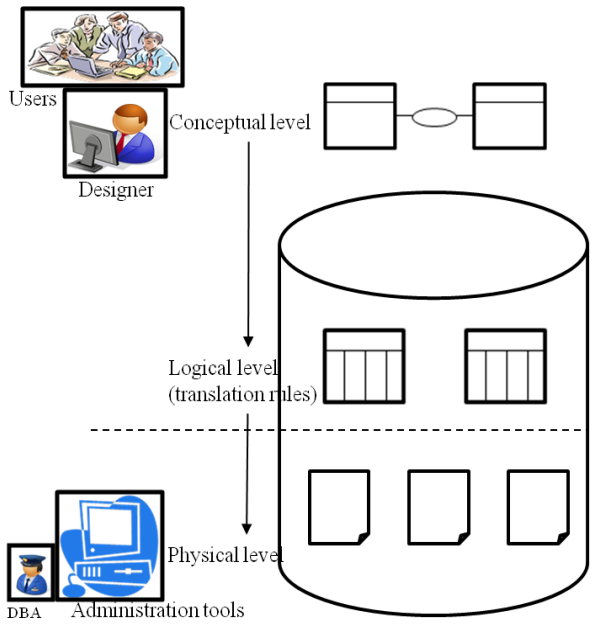

Figure 1. ANSI/SPARC architecture for DBs/DWs

To solve this issue, we propose a new version of ANSI/SPARC architecture (see Fig. 2.(b)) that: (i) gives the designer a bigger role who is present all along design phases and (ii) makes requirements persistent within the BD/DW structure. In this architecture, we try to reduce the gap between logical and physical design phase to help designers in their design tasks. We take as an example of physical design task, the 'index selection problem'. We assume that this task can be performed by designers during logical phase using user requirements. Usually, DB or DW indexes are defined relying on a set of frequent queries and a set of constraints (space storage, update cost, etc). Those queries are obtained only once the DB/DW is defined and used during a certain period. During this warm stage, where no statistical information is available, requirements can be used in order to define some relevant optimization structures.

III. BACKGROUND

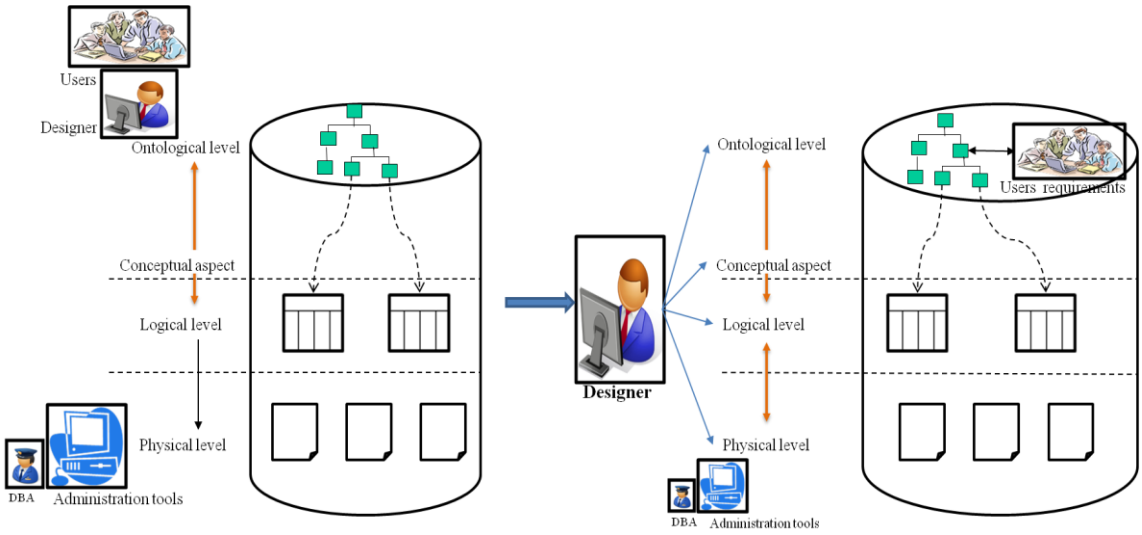
We review in this section, relevant concepts to understand our methodology which are: Ontologies and Ontologies for Databases.

A. *Ontologies: Formal model*

Ontologies have been introduced in DW design field first to provide an integrated view of data sources. It is recognized that an effective approach to deal with integration and interoperability is the use of common standards. Many integration applications used domain ontologies as a reference model. We proposed and analyzed in [1] different integration scenarios where a domain ontology integrate a set of semantic sources. We assume in our method this integrating ontology existing as integration issue is out of the scope of this paper.

Ontologies can be formalized following different ontological languages such as: PLIB for engineering applications or semantic web languages like RDF, RDFS, OIL, DAML and OWL. We formally define domain ontology as follows. We define a core ontology model that is common to all ontology formalisms [1]: O: <C, P, Sub, Applic>:

- C: is the set of classes describing the concepts of a given domain.
- P: is the set of properties describing the instances of C.
- Sub: C → 2^C is the subsumption function, which associates each class C*i* to its direct subsumed classes. Two subsumption relationships are introduced in our framework: (i) OOSub: describing the usual subsumption of inheritance relationship, where the whole set of applicable properties is inherited. (ii) OntoSub: describing a subsumption relationship without inheritance, where only a part of applicable properties may be



(a) ANSI/SPARC : extended version with ontologies **(b) ANSI/SPARC : extended version with actors**

Figure 2. ANSI/SPARC architecture: extended version

imported. OntoSub can be seen as the operator of ontological modularity.

- Applic: C → 2^P is a function that associates to each ontology class, the properties that are applicable for each instance of this class.

B. *Ontologies for databases*

The amount of data described by ontologies can be huge, especially since the emergence of ontologies in various domains such as E-commerce or Semantic Web. As a consequence a scalable storage system is required for ontologies and its associated instances. We call Ontology Based Data Base (OBDB) a database that stores data together with the ontologies defining their semantics. Many OBDBs have been proposed in the literature following different architectures. We proposed in [3] a new architecture of OBDBs called *OntoDB*, where a new part *"the meta-schema"* is introduced. OntoDB architecture is composed of 4 parts as illustrated in Fig. 3. Parts 1 and 2 are traditional parts available in all DBs, namely the *meta-base* part that contains the system catalog and the *data part* that contains instance data. Part 3 *"ontology"* allows representing ontologies in the database. The part 4 *"meta-schema"* is specific to OntoDB and records the ontology model into a reflexive meta-model. The presence of the meta-schema part offers flexibility of the ontology part, since it is represented as an instance of the meta-schema. We use the meta-schema in this paper, in order to store user requirements. Specific languages have been designed to query ontologies and their instances such as SPARQL or RdQL. The OntoQL language has been proposed in OntoDB project.

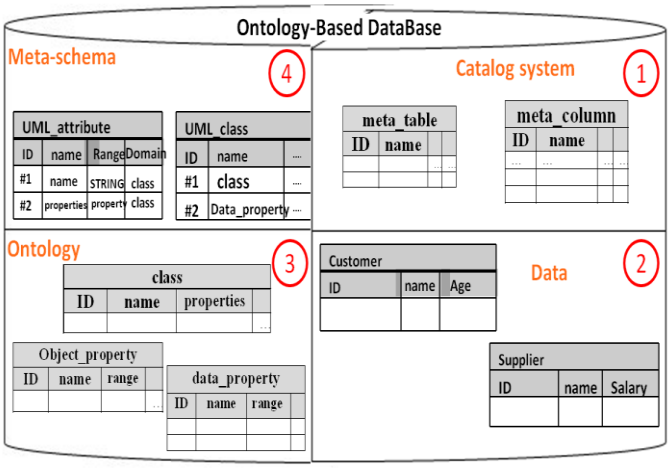


Figure 3. General architecture of OntoDB

IV. PROPOSED METHODOLOGY

We present our methodology according to the steps described in the new version of ANSI/SPARC architecture (Fig 2.b). We start by defining the requirements model proposed and its connection to the ontology model. The conceptual model defined is then translated into a relational logical model. We then present the final ontology-based data warehouse making requirements persistent. The example we follow all along the method is based on SSB *Star Schema Benchmark* (ttp://www.cs.umb.edu/~poneil/StarSchemaB.PDF) benchmark specification for DWs. The conceptual model of this benchmark is considered as our domain ontology. This conceptual model is obtained from a normalized version of SSB relational model by a reverse engineering process. Fig. 5.(C) presents the ontology model in a UML class diagram. We consider business questions provided in the specification of SSB as user requirements.

A. *Ontology and user requirements models*

The requirements model we propose follows a goal-driven approach that has been used in DW context. A goal is an objective that the system under consideration should achieve. After analyzing works of goal-oriented literature, we propose our Goal-oriented model following the GQM definition (Goal/Question/Metric): "A goal is defined for an object, for a variety of reasons, with respect to various

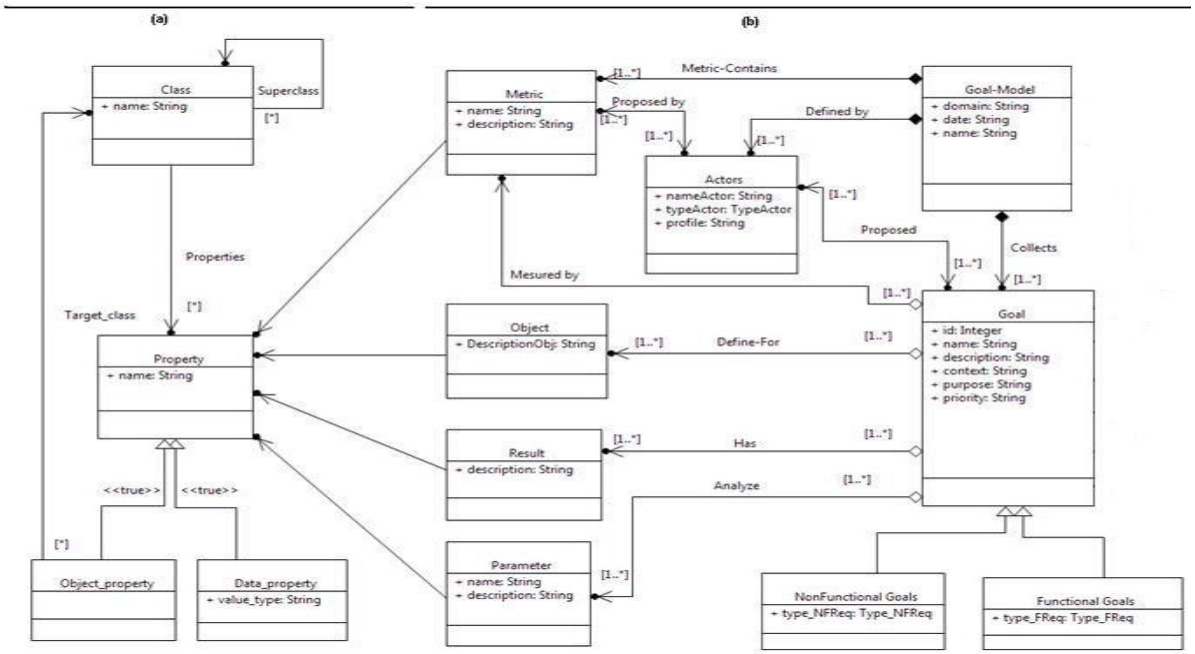

Figure 4. Requirement model (part b) connected to the ontology model (part a)

models of quality, from various points of view, relative to a particular environment".

Fig. 4.(b) presents the goal model we defined, as an UML class diagram. This model is composed of a main class *Goal-Model* that stores all *Goals*. Let us consider the first requirement of SSB specification **Goal_1**: This requirement *measures the revenue increase from eliminating various ranges of discounts in given product order quantity intervals shipped in a given year. The revenue is equal to (extendedprice*discount)*. This goal is described by the following properties: goal identifier (Id), name (Goal_1), description, purpose (*measure*) and a priority (mandatory or optional goal). Three reflexive relationships between goals are distinguished: (i)Influence relationships (positive or negative), (ii) ParentChild relationships decomposing a general goal into sub-goals and (iii) GoalRelation representing relations of conflicts, refinement, containment and equivalence between goals. A goal is characterized by three classes related to Goal class by aggregation relationships, that we call *coordinates* of the goal: a *Metric* measuring the satisfaction of a goal (*extendedprice*discount*), a *Result* to analyze (*Revenue increase*), and *Parameters* influencing the goal (*Discount, Quantity, Year*). Each goal involves one or more actors interacting with the system to fulfill the goal (eg. *Sales manager* for Goal_1).

Users' goals are expressed at the ontological level where we defined a mapping between coordinates of each goal (Metric, Result and Parameter) and the properties of the domain ontology. Designer picks from the ontology the most relevant properties to define coordinates of each goal. Those goals will be used to define the conceptual view of the DW. Fig. 4.(a) presents a fragment of the ontology meta-model connected to our goal model. Concretely speaking, meta-classes like class Goal has been created in the ontology meta-model. Coordinates of each goal are defined as object-properties which domain is the meta-class Goal, and which range is the meta-class Property.

B. Conceptual view

A conceptual view of the DW (that we call DW ontology (DWO)) is defined by extracting concepts and properties of the ontology used to express user goals. Three scenarios are possible: (1) **DWO = DO**: the DO corresponds exactly to users' goals, (2) **DWO⊂DO**: the DWO is extracted from the DO using OntoSub operator and covers all requirements, (3) **DWO ⊃ DO**: the DO does not fulfill the entire users' requirements. The designer extracts the fragment of the DO corresponding to requirements and can locally enrich it with new concepts and properties. DWO is then annotated with multidimensional concepts. DW design must follow the *multidimensional* paradigm which organizes data into central concepts called *Facts* representing the subject analyzed, and *Dimensions* representing different perspectives of analyzing the fact. Facts are generally linked to their corresponding dimensions by means of (1,n) relationships.

C. Logical level

A set of transformation rules is used to translate the conceptual model into a logical relational model. Several works in the literature proposed methods for translating ontologies described in a given formalism (PLIB, OWL, RDF) to a relational or object-relational representation. We use the set of translation rules proposed in the context of OntoDB project [3].

In our case study scenario (ontology model and requirements), the DWO was equal to the DO. The relational model defined (Fig. 6) has one main fact *Order* having the following dimensions *Customer*, *Supplier*, *Brand* and *Time*. Each dimension is divided into levels. Note that this schema covers totally the relational model of SSB benchmark (tables and attributes) after de-

normalization (i.e regrouping dimension levels into one dimension table). We have also proposed in [10] a case tool implementing these design steps.

D. *Definition of the ontology-based DW*

The DW we define is validated using *OntoDB* OBDB. OntoDB introduce the meta-schema of the ontology that we extend by the goal model in order to keep a persistent trace of requirements during the DW life cycle (Fig.7.(b)).

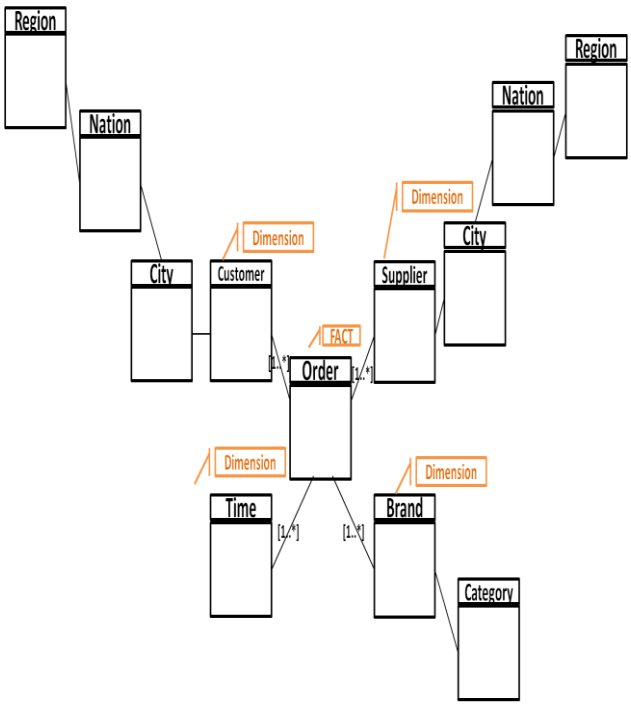

Figure 5. Multidimensional model obtained after at the design logical step

This extension is done using OntoQL statements (Fig. 7.(a)). This solution satisfies perfectly the new ANSI/SPARC architecture we revisited. The ontology layer is represented through the domain ontology. A conceptual view of the DW is materialized by storing the DWO. The requirements model is stored, on which designers rely for their different design tasks at the conceptual, logical and physical design phases.

```
Create Entity #GoalModel(#Property (#Domain String, #Name
String, #Date Date), #collects REF(#Goal))

Create Entity #Object (#its_properties REF (#Property) Array)

Create Entity #Result(#its_properties REF (#Property))

Create Entity #Metric(#its_properties REF (#Property))

Create Entity #Parameter (#its_properties REF (#Property)
Array)

Create Entity #Metric(#its_properties REF (#Property) Array)

Create Entity #Goal (#Property (#Id Int, #Name String,
#Description String, #Context String, #Purpose String),
#defined_for REF (#Object), #has REF (#Result), #Measured_by
REF (#Metric), #analyze REF (#Parameter), #concern
REF(#Actor))

Create Entity Functional_Goal UNDER #Requirement

Create Entity NonFunctional_Goal UNDER #Requirement
```

(a) OntoQL statements

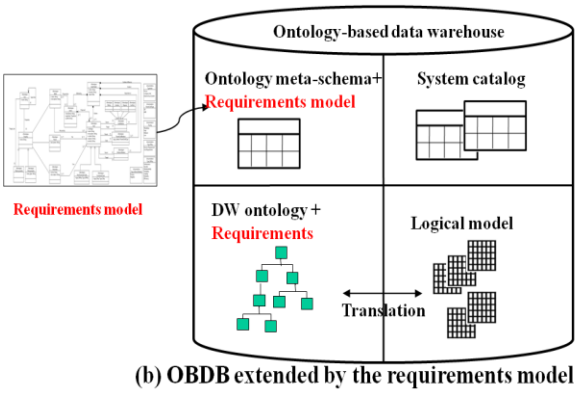
V. VALIDATION: REQUIREMENTS-DRIVEN OPTIMIZATION

We propose here to define index optimization structures from the set of specified requirements. The purpose of this step is to help the designer identifying relevant optimization structures basing on the only resource he possesses: users' requirements. The traditional index selection problem (ISP) is formalized as follows: Having on the following assumptions:

- $I = \{I_1,...,I_n\}$ set of candidate indexes (obtained from selection predicates of queries).
- $Q = \{Q_1,...,Q_m\}$ set of queries.
- S storage space allocated for indexes.

The resolution of the problem consists in finding an index configuration such that: the execution cost of queries is minimal, and the space allocated for storing indexes does not exceed S.

We adapt this problem by considering user requirements instead of queries that are not yet available at this design step. Many algorithms have been proposed to solve ISP. We follow the algorithm we proposed in [2] for selecting bitmap join indexes (BJI). We start by translating the set of requirements stored in the goal model proposed above (Fig. 4.(b)), into queries. Note that this translation is natural since an OLAP query corresponds to the definition of a goal presented above, expressed using SQL syntax. This translation is done using plugin Accelio available within Eclipse environment. Accelio provides templates for translation from Model to Model and from Model to text. We use Model to Text translation to translate each goal instance to an SQL query. We defined the following translation algorithm, applied to each goal instance:



(b) OBDB extended by the requirements model

Figure 6. OBDW: Extended OBDB of type III by the requirements model

TABLE I. INDEX GENERATED AND OPTIMIZATION RATE FOR EACH REQUIREMENT VS QUERY

Storage (GO)	***Requirements***		***Queries***	
	Index	**Cost (%)**	**Index**	**Cost (%)**
1	d_year	**46.7**	d_year	**46.7**
1.5	d_year, s_region	72.7	d_year, s_region	72.7
2	d_year, s_region, p_category	75.1	d_year, s_region, p_category	75.1
2.5	d_year, d_yearmonth, s_region	87.9	d_year, d_yearmonth, s_region	87.9
3	d_year, d_yearmonth, s_region	87.9	d_year, d_yearmonth, s_region	87.9
3.5	d_year, d_yearmonth, s_region, p_category	90.2	d_year, d_yearmonth, s_region, p_category	90.2
4	d_year, d_yearmonth, c_region, s_region, p_category	91.7	d_year, d_yearmonth, c_region, s_region, p_category	91.7
4.5	d_year, d_yearmonth, c_region, s_region, p_mfgr, p_category	92	d_year, d_yearmonth, c_region, s_region, p_mfgr, p_category	91.9
5	d_year, d_yearmonth, c_region, s_region, s_nation, p_category	92.7	d_year, d_yearmonth, c_region, s_region, s_nation, p_category	92.6

SELECT Properties used as (Result or Metric) in the goal model

FROM Properties used as (Objects) in the goal model

WHERE Properties used as (Parameter) in the goal model

We adapted algorithm proposed in [2] by considering queries obtained from user requirements. The algorithm is based on the following inputs: workload of queries (extracted from requirements), a given storage space, selection attributes and data of the cost model. Those data are: size of the fact table, attributes cardinalities, size of a fact tuple, size of a page system, frequency of execution of each query. All these data can be estimated at the logical level. We consider for the frequency of execution of each query the number of actors formulating the corresponding requirement. For simplicity reasons, we assumed that frequency is equal to 1 for each requirement. The algorithm proposed a set of indexes that we compared with the real set of queries (workload) provided by SSB benchmark. Table 1 summarizes obtained results and shows this comparison. We notice that the set of indexes generated from the set of requirements, covers the set of indexes generated from queries of the benchmark. We demonstrated here that some relevant optimization structures can be proposed by designers from the logical level.

VI. CONCLUSION

DBs and DWs usually follow the ANSI/SPARC architecture during their design, consisting in three layers: conceptual level assumed by designers, logical level based on a set of translation rules and physical level assumed by DBA. This design levels relies on elicitation and analysis of user requirements. In this current architecture, two issues are noticed: (i) the role of DBA is constantly minimized by the introduction of administrator tools, (ii) user requirements represent the most valuable information on which designers rely for their task but no trace of those requirements is stored in the final DB/DW structure. ANSI/SPARC architecture has already been extended by the introduction of an ontological level. Due to their similarity with conceptual models, many DB and DW methods have used ontologies as a first level of specification. We proposed a new ANSI/SPARC version and a methodology for reconsidering the role of designers and making requirements persistent. We propose a requirements-driven optimization process as validation. The final DW materializes the requirements model, the conceptual DW and the logical model. As perspectives, we project to study new optimization structures based on requirements, to consider other types of requirements like non functional requirements and to study the evolution of requirements on the DW management.

How Cloud Computing Is (not) Changing the Way We Do BI

Arian Stipić and Tomislav Bronzin

arian.stipic@in2.hr, tbronzin@citus.hr

Abstract - Cloud computing and BI (Business Intelligence) are technologies of choice to address today's business needs. They allow companies to optimize IT and become more competitive and productive. Implementing BI solutions in the cloud brings not just benefits, but also new challenges that need to be addressed. On technology side there are security, communication infrastructure (increasingly mobile) and speed. New technology and business models are arising because we are dealing with large quantities of distributed data which BI can (and often have to) use as new sources of information. Combining these data sources with new cloud services may significantly change the way some businesses are being run today. In order to do that successfully, we have to understand the basic principles of solution architectures in the world dominated by clouds. The new idea presented in the paper is that two additional types of service models, specifically the DaaS (Data as a Service) and AaaS (Analysis as a Service) will be widely used in cloud environments in very near future. The paper also addresses the "marriage" of cloud and mobile computing, entirely new area crowded with business and IT opportunities and new models that might be used to create and implement BI using private, public and hybrid cloud solutions.

I. INTRODUCTION

It is always a good idea to have a reasonable level of understanding about the meaning of any new term or acronym coming from rapidly developing IT technologies. It helps avoiding many common misunderstandings and focuses all parties in the discussion to more or less same mindset. And of course, the best way to do it is to try to define things in order to be able to compare arguments in the later discussion with the proposed definition. That is why we are going to do the same thing at the very beginning of this paper.

Cloud computing is relatively new concept and, typically for all new concepts in the industry, it is not always commonly (or sometimes even properly) understood and interpreted. Depending on whom you may be talking to, you are most likely to get quite a lot of different answers about the cloud computing, not all of them mutually consistent. Therefore, let us adopt the following NIST (*National Institute of Standards and Technology, USA*) definition [1] from September, 2011 released in its "Special Publication 800-145":

> *"Cloud computing is a model for enabling ubiquitous, convenient, on-demand network access to a shared pool of configurable computing resources (e.g., networks, servers, storage, applications, and services) that can be rapidly provisioned and released with minimal management effort or service provider interaction. This cloud model is composed of five essential characteristics, three service models, and four deployment models."*

This is a very short but also very important document and there is one very peculiar thing about this definition. Interestingly enough, it's not about what is enclosed in the definition, but rather about what is left out of it. If you take a good look you will find out that the definition describes hardware and software but it never says anything about the data. That's strange for several reasons. First of all, there is no application that does not process some kind of a data and that data has to be carefully collected and stored somewhere. Once you have a cloud it is very likely that data will be stored there also. In fact, even today you can see many clouds that only seem to serve as data storage. And, of course, there are some differences in handling all kinds of data when we speak about clouds.

Later in this paper we will introduce two significant extensions to the definition's existing content and explain the reasons for doing that. But, before we do it, it is important to explain what cloud really is and what characteristics does it have.

II. THE CLOUD EXPLAINED

According to the NIST definition there are three (3) different areas that really define the essence of cloud computing and differentiates it from the other existing computing models. They are:

1. Essential characteristics
2. Service models, and
3. Deployment models

Today's prevailing opinion describes a cloud as computing architecture and environment that has several essential characteristics:

- **On-demand self-service** - A consumer can unilaterally provision computing capabilities, such as server time and network storage, as needed automatically without requiring human interaction with each service provider.
- **Broad network access** - Capabilities are available over the network and accessed through standard mechanisms that promote use by heterogeneous thin or thick client platforms (e.g., mobile phones, tablets, laptops, and workstations).
- **Resource pooling** - The provider's computing resources are pooled to serve multiple consumers using a multi-tenant model, with different physical and virtual resources dynamically assigned and reassigned according to consumer demand. There is a sense of location independence in that the customer generally has no control or knowledge over the exact location of the provided resources but may be able to specify location at a higher level of abstraction (e.g., country, state, or datacenter). Examples of resources include storage, processing, memory, and network bandwidth.
- **Rapid elasticity** - Capabilities can be elastically provisioned and released, in some cases automatically, to scale rapidly outward and inward commensurate with demand. To the consumer, the capabilities available for provisioning often appear to be unlimited and can be appropriated in any quantity at any time.
- **Measured service** - Cloud systems automatically control and optimize resource use by leveraging a metering capability at some level of abstraction appropriate to the type of service (e.g., storage, processing, bandwidth, and active user accounts). Resource usage can be monitored, controlled, and reported, providing transparency for both the provider and consumer of the utilized service.

Probably the most distinguishing (and too often poorly understood) thing about the cloud is the notion of service models. The service model is delivery of some aspect of computing as a service as opposed to being a product. It provides computation, software, data access, and storage resources without requiring cloud users to know the location and other details of the computing infrastructure. NIST definition explicitly states these three (3) service models (without going into the description of this models, as authors presumes that they are matter of general knowledge in IT):

- **Software as a Service (SaaS)**
- **Platform as a Service (PaaS)**
- **Infrastructure as a Service (IaaS)**

In reality, SaaS is just a licensing structure. Many vendors (open source, for example) offer SaaS software subscription models, which has nothing to do with cloud-based hosting. Cloud, on the other hand, should be all about multitenant software hosted on public or private clouds. It's not about cloud hosting of traditional software architected for single tenancy.

Having all that in mind we can describe business intelligence cloud-based SaaS as:

> *"BI platforms and solutions specifically designed and architected for multitenant hosting in public/private clouds. These platforms and solutions are often licensed on a subscription (SaaS) basis because the nature of their architecture and purpose often do not warrant capital investments and perpetual licenses."*

Finally, there is a cloud and there is a cloud. Not all clouds are equal, not only in capabilities and size but also in their primary target audience. This aspect of cloud computing is called a deployment model. There are four (4) different cloud deployment models:

- **Private cloud** - The cloud infrastructure is provisioned for exclusive use by a single organization comprising multiple consumers (e.g., business units). It may be owned, managed, and operated by the organization, a third party, or some combination of them, and it may exist on or off premises.
- **Community cloud** - The cloud infrastructure is provisioned for exclusive use by a specific community of consumers from organizations that have shared concerns (e.g., mission, security requirements, policy, and compliance considerations). It may be owned, managed, and operated by one or more of the organizations in the community, a third party, or some combination of them, and it may exist on or off premises.
- **Public cloud** - The cloud infrastructure is provisioned for open use by the general public. It may be owned, managed, and operated by a business, academic, or government organization, or some combination of them. It exists on the premises of the cloud provider.
- **Hybrid cloud** - The cloud infrastructure is a composition of two or more distinct cloud infrastructures (private, community, or public) that remain unique entities, but are bound together by standardized or proprietary technology that enables data and application portability (e.g., cloud bursting for load balancing between clouds).

III. THE DATA ISSUES

The NIST definition does not say anything about the data in the cloud computing. We believe that it leaves the opportunity to extend the definition with at least two additional elements of the service model that specifically address data in the cloud environment. When speaking about the data contained in the cloud, we can safely reduce the previous four deployment models to only two possible variations: public and private clouds.

Public clouds would either store or otherwise make available public data, either in form of a commercial

service or available free of any charge. Virtually anyone would be able to access that data and some of the services would even allow the consumers to actually download the selected portions of the data and use it in its own BI environment as a valuable extension to its own data. The typical example of public cloud data would be various governmental and statistical data that is being produced in every single country.

Private clouds, on the other hand, provide the very same type of services but with a difference: the data available in these clouds are not accessible to everyone who asks or pays for it. There are all kinds of data that might be stored in private clouds: from individual files (music, videos, movies, documents …) to corporate information (data-marts, reports, documents…) and all the way up to sensitive governmental (sometimes even secret) information that needs to be available only under very strict security restrictions.

It is quite obvious that when data is concerned, the two types of cloud environment are very much different even when they may be technically identical. Therefore, we believe that this data issue has to be somehow included in the service model definition.

Everybody in the industry knows the reality of existing clouds: there are some services available (i.e. Windows Azure Data Market) that offer not only software services (SaaS) but also a separate data services. It is, completely in accordance with current cloud terminology, called **DaaS** (*Data as a Service*). So, the DaaS concept is already here and it has a very bright perspective for future growth.

We all understand that there is a big difference between software and data. Companies are always in search for better software to help them with their business, but ultimately it's the data that defines the company. It contains their past, their present and, sometimes, determines their future. Therefore the **DaaS** should be the first addition to the NIST service model definition. An important future development might be the integration of some *publicly collected and maintained* data that might then be used in most enterprise as well as commercial applications. Some examples of this would be census data, traffic data, statistical data and so on. The point here is that some very complex parts of maintaining Master Data[7] can be delegated to some other authorities and then simply used as a cloud service. In the standard SOA model this is sometimes called **DMaaS** (*Data Management as a Service*) and it is not restricted to clouds.

As BI is becoming more complex, an analytical approach can be applied to almost any sort of information, regardless of volume, format and origin. We can see that businesses are gravitating to the mobile tablet computer market, which, combined with cloud computing technologies, opens up a whole new wealth of information to the BI system, where by the mobile workforce can work just as efficiently. This situation produces steadily increasing need for transforming data into usable information which can only be served by applying some meaningful analysis and suggesting the appropriate interpretation of the results of this analysis.

We see a huge potential for services that may fill this part of the market. They may be very generic or very specific in nature but whatever the case might be, they must process some data and therefore, they need to closely cooperate with **DaaS** type of cloud services. This brings us to the second extension of the NIST service model definition and that is **AaaS** (*Analysis as a Service*).

While DaaS (although not mentioned in the NIST definition paper) already exists for some time now, AaaS is entirely new concept in the cloud computing and it is also the central suggestion of this paper. The idea behind it is really a very simple one. There is rapidly growing amount of data out there and a large portion of it is sure to have a very short lifetime. However, people are interested in the information hidden within all those data and someone should be able to deliver that information in form of analysis performed on the selected (or available) portion of data. Of course, great volume, huge variety of data and infinite number of potentially interesting combinations require many different types of analyses to be performed. Consequently, it is very likely that there will be a large number of such AaaS services in all kinds of clouds in the near future.

IV. BI IN THE CLOUD

Cloud or no cloud, BI is always very similar. All "BI aware" corporations and institutions use more or less the same patterns and methods in order to use many powerful BI capabilities to help them run their business. All of them have their own data (lots of data!) and they build their data warehouses and data marts and they use them to analyze this data using all kinds of tools and applications. The very same thing happens when they start using the cloud infrastructure. However, clouds are somewhat different from traditional environments and there are some specifics that need to be understood. The most important is the difference between public and private clouds.

Generally speaking, there are at least these six (6) options available for building "Standard BI" or the "BI in the cloud" type of the solution:

1. Dedicated hardware based BI system (not really a cloud; this is what most companies have today)
2. Private cloud based BI system running internally
    a. It is still not clear what the real TCO for private cloud solutions is.
    b. It is still very early for BI deployments on internal private clouds. There are some initial solutions on the market based on the "appliance model" of the HW & SW combinations (Microsoft, IBM Cognos, Microsotrategy…).
    c. Most probably the very large data warehouses and complicated ETL tools and procedures will not dominantly leave the standard IT infrastructure, but some parts of the data (DaaS) and some parts of the analysis (AaaS) will be made available in the cloud environment.

3. Public cloud based IaaS for a BI system
    a. subscribe to an IaaS vendor (Savvis, Amazon, Microsoft, Rackspace, GoGrid…) with "pay as you use" model on hardware and systems software and then buy and deploy your own ETL, DBMS and BI software
4. Public cloud or externally hosted BI/DW PaaS for building your own cloud-based BI system (could be a multi-vendor or single-vendor BI PaaS offering)
    a. Build BI/DW platform as a Service (PaaS) option on public (or even externally hosted) cloud.
    b. An example of a multi-vendor option might be the combination of the RightScale, Talend, Vertica and Jaspersoft PaaS offering on Amazon EC2.
    c. An example of single vendor solution might be SAP BusinessObjects On-Demand, Birst, Indicee, PivotLink or similar.
    d. A key question here is: "Is Data Integration included?" and how are you going to handle it in your solution.
5. Public cloud or externally hosted SaaS BI packaged analytical applications
    a. This is a fast growing market with many new (Cloud9 Analytics, Rosslyn Analytics, Lixto…) as well as traditional mainstream vendors (SAS, IBM Cognos...). These are pre-built solutions ready to be used, primarily interesting for small and medium businesses (SMBs), but also for some specific lines of business in large organizations.
    b. This option has the most potential for rapid implementation and integration of DaaS and AaaS as a part of the solution.
6. Public cloud or externally hosted SaaS BI for operational reporting on cloud based operational data
    a. This is typically a cloud based reporting system on operational data from a cloud based transaction processing system such as SalesForce.com which is dominant in this area. An example could be CrystalReports.com for SalesForce.

On the public cloud we have a complete set of possibilities; from plain IaaS (*Infrastructure as a Service*) all the way through to SaaS (*Software as a Service*) based packaged analytic applications. Obviously, it is the inclusion of the public clouds that makes things complicated. It should be noted that all scenarios at least implicitly open the doors for DaaS (*Data as a Service*) and AaaS (*Analysis as a Service*) service models.

What kind of services can we expect in the cloud environment? Well, the obvious answer would be: "All of them!" meaning everything that we already have in traditional BI environments. And then some. This is probably not very realistic (maybe even not desirable) but it is certainly the truth that some entirely new areas are emerging with the introduction of cloud computing. Maybe the three (3) most important ones are:

1. We can now gain access to large quantities of both structured and non-structured data (sometimes even from various sources).
2. Even some short-living data may become the source for the complex analyses. The data will be discarded but the analysis based on it may live on for a considerable period of time.
3. There is a rapidly growing need for both globally standardized (*Semantic Web*) and individually shaped[5] (*Guardian Angels*) metadata that might be dynamically created by analyzing associative context relations among data.
    a. Metadata is information that allows organizing, indexing, finding and using content. Metadata can exist at many levels ranging from simple descriptions of a thing or event, to observations of feelings about the thing or event and introduced by an observer, to statements or expressions of meaning or intention. Types of metadata and their independent or contingent relationships evolve with time.

Another important consideration here might be the fact that the role of metadata (and associated business context) is probably going to become more and more important over time. The majority of architectural problems are caused by data, the rules of data exchange between different systems, the interpretation and manipulation (analysis) of that data on different platforms and the intrinsic lack of some kind of common framework that would facilitate the understanding of the actual meaning of some data. Cloud computing promises better connectivity of all kinds of data but this can also become the source of huge problems because differently structured (or unstructured!) data may actually describe some very similar patterns. Therefore, we must find a way to somehow standardize the process of generating and manipulating the metadata in order to recognize similar data in otherwise very different systems

Most of these new opportunities result in entirely new areas like "*Data Science*", and the root of most of them is the fact that we have to face new issues with (very unstructured, very large in quantity and very unpredictable in nature) various data on a daily basis.

If we had to sort out a single most important difference between traditional and cloud environment, that it would most certainly have to be the data itself. Lots of data. Very large data warehouse may contain 100 terabytes (10^{12}) of data but that is still much less than the amount of data stored in Facebook (>15PB), for example. In such cases we are speaking in terms of petabytes (10^{15}), and the amount of data being used in some kind of analysis is still rapidly growing up. Very soon we shall start talking about exabytes (10^{18}) or even zettabytes (10^{21}) of data as the next frontier. Just for a comparison, the adult human brain has been estimated to store a limit of up to 2.5 PB of binary data equivalent.

Table I lists some interesting facts about existing PB cases today.

TABLE I: EXISTING PB CASES TODAY

Year	*Example*	*Size (PB)*
	adult human brain	2.5
1986	The world's effective capacity to exchange information through two-way telecommunication networks (optimally compressed size)	281
1993		471
2000		2,200
2007		65,000
2008	Teradata Database 12 compressed capacity	50
2008	AT&T network transfers (per day!)	20
2009	Google processing (per day!)	25
2009	Large Hadron Collider production (per year)	15
2009	World of Warcraft (game)	1.5
2009	Avatar 3D rendering	1
2009	German Climate Computing Center (DKRZ) storage capacity for climate data	60
2010	BBC's iPlayer (used bandwidth per month)	7
2011	Internet Archive	6
2011	IBM have built the largest storage array ever	120
2012	Cray began construction of the Blue Waters Supercomputer	500

Obviously, the race for ever increasing sizes of data and memory continues at a very fast pace. Scientists regularly encounter this problem in meteorology, genomics, connectomics, complex physics simulations, biological and environmental research, Internet search, and finance and business informatics. New data provokes new requirements, new requirements result in new metadata, new metadata result in new analyses and all of that ultimately produces: some more new data.

This entirely new territory is popularly called the "Big Data". It is expected to become one of the most important areas of computing within the next few years and we shall briefly discuss it in the next section.

V. THE "BIG DATA" CHALLENGE

Today, the so called "Big Data" is one of the hottest topics in the industry today. It exceeds the processing capacity of conventional database systems; it is too big, moves too fast and often doesn't fit the structures of conventional database architectures. Big data consists of datasets that grow so large that they become awkward to work with using on-hand database management[8] tools. Difficulties include capture, storage, search, sharing, analytics and visualizing.

We have already seen some real-life big data numbers and let's have some more of it here. There are more people interacting with data or information than ever before. Between 1990 and 2005, more than 1 billion people worldwide entered the middle class which means more and more people who gain money will become more literate which in turn leads to information growth. Cisco predicts that the amount of traffic flowing over the internet will reach 667 exabytes annually by 2013.

Big Data can be seen as a multi-phase problem including the acquisition, organization, storage, and analysis of large amounts of data originated in various sources and coming in multiple formats.

Although most of the sources only discuss the first three[9] V's form the list, according to Forrester Research, big data can be described by these four (4) independent dimensions (the so-called *"4 V's"*), as described in Table II.

TABLE II: FORRESTER'S 4V'S DIMENSIONS

(1) Volume	As we already saw in the previous section, the volume is typically measured in range of petabytes, although you may face somewhat smaller amounts (100's of TB) of data that exhibit all other characteristics usually associated with big data
(2) Velocity	The big-data may often be time-sensitive and must be used as it is streaming in to the enterprise in order to maximize its value to the business. We can clearly see the increased point-of-interaction (POI) speed. POI performance is increasingly perceived as a competitive differentiator (Web site response, inventory availability analysis, transaction execution, order tracking update, product/service delivery…)
(3) Variety	Big data extends beyond structured data, including unstructured data of all varieties (text, audio, video, click streams, log files and more)
(4) Variability	The same data can have different meanings and format over different time periods

The potential for analytical use of big data is in the focus of interest for this paper and the most important questions here are:

- How well are traditional (DB, storage, analytical tools…) technologies suited for the big data problems?
- Is the cloud a proper environment to work with big data?

Big data requires exceptional technologies to efficiently process large quantities of data within acceptable processing speed. Technologies being applied to big data include massively parallel processing (MPP)

databases, data mining grids, distributed file systems, distributed databases, cloud computing platforms, the Internet, and scalable storage systems. Most of the items from this list will not be found in any standard IT environment but this is about to be changed.

The first thing that has been noticed about big data was gained as experience from early installations that encountered data problems of this size. Google, Facebook and similar service providers have been on the very front of this wave. Very soon they found out that some of the traditional technologies that worked (and are still working!) well in standard environment do not work that good in the world of big data, especially in the cloud environment.

The majority of traditional data warehouses run on some relational or a columnar database and the most BI tools use SQL to access data from these DW. These databases are not designed to run natively on the cloud. On top of that, the optimizations performed on these DW such as horizontal partitioning (*database sharding*), indices, compression etc. don't translate well into the cloud either since cloud is a horizontally elastic scale-out platform and not a vertically integrated, scale-up, system. Therefore, traditional SQL-based databases and multidimensional OLAP databases may not be the best choice for the big data in the cloud. Big players like Microsoft, Oracle, IBM and some others are working on redesigning their products to fit into this new environment, but in the meantime, many new ideas have been realized and used in practice.

The technical foundation of this brave new world of big data bases its stronghold on two levers:

1. **Apache Hedoop** - distributed (node-based) file system which, paired with the Google ReduceMap programming framework, represent the basis for big data infrastructure, and
2. The so called **NoSQL databases** – a new breed of simplified DB products specifically aimed at big data scenarios

One good example of such infrastructure would be Hortonworks Data Platform announcement represented in the Figure 1 (source: Hortonworks web & presentations).

The two gray rectangles (**HDFS** and **MapReduce**) represent the core Apache Hedoop elements and everything else is some kind of specific platform extension. Let us briefly explain all elements here.

HDFS (Hedoop Distributed File System) is the primary storage system used by Hedoop applications. HDFS creates multiple replicas of data blocks and distributes them on compute nodes throughout a cluster to enable reliable, extremely rapid computations.

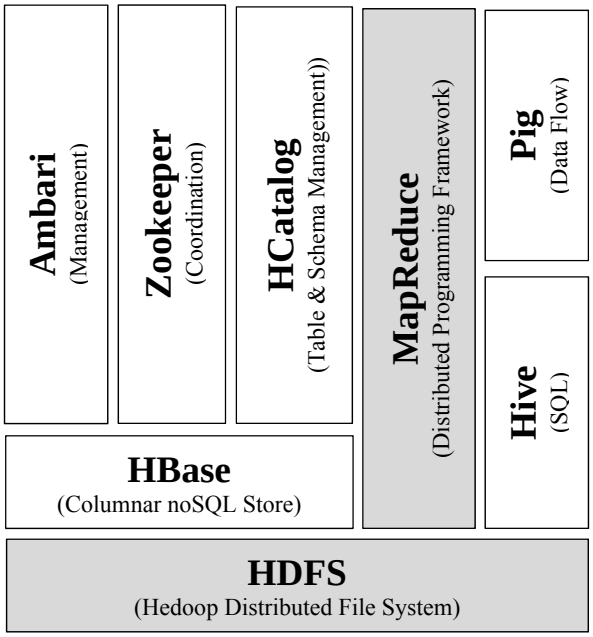

FIGURE 1. HORTONWORKS DATA PLATFORM

MapReduce is a framework for processing highly distributable problems across huge datasets using a large number of computers (nodes), collectively referred to as a cluster (if all nodes use the same hardware) or a grid (if the nodes use different hardware). Computational processing can occur on data stored either in a filesystem (unstructured) or in a database (structured). The two steps in the MapReduce process are:

- **Map** - the master node takes the input, partitions it up into smaller sub-problems, and distributes them to worker nodes. A worker node may do this again in turn, leading to a multi-level tree structure. The worker node processes the smaller problem, and passes the answer back to its master node.
- **Reduce** - the master node then collects the answers to all the sub-problems and combines them in some way to form the output – the answer to the problem it was originally trying to solve.

MapReduce allows for distributed processing of the map and reduction operations. Provided each mapping operation is independent of the others, all maps can be performed in parallel – though in practice it is limited by the number of independent data sources and/or the number of CPUs near each source. Similarly, a set of 'reducers' can perform the reduction phase - provided all outputs of the map operation that share the same key are presented to the same reducer at the same time. While this process can often appear inefficient compared to algorithms that are more sequential, MapReduce can be applied to significantly larger datasets than "commodity" servers can handle - a large server farm can use MapReduce to sort a petabyte of data in only a few hours. The parallelism also offers some possibility of recovering from partial failure of servers or storage during the operation: if one mapper or reducer fails, the work can be rescheduled – assuming the input data is still available.

Hive is a data warehouse system for Hedoop that facilitates easy data summarization, ad-hoc queries, and the analysis of large datasets stored in Hedoop compatible file systems. Hive provides a mechanism to project structure onto this data and query the data using a SQL-like language called HiveQL. At the same time this language also allows traditional map/reduce programmers to plug in their custom mappers and reducers when it is inconvenient or inefficient to express this logic in HiveQL.

Pig is a high-level data-flow language and execution framework for parallel computation. Pig offers SQL-style high-level data manipulation constructs which can be assembled in an explicit dataflow and interleaved with custom "Map and Reduce" style functions or executable. Pig programs are compiled into sequences of Map-Reduce jobs, and executed in the Hedoop Map-Reduce environment. Both Pig and Hedoop are open-source projects administered by the Apache Software Foundation.

HBase is an open source, non-relational, distributed database modeled after Google's BigTable and is written in Java. It is developed as part of Apache Software Foundation's Apache Hedoop project and runs on top of HDFS providing BigTable-like capabilities for Hedoop. It provides a fault-tolerant way of storing large quantities of sparse data.

HCatalog is a metadata abstraction layer for referencing data without using the underlying filenames or formats. It insulates users and scripts from how and where the data is physically stored.

ZooKeeper is a centralized service for maintaining configuration information, naming, providing distributed synchronization, and providing group services. All of these kinds of services are used in some form or another by distributed applications. Each time they are implemented there is a lot of work that goes into fixing the bugs and race conditions that are inevitable. Because of the difficulty of implementing these kinds of services, applications initially usually skimp on them, which make them brittle in the presence of change and difficult to manage. Even when done correctly, different implementations of these services lead to management complexity when the applications are deployed.

Ambari is a monitoring, administration and lifecycle management project for Apache Hedoop clusters. Hedoop clusters require many inter-related components that must be installed, configured, and managed across the entire cluster.

Just as an illustration of how far has all this gone today, Figure II shows client connectivity with **Cloudera** (another Hedoop oriented company) platform for **Tableau 7.0** (one of the leading vendors in the area of traditional BI tools) product.

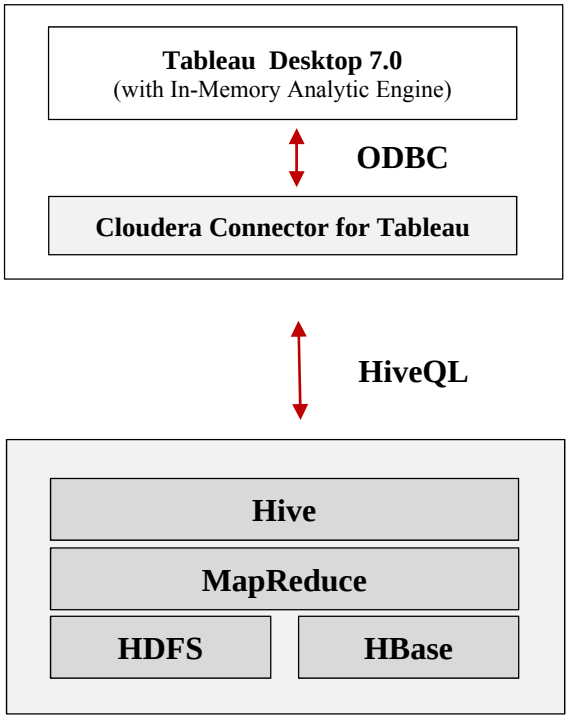

FIGURE 2. CLOUDERA CLIENT CONNECTIVITY

To gain value from this data, we must choose an alternative way to process it. Its value to some organization falls into two categories:

1. Analytical use, or
2. Enabling new products

Although Big Data Analytics systems insist on system performance, commodity infrastructure, and low cost, it is usually connected with big money, too. There should be no surprise about this because useful analysis of some problem that has big data associated with it may reveal some alternative approaches and improvements that will ultimately save some money in the process. As big data is all about big numbers, the small savings may quickly accumulate to very significant amounts of money. There are many examples of this, but one of the most convincing is about the U.S. power grid. At some places it is over 100 years old, outdated and not at all flexible and adjusted to actual needs. According to the U.S. Department of Energy, if the existing grid was only 5 percent more efficient "*The energy savings would equate to permanently eliminating the fuel and greenhouse gas emissions from 53 million cars*". And that, by any standard imaginable, is very, very big money indeed.

The phenomenon of big data is closely tied to the emergence of data science, a discipline that combines math, programming and scientific instinct. Benefiting from big data means investing in teams with this skillset, and surrounding them with an organizational willingness to understand and use data for advantage.

VI. CLOUD & MOBILE, A MATCH MADE IN HEAVEN

It is very interesting effort to compare two very different things like mobile computing and cloud computing. We all know that mobile devices are small and therefore we "feel" that mobile computing does not involve very big and complex architectures and infrastructure. A very common perception is that a cloud has to be "something big" while mobile has to be "something small" and that the two of them do not have much in common. It is not entirely false but it would be very wrong to draw conclusion that there is no place for mobile computing in the "cloudy" world. As we shall see shortly, it is quite the opposite.

Let us start with some pretty obvious argument. First of all, a mobile application, especially mobile BI application, has to work with some kind of data. The data might be temporarily stored locally for performance reasons, but most probably it will reside somewhere else. The exact location may depend on the nature of the data, security constraints and the purpose of the application.

We believe that it is very important to acknowledge that this data may not always come from the same place. In standard computing environments and architectures this data would probably be somehow centralized in a single place. If we are dealing with large companies or a public sector this would typically be some well-maintained data warehouse (or a data mart) with highly structured data. But it is also increasingly probable that our application (or at least some particular request) may not work well if it does not have an access to other, mainly unstructured data as well. We can also see a need for a mobile application to present (visually properly formatted and displayed to the end user) information that may be very limited in amount (perhaps a couple of rows or even a single number) but still extremely useful from a business perspective. A complex trend calculation may be an example of this kind. It would be impossible to run this calculation on a mobile device itself, but it is entirely possible to do it in background and return the results back to the mobile client. Granted, we do not need a cloud for that but, if you remember, earlier in this paper we have already introduced the concepts of **DaaS** and **AaaS** as proposed extensions to the NIST definition.

Having that in mind, there is absolutely nothing that may be preventing mobile clients to use these very same types of cloud services. On the contrary, we believe that mobile clients are very likely to be among the first to do that.

What types of business problems should be addressed with "mobile in the cloud" solutions? It should not be too complicated to identify the candidates. The variety of potentially interesting data, its wide dispersion and possibly high volume (as in the case of "big data" discussed earlier) makes an excellent case for bringing together the cloud architecture of distributed data and services and needs of mobile clients.

Recognizing potentials is just the first step on the path towards successful "marriage" between mobile and cloud world. It can be considered as an "engagement" but for a complete success it has to be followed by the next step which is, of course, identifying actual opportunities. Therefore, in order to complete this promising "relationship" between mobile and cloud computing, we must answer at least the following question: "*What types of cloud usage scenarios and accompanying services (existing or still non-existing) will be most important in the near future?*"

We believe that there are at least four (4) very different usage scenarios here:

1. Accessing some kind of corporate data
2. Accessing combined data compiled together from different origins (possibly different clouds); most probably it would be in the form of an analysis (the actual result could even be a single number!) of some kind that is otherwise not available because you need a specialized DaaS & AaaS services in order to perform and deliver the results of such analysis
3. Accessing all kinds of highly distributed data generated within different social (both public and private) networks
4. Storing data that has originated on mobile devices (most probably tablets) in the cloud

The first case of corporate data is something that's going to be increasingly important, especially in various self-service BI scenarios. This is already being done for some time and we believe that this trend is going to continue in the future. One of the most promising areas here might be within various CRM implementations that are gaining in popularity in the last couple of years.

The combined "multi-cloud" scenario is highly important for making strategic business assessments in a very short period of time. We are speaking about specialized services that are able to provide both data (coming from several or even many different sources) but also some insight to that data (the analysis) to the end users who are willing to pay for this kind of a service. This scenario may have the characteristics of cooperative BI in a sense that companies may be willing to (anonymously) share some important information with all other participating companies (most probably from the same vertical industry) in order to get accurate comparisons of various performance indicators. That, of course, is the cornerstone of the benchmarking process.

It should also be pretty obvious that mobile devices may often be used to access data that is not primarily of the corporate nature (related to your business) but, instead, individuals may be more interested in exploring data that are generated within the operations of various social networks, for example. Those cases are often referred to as "*Social Intelligence*", a specific BI domain that primarily analyzes this kind of information. It is often the case of large volume data, potentially sometimes even a "big data" with a short-term validity or availability.

Finally, the last case is significantly different from the previous three because instead of pulling data and results from the cloud to the mobile device, it does exactly the opposite: transfers the collected data from the mobile device to the cloud.

Some of these scenarios (case 1) are already being exploited, not necessarily in the cloud environment, but this is only a matter of time. The advancements in available mobile client technologies will further broaden the availability of this kind of solutions. Some other scenarios (case 2) are only partially available and the reason for that is twofold: we are still speaking about emerging technologies (cloud computing is still in its very early stages) and many companies are simply not ready yet to expose its data to the mobile devices, let alone to actively participate in cooperative BI efforts mentioned earlier. However, this is also just a matter of time because companies around the world are rapidly [2] implementing all kinds of mobile BI solutions.

And finally, we already see the enormous interest of (prevalently young) individuals from all around the world in various aspects of social networking. Very large amount of both structured and unstructured data is being collected every single day but there is still very little support for integration and analysis of this data. If you keep in mind that smart phone is becoming the preferred way to access the social network it is only logical that this same device become not only the main source of data about the users participating in the same social networks but also a principal consumer of the analysis performed on that very same data (cases 3 & 4).

There are quite a few additional services available for some of the existing social networks (mostly for "Tweeter") and some of them offer various analytical capabilities that can be considered as an example of the early stage of true AaaS expected in the future.

Data is tamed and understood using computer and mathematical models. These models, like metaphors in literature, are explanatory simplifications. They are useful for understanding, but they have their limits. A model might spot a correlation and draw a statistical inference that is unfair or discriminatory, based on online searches, affecting the products, bank loans and health insurance a person is offered, privacy advocates warn.

However, new opportunities also bring new dangers. Big data can be very useful, but it can also easily be misunderstood and misinterpreted, sometimes with malice. Just by having a huge amount of data does not mean it is more worthy than much smaller, carefully chosen set of representative data. Not everything can be properly explained only by using statistical methods, no matter how advanced they might be.

VII. CONCLUSION

Cloud computing is becoming very popular as it promises higher availability and scalability at a lower cost. This may not always be true and there are many complex issues involved in your decisions, whether you are offering cloud services, using them or developing software to be used in a cloud environment. In any case, we must understand the definition of the cloud as well as what is missing from it.

If we accept the cloud computing as next step along the path of distributed computing it will immediately become apparent that the definition should be somewhat altered to accommodate for new types of service models that have not been incorporated in the existing NIST definition. This paper specifically proposes two such extensions, DaaS and AaaS that already are or will become very important in the near future. Both of them are derivatives of a simple fact that data (and the ability to analyze those data) should somehow be recognized as important element in cloud computing. That brings us to the second major point affecting BI in the cloud: the big data story.

Naturally, BI cannot be left behind these new trends and it is important to understand not only what the cloud is, but also what kind of new challenges it brings to the picture, how is it different from standard environment and what are the implications on the application and overall solution architectures.

Finally, it is interesting to see how two seemingly different worlds, the world of interconnected clouds and the world of mobile devices may fit perfectly together. Even more interesting (and important) is the fact that it is BI in combination with both DaaS and AaaS that will mostly benefit of this unexpected marriage.

Some Aspects of Information Systems Integration

Mladen Varga, Katarina Ćurko

mvarga@efzg.hr, kcurko@efzg.hr

Abstract: The paper describes several increasingly important aspects of information systems integration, of which data integration is given most attention. The common techniques of data integration, such as data consolidation, data federation and data propagation are discussed. Avoiding information inconsistency in the process of data integration can improve data quality. Among the important features of an integrated information system special attention is devoted to the close-loop between the operational and analytical part that can be achieved with an active data warehouse.

I. INTRODUCTION

An enterprise's information system plays an important role in achieving enterprise integration. In an information system integration can be accomplished at various levels: data, business process, application, or user interaction [15]. Data integration provides a unified view of the business data of an enterprise, business process and application integration provides a unified view of enterprise's business processes and applications, and user interaction provides a single personalized and secure interface to data, processes and applications.

The purpose of the paper is to discuss some aspects of information systems integration. Section II defines the information system, its purpose and components. Section III describes the main, though not all, aspects of data integration. General aspects of the whole information system integration are described in Section IV. Section V describes how the information system's close-loop may provide operational intelligence.

II. INFORMATION SYSTEM

An information system is a subsystem of the organizational system whose task is to link processes on the operational, management and decision-making level. Its goal is improving performance efficiency, supporting good quality management and increasing decision-making reliability [2]. It is a complex system that has to fulfil all informational tasks related to the operational, management and decision-making activities of the enterprise. Effective integration of operational and analytical (sub)systems of an enterprise's information system [14] can be crucial for the success of the enterprise's business.

The *operational* (transactional) *subsystem* is responsible for the executing of transactions of the enterprise's business processes. Transactions insert, update, or in any other way process data in an operational database.

The *analytical* (decision support, business intelligence) *system* is responsible for the decision making support functions, usually known as business intelligence (BI). It is executed on the data in a data warehouse. *Decision making* is an essential managerial tool.

Decisions are usually classified as programmed and non-programmed. The programmed decisions are used for solving routine problems in repetitive situations, in which the decision-making procedure is known. *Programmed decisions* may be implemented in an operational system, such as granting simple loans according to the credit seeker's data. *Non-programmed decisions* are used for solving non-routine problems in unrepeatable situations in which the decision-making procedure or the decision-making model are unknown. Decision makers take full responsibility for their decisions, but the decision support system may provide relevant data and support the analysis of this data. The decision support system has to be easy to use and flexible enough to function in varied decision conditions. Data warehousing systems fulfil these tasks by storing its multidimensional data in the data warehouse and by facilitating various kinds of analytical processing.

Decisions are ranked as operational, tactical and strategic according to their importance. They differ by the character of data usage - from simple usage, such as reading the data, to complex ones, e.g. conducting complex predictive analysis. Table 1 shows types of data usage employed in decision making (type of decisions) in specific circumstances (tasks and examples).

Table 1 Data usage and tasks

Data usage	Type of decisions	Tasks and examples
Reporting & Monitoring (static reporting)	*Operational decisions (based on rules)*: Decisions that involve routine tasks, such as planning, execution and controlling of business processes.	Looking at a pre-defined report for specific information pertaining to the subject; monitoring information at a specific period of time. Example: (a) The user reads inventory report through products looking for quantity on hand. (b) The user opens daily business reports to understand how the business is progressing.
Elementary analysis (dynamic reporting)	*Tactical decisions (based on skills)*: Tactical analysis of business processes, diagnosing business problems.	Delivering more complex information, most often in an iterative manner. Example: Product sales analysis aimed at finding reasons of a drop in sales. The user analyses trends - new information is seen in the context of historical data in order to understand the change in time.
Complex analysis (knowledge discovery from data)	*Strategic decisions (based on knowledge)*: Strategic analysis with insight into the nature of business phenomena.	Analysing data combined with problem modelling to understand data and uncover hidden insights into data. Example: Basket analysis to understand customer behaviour.

Operational decisions usually involve routine tasks, i.e. well structured problems that can be solved by accepted procedures. Routine tasks occur frequently and at predictive intervals. There are many examples: granting discounts based on loyalty scheme, accepting/rejecting request for a loan based on customer data, withdrawing a product based on sales result, etc. Reporting and monitoring are examples of data usage *based on rules*. Predefined reports (static reporting) based on transactional data may be implemented in the operational system. The quality of the reporting subsystem depends on the degree of data integration across enterprise's functional areas. Decision-makers are nowadays provided with predefined standardized and parameterized reports or they have to make ad-hoc queries via the reporting tool to make necessary reports. If a particular option involves predefined reports with no access to deeper information, the situation is described as "data rich but information poor".

Tactical decisions usually involve semi-routine tasks that require a non-routine solution. Analytic solutions are examples of data usage *based on skills*. They are different from reporting solutions as they are intended to facilitate the analysis of information by way of inspection, exploration etc., in order to assimilate and understand information. Menu items of analysis tools facilitate information exploration, information patterns, historical content analysis etc., and use advanced data visualization to help users to evaluate the relevance of the information. The analytic system must help the decision-maker to understand the information and to gain the information insight. It must enable the user to understand why and how something happens on the basis of information given in an analysis report. An example of this kind of analysis is "The sales are lower than before, why? Is it because of a specific product, a specific market, a specific customer or a combination of all of them?" Dimensional analysis of data, such as On-line Analytical Processing (OLAP) in data warehouses, is a good example of analytics. The multidimensional data structure in data warehouses is generally more visual than the table structure used in the operational data base. Namely, the dimensional structure can reveal interesting interrelationships between dimensional attributes. These interrelationships may uncover hidden business information and result in valuable insights.

Strategic decisions usually involve non-routine tasks that do not have generally accepted decision criteria. Strategic decisions are usually made by upper management within the organization. They occur less frequently than tactical decisions and can impact many departments and functional areas within the business. Strong data analysis is recommended for strategic decision-making. The analysis often leads to additional questions and additional requests for data. The examples of strategic decisions are: "What distribution channel is suitable for the global market?" and "Is it the appropriate time to launch a new product on the market?" The best example of data usage *based on knowledge* is data mining. Data mining [4] is an analytic process designed to explore usually large amounts of business data in search of consistent patterns and/or systematic relationships between variables, i.e. this is an information extraction activity whose goal is to discover the hidden facts contained in data. The goal of data mining is prediction so predictive data mining is the most common type of data mining. It has the most direct business applications. Typical applications include market segmentation, customer profiling, fraud detection, evaluation of retail promotions, and credit risk analysis.

III. DATA INTEGRATION

In many enterprises different parts of the organization use different systems to produce, store, and search their critical data. Only by combining the information from these various systems can the enterprise realize the full value of the data they contain. Although the data integration problem has been theoretically extensively studied both in business and science, many problems still need to be solved in practice. Nonetheless, we may recognize a few basic models of data integration approach: data consolidation, data federation, and data propagation [15].

A. Data consolidation

Data consolidation, shown in Fig. 1, captures data from multiple data sources A and B and integrates it into a single persistent data store C. This store may be used as an operational data store in the operational subsystem, or used for analysis as a data warehouse in the analytical subsystem. This model, also known as the *data warehouse model*, is frequently and successfully used in many commercial systems oriented on data analysis and decision support. After *extracting* data from sources, data may be *transformed* according to business needs, *loaded* into target integrated data source (ETL process), and queried with a single schema, which is ideal for querying purposes. Enterprise content management (ECM) is a similar consolidation technique used in the integration of unstructured data. This technique focuses on the consolidation of unstructured or semi structured documents.

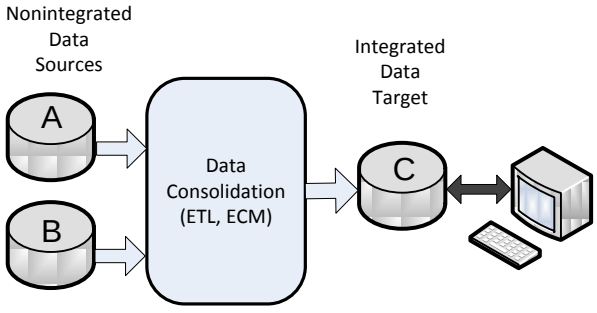

Fig. 1 Data consolidation

Data consolidation process may produce a delay, or latency, between the time of data update in source system and the time of data update in target system. What is defined as acceptable latency depends on business needs; it can vary from several seconds to hours, or even days. The hardly achievable zero latency data results in real-time data. Low and acceptable latency data is known as near real-time data. Batch data consolidation pushes data

from the source system to the target system at scheduled intervals.

The main advantage of data consolidation is that data can be transformed in order to restructure, reconcile, clean, aggregate, raise the quality, or for any other reason change the data flowing from data source to data target.

As business becomes more real-time, the system that supports it needs to be more real-time. Here are some techniques for making data target, such as a data warehouse, more or less real-time [7]:

- "Near real-time" ETL – The easiest way is to execute the ETL process again. For some applications, increasing the frequency of the existing data load may be sufficient.
- Direct trickle feed – This is a true real-time data warehouse where the data warehouse is continuously fed with new data from data sources. This is done either by directly inserting or updating fact tables in the data warehouse, or by inserting data into separate fact tables in a real-time partition.
- Trickle and feed – The data is continuously fed into staging tables and not directly into the actual data warehouse tables. Staging tables are in the same format as the data warehouse actual tables. They contain either a copy of all the data or a copy of the data of current period of time, such as a day. At a given period the staging table is swapped with the actual table so the data warehouse instantly becomes up-to-date. This may be done by changing the view definition where the updated table is used instead the old one.
- External real-time cache – this is a variant of trickle and feed where the real-time data are stored outside the data warehouse in an external real-time cache, avoiding potential performance problems and leaving the data warehouse largely intact.

B. Data federation

Data federation, shown in Fig. 2, loosens the coupling between various data sources and thus avoids the problem of replicated data and delayed update in the data consolidation model. This approach uses a virtual database (virtual view) with a mediated schema and wrapper, i.e. adapter, which translates incoming queries and outgoing answers. Wrapper wraps [13] information source and models the source using a source schema. The situation emerges when two independent data sources have to be merged or combined into one source, such as integration of two similar databases when two organizations merge or integration of two document bases with similar structure content.

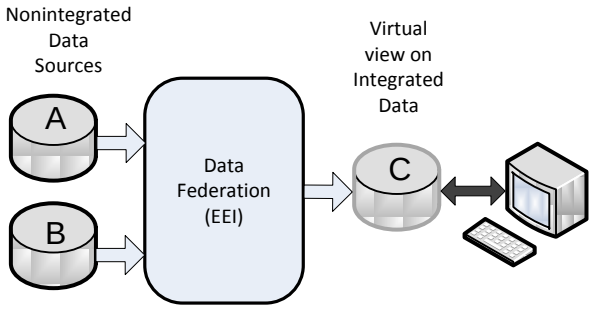

Fig. 2 Data federation

The users of the integrated system, i.e. integrated data C, are separated from the details of the data sources A and B at the schema level, by specifying a mediated or global schema. The *mediated schema* is a reconciled view of data in sources A and B, so the user needs to understand the structure and semantics of the mediated schema in order to make a meaningful query [8]. The task of the data integration system is to isolate the user from the knowledge of where data are, how they are structured at the sources, and how they are reconciled into the mediated schema.

The source databases are approachable through a wrapper code which transforms the original query into a specialized query over the original databases A or B. This is a view based query because each of the data sources A or B can be considered to be a view over the virtual database C. The first step in the approach involves setting up the mediated schema either manually or automatically [10]. The next step involves specifying its relationships to the local schemas in either Global As View (GAV) or Local As View (LAV) fashion.

In the GAV or global-centric approach the mediated or global schema is expressed in terms of the data sources, i.e. to each data element of the mediated schema, a view over the data sources must be associated. In the GAV approach, mediator processes queries into steps executed at sources. Changes in data sources require revising of the global schema and mapping between the global schema and source schemas.

In the LAV or source-centric approach the mediated or global schema is specified independently from the sources but the sources are defined as views over the mediated schema. LAV is better at scalability because the changes in data sources require that only the description of the source view be adjusted. Nevertheless, query processing in LAV is more difficult. Some approaches try to combine the best of GAV and LAV approach [3, 16].

The query language approach propagates extending query languages with powerful constructs to facilitate integration without the creation of the mediated or global schema. SchemaSQL [6] and UDM [8] are examples of this approach. They serve as the uniform query interface (UQI) which allows users to write queries with only partial knowledge of the "implied" global schema.

The main advantage of data federation is that it provides access to data that need not be consolidated from data source into another data store. Nevertheless,

this approach is not appropriate for maintaining large sets of data. Data federation may be the only choice when security or any other reasons prevent data source being copied.

C. Data propagation

Data consolidation and data federation approaches may not be enough as some situations call for the *data propagation* technique which copies data from one location to another. Updates of a source system can be propagated synchronously or asynchronously to the target system. The technique can be used for the real-time or near real-time synchronization of target and source system.

In real situations it is common to use a hybrid approach which involves a combination of data integration techniques mentioned above.

D. Push or pull mode of data integration

No matter which data integration method is used, what triggers synchronization of data sources and data target?

In *push mode*, shown in Fig. 3, some event triggers the operation of synchronization, i.e. push mode is always event-driven. Push mode is used in low-latency data consolidation systems where data target is updated online by data integration application that continuously capture data changes and *push* them to the target system. This approach requires the technique of identifying data changes to be captured for data consolidation.

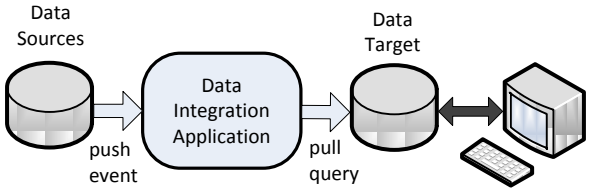

Fig. 3 Push / pull mode

In *pull mode* a query executed on data source pulls data from the data sources, i.e. pull mode is always on demand. In a high latency data consolidation system the data is *pulled* from the source system to the target (data warehouse) at scheduled intervals. Data queries take periodic snapshots of the source data which are then transferred into the target system.

E. Avoiding information inconsistencies

Data sources integration can lead to information conflicts which need to be eliminated. The issue has recently received increased attention. *Intensional inconsistencies*, often referred to as semantic inconsistencies, appear when the sources are in different data models, or have different data schemas, or the data is represented in different natural languages or in different measures. For example: "Is 35 degrees measured in Fahrenheit or in Centigrade?" this type of inconsistencies may be resolved by the usage of ontologies which explicitly define schema terms and thus help to resolve semantic conflicts. This is ontology based data integration.

Extensional inconsistencies, often referred to as data inconsistencies, are factual discrepancies among the data sources in data values for the same objects. Extensional inconsistencies are visible only after intensional inconsistencies are resolved. Motro [9] argues that "all data are not equal", and "that data environment is not egalitarian, with each information source having the same qualification". In a diverse environment "the quality" of information provider's data is not equal. Many questions arise, such as: Is data enough recent or is outdated? Is the data source trustworthy? Is data expensive? An interesting approach is suggested by [9]. In Internet era when the number of alternative sources of information for most applications increases, users often evaluate the information about data sources. The meta data, such as timestamp, cost, accuracy, availability, and clearance, whether provided by the sources themselves or by a third-party dedicated to the ranking of information sources, may help users judge the suitability of data from the individual data source.

IV. INTEGRATED INFORMATION SYSTEM

A good information system relies on its *operational subsystem*, for example Enterprise Resource Planning system (ERP), which uses a multitude of interrelated program modules that process data in the operational data base on individual functional areas. In Fig. 4, the operational subsystem is exemplified by three basic functions: supply, manufacturing and sales. They stretch from the top to the bottom of the operational pyramid. The operational subsystem of an information system is supplemented by the *analytical subsystem*. Its analytical data processing capabilities process data in the data warehouse. The complete operational and analytical solution is called Enterprise Information system (EIS) or simply Enterprise System (ES).

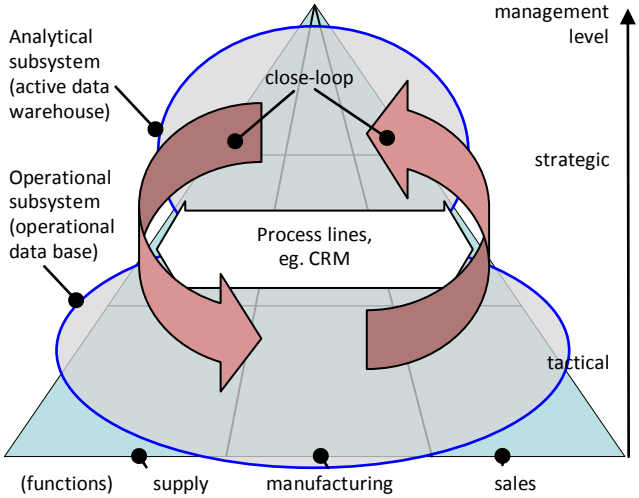

Fig. 4 Information system

Even though most organizations have a functional structure, an examination of business processes provides a more authentic picture of the way business is run. A business process is a structured, measured set of activities designed to produce a specific output for a particular

customer or market [5]. According to business process approach, some typical process lines may be used, of which only one is shown in Fig. 4: *Financial and Business Performance Management* (a set of processes that help organizations optimize their business or financial performance), *Customer Relationship Management* (CRM) (a set of processes utilized to provide a high level of customer care), *Supply Chain and Operations* (a set of processes involved in moving a product or service from supplier to customer).

A *vertically integrated* information system connects activities on the lowest level of a particular function (e.g. a process of transactional retailing) with data analysis and data representation on the decision-making level (e.g. reports on sales analysis for the general manager). If the vertical coverage of data from a particular functional area is insufficient, the data does not comprise all levels of this functional area. This is the case when, for example, only operational sales data exist, whereas sales data for the tactical and strategic level of decision-making are missing due to the lack of appropriate sales reports or if there is no possibility to interactively analyse sales data.

A *horizontally integrated* information system enables a systematic monitoring of specific business processes from end to end. For instance, as soon as a purchase order arrives, an integrated information system can receive it, forward it "automatically" to sales and delivery process which will deliver the goods to the customer and send the invoice to his information system, open a credit account, record the quantity of goods delivered in warehouse evidence; in case that goods first need to be produced in a manufacturing plant the system will issue a work order to manufacture the required quantity of goods; the production process can be supplied by a production plan; sales results will be visible to the sales manager and analysed using analytical tools of the information system; etc. An integrated information system enables recording of all business events so that the data can be used an analysed effectively throughout the organization. Insufficient horizontal integration of different functional areas results when functional areas are not integrated. In case that production data are not visible in the sales application, or they need to be re-entered (although they already exist in the production application), operational sales data will not be well integrated with operational production data.

Finally, if data in an information system are not sufficiently integrated, the information system will be comprised of isolated information (data) islands. An information system is not integrated unless individual functional areas are mutually integrated with other functional areas by data. For instance, sales data may not be integrated i.e. connected with production data; or they may be integrated in indirect and complicated ways. Problem occurs because some older applications were designed for individual functional areas without concern for other functional areas.

V. INFORMATION SYSTEM'S CLOSE-LOOP

Over the years, enterprise's analytical subsystems with data warehouses evolved from relatively simple reporting tools to sophisticated analytical applications used for analyzing customer lifetime values, market basket analyses, potentially defecting customers, fraud patterns, customer churns, etc. Even today, however, many data warehouses do not offer any integrated data with operational data bases other than the snapshots of data from the day before or even last week. According to the refreshment speed, data warehouses may be classified as (1) updated or synchronized immediately (*real time data warehouse*) or almost immediately as the operational data base (*near real time data warehouse*), (2) updated in relaxed time, such as half hour, (3) or updated lately, typically in batches on daily basis.

The typical data warehouse primarily supports tactical and strategic rather than operational decision making processes. However, operational decision making processes can be achieved with active data warehousing. *Active data warehouse* [12] supports automatic decision making processes with routine decision tasks and can make routine some elements of semi-routine decision tasks. Routine decisions are mostly operational decisions; semi-routine decisions are operational or tactical decisions. Here is an example of how an operational decision is automated: After the product has been launched, analysis showed that the total quantities of product sold were below the planned quantities so the price of the launched product may need to be reduced significantly in some markets. The active rule which analyses sales data in the data warehouse and propagates result of analysis into the operational data base can be used to automate the decision making process. Clearly, the operational processing can be driven by the data warehouse.

Some characteristics of an *active data warehouse* are:

- An active data warehouse represents a single, canonical state of the business, i.e. a single version of the truth.
- It represents a logically consistent store of detailed data available for strategic, tactical, and event driven business decision making.
- It relies on timely updates to the critical data - as close to real time as needed.
- It supports short, tactical queries that return in seconds, alongside of traditional decision support.
- It represents a closed loop process between the operational (transactional) system and analytical (data warehousing) system.

The transactional system feeds the data warehouse, and the data warehouse feeds back the transactional system in order to drive and optimize transactional processing. So the close-loop between the analytical and operational system is completed. Therefore, the data warehouse is *active* only if it automatically delivers information to the operational data base. The transfer from the data warehouse to the operational data base is accomplished by means of automated system mechanisms such as triggers, special purpose programming interfaces, a message broker or even an ETL tool. The active data warehouse uses technology that transforms passive database systems into reactive systems which respond to

database and external events through the use of rule processing features [1, 11]. In such a way the data warehouse *provides operational intelligence* and, as an active data warehouse, drives operational processing.

If the data warehouse doesn't automatically deliver information to operational systems, then it is not active. Manual interventions do not make a data warehouse active.

The closed-loop must be implemented thoroughly. For example, if the data warehouse supports customer relationship management (CRM), the close-loop is fulfilled only if the data warehouse creates a complete and unified view of customers, product, sales etc. and hooks back into the operational data base. The interface between operational and analytical systems, in both directions, is the essence of active data warehousing.

The best way to make a data warehouse active is by automation. Whenever the decision support system generates operational initiatives it is necessary to propagate it to the operational system.

VI. CONCLUSION

Enterprise's information system is an important factor in enterprise integration. Integration can be accomplished at various levels: data, business process, application, or user interaction.

Effective integration of the operational and analytical (sub)systems of enterprise's information system is crucial for the success of the enterprise's business.

Only by combining the information from these two systems can the enterprise realize the full value of the data they contain. Data integration is mostly achieved by data consolidation, data federation and data propagation. Since integrated data can be jeopardised by information conflicts, all intensional and extensional inconsistencies have to be resolved.

A good information system relies on its operational subsystem, which is supplemented by an analytical subsystem. As a whole, the system provides complete operational and analytical solutions. A vertically integrated information system connects activities on the lowest level of business functions with data analysis and data representation on the high level decision-making. A horizontally integrated information system enables a systematic monitoring of business processes from end to end.

Moreover it is important to close the loop between the analytical and operational information subsystems. Until now, the operational subsystem was only used to deliver data to the analytical subsystem which would use it to produce the analytical information needed in decision-making process. If the active analytical subsystem (driven by an active data warehouse) delivers useful analytical data back to the operational subsystem, the loop is closed and the business can benefit from operational intelligence. Closed loop systems allow the enterprise to automatically respond to opportunities with agility. In many cases, the human involvement in routine decision making may be eliminated.

PAPERS

Semantic Inter-organizational Performance Analysis using the Balanced Scorecard Methodology*

Worarat Krathu, Christian Pichler, Marco Zapletal, and Hannes Werthner
Institute for Software Technology and Interactive Systems
Vienna University of Technology, Austria
{worarat, pichler, marco, werthner}@ec.tuwien.ac.at

***Abstract*—Evaluating inter-organizational relationships (IORs) is important in todays businesses for increasing competitiveness and business potential. Typically, IORs are measured by high-level key performance indicators (KPIs) such as trust, knowledge sharing, and others. However, these high-level KPIs are difficult to be measured quantitatively. It is therefore difficult to determine IORs and their outcomes since the evaluation of IORs results in a complex and ambiguous task. In this vision paper, we propose a set of research questions dealing with measuring and evaluating IORs. Based on these research questions, we define a conceptual framework including (i) the identification of KPIs from inter-organizational processes in combination with business information derived from EDIFACT messages and (ii) the alignment of KPIs to business goals by means of the Balanced Scorecard methodology and semantic technology. Having the approach at hand supports us in lifting operational information to the business level. The alignment between KPIs and business goals allows evaluating an organizations' IORs and results in two distinct advantages. First, the explicit connection between KPIs and business goals results in a justification of the relation between IORs and business achievements. Second, the evaluation of IORs against strategic goals can be achieved semi-automatically.**

I. Introduction

Inter-organizational collaboration impacts an organization's performance [1], [2]. In particular, organizations require inter-organizational collaboration to increase profitability, growth, and competitiveness. This is especially relevant in the B2B context where partnership is important to increase business potential. To understand the impact of business collaboration and to provide a benchmark for judging business partners, the evaluation of *inter-organizational relationships (IORs)* is required [3]. However, the evaluation of IORs is typically difficult and ambiguous since it is usually measured by high-level *key performance indicators (KPIs)*. Such KPIs, including trust, knowledge sharing, and others, are difficult to be measured quantitatively since these KPIs are often intangible. Thus, the interpretation of these KPIs depends on the experience of business professionals. This problem motivates us to seek for an approach for making KPIs more tangible as well as provide means for evaluating IORs in a concrete manner.

During collaboration, business activities and transactions are executed within the network of organizations forming an inter-organizational process, which we refer to as *choreography*. These choreographies specify the exchange of business documents, i.e. actual business information, as part of business processes. We believe that knowledge on IORs can be derived by investigating choreographies as well as exchanged business documents. Hereby, we propose the framework architecture supporting the evaluation of IORs from electronic business messages.

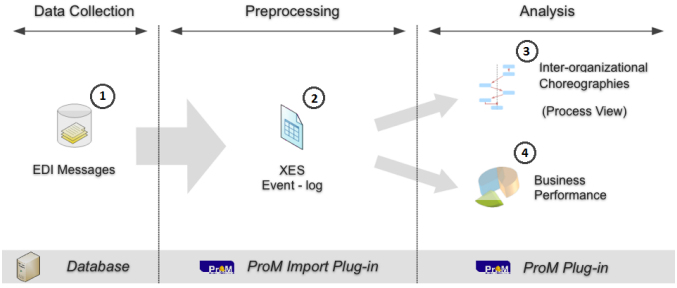

Fig. 1. EDImine Framework

The framework described in this vision paper is part of the *EDImine* project [4], [5] whose main objective is to extract inter-organizational knowledge from electronically exchanged messages. In particular, we concentrate on the United Nations Electronic Data Interchange For Administration, Commerce and Transport (UN/EDIFACT) standard, since it still plays a dominant role in the inter-organizational practice [6], [7]. As illustrated in Fig. 1, the overall framework of EDImine is realized as a set of plug-ins for ProM[1], a well-known process mining tool. In particular, as depicted in Fig. 1, the collection of EDIFACT messages are correlated to the corresponding process instances (cf. Fig. 1, Mark 1) and transformed to the *eXtensible Event Stream (XES)* [8] event log file format (cf. Fig. 1, Mark 2) compatible with ProM plug-ins. This log file, containing process instances and the actual corresponding business information, is further processed in different analysis plug-ins of EDImine. The analysis stage of EDImine aims at (i) discovering the choreography model by using process mining techniques [9], [10] (cf. Fig. 1, Mark 3) and (ii) extracting inter-organizational knowledge by means of business performance analysis (cf. Fig. 1, Mark 4).

The latter is the focus of this vision paper. Therefore, the

* This paper has been produced in the course of the *EDImine* project jointly conducted by the Vienna University of Technology and the Eindhoven University of Technology. *EDImine* has been funded by the Vienna Science and Technology Fund (Wiener Wissenschafts-, Forschungs- und Technologiefonds, WWTF - http://www.wwtf.at) through project ICT10-010.

[1] http://www.processmining.org (visited Jan 24, 2012)

main research question is whether we can evaluate IORs from the electronic business messages exchanged during business process execution. This results in two sub-research questions dealing with (i) determining KPIs related to an inter-organizational context as well as (ii) interpreting these KPIs on the business level. In addressing these problems the framework proposed earlier is used for evaluating IORs from EDIFACT messages. Therefore, first, inter-organizational KPIs are identified based on EDIFACT messages and, second, these KPIs are linked to business goals based on the *Balanced Scorecard (BSC)* methodology [11]. Thereby, the analysis and evaluation of KPIs against business strategies can be achieved by aligning KPIs with business goals. In other words, information on the operational level is lifted to the business level. Furthermore, for implementing the BSC methodology semantic technology is used. Utilizing semantic technology allows representing business information on the conceptual level and, thus, supports the semi-automatic evaluation against business strategies.

The remainder of the paper is organized as follows: Section II provides an overview on related work. The research questions and their resulting contributions are explained in Section III. Section IV describes the framework architecture for the evaluation of IORs from EDIFACT messages. Finally, we conclude the paper by providing an outlook on the vision of the work presented in this paper in Section V.

II. Related Work

The challenge in the evaluation of IORs is the ambiguity of measurement since it is typically intangible and the outcomes are difficult to determine: most of the studies regarding the evaluation of IORs (e.g. [12], [13], and [14]) tend to focus on high-level KPIs such as trust, information as well as knowledge sharing, and involvement in project and decision making. These KPIs are, however, still difficult to be measured and the resulting outcomes are hard to be interpreted. In contrast, we argue that it is more sensible to evaluate IORs with operational KPIs. This is because KPIs derived from operational information are more tangible and truly reflect actual business operations. In doing so, the performance of business partners can be monitored and evaluated more concretely. To the best of our knowledge, there are no existing approaches exactly fitting our needs. Related approaches exist in the area of supply chain management (SCM), which aims to harmonize the collaboration between business partners in the logistics domain. Their approaches are based on KPIs which are typically derived from business information in enterprise resource planning systems. However, these approaches are limited to the SCM domain and are considered as static approaches since they extract information at a given point in time. In our case, we intend to combine information concerning the process perspective as well as the document perspective, both extracted from EDIFACT messages. Having both kinds of information at hand, it is possible to capture change in business information (e.g. order changes, delivery schedule changes, etc). In other words, considering business information against business process information allows to observe change in business information over time.

As mentioned earlier, our approach applies the BSC methodology for lifting operational measurements to the business level. Originally, the BSC methodology is used for internal performance analysis tasks [11]. The essence of the BSC methodology is to help align KPIs with business goals deliberately across different perspectives (i.e. Finance, Customer, Process, as well as Learning and Growth). Thereby, it provides a brief overview on organizational performance. Following the BSC methodology, the evaluation is score-based where each business objective has its own score calculated from its corresponding KPIs. Thus, the KPIs used in the BSC methodology must be measured quantitatively for providing the score for an objective evaluation. Because of its benefits, the BSC methodology became one of the most promising measurement systems [11] and is currently widely applied as the strategic planning and management system within an organization [15]. Several attempts have been made in applying the BSC methodology in the SCM domain. For instance, [16] discusses the interrelationship between the BSC methodology and the SCM area and introduces the example of supply chain performance analysis based on balanced scorecards. Similar work has been addressed by [17]. Furthermore, [18] and [19] study the examples of KPIs commonly used to measure supply chain performance following the BSC manner. These works prove the usefulness of applying the BSC methodology in an inter-organizational context. In our context, however, we aim at integrating inter-organizational evaluation as well as internal evaluation by utilizing inter-organizational KPIs for measuring internal business goals.

The cornerstone for implementing the BSC methodology in our approach is semantic technology. Thereby, ontology linking is utilized for establishing relationships between business goals and the corresponding KPIs. For instance, [20] focuses on modeling and monitoring of KPIs. However, no relationships between business goals and KPIs are considered in their work, whereas we mean to do so. In [21], the authors introduce an approach that integrates business goal ontologies and a business process modeling framework to perform the analysis against strategic business goals. This can be considered as a top-down approach since, in order to perform the evaluation against the goals, the goal-based business process is required to be modeled before. In contrast to [21], we concentrate on extracting KPIs resulting from existing business processes and the corresponding business data, as well as relating those KPIs to business goals. Furthermore, existing concepts in the areas of business goals and KPIs are well-defined and reusable. However, these concepts have to be modified and extended appropriately to fit the needs of inter-organizational message exchanges.

III. Research Questions

The ultimate aim of this work is to assess IORs from messages exchanged during electronic business transactions. Accordingly, the main research question is defined as: *"Can*

we measure IORs by observing and analyzing electronically exchanged messages?". In the particular context of the work presented we focus on EDIFACT messages whereas the approach is developed in a generic manner for the sole application beyond EDIFACT standards. To answer this research question the following two sub-research questions are derived.

A. "What are useful KPIs derived from mined choreographies and the corresponding content of EDIFACT messages for evaluating IORs?"

For addressing the first research question we intend to perform the following steps: first, choreographies are mined based on the exchange of business messages. Second, these choreographies are analyzed in combination with actual business information conveyed in electronic business transactions. Thereby, we intend to identify inter-organizational KPIs. In other words, we aim at defining measures playing a key role for performance measurement. Compared to existing KPIs, the KPIs defined as part of the approach represent concrete measures implying the fulfillment of a companies' business goals. We believe that measuring the performance for IORs, based on KPIs which are derived from an operational perspective, gives us a clearer view and a better understanding of IORs.

KPIs are usually identified dependent on the context of a particular business scenario. Moreover, they are flexible and vary from organization to organization. Most likely, organizations might want to define their own KPIs in case the predefined KPIs, developed as part of the approach presented, are not enough for them. For these reasons, we also intend to develop a business cockpit facilitating the modeling and the querying of KPIs from existing business messages. In particular, the business cockpit is provided as a ProM plug-in. By viewing the choreography model and the actual business content at the same time, the relation of each activity in the choreography and its related exchanged information can be examined simultaneously. By this, the analysis can be achieved based on the integration of both, business process view and business document view. Corresponding to the first research question, the following contributions are described.

Inter-organizational KPIs. A set of potential KPIs for inter-organizational business use cases are defined. As described before, we attempt to extract inter-organizational knowledge as operational measures for the assessment of IORs from EDIFACT messsages. The identified KPIs can be used as concrete evidence supporting the evaluation of IORs.

Process View and Document View Integration. Generally speaking, the business cockpit allows business analysts to model their own KPIs. By integrating the business process view with the business document view the modeler can observe the coherent information between executed business processes and the related business information conveyed in electronic business transactions.

B. "How can we relate KPIs to business goals for measuring business performance using the Balanced Scorecard methodology?"

Besides the ambiguity of evaluating IORs it is also difficult to determine the outcome from IORs [3]. In the approach presented in this paper, inter-organizational KPIs are derived from operational information, i.e. the content of business documents. These KPIs are considered as operational information since they reflect IORs at the operational level. Consequently, for understanding IORs, their outcome, as well as their impact on an organization's performance, we need to lift the evaluation of KPIs to the business level. For these reasons, the BSC approach is applied as a bridge between these levels. In general, the BSC methodology allows analyzing an organization's performance against business goals by linking each business goal to a set of corresponding KPIs across different perspectives. The evaluation in terms of the BSC methodology is based on the score concepts. In particular, each business goal has its own score which is calculated based on its assigned KPIs. Such an approach makes quantitative measurements obvious and meaningful and hence, reveals the impact of IORs on a firm's performance.

Therefore, we also aim to extend the aforementioned business cockpit for serving as an inter-organizational analysis and monitoring tool supporting the BSC methodology. One of the challenges to be addressed as part of this research question is ensuring the correctness of user-defined KPIs in terms of compliance with the Balanced Scorecard methodology. The underlying foundation of the BSC methodology used in this approach is based on semantic technology. This in turn allows ontology-based linking between KPIs and business goals. Hereby, the EDIFACT data, KPIs and business goals are lifted to the business level through concepts in ontologies. Consequently, existing concepts in EDIFACT messages can be used to model KPIs on the conceptual level. Similar to predefined KPIs, these user-defined KPIs may again be linked to business goals. Utilizing semantic technology offers several advantages. These include reasoning over EDIFACT messages and facilitating the semi-automatic calculation of KPIs as well as their evaluation against business goals. Therefore, the contributions of the second research question are defined as follows.

Inter- and Intra-organizational Evaluation, and Balanced Scorecard Integration. The BSC methodology is commonly applied as an internal performance measurement system inside an organization. We aim at combining the evaluation of both, the internal as well as the inter-organizational perspective by analyzing IORs. This is supported by a business cockpit supporting the linking of inter-organizational KPIs to internal business goals of an organization. Thereby, organizations can understand the impact of IORs on their performance based on the explicit links between KPI measurements and business goals.

Semantic Performance Analysis. For utilizing the BSC methodology on the conceptual level, semantic technology

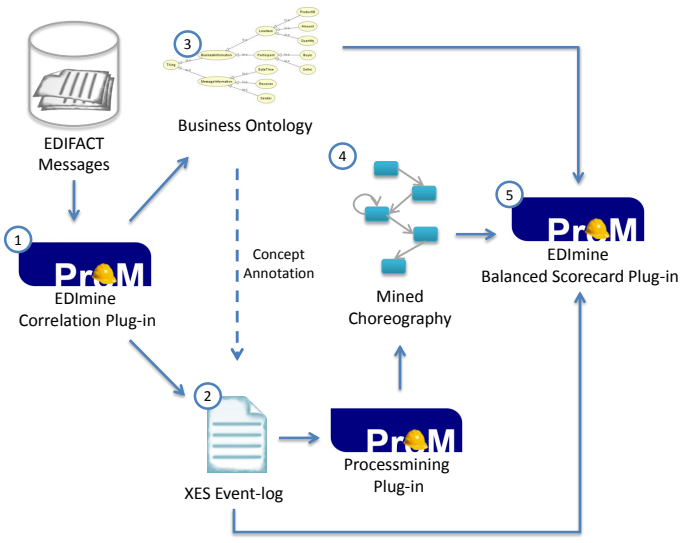

Fig. 2. Preprocessing Stage

is used. Therefore, business information, KPIs, and business goals are represented and modeled as an ontology. These ontologies enable the semi-automatic calculation of KPIs as well as the evaluation of the corresponding business goals.

IV. Architecture

In the following the architecture of the proposed framework is described. As introduced earlier, dealing with business processes as well as business documents requires the preprocessing of actual business data. Therefore, first, the preprocessing stage is described followed by framework architecture for semantic performance analysis.

A. Preprocessing

An overview of the preprocessing stage is illustrated in Fig. 2. As shown in Fig. 2, Mark 1, the first step is to correlate EDIFACT messages to process instances. In the course of the EDImine project, a correlation plug-in[2] is developed for grouping related EDIFACT messages into process instances which are then converted to an XES event log [5] (cf. Fig. 2, Mark 2). The XES file format stores data as an event log where each trace represents a process instance and where each event corresponds to exchanged messages. The XES file format also provides an extension mechanism for storing additional information. In other words, the extension mechanism allows us to create additional attributes for storing information in logs, traces, and events.

By leveraging this extension mechanism we extend the correlation plug-in for extracting business content from business messages and store the extracted information in the XES event log. Moreover, the correlation plug-in is extended for deriving business concepts and the relationships between these concepts from business messages. The extracted concepts are then modeled and stored as a business ontology (cf. Fig. 2, Mark 3). In other words, the business ontology is used for describing EDIFACT data as well as the relationship between the concepts on the conceptual level. Furthermore, the concepts of the business ontology are annotated with additional information referencing data elements stored in the XES event log.

The XES event log is then used for mining business processes utilizing existing process mining plug-ins provided through the ProM tool. The result of applying process mining to the XES event log exposes a choreography model (cf. Fig. 2, Mark 4) showing the information exchange in business processes. Summarizing, the XES event log, the business ontology, as well as the mined choreography model serve as input for further processing based on the BSC methodology (cf. Fig. 2, Mark 5), i.e. for tackling the research questions defined earlier. So far, a mechanism for extracting business ontologies from EDIFACT message types has been developed. Thereby, the mechanism parses the EDIFACT directories and aggregates message type definitions with descriptive information of data fields, code lists, etc. This enables the users to work with conceptualized business information instead of codified EDIFACT documents for defining KPIs. Furthermore, the correlation plug-in is currently being extended for annotating the XES event log with information from the extracted business ontologies.

B. Business Performance Analysis

Regarding to the BSC methodology, the score of each objective is calculated by measuring the related KPIs and convert the resulting values to KPI scores. The four basis elements of the BSC methodology include: objective, KPI, perspective, and initiative. An objective (cf. Fig. 3, Mark 5) describes what an organization wants to achieve and KPIs (cf. Fig. 3, Mark 4) are used for measuring the achievement. These objectives are typically assigned to perspectives (cf. Fig. 3, Mark 6). Furthermore, initiatives are assigned to KPIs representing actions to help an organization in achieving its business goals. In the approach presented in this paper we focus on objectives, KPIs, and perspectives. The reason is that objectives and KPIs are commonly used for calculating achievements in practice. Furthermore, the development of objectives and KPIs is constrained according to perspectives. As illustrated in Fig. 3, the main elements supported by the BSC plug-in include KPI Modeling and Querying (cf. Fig. 3, Mark 1) and Balanced Scorecard Implementation (cf. Fig. 3, Mark 2). Note that the description of the framework in the following refers to the example illustrated in Fig. 3.

The KPI modeling and querying functionality allows users to model their KPIs from existing business information based on the mined choreography model as well as the extracted business information. It is designed to visualize the choreography model together with the business information related to each activity of the choreography model (cf. Fig. 3, Mark 3). Each activity may then be expanded causing all available related concepts from the business ontology to be listed. Hereby, users can select data at the conceptual level instead of

[2] http://edimine.ec.tuwien.ac.at (visited Jan 24, 2012)

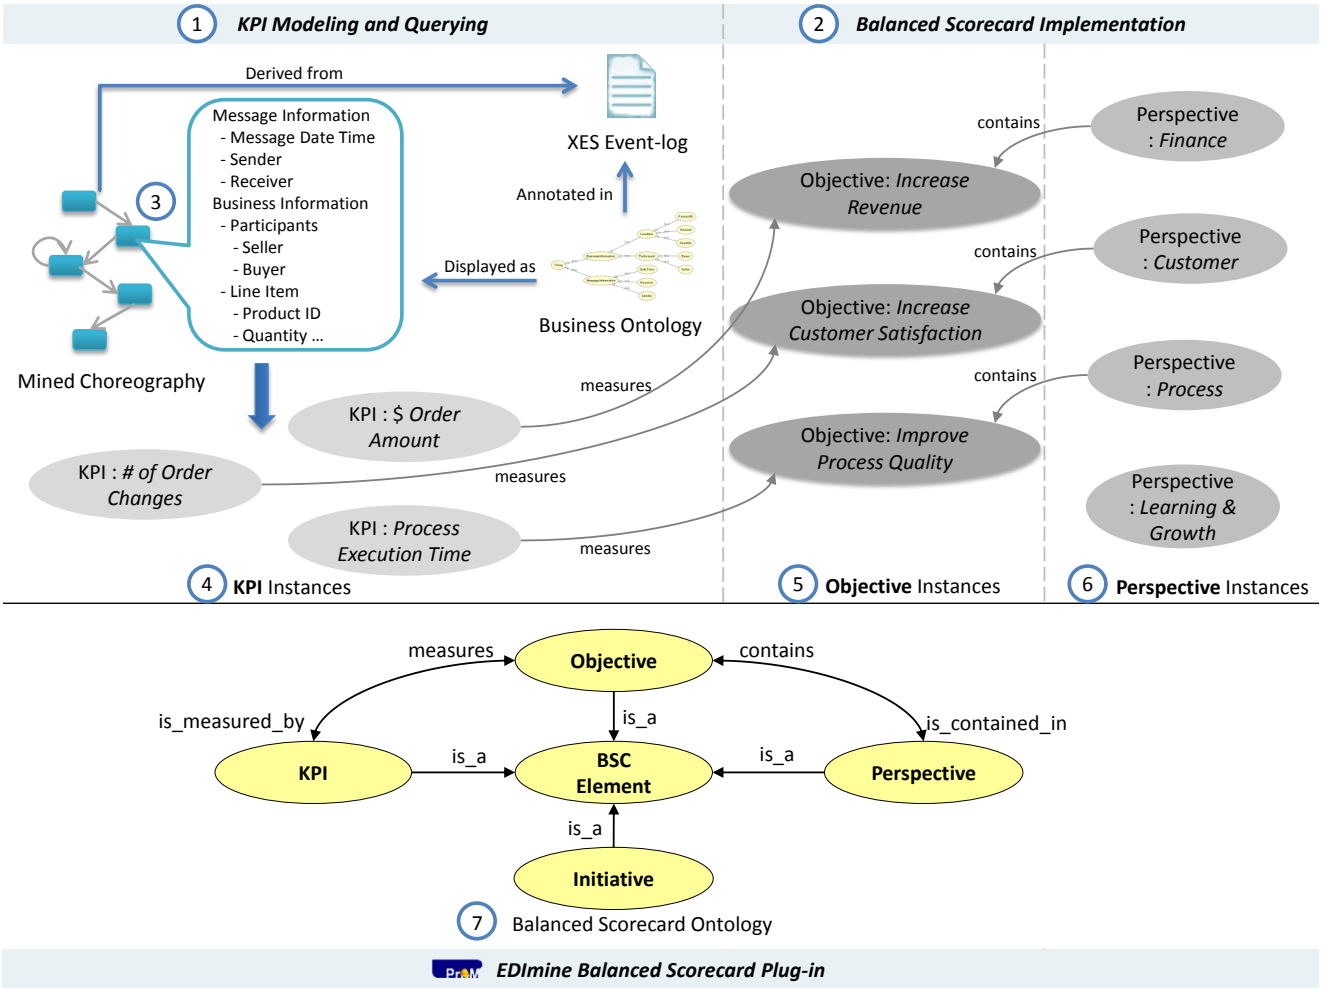

Fig. 3. EDImine Balanced Scorecard Plug-in

low-level EDIFACT data elements. The benefit of combining both, the business process view and the business information view, is two-fold. First, it makes the information coherent which is easy to perceive. Second, it captures the flow of information. For instance, order changes can be investigated by looking through a particular process instance. For modeling KPIs (cf. Fig. 3, Mark 4), users are supported in creating a calculation expression using available concepts from the business ontology. When KPIs are calculated, the plug-in searches for corresponding data elements in the XES event log which are annotated with relevant concepts. Thereby, the hierarchy in the business ontology is utilized for supporting the search of corresponding data elements in the XES event log. For example, in case users aim at querying the quantity of a product order, the users may choose to query for either all products (i.e. the main concept) or for a specific product (i.e. a subconcept).

The second functionality of the plug-in is the balanced scorecard implementation as depicted in Fig. 3, Mark 2. The BSC implementation supports the modeling of business objectives (cf. Fig. 3, Mark 5) and perspectives (cf. Fig. 3, Mark 6) according to the BSC methodology. Consequently, the plug-in supports assigning objectives to perspectives, and KPIs to objectives. In other words, the modeling of BSC elements has to conform to the Balanced Scorecard Ontology, illustrated in Fig. 3, Mark 7. This results in a BSC model serving as a basis for analysis and calculation of KPIs and business achievements.

At the time of writing, a modeling environment for modeling balanced scorecards has been created. Furthermore, a model for ontology linking has been defined. In other words, the model allows assigning KPIs to objectives of the BSC methodology via the explicit relationship defined in the Balanced Scorecard ontology illustrated in Fig. 3, Mark 7 (i.e. ”measures” relationship). Details on the model for ontology linking are, however, beyond the scope of this vision paper. The next steps include finalizing the implementation for modeling KPIs as well as integrating the model for ontology linking into the modeling environment. Based on the modeling environment, the analysis and the calculation may be achieved utilizing semantic technology which is subject to further research.

V. Outlook

In this vision paper we presented two research questions dealing with the evaluation of IORs and their impact on an organization's performance based on EDIFACT messages. In other words, the overall aim of the proposed approach is finding strategies for supporting the evaluation of IORs from electronically exchanged business messages. The fundamental idea pursued is examining EDIFACT messages for deriving inter-organizational KPIs and utilizing these KPIs for evaluating IORs based on the BSC methodology. So far, the BSC methodology has been widely applied for performance analysis within organizations. In the context of the work presented, a framework based on the BSC methodology is provided for enabling inter-organizational performance analysis. Moreover, intra- as well as inter-organizational performance analysis is combined for leveraging the benefits of both.

In addition, a corresponding tool implementation of the proposed framework helps bringing the evaluation of IORs into practice. This way, business analysts are provided with the necessary support for assessing business collaborations with business partners in terms of a collaboration's values and benefits. Although we concentrate on EDIFACT standard, the performance analysis approach is developed in a generic manner independent from any particular message standard. For the application of the approach to other message formats, only a representation of business information according to the XES event log and in addition a corresponding business ontology describing the concepts in the business messages, are needed. Therefore, the framework is flexible to be applied for other EDI standards or message exchange approaches. So far, the BSC ontology and the plug-in supporting the modeling of BSCs have been and are continued to be developed. In a consecutive step, the functionality for KPI querying as well as for BSC calculation is being tackled.

Emergency situations monitoring using OLAP tehnology

T.G. Penkova, A.V. Korobko, V.V. Nicheporchuk
Institute of Computational Modeling of the Siberian Branch of the Russian Academy of Science, Krasnoyarsk, Russia
penkova_t@icm.krasn.ru, lynx@icm.krasn.ru, valera@icm.krasn.ru

An approach to efficiency improvement of monitoring of the emergency situations for the Siberian region is suggested in this paper. It is based on integration of data processing and storage technologies: Data Warehouse, OLAP and Expert systems. The data warehouse provides accumulation of data from isolated monitoring services. The OLAP tools allow a user to perform multiaspect monitoring of natural and anthropogenic emergency situations. The expert systems technology enables user to estimate of the emergencies risk based on state indicators. Suggested original methods and tools are embedded in emergency situations monitoring system "Espla-M". The system "Espla-M" is implemented in Ministry of emergency of Siberian Region.

I. INTRODUCTION

Great amount of data should be processed everyday for natural and anthropogenic emergency prevention and forecast in time. Nowadays, an automatic monitoring system is developing in Siberian region for operative observing of technosphere objects and environmental conditions. There are many isolated monitoring services with local operative databases. But, there isn't integrated monitoring system. Monitoring data consolidation, operative data downloading from heterogeneous sources, on-line analytical data processing and emergencies state control are required to improve efficiency of emergencies monitoring.

In the paper, an approach to efficiency improvement of monitoring of the emergency situations for the Siberian region is suggested. It is based on integration of data processing and storage technologies: Data Warehouse, OLAP and Expert systems. The data warehouse provides accumulation of data from isolated monitoring services. The OLAP tools allow a user to perform multiaspect monitoring of natural and anthropogenic emergency situations. The expert systems technology enables user to estimate of the emergencies risk based on state indicators. Suggested original methods and tools are embedded in emergency situations monitoring system "Espla-M". The system "Espla-M" is implemented in Ministry of emergency of Siberian Region.

The paper is structured as follows. Section II describes monitoring of the emergency situations for the Siberian region and main problems. Section III presents storage schema and content of the original emergencies data warehouse. In section IV the OLAP tools and a set of particular analytical models for monitoring fields are considered. Section V describes the approach to emergencies risk estimation based on a comparison of the actual monitoring data with their crucial values. Section VI represents the paper conclusions.

II. EMERGENCY SITUATIONS MONITORING OF SIBERIAN REGION

The Siberian territory is characterized by high level of natural and anthropogenic emergency hazard. Because of geographic location, climatic conditions and social-economic reasons, the risk of mortality in an emergency in Siberia exceeds ten times acceptable international and average Russian levels [1]. Today, to improve safety of population and territories, a number of emergencies preventing and mitigating actions is implemented. One of the most important preventing actions is the developing of the emergency monitoring and prediction system.

Regional organizational system of emergency monitoring and prediction is the administrative form of territorial management in the field of civil defense, emergencies and elimination of consequences of natural and anthropogenic disasters [2]. The system includes subdivisions of federal authority, region government departments and other organizations that provide supervision of natural and anthropogenic emergency situations in Siberian region. The scheme of information interaction between participants of the emergency monitoring system is presented on Fig.1.

In accordance with established normative acts [2, 3] the Regional organizational system of emergency monitoring and prediction is coordinated by Center of emergency monitoring and prediction of Krasnoyarsk region (CMP).

The main tasks of the CMP are:

- realization of regional policy safety of population and territories;
- observation of sources natural and anthropogenic emergency situations;
- risk factors monitoring;
- emergency data accumulation;
- analytical data processing and forecasting;

- estimation of emergency risk and consequences;
- forming of preventing and mitigating recommendations.

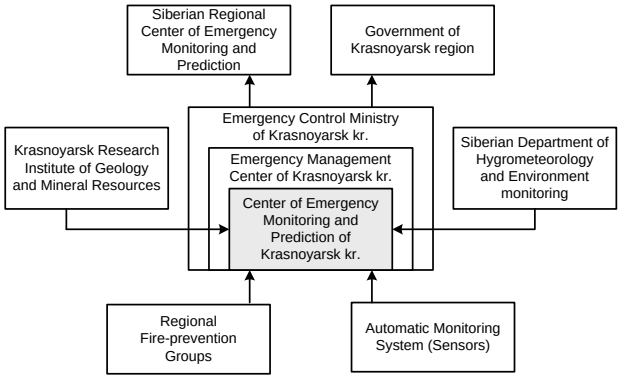

Figure 1. The scheme of information interaction between participants of the emergency monitoring system

Nowadays, there are number of important fields of emergency situations monitoring: meteorology, hydrology, seismology, radiation, spring flood, housing and communal services. Characteristics of technosphere objects and environmental conditions are registered by several different monitoring services.

The system of meteorological and hydrological monitoring in Krasnoyarsk Region consists of 80 weather-stations and 300 hydrological posts. Observations of water bodies are conducted by 9 hydropower stations.

The system of seismic monitoring consists of 12 seismic stations that are located in Baikal-Altai Region of Siberia South and on important industrial objects of Krasnoyarsk Region. Seismic stations can record basic parameters of seismic events in the 300 km area quickly and precisely. The sensors register even low-energy earthquakes and allow observer to distinguish industrial explosions and to control "seismic weather".

The radiation supervision system ASKRO – Automated system of radiation state monitoring – is presented by 34 controlling posts which are situated in 100 km area of Mining and Chemical Plant. The sensors register value of the expose dose of gamma-ray, meteorological parameters and value of gamma-emitting radionuclides activity in Yenisei River. [4].

The system of technosphere objects monitoring provides control of long-span constructions in crowded places and objects of housing and communal services (e.g. heat source, energy supply, fuel supply). The control of these objects is very important for population safety because the number of accidents in the systems of housing and municipal services and severity of their consequences have been increased in the last years.

In addition, the emergency monitoring system includes the number of sensors for automatic control of hydrological, seismic and flood situations. As a result, the CMP accumulates a numerical data (e.g. water and snow level) and nonparametric data, such as photography, video of flood areas and the situation on the highways.

Domain research of regional organizational system of emergency monitoring and prediction allows us to detect some specific problems. There are many isolated monitoring services with local operative databases. There isn't permanent data flow from the different monitoring services to the CMP. So, accumulated data can't be processed comprehensively by the CMP.

For informational analytical support of CMP activities, methods and tools of monitoring data integration and processing are required.

The original emergencies monitoring system "ESPLA-M" has been developed for on-line analytical decision making support of CMP at the Institute of Computational Modeling of the Siberian Branch of the Russian Academy of Science. The system is aimed to solve the problems of data integration, comprehensive analytical processing and visualization of analytical results. The goal is reached by simultaneous using of data processing and storage technologies: Data Warehouse, OLAP, GIS and Expert systems.

III. DATA WAREHOUSE OF EMERGENCIES MONITORING

A data warehouse technology is widely used in business analysis and decision making process. Data warehousing is an approach to integrate information from multiple, very large, distributed and heterogeneous operational databases and other sources.

A data warehouse is a subject oriented, nonvolatile, integrated, time variant collection of data in support of management's decisions [5]. The data in the data warehouse can be arranged in different ways. Data structure defines the opportunity for applying such modern technologies as OLAP and Data Mining.

The original data warehouse managing tool (data warehouse manager – DWM) and storage schema have been developed for emergencies monitoring support in CMP [6]. The domain specific requires special data warehouse structure and particular DWM functions.

In accordance with CMP tasks, organizing DW structure includes three basic layers: the layer of stationary storage, the layer of analytical objects and the layer of pre-loading processing (Fig.2).

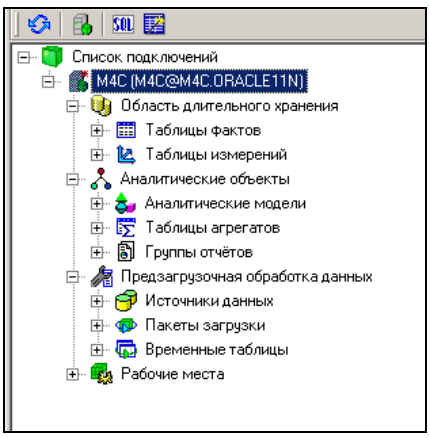

Figure 2. The DWM objects tree

The stationary storage layer contains main part of monitoring data and consists of fact tables and dimension tables. The layer of analytical objects includes analytical models, aggregates tables and reports. These analytical objects are used for on-line analytical processing. The layer of pre-loading processing provides loading and preliminary processing of monitoring data from heterogeneous operational databases. This layer includes data sources, loading scripts and temporary tables.

There are historical and actual data in the fact tables in the stationary storage. Historical data includes archive monitoring data. Referenced data as a dimension tables includes Russian, regional and specialized classifiers and glossaries. The stationary storage content is represented in Table 1.

TABLE I. THE STATIONARY STORAGE CONTENT

Monitoring fields	Fact tables	Dimension tables
Emergency situations	– Emergencies data; – Accidents data.	– Territories; – Emergency types; – Emergency scale; – Emergency causes; – Fire-prevention groups.
Meteorological situation	– Meteorological data from meteostations (e.g. temperature, speed and direction of wind, atmospheric precipitation, air moisture, atmospheric pressure); – Weather forecast; – Meteorological data from sensors.	– Territories; – Meteostations; – Dangerous weather events; – Sensors.
Hydrological situation	– Water level of the rivers; – Water discharge of the hydro power plants; – Water level of hydro power plants; – Ice conditions.	– Territories; – Water bodies; – Hydroposts; – Hydro power plants; – Crucial water levels of the rivers; – Crucial water levels of hydro power plants; – Acceptable levels of water discharge; – Freezing-over types.
Seismological situation	– Seismic events characteristic (e.g. depth, magnitude, diameter of the transient cavity, epicenter coordinates).	– Territories; – Seismic stations; – Seismic event types.
Radiation situation	– Expose dose of gamma-ray; – Volumetric activity of gamma-emitting radio nuclides in water.	– Territories; – Sensors; – Crucial doses of gamma-ray.
Flood situation	– Flood areas; – Condition of hydraulic facilities.	– Territories; – Hydraulic facilities types; – Hydraulic facilities states; – Water bodies; – Dangerous objects.
Housing and communal services	– Data about the preparation for heating season (e.g. fuel reserves, fuel supply, equipment reserve, material and financial resources); – Condition of objects (e.g. heat source, energy source, electric power lines, communication); – Housing and communal accidents.	– Territories; – Housing and communal objects; – Housing and communal objects types; – Housing and communal accidents types; – Fuel types; – Financing sources; – Communal services.

The analytical models of the analytical objects layer are set of data marts for on-line analytical processing of monitoring data. Each data mart has a number of prepared data representations as the analytical models (OLAP-models). The aggregate tables store intermediate results for complex analysis. Important results of analytical processing can be represented as the analytical reports and can be saved in the analytical objects layer too.

The data sources of the pre-loading processing layer provide connections with heterogeneous operational databases. The loading scripts enable DWM to load and refresh monitoring data from different sources, according to timetable. The temporary tables of the pre-loading processing layer are used for storing intermediate loading data during their conversion.

In addition, DWM has special section “The analytic portfolios” that consists of analytical portfolios – a set of analytical models for different user roles.

So, the data warehouse of emergencies monitoring accumulates data from different monitoring services for the further multiaspect analytical processing.

IV. ON-LINE ANALYTICAL PROCESSING OF MONITORING DATA

The On-line analytical processing (OLAP) is used for analytical decision making support [7]. The OLAP tools and methods developing and extension of OLAP implementing scope are of importance today.

The DWM is integrated with original on-line analytical processing tools for emergences monitoring. The “Espla-M” means allows user to create and modify analytical models and to use these for analytical portfolio forming. OLAP-models are used for situations multiaspect analysis, on-line estimating of the emergencies risk and forecasting of the emergencies consequences.

A set of particular OLAP-models have been developed for each of the monitoring field.

Field: Emergency situations

OLAP-model: Controlled emergencies

Dimensions: Year, Emergency date, Emergency liquidation date, Place, Emergency type, Emergency scale and Emergency cause.

Facts: Died people, Victims, Emergencies count and Material damage.

Field: Meteorological situation

OLAP-model: Temperature
Dimensions: Year, Place, Date, Meteostation
Facts: Temperature

OLAP-model: Speed and direction of wind
Dimensions: Year, Place, Date, Meteostation
Facts: Speed of wind and Direction of wind

OLAP-model: Weather forecast
Dimensions: Date, Territory
Facts: Weather forecast description

OLAP-model: Meteorological data from sensors
Dimensions: Year, Place, Date, Sensor
Facts: Temperature, Speed and direction of wind, Air moisture, Atmospheric pressure

Field: Hydrological situation

OLAP-model: Water level of the rivers
Dimensions: Year, Date, Month and day, Hydroposts, River
Facts: Water level of the rivers, Crucial water level of the rivers, Exceeding of crucial water level

OLAP-model: Water discharge of the hydro power plants
Dimensions: Year, Date, Hydro power plant
Facts: Minimal acceptable level of discharge, Maximal acceptable level of discharge, Water discharge level

OLAP-model: Ice conditions
Dimensions: Year, Date, Hydroposts, River, Freezing-over type
Facts: Count of ice events, Ice event description

Field: Seismological situation

OLAP-model: Seismic events
Dimensions: Year, Date, Place, Seismic station, Seismic event type
Facts: depth, magnitude, diameter of the transient cavity, epicenter coordinates

Field: Radiation situation

OLAP-model: Expose dose of gamma-ray
Dimensions: Date, Place, Sensor
Facts: Expose dose of gamma-ray

OLAP-model:
Dimensions: Date, Place, Sensor
Facts: Volumetric activity of gamma-emitting radio nuclides in water

Field: Flood situation

OLAP-model: Flood forecast
Dimensions: Year, Territory, Hydroposts, River, Date of expected flood, Date of fact flood in the last year
Facts: Minimal expected water level, Maximal expected water level, Fact water level in the last year

OLAP-model: Hydraulic facilities condition
Dimensions: Year, Place, Water body, Hydraulic facilities, Hydraulic facilities type, Hydraulic facilities state
Facts: Volume of hydraulic facility, Square of hydraulic facility

Field: Housing and communal services

OLAP-model: Housing and communal accidences
Dimensions: Year, Place, Accidence date, Liquidation date, Emergences types, Communal services
Facts: Adult victims, Children victims, Count of accidence, Accidence causes description, Liquidation actions description

OLAP-model: Housing and communal accidences forecast
Dimensions: Year, Place, Report date, Housing and communal object
Facts: Population, Probable victims, Probable accidence description, Description of the probable liquidation actions

OLAP-model: Fuel reserve
Dimensions: Year, Territory, Fuel types, Report date
Facts: Requirement of fuel, Fact reserve of fuel, Readiness

The OLAP-models are used for analytical portfolio forming in accordance with different user's roles. The OLAP-models can be represented as statistical table, cross-table, diagram and map for geographical data. All these facilities of the data visualization give user opportunity to change traditional view point and discover new analytical relations between monitoring data [8-10].

The statistical table represents analytical processing result as a relational table (Fig.3). Using statistical tables, user can filter data, change font color for fact value interval and sort data. Moreover, the statistical table enables user to process data with standard statistic functions: expectation, variance, quintiles, correlation and cluster analysis.

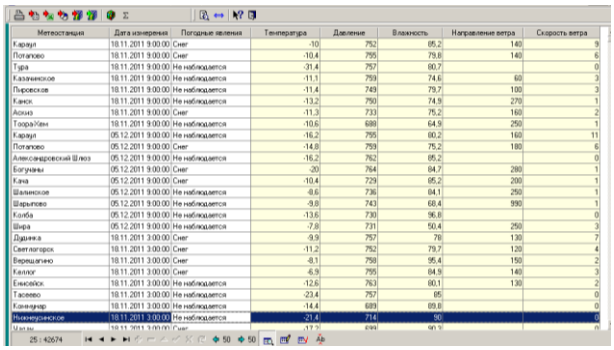

Figure 3. The statistical table

The cross-table provides interface for intuitive manipulation of analytical results. It allows user to change fields order in vertical and horizontal header of table, interchange facts and dimensions (table pivoting), choose needed level of aggregation and detailing by dimension hierarchy, "slice" and "dice" data set (Fig.4). OLAP

operations enable users to navigate data flexibly, define relevant data sets, analyze data at different granularity and visualize results in different forms.

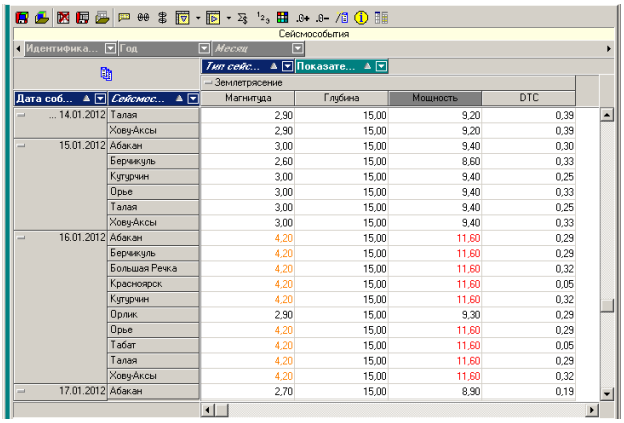

Figure 4. The cross-table

The "Espla-M" analytical tools support various types of diagrams: horizontal and vertical bar charts, pie charts, point charts, line charts, area charts, etc. The diagram tools provide the selection of user preferences. The user can choose a dimension and generate series of diagrams, according to dimension values. The diagram is the special OLAP tool. It allows user to do data visual comparison and forecast. For example, if user constructs hydrographs for several years, he can define "analog-year" and forecast water level of river (Fig.5).

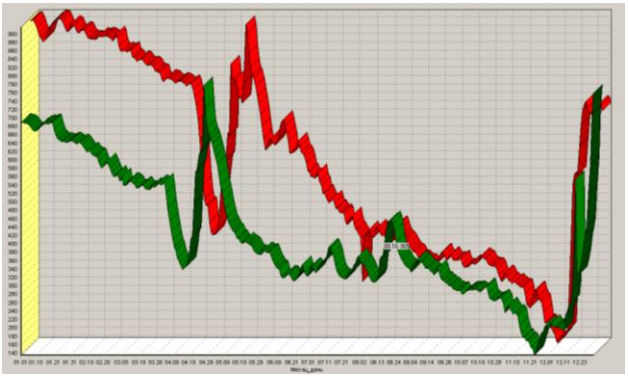

Figure 5. The river hydrograph

If the OLAP-model has geographical dimension, it can be processed as map (Fig.6).

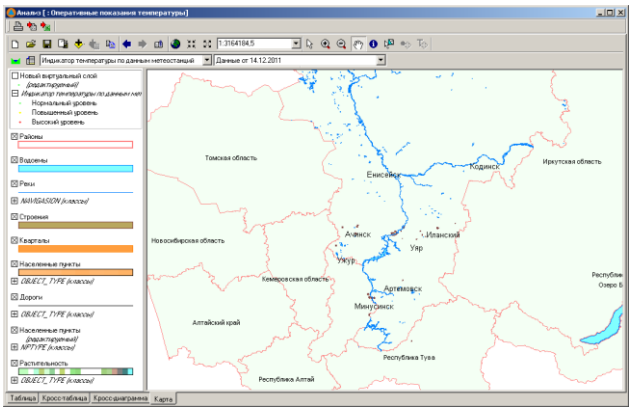

Figure 6. The map

Map layers and polygons relate to analytical model facts. Values or indication marks of facts are represented by color of map objects. It is the most demonstrative way of geographical data representation.

The OLAP tools allow a user to perform multiaspect monitoring of natural and anthropogenic emergency situations. Using the OLAP technology into new fields and for new tasks improves OLAP tools and methods.

V. ON-LINE STATE CONTROL

The original visualization tool "Semaphore" has been developed for on-line control of the monitoring parameters in system "Espla-M" (Fig.7). This tool allows user to estimate of the emergencies risk based on a comparison of actual monitoring data with their crucial values. There are three levels of emergencies risk:

"Green" – the situation is normal; the parameter value doesn't exceed crucial value.

"Yellow" – the situation requires attention; the parameter value is approaching to crucial value.

"Red" – the situation is dangerous; the parameter value exceeds crucial value.

The absence of actual data is marked as grey indicator.

The criterions of the emergencies risk are represented in Table 2.

TABLE II. THE CRITERIONS OF EMERGENCIES RISK

№	Parameter	Cause	Level
1. Emergency situations			
1.1	Emergencies Accidents (EA)	EA count = 0	green
		EA count > 0, 1 or more days ago	yellow
		EA count > 0 today	red
2. Meteorological situation			
2.1	Temperature (T)	else	green
		$30 \le T < 35$ or $-40 < T \le -35$	yellow
		$T \ge 35$ or $T \le -40$	red
2.2	Speed (WS) and direction of wind	$0 < WS < 15$	green
		$15 \le WS < 25$	yellow
		$WS \ge 25$	red
3. Hydrological situation			
3.1	Water level of the rivers (RL)	0 < RL< critical-10%	green
		critical -10% ≤ RL < critical level	yellow
		RL ≥ critical level	red
3.2	Water level of hydro power plants (HL)	min+20<HL<max-20	green
		min<HL≤min+20 **or** max+20≤HL<max	yellow
		HL≤min or HL≥max	red
3.3	Ice conditions	else	green
		ice jam	yellow
		-	red
4. Seismological situation			
4.1	Earthquake, magnitude (M)	M < 3	green
		3 ≤ M < 5	yellow
		M ≥ 5	red
5. Radiation situation			
5.1	Expose dose of gamma-ray (ED)	ED < 20	green
		20 ≤ ED < 40	yellow
		ED ≥ 40	red

№	Parameter	Cause	Level
6. Flood situation			
6.1	Flood areas	else	green
		residential buildings are in flood area	yellow
		dangerous industrial objects are in flood area	red
6.2	Condition of hydraulic facilities	else	green
		pre-crash state	yellow
		state of emergency	red
7. Housing and communal services condition			
7.1	Housing and communal accidents (HA)	HA count = 0	green
		HA count > 0, 1 or more days ago	yellow
		HA count > 0 today	red

As usual, the intervals of acceptable values are individual for each monitoring parameter. The crucial values for meteorological, hydrological, seismological, radiation situations are determined in accordance with natural characteristics of the Siberia territory.

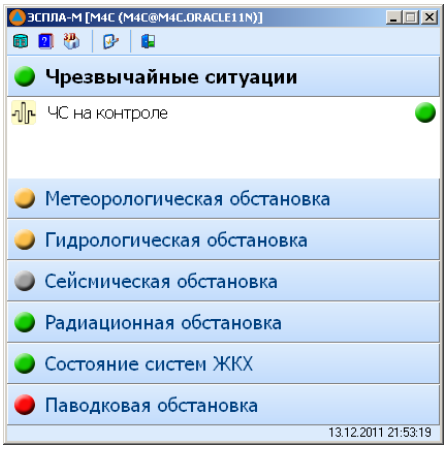

Figure 7. The “Semaphore” tool

The original result of the research is OLAP-models and “Semaphore” tool integration. Each of analytical models is associated with significant monitoring parameter and indicator causes. So, it allows user to observe field’s and model parameter’s states and detail analytical information. On-line state control provides immediate emergency reaction of the CMP.

VI. Conlusion

The integration of OLAP, data warehouse and expert systems technologies improves an efficient of emergency situation monitoring. The data warehouse technology provides accumulation of data from different monitoring services and storing of processing methods as the prepared OLAP-models and analytical portfolios. The OLAP technology allows a user to perform multiaspect monitoring of natural and anthropogenic emergency situations. The expert systems technology enables user to estimate of the emergencies risk based on state indicators. On-line state control provides immediate emergency reaction of the CMP.

Using the data processing and storage technologies into new domains and for new tasks solving improves tools and methods of decision making support.

Abstract - In today's every-day changing economy, direct sales is of big importance both as a sales and customer satisfaction tool but also as an information retrieval process. In direct sale business there is a problem of geographical deployment of the salesmen and thus utilization of the complete clients population dispersed geographically. In this paper we analyze those parameters on the example from the Croatian market. Problems are identified and possible improvements by utilizing some of the travelling salesmen problem solutions are analyzed.

I. INTRODUCTION

In business today, direct sales is an increasing trend. [1] Direct sales bring numerous benefits to businesses and not just in terms of sales performance but also in terms of data acquisition directly from the field and increase customer satisfaction. Problems that arise in direct sales planning are of course of combinatorial nature when thinking about the salesmen deployment on the field. But also, there are some businesses that require consideration of the time dimension i.e. the moment when sending the salesmen to the specific area is most feasible. In this paper we present short data mining analysis performed on the data from the Croatian market. After that we present existing solutions for Traveling Salesman Problem. Finally we conclude with some criticism of the existing methods and give thoughts on future research from the field.

II. RESEARCH PROBLEM

Motivation for this paper derives from a real world problem from the Croatian market. In this chapter we will present analysis performed on the data from one Croatian market. Some exact numbers i.e. specific clients count per city is not shown because of data privacy & security laws and company's regulations, but gross figures are disclosed and just enough to present the point from this research.

A. Distributions analysis

As we have presented earlier in this paper, problem is of geographical nature. To start working on the solution, our first step was distribution analysis. Hopefully this will give us some hints on how to approach the problem.

By using the SQL queries and SAS JMP software package [2] we have conducted initial statistical analysis to see if there are geographical areas that are somehow more or less ignored by the company and to see if there are differences in acceptance rate for the selling process between the areas.

Data set used for calling success rate analysis consisted of 653.377 observations. Observed were calls made by call centre employees and their outcomes i.e. if the sales meeting is arranged or not. Possible outcomes were "meeting accepted", "meeting not accepted", "call later". Observed variables were "user" i.e. employee that was making the call, "area" representing area or city where customer that is being called is located and "region" representing geographical region.

First analysis is considering the global information value of each variable. Table 1. shows results calculated in Orange data mining tool [3] that are at first thought rather disappointing. To find out the value of information of the observed variables, we calculate information gain. Information gain is a measure that shows mutual information between the observed and a goal variable [4]. We can see that each of our variables has a very small information gain. First variable that is representing users has relatively highest information gain. This means that call centre employee has more impact on the selling process than the area in which the client is located. Small information gain has a logical explanation - all of the employees go through a similar training and have similar selling arguments. But still, there are differences among them. As this is not main topic of this research, here we will focus more on next two variables. We can see that both of them have very small information gain, but interesting thing is that variable "area" has slightly more influence than "region". This tells us that we will need to drill down to the area level if we want to make conclusions there and thus precise selling prediction model.

TABLE I. INFORMATION VALUE OF THE OBSERVED VARIABLES REGARDING THE SALES SUCCESS

Variable	Number of observations	Information gain
user	141	0.158
area	922	0.032
region	23	0.022

Next step is to get more insight into distributions of the calling success rate by areas i.e. places where clients are. For that purpose we have calculated success rates of the calls grouped by areas. Because success calculations of interest for this analysis are those that can be calculated i.e. where at least one successful call was made, we have omitted some areas so gross population for this data subset is smaller. Exact distribution analysis calculated in SAS JMP tool can be seen in Table 2.

TABLE II. DISTRIBUTION ANALYSIS ON COMPUTED VARIABLE "SUCCESS"

Percent	Statistic	Success rate
100,0%	maximum	100,00
99,5%		100,00
97,5%		100,00
90,0%		39,96
75,0%	quartile	28,98
50,0%	median	22,73
25,0%	quartile	19,09
10,0%		16,32
2,5%		11,00
0,5%		6,25
0,0%	minimum	5,26

Moments that are characteristic for our data set calculated in SAS JMP tool are shown in Table 3.

TABLE III. INFORMATION VALUE OF THE OBSERVED VARIABLES REGARDING THE SALES SUCCESS

Statistic	Value
Mean	26,89477
Std Dev	15,93336
Std Err Mean	0,688216
Upper 95% Mean	28,2467
Lower 95% Mean	25,54283
N	536
Sum Wgt	536
Sum	14415,6
Variance	253,8721
Skewness	3,149492
Kurtosis	11,3529
CV	59,24336
N Missing	0

From these numbers we can conclude that we maybe have outliers on the right side of our distribution. To make this clearer, we give histogram on Figure 1.

Further analysis showed that these outlier areas are those with small number of clients and calls established. To further prove this, we have done Bivariate Fit Y by X analysis using two variables, "success" and "calls count". This is shown on Figure 2.

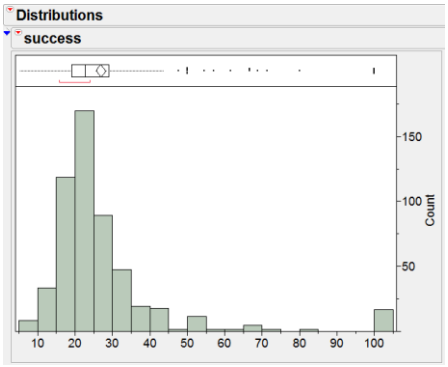

Figure 1. Histogram showing success rate distribution by area

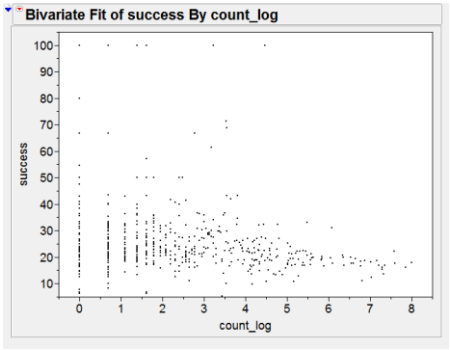

Figure 2. Fit on variable success by total clients count grouped by area

Interesting phenomena can be seen as vertical "lines" formed by dots in the left area of the Figure 2, ranging from very small success rate to highest success rate. This means that we have many small areas and statistical results there are not representative. X axis on the graph represents clients count in the area transformed into logarithmic scale so that very small areas can be compared to large cities.

By doing these analyses we got deep insight into our data and next assumption was that areas with small number of calls and thus non-realistic success rates are in fact areas with small number of clients. To further confirm this, we made bubble plot graphical analysis comparing actual number of meetings arranged to a success rate. Bubble sizing is done on the actual clients count variable. This is shown in Figure 3.

Here, X axis represents calling success rate and Y axis represents actual number of meetings arranged in logarithmic scale. It is obvious that areas with very big or very small success rate in fact have small number of arranged meeting and thus their statistics are not representative.

In this way we confirmed that both small number of clients on the area and small number of calls have big impact on success rate bias. As areas that have success

rate between approximately 10% and 35% include most of the population interesting further observation is that this "belt" includes most of the overall areas populations and most of the mid-sized ones.

Formal proof that small areas are in fact outliers in this analysis is as follows.

Resulting from statistics presented in Table 1. and Table 2. we have

$$\bar{X} = 26{,}89$$

as being the mean and

$$\sigma = 15{,}93$$

as being the standard deviation.

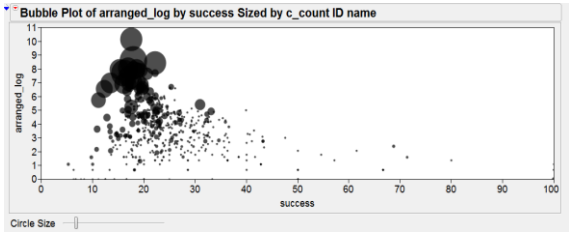

Figure 3. Bubble plot of success rate and arranged meetings grouped by areas and sized by clients count

If we consider outliers as being values over 3 standard deviations than we can check each area success rate over the Z score ie. normalizing our distribution to standard normal distribution and comparing the values to standard deviation [5]. Continuing we can conclude that success rates ranging from 74,68% to 100% are definitely outliers. Since most of the areas have success rate lower than 74,68% threshold we can say that all of them have significant importance in business sense i.e. we should consider them for sales process.

B. Geographical problem visualization

Bubble plots on Figure 5 are plotted by geographical coordinates of areas showing overall clients distribution on the upper image and distribution of clients that have never been called on lower image. Bubble size represents clients count on the respective area. Interesting to note here is different distribution of medium sized and big sized bubbles on those images. This means that there are areas that are somewhat ignored by the sales process.

Figure 6 is actually combination of the plots shown on Figure 5. Bubble sizes represent number of clients in the area. From Figures 5 and 6 we can conclude that there are many areas where clients have never been called. On Figure 6 that is shown with red color, and total number of clients in the area is shown in blue color.

Obviously bubbles will overlap at each area but interesting thing here to note is that blue bubbles indicate areas where all clients are called. Red bubbles indicate that almost all or all of the clients in area have never been called, and areas where blue bubble is bigger than the red one indicate that some of clients from that area have never been called. If the concentric red bubble is significantly smaller than the blue one, then most of the clients in the area have been called.

Furthermore, if only red bubble is visible on the area than those are in fact areas of interest here, because layer with red color is on top of the blue one, and that means that these are areas that are out of reach of the sales process.

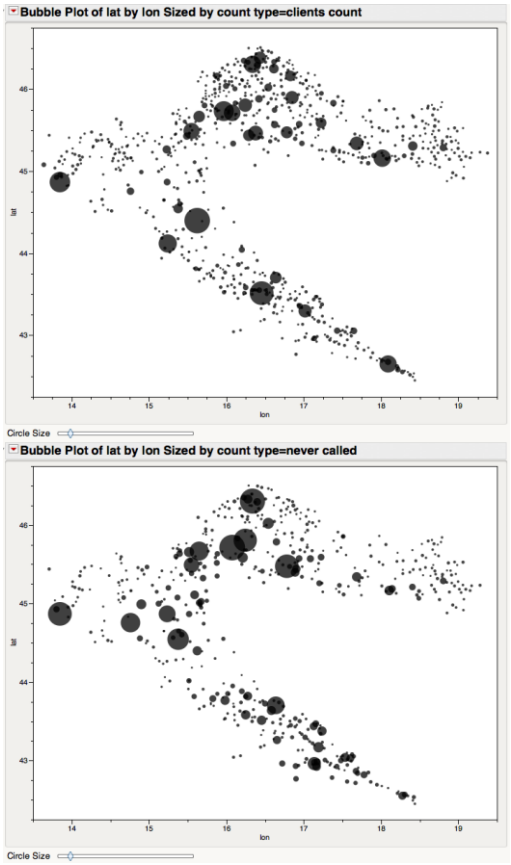

Figure 5. Bubble plot of overall and never called clients distribution by location

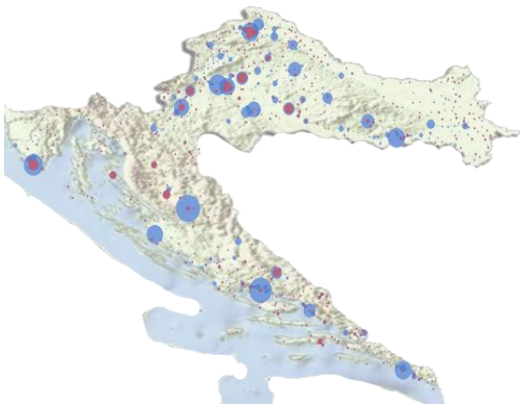

Figure 6. Overlapping sales reach with topographic map

Figure 6 indicates that areas that are out of reach of the sales process are mostly mountain regions, islands and areas near border and away from big regional centers.

III. TRAVELLING SALESMAN PROBLEM AND SIMILAR SOLUTIONS REVIEW

Interest for direct selling does appear to be growing. Financial advisors and investors both are seeing direct selling companies with new eyes, focusing on the efficient business model, rapid growth and generally low ongoing capital investments after the initial surge [1]. But what does a traveling salesman do when he has to visit several cities in one day keeping in mind optimization of traveling costs? He has to combine a lot. Given a collection of cities and the cost of travel between each pair of them, the traveling salesman problem, or TSP for short, is to find the cheapest way of visiting all of the cities and returning to the starting point. The importance of the TSP is that it is representative of a larger class of problems known as combinatorial optimization problems. The TSP problem belongs to the class of combinatorial optimization problems known as NP-complete. If the solution for TSP would be found than all the problems in class NP could be solved in polynomial time[8].

The first step to solving instances of large TSPs must be to find a good mathematical formulation of the problem. Travelling salesman problem can be modeled as an undirected weighted graph, such that cities are the graph's vertices, paths are the graph's edges, and a path's distance is the edge's length (cost). A TSP tour becomes a Hamiltonian cycle if and only if every edge has the same distance. Often, when the salesman can get from every city to every other city directly, then the graph is said to be a complete. If no path exists between two cities, adding an arbitrarily long edge will complete the graph without affecting the optimal tour. The length of a tour is the sum of the lengths of the lines in the round-trip[7]. In the standard version we study, the travel costs are symmetric in the sense that traveling from city X to city Y costs just as much as traveling from Y to X [5]. But, there are two versions of TSP: symmetric and asymmetric. In the *symmetric TSP*, the distance between two cities is the same in each opposite direction, forming an undirected graph. This symmetry halves the number of possible solutions. In the *asymmetric TSP*, paths may not exist in both directions or the distances might be different, forming a directed graph.

Applications of the TSP and its variations are much larger than a simple route planning of a salesman. Those can be found in different area of knowledge like mathematics, computer science, operations research, genetics, engineering and electronics.

Stated problem in its general form has its origins back in '30s of the past century but it became popular in the '80s [6] and since then, a lot of scientific papers, articles and books have been written about it. A lot of people tried to find generally applicable solution of the problem, mostly based on complex mathematic algorithms and focused on just a few variables, like the shortest route and optimization of traveling costs.

There are different variations of TSP [7] that have been originated from various real life or potential applications, like *The MAX TSP, The Bottleneck TSP, TSP with multiple visits, Period TSP, The delivery man problem, Black and white TSP, Angle TSP, The Selective TSP, The Euclidian TSP* etc. Some of mentioned variations are the simple ones, which can easily be formulated to regular TSP – like *The MAX TSP, The Bottleneck TSP or TSP with multiple visits.*

We have reviewed and analyzed large amount of scientific papers, books and online sources on traveling salesman problem theme. There are many proposed solutions of TSP, but to keep it simple and comprehensive, solutions are grouped due to their basis: mathematical algorithms and software support.

IV. MATHEMATICAL ALGORITHMS AS A BASIS FOR TSP SOLUTIONS

A. Branch and bound model

Branch and bound search method represents an organized way to make exhaustive search for the best solution in a specified set. Each branching step splits the search space into two or more subsets in an attempt to create sub problems that may be easier than the original. Before searching a sub problem and possibly splitting it further, a bound is computed on the cost of routes in its subset. The purpose of the bounding step is to attempt to avoid the fruitless search of a sub problem that contains no solution better than those that have already been discovered. The idea is if the bound is greater than or equal to the cost of a route that is already found, then the sub problem is discarded without any danger of missing a better route [10]. Branch and bound model was discussed in many papers [11], [12], [13], as a proposed solution for TSP.

But, the algorithm has its big disadvantage: it is extremely time-consuming - the number of nodes in a branching tree can be too large. The algorithm finds the first complete schedule and then tries to improve it. Often developing the “promising” branches may lead to a huge number of offsprings that finally may not give an improvement. Thus the size of the tree may grow exponentially without improving the best solution obtained [28].

B. Heuristic search algorithms

Heuristic search algorithms are designed to run quickly and to return a hopefully good solution of a given problem. There are several kinds of heuristic algorithms that serve as a basis for TSP solution.

Local search algorithm takes as input an approximate solution to a problem and attempts to iteratively improve it by moving to new solutions that are in some sense close to the original. It is based on a notion of a neighborhood, which implicitly defines the list of candidates that can be considered in a given iteration. More about use of local search algorithms in solving the traveling salesman problem can be found in [14-16].

Simulated annealing algorithm– a typical local search algorithm follows the hill climbing strategy of only moving to a neighboring solution if this one is better. In simulated annealing heuristics, this is relaxed to allow the algorithm to accept with a certain probability a neighbor that is worse than a current solution. The probability of acceptance is high at the beginning but it gradually decreases as the run progresses. The idea is to allow the

algorithm to jump over to a better hill before switching to a steady climb. Use of this algorithm in traveling salesman problem has been popular in last few years. In different studies the application of it on TSP is shown more detailed [17-20].

Neural network algorithms follow a computational paradigm that is based on models of how brain processes information. The basic components of a neural network are large numbers of simple computing units that communicate via a network of connections, simulating the parallel operation of neurons in the brain. Some of new proposed solution based on neural network algorithms can be found in [21-23].

Genetic algorithms work with a population of solutions that are combined and modified to produce new solutions, the best of which are selected for the next generation of population. The general scheme is modeled after evolutionary processes in nature. Improvements and new ideas regarding applications of genetic algorithms in TSP solutions can be read in [24-26]. Due to number of available original research papers, the use of genetic algorithms in solving TSP appears to be the most popular of all mentioned algorithms.

C. *Ant colony optimization*

Ant algorithms are multi - agent systems in which the behavior of each single agent, called artificial ant or shortened ant, is inspired by behavior of the real ants. These algorithms are one of the most successful examples of swarm intelligent systems and have been applied to many types of problems, including TSP [12]. More about application of ant colony algorithms on TSP solution can be found in recent papers [26-27].

All mentioned methods of finding the best solution of TSP do not deal with temporal component of the problem, which is the key aspect of our problem. These algorithms are not applicable on dealing in the same time with both finding the shortest route and keeping it timely optimal.

V. SOFTWARE SUPPORT FOR TSP SOLUTION

There are different software solutions which are being used as a support in direct sales, including campaign management, logistics, resource planning, back office etc. One of the software products for sales with temporal component is SAS Customer Intelligence[1].

Important software which offers the integration of various things: Contact database, CRM Integration, data import/export, graphical planning, multi-campaign, multi-channel management, reporting, ROI analytics, sales analytics, telemarketing management, up-sell management etc is also Microsoft Dynamics CRM[2]. SAP CRM[3] is also very used software in sales, it supports sales planning and forecasting, territory management, accounts and contact management, activity management, opportunity management, sales contract management, sales performance management, sales analytics etc. Very similar to SAP CRM is Oracle SIBEL CRM[4] solution for Sales. The Salesforce's Sales Cloud[5] is also very popular CRM Sales solution, different from others mentioned because of its cloud infrastructure. It offers pretty much the same sales features like mentioned ones, but it doesn't have geographical representation of places which need to be visited to complete the sale, like MS Dynamics or Salesforce's Sale Cloud have. Here are mentioned some of very popular and very trusted CRM software, which all have pretty similar features. All mentioned solutions are CRM tools.

Although some of these tools offer territory management, they are quite different than our solution, as mentioned in previous paragraph.

VI. CONCLUSION AND FUTURE WORK

In this paper we have presented results from one case study research performed on the data from the Croatian market. Research had a goal to find out whether sales process is reaching all clients and if not, why not. Research showed that there are areas that are not being affected by the sales process. After that we give analysis of the existing mathematical, heuristic and software support on the traveling salesman problem. Since all solutions deal with geographical aspect i.e. finding the shortest route and considering the fact that there are no solutions for solving the problem of selling services and products with temporal characteristics, our next research from this field will be focused on finding the best methodology for choosing the right moment for salesman deployment on the field and thus prepare the data for applying the existing TSP solutions.

Abstract—**Defining structural constraints in multidimensional models is certainly a necessity to ensure the consistency of such models, especially the hierarchical structure of dimensions. This necessity increases when considering temporal and multiversion multidimensional models due to their temporal extension. Our proposed model for managing multiversion data warehouses (MV-DW) supports several structural and temporal constraints. In this paper, we enrich these constraints by the temporal fact-dimension dependency constraint which deals with relationship between fact and dimensions in a temporal context. Besides, schema and instance evolution operators can introduce inconsistencies in MV-DW schema and/or data. Such inconsistencies can be avoided by checking the defined MV-DW constraints. To this end, we define two classes of technical issues. The first one deals with algorithms that have to be run following to schema evolution operators to check the consistency of the changed DW schema. The second issue deals with triggers that have to cancel data propagation when detecting any instance constraint violation.**

I. INTRODUCTION

A Data Warehouse (DW) is a special database that stores information oriented to satisfy decision-making requests. The most popular architecture for DW is based on multidimensional data cubes [14], where the analysis subject (fact) is described by numerical measures and several dimensions, constituting analysis axes. A dimension is organized according to one or more hierarchies which organize levels from the finest level to the less detailed. Level instances are called dimension members (DMem)

Many changes can occur at the DW schema and instances. These changes may come from data source structures and their content changes; or from new analysis requirements expressed by users. Indeed, data sources are subject to several evolutions; customers can change their addresses, countries can be merged or partitioned, etc. Moreover, users can express new analysis requirements such as adding a new dimension or a new measure to a cube. In order to ensure the accurateness of analysis queries, it is necessary to take these evolutions into account and to reflect them correctly in the DW. Several issues often grouped under the term "temporal data warehousing" [11], have been proposed. Our issue consists in a multiversion DW (MV-DW) management system based on DW schema and instance versioning.

In order to ensure the consistency of the DW model, several Built-in constraints have to be defined, especially on the hierarchical structure of dimensions [15]. In [21], we have defined built-in MV-DW constraints that ensure the consistency of hierarchy structures in temporal context. In this paper, we propose temporal fact-dimension dependency constraint to ensure summarizability of measures according to dimension versions. Then, we propose technical issues to maintain the validity of the MV-DW constraints when performing evolution operators. We classify these issues in two classes depending on whether we perform a schema evolution operator or there is a propagation of instance evolution operator.

- The first one deals with checking MV-DW constraints after having performing schema evolution operators, e.g., Add_Level. Hence, specific algorithms have to be run to check if the changed DW schema still respect built-in constraints, e.g., up connectivity.

- The second one deals with checking MV-DW constraints during propagating instance evolutions in the DW, which are first detected from data sources, e.g., Split_Member [20]. Indeed, specific triggers should be used to ensure data consistency in the concerned DW.

The rest of this paper is organized as follows. Section 2 presents related work dealing with managing constraints in temporal DW. In section 3, we present basic principles of our MV-DW model, its formal expression and the evolution operators which it supports. In section 4, we introduce MV-DW dimensional and fact constraints. Section 5 deals with managing consistency in MV-DW through maintaining the validity of the defined constraints. Finally, section 6 concludes the paper.

II. RELATED WORK

Several approaches have been proposed to deal with schema and instance evolutions in DW [11]. They differ in several aspects. For instance, some of them allow tracking the history of DMem evolutions [4, 7]. Others ensure the registration of temporal versions for DW schema and instance components through an implicit or an explicit schema and data versioning [8, 5, 3, 10, 17, 18]. They include our own approach [19, 20, 21] based on a MV-DW management system.

Several integrity constraints have been defined in non temporal multidimensional model. Conceptual semantic constraints are defined in [6]. In [9], semantic constraints between dimension hierarchies (inter- and intra-dimension constraints) are defined. In [13], authors propose seven constraints which must be satisfied by dimension members (e.g., up connectivity, partitioning). From another side, several works focus on solving summarizability problems in complex multidimensional structures [16]. Authors of [13] deal with enriching hierarchy schema with dimension

constraints which allow inferring summarizability in heterogeneous dimensions. In this paper, we consider homogeneous dimensions with strict hierarchies as introduced in [14] or models in the first multidimensional normal form (1MNF) as presented in [15].

Some temporal multidimensional models integrate constraints. The temporal star schema proposed in [4] allows maintaining two integrity constraints: (i) *Self-Consistency*, that means that the timestamps of rows representing the same object must neither overlap others nor leave gaps, and (ii) *Referential Integrity*, that constitutes a temporal extension of the classic referential integrity between fact table and dimension tables. Abello et al. [1] define a bitemporal storage structure where each attribute is associated with transaction and validity timestamps including classic database integrity constraints (e.g., primary key). The COMET model proposed in [8] includes integrity constraints which have to check the consistency of the assignments between DW. In [17], DW schema version is extended by integrity constraints (e.g., primary key, null/not null) associated to level attributes and fact attributes. Besides, constraints dealing with valid time of real and alternative DW versions were proposed.

Most of the proposed temporal multidimensional models do not define integrity constraints. Only constraints that describe restriction on time-stamping intervals or conceptual constraints were defined in few models [8, 17].

III. MULTIVERSION DW SYSTEM

A. Basic principles

We define a time interval, denoted by $[t_1, t_2]$, as a set of consecutive equidistant time instants, where t_1 is the starting instant and t_2 is the ending instant [12]. Note that instant is a time unit of measurement. We propose to version DW through keeping versions for cubes, dimensions, levels and dimension members [19]. When we create or drop an attribute, we create a new level version. Besides, we time-stamp attribute values to keep track of their history. Each version of the versioned components is characterized by a number and an application time interval [ATs, ATe]. ATs (Application start Time) is the instant at which the administrator decides to bring into application this version. ATe (Application end Time) is the instant at which he decides to stop this application. The distance between two consecutive time instants of the application time interval, is adjusted to the granularity of time dimension in the DW. For each time point t, it is possible to determine the current DW version; it is constituted by the current version of each component of this DW. Note that several cube versions may share one dimension version and several versions of the same dimension may share the same level version. In order to re-affect measure values to another member version, our system supports transformation functions based on weight factors or specific queries [19].

B. Formal expression of Multiversion DW

- Illustrative example

We study here the water sale management cube inspired from the commercial activity of SONEDE (National Company of Water Exploitation and Distribution in Tunisia). As shown in Figure 1, this cube analyses the *Water Sales* fact relatively to the following dimensions: *Time*, *Water Use* and *Water Connection*. The latter is organized according to two hierarchies *H_Org* and *H_Kind*. *H_Org* describes the organizational unities of the company going from the water connection to the correspondent Regional Direction. *H_Kind* describes the brand and the kind of water meters relative to water connections.

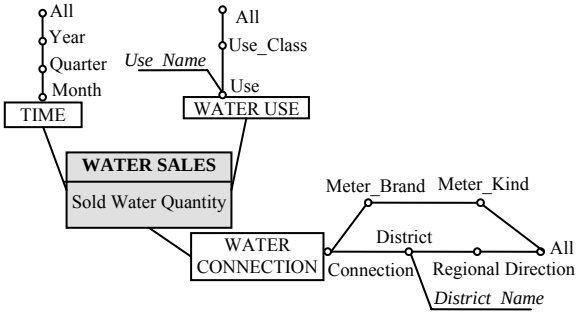

Figure 1. Water sales management cube

- MV-DW schema components:

As we have introduced in former works [19, 21], the MV-DW schema components are DW, cubes, dimensions, hierarchies, attributes and levels. The versioned components, i.e. cubes, dimensions and levels are described through their versions as follows.

Cube version. A cube version CV_j is defined as follows: $CV_j = <C_ID, CV_j_Num, \mathcal{DV}_j, \mathcal{M}eas_j, ATs_j, ATe_j>$. CV_j_Num and $[ATs_j, ATe_j]$ are respectively the version number of CV_j and its application time interval. $\mathcal{DV}_j = \{(DV_k, ATs_k, ATe_k), \ldots\}$ is the set of dimension versions belonging to CV_j. $[ATs_k, ATe_k]$ is the time interval of the assignment of DV_k to CV_j. $\mathcal{M}eas_j$ is the set of measures of CV_j.

Dimension version. A dimension version DV_j is defined as follows: $DV_j = <D_ID, DV_j_Num, \mathcal{LV}_j, \mathcal{H}_j, ATs_j, ATe_j>$. DV_j_Num and $[ATs_j, ATe_j]$ are respectively the version number of DV_j and its application time interval. $\mathcal{LV}_j$ and $\mathcal{H}_j$ are respectively the set of level versions and the set of hierarchies belonging to DV_j. A hierarchy H_k is defined as follows $H_k = <H_k_ID, Order_k>$, where H_k_ID is the identifier of H_k. $Order_k = \{(L_lV_x, order_l), \ldots\}$ is a set of pairs describing the organization of levels belonging to H_k. L_lV_x is a level version belonging to H_k. its order in H_k is $order_l$.

The base level of a dimension version DV_j belongs to each hierarchy of DV_j having an order equal to 1.

Example:

The Dimension *Water Use* identified by *Wat_Use includes one dimension version* $Wat_Use\mathbf{V_1} = <Wat_Use, 1, \{Use\mathbf{V_1}, Use_Class\mathbf{V_1}\}, \{H_Use\}, 01\text{-}2000, \infty>$, where $Use\mathbf{V_1}$ and $Use_Class\mathbf{V_1}$ are versions of the respective levels: *Use* and *Use Class*. $Wat_Use\mathbf{V_1}$ contains a unique hierarchy *H_Use:* $<H_Use, \{(Use\mathbf{V_1}, 1), (Use_Class\mathbf{V_1}, 2)\}>$.

Level Version. A level version LV_j is defined as follows: $LV_j = <L_ID, LV_j_Num, \mathcal{A}_j, ATs_j, ATe_j>$, where LV_j_Num and $[ATs_j, ATe_j]$ are respectively the version number of LV_j and its application time interval. $\mathcal{A}_j$ is the set of attributes belonging to LV_j.

- MV-DW instance components

MV-DW instance components are members (DMem), described through their versions, member relationships, transformation functions and fact valorization functions. In the following we define member version and fact valorization function.

Member version. A DMem version MV_j is defined as follows: MV_j= <*M_ID*, MV_j*_Num*, *Key_Val*$_j$, *LV*, $\mathcal{V}al\mathcal{A}_j$, *ATs*$_j$, *ATe*$_j$>, where MV_j*_Num*, *Key_Val*$_j$, [*ATs*$_j$, *ATe*$_j$] are respectively the version number of MV_j, its key value, and its application time interval. *LV* is the level version to which MV_j is assigned. $\mathcal{V}al\mathcal{A}_j$ is a set of tuples describing the attribute values of MV_j. It is defined as follows: $\mathcal{V}al\mathcal{A}_j$ = {(*A*$_k$, *val*$_k$, *ATs*$_k$, *ATe*$_k$), …}, where A_k is an attribute and *val*$_k$ is its value according to MV_j during [*ATs*$_k$, *ATe*$_k$].

Fact valorization function. To each cube version CV_j, we define a fact valorization function which associates for each set of base DMem (instances of the base levels), a value for each measure belonging to CV_j. A fact value is a tuple of the fact table. It consists of a set of base DMem and the corresponding measure values.

Example: The fact valorization function of the cube version *WaterSaleManagement_V1* is defined as follows.

$\mathcal{F}actVal$: *Month, Connection, Use*→ *Dom (SoldWaterQtity)*.

C. Multiversion DW evolution operators

Our system supports schema, instance and nomenclature evolution operators.

Schema evolution operators include: adding a dimension to a cube, removing a dimension from a cube, adding a level to a dimension, removing a level from a dimension, adding an attribute to a level, removing an attribute from a level, adding measure to a cube and removing a measure from a cube.

Instance evolution operators include: inserting a DMem deleting a DMem, splitting a DMem into n new DMem, merging n DMem into a new DMem, updating a DMem, regrouping a DMem, connecting a DMem to a new parent DMem (instance of a new superlevel)

Nomenclature evolution operators deal with DMem key value changes. They include key value change, key value reassignment, disturbing DMem split, disturbing DMem reclassification, disturbing DMem merge and disturbing level removal.

Readers are referred to [19, 20] for more details about evolution operators.

IV. MV-DW CONSTRAINTS

In this section, we define dimensional and fact constraints allowing maintaining the consistency of our model.

A. Dimensional constraints

A summary of the dimensional constraints which we introduced in a former work [21] is presented in Table 1. We classify these constraints into two classes: "structural constraint" and "temporal and versioning constraints". Note that "ATI" refers to Application Time Interval.

TABLE I. MV-DW DIMENSIONAL CONSTRAINTS

	Constraint	Description
Structural constraints	No empty dimension version	For each time point *t* of the ATI of a dimension version *DV*, there is at least one level version *LV* (≠ *All*) assigned to *DV* and its ATI includes *t*.
	Up connectivity	For each time point *t* of a level version L_iV_x (≠ *All*), there is at least one level version L_jV_y that is parent of L_iV_x and its ATI contains *t*.
	Level acyclicity	For each time point *t* of the ATI of a level version L_iV_x, there is not any level version L_jV_y such that L_iV_x is parent and child of L_jV_y at the same time t.
	Connectivity	If there is a relationship $\mathcal{R}$ between two DMem versions M_iV_x and M_jV_y, for each time point t of the ATI of $\mathcal{R}$, it must be a hierarchy relationship between their respective level versions.
	Partitioning	For each time point t of the ATI of a DMem version M_iV_x other than *all*, corresponds one and only one DMem version M_jV_y among the DMem versions of each successor level version.
Temporal and versioning constraints	DimVers/LevVers assignment	If a level version *LV* is assigned to a dimension version *DV* through the hierarchy *H*, then the ATIs of *LV* and *DV* must overlap.
	LevVersion instances	If a DMem version *MV* is an instance of a level version *LV*, then the ATI of *MV* must be included in that of *LV*.
	DMemVersion relationship	If there is a relationship *MR* between two DMem versions then their ATIs must overlap and the overlap-resulting interval must include the application time interval of *MR*.
	Version disjointness	The ATIs of two different versions of the same DW component are not overlapping.
	Unique dimension for each hierarchy	A hierarchy can be part of several dimension versions which must belong to the same dimension.
	Unique level for each level attribute	An attribute can be part of several level versions which must be relative to the same level.

B. Fact constraints

Certainly dimensional constraints, dealing with careful definition of dimensions and their hierarchies, ensure summarizability in multidimensional models. Nevertheless, further constraints dealing with relationships between facts and dimensions are needed to ensure summarizability [16]. Table 2 presents a summary of the fact constraints that we introduced in [21].

TABLE II. MV-DW FACT CONSTRAINTS

	Constraint	Description
Struct. Const.	No empty cube version	At each time point *t* of the ATI of a cube version *CV*, there is at least one dimension version assigned to *CV* at *t*.
Temporal and versioning constraints	CubVers/dimVers assignment	If a dimension version *DV* is assigned to a cube version *CV* then the ATIs of *DV* and *CV* must overlap. The overlap-resulting interval constitutes the ATI of the assignment *CV_DV*.
	CubVers/dimVers assignment disjointness	At each time point t of its ATI, a cube version should not contain more than one version of the same dimension.
	Unique Cube for each measure	A measure can belong to many cube versions which must be relative to the same cube.

- **Temporal fact-dimension dependency constraint**

In [16], authors affirm that it is necessary to define a constraint related to the grain of the fact in such a way that every measure in the fact must be determined by all dimensions. Such constraint has been dealt with in [15] through the first multidimensional normal (1MNF). Indeed, 1MNF makes sure that the base levels of all dimensions of a cube form a key for every measure and implies that all measures are recorded with the same granularity. It is in this context that we define the temporal fact-dimension dependency constraint as an extension of the 1MNF in the temporal multiversion context.

Note that a fact value is implicitly time-stamped by the dimension Time. Assume that I_{fact} is the time-stamp interval of a given fact value F_{val}. We define the temporal fact-dimension dependency constraint as follows.

Temporal Fact-dimension dependency: At each time point of the time-stamp interval of a fact value, belonging to a cube version *CV*, each measure must be determined by base levels of all dimensions. This means that, the time-stamp I_{fact} of a fact value F_{val}, has to be included in the application time interval of each DMem version belonging to a given base member version set of *CV*.

Example: Assume that M_1V_1, M_2V_2 and M_3V_1 are DMem version, instance of the respective base level version *USE_V1*, *CONNECTION_V1* and *MONTH_V1*.

M_1= <*keyVal: 17, NumVers:1, …, ATs: 01-2010, ATe: ∞* >

M_2= <*keyVal: D33_83_58, Num_Vers: 2, …, ATs: 07-2011, ATe: ∞* >

M_3= <*keyVal: 05-2011, NumVers: 1, …, ATs: 01-2010, ATe: ∞*>

F_{val} is a fact value, such that F_{val}= (M_1, M_2, M_3, 350). "350" is the value of the SoldWaterQuantity measure. The timestamp interval of F_{val} is [*05-2011*, *06-2011*] (the quantum is the month). For this example, we remark that the temporal fact-dimension dependency constraint is violated since during the interval [*05-2011*, *06-2011*], the fact value is determined only by M_1 and M_3. However, in this case, the base member version set is (M_1, M_2, M_3).

C. Constraint Algorithms

We define a specific algorithm for each of the defined MV-DW constraint in order to explain how it will be implemented.

To manipulate time intervals in these algorithms, we use Allen operators, such as *overlaps* and *during* [2]. Besides, we use a specific function called *Cover_Interval*, which allows checking whether a given time interval *I* is covered by S, a set of elementary intervals (cf. Figure 2). This function returns the non covered sub interval of *I*. It uses the time interval parameter I_{merge} which constitutes the result of merging contiguous or overlapping elementary intervals of S (cf. Figure 3). Note that we mean by "*I is covered by a set of time intervals S*" that each time point of *I* belongs to at least one elementary interval of *S*.

We remind here that *t*1 is the starting instant of a time interval and *t*2 is its ending instant.

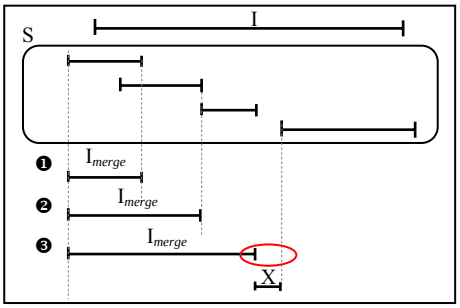

Figure 2. Cover_Interval function principles

Function *Cover_Interval*
Input : I: a time interval
S: a set of elementary intervals
Output : I_{res} : the non covered sub interval of I
Begin
if S is empty **then**
return I **end if**
Sort (S,n) // *Sort function allows to sort S according to t1*
I_{merge} ← S[1]
if I.t1 > I_{merge}.t1 **then**
I_{res}.t1 ← *I*.t1
I_{res}.t2 ← min(I_{merge}.t1, I.t2)
return I_{res} **end if**
return *recursive_check* (I_{merge}, I, S)
end

Function recursive_*check*
Input : I_{merge} , I : time interval
S: set of elementary intervals
Output : I_{res} : time interval // *the non covered sub interval of I*
Begin
if S is empty **then**
if I during I_{merge} or I equal I_{merge} **then** // *i.e., I is covered by* I_{merge}
return ∅
end if
I_{res}.t1 = I_{merge}.t2
I_{res}.t2 = I.t2
return I_{res}
end if
Y ← S[1] // *Y is a time interval*
if I during I_{merge} or I equal I_{merge} **then** // *i.e., I is covered by* I_{merge}
return ∅
end if
if I_{merge} before Y **then**
I_{res}.t1 ← I_{merge}.t2
I_{res}.t2 ← Y.t1
return I_{res}
end if
if I_{merge} meets Y or I_{merge} overlaps Y or I_{merge} starts Y **then**
I_{merge}.t2 ← Y.t2
end if
delete_first (S) // *this function deletes the first element of S*
return **recursive_*check*** (I_{merge}, I, S)
end

Figure 3. Algorithm of the "Cover Interval" function

By constraint of space, we present the algorithm of one constraint: *No empty cube version* (cf. Figure 4). Here, we show that the application time interval of a cube version *CV* must be totally covered by the application time intervals of the dimension versions assigned to *CV*. Hence, there is no time point t, belonging to the application time interval of *CV*, at which *CV* has no assigned dimension version.

```
Algorithm Check_NoEmpty_CubVers
Input: CV: Cube version
Output: I: Time interval // I ⊆ I_CV. During I, CV has not any assigned dimension version.
Variables: S[]: time interval array , n: integer
Begin
I_CV ← [CV.ATs, CV.ATe]
n ← 0
For each x in CV.getAssignedDimVers do
        n ← n+1
        S[n] ← [x.ATs, x.ATe]
End For
I ← Cover_Interval (I_CV, S, n)
return I   End
```

Figure 4. Algorithm of "No empty cube version" constraint

V. MANAGING CONSISTENCY IN MV-DW SYSTEM

In this section, we present technical issues to maintain the validity of the MV-DW constraints in our MV-DW system, *SysVersDW*. We classify these issues in two classes depending on whether there is a schema evolution operator or there is a propagation of instance evolution operator.

Figure 6 presents the framework that characterizes our approach to manage schema and instance evolutions in MV-DW. Using the ***schema evolution manager*** module the administrator defines schema evolution operators (e.g., ADD_LEVEL, ADD_DIMENSION). Then, the changed DW schema has to be checked. For this end, we propose to run a specific algorithm allowing to check the several MV-DW constraints concerned by the performed schema evolution operator. These algorithms are stored in ***DW Evolution Register*** and will be run by the ***executor module*** when the schema validity is checked.

To manage instance evolutions, we proposed a semi-automatic approach to detect simple and complex instance evolutions that occurred in data sources and propagate them in the MVDW [20]. Through the ***instance evolution manager***, the administrator specifies the evolution operation type (insert, split, etc.) and other information about the DMem concerned by this operation (dimension name, level name, etc.). He/She also choose from the set of change events (insert/update/delete record) provided by the ***detector***, those corresponding to the chosen evolution operation, as well as the necessary application times and transformation data (weight factors, queries, etc.) that will be defined for the transformations between the resulting DMem versions.

The ***Executor module*** allows propagating evolution actions in the MV-DW. Based on the evolution actions defined in the ***DW evolution register***, the *Executor* executes the suitable actions in MV-DW metadata. E.g., it adds new DMem versions, deletes others, etc. ***DW evolution register*** stores also triggers allowing checking automatically MV-DW constraints that are relevant to the detected DMem evolution operator. The violation of such constraints can be detected when the *Executor module* propagates selected change events in the DW and evolution actions in MV-DW metadata. In response to such constraint violation, specific triggers are executed on the corresponding DW tables and meta-tables to cancel the propagation of the DMem evolution and notify the DW administrator by the problem.

- **Example of checking schema evolution operator**

Let consider the *Adding Level* operator which adds a given level *L* to the dimension *D* under its current version DV_i, at the application time T. Let $\mathcal{HOrder}$, be the set of the orders of *L* in the hierarchies of DV_i. The effects of this operator at the schema level are:

- Historisation of DV_i, i. e. changing the value of its ATe to T-Q (Q is the temporal quantum)

- Creation of a new dimension version DV_{i+1} such that DV_{i+1}.ATs = *T*. This implies the creation of new hierarchies in DV_{i+1} to include *LV* according to the set $\mathcal{HOrder}$.

- If *LV* becomes the base level of DV_i, then historisation of the current versions of the cubes including DV_i and creation of a new version for each of them.

After executing the *Add_Level* operator, the algorithm ***Check_Add_Level*** should be run to check the consistency of the resulted DW schema (cf. Figure 5). This algorithm allows to validate essentially the following constraints.

- ***No Empty_Cube Version*****:** The violation of this constraint depends on *T*, the application time of the *Add_Level* operator. Indeed, the historisation of *DV* means fixing its ATe. This can result in an instant $t \in I$, at which *CV* has no assigned dimension. I is the application time interval of a cube version *CV* to which DV_i is assigned.

- ***Up_Connectivity*****:** This constraint is violated if the DW administrator specifies erroneous *orders* for *LV* in the hierarchies of DV_{i+1}. Besides, it can be violated due to the time application of the *Add_Level* operator. Indeed, this can result in having the child level versions of *LV* without parents during a time interval I.

- ***Level_Acyclicity:*** The violation of this constraint is due to the position of the added level *LV* in DV_{i+1} hierarchies. Indeed, the DW administrator can choose a level version *L'V* as parent of the added level *LV* according to the hierarchy H_1 of DV_{i+1}. Then he can choose the *L'V* as the child of *LV* in another hierarchy H_2 of DV_{i+1}.

```
Algorithm Check_Add_Level
Input: S_CV[]: array of cube versions containing all versions of the cube C, DV: Dimension version,
LV: Level version
Output:
Message: string // Message indicates the violated constraint name
Begin
For each CV in S_CV do
 I ← Check_NoEmpty_CubVers (CV)
 If I ≠ NULL then
    Message ← "Violation of the constraint No Empty Cube Version"
    Exit
End if    End For
I ← Check_Up_Connectivity (LV)
If I ≠ NULL then
  Message ← "Violation of the constraint Up Connectivity"
    Exit
End if
If Check_Level_Acyclicity (LV) is FALSE then
  Message ← "Violation of the constraint Level_Acyclicity"
  Exit   End if   End
```

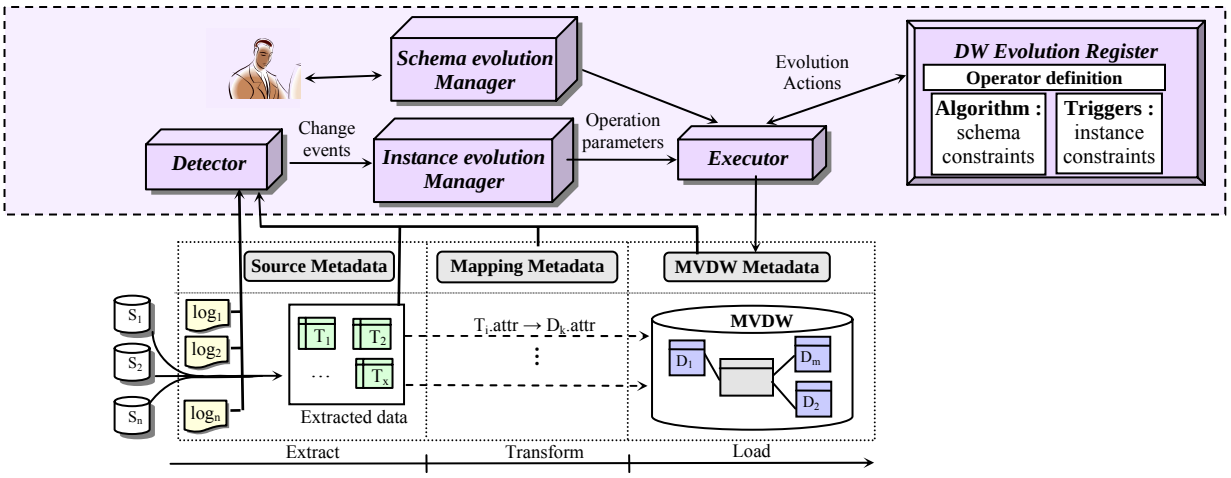

Figure 6. Framework for managing schema and instance evolutions in MV-DW under constraints

VI. CONCLUSION

As in classic multidimensional model, temporal and multiversion one requires intra-dimension and inter-dimension constraints to ensure the consistency of its schema and data. Our multiversion data warehouse (MV-DW) model supports the versioning of schema components (cubes, dimensions, levels) and instance components (members). This model supports structural, temporal and versioning constraints allowing preserving its consistency. We have also defined a temporal fact-dimension dependency constraint that ensures the summarizability of measures according to dimension versions. Besides, we have proposed technical issues to maintain the validity of these constraints in our MV-DW model. Based on the defined MV-DW constraints, several algorithms have to be run after schema evolution operators to check the consistency of the resulting changed schema.

In the future, we consider defining specific constraints at the extract-transform-load (ETL) level, in the context of multiversion DW. It is about studying the consistency of the DW schema and data, not only when data is already loaded in the DW but also when data is selected and extracted from sources.

The impact of threshold parameters in transactional data analysis

M. Vranić, D. Pintar and M. Banek

Abstract - Today's information systems store large quantities of transactional data which may contain valuable but hidden information. Association rules generation is a method developed for analysis of this type of data. This method is however very resource-intensive. Both the execution time and the final model highly depend on threshold parameters set by the analysts. In this paper we analyze the impact of the minimal support parameter on the number of closed frequent itemsets discovered for various datasets. The analysis is conducted on referential datasets as well as real-life datasets which classify transactional elements in categories organized in hierarchical manner. Datasets that are not originally transactional can be transformed into a transactional form. They exhibit somewhat different relations between the minimal support parameter and the number of discovered closed frequent itemsets. Findings presented in this paper can serve as guidance in setting up support as the most important parameter affecting the final execution time. In order to analyze data characteristics from another perspective, we also present how varying confidence, lift and support can affect the number of formed association rules containing two elements.

I. INTRODUCTION

Current information systems store large quantities of transactional data. This data is often summarized and further analyzed in an aggregated form. However, analysis of raw transactional data at the lowest level can offer different insights into the data. These insights mainly refer to relationships between specific transactional elements. The data mining method developed to explore this specific type of data is association rules generation. This method is very resource-intensive and thus often accompanied with long execution time – especially if the threshold parameters are set too low. In this case very large number of rules is generated, with many of them redundant or uninteresting. Alternatively, if the threshold parameters are set too high, the generation of rules will be finished in short time, but only a small number of rules will be produced, if any, and will most probably express some facts previously known to the business analysts.

The most resource-intensive step in association rules generation is finding closed frequent itemsets (CFIs, definition given in Section III). The number of CFIs determines the total execution time of the final model generation. Knowledge about the relationship between the number of frequent itemsets and the threshold parameters can be a useful guidance for the analysts to ensure acceptable execution times and satisfactory results, especially if coupled with domain knowledge and specificities of similar datasets. The concerned relationship depends on various factors such as: data domain and inherent relationships between the elements, number of transactions, number of available items, average number of items per transaction etc. Some other measureable statistics of observed dataset could also be of importance (such as mode, median, etc.).

In order to investigate the problem from different perspectives, we used various natively transactional datasets: a small referential dataset and a collection of datasets extracted from a large real-life database concerning sales, courtesy of a major Croatian retailer. The extracted datasets present elements across different hierarchical levels of categorization, so that the analyst can observe the behavior of threshold parameter settings in different scenarios. The conclusions drawn from our experiments can serve as guidance for choosing most promising hierarchical level for exploration as well as setting up threshold parameters.

We also considered possible appliance of the developed concepts on other types of data. Non-transactional data can be adapted into a transactional form before conducting the analysis, which may enable new insights into the dependencies between the observed objects or the variables connected to them.

There are also additional parameters that could be set up by analysts which affect the finally presented association rules. The most commonly used parameters are *confidence* and *lift*. When considering relationships between pairs of elements, it is interesting to see how many of them are filtered out by combinations of support and lift or support and confidence. The resulting graphs presenting the number of unfiltered association rules are useful for drawing certain generic conclusions that can be applied across various datasets.

Our analysis was conducted using the Apriori algorithm [10] implemented through a Python program module. It enabled us to control all steps in rule generation process, measure the execution time and the total number of CFIs resulting from different support threshold settings.

It also enabled us to further investigate the filtering of two-element rules using different filter combinations.

The paper is structured as follows: Section II presents the related work on the subject. Section III gives important definitions and explains the used terminology. In Section IV, the solution framework for analysis is introduced. Sections V and VI present the details of our experiments and discuss their results. Finally, in Section VII a conclusion is given.

II. RELATED WORK

The natural method intended for transactional data examination is association rules generation firstly presented in [1]. One of the problems regarding it is the fact that it is very resource-demanding and dependent on threshold parameters. The best-known algorithm for finding CFIs is the Apriori algorithm. There are many papers concentrated on finding more effective algorithms ([2], [3], [4], [5]) but no significant improvements have been achieved. Recently, the focus has been put on finding rules that would be significant and new to the analysts ([6], [7], [8]). Still, setting up parameters is not an easy task. This paper is focused on examination of various datasets characteristics that strongly affect the process and the final model of association rules generation. The strategy of setting up the threshold parameters should be guided by these examined characteristics.

Association rules generation can also be used for examination of data which is not originally transactional. Transformation to required form can reveal new cognitions about relationships between variable values [9]. It is useful to explore properties of this specific type of transformed data which expose an extreme case of investigated relationships.

The basic steps of the Apriori algorithm are presented in [10]. The most resource-intensive step is the generation of multi-element frequent itemsets (e.g. containing *M* elements) which are formed by combining of already identified frequent itemsets (FI) containing *M-1* elements. Here, the notion that FI cannot be frequent if not all of its subsets are frequent is used to eliminate certain FIs from further examination. This is the basic Apriori property which speeds up the entire process.

Finally, to the best of our knowledge, there is currently no other research dealing with the interdependence between the number of closed frequent collections containing a specific number of elements and varied threshold parameters (especially when two threshold parameters are tweaked in conjunction).

III. IMPORTANT TERMS AND DEFINITIONS

This section provides definitions and explanations of the terms used later in this paper.

Let I be a set of possible elements found in transaction: $I = \{I_1, I_2,...I_n\}$. **Transaction** $t \subseteq I$ is a record of a business event modeled as a set of elements and stored in the input dataset D. **Itemset** $A \subseteq I$ is a set of elements from I used by the data mining process and possibly provided as part of its results. **Support** of the itemset A (*supp(A)*, *s*(*A*)) is a proportion of transactions in D which contain A. Absolute support (*AbsSupp*(*A*)) is the number of transactions in D which contain A. Itemset A is a **superset** of itemset B if $B \subseteq A$. B can be referred to as a **subset** of A.

An **itemset is frequent** if its support is larger than the proposed minimal support on given dataset. An **itemset is closed** if no superset of it exists with the same support on the given dataset. The existence of itemsets that are not closed is implied by appearance of their supersets. That is why the main issue in the analysis of transactional data is finding the **closed frequent itemsets (CFIs)** – itemsets that are both closed and frequent.

Based on certain multi-element CFIs, different association rules can be produced. Association rules appear in the form A⇒B, accompanied with certain parameters. A and B may consist of one or more transaction elements, and A and B together form one CFI ((A∪B)∈ $\mathcal{CFI}$, where $\mathcal{CFI}$ is set of all CFIs with a certain support threshold).

Confidence (c) indicates the probability of an element appearing on the right side of the rule if the left side of the rule is present in the transaction:

$$c(A \Rightarrow B) = \frac{s(A,B)}{s(A)} \quad (1)$$

Confidence evaluates to a number contained in the interval [0, 1]. As opposed to support, however, this is an asymmetrical measure, meaning that the order of attributes is important and that different orderings can produce different values.

Lift (L) is a measure used in association rules generation which implies the strength of the relationship between two elements as opposed to those elements being together in a transaction by random chance:

$$L(A \Rightarrow B) = \frac{c(A \Rightarrow B)}{s(B)} = \frac{s(A,B)}{s(A)s(B)} \quad (2)$$

Lift is a symmetrical measure with preferred values being larger than 1.

The final set of rules depends directly on the number of CFIs. All possible rules that could be formed on the basis of found CFIs are tested to conform to confidence or/and lift threshold parameters. The final model of association rules is consisted of all rules that comply with those parameters.

IV. SOLUTION FRAMEWORK

In order to be able to analyze the characteristics of various datasets our research included development of software application. With regards to the overall functional requirements, our application needed to perform the following:

- interpret and/or adequately transform transactional input data
- prepare foundation models for storing and manipulating frequent datasets (collections)
- implement the Apriori algorithm to mine frequent datasets

- organize the mined datasets in a structure which would facilitate further calculations and manipulations
- allow the input of additional threshold parameters and perform analysis over mined datasets with regards to the effect of said thresholds
- present the overall results in a readable, rapidly interpretable way using tables and graphs

We initially developed data preparation scripts able to pull data out of various sources and convert them to the standardized tab-delimited format. Next we modeled software representations of transactions and collections, with corresponding structures for storing and manipulation. For this, as well as the subsequent data mining and analysis routines, we chose the Python programming language, since it suits the rapid development requirements and also allows easy integration with the open source Orange data mining tool, also developed in Python. In order to enable easy result interpretation, the implementation tool exports the results as text files in tabular form, accompanied by appropriate statements used by the Mathematica software which allows instant representation of results in 2D and 3D graph form.

Object representations of the input data were named Transaction and Collection. Transaction is basically a binary vector (or list) corresponding to one of the rows in the input data. Collection is a subclass of Transaction, and it represents one of the ultimately mined frequent datasets. It is expanded with some additional numeric parameters (such as support). Transactions are bundled inside a TransactionSet, which, aside from being a container for transactions, also stores attribute names, original filename etc. Collections, on the other hand, are placed inside a LayeredCollectionSet – a structure that houses but also organizes mined frequent collections based on their support, number of attributes etc.

CollectionSetFactory is the main module for converting input data into TransactionSets and, subsequently, LayeredCollectionSets. It implements the Apriori algorithm but also a number of extra functionalities which calculate additional numerical parameters for the set. It allows caching of already processed datasets to avoid unnecessary repeated analyses and even enables internal linkage of collections with custom-typed links, which can be used to superimpose additional organizational structures over the mined collections. Finally, Threshold Analysis Module uses the LayeredCollectionSet to perform additional analysis described in Section VI. As a result, it produces tables in textual form as well as prepared statements for the Mathematica tool.

Figure 1 presents the developed software tool from the perspective of process execution flow, together with all the implemented components.Our implementation also enabled us to analyze time consumption, which depends mainly on the support threshold parameter affecting the final number of CFIs (dependencies are presented through graphs in Section V).

The application was operating on a PC with the following characteristics: Intel® Core™ i3 CPU running at 3.07 GHz, with 4.00 GB of RAM and with Windows®7 Professional installation (32-bit operating system). Although this machine is rather suboptimal concerning the expected performance of data mining analysis hardware, the required analysis has been done successfully and within reasonable time.

V. DEPENDENCY OF CFI NUMBER ON SUPPORT THRESHOLD

The interdependency between number of CFIs and support threshold parameter is a characteristic of every dataset. It depends on relationships between transactional elements, data domain and semantics. Taking market basket analysis for example, it can be stated that combinations of transaction elements can be a consequence of customer habits, season, weather, various customers' characteristics, but also specific store offerings, product characteristics and so on. However, examination of various datasets revealed that regardless of dataset specifics and origin, lowering the support threshold commonly results in an explosion of the total number of CFIs. An immediate consequence of this is a drastic increase in execution time and resource requirements.

In order to show an interdependency between support, execution time and the number of CFIs, a real-life dataset describing the appearance of certain category members in transactions was chosen (a detailed description of this dataset is given in subsection C). Graph presented in Figure 2 shows how lowering the absolute support value

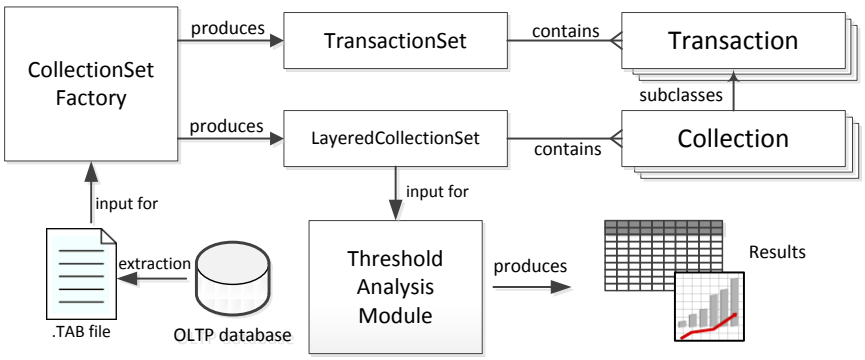

Figure 1. Architecture of developed tool

results in a rapid increase of total CFIs, especially when support is set lower than a certain threshold (this brink actually depends on the dataset at hand, in this case 30 transactions is the approximate value at which the number of CFIs explodes). Plotting the interdependency between execution time and support would result in an almost identical graph. In order to gain a better view of relationship between execution time and number of CFIs, the correlation of these two variables is shown in graph in Figure 3. As expected, these two variables exhibit an almost linear interdependency. In other words, execution time is directly affected by the number of gained number of CFIs at a certain support threshold. Specific coordinates in Figure 2 (represented as dots) correspond to the CFIs represented by coordinates in Figure 3, resulting in a high density of measured values for the absolute support threshold higher than 50 transactions.

The dependency between the number of CFIs and the minimal support threshold is further investigated in the following subsections. Each subsection is dedicated to specific dataset.

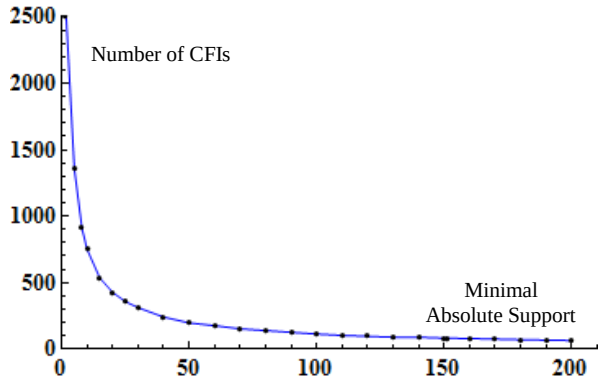

Figure 2. Relationship between number of CFIs and minimal absolute support threshold – real-life retail dataset

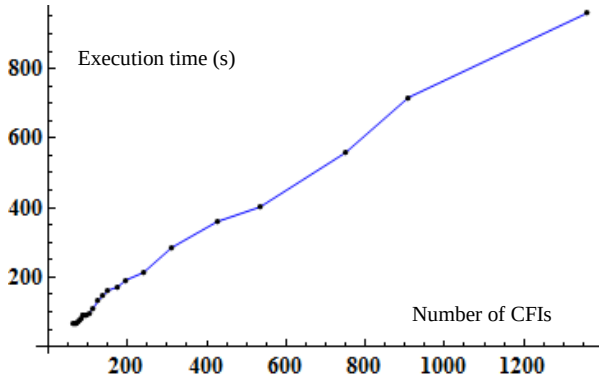

Figure 3. Relationship between execution time and number of CFIs

A. *Referential dataset analysis*

The first analysis was conducted on a small, realistic, natively transactional dataset describing purchases of computer equipment. Dataset is called *Computer shop* dataset and is available as one of the test datasets for the *Oracle 11g Database Management System*. Some earlier research regarding tree structure formations over this dataset is presented in [11] and [12]. *Computer Shop* dataset contains 940 transactions and 14 transaction elements. Each transaction is a record of a purchase in a shop dealing with electronic equipment. Average number of elements per transaction is 2.98, and the most frequent element appears in 32% of transactions.

The density of this transaction dataset is relatively high, meaning that each transaction holds a large proportion of available elements. Eleven elements show up in more than 18% of all transactions. Furthermore, the total number of elements and transactions isn't too large which allows for acceptable execution times even with low support thresholds. Lowering the support threshold from 9% to 1% causes a ten-fold increase in the total number of CFIs (at the minimal support of 9.38% the total number of CFIs is 21, while 1.25% results in 235 CFIs).

The behavior of 2-element CFIs is perhaps the most interesting, since their number is pretty stable from 5% support threshold downwards (Figure 4). If the analyst is interested in relationships between pairs of elements, 5% represents a threshold under which no further benefits are gained. On the other hand, the number of collections with three or more elements is rising steadily at a nearly exponential rate as the support threshold is lowered – at lower values more and more subtle relationships are constantly being revealed, at the cost of execution time and final model presentation clarity.

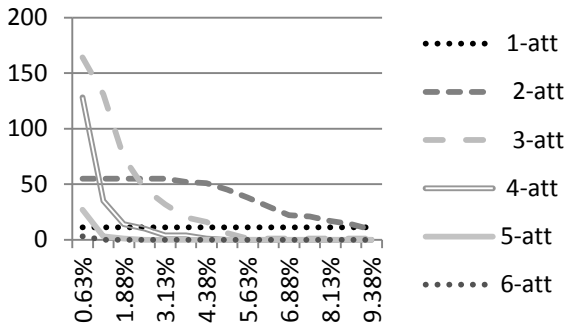

Figure 4. Relationship between minimal support threshold and number of CFIs – Computer shop dataset

B. *Analysis of a non-natively transactional dataset*

In this subsection an analysis of the well-known car evaluation dataset [13] is given. It is intensely explored in evaluation of different predictive data mining methods and thus is suited to serve as an example of dataset not natively transactional. Dataset keeps data about 1728 cars described by 7 attributes, each having a domain containing several values (Table I). Attribute describing class will be treated the same as other attributes. Other attributes describe different car characteristics – such as price, maintenance cost etc. Transformation of the dataset to an appropriate transactional form is done by representing each attribute value as a separate attribute in the new transactional dataset. Consequently, for each car instance a new attribute was set to value *1* if in the original dataset the corresponding attribute was described by this value, and *0* otherwise. The final transactional dataset contains 1728 instances described by 25 attributes.

An inherent characteristic of this kind of dataset – i.e. a non-natively transactional dataset transformed in the described fashion – is its fixed density. Each row will contain the exact number of present elements as was the

TABLE I. ATTRIBUTES AND VALUES FOR CAR EVALUATION DATASET

Attribute	*Possible values*
Class variable	unacc, acc, good, vgood
buying	vhigh, high, med, low
maint	vhigh, high, med, low
doors	2, 3, 4, 5more
persons	2, 4, more
lug_boot	small, med, big
safety	low, med, high

number of attributes in the original dataset. In this case this density is 7/25=28%. This high density together with coverage of different car descriptions results in a vast number of CFIs as the support threshold is lowered – lowering the support from 9% to 1.25% results in 23 times more CFIs (from 75 to 1378). If the analyst chooses to use the minimal support value lower than 10%, he must use additional stronger filtering mechanisms such as confidence or lift to keep the results manageable.

A careful examination of 2-element itemsets reveals that relatively high support values already result in a large number of CFIs and that their number stays relatively stable with lowering the support threshold (Figure 5). For example, the minimal support of 6.25% results in 175 2-element CFIs, while lowering the minimal support to 1,25% generates 193 2-element CFIs. The total number of possible combinations is $\binom{25}{2} - 4 \cdot \binom{4}{2} - 3 \cdot \binom{3}{2} = 267$, which means that a significant portion of all combinations has been covered. This is especially true when taking into consideration that the mentioned number of 2-element CFIs does not include those (which are contained in larger CFIs which mask them by having the same support, as is the property of closed collections).

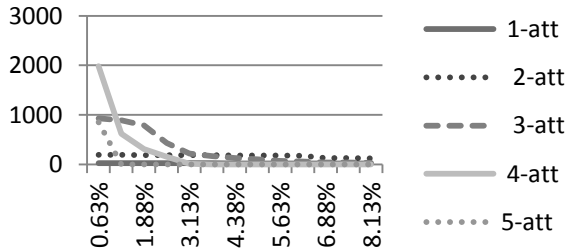

Figure 5. Relationship between minimal support threshold and number of CFIs – Car evaluation dataset

What is also specific for this dataset is a sudden increase in the number of 5-element CFIs with low support values – over 150 CFIs has exactly the same absolute support value of 12. This indicates that the dataset is most likely artificially constructed to cover most scenarios and present a challenge for predictive analysis. Additional proof for this conclusion stems from the fact that counting the exact support of certain maximal CFIs result in a repeated appearance of same numbers.

C. *Real-life dataset analysis with presentation of elements on different levels of categorization*

Analysis of different datasets extracted from the real life database enabled interesting and applicable conclusions. Data about 73009 transactions were available, which referred to 19893 different products. There were 1368 product categories organized in 4 hierarchical layers. Multiple analyses were conducted, out of which one will be briefly discussed. This one concerns the subset of 29 lowest layer categories dealing with cosmetic products. The dataset depicted 23674 transactions. Each observed category held approximately 60 products.

A typical graph for the lowest level of categorization can be seen in Figure 6. Even though the number of transactions is significantly higher than in the previous datasets, the number of CFIs is noticeably lower even with using very low support values. Also, the lines are smoother, meaning that the number of CFIs changes more gradually and constantly with support lowering.

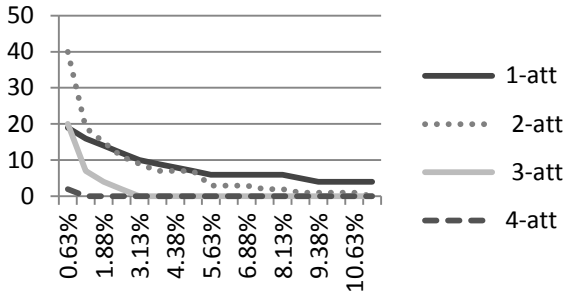

Figure 6. Relationship between execution time and number of CFIs – real-life retail dataset, 1st level of categorization

Apart from working with categories, we also prepared a dataset describing the products at the basic level. With that dataset, density was extremely low so supports had to be drastically lowered to get any interpretable results. We conclude that staying on the category level should be recommended since the research at that level tends to be more productive. The results are therefore easier to interpret and can be used as a basis for the decision making process.

VI. DEPENDENCY OF NUMBER OF TWO-ITEM ASSOCIATION RULES ON DIFFERENT THRESHOLDS

Observing just relationships between pairs of elements can also showcase certain characteristics of the dataset at hand. For this reason an analysis of the total number of two-element association rules in relation to pairs of threshold parameters was conducted. The most common combination of parameters is (support, confidence) or (support, lift). The results were plotted in 3D graphs, a sample of which can be seen in Figure 7 and Figure 8.

The graph in Figure 7 tied to the transformed dataset results in visible plateaus and emphasizes specific threshold values. The brinks on the graph are thresholds where large number of rules gets filtered out. Lift measure of 1.0 is particularly interesting, since at that value almost all rules are instantly being discarded. Using confidence, a very similar graph with sharp slopes is produced. This dataset exposes an extreme case of interconnections between transactional elements. Therefore, if an analyst is interested in two-element rules, he will gain very few of them by setting lift above 1. However, an analyst will probably also be interested in more complex rules, with

low support, high confidence and/or high lift, but care should be taken in order to avoid overfitting.

For the retail datasets, graphs of entirely different appearance are produced (Figure 8), with no plateaus and a constant but gradual change of the rule number. Still, the sharp edge of the graph means the support parameter needs to be lowered significantly to achieve a certain number of results. However, attention is needed in order to avoid an explosion due to the exponential nature of the support projection of the graph. The lift value should preferably be kept larger than 1.0 though, in concordance with the semantic interpretation of this particular measure. All researched real-life datasets presenting products at a specific categorization level expose similar characteristics.

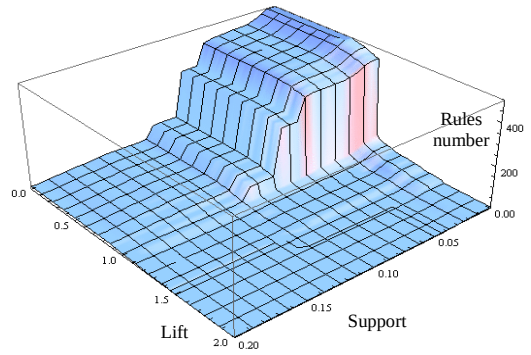

Figure 7. Number of survived rules with varying support and lift thresholds – Car evaluation dataset

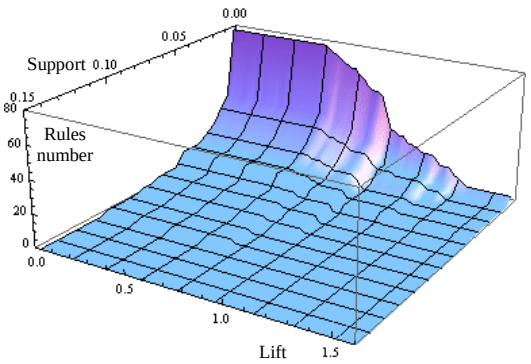

Figure 8. Number of survived rules with varying support and lift thresholds – retail, 1st level of categorization

VII. CONCLUSION

Transactional data plays an increasingly larger role in business decision making process. Today's analyses require methods which can be executed in real time and provide meaningful and rapidly interpretable results. This paper demonstrated the impact of the threshold parameter choice in association rules generation on the execution time and the resulting model, concerning its volume and the ease of its interpretation. These findings are generic in nature and can be easily applied on other datasets when the association rule generation method is used.

Additionally, in order to reveal other interesting properties of transactional datasets, different datasets with varying characteristics were analyzed – a referential transactional dataset, a dataset non-natively transactional but transformed into the transactional form, and – most importantly – a real-life retail transactional dataset. The choice of datasets covered broad scenarios that can be expected in association rules generation process. Specific results are expected to slightly vary from one natively transactional dataset to another. Future work will include discovering mathematical relationships between various dataset properties and the expected number of CFIs with varying support thresholds.

We can conclude that generally speaking, in order to properly leverage the impact of threshold parameters on the transactional data analysis, the analyst needs to have certain a priori knowledge about the dataset or at least its characteristics shared with similar datasets. Execution time needs to be kept acceptably low, while the number of CFIs should stay manageable to allow efficient interpretation. With real-life datasets, which are the true focus of this work, the analyst needs to adapt to the chosen level of categorization and to tweak the support threshold accordingly.

Abstract - This article examines the possibility of publication of students' data, such as secondary school success, state graduation exam scores and success during their first year of university study for analyses. In order to discover data patterns and relationships using data mining techniques, the data must be released in the form of original tuples, instead of pre-aggregated statistics. These records contain sensitive and even confidential personal information, which implies significant privacy concerns regarding the disclosure of such data. Removing explicit identifiers prior to data release cannot guarantee anonymity, since the datasets still contain information that can be used for linking the released records with publicly available collections that include students' identities. One of the privacy preserving techniques proposed in the literature is the *k*-anonymization. The process of anonymizing a data set usually involves generalizing data records and, consequently, it incurs loss of relevant information. In the primary research undertaken in the University of Dubrovnik's students' database the effect of anonymization has been measured by comparing the results of mining the original data set with the results of mining the altered data set to determine if it is possible to use anonymized data for research purposes.

I. INTRODUCTION

Privacy, as defined in [1], is the right of a person to determine which personal information about himself/ herself may be communicated to others. In the terms of data publishing, privacy is the right of a person or an entity to be secure from unauthorized disclosure of sensitive information. Sensitive information could be contained in an electronic repository, or can be derived as aggregate or complex information from data stored in an electronic repository.

Privacy preservation has become an important issue in many data mining applications. Traditionally, the data are published in the form of representative statistics, or pre-aggregated parts that others might be interested in. Data released in these forms lack flexibility as it cannot be used for data mining purposes. In order to discover data patterns and relationships using data mining techniques, the data must be released in the form of microdata, i.e., data in the original form of individual tuples. Obviously the release of microdata offers significant advantages in terms of information availability. However, the publication of microdata raises privacy concerns when published records contain sensitive or confidential information.

Croatian legal system settles data privacy with the *Law on the protection of data confidentiality* and the *Law on the protection of personal information*. Trade secret, as described in the *Law on the protection of data confidentiality* [2], is data defined as trade secret by law, other regulation or general act of a company, institution or other legal entities, which represent the manufacturing secret, the results of research or design work whose disclosure to an unauthorized person could have harmful effects on the person's economic interests. The *Law on protection of the personal information* [3] regulates the protection of individuals' personal data as well as supervision over collecting, processing and use of personal information in the Republic of Croatia. The purpose of the protection of personal information is the protection of private life and other basic human rights and freedoms during collecting, processing and using personal data.

According to the Croatian legislature [3], personal data are any information which refer to an identified person, or a person who can be identified directly or indirectly, based on one or more specific traits based on his or her physical, psychological, mental, economic, cultural or social identity. Personal information contained in the databases must be adequately protected from deliberate or accidental misuse, destroying, loss or unauthorized access or tampering. Persons with authority to manage databases containing personal information, as well as the database users, must take all possible technical, human resources and organizational actions in order to protect the databases from the described unwanted events, as well as from any other misuse. It is also necessary for the keepers of personal information to know and understand their obligations in terms of protecting confidentiality of this information.

Privacy preserving data mining [4] has been proposed as a paradigm of exercising data mining while protecting the privacy of individuals. To protect the privacy of the respondents to which the data refer, released records are usually "sanitized" by removing all explicit identifiers such as names, personal identification numbers, addresses, and phone numbers. Although apparently anonymous, the de-identified data may contain other data that often combine uniquely and can be linked to publicly available information to re-identify individuals. To avoid such linking attacks, while preserving the integrity of the released data, Samarati and Sweeney have proposed the concept of *k*-anonymity [5, 6].

A dataset is said to provide *k*-anonymity when the contained data do not allow the recipient to associate the released information to a set of individuals smaller than *k*, meaning that each record is indistinguishable from at least $k - 1$ other records within the dataset. Since it is highly impractical to make assumptions on which data are known to a potential attacker and can be used to identify respondents, *k*-anonymity requires that, in the released dataset, the respondents be indistinguishable (within a given set) with respect to the set of attributes, called quasi-identifier, that can be exploited for linking [7]. In other words, k-anonymity requires that if a combination of values of quasi-identifying attributes appears in the dataset, then it appears with at least *k* occurrences [8].

II. PROBLEM DEFINITION

Students enrolling in programs at the University of Dubrovnik come from different surroundings, and have diverse backgrounds and abilities. They have finished secondary education in various secondary schools, while having significantly diverse success. At the same time, in every generation at the University, there are several students who are unable to keep pace with the lectures and cannot achieve the learning outcomes of the curriculum.

Experience shows that factors like background knowledge, success in secondary school and social background, among others can influence academic success or failure. Discovering the patterns and regularities between these factors and academic success can be used to identify potentially unsuccessful future students already upon enrollment. These students could then be assisted and supported to approach university studies in a way that will increase their chances of success (e.g. additional tutoring, mentorship).

Dataset containing information about students' background and academic success should be disclosed for the analyses to the various departments at the University, and perhaps even outside the institution. To enable performing detailed analyses of the students' data, the data ought to be released in the form of original tuples. Meanwhile, the original dataset contains students' personal and confidential data; therefore its disclosure raises significant privacy concerns, and the dataset should be anonymized prior to the disclosure.

The given dataset consists of records for the students who enrolled in the University for the first time in the 2010/2011 academic year. It contains information on 255 students. Each student is described by 21 attributes.

In order to describe students' backgrounds and secondary school performances, several attributes are used in the dataset. For instance, their place of residence, finished secondary school, profession, secondary school GPA (*Grade Point Average*) and scores on state graduation exams (SGE) in general education subjects that student was taught during secondary school, i.e. the Croatian language, mathematics and a foreign language. For the description of student's academic success, attributes, such as first year GPA, earned credit points (*European Credit Transfer System* - ECTS) and number of passed courses in the first year, can be used.

Even without explicit identifiers such as student's name and student identification number, there are still attributes in the dataset that can be used in combination to identify certain students. E.g. place of residence, secondary school and scores on the state graduation exams combined can distinguish certain students, making them recognizable in the set.

III. EXPERIMENTAL RESULTS

A. Data anonymization

Two main techniques that have been proposed for enforcing *k*-anonymity on a dataset are generalization and suppression, both preserving the truthfulness of the data. The application of *k*-anonymity algorithms produces more general datasets that provide protection of the identities. While applying those algorithms it is important to minimize loss of precision and completeness, in order to keep data mining results as accurate as possible.

Ensuring *k*-anonymity of the students' data in the described dataset is done using the Samarati's algorithm. That algorithm uses generalization and tuple suppression over quasi-identifiers to find a *k*-minimal generalization that suppresses tuples. Data owner sets a maximum number of tuples that can be suppressed, and the algorithm computes a generalization that satisfies *k*-anonymity within that constraint. The proposal considers the application of generalization at the attribute (column) level and suppression at the tuple (row) level [7].

However, if the data contains a large number of attributes which may be considered quasi-identifiers, sometimes it becomes difficult to anonymize the data without an unacceptably high amount of information loss [9].

Among the attributes in given student dataset, the following were chosen as quasi-identifiers:

- place of residence (postal code),
- secondary school,
- age at enrollment,
- profession,
- secondary school GPA and
- scores on the state graduation exams.

Generalization hierarchies are determined for each of the quasi-identifiers. Generalization at the attribute level ensures that all values of an attribute belong to the same domain. However, as a result of the generalization process, the domain of an attribute can change. Note that, since the domain of an attribute can change and since generalized values can be used in place of more specific ones, it is important that all the domains in a generalization hierarchy be compatible [6].

Figure 1 shows an example on generalization hierarchy for postal code attribute. Postal codes can be generalized by dropping, at each generalization step, the least significant (rightmost) digit. Since majority of students at the University of Dubrovnik comes from Dubrovnik and Dalmatia area (postal codes starting with

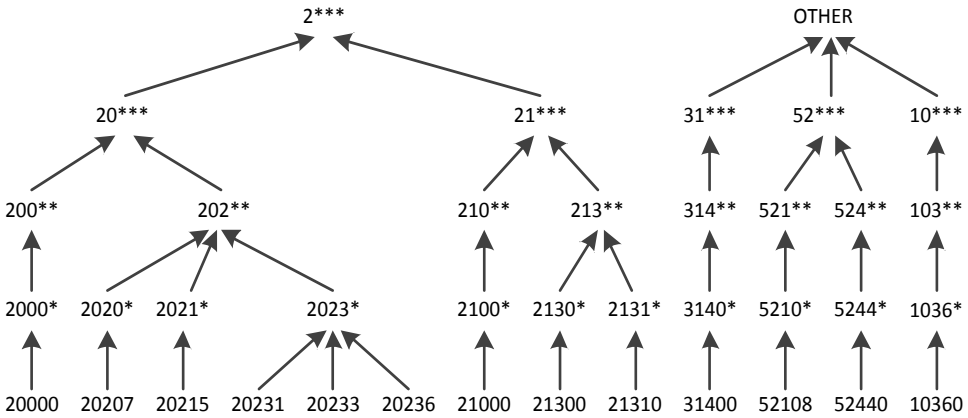

Figure 1. An example on generalization hierarchy for postal code

digit "2"), to decrease the probability of suppressing the minority who comes from different cities, the last step of postal code generalization consists of grouping the postal codes into two groups: "postal codes starting with digit 2" and "others".

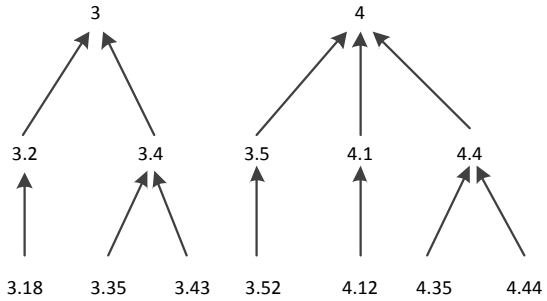

Figure 2. An example on generalization hierarchy for secondary school GPA

For the example of generalization hierarchy for secondary school GPA consider Figure 2. At each generalization step, the GPA is rounded to a certain number of decimal places, while that number being smaller at each step.

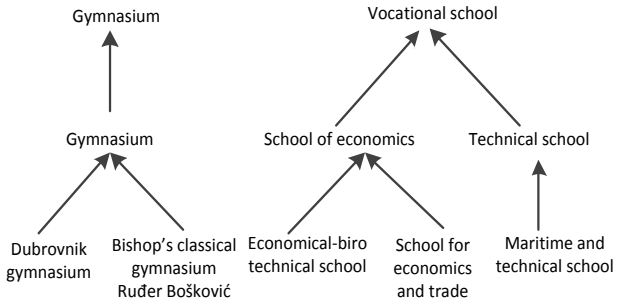

Figure 3. An example on generalization hierarchy for secondary school

Secondary schools, as shown in Figure 3, can be generalized by grouping specific schools into more general ones at each step.

Anonymity of the data is provided using Samarati's algorithm exploiting both the generalization and suppression with the level of anonymity *k*=2 and the maximum number of tuples that can be suppressed set to 10%. The goal of 2-anonymization is to alter the data in the dataset in a way that every combination of values of quasi-identifiers can be indistinctly matched to at least 2 students. Since the dataset is relatively small and level of anonymity *k*=2 ensures basic anonymity, that level is selected for the experiment.

The attributes are generalized each one step at a time, until the 2-anonymity of the data is satisfied, or there are less than 10% outliers that can be suppressed left. When the second condition is satisfied, the outliers are suppressed to avoid the overgeneralization of the significant attributes.

In order to keep the utility of the data, while still preserving students' privacy it is important to choose the order of the generalization of the attributes carefully. It is assumed that in determining the outcome of data mining, less significant attributes can be generalized more than more significant attributes. Based on that presumption, the quasi-identifiers are generalized in the reverse order of their significance. The result of that is that the most significant attributes are less generalized then those of lower importance.

The order of the attributes to be generalized is determined using *ReliefF* method [10]. *ReliefF* algorithm is a general and successful attribute relevancy estimator. It is able to detect conditional dependencies between attributes and provides a unified view on the attribute relevancy estimation in regression and classification.

In this case the *ReliefF* evaluation algorithm gives all attributes an average merit score and an average rank according to the importance of attributes in the classification:

0.1011765 2 Department
0.092549 1 Undergr_Study
0.0729412 18 Enroll_Date
0.05435 11 Sec_School_GPA
0.0478431 8 Profession
0.0321569 4 Sec_School
....

TABLE 1. THE NUMBERS OF DISTINCT VALUES THROUGH THE PROCESS OF ANONYMIZATION

Attribute	Distinct values				
	Original dataset	*After 1st step of generalization*	*After 2nd step of generalization*	*After 3rd step of generalization*	*After 4th step of generalization*
Postal code	52	32	19	11	3
Secondary school	35	7	3	-	-
Age at enrollment	9	3	2	-	-
Profession	13	10	5	-	-
Secondary school GPA	158	27	4	-	-
SGE results - Croatian language	114	79	12	4	2
SGE results - Foreign language	190	89	13	4	2
SGE results - Mathematics	54	48	12	4	2

-0.0074952 15 State_Grad_FL_Result
-0.0094118 10 Sel_Rank
-0.0109804 12 State_Grad_FL_Level
-0.0243137 7 Gender

Table 1 shows hierarchical levels for attributes that are finally chosen and how many possible values there are for each attribute through the process of anonymization. After performing the generalization, there are still 22 instances left that don't satisfy the given level of anonymity. Those instances are suppressed.

The anonymity of the dataset is enforced through the combination of SQL statements and scripts written in C programming language. Development of such data anonymization software is planned for the future work.

B. *Data mining*

The patterns and regularities in the student dataset are discovered using data mining techniques. The data are analyzed with different data mining methods using 10-fold cross-validation. For the purpose of this research, students' success is evaluated by the number of earned ECTS credits, where the workload for an academic year totals to 60 ECTS credits. Credits are analyzed as continuous and discrete class, but since the goal is to identify students who will not successfully meet all requirements specified with the program of studies even two-class classification gives satisfactory results. The tool used for data mining research is WEKA (*Waikato Environment for Knowledge Analysis*) [11].

The best results are achieved using the classical *Naive Bayes* method [11] based on Bayes' rule which says that for a hypothesis H and evidence E that bears on that hypothesis, the conditional probability of H given E can be calculated as

$$Pr[H \mid E] = (Pr[E \mid H]Pr[H])/Pr[E], \quad (1)$$

where Pr[A] denotes the probability of event A and Pr[A|B] denotes the probability of A conditional on

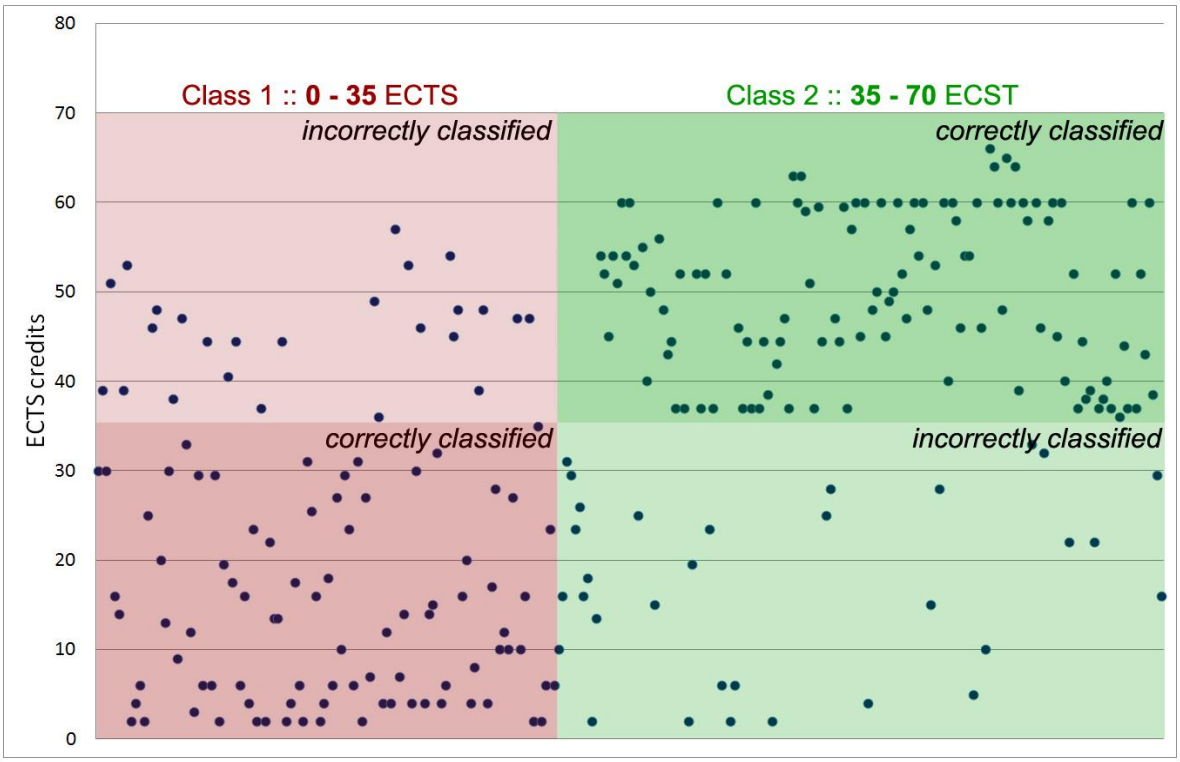

Figure 4. Two-class classification results

another event B.

This method goes by the name of *Naive Bayes* because it assumes that attribute values are independent of each other given the class. The assumption that attributes are independent (given the class) in real life surely is a simplistic one, but *Naive Bayes* works very effectively when tested on actual datasets.

First, the two-class classification is performed with the original learning dataset (with no anonymization applied) and 77.647% of instances were correctly classified. Figure 4 shows the results of two-class classification.

It is important to mention that confusion matrix shows that among 22.353% incorrectly classified instances there are only 9.8% of students who will not achieve satisfactory results (false positives).

In the second step, the effects of anonymization (i.e. generalization and suppression) were analyzed. It was necessary to verify that it is still possible to achieve satisfactory performance of the classification process. Experiments have shown that the classification accuracy remained almost unchanged (76.394%). Good results are partly a consequence of the fact that the process of anonymization of the dataset takes into account the impact of individual attributes on the results of the classification. That result has proven our presumption on role of significance of quasi-identifiers in the generalization process.

IV. CONCLUSION

Release of the personal data in the form of microdata for the analyses poses a threat to the privacy of respondents' whose information is included in the datasets. In order to protect the respondents' privacy and still be able to perform analyses of their information, the data in the dataset must be de-identified.

This article provides an example of combining generalization and suppression using described algorithm to achieve *k*-anonymity within a dataset containing personal information of students at the University of Dubrovnik. It demonstrated that carefully planned and implemented data anonymization that takes into account the impact of the individual attributes on the result of data mining, can at the same time preserve privacy of the students and keep the results of data mining almost intact, making it possible to release anonymized data for research purposes.

Setting up, managing and using a complex Business Intelligence platform

M.Boero* and M.E. Jackson*
*CSI-Piemonte/Direzione Governo e Gestione, Turin, Italy
Marco.Boero@csi.it
MichaelaElisa.Jackson@csi.it

Abstract - CSI-Piemonte (Consortium for Information Systems in Piedmont) builds and manages Information Systems for public authorities in Italy in the Piedmont region. The consortium has adopted a Business Intelligence (BI) platform made up of SAS® and SAP BusinessObject® solutions. The company has been working with SAS® for 30 years and nowadays it has a BI Competency Centre (BICC), set up in order to use and manage the platform as its optimal level; the BICC's roots date back to the 80s.

In this platform both hardware and software of all customers converge on a single high reliable infrastructure based on SAS® 9.2 and SAP BusinessObject® XI and the SAS® component is designed as a Grid Platform. On this architecture CSI-Piemonte design a wide range of BI applications to support the Piedmont local institutions.

Applications cover all BI use cases, taking into account also Data Quality and Data Mining issues.

The platform includes Data Integration, Data Quality, Data Mining, other Analytics, Query and Reporting and Master Data Management tools.

The paper focuses on the overall experience of setting up and managing a BI platform of such complexity and on a success case study on e-government.

I. INTRODUCTION

A. The Company

CSI-Piemonte (Consortium for Information Systems in Piedmont) was founded by the Piedmont Region, the University of Turin and the Polytechnic of Turin in 1977 in order to promote the modernization of local public administrations by means of the most advanced solutions for information services and systems. It now counts 82 stakeholders (see Tab. I): among them, the Piedmont Region, the Turin Province of Turin and the Municipality of Turin, with complementary roles in the governance of the Piedmont area.

Today, thanks to CSI-Piemonte, our region has become an "integrated administration system", able to face the e-government challenge, to simplify administrative processes and to meet the expectations of both citizens and companies [3]. Nowadays the consortium is a unique ICT (Information and Communication Technology) player in Europe in the field of public services and the largest Italian ICT company developing e-government projects sponsored by the Italian central government. The increasing commitment of CSI-Piemonte on the European scenario and the manifold initiatives at international level by the members of the consortium lead CSI-Piemonte to acquire greater action capacity in its relationship with foreign interlocutors and, in particular, with the European Union, still preserving its specificity as a subject operating at regional level.

TABLE I. KEY FIGURES

Figure	*Total*
Consortium members (including municipalities, municipality associations, local health bodies, hospitals, etc.)	82
Annual turnover (in euros)	176 millions
Number of headquarters in Piedmont	6
Personnel resources	> 1200

Thanks to crossover activities between regional bodies, the consortium is able not only to set up and manage individual databases but also to integrate databases belonging to various administrations. This enables the use of Business Intelligence (BI) systems, including Data Quality (DQ) and Data Mining (DM) applications, in several areas for both local bodies and central public administration.

Since 1997 CSI-Piemonte had been in charge of supporting data exchange and system information integration between different public administrations and putting into operation their strategic programming by setting up analyses, statistics, simulations, dashboard indicators, investment monitoring tools, balanced scorecards. The consortium operates in several fields of activity, namely: agriculture and forestry, environment and territory, demography, land registry and taxation, private sector activities, vocational training and work, education and cultural heritage, internet and multimedia, healthcare and social welfare services, administration, accounting and personnel systems, state and justice department.

At the 2007 SAS® Forum CSI-Piemonte was awarded the Enterprise Intelligence Award for its wide range of BI applications supporting the Piedmont public institutions, its innovative use of SAS® technologies and solutions and the setting up of a BI Competency Center (BICC) [1].

In section II the paper reports CSI-Piemonte's experience about its BI Division and Platform.

In section III we have illustrated the specific experience about a particular application.

Section IV contains the conclusions.

II. THE BUSINESS INTELLIGENCE DIVISION

Since the beginning, CSI-Piemonte promoted innovation in public administration sector through the use of modern information technology and internet tools. As a provider of BI services and IT (Information Technology) platforms to the public administration of the Piedmont Region, the consortium has included SAS® platforms in its solutions since 1980 (see Figure 1).

In the last 20 years, the Piedmont Region, using technologies from CSI-Piemonte, built a substantial information asset. Since 1996 this important information base has been organized in sector data marts that contain historical and integrated information concerning different domain of activities (tourism, instruction, health, agriculture, environment, cultural heritage, demography, justice, etc.).

We count on SAS® to support projects in a wide variety of areas. For instance, we support the Piedmont Region with its healthcare planning policy: we track and observe pharmaceutical prescriptions, monitor epidemiology and oncology activity and provide several human resource management and budget optimization solutions for the regional public sector. With more than 70 BI analysts and developers, plus some resources from verified partners, CSI-Piemonte delivers SAS® solutions to thousands of end users throughout Piedmont's public administration offices. The consortium uses SAS® solutions to develop the largest part of the regional decision making information system, which helps public administration managers to provide vital information such as budgetary forecasts and revenue analysis.

Our BI Division has considerably grown in the last few years, because Data Warehousing (DW), BI, balanced scorecards and statistical solutions are indispensable to politicians and decision makers who need to measure activities and prepare forecasts for the future. As more and more Piedmont public administrations began to rely on CSI-Piemonte's solutions, the consortium saw the need to create the BICC organization to support its users. CSI-Piemonte's BICC offers help through a centralized call center that can dispatch specialists by phone or in person throughout Piedmont. The BICC staff also communicates regularly with its customers' data centers and it manages all software products within its applications. Today we have reached a very good practice level in SAS® 9 platform and solutions.

The BI Division has enhanced CSI-Piemonte efficiency and discipline as a service provider [2] [4]. The main benefit has been a better use of resources. In the past few years there has been an important growth of activities because public administration is investing very much in modernizing its information systems. So we had to be organized to follow that growth. Our Division has helped us to become more organized and more customer-oriented as we've managed that growth.

Moreover, in February 2006 CSI-Piemonte signed a Master Services Agreement with SAS® to provide professional services in the public sector market in all EMEA countries.

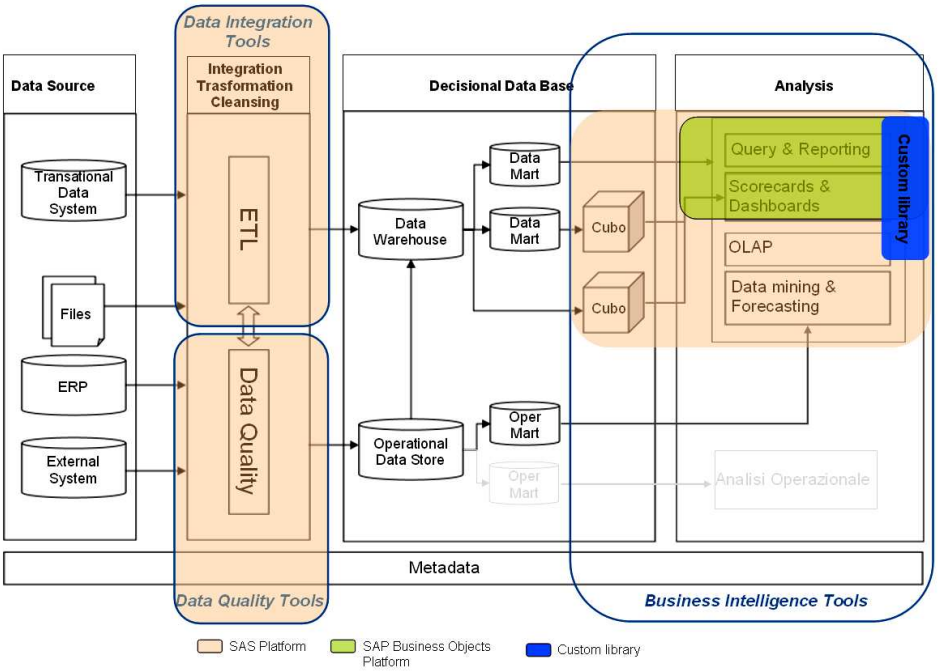

Figure 1. Business Intelligence Platform in production environment at CSI-Piemonte

SAS®, Dataflux®, SAP BusinessObject®.

A. *Main Activities of the BI Division*

The main activities of the Division are:

BI and DW

- Definition of the decision making information system's architecture for the involved public bodies.
- Definition of the lines of action for development and management of DW alphanumeric component (metadata and alphanumeric data).Analysis, design and implementation activities on DW' alphanumeric components.
- Collection services of statistical data (data entry of paper questionnaire, local or internet procedures for the automatic collection of data).
- Extraction of alphanumerical data from administrative, operational and technical archives that will be used for decision making purposes.
- Automatic data processing services: elaboration, DQ services (profiling, validation, standardization, record matching, cleansing), data accounting, indicators, application of statistic or mathematical models.
- Management of data warehouse databases: periodical updates of data and metadata, coding alignment.
- BI services: production of paper reports, production of statistic publication, static query and reporting, dynamic query and reporting, multidimensional analysis, decision making support instruments.

Databases

- Census of existing databases in CSI-Piemonte using the Company data dictionary.
- Preparation of the metadata update to support the database design or re-planning.
- Periodical analysis in case of need of external databases.
- Contacts with supplier of external databases for data acquisition.
- DQ analysis.

III. The Procurement Data Mart for the Municipality of Turin: a Business Intelligence Complete and Successful Experience

In 2006 CSI-Piemonte began the development of a dashboard prototype for tracking purchases of the Municipality of Turin. This development, as a result of positive feedback from the user, is continuing today towards an advanced decisional system: the Procurement Data Mart for the municipality of Turin.

The aim of the solution is to provide a complete picture of expenditure flows of the Municipality, providing information on:

- Who makes the purchase;
- What is purchased;
- In what way it is purchased;
- From which provider it is purchased;
- For whom it is purchased;
- How much is spent.

The focus is also on trying to picture the flow as a unique process that can be seen from different standing points, not only from a dimension point of view, but also with reference to the different facts the process includes as phases. These phases are typically (see Figure 2):

- the issuing of a formal institutional act;
- an order of some goods;
- the fulfillment of the order;
- invoicing;
- settlement;
- money order.

Data are read from the procurement management system's operational database: the systems tracks purchases by means of a process that is founded on the concepts of Order.

The analysis phase of the project addressed, as a very first step, the creation of a conceptual data model about the specific domain of procurement, in order to clarify the relation between all the concepts. This is a best practice in CSI-Piemonte, always to have a conceptual domain data model (as an important asset of any project) that describes the context specific information.

A second data model was then derived from the first. This is a classical decisional data model: dimensions and facts were identified from the conceptual domain data model and a purchase-centric star schema was designed to meet all the analysis needs that the Municipality of Turin expressed. The facts correspond to the procurement process's phases, related to the "Who", "What"; "In what way", "From whom", "For who dimensions".

But not all information about all the Municipality's purchases are registered in the management system. Some kind of purchases, such as leases, rents, consultancies and utility contracts, don't follow the same process as all other purchases. The only thing that all purchases have in common is the fact that they rise from a formal act, and this since we are in the domain of a public body and every internal process starts always from a formal act.

A purchase executive decision act is called a commitment executive decision act and it is a document in which all details about the purchase/purchases are written, including funding details. Being a text document, it can be analyzed by means of Text Mining (TM) tools.

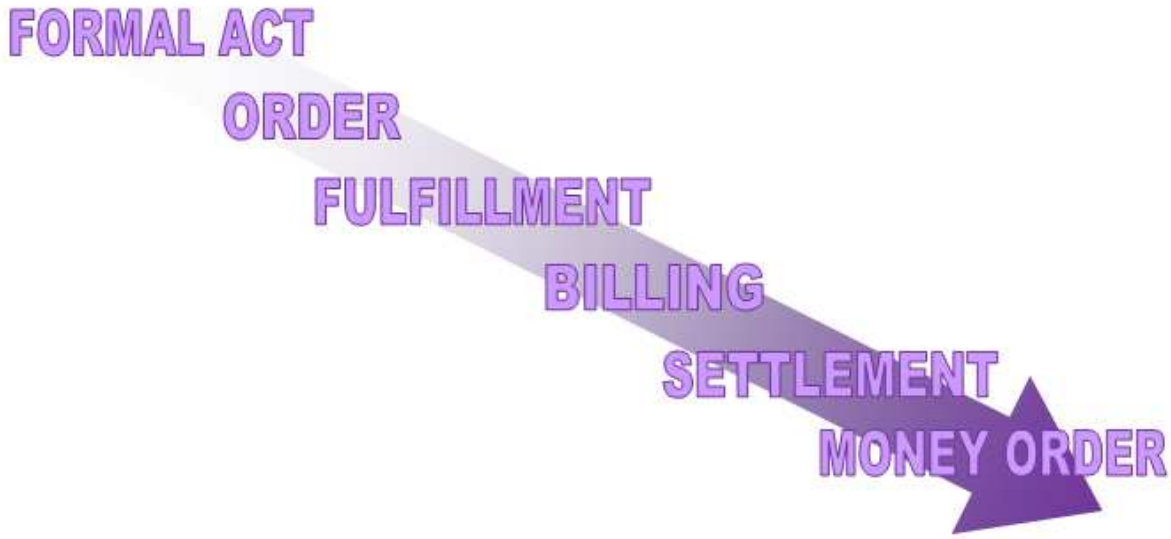

Figure 2. Phase (or facts) of the procurement process.

For all purchases registered in the management system, structured data are available for every kind of information; for those purchases that aren't registered, instead, commitment executive decision acts are read from a web source and analyzed, by means of TM tools, in order to achieve some structured data from unstructured ones. The TM analyses allows to meet the "What" and the "In what way" points also for the non registered purchases, being these details not available any were else for them.

The TM analysis is a supervised classification use case (see Figure 3). SAS® Enterprise Miner provides a rich suite of tools for discovering and extracting knowledge from text documents. It transforms textual data into a usable, intelligible format that facilitates classifying documents, finding explicit relationships or associations between documents, and clustering documents into categories.

Figure 3. Extract of a SAS® 9.2 Enterprise Miner 6.2 flow that resolves a supervised classification use case.

The "What" point corresponds to the product categories in which purchases can be placed. A set of product and type of purchase topics was set from the classes in which a purchase can be categorized in the management system. Some key words were associated to the topics, as in a supervised classification use case, in order to allow the tool to categorize the non registered purchases in the right product class. The set up of such a mechanism is quite a long and meticulous activity that needs tuning iterative steps and a statistic qualification. Before entering the TM process, data are prepared by means of DQ tools, that is they are cleansed and standardized in order to avoid false results in the TM process. The TM process can be scheduled as a batch service for periodic automatic execution.

Then, for all kind of purchases, data are integrated with budget information in order to provide a complete picture of the situation.

DQ is applied also in the flow that feeds the star schema of registered purchases. This is done in order to have both clean data and homogeneous information among registered and non registered information. This allows having a unique view about all data, even if non registered purchases give origin to data that have a lower level of detail.

As a final step, some sort of basket analysis is made by means of DM processes.

Hence, the back end solution is a sophisticated decision-making system, which integrates ETL, TM, DQ, DM and general BI techniques, all of which implemented through SAS® tools within the CSI-Piemonte's SAS® platforms.

The front end component is based on a combined SAP BusinessObject® and a content framework custom solution. The framework can contain links to reports and several kind of graphical contents, such as Gantt-like graphs, bubble graphs, cake and bar graphs, as well as a link to a searching engine, tags and much more (see Figure 4): it can, actually, include many graphical contents developed, for example, in Flash or HTML5 and allows the creation of dashboards customized for the users' needs.

When our users are decision makers, they need some graphics that allows them both to quickly get to information and to contextualize data properly. Lately we've been trying to implement some new way of presenting analytical results: we've been working on info-graphs, since we think that embellishment is not only for the sake of beauty.

This solution allows the municipality of Turin to monitor its purchase processes from every point of view, reduce waste, increase economies of scale and plan future purchases.

A. *Technical Details*

The back end solution is implemented through SAS® tools within the CSI-Piemonte SAS® platforms.

All data integration steps are developed with SAS® 9.2 Data Integration Studio 4.2.

TM and DM steps are implemented with SAS® 9.2 Enterprise Miner 6.2.

DQ steps are implemented using Dataflux® 8 functions embedded in the data integration steps.

The front end is a combination of SAP BusinessObject® and custom solutions.

Reports are developed using SAP BusinessObject® XI.

IV. CONLUSION

The setting up, managing and using of the complex BI platform descript in this paper needs a consolidated qualification and years of experience in the field.

Having the possibility to count on a platform of such completeness and reliability allows developing high quality solutions that may also be replicated for several clients.

The SAS®, Dataflux® and SAP BusinessObject® tools included in the platform are high quality instruments that can be properly exploited only by properly qualified human resources.

The result is a high quality product deployed on a high reliability platform.

ACKNOWLEDGMENT

The authors thank all their colleagues that work with them every day with and on the platform.

Abstract - This paper describes PSALM, a recently developed tool for business intelligence. The tool is based on MySQL database and web robot, both supported by routines developed in Java and PHP. The PSALM assembles patent data from publicly available data bases, it collects and analyses bibliographic parameters of patents but also does text mining. High-dimensional data contained in the patent documents are transformed into much lower dimensionality space (2D or 3D), clustered and visualized. The PSALM functionality and usability is demonstrated on MPEG-2 essential patents' portfolio.

I. INTRODUCTION

Patents are a powerful business tool for companies. They can gain exclusivity in the market or make additional profits through licensing. At the same time patens are a unique information resource. They are extremely valuable as source of technical information because approximately 80% of all scientific and technical information can be found only in patent documents [1]. In addition to technical data, patent document provides legal as well as business and public policy relevant information. All information found in a patent document are collected and verified according to internationally agreed procedures. They are presented in a systematic manner, as a combination of structured and unstructured data, and published in unified format. Information are either published in a patent document or derived from analyzing patent filing statistics. Table 1 summarises the format and information contents of patent documents.

The availability of all these information inside patents offers a full spectrum of possibilities for using them in key areas of technology management, including: competitors monitoring, technology assessment, the identification and assessment of potential sources for the external generation of technological knowledge and R&D portfolio management. Patent professionals, researchers and inventors, entrepreneurs, SMEs and commercial enterprises are among main stakeholders interested in using patents as a source of information. In order to make decisions about usage and management of patents they have to understand the strengths, weaknesses, opportunities and threats related to the managed patent assets.

However, there are barriers to frequent and efficient usage of patent information. The most important are: extremely high number of patents produced every year, increasing number of pages per patent, difficult language used in patents and lack of ability to understand relations between patents. Various software tools have been developed in the patent field in order to overcome these barriers. They could analyse individual patents as well as patent portfolios; retrieve patents and make basic statistics as well as visualize, map and landscape the same data. Most of these tools use statistical methods to analyze

TABLE I. FORMAT AND INFORMATION CONTENTS OF PATENT DOCUMENTS

Part of patent document	Where can be found?	Contents	Type	Use
Title and abstract (accompanied by a drawing)	Front page	Gives a concise summary of the technology of the invention.	Unstructured – free text	Archiving
Bibliographic data	Front page	Provides bibliographic information on the granted patent or patent application, which includes the document number (patent identification number - PID), filing and publication dates, name of the inventors, assignees and addresses, etc	Structured - information follow a strict format	Business and public policy relevant information
Description (in most cases including drawings)	Main body	Discloses clearly the technical details of the invention concerned, normally illustrated by working examples showing how to carry out the invention into practice.	Unstructured – free text	Technical and legal
Claims	Main body	Define the scope of protection for the invention under consideration; hence satisfying the legal aspect of the patent document.	Unstructured – free text	Legal

patent data in a specific period, and represent patent trends by various graphs and tables. They provide various facilities for researchers, managers, specialists and R&D practitioners. Good overview of different tools can be found in [1] and [2].

Nevertheless, most of the patent databases and tools available today are expensive as well as these tools can be complicated to use or ask for a strong expertise in the field of intellectual property. Therefore, SMEs and academic institutions, especially in developing countries, do not take a full advantage of using patents as a source of information for their own research, market and innovative activities [3]. Bearing this in mind, research group, composed of academics from University of Novi Sad and practitioners from RT-RK Computer Based Systems LLC, has started developing a tool for patent data analysis and management. The tool is named PSALM. It allows fast access to free patent databases, provides an easy way to build up patent databases and to automatically analyze patents. PSALM is designed to analyse both structured and unstructured patent data, and to visualize the results of both categories. The tool collects and analyses bibliographic parameters of patents but also does text mining. It shows huge potential for use in SMEs for monitoring competitors and technological trends. The objective of this paper is to describe structure and functions of developed version as well as to demonstrate its functionality.

The remainder of the paper is organized as follows. In Section 2, we describe structure and functional modules of PSALM. Section 3 describes user interface of business tool, while Section 4 demonstrates PSALM functionality on MPEG-2 essential patents' portfolio. Finally, in Section 5 we conclude with a summary of our results and a discussion of further research.

II. STRUCTURE AND MODULES

PSALM is a software tool developed for patent analysis. It is designed to analyse both structured and unstructured patent data, and to visualize the results of both categories. The tool is based on MySQL database and web robot, both supported by routines developed in Java and PHP. The PSALM collects data on patents from publicly available data bases (USPTO and EPO) and analyses their bibliographic parameters (like: title, inventor(s), applicant, date of application, priority date, country of publication, priority number, priority country, references cited by the patent, patents citing the patent, abstract, international patent classification) but also does patent mining [4]. This approach enables identification and extraction of undetected or unexpected patterns of concentrations embedded in a set of patents and visualization with respect to various contexts such as technological similarities or scope of claims. Fig. 1. presents main structure of PSALM tool.

The PSALM software consists of the following functional modules: web robot, text clustering, multi-dimensional scaling, visualization, analysis of the IPC codes, extraction and display of citing and cited patents, progress report module, module for recording data in the CSV file, and evaluation of a patent. First four modules are described here in more details.

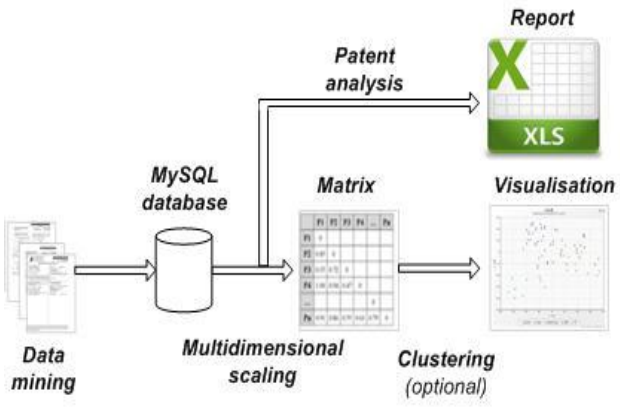

Figure 1. Structure of the PSALM tool

A. Web Robot Module

Main goal of data mining [5] is to extract important attributes and keywords from a patent data structure. As presented in Table 1 structure of the patent is designed as combination of structured and unstructured data. First task is to translate free text to structured data form. Web robot assembles patent data from publicly available data bases (USPTO and EPO), parse and place them in a local MySQL database for further analysis.

Database functions through several classes: classes which start and adjust data search (control data), classes which process contents of web pages (input data), classes which write data in MySQL database (output data) and the supporting classes that perform additional processing and storage. All collected patents' data are placed in Patents MySQL database. The base has the following tables:

- *searchSetup* table stores information about every search that is carried out . The primary key of this table is used to connect every patent in mainData table with the search in which patent is found.
- *mainData* table stores data on patents. Each patent in the table must be unique. The primary key of this table is used to connect data located in other tables.
- *caseData* table links patents from mainData table in specific case. The links are based on search in which patents are found, or on grouping criteria selected during the data analysis.
- Each row of *citationData* table connects main patent with its citations (cited and citing patents) using the primary key of mainData table.
- *claims* table contains additionally parsed claims data for each patent from mainData table. In this table claims are grouped as dependent and independent claims and connected to mainData table by its primary key.
- *ipc* table contains the IPC codes for each patent from mainData table.
- *apa* table contains information about the various publications of the same patent, and links

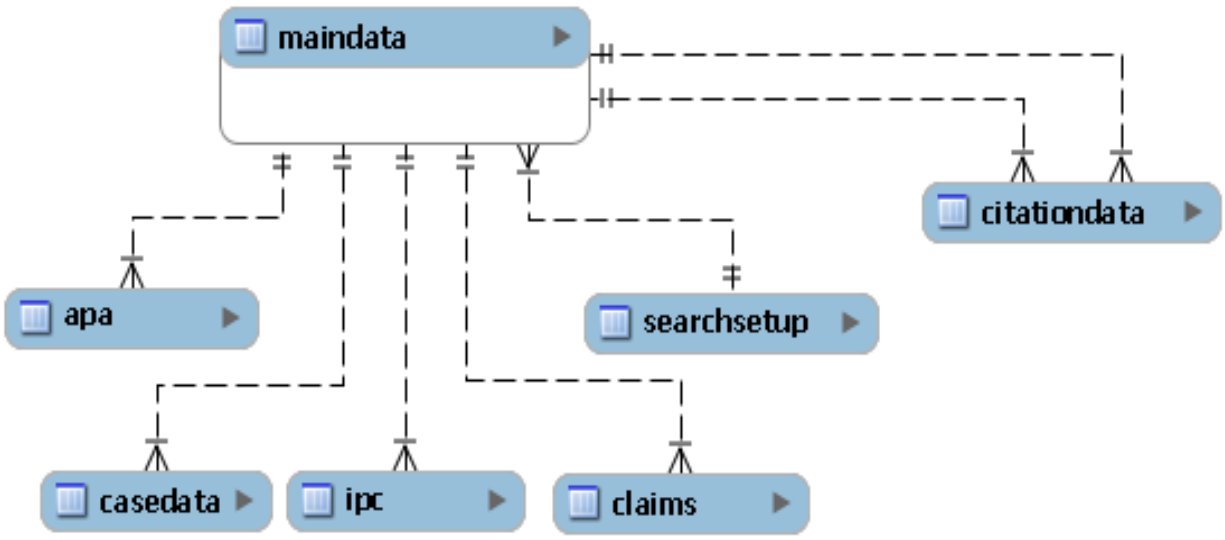

Figure 2. Enhanced Entity Relationship model of MySQL database *Patents*

different PIDs under which the patents have been stored in mainData table.

All tables are InnoDB type, which allows us to have the true relational database structure with foreign keys that preserve better database functionality and integrity (Fig. 2). Relationship between database tables are mandatory non-identifying (indicated by a dashed lines in Fig. 2). That means the primary key of the parent entity is included in the child entity but not as part of the child entity's primary key and the value in the child table cannot be null. These relationships are of the *one-to-many* type in which one instance of the parent entity relates to many instances of the child entity. In our case each row of mainData table contains a unique key which connects it (mainData table row) with one or more rows in child tables: *caseData, citationData, claims, ipc* and *apa*.

B. *Text Analysis Module*

Text analysis module analyse patent text (abstract, description and / or claims data) using term frequency - inverse document frequency (tf-idf) as a weighting scheme for keyword extraction. TF-IDF is a statistical method for determining the importance of words within a document, which belongs to a larger set of documents [6]. The importance of words within a document is directly proportional to the number of repetitions of the word in the document, to thereby compensate for the number of repetitions of the word in other documents.

C. *Multidimensional Scaling Module*

Multidimensional scaling Module is a part of software that has a task to transform high-dimensional data contained in the patent documents into much lower dimensionality space (2D or 3D), maintaining the most similar structure to the original. This module is based on the multidimensional scaling (MDS) scheme. The importance of words within each patent document which is derived by TF-IDF method is used for creation of distance matrix. Cosine of vectors assigned to the each document is used as measure of similarity and distance between each pair of patent documents. A squared distance matrix is configured from it, after which is estimated inner product matrix that can be rewritten in manner to perform operation centring. Classical MDS further extracts the eigen values and eigenvectors based on singular value decomposition from that centred inner product matrix, and estimates coordinate matrix, where the new coordinate matrix is lower-rank approximation of the original one. The main idea of classical MDS is to minimize squared errors of distances between these two matrices of coordinates. Detailed explanation of the method is presented in [7].

D. *Clustering and Visualization Module*

The output of the MDS module is a 2-dimensional matrix that can be easily used to visually present patents similarities. All 2-dimensional matrices are further analysed and clustered. Clustering helps identify meaningful patterns, undetected or unexpected groups from a set of unlabeled objects. PSALM is based on fuzzy c-means clustering algorithm where each patent has a degree of belonging to clusters, rather that belonging to just one cluster [8]. This unsupervised clustering technique group the given unlabelled collection of patents into meaningful clusters without any prior information. The clustering of patent document is carried out in reduced data dimensional space.

Patent data is processed with data and text mining techniques in order to present the data in some visual form which allow the human better understanding of and interaction with the data [9]. The clustered patent data space can be presented and visualized with respect to various contexts. The PSALM enables visualizations of high as well as low-dimensional data. High-dimensional data are visualized by mapping patents and clusters in proportion to each other, i.e. creating patent maps. Documents with similar subjects appear close to each other in maps. This makes it very easy to locate the most developed areas in technology. It also shows outliers in

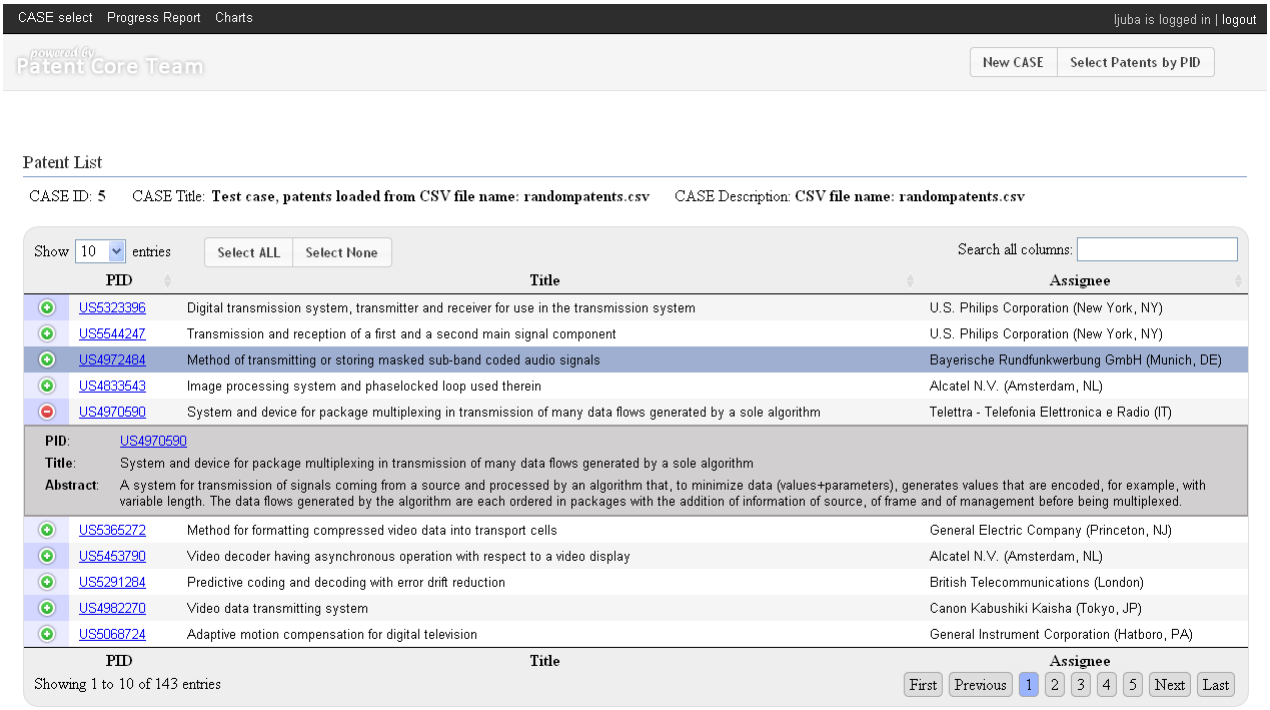

Figure 3. A example of PSALM interface – List of patents in the CASE

the data, patents that do not have much to the subject but are in the data by accident. Low-dimensional (structured) data are presented as bar charts and pie charts of bibliographic data and could also help in better understanding of the technology areas, changes in the technology development, company competiveness etc.

III. User Interface

The software is structured to serve multiple networked users at the same time in server – client manner. The user interface is built using PHP, HTML and JavaScript programming languages as well as JQuery JavaScript library, DataTables and HighCharts library for displaying the results of data processing.

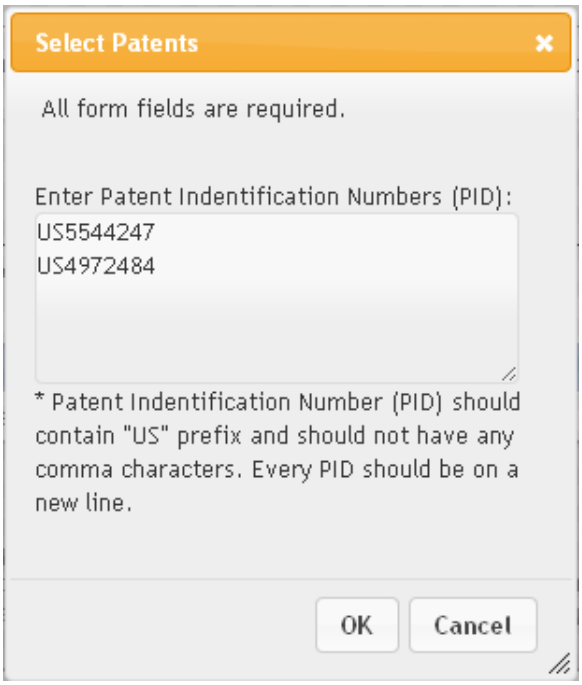

Figure 4. A example of PSALM interface – Select patents

PSALM is a tool developed to analyze a larger number of patents. The whole system is case-based (Fig. 3), where each case is made of group of patents selected on basis of the users' defined criteria. Patents should be entered directly number-by-number (PID) or as list in .csv form (Fig. 4). Criteria for creating a new case can be based on: assignee, IPC codes and cited and citing patents. In addition to these criteria, the user can create unlimited number of criteria for selecting patents based on keywords and bibliographic attributes. Each case is unchangeable after creation. However, it is possible to create a new case with a different set of patents combining existing cases.

Regarding the processing time, PSALM collects and stores patent data (access to the web page and download web page with the patent data; Parse the web page; Store data in database) within 2s (download/upload speed 26/1 Mb/s). TF-IDF processing time for group of 1800 patents is around 15 minutes, while MDS and visualization are done within 3s.

IV. Experimental Evaluation

In this section the PSALM functionality is demonstrated. To do this we selected 147 US patents which belong to MPEG 2 essential patent portfolio. MPEG-2 is a standard for the generic coding of moving pictures and associated audio information. It describes a combination of lossy video compression and lossy audio data compression methods which permit storage and transmission of movies using currently available storage media and transmission bandwidth [10]. A patent is essential to a standard, if making a product or using a

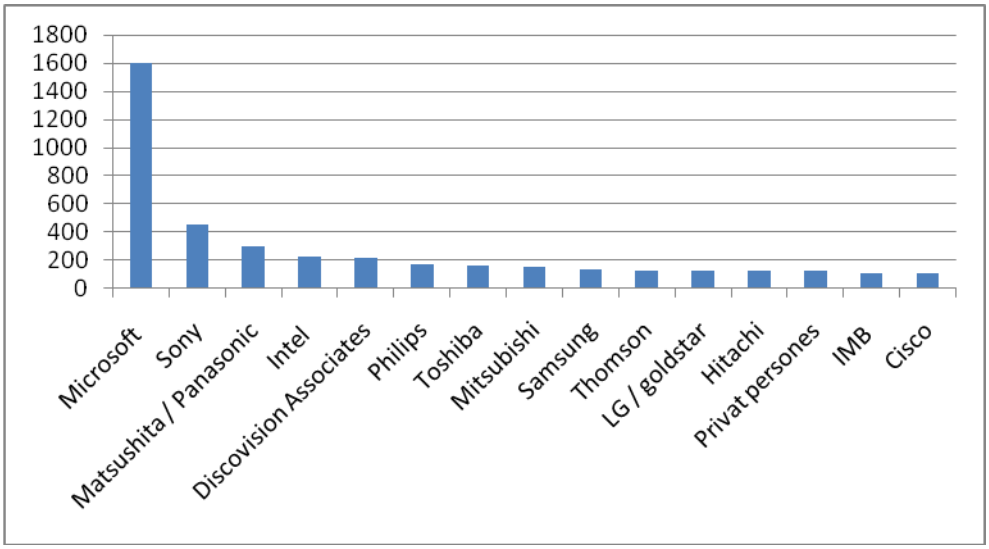

Figure 5. Companies whose patents have been citing essential patents

method, complying with the standard, requires use of the patent [11]. Using PSALM it is easy to understand structure of portfolio. In order to demonstrate some basic features of PSALM in analysing low-dimensional data, Fig. 5 present the result of analysis of citing patents. In order to detect main players in the field of MPEG-2 one can be interested in companies whose patents have been citing essential patents. PSALM will quickly produce the results presented on Fig. 5, indicating that Microsoft with 23.90% of all citations is much in front of Sony (5.21%) and Matsushita (3.73 %).

On the other hand, Fig. 6 demonstrates PSAML's capability to analyses high-dimensional patent data (free text) and to visualise them based on text mining. The task was to indicate strength of some companies in MPEG-2 field comparing essential patents and patents citing them. Fig. 6 shows specific areas in which two selected companies LG (green triangles) and Toshiba (red squares) have technology advantages or disadvantages comparing with the set of essential patents (blue rhombs). From Fig. 6 it is possible to conclude that LG has strong position in audio coding and video transmission, while Toshiba is better positioned in coding/decoding digital signals. On the other hand, both companies are in good situation in areas of video coding/decoding and video compression

At the same time Fig. 6 verifies PSALM's ability to

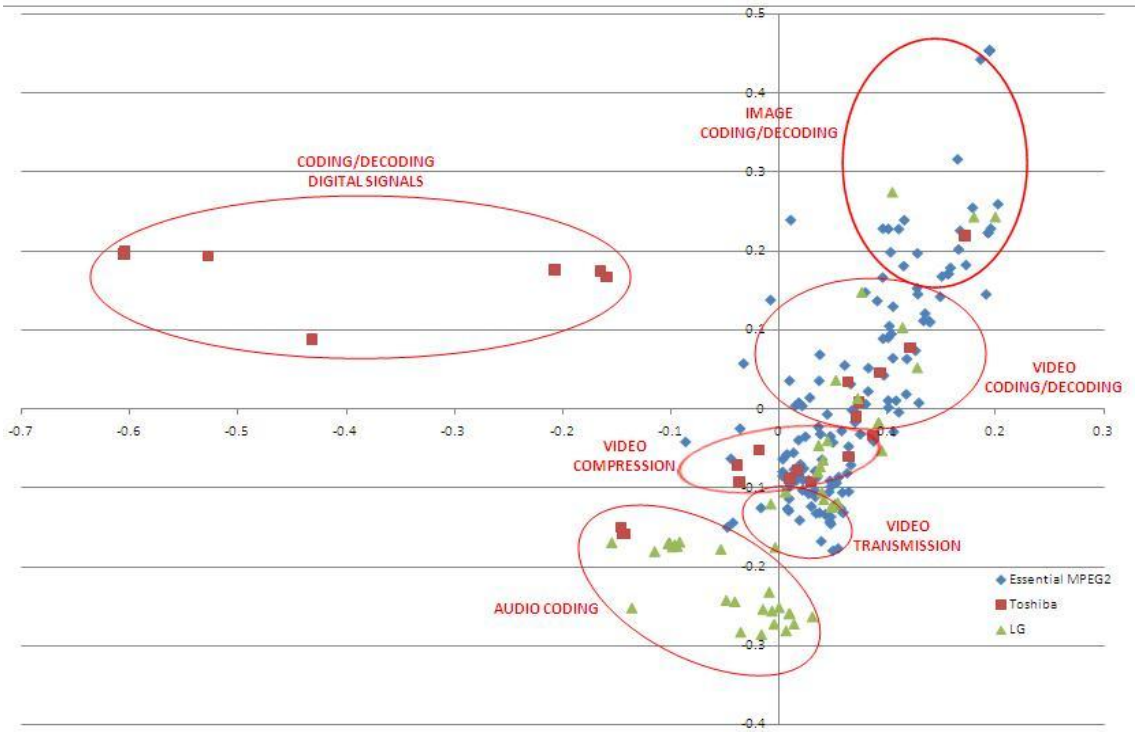

Figure 6. Example of high-dimensional data visualisation

assemble patents into technology meaningful groups. Namely, these patents were first analysed by experts and clustered. Ellipses in Fig. 6 are placed additionally for the purpose of illustration only, to show satisfactory matching between the tool and human experts' results.

V. CONCLUSION

In this paper we described a version of PSALM – a tool for patent data analysis and visualization developed by academics from University of Novi Sad and practitioners from RT-RK Computer Based Systems LLC. The basic functionality of this tool for business intelligence is demonstrated on MPEG-2 essential patents' portfolio.

The tool is based on MySQL database and web robot, both supported by routines developed in Java and PHP. The PSALM assembles patent data from publicly available data bases, analyses bibliographic parameters of patents but also does text mining. It is based on tf-idf weighting scheme to determine the "weight" of words, multidimensional scaling to transform high-dimensional data into much lower dimensionality space (2D or 3D). The low-dimensional data is than visualized. The PSALM enables visualizations of high as well as low-dimensional data with respect to various contexts.

The real power of the tool is in analyzing portfolios with a larger number of patents. Patent data analyzes will still be hard, time and manpower consuming experts' work, but PSALM could help people involved in IP management to focus their time and efforts on the most interesting and most promising patents, but also to save time in preliminary grouping them. For example, based on PSALM results it is easier to target technology week areas or to select with higher probability patents interesting for infringement sues. Knowing which patents are interesting and why they are interesting is important especially for those who make decisions about usage and management of patents.

Results presented in this paper are results of current version of PSALM and significant improvements are expected in the next period. Further research will be directed towards tool improvement using WordNET for comparing words in the text, using SAO structures for text analysis and clustering based on IPC codes for technology finding.

ACKNOWLEDGMENT

Data mart design for managing IT department in a telecommunications company

Jasna Mirković, M.Sc*, Ljiljana Kašćelan, PhD**
* Telecom Montenegro/ IT department, Podgorica, Montenegro
** University of Montenegro/Faculty of Economics, Podgorica, Montenegro
ljiljak@ac.me

Abstract – This paper deals with the data mart design in the area of analysing problems and requests in the IT department of a telecommunications company. Efficient resolution of problems and execution of requests is very important to operate smoothly and ensure that the services this company offers to users are available on time. Main decision-making processes have been identified during the research in the IT department of a telecommunications company. In that respect adequate data mart was designed. The concept of realisation of the data mart was presented using business intelligence tools. The implemented system was tested on data from the case study of a company – "Telecom Montenegro" AD, where outputs with good performance were successfully generated.

I. INTRODUCTION

Having the right information on time represents basis for making good decisions. No matter how good a manager who manages the business is, the success is not guaranteed if relying only on intuition without timely information.

In modern business conditions a manager must know what information to look for and how to get them before the competition. Therefore, business intelligence tools are means for getting the information in a timely manner. If these tools are properly and skilfully handled, they will give good results.

The subject matter of this research is data mart design in the area of managing IT department, as in [3], which means that:

- It must be implemented in the manner to be included in integral data warehouse
- It should correspond to specific requests of the users
- It should enable development of OLAP model under the presented requests

The basis for designing data mart lies on the following assumptions:

- Main decision-making processes have been identified in the area of managing IT department in telecommunications companies, i.e. data mart targets have been identified
- Logical model was defined and RDBM system was selected;
- Logical model was mapped and physical model was developed;
- OLAP models were developed based on user's requests;
- Model was tested on data of real system "IT Help desk application" of the company "Telecom Montenegro".

The results obtained pointed out that model corresponds to the presented requests and the time of responses in real system has parameters that correspond to standards of the business intelligence system.

II. DEFINING THE OBJECTIVES OF DATA MART

The work of the IT Department of the telecommunications company and the decisions that are passed in this area reflect on business success of the company in many ways. The main objective of IT Department is to provide the support to the operations of the company through adequate support of internal users and IT systems that enable the operations of the company. The time of responses in resolving problems and requests influences directly the revenues of the company.

For an optimum organisation of IT department and monitoring of its work, in addition to various analyses, the most important ones with regard to the IT Department management are the following:

1. **Analysis of problems/requests of internal users** – This analysis will enable easier and better insight in all problems/requests reported in specific time period, as well as the analysis of duration and pricing of resolving problems. In this way, information needed for more efficient and effective resolution of problems and requests have been obtained. Detecting problems that appear most frequently enables their prevention and saves time of the employees.

2. **Analysis of users** – This aspect answers the questions on end users that report problems and requests: who are they, which sectors do they come from, which users repeat requests, which users make the same mistakes.

   This analysis may give answers, for instance, which internal user needs additional training and in what area.

3. **Analysis of executors** – These analyses are particularly important for IT managers as they enable detection of most efficient executors and those that are not efficient. It also gives an insight in areas where executors need additional education. It is also possible to establish key performance indicators (KPI) through this analysis which will be set up as a target to all employees from certain group and encourage achievement of targets and higher efficiency.

Main targets of data mart are:

- To provide implementation of OLAP model which will be enabled by previous analysis;
- The possibility of integration in data warehouse system of entire company;
- The possibility of its implementation using some of standard tools for development of data warehouse;
- The possibility of integration with standard OLAP tools;

III. DATA MART DESIGN – SELECTION AND SPECIFICATION OF BUSINESS FACTS AND DIMENSIONS

Modelling of data through star schema i.e. using fact tables and dimension tables is selected for data mart design. Fact table is in the centre of star schema connected by surrogate keys with dimension tables. Dimension tables are denormalized with surrogate keys that enable storing of dimension history.

Fact table for data mart with targets recognised in the previous chapter is the following table:

- *helpdesk (HELPDESK_F)* – which will record all resolved problems/requests by IT department. Attributes of this table, in addition to surrogate keys of dimension tables, are: price_of_resolving_problems and duration_of_resolving_problems.

In data mart design, the selection on the *level of granulation* should be taken into consideration which should be respected in all tables that make star schema.

Granules represents the main, the smallest level of data to be represented in the fact table for a given business process. Granules in the fact table should be determined at as low level as possible, which represents individual transaction. Lower level of granulation gives more robust but more flexible design of star schema, which means that it is more ready to answer to various types of queries and enable possible introduction of new dimensions.

Specifically, for the selected fact, *helpdesk* granules could be: problem/request which internal user reports and the employee in IT department resolves. This enables the possibility of data manipulation at atomic level – each single problem/request of any type regardless of period when it is reported. In this way, it is possible to come to the following information:

- when certain problems/requests have been reported and resolved.
- Who solved them, i.e. who reported certain problem/request.
- What is the average number of resolving problems/requests in specific categories, and the like.

It should be noted that the selection of granulation level of dimension tables depends on the level of granulation of fact tables. The level of granulation for all tables must be the same.

Dimensions for fact *helpdesk* are the following:

- *Time dimension (Datum)* – which should reflect hierarchy of time: year → quarter → month → day
- *Executor dimension (IZVRSILAC_DIM)* – Each problem or request is resolved by employee in IT department.
- *User dimension (KORISNIK_DIM)* – each problem or request is reported by an internal user. This dimension corresponds the hierarchy of type: department → user
- *Problem dimension (PROBLEM_DIM)* – Insight in problems and requests that are reported by end users to the employees in IT department. This dimension corresponds the hierarchy of type: type_of_application → list_of_application → list_of_problems

IV. DATA MART REALISATION

Tools to be used for realisation of data mart are Oracle Warehouse Builder (OWB) and Oracle Discoverer.

OWB is a tool for designing, implementation, development and managing data warehouse system, as well as the system of business intelligence, in general. This tool combines key components of ETL tools and tools for

designing, thus enabling integration of ad-hoc inquiries as well as OLAP solutions. It enables realisation of Data mart through three stages, the defining stage, generating stage and data loading stage, as in [1], [5].

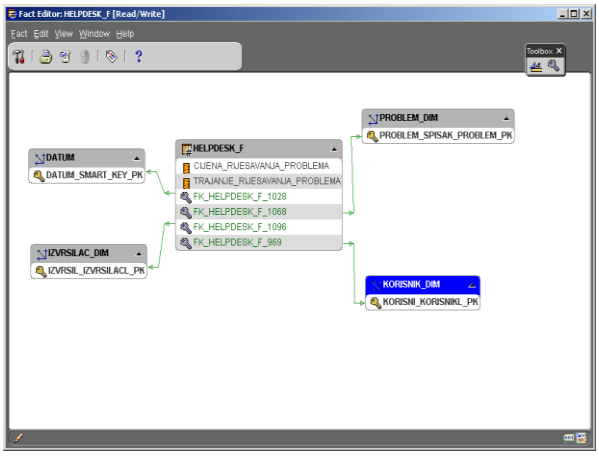
The defining stage includes:

- Defining of targeted warehouse schema – defining of multidimensional models and aggregations;
- Defining of sources of data
- Defining of mapping operations i.e. transformation and data loading – ETL procedure.

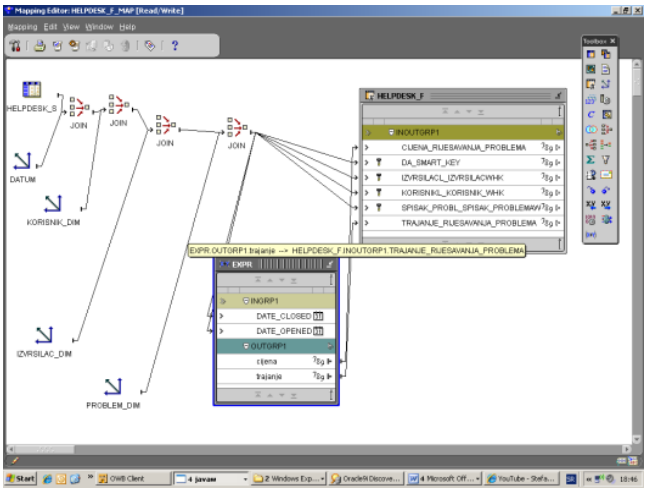
In the generating stage, scripts for creating warehouse schema and ETL procedures are generated and executed. The initial data loading is performed through the execution of ETL procedures.

Targeted warehouse schema for data mart designed in the previous chapter and defined by OWB, is shown in Picture 1. The Picture 2 shows mapping of facts *helpdesk*.

Oracle Discoverer was used for creating OLAP models. Administrative component of this tool, as in [7], enables designing and presenting the groups of data from corresponding business areas, which user accesses through user component *Discoverer Plus*. *End User Layer (EUL)* represents a component that hides database complexity and its change from end user and which is located between *database dictionary* and *Discoverer*. From operational standpoint, *EUL* generates SQL statements at client's level and communicates with database. When a user selects an object within a *business area*, *EUL* generates a SQL statement that defines the selection over table and view. When a user makes a query, *EUL* executes this SQL statement, sends it further to the database which returns results to the user's component. In this way, end user does not need to be familiar with SQL to access and search for data. This inter level protects database integrity since nothing that user does on *Discoverer* reflects on database but it reflects on metadata within *EUL*.



Picture 1. Star schema



Picture 2. Mapping of facts helpdesk

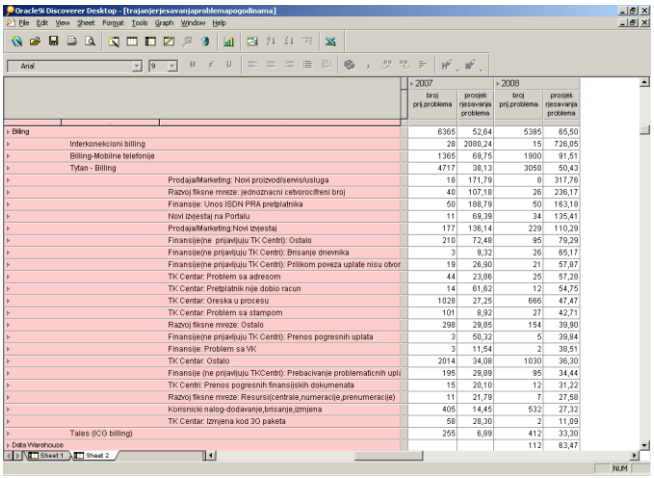
All OLAP models were realised for all three analysis that were defined as the targets of this data mart, as in [2], [6]. One of OLAP models defined using this tool is shown on Picture 3.

V. CASE STUDY

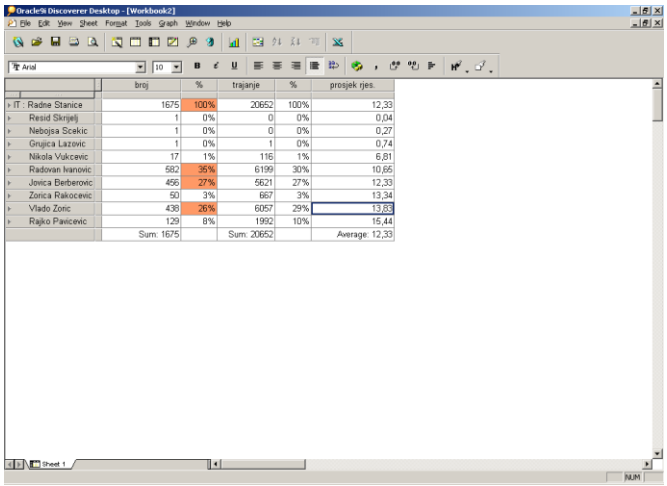
For the analysis within case study, a data of telecommunications company "Telecom Montenegro" AD were taken from helpDesk information system of IT department, as in [3]. This company deals with provision of telecommunications services, and IT department is responsible for entire information system of the company without which the company could not perform its business.

Information system helpDesk is organised in a way that internal users report requests through simple interface and also the problems occurred during their work. Furthermore, employees in IT take over and resolve these problems and requests, and the information on who took over the problem and when the problem was resolved was sent to internal user. The reporting of problems and requests using phone or email to system manager of the division was valid until 1 January 2006, which required that the manager would spend significant portion of time as a mediator between end users and employees of IT and it was difficult to follow up the quantity of these requests. Automation of information system of IT department was done at end-2005 and it was put in operations on 1 January 2006. Total 5975 of requests were evident in 2006, total of 12192 requests were evident in 2007, and in 2008 there were 14461 requests.

Source data used for data mart design in this research represent business data of IT department of "Telecom Montenegro" on problems and requests of internal users during 2006, 2007 and 2008. Source data were placed in *SQL server* relational database where they were taken in the form of Excel tables.



Picture 3. Workbook of number of reported problems with average solution



Picture 4. Distribution of resolving user's requests within group of employees dealing with removal of problems concerning work stations

Initial data loading (about 40 000 records) into designed data mart was less than two minutes. Almost in all cases, initial importing of data into workbooks is 1 - 3 minutes, if data for all years are loaded. After that, all operations in slicing last less than one second, as well as operations drill-up/drill-down if all hierarchies are already present in the workbook. If some of hierarchy is not present in workbook, the operations drill-up/drill-down require data uploading, which has the same level as the initial uploading of workbook. This leads to the conclusion that it is better to implement workbook with all anticipated hierarchies if the time of responses matters.

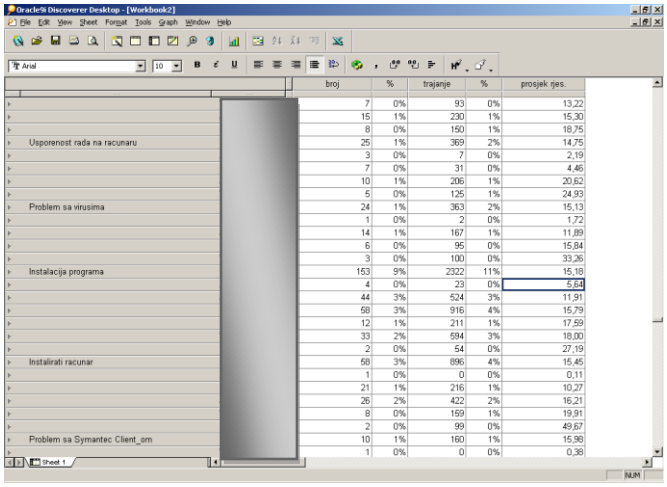
Several interesting analysis, as in [3], realised through OLAP models over case study data from the aspect of IT managers follows.

Picture 4 shows distribution of solving users' requests within the group of employees dealing with removal of problems on work stations in 2008.

The analysis shows unequal distribution of resolving problems. To wit, 88% of requests were resolved by three employees out of total of nine employees. Time spent on resolving problems also differs.

Picture 5 shows drill made based on the description of problems. This report shows that certain executors were "faster" than others within the same category. Overall analysis points that time of employees dealing with resolving these problems has not been used in the best manner; therefore, the appropriate actions should be taken, for instance, rearrangement of employees or reduction of their number in IT department, further training and follow up of the progress of employees being 'poor' executors.

The following analysis (Picture 6) shows distribution, duration and average of resolving problems and requests by types of applications, observed only in 2008 aimed at detecting the area of the highest engagement of human resources. The analysis shows that majority of IT resources were engaged on type of application "Billing".

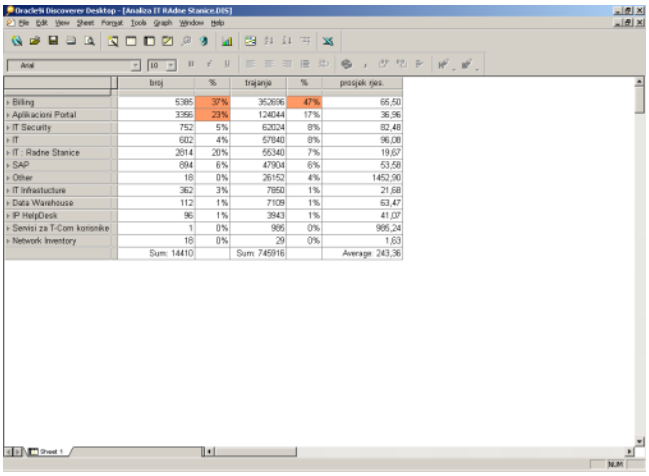


Picture 5. Distribution of user's requests within the group of employees dealing with removing problems concerning work stations – drills based on the description of problem

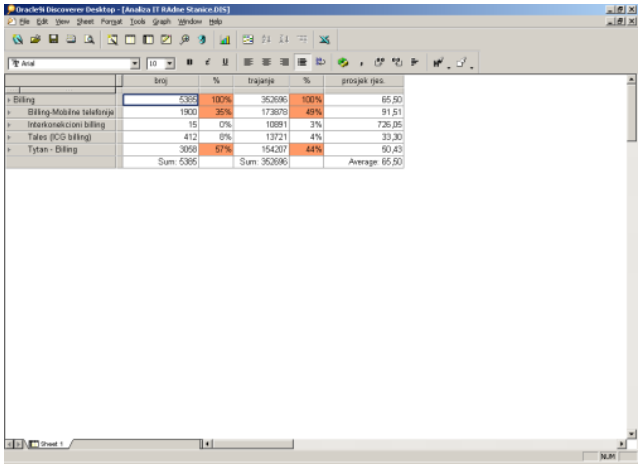
Further analysis (Picture 7) shows that there are several billing systems within type of application "Billing", and majority of reported problems and requests are within the category "Tytan-Billing" (Billing of landlines), and then "Billing-mobile phones", while time spent on resolving these problems/requests is almost equal. This point out that Tytan billing system has several problems in its work, but those problems require shorter time for their resolution.

Further analysis of problems/requests of Tytan billing system drills to the description of the problem (Picture 8) and points out that the majority of requests comes from the category "TK Centre: Error in process".

The category "Other" remains neglected as these are problems that cannot be grouped in any of the categories. If number of errors in processes is reduced, it would save up to 21% of time of the team that deals with resolving these requests and problems.



Picture 6. Distribution, duration and average of resolving problems and requests by types of application



Picture 7. Distribution, duration and average of resolving problems and requests for the type of application 'Billing'

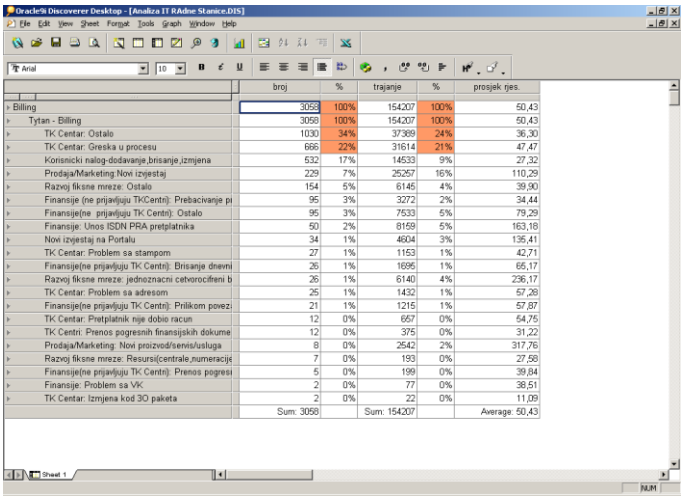
This team consists of six employees, which means that the team could be reduced to 5 persons or the efficiency of the team should be improved – both activities directly influence the profit of the company.

The following analysis (Picture 9) represents monitoring of key performance indicators, number of resolved problems/requests within 3 days, and comparative analysis for 2006, 2007 and 2008.

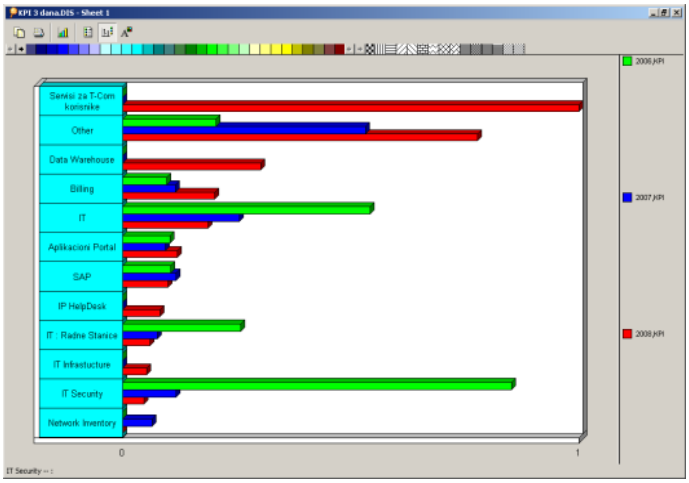
It can be noted that KPI trend improves in the most important part for the support of internal users "Billing". However, the trend within domain "IT: Work Stations" is rather poor. It means that actions should be taken in this area to improve the efficiency considering the analysis from the previous chapter.

VI. CONCLUSION

This paper defined designing of data mart for the support to the decision-making process of IT department in a telecommunications company. The process of data mart design included the following:



Picture 8. Distribution, duration, and average of resolving problems and requests for type of application 'Tytan' billing system, drill to the description of the problem



Picture 9. Number of resolved problems/requests within 3 days, by years

- Identification of main decision-making processes in IT department of telecommunications company;
- Definition of sources of data for identified processes;
- Projection of data mart design for the support to identified decision-making processes;
- Definition of concepts and methodologies for the realisation of this data mart using "business intelligence" tool;
- Realisation of defined targets of data mart, i.e. OLAP model;

Data mart design based on identified decision-making models gave expected results. It means that the proposed model gave efficient and qualitative outputs for all identified decision-making processes. This paper also gave the concept of realisation of data mart. Realised system was tested on data from the case study of the company –

"Telecom Montenegro" AD, where successfully generated outputs with good performances showed accuracy of the proposed design. Further research could be focused on the possibilities of integration of data mart defined in this manner into uniform data warehouse and expansion of possibilities, i.e. higher number of analysis.

Abstract - An e-invoice is the most widely used electronic document in the world. Although it covers only one segment of the entire supply chain, the e-invoice has a central role in the development of electronic business. An electronic invoicing system named an *FER e-invoice* is built at the University of Zagreb Faculty of Electrical Engineering and Computing (FER). The *FER e-invoice* system contains business processes that should be monitored and analyzed. Therefore, a data warehouse, containing data extracted from e-invoice XML documents, has been developed. Multidimensional model of the data warehouse consists of two fact tables, one for the invoice heading and one for the invoice items, and of 14 dimensional tables. In this paper the developed data warehouse is presented.

Key words: data warehouse, e-invoice, electronic business, XML, XSLT, ETL, dimension table, fact table

I. INTRODUCTION

Electronic business (e-business) includes business transactions and information interchange using information and communication technology in an enterprise, between enterprises and their customers or between enterprises and public administration [1]. The basic part of electronic business is the supply chain which consists of business processes that include catalog, tendering, contract, order, scheduling, invoice, payment and remittance advice. To be able to implement such a supply chain together with the entire process of e-business it is necessary to establish specific electronic documents and procedures such as e-catalog, e-order, e-invoice, e-invoice user registry, e-payment, e-signature, e-identity altogether with semantic and technical interoperability. The goal of electronic business is to achieve the highest possible rate of automation and digitalization of business processes. For example, in a world where electronic documents do not exist, a customer would have to write his order on a piece of paper and send it to the seller using the mail service, fax or electronic mail service. The seller would have to manually analyze the order and approve it if it is a feasible one. After that, he would have to manually copy the elements from the order to the invoice and send the invoice through the same communication channel he received the order. In a world where electronic business is used the same procedure would be arranged by a simple exchange of a digital order, usually in a XML format. After the seller would approve the order, it would be feasible to automatically generate an invoice from its elements. That way it is possible to save time (faster invoice delivery, processing and charging), paper (environment friendly) and eliminate possible mistakes during manual copy of information which in the end results with financial gain.

E-invoice is the most outspread electronic document in the world. Its development is the key to the success of electronic business although it covers just one segment of the entire supply chain. It contains important data for the calculation of VAT therefore its usage has extra significance for the enforcement of the national fiscal policy. The widespread usage of internet banking in Croatia is the cornerstone to achieving the maximum effects of e-invoice introduction. Electronic document interchange in Croatia is regulated by the Electronic trade law [2], Electronic document law [3] and Electronic signature law [4]. Accounting law [5] regulates book-keeping documents composed in electronic notation while Common tax law [6] prescribes electronic data management. The VAT regulation has obstructed the vast implementation of e-invoice interchange by not allowing enterprises involved in the VAT system to use e-invoices for tax purposes. That obstacle was bypassed finally in July 2011 by the new VAT regulation [7] that states that electronic invoices are legally equal to the paper ones.

E-invoice implementation is a good example of a horizontal integration inside e-business and therefore should attract interest on one side from large and small enterprises and on the other from the public sector [8]. A system, where all entities must receive e-invoices in tax purposes (VAT) in case two conditions have been met, has been established in all European Union countries. The first condition is that the e-invoice receiver must agree to receive the invoice in an electronic form whereas the second one requires that integrity of the contents and the authenticity of the origin must be guaranteed during transport and archiving [9]. The transition from the paper invoice to the e-invoice brings several benefits. E-invoice utilization brings faster and easier management of invoice publishing, receiving and archiving. Moreover, all the sent and received invoices are archived in an electronic form. European analyses show that the costs of sending and receiving invoices should be lower for 60 - 70 percent compared to today's costs. According to [10], the implementation of e-invoices only in Croatia should bring six billion kuna savings annually, whereof 350 million just in public administration.

Electronic invoices in XML format as like as paper invoices contain important data that can be used for

business analysis. Data warehouse can be built based upon the data collected from e-invoices. Data warehouse is a database that contains historical unchangeable data which is collected and processed to support business decision making [11]. In such a data warehouse business processes can be analyzed with regard to the supplier, customer, way of payments, etc. As the source data is in XML format, it has to be transformed by using XSLT transformations in order to eliminate irrelevant data. Finally, the data is inserted into the data warehouse.

The paper is organized as it follows: chapter II briefly describes the *FER e-invoice* system (FER is abbreviation of Faculty of Electrical Engineering and Computing in Croatian); chapter III defines the concept of a data warehouse and specifies the procedure of data warehouse development and data loading; chapter IV depicts the development, data loading and the usage of the data warehouse implementation in the *FER e-invoice* system; the final chapter V contains the conclusion.

II. *FER E-INVOICE* SYSTEM DESCRIPTION

A pilot system for electronic invoice interchange has been developed on the University of Zagreb Faculty of Electrical Engineering and Computing. E-invoice interchange implies processes of e-invoice formatting, sending, receiving, storing and searching. A model for e-invoice users registry has been proposed and developed in order to support the e-invoice interchange system. Users can utilize the system through two basic applications. The first one is the application for e-invoice interchange which consists of the application for sending the e-invoice and the application for accessing the e-invoice archive. The second one is the application for accessing the e-invoice users registry. An additional application (registry form) is used for registering new e-invoice users.

A. *System architecture*

FER e-invoice system architecture is based upon 4 corner model (4C). As the name suggests, it has four basic components: user in role of an e-invoice sender, sender's service provider, receiver's service provider and user in a role of an e-invoice receiver. Fig. 1 shows the design of the 4C model (user 1 and 2 – e-invoice sender/receiver, SP – service provider).

E-invoices are being sent in such a way that the sender forms (manually or through the application) an e-invoice and forwards it to its service provider. The sender's service provider forwards the invoice to the receiver's service provider which passes it over to the e-invoice receiver. The e-invoice is archived on the sender's and receiver's service provider.

E-invoice user's data needs to be stored permanently. That is the reason why every service provider has an e-invoice users registry which stores all important data concerning the users that are the service provider's clients.

The important feature of this system architecture is the fact that the central part of the system is totally decentralized and at the same time built around a set of service providers. However, as the number of information

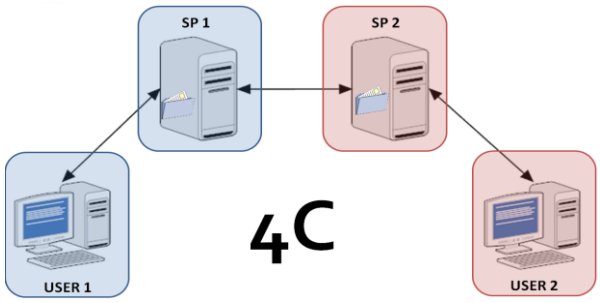

Fig. 1. The design concept of the 4C model

providers increases, it becomes more difficult to know precisely to which service provider the invoice must be sent to reach the designated receiver. That is the reason why the central e-invoice users registry has been developed and introduced into the system. It stores the essential information needed for e-invoice routing. After the e-invoice sender hands over the e-invoice to its service provider, the provider will fetch the receiver's OIB (personal identification number in Croatia) parameter from the invoice. Then it will contact the central users registry to find out the service provider it needs to send the e-invoice to so that the e-invoice reaches its designated receiver. The skeleton of the developed system for e-invoice interchange is shown in the Fig. 2. The image depicts the system's integral components and web services used for their communication.

FER e-invoice system consists of:

1. Applications that facilitate e-invoice formatting and sending, reading the archive of received and sent e-invoices and registering new users together with examining the data about current users
2. Service providers (with local e-invoice users registries) that facilitate e-invoice interchange
3. Central e-invoice users registry
4. Web services that enable the e-invoice interchange from the technical point of view.

III. DATA WAREHOUSES

Data warehouse is an important functional extension of *FER e-invoice* system described in previous section. It allows different business analyses based on e-invoice. This chapter shows basic characteristics of the data warehouse, while design of a *FER e-invoice* data warehouse is described in the next chapter.

The data warehouse is a subject-oriented, integrated, time-variant and non-volatile collection of data in support of management's decision making process [12]. Subject-oriented means that the data warehouse can be used to analyze a particular subject area. For example, "sales" can be a particular subject. Integrated means that data warehouse integrates data from multiple data sources. For example, source A and source B may have different ways of identifying a product, but in a data warehouse, there will be only a single way of identifying a product. Time-variant means that historical data is kept in a data warehouse. This contrasts with a transactions system, where often only the most recent data is kept. Non-volatile means that once data is in the data warehouse, it will not change. So, historical data in a data warehouse should never be altered.

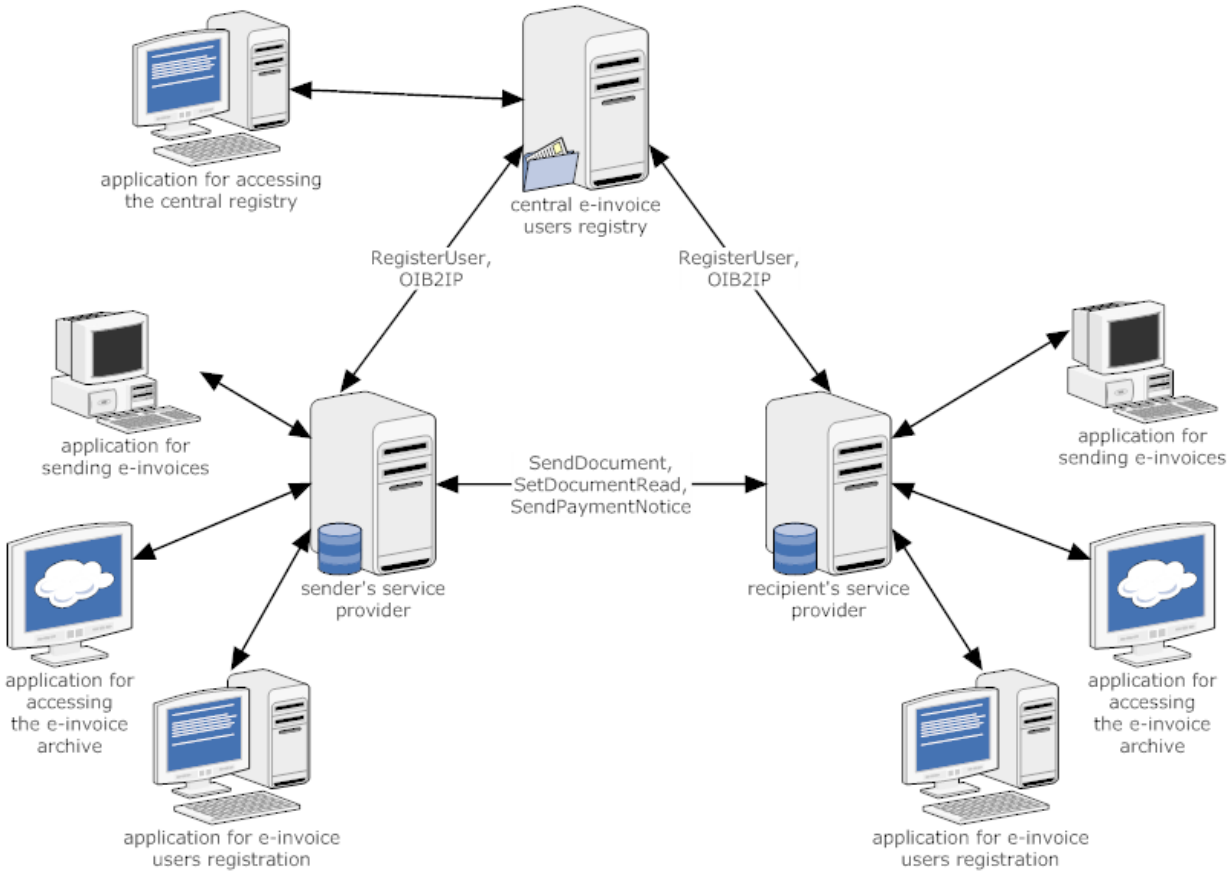

Fig. 2 The concept of *FER e-invoice* system architecture

The usual way of developing transactional databases is not suited for developing data warehouses. The most important difference between transactional databases and data warehouses is that data in transactional databases, unlike data warehouses, can often change. That is the reason why the transactional database must be normalized (in third normal form). In data warehouses the query execution speed is more important and that is why denormalized multidimensional modeling is used for developing data warehouses. Fig. 3 shows the basic activities that can be done on the data warehouse. Those are extraction, transformation and data loading (ETL); data storing and data management; data usage in the process of business decision making. Multidimensional modeling consists of conceptual, logical and physical modeling [13]. The result of conceptual modeling is the data warehouse schema that is DBMS (database management system) independent. Logical modeling results with a logical data warehouse schema which defines the way the data warehouse will be implemented. Physical modeling depends of the used DBMS.

Data warehouse development consists of four phases [14]:

1. Select the business process
2. Declare the grain
3. Choose the dimensions
4. Identify the facts (measures).

Data warehouse once designed and implemented must be loaded with data which can be done with the ETL procedure. ETL can be divided into initial and incremental loading.

IV. *FER E-INVOICE* SYSTEM DATA WAREHOUSE

FER e-invoice system holds important data about the business activities of every participant in the process of e-invoice interchange through its archived e-invoices in

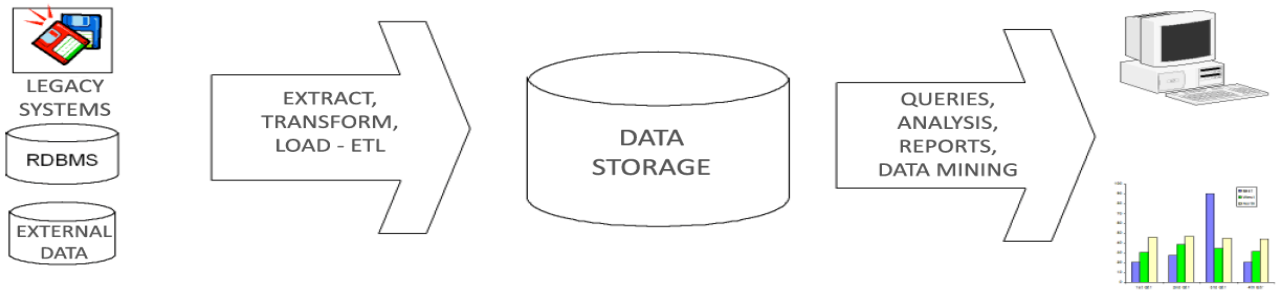

Fig. 3 The essential activites during the process of data warehousing

XML format. The data is related to the business entities (supplier, customer, deliverer and tax agent), business processes (delivery, payment method) and business objects (invoice, invoice item, tax, expenses, discount, article). Based upon such data with the goal of providing a service of quality business analysis to the business entities involved in the system, a data warehouse has been developed and implemented into the *FER e-invoice* system. The important characteristic of the system is that every service provider has its own data warehouse (data warehouse would be hosted on the separate server), but with the same conceptual model that enables later data integration for entire *FER e-invoice* system. Thanks to it, the provider can offer to his clients access to the data that are of their interest. In other words, it can offer business entities a possibility of analyzing their own business activities.

A. *Data warehouse model*

The first step of the data warehouse modeling was the analysis of the input specification. The input specification was the technical specification of e-invoices that are being interchanged in the *FER e-invoice* system. It is specified in [15]. Based upon the analysis, a data warehouse conceptual multidimensional model has been built [16]. Fig. 4 illustrates it. Business processes that have been modeled are the e-invoice and its items. These processes represent the master/detail relationship that is modeled by two fact tables: *fInvoice* and *fInvoiceItem*. Data source system's granularity has been adopted to the data warehouse's granularity, meaning that table *fInvoice* has one entry for each e-invoice while the table *fInvoiceItem* has one record for every invoice item of every e-invoice. Dimension tables relate to entities and their elements present in the e-invoice: *dCost* (contains cost data), *dDiscount* (contains discount data on the invoice level), *dDelivery* (contains delivery data), *dCustomer* (contains customer data), *dTaxAgent* (contains tax agent data), *dDeliverer* (contains deliverer data), *dSupplier* (contains supplier data), *dPaymentMethod* (contains payment

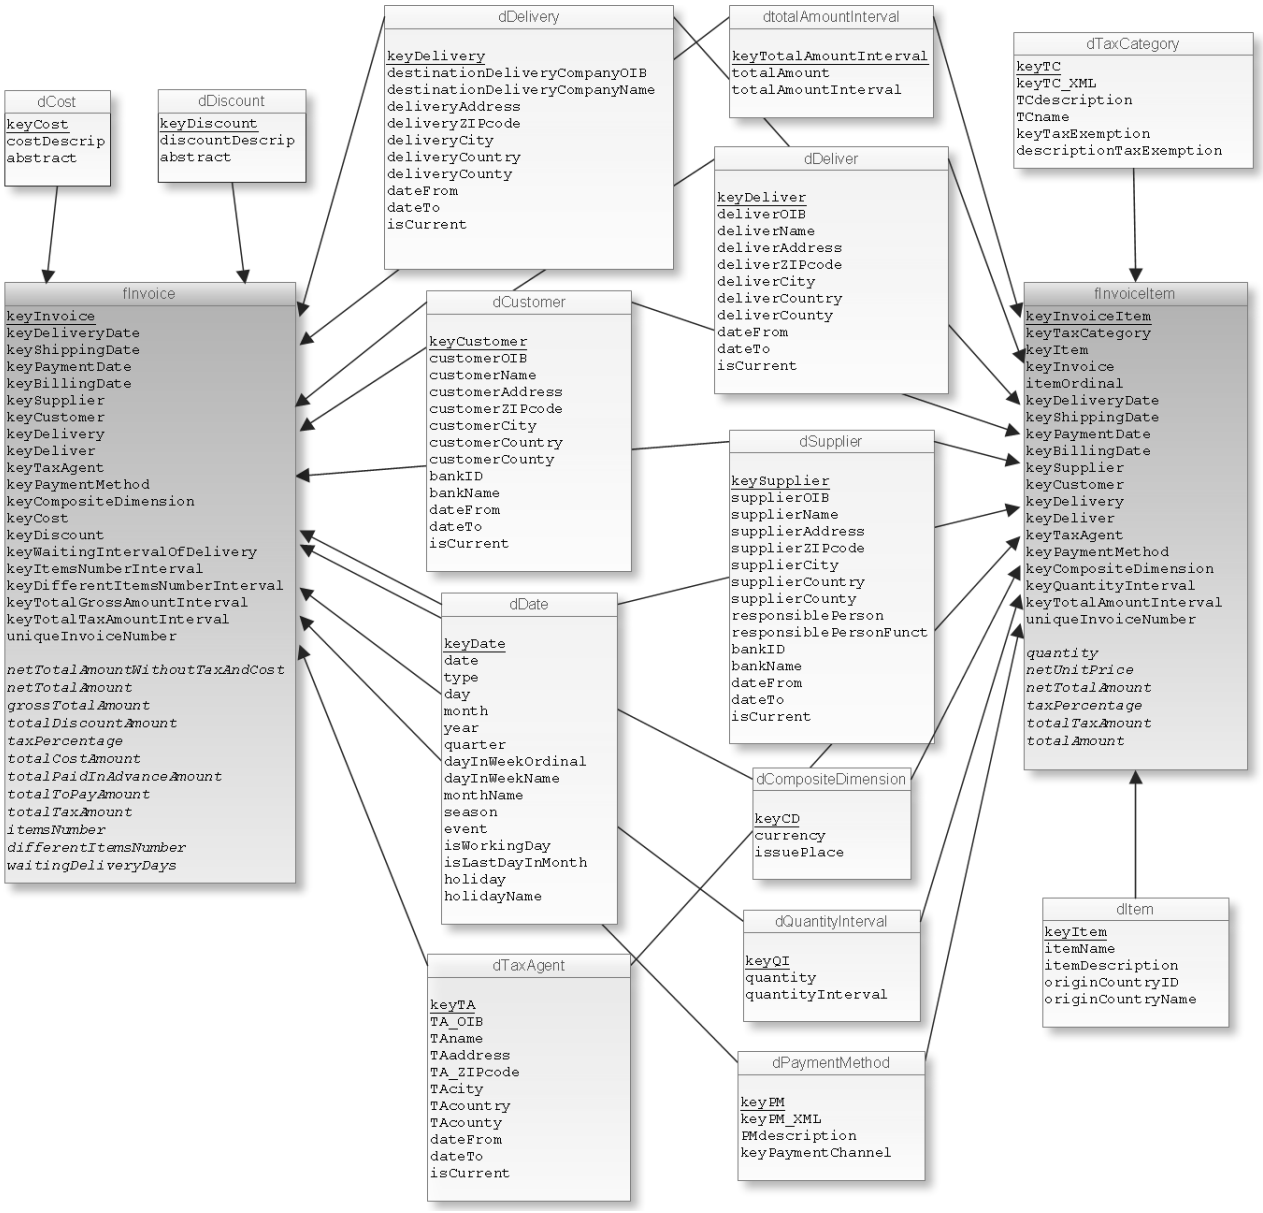

Fig. 4 Conceptual multidimensional model

method data), *dTaxCategory* (contains tax category data that is calculated for every invoice item) i *dArticle* (contains article data). The *dCompositeDimension* table is an example of a composite dimension. It is a dimension table that contains different types of flags and indicators of low cardinality. The role of composite dimension is to store flags and indicators outside of the fact table to achieve significant savings in disk space while suffering an insignificant loss in performances. Dimension table *dDate* is the data warehouse's time dimension. That means it takes over the meaning of all the date entries in the e-invoice (delivery date, dispatch date and similar). Interval dimension tables (*dQuantityInterval* i *dTotalAmountInterval*) have been created in the process of enrichment of the fact tables. Namely, attributes *itemsNumber*, *differentItemsNumber*, *grossTotalAmount*, *waitingDeliveryDays*, *totalDiscountAmount*, *quantity* and *totalAmount* can be inserted in specific intervals. That is the reason why dimension tables that define such intervals have been created. That way through the foreign key in the fact table it is noted which interval a certain value refers to. The foreign key points to the appropriate record in the interval table. As a result the representation of data is enriched and a sum report can be developed in an easier way during the process of conducting analytical processing over data in the data warehouse. Most of the dimension tables refer to the whole e-invoice (*fInvoice*), however the same dimension tables are connected also with the e-invoice items (*fInvoiceItem*) because the data that refers to the whole e-invoice refers to the every e-invoice item as well.

Measures are attributes listed in the bottom part of the fact tables shown in Fig. 4. Most of them are a direct copy of the appropriate elements of the e-invoice, while others (*fInvoice*: *itemsNumber*, *waitingDeliveryDays* i *discountPercentage*; *fInvoiceItem*: *totalAmount*) are the result of additional calculations done on the basic ones.

B. Data warehouse data loading

Data warehouse data loading consists of "manual" data loading of six dimension tables (*dDate*, *dQuantityInterval*, *dtotalAmountInterval*, *dTaxCategory*, *dPaymentMethod* i *dCompositeDimension*) and of an ETL procedure. It is used to insert the data into the rest of the dimension tables and into the fact tables based on the data stored in the e-invoices.

The ETL procedure can be divided into two parts: data warehouse initial data loading and incremental data loading which is used for keeping the data warehouse up-to-date. Fig. 5 shows the flow of the entire ETL process. The first step is to fetch e-invoices (initially all, after that just newer ones that have not been fetched) from the e-invoice archive. The e-invoice files have to be transformed with a series of XSLT transformations in order to eliminate data that is irrelevant for the data warehouse. Finally, data from the transformed files is inserted into the data warehouse with the ETL operations developed in the *SQL Server Business Intelligence Development Studio* tool.

C. Business analyses by using data warehouse

The way the data warehouse has been developed and loaded with data has been described so far. All that remains is to explain how data stored in the data warehouse can be used for business analysis. The data warehouse has been implemented in the *Microsoft SQL Server 2008 R2* DBMS. *SAP Business Objects* tool is used for complex analyses. For simpler analysis a web application has been developed. It can be easily used for running queries in the data warehouse. Fig. 6 depicts the application's user interface. Application has been developed in the Croatian language since the *FER e-invoice* system has been built for use in the Republic of Croatia. In the upper left corner the user can pick the fact table that will be analyzed. Under the list of the fact tables, is the list of measures and dimensions that can be selected. Based upon the selected measures and dimensions an SQL query shall be generated and executed on the selected fact table. The query results are shown in a form of a table in the central part of the web page. The table attributes are the selected measures and dimensions. To familiarize the user with the data warehouse the generated SQL query is shown over the results table.

V. CONCLUSION

The paper describes the architecture of the *FER e-invoice* system, the concept of data warehouses and the procedure of data warehouse development and data loading. The main part of the paper describes the *FER e-invoice* data warehouse system. The data warehouse is implemented around two fact tables: *fInvoice* and *fInvoiceItem*. Table *fInvoice* stores data that refers to the whole invoice, while *fInvoiceItem* contains data referring to every single invoice item. ETL procedure fetches data from the e-invoice archive, cleans them and as such inserts into the data warehouse. It includes the initial data loading and the incremental data warehouse data loading. An additional web application for data warehouse data analysis has been developed and incorporated in the *FER e-invoice* system.

The data warehouse developed out of e-invoices in XML format is an important contribution because it allows efficient realization of the different queries about the business activities of an enterprise.

Data Value in Decision Process: Survey on Decision Support System in Small and Medium Enterprises

M. Pighin*, A. Marzona **
* University of Udine, Department of Mathematics and Computer Science, Udine, Italy
maurizio.pighin@uniud.it
** LiberaMente Srl, Udine, Italy
amarzona@mentelibera.it

Abstract – This paper describes a survey on the actual use of Business Intelligence (BI) methodologies in Small Medium Enterprises (SMEs) of Udine district, a medium industrialized area in the North East of Italy. The companies were asked to give answers to a questionnaire prepared by our staff; we got also deeper information through specific interviews. The sample was composed of 45 enterprises different for geographic area, dimension and product specialization. In the paper we describe the rationale, the knowledge target and the methodology of the survey. We review the economical and cultural contest of the district. At last we analyze the results about the effective and desired use of BI as Decision Support System (DSS). We describe business specializations, company fields and typology of enterprises where BI has higher appeal. We remark the different implementations of data-warehouses, the tools of analysis mostly used, the personal involved. In the conclusions we summarize all the result and we discuss about the difficulty of developing correct and effective BI systems in SMEs.

I. INTRODUCTION

One of the main trends in business information systems is the extension of their scope: from the mere support of operational activities to a wider support in decision processes. Until the mid-'90s, the purpose of the major investments in ICT in businesses of all sizes was almost exclusively to support the operational flows, affecting in a more or less complete way the wide executive level that forms the basis of any organization.

For a decade or so, however, attention has also focused on management, looking for solutions that can somehow facilitate the decision-making process and make it faster and objective. Traditionally, the key factors upon which the ability to make "good decisions" are intuition and experience, based on the knowledge of what happens in the organization and in the market. A computer system can certainly not replace the intuition of a decision maker, nor can increase immediately his experience, but may be of great help in understanding the actual dynamics of the business.

The need for adequate tools to support intuition and experience in decision-making process has been stimulated recently by at least three separate factors.

The first factor is the globalization, which requires comparison with an extremely dynamic and complex environment. The second is the growing volume of data within organizations, collected during the operational processes. The last factor is the absence, in ERP systems, of effective solutions specifically designed to support decision processes.

The data warehousing solutions are therefore constructed explicitly on the needs of decision makers, exploiting the information potential of data already present in the company and allowing the objective measurement of organizational dynamics.

The common use of data warehousing tools started in large companies. These are complex organizations that feel the need for tools to measure their key process indexes (KPI) and to steer their strategies.

Soon, however, smaller companies caught the potential of these systems as well.

The growth of the ICT market for data warehouse systems is effective: it has been detected by different studies conducted by several major observatories. The main difficulties seem to be the complexity of calculating the return on investment (ROI) in this direction and, in the companies of smaller size, a cultural predisposition to believe that managers do not need any help.

We wondered how our territory welcomes these innovative solutions: the economic environment of Friuli Venezia Giulia is composed mainly of small size companies, which usually have some resistance to investments not directly related to productivity.

We decided therefore to investigate the use of data warehousing systems in companies in the province of Udine, and in particular in those of the mechanical sector, one of the most articulated and developed in the region.

This work gives an overview of the local economy and describes our survey on decision support systems.

II. DATAWAREHOUSE SYSTEMS

The idea behind data warehousing is to separate analytical processing (OLAP) from data processing related to transactions (OLTP). It produces new databases that integrate and organize primary data from various sources, and make them available for analysis.

Data warehousing can then be defined as a collection of methods, technologies and tools to help knowledge workers to conduct data analysis and decision-making processes aimed at implementing the improvement of information assets.

The basic objective of data warehousing systems is to assist management in decision-making, transforming operational data into usable knowledge. The end user usually has no high computer skills and utilizes the analysis tools sporadically: therefore the analysis tools must be simple, usable in an intuitive way and present data clearly.

III. SURVEY

Over the past twenty years the increase in computerized processes at the operational level has led to the storage of large amounts of data.

The factors that have contributed more than others to growth of computerization has been the increase in the number of laws that the company must follow in its work, in the complexity of products, in the mobility and competition of the market.

The company management can now find support for the decision making process in the available datasets. The data, however, do not always lead information. Knowledge workers target is to find and extract useful information from the company data.

Literature shows that, in the close past, managers responsible for marketing and strategic analysis fixed their attention on the economic performances of the company in terms of costs and revenues.

Today, however, the focus shifts to the outside with the profiling of behaviours (the behaviour of each customer, product, market...).

In order to make strategic decisions, knowledge workers try to contextualize corporate data focusing their relationship with individuals outside the company (customers, suppliers, competitors...) and with internal items (products, plants...).

A. Economical Contest

Before defining the detailed targets of the survey and to explain the methods adopted for its development, we describe the economic environment of the territory under analysis, the province of Udine, Italy.

The data are extracted from the Association of Industrialists of Udine report, from the Research and Statistics Office of the Chamber of Commerce of Udine, and from the Atlas of the Competitiveness of Unioncamere.

The province of Udine with its 4,905 sq km is about 62% of the territory of Friuli Venezia Giulia region and is the largest province in the region not only by extension but also for:

- Concentration of population, with 529,000 inhabitants, representing 44% of regional total
- Number of employees, with 228,000 employees, representing 44% of regional total
- Number of businesses, with 49,500 businesses, 48% of the regional total.

The province of Udine is characterized by the high rate of entrepreneurship: one production company every 9.4 inhabitants. The companies are mainly small ones (such as considering up to 49 people). These affect the total number of employees by 78%.

As for production specialization, the province is divided mainly in two areas, the metal-mechanical production with 1,600 units (26% of total manufacturing) and woodworking and furniture production with 2,020 units (33% of total manufacturing).

Another feature of the Friuli region is represented by its strong propensity to export. The main market is the European Union with 60% of export value, followed by America (especially Northern) (11% of exports) and Asia (8% of exports).

Regarding the type of products exported, the furniture hold primacy, followed by special and general purpose machinery and ferrous materials.

The more imported goods are iron and chemicals from Germany and Austria.

B. Survey Targets

In light of the described economic environment, we have chosen to conduct the survey on the use of Decision Support Systems on mechanical companies.

We are interested to have an overview of the use of decision support systems that it may be, at first, representative of the trends of the entire territory. Companies that fall in this sector are in fact extremely heterogeneous in size, incoming, type of products and processes: they range from steel mills, large manufacturing plants, carpentry, to electronics and precision instruments.

We inquiry how many companies use data warehouse systems, what is their profile, what are the goals and methods of use. We would also like to understand what is the attitude of companies towards these tools and also what are their perspectives.

In general we expect that companies that make greater use of data warehousing systems are those of medium-large size. We believe that small businesses are hardly interested in these systems.

The reason for this hypothesis lies in the characteristics of small businesses: the amount of data to be analyzed is not so important, both for the small size of the business and because the processes which usually allow the collection of information are usually less computerized. Moreover, smaller organizations' proneness to investment is usually low, as well as the attention to new technologies and innovative practices.

We also expect that companies with data warehouses are those with higher technology as more culturally used to innovative tools.

The percentage of exports and foreign relations should have a positive impact on the use of these systems, due to the needs of companies to control, through appropriate means, their position in the global market.

C. Survey Sample

The sample of companies on which the survey was made is extracted from the public lists provided by the Association of Industrialists of Udine.

The choice of our data source depends on the completeness of available information on companies.

Since the very small companies usually do not have the resources to develop their information system consistently, our investigation will target companies with more than 20 employees.

To compose the sample, we divided the companies into 3 categories based on the number of employees using the following classification

Group A: number of employees greater than 100

Group B: number of employees between 51 and100

Group C: number of employees between 21 and 50.

In selecting the companies to be interviewed we adopted a method of sampling reasoned: we took all companies of large and medium-size (Group A and Group B). For C group companies, we made a selection based on sales and company type, looking for a representative sample of each product group and considering only those companies with high income.

D. Knowledge Target

We want to get an overview about:

- General structure of companies
- Characteristics of information systems used to support business processes
- Sectors affected by data analysis and used analysis tools
- Characteristics on the use of data warehouse, if present
- Trends for the future

The ultimate goal remains the definition of a profile of companies using data warehousing systems that allows us to understand whether there are common elements that could be used as indicators of trends, or factors facilitating the cultural approach to Decision Support Systems.

E. Survey Methodology

In conducting the survey we adopted a mixed method, depending on the size of the company and on the presence of data warehousing systems.

Personal interviews were held to Information Systems managers of every large company and of small to medium sized companies that have data warehousing systems.

In the small or medium sized companies without data warehousing systems, the survey was conducted through telephone interviews, considering the fact that in the absence of decision support systems in the questionnaire was reduced to ten short, simple closed questions.

F. Survey Questionnaire

The questionnaire, consisting mainly of closed questions, is divided into three sections:

- The first relating to the presence of an information system and its coverage of business process.
- The second, on the presence of a data warehousing decision support system: this system is investigated in terms of coverage and architecture, period of introduction, difficulties in the phases of design and implementation and usefulness of the available tools.
- The third, through which we collect information useful to consolidate the company profile.

Across thirty-three questions, three investigate the degree of difficulty and perceived usefulness and complexity of the activation process of the DW; their answers are given using a scale-interval method.

Not much space is devoted to open questions, too subjective to be compared easily and quickly among all the companies under investigation.

All the raw data are available - in italian - upon request (the trace of the interviews, the questionnaire and its answers).

IV. Survey Results

In this paragraph we analyse the principal results of the survey describing the aspect relevant to verify our hypothesis on the use of BI methodologies. We leave in background technical and pure statistical aspects. The data are at disposal on request.

The sample under investigation is composed of 45 companies; table 1 describes their group distribution.

Attention over the expectations has been found from large companies where the interest in the survey was high, with a great desire to compare with the business environment to understand how each company fits the current trend.

TABLE 1: SAMPE COMPOSITION

Companies	In sample
Group A	16
Group B	14
Group C	15
Total	**45**

In our sample, companies are also distinguished according to the product market.

We study in detail the classification according to the market because we want to find out any correlation between this and the use of DW. In particular we will try to see if there is any relationship between the technological level of products offered and the use of innovative tools in the company.

With regard to sales volumes, the sample seems fairly different, but does not show a class of income that clearly overrides the other; however the 38% of companies' income is between 5 and 15 million euros (Table 2).

TABLE 2: PARTITIONING BY INCOME

Income in million €	% companies
> 50,0	13%
25,0 – 50,0	9%
15,0 – 25,0	18%
5,0 – 15,0	**38%**
2,5 – 5,0	15%
0,5 – 2,5	7%

Table 3 shows the average age of companies: this is about 36 years of activity, with companies of group B, significantly more recent (29 years) and companies of group A on the market for about 45 years.

The group C companies attest, however, on the average of 31 years.

TABLE 3: COMPANIES' AVERAGE AGE IN SAMPLE

Company	Average start year	Average years of activity	St. Dev.
Group A	1961	45	24
Group B	1977	29	13
Group C	1975	31	13
Total	**1970**	**36**	**18**

Another highlight is the parameter relating to exports or foreign relations shown in Table 4.

TABLE 4: AVERAGE EXPORT PERCENTAGE

Company	% avg. Export
Group A	65%
Group B	41%
Group C	25%
Total	**43%**

High, finally, is the average percentage (75.5%) of companies with quality certification, with extreme values of approximately 94% of companies of group A and 53% of group B.

A. Information system structure

All companies surveyed have an Information System to support the work activity.

Almost all the companies in group A and B provide a function within the corporate organization specifically dedicated to the Information System, with an average number of employees that is about 2.5 for the former and 1.5 for second.

Still far behind are the companies of group C, which reserve a specific function to the information system only in the 26% of cases, while in the remaining 74% the handling of Information System is kept by various executives or even by top management.

TABLE 5: SPECIFIC FUNCTION FOR I.S.

Company	% specific function for I.S.	Avg. number of I.S. staff
Group A	100%	2,4
Group B	93%	1,4
Group C	26%	2
Total	**73%**	**2**

The areas mainly computerized are Administration, Sales, Purchase, Logistics and Production, with a percentage that varies between 100% of the administrative sector and 84% of production and logistics.

TABLE 6: COMPUTERIZED AREAS

Area	Group A	Group B	Group C	Average
Accounting	100%	100%	100%	**100%**
Logistics	94%	93%	67%	**84%**
Sales	94%	100%	93%	**96%**
Purchase	100%	100%	87%	**96%**
Production	100%	86%	67%	**84%**
Quality assur.	87%	57%	60%	**69%**
CRM	44%	21%	13%	**27%**
Control	87%	64%	53%	**69%**

The percentage drops to 69% of companies in the areas of Quality and Control, while still not widely used are the CRM subsystems.

The areas most involved in the data analysis are, as you can imagine, Administration, Sales and Purchase. Logistics, despite having a high percentage of computerization, is less often the subject of data analysis.

B. DW Usage

Contrary to our initial expectations, the declared knowledge of data warehouse is quite high and not only in companies of groups A and B.

TABLE 7: USE OF DATA ANALYSIS PER AREA

Area	Group A	Group B	Group C	Media
Accounting	100%	100%	87%	**95%**
Logistics	69%	43%	33%	**49%**
Sales	88%	93%	100%	**93%**
Purchase	88%	86%	80%	**84%**
Production	88%	71%	73%	**78%**
Quality assur.	75%	36%	47%	**53%**
CRM	31%	21%	6%	**20%**
Control	88%	36%	60%	**62%**

Among the companies of group A, 94% said they were aware of the existence of these systems for the data analysis, while the percentage drops to 50% of companies of group B and 47% of group C.

TABLE 8: DATA WAREHOUSE KNOWLEDGE

Company	% Knowledge
Group A	94%
Group B	50%
Group C	47%
Total	**64%**

The survey showed that 24% of companies use data warehousing systems for data analysis.

In fact, the percentage of use of DW is 50% of group A companies, denoting their particular interest on innovative tools.

Among companies of group B, the percentage drops to 21%, while in Group C are not recorded cases of use.

TABLE 9: DATA WAREHOUSE USAGE

Company	% Usage	% Future usage	% Future usage in short term
Group A	50%	31%	6%
Group B	21%	14%	7%
Group C	0%	33%	20%
Total	**24%**	**26%**	**11%**

As you can see from Table 9, among the companies that still do not have this tool, 26% said they were willing to adopt one for the future, and 11% in the short term.

Very interesting is to note that the percentage increases to 20% of companies of group C, which demonstrates the ongoing orientation of small organizations into decision support systems.

On average, the introduction of the DW in companies was fairly new: except some rare cases, DW systems were introduced in the last 3-5 years.

The companies that use DW systems have the high percentage of export. The use of the data analysis tools could be explained by the need to keep under control the activities of foreign subsidiaries or any international trade (Table 10). The initial assumption is reflected by the survey.

TABLE 10: DW-EXPORT RELATIONSHIP

Company	% Export
Using DW	66%
Not using DW	36%

Inquiring among the companies that use of DW systems we obtain the following distribution according to the market:

TABLE 11: DW USAGE PER PRODUCT MARKET

Product market	% DW usage
Electronic and automation	**66%**
Tools	**66%**
Components and subsupply	**25%**
Mechanic workshop	20%
Machinary production	20%
Carpentry and assembly	16%
Installations	-
Third party work	-
Metal furniture	-

As hypothesized, we note the high percentage (66%) of use of DW systems in companies of Electronics and Automation products; this shows that high-tech companies tend to adopt innovative tools.

The same percentage is found for companies of the Tools market; these companies are younger than the industry average and with a higher proportion of export.

Let us now analyze in more detail some features of DW used by the companies.

The data that flow into the data warehouse comes from ERP sources (in 100% of cases), other external sources (73%) and other internal sources (63%). These percentages confirm the nature of DW as instrument of data reconciliation.

We also found that, in most cases (80%), companies use a simple one-level-architecture system.

Only in 10% of cases data warehouse system is on a two-levels-architecture and the same percentage is for the three-levels-architecture.

TABLE 12: DW ARCHITECTURE USAGE

Architecture	% Company
1 level	80%
2 levels	10%
3 levels	10%

Another factor is the source of the data warehousing system: in the 80% of the cases, the DW was built by the supplier of the ERP system, while in the remaining 20% of cases it was designed by other suppliers or consultants.

This indicates the willingness of companies to have a single partner who already knows the company's information system, and that can understand better its dynamics and needs.

The data related on architecture and implementation of data warehousing systems, having very similar percentages, lead us to examine the possible presence of correlations between these two factors.

The analysis showed that 88% of cases companies that use the same ERP vendor to develop the DW, the used architecture is a simple one-level. It is quite rare the case (12%) in which the vendor proposes more sophisticated solutions. In the set of companies where outside consultants designed the DW system, instead, 50% of DW has a two-levels architecture.

We can therefore conclude that in general ERP vendors also offer solutions for Business Intelligence, but these are of a lower profile compared to solutions proposed by specialized consultants.

The pure Reporting is the most commonly used analysis tool, adopted by all the companies that make use of DW; OLAP tools are used in 73% of companies. Tools for Data Mining are little used, only in 18% of companies.

This survey shows that companies that have decided to adopts DW systems use mainly tools that allow simple and easy reading of the information (Reporting) and tools easy to use, intuitive and interactive (OLAP). Simplicity and timeliness are confirmed once again the essential features. Probably some of the companies that declare to use OLAP tools really utilize only dynamic reporting with some “drill-down” or “roll-up” features offered by several vendors. Similarly, some of the companies that declare to use Data Mining tools really utilize features embedded in some simple data analysis package, like “classification and prediction” or “association” analysis.

TABLE 13: ANALYSIS TOOLS

Tool	Group A	Group B	Group C	Average
Reporting	100%	100%	-	100%
OLAP	75%	67%	-	73%
Data Mining	13%	33%	-	18%

Let us now see generally who is involved in carrying out analysis, and with which frequency.

In most companies the area managers are directly involved in data analysis, but almost never they are the only ones to do so. In fact, depending on the organization and company policies, these tasks are performed also by final users and CEO’s functions.

CEOs are directly involved in the case of companies of group B. In companies of group A the trend is to delegate everything to area managers who then report to the top management. The average number of people that carries out analysis is of about 10.

Finally, the frequency of analysis depends on the type of information needed. There are certain sectors or certain corporate events that will need to be analyzed daily and some other issues that will be "photographed" on a monthly basis.

TABLE 14: DATA ANALYSIS USERS

Role of users	Group A	Group B	Group C	Average
Area managers	88%	67%	-	**82%**
Staff	63%	67%	-	**64%**
CEO	38%	67%	-	**45%**

The general trend is to perform global monthly analysis and to investigate some small data on a daily basis.

In 90% of cases data is updated daily and automatically.

The survey also shows that the budget spent by companies to acquire data warehousing systems is on average between 10,000 € and 20,000 €, while the annual budget for planned maintenance or for any developments of the system is less than 10,000 €.

Asking for a subjective opinion, the simplicity of the analysis tools used, in a scale of 0 to 10, has an average answer value of about 6.5 with a median of 7 and a variance quite low (1.25). This shows a certain uniformity of opinion, considering fairly simple the analysis tools available.

In addition to the degree of simplicity, was also asked to provide an assessment of the usefulness of these tools.

As might be expected, they were found positive with an average value of about 8 on a scale of 0 to 10, with a median of 8.5 and variance1.67.

The activation process of a data warehousing system is analyzed to understand how this step is simple or complex for a company. The survey shows that this process is not very simple: the mean value is 5 (as the median) on a scale of 0 to 10.

Exploring the reasons for this difficulty through the use of open questions, we found various factors that complicate the transition to DW systems. One of the most important is the difficulty in determining what information to require. Besides this, the lack of internal knowledge: the design is almost exclusively dependent on external consultants or on the same suppliers of ERP.

We have investigated also what are the reasons that push companies to invest in business intelligence systems and data warehouse.

Almost 60% of companies say they have been pushed to invest in this direction to be more competitive on the market: competition requires the immediacy of information to take appropriate strategic decisions in the shortest possible time.

Another reason is the need to have a single tool to conduct analysis and obtaining clear and usable information.

Barriers to investment are a lack of knowledge and the cost, often considered too high.

Regarding the cost, the companies evaluate not only the pure cost of the investment, but also the cost in terms of staff time required for education.

V. CONLUSION

At the end of the survey, we had the perception that there is a fairly widespread desire to use methods and tools of business intelligence: companies perceive their utility or their need, given the amount of data that modern transaction systems generate.

A different aspect is how to implement such a requirement.

From a general point of view, there is a clear need to use synthetic indicators that allow to monitor corporate performance and to have crossed and parametric analysis on raw data provided by operational systems. The declared desire is to be more competitive on the market, taking quick and appropriate strategic decisions based on fast and complete information.

The theoretical foundations that underlie the formation of these indicators are fairly consolidated, in the corporate knowledge, much less are foundational aspects and engineering skills with which to build business intelligence systems.

For example, people know the concept of KPIs and Balanced Scorecard, but they do not know clearly how to extract the necessary information from corporate databases to build these indicators in a reliable, fast and repetitive way.

In practice we notice that the instruments used are not always appropriate to the target: often there are solutions that are based on spreadsheets, and that require complex manual operations, copying and recopying data among spreadsheets and tables. These methods generate a significant workload and therefore are disappointing or of limited application. Anyway, the adoption of this method is due to several phenomena.

Software companies often push to solve the informational question through their ERP. Therefore, they tend to develop reporting or interactive investigations as customized ERP functions; in the best case they propose the use of OLAP navigation instruments that read directly the operational database (one-level-architecture). The reasons for this choice may be different: for example, poor knowledge of tools and methodologies of business intelligence; attention mainly directed to operational core business, the ERP system; even some understandable jealousy of their customers, which leads to solutions that are not always optimal from technological and organizational point of view.

Moreover, the survey showed that in most cases data warehousing systems are made by the ERP vendors, thereby demonstrating the desire of companies to turn to suppliers with whom they have already worked and established a relationship of trust rather than relying on consultants and / or specialized external companies.

Producers of business intelligence tools such as browsers or OLAP multidimensional databases management systems, on the other hand, are very oriented to architectural and technological aspects, much less to application and organization. As a result, often the solutions they propose oversimplify the collection, cleaning and physical organization of data. For example, ETL tools they provide "embedded" in the systems are semantically relatively poor and are therefore unlikely to solve properly and autonomously data re-construction and re-organization in data warehouses.

Another example is the need, even for small and medium businesses, to build DW systems with at least a two-levels-architecture. In these solutions analysis is carried on a separate database, the data warehouse, which is fed asynchronously with data taken from the operative sources. In more complex architectures, analysis tool read data from an additional data level, the data-mart level, where data warehouse data is pre-filtered/pre-aggregated for the analysis. Often, however, manufacturers propose one-level-architecture solutions, with the analysis tool connected directly to the operational database. This generally results in a vertical decay of performance and in a unacceptable complexity of user views.

Finally, companies, and particularly the EDP areas, often have an unrealistic idea of data warehousing systems and of the procedures necessary for their construction. Even here the reasons are manifold, but the main phenomena are related to this kind of solutions relative novelty.

The time in which innovative methodologies (a) are proposed in formal terms, (b) are perceived by the market as a whole, (c) are tuned, (d) are successfully transposed to the end user, especially the SMEs, undoubtedly requires years of gestation.

The analysis carried out that the surveyed companies have gained only partial knowledge of data warehousing systems and often they use in a partial and elementary way the available tools.

The trend for the future, however, shows a higher intention to invest in business intelligence tools, especially in SMEs.

The search for competitiveness in the market is one of the main factors driving companies to adopt these systems. The management asks to take the right strategic decisions in the shortest possible time, making the immediacy of information as an essential feature.

Often the lack of a specialized figure within the company is a barrier to investment. To this we add the costs that are deemed too high compared to business needs, the lack of staff resources to be devoted to these new projects and the complexity of the activation of data warehousing.

At this point we can state a profile of the companies that makes use of data warehousing systems:

- They are mostly medium to large companies;
- They are in the market since long time, and have a consolidated position; there are few new companies that use DW systems;

- There is also a correlation between the use of the DW and the percentage of export; companies with higher export percentages are better adapted to DW use because of the need for control over foreign operations: the usefulness of a centralized data warehouse is high;
- The nature of the products may be related to the use of DW; high-tech companies are more likely (from the cultural point of view) to adopt innovative tools than other.

At the end of the survey, as a final thought we believe that the usefulness of data warehousing tools and more generally of decision support systems is still not fully understood in companies; in many cases investments are held back by difficulties to quantify (not only in terms of money) the ROI. To develop further our survey on the usage of DW systems, we plan to check periodically the companies of the set that adopt BI tools, to verify the evidence of some correlation between the usage of these methodologies and the variation of company's performance.

Surely, given the survey results and the expectations expressed by the companies, the adoption of these tools is going to increase, especially in small and medium enterprises seeking to gain competitive market share.

This evolution, however, must go hand in hand with the transformation of corporate culture that must be open to innovation.

CAR (Collect-Analyze-Report) Ad hoc baza i korisničko sučelje

Marino Ljubić, Slavko Skular
Multicom d.o.o., Zagreb, Hrvatska
marino.ljubic@multicom-is.hr, slavko.skular@ multicom-is.hr

Rad predstavlja ključne osobine aplikacije CAR, njenih osnovnih komponenti razvijenih u tehnologijama Oracle PL/SQL, Java i JavaScript. Sustav se može opisati kao napredni OLAP mehanizam s mogućnošću dinamičkog kreiranja i modificiranja podatkovnih kocki i njihovih dimenzija prema korisničkim potrebama. Podaci se pohranjuju putem korisnički kreiranih obrazaca ili kroz ETL proces. Aplikacija ima web korisničko sučelje kroz koje se administriraju multidimenzijske baze, određuju izračuni i transformacijska logika, dizajniraju i pregledavaju ulazni obrasci i izvješća, dostavljaju XML datoteke, izvoze analizirani podaci u nekoliko formata. Sigurnosni modul omogućuje administratoru precizno određivanje sigurnosnih privilegija kojima se učinkovito sužava korisnička perspektiva na točno određene dijelove kocke.

I. UVOD

Gotovo cijela današnja informatička industrija zasniva se na relacijskim bazama podataka i visoko standardiziranom SQL-u (Structured Query Language) kao programskom jeziku za dohvat i upravljanje podacima. Operativni, transakcijski sustavi modeliraju se po konceptu treće normalne forme (3NF), dok se u analitičkim aplikacijama i skladištima podataka koristi multidimenzijsko modeliranje, koje u svojoj relacijskoj izvedbi rezultira ROLAP (eng. Relational Online Analytical Processing) sustavom. Unatoč svojim brojnim prednostima (ogromni volumeni podataka, podaci na razini transakcije, dimenzije s vrlo visokom kardinalnošću itd.), u nekim primjenama ROLAP ima evidentne nedostatke u odnosu na MOLAP (Multidimensional Online Analytical Processing) – naizgled vrlo sličan, a opet toliko različit koncept. Planiranje, budžetiranje, alokacije, financijsko izvješćivanje – područja su u kojima nepromjenjiv relacijski model, te standardni SQL pokazuju svoja ograničenja [1].

Osim različitog načina pohrane, MOLAP sustavi imaju vlastiti višedimenzijski jezik koji više liči na izraze u tabličnim kalkulatorima. U ad-hoc izvještajnom sučelju ne odabiru se razine, već pojedinačni članovi dimenzija, što čini ključnu razliku, a uzrokovano je različito organiziranim hijerarhijama. Gledano iz korisničke perspektive, najočitija razlika je u tome što je ROLAP sustav u nadležnosti informatičkog (IT) sektora koji ga projektira i modificira prema funkcijskoj specifikaciji poslovnog sektora. Za razliku od njega, MOLAP je ad hoc sustav kojega samostalno kreira sam poslovni korisnik (administrator, ali ne informatičar), što rasterećuje IT sektor, a korisniku daje osjećaj upravljačke moći i nezavisnosti.

Povodom specifičnih poslovnih zahtjeva na nekoliko, prema poslovnoj tematici, potpuno različitih projekata, razvijeno je inovativno aplikativno rješenje s potencijalom proizvoda. Radi se o interno razvijenom višedimenzijskom logičkom serveru nad fizičkom relacijskom bazom, s pripadajućim korisničkim sučeljem za unos podataka i izvješćivanje. Sustav ima sva vanjska obilježja MOLAP servera, što podrazumijeva visok stupanj generičnosti i skalabilnosti podatkovnog modela (zapisanog u aplikativno održavanim metapodacima), te prirodnu podršku za nebalansirane hijerarhije. Relacijska baza koristi se isključivo kao spremnik podataka, što znači da se ne koristi zvjezdasta struktura (eng. Star Schema), tipična za ROLAP, a nad rezultatima osnovnog SQL upita definira se memorijsko višedimenzijsko polje.

II. POSLOVNI SLUČAJEVI („NEMOGUĆA MISIJA“)

A. *Generičnost (Nedefiniranost)*

Sustav prikuplja raznovrsne (primjerice energetske ili financijske) podatke putem web sučelja od raznih pravnih osoba ili organizacijskih jedinica. Podaci se unose ručno ili automatizirano (slanjem XML datoteka). Administrator sustava ima mogućnost stalnog širenja strukture baze podataka kako bi osigurao prihvat novih vrsta podataka. Podaci mogu biti opisni (atributi) i numerički (mjere).

Osim potpuno generičkog baznog modela, administrator na jednostavan način dizajnira obrasce kroz koje će vanjski korisnici dostavljati podatke. Podaci mogu biti različitih razina granularnosti, npr. neke tvrtke imaju podatke na mjesečnoj razini, a neke druge samo na godišnjoj. Jedinice mjere također mogu biti različite (npr. manji proizvođači energiju proizvode u kWh, a veći u MWh), što u kumulativu ne predstavlja problem.

B. *Kalkulacije*

Kroz izradu ad-hoc izvješća, podatke je nužno moći filtrirati i agregirati/kalkulirati s time da je, osim najčešće operacije zbrajanja, npr. kvartal kao zbroj mjeseci:

$$Q1 = M01 + M02 + M03, \quad (1)$$

moguće i oduzimanje, npr. obračun dobiti:

$$\text{Dobit} = \text{Prihod} - \text{Trošak}. \quad (2)$$

Za kompleksnije izračune, potrebno je omogućiti unos slobodnih izraza, npr:

$$\text{Energija} = (\text{Kol1} + \text{Kol2}) \times \text{Ogrjevna vrijednost}. \quad (3)$$

Pojednostavljeno rečeno, aplikacija ima osnovne mogućnosti tabličnog kalkulatora, sa stalnim mogućnostima proširenja radnih listova (eng. Spreadsheet) i s tom razlikom da se podaci nalaze na serveru u strukturiranoj bazi podataka.

C. *Nebalansirane hijerarhije*

Financijska izvješća, kao što su Izvješće o bilanci (eng. Balance Sheet) ili Račun dobiti i gubitka (eng. Profit & Loss Report), u pravilu uvijek imaju izvještajne stavke organizirane u nebalansiranu hijerarhiju tipa roditelj-dijete (eng. Parent-Child), koja se uz to i vrlo često mijenja (Slika 1). Poslovni procesi planiranja proračunskih prihoda i rashoda (eng. Planning & Budgeting) također su vrlo dinamični, te gotovo uvijek iterativni. Granularnost i broj planskih stavki stalno se mijenja, a analitička dubina razlikuje se od jedne do druge sintetičke stavke. Aplikacija omogućuje korisniku da kontinuirano mijenja hijerarhijsko stablo i njegovom strukturom definira način na koji se hijerarhijski viši članovi (eng. Members) kalkuliraju iz nižih.

D. *Izvedeni atributi*

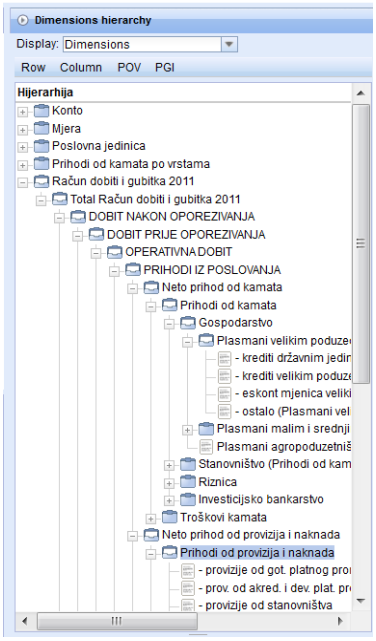
Različite regulatorne ustanove od svojih subjekata zahtijevaju izvješćivanje prema propisanim skupovima atributima. Npr. nacionalne banke propisuju obilježja i modalitete po kojima se dostavljaju redovna bankovna izvješća, dok propisi EU zahtijevaju od svojih članica energetsku bilancu po stavkama definiranima u standardiziranim šifrarnicima. Izvještajne stavke financijskih izvješća također su uvijek izvedene iz drugih atributa.

Ovakve izvještajne dimenzije i njihovi atributi ne postoje u izvornim sustavima, pa se niti ne unose kao ulazni podaci. Regulatorni propisi i izvještajne definicije se, uostalom, vrlo često mijenjaju. Aplikacija omogućuje transformacijsku logiku uz pomoć koje se atributi izvještajnih dimenzija izvode iz poznatih ulaznih podataka i vezanih poslovnih atributa.

Npr. kombinacija određenog knjigovodstvenog konta, organizacijske jedinice i valute, na RDG izvješću preslikat će se u izvještajnu stavku - Održavanje informatičke opreme.

III. VIŠEDIMENZIJSKI LOGIČKI SERVER

Izrada ovakvog sustava u kojemu ništa nije čvrsto definirano, nametnula je napuštanje standardnih metoda modeliranja i ustaljene programske logike. Maksimalni stupanj generike u relacijskom svijetu (barem za analizu) predstavlja ROLAP, no dodavanje novih mjera, dimenzija ili dimenzijskih atributa zahtijeva modifikaciju modela i aplikacije. Cilj je dobiti aplikaciju kojoj ne treba IT podrška, niti poznavanje SQL-a.



Slika 1. Nebalansirano stablo

Drugo značajno ograničenje ROLAP-a jesu hijerarhije koje se zasnivaju na razinama (eng. Level Based Hierarchies). Poznati su problemi „poderane“ hijerarhije (eng. Ragged Hierarchy) i hijerarhije s preskočenom razinom (eng. Skip-Level Hierarchy) [2]. U oba slučaja radi se o nebalansiranoj hijerarhiji, s tom razlikom da u prvom slučaju krajnja razina (eng. Leaf Level) nije ista za svaku hijerarhijsku granu (npr. neke Poslovnice imaju Ispostave, dok neke nemaju), a u drugom slučaju se jedna ili više hijerarhijskih međurazina preskače (npr. Proizvod pripada određenoj Kategoriji Proizvoda, ali Podkategorija mu nije definirana, za razliku od nekih drugih proizvoda).

No najveći problem ipak predstavljaju već spomenute, najslobodnije hijerarhije tipa roditelj-dijete (eng. Parent-Child). Ovakav tip hijerarhije prirodan je za MOLAP, čije dimenzije nemaju razine, nego članove (eng. Member Based Hierarchies ili Value Based Hierarchies). Svaku, pa i najproblematičniju razinsku hijerarhiju uvijek je moguće prevesti u hijerarhiju tipa roditelj-dijete bez kvalitativnog gubitka hijerarhijske strukture, dok je obrnuti slučaj najčešće nemoguć, tj. moguć je samo za potpuno balansirane hijerarhije (npr. vremenska dimenzija).

Evidentno je da rješenje bazirano na MOLAP-u jedino daje kvalitetan odgovor na sve postavljene probleme i korisničke zahtjeve. Kako je Oracle u zadnjim izdanjima svojeg RDBMS-a (eng. Relational Database Management System) uveo mnoga funkcijska proširenja, umjesto da se napravi odabir komercijalne MOLAP tehnologije, kao tehnološki temelj CAR aplikacije koristi se Oracle relacijska baza. Za manipulaciju nad podacima koristi se standardni SQL DML (eng. Data Manipulation Language), dok se za dohvat podataka i kalkulacije koristi SQL Model Clause - napredna ekstenzija SQL–a koja omogućuje izraze slične onima u tabličnim kalkulatorima za osobna računala.

SQL Model Clause [3] omogućuje da se nad dohvaćenim relacijskim podacima definira višedimenzijsko polje u radnoj memoriji računala (Slika 4). Kolone se grupiraju u tri grupe elemenata: particije (logički blokovi), dimenzije i mjere. Nad ćelijama ovog polja zatim se određuju kalkulacijska pravila (eng. Computation Rules) koja predstavljaju logičke višedimenzijske izraze kojima se računaju nove vrijednosti. Kao i u bilo kojem drugom MOLAP jeziku, kalkulacijski izrazi su u terminima vrijednosti dimenzija, a primjenjuju se nezavisno na ćelije svake logičke particije.

Proces kreiranja višedimenzijske baze, poznate kao kocka (eng. Cube), sastoji se od nekoliko jednostavnih koraka:

- Definicija dimenzija
- Definicija mjera
- Definicija kocke

A. *Definicija dimenzija i mjera*

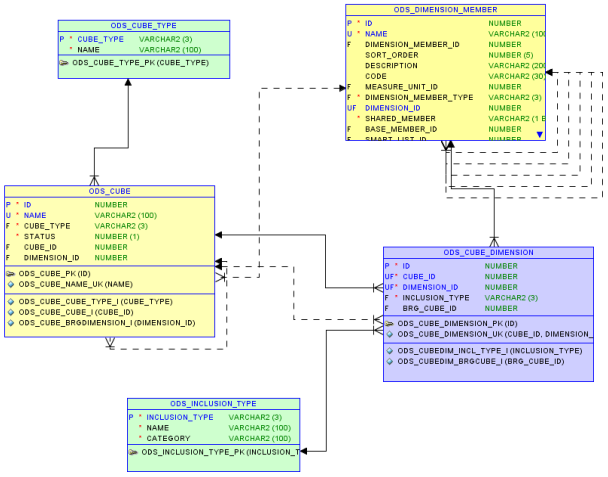
Dimenzije i mjere sastoje se od članova, organiziranih u obliku hijerarhijskog stabla (Slika 2). Bitna razlika u odnosu na tipičan relacijski model jesu mjere koje nisu kolone u tablici, već njihovi nazivi kao metapodaci čine jednu od dimenzija (eng. Measures Dimension). Sve dimenzije i njihovi članovi zapisani su u jednoj relacijskoj tablici, a najviši član svake grane je sama dimenzija.

Kako u ovom tipu hijerarhije svaki član može imati samo jednog nadređenog (roditelja), ukoliko postoji potreba za dodatnim grupiranjima članova, te time stvaranjem alternativnih hijerarhija, koriste se tzv. dijeljeni članovi (eng. Shared Members) [4]. Npr. član Austrija je istovremeno ispod članova Sve zemlje, EU i Uvoznice nafte. Dijeljeni članovi su pokazivači (eng. Pointers) na osnovne članove (eng. Base Members) uz koje se vežu spremljeni numerički podaci.

Dimenzije mogu imati atribute koji se mogu svrstati u dva tipa: domenski i korisnički. Domenski atributi imaju dozvoljeni skup vrijednosti (npr. vrsta elektrane, kategorija klijenta itd.), dok se korisnički atributi slobodno unose (npr. datum puštanja u pogon, proizvodni kapacitet i sl.). Svi atributi unose se u sustav kao atributne dimenzije (eng. Attribute Dimensions), s time da dimenzije domenskih atributa imaju i svoje članove. Nakon pridruživanja atributa običnim, neatributnim dimenzijama, mogu se pridruživati i njihovi članovi ili slobodno unositi vrijednosti, ovisno o tipu atributa. Atributi se kasnije u aplikaciji mogu koristiti za filtriranje i grupiranje.

B. *Definicija kocke*

Kocka se određuje na način da joj se pridružuju dimenzije. Svaka dodijeljena dimenzija mora biti označena kao ulazna (eng. Data Input Dimension) ili isključivo izvještajna (eng. Report Only Dimension). Tijekom unosa podataka, sve ulazne dimenzije moraju biti eksplicitno referencirane. Svaka kocka mora imati točno jednu ulaznu dimenziju s mjerama. Izvještajne dimenzije nisu vidljive na ulaznim obrascima, a reference na njih



Slika 2. Dimenzije, mjere, kocka

ostvaruju se korištenjem transformacijske logike zapisane u tzv. mostovima (eng. Bridges).

C. *Pohranjivanje vrijednosti*

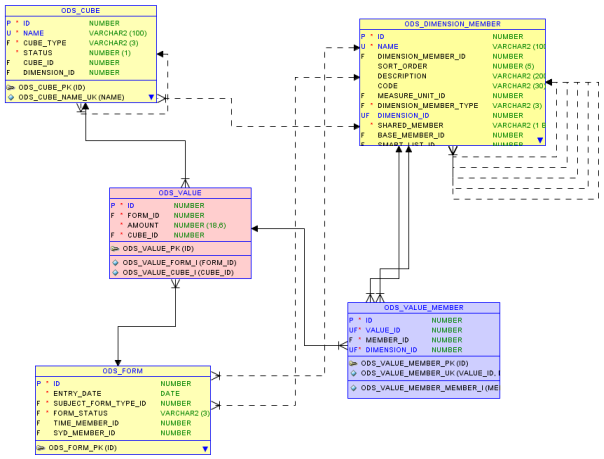
Kako se OLAP baza može zamisliti kao višedimenzijska kocka, definirane dimenzije (uključujući i dimenziju mjera) čine njene osi (Slika 3). Numeričke vrijednosti pohranjene su unutar volumena kocke. Ako se svaka vrijednost zamisli kao jedna točka, ona mora imati točno onoliko koordinata (referenci prema osima) koliko ima pridruženih dimenzija u definiciji kocke.

D. *Izračunski mehanizam*

Kalkulacijske sposobnosti jedna su od najmoćnijih značajki ovog sustava. Podloga za računanje zapisana je u dimenzijskom stablu. Jedno od svojstava svakog pojedinačnog člana dimenzije jest agregacija (konsolidacija) koja može poprimiti vrijednosti: + (plus - pretpostavljeno) ili – (minus). Svojstvo multiplikacije (pretpostavljena vrijednost 1) omogućuje jednostavne konverzije (npr. različite mjerne jedinice), kao i izostavljanje člana u kalkulaciji (u slučaju kada je 0). Oba svojstva odnose se na kalkulacijski izraz nadređenog člana (roditelja), tj. određuju način na koji se njemu podređeni članovi računaju.

Dijeljeni članovi imaju nezavisna svojstva agregacije i multiplikacije, što znači da ih ne nasljeđuju od osnovnog člana kojega referenciraju. Na taj način se isti član može različito računati prema svom roditelju ovisno o hijerarhiji u kojoj se nalazi. Npr. porez na dobit oduzima se od bruto dobiti, a zbraja u ukupnim izdacima prema državi.

Osim konsolidacije po hijerarhiji koja vrijedi za sve dimenzije, mjere se dodatno mogu računati na drugačiji način. U slučaju kada standardne funkcionalnosti agregacije i multiplikacije nisu dovoljne, složeniji izraz (formula) može biti unesen kao svojstvo člana (mjere). Takav izračunski član (eng. Formula Member) ne može imati hijerarhijski podređenih članova jer se način njegovog izračuna određuje formulom, a ne stablom. Isto



Slika 3. Pohranjivanje vrijednosti

tako, uz njega se ne mogu vezati nikakve ulazne vrijednosti kocke.

U trenutku kada korisnik pokrene neki obrazac ili izvještaj, aplikativni generator koda dinamički generira SQL upit čije rezultate koristi mehanizam prikaza (eng. Rendering Engine) i smješta ih u odgovarajuće ćelije u rešetki (eng. Data Grid Cells). Kako bi se dobilo na performansama, upit vraća samo one vrijednosti (i njihove koordinate) koje nisu prazne (eng. Not Null Values).

Generirani SQL upit sastoji se od sljedećih dijelova/faza:

- Filtriranje samo traženih članova izvješća (eng. Cube Slicing), a to su direktno ili indirektno (preko hijerarhije ili u formuli) referencirani osnovni članovi
- Izvlačenje svih neophodnih dimenzija u zasebne kolone (eng. Pivoting) iz dohvaćenog skupa spremljenih vrijednosti u obliku redaka (eng. Unpivoted Recordset) i grupiranje po pojedinačnim vrijednostima (točkama) kocke
- Definiranje višedimenzijskog polja i računanje izračunskih članova (ako postoje)
- Reduciranje kolona i grupiranje samo po traženim dimenzijama izvješća
- Definiranje višedimenzijskog polja i izračun ostalih traženih članova prema položaju u hijerarhiji (jedna dimenzija = jedna iteracija)
- Pretvaranje kolona u retke (eng. Unpivoting) kako bi se dobio izlaz generičkog oblika

IV. KORISNIČKO SUČELJE

Veliku prednost u odnosu na druga postojeća rješenja ovaj sustav ostvaruje zbog svog intuitivnog korisničkog sučelja prilagođenog čak i onim korisnicima koji nemaju stručna znanja na području baza podataka i OLAP sustava.

Slika 4. Uvid u višedimenzijski dio upita

Da bi se sustavu omogućio visoki stupanj generičnosti i dinamičnosti, za korisničko sučelje napravljena je web aplikacija koja podržava sve važnije web preglednike. Za izradu interaktivnih elemenata na stranici i asinkrono komuniciranje s poslužiteljem korišten je Dojo Toolkit, JavaScript biblioteka otvorenog koda posebno dizajnirana da olakša brzi razvoj web aplikacija neovisno o platformi klijentskog računala i instaliranog web preglednika, prvenstveno zbog njene široke prihvaćenosti i službene podrške velikih tvrtki poput IBM-a [5] i Sun Microsystems-a [6]. Osim Dojo-a korišten je i jQuery, također JavaScript biblioteka otvorenog koda, ali dizajnirana tako da pojednostavi programiranje aplikacija na klijentskom web pregledniku, prvenstveno zbog njenih vrlo velikih mogućnosti i raširenosti. Na poslužiteljskoj strani korišten je Java programski jezik sa Struts i Hibernate razvojnim okvirima, te JasperReports izvještajnim alatom koji omogućuje izvoz generiranih izvještaja u Microsoft Excel, RTF i PDF formate [7].

Aplikacija podržava višejezičnost i omogućava administratoru da definira prijevode naziva stavaka u aplikaciji na druge jezike, a trenutno je prevedena na hrvatski i engleski.

A. *Unos podataka*

Upravo zbog potreba korisnika da za svaku poslovnu potrebu definira nove tablice i web-forme za unos podataka u bazu za njihovu kasniju analizu, ovaj rad je bio posebno fokusiran omogućiti korisniku da sam definira forme, odnosno obrasce, za unos podataka kojima će se puniti kocka. Kako svaka kocka može imati u potpunosti drugačiji skup dimenzija od ostalih, osmišljen je dizajner obrazaca koji omogućuje dodavanje dimenzija kocke na predložak obrasca s nekim ili svim njenim članovima u jednoj od četiri smještajne pozicije: dimenzija retka i dimenzija stupca za definiranje tablice za unos, te dimenzija točke gledišta i dimenzija stavke stranice za povezivanje unesenih vrijednosti u tablici s ostalim dimenzijama kocke [8]. Na svakoj smještajnoj poziciji može postojati više od jedne dimenzije, a ukoliko ih je više od jedne u retcima ili stupcima za prikaz tablice za unos podataka na obrascu određuje se Kartezijev produkt članova svih dimenzija u toj ulozi, a dimenzije se prikazuju kao zaglavlja tablice u više razina (Slika 5). Dimenzije točka gledišta i stavka stranice na obrascu se prikazuju kao padajući izbornici u kojima se kao vrijednosti ponuđene na izbor nalaze članovi tih dimenzija. Tako svaka ćelija u tablici na obrascu jednoznačno predstavlja jednu točku u kocki, a vrijednosti stupaca i redaka s obzirom na položaj te ćelije u tablici, zajedno s odabranim članovima ostalih dimenzija na obrascu, predstavljaju njene koordinate.

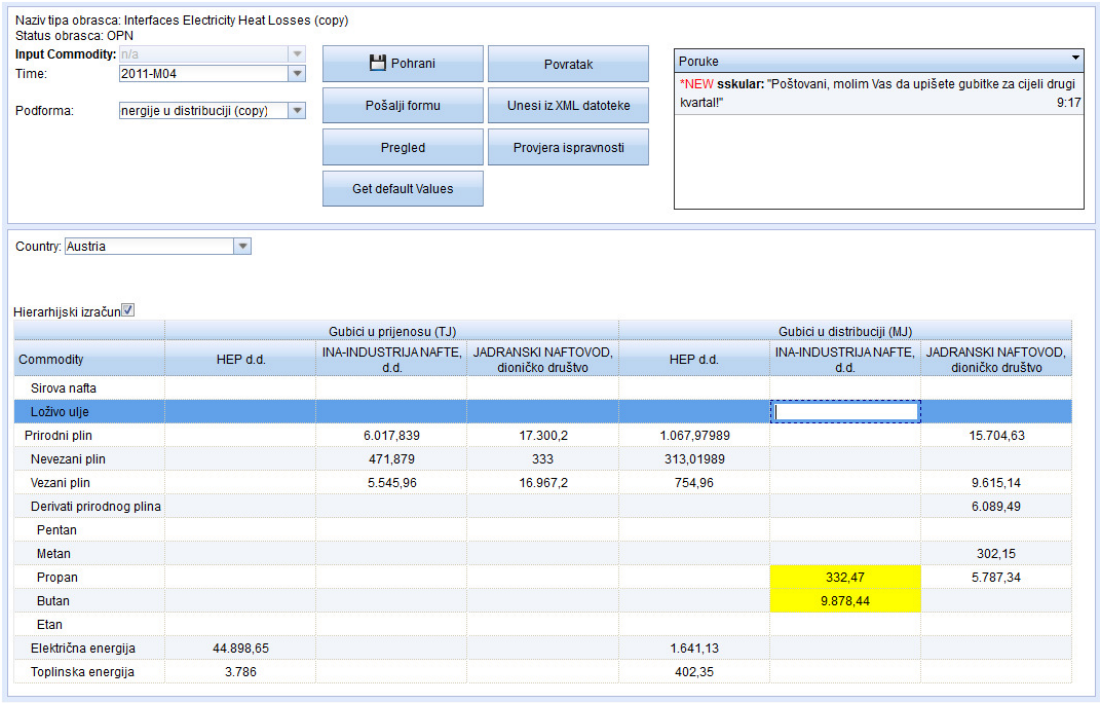
Za tablicu za unos na obrascu korištena je komponenta dojox DataGrid kojoj jedan zapis predstavlja jedan redak. Zbog toga su svakom retku dodani dodatni atributi kako bi svaka ćelija bila dostupna pomoću jedinstvenih koordinata točke koju predstavlja u kocki.

Administratoru sustava aplikacija omogućuje kreiranje poslovnih subjekata s njihovim kontakt osobama i zaduživanje poslovnih subjekata i kontakt osoba za periodičnu dostavu podataka kroz prethodno definirane obrasce. U bazi podataka procedura periodično kreira nove obrasce za poslovne subjekte po predlošku i obavještava poslovne subjekte i administratora ukoliko postoji kašnjenje u njihovoj dostavi.

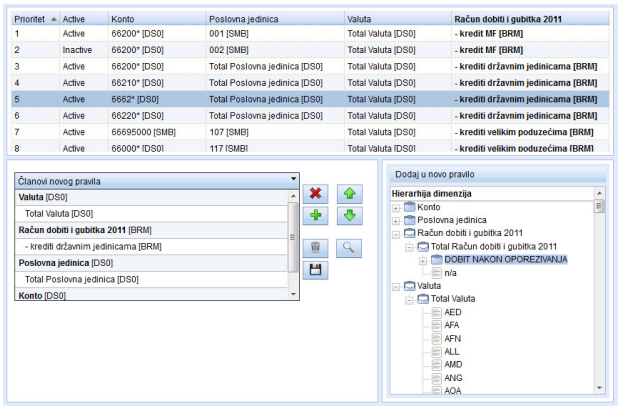
Za veće količine podataka i u slučaju da strana odgovorna za dostavu podataka posjeduje informatičku opremu sposobnu za njenu automatizaciju, omogućen je unos obrazaca pomoću uvoza XML datoteke. Da bi XML datoteka bila u ispravnom stanju i da bi podaci u njoj bili prihvaćeni i pohranjeni u kocki, za određeni obrazac ona mora biti kreirana po XSD (XML Schema Definition) specifikaciji preuzetoj s aplikacije. U toj specifikaciji definirano je koje se sve dimenzije i članovi dimenzija koriste u obrascu, efektivno pružajući podskup točaka kocke za koje je moguće unijeti podatke.

B. *Definiranje mostova (Bridge)*

Znatno olakšanje u upotrebi sustava korisniku se pruža putem sučelja za definiranje mostova, koje je izrađeno na način da maksimalno olakša izradu njegovih pravila (Slika 6). Na ovaj način postiže se veća transparentnost transformacija u odnosu na ostale MOLAP sustave u kojima se one obično realiziraju izvršavanjem kalkulacijskih skripti, čije pisanje nije intuitivno poslovnom korisniku.



Slika 5. Primjer obrasca



Slika 6. Definiranje pravila mosta

Svako pravilo mosta definirano je presjekom članova ulaznih dimenzija koji se preslikava u točno određeni član izvještajne dimenzije. U definiciji pravila mosta za svaki član ulazne dimenzije definira se njegov tip uključenja kojim se mogu obuhvatiti i ostali članovi te dimenzije relativni s obzirom na njegovu poziciju u hierarhiji dimenzije, kao na primjer DSC (Descendants) za uključenje svih članova hierarhijski ispod odabranog člana, CHI (Children Including Member) za uključivanje svih članova hierarhijski nižih za jedan nivo u odnosu na odabrani član s njim samim, DS0 (Level 0 Descendants) za sve krajnje članove u stablu itd. Tip uključenja uvelike smanjuje broj pravila koji se trebaju definirati i time povećava preglednost definicije mosta. Zbog upotrebe tipa uključenja moguće je preklapanje presjeka dva ili više pravila nakon razlučivanja tipa uključenja. Za takve slučajeve koristi se prioritet pravila po kojem se određuje koji izlazni član izvještajne dimenzije ima najviši prioritet. Posebno izrađen pregled mosta daje detaljan uvid u sva preklapanja i rezultirajuće izlazne članove za sva pravila mosta (Slika 7).

C. *Izvještaji*

Izvještaji služe za analizu podataka pohranjenih u kocki. Za razliku od obrazaca za unos podataka izvještaji u svojoj definiciji ne moraju sadržavati sve ulazne dimenzije kocke, a osim ulaznih dimenzija mogu sadržavati i izvještajne dimenzije. Definiraju se na gotovo identičan način kao i obrasci, a za izračun izvještaja sustav umjesto da koristi agregatne tablice izračun stavaka izvještaja pokreće na zahtjev korisnika. JasperReports korišten u implementaciji aplikacije na poslužitelju omogućuje izvoz i pohranu generiranih izvještaja u XLS, RTF ili PDF formatu.

Rezultati izračuna nad izvještajem filtrirani su s obzirom na sigurnosne postavke za korisnika koji pokreće izvještaj. Sigurnosna pravila mogu se definirati za sve korisnike koji pripadaju određenoj korisničkoj ulozi ili za svakog korisnika zasebno. Ona su definirana kombinacijom članova dimenzija, čime određuju stablo dimenzija koje korisnik može vidjeti prilikom definiranja stavaka na izvještaju, te prostorni presjek kocke za koje korisnik može dohvatiti izračunate vrijednosti na iscrtani izvještaj.

PRIORITY	Valuta	Poslovna jedinica	Konto	Račun dobiti i gubitka 2011
2	Total Valuta (DS0)	002 (SMB)	66200* (DS0)	- kredit MF (BRM)
1	*Total Valuta (DS0)*	*001 (SMB)*	*66200* (DS0)*	*- kredit MF (BRM)*
3	Total Valuta (DS0)	Total Poslovna jedinica (DS0)	66200* (DS0)	- krediti državnim jedinicama (BRM)
1	*Total Valuta (DS0)*	*001 (SMB)*	*66200* (DS0)*	*- kredit MF (BRM)*
2	*Total Valuta (DS0)*	*002 (SMB)*	*66200* (DS0)*	*- kredit MF (BRM)*
4	Total Valuta (DS0)	Total Poslovna jedinica (DS0)	66210* (DS0)	- krediti državnim jedinicama (BRM)
1	*Total Valuta (DS0)*	*001 (SMB)*	*66200* (DS0)*	*- kredit MF (BRM)*

Slika 7. Pregled mosta

Ukoliko korisnik koji pokreće izračun izvještaja nema sigurnosna prava za neke ćelije, u te ćelije na izvještaju upisuje se 'n/a'.

V. ZAKLJUČAK

Aplikacija CAR prisutna je na nekoliko produkcijskih okolina, čime je dokazala kako njene planirane mogućnosti nisu samo na razini teorije. Radi se o inovativnom proizvodu koji korisniku daje iznimnu slobodu potpuno samostalnog kreiranja baze i korisničkog sučelja. Ispravno dimenzioniranje kocke čini ključ uspjeha svakog projekta, a određivanje kalkulacijskih izraza preko hijerarhijske strukture transparentno je i intuitivno. Hijerarhije također uvelike olakšavaju izradu korisničkog sučelja, transformacijskih mostova i sigurnosnih pravila, jer odbacuju potrebu za pojedinačnim odabirom članova. Aplikacija svoju najširu primjenu ima u područjima s visokim stupnjem neodređenosti i dinamičkih promjena, u kakvima se i danas gotovo u pravilu koriste jedino tablični kalkulatori.

Web sučelje za unos u obliku podatkovne rešetke korisnicima je dobro poznato pa se na njega lako navikavaju, a postoji i mogućnost masovnog uvoza, te izvoza u niz raširenih formata. Krunu sustava čini izvješćivanje koje obuhvaća podatke dostavljene kroz razne instance unosa. Specifične izvještajne definicije i kategorije, izvedene iz drugih atributa, također se određuju kroz grafičko sučelje, te se tako bitno olakšava njihovo održavanje.

E-mail: adam.bojcic@multicom-is.hr, josip.pavlic@multicom-is.hr

Sažetak – Ovaj rad se bavi područjem analize prometa elektroničke pošte u kompleksnim sustavima kao što su Postfix i Cyrus. U radu opisan je sustav koji nudi rješenje problema, zajedno sa svojim prednostima i nedostacima. Sustav nudi brzu i sistematiziranu ekstrakciju teško čitljivih i razdvojenih tekstualnih podataka, koji su generirani od strane sustava za bilježenje aktivnosti, te spremanje podataka u skladište podataka kao centralno mjesto za spremanje, čineći ih tako dostupnima za kasniju multidimenzionalnu analizu i izvještavanje. Rješenje je bazirano na besplatnom i otvorenom softveru, što reducira troškove i čini ga pogodnim za šire korištenje. Implementacija je bazirana na Oracle 10g XE DBMS, skriptnom programskom jeziku Perl i programskim rješenjima tvrtke JasperSoft.

I. UVOD

Iako je donedavno doseg većine tvrtki bio informatizirati svoje poslovanje, u današnje doba tvrtke sve više traže analizu već postojećih informacijskih sustava. Kroz te sustave svakodnevno se prenose gomile informacija tijekom interakcija korisnika i računala. Podatci kolaju sa svih strana, putem Interneta ili mnogobrojnih privatnih mreža tvrtki. Analiza poslovanja prošlih godina ili desetljeća, uspjesi odnosno neuspjesi, usponi i padovi, svi oni zajedno mogu biti presuđujući uteg na vagi kada treba donijeti važnu odluku. S obzirom na mnoštvo podataka i informacija koje se mogu saznati iz prošlosti vrlo je važno izdvojiti one podatke koji su bitni, izvući neke zaključke te na temelju tih zaključaka donijeti poslovnu odluku.

Jedan od takvih sustava je i skladište podataka. Skladište podataka je baza podataka koja skuplja u sebi povijesne, nepromjenjive podatke te se onda ti podatci obrađuju i na adekvatan način prikazuju.

Tema rada je opis stvaranja sustava za jednu veliku hrvatsku tvrtku u sklopu diplomskih radova na Fakultetu elektrotehnike i računarstva u Zagrebu [1] i [2]. Zahtjev te tvrtke je analiza prometa elektroničke pošte, prometa koji se prati i zapisuje na serverima na kojima se nalaze programski sustavi Cyrus i Postfix. Cyrus je MDA (eng. *Mail Delivery Agent*) odnosno visoko skalabilan e-mail sustav koji se može koristiti za samostalnu uporabu ili u velikim tvrtkama kao centralni sustav [8]. Postfix je MTA *(eng. Mail Transfer Agent)* sustav čija uloga je razmjena e-mail poruka između računala unutar mreže, bilo privatne ili Interneta, pomoći SMTP *(eng. Simple Mail Transfer Protocol)* protokola [6]. To nije lagana zadaća jer podatci koji se produciraju nisu na prvi pogled pripremljeni za analizu i prikaz, nego ih je potrebno pažljivo izvući i transformirati u oblik koji je pogodan za stvaranje izvještaja i stvaranje zaključaka na temelju njih.

Drugo poglavlje bavi se samom analizom dnevničkih zapisa koji su napunjeni podatcima koje Cyrus odnosno Postfix svojim radom stvaraju. Osim analize bit će govora i o ETL-u, o procesu izvlačenja podataka, transformiranja istih te učitavanja u skladište podataka. U trećem poglavlju opisuje se samo skladište podataka i njegove značajke. U četvrtom poglavlju značaj se daje na rezultate analize i način na koji se ti rezultati prezentiraju.

II. ANALIZA DNEVNIČKIH ZAPISA

Podatci koje proizvode Postfix i Cyrus sustavi zapisani su prema syslog protokolu u dnevničke zapise. Syslog je standard za zapisivanje programskih poruka koji dozvoljava razdvajanje dijela softvera koji generira poruke od sustava koji ih sprema, od dijela softvera koji je zadužen za izvještavanje i analizu poruka. Tako se na serveru na kojem je smješten Cyrus odnosno Postfix generira mnoštvo dnevničkih zapisa o stanju sustava, odnosno, podatci o vremenima uspostavljanja konekcija, IP adresama, korisničkim imenima i slično. No, osim korisnih, postoji i zamjetan broj podataka koji su nekorisni (nekorisni u smislu dizajniranja sustava prema zadanim zahtjevima). Bitno je ocijeniti koji su podatci korisni, a koji nekorisni jer krivom procjenom neke se informacije mogu izgubiti ili pak mogu postati redundantne u sustavu.

Arhitektura programskih sustava Postfix i Cyrus raspodijeljena je na nekoliko međusobno povezanih manjih programa, čime se ostvaruje skalabilnost i robusnost. Svaki od programa izvršava se u više instanci, te odrađuje dio posla obrade poruke od zaprimanja u sustav do njezinoga daljnjeg prosljeđivanja. Programi koji sudjeluju u prosljeđivanju poruke su: smtpd, pickup, cleanup, qmgr, smtp i local u Postfix, te pop3, pop3s, imap i imaps u sustavu Cyrus.

Dnevnički zapis koji sadrži podatke iz vremenskog perioda od recimo tjedan dana može u svom izvornom obliku sadržavati nekoliko desetaka milijuna redaka. Doduše, svaki redak sam za sebe ne predstavlja cijelu informaciju, nego tek kada se ti redci grupiraju po određenom ključu, tek se onda mogu izvući određene informacije. Taj dio zadaće na sebe preuzima skripta pisana u programskom jeziku Perl [5]. Ona grupira retke dnevničkog zapisa, izvlači iz njega korisne podatke, te stvara novu datoteku koja je formatirana na takav način da se pomoću Oracle alata, SQL*Loader, može brzo i efikasno prebaciti u bazu podataka.

U oba sustava mogu se pratiti sljedeće korisne informacije:

Cyrus – vrijeme početka konekcije, vrijeme završetka konekcije, ime servera, vrsta protokola, IP adresa, korisničko ime, tip autentifikacije, status autentifikacije;

Postfix – vrijeme preuzimanja i prosljeđivanja poruke, IP adrese i nazivi poslužitelja koji sudjeluju u prijenosu, statusi filtriranja.

Iako će skladište podataka biti objašnjeno tek u sljedećem poglavlju, važno je objasniti korak koji se odvija na prijelazu podataka s izvora u skladište, opće poznat kao ETL *(eng. Extract, Transform and Load)*. ETL se sastoji od tri temeljna koraka: izvlačenje podataka, njihova transformacija i pročišćavanje, te učitavanje u skladište. U ovom radu za izvlačenje se koristi Perl skripta, koja vrlo brzo, u roku nekoliko sekundi, obrađuje tekstualne datoteke veličine i do par gigabajta. Radi optimiziranja i razdvajanja posla procesa ETL-a, Perl skripta transformira informacije iz tekstualne datoteke u oblik prikladan za učitavanje u pripremne tablice u Oracle DBMS-u. Na taj način složenost obrade se prebacuje na DBMS, a time se i smanjuje potrebna komunikacija s istom. Za unos u Oracle DMBS se koriste tehnike Oracle podatkovne pumpe *(eng. Oracle Data Pump)* čime se proces prijenosa svodi na svega nekoliko minuta. Pripremne tablice vrlo su slične tablicama skladišta podataka, ali su prilagođene za lakši unos podataka i prijenos. Podatci se nalaze u pripremnim tablicama sve dok ne budu spremni za prijenos u skladište. Na taj način riješen je problem kad su podatci na izvoru razlomljeni kroz više datoteka, na primjer sesije i transakcije slanja poruka koje mogu trajati i do nekoliko dana, tada skripta za obradu ne mora pamtiti stanje u kojem se nalaze podaci i njihovu cjelovitost.

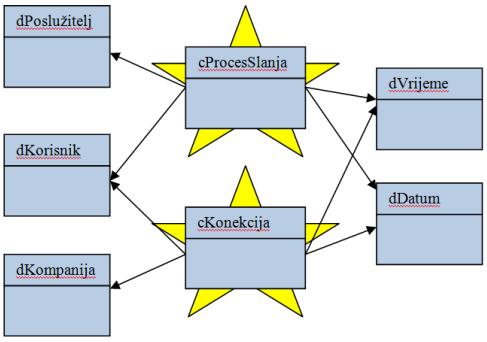
III. SKLADIŠTE PODATAKA

Kada se govori o skladištima podataka, danas postoji više objašnjenja i definicija. U ovom radu oblikovanje i izgradnja skladišta podataka temeljena je na radu Ralpha Kimballa, koji definira skladište kao kopiju transakcijskih podataka specijalno strukturiranu za upite i analize [4]. Prema Kimballu, svako područno skladište podataka *(eng. data mart)* se modelira prema četiri ključna koraka. U prvom koraku definira se poslovni proces koji se prati u poslovnoj domeni. Zatim se za dani proces definira granularnost informacija poslovnog procesa. Pa tako u ovom radu zapisi u činjeničnim tablicama predstavljaju jednu transakciju slanja poruke kroz mrežu, a u drugom slučaju jednu transakciju korisnika tijekom pristupa pretincu elektroničke pošte. Nakon toga definiraju se dimenzijske tablice za pojedinu činjeničnu tablicu. U našem radu dolazi do dijeljenja dimenzijskih tablica čime je dobiven tzv. pahuljasti spoj *(eng. snowflake)*. U zadnjem koraku se određuju mjere poslovnog procesa.

U dizajnu odozdo prema gore *(eng. bottom-up)* prvo se definiraju područna skladišta podataka kojima se prate poslovni proces. U ovom radu fokus pada na dva područna skladišta podataka, prvo koje prati slanje i primanje poruka kroz mrežu tvrtke, te drugo koje prati dohvaćanje poruka iz poštanskih pretinaca. U budućnosti ovakva područna skladišta podataka mogu se povezati sa još nekim kako bi se pratila prodaja ili proizvodnja u tvrtci, te se omogućila naplata usluga i izvlačenja zaključaka o uspješnosti pojedinog odjela.

Skladište podataka korišteno u ovom radu sastoji se od nekoliko dimenzijskih i činjeničnih tablica prikazanih na slici 1.

Činjenične tablice posjeduju veliki broj zapisa, mjerljiv u milijunima, koji se skupljaju tijekom vremena. Stoga je tablica normalizirana i posjeduje minimalan skup atributa



Slika 1. Shema skladišta podataka

malih veličina. Atributi su podijeljeni u dvije skupine: ključevi i mjere. Atribute ključeva predstavljaju primarni surogat ključevi tablice i referencijski ključevi prema dimenzijskim tablicama. Važno je napomenuti da se tablice dimenzija referenciraju i po nekoliko puta, ovisno o ulogama koju imaju dimenzije. Pa se tako vremenske dimenzije pojavljuju kao *dDatumPrimanja, dDatumSlanja, dVrijemePrimanja, dVrijemeSlanja, dKorisnikPrimatelj, dKorisnikPosiljatelj, dPosluziteljPrimatelj* i *dPosluziteljPosiljatelj*, itd. Drugu skupinu atributa čine atributi zvani mjere, koji svojom vrijednošću daju ocjenu danom poslovnom procesu. Mjere su najčešće brojčani atributi poput veličine poruke u bajtima, trajanje slanja, logičke oznake prisustva ili odsustva nekog svojstva i druge. Takve mjere omogućuju jednostavna agregiranja vrijednosti po određenim dimenzijama poput *roll-up, drill-down, cross-join* i drugim metodama prisutnima u OLAP sustavima [3].

Dimenzijske tablice služe za opise zapisa u činjeničnim tablicama. Obično posjeduju puno manji broj zapisa, do nekoliko desetaka tisuća zapisa, u odnosu na činjeničnu tablicu koja konstantno raste kroz vrijeme. Dimenzijska tablica nije normalizirana i prosječno sadrži veće atribute, obično tekstualne nazive i opise. Zbog denormaliziranosti tablice često postoji hijerarhija među atributima, poput *godina>mjesec>dan, sat>minuta>sekunda* ili *tip domene>domena*, o kojima je potrebno posebno voditi računa jer se njihova ispravnost ne osigurava na razini skladišta nego se tek provodi kod izgradnje izvještaja i upita u sustavima za izvještavanje. Prema danim hijerarhijama mogu se raditi *roll-up* i *drill-down* upiti agregiranjem. U ovom skladištu podataka postoje sljedeće dimenzije vidljive u tablici 1.

Vremenske dimenzije *dDatum* i *dVrijeme* pune se unaprijed tijekom početne inicijalizacije skladišta, kako bi se ubrzao proces inkrementalnih unosa podataka u skladište podataka, te se omogućilo postojanje potrebnih podataka. Mana takvog pristupa je što administrator mora paziti da postoje podatci za sva potrebna vremenska razdoblja i da ih se na vrijeme proširuje, ali opet da se ne unosi previše podataka unaprijed koji se neće koristiti, jer usporavaju rad sustava.

Ostale dimenzije u skladištu također inicijalno posjeduju univerzalne zapise koji predstavljaju neka nepoznata stanja u kojima se mogu pojaviti podaci tijekom unosa, poput nedostatka neke informacije „Nepoznato“ ili „Nije dostupno“.

TABLICA 1. Popis dimenzija u skladištu podataka

Naziv dimenzije	Opis:
dPoslužitelj	Sadrži podatke vezane za poslužitelje. IP adresu, ime poslužitelja, tip poslužitelja
dKorisnik	Korisničko ime
dKompanija	IP adresa, naziv kompanije
dVrijeme	Dimenzija koja pokriva vremenske intervale unutar jednog dana. Dan je raspodijeljen u intervale od po pola sata
dDatum	Dimenzija koja pokriva vremenske intervale po datumima

Na temelju provedene analize može se donekle predvidjeti rast činjeničnih i dimenzijskih tablica. Na slici 2. može se vidjeti kako veličina činjenične tablice raste linearno svakim inkrementom unosa podataka, pri čemu se pretpostavlja da izvor isto tako linearno stvara nove informacije.

Za razliku od činjenične tablice, dimenzijske tablice brzo se pune u početku rada skladišta podataka kroz prvih nekoliko inkrementalnih punjenja, te se u daljnjem radu dimenzijski podatci većinom ponavljaju i nema puno novih dodavanja. Na slici 3 prikazan je logaritamski pad potrebnog prostora za nove informacije dimenzijske tablice.

Može se zaključiti da je skladište podataka baza podataka koja se koristi u analizi i izvještavanju poslovnog procesa i da predstavlja slijed zapisa poslovnog procesa nekog poduzeća za određene vremenske periode, pri čemu se podatci čuvaju pet, deset ili više godina. Takvi dugoročni sustavi ne mogu se u potpunosti automatizirati, te zahtijevaju konstantan nadzor administratora sustava. Sustav je potrebno nadzirati na razini rada sustava baze podataka optimiziranjem upita i particioniranjem tablica radi bržeg odziva, izmjenom i dodavanjem novih dimenzija, atributa i mjera radi proširenja korisničkih zahtjeva i potreba. S druge strane potrebno je redovito nadzirati ETL proces zbog čestih iznimaka koje nastaju zbog neadekvatnih podataka s izvora, te biti spreman na odbacivanje podataka koji predstavljaju prevelik utrošak u prebacivanju. Prebačene podatke moraju povremeno nadzirati i ispravljati administratori upoznati sa domenom procesa koji se prati skladištem, kao i sami korisnici kojima su namijenjeni rezultati analize. Potrebno je također paziti i na ispravnost i na valjanost izvještaja koji se dobivanju nad danim podatcima. Sve ove aktivnosti čine jedan živi sustav koji se odvija oko skladišta podataka.

IV. REZULTATI ANALIZE

Podatci u skladištu podataka prilagođeni su za višedimenzionalne upite i analizu. Da bi informacije u skladištu bile korisne zainteresiranim korisnicima potrebno je informacije adekvatno prezentirati. Koriste se dva pristupa prezentacije.

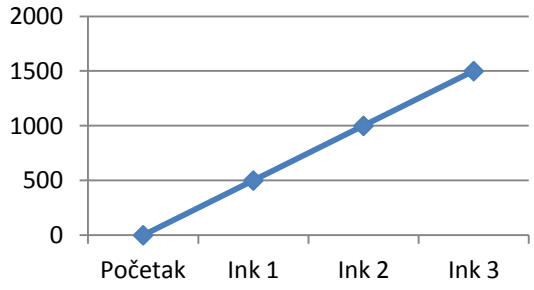
Prvi pristup je preko OLAP alata, kojim se omogućuje dinamičko pregledavanje podataka skladišta, filtriranjem i agregiranjem vrijednosti dimenzija. Ovaj pristup nudi mnogo mogućnosti korisnicima, ali zahtijeva od korisnika i određeno poznavanje domene koja se analizira, kao i neka osnovna znanja korištenja OLAP alata.

Drugi pristup nudi konkretne informacije pomoću već gotovih izvještaja. Izvještaji su unaprijed osmišljeni i namijenjeni određenoj grupi zainteresiranih korisnika. Izvještaji ne nude preveliku dinamičnost upita, ali i ne zahtijevaju nikakva posebna znanja od njihovih korisnika.

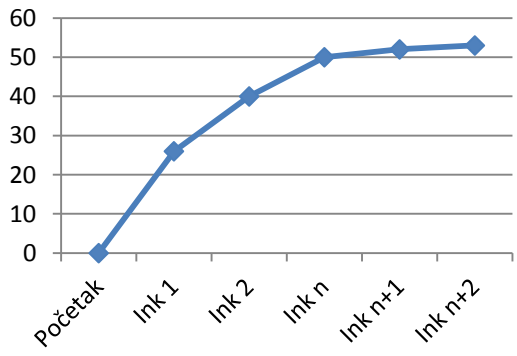
Oba pristupa dostupna su putem centralnog sustava za izvještavanje koje dolazi kao dio Jaspersoft OLAP poslužitelja. Jaspersoft nudi web sučelje kojim je moguće upravljati pravima pristupa korisnika, izgradnjom i pregledom OLAP izvještaja, pregledavati gotove izvještaje, prebacivati izvještaja u MS Excel, PDF, te druge opcije.

Jaspersoft sustav posjeduje relacijski OLAP (ROLAP) mehanizam otvorenog koda kojeg u pozadini pokreće Apache Tomcat poslužitelj u kombinaciji s MySQL bazom podataka u koju sprema informacije o korisnicima i upitima. S obzirom da se radi o ROLAP poslužitelju, svi podatci korišteni u izvještajima drže se na izvoru podataka, tj. Oracle relacijskom skladištu podataka. Jaspersoft koristi Mondrian XML (eng. extensible markup language) shemu za definiranje OLAP kocke i MDX (eng. multidimensional expression language) [7]za postavljanje višedimenzionalnih upita.

Za oblikovanje sheme potrebno je prekopirati osnovnu shemu relacijskog modela skladišta podataka u programu JasperAnalysis Schema Workbench, koji nudi osnovne mogućnosti grafičkog editiranja podatkovne kocke, dimenzija i mjera, uz jednostavnu mogućnost izvršavanja testnih MDX upita nad kockom. Tijekom izgradnje sheme moguće je proširiti izvorni model novim atributima nastalim jednostavnim transformacijama izvornih



Slika 2. Pretpostavljeno inkrementalno povećanje veličine činjenične tablice [MB]



Slika 3. Pretpostavljeno inkrementalno povećanje veličine dimenzijskih tablica [MB]

informacija, poput pretvorbe mjernih jedinica ili uljepšavanje formata prikaza informacija.

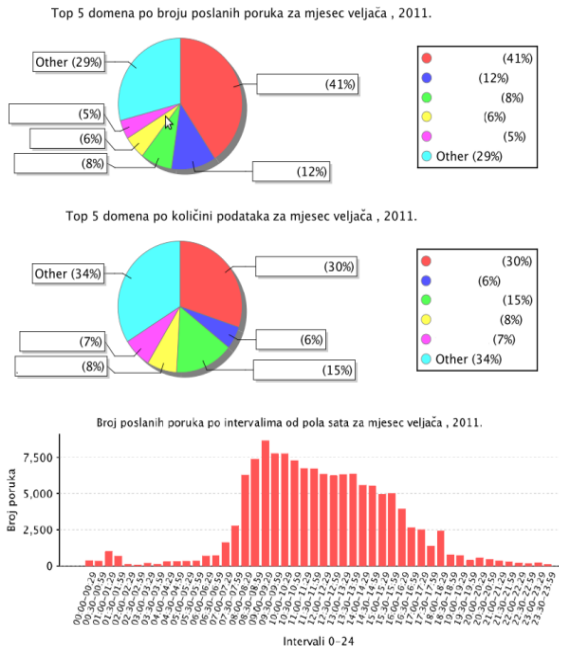
Jaspersoft OLAP web sučelje omogućuje jednostavno grafičko klikabilno pregledavanje podataka po dimenzijama i njihovim hijerarhijama, uz za sada dosta nedostataka u grafičkom prikazu podataka.

Jaspersoft iReport alat služi za izradu unaprijed definiranih izvještaja za pojedine korisničke grupe poput uprave, prodajnih menadžera i drugih korisnika koji donose pojedine odluke na temelju rezultata analize. Za razliku od OLAP sustava iReport omogućuju veću vizualnu slobodu kod izrade izvještaja, ali smanjuju slobodu korisničkih zahtjeva.

Na sljedeće dvije slike mogu se vidjeti primjeri dva jednostavna izvještaja. Na slici 4 može se vidjeti izvještaj koji daje neke od informacija koje se mogu saznati iz sustava Postfix: top 5 domena po broju poslanih elektroničkih poruka iz veljače 2011. godine, te broj poslanih poruka po intervalima u danu. Iz tih podataka može se zaključiti koje domene (tvrtke) najviše šalju elektroničku poštu, te se po toj osnovi može odrediti određeni plan naplate usluge.

Na slici 5 može se vidjeti broj konekcija po protokolima za određeni vremenski period. Iz tih podataka mogu se vidjeti omjeri e-mail protokola te nakon nekog vremena praćenja podataka, može se saznati da li korištenje određenog protokola raste ili pada, te prema tome odrediti koje daljnje korake je potrebno poduzeti.

Ta dva izvještaja samo su mali pokazatelj informacija koje se mogu izvući iz skladišta podataka. Za sustav Cyrus moguće je recimo saznati broj konekcija po domenama za određeni period ili prosječni broj trajanja u sekundama konekcije po domenama, itd. Što se tiče sustava Postfix moguće je saznati vremena obrade poruke kroz sustav, broj odbijenih i filtriranih poruka, raspodijele poruka po korisnicima, i druge izvještaje.



Slika 4. Primjer izvještaja za Postfix

Slika 5. Primjer izvještaja za Cyrus

V. ZAKLJUČAK

Analiza informacijskih sustava tvrtki krije mnogobrojne mogućnosti i probleme. U ovom radu analiza dnevničkih zapisa pokazala se kao pravi izazov. U početnoj fazi veliki problem predstavlja nedovoljna količina informacija o izvoru podataka i formatu njegovih dnevničkih zapisa, što predstavlja opasnost izrade krivog modela skladišta. Često je potrebno korisne informacije i veze među njima otkriti reverznim inženjerstvom i metodama pokušaja i pogrešaka uz sugestije korisnika iz poslovne domene problema. Unatoč izazovima izrade skladišta podataka pokazala su se kao odličan univerzalan pristup u praćenju i analizi komunikacijskog sustava. Oracle 10g DBMS-s posjeduje mnogo zanimljivih alata za korištenje u sustavu punjenja skladišta podataka, od SQL Loadera do specijalnih SQL naredbi poput *merge* naredbe, kojima se ubrzava prijenos podataka izmemeđu tablica. Jaspersoft alati omogućuju jednostavno, brzo i besplatno postavljanje centralnog poslužitelja za višedimenzionalno izvještavanje, što izrazito pogoduje malim tvrtkama koje žele brze rezultate bez skupih ulaganja. Mondrian OLAP kocka oblikuje se lakoćom, ali glavnu prepreku u OLAP izvještavanju predstavlja MDX upitni jezik, za kojeg kronično nedostaje dokumentacija njegove strukture, mogućnosti i dostupnih funkcija, kao i alat za njegovo oblikovanje. Isto tako, veliki nedostatak Jaspersoft alata je nedostatka kvalitetnog i intuitivnog dizajna web korisničkog sučelja, nedostatak dizajnera upita, te mali broj mogućnosti za analizu podataka. Čak ni komercijalna verzija njihovog proizvoda ne donosi nikakva ozbiljna poboljšanja i mogućnosti. Izvještaji dobiveni iReport grafičkim alatom za izradu izvještaja pokazali su se zasada kao bolje rješenje od OLAP analize, prvenstveno zbog zanimljivih i dizajnerski ljepših izvještaja koji su korisnicima zanimljiviji od grafički nedovoljno dorađenog i kompliciranog kreiranja upita u OLAP kocki.

Unatoč mnogobrojnim problemima koje još uvijek vrebaju tijekom dizajniranja i rada ovakvog sustava za

analizu podataka, dobiveni rezultati u izvještajima predstavljaju zlatnu vrijednost za njihove korisnike. Skladišta podataka predstavljaju dobar pristup u rješavanju ovakvih problema analize, a ETL i OLAP alati postat će sve bolji u skorašnjim verzijama, za što već postoje i naznake velikih proizvođača poput Oraclea i Microsofta, koji svakodnevno guraju svoja nova rješenja na ovu temu. Za ovim tehnološkim područjem postoji velika potreba u poslovnom svijetu, te ono ima veliki potencijal i vrijednost svojim korisnicima.

Sažetak - Temeljna zadaća Zagrebačkog holdinga je obavljanje komunalnih djelatnosti uz zaštitu okoliša i javnog interesa lokalne zajednice. U svrhu optimizacije poslovnih procesa Zagrebački holding razmatra mogućnost implementacije sustava za centralizirano upravljanje matičnim podatcima o klijentima, lokacijama i objektima, te proizvodima i uslugama koje nudi svojim klijentima. U radu je opisana analiza poslovnih procesa i postojeće infrastrukture, definirani su funkcionalni zahtjevi i predložena arhitektura takvog sustava.

I. UVOD

Zagrebački holding d.o.o. (ZGH) osnovan je 2007. godine prema Zakonu o trgovačkim društvima i u 100-postotnom je vlasništvu Grada Zagreba.

Sastoji se od Direkcije i 18 podružnica koje obavljaju djelatnosti nekadašnjih gradskih poduzeća, a ukupni broj zaposlenih je oko 12.000. ZGH. vlasnik je i 6 trgovačkih društava i ustanova s još oko tisuću zaposlenih.

Djelatnosti Društva grupirane su u tri poslovna područja:

- Komunalne djelatnosti
- Prometne djelatnosti
- Tržišne djelatnosti.

Podružnice udružene u ZGH inicijalno su poslovale kao zasebne tvrtke, te je svaka od njih imala zaseban informacijski sustav ili više sustava za podršku operativnom poslovanju.

Projekt uspostave centralizirane baze podataka započeo je ubrzo nakon osnivanja ZGH, s ciljem objedinjavanja podataka i razvoja integralne baze podataka. U to je doba svako trgovačko društvo imalo svoju bazu podataka te je svako zasebno izdavalo svoju uplatnicu za komunalne naknade i usluge. Takav je sustav generirao velike troškove, stoga je bilo nužno formiranje centralizirane baze podataka.

Uvođenje jedinstvene uplatnice (JUP) donosi pogodnosti i građanima jer se obveze za komunalne naknade i usluge mogu platiti na jednom mjestu i bez provizije.

Jedinstvena baza podataka omogućuje, među ostalim, optimizaciju troškova održavanja i korištenja, provedbu integracije poslovnih procesa, nadzor sustava te uvođenje jedinstvenog uplatnog dokumenta.

Unutar ZGH, prepoznate su tri glavne grupe matičnih podataka:

- Korisnici – podaci o pravnim i fizičkim osobama korisnicima usluga ZGH
- Lokacije i Objekti – podaci o lokacijama i objektima na kojima se korisnicima pružaju usluge
- Proizvodi i usluge – podaci o proizvodima i uslugama koji se korisnicima pružaju na određenim lokacijama.

Svaka od ove tri glavne grupe matičnih podataka ima i međusobne veze unutar grupe, te veze među pojedinim grupama.

U svrhu optimizacije poslovnih procesa te uz istovremeno smanjenje svih nepotrebnih troškova, ZGH razmatra mogućnost implementacije rješenja za centralizirano upravljanje matičnim podatcima (Master Data management – MDM) o klijentima, lokacijama i objektima, te proizvodima i uslugama koje ZGH nudi svojim klijentima

U radu će se izložiti analiza poslovnih procesa i postojeće infrastrukture, definirati funkcionalni zahtjevi sustava i predložiti arhitektura MDM sustava.

II. ANALIZA POSLOVNIH PROCESA I POSTOJEĆE INFRASTRUKTURE

Postojeća jedinstvena baza ne sadržava sve referentne matične podatke, budući da nisu sve fizičke i pravne osobe korisnici svih proizvoda i usluga. Također, postoje i prilično veliki problemi s kvalitetom podataka.

Podružnice koje su okosnica komunalnih djelatnosti i pripadajući sustavi su prepoznati kao sustavi u kojima se nalazi glavnina matičnih podataka i koji bi trebali biti izvor za centralni repozitorij matičnih podataka.

Podružnica Čistoća koristi aplikaciju Imperios koja je razvijena na MS SQL server platformi. Aplikacijom su podržani poslovni procesi kao npr. obračun plaća, izlazni računi, ulazni računi, skladišno poslovanje, blagajna, obrada radnih naloga itd. U Imperiosu se vode pravne osobe (firme) dok se fizičke osobe vode u Registru. Jedan, manji, dio obrtnika je u Imperiosu, a ostatak je u Registru. Aplikacija Imperios sadrži matične podatke koji se odnose na klijente, adrese, objekte, proizvode i usluge.

Registar je nova aplikacija koja podržava najveći skup matičnih podataka iz područja komunalnih djelatnosti. Ova aplikacija je izravna podrška za jedinstvenu uplatnicu koja se mjesečno obrađuje za cca 400.000 korisnika komunalnih naknada i usluga. Aplikacija Registar sadrži matične podatke o obveznicima, objektima, adresama i većem broju komunalnih naknada i usluga. Komunalne naknade i usluge za stambene,

poslovne i garažne prostore na području Grada Zagreba su: pričuva, komunalna naknada, naknada za uređenje voda, najamnina, zakupnina i spomenička renta. Registar je realiziran korištenjem J2EE tehnologije i koristi IBM DB2 UDB bazu podataka.

Podružnica Vodoopskrba i odvodnja radi pripremu i obračun svojih usluga s više aplikacija. Jedan proces je definiran za stambene zgrade sa zajedničkim vodomjerima: podružnica očitava vodomjere i održava promjene broja obveznika u kućanstvima u aplikaciji Registar, te se na osnovu ovih podataka radi obračune potrošnje vode. Ovi podaci se povezuju sa svakim pojedinim objektom i sastavni su dio jedinstvene uplatnice.

Drugi proces se odnosi na sve ostale objekte, gdje se nakon očitanja vodomjera obračun potrošnje vode izvodi u aplikaciji Risov. Aplikacija Risov na Oracle 8 bazi podataka, izrađena je s Oracle Forms 3.0 i Reports 2.0 alatima. U aplikaciji se nalazi analitičko knjigovodstvo kupaca. Analitičko knjigovodstvo se vodi za privatne kuće, gospodarstvo i za stanove koji imaju vodomjer. U tijeku je razvoj UPN aplikacije koja će zamjeniti Risov u budućnosti. Risov aplikacija sadrži matične podatke o klijentima i lokacijama.

Posebna aplikacija eKomis se koristi za obračun usluga u gradu Samoboru. eKomis je aplikacija na Oracle 11g R2 bazi podataka, dostupna potrošačima na Internetu – tamo su podaci o stanjima, računima i uplatama koje građani mogu pregledavati on-line, građani imaju username / password.

Gradska Plinara Zagreb (GPZ) je razdvojena na opskrbu i distribuciju. Opskrba i distribucija su bile u sastavu GPZ, dok se nisu razdvojile prema zahtjevima za deregulaciju tržišta iz izmijenjenog zakonodavstva. Sukladno tom procesu, sada je u tijeku i proces razdvajanja IT sustava. Distribucija će nastaviti održavati sve sustave, te pružati uslugu korištenja sustava Opskrbi.

GPZ-Opskrba priprema novu aplikaciju za obračun potrošnje plina, koja će biti implementirana na Oracle 11g R2 bazi podataka. Ova aplikacija će podržavati i matične podatke o klijentima, lokacijama, objektima. GPZ nije integrirana u sustav jedinstvene uplatnice i podaci o njihovim korisnicima, lokacijama i priključcima ne nalaze se u Registru.

Podružnice Gradska groblja, ZET i Zagrebparking u svojim IT sustavima također imaju podatke o korisnicima svojih usluga.

U kontekstu Gradskih groblja partneri su korisnici grobnih mjesta koji su ih kupili i plaćaju godišnje održavanje. Gradska groblja koriste aplikaciju Memento koja je razvijena na Microsoft tehnologiji.

ZET koristi Fare On aplikaciju koja pokriva ured putnih karata. Osim tog sustava, ZET koristi aplikaciju za financije i knjigovodstvo, te sustav za nadzor prometa koji nije predmet interesa MDM projekta. Baza podataka je Microsoft SQL Server, koristi se .NET tehnologija, dio platforme je Windows aplikacija, a jedan dio funkcionalnosti je i web aplikacija. Iz aplikacije putnih karata se radi temeljnica za knjiženje u aplikaciju za financijsko knjigovodstvo. U Fare On aplikaciji od podataka o korisniku nalaze se ime, prezime, datum rođenja, OIB, adresa stanovanja, adresa za slanje pošte i broj telefona za kontakt.

Za svakog korisnika postoji profil koji je validan za neki period. Nakon proteka perioda profil se produžuje ili mijenja. Profil može biti – učenik, student, opći (zaposleni), nezaposleni, umirovljenik, socijalni slučaj, davatelj krvi. Za aktivaciju profila korisnik mora donijeti potvrdu o statusu.

ZET-u su potrebne iz MDM sustava informacije o tome tko su zaposlenici ZGH, budući da ZET ima ugovore sa svim podružnicama po kojima ZET naplaćuje mjesečne karte direktno podružnicama.

Zagrebparking posjeduje podatke o vlasnicima vozila. Sustav naplate parkinga je podržan s aplikacijom mParking. Od ove godine vrijedi novi Zakon o sigurnosti prometa na cestama. Po tom zakonu jedinica lokalne uprave može ovlastiti koncesionara za razmjenu podataka s MUP-om, što je u ovom slučaju Zagrebparking. Razmjena podataka između Zagrebparkinga i MUP-a udvija se korištenjem Web-servisa.

Baze pretplata i kazni (dnevnih parkirnih karata) su dvije odvojene baze. Ima oko 10.000 korisnika godišnjih karata, a puno više ima kazni.

Direkcija ZGH aktivno radi na centralizaciji i standardizaciji IT sustava i sustava za upravljanje podacima, u okvirima budžeta i uvjeta u okruženju. Što se tiče standardizacije sustava, zajednički ERP sustav bi trebao podržavati sve bitne podružnice i temeljiti se na zajedničkim matičnim podacima.

Konsolidacija podataka je preduvjet za ERP. U fazama će se pristupati pojedinim podružnicama za uključivanje u MDM sustav. Puno je realniji koncept da se ide na referencijalni model MDM-a s obzirom na poslovne potrebe i buduću strategiju.

Centar za korisnike je otvoren u ljeto 2011. godine u cilju pružanja cjelovite podrške korisnicima komunalnih naknada i usluga na razini ZGH. Na računalu agenta Centra za korisnike su instalirane sve klijentske aplikacije koje su neophodan izvor informacija o komunalnim naknadama i uslugama. Ne postoji aplikacija u koju se upisuju CRM podaci o kontaktima i zahtjevima korisnika koji dolaze u Centar za korisnike.

III. MDM SUSTAVI

Upravljanje matičnim podacima (MDM) je jedna od strateških inicijativa koja spada u područje strateškog upravljanja podatkovnim resursima (eng. Data Governance).

Data Governance konvergira područja kvalitete podataka, upravljanje podacima, politika upravljanja podacima, upravljanje poslovnim procesima i upravljanju rizicima vezanim za obradu podataka u organizaciji. Kroz Data Governance, organizacije uspostavljaju nadzor nad procesima i metodama koje koriste njihovi zaposlenici. [3]

Data Governance je skup procesa koji osigurava da se važnim podacima formalno upravlja kroz poduzeće i da ih se tretira kao imovinu. Data Governance osigurava da podaci budu pouzdani i da se zna odgovornost za bilo koji štetni događaj koji se može dogoditi zbog niske kvalitete podataka, uključujući postavljanje ljudi zaduženih za sprečavanje nastajanja problema s podacima. Strateško upravljanje podatkovnim resursima potrebno je razlikovati od pojma Data management, koji se odnosi na operativno upravljanje podacima. Strateško upravljanje podatkovnim resursima također opisuje evolucijski proces promjene upravljanja informacijama za tvrtke, promjenu načina razmišljanja tvrtke i postavljanje procesa za obradu informacija, tako da podaci mogu biti korišteni od strane cijele organizacije. Tehnologija je ključna u mnogim oblicima pomoći tijekom procesa strateškog upravljanja podatkovnim resursima.

MDM kao disciplina obuhvaća skup procesa i alata koji dosljedno definiraju upravljanje netransakcijskim podatkovnim subjektima organizacije. Cilj implementacije MDM sustava je implementacija procesa za prikupljanje, uparivanje, konsolidiranje, osiguranje kvalitete distribuiranja matičnih podataka u cijeloj organizaciji, kako bi se osigurala dosljednost i nadzor nad podacima i informacijama. [1]

Osnovni pojmovi vezani za MDM sustave su:

- Referencijalni / transakcijski MDM sustavi
- Jedno / Više domenski MDM sustavi
- Čišćenje i kvaliteta podataka
- Inicijalno / inkrementalno punjenje podataka
- Integracija s poslovnim sustavima u realnom vremenu (SOA)
- Upravljanje hijerarhijama
- Kreiranje veza među podacima
- Proces odobravanja promjena podataka (stewardship).

Referencijalni sustavi sadrže veze (linkove, adrese) prema izvornim sustavima i kod sebe ne spremaju sav sadržaj iz izvornih sustava, nego samo identifikatore, ključeve i poveznice prema tom sadržaju. Kreiranje referentnog sloga radi se u realnom vremenu, na upit. Nikakve izmjene se ne rade nad podacima u samom MDM sustavu i ne propagiraju se u druge sustave. Na engleskom se takvi sustavi nazivaju i Registry Style MDM. *Transakcijski* sustavi sadrže sve potrebne podatke iz izvornih sustava, koriste se za standardizaciju, održavanje, uparivanje i nadopunjavanje podataka u MDM sustavu, te za promoviranje podataka u druge sustave u batch modu ili realnom vremenu. Postoje i hibridni MDM sustavi, a kod njih je prvenstveno riječ o referencijalnim sustavima, koji uz identifikatore sadrže i druge, opisne atribute, kako bi se smanjila komunikacija prema drugim sustavima i poboljšale performanse. Referencijalni MDM sustavi su, uzevši u obzir zahtjeve za integraciju, brži, jednostavniji i jeftiniji za implementaciju od transakcijskih sustava. [2]

Domena predstavlja poslovni subjekt čijim podacima treba upravljati. [2] Domena u kontekstu ZGH može biti korisnik (partner), proizvod, lokacija ili objekt. Jednodomenski (engl. Single domain) MDM sustavi su specijalizirani MDM sustavi koji su napravljeni za upravljanje matičnim podacima vezanim za jedan poslovni subjekt. Višedomenski (engl. Multi Domain) MDM sustavi mogu upravljati s matičnim podacima za više subjekata / domena na jednoj platformi, te njihovim međusobnim vezama. Višedomenski sustavi omogućavaju potpuni uvid u matične podatke, budući da među različitim domenama najčešće postoje vrlo složene međuovisnosti. Inicijalno su MDM sustavi bili jednodomenski, ali sve više prevladava višedomenski koncept, budući da su matični podaci iz različitih domena logički povezani, te se kompletna slika subjekta iz jedne domene (primjerice korisnika) dobiva tek ako se na istom mjestu održavaju matični podaci iz ostalih povezanih domena (proizvodi, objekti, lokacije).

Sustavi za upravljanje matičnim podacima se snažno oslanjaju na funkcionalnost platformi za poboljšanje kvalitete podataka, koje se uvijek nalaze implementirane kao dijelovi takvih sustava, prvenstveno u funkciji standardizacije, uparivanja i deduplikacije. Kod sustava za upravljanje matičnim podacima se komponente platformi za poboljšanje kvalitete podataka koriste i u batch procesima i prilikom obrade u realnom vremenu, posebice kod transakcijskih sustava za upravljanje matičnim podacima.

Postoje tri osnovna tipa punjenja podataka u MDM sustav – inicijalno, inkrementalno i real-time:

- Inicijalno punjenje podataka se radi na početku primjene platforme kada se učitavaju svi potrebni aktualni i povijesni podaci i zapisi iz izvornih sustava, podaci iz različitih izvora se uspoređuju i uparuju međusobno, te se kreira inicijalna verzija standardiziranih, uparenih i dedupliciranih podataka.
- Inkrementalno punjenje podataka je metoda osvježavanja sadržaja MDM sustava. Radi se o batch procesu koji se najčešće odvija jednom dnevno, koji nove i promijenjene podatke iz jednog izvora uspoređuje i uparuje s konsolidiranim podacima u MDM sustavu.

Real-time punjenje podrazumijeva da se unos ili promjena zapisa koja se u nekom trenutku desi u nekom od izvornih sustava i iz MDM sustava prema ostalim sustavima, odmah nakon spremanja zapisa, u realnom vremenu promovira prema MDM sustavu, bilo direktnom komunikacijom, bilo korištenjem ESB (engl. Enterprise Service Bus) platforme. Matični podaci moraju proći proces verifikacije od osoba zaduženih za održavanje matičnih podataka kod unosa ili promjene u nekom od sustava, za slučaj da se ne mogu automatski povezati s nekim već postojećim zapisom ili prepoznati kao potpuno novi zapis. Te osobe se nazivaju Data Stewardi ili Upravitelji podataka. Tek nakon odobrenja podataka, podaci se promoviraju i ažuriraju u ostalim sustavima.

MDM sustavi se trebaju integrirati s poslovnim sustavima u realnom vremenu. Integracija u realnom vremenu podrazumijeva da se unos ili promjena zapisa koja se u nekom trenutku desi u nekom od izvornih sustava, odmah nakon spremanja zapisa, u realnom vremenu promovira prema MDM sustavu, koji ga u realnom vremenu obrađuje, te ako nije potrebna intervencija upravitelja podataka prosljeđuje ciljnim sustavima također u realnom vremenu. Ako je potrebna intervencija upravitelja podataka on dobiva notifikaciju o novom zadatku, te se promjena promovira nakon njegove intervencije. Integracija u realnom vremenu se radi korištenjem SOA (engl. Service Oriented Architecture) i putem Web servisa za razmjenu podataka. Integracija može biti realizirana između MDM sustava i ostalih poslovnih sustava bilo direktnom razmjenom poruka bilo korištenjem ESB infrastrukture.

MDM platforma mora omogućiti upravljanje hijerarhijama koje postoje u matičnim podacima, a koje postoje ili ne postoje u izvornim poslovnim sustavima. Definiranjem hijerarhija, podaci dobivaju još jednu dodatnu dimenziju. Održavanjem hijerarhija dobivamo kvalitetniju podlogu za izvještavanje i analizu podataka.

Matični podaci su povezani raznim vezama koje nisu zapisane u izvornim poslovnim sustavima. MDM sustavom omogućen je unos i održavanje veza među objektima. Radi se formalnim i neformalnim grupama koje se kasnije mogu upotrijebiti u izvještavanju u analizi podataka. Veza među podacima može biti veza unutar iste domene kao što je veza između dvije osobe koje su rodbinski povezane (otac i sin, brat i sestra), koja u izvornom sustavu ne postoji. Veza može biti između više domena u kojoj je definirano da su osoba A i osoba B (domena korisnika) prijavljeni u objektu C (domena objekta) te su zaduženi komunalnom uslugom D (domena proizvoda). Ovakve veze u izvornom sustavu postoje, ali u svakom izvornom sustavu samo za dio korisnika, objekata i usluga koje se u njemu vode – MDM sustav bi trebao imati potpune podatke bazirane na podacima iz svih izvornih sustava.

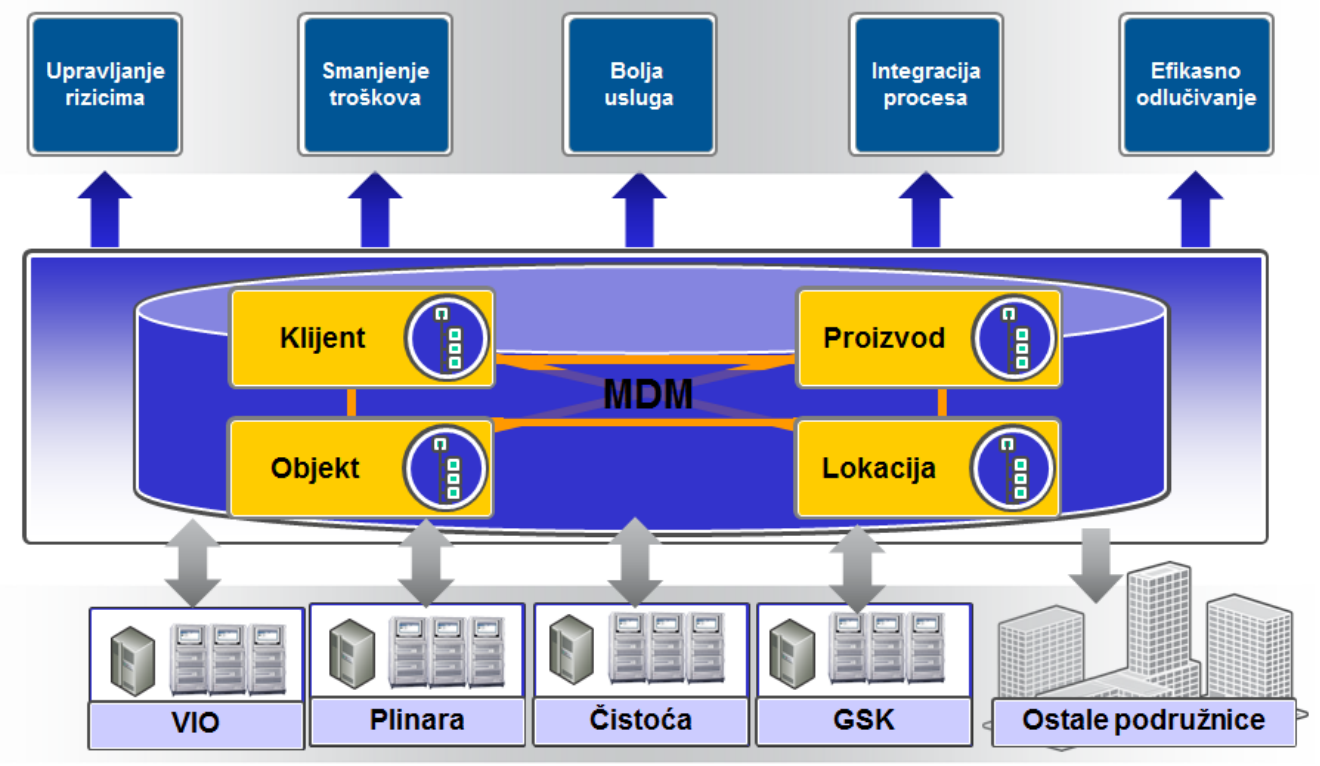
IV. DEFINICIJA FUNKCIONALNIH ZAHTJEVA SUSTAVA

MDM sustav u ZGH idejno je zamišljen na način da podružnice komunalnih djelatnosti mogu unositi i mijenjati matične podatke. Kada jedna od podružnica ažurira podatak, taj podatak se automatizmom ili uz odobrenje upravitelja podataka prenosi u sve ostale podružnice. Matični podaci o klijentima, objektima, proizvodima te lokacije su predmet MDM projekta. Inicijalno je razmišljanje da bi sustavi u ostalim podružnicama bili konzumenti podataka iz centralnog repozitorija.

Ovakav centralizirani MDM sustav bio bi okosnica budućeg sustava za upravljanje odnosima s korisnicima – Customer Relationship Management (CRM) koji bi trebao omogućiti ZGH kvalitetniju i centraliziranu komunikaciju s korisnicima usluga, poboljšanje kvalitete usluge, brže rješavanje problema i otvorenih pitanja, te osmišljavanje, realizaciju i prodaju novih usluga za korisnike.

Na slici 1. prikazan je koncept mogućeg rješenja MDM sustava ZGH.

ZGH želi izbjeći "big bang" pristup, te će početi s osnovnom arhitekturom i faznim pristupom, kako bi se sustavi integrirali korak po korak, s ograničenim brojem atributa i dodavanjem novih atributa u fazama. Izbor arhitekture je vrlo važan jer ima veliki utjecaj na opseg isporuke i konačnu arhitekturu. U dugoročnoj strategiji ZGH, cilj je imati transakcijsku MDM platformu.



Slika 1: Koncept MDM sustava ZGH

Sustavi u podružnicama Vodopskrba i odvodnja, Gradska plinara, Čistoća i Gradsko stambeno komunalno gospodarstvo su u budućem sustavu predviđeni kao „Master" sustavi u kojima se mogu kreirati i mijenjati matični podaci, koji će se u realnom vremenu promovirati u MDM sustav, u njemu obrađivati, te promovirati u ostale sustave. Sustavi u ostalim podružnicama su predviđeni kao „Slave" sustavi koji će razmjenjivati podatke s MDM sustavom u dnevnim batch obradama.

Arhitektura budućeg MDM sustava morat će se uklopiti u postojeću IT infrastrukturu ZGH, biti prilagodljiva i dovoljno fleksibilna da se može proširiti prema budućim potrebama ZGH. Svaki novi sustav, uključujući i MDM, bi se trebao uklopiti u ciljanu Enterprise Service Bus arhitekturu.

V. PRIJEDLOG LOGIČKE ARHITEKTURE SUSTAVA

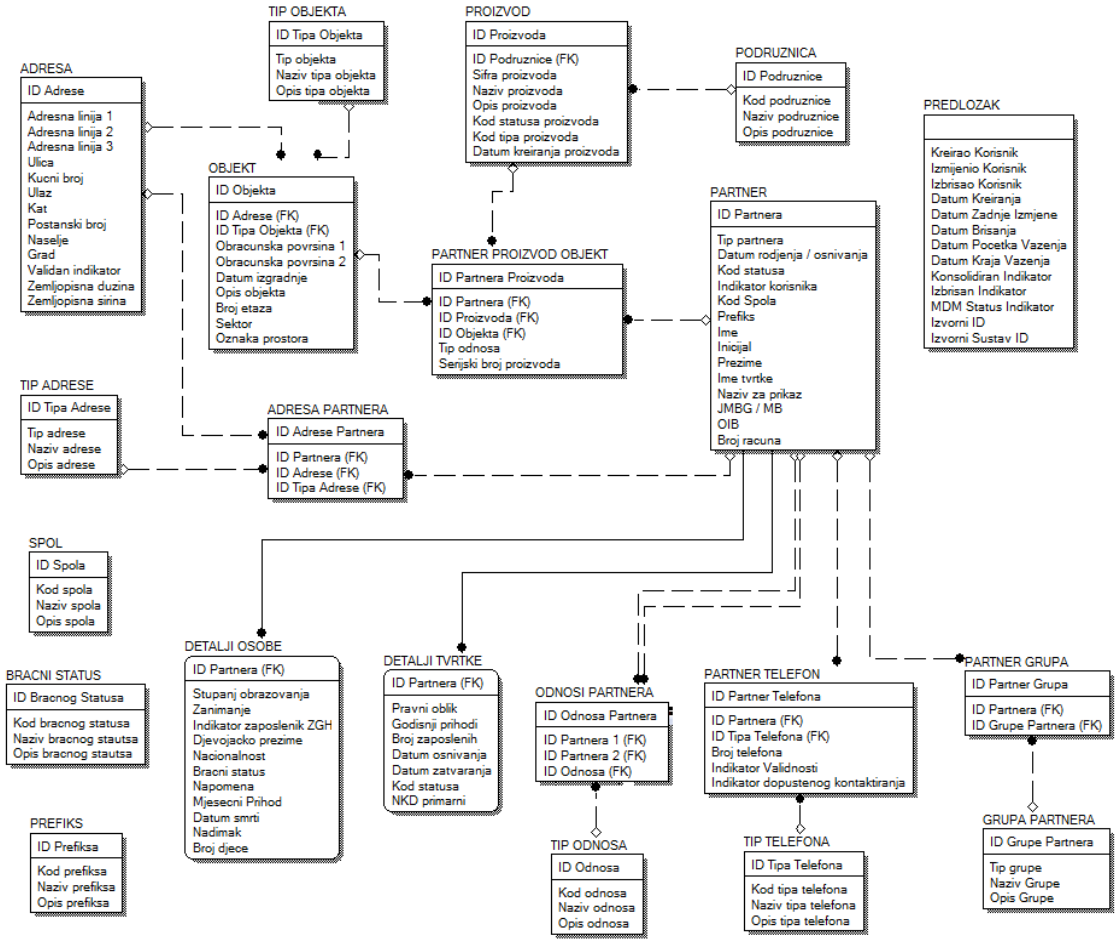
U ovom poglavlju je opisan logički model podataka MDM sustava i predložena arhitektura. Logički model opisuje potrebnu arhitekturu MDM sustava, domena i atributa kojima će se upravljati, a osnova je za definiranje funkcionalnih zahtjeva koji će biti korišteni u procesu odabira tehnološkog rješenja, zajedno sa popisom funkcionalnih zahtheva.

Glavne tablice u modelu su tablice koje sadrže matične podatke i atribute kojima se upravlja za četiri glavne domene (partnere, adrese, objekte i proizvode/usluge).

Odnosne tablice su tablice koje sadrže informaciju o međusobnim odnosima pojedinih matičnih zapisa, bilo da se radi o odnosima unutar iste domene (odnosi među partnerima) ili među različitim domenama (zaduženja, instalacije, vlasništvo nad objektima).

Pomoćne tablice su šifarnici koji određuju vrijednosti koje su validne za pojedine vrijednosti atributa u glavnim i odnosnim tablicama.

Prikaz predloženog logičkog modela podataka s glavnim atributima je na slici 2.



Slika 2: Prijedlog logičke arhitekture MDM sustava ZGH

Ovakav logički model je osnova za dalji razvoj logičkog i fizičkog modela, te nadopunu dodatnim atributima. Ovaj model opisuje arhitekturu podataka u MDM sustavu, a dodatno je potrebno ovisno o strukturi ulaznih podataka i korištenoj platformi definirati model za prihvat i obradu podataka. Fizički model koji će biti implementiran se može razlikovati ovisno o platformi koja će se koristiti. U njemu će biti definiran način praćenja povijesnih vrijednosti pojedinih atributa u primarnim tablicama. U logičkom modelu ne nalaze se ni tablice koje se odnose na korisnike sustava i ovlasti korisnika sustava, ali podrazumijeva se da će buduće rješenje zadovoljavati sve zahtjeve ZGH vezane za sigurnost korištenja.

VI. ZAKLJUČAK

Matični podaci o korisnicima, lokacijama i objektima su istovremeno izuzetno vrijedna imovina i velik operativni problem ZGH.

Način na koji se sada matični podaci održavaju je kombinacija naslijeđenih procesa iz doba prije uspostave ZGH, te implementacije JUP sustava koji se trebao oslanjati na centralizirane matične podatke. Dio matičnih podataka je centraliziran u Registru, dok se dio matičnih podataka održava u informacijskim sustavima podružnica. Podaci koji se održavaju centralizirano u Registru također nisu potpuno ispravni – u mnogo slučajeva ima nepotpunih, duplih i nevalidnih unosa, ponajviše zbog toga što se morao pronaći način za unos podataka kako bi se zadovoljili poslovni i procesni zahtjevi.

Dodatan problem je nedostupnost matičnih podataka koji su u nadležnosti MUP-a (prijave boravišta), Porezne uprave (OIB) ili Ureda za upravu (podaci o rođenima, vjenčanima i umrlima). Također, postojeća regulativa propisuje da se promjene u obveznim odnosima moraju dojaviti ZGH, ali ne predviđa nikakve mjere u slučaju da se ne dojave, pa postoji puno zaduženja koje su vezana na pokojnike i sličnih situacija.

Implementacija MDM sustava će ZGH omogućiti centralizirano upravljanje matičnim podatcima o klijentima, lokacijama i objektima, te proizvodima i uslugama koje ZGH nudi svojim klijentima. Za kvalitetnu implementaciju takvog sustava potrebno je osigurati potrebne infrastrukturne, procesne i organizacijske preduvjete, kako bi takav sustav u potpunosti ispunio svoju funkciju i ostvario predviđena očekivanja.

Empirijsko istraživanje o poslovnoj inteligenciji u Hrvatskoj

Krešimir Futivić (IN2 d.o.o., Zagreb, Hrvatska)
Kresimir.futivic@in2.hr

Sažetak – Tokom 2011. napravljeno je empirijsko istraživanje u RH usredotočeno na ocjenjivanje važnosti funkcionalnosti sustav poslovne inteligencije s aspekta kontrolera. Djelatnici odjela kontrolinga ocjenjivali su niz predloženih funkcionalnosti aplikacija poslovne inteligencije. Osim samih funkcionalnosti istražene su i karakteristike implementacija tih aplikacija. Rezultati pokazuju nekoliko bitnih informacija korisnih kako poduzećima koja namjeravaju uvesti sustav poslovne inteligencije tako i implementatorima tih aplikacija. Prvo – potreban je individualan pristup svakom poduzeću i njegovim potrebama, različite funkcionalnosti često pokazuju bimodalne distribucije (nekima su određene funkcionalnosti važne, a drugima nisu). Drugo – izvještavanje (standardno i po zahtjevu) te usporedba plana i realizacije su daleko najtraženije karakteristike aplikacija poslovne inteligencije. Treće - niz "naprednijih" funkcionalnosti kontroleri ocjenjuju relativno nisko. Četvrto – sustav prava izuzetno je bitan u svim sustavima poslovne inteligencije i korisnici ga redovito ocjenjuju kao važnog.

I. UVOD

U okviru završnog rada na Fakultetu Informatike i organizacije napravljeno je tokom 2011. istraživanje o karakteristikama aplikacija za podršku poslovnoj inteligenciji. Istraživanje je napravljeno u Republici Hrvatskoj a imalo je za cilj pronaći ključne funkcionalnosti koje aplikacije za poslovnu inteligenciju trebaju podržavati. Jedan od najvažnijih ciljeva rada bio je prikaz korisničke perspektive bez zadiranja u tehnološku dimenziju aplikacija (način izvedbe, modele podataka, načine pohrane (OLAP, RDBMS i sl.) Istražen je odnos karakteristika poduzeća i funkcionalnosti aplikacija za poslovnu inteligenciju i to po ocjenama kontrolera te karakteristike projekata uvođenja aplikacija poslovne inteligencije u rad. Sustavi poslovne inteligencije su alat kako menadžera tako i kontrolera. Prije prezentacije menadžeru informacije se najčešće pomno pripremaju i analiziraju. Zadaća kontrolinga je komunikacija s menadžmentom te izvještavanje i proaktivno informiranje menadžmenta pa je time sustav poslovne inteligencije jedan od vrlo važnih alata u svakodnevnom radu kontrolera [1]. Glavni korisnici informacija koje se formiraju u odjelu kontrolinga su menadžeri [2]. Cilj poslovne inteligencije (eng. *business intelligence, BI*) definira se kao „…podrška i unapređenje postupaka donošenja poslovnih odluka u poduzećima" [3]. S obzirom da je to također jedan od ciljeva informacijskog sustava za kontroling, sustav poslovne inteligencije se može smatrati i jednim od najvažnijih informacijskih sustava u odjelu kontrolinga. Pojam poslovna inteligencija načelno ne donosi nešto zaista novo u rad menadžera. Upotreba skupa alata donosi novost zapravo utoliko što su informacije prikupljene i prezentirane na brz i jednostavan način te pružaju znatno šire mogućnosti upita po zahtjevu (eng. *ad-hoc* upita), a time i izvještavanja [4]. Korisnici aplikacija za podršku poslovnoj inteligenciji različito od implementatora doživljavaju važnost određenih karakteristika informatičke podrške pa se empirijsko istraživanje usredotočuje na korisničku perspektivu - što je to što je u aplikacijama za podršku poslovnoj inteligenciji važno, odnosno koje funkcionalnosti su bitne pa su time i važni kriteriji prilikom ocjene kvalitete tih aplikacija. Osim samih funkcionalnosti aplikacije kriteriji za izbor aplikativne podrške ne moraju nužno biti povezani samo sa funkcionalnostima aplikacije, važni parametri mogu biti i karakteristike dobavljača informatičke podrške, troškovi informatičkog rješenja, mogućnosti edukacije i slično.

Ovaj rad prikazati će sažeto rezultate empirijskog istraživanja o važnostima različitih funkcionalnosti aplikacija za podršku poslovnoj inteligenciji te kako bi cjelokupna slika implementacije bila upotpunjena, dati će i kratki prikaz korisničkog viđenja projekata implementacije. Uzorak na kojemu je obavljeno istraživanje je bio namjeran jer je bila želja da se osigura prihvatljiva stopa povrata odgovora, ali i istražiti upravo ona poduzeća koja imaju odjel kontrolinga i prošla su kroz implementaciju aplikacija za podršku poslovnoj inteligenciji. U toku srpnja 2011. poslana je molba da se ispuni upitnik na 67 adresa. Ispunjeno je ukupno 35 upitnika što predstavlja stopu od 52%. Anketni upitnik sadržavao je pitanja podijeljena u četiri grupe. U okviru ovog rada prezentirane će biti grupe pitanja – funkcionalnosti aplikacija poslovne inteligencije i karakteristike projekta. Ostale grupe pitanja bavile su se općim karakteristikama poduzeća te zadovoljstvom korisnika aplikacijama za podršku poslovnoj inteligenciji. Jedna grupa pitanja ispitivala je stav korisnika prema važnostima različitih funkcionalnosti aplikacija, odnosno ispitanici su ocjenjivali koliko su koje funkcionalnosti važne za taj sustav. Ova je grupa pitanja podijeljena je bila u podgrupe koje grupiraju skupove funkcionalnosti u logičke cjeline. Druga grupa pitanja fokusirana je bila na karakteristike projekta i implementatora. Ta grupa pitanja imala je za cilj istražiti tipične slabosti rješenja koje je trenutno u upotrebi. Prikupljanje rezultata realizirano je pomoću web upitnika (google documents). Ciljani ispitanici bili su osobe koje rade kao voditelji odjela kontrolinga ili financijski menadžeri.

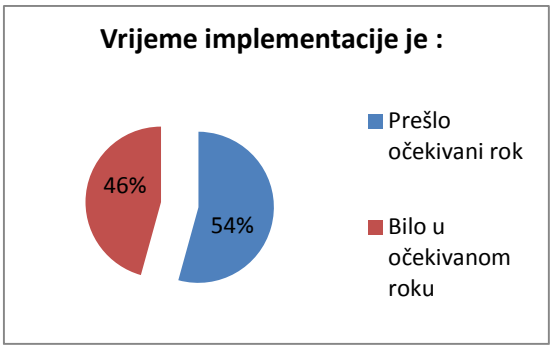
II. IMPLEMENTACIJA APLIKACIJA ZA POSLOVNU INTELIGENCIJU

U okviru empirijskog istraživanja postavljen je niz pitanja ispitanicima o tijeku implementacije i angažmanu implementatora. Vrste aplikacije koje se koriste u kontrolingu su prikazane u tablici I.

TABLICA I. VRSTE APLIKACIJA KOJE SE KORISTE U KONTROLINGU

Aplikacije koje se koriste u kontrolingu:	**%**
Excel ili drugi tablični kalkulatori	28,57
Aplikacija za BI i Excel	28,57
Aplikacija namijenjena podršci BI-u (u okviru ERP-a)	42,86

Na pitanje da li su svi potencijali aplikacije iskorišteni samo 29% ispitanika odgovara da su potencijali aplikacije u cijelosti iskorišteni. To znači da su kupljene aplikacije koje načelno pružaju veći skup funkcionalnosti od potrebnog ili implementiranog. To može biti posljedica niza uzroka od kupnje gotovih aplikacija do loše implementacije itd. Na pitanje o tome je li korisnik u interakciji sa aplikacijom samostalan tj. koliko je aplikacija fleksibilna za svakodnevni rad tek nešto više od polovine ispitanika (54%) odgovara da im nije potreban čest angažman IT stručnjaka u svakodnevnom radu. To znači da skoro pola aplikacija ne pruža korisnicima u cijelosti alat s kojim mogu samostalno rukovati, već im je za obavljanje svakodnevnih poslova potrebna pomoć drugih (IT odjela, dobavljača…). Oko polovina (54%) implementacija aplikacija prešla je predviđeni rok za implementaciju (prikazano na slici 1). S obzirom da je ovo ipak značajan postotak ovim podacima treba pristupiti s nešto više ispitivanja.



Slika 1. Udio implementacija aplikacija za poslovnu inteligenciju koje su implementirane u predviđenom roku

U tablici II. prikazane su vrste aplikacija te podatak o kašnjenju implementacije. Možemo zaključiti da postoje ozbiljne razlike u kašnjenju projekata gdje je sustav poslovne inteligencije integralni dio *ERP* sustava (integrirani informacijski sustav) u odnosu na samostalne projekte. Najme čak 70% samostalnih projekata kasni u odnosu na 40% projekata gdje je sustav poslovne inteligencije podsustav u okviru *ERP*-a. Usprkos činjenici da više od polovine projekata kasni, cijena aplikacija je samo kod 29% slučajeva veća. Može se zaključiti da postoji niz projekata koji imaju fiksnu cijenu. Ipak, činjenica da 29% projekata premašuje inicijalno očekivane cijene je značajan postotak. Jedno od važnih pitanja je bila i ocjena kvalitete prijenosa znanja sa implementatora na klijenta. To se smatra jednim od kritičnih faktora za uspjeh uvođenja i kvalitetu aplikacija u cijelosti. Samo 37% poduzeća ima sva potrebna znanja za korištenje aplikacije. To znači da korisnici često ne razumiju u potpunosti rad aplikacija.

TABLICA II. ODNOS VRSTE APLIKACIJE I ZACRTANIH ROKOVA ZA IMPLEMENTACIJU

Vrste sustava	**Vrijeme implementacije je**	
	prešlo rok	**bilo u roku**
Excel ili drugi tablični kalkulatori	60%	40%
Aplikacija za kontroling i Excel	70%	30%
Aplikacija namijenjena podrški kontrolingu (u okviru *ERP*-a)	40%	60%
Ukupno	54%	46%

III. IZVORI INFORMACIJA ZA APLIKACIJE ZA PODRŠKU POSLOVNOJ INTELIGENCIJI

U istraživanju o izvorima informacija za kontroling i znajući da je kontroling odjel jedan od najvažnijih korisnika aplikacija za podršku poslovnoj inteligenciji pokazuje se da su glavni izvori informacija računovodstvo, prodaja i financije [2]. Tablica III. prikazuje izvore informacija za kontroling.

TABLICA III. IZVORI INFORMACIJA ZA KONTROLING

Red. br.	**Izvori informacija**	**zastupljenost informacijskog aplikacija kao izvora informacija za kontroling**
1.	Računovodstvo	94%
2.	Prodaja	69%
3.	Financije	66%
4.	Nabava	49%
5.	Marketing	20%
6.	Excel	63%
7.	Okolina	23%

Elementi po kojima se izvještava, planira ili analizira (organizacijske jedinice, proizvodi, konta…) moraju biti povezani sa metapodacima i šifrarnicima izvorišnih aplikacija. To znači da ukoliko se u *ERP* sustav unese nova organizacijska jedinica ona se mora (automatski ili po zahtjevu) pojaviti i u aplikaciji za podršku poslovnoj inteligenciji ukoliko ista preuzima organizacijsku dimenziju za potrebe planiranja, izvještavanja ili analize. Usprkos tome vidimo da samo 42 % aplikacija ima u cijelosti automatiziran prijenos potrebnih šifrarnika. U drugom skupu aplikacija treba posebno obratiti pažnju na one sustave koji zahtijevaju u potpunosti manualni pristup prijenosu elemenata dimenzija jer to znači dodatni angažman kontrolera na praćenju metapodataka. Tablica IV. pokazuje zastupljenost pojedinih metoda preuzimanja podataka iz izvorišnih šifrarnika u ispitanima aplikacijama a podršku poslovnoj inteligenciji.

IV. OCJENE VAŽNOSTI FUNKCIONALNOSTI APLIKACIJA POSLOVNE INTELIGENCIJE IZ PERSPEKTIVE KONTROLERA

A. *Funkcionalnosti planiranja*

Kako bi se istražilo po kojim dimenzijama kontroleri smatraju da je nužno omogućiti planiranje ponuđeno je bilo nekoliko tipičnih odgovora.

TABLICA IV. NAČIN PREUZIMANJA ELEMENATA DIMENZIJA IZ IZVORIŠNIH APLIKACIJA

Vrsta sinkronizacije metapodataka:	**%**
Potrebno je ručno dodati novi element u aplikaciju	34
Preuzima taj podatak iz izvorišnog aplikacija	42
Djelomično preuzima nove strukture iz ERP-a	22

Na osnovi dobivenih podataka prikazanih u tablici V. možemo zaključiti da je planiranje potrebno po prihodima i troškovima, kontnom planu i proizvodima što smatra preko 50% ispitanika. Osim spomenutih važno je primijetiti da su još neke dimenzije bitne jer trećina ispitanika smatra da se planirati mora po još nekoj nenavedenoj dimenziji.

TABLICA V. DIMENZIJE U PROCESU PLANIRANJA

Dimenzije u planiranju:	**%**
Prihodi / troškovi	77%
Organizacijska struktura	74%
Kontni plan	63%
Proizvodi	54%
Neke druge dimenzije	34%
Ne treba nužno podržavati planiranje	11%

Na pitanje koliko je važno da su sva poslovna područja pokrivena unutar planskog procesa odgovori ukazuju na bimodalnu distribuciju. Određenom broju ispitanika to predstavlja vrlo važnu karakteristiku (ocjenom 7 ili iznad ocjenjuje to 38% ispitanika) dokle je to ocjenom 3 ili niže ocijenilo 35% ispitanika. Na pitanje koliko je važna usporedba plana i realizacije po očekivanju veliki broj ispitanika to smatra važnim. Čak 63% ispitanika je u gornjem dijelu skale (iznad 5). Funkcionalnost usporedbe plana i realizacije znatno je ispred većine ostalih funkcionalnosti. Ova funkcionalnost donekle spada kako u proces planiranja, tako i u proces izvještavanja i analize (to je mogući uzrok visoke ocjene s obzirom da je to jedan od temelja izvještavanja i analize). Omogućavanje usporedbe plana i realizacije i proces unosa planskih brojeva spada u proces planiranja, dok je sama prezentacija rezultata tog procesa u grupi funkcionalnosti izvještavanje. Nakon prezentacije provodi se proces analize pregledavanjem izvještaja i svrdlanjem (eng. *drill*) po pozicijama koje previše odstupaju od plana kako bi se našli razlozi anomalija.

B. *Funkcionalnosti analize*

U ovom dijelu anketnog upitnika korisnici su ispitani koliko važnim ocjenjuju podršku određenim tipičnim kontrolerskim instrumentima u okviru aplikacije za poslovnu inteligenciju. Tako na pitanje o važnosti 80/20 analize čak 71% ispitanika smatra da je to po važnosti u donjem dijelu skale. Samo 24% ispitanika 80/20 analizu ocjenjuje sa visokim ocjena (iznad 7). Za razliku od 80/20, XYZ analiza još je manje percipirana kao bitna funkcionalnost u okviru aplikacija za podršku poslovnoj inteligenciji. ABC i XYZ (u dimenzijama proizvoda i materijala) analize zajedno su podloga su za strategiju držanja zaliha i proizvodnju. Samo 14% ispitanika XYZ analizu kao funkcionalnost smatra vrlo važnom za aplikacije poslovne inteligencije (ocjenom 7 ili većom). Na pitanje o važnosti funkcionalnosti sustava pokazatelja također veliki broj ispitanika odgovara s malom ocjenom, sa 3 ili manje ocjenjuje tu funkcionalnost 45% ispitanika. Oko polovice ispitanika je u gornjem dijelu skale ocijenilo važnost te funkcionalnosti, a s ocjenom 7 ili većom 32% ispitanika. Posljedica ne izrađivanja sustava pokazatelja je činjenica da nema jednostavnog načina da menadžment na brz i efikasan način može pogledati stanje poduzeća u nekoj dimenziji poslovanja koja ih zanima u tom trenutku, već se to mora raditi kroz veliki broj formalnih izvještaja. Funkcionalnost multidimenzionalne analize točke pokrića veliki broj ispitanika ne smatra važnom. U donjem dijelu skale nalazi se čak 80% odgovora. Posljedica ne računanja točke pokrića po linijama proizvoda, distribucijskim kanalima i ostalim dimenzijama je činjenica da u poduzećima ne postoji jasna slika o profitabilnosti na nižim nivoima zrnatosti (granularnosti) podataka od nivoa poduzeća. To znači da nije moguće usporediti račune dobiti i gubitka tj. izračunati profitabilnost po proizvodu, liniji proizvoda i sl.

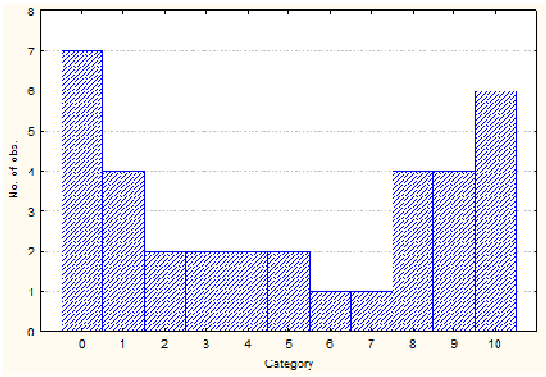
C. *Funkcionalnosti izvještavanja*

Standardno se izvještavanje ocjenjuje jako visokim ocjenama što je očekivano i normalno. To je redovni proces i zadaća kako menadžmenta u ulozi korisnika informacija tako i kontrolera u smislu pripreme informacija na koju se i dan danas troši jako puno vremena. U okviru ankete i rezultata ovog istraživanja to je dobar pokazatelj kako će ispitanici ocijeniti funkcionalnost koja je zaista bitna. Samo 8% tu funkcionalnost ocjenjuje u donjem dijelu skale. Slično kao i redovno, vrlo važnim ispitanici ocjenjuju i izvještavanje po zahtjevu. Visokom ocjenom (preko 7) tu funkcionalnost ocjenjuje polovina ispitanika. Zaključujemo da aplikacije poslovne inteligencije definitivno moraju na kvalitetan način podržavati izvještavanje po zahtjevu jer u suprotnom kontroleri ne bi bili u stanju brzo i efikasno odgovoriti na specifična pitanja. Nadzorne ploče (eng. *dashboard*) funkcionalnost predstavlja korisnički definirani portal na kojemu se nalaze izvještaji (koji su gotovi i već prezentirani) koje je korisnik sam napravio ili mu ih je netko drugi pripremio. Histogram prikazan na slici 2. napravljen na osnovi odgovora o ocjeni važnosti funkcionalnosti nadzornih ploča pokazuje vrhove i u donjem i u gornjem dijelu skale.

Za razliku od redovnog i izvještavanja po zahtjevu funkcionalnost nadzornih ploča je očito nekima jako važna, a isto takvom sličnom skupu je nevažna. To ukazuje na nekoliko mogućih činjenica.

- Neke osobe ne znaju što je to

- To je previše napredno jer se većina vremena troši na standardno izvještavanje
- Redovno izvještavanje (često papirnato) pokriva potrebe i nema potrebe za portalima s izvještajima



Slika 2. Distribucija odgovora o važnosti dashboarda

Na pitanje o automatizaciji slanja izvještaja (izvještaj na mail i sl.) u donjem dijelu skale nalazi se 71% odgovora. Može se zaključiti da ova funkcionalnost nije od presudne važnosti. S obzirom da je većina odgovora u donjem dijelu skale možemo zaključiti da je korisnicima dovoljno dobro imati izvještaje na zahtjev, a da im automatizacija dostave ne predstavlja osobito važnu funkcionalnost. Ipak, treba uzeti u obzir i 28% ispitanika koji ovu funkcionalnost ocjenjuju maksimalnom ocjenom, što opet ukazuje na dva skupa korisnika, onih naprednijih i onih koji se zadovoljavaju sa jednostavnijim aplikacijama za poslovnu inteligenciju. Upozoravanje (eng. *alerting*, automatizirano upozoravanje na predefinirana odstupanja) je posebno nisko ocijenjeno. U donjem dijelu skale je 80% odgovora što je pomalo iznenađujuće. Uzroci tome mogu biti nedostatak znanja o mogućnostima ove funkcionalnosti, nepovjerenje da sustav upozorava i sl. Po autorovom mišljenju rano upozoravanje je vrlo koristan način interakcije aplikacija sa korisnikom korisnika i proaktivna funkcionalnost aplikacija za poslovnu inteligenciju. No za to korisnici očito još uvijek nemaju svijesti o potrebi.

V. OCJENE VAŽNOSTI FUNKCIONALNOSTI APLIKACIJA ZA POSLOVNU INTELIGENCIJU

Funkcionalnosti planiranja (osim pitanja po kojim se dimenzijama može planirati), izvještavanja i analize ocjenjivane su ocjenama 0 – 10. Kako bi se moglo usporediti različite funkcionalnosti aplikacija za poslovnu inteligenciju napravljena je lista koja pokazuje srednje vrijednosti ocjena za svaku funkcionalnost te standardnu devijaciju. Neke od funkcionalnosti ovdje nisu posebno obrađene u tekstu rada, no radi ukupne slike ipak su navedene u tablici IV.

VI. ZAKLJUČAK

Na osnovi liste zaključujemo najvažnije funkcionalnosti su izvještavanje po zahtjevu i standardno izvještavanje, a u okviru izvještavanja najvažnijom je ocijenjena funkcionalnost usporedbe plana i realizacije. Vjerojatno uzroci toj percepciji leže u tome da se na te poslove troši najviše vremena i samim tim se to smatra najvažnijim.

TABLICA VI. RANG LISTA FUNKCIONALNOSTI U SUSTAV POSLOVNE INTELIGNECIJEIMA

Red br.	**Funkcionalnost**	Srednja vrij.	Std. devijacija
1	Standardno izvještavanje (formalni izvještaji)	7,51	2,78
2	Usporedba plana i realizacije	6,82	3,36
3	Izvještavanje na zahtjev	6,28	3,31
4	Mogućnost definiranje prava pristupa po vrsti podataka	6,00	3,53
5	Mogućnost definiranje prava pristupa po strukturi organizacije	5,88	3,83
6	Sva (za poduzeće relevantna) poslovna područja su pokrivena u okviru planskog procesa	5,11	3,44
7	Nadzorne ploče	4,94	3,92
8	Aplikacija zadovoljava paralelne usporedbe više verzija plana kroz cijelu aplikaciju (u analizi, u izvještavanju...)	4,57	3,93
9	Izradu aplikacija pokazatelja (npr. ROI ili druge, za poduzeće bitne pokazatelje)	4,54	4,00
10	Aplikacija omogućava planiranje po načelima menadžerskog računovodstva	4,05	3,78
11	Automatizacija dostave izvještaja (aplikacija sama šalje izvještaj na e-mail),	3,65	3,87
12	ABC, Paretto, 80/20 analizu	3,6	3,81
13	Mogućnost opisa podataka (objašnjenja koja su povezana uz određeni izvještaj ili uz iznose na izvještajima (kako je nastao neki broj i zašto je takav) i sl.)	3,45	3,32
14	Aplikacija ima mogućnost definicije toka radnog procesa	3,11	3,49
15	Analizu točke pokrića i obračun točke pokrića i to po proizvoljnim dimenzijama	2,74	3,60
16	Upozorenja	2,71	3,45
17	XYZ analiza, učestalost nabave	2,14	2,97

Ta se lista uglavnom poklapa i sa listom zadatka kontrolera iz istraživanja „komparativna analiza prakse kontrolinga u Hrvatskoj“ [5]. Za sustave poslovne inteligencije na slijedećem mjestu po važnosti je sustav prava koji mora pružati mogućnosti detaljne dodjela prava po više kriterija za određene korisnike aplikacija. Osim toga na osnovi dobivenih rezultata može se zaključiti da je potreban individualan pristup svakom poduzeću i njegovim potrebama jer različite funkcionalnosti često pokazuju bimodalne distribucije (nekima su određene funkcionalnosti važne, a drugima nisu). Također, važno je primijetiti da niz “naprednijih” funkcionalnosti, često posebno isticanih sa strane proizvođača aplikacija za poslovnu inteligenciju kontroleri ocjenjuju relativno nisko.

PAPERS

Decision Framework for Building Platform as a Service (PaaS) based Government Services

Ratko Mutavdžić
Microsoft Croatia, Zagreb, Croatia
ratkom@microsoft.com

Abstract - PaaS is the operating environment of the cloud with the tools you need on demand to create and host online services, software, Web sites, and mobile applications. With PaaS, you can concentrate on delivering applications rather than on the underlying infrastructure, which a service provider maintains and updates in its data centers. With PaaS, government can develop new applications or services in the cloud that do not depend on a specific platform to run, and you can make them widely available to users through the Internet.

PaaS delivers cloud-based application development tools in addition to services for testing, deploying, collaborating on, hosting, and maintaining applications. The open architecture of PaaS can support integration with legacy applications in the government and interoperability with on-site systems—important considerations because government operates in a mixed IT world. Interoperability gives you the flexibility to take advantage of cloud benefits while retaining data and applications on-site as needed.

This paper will showcase new decision framework model that will enable governments to decide what type of PaaS implementation Government can drive, and what level of flexibility, given the fact described above, that platform needs to have.

I. INTRODUCTION

An increasing number of companies and government organizations are turning to cloud services to increase the productivity of their workforce. We are seeing widespread adoption of cloud-based email services and productivity tools, which enable "always-on" access to emails and files from virtually anywhere. Businesses are also running different applications in the cloud.

Dramatic costs savings are a primary driver and benefit of cloud computing. The reality is that on premise computing can be expensive: you need to buy the hardware and software and pay people to install, configure, test, maintain, upgrade and secure everything. Not to mention real estate, bandwidth and energy costs.

With cloud computing, somebody else manages and maintains these systems, and you pay only for what you use. Using computers in the cloud makes a lot of business sense, but in the long term using the cloud to go beyond business as usual. There are thousands of examples of organizations that have harnessed the power of cloud computing to introduce new services—even build brand new businesses—more quickly and less expensively than ever before. In the public sector, cloud computing has been used to enhance everything from public transportation to healthcare to education and emergency services.

The cloud is really about using massive computing power stored in huge data centers. In cloud computing, data and processing (i.e., storage and computing) are moved out of the direct control of individuals and IT departments and centralized in shared data centers managed by the cloud service provider. This is has important policy implications in areas such as data security, privacy and sovereignty.

II. MAIN CHARACTERISTICS OF CLOUD COMPUTING

Definition by NIST defines Platform as a Service as the capability provided to the consumer is to deploy onto the cloud infrastructure consumer-created or acquired applications created using programming languages and tools supported by the provider [1]. The consumer does not manage or control the underlying cloud infrastructure including network, servers, operating systems, or storage, but has control over the deployed applications and possibly application hosting environment configurations.

Platform as a service (PaaS) is a generally referenced as a middle layer services stack that exists in the cloud environment and that we usually refer as application infrastructure services. Also, that services include technologies of application servers, database management systems, portals, application and data integration, business process management suites, messaging and many other forms of application infrastructure. It is important to note that all those systems must be and they are available in the form of services. [2]

Cloud computing can benefit governments in three areas: increasing national competitiveness, enhancing citizen services and driving down costs. Cloud computing has the potential to catalyze job growth and spur sustained economic growth, in part by facilitating a knowledge economy.

Governments can use cloud computing to engage and inform citizens and organizations more effectively and to deliver enhanced, more efficient services. For instance, cloud computing can improve healthcare by providing broader, more timely access to electronic health records and other medical information. It can provide teachers with new tools that can turn classrooms into more vibrant

learning places. And it can dramatically increase the ease and speed with which people access and share information enabling improvements in everything from roadway maintenance and green living to revenue collection and emergency management.

III. PLATFORM AS A SERVICE AS INTEGRATION PLATFORM

Every modern platform as a service has several main elements that describe the characteristics of the service: compute, storage, application experience, security and identity.

A. Compute

One of the core services for a PaaS environment is compute. In this definition, compute refers to the ability for a developer to deploy and run an application on a platform provided by a vendor. The platform is responsible for ensuring that incoming requests are served correctly to users accessing the application, and adhering to any service level agreements, especially around infrastructure availability. The platform offered to the application provider will normally support one or more programming languages together with a set of core services for invoking the programming code (e.g. pages, background tasks, queues, etc.).

The application provider is responsible for creating a package for deployment which will include the developer's code, any required libraries for the platform, and configuration for that deployment. The PaaS vendor will typically offer a custom set of configuration options which allow the application provider to specify how the application will be deployed (e.g. what locations, how many machines, entry points to the application, etc.).

B. Storage

All applications typically require some kind of storage, and this is also true of applications that run in a PaaS environment. Unlike applications that run on-premise however, storage in in the cloud can take many forms, often optimized for different types of data. These can include one of the following four storage mechanisms:

- Relational Storage. A familiar and well used storage option for many developers is a relational database. Many PaaS vendors offer, or are starting to offer, a relational storage option for developers.
- Non-Relational Storage. One of the drawbacks of many relational storage engines is that they don't scale well across multiple instances. They tend to work well for databases up to a certain size, but for more distributed queries (e.g. querying user profiles on Facebook), an alternative is often required. This alternative tends to be a schema-less, structured store.
- Blob Storage. Many users look to the cloud to store binary data, such as photos, videos, and music. Cloud applications that need to support these types of data often store it using a Blob (Binary Large OBject) Storage mechanism, optimized for storing large amounts of data and often supporting outgoing mechanisms such as streaming.
- Volume Storage. When developers deploy applications to a PaaS environment, they often require access to durable data storage, to prevent data loss in the event that the application or underlying virtual machine is restarted. This is often referred to as volume storage.

C. Development Experience

Development and deployment to a PaaS environment is normally controlled and initiated through the Integrated Development Environment (IDE). The IDE is used to create new projects, write code, and deploy to the cloud environment. This is normally performed in conjunction with a Web based portal. In addition, many PaaS environments include the ability to run a local version of the cloud known as a local development environment. This ensures that the application will work correctly when deployed in the cloud (e.g. security restrictions) without having to actually deploy to the cloud, and therefore potentially running up costs up during the development.

D. Security

If vendors are going to attract organizations to move their business applications to a PaaS environment, demonstrating security for that environment is paramount. Security concerns for many organizations include:

- Physical Security. Does the cloud datacenter conform to security standards such as SAS70 Type II compliance? What are the procedures in place to protect applications from other deployed applications and employees?
- Access Control. Can the application be restricted to a certain number of users or groups? Can access control lists be applied on the data?
- Transport Security. How is the data and network secured between users of the application and the application running in the data center?
- Data Security. How is the data protected when stored in the PaaS environment? What are the encryption techniques? How is integrity of the data maintained?
- On-premise Connections. Does the PaaS vendor offer any solution for creating a VPN between applications in the cloud and applications running in an on-premise data center?

E. Identity

Moving applications from on-premise locations to the cloud often results in challenges with managing user identities. Few organizations want to expose their identity environment externally, yet at the same time many organizations don't want to deal with the management and security concerns of multiple accounts for their employees. To be successful, PaaS vendors must provide an identity solution that enables secure access to applications, with federation options to other identity

stores. When looking at federated identity solutions today, we often find one of two configurations:

- Federation with on-premise. Allows organizations to use their on-premise credentials (for example, Active Directory) to access applications in the cloud.
- Federation with other Online services. Allows users to use the same credentials between multiple online services – for example, the same username and password between hosted Email (a SaaS service) and an application deployed in a PaaS environment.

IV. Decision Framework for Architecture Scenario to be Applied

Regardless of number of possible scenarios that can be used to define the problem and thus apply architecture scenario that will be built on providers cloud computing infrastructure, there is final number of components that could be used to deliver such a solution.

There are four general groups of components and each group has one or two entities that can be used. Some entities can produce more than one instance – increasing the capabilities of specific component group.

A. *Component Group: User (Figure 1.)*

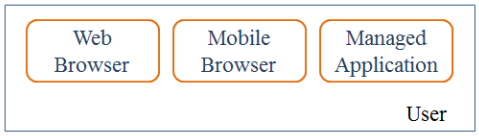

Figure 1. Component group: USER

This component group hosts basic workloads that most of government applications need to have. This group also defines what kind of interface will be used to communicate with PaaS solution:

- Web Browser (requirement that they need to be accessible by browser interface on different computing platforms) imply that application should be built on three tier or two tier model hosed on providers cloud that enables scalability and availability,
- Mobile Browser (requirement that application needs to be accessible through mobile devices) imply that users will use variety of mobile devices that require specific formatting of data and end user elements to enable limited interaction with the end user,
- Managed Application (requirement that application will be built using managed code and hosted on PaaS platform if that is supported by the platform) imply that we need to use the PaaS platform that supports chosen managed language and/or can enable execution in native environment (without virtualization of the code).

B. *Component Group: Compute (Figure 2.)*

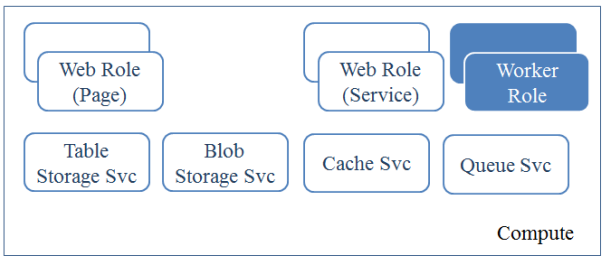

Figure 2. Component group: COMPUTE

This component group hosts computing resources that are used to execute application in PaaS environment. This is usually highly scalable environment and has local components that enable some basic scenarios for execution:

- Web Role (page) (requirement that application communicate with environment through web interface and generate read/write pages that communicate the information) imply that we will implement standard HTTP based services that generate pages using different execution environments depending on operating system and services below,
- Web Role (service) (requirement that we have externally published web services that are accessible by other, third party web services who can relate and communicate the requests for services) imply that we need to build those services implementing standard WS* design (or other applicable) that can expose that services externally,
- Worker Role (requirement that we have internally published web services that are accessible by Web Roles, web services which can relate and communicate the requests for services) imply that we need to build those services implementing standard WS* design (or other applicable) that can expose that services internally,
- Table Storage Service (requirement that we need a storage to temporarily store processed data without need for full persistence of the data) imply that we need to enable mechanisms that will store processed information for single request / session in local storage and that that data can be purged after the request / session terminates,
- Blob Storage Service (requirement that we need a storage and handling mechanism to temporarily store large quantities of binary data that represents different information streams) imply that we need to enable mechanisms that will store processed information here in large quantities for single request / session in local storage and that that data can be purged after the request / session terminates,

- Cache Service (requirement that we need a local cache mechanism that will enable reuse of the data in multiple requests) imply that we need to enable mechanisms that will store information that needs to be accessed frequently and that we know it will not be changed over the specific period of time,
- Queue Service (requirement that we must handle specific requests and objects in specific order, synchronously or asynchronously) imply that we need to enable mechanisms that will track the order, execution and release of specific tasks in specific execution timeframe.

C. *Component Group: Database (Figure 3.)*

Figure 3. Component group: DATABASE

This component group hosts resources that are used to persist the data used in the execution in the storage where that data can be manipulated in the number of ways:

- Application Data (requirement that we need permanent storage for the information objects) imply that we need to enable / use relational, object, hierarchical or integrated data storage model that will persist our data for a specified timeframe,
- Data Services (requirement that we need web services implementation that will enable services to service communication and exchange of persisted data) imply that we need to enable / build WS* standard based services that will open the persisted data through web services and publish the integration interface in defined services catalog,
- Business Intelligence Services (requirement that we need to implement number of services that will perform an analysis and return an insights on the raw persisted data) imply that we need to enable framework that will load, transform and analyze the persisted data in such a manner that it becomes more understandable and enable additional view on persisted data.

D. *Component Group: Fabric (Figure 4.)*

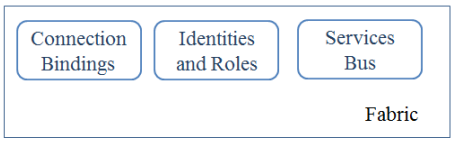

Figure 4. Component group: FABRIC

This component group is one of the most interesting in any PaaS scenario, given the fact that there is an requirement that some of the applications implemented in the cloud must be connected and exchange the data with on premise implementations. For that, we need to implement a number of new services that will enable enterprise style application and data delivery:

- Connection Bindings (requirement that we need a connection mechanisms to enable different technology protocols to connect to application instance) imply that we need to build a endpoints where web services will connect to,
- Identities and Roles (requirement that we need to use models for managing user identities and their roles that will be used in the application and environment) imply that we need to implement security mechanisms that will enable identity management and use of these through roles that will use the application,
- Services Bus (requirement that we need to enable connections between internal applications but also internal and external applications and services) imply usage of service bus mechanism to uniformly access and share services and data through the platform.

V. TYPICAL ARCHITECTURE SCENARIOS IN THE COLUD

Depending on the component groups that are required by the PaaS applications, we can define number of typical applications architectures and patterns that will be used to build the application itself.

To build applications that will maximize benefits, application provider must apply Cloud application design patterns to build systems that exhibit parallelism, multi-tenancy, autonomy, distributed interactions, declarative definitions, separation of concerns, and federation.

Cloud applications are not simply web applications deployed on external provider infrastructure. Cloud applications represent an evolution of the application model away from sequential processing, synchronous interactions, shared resources, and static clusters. There are some core issues that development teams should look at while architecting for the cloud:

- Manage resource capacity to ensure consumer demand is satisfied while maximizing resource utilization
- Scale workload processing and increase performance while minimizing infrastructure spend
- Allocate, provision, monitor, manage, and administer resources across multiple tenants
- Operation's desire to right-size the infrastructure.
- Is the application architecture flexible enough to deploy on any topology while meeting deterministic performance requirements?

Depending on the application model and scenario, there are number of similar architecture questions that drive final decision on what type of architecture should be applied for a specific government application scenario.

A. *Application Pattern: Portal*

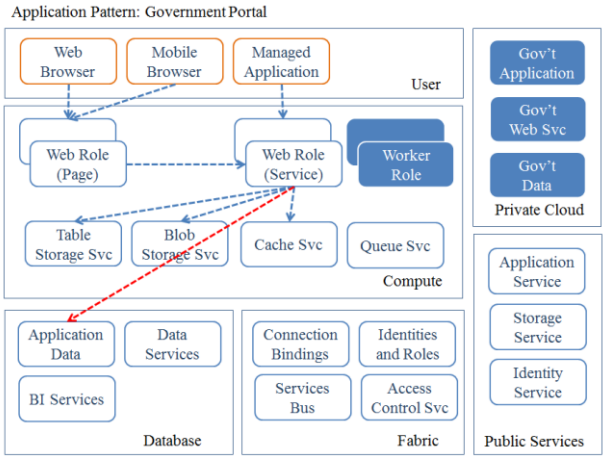

Figure 5. Application Pattern: Government Portal used for high scalability and availability of the services and applications

Host traditional Web apps and interactive apps that compose two or more data sources and services. These include traditional hosted Web applications, emerging composed applications that may utilize two or more data sources and services. These applications need automatic scale-out and scale-down capabilities.

An application like Government Citizes Services Provider is a good example. In such scenarios the organization may be a government agency that wants to spend little capital on infrastructure while being able to handle increasing demand. Or suppose the application's load will vary significantly, with occasional spikes in the midst of long periods of lower usage. An online form for specific government service site might display this pattern, for example, as might news information sites with occasional important stories, sites that are used mostly at certain times of day, and others.

B. *Application Pattern: Transactional Line of Business*

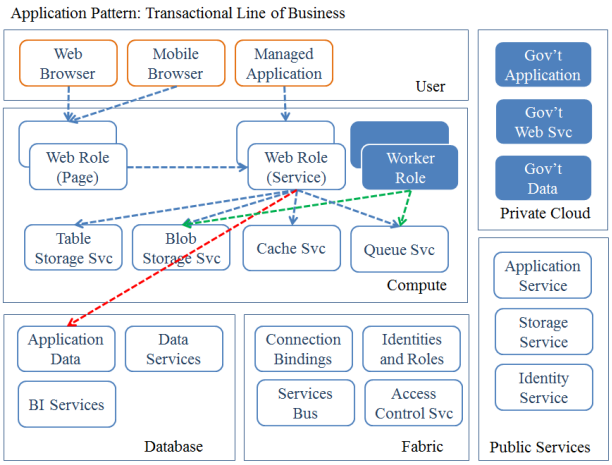

Figure 6. Application Pattern: Transactional Line of Business used for high availablity, 24 x 7, of the services and applications

New applications are trying to continuously innovate and bring feature rich applications to their user base while continually building to differentiate from other and offering solutions in a frictionless manner with lower costs to the end customers.

Typical architecture in this category will follow the traditional 3-tier model with front end-middle tier-back-end database; this kind of an application fits well with the growth pattern scenario; the application can be run as single tenant or multi-tenant where a multi-tenant application will have additional benefit of cost optimizations for running the application.

C. *Application Pattern: Massive Computational Needs (Parallel Computing)*

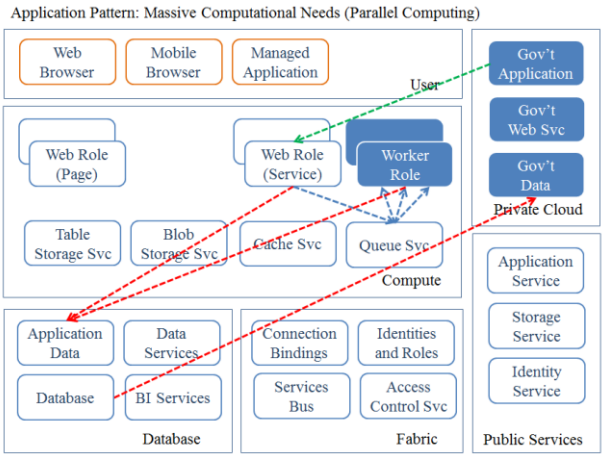

Figure 7. Application Pattern: Massive Computational Needs (Parallel Computing), where we need a high number of parallel computational tasks delivered usualy by worker roles

Large-scale parallel execution of compute tasks. Normally these tasks execute for a short period of time utilizing more compute and storage resources. There are the parallel computing applications that need to perform multiple tasks in parallel so that a huge project can be executed in a short period of time.

There are plenty of examples of this: rendering situational awareness on the battlefield, new drug development in a pharmaceutical company, financial modeling at a government agency, and more. While it's possible to maintain a large cluster of machines to meet this occasional need, it's also expensive.

Cloud computing can instead provide these resources as needed, offering something like an on-demand supercomputer. Again, paying for the one-time-only large capacity that cloud computing can provide is a cost-effective solution.

D. *Application Pattern: Analytical Services*

Large-scale parallel Analytical processing executes various analytical and data mining algorithms over the same data again and again. There are lots of situations where Web-accessible software also needs to initiate work that runs in the background, independently from the request/response part of the application.

Large-scale parallel Analytical processing executes various analytical and data mining algorithms over the same data again and again.

E. *Application Pattern: Building Block Services*

A building block service is an example of a cloud component/service which fills a gap within the platform. Consider a cloud provider which provides monitoring data for services running on its cloud and applications can leverage to automatically scale by increasing or decreasing the number of instances for a particular scale unit within the application.

Now every customer could use the monitoring APIs within their application and build this functionality or an customer could build this functionality as a component that could be leveraged by other customers to scale their solution.

This would be a canonical example of a building block service which by itself has no use or function but once employed within another service can provide significant value.

F. *Application Pattern: Collaboration and Data Exchange*

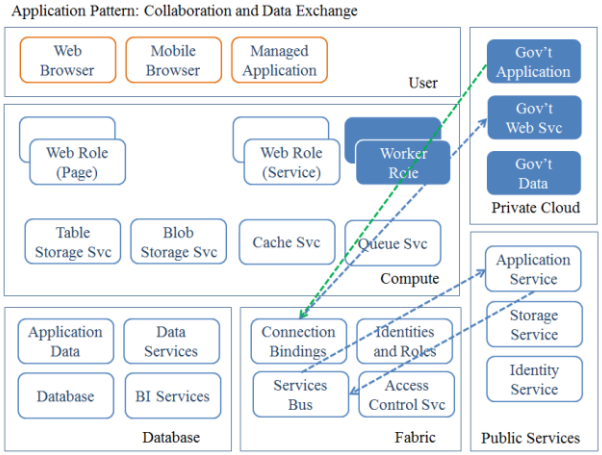

Figure 8. Application Pattern: Collaboration and Data Exchange, we are opening internal interfaces to access the data through web services to enable new scenarios

Service / data sharing between partners and customers: Tis application pattern can have numerous uses such as multi-enterprise integration, B2B & e-commerce applications; supply chain management, health and life sciences and domain specific services.

G. *Application Pattern: Software + Services*

Software + Services represent an industry shift towards a design approach that is neither exclusively software-centric nor browser-centric. By deeply and genuinely combining the best aspects of software with the best aspects of cloud-based services, we can deliver more compelling solutions for consumers, developers and businesses.

H. *Application Pattern: Data Provider*

This is the way for the Government to monetize information as a service, if that is feasible for the Government. There are numerous examples where

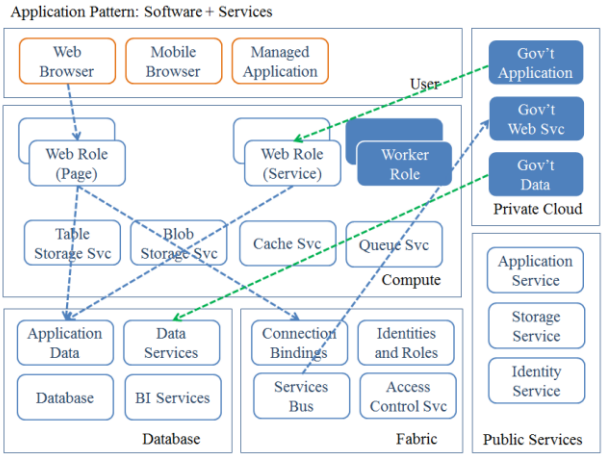

Figure 9. Application Pattern: Software + Services that extend existing on premise infrastructure through services built on cloud computing

governments have datasets which they could potentially license to customers: for example geographical shape files, digital renderers shared with production houses. In such scenarios the government is publishing data to services consumer so that he can use it in any specific way.

I. *Application Pattern: Business Inteligence and Reporting*

Another application pattern involves providing business intelligence as a service. With the advent of data, the ability to provide mining and intelligence on specific datasets is becoming increasingly important for companies to remain competitive and build optimization in their manufacturing, selling and marketing processes.

VI. CONLUSION

With immediate, affordable access to high-power computing resources, organizations can bring to market innovative products faster and more cheaply than ever before. The software economy will particularly benefit because developers everywhere can participate in the global IT market, regardless of the local technology industry infrastructure.

There are number of architecture patterns that can be applied to the effort of building of government or any other application or services. Understanding the requirements of specific end customer but also the capabilities of the services provider, lead to a specific architecture pattern that can be used in building desired solution.

Abstract – This paper presents an example of the combined application of multicriteria analysis and ISO 9126 standards in the selection of the optimal open source GIS software for use in GIS is the local government. Due to the large number of open source GIS solutions, the question of choosing the best open source GIS software in depending on the objectives, is becoming increasingly topical. In particular, the case is in the development of local government GIS, where the quality obtained depends quality of decisions made, and thus the direction of community development. The paper highlights this basic AHP methodology and observed opensource GIS software, and explained the criteria defined software quality standard ISO9126. For example, GIS software of choice the best solution for local government is shown in AHP evaluation process and the observed ranking software. Taking into account the current market trends in opensource, the software monitored, identified those who would in the future should play a significant role.

I. INTRODUCTION

Collection and processing of spatial information is a significant segment of the decision-making process, particularly in the management of resources limited by the local community. Applying information technology in this process of decision-makers were given powerful tools that enable gathering and processing large amounts of spatial data quality and create for a short time. Information systems that enable the processing of spatial data and presentation of an adequate form of treatment called geographic information system (GIS for short). These are five-component information systems make up following components: procedures, people, data, hardware and software. This paper presents one way of selecting the most optimal opensource GIS software used in decision-making in local government.

The first part, that is, the first three chapters present basic information on the AHP method, the open source GIS software that will be evaluated and criteria that can use the parking during the specified quality appraisal software. The second part describes the processes and tools use AHP methods in choosing the most optimal opensource GIS software. Finally, they presented the research results and conclusions.

II. AHP METHOD

Optimal choice of open source GIS software for use in local administration was carried out using multicriteria analysis methods, Analytic Hierarchy Process - AHP. The conceptual and mathematical setting AHP Thomas Saaty gave [1]. This method is a useful and simple method designed to provide assistance to decision makers in solving complex decision problems involving a number of criteria and decision makers [2].

This is a multicriteria technique based on the decomposition of complex problems in the hierarchy. The goal at the top of the hierarchy, while the criteria, subcriteria and alternatives at lower levels. As an illustration, Fig. 1. given is a hierarchy consisting of the goal, the four criteria and three alternatives. The hierarchy may not be complete, for example, element at some level need not be a criterion for all elements in the sub-levels, so that the hierarchy can be divided into sub- hierarchy which is the only common element in the hierarchy.

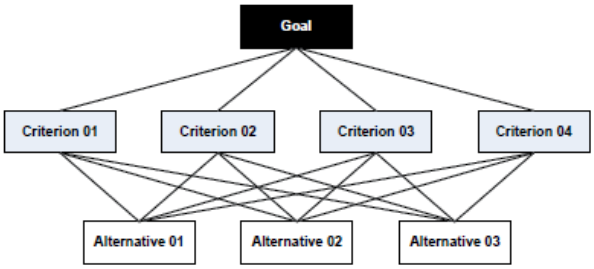

Figure 1. Example of a hierarchy of criteria/objectives [3]

As mentioned establish hierarchical structure, structure of the elements and each other in pairs compared, with the expressed preferences of decision makers with the relevant scale (Saaty's scale relative importance). It has 5 levels and 4 interstage verbally described the intensity and the corresponding numerical values for them in the range 1-9. From estimates of the relative importance of elements appropriate level of the hierarchical structure of the problem using appropriate mathematical model to calculate the local priorities (weights) of criteria, sub-criteria and alternatives, which are then synthesized in the

overall priorities of alternatives. Finally, sensitivity analysis is conducted and deduced.

III. OPENSOURCE GIS SOFTWARE

Open source software is a type of "free" software to be accessed, used or modified by their user groups and developers. There are several organizations that can provide free software license templates, such as General Public License (GPL) and Berkeley Software Distribution (BSD).

The subject of this paper is the optimal choice of opensource GIS software for the GIS community. This problem is particularly significant since we are available to a number of opensource GIS software that are in various stages of development. Analyzing the most usable software listed in the region of Western Balkans as a case assessment were selected following software [5]:

- GRASS GIS (Geographic Resource Analysis Support System) is one of the first open source GIS software. It offers comprehensive GIS analysis functions for both vector and raster datasets. The original user interface of GRASS was in command line only. Quantum GIS GRASS can embed all functions via a graphic user interface (GUI) for easier public use. Multiple data input formats are available, including MySQL, DBF, Post GIS, and SQLite.
- Quantum GIS (QGIS) is a free software desktop Geographic Information Systems (GIS) application that provides data viewing, editing, and analysis capabilities. Quantum GIS (QGIS) provides a very nice integration with Python, a scripting language to automate or customize GIS functions. The software provides useful tools in GIS spatial analysis, geoprocessing, geometry, and data management tasks. Two unique features of QGIS include the linkage (expendable) to GRASS functionalities and the support of DWG file formats.
- KOSMO is one of the most popular open source desktop GIS (Java-based), providing a nice Graphic User Interface (GUI), GIS data editing tools, and spatial analysis functions [6]. KOSMO has improved cartographic and spatial analysis functions from OpenJUMP, providing a friendly and comprehensive GIS package for desktop computers. One major advantage of the capability KOSMO is for users to edit / modify vertices (a very detailed level of segment nodes) in vector-based layers.
- gvSIG was developed by the European GIS community offering multiple language user interfaces. gvSIG has nice vector data editing functions. gvSIG is well known for its flexible GIS data input format. You can use various GIS data formats (both vector and raster) and online resources (such as WMS, WFS and WCS). Some professionals believe that GIS gvSIG is becoming close to replacing ESRI ArcMap software.
- uDig is also a popular Java-based desktop GIS software. uDig offers strong capabilities to integrate Web mapping technologies, such as WMS, WFS, remote ArcSDE, WCS, GeoRSS and KML. The uDig website includes great tutorials and walkthrough documents for first-time users. uDig is built upon IBM's Eclipse platform with a "clean" user interface. uDig GIS provides several good functions, including the Styled Layer Descriptor (SLD) support, Web Catalog Server support, and thematic mapping with advanced symbology.

IV. CRITERIA FOR SELECTION SOFTWARE

To use the appropriate software is essential for obtaining high quality information as a pre-requisite for making decisions effective. This is especially important when making decisions important to the future development of the local community. To ensure proper quality it is necessary to properly execute the specification and evaluation software.

Evaluating software characteristics above stated, in relation to its objectives, was performed based on defined criteria ISO 9126 standard for software quality assessment. This is now one of the most influential standards in software engineering. Its hierarchical structure of criteria and sub-criteria makes it very suitable for the application of the AHP methodology. This standard defines six criteria and 27 sub-criteria to assess the quality of software [7]:

- Functionality - This attribute is defined as the degree to which functions the software satisfies stated or implied needs and can be broken down into five sub-characteristics as follows: suitability, accuracy, interoperability, compliance and security.
- Reliability - This attribute is defined as the capability of software that could maintain its level of performance under stated conditions for a stated period of time. It can be decomposed into three sub-characteristics as follows: maturity, fault tolerance and recoverability.
- Usability - This attribute is defined as the degree to which the software is available for use and can be broken down into three sub-characteristics as follows: understandability, learnability and operability.
- Efficiency - This attribute is defined as the degree to which the software makes optimal use of system resources. It can be decomposed into two sub-characteristics as follows: efficiency of this behavior and efficiency of resource behavior.
- Maintainability - This attribute is defined as the ease with which repair may be made to the software and can be broken down into four sub-characteristics as follows: analyzability, changeability, stability and testability.
- Portability - This attribute is defined as the ability of software that can be transferred from one

environment to another. It can be decomposed into four sub-characteristics as follows: adaptability, installability, conformance and replaceability.

V. EVALUATION OF SOFTWARES

A. *Process of evaluation*

On the basis of the completed surveys and interviews with several municipalities on the territory of Bosnia and Herzegovina, which geographically used information system in their daily work and decision making processes came to the conclusion that the application of GIS software commercial in small municipalities is unsustainable because of the large allocations for its maintenance in relative to their small budgets. The application of open source GIS software is the solution to this problem. However, the problem of implementation of the above software to answer the question "What is open source software that meets the specific requirements of local government?", As the offer of this software is really great.

This paper presents the application of AHP methodology in selecting the best opensource GIS software application at the local level. As for the evaluation criteria were used criteria defined software quality standard ISO 9126. It examined five opensource GIS software that have been identified based on interviews with experts who can base the development of open source modules for use in local communities: GRASS, QGIS, KOSMO, uDig and gvSIG.

To create a model applicable to AHP Expert Choice software, which fully supports the structure hierarchical structure of AHP methodology. The program allows structuring hierarchical model problem in several ways, and also comparing the couples in several ways. A special value of the program give different possibilities for the sensitivity analysis based on the visualization result of the input data changes.

The first step in this process was the definition of the goal. In this study, it was: "The choice of optimal opensource GIS software for use in local government", which is the aim of the research. The second step is to define an alternative. In this study it was five previously selected open source software's GIS (GRASS, QGIS, KOSMA, uDig and gvSIG). The third step is to enter the criteria against which assessment will be done. In this study, it was the six criteria of software quality: functionality, reliability, usability, efficiency, maintainability and portability. Fig. 2. showing workplace Expert Choice 2000, defined the elements of AHP model.

Since the establishment of a hierarchical structure of decision problems is made of elements in mutual comparison levels. Comparison is done in pairs, and compares the node with the higher level nodes of the next lower level. In our study we compared the criteria with a set objective, criteria and alternatives. When it is compared to every member of the lower level with all members of the first higher level. In comparison criteria in relation to the objective of evaluate the importance of that. weight the criteria to achieve this goal. In comparison

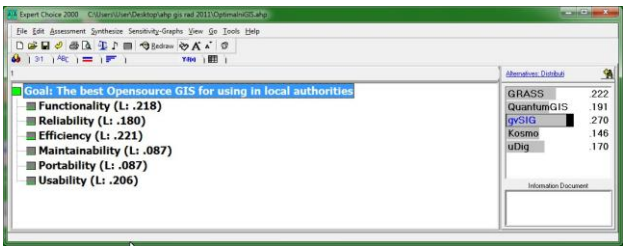

Figure 2. Windows of Expert Choice 2000 software with structured hierarchy AHP

alternative to the criteria evaluates the extent to which the benefits of one alternative to another alternative in comparison to the criterion. For the evaluation used a balanced Saaty scale (Tab. 1.) [8], since a large number of papers showed that the scale increases the reliability of the overall consistency of assessment and evaluation process reduces the waste hierarchy and calculating weight values.

During the evaluation were taken into account the

TABLE I. BALANCED SCALE

Definition	Balanced scale
Equal importance	1
Weak dominance	1.5
Strong dominance	2.33
Demonstrated dominance	4
Absolute dominance	9

comparative analysis of these available software, GIS expert opinion, and accumulated experience and expert knowledge of application technology in the local information Administrative community. Fig. 3. table shows the Expert Choice 2000 environment in which they entered ratings that compare the priority criteria in relation to its objectives. We note for example. functionality to the criteria and have the same usability significance in relation to the goal and put the score 1 (Equal importance), while the functionality significantly more important criteria in relation to the objective criteria than portability and therefore the score is placed 2.33 (Strong dominance).

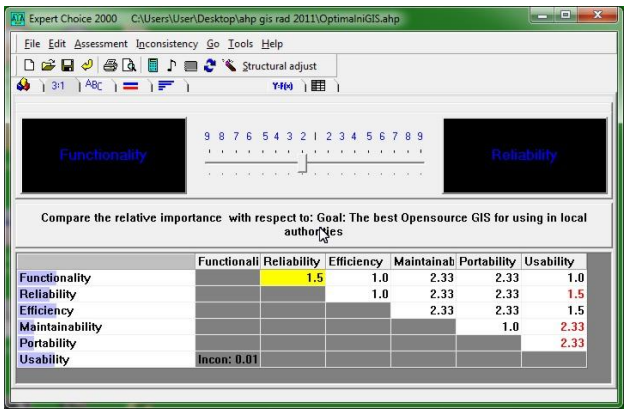

Figure 3. Windows of software Expert Choice 2000 - table with marks

Analogous to evaluate the criteria was performed according to assessment of alternatives, i.e. software in relation to criteria (or sub criteria). Fig. 4. table shows the Expert Choice 2000 environment in which they entered the grades compare alternative features (opensource GIS software) in relation to one of the criteria (e.g., functionality). We note for example. GRASS software that has significantly greater functionality than the software and the data QGIS score 2.33 (Strong dominance). The same software compared to software evaluation is gvSIG 1.0 (equal importance), which means that these two software-the same level of functionality.

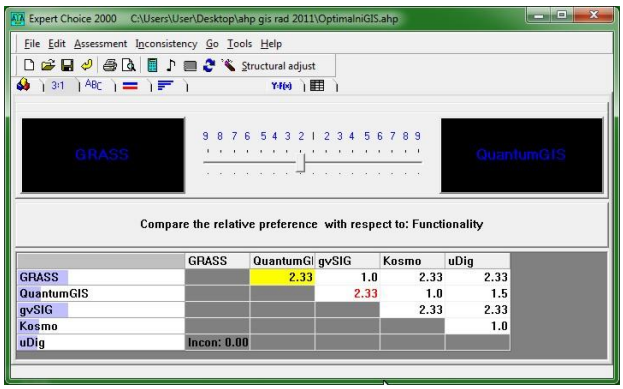

Figure 4. Windows of software Expert Choice 2000 - table with marks

During the assessment it is important to take into account the consistency of the appraisal process. This parameter is very important because any assessment of where a person is an important factor has a significant degree of subjectivity. Expert Choice 2000 software automatically calculates the degree of consistency when you type rating. If the result was sufficiently accurate and there is no need for correction in the reopening of comparisons and calculations necessary to the said level is less than 0.10. In Fig. 3. we can see that the degree consistency is 0.01 which is within tolerable limits.

B. The results of evalauation

Final results of AHP methods are weights of alternatives in relation to the goal, which is the sum of the first the greatest weight ratio is the best alternative, and the smallest - the worst. In Tab. 2. are given by weight coefficients obtained in this study:

TABLE II. RANKING OF ALTERNATIVES

Alternatives	Weight coefficients
gvSIG	0.270
GRASS GIS	0.222
QuantumGIS	0.191
uDig	0.170
KOSMO	0.146

Based on the values obtained by weight coefficients can be concluded that the open source gvSIG GIS software has the highest weight ratio and is most optimal for use in the development of geographic information systems of local governments. Fig. 5. shows a chart on which are displayed ranked software that was subject research and impact on the defined set of criteria aimed research.

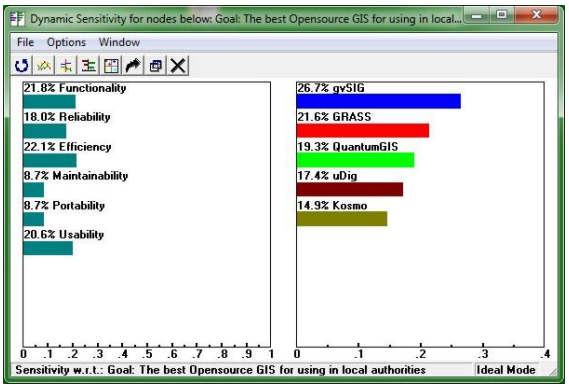

Figure 5 Windows of software Expert Choice 2000 - Dynamic graph

In addition to ranking the alternatives used Expert Choice 2000 software offers a graphical display that allows a sensitivity analysis. For example, what the alternative was the order if certain criteria given greater importance in relation to the goal. The Expert Choice 2000 following charts are available:

- Performance - to compare the characteristics of alternatives (in our example software) with criteria (Fig. 7.).
- Dynamic - allows you to see how to dynamically change priorities alternatives if we change just by dragging the weight of individual criteria
- Gradient - allows you to see how the priorities of alternatives are sensitive to changes of certain criteria (Fig. 6.).
- Head to head - provides an overview of the advantages of one alternative over the other criteria.
- 2D – two-dimension comparison to the value of the two criteria in relation to alternatives.

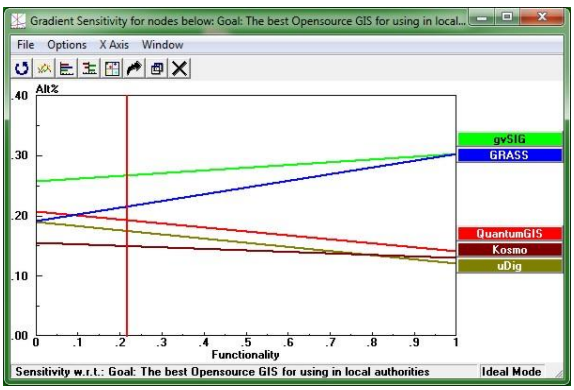

Figure 6. Windows of software Expert Choice 2000 - graph Gradine

In Fig. 6. chart type "gradient" which shows the relationship between functionality and performance criteria that is an alternative. the software. From the diagram it can be seen that the two software GRASS and gvSIG have the best in terms performance functionality software.

This analysis significant especially when the difference between the weights of individual small or alternative simulation of the planned future state where it will get some criteria more important than now. An example of this trend of development of the QGIS software in new versions of a more integrated function of GRASS software. In this way, the software in the future to significantly increase its functionality. In that case, the functionality of the software QIS and gvSIG were the same, and the software then the two had almost the same weight ratio. Fig. 7. shows the ranking of alternatives in these conditions and the impact of increased usability criteria. On the chart shows that in these conditions there were two open source GIS software that meet the optimal conditions for the use of GIS in local government.

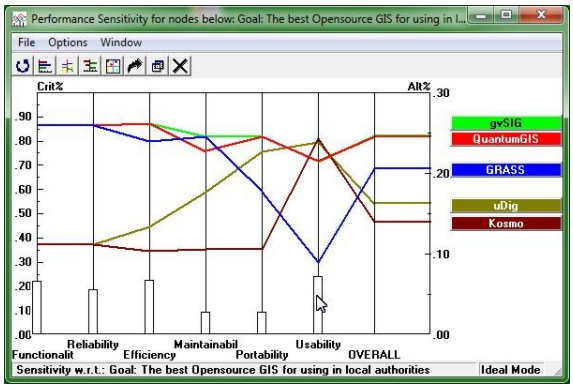

Figure 7. Windows of software Expert Choice 2000 - Performance graph

VI. CONLUSION

Solving the problem of optimal choice of GIS software for use in GIS applications in local government applying appropriate mathematical methods. Since optimal solutions to these problems generally do not exist, this paper applied the multicriteria analysis (AHP method) based on the criteria of ISO 9016 standards.

The presented results of a can't be generalized, but regarded as a representation of a single methodology to solve this problem specifically.

Finally, it can be concluded that the combination of a hierarchical structure of criteria and AHP methodology has proven very successful in the selection of the optimal analyze software. Displayed methodology can be successfully applied to a wide range of problems encountered during the development of GIS.

***Abstract* — The paper defines key terms in this area and described has the modern trend organizations of public service inspection services. Shown are the essential elements of the model of expert system based on fuzzy logic, presented in the case of electronic records of the inspection control. The characteristic of this system is a simple application of expert knowledge. Established is the model of deployment of knowledge in expert system through the checklists and the production's rules. The decision-making mechanisms presented an expert system has a universal character of decision making.**

Unlike the traditional method, conducting the inspection with the assistance of expert systems is suitable for raising the level of quality the inspection control. The procedure of the inspection control is more transparent and objective and subjective errors were reduced to minimal levels

Given the characteristics of the model of an expert system, its application is simple and in other organizations, public administrations and businesses.

***Keywords* — knowledge base, expert system, inspection control, public administration**

I. INTRODUCTION

Informational - Technical (IT) systems are an essential part of management information infrastructure of any economic entity or administrative authorities, which in addition are used for recording, processing, storage everyday and standard business transactions.. The concept of using information technology is based on the assumption that providing the right information to right people at the right time can lead to significant changes in the work of an organization. Today it is impossible to imagine effective business processes without the existence of these systems. Results that are expected of business management information systems are accurate, timely, precise and highly reliable information, which by its content and form appropriate to the needs and requirements management. For making good decisions, it is necessary to introduce a range of information in different ways, and if necessary apply the simulation mechanism by which we can see the consequences of decisions.

The essential feature of modern business is the ability to quickly respond to new customer needs, and constant adaptation to changing circumstances in the environment. Successful management of the organization and tracking of information through the strategic level, management level and operational level implies a continuous monitor running processes and early diagnosis of problems through proper analysis and decision support systems.

U Nowadays, when we are overwhelmed by large amounts of the information's, it is important to distinguish the important from the unimportant, to identify useful sources of information, collect information, analyze it in the context of specific decisions and to deliver results. All this requires the use of professional knowledge, skills and experience in decision quality decisions. Processing this information without expert IT system would be unthinkable, and their task is to provide all relevant information and enable the investigation of impacts of possible decisions. Of course, that should the desired outcome was achieved, needed is a way of setting and effectiveness of business information infrastructure tailored to the needs of business and strategic objectives.

The goal of the introduction of new methodologies, technologies and platforms is the strategic use of information aimed at continuous improvement of business processes. The advantages are realized in part to increase the quality of strategic and operational decision-making, faster decision-making process, ease and promptness to recognize changes in the environment, efficient management of information accessible to employees in the organization, increase competitiveness and profitability, and predicting customer needs for simple business.

Using fuzzy logic in the process of implementation tools for the electronic records of inspection outlook should improve the use of such systems and provide an even better to understand the behaviour of supervised entities.

II. ANALYSIS OF THE ENVIRONMENT

A. The reorganization of public administration

The introduction and application of modern information and communication technologies is one of the priorities within the overall construction and operation of the administrative system in Bosnia and Herzegovina. The basic intention is that, according to changes in economic and political spheres and

reorganization of the overall structure of the management and leadership, establishes important new position, organization and operations of public administration, to ensure faster and cheaper, and better services to citizens. Reorganize the structure of the management system should be made so that the new organization of all services to support the expected changes, which creates a more certain and more modern vision of the future of Bosnia and Herzegovina [1].

Generally, inspection control involves tasks of control and monitoring implementation of the regulations prescribed by the particular social and political community. Inspection control is a very important function in the functioning of the economy and in the functioning of state institutions and public sector in general. A large number of factors have contributed to the necessary use of information technologies in inspection services in order to overcome a series of problems that have burden level of development of inspection systems (planning, managing, executing, monitoring and reporting of inspections, recording of communications, etc.) [2].

The result of the business activities of the inspection service is a set of documents in different formats and on various media: business documentation, project documentation, commercial classical and electronic mail, audio and video recordings, faxes, documents quality systems, contracts, etc. The documentation that is now generated in electronic form is are functionally linked to already existing documents in paper form, and this is the next stage in the process of business inspection services towards overall management and decision making using information technology.

Electronic records inspection controls is a new type of processing inspection controls, according to the tests performed over the Internet, and contacts with local and foreign experts in the field of inspection services, has not confirmed the information that has implemented a project of this form and purpose in neighboring countries or in other European countries [3].

The goal of such systems is designed to establish the so-called intelligent enterprise which combines rational, emotional and spiritual intelligence, and has the ability to analyze and socialization skills. The electronic record becomes also a place where users focus on the rapid distribution of the learning process in order to on the grounds that capitalize the potential of knowledge achieved in the organization. Reduction of the time between learning and teaching could be the best indicator quotient of intelligence in entrepreneurship [4].

B. Informational - Technical Systems

IT systems in technical view can be defined as a set of interrelated components that collect, process, record and distribute information to support decision-making, coordination and supervision in the organization. Construction and management of such systems today, including a much larger part of the organization than in the past. Previous systems produced was technical changes that have acted for only a few people in an organization, while modern systems make managerial changes (who has that information, and to whom, when and how often to take an adequate decision, etc.) and institutional changes (which services are available, under any circumstances, by whom). Considering that organization of public administration move toward "digital organizations", almost all managers and employees in the organization of public administration, as well as users and providers participating in the various systems of government directly or indirectly, all of which are interconnected by a digital informational environment. According to one of the standpoint of [5] modern IT systems organization supported based on information technologies can be divided into: operating IT systems and management IT systems.

Operating IT systems are designed to handle data generated in the business and technological processes, and also provide data and information for business operations. Managerial IT systems occurring as a reflection of the needs management to adequately ensure necessary information for decision making and management [5].

When it comes to IT systems, it is important to emphasize that the purpose of IT systems is reflected in the fact that by using technical support made to the necessary operations with data and information. Therefore, the collection and exploitation of knowledge (data and information) becomes the reason for its existence, not just a useful initiative. In addition, the collected knowledge should be shared so that it exceeds the individual knowledge into the collective knowledge. Accumulated knowledge so represents structured capital that can serve as a springboard for innovation and creating value. To the knowledge functioning, necessary is the knowledge to give explicit and strictly defined rules. Nowadays, organizations must provide the conditions and organizational practices that will enable the sharing of accumulated knowledge. Thus, the sharing of knowledge becomes the most important factor in the internal organization of each organization [4].

III. STRUCTURE IN THE MODEL OF EXPERT SYSTEM

A. Expert Systems

IT systems that include organized knowledge, so that an appropriate level may perform the role of an experienced consultant in the area, represent a system based on knowledge or expert systems (ES). In the available literature may be found different definitions of ES, one of them is that the ES implies this kind of software or software on the computers, which in greater or lesser extent, replaced by man-expert. ES should be able, on the basis of input data and built-in logics algorithms (decision rules) and thus created knowledge base, effectively assisted for users in solving specific problems [6].

ES is a highly complex software package, which consists of a number of smaller software units and modules, and two main parts are: connected modules (interface) and the nucleus of ES (knowledge base and

decision-making modules) [6]. Therefore we can say that the ES based on the knowledge bases, and the quality of the knowledge base and method of making a direct impact on the performance of these systems. Knowledge bases are formed from the factual data (e.g. legislation, documents, etc.) and heuristic knowledge (knowledge which a man acquires based on experience).

Adherence to these methods of classification of information is necessary to form an expert group whose task is to present the knowledge in the form of suitable data structure, so that they can be effectively used in solving problems. In addition, the task team is to encompass as much as possible more data, facts and logical decisions, so that ES can help in finding appropriate solutions in the shortest time. ES must be able to ''learn'' and ''accepting'' new knowledge in areas that include. With the aim to a better knowledge transfer to the users ES, other than the proposed solution, the user always has at its disposal the use of statistical data and intuitive knowledge (called heuristics) [7].

B. Development of the structure model of an expert system

Structure of the model ES starts from the fact that the ES is not designed to gives a final and irrevocable decision, on the one hand, while on the other hand, users must have easy communication with the computer system and the accompanying application. Based on the analysis, it was found that the implementation the data of ES in the observed environment, enabled through the control list (check list) as a module for the interpretation of knowledge. The application of control lists is extremely wide and often in today's informational processing. Way of making these check-lists can be created in different ways and it is difficult to determine the reference model. The obligation of the expert team for drafting the ES was to be used by contemporary developments in the subject area, but also to identify significant results arising from long-standing practice.

In the observed organization of public administration expert team has determined that the preparation of the control list to make the most appropriate combination of legal regulation and business processes within an organization [3]. Or in our case, where was suggested creating the following key elements of the control lists:

- the areas of control;
- groups and subgroups of items control;
- elements of connection to members of the regulations;
- determine the appropriate questions and answers;
- determine administrative, foul, and other measures
- elements of the relationship measures against members of the regulations;
- determine the penalty provisions;
- determine the mechanism of logical decision-making (using rules of type "IF .. $\rightarrow$ THEN").
- identify documents for presentation of the measures; ...

Specified key elements should be properly defined and designed so that they can function as a unit. These elements are used to create a base rules by the method of production's rules. The basic component of this system is the appropriate mechanism for deciding. Otherwise, the mechanism of decision making represents simple programming loops whose task is to determine the authenticity of the conditions and rules to carry out appropriate actions when the condition is fulfilled [6]. The quality of this mechanism depends on the well-chosen control questions, well-chosen answers, and properly conducted of assessment.

Production rules usually are the most popular methods of representing knowledge in the ES, because they are very suitable for the formal presentation of recommendations, directives and strategies, are particularly suitable for the implementation of intuitive knowledge. In the organization of public administration is often used intuitive knowledge, given the specific tasks that are performed in these organizations. Rules are created for all variants and should be presented in a universal form. After that, they can be classified into appropriate fuzzy sets. The next step requires the definition of linguistic variables and defines the area and joins a typical list of adjectives for each linguistic variable [8].

In continue this paper we give examples of decision-making mechanisms that was implemented in the model ES electronic records inspection. We should not forget that the decision-making mechanisms have universal character, and its application can be integrated to other organizations and their IT systems.

Simplest example of decision-making takes place in the case of the control issues when it is established that an entity meets the control law defined obligations specified in question of control. The degree of fulfillment of defined the obligations the user will specify when you create a description of the facts. As an aid in preparing the description of the facts the user can use the knowledge base description of the facts developed as a result of analysis by an expert team, with respect to the area that includes a control issue. Specifically experiential knowledge and practice have shown that the description of the facts in the processing of the same control issues the same or very similar in most cases. However, users of the system can perform the necessary additional correction offered a description of facts and bring additional specifics related to the specific control.

The following example includes control, in which it was established that the observed subject of supervision does not fulfill the obligations prescribed by law and specified in the control issue. Then a mechanism decision-making should provide support to user when decision on taking the necessary measures. . Description of the facts, which is here required, using the logic of decision making referred to in the previous example. For the selection of measures that can be applied in this case, users can use a knowledge base measures. The choice of measures is taking place so that the mechanism of decision-making depending on the importance of the area

of surveillance, the type and nature of the misdemeanor committed, propose appropriate measures to users of the system can take to the subject of supervision in the reference case (eg the area of surveillance, which includes food control or field control, which includes safety employees, etc. are very important, unlike the area of supervision imposed by the general measures for the control subject).

When performing the inspection, it is necessary to take into account that a user of system can get the input data for which is not sure to be completely accurate, or not sure in the data collected from the environment, or there is uncertainty about the degree of relevance to the problem. All these sources of uncertainty must be taken into account during the process of reasoning. The final advice that an expert person given must be qualified certain degree of certainty [6]. Therefore, it is important to address issues in the control users of system is allowed to come into a situation of uncertainty in decision making. Problems of this type are solved by using the mechanism and the factors of certainty, with the task to user of the system provide indicators that will user refer the user that to properly render its decision. The values of parameters in our case can be obtained on the basis of data on pre-treated and control issues and may include the following parameters: the number of inspections, number and type of measures taken, and information about users who have undertaken such measures. In this way, users of the system for correct make a decision have the following possibilities: to introduce one or more factors of certainty, execute an individual insight into the previous control, how to take the decision of another user who is considered to possess significant experience in performing inspections.

The observed ES is based on production rules, which can be applied to the module of abstraction knowledge. The architecture of these modules is based on programs for analysis and synthesis, a common is commonly referred to as mechanism the introduction of information, with the task of to prepare information in a form suitable for logical processing. There are different forms and types an abstraction of knowledge, while common to them all is the general mechanism of learning and independent decision making [6]. Systems for the abstraction of knowledge as a mechanism of decision making can be used by the feedback. The characteristic of these systems is to require that each "new term" pass additional expert test and / or decision-making mechanisms [7].

An example of this form of abstraction of knowledge has been applied in the data generated as a consequence of the description of a particular event, in our case the description of the facts. The task of the expert team to process newly created record in the database, and determines whether the data represent "a new knowledge" in the subject area or are already familiar with the facts.

All elements of the control questions (measures, documents and other consequential measures) should be assigned specific weighting factors that influence the outcome of the review of inspection control. When choosing the weight factors important role has the expert team, and from their knowledge and skills depends on the size, shape and fineness of division weighting factors.

Consider following the example: in inspection control has been processed a certain number of control issues in certain administrative areas. For each question there is a clearly defined answer: that subject supervision or fulfilling or not fulfilling the obligations stipulated by the law, that is control question was properly or disorderly. What can we introduce the following manner:

- IF the subject of control meets the legally prescribed obligations THEN the control question properly; or
- IF the subject control does not meet the obligations stipulated by the law THEN the control question incorrectly.

After processing all the anticipated questions in one inspection control is necessary to determine the state of inspection control. Classical logic, in which are permitted only sharp boundaries between the classes, what it is much farther from the human perceptual mechanisms, rather than this is the case with fuzzy logic. In our case the processing state of the inspection control the application of classical logic would have to choose between two states, that the finding of a neat or messy, or simply put, this outcome points to the fact that all the questions orderly or disorderly. This approach is relatively simplify the actual situation which is obviously imprecise because they are neglected the nuances that exist in carrying out the inspection. From the foregoing, the visible are limits deriving using the classical logic.

Therefore, the definition of key indicators using fuzzy logic contains a classification system that has a truer to reflection of human decision-making process. These systems allow the definition of a range of key indicators using fuzzy logic, which is very close to human thinking and understanding of categorization.

Determining the state of inspection control is based on the input parameters define the following terms: orderly control (OC), partial orderly control (PC), messy control (MC), more messy control (MMC), critical control (CC). This approach provides a finer division of the state of the inspection control. The share of neat and messy questions to assess the inspection control determines are by a team of experts by a number of defined elements. In our case it was found that the inspection control orderly, if control issues witch are messy belong to set (0, 1); partly orderly control if the set (0, 2); messy control if the set (1, 3); more messy control if the set (2, 4), a critical control if the set (3, and more). Figure 1. give provides a way of defining the range of indicators of state inspection control.

The next task is to ES based on the data collected to make a decision about the character of the subject control. Of course, we should define a set of basic data that will on adequate means to make a finer division of character of the subject control.

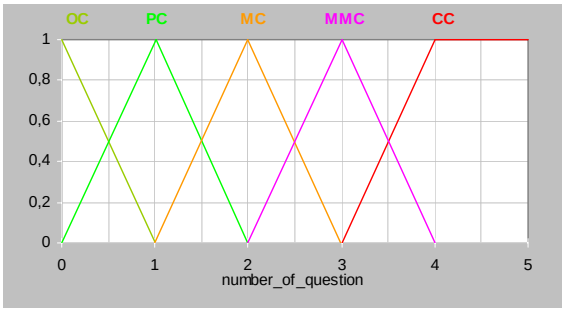

Figure 1. Defining the fuzzy classes level indicator for inspection control

In establishing these categories, except for data on the status of the inspection supervision, an important role has the number and type of measures imposed by the subject control to be met, the degree of compliance with measures imposed, and the collaboration of subject control during the supervision of an authorized person. In a similar way as in the previous case, and here you can import the following expressions for the evaluation of the character of a subject control such as a neat, mostly normal, unknown, messy and risky. Here it should be noted that the estimate of the character of the subject control can not be equated with the status of the inspection control. The model presented the results of the inspection control joins categories that provide further information on the subject control, the inspectors who supervise and control areas. All of the above allows better undertake the planned activities within the observed organization of public administration.

However, the performance of ES greatly depends on the quantity and quality of data used in decision-making mechanisms and decision-makers (the smaller number of data in knowledge bases and provides a low-quality decisions ES) [6]. Therefore, ES has duty registration new cases, creating new rules in the algorithm of learning and preparation for the recording of data in knowledge base.

Knowledge management does not have its final definition it is generally regarded as a process through which organizations create value-added "accumulating knowledge base". The process of accumulation or the formation of such "a knowledge base", respectively values of the organization through the enrichment of its academic resources, involves the sharing of knowledge between employees, organizational units within the organization, thee many different organizations together. Also, an important way of generating knowledge is getting information from clients, through which organization can assess the quality of service, and adapt their internal processes are constantly fluctuating demands of customers [10].

IV. Conclusion

From the viewpoint of public administration timely information, as well as the possibility of successful accumulation, storage and sharing of knowledge, are all important factors involved in creating a public benefit. The process of knowledge sharing takes place between actors in the public sector as well as between public and private sectors, and most importantly, between government and citizens. Besides a good knowledge management will enable the delivery of quality, and adapted public services to citizens, and will create conditions for making decisions that could improve outcomes of public policies. At the same time, the creation of knowledge among citizens about the nature of public policy and action authorities, will contribute to the growth of trust. Especially in the decision-making, in the form of documents or measures, public authorities will often have to deal with complex and chaotic environment, how human society actually is. These challenges will require of decision-makers constant access to new and relevant information and work in a collaborative environment.

In contrast, the bureaucracy have traditionally monopolized and centralized knowledge, and they are it linked by transmitter in the direction up the ladder, instead of that it do of a widely accessible. Logic, however, goes in favor of that maximization of knowledge requires multiplication of common space for the creation of knowledge, of their integration and participation as many as possible number carriers of knowledge, apropos people.

We may conclude that the work of public administration largely boils down to knowledge management and information. Whether it was on the nomination and voting laws, keeping records for the regulation of certain social and economic sectors, to conduct administrative proceedings, or decision-making at all levels within the public administration on adequately available to the reach and speed of data is crucial for its successful operation. In the context of delivery of public services, the knowledge gained through transactions with citizens, will be used to adapt service and changing them according to the demands of citizens.

The task ES is to enable all users of the system using of formalized the knowledge of expert team. The expert team has worked to develop the necessary indicators and their threshold value, belonging to the individual of categories, determining the model rules, the interactions among the rules, and optimization and interpretation of the created model. This team is constantly working on the updating and optimization of a defined model, defining a development strategy in relation to all participants on the basis of the results achieved.

Using modern tools in formalize knowledge of the expert team, this is enabled the development of ES for the Cantonal Administration for Inspection Affairs of Tuzla Canton. Period of development and testing lasted since 2008th – 2009th year. From 2010th year the electronic records of the inspection controls with the use of ES in its entirety applies to all the inspections controls. Using the proposed structural model ES, it is enabled better control and transparency in the work. Also, this system provides very faster and efficient analysis of data on the subjects of surveillance, the number of performed

supervision and the measures taken, etc. On the basis of a number of reporting tables and associated the application and knowledge of the ES, the inspectors have enabled rapid and accurate the inspection control with very little likelihood of making mistakes in creating documents.

A positive result of the quality of the observed ES and its applicability can be verified and the implementation of the same ES in the Federal Administration for Inspection Affairs and any remaining Cantonal Administration for Inspection Affairs in the Federation of Bosnia and Herzegovina. This implementation was done during the 2011th year. The proposed model ES is fully applicable in the real business environment, and what is also recognized by the World Bank Office in BiH. Mention Office has funded the entire project implementation "e-Inspections" in the Federation of Bosnia and Herzegovina.

Using knowledge of the expert team, presented by in the described ES will certainly help in achieving better communication with subjects of the controls, and inspectors. Respectively increasing the quality of inspection controls by structural ES, inspection control is lifted to a higher level and enables to develop a so-called modern (intellectual) Public Administration.

Usklađivanje pravnih sustava zemalja u tranziciji i neizrazita logika

A.J. Klasinc
Vertex projekt d.o.o. i Institut za javnu upravu, Zagreb, Hrvatska
ajklasinc@yahoo.com

Sažetak - U ovom radu razmatra se problematika konvergencije pravnih sustava tranzicijskih zemalja s pravnom stečevinom EU iz perspektive neizrazite logike. U nekim zemljama, osobito anglosaksonske tradicije, vlada "Common Law" sustav, dok u kontinentalnom (francusko-njemačkom) pravu prevladava "Code Law". Po načinu primjene zakona, nalazimo normativističke sustave, utemeljene na pravilima ("rule-based") i sustave utemeljene na načelima i standardima ("model normativne kontrole"; "principle based"). Globalizacija proizvodi fenomen tzv. "postmodernog" ili hibridnog prava. Pravni sustav EU je utemeljen uglavnom na načelima, no u Hrvatskoj je tradicionalno dominantan normativistički sustav. Ako stvar sagledamo sa stanovišta uprave, možemo uočiti da ta dva tipa korespondiraju s dva različita modela uprave - upravom kao strojem i upravom utemeljenom na načelima, gdje je za uspješnu provedbu vrlo važan razvoj odgovornosti službenika (eng. accountability). Budući da službenici ne funkcioniraju strogo algoritamski kao strojevi, neizrazita logika može se koristiti kao metafora za njihovo odlučivanje, što je i logika samog sustava. Budući da se pravni sustavi temelje na djelovanju ljudskog faktora, koji djeluje sebi svojstvenom "neizrazitom" logikom, a ne kao programirani stroj, moguće je stupanj usklađenosti zakonodavstva zemlje s pravnom stečevinom EU prikazati matematičkom formulom hibridnog pravnog sustava, vodeći računa i o donošenju provedbenih propisa i intenzitetu njihove primjene.

I. Uvod

Usklađivanje pravnih sustava tranzicijskih zemalja sa zemljama EU i općenito zapadnim zemljama predstavlja do sada još nepoznat problem u svjetskoj povijesti. Naime još se nikada nije dogodilo da se zemlja svojevoljno usklađuje s pravnim sustavom druge zemlje, ukoliko se ne radi o osvajanju i gubitku suvereniteta. U tom smislu neki danas govore o EU i kao o regulatornom carstvu (regulatory empire), a u svakom slučaju radi se o jednoj od posljedica globalizacije i za zajedničkim okvirom pravila i propisa kako bi se olakšala trgovinska razmjena među zemljama u svijetu. Takva razmjena podrazumijeva određeno odricanje od suverenosti, kako bi se učincima skretanja i stvaranja trgovine na kraju uspjelo doći do pozitivne bilance, od čega u konačnici imaju koristi svi [14]. Međutim, takva drastična promjena sustava u kojoj jedan sustav doslovce penetrira u drugi stvara hibridne sustave, a na globalnoj razini i potencijalno opasne neravnoteže, koje mogu uroditi različitim problemima, pa i krizama. U ovom radu bavimo se načinom kako bi se moglo analizirati prelazak iz jednog u drugi sustav i odrediti stanje pravnog sustava tranzicijskih zemalja uz pomoć teorije neizrazitih skupova, što bi moglo biti primjenjivo i u slučajevima kada je potrebno eliminirati veći broj nepotrebnih zakona i propisa, te kako bi se moglo točnije analizirati moguće posljedice takvih postupaka. Ovaj rad predstavlja određeni korak u tom pravcu, kao teoretska nadopuna empirijskim istraživanjima na konkretnim primjerima, kao što je analiza utjecaja zakona (Regulatory Impact Assessment).

II. PRAVNI SUSTAVI: KAKO IH USKLADITI?

2.1 Tipologija sustava; Code law i Common law

Pravni sustavi na zapadu općenito se dijele na dva tipa: više kodificirani kontinentalni francusko-njemački sustav (*code law*), i anglosaksonski (*common law*), koji oslanja na dugu tradiciju i kvalitetan pravni sustav. Tri velike zemlje kontinentalne pravne tradicije su Njemačka, Francuska i Italija, a anglosaksonski sustav primjenjuje se u Velikoj Britaniji i drugim anglofonim zemljama (u velikoj mjeri i u SAD-u). Drugi sustavi su hibridi ta dva osnovna tipa, od kojih prvi više ovisi o zakonu i njegovim načelima, a drugi o sucima i izvrsnosti sudstva. Premda pravni sustavi ne mogu biti savršeni, oni predstavljaju referentni okvir za suđenje o nekom činu. Osim toga, svaki zakon ostavlja «mračna područja», i suci moraju odlučiti ovisno o slučaju. Mogu se primijetiti jednako važne razlike s obzirom na općenitost koja bi (normativno) trebala biti u temelju sudskih odluka (svih vrsta – kaznenih, građanskih ili drugih). U zemljama romansko-germanske pravne tradicije (kontinentalne tradicije, tzv. «code law»), zakon se treba rukovoditi općim načelima i primjenjuje se izravno na konkretne slučajeve. Sudska praksa kao pravni izvor ima tek sekundarnu ulogu. Svakako, ona utječe na stvaranje pravne doktrine, ali privilegiranu ulogu imaju zakoni, te otuda potječe jaka ideja zakonitosti neke radnje u zemljama kontinenalne pravne tradicije. S druge strane, u anglosaksonskoj tradiciji postoji određeno nepovjerenje u zakone, jer su previše formalni, općeniti i izražavaju načela. Umjesto toga se preferira istraživati konkretne situacije i posebne slučajeve. Slučajevi ili «cases» su

akumulirane konkretne sudske odluke, koje postaoju glavni pravni izvor. Sustav «common law»-a dopunjen je pravnim lijekovima koji se nazivaju *equity*, i koji kompenziraju nedostatke sustava Kada zakon nije funkcionirao, pojedinci su se mogli obratiti izravno kralju kako bi intervenirao. Postoje i razlike između pravne realnosti i pravosudne realnosti. U Njemačkoj, Francuskoj i Italiji pravna realnost je u najvećoj mogućoj mjeri integrirana u pravosudnu. Treba istaknuti da pitanje primjene pravne realnosti ovisi o razini legitimiteta koju nekoj radnji pripisuju oni koji je primjenjuju (službenici, građani i suci), jer velike pravne tradicije ostavljaju određenu diskrecijsku slobodu u ocjenjivanju. Što se tiče zemalja u tranziciji, koje je karakterizirao pojam kolektivnog vlasništva i više «socijalna» nego ekonomska definicija rada, te gotovo potpuno nepostojanje trgovačkog i poslovnog prava u zapadnom smislu, one su privremeno stavljene u situaciju izvan-zakonitosti..[1]

2.2. Normativistički model nasuprot modelu normativne kontrole

Nakon što smo prikazali podjelu pravnih sustava kako si se povijesno pojavljivali u različitim zemljama, treba ispitati jednu drugu podjelu, koja se prije svega tiče smisla neke norme i implicira karakter njene primjene od strane uprave i sudske prakse. Riječ je o sustavima koji su utemeljeni na načelima, za razliku od sustava utemeljenim na pravilima. Izvori oba sustava su poznati, i jasno je samo po sebi da je normativistički sustav stariji, zbog jednostavnosti stvarnosti života u staro doba u odnosu na modernu stvarnost. Proijeklo novca također je u jednostavnim pravilima, gdje je, na primjer, jedan konj vrijedio 10 koza. Na primjer, ako bismo slučajno ubili konja svojeg susjeda, mogli smo ga obeštetiti dajući mu 10 koza za konja. Taj primjer pokazuje vrlo jednostavno pravilo. Također je očigledno da situacije u kojoj pojave koje se uređuju postaju složenije, primjena načela porizvodi konzistentniji sustav od primjene pravila. To se objašnjava time da sukcesivno inzistiranje na preciznosti izoliranih pravila čini složeni sustav pravnih propisa samo nepreciznijim [1] . Drugim riječima, povećavajući parcijalnu preciznost zakona, smanjujemo pouzdanost ukupnosti prava. Osim toga, zakoni se evaluiraju ne osvrćući se na kontekst u kojem se primjenjuju[2]. Ovdje se nameće ključni odabir između obaveznih pravila koje tumače neobavezna načela s jedne strane i neobaveznih pravila kojima kao potpora služe obavezna načela s druge strane.

Postoji i još jedan argument važan za zemlje u tranziciji : procjenjuje se da bi siromašne zemlje imale više koristi od normativističkog sustava, jer bi to bila jedina moguća zamjena za nedostatak ljudskog kapitala [28]. To znači da je uprava i pravosudni sustav koji su vrlo skupi, a bez obrazovanja i stručnih kvalifikacija za upravljanje obvezujućim načelima i neobvezujućim pravilima proizveli bi manju konzistentnosti i pravnu sigurnost od jednostavnog sustava koji bi se temeljio na obvezujućim fiksnim pravilima i neobvezujućim načelima. Svakako, to se ne bi moglo odnositi na Hrvatsku, koja bi uskoro trebala postati članicom Europske Unije.

2.3. Usklađivanje zakona i konvergencija sustava

Već je rečeno da jedan vrlo poseban sustav koji je nastao iz određene tradicije predstavlja prepreku za kompatibilnost takvog sustava s nekim drugim sustavom. Čak i kada ne možemo izbjeći te prepreke, približavanje zakona i konvergencija pravnih sustava je proces koji se odvija u cijelome svijetu, zbog unificiranja standarda i stvaranja jednistvenog svjetskog tržišta. Što se tiče Europske Unije, konvergencija nacionalnih zakona je obvezna i potiče ju Sud u Luksemburgu, ali nije dovoljno samo promijeniti zakone. Varijabla provedbe i primjene treba također biti uključena u formulu konvergencije, kako bismo došli do istih rezultata u smislu javnih politika (*policy outcome*). Naime, ako u međunardnoj perspektivi zakoni postaju sve sličniji, pitamo se da li postoji paralelno takvo približavanje u njihovoj primjeni u različitim zemljama. Ako je to tako, možemo govoriti o stvarnoj (a ne samo nominalnoj, odnosno na osnovi pravila postojećoj) međunarodnoj konvergenciji financijskih propisa. Drugim riječima, samo u slučaju da dvije varijable – propisi i njihova primjena – zajedno konvergiraju, možemo smatrati da ćemo kao rezultat takve politike dobiti kontroliranu konvergenciju. Gotovo svi komentatori prešutno smatraju da, nakon što se otisnu u knjigama, pravila neke Direktive nužno vode prema određenom financijskom uređenju, što ne mora biti slučaj, budući da će različite razine (intenziteti) primjene dovesti do različitih regulatornih rezultata, čak i ako se primjenjuju ista pravna pravila i propisi. Intuitivno osjećamo da ta pretpostavka mora biti dosta vjerojatna. Pretpostavimo da zemlja A i zemlja B imaju iste razine definicija i kazni za insajdersko trgovanje, ali zemlja A uhiti i kazni svakog petog počinitelja tog kaznenog djela, dok zemlja B to učini samo u svakom stotom slučaju. Usprkos jednakim vrijednostima za varijablu pravila, uređenje insajderskog trgovanja u velikoj će se mjeri razlikovati između zemlje A i zemlje B. [12]. Danas je dobro poznato da je 10 zemalja koje su pristupile 2004. i postale nove članice EU ne primjenjuju zakone Acquis Communautairea istim intenzitetom kao i stare zemlje članice EU. Stoga Unija insistira da Hrvatska ne izbjegne uvjetima provedbe Acquisa i da rezultati primjene zakona trebaju biti mjereni putem RIA (regulatory impact assessment), kako bi se osigurao isti intenzitet primjene zakona kao i u EU. Jasno je da bi trebalo uvesti nove standarede mjerenja stupnja usklađenosti hrvatskog

[1]«što omogućava mnoge postupke koji bi se smatrali čistim kriminalom u ostatku svijeta» (Verna, G. i Usunier. J.-C., Rélativite des conceptions éthiques et affaires internationales, 1992)

[2]«Stoga ne možemo razumjeti kada policija zakon sustavno primjenjuje, a kada ne, ako ne uzmemo u obzir činjenicu da je policijska kultura više knjiga priča, nego knjiga pravila. U složenim područjima u kojima policija, inspektori propisa i suci sustavno nameću pravila, rezultat je zbroj njihovih senzibiliteta. Razgovor o propisima koji ističu obavezna načela podržana neobaveznim pravilima iz pozadine, bio bi ...pitanje pravne sigurnosti na tako složenom terenu» (Braithwaite, 2002).

pravnog sustava s EU, o ćemu će biti više riječi govoriti u nastavku rada.

2.4. Problemi postmodernog prava

Proces globalizacije nameće stvaranje novog, postmodernog prava. Fenomen konvergencije pravnih sustava popraćen je također fenomenom njihove transnacionalizacije, odnosno na načelu razvoja upravljanog tržištem, a ne na temelju države[3]. Hrvatska nije iznimka od tih kretanja, i može se također smatrati jednim od primjera tradicije koja iščezava u sukobu s nužnošću olakšavanja trgovine. Jedan od novijih primjera je projekt HITROREZ kojim se brišu kontradiktorna pravila i propisi koji ometaju razvoj tržišta, ulaganja i poduzetništvo. Ključno je pitanje da li se može nastaviti s takvim pozitivnim razvojem u onim dijelovima zakonodavstva koji nisu usko povezani s trgovinom. Prije svega, treba konstatirati da jednostavno smanjivanje, «pojednostavljivanje» ili *streamlining* jednostavnih pravila ne pomaže dovoljno funkcioniranju sustava «normativne kontrole» koji se temelji na obvezujućim načelima, kao što su načela slobodnog protoka roba, kapitala i pružanja usluga, a niti upravnom sustavu. Ta je ideja korisnija u anglosaksonskom sustavu (*common law*), a osobito u sustavu SAD-a, koji je uglavnom utemeljen na obvezujućim pravilima, gdje se načela ne smatraju obvezujućima. Pa ipak, taj postupak bio bi koristan zakonodavcima i siromašnim zemljama koje imaju sudstvo i upravu slabe kvalitete, budući da smanjuje trošak reforme i pravnu nesigurnost u slučajevima kada poznavanje primjene načela u sudstvu i upravi nije dovoljno, i kada se ustalilo primjenjivati obvezujuća jednostavna pravila. Umjesto pukog «dereguliranja» koje proizvodi kratkoročne učinke, ali u konačnici dovodi do ponovnog, još jačeg reguliranja, potrebno je stvaranje učinkovite uprave i upravljanja, prema doktrini dobre vladavine ("good governance")..

2.5. Uloga državnog aparata u izradi i provedbi zakona

Već je rečeno da zakoni u demokracijama imaju jednaku snagu, ili čak i veću od državne suverenosti. Da se poslužimo «mesićevskom» terminologijom, država je samo «hardver», koji omogućava izvršavanje pravnog «softvera», i to neutralno i nepristrano. No, ako previše pojednostavimo stvari, moglo bi izgeldati da državna uprava postoji u stvarnosti odvojenoj od građana, i da demokratska volja građana postaje manje važna od očuvanja birokratskog sustava. Međutim, stvar je upravo suprotna i volja naroda iskazuje se u parlamentu, budući da on ima pravo odbiti zakone koji toj volji ne odgovaraju. Ono što djeluje diskutabilno je da tehnologija moći u modernim demokracijama postaje sve složenija i da građani moraju biti informirani na transparentan i razumljiv način, kako bi mogli iskazati svoju volju. Ako to nije slučaj, radi se o demagogiji, što je u Hrvatskoj čest slučaj. Velik broj hrvatskih građana tako je razočaran demokratskim procesom u Hrvatskoj, da im se čini da političari isključivo prodaju demagogiju. To mišljenje podupire i velik broj novinara, jer novine žive od zanimljivih priča, a ne od istine. Primjena zakona od strane uprave nije toliko zanimljiva, premda svi znaju da «ništa nije onako kako bi trebalo biti», a postoje i skandali koji nam redovito daju informaciju o nefunkcioniranju sudsakog, upravnog i policijskog aparata, kao dijela državne vlasti i uprave koji najizravnije utječe na interese građana. Ako bismo pokušali napraviti podjelu upravnih tipova ili stilova, mogli bismo ih svrstati u dvije kategorije: uprave kao strojevi (normativistički model) i uprave utemeljene na načelima – model normativne kontrole. To upravo odgovara našoj podjeli pravnih sustava, i logično je, budući da je uprava usklađena s pravnim sustavom koji se u nekoj državi primjenjuje.

2.6. Uprava kao stroj naspram uprave koja se temelji na načelima

Problem normativističkog modela je u tome što je odvojen od ljudske stvarnosti. Ako uprave ne uzimaju u obzir razloge zbog kojih neki zakon postoji, moguće je upasti u situacije koje su suprotne namjeri zakonodavca. To djeluje jednostavnije, a načela zakonitosti i pravne sigurnosti su zadržana, no zakoni postoje za ljude, a ne obratno. U jednostavnim sustavima, mogućnost manipuliranja zakonima je smanjena [21], no u složenim društveno-političkim sustavima ta mogućnost postaje realna[4]. Model normativne kontrole omogućava vladama i građanima da poštuju načela umjesto običnih pravila. No, kako bi se došlo do cilja, načela moraju biti jasna onima koji primjenjuju zakone.[5]

2.7. Značaj odgovornosti službenika (accountability)

Odgovornost službenika, odnosno načini kontrole njihova rada, u uskoj je vezi s problemima

[3] Nova *lex mercatoria* globalne akumulacije kapitala, ili pak novi američki rat protiv terorizma, ako su izraz nove globalne kulture, također su i njegove najvidljivije i najdramatičnije manifestacije» (Dorland, M., Postmodern law and translation of cultures, Montreal, 2001)-

[4] Ako se zakon odnosi na usko određenu situaciju, odnosno ako se radi o zakonu «crno na bijelo», koji se temelji na pravilima, onda se ciljevi javne politike zakonodavaca mogu iskriviti vještim izigravanjem zakonskih odredbi. Na interakcije utječe način na koji su zakoni uklopljeni u cjelinu. Zakoni koji se temelje na načelima jasno pokazuju cilj pravnih pravila onima koji ih moraju poštivati, dajući im motivaciju da se usklade s njihovim ciljevima. Zakoni koji se temelju na pravilima samo propisuju određene radnje koje mogu – ali ne moraju – biti izvršene, premda ograničavaju svoju primjenu na određene posebne kategorije aktera. Na temelju pravila, funkcioniranje sustava može jednostavno odgovarati modelu Mintzbergove uprave kao stroja, sa svim ograničenjima koje ona opisuje; na temelju načela, on bi bio bliži modelu normativne kontrole" (Coghill :: 2002).

[5] Poznat je slučaj kada je policija uhitila nizozemskog fotografa kao kriminalca, odnosno pedofila, a pritom ništa nije učinila protiv napadača koji su ga samoinicijativno pretukli, kao i slučajevi u kojima organi reda i zakona ispijaju kavu s osumnjičenicima za teške nesreće ili zločine, dok s druge strane i policija i mediji olako kriminalcima proglašavaju obične građane zbog sitnih prekršaja u prometu ili na temelju nedokazanih tvrdnji o raznim iskonstruiranim zločinima; stoga se čini da u hrvatskoj upravi postoji problem s poštivanjem načela, a ne s poštivanjem pravila.

korupcije i transparentnosti. Ako službenici ne poštuju načela, ili ako su krivi za kriminal, normalno je da bi morali biti suspendirani, smijenjeni ili kažnjeni. No, promjena mentaliteta i sustava je teža i ne može se provesti u kratkom vremenskom roku. Uloga civilnog društva u tom procesu ne može se isključiti, budući da civilno društvo i građani moraju imati svijest o nepravdama i nezakonitostima u društvu i pokretati kampanje, biti glasni, sve dok ne postanu dovoljno važni da ih političari primijete. Uloga međunarodnih organizacija, kao što su USAID ili EU, je pomaganje građanima i jačanje pritiska na političare, kako bi se problemi koje građani razotkrivanju pretvorili u politička pitanja. Taj proces nije jednostavan, jer iziskuje raspravu između svih upletenih skupina, no na kraju se situacija može poboljšati ako je riječ o stvarnom problemu, a ne o politizaciji problema iz drugih razloga. Značaj organizacija kao što je OECD je u tome što one mogu analizirati i davati primjere «dobrih praksi», kako bi pomogli građanima u zemlji koji pokušavaju poboljšati vladavinu/urpavljanje. Čak i kada se čini da je neki sustav transparentan, primjećujemo probleme u njegovom funkcioniranju, kao u slučaju Enrona u SAD-u [3], što kompromitira pravni sustav o kojem je riječ (normativistički).[6]

III. NEIZRAZITA LOGIKA I PRAVNI SUSTAVI

3.1. Neizrazita logika u složenim sustavima

Termin "neizrazita logika" (eng. "fuzzy logic") je izvedena iz teorije «neizrazitih skupova» . Teorija neizrazitih skupova je dio klasične teorije skupova i njima se služimo u neizrazitoj logici. U klasičnoj teoriji, postojanje elemenata s obzirom na skup (×) procjenjuje se u binarnim terminima prema slijedećem uvjetu – jedan element ili pripada ili ne pripada skupu (0 ili 1). Suprotno tome, teorija neizrazitih skupova omogućava progresivno procjenjivanje pripadnosti elementa skupu, što se opisuje pomoću funkcije pripadnosti (ě$A(x)$), koja kvantificira stupanj pripadnosti elemenata x temeljnom skupu (×). Element čija vrijednost postane 0 znači da član ne pripada zadanom skupu, a 1 znači potpuno uključivanje člana. Neizraziti članovi su karakterizirani vrijednostima između 0 i 1 [15]. U neizrazitoj logici riječ je o razmišljanju u aproksimativnim kategorijama koje se ne može u potpunosti povezati s klasičnom predikativnom logikom. Takvu logiku možemo zamisliti kao jednu vrstu primjene teorije o neizrazitim skupovima koja se bavi stvarnim, dobro razrađenim ekspertnim vrijednostima u uvjetima primjene na složene probleme u stvarnom svijetu. [17]. Često određene stupnjeve istinitosti smatramo vjerojatnostima. No ipak, riječ je o različitim konceptima, budući da se neizrazita istina nalazi u neprecizno definiranim skupovima, a ne u vjerojatnosti nekog događaja ili uvjeta. Kako bismo ilustrirali tu razliku, uzmimo u obzir slijedeći scenarije: Ivo je u stanu s dvije povezane sobe: kuhinjom i blagovaonicom. Status Ive unutar skupa «u kuhinji» je posve jasan – on «jest u kuhinji» ili «nije u kuhinji». A što bi se dogodilo kad bi Ivo bio na samom ulazu u kuhinju? Moglo bi se smatrati da je on «djelomično u kuhinji». Kada bismo, na primjer, htjeli kvantificirati to «djelomično» stanje, završili bismo u neizrazitom skupu. Ako bi mu samo jedan dio tijela, recimo stopalo, bio «u kuhinji», mogli bismo reći da je Ivo 90% «u kuhinji», a 10% «u blagovaonici». Niti jedan događaj ne presuđuje da li Ivo u potpunosti «jest u kuhinji» ili «nije u kuhinji» sve dok ostaje na samom ulazu. Neizraziti skupovi temelje se na neizrazitim definicijama skupova, a ne na sreći. Neizrazita logika omogućava u skupu vrijednosti između 0 (uključena) i 1, nijanse sivoga između crnog i bijelog, a u svojem lingvističkom obliku, neprecizne koncepte kao «malčice», «dovoljno» i «puno». Napose, to omogućava djelomično pripadanje nekom skupu. Osnovne karakteristike neizrazite logike su slijedeće: 1) egzaktno znanje smatra se graničnim slučajem aproksimativnog znanja; 2) sve je pitanje stupnja, odnosno metaforički rečeno, «da li je čaša više puna ili više prazna»; 3) svaki logički sustav može postati neizrazit (Boole-ova logika je, stoga, pod-sustav neizrazite logike); 4) znanje se tumači kao skup elastičnih graničnih uvjeta – ili neizrazitih – na nekoj skupini varijabli; 5) Indirektno zaključivanje (inference) se smatra procesom širenja elastičnih graničnih uvjeta. [16]

3.2. Neizrazita logika u društveno-političkim sustavima

Neizrazita logika se koristi za upravljanje strojevima na sličan način na koji je ljudi koriste u svakodnevnom životu. No, taj je termin također i metafora kojom pokušavamo sshvatiti događaje i postupke u vrlo složenim sustavima, gdje su informacije približne ili neprecizne, i gdje postoji značajn udio nesigurnosti i nepoznatoga, kao što je to slučaju u društveno-političkim sustavima. Ovaj se termin također primjenjuje na postupke kojima nedostaje preciznosti, ali u kojima se rezultati smatraju logičnima [3]. Odluke koje ljudi donose drže se iste neizrazite logike, kada vozimo auto ili kada kupujemo akcije poduzeća. Donositelji odluka u politici i trgovini žele vjerovati da se drže stroge logike, no slučajevi kao što je Enron pokazuju drugu stvarnost, koja nije tako precizno definirana. Da su donositelji odluka na različitim razinama upravljanja Enrona pratili točne brojke, odlučili bi da je previše opasno nastaviti u smjeru kojim su krenuli. No, oni nisu mogli analizirati tako veliku količinu informacija, i znali su da postoji drugi sustav, izvan stroge pravne logike, a to je «politička logika», koja im je omogućavala da djeluju na način na koji su uistinu i djelovali. Stoga tranizicija iz jednog sustava u drugi nije jednostavna i ne svodi se samo na promjenu zakona u klasičnom normativnom

[6] "učinkovitost interakcija biva kompromitirana ljudskim ograničenjima – sposobnošću prihvaćanja, obrade i analiziranja podataka. Iz tog razloga, najbolje namjere zakonodavaca, a nesumnjivo i izvršnih organa, tj. uprave, koje su izražene obuhvatnim formalnim pravilima, nisu osigurale – a možda to nisu ni mogle – prikladan karakter postupanja neizrazite logike, pomoću koje ljudski akteri donose odluke i djeluju. Iza svega toga, nalazi se odgovornost (*accountability*), upravo se o tome radi u mnogim aspektima interakcije" (Coghill, 2002).

modelu. Osim promjene institucija, treba također promijeniti i čitav sustav neizrazite logike, učiniti je više «strogom» ili više «elastičnom», kako bi rezultati europskih politika bili isti u zemljama kandidatima (ili onima koje nisu kandidati, ali žele primjenjivati iste standarde) i novim članicama, kao i u starim članicama. Govoriti o problemu korupcije i transparentnosti znači pomoći smanjiti neizrazitost u odlukama odlučitelja u «korumpiranim zemljama», ali budući da je nemoguće izbjeći neizrazitu logiku, koja je jedina ljudska logika, radi se zapravo o pokušaju približavanja neizrazite logike u «korumpiranim zemljama» neizrazitoj logici u europskim zemljama. Takav pokušaj može se u tim zemljama smatrati «nastrajem» strane kulture, «neoliberalnim kolonijalizmom» razvijenih zemalja, i stvoriti probleme nerazumijevanja istinski korisnih inicijativa koje su usmjerene na ekonomski razvoj i korist tih zemalja i njihovih građana[7].

3.3. Vladavina i uloga vlade i javne uprave

Ako želimo raspravljati o primjeni europskih standarda u državama, prvo treba transformirati državnu i javnu upravu. Koncept dobrog upravljanja ne bi puno vrijedio ako tri sektora ili pod-sustava koji međusobno interagiraju ne bi poštivali iste standarde i načela, u prvom redu otvorenosti, sudjelovanja, odgovornosti, djelotvornosti i pravodobnosti i koherentnosti, koja su zacrtana u Bijeloj knjizi o europskom upravljanju, a zatim i načela proporcionalnosti i supsidijarnosti, koja bi tim načelima bila ojačana. Također je potrebno da nacionalne uprave poštuju i opća upravna načela, zasnovana na demokratskim, ekonomskim, socijalnim i pravnim vrijednostima, kao što su odazivnost, transparentnost i učinkovitost, a osim toga, odnosi između tri sektora odvijaju se u tri oblika – preplitanje (interconnection), međuovisnost i interakcija [3]. Stoga transformacija treba početi u vladama i političkim strankama. Treba osigurati da vlada poštuje europske standarde i poznaje europska načela, kao i odvojenost političke od upravne vlasti (makar i kao «séparation souple» ili labavu odvojenost), kako bi se smanjila politizacija i korupcija i društvo preoblikovalo na način da se europske vrijednosti poštuju u cijelom društvu. Transformacija institucija treba početi odozgo, a ne odozdo, jer je riječ o dugotrajnom procesu, te je politička volja i autoritet presudan da bi promjene institucija, pa i na razini neformalnih pravila i postupanja, uistinu bile prihvaćene ne samo u upravi, nego i u cijelom društvu. Osim toga, uprava mora biti reorganizirana i obrazovana na način koji omogućava učinkovitu primjenu europskih normi.

[7]Na primjer, bosanski predstavnik na jednom regionalnom međunarodnom skupu o korupciji izjavio je da zapadni smisao riječi «korupcija» zapravo označava kulturu življenja u Bosni, jer je upravo društvena obveza ljudi biti korumpiran u smislu «zahvaljivanja» doktorima i slično, a ne postoji diskriminacija u primjeni tih «društvenih pravila».Bosansko shvaćanje odgovornosti i sudbine, ukorijenjeno u društvenoj kulturi podrazumijeva i određeni "nemezis", stjecaj okolnosti koji pojedinca oslobađa odgovornosti i krivnje za svoje postupke.

3.4. Neizrazita logika u postmodernim pravnim sustavima i u sustavim u tranziciji

Ako bismo htjeli analizirati pravne sustave koristeći metodologiju koja se temelji na ideji neizrazite logike, mogli bismo reći da ona može naći vrlo korisnu primjenu u postmodernim pravnim sustavima i u zemljama u tranziciji. «Idealan», veberijanski sustav 19. i 20. stoljeća nije smio ostavljati nejasnoće, neizrazita mjesta, a svi zakoni su bili organizirani u normativnom sustavu koji je morao izbjegavati kontradikcije, omogućavajući tako maksimum pravne sigurnosti. U današnje vrijeme ekonomske integracije i stvaranja globalnih tržišta, maksimizirati se mora uklanjanje prepreka za ulagače i poduzetnike, čak i kada to predstavlja da se pravni sustavi moraju prilagoditi toj situaciji, ostavljajući pri tome neke nejasnoće u primjeni. Pretpostavimo li da je hrvatski pravni sustav u trenutku ratificiranja SSP-a bio savršen, bez ikakvih nejasnoća, rupa i kontradiktornih pravila (što nije slučaj, i stoga nejasnoće i kontradikcije treba eliminirati «pravosudnom giljotinom», kod nas nazvanom "Hitrorezom"); Novi zakon koji bi se donio radi prilagodbe pravnoj stečevini promijenio bi tu situaciju, i pravni sustav u svojoj cjelokupnosti više ne bi bio apsolutno logičan i konzistentan. Postao bi hibridan, s mogućnošću kontradikcija s drugim zakonima i propisima istoga sustava. Stoga je potrebno tranzicijsko razdoblje kako bi se sustav «uredio», kako bi postao konzistentan i garantirao pravnu sigurnost. Ako sustav nije konzistentan, pravna praksa mora dati pravi smisao sustavu i njegovim zakonima.

No, kako smo to vidjeli prije, zakon koji se usklađuje s Acquis-om ("*rule variable*") nije jedini kriterij za osiguravanje kompatibilnosti s Acquis-om. Također je bitan i intenzitet primjene ("*enforcement variable*") – funkcioniranje uprave i pravosuđa, koje predstavlja presudan element u ukupnoj formuli. Svemu tome treba nadodati i usklađivanje pravnih propisa, odnosno podzakonskih akata koji su podvrgnuti zakonima – moguće je da prethodni propis (povezan s novim zakonom koji je već usklađen s Acquisom, ali isto tako i propis povezan s nekim zakonom koji još nije usklađen) bude u sukobu s nekim novim zakonom, i da taj novi propis još nije donesen. Možemo se pitati o pitanju prvenstva – usklađeni i neusklađeni zakon su na istoj razini hijerarhijske ljestvice, čak i ako bi zakon trebao biti na višoj razini od propisa, pa čak i ako je usklađeni zakon uvijek recentniji od neusklađenog propisa koji mu je podvrgnut, ipak prednost ima neusklađeni propis koji se nastavlja primjenjivati, sve dok ne bude zamijenjen usklađenim propisom!

Zbog toga predlažem da se sustav učini transparentnijim i jednostavnijim za potrebe analize, tako da svaki zakon postane element (član) u pravnom sustavu predstavljenom kao «neizraziti skup» čije vrijednosti od 0 i 1 bi odgovarale stupnju usklađenosti s Acquis Communautaireom. Kvantificiranje bi nam dalo točniji pojam o stvarnoj situaciji, omogućavajući nam korištenje neizrazitih skupova za matematičke operacije –

izračunavanje kompatibilnosti s drugim pravnim sustavima ili dijagnosticiranje problema koji bi mogli nastati prilikom primjene zakona. To se može opisati jednadžbom (1)[8]:

$$\mathbf{Q_{eu} = Q_{adm}\ x\ (Q_{loi}C_{loi} + Q_{loi}Q_{reg}C_{reg})} \quad (1)$$

Očigledno je $\mathbf{C_{loi} + C_{reg} = 1}$, te dobivamo skraćeni oblik:

$$\mathbf{Q_{eu} = Q_{adm}\ x\ Q_{loi}\ x\ (C_{loi}(1\text{-}Q_{reg}) + Q_{reg})} \quad (2)$$

Na primjer, ako je jedan zakon savršeno usklađen ($\mathbf{Qloi = 1}$) i primjenjiv bez ikakvih provedbenih propisa ($\mathbf{C_{reg} = 0;\ C_{loi} = 1}$), jednadžba se reducira na izraz:

$$\mathbf{Q_{eu} = Q_{adm}Q_{loi.}} \quad (3)$$

Ako to nije slučaj, $\mathbf{Q_{eu}}$ ovisi na jednak način o $\mathbf{C_{loi}}$, kao i o $\mathbf{Q_{reg}}$ – o ponderiranom postotku zakona bez provedbenih propisa u cjelokupnoj zakonskoj normi, kao i o stupnju usklađenosti povezanih provedbenih (podzakonskih) propisa, što znači da u sustavu u kojem zakoni izražavaju više načela a manje točno određene propise, pitanje usklađivanja provedbenih propisa ima veću težinu. Osim toga, budući da vjerojatno postoji vrlo jaka korelacija između $\mathbf{Q_{adm}}$ i ukupne sume $\mathbf{Q_{reg}}$ u pravnom sustavu (i po upravnim jedinicama), logično je da je jedan može izraziti kao funkcija ovog drugog.

IV. ZAKLJUČAK

U ovom radu analizirana je probematika prilagodbe pravnih sustava zemalja u tranziciji sustavu razvijenih zapadnih zemalja i osobito zemljama EU, odnosno pravnoj stečevini (*Acquis Communautaire*). S jedne strane se problemi usklađivanja zakonodavstva mogu gledati sa stanovišta općenite globalizacije pravnih sustava u svijetu (*lex mercatoria*), a s druge i sa stanovišta provedbe, odnosno sa stanovišta uprave koja može funkcionirati kao stroj na temelju strogo definiranih propisa (*rule based*) ili na temelju principa (*principle based*). Budući da je prvi sustav pogodniji za siromašne zemlje, a drugi se koristi u EU, već time je postavljena određena prepreka za prilagodbu tranzicijskih zemalja koje moraju ispuniti uvjete za pristupanje EU i njenom pravnom sustavu. Pojam neizrazite logike u radu s jedne strane koristimo kao metaforu pomoću koje pokušavamo objasniti donošenje odluka ljudi unutar pravnih sustava u tranziciji i probleme koji iz toga mogu proizaći, a s druge strane naglašavamo i mogućnost praktične primjene neizrazite logike u analizi tranzicije pravnog sustava iz polaznog u završni (EU) oblik, te predlažemo formulu za određivanje usklađenosti pravnog sustava zemlje u tranziciji s pravnom stečevinom EU koja bi obuhvaćala i varijablu intenziteta primjene, odnosno kvalitete same uprave koja primjenjuje zakon putem provedbenih propisa, kako bi se obuhvatio i taj dio usklađivanja s pravnim sustavom EU.

[8] Q_{adm} = kvaliteta uprave; Q_{loi} = stupanj usklađenosti nekog zakona s Acquisom; C_{loi} = indeks (ponder) nekog zakona; C_{reg} = indeks (ponder) podzakonskih provedbenih propisa; Q_{reg} = stupanj usklađenosti podzakonskih provedbenih propisa s Acquis-om ; Q_{eu} = stupanj usklađenosti zakona zajedno sa svojim provedbenim propisima s Acquisom

Sažetak - Svrha ovoga rada je analizirati razvoj e-uprave u hrvatskim gradovima, tražeći dokaze u prilog hipoteze da bi e-uprava mogla biti novi način da se poveća sudjelovanje građana u kreiranju javnih politika, te tako poboljša upravljanje na lokalnoj razini. Bitni elementi za to su decentralizacija i organizacijska strukture, organizacijska kultura i ljudski kapital. Hipoteza nalazi potporu u činjenici da je za poduzeća na višoj tehnološkoj razini razvoja bolji decentralizirani način upravljanja s većim sudjelovanjem radnika i većim ovlastima, jer smanjuje razine srednje uprave i širi znanje od nekoliko specijaliziranih na sve radnike, dok je u poduzećama s nižom tehnološkom razinom superioran centralizirani način. To vrijedi i za gradove, gdje bi decentralizirano odlučivanje moglo povećati razinu sudjelovanja građana u kreiranju politika. Slijedi usporedba s modelima kolektivne inteligencije, razvijenima na temelju sličnih modela u prirodi, a koji mogu biti superiorni centraliziranim modelima odlučivanja. Na temelju analize se mogu uočiti dva jasno određena modela razvojne strategije informacijsko-komunikacijske infrastrukture u hrvatskim gradovima: hardverski model (Zagreb) i softverski (Rijeka). Prvi se temelji na vlasništvu grada nad informatičkom infrastrukturom, te tretmanom te infrastrukture kao komunalne a drugi na outsourcingu informatičkih usluga i decentralizaciji upravljanja. Na trenutnom stupnju razvoja hrvatske ICT infrastrukture, drugi je model ipak superioran prvome.

I. Uvod

Elektronička uprava novi je način osiguravanja sudjelovanja građana. Predstavnička demokracija zapravo je nužan kompromis između želje za sudjelovanjem svih u odlučivanju i tehničkih nemogućnosti provedbe takve opcije za veće mase ljudi.

Veliki gradovi predstavljaju poseban problem. Ljudi u njima imaju konkretne probleme koje moraju riješiti – vodovod, škola, bolnica, itd., no teško mogu izravno iznijeti svoje mišljenje pred gradonačelnika. Potrebna je veća decentralizacija, no uvođenjem gradskih četvrti, bivših općina, stvar ne postaje bolja, jer «posrednik» između volje građana i gradonačelnika kojeg oni biraju izravno nema puno smisla[1].

Postavlja se pitanje da li e-uprava postaje novi model decentralizacije, u kojem ne bi bio potreban odnos između «onih gore» i «onih dole» u odlučivanju[2], odnosno koji bi predstavljao put prema kolektivnom odlučivanju. Pravu kolektivnu inteligenciju imaju neka druga stvorenja na našem planetu; na primjer, pčele. Pčela koja treperi krilima na hladnoći nije svjesna da i drugih milijun pčela čini to isto kako bi ugrijale košnicu i sačuvale potomstvo, te osigurale budućnost cijeloj koloniji[3]. Ili, recimo, stado antilopa koje izbjegava vuka nije svjesno taktike koju primjenjuje u tom trenutku, nego nagonski vrše pokrete[4], određujući svoje mjesto u odnosu na druge pripadnike stada, na način koji se uvriježio tijekom milijuna godina evolucije. Ptice ili ribe koje u jatu drže točno određeno odstojanje od drugih ptica čine to isto[5]. Modeli koje nalazimo u prirodi često mogu poslužiti kao inspiracija za modele u ljudskim organizacijama, bilo da služe kao metafora ili predstavljaju neku objektivnu zakonitost [20]. Na isti način, možemo se pitati da li osoba koja odlučuje o nekom konkretnom problemu u svojoj mjesnoj zajednici – novom vodovodu, školi, itd., može imati uvid u veliku sliku potreba cijeloga grada. S obzirom na složenost sustava jednog velikog grada, jasno je da to nije moguće. Također nije moguće da gradonačelnik «dežura na svakom šahtu»[6]. Međutim, su-odlučivanjem velikog broja pojedinaca, uz potporu informatičko-komunikacijskih tehnologija[7], čini se mogućim osloboditi potencijal «skrivenog znanja»[8] cijelog sustava, te doći do boljih rezultata u odlučivanju nego da se planiranje vrši centraliziranim odlučivanjem iz središta moći – ureda gradonačelnika ili gradske vijećnice. U svakom slučaju, mogućnost da građani budu informirani i da svoje

informacije podijele s drugima i s onima na vlasti daje mogućnost dolaženja do boljeg rješenja nego kada bi se odlučivalo bez takve podjele informacija, što je posljedica asimetričnih informacija, koja predstavlja i pogodno tlo za razvoj korupcije. U ovom radu iznijet ćemo osnove elektroničke uprave i sudjelovanja građana putem e-Uprave na primjeru grada Rijeke, kao primjera najbolje prakse, te dati usporedbu sa Zagrebom i drugim gradovima u RH i gradovima u EU..

II. Što je e-uprava i kako se primjenjuje u gradovima

E-uprava obuhvaća sve aktivnosti uprave i nadilazi obično e-poslovanje ili e-trgovinu, te u sebi može uključivati sva četiri glavna područja upravljanja i javne uprave: ekonomske i socijalne programe, odnose s građanima i vladavinu prava (e-demokracija). Temelji se na orijentaciji uprave prema korisnicima pri čemu se informacija tretira kao javno dobro, odnosno pružanju usluga građanima putem novih informacijsko-komunikacijskih tehnologija. To znači da temelj organizacije više nije funkcionalna struktura, kao u klasičnoj upravnoj organizaciji, nego ona postaje orijentirana na usluge, a u skladu s time dizajniraju se i posebni elektronički sustavi koji omogućavaju povezivanje funkcionalnih jedinica u servise, odnosno procese koji za cilj imaju pružanje potpune usluge građanima i tvrtkama, po mogućnosti na jednom mjestu (npr. One-Stop-Shop). Naravno, to zahtijeva potpuno nove vještine službenika i nove odnose unutar uprave i s građanima, te stvaranje novih institucija koje odgovaraju e-Upravi [4].

Postoje u osnovi četiri faze razvoja e-Uprave (i e-Poslovanja), gdje se u prvoj fazi mogu samo dobivati informacije (obične web stranice i e-mail), u drugoj te stranice prelaze u portal koji ima samo funkciju «oglasne ploče», ali postoji jednosmjerna interakcija (mogućnost učitavanja obrazaca, i sl.), u trećoj postoji i dvosmjerna interakcija (autentifikacija, e-potpis), dok u završnoj, četvrtoj, postoji mogućnost potpunog obavljanja transakcija. Hrvatska još nije uspjela doći do četvrte faze. Na temelju istraživanja e-upravljanja/vladavine [22], europske gradove možemo također podijeliti u četiri skupine, na temelju bodovanja raznih vrsta e-Usluga (Slika 1). U prvoj su gradovi u kojima je obuhvaćena većina usluga, s rezultatom većim od 35%, u kategorijama interakcije i transakcije (Beč, Stuttgart, Birmingham, Minhen, Zaragoza, Essen, Barcelona i Sheffield). U drugoj kategoriji ima nešto manje usluga, odnosno s rezultatom većim od 26% u tim kategorijama (London, Dublin, Cardiff, Genova, Koln, Valencia, Glasgow, Edinburg, Amsterdam, Berlin, Madrid i Luksemburg). U trećoj kategoriji prevladava model «oglasne ploče», odnosno mogućnosti interakcije i transakcije su male (Rim, Brisel), dok su u četvrtoj oni gradovi koji imaju najmanji broj tih usluga, gdje je velik broj južnih i mediteranskih, odnosno francuskih, talijanskih i portugalskih gradova (Milano, Lyon, Marseille, Lisabon, te Palermo). Gradovi jugoistočne Europe u skupinama 3 i 4 uklapaju se u tu «južnjačku» sliku kojoj izgleda proturječi Španjolska (osobito Barcelona, koja je zapravo u Kataloniji, koja je gospodarski najrazvijenija španjolska regija s najviše ulaganja), s obzirom da usprkos značajnoj penetraciji Interneta i broju širokopojasnih priključaka, tradicionalna birokratizirana administracija s niskom kulturom odazivnosti i spremnosti na sudjelovanje građana ne omogućava veći razvoj.

Dakle, razlog za slab razvoj e-Uprave nije uvijek samo ekonomske i tehnološke prirode, nego se tiče i načina upravljanja. U gradovima gdje se poštuju vrijednosti «dobrog upravljanja», kao što su transparentnost (razvidnost), odazivnost i odgovornost, a pogotovo vrijednosti koje ulaze i u domenu klasične uprave – poštivanje ljudskih prava i vladavine prava [14], lakše će se razvijati e-uprava, za razliku od gradova u kojima vlada autoritarna upravljačka kultura i netransparentnost, koja može ići i do «zakona šutnje». Modeli upravljanja koji se povezuju s e-upravom dovode do veće decentralizacije odlučivanja, a pretpostavlja se da bi se time trebala ostvariti i veća demokracija (o načinima upravljanja u e-upravi i decentralizaciji bit će riječi u slijedećem, trećem poglavlju). U Hrvatskoj u razvijenosti e-uprave prednjači Rijeka, koja već možda ulazi u drugu skupinu gradova, a slijedi je i Varaždin, no model Rijeke ne slijede svi hrvatski gradovi – osobito Zagreb ima drukčiju strategiju razvoja, a slijedi ga i Split. Ove modele detaljnije ćemo analizirati u poglavlju o empirijskoj situaciji s e-upravom u gradovima.

III. E-uprava i decentralizacija

Nije sigurno je li decentralizacija uvijek korisna. Postoje mnoge manje države koje nisu provele značajnu decentralizaciju, a funkcioniraju učinkovitije i ekonomičnije od vrlo decentraliziranih ili federalnih država. Uzmimo, na primjer, Irsku. U svakom slučaju, velike države poput bivšeg Sovjetskog saveza, sa sustavom centralnog ekonomskog planiranja (tzv. GOSPLAN) gdje se o svemu odlučivalo iz Moskve, također se ne doimaju previše učinkovitima[9]. No, moguće je da se čak i u tom slučaju veća decentralizacija u jednom trenutku mogla pretvoriti u dezintegraciju, s obzirom da se radilo o državi s izuzetno velikim brojem

[9] za analizu problema upravljanja i decentralizacije, v. također K. Kelly, Out of Control, op.cit., Poglavlje 3

različitih naroda, pa i plemena, razbacanih po ogromnom i slabo povezanom teritoriju. Nedavno je jedan nizozemski autor iznio argument da su veliki radovi na preusmjeravanju čitavih riječnih tokova u SSSR-u, te isušivanje dijelova Kaspijskog jezera, ustvari bili motivirani željom za centralizacijom vlasti, jer je takve radove moguće izvršavati jedino uz suradnju svih dijelova države i mobiliziranjem velikog broja radnika iz različitih krajeva države[10]. Za usporedbu, autor navodi stari Egipat, odnosno primjer velikih radova na rijeci Nil, što bi možda moglo objasniti i važnost, odnosno potrebu izgradnje piramida u Egiptu. U slične svrhe nastala je u vrijeme željezne zavjese i predsjednička palača u Rumunjskoj, u koju je posljednjih godina prije pada komunističke vlasti utrošena enormna količina luksuznih materijalnih sredstava, dopremanih iz svih dijelova te zemlje, a poneke proizvodne grane postojale su isključivo u svrhu izgradnje te palače. Premda je tijekom gradnje bilo potrebno razoriti cijele gradske četvrti među kojima je bilo i kulturnih vrijednosti, a sve to naravno bez ikakve konzultacije s dotičnim građanima koji su tamo obitavali, danas ta građevina nema nikakvu praktičnu svrhu, a često je i predmet sprdnje, izazivajući i određenu jezu svojom nezasluženom impozantnošću i jednoobraznim stilom[11]. I u nas u XX. stoljeću ima takvih primjera integracije putem nepotrebne ili upravo apsurdne mobilizacije, recimo poput obaveznog služenja vojnog roka, izgradnje politički motiviranih tvornica bez ekonomske logike, itd. Nasuprot toj logici nametanja volje iz centra radi veće integracije, model Europske unije želi ostvariti veću mobilnost poticajima, odnosno programima sveučilišne razmjene i suradnje (npr. TEMPUS) i partnerstvima u komercijalnim i istraživačkim projektima, odnosno programima kao što je Okvirni program (FP7). Svrha navođenja prethodno navedenih primjera je ukazivanje na činjenicu da decentralizacija ipak obično ide korak u korak s demokracijom, bez obzira što i na lokalnoj razini, osobito ako je riječ o kulturno zaostalim ili gospodarsko-financijski nerazvijenim sredinama, mogu opstojati mali lokalni autokratski vladari.

U privatnim tvrtkama decentralizacija se pokazuje učinkovitijom od centralizacije jer decentralizacija odlučivanja smanjuje potrebu za većim brojem hijerarhijskih razina i srednjih menadžera, što cijeli sustav čini učinkovitijim. U takvom sustavu znanje nije lokalizirano kod specijaliziranih radnika, nego svaki radnik sudjeluje u učenju, komunikacija i uključenost se poboljšavaju, raste motivacija radnika, te se smanjuje opasnost od pritužbi i nezadovoljstva koji smanjuju učinkovitost. No ipak, to ne važi za sve slučajeve. Tvrtke na niskom stupnju tehnološkog razvoja efikasnije su kada primjenjuju centralizirani model odlučivanja [11]

Ukoliko bismo ovaj poučak primijenili na e-upravu, jasno je da već samo uvođenje informacijsko-komunikacijskih tehnologija u lokalna upravna tijela podiže tehnološku razinu, pa bi samim time morala rasti i efikasnost odlučivanja. Ako bismo se vratili na primjer «kolektivne inteligencije roja» iz uvoda, zamislimo pčele koje trebaju naći najbolje mjesto za košnicu od ponuđenih nekoliko. One će u tom slučaju poslati izvidnicu, a svaka pčela će izvoditi određene karakteristične instinktivne pokrete iznad mjesta koje joj se najviše svidi kako bi privukla druge pčele. Kada dovoljan broj pčela, recimo oko petnaest, bude izvodio takav «ples» iznad jednog od mogućih mjesta sve će se pčele premjestiti na njega. Takvi modeli se lako mogu primijeniti i u ljudskom odlučivanju, recimo kad se *brainstormingom* utvrdi više ideja, pa se zatim tajnim glasanjem odabere jedna od njih kao najbolja. Ako bismo sad usporedili pčele s građanima velikog grada, vidjeli bismo da građani imaju također potrebe, ali drukčije: moraju odrediti najbolje mjesto za školu, urediti kanalizaciju, vodovod, promet, javni prijevoz i slično. Za razliku od pčela, neće izvoditi trbušni ples, nego će svoje glasove za određeno rješenje dati elektronskim putem. Da li je ta metoda učinkovitija od tradicionalnih izrada GUP-a, evaluacija, i sličnog? Ako bismo zaključivali na primjeru kladionica koje primaju oklade za konjske utrke, onda bismo se s time morali složiti, jer, omjeri klađenja gotovo nepogrešivo predskazuju konačni redoslijed konja u utrci. To znači da kada se zbroji ukupno znanje svih ljudi koji se klade, dobivene vjerojatnosti daju najtočniji rezultat, u pravilu točniji nego kad bi rezultat određivala skupina stručnjaka za konjske utrke ili uprava kladionice[12]. Mogućnost korištenja takvog «skrivenog znanja» u velikim gradovima omogućila bi velike uštede i olakšala upravi grada odlučivanje. No, postoji i preduvjet za ostvarivanje te koristi; naime potrebno je da svaki građanin bude pošten, samostalan, razuman i da nezavisno donosi svoje mišljenje. Ukoliko se prosudba donosi pod utjecajem raznih «lobija», «klanova» i slično, ona neće biti tako dobra, o čemu se možemo osvjedočiti na primjeru glasovanja u nekim TV programima. Takav način odlučivanja otvorio bi put novoj vrsti korupcijskih praksi, koje bi zasjenile moguće dobrobiti od uvođenja e-uprave. Građani bi morali postati svjesni da glasanje po vlastitoj savjesti najviše koristi upravo njima, dok od sudjelovanja u «klanovima» korist izvlači mala, probrana elita, ostavljajući ostalima samo mrvice[13]. Također se mora postaviti pitanje postojanja dovoljne količine ljudskog kapitala, kako unutar tako i izvan uprave kako bi se mogle izvući koristi od novih tehnologija, te prevladavanja tzv. «digitalne razdjelnice», (eng. «digital divide»), zbog kojeg bi neki slojevi društva koji nisu informatički pismeni mogli biti isključeni iz sudjelovanja u odlučivanja, odnosno bili bi im onemogućeni ili otežani pristup informacijama, konzultiranje i politička participacija [18]

IV. E-UPRAVA I ORGANIZACIJSKA STRUKTURA

Blisko povezana s ljudskim kapitalom je uloga organizacijske promjene. Studije koje se bave utjecajem ICT-a u poslovnom sektoru obično nalaze da se najveće

[10] v.npr. F. Westerman, Inženjeri duše, Durieux, Zagreb, 2008

[11] Autor ovog rada osobno je pogledao palaču 2004. godine tijekom boravka u Rumunjskoj na sastanku OECD-a i SPAI-a, te je mogao čuti i komentare domaćina o nastanku zgrade i njenoj sadašnjoj funkciji i značaju.

[12] Za više o ovom pitanju, v. npr. Surowiecki, James. *The Wisdom of Crowds*. Anchor Books, 2004.

[13] Za više o korupciji u gradovima, v. R. Klitgaard, R. MacLean-Abaroa, Lindsey Parris: «Korumpirani gradovi», Praktični vodič za suzbijanje i prevenciju korupcije, Chronos Info, 2007

koristi od ICT-a ostvaruju kad se ICT ulaganja kombiniraju s drugim organizacijskim promjenama, kao što su nove strategije, novi poslovni procesi i prakse i nove organizacijske strukture [6]. U prošlosti se od radnika zahtijevalo izvršavanje specijaliziranih zadaća u okviru standardiziranih proizvodnih procesa. Danas se u poslovanju traži tzv. «multitasking», odnosno sposobnost istovremenog obavljanja više poslova za koje su potrebne razne nepovezane vještine, te sposobnost timskog rada. Taj fenomen se ogleda u velikoj raznovrsnosti novih radnih praksi koje uključuju timski rad, upravljačke strukture s manje hijerarhijskih razina (spljoštene strukture, eng. «flat structures») i programe uključivanja zaposlenika i davanja prijedloga od strane zaposlenika. Zajednički element tih praksi je veći stupanj odgovornosti radnika za svoj rad i veća bliskost i povezanost između rukovodstva i radnika. Budući da su takve organizacijske promjene specifične za tvrtku, empirijske studije u prosjeku pokazuju pozitivan povrat na ulaganje u ICT, ali s velikim razlikama između organizacija [6]. Nekoliko studija sa službenim statistikama u SAD-u bavilo se pitanjem veze ICT-a s ljudskim kapitalom i organizacijskim promjenama, te je otkriveno da je uloga ljudskog kapitala u praksi važna za produktivnost zbog procesa koinvencije ili suizumljavanja [2] a da bi se on potaknuo bitno je npr. davanje zaposlenicima većeg udjela u donošenju odluka, mehanizmi učestvovanja u dobiti (npr. putem opcija i radničkog dioničarstva) i nove prakse industrijskih odnosa. Otkriveno je da su tvrtke čiji su sindikati prihvatili takve prakse imale veću produktivnost od onih gdje to nije bio slučaj, što znači da je participacija značajan faktor u stvaranju pozitivne klime za uvođenje novih organizacijskih praksi [17].

Ako bismo ove spoznaje pokušali primijeniti na lokalnu upravu i samoupravu, teško da bismo mogli naći zadovoljavajuće stanje u Zagrebu. Naime, donekle autoritaran način upravljanja gradom uz mrežu suradnika koji ne djeluju po načelu stručnosti ne odgovara modelu visokotehnološkog razvijenog načina upravljanja gradom. Takav model, naime, formalno prihvaća neke značajke Novog javnog menadžmenta, zalažući se navodno za ekonomičnije, djelotvornije i učinkovitije upravljanje gradom, dok praksa pokazuje porast troškova i računa komunalnih usluga, odnosno da se trošak upravljanja gradom prebacuje na građane, dok s druge strane privatni partneri grada, financijske institucije i kreditori razvoja uživaju u dobiti, često na posve netransparentan način. Nedavni aranžman kojim su već izgrađena sredstva javnog prijevoza u vlasništvu grada prodana jednoj banci, pa zatim opet iznajmljena od te iste banke kako bi se namakla sredstva za izgradnju novih prometala ne djeluju kao ozbiljna financijska konstrukcija, a pretpostavka da bi taj i takav proizvod mogao postati izvozni adut nije se pokazala previše realnom i više djeluje kao demagogija.

Nadalje, temeljitom analizom organizacijske strukture grada Zagreba pokazao bi se vjerojatno prevelik broj raznih ureda, među kojima nije točno jasno tko je kome nadređen i podređen, te koji im je djelokrug i opis poslova, pri čemu su u gradskoj upravi angažirani i dobro plaćeni pripadnici suprotnih političkih opcija i struja od one koju zastupa formalno vladajuća stranka u gradu. Međutim, pitanja plaća i funkcija lokalnih službenika su u domeni lokalne uprave i samouprave, pa središnja država u njih nema pravo zadirati, čak i kad se ne slažu s proklamiranim politikama niti jedne od vodećih političkih opcija.

Ako ne gledamo samo internu komunikaciju unutar gradova, najvažniji način na koji ICT omogućava sudjelovanje građana je putem portala grada. U Zagrebu taj portal nije osobito uspješno komunicirao s građanima, a za vrijeme prošlih izbora podaci o glasanju bili su izrađeni na nepregledan način. Nedavno su grad Zagreb i vlada zajednički osnovali informatičku tvrtku koja izrađuje stranice Vlade RH, no one također nisu uspjele ostvariti značajniju otvorenost i participaciju građana[14]. Taj, pa i drugi primjeri suradnje različitih političkih opcija, a pogotovo primjeri suradnje kako bi se udovoljilo želji privatnih investitora bez konzultiranja građana Zagreba pokazuju da Zagreb zapravo i nije klasična lokalna samouprava, nego je riječ o žarištu u kojem se isprepleću različiti financijski i drugi interesi, koji nadilaze interese političkih stranaka, a pogotovo nevladinih organizacija i raznih strukovnih tijela, tako da je ostvarivanje sudjelovanja građana u tom gradu ujedno i ne samo problem sudjelovanja u lokalnoj upravi i samoupravi, nego i u državnoj upravi.

S druge strane, organizacijska struktura grada Rijeke možda bi pokazala da se smanjio broj hijerarhijskih razina u odlučivanju zbog uvođenja elemenata e-uprave, te da e-uprava utječe povratnom spregom na promjenu organizacijske strukture, što bi trebalo istražiti.

V. Empirijska situacija s e-upravom na lokalnoj razini

Ukoliko i ne uvažimo argumente iz prethodnih poglavlja, morat ćemo se složiti da su lokalne zajednice dinamičnije i fleksibilnije mogu odgovoriti na potrebe građana. Razlog je u tome što se nalaze bliže konkretnom problemu i građanima, te stoga mogu i brže analizirati taj problem i doći do rješenja. U Europi je na razini grada standardizirano oko 740 različitih vrsta usluga i više od 200 usluga državne uprave i županija, odnosno ukupno više od 1000 raznih usluga. Takve usluge najčešće su razni servisi kojima se olakšava plaćanje, tako da se uplate vrše brže i odjednom, uz visoku realizaciju naplate. Tako je u Rijeci moguće platiti troškove stanovanja, kupiti kartu za kazalište, kino ili sportski susret[15]. Također, kao i kod privatnog sektora, uvođenje decentralizacije i nove tehnologije smanjuje potrebu pročelnika da nadziru i tjeraju službenike na rad. Umjesto

[14] O važnosti sudjelovanja građana v. npr. «Građani kao partneri – informiranje konzultiranje i participiranje javnosti u kreiranju provedbene politike», Oksimoron, Zagreb, 2004., M. toga, sami građani mogu se od kuće registrirati, dobiti gradsku karticu i pratiti realizaciju svojih zahtjeva, tako da oni umjesto pročelnika mogu tjerati službenike na rad. Na taj način bi se u konačnici omogućilo da sami građani sudjeluju u gospodarenju gradom.

U osnovi se u Hrvatskoj primjenjuju dva modela razvoja e-Uprave, koje neki nazivaju «softverski» i «hardverski»[16]. Prvi je primijenjen u Rijeci, gdje je tri posto gradskog proračuna rezervirano za informatičku djelatnost u kojoj sudjeluje 40 djelatnika uz outsourcing usluga drugih tvrtki. Također, činjenica da se koristi portal koji ima CMS sustav bitno olakšava rad s portalom djelatnicima gradske uprave, a građanima uslugu čini brže dostupnom. Postavlja se, međutim, pitanje cijene takvog outsourcinga, koja nije javno dostupna, a pretpostavlja se da je riječ o «sitnici»; međutim, angažman i izobrazba vlastitih stručnjaka bi svakako bio znatno skuplji, a i pitanje je da li bi tada bili ispunjeni i svi elementi informacijske sigurnosti. U Zagrebu se, naprotiv, primjenjuje hardverski model po kojemu je IT infrastruktura proglašena komunalnom infrastrukturom, čime je dobila pravo na financiranje iz gradskog proračuna, te putem naplate od ovrha dužnika. Grad namjerava izgraditi vlastitu DTK infrastrukturu – kanale za optičke kablove i same te kablove - uz *outsourcing* privatnoj tvrtki. Status postojeće infrastrukture još nije pravno riješen, s obzirom da se postoji spor oko vlasništva nad njom, ali uz velike izglede da on bude riješen u korist grada. Tako bi, zapravo, grad stekao mogućnost da ima ekskluzivno vlasništvo nad ICT infrastrukturom, koju bi onda unajmljivali razni pružatelji usluga, čime bi se uspostavila normalna konkurencija na ICT tržištu, dok za sada postoji gotovo monopolski položaj na TK tržištu, kojem na ruku ide i vlada, privilegirajući ga svojim zakonima. Jedan od tih je i Zakon o elektroničkim komunikacijama koji pitanje DTK kanala pokušava riješiti tako da se TK tvrtkama osigurava «pravo prolaska», što bi im lokalne zajednice bile obavezne omogućiti. U svakom slučaju, ono što je ispod gradskih ulica trebalo bi također biti vlasništvo grada, što ne bi smjelo biti sporno.

Ukoliko bismo htjeli usporediti Rijeku i Zagreb po drugim pogodnostima, činjenica je da je u Rijeci uvedena zona besplatnog Interneta u središtu grada, dok je to u Zagrebu nezamislivo, a rijetki su i Internet kafići, sigurno jednim dijelom i zbog mentaliteta korisnika koji takve usluge zloupotrebljavaju. Također, ima mnogo primjera nemarnog održavanja infrastrukture u Zagrebu što nažalost vrijedi i za TK infrastrukturu.

Zanimljiv je i projekt «Inteligentni grad» u Varaždinu, gdje gradska uprava ima viziju povezivanja stanovnika, privatnog sektora i javne uprave. Interes poslovnog sektora za stvaranje jake mreže je jasan, jer samo putem takve mreže se mogu isplatiti ulaganja u nove informacijsko-komunikacijske tehnologije, budući da omogućavaju pristup velikom broju potencijalnih kupaca i dobavljača. Također, jeftina infrastruktura smanjuje i same troškove ulaganja u informatizaciju. Stoga je ulaganje u ICT imperativ već i zbog držanja koraka s Europom u pitanju konkurentnosti poduzeća. Također, takvo ulaganje koristi i građanima, jer i njima smanjuje troškove i omogućava pristup velikom broju usluga. Međutim, državna uprava postaje ometajući faktor, jer želi zadržati monopol na ulaganja i suradnju s poslovnim subjektima kako bi mogla trgovati političkim utjecajem. Imajući to u vidu, zaključno bismo mogli reći da su određeni vidovi korupcije brana ne samo decentralizaciji, nego i većem razvoju e-uprave na lokalnoj razini u Hrvatskoj.

VI. ZAKLJUČAK

E-Uprava u hrvatskim gradovima još uvijek nije dostigla razinu razvijenih europskih gradova, te se može uspoređivati samo s novim državama članicama i južnim/ mediteranskim državama. Zbog slabe i autoritarne kulture upravljanja u hrvatskoj javnoj upravi, kako na državnoj, tako i na lokalnoj razini, taj je razvoj dodatno otežan, usprkos relativno dobroj ekonomskoj situaciji i razvijenosti ICT infrastrukture. Problem predstavlja i postojanje prikrivenog telekomunikacijskog monopola, tako da mnogo toga u budućnosti ovisi o tome da li će gradovi biti vlasnici DTK mreže na svojem teritoriju. U osnovi, postoje dva modela razvoja, model grada Rijeke ili softverski, koji koristi CMS portal s vanjskim poslužiteljem i druge modele outsourcinga IT usluga, dok bi se drugi mogao nazvati hardverskim, a primjenjuje ga grad Zagreb za kojim se povodi i Split. Softverski model usmjeren je više na pružanje usluga i decentralizaciju upravljanja, te sudjelovanje građana uz uvažavanje elemenata «dobrog upravljanja», tako da u njemu postoji plodno tlo za razvoj e-demokracije, dok hardverski više odgovara kulturi autoritarnog i netransparentnog upravljanja, poslovanja i zapošljavanja koja postoji u većini hrvatskih gradova, te je usmjeren više na modele Novog javnog menadžmenta koje motivira želja za zaradom - bez poklanjanja pažnje elementima «dobrog upravljanja» i bez želje za omogućavanjem većeg sudjelovanja građana. Tu je, zapravo, riječ o sprezi između lokalnih političara i privatnih ulagača, gdje trošak financiranja uprave i projekata snose građani, a eventualnu dobit odnosi manjina koja malo riskira, bez obzira da li su projekti koje grad financira ekonomski isplativi ili nisu, tako da u konačnici nisu ostvarene niti ekonomske vrijednosti uprave, a demokratske/političke i pravne su značajno umanjene. Takvo stanje u ovim drugim gradovima pogoduje i razvoju korupcije. S obzirom na to, bit će zanimljivo pratiti razvoj e-Uprave u hrvatskim gradovima, s obzirom da se podjele na dva različita modela razvoja e-uprave i kulture upravljanja u velikoj mjeri poklapaju i s konstelacijom političkih snaga u zemlji, odnosno da li će pritisak tehnološkog i upravljačkog razvoja natjerati i vlast na državnoj razini na otvaranje prema građanima i veću transparentnost ili će državna razina nastojati što više ograničiti decentralizaciju, boreći se ne samo protiv političkog protivnika, nego istovremeno i protiv izvjesnog razvoja e-demokracije i bolje i građanima naklonjenije kulture upravljanja na svim razinama uprave.

Abstract – Public administration business system can be classified as a hierarchical system where the development of suitable information system has to allow data collection, business processes integration, and knowledge distribution and usage. Public administration hierarchical structure enjoins data and information flow from the end user to the management in business plan and the realization domain, and in the reverse direction in the tasks distribution and related information domain. Each autonomous organizational structure (state, local and regional governments) should provide an unambiguous and transparent data management by defining criteria (called classification) carrying information. Business areas should interconnect within a single organization (horizontal integration), or among the entities in the hierarchy (vertical integration). The information system as a whole and its subsystems enable high quality knowledge creation and its application through knowledge management at all hierarchical levels.

This paper emphasizes data, business processes modeling and design in the general conceptual knowledge model using ontology. A method to identify and design a model at the entity level, to compare these models and create a general model at public administration individual units level, and develop meta-level model on the number of independent units is presented. Ontology is an integral part of the domain process and data modeling at the meta-information level. Applying ontology enables the conceptual knowledge design and the use of formal knowledge.

I. INTRODUCTION

Using information technologies as business support is inherent in almost all enterprises, private trade, profit and nonprofit associations and organizations today. Information system or a number of software applications is also used in almost all public administrations.

The focus of this paper is considering the possibility to use ontology as a knowledge treasury directed to public administration systems. We considered elements of organizational structures that dictate the architecture of software applications and the information exchange need. Rare subjects have implemented complete and fully integrated software solutions. There are more software products represented by different vendors using different platforms providing a partial link between data and business processes.

Integration plan should take into account (accept and retain) the existing IT solutions wherever they provide efficient and quality support.

This paper considers a knowledge distribution and use method through modeling and ontology use. In this case the structure of the conceptual model of ontological presentation of information and function represented the default form for a variety of software solutions. By using these solutions entities providing information and those who seek information have default formats for the detection, charging and use, and therefore the adaptation and modification of existing information systems.

II. ONTOLOGY AND KNOWLEDGE

Ontology is a formal, explicit specification of shared (common) conceptualization, with further clarification of the concepts that make the definition [1]. Conceptualization is an abstract model of some phenomenon in the world that recognizes the essential concepts and phenomena. As such, ontologies can be a tool for sharing and reuse the knowledge.

Information systems design can be implemented in top of ontologies since they specify the knowledge that information systems has to address to perform required tasks [2]. To be able to design a system a kind of domain knowledge is required. One way to organize, structure, store and use knowledge is the ontology creation as part of existing or separate software solution. By using ontology, knowledge is modeled and organized on a conceptual level, and formalized to be accessible to systems software and people (commonly named agents) [3].

Business systems are typically complex, and also specific to working environment. It is therefore necessary to create a system model representing a generalized picture of the world that is then used to build computer programs. If the domain ontology exists, then a system model embedded in software solution can be compared to this ontology, and adjusted if necessary. Model of considered system is developed by using the ontology describing a system found in the real world, as shown in Figure 1. This model development approach allows gradual refinement of the model according to new findings or new views on the system.

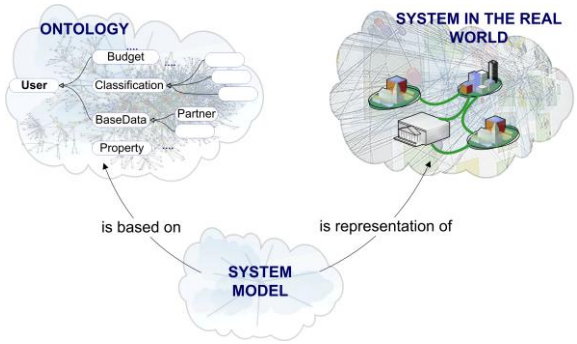

Figure 1 System model based on ontology

Ontology can be considered as study of the organization and nature of the world around us regardless of the shape of our knowledge about the world [4].

Without ontologies, knowledge embedded in systems of a given domain is presented in general incompatible ways, although it uses the same knowledge model [3]. Software systems that are different in designs and similar in functionality have the domain knowledge specific to that implementation. The system model implemented in a specific software solution can be harmonized with the reference ontology. Thus, knowledge embedded in the ontology completes specific software knowledge.

In order to figure out the alignment technique of existing public administration software solutions the organizational structure and communication modes should be analyzed first.

III. ORGANIZATIONAL STRUCTURE

The efficiency of each independent organizational structure (state, local and regional governments - public administration) depends on timely and reliable data and information flow. The efficiency can be looked at from internal business system or public service provider point of view. Regardless of the point of view it is important to integrate public administration on all levels and throughout all independent entities owning or processing data related to mentioned tasks.

For example, actual organizational project in Croatia deals with unification of citizen's data found at this point across various public administration subjects. The aim of the project is to improve efficiency when various types of documents containing a large number of equivalent information about citizens are needed. Unifying all data needed result in creation of single point of reference for citizen's needs. In the same context many different databases used by various state institutions, agencies, banks and local governments information systems, store redundant data not related to each other [5] [6]. Taking into account above mentioned facts, almost always, when the legal/ natural person requests a document, it is necessary to physically go to the office belonging to a particular institution. Only on site the person is able to get the document requested and even then the information is based on the local database, generating sometimes ambiguous information.

The need to establish a common database is only figurative, since it is unlikely that a universal solution exists that can replace existing software solutions of all included public administration subjects. Technically, operationally and financially such a replacement is very difficult. Since, public administration subjects are covering a variety of business domain including domain-specific tasks and business processes, specific software solutions are required. Taking into account all that a data and information set can be, generally, divided in two categories: common and specific.

Therefore, perceiving public administration business common concepts that are used as basis for the associated ontology modeling can be divided into several categories:

- Common concepts, information carriers, in the database often called a common or basic data, or master data. For example, basic citizen's data such as name, surname, or identification number.
- Common concepts related to specific activities. For example, the health system contains the data required for registration and functioning of public healthcare system.
- Common concepts related to business management and supervision process. This set of concepts is common to all public administrations and belonging subjects. For example, these are tasks related to planning and monitoring budget execution plan.

Observed set of concepts and their mutual relationship, together with the organizational structure of public administration constitutes the basis for the modeling and development of ontologies.

A. The basic model of concepts

A prerequisite for successful communication among different information systems is defined structure and behavior rules when exchanging data. The first step is definition of conceptual model of basic data structures which are part of the so-called classification [7] (Figure 2). A basic data structure should be an integral part of each information system. Since the realization of each database is different, individual information systems should be able to map their structure in a shared concepts model. This mapping can be realized by query that will return a structure of a given concepts model.

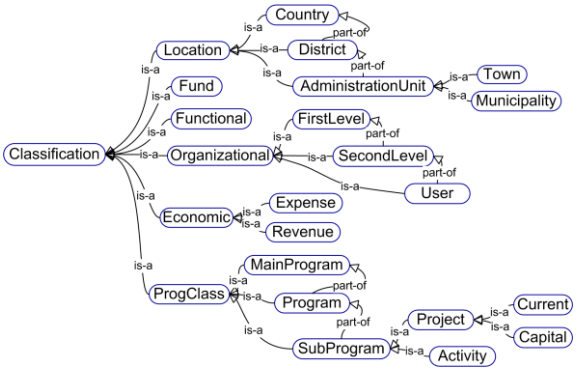

Figure 2 Concepts of classification of public administration

This assumption is the basis for communication between the public administration information systems agents.

B. *Ontologies of hierarchical systems of public administration*

When analyzing the communication between public administrations subjects the exchange of data and information, integrated vertically and horizontally should be taken into consideration.

Hierarchy is a fundamental feature of many complex systems [8]. Generally one can say that the hierarchical system of public administration (Figure 3a) has two to three levels of entities whose structure can be inferred from the organizational classification in Figure 2. Thus, the state level administration has all three levels of elementary subjects, while local government has two, where the first and second are encapsulated in the central subject.

In the public administration hierarchical model end users are independent entities that carry out their specific business activities (such as courts, schools, hospitals, communal companies). End-user ontology model (Figure 3b) is composed of concepts related to specific business activities, common business processes and basic data.

At higher levels of the hierarchy systems of public administration receive data and information arriving from lower level entities. Procedures of integrating and processing data and information are aggregation of knowledge and tasks specific for this decision making level. Therefore, associated ontology contains concepts of an aggregated knowledge of specific activities, common business processes and basic data.

In the case of the state administration previously mentioned subjects are middle level of hierarchical organization. Middle layer forwards information to subjects found on higher level where they are again aggregated creating new knowledge specific for the highest level of management and decision making.

C. *Communication with ontology*

The first step of this analysis was to determine responsibilities when communicating vertically. Equally important is the horizontal communication since performing identical tasks and tasks of the same domain means sharing the knowledge stored in the corresponding ontologies (Figure 3c). In this model specific business domain related elements are found i.e. all schools have the same referent school ontology model.

In addition to simple horizontal communication complex tasks requiring information sharing between different decision-making levels exists including both, vertical and horizontal communication. To illustrate cooperation between several entities of public administration various projects are mentioned (program classification in Figure 2) bringing together public administration and local government, participating in different activities. For example, in prevention and struggle against drugs projects all mentioned segments of the public administration as well as health facilities, schools, courts and other institutions are involved. This means that we need to ensure knowledge sharing between ontologies of different domains so that agents of each system can gain complete information required for its related business operations and decision making.

D. *Ontology modeling for public administration*

Previous analysis of the organization and business activities of public administration leads to the conclusion about natural knowledge distribution within a hierarchical organization. Conceptual modules related to business domain and positions in the hierarchy are perceived. Guidance for modeling of related ontology for two levels of hierarchy is proposed. At a lower hierarchical level ontology for the end user is proposed containing the knowledge of specific business areas. At a higher hierarchical level, level of public administration ontology for main entity is proposed, containing the knowledge of business management and decision-making. Above mentioned model represents a meta-model for the end user ontology.

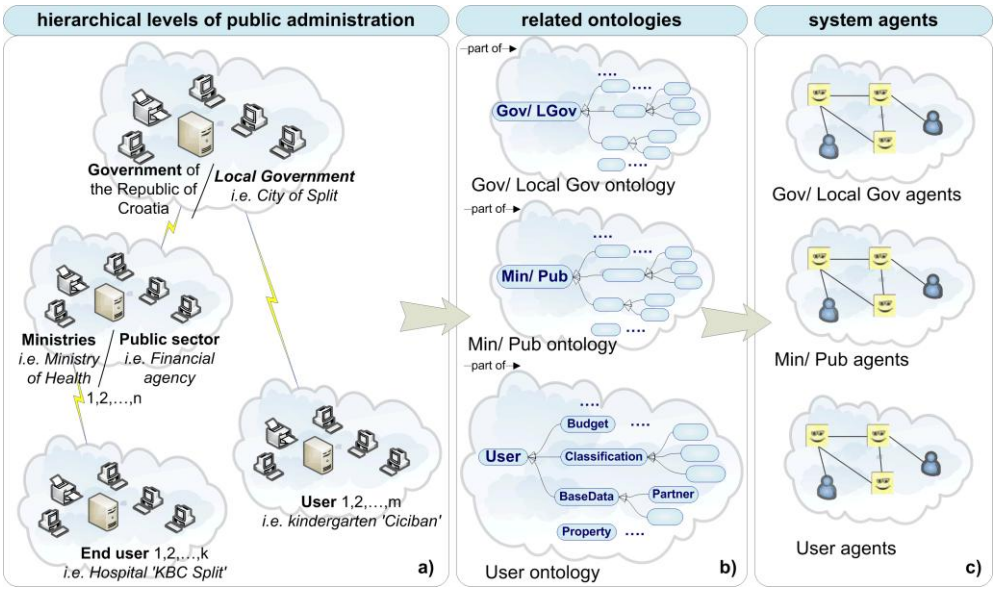

Figure 3 Ontologies of hierarchical systems of public administration

After modeling the knowledge contained in ontology has to be used. To use the knowledge it is necessary to explore possibilities of adjusting, tuning and upgrading the existing information systems and partial software solutions..

IV. CHANGES OF THE SYSTEM STRUCTURE

A. Changes of the hierarchical structure

Hierarchical organization is structured so that each the organization entity, except one (the root), is subordinate (dependent), on one other entities of the organization.

If we assume that the hierarchically organized system is presented by graph (Figure 3a), then it is necessary to predict the possibility to change the system structure in time. In information systems this change is motivated by an upgrade, conversion, reorganization or deterioration of the existing system. To support the modification request of the graph representing the system that can vary in time, we define three basic operations: insert, remove and update.

Due to the simplicity and the nature of technical systems we assume that the entity represents the observed object, while attributes represents object features therefore not additionally represented by graph nodes. Based on the definitions presented for similar graphs [9], [10], [11] node modification for the graph representing a hierarchical system is defined as follows.

Definition: Let the node of graph G be labeled as x, represent a number of attributes and associated values describing more closely the node and defined as a ordered pair <'*name*', '*value*'>, and a parent node of x is labeled as y. Then we define a basic set of graph nodes operations {*insert*, *remove*, *restore*} as:

insert (x, string(<'*name* a_1', '*value* a_1'>; <'*name* a_2', '*value* a_2'>; …), y) – input node x, if it does exist and a number of attributes with associated values (<'*name* a_1', '*value* a_1'>, …), as a leaf node, a descendant of node y. If node x exists, these attributes are inserted with the corresponding values and connection to the parent y. It is possible to define more attributes and corresponding values for the node, thus defining a new subtree, but not shown on the graph but treated as property of the node x belonging to specified attributes.

remove (x, ('*name* a_1'; '*name* a_2'; …), y) – deletes named attributes and the corresponding value of node x and a link to the parent of y. If a parent node is specified then the connection between them is removed. If attributes of a parent are not specified, then the specified node x with all attributes, values and relationship to the parent of y is removed.

restore (x, (<'*name* a_1', '*value* a_1'>; <'*name* a_2', '*value* a_2'>; …), y, y') – if a node x exists, change the value of named attributes and relations to the parent y, of the observed tree.

Figure 4 shows some examples of changes in the structure of the hierarchical system.

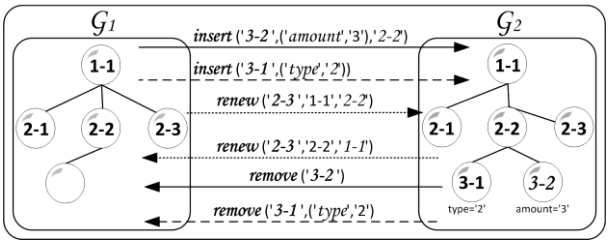

Figure 4 Example of the operation of graph nodes

Definition and example illustrates the ability to change the system as a whole (node) or to change its components. Over time the need for changes in the information system is eminent. The ontology is changed due to changes in the area of interest [12]. Change of the ontology is implemented, among other things, because it solves the problem of heterogeneity (diversity) among the systems modeled over ontology, as in the case presented in this paper.

Let's have a look at an example of how the ontology change is required and how to realize perceived needs.

B. An example of changes in ontology structure

Ontology description should identify the connection and the importance of elements such as (1) components of ontologies used for knowledge modeling, (2) knowledge representation paradigms to be used in the display components, and (3) the language used in the ontology implementation within the given knowledge representation paradigms [13]. Ontology components used for knowledge modeling are concepts, instances, relations, functions, and axioms [14].

For ontology defined in such way we assume that implementation of some changes is needed. The ontology modification need resulted due to the emergence of new knowledge about the observed domain ontology. If the ontology is presented by graph (Figure 3b and Figure 4), then ontology changes can be documented as defined by the node graph modification operation. Figure 5 illustrates the node changes of the hierarchical system, and the resulting change in the form of new ontology.

Modifications of ontology relationships are done in accordance to the definition of nodes conversion operation in the hierarchical system. After the changes publishing of resulting ontology is required to enable all users to apply the new version of the ontology [15].

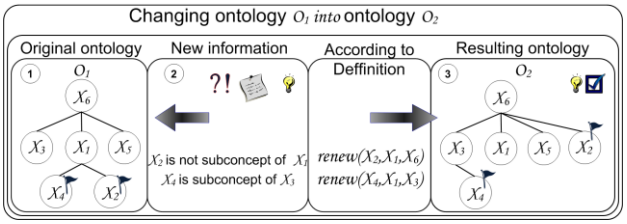

Figure 5 Example of ontology development driven by new knowledge

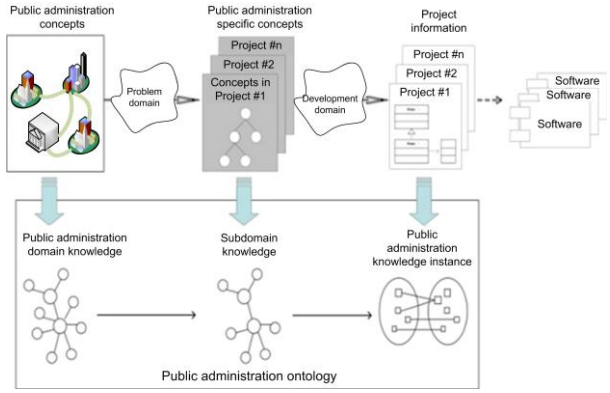

Figure 6 Common conceptualization domain ontology

C. *The use of ontological knowledge in the development/ adaptation of the information system*

A similar analysis and application of change operations in the hierarchical structure can be implemented in the hierarchical structure of information systems. Ontology affects the information system and vice versa. Ontological structure is actually a meta-structure that can be used for a variety of information systems implementation, ontology knowledge is referent when adjusting specific software solution to shared ontological conceptualization. Figure 6 shows the common conceptualization domain ontology.

Specific sub domain knowledge is referent for the adjustment of individual projects development making part of information systems. Customized software should enable higher communication quality among the stakeholders.

The proposed ontology hierarchy of public administration structures and existing information systems structure supports the public administration hierarchical organization. By taking into account all the above mentioned it can be concluded that changes in the organizational structure of public administration can also be described by changing the hierarchical tree representing it. For example the reorganization of the public administration [5],[6] where the proposed operation provides support for the new architecture. Adjustment of related ontologies has commenced. Furthermore, such adapted and evaluated ontological knowledge helps in adapting information systems to support the reorganized business of public administration.

V. THE METHOD OF KNOWLEDGE DISTRIBUTION AND USE

In this paper we propose a method of distribution and use of knowledge based on three well-known approaches of the system analysis: top-down, bottom-up and middle-out [16].

Bottom-up approach starts from the specific end user scenario that can be generalized to create (1) generalized view of the domain and (2) a generalized business tasks. This is the way that leads to the conceptualization of the end user domain and task ontology.

Top-down approach starts with the description of the entire area at a high level of abstraction. Planning and monitoring of business, and management and decision making in public administration can be conceptualized in the ontology of the leading entities of public administration.

Middle-out approach is applicable for entities of public administration (such as ministries) that lead their specific business areas in the same way. Down (towards end users) they distribute business tasks. This means that the entities tasks ontology in the middle level is end users tasks meta-ontology. On the other hand, upward (toward the leading entities) middle level entities communicate with the aggregated information of their specific areas. Therefore, the ontology of the business area is an instance of the ontology of leading entities.

Ontology obtained by the proposed method of distribution and use of knowledge is valued by the entities of public administration. When needed, operations mentioned in the section "Changes of the system structure' are applied over this ontology. These steps are repeated until the evaluation procedure results with the final solution.

Such a knowledge distribution is a precondition for its use in multiple ways and by multiple entities. The subject of further research is communication among information systems providing timely and effective public administration business activities. Support for achieving this goal can be found in the knowledge that offers the possibility of adjustment by information systems and individual software solutions. Using ontologies enables the interpretation of identical concepts by different development teams. With the present model of structure change development teams can notice questionable position in the hierarchical organization of the system and the corresponding ontology and decide on how to change/ adapt existing solutions.

VI. CONCLUSION

The proposed method of distribution and use of knowledge stored in ontology emphasizes that it is not important how a particular software solution has been developed and implemented. Naturally grouped structure of concepts, their relationship and embedded behavior rules are forming the structure of ontologies distributed within the hierarchy of public administration. The corresponding software solutions and associated databases are instances of respective ontology. Such instances can complement each other according to their knowledge of the meta-structure. This creates basics to establish a good communication among the agents in the system ensuring data transparency and availability of relevant information, wherever located.

sandro.rambaldi@unibo.it

Abstract - In this paper we analyze the speed profiles on the whole Italian road network. More precisely, using Octo Telematics GPS data (about 3% of the total Italian cars amount) collected during four weeks of May 2011, we have built up for everyday of the week a mean speed profile with a time resolution equal to 15 minutes, obtaining about one million speed profiles. For this research working we developed software able to efficiently navigate the full Italian road network designing its topological properties, and algorithms for traffic control, prevision and governance. Moreover we discovered that a strong correlation function (>90%) represents 96.4% of all data with a reduced number of profiles (256). This work was performed in order to construct an ICT (Information Communication Technology) system for monitoring and managing traffic, with a particular attention to the safety for individual passengers, vehicles and goods.

I. INTRODUCTION

Human mobility is significant for human freedom, for migrations and different populations mixing, for urban planning[1], for designing the transportation systems [2], forecasting the diffusion of infectious diseases [3,4], and finally it is a strategic problem when we face catastrophic social phenomena (riots for instance) and/or natural ones (earthquakes, tsunami, etc.). Moreover mobility and transportation is a common need in many and different natural systems, everywhere individuals interact with each other by cooperating and/or competing for the same resources (energy, food, money...). Usually for the human social systems, and also for other natural ones, we found that the mobility features and transportations systems are closely related to the community structure, and to the quality of life [5,6]. As it is well known, the human mobility is specified by different means: feet (pedestrian dynamics), bikes and private motor vehicles (traffic dynamics), and public transportation means (in principle a deterministic dynamics). We focus our investigation on the traffic dynamics, more precisely measuring the car mobility on the whole Italian road network. The new information technologies allow direct measures of individual mobility behavior [7,8,9], opening the concrete possibility to build up a new class of models able to describe and also to predict, at least statistically, the traffic dynamics, so that the mobility governance could be more effective, especially to control and prevent critical situations such as congestions [10,11,12]. In Italy a sample of ≈ 3% for the whole vehicles population has an Octo Telematics GPS system for insurance reasons. Any car is associated with an ID number, so that it is possible to follow its motion over a long period of time. Each datum gives position, velocity, distance covered from the previous datum, and the signal quality [13].

The data sample is constituted by trajectories points at a space interval of about 2 Km; an extra datum is also recorded any time the engine is switched on or off. The data suffer from the GPS limited precision, in particular when the GPS loses the satellite signal. These problems are especially relevant at the beginning of a trajectory when the vehicles are parked inside a building. When the signal quality is good the time precision of the recorded data is "perfect", whereas the space precision is of the order of 10 m, often sufficient to localize the vehicle on the road in a unique way. Both the instantaneous velocity and the space covered are given with an adequate precision since they result from a calculation based on the GPS recorded, but not registered data. We have developed several methods to clean the data from spurious effects in order to avoid possible bias in the sample. Traffic on a road network is the consequence of individuals mobility demand, and as matter of fact often in real situations the presence of different driver types is crucial to understand urban mobility [14,15]. From one side the microscopic traffic dynamics is forced on a one dimensional space (the road), from the other its spatial scale is in principle extended to the whole road network, the microscopic drivers behavior can be responsible of local congestions that may propagate on the network, producing a macroscopic phase transition. Furthermore the driver behavior can be related to individual social characters (sex, age, social status...), so several social mesoscopic sets can be identified, with associated common mobility features. The global emergent properties of traffic cannot be understood, described, and statistically predicted only via microscopic dynamics, but a global cognitive time dependent field interacting with individuals is needed. Injecting the empirical data and taking into account the vehicles mobility characteristics, we can implement algorithms, which can simulate the traffic in a realistic way. In this paper we consider a very large GPS car mobility data set, and we operate reducing this set to a reasonable number of elements, without losing the dynamical significant information. To be more specific, when working in traffic modeling, in urban planning or simply in routing it is mandatory to know the speed profiles of each road or at least its mean value [16]. We would like to have a real-time speed profile but, being not available at the moment, the best we can do is to work with an average speed profile for the different days of the

week. In this paper we explain how to build a compact representation of the speed profiles for a full country road network.

II. CHARACTERISTICS OF THE SPEED PROFILES DATA SET

We collected the GPS data along 4 weeks of May 2011, constructing for every day the velocity profiles, averaged on time intervals of 15 minutes. The whole Italian road network measures about 1.7 million km but only 62.8 thousands km, corresponding to a percentage of 3.6, have a monthly flow of cars equipped with Octo Telematics GPS, from here Octocars, greater than 3000. The choice of this threshold is needed to give, during the traffic intense periods, a resolution of 15 minutes and corresponds to a daily mean flow of about 150 vehicles/h. Below this value we have low traffic and the time variability of the mean speed is negligible. Moreover only 10.1 thousands km, corresponding to a percentage of 0.6%, are sensitive to traffic with a daily variability larger than 10%. In this way we limit our sample to about one million speed profiles (N=996704). With i being the profile index we write:

$$V_i(t): i = 1 \dots N, \tag{1}$$

defining the velocity profile Vi(t) along every arc. Then we introduce the scalar product <A|B> as

$$< A|B \geq \frac{1}{M}\sum_{k=0}^{M} A(t_k)B(t_k)$$

(M = 96, if we consider a time resolution of 15 minutes) and the associated distance between velocity functions, defined on L^2 (Hilbert Space). Let the mean velocity $\overline{V_i}$, we approximate Vi(t) with a limited number of normalized profiles $\Phi_j(t)$:

$$V_i(t) \cong \overline{V_i} + A_i\Phi_j(t). \tag{2}$$

where the amplitude A_i measures the departure of $V_i(t)$ from the mean velocity $\overline{V_i}$. We can compute A_i according to:

$$A_i = < V_i(t) - \overline{V_i} \mid \Phi_j > \tag{3}$$

III. CHOOSING PROFILES

At this point we want to reduce the number of profiles, in order to introduce categories and to get a system light to handle from the informational point of view. Looking for a limited profiles number, we firstly associate a different profile to every arc following

$$P_i = a_i(V_i(t) - \overline{V_i})/A_i' \tag{4}$$

where A_i' is the speed fluctuations around the mean value (computed assuming $< P_i|P_i > = 1$) and we implement an algorithm to minimize the global error in the evaluation of the travel time along the chosen arc.

To define the error of our representation, we consider

$$\Delta V_i = V_i - V'_i = A_i|P_i > - A_i' |\Phi_j > \tag{5}$$

where $A_i' = A_i < \Phi_j|P_i >$ and we evaluate the error as:

$$|\Delta V_i| = A_i\sqrt{1 - < P_i|\Phi_j >^2} \tag{6}$$

Then we consider the travel time estimation error ΔT, which is made by all the vehicles, n_i, covering the arc along a day finding:

$$\begin{aligned}\Delta T_i &= n_i L_i \left|\frac{1}{V_i} - \frac{1}{V'_i}\right| \cong n_i L_i \frac{|\Delta V_i|}{\overline{V_i}^2} \\ &= W_i\sqrt{1 - < P_i|\Phi_j >^2}\end{aligned} \tag{7}$$

where $W_i = (n_i L_i A_i/\overline{V_i}^2)$, can be considered as a weight function for every arc, i.e. the error measured by hours/day without using the velocity profiles. To minimize uncertainties we consider the quadratic mean error:

$$E^2(\Phi) = \sum_i \Delta T_i{}^2 = \sum_i W_i^2\,(1 - < P_i|\Phi_j >^2) \tag{8}$$

The total error on the network becomes:

$$E(\Phi) = \sum_i \Delta T_i = \sum_i W_i\sqrt{1 - < P_i|\Phi_j >^2} \tag{9}$$

if we don't take into account the velocity profiles ($\Phi_j \equiv 0$), but simply we use the averaged values, the total error is $\sum_i W_i$ hours. This error considering only the Octocars is more than 50000 hours/day, in real life also the mean value is approximated. In the following sections we will show that this error can be strongly reduced of above 80%, introducing a framework of 256 profiles.

IV. NUMERICAL METHODS

The implemented numerical method is iterative. At the beginning we choose a number J_{max} of profiles Φ_j. The starting choice of these functions is not critical but it influences the rate of convergence of the process.

Once defined this set of functions we start the iterative process. We examine all the functions P_I as in (4) associating to the closest profile function Φ_j. Then for each j we consider the set of all the P_i associated to Φ_j, and using the weight W_i we calculate a new function Φ_j able to minimize the error on this set. After this computing, we get a new set of profile functions Φ_j and the process can be iterated.

In order to avoid the convergence on local minima, we perturb the system, using a simulated annealing technique [17]. We run a series of processes with heating and cooling and we choose the lower minimum found. Typically we use a computer time of few hours on a quad core PC. Now we examine the cycle in a more precise way.

V. THE CYCLE

A. Initialization (the starting point)

We order all the arcs, using W_i function to privilege the road with more traffic and with higher oscillations. We choose the first one, and we review all the other arcs, selecting those correlated with the first by a factor larger

than 0.9. In this class, using the weight W, we select the best representative profile. Then we eliminate this class from the global data set and we select the second class and so on till we get the J_{max} wanted representative profiles, which are the input data to start up the computing process.

B. Step one: class selection.

We review all the functions P_i associating to each one the closest profile function Φ_j to build up J_{max} classes.

Errore. L'origine riferimento non è stata trovata. shows a space partition in three regions, each blue dot indicates an arc profile P_i and the stars denote the class representatives. Every function P_i is associated to the closest star Φ_j. We implemented a procedure similar to the Voronoi tessellations with generators Φ_j on a 96 (M) dimensional space with an L^2 distance $d(P_i,\Phi_j)$ defined by

$$d(P_i,\Phi_j) = W_i\sqrt{1 - < P_i|\Phi_j >^2} \qquad (10)$$

C. Step two: best class representative.

Taking into account all the functions P_i associated to Φ_j and using the weight function W_i, we calculate a new representative Φ_j minimizing the quadratic mean error

$$E^2(\Phi_j) = \sum_{i \in classe\ j} W_i^2(1 - < P_i|\Phi_j >^2) \qquad (11)$$

Errore. L'origine riferimento non è stata trovata. shows a vector analogy. The dashed vector indicates the direction of the class representative element |n> we want. We must minimize the following positive defined functional

$$E^2(n) = \sum_i W_i^2\,(1 - < P_i|n >^2) \qquad (12)$$

i.e. we must find the maximum of

$$M^2(n) = \sum_i W_i^2 < P_i|n >^2 = < n|\Omega|n >. \qquad (13)$$

Where the matrix Ω is

$$\Omega = \sum_i W_i^2|P_i >< P_i| \qquad (14)$$

and represents the weighted mean projector.

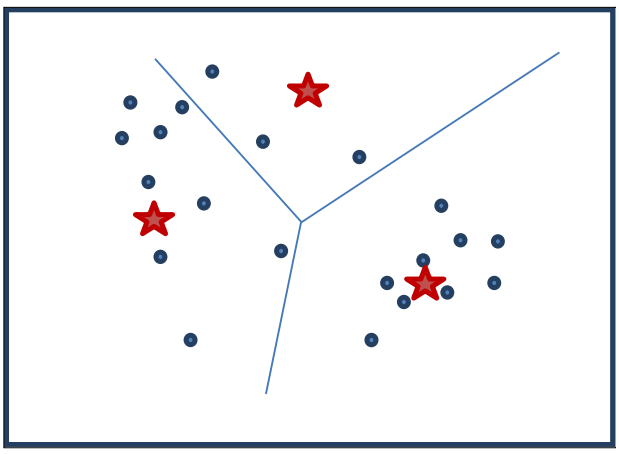

Figure 1

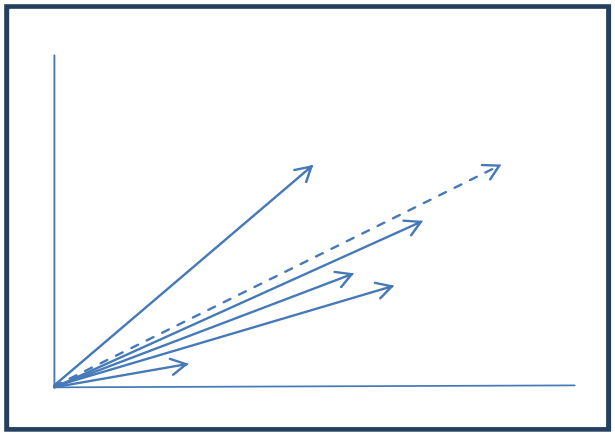

Figure 2

The direction |n> is therefore defined by the eigenvector with the largest eigenvalue of Ω. The method is similar to the principal component analysis.

After the |n> calculation for each class, we return to step one and iterate. Moreover we underline that in both steps, the quadratic mean error decreases in a monotonic way.

D. Thermalization

The system shows many local minima, and our monotonic algorithm finds one minimum for every run, but we don't want to choose the first local minimum, and so we perturb the system in order to continue the space scanning. In this process the choice of the perturbation functions is crucial, and our best choice is to change the less representative profiles using linear combinations of the most representative. This facilitates the exchange of the class components. Typically we considered several thousands of iterations and we chose the lowest local minimum.

E. Results

Errore. L'origine riferimento non è stata trovata. shows the quadratic mean error as function of the number of profile M:

$$E^2(M) = \sum_{i,j=1}^{M} W_i^2\left(1 - < P_i|\Phi_j >^2\right) \qquad (15)$$

With only one profile the quadratic mean error is reduced to 9 % , and with 4 profiles to 4.5 %, till 0.6 % with 256 profiles.

For a quantitative study it is important to include many profiles, in Fig. 4 we show the percentage of weight explained by the different profile functions, when M=256. We see that all the functions contribute with a comparable role to the description of the road speed profile system.

For a qualitative study we see that even with few profiles we describe the main features, in Fig. 5 we show the profile functions during the 24 hours (GMT) and the relative role for M=1, M=2, M=4. The most important function (M=1) describes two congestion situations: one early in the morning and one in the late afternoon. Introducing a second mode we find still the presence of

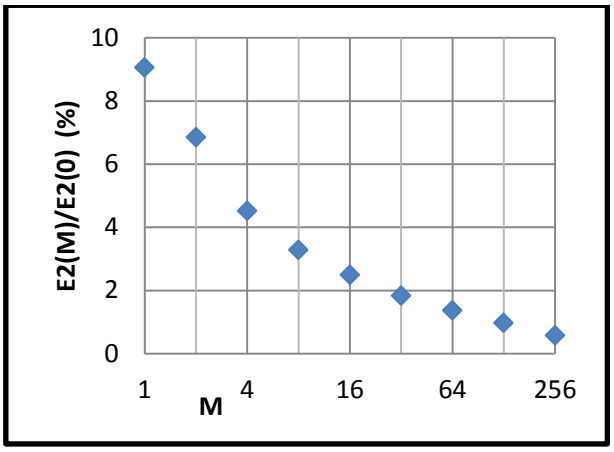

Figure 3

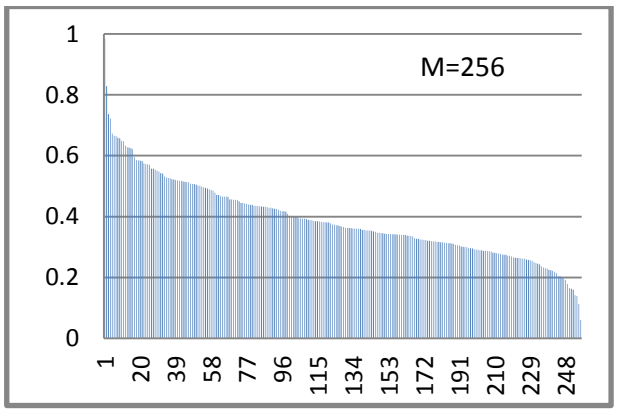

Figure 4

the previous one and a new one with a very well defined decrease in speed earlier in the morning and a weak congestion in the afternoon. For M=4 we see that the first mode now splits into three similar parts with a small phase shift and one describing an afternoon congestion.

VI. Conclusion

In this paper we have shown how to compute basic speed profile functions useful for the modeling and the governance of car mobility and logistics in a whole country. Furthermore we discussed the quality of the approximations.

Acknowledgment

We are in debt to OctoTelematics S.p.A. for the access to the GPS data set. We thank Prof. N. Geroliminis for several useful discussions.

NEO-MRVE-programsko rješenje za vođenje evidencije

A.B. Tomislav Galba mag.ing.*, C.doc.dr.sc.Alfonzo Baumgartner**
* Elektrotehnički fakultet Osijek/Zavod za računalno i programsko inženjerstvo, Osijek, Hrvatska
** Elektrotehnički fakultet Osijek/Zavod za računalno i programsko inženjerstvo, Osijek, Hrvatska
tgalba@etfos.hr, baumgart@etfos.hr

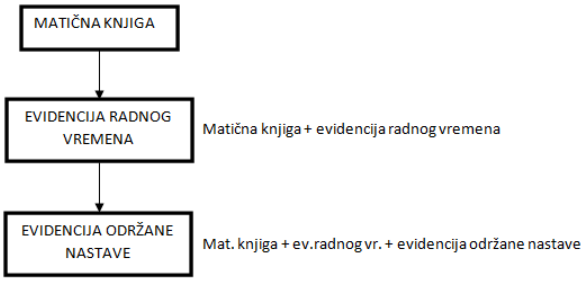
Sažetak - Uvođenje informatizacije u upravama uvelike olakšava kontrolu i povezanost nad odabranim faktorima. NEO-MRKVE programsko je rješenje za evidenciju zaposlenika i radnog vremena na fakultetima koje je centralizirano na jednom serveru. Aplikacija se bez problema pokreće na Windows i Linux platformama. Tehnologije u kojima je rađena su PHP, HTML, CSS i MySQL. Program je uveden na svih 18 sastavnica sveučilišta J.J.Strossmayera u Osijeku. Svako računalo na pojedinom fakultetu ima instaliranu vlastitu klijentsku aplikaciju koju koriste administrativne službe tog fakulteta. Aplikacija omogućava opcije unosa i promjene podataka o djelatnicimaa, podataka o radnom vremenu, norma satima, izvješća o nastavi, kolegije i druge bitne informacije. Skripte koje su neophodne za rad aplikacije automatski se ažuriraju kada se nova skripta pojavi na serveru. Za izradu izvješća koje zahtjeva rektorat, postoji mala aplikacija na serveru koja grupira pojedine podatke svih fakulteta u jednu zajedničku bazu podataka.

I. UVOD

Ručno vođenje evidencije bilo koje vrste vrlo je mukotrpan posao za ljude koji to provode, dakako, još veći problem nastaje prilikom pretraživanja i modificiranja unesenih podataka kojih može biti previše ukoliko se radi o velikom poduzeću. Sve većom dostupnošću računalne tehnologije polako se uočava moguća primjena na tom području. Neki od načina digitalne evidencije su bar-kod oznake, magnetne kartice, RFID kartice, biometrija i slično. Na Elektrotehničkom fakultetu u Osijeku već se duži period koristi digitalna evidencija dolazaka pomoću RFID tehnologije. Dolaskom zakona koji propisuje obvezu poslodavca da vodi digitalnu evidenciju zaposlenika i radnog vremena, na našoj instituciji pokazala se potreba za izradu takvog softvera. Samom izradom softvera zbog istih potreba i na drugim fakultetima koji su sastavnice sveučilišta J.J.Strossmayera u Osijeku, napravljen je integrirani sustav na razini sveučilišta koji je centriran na jednom serveru. Potreba za ovakvim zajedničkim rješenjem došla je od strane uprave sveučilišta J.J. Strossmayera u Osijeku.

II. NEO-MRKVE

Neo-mrkve je softver koji se sastoji od matične knjige, evidencije radnog vremena i evidencije održane nastave (vidi *Sliku 1*).

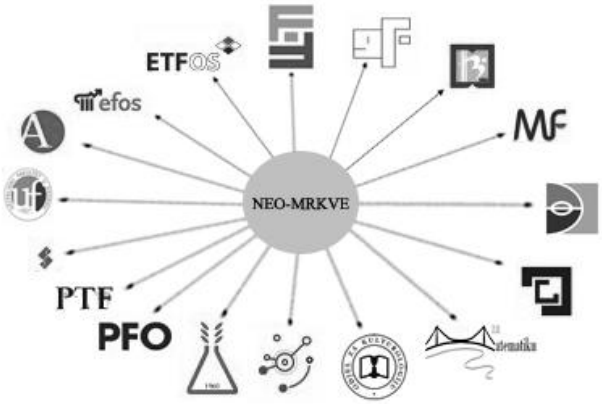


Slika 1. Dijagram osnovnih dijelova programa

Princip rada programa organiziran je tako da sva administracijska računala na svim sastavnicama sveučilišta J.J.Strossmayera (vidi *sliku 2*) u Osijeku imaju klijentski pristup putem web-preglednika aplikaciji koja se stavlja na neko od serverskih računala ili ako se nema mogućnost takvog, onda na osobno računalo. Korisnik se logira upisivanjem korisničkog imena i lozinke. Na jednom serverskom (ili u nekim slučajevima običnom osobnom) računalu na kojem je instaliran program nalazi se baza podataka koja sadrži podatke matične knjige, djelatnika, radnog vremena, kolegija i drugo. Između ostalog, nalaze se i pristupni podaci kao što su korisničko ime i lozinka. Prilikom ulaska u aplikaciju, potrebno je unijeti korisničke podatke. Skripte koje su napisane u PHP jeziku vrše komunikaciju s bazom podataka i provjeravaju da li su uneseni podaci točni. Nakon uspješnog logiranja otvaraju se osnovne mogućnosti programa:

- Prikaz djelatnika
- Promjena podataka djelatnika
- Prikaz podataka o radnom vremenu
- Promjena podataka o radnom vremenu
- Promjena podataka o norma satima
- Izvješća o održanoj nastavi
- Kolegiji
- Studiji
- Promjena podataka o poduzeću
- Ažuriranje aplikacije
- Slanje podataka na centralno mjesto (rektorat sveučilišta)

Postoje dva načina rada, gdje svaki od njih ima određeni model pristupa. Administratorski način ima pristup svim mogućim funkcijama u programu koje uključuju modifikaciju i brisanje podataka. Isto tako zadatak administratora jeste i da dodjeli različite uloge različitim korisnicima aplikacije.



Slika 2. Sastavnice sveučilišta koje koriste NEO-MRKVE

Ugrađena je i 'gost' opcija koja ima mogućnost samo pregledavanja unesenih podataka (read-only). Što se tiče korisničkih uloga, njih može biti nekoliko. Tako razlikujemo:
- **voditelja matične knjige** (to je obično osoba iz tajništva ustanove)
- **voditelj evidencije radnog vremena** (može biti također osoba iz tajništva, ali može biti i bilo koji drugi djelatnik, bitno je da ima pristup informacijama o trenutačnim bolovanjima, godišnjim odmorima i ostalim zakonski propisanim vrstama radnih sati)
- **voditelj evidencije radnog vremena nastavnika** (također može biti jedna te ista osoba, ali mora imati dodatno uvid u raspored sati i eventualno nastavni plan i program)

Program sadrži niz zakonski propisanih obrazaca: karticu djelatnika iz matične knjige, mjesečne ispise radnih sati po djelatnicima, detaljni ispis radnih sati za svakog djelatnika posebno, ispise radnih sati nastavnika važne za evidenciju o održanoj nastavi.

Svaki primjerak serverske aplikacije sastoji se od nekoliko desetaka skripti koje su neophodne za rad same aplikacije. Svaku promjenu u zakonu vezanu za bilo koju opciju u aplikaciji potrebno je unijeti. Promjene u radu programa izvršava Elektrotehnički fakultet u Osijeku. Izvršavanje promjena izvedeno je na način da se na centralnom serveru nalaze folderi sa datotekama koje se nalaze i na lokalnom računalu. Glavna kopija skripte ili datoteke koja se nalazi na serveru je ta koja se izmjenjuje. Modul za ažuriranje koji je ugrađen u aplikaciju na lokalnom računalu vrši automatsku sinkronizaciju sa tom glavnom datotekom na serveru tako da se prilikom pokretanja ažuriranja pretražuju sve ili samo odabrane datoteke na serveru te se uspoređuju njihove vremenske konstante sa onima koje se nalaze na lokalnom računalu. Ona datoteka koja ima najkasniju vremensku konstantu skida se sa servera i zamjenjuje s datotekom koja se nalati na lokalnom računalu.

Aplikacija je izvedena koristeći nekoliko web tehnologija. Neki od njih je PHP, HTML, CSS, MySQL i Javascript s lokalne strane i Qt sa super-serverske strane. Super-MRKVE je posebna aplikacija dodatno postavljena na rektoratu sveučilita J.J. Strossmayera koja je u stanju prihvatiti podatke od strane njegovih 18 sastavnica u jednu zajedničku bazu podataka, kako bi se dobio uvid u zbirno stanje, te ostvarili potrebni ispisi i obrasci zahtjevani od strane samog rektorata. Kako faukIteti imaju samostalnost kao poslovni subjekti, za razliku od odjela, podaci fakulteta zamole se od strane rektorata, te program NEO-MRKVE ima mogućnost da te podatke pošalje. Super-MRKVE prihvaća te podatke i integrira ih u zajedničku bazu, dobivajući tako zadnje aktualno stanje s obzirom na zadnji datum kada su podaci dobiveni.

PHP je poslužio za kreiranje skripti pomoću kojih obavljamo određene zadaće. Primjerice spajanje na bazu podataka:

```
<?php
$link = mysql_connect('localhost','xxxx','yyyy');
if (!$link) { die('Nemoguæe se spojiti na bazu podataka: '
. mysql_error()); }
mysql_select_db('mrkve', $link);
mysql_query("SET NAMES cp1250", $link); ?>
```

Isto tako i za druge bitne funkcije kao što su logiranje u aplikaciju, dohvaćanje podataka djelatnika, izmjene podataka i drugo.
HTML (HyperTextMarkupLanguage) kao prezentacijski jezik poslužio je kao jezik s kojim je određen izgled stranice i postavljene poveznice na pojedine funkcije. U kombinaciji sa CSS (CascadingStyleSheets) s kojim su definirani svi elementi koji se nalaze u aplikaciji. Pod definiranjem elemenata misli se na grafički dizajn i poziciju unutar sučelja (slika.3). Primjer definiranja dijela izbornika:

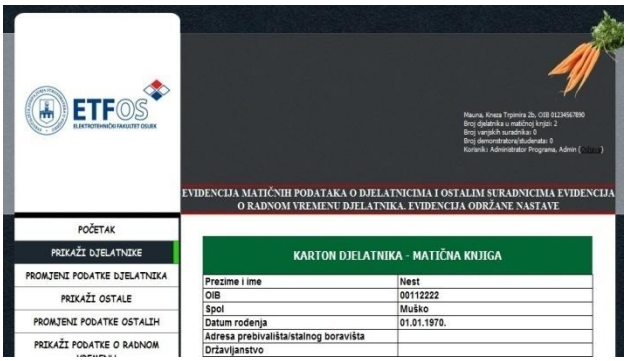
```
#login
{
width:750px; height:450px; position:relative; margin-
left: auto;  margin-right: auto;
background-image:url(slike/login1.jpg); border-bottom-
left-radius:35% 35%;
border-top-right-radius:35% 35%; border-width:5px;
border-style:inset;
}
```

MySQL jezik korišten je za kreiranja baze podataka. Na svakom klijentskom računalu nalazi se baza podataka u koju se spremaju određeni parametri koje administrator unese. Na zajedničkom serveru nalazi se glavna baza podataka u koju se spremaju zbirni izvještaji sa svih sastavnica sveučilišta J.J.Strossmayera u Osijeku.

Navedene tehnologije korištene za izradu ovog softvera su besplatne i to je jedan od glavnih razloga njihovog korištenja. Drugi vrlo bitan razlog jeste portabilnost naše aplikacije koja se od sastavnice do sastavnice sveučilišta izvodi na različitm verzijama Windows i Linux operacijskih sustava.

Osim navedenih tehnologija u maloj mjeri korišten je i Javascript kao alat za kontrolu nekih upita, primjerice provjere upita o brisanju korisnika:

```
<script language="JavaScript" type="text/javascript">
function CheckDelAndGo() {
  var rez = confirm("Jeste li sigurni da želite obrisati
djelatnika "+document.djeleditform.ime.value);
  if (rez){
    document.djeleditform.akcija.value = 3;
    document.djeleditform.submit();   }
}
function CheckAndGo(akc) {
  document.djeleditform.akcija.value = akc;
  document.djeleditform.submit();
} </script>
```



Slika 3. Grafičko sučelje aplikacije

Međutim, kako je sekundarni cilj ostvariti dobru portabilnost i koristiti open source alate, nije bilo moguće iskoristiti Javascript kao alat za izradu kompletne aplikacije. Glavne razlike između PHP-a i Javascripta je ta što je PHP kompletno open source dok Javascript nije. Isto tako PHP je podržan na svim Linux i Windows serverima dok Javascript nije.

Portabilnost (prenosivost) je karakteristika programa koja se odnosi na njihovu upotrebljivost na različitim sistemskim platformama različitim od platforme na kojoj je kreiran, primjerice, NEO-MRKVE izrađen je na Windows platformi, a bez problema se pokreće na Linux ili MacOS platformi. Ukoliko se o tome ne vodi računa prilikom izrade aplikacije, prilikom prelaska na drugu platformu potrebno je izvršiti "portanje", drugim riječima, potrebno je prilagoditi aplikaciju za drugi operativni sustav. To uzrokuje gubitke vremena, a samim time i novca. Upravo ta mogućnost NEO-MRKVE čini robustnom i otpornu na pojavu greški uslijed pokretanja na nekom operacijskom sustavu koji nije matični.

III. ZAKLJUČAK

U ovom radu opisano je jedno centralizirano rješenje za vođenje evidencije matičnih podataka, radnog vremena, te norma sati nastavnika. Po našem mišljenju ovo rješenje bi se odmah moglo upotrijebiti i na bilo kojem drugom hrvatskom sveučilištu ili veleučilištu.
Korištenjem SQL-a uspješno smo pomogli mnogim sastavnicama da ugrade svoje već postojeće podatke o djelatnicima ili bilo kakve druge podatke koje su imali u digitalnom obliku u naš program, te s time im bitno olakšali unos podataka.
Naš daljnji plan jeste povezati vođenje sati radnog vremena s aplikacijom za računanje plaća, jer mjesečni iznosi radnih sati koji se dobivaju ovom aplikacijom direktno se koriste kod izračuna plaća. Ovaj dio se može automatizirati tako da se ti podaci ne prepisuju kao što je to trenutačno slučaj.

Destination information system in the function of forming an identity for Zadar County as tourist destination

Ph.D. Đani Bunja
Deputy president
Zadar Conty
Božidara Petranovića 8, Zadar, 23000, Croatia
Phone: ++385(0)23-350 409, Fax: ++385(0)23-350 416, E-mail: zamjenik-bunja@zadarska-zupanija.hr

This article elaborates the importance of implementing the destination information system (DIS) as an instrument of forming the identity of Zadar County as tourist destination. The introductory part treats DIS in current market conditions, as a generic instrument which is very important for tourist destinations. In the concluding part it is asserted that tourist destinations must pay necessary attention to the collecting, processing, storing and disseminating of information, which should result with adequate messages, later conveyed to the tourism market.

I. INTRODUCTION

Tourists look for a maximum of flexibility from tourist destinations in order to satisfy their desires and demands. Interests related to tourist experience assume that tourists have access to information about the destination. Tourists receive information about tourist destinations from different sources - their own previous experiences, recommendations, tourist guides, advertisements and different publications and video materials about offers for tourists, tourist offices, travel agencies etc. Acquiring information from the above mentioned sources normally implies spending time and a certain part of one's own income, and since this information is very often incomplete, this can affect the level of satisfaction in tourist trips. Recent research has shown that the accessibility to information influences the choice of destination, the degree of tourist satisfaction, as well as the possibility of a renewed visit. Accordingly, destinations must enable easy access to understandable and timely information about themselves, in order to be competitive on the tourist market.

Enlarged number and fluctuation of information, aided by new information-communication technologies (ICT) are not only of vital interest to academic and research community. ICT directly effects managing and transacting business. The business world, because of the nature of its activity, has accepted the support that digitalization and electronic communication provides to vital managing and business conducting functions.

Constant improvement of ICT considerably influences the flow of tourists. Tourists are exposed to a mass of information, and tourist destinations must carefully participate in gathering, elaborating, storing and disseminating, i.e. managing information, because this process should result in adequate messages that will be forwarded to the tourist market [25]. Managing information is becoming more important because of the insecurity that growing competition causes, shortening time limits for making decisions and the permanent changes in market conditions.

II. THE DESTINATION INFORMATION SYSTEM

Destination information systems are based on the application of information technologies. They can be defined as systems that contain complete and relevant information about the destination on offer, in other words the elements of the tourist product that are available to tourists themselves as well as the management of the public and tourist sector, that is to all parties interested in the development of a particular destination. The goal of destination information systems is to provide tourists and potential tourists with the necessary information for planning and organizing their trip. Data from tourists who have already visited the destination, together with more general data about the tourist market, is recorded in databases and is also used for different analyses of the needs of tourists [12].

The destination information system contains information related to the tourist products of a particular destination. It must enable access to the information to multiple users – tourists and potential tourists, the tourist sector, national, regional and local tourist organizations, the public sector and investors. Information that it contains must be accurate, timely and understandable. Its successful application is not only that it improves the effectiveness of the market but that it serves to promote all those who participate in the providing of information resources to be input in such a system. The implementation of a destination information system presupposes the solution of a number of technical (information inputs, heterogeneity of the data, connection with the global electronic market, architecture of the system etc.) and organizational (especially the interorganizational collaboration) problems and questions. As a rule, the decision to establish and operate such a system is made by the public sector or its body and/or bodies whose area of business is related to tourism[12].

There are different types of destination information systems and considering their purpose they can be classified in two basic groups: those founded for the purpose of promotion, and those founded to support the decision making process. In the first group are included those systems which serve to promote a particular tourist destination, by offering topics that, with the provision of a system by inputting information resources, in fact promote themselves. The second group includes those systems that provide the management of the public and tourist sector with management information, that is, with business reports.

III. IDENTITY AND IMAGE

Abratt [26] defines organizational identity as an agglomerate of visual signs and conduct used by the public or the market in order to recognize an organization and distinguish it from other organizations. Gray and Balmer [10] define identity as the unique characteristics of a certain organization. The definition includes elements such as organizational personality. Cornelissen and Harris [13] assume that the personality of an organization is a decisive attribute that defines its identity. Balmer, in his article *Corporate branding and connoisseurship* [17], offers a simple definition of organizational identity, where it would represent a reflection of what the organization really is. Van Rekom [15] defines organizational identity as the denoting of something that organization in fact is. He claims that organizations create the type of identity that the public, or the market, wants to notice. Such an identity is made up of central organizational values, which in certain moments can make impact on it and change it, i.e. adjust it according to the management's views of identity. Van Riel in his work *Principles of corporate communication* [4] defines organizational identity as a planned and operational external and internal self-presentation of an organization based on agreed organizational philosophy. On the other hand, some authors like Moingeon and Ramanantso [2] or Ind [22] equalize organizational identity and personal identity and think that it cannot be changed instantly, but in a long-run evolutionary process. The most widely accepted definition is that the identity represents what an organization really is.

The identity of a tourist destination is a concrete manifestation of its reality. If there is a wide choice of tourist destinations with equal attributes, than the identity is a distinctive category. When a tourist has to decide between two tourism products, beside the location, only impalpable factors can contribute to the decision of buying (in case of similar prices). Tourists are becoming aware of the differences based not only on the product itself but on their conceptions of it as well. The identity contributes to the most powerful communication effect because it increases chances for the tourist destination to be kept in memory of tourists and potential tourists.

A tourist destination can be different from other tourist destinations by means of symbols. Symbols, according to Argenti and Forman [24] create an essential dimension of identity. Visual manifestations attract attention because of their focusing on the visual and of being exposed to the media. Tourists create conceptions on the basis of the information conveyed to the market by a tourist destination, i.e. its self-presentation. In spite of developed awareness of the importance of identity, there are a surprisingly small number of managers who understand the ways of creating a consistent identity and who can make use of perceiving the public and the market.

Argenti and Forman [24] think that individuals are not just an interested party, but they can make part of a number of them. Consequently, the message of a tourist destination must be sent to various interested parties. In the past all interested parties could be easily differed, but nowadays they are interlaced, which makes communication more difficult. Therefore, the clarity of identity is a decisive factor that will contribute to the consistency of tourists' views of a tourist destination. As the rhythm of everyday life is speeding up in this new millennium, many tourists will look for clarity and stability, so the identity building will become ever more important for a tourist destination. Tourists have certain views of a tourist destination before starting to communicate with it. Such views are based on their everyday experience, and they either enhance or diminish the sense of credibility. They derive from their former experiences with the tourist destination, from what they found out in the media about it, from the experiences of other people gained in interaction with it, and from visual symbols they recognize.

The widest accepted definition is the one that explains the image of a tourist destination as a reflection of its identity. In other words, the image of a tourist destination is the way it is perceived by tourists and the others who are in a certain way related to the tourist destination.

Every interested party – tourist, human potentials, domicile community or investors – have different views of a tourist destination. Associations and impressions left after interaction with a tourist destination participate in forming its image. The image of a destination is based on how groups and individuals perceive the destination. As this image is based on numerous individual aspects, it is not surprising that various types of tourists perceive differently the same destination. According to Briggs [28] it is easy to talk about tourists as an anonymous mass of people, but there are, of course, different types, and every group or segment has different needs and motivations. Different types of destinations will probably attract different segment in different ways.

The main source of information about a tourist destination that holidaymakers can rely on include newspaper articles and articles from various kinds of magazines; radio and TV broadcasts; debates on a tourist destination with other people and the direct interaction with the tourist destination. If the ones that carry out the activities of a tourist destination do not know what a tourist destination really is, no one can expect from tourists to understand its reality. Namely, the management involved in running the tourist destination can have a significant impact on either positive or negative market views of it.

Since the individual recommendation is the most important source of information for tourists, it seems

opportune for the domicile community to be well informed about tourist attractions of the destination, and to treat them in a positive manner, which eventually can have a positive impact on potential tourists regarding their decisions about visiting such a destination [27].

The latest researches show that the image is not made up of a single reality, but every individual has an array of connected images consisting of many elements in their interaction [29]. If the ideas of the public are different from reality, which is, according to Argenti and Forman [24], a frequent case when tourist destinations do not analyze whether harmony exists at all, then the strategy of harmonizing the identities and image is either unsuccessful or the reality of the tourist destination, i.e. its identity, requires to be changed. The developing of a tourist destination identity can be completely controlled because the identity is conveyed in the details created by the tourist destination in order to communicate with the public or the market.

Kotler, Bowen and Makens [23] claim that the image can be very specific or much extended. On the one hand, particular tourist destinations aim at creating a specific image, and on the other certain destinations rather choose an extended image in order to attract various segments of consumers.

IV. TOURISM INDICATORS OF ZADAR COUNTY

An assessment of the importance of tourism as an economic sector for Zadar County can be made on the basis of analysis of tourism indicators. Evaluation of the success of tourism in Zadar County is doubtful. The reason lies in unattractiveness of our offer unable to attract tourists out of high season. In addition, tourism in Zadar County is characterized by its unfavorable structure and low capacity utilization and turnover.

The structure of accommodation units is dominated by the so-called complementary capacities (90% share) as opposed to the basic ones which include hotels and holiday villages.

The degree of utilization of tourism capacities is insufficient. This assessment necessarily exempts camps, which actually show a satisfactory level of capacity utilization due to their uniqueness in the business, limited to the summer period. Utilization of hotel capacities in our competing tourism countries is on average 60%, which is significantly higher if compared to hotel business in Zadar County (i.e. 40%).

The bulk of tourism capacities are located in coastal areas (99.99%), and mostly operate only during the summer season. This explains the low level of capacity utilization.

The bulk of tourism turnover in Zadar County is realized in July and August, i.e. during so-called high season. 64.58% of overall tourist arrivals are registered in the two months of 2010, which accounts for 74.59% of total overnight stays. In the period June - September, and during the tourist season, of the same year, there were 86.76% of total tourist arrivals, or 93.55% of total overnight stays. The time distribution of tourism turnover indicates that the tourism offer of Zadar County is characterized by strong seasonality.

Gross income from tourism activities in Zadar County is possible to estimate on the bases of tourism statistics of the World Tourism Organization (UNWTO), which, among other things, collects data on tourist arrivals and the revenue generated from the tourism turnover of foreign tourists (i.e. these statistics exclude domestic tourists and their activities). According to this source, it turns out that the Republic of Croatia in 2009 registered 9.335 million foreign tourists who spent 8,880 billion USD (6,204 billion EUR), or 45,288 billion HRK (according to the average annual exchange rate of 1 USD = 5.10 HRK for 2009). According to data from the HNB (Croatian National Bank) and DZS (Central Bureau of Statistics) for the same year, the revenue generated from foreign tourists amounted to approximately 46 billion HRK or 6.3 billion EUR.

As Zadar County in 2009 registered 886,425 foreign tourists, it appears that the revenues from foreign tourists and their tourism activities amount to 843,211,781 USD (589 million EUR) or about 4,300 billion HRK. The total revenue from tourism activities in the County of Zadar in 2009, including the consumption of domestic tourists, is presumably estimated to the amount of approximately 5 billion HRK. This estimate is based on data of the Tourism Institute, which conducts regular annual surveys on the preferences of tourists and their spending according to the TOMAS methodology.

V. THE NEED FOR STRATEGIC MANAGEMENT OF TOURISM DEVELOPMENT IN ZADAR COUNTY

Zadar County is the only one among coastal counties of the Republic of Croatia which so far has not produced a *Master Plan for Tourism Development*. Since tourism is a strategically important economic sector for Zadar County, such a situation is unacceptable. Namely, the development of tourism needs to be managed and not left uncontrolled. The reasons for managing the development of tourism in the form of a *Master Plan for Tourism Development* in Zadar County, as much as the authorities responsible for its creation, will be suggested in the text below.

The public sector approaches tourism with special interest due to its positive impact on the economy. However, in order to realize the benefits of the effects of tourism, the public sector must achieve certain prerequisites for the development of tourism. WTO [32] indicates adequate utility infrastructure as the underlying predisposition for tourism development in a particular area. This infrastructure must be designed and constructed to serve the domestic community. Consequently, the public sector should invest in sporting, recreational, cultural and entertainment activities and use them in order to enrich the tourism offer. Ultimately, the development of tourism must stimulate the development of the economic activities that do not belong to the tourism sector.

Achieving a balance between the needs of each interested business and a sustainable development of tourist destinations is a real challenge. Therefore, the

management of tourism is a complex task and there are good reasons why the public sector is usually in charge of its good functioning in society.

The fundamental role of the public sector in tourism lies in planning its development. The public sector by its intervening in tourism development seeks to achieve its long-term sustainable development, i.e. the maximization of benefits from tourism activities while preserving the attractiveness of tourist destinations. Tourism planning process typically includes [30]:

- Preparation of a study - as a rule, although a number of institutions may be actively involved in the process, usually a legislative body of a certain level can be the one that carries out the procedure.
- Determination of goals - the main purpose of the plan and objectives to be achieved by the development of tourism are determined.
- Situation analysis - inventory of existing tourism resources in relation to the reached stage of development. This includes collecting data about the tourism market, the structure of the local tourism industry, investments and funds available for future development.
- Data Processing – the data collected in the previous stage are processed in order to formulate the plan.
- Plan design - information from previous stages is used to determine different options or scenarios for tourism development. The three main elements of tourism plans are satisfaction of visitors, protection of environment and incentives for investors.
- Analysis of proposals - a plan for tourism development is prepared and delivered to authorities or an institution responsible for the planning process. In most countries there is usually a period meant for public discussion. The draft plan is then available to the public, so that they could express their views of the plan. Once this procedure is completed the plan will be approved by the authorities in charge of planning and the final plan will be made.
- Implementation and monitoring of the implementation of tourism plans - along with its implementation the plan will have to be monitored. This is a permanent process in which authorities or institutions responsible for planning estimate whether the objectives of the plan are achieved. The application of a tourism development plan usually includes a time frame of five years, after which it becomes reviewed.
- Periodic audits - refers to the process of the progress assessment, after the plan is implemented. Some of the reasons for the failure of the plan may be associated with changes in the political constellation of forces, the failure to reach consensus between the private and public sectors on how to approach the provision of tourist facilities, inadequate infrastructure, and public opposition to tourism.

Frequently limited and shared interests result in the fact that a particular destination has no defined strategy with a vision of the future forms tourism is likely to take. The effects of tourism are difficult to monitor due to the structural nature of the tourism sector. However, in perspective, each destination that avoids planning will not evaluate systematically its position in the market. Regardless the applied form of tourism development in a certain destination, it needs to have a strategic approach in identifying and using a number of tourism resources.

The reasons for the public sector interventionism in connection with the strategic objectives of tourism development can be systematized in the following two sets of issues [8]:

- seasonal redistribution of tourist activities and
- geographic redistribution of tourist activities

Successful management of tourism as much as tourism planning and regulation of activities related to tourism, requires coordination between government bodies, interest groups, private sector and the involvement of local and regional government[9]. The public sector, on the one hand, generally has a reactive role in terms of the regulation and control of tourist activities on the other hand, has a proactive role in planning and managing tourism.

The public sector manages the activities of public importance. Since tourism is resulting in significant implications which are of public importance - the public sector faces an imperative of being engaged in planning and controlling tourist activities, or generally to manage the development of tourism. Permanent growth of tourism requires from the public sector to assume the role of a coordinator of overall tourism activities. In this context, the performance evaluation of tourism policy in a specific tourist destination is often a political issue, resulting in conflicts among political options, which is especially the case in Croatia.

Consequently, there is no doubt that Zadar County lacks an important document such as a *Master Plan for Tourism Development*. I personally believe that making such a document can and should involve ZADRA - Zadar County Development Agency, which has qualified staff trained to give their contribution in producing such a document. There is no doubt that an important part of this document should emphasis to Destination Information System (DIS). Also, it is my belief that the County of Zadar in the preparation of *Master Plan for Tourism Development*, unlike other coastal counties, should refer to domestic authors (in accordance with the legislation that governs public procurement). I am convinced that local experts have more sensitivity for Croatian particularities and needs derived from the developmental effects of tourism.

The price of *Master Plan for Tourism Development* in the County of Zadar, in this sense, could be between 1 and 1.5 million HRK, which is significantly lower than the average price for the same type of document paid by other coastal counties, which amounts to approximately 2 million HRK.

I would define the terms of reference for the *Master Plan for Tourism Development* as follows:

- The introductory part - except for defining the objectives and methodology to determine the relationship of this Plan to other planning and development documents.

- Characteristics of the Zadar County - geographical, socio-demographic, economic, etc.
- Analysis of the current state of tourism development - which includes an analysis of tourism resources, tourism development indicators, characteristics of tourist products and factors of tourism development.
- Development scenario - as the most important part of the plan, I believe should include the concept of spatial organization of tourism, assessment of accommodation capacities and their limits, specific approaches to different types of tourism, development of marketing policies, etc.
- Models for the development of second class destinations - I think that Zadar County as a tourist destination may be divided into a number of different second class destinations, e.g. Zadar and its surroundings, Biograd with the Vrana lake, Islands of Ugljan and Pasman, Island of Pag, small islands of Zadar, Dugi Otok, Ravni Kotari area, Lika, Velebit – foothill coast.
- List of projects - with regard to the requirements of potential investors directed to the County Administration, the plan should include a number of projects that would be described in detail, and which would have a certain priority in their implementation.
- Assumption for implementation of the Plan – tasks of the public sector, expectation of the local tourism industry, education of the domestic community and others involved in the tourism development, etc.
- Monitoring of the implementation of the Plan.

I believe that the above draft of the project terms of reference contain all the essential elements of the *Master Plan for Tourism Development* which is needed in Zadar County. However, its creation stood in the lack of budgetary resources. In the budget year 2010 100,000 HRK were provided for the preparation of the Plan, which was insufficient to start its preparation, and in the past fiscal year, this item has not been listed. The preparation of the Master Plan for Tourism Development is planned to be realized from pre-accession funds. Finally, I am unable to predict when time will be ripe for its preparation.

VI. CONCLUSION

Tourism industry is very important economic sector for Zadar County. However, it is doubtful whether it can be recognized as a destination on the tourism market.

Consequently, there is no doubt that Zadar County lacks an important document such as a *Master Plan for Tourism Development*. Also, there is no doubt that an important part of this document should emphasis to Destination Information System.

In Croatia, information systems created for promotional purposes dominate, and the usefulness of these systems is limited. The public sector, tourist sector and investors are not able to use them in the process of decision making as the information from such systems is not complete or relevant. Accordingly, for the development of tourism in Zadar County, it is necessary to create such destination information systems that, apart from being used for promotional purposes, can also produce correct information, which is accessible at the right time and in the right place, and which can be used as the basis for decision making. Tourist are exposed to a large quantity of information, so tourist destinations must seriously pay attention to collecting, processing, storing and dissemination of information, which should result in adequate messages conveyed to the tourism market. Their positive conception of the identity and image of Zadar County as a tourist destination can contribute to the growth and development of tourism in Zadar County. The identity of a tourist destination is a concrete manifestation of its reality, and the image is the way it is perceived by tourists and the others who are in a certain way related to the tourist destination.

Efficiency analysis of e-business in Croatian city governments

Jelena Jardas Antonić, Ph.D.(assistant-novice researcher) *, Daniel Antonić **
* Faculty of Economics Rijeka, Rijeka, Croatia
** City of Rijeka/ IT Department, Rijeka, Croatia
E - mail: jjardas@gmail.com, danijel.antonic@rijeka.hr

Abstract – **E-business, being one of the economic and social development generators, represents an important factor for the functionality of the modern society and is integral part of the globalization process. Digitalization process is being included into all layers of life, from business all the way to the private life, changing the ways of interaction between people, their life environment and habits, and imposing a question on how do these changes reflect on surrounding institutions and their business.**
Modern e-government puts citizens in the center of their business processes, offering them a maximum accessibility of their services, 24 hours a day, 365 days a year, while taking care of high reliability and data security at the same time. On the other hand, high technology brings a long list of dangers and misusage capabilities, which represent a huge threat to e-business.
For these reasons, the goal of this paper is to examine just how much has business process digitalization taken hold inside city government and how successful is it being implemented. The challenge in deployment of such a complex process is big, since one has to find a compromise between a full range of aspects such as security and openness, so that the modernization of the local government wouldn't result with an opposite effect and cause a loss of public confidence in the system.

I. INTRODUCTION

In this research, in the center of interest is e-business of city government and how digitalization of processes at the state level affects the functioning of city governments and citizens of Croatia. Within the national strategy on electronic administration there isn't a single strategic document that defines the guidelines for the development of e-government at the local level. It's not even defined whether the forms and experience of e-government at the state level should be taken over and used for the digitalization of government at the local level. For this reason and conduction of this research, a survey was formed based on the knowledge compiled out of literature and "E-government development strategy for Croatia in period 2009-2012" in order to obtain necessary data describing the phase and degree of digitalization for individual city governments [1].

II. EFFICIENCY ANALYSIS OF E-BUSINESS IN CITY GOVERNMENTS

City government's information system was analyzed using questionnaire through 5 fields important for the functionality of e-business. In order, these are:

- computer and communication infrastructure,
- information security,
- human potentials,
- data-information and documentation baseline and
- availability of electronic services.

A) *Computer and communication infrastructure.*
Questions in the area of computer and communication infrastructure were used to determine the number and age of servers an individual city government possesses, number of workstations, which operating systems is being used on most of them, whether there is a secure backup of important data being created on daily level, and it also includes characterization of the system given the number of failures per year, and Internet access technology.

B) *Information security*.
Regarding the safety area it was determined whether the city government possesses ISO 27001, if there is a safety policy concerning access to official documents, surveillance and Internet content prevention system, if some of the advanced authentication methods are used, etc. [2],[3,]

C) *Human potentials.*
Third area covered by the questionnaire refers to human potentials providing answers to the existence of helpdesk for IT system users, education of citizens and IT department, information on the number employees in IT department, as well as whether outsourcing is being used for the support and administration of the IT system.

D) *Data-information and documentation baseline.*
In the fourth area, data-information and documentation baseline, data on the coverage of specialized software regarding the business areas (applications for accounting, public procurement, asset management, etc.) were obtained, whether is it possible to discover unauthorized data modifications, which documents are devoted to the development of e-government, and the assessment of degree of system maturity using the COBIT model [4].

E) *Availability of electronic services*
Fifth and final area covers questions which gave information on availability of electronic services on web portal, possibilities of e-participation, and assessment of the degree of web service development for each city government.

By analyzing the acquired data, even 15% of surveyed city governments, don't have secure data backup on daily basis, which represents a huge risk for data loss (see Figure 1). Such governments often don't own a mechanism for the creation of secure data backups or for archiving important data in electronic form. In a case of malfunction, loss of power or infection with electronic virus, such systems often end up entering the data gathered during several years once again in the system, resulting in a great dissatisfaction of employees, unnecessary waste of time and loss of funds, and difficulties in providing customer services.

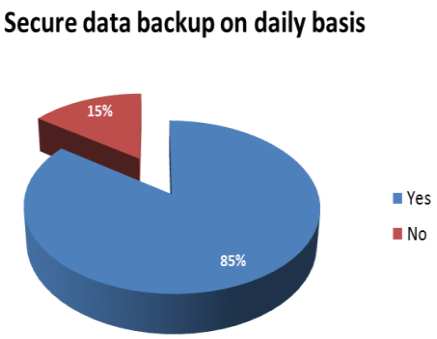

Figure 1. Secure data backup on daily basis

The analysis has also shown that a certain number of surveyed city governments don't have broadband Internet access, although the Government of the Republic of Croatia had released a broadband Internet access strategy for Croatia back in 2006, as one of the foundations for the realization of a knowledge society and Croatia joining the European developed countries. It's also important to point out that 22% of the surveyed city governments don't have a server that would ease the administration and represent the city's centralized documents repository.

Such a business organization questions the competence of companies offering outsourcing of IT support to the given city governments because the very foundation of e-business lies in the creation of infrastructure which cuts the maintenance costs, increases the safety of stored data and simplifies data exchange among employees of city governments as well as between citizens and city government.
In the part of questionnaire that covers human potentials, even 28% of city governments don't have an employee responsible for the maintenance of ICT infrastructure, but rather outsource this are. (see Figure 2.)

TABLE I . NUMBER OF EMPLOYEE IN ICT DEPARTMENT

Number of employee in ICT department	%
0 Employee	28%
1 Employee	43%
2 Employee	15%
3 -7 Employee	10%
More than 7 Employee	5%

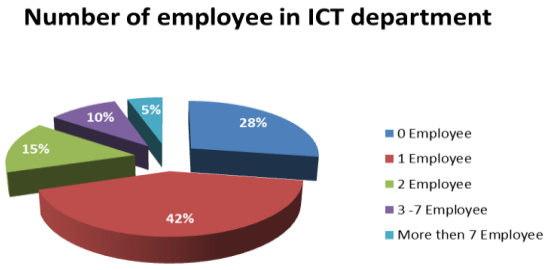

Figure2. Graphical view showing number of employee in ICT department

City budget of smaller towns and low understanding of information technologies could be one of the possible causes for this situation.

Furthermore, only 10% of city governments seek industry certificates for their employees in the IT sector, providing them with necessary knowledge that is in the line with profession's trends in the world. When taking Croatian situation into account, it's assumed that the reason of such a low certification level, regardless the great opportunities being offered to the employee on the labor market, lies in high costs of such a certification. Another reason is low motivation of government's staff, since this form of education doesn't reflect on their incomes, but requires a great amount of energy and time outside their regular working hours at the same time. It's also important to point out that 18% (see Figure 3.) of city governments invest in the education of citizens in some way, which shows an awareness that e-business is widely being conducted for the sake of citizens and that otherwise there is no justification for such an investment without showing the sensitivity for the promotion and encouragement of citizens awareness on how does the usage of ICT technology and city government's e-services benefit them. On the other hand, investing into citizen's knowledge of ICT technology helps them in the labor market.

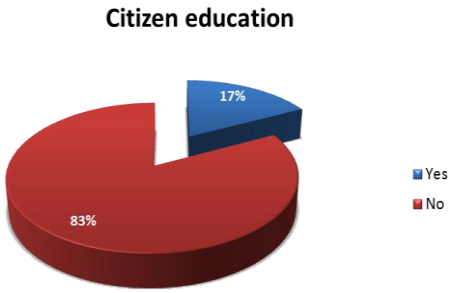

Figure 3. Graphic view in percentage of citizen education

The part of questionnaire dealing with the data-information and documentation baseline shows that city governments are best equipped with applicative solutions for tracking business processes. Among the city governments included in the sample, 18% of them use all applicative solutions. Only 8% use maximum of 3 applications and those cities are in minority. The greatest percentage, 25% of the cities covers 75% of internal business with applicative solutions (that's 6-8 possible solutions). However, coverage with applicative solutions doesn't necessarily mean that all of them are united through a single database. Mostly each application uses its own database, resulting in a need of entering the same information several times into different databases. This is a result of nonsystematic implementation of informatics related business in city governments.

TABLE II. TABLE REPRESENTATION SHOWING THE COVERAGE WITH APPLICATIVE SOLUTIONS

Coverage with applicative solutions	Percentage
8 Solutions 100%	18%
7 Solutions 88%	13%
6 Solutions 75%	25%
5 Solutions 63%	15%
4 Solutions 50%	20%
3 Solutions 38%	8%

Figure 4 Show data from Table 2

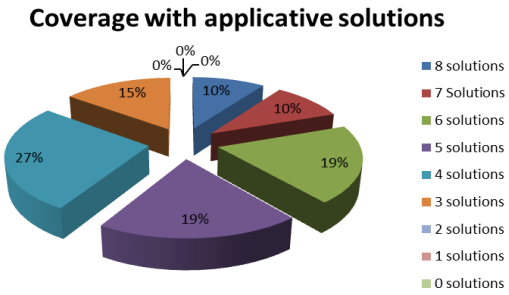

Figure 4. is a graphical representation showing the coverage with applicative solutions of information and documentation baseline

It's also important to mention that 57% of cities segregate special budget funds for e-government development, while 38% also possess strategic documents devoted to the strategic development of e-government. This shows us just how much the development of e-government is financially supported; however the percentage of clearly defined documents that define what those funds are meant for (38%) is very small. It's also necessary to point out that from all the surveyed cities, even those covering 100% of business with applicative solutions, there isn't a city that implements appropriate mechanisms for maintenance, usage and improvement of the (program) code. Considering the acquired data on the maturity of management of information system, it's possible to say that 43% of the surveyed policies on IT system management were defined as proactive, 18% chaotic, while 25% were defined as reactive, i.e. based on the "fire extinguishing" principle (taking the necessary actions after the incident). Sadly, there isn't a single city government using the managed and measured policy, while 15% have a defined, but not fully adopted business policy. From the acquired data it's visible that without determination, desire and education of the city government management, the e-Government implementation will be elementary,

which is also supported with the fact that the e-Government strategy was adopted just in 2009.

Information security is the fourth foundation of modern e-government that's accessible 24 hours a day, 365 days a year, and which resists all possible information risks. Effectively, all areas covered with the questionnaire are imbued with the elements of information security, since its primary function is to ensure continuity of business processes while reducing risks that may influent those and their integral part extends throughout remaining 4 foundations of e-business. Regarding the carried questionnaire, a sample of 40% city governments don't have precisely determined rights and roles to work with the information system. Sadly, even 73% of city governments don't have a defined policy for accessing official documents, i.e. it's pretty hard to determine responsibilities in a case of intended or accidental loss or unauthorized exchange of data.

Regarding the world trends, the best protection against electronic viral attack is a regular application of software patches and update of antiviral software, where 35% of the surveyed city governments failed (see Figure 5.). The above mentioned oversights represent great security risks for the continuity of e-business which can lead to the stagnation in offering services resulting in the end with a financial loss and the loss of end users trust.

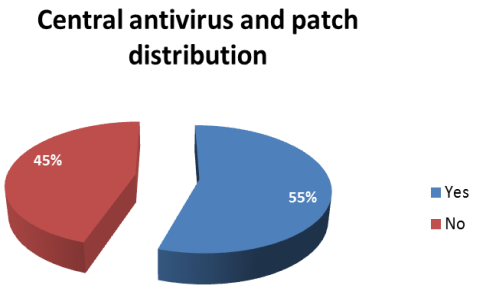

Figure 5. Central antivirus and patch distribution

In the segment of the availability of e-services, it's possible to say that every city government has its own website. 3% satisfied only the necessary website form, 33% of them have only the basic information regarding the services their city government offers, while 55% have the ability to accept and print out empty web forms, and only 5% of city governments offer the service of filling interactive web forms with authentication out (see Figure 6). Following the trends and standards appointed from the EU, it's concluded that there isn't a single city government that offers such level of services and categories, which contain a complete service on web portal like completing web forms, authentication, payment and delivery confirmation through the web.

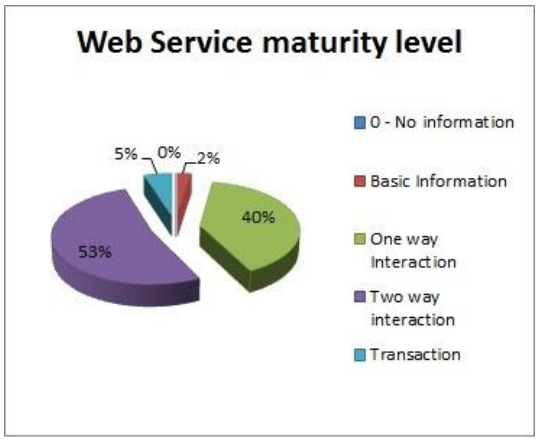

Figure 6 Degree of web service development

The analyzed data represent only a part of data acquired through the questionnaire. Only the most important data, which are crucial for the achievement of efficiency of e-business, and according to the opinions of the experts, as well as scientific literature, were taken into consideration.

III. PROPOSAL FOR THE IMPROVEMENT OF FUNCTIONALITY OF E-BUSINESS IN CITY GOVERNMENTS

The conducted analysis of e-business in city governments indicates the need of creating the e-government development strategy on local level, and coordinate it with the development of e-business on state level. Furthermore, establishment of task forces and associations which would comprise of representatives from both state and local level would ensure exchange of experience in the implementation of certain e-government technological solutions, ease choosing the most qualitative solutions while lowering the costs of implementation at the same time, coordinate with interoperability standards of state administration and EU, and result in the creation of strategy which would unite the needs of every city, never mind their size. Participation in an association which would contain representatives of every city would greatly assist in the development of those cities that don't have permanent staff employed in the ICT sector. Education and information in e-government would at least somewhat equalize digital services offered to the citizens by the local administration. Fundamental role in ensuring the minimum technological requirements in the implementation of e-government at the local level should be ensured by the state which should define rules and laws that prescribe the technological framework and standards for the use and manipulation (input, processing and storage) of data.

Looking back at the coverage of city governments with software applications, it's necessary to unite and standardize all the data inside a joint database, primarily to ensure efficiency in their use. This would also ensure the accomplishment of fundamental requirement of interoperability in information exchange with other institutions.

From the aspect of information security it's necessary to ensure monitoring of legislation in this field, appoint a person responsible for the enforcement of those, and basically enlighten the management about the risks that city government's business is being exposed to if they don't show a required attention in the mentioned field.

One of the possible solutions which should be initiated and ensured by the state is the implementation of e-business through "cloud" services. Such a solution would ensure the same service quality and development of all cities regardless of their financial and geographical development. It would also ensure that all Croatian citizens, regardless of their place of residence, have the same service quality in interaction with local and state administration. Although this is financially acceptable solution, a necessary requirement in achieving the "cloud" service lies in enabling broadband Internet access to every Croatian citizen.

EU development strategies like Digital agenda 2020 put development of digital society in the center, as one of the factors of economic and social development. It should also be noted that e-government represents a barycenter, as a mean that removes administrative barriers, while ensuring high degree of privacy, reliability and safety in offering their services at the same time, and as such it represents one of the EU priorities and its future state members[6][7].

IV. CONCLUSION

Regarding the e-readiness index, according to which Croatia is ranked on 54th place and which was obtained considering the research that was focused on the state level institutions whose e-service is more developed than from those on city level which belong to the city governments, and considering the acquired data and carried analysis, it's possible to conclude that city government's e-business has just begun to develop and, depending on the individual city government, is currently situated in the first 2 phases of development (administration centric and customer aware). From the Croatian e-government development strategy, it's clearly evident that there is a hurry with the harmonization of the legislative for the development of e-government only in those areas which are crucial for the joining with the EU, while the development of e-services is only being mentioned as a mean for satisfying the form. A great number of Croatian local administrations have just entered the phase of business process automation and process of digitalization of their own data. The informatization process is being implemented violently, often without interconnecting all the business processes into a single system, and therefore there is a need for a systematic and methodical investment into e-business, which would accelerate and optimize business processes and cut the need for human staff. On the other hand, a nonsystematic implementation of e-business would require extra implementation and maintenance costs, without the optimization of business processes and increase in efficiency.

E-Government Service Generator

use case project E-Government Montenegro

Milan Maric
S&T Montenegro/ Podgorica, Montenegro
milan.maric@snt.me

ABSTRACT

Different authorities, government and municipalities, use to develop their own solution for delivering e-services to citizens and other subjects. As every authority has different priorities to solve, culture, knowledge, IT infrastructure, and sometimes different law, standards and policy, developed solutions could hardly communicated between each other. Also, already developed e-service solution could hardly be applied in another E-Government project, as there are no standard tools for importing already developed solution. Therefore , in this article , we described E-Government Service Generator Tool which could be used for delivering standardized E-Services, that could be easily exported and reused, or even copied in another E-Government project, which is developed by the same tool .

Keywords: service generator, reusing, multi language, import service, design forms

I. INTRODUCTION

E-Government Service Generator tool is solution is based on multi language interactive visual form designer for web build and deployment forms with features:

- 100% web-based and does not require installing any software on the user's computer.
- Easy grid-based layout based on sections and grids for forming elements.
- Rich data validation and controls supporting common data types for validation and user interface controls, as well as attachments and pictures. It also lets you import your own XML Schema and use the imported types.
- Easy HTML and PDF output for exporting to other applications**.**
- Build simple services and actions right from the editor without writing code. Using WEB application administrator from any Government Institution has opportunity to create service (Figure 1).

II. GENERATOR DESCRIPTION

It is possible to create a new service in 3 ways :

1. By creating an entirely new services
2. Creating a service based on the existing service and make editing an existing template.
3. By importing an XML file, and make editing on imported template (Figure 3)

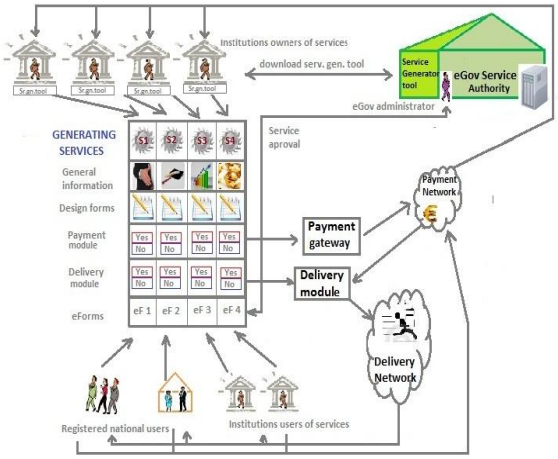

Figure 1. E-Government service generator scheme

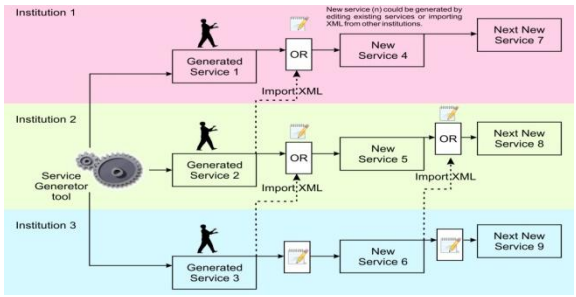

Figure 2. Services generation using existing template or import XML Service Generator tool

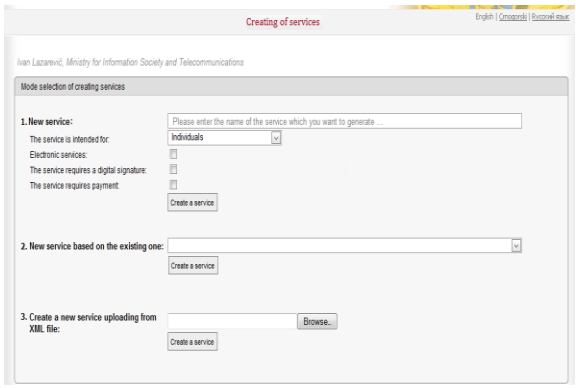

Figure 3. Creation of Services

A. Reusing

Reusing is fully achieved by editing on existing service template or importing XML forms from external services in time needed for creation of new service less than 1 hour (Figure 2). International oriented services could be produced, with just one click swapping between languages, including labels, help and error messages. Expert talk to the outside world is provided with its built-in Web Services editor. By implementing XForms technology every service designed in one institutions could be easily exported to other applications using XForms and XML export

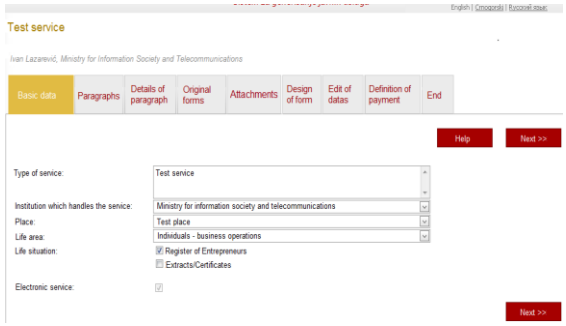

Figure 4: Basic data

B. *User created and definable paragraphs*

Next step is defining the new basic data: service name, type, responsible institution, target subjects /group, life situation. This data is defined by paragraphs. The list of Paragraph names and the content to be shown is fully managed.
In the first step the list of paragraphs is managed. Once defined, the content of individual paragraphs is filled in the second step „Details of paragraph“. Paragraph content is edited in HTML editor.

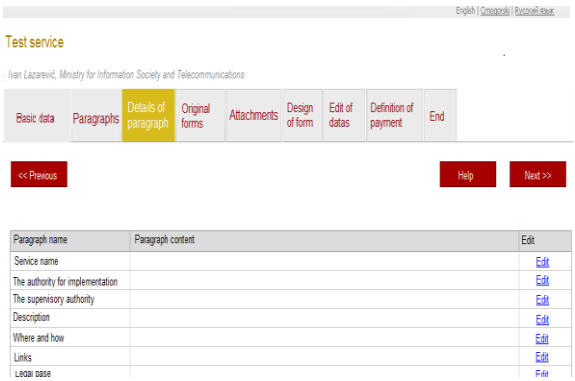

Figure 5. User created and definable paragraphs

C. *The original forms*

The next step is to enter the original forms (original forms are available for users to print, Figure 6). Selecting Add opens a window for adding forms. First define the name of the form and then submit it by finding the file by clicking on Choose File.
Types of documents that can be attached are: jpeg, gif, pdf, doc and docx. By clicking on the Save data will be accepted. The procedure is repeated for each following form.

Figure 6. The original forms

D. *Attachments*

The next step is to define an attachment (Figure 7). Attachments are documents submitted by the applicant as required or optional with the application

It is necessary to provide a text description attached, additional information about this document, the authority which issued the document, mark whether the documents are required and whether the necessary personal delivery. By clicking on the Save data will be accepted. The procedure is repeated for each subsequent document by clicking on Add. Allowed document formats are .doc, .docx, .pdf, .jpeg, .gif, .zip. Also, the user can add a digitally signed documents.

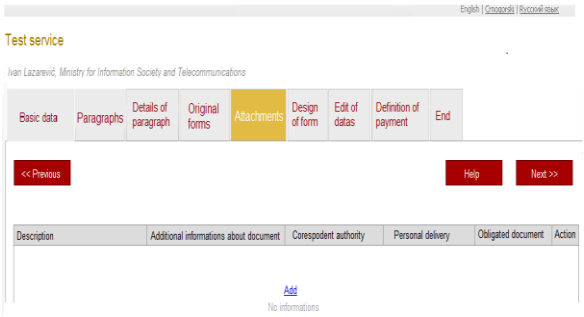

Figure 7. Attachments

E. *Design forms*

An integral part of service creation wizard is a tool (Figure 8) which in a simple and intuitive way, providing the ability to create an electronic form. By putting the elements of the form and their subsequent deploying (drag and drop) it is possible to make a pattern on the model of the original. That created an electronic form used to apply and enter the necessary data when carrying out the service by end users.
Deployment - here is a typical life for a form:

Design time — The form author

Edits the form definition from the Form Builder editor> >Saves the form definition>>Tests the form definition>>Multiple edit/save>>test cycles can take place>>Publishes the form definition

Runtime — The form user

Initiates the creation of new form data from the form's summary page>>Enters data into the form>>Reviews, saves, submits, or downloads form data

F. *Edit service data details*

- Service requires digital signatures
- Service requires payment
- Level of authorization.

Below are the parameters of processing services:
- Period of treatment services (time in days that is stipulated by law or other act)/ Deadline for payment (if the service requires payment period should be determined in the days that leaves the user to make the payment)/ Send notification of default of payment every N days

G. *Defining payment*

The window for completing the payment slip (Figure 10). Administrator must enter a payment order >> the name of the responsible institution which tax is paid >> place of institution >> account information >> ammount >>, the model and reference number>>municipality . Budget accounts for the automatic model , a reference number is entered.
The user has a choice of different payment methods. The user can make payments using the payment slip or directly through the portal, choosing one of the banks from the list.

Figure 8. Typical applicant form captured in run time

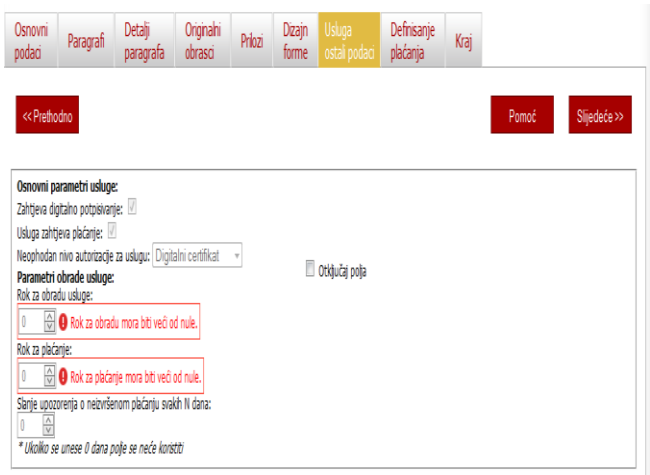

Figure 9 . Editing Service data details

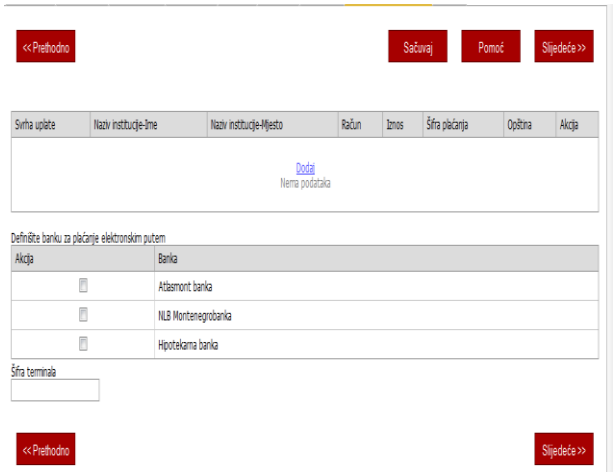

Figure 10 . Defining payment

H. *End phase – delivery*

The last phase is the choice of downloading the document (Figure 11). If you choose to document delivery service is the end user will appear in all ways of delivery. You can mark one or more modes of delivery and at the same time the user selects a way that suits him more. By selecting Edit on the particular choice of where and how you enter - a description of the delivery. By clicking on the Save public service, the service is recorded and the message "You have successfully created a service that is generated. Contact the administrator of your institution, **SERVICE** is ready for publication. "

Full integration and enterprise transaction is achieved with document delivery and mobility of e-services across administrative boundaries. End user could finish all requests from one service point. Government changes its structure and provides full sophisticated, integrated and personalized services to end users. With third party partners, institutions will enable even delivery of requested service, at home or office of request issuer. This is very helpful in case when we have old age people with handicap or business subjects in lack of time.

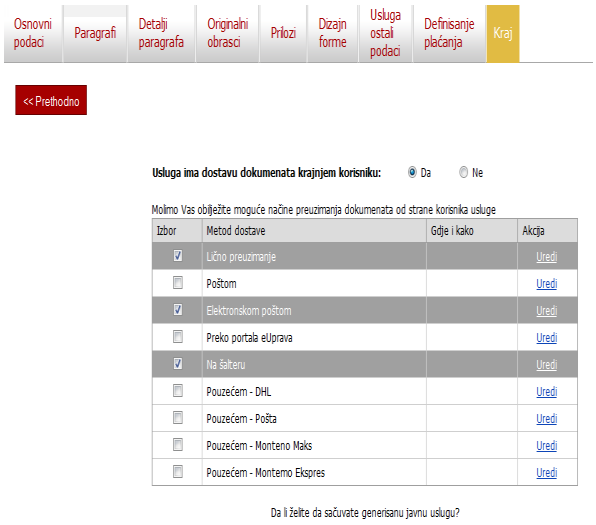

Figure 11 . Delivery

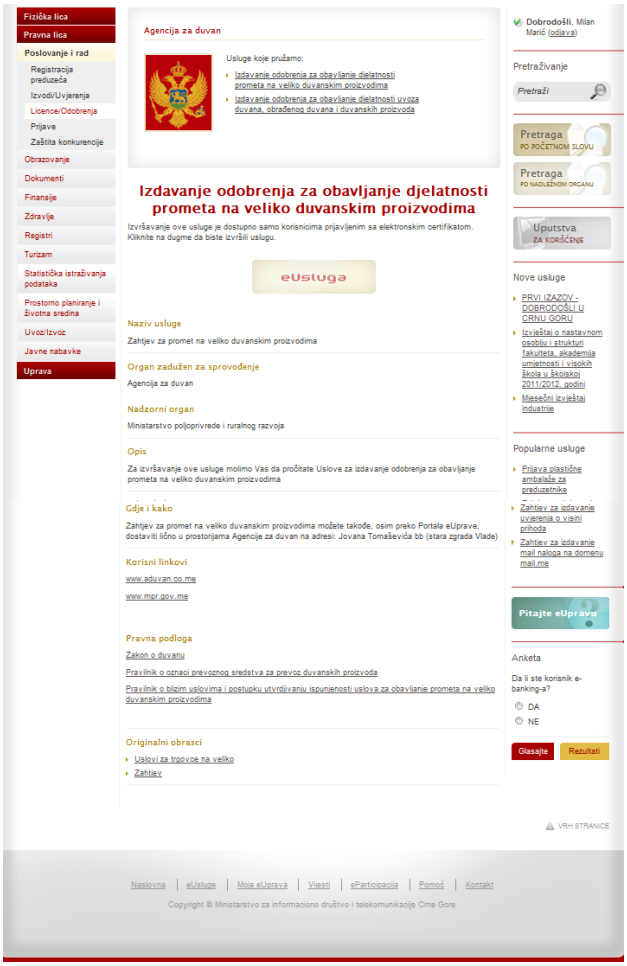

Figure 12 . One E-Government service – user look

III. CONCLUSION

E-Government is a technological phrase of Internet usage by government and authorities , to deliver services , collect data and enhance democratic processes . Surveys clearly shows that citizens asked for more services , integrated with complete transaction , including payment and delivery done with one stop . But , each service is a new expensive and long term challenge for government , and most often , new service is not able to communicate with existing one , due to inoperability between them .

Service generator is a unique tool which provide web based , clientless , free , fast and easy production of interoperable products in process of designing E-Government services . This means that final product is service , capable to communicate with other services produced by similar tool , which could be reused by numerous institutions in one Government , even on different language base .

Both , citizen and government institutions could interact in more sophisticated way , even during filling electronic forms while submiting request for service . This gives efficient and productive transactions for all parties in E-Government processes . Each service could be modified and reused from existing one , or multiplied as many times as needed from government institutions or citizens .

New Generation Operations Systems and Software and SOA Improving the Business of Telecom Operator

Amela Hadžić*, Tadej Mateljan**, Kemal Hajdarevic***
*BH Telecom Sarajevo, Bosnia and Herzegovina, **,***Faculty of Electrilcal Engineering University of Sarajevo
*Amela.Hadzic@bhtelecom.ba, **Tadej.Mateljan@etf.unsa.ba, ***Kemal.Hajdarevic@etf.unsa.ba

Abstract Telecom operators need business transformation towards the next generation model in order to achieve business process effectiveness. Enterprise architecture and production models have to be reviewed and optimised where possible. Service Oriented Architecture provides solution to the problem of deliverance of new and innovative services in rapid and flexible way. NGOSS provide specifications and guidelines which address business and technical concerns of operational and business support systems.

I INTRODUCTION

In Figure. is shown business relations before SOA implementation.

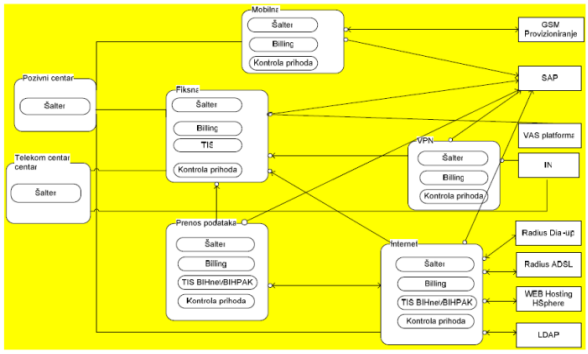

Figure 1. Information system to support operations before JRK / PPP project [2]

Service-oriented architecture encapsulates a variety of enterprises capabilities into reusable services, supporting business agility. If these services are designed using SOA principles, they constitute elementary building blocks that can be combined and rearranged to support changes in the business demands. Service-Oriented Architectures and NGOSS (New Generation Operations Systems and Software) offer complementary approaches for managing complexity. Business transformation with NGOSS and SOA introduces SOA and NGOSS concepts. Both provide unified approach for addressing complexity. SOA defines an architectural pattern and design principles for distributed IT systems that will result in loosely coupled application platform. The TM Forum Solution Frameworks with their lifecycle phases, views and artefacts provide the tools to model a service provider's business and leverage SOA to accomplish business modularity.

Application systems to support business operations are mainly developed within the company, while some are purchased and as such had minimal opportunities for changes. The fragmented system of business support needed to meet the increasing number of requests to establish a mutual exchange of data in order to support the execution of business workflows. Each technology unit had available data on 'their' customers. Providing data for business analysis at the company level was a very complex task. Service delivery includes work of several organizational and technological units. To make the service available, it is necessary to establish links between the application systems on the principle each system with each. The trend in the business flowed in the direction of providing convergent services in terms of bundling services of various technologies, giving a discount on the basis of traffic level that has been made trough services of different technologies. Creating new services should be faster and easier. Business environment in the telecom operator has become competitive. On the telecommunications market there are a large national operators, as well as many smaller competing telecom operators. Users are no longer passive, but an educated, well-informed and more difficult to satisfy the personalized demands. Therefore, the telecom operator should provide:

- Establishing relationships with customers to ensure the loyalty of existing users and acquiring new ones.
- Introduction of innovative products and services aimed at target audience.

- The introduction of high-quality services that are offered at a possible lower cost and with short term activation of services.
- Exploiting the knowledge of employees to improve service quality.

The efficiency of the sales process has a significant role. The new converged services to support the new business processes and existing sales processes should be improved and accelerated. An information system for business support, divided into monolithic, technology oriented units is no longer able to support new business requirements.

II Modeling the business processes of telecom operators

There is the need to provide the following features:
- Multiple channels of access for purchasing services on the simple way.
- Multiple channels of access to after-sales support, which allows an adequate and timely payment and problem resolve.

To achieve this capability, it is necessary to ensure the convergence of business processes that are related to the provision of services from creating leads, sales of services, monitoring the quality and level of service, billing and collection process to control revenues. The convergence of business processes is performed by modeling business processes, which included designing, managing and executing business processes. Modeling business processes was focused on integrated business processes, regardless of which organizational units perform or took a part in the process. Both, business analysts and technical staff, had the task to improve business processes. Modeling business processes needed to provide:

• Formalization of existing processes,
• Better understanding of the process that leads to introduction of improvements,
• Efficient execution of business processes by use of software business process modeling,
• Increase productivity and reduce the participation of people in the execution process.

III NGOSS AND THE TELECOM OPERATORS BUSINESS

Telecom operators need efficient, cost effective OSS/BSS systems. These systems will need to solve the task of automation of complex business processes in a short period of time and thus to adapt to new demands of the business environment. The OSS/BSS systems have to provide a rapid return on investment. On the other hand, they need long-term strategy to develop their information systems. Telecom operators that have created their OSS/BSS systems without long-term planning, have to invest significant resources in expanding the functionality of their OSS/BSS systems to manage complex networks, services and processes.

NGOSS that stands for for New Generation Operations Systems and Software is the TeleManagement Forum's programme to provide ways to help Communication Service Providers to manage their business [3]. NGOSS consists of:

- Business Process Framework (eTOM),
- Information Framework (SID),
- Integration Framework (TNA),
- Application Framework (TAM).

eTOM

eTOM Business Process Framework represents a comprehensive detailed map of business processes used by telecom operators. eTOM framework can be used as a tool for analyzing existing business processes and as a framework for defining the scope of the new software solutions. Business process functionalities should be implemented according to eTOM process map. Process of integration of new software components into an existing information system is easier and faster to implement if the existing system is organized is standardized schema.

SID

Shared information and data model provides a common glossary of terms, entity definitions and entities relationships which allows easier and more efficient integration of OSS/BSS systems that are usually a combination of applications of different suppliers. SID provides the concepts and principles necessary to define a shared information model, entities model, business oriented UML class model and sequence diagrams that provide a systematic look at the data. The SID is organized from a general perspective as it is an abstract model. Data services and sources often contain flat data structures because they represent APIs of systems that are older. This discrepancy requires complex mapping between the external data structures and the more abstract SID details. SID model can be customized in terms of adding attributes that are needed by specific implementation.

Technology-neutral architecture and contracting interface

The concepts of technology-neutral architecture and interface are the essence of the NGOSS integration framework. In order to successfully integrate applications from different suppliers as components of the OSS/BSS system, it is necessary to provide a uniform method of integration. Technology Neutral Architecture defines the principles of architecture components that enable the development of OSS/BSS systems into successfully integrated distributed system. Contractual interface provides definitions of application programmed interfaces that enable communication and coordinated functioning of various components of the system

IV SINGLE REGISTER OF USERS AND A UNIQUE OFFERS AND SALES

BH Telecom has began introducing SOA integration platform with the project of single register of customers and single offers and sales. The project was carried out according to the rules of standardization and convergence of business processes according to recommendations of TM Forum ([3], [4]). The objectives of introducing SOA integration platform are:

- Management and monitoring of business processes related to services,
- Timely support to business requirements,
- Introduction of new technologies.

The project should provide the possibility that through different approaches such as telecommunications center, a standard teller, contact center, via web portals, in the same way, users may require any individual service or any available combination of services.

V OBJECTIVES OF THE PROJECT

The main objectives of the project according to [2] were:

1. Build and deploy application solutions for a single register of customers (JRK) and the single offers and sales (JPP).
2. Build a hierarchical structure of users, as a precondition for invoicing grouped by the user request.
3. JRK - should be the integration point for parts of convergent billing.
4. JPP should allow flexibility and quick implementation of a function of supply and sales in accordance with the NGOSS frameworks: eTOM [4] and SID [5] model across all access channels.
5. Provide conditions of service to customers through multiple channels of access uniformly, requiring each individual service or any combination of services available.
6. The aim of the project was to introduce the new technologies and architectures (SOA) in information system of telecom operator in order to overcome problems of monolithic application systems to support business.

VI THE FRAMEWORK OF THE PROJECT

Expected results of the project, set up by management should be application solutions for converged platform. Within this project, all existing modules for customer registration and sales need to be replaced by new application solutions for a unique register of customers and the unique offers and sales. Other modules of the existing system need to adapt and integrate with the new application solutions for a unique register of the unique offer and sales.

VII THE CONCEPT OF INTEGRATION

New application system of a unique offers and sales had to ensure integration with others systems: provisioning, billing, inventory, SAP, WEB portal. Integration with applications in the environment through which it performs activation of products or services was implemented through interfaces that allow the transfer of data and mapping required. Module integration is implemented through a set of services with a pre-defined methods input and output data types. Services are Web services, or PL/SQL (Procedural Language/Structured Query Language) application programmable interfaces (Application Programming Interface API).

Key tactics design to achieve the basic SOA values are:

- Creating a Service Portfolio Plan - used to monitor all services within the company, to ensure the reuse of services where it is possible.
- Provide that the aims and requirements do not drop the key values of SOA: reuse and loose coupling of services.
- Limiting dependencies, and to use the process for service orchestration instead of coding dependencies within a component.
- The use of patterns during design to ensure the standards and proven principles.

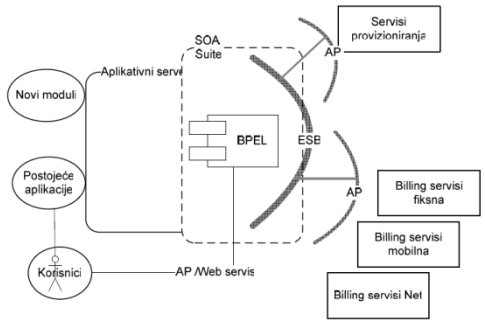

Figure 2. Architecture of the integration solutions [1]

After implementation of this project, the company has got the platform that is ready for implementing new service-oriented components and which is adjusted to recommendations of the TM Forum - NGOSS TNA. The integration solution is based on the enterprise service bus. The global architecture of the solution is presented in Figure 6. The basis of the integrative platform consists of:

- Business process management through BPEL Process Manager,
- Enterprise service bus,
- A common data model.

Managing business processes to create workflows and integration business streams with BPEL processes. The logic of integration is defined in XML documents and is contained in one place. Enterprise service bus provides communication and data exchange between new system and

the rest of OSS/BSS system that still have remained divided by technologies. Integrated applications are loosely coupled, applications do not depend on the data structures of other applications and their database schema. Data is exchanged in the form of XML documents and can be transformed to achieve independence of data structures. The implementation runs over an ESB application server infrastructure. Most of the application programming interfaces (APIs) are Web services. During processing of an order, the Web service APIs pass messages in the form of XML documents that represent aspects of an order. The SID common model is the used between all the application interfaces.

Such platform enables use of existing and adding new functionalities in a simple and uniform way. Existing applications developed on the technology of monolithic blocks are integrated with the new system through adapters. In this way they become more usable and accessible to the rest of the system. For implementation of new functionalities are developed dedicatedly Web services. New application system for registration of customers and the offers and sales have been developed by principles of NGOSS neutral architecture:

- Separation of business process from the implementation process. BPEL language was used to describe the business processes flows within the system. BPEL allows Web services calls in a simple way. It allows the use and specification of rollback functions, fault management, and support for processes that are long running. BPEL is used to design service orchestration functionality. Integration with existing systems is provided through a BPEL/ESB integration flows.
- Shared information model

  Shared Information and Data model (SID) provides common language used in software development. SID gives concepts and principles necessary to define a shared data model, as well as entities of the model. SID is a layered framework for distribution of shared information in eight domains (Market and Sales, Customer, Product, Service, Resources, Supplier/Partner, Enterprise, Common Business Domain) that are aligned with eTOM procedural framework. Within each domain SID defines aggregate business entities. Key business entities are Party, Customer, Location, Interaction and Contract. Database for a single offer and sale and a single register of customers was designed to be mapped to SID domains: Product, Customer, Service and Party. A hierarchical structure of the customer was established. That is one of the preconditions for issuing invoices grouped by choice of users regardless of location of issuing the requirements. The shared data model consists of components, resources and services allowing the flexibility of building catalogs products.
- Use of NGOSS contracts to define interactions between components.

The service functionality is available through the interface that is defined in the agreement. NGOSS defines the interface as a named set of operations that provide the functionality of services. Arguments of interfaces are defined using shared information entities.
Software entities of the JRK/JPP system provides services to other system's entities and users of the system trough interfaces. Each service has specification of:

- Meta data to describe the interface,
- Meta data that are used to describe operations that service calls,
- A set of results that can be returned to service after calling certain operations.
- Preconditions that must be met in order to invoke operations.
- Conditions which define the possible states in which the system resides after execution of operations.

SOA methodology based on the working framework includes four phases:

1. Gathering business requirements,
2. Building SOA Work Plan,
3. Design and implementation of SOA services.
4. Implementation of SOA solutions and changes in enterprise organization.

In the phase of collecting business requirements the documentation of existing systems and processes was produced. Decomposition of business processes was carried out in order to consolidate existing business processes. Scenarios for business cases were made through the sequence diagrams. The planning of the service portfolio for the customers of telecommunications of services was made.
In the phase of building SOA business plan the classification and specification of Web services was carried out. In this phase the specification of the database model has been made.
In the stage of design and implementation of SOA services, the specification for automated Web service coordination was produced to ensure execution of complex business processes. Service orchestration functionality is developed. Integration with existing systems is provided through the BPEL/ESB integration flows.
Together with the new modules in the final solution are incorporated parts of existing applications. The project replaced all modules that were covered by the specified functionality and which were mutually isolated by specific telecommunications technologies. Single application solution is introduced that provides functionality of registering customers and providing offers and sales for any combination of services, regardless of the telecommunication technology and regardless of the access point. The project required

adjust the existing billing system in accordance with the new organization of business processes, which are facing the user, rather than a specific technology.

Benefits of the implementation of the project unique register of customers and of the unique offers and sales are as follow:

- Construction of a complex hierarchy structure that allows the customers to define the point of contract and point of bill collection upon their needs.
- Construction of a unique and flexible product catalog of telecom operator.
- Standardization of processes and solutions, thus achieving uniformity of solutions and ease of maintenance.

The architecture of the overall information system of telecom operators is simpler compared to the situation prior to project implementation and is oriented towards the user.

VIII THE EXPERIENCE OF USING THE INTEGRATED SYSTEM

Main benefits of implementing SOA architectures through the project JRK and JPP can be seen through:

- Easier introduction of new services and channels of access. Services can be reused which facilitates the introduction of new services and channels. Using SOA architecture provides to generate business processes flexible and suitable for rapid adjustments depending on changes in the integrated applications and systems.
- Stronger relationships with customers. Establishing new application system, as well as business services to customers, enhances the cooperation and satisfaction between the company and service users. Monitoring of the realization flow of customer's requests can be made from a single point, from the moment of request for sale, to activation of required services at the network elements.
- Improving of decision-making process. Aggregation of access to services and information through the application JRK/JPP, decision makers gain more accurate and comprehensive information for a shorter time and lower costs.

The introduction of SOA architecture through design of JRK/JPP has created the prerequisites for further information system development in the direction of convergence. Weaknesses and problems identified through the implementation of the SOA architecture and the JRK/JPP project can be expressed as follows:

In the case of JRK/JPP projects, the aggravating circumstance that the project construction of a service-oriented architecture moved starting from the stage where the existing systems for registering users, selling and managing of orders were divided into separate application systems. Additional effort is needed to invest in construction of a common system of the codebook, migration plan and migration of existing users with all the general information and data on the use of services new common data model.

Aggravating circumstance for the functioning of the new system is the integrated current systems significantly affect the quality of functioning of the entire platform. Return on Investment (Return Of Investment - ROI) through the implementation of this project can not be achieved in a short time interval. The processes of implementing SOA projects are lengthy and require a significant level education of all participants. SOA governance should be used from the very beginning in stage of design of SOA solution.

IX SOA GOVERNANCE METRICS

SOA governance refers to the processes used to oversee and control the adoption and implementation of service-oriented architecture (SOA) in accordance with recognized practices, principles and government regulations. SOA governance provides optimum service quality, consistency, predictability and performance, ensures that personnel follow prescribed policies and corrects system problems or policy infractions as they occur.

SOA governance consists of three major components: a registry, a policy and a testing procedure[7].

SOA governance metrics measure compliance and verify policy enforcement regarding service use. They will measure trends, including the level of reuse, and the number of violations and requests for waivers. The success of SOA governance and policies in relation to directing service consumption will be determined by these metrics.

SOA metrics include the following types of metrics: Business Process, Return on Investment, Service level, and SOA Conformance. [6]

Business Process Metrics: Define business process metrics. Metrics may include: customer satisfaction metrics, metrics that measure internal work processes, and profitability metrics.

Return on Investment Metrics: Define metrics for return on investment. Metrics may include metrics defined in the SOA business case, and metrics defined in the business case for a particular service.

Service Level Agreements: Define Service Level Agreements for each service and/or business process. Metrics may include: allowed down time, etc.

SOA Conformance: Identify SOA related metrics that are important to the state or agency. These metrics may include metrics that measure service reuse, process efficiency, and business agility.

X CONCLUSION

The paper elaborated the need for change within the company as a provider of telecommunication services. Providers in the telecom industry need to improve agility regard change the business environment and efficiency, in its effort to become more flexible and to transform the company into a service oriented company. Companies are faced with the reality of business with existing applications, processes, data models, and organization, all of which is difficult to regulate.

To become effective in its operations, telecom operators, need to gradually abandon the existing way of doing business. The first step in this effort is to reduce the complexity. It is necessary that companies establish business modularity, which can be achieved by introducing structured, flexible and reusable modules - SOA services.

The realization of the project JRK/JPP architecture overall information system is simpler than before project implementation. The project replaced all modules that cover the functionalities of customer registration, offers and sales, which were mutually isolated and linked to specific technology. Single application solution was introduced for record of customers and customer requirements for sale, regardless of the technology and channel of access. The basis of the integrative platform consists of business process management, integrative flows generated through the enterprise service bus and a common data model. Optimized core is achieved through a joint information platform, which is governed by reusing business processes along the enterprise service bus. Main benefits of implementing SOA architectures through the project JRK/JPP can be seen through:

- Simple introduction of new services and channels of access.
- Stronger connections with customers.
- Improve decision making process.
- Increase productivity.

The good side is that SOA is not specific for a certain technology. Although clearly defined design features and principles, however, allows a wide scope of deployment and technological options. Return on investment by implementing such projects can not be achieved in a short time interval. The processes of implementing SOA projects are long term and require a significant level of education of all participants. SOA approach based on the framework decision in spite of the shortcomings listed serves as a leader in the ICT industry faces the challenge of implementing business modularity.

gregor.lenart@fov.uni-mb.si

The paper presents the Living Lab approach for the creation of a prototype solution aimed for supporting sustainable tourism in Gorenjska region. Involving users in the process of co-creation is one of the key elements in the Living Lab approach. A Living Lab is an environment in which researchers, developers and users cooperate with the common objective of delivering a tested product, solution or service respecting the users' requirements. The motivation is to bring together various actors in the field of tourism services development in the Gorenjska region, to create innovative solutions for supporting, promoting and encouraging development of sustainable tourism in the region and development of the region itself. The aim is to develop a web-based prototype solution that include geo location information and social networks in the Living Lab approach. The result of our research is a design of a prototype and a critical analysis of the co-creation process.

I. Introduction

A Living Lab is an environment in which researchers, developers and users cooperate with the common objective of delivering a tested product, solution or service respecting the users' requirements and in a shortest time possible. The environment may be a city, a region within a country, an industry, a supply chain or a whole country (slovenianlivinglab.org).

In the Living Labs actors exploit opportunities and IT solutions to connect themselves. The cooperation among businesses, government organizations, universities and other research institutions in forming the IT solutions and services can be seen as a big, broadly conceptualized laboratory. The name Living Lab, living laboratory, derives from the fact that it involves a lot of actors who co-create a certain innovation. In Living Labs, issues are examined from a technological, economic, organization, social, legal and other viewpoint (Lenart, 2012).

In this article we will discuss the concept of Living Labs as an approach involving users in the process of developing web solutions in the field of sustainable tourism. The problem of involving users in the process of developing IT solutions in a certain field is the user's perception of the problem and the needs, requirements, skills, interests and motivation to solve this problem (Hyysalo, 2003).

The main question of our research will therefore be how to motivate users to engage in the process of developing web solutions.

Living Lab in the field of forming a web solution for the development of sustainable tourism includes tourists, tourism service providers, researchers and web solution software developers.

The involved tourist service providers are:

- Local Tourist Organizations: Institute for Tourism and Culture Žirovnica, Bled Tourism, Tourist Association Radovljica
- Nature Parks: Triglav National Park
- Tourist Farms: Tourist Farm Mulej
- Hotels: Sava Hotels Bled
- Cultural Institutes: Bled Culture Institute

The types of the involved tourist groups are:

- Domestic tourists (young, families, retired…)
- Foreign tourists (young, families, retired…)

The concept of motivation includes the user's needs. These depend on the type of users and the social circumstances which the users are facing. Different types of users have different needs. In the case of creating a web solution for the development of sustainable tourism, the end users, users of the tourist services, become actively involved in the co-creation process, so that they help create and /or improve tourist services. So our goal is to develop such a platform that would enable stakeholders to co-create a sustainable tourist services.

The user's needs depend on their values, goals and on creating the added value. The recognition of the types of users and their needs helps us in analysing the development of IT needs. The needs of users represent the driving force behind the development of new services. One of the methods of determining the user's needs and developing new service solutions is the research of user's behaviour before and after the implementation of a new IT solution. In this way, we can determine how a new IT solution and services have a retroactive effect on the change of their needs and demands. In most cases, the users have a problem in clearly defining their need or are simply unaware of their needs. In some cases the users are aware of their need, but cannot see a way of resolving it or a means to satisfy it. In such cases we can inform the user of possible solutions (Stahlbrost, 2008).

In theory, there are different definitions of user needs. The marketing definition states that a user is only interested in individual benefits of service development. Improvements in the area of IT solutions therefore stem from the desire to improve the user's life and work. According to this theory, the users have the power to through non-cooperation stop the development of a certain IT solution; insofar it does not fulfil their needs. Motivation theory takes into regard the user's desires for power, curiosity, autonomy, status, inclusion, competition, pride, idealism, athletic participation, romance, spending time with the family, organization, healthy nutrition, social acceptance, relaxation, collecting and once again the experience of joy when satisfying a certain need (Stahlbrost, 2008).

The user's needs also often depend on momentary circumstances, which can of course change when the circumstances change, whereas solutions depend on developing user-friendly services and products.

In this article, with the help of researching motivation and user's needs, we plan to analyse the process of designing web prototype solutions in the framework of developing eco-tourism pilot using the concept of Living Labs.

The pilot is taking the place within the Project CentraLab, which tries to explain the competitive advantages of the use of the methodology of Living Labs for innovation in the area of Central Europe. The goal of the project is to increase territorial cohesion, encourage internal integration and to strengthen competiveness through mutual learning and partnership strengthening.

We will use a prototype solution as the basis for the pilot development in the area of developing sustainable tourism in the Gorenjska region. The Gorenjska region is facing with scattered, incoherent, diverse and noninnovative tourist offer in the area of sustainable tourism development, with a weak cooperation of the tourist participants, weak reaction to the changes in tourist demand and low entry and participation of SME's in tourism. It is estimated that the reasons behind this are the poor use of potentials, bad organizational support for the marketing of integrated wholesome services and developed wholesome regional products (Strategy 2010-2015).

A developed web solution will in the area of sustainable development of eco-tourism of the Gorenjska region join the existing stakeholders and their services with other services, which will represent the basis for innovative and complete offer of tourist services. The goal of the web solution will be to design innovative linked and individualized services, which an individual tourist can reach online, and offering help when planning a trip, interactive communication on the way and when documenting the trip. The web solution will include:

- General information, (culture, history, gastronomy …).
- Geo location services (like Google Earth/Maps).
- Functionalities of the Web 2.0 (such as Drupal).
- Links to existing social networks (Facebook, Twitter, LinkedIn …).
- Possibility of evaluating the tourist offers to acquire feedback on the quality of tourist services and tourist satisfaction.

II. Methodology

Our paper deals with the question how to develop such a platform that would motivate and enable users to co-create a sustainable tourist services.

Concerning the types of users, we assume that the motive for cooperation of the tourist service providers in the development of the web solution in the area of sustainable tourism is in the need for an increased number of tourist visits. The motive for cooperation of tourists in the development of online solution in the area of sustainable tourism is behind their need for a quality spending of leisure time.

The motives of these two types of users will be checked with the help of an online survey in the setup application. The results of the survey will be compared with the notes in the research diary, where we will record all the new entries of tourist services and comments of the new users of the application.

The process of the setup of the Living Lab will include the following stages:

1. Definition of the group of stakeholders
2. Definition of the user's needs
3. Developing the prototype solution
4. Testing of the prototype solution
5. Use of the prototype solution
6. Updating the prototype solution

Since we are focusing on the research of a practical problem and because we are actively including, apart from the researches, also users and the web solution software developers. For the acquiring of information in the framework of active research method we will use next methods:

- Online survey
- Analysis of the development of the web solutions in the area of sustainable tourism.
- Living Labs approach in the development of user-friendly services also use the method
- Research diary

In the research diary, we will record all the new entries of tourist services and comments of the new users of application, which we will then compare with the answers gathered by the online survey.

As the basis for determining the user's needs in developing the web solution, we used the approach of soft systems methodology, which served also for the description of the general research issue (see picture 1).

Web-based prototype solution will be developed by prototype method of information system development, since the draft of the web solution will be improved in a repetitive process so that it will continue to better suit the demands and needs of the users. Using the solution, the users can see for themselves the advantages that this type of work offers (Pucihar 1999, 59).

III. Results

The goal of our research is to motivate and engage the users in the process of developing web solutions. We plan to use an online solution as a research tool for the operation of a Living Lab in the area of development of eco-tourist services. The first meeting of all the stakeholders can be depicted by the following image:

Picture1: Living Lab for the design and growth of eco-tourist services of the Gorenjska region

Picture 1 demonstrates the Living Lab for the design and growth of eco-tourist services of the Gorenjska region. The picture includes all stakeholders, which participate in the development of the web-based prototype solution: tourists (right part of the picture), providers of tourist services (left part of the picture), researchers (upper part of the picture) and developers of the web solution (bottom part of the picture). The common point of the providers of tourist services represents the need to retain the existing and to attract new tourists. The common point among tourists is the need to discover new places and stories. The motive of researchers is the research of Living Labs in the example of developing a prototype solution for a web application for the development of sustainable tourism of the Gorenjska region. The need of developers of online solutions is the opportunity to use geographic information technology systems.

The web-based prototype solution will be implemented as a part of the portal supporting development and growth of eco-tourist services. The portal will be developed in an open source – content management system CMS connected to a database. The basic functionality of the prototype will be to present various tourist trips and points of interest in the area of eco-tourism, so called itineraries. The database will include all online contents, users and portal settings. The portal will be constructed in a way that it will be possible to maintain the operation of the portal by minimum costs after the pilot will be completed and to exploit as much as possible the already existing sources of

implementation such as e.g.: social networks Facebook/ Twitter, Google Earth/Maps, open source code platforms for the management of online contents, such as Drupal, links to existing online sites of the providers of tourist services. Upon completing the project our goal is to submit the portal for use to a local tourist organization (Lenart, 2012).

The results of the activities of the Living Lab so far:

- Development of the group of stakeholders,
- Organization of workshop, where goals of the project and possibilities for cooperation were presented,
- Definition of individual needs of the users,
- Definition of the concept of prototype solution on the basis of recognized possibilities and
- Use of modern IT systems for the development of prototype solution.

The next steps in the research of the Living Lab in the area of developing a web solution for the promotion of eco-tourist services will include the following stages

- Development of the prototype solution,
- Testing of the prototype solution,
- Use of the prototype solution and
- Perfection of the prototype solution

IV. Discussion and conclusions

Based on the analysis of the results of the online survey, we expect that the providers of tourist services will co-create those IT services in the area of sustainable tourism on the web solution, which will lead to a bigger number of tourists and prolong the average duration of a tourist staying with them. Their contribution to the development of the online application will stem from the above mentioned marketing theory of the origin of the user's needs for a certain service.

On the other hand, we can expect that different groups of tourists will co-create those tourist services in the area of tourism on the website, which will be in accordance with their needs for spending vacation and free time. Their contribution to the online solution development will stem from the above mentioned motivation theory of the origin of user's needs for a certain service.

The main problem we can expect in this co-creation of the web solution is a low response from the users. Above all, there is fear that the tourists will not recognize the useful value of the solution and in this way we could lose one of the key actors in co-creating tourist services, leading to the solution becoming only one of the many already existing, offering tourist services, but not co-creating them. To avoid any potential problems, we will need to consider different kinds of promotion of the solution among the tourist groups and informing the providers of tourist services on the advantages of co-creation of the online application. We are also considering the problem of the lacking information on tourist services and lack of computer skills of the users, both on the side of certain tourist groups, as well as on the side of tourist service providers. One other possible and anticipated problem could also be untrue and misleading feedback information, because of which we will need to introduce a position of the caretaker of the solution and lack of financial means for the promotion of the solution.

Acknowledgment

Since our research is taking place within the project CentraLab (Central European Living Lab for Territorial Innovation) I would like to thank to Central Europe programme which in the framework of European Territorial Cooperation objective of ERDF co-funded the project.

Integracija društvenih mreža i utjecaj na oglašavanje u javnom sektoru

Alen Šimec, Sanja Duk
Tehnical Polytehnic in Zagreb/Vrbik 8, 10000 Zagreb, Croatia
alen@tvz.hr, sanja.duk@tvz.hr

Abstract - Ekspanzija društvenih mreža kao što su LinkedIn, Facebook, Google+, Twitter, YouTube rezultirala je činjenicom da su društvene mreže u današnjoj kulturi postale nezaobilazan dio svakodnevice. Novi korisnici pridružuju se društvenim mrežama zbog posla, oglašavanja, dijeljenja informacija, zabave ili druženja. Marketinška industrija uvidjela je u njima plodno tlo, te su se počeli razvijati različiti načini oglašavanja putem društvenih mreža. Kao najbolje sredstvo za komunikaciju s klijentima pokazali su se fotografija i video pa oglašivači iz dana u dan traže inovativna rješenja na ovom području. Sve društvene mreže podložne su napadima te se kontinuirano ulaže u sigurnost sustava. Facebook kao najpopularnija među navedenim društvenim mrežama vodi borbu s problemom sigurnosti, te je razvio sustav Facebook Immunity System koji služi za provjeru sadržaja koji se objavljuje od strane korisnika. Proučavanje društvenih mreža najviše je usmjereno na Facebook s obzirom da je najzastupljeniji među društvenim mrežama na tržištu. U radu je prikazana struktura korisnika društvenih mreža. Potvrđeno je da radi jednostavnosti korištenja korisnici bez ikakvog naprednog znanja o tehnologijama mogu koristiti ovakve kanale u komercijalne svrhe. Mnogi su faktori utjecali na njihovo populariziranje, a među istaknutijima je pristup društvenim mrežama putem mobilnih uređaja.

I. UVOD

Informacijska revolucija širi se gospodarstvom, te nema tvrtke koja može izbjeći njenom učinku. Drastično smanjenje troškova dobivanja, obrade i prijenosa informacija mijenja način na koji poslujemo. Tehnološki osviještene tvrtke vide Facebook kao odličan način komuniciranja s postojećim i novim potrošačima, te za podizanje prepoznatljivosti tvrtke u krugovima, prema tehnološki osviještenoj populaciji prema poslovnim ljudima. Razvojem društvenih mreža razvila se i zajednica koja upravlja zajedničkim resursima kroz kolektivno djelovanje volontera i sudionika (eng. *community management*) kao kombinacija korisničke podrške, marketinga i odnosa sa javnošću. Facebook ima preko 800 milijuna korisnika na cijelom svijetu, uz očekivanje da će u lipnju 2012. godine imati oko 1 milijarde korisnika. U poduzeću je zaposleno više od 2000 ljudi, a vrijednost mu se procjenjuje na oko 100 milijardi američkih dolara i stalno raste. O vrijednosti Facebooka najbolje govori podatak da je Microsoft 2007. kupio 1.6% udjela u dionicama za - 240 milijuna dolara.

Facebook je najpopularnija društvena mreža na internetu, te se nametnuo i kao medij za oglašavanje raznih organizacija i pokreta. Razne tvrtke, političke stranke i drugi shvatili su važnost i snagu Facebooka kao alata u borbi za kupcima ili glasačima.

II. PREGLED KORISNIKA FACEBOOK DRUŠTVENE MREŽE U HRVATSKOJ, REGIJI I SVIJETU

Tabela 1 – Podaci se odnose na razdoblje od 01.09.2011. do 01.12.2011.[1]

	Korisnici	Broj novih korisnika	Promjena u %
Hrvatska	1,452,900	+6,340	+0,44%
Srbija	3,172,420	+95,180	+3,09%
Bosna i Hercegovina	1,160,380	+13,440	+1,17%
Slovenia	670,660	+4,660	+0,70%
Crna Gora	292,700	-4,700	-1,58%

Tabela 2 - Podaci se odnose na razdoblje od 01.09.2011. do 01.12.2011.[2]

Država	Broj stanovnika	Internet korisnici	Facebook korisnici
Hrvatska	4,483,804	2,244,400	1.413,200 (31,5%)
Bosna i Hercegovina	4,622,163	1,441,000	1,118,480 (24,2%)
Srbija	7,310,555	4,107,000	2,866,200 (39,2%)
Slovenija	2,000,092	1,298,500	660,500 (33,0%)
Crna Gora	661,807	303,480	294,000 (40,6%)

Prema svjetskim podacima Hrvatska zauzima 66. mjesto u svijetu i 27. mjesto u Europi prema broju registriranih korisnika. Broj se odnosi isključivo na

[1] prema http://www.socialbakers.com
[2] prema http://www.socialbakers.com

registrirane korisnike, premda postoji puno neaktivnih i lažnih osoba sa više otvorenih korisničkih profila. U Europi najveći broj korisnika ima Velika Britanija (oko 30 milijuna) koja u svijetu drži 4. mjesto. SAD uvjerljivo drži prvo mjesto, dok su iza njih Indija i Indonezija. Zanimljiv je podatak da u Monaku skoro svaki stanovnik ima otvoren profil (95.47%).

Tabela 3– Podaci se odnose na razdoblje od 01.09.2011. do 01.12.2011.

R.B.	Država	Broj Facebook korisnika	Broj Facebook korisnika u odnosu na ukupan broj stanovnika
1.	Monaco	29200	95,47%
2.	Island3	203040	65,73%
3.	Gibraltar	17540	60,74%
4.	Faraonski otoci	28300	57,69%
5.	Norveška	2554780	54,63%
6.	Danska	2679240	48,58%
7.	Velika Britanija	29789040	47,78%
8.	Švedska	4244020	46,77%
9.	Crna Gora	308500	46,27%
10.	Malta	184340	45,32%
11.	Makedonija	872800	42,12%
12.	Irska	1946280	42,10%
13.	Cipar	449100	40,73%
14.	Belgija	4129380	39,62%
15.	Srbija	2884560	39,27%
16.	Finska	1936040	36,84%
17.	Albanija	1095720	36,68%
18.	Turska	28505520	36,64%
19.	Luksemburg	173520	34,88%
20.	Portugal	3684840	34,32%

Tabela 4 – Analiza korisnika po dobnoj skupini u Hrvatskoj[3]

Dobna skupina	Zastupljenost
13 - 15	10%
16 - 17	10%
18 – 24	31%
25 – 34	28%
35 – 44	13%
45 – 54	5%
55 – 64	2%
65 +	2%

[3] prema: http://www.socialbakers.com/facebook-statistics/croatia

Tabela 5 – Podjela korisnika po spolu[4]

Muška populacija	Ženska populacija
51%	49%

Od 1,400,000 registriranih korisnika, muškarci čine 51%, a žene 49%. Mladi od 18 godina do 24 godine čine 31% korisnika Facebook društvene mreže. Populacija od 18 godina do 34 godine čine približno dvije trećine Facebook korisnika u Hrvatskoj. Hrvatski korisnici Facebook društvene mreže su gotovo najmlađi na svijetu, a niži prosjek godina ima samo Indonezija. Društvene mreže nisu više rezervirane isključivo za mlade. Sjedinjene Američke Države imaju dvostruko više korisnika starijih od 50 godina nego mlađih od 18 godina.

Internet najviše koriste osobe sa srednjom stručnom spremom ili gimnazijom (23%), te visokoobrazovani (29%). Društvenu mrežu čini 96% studenata s pristupom na Internet. 50% tinejdžera kažu da razgovaraju sa svojim vršnjacima o školi online (preko IM, blogova ili društvenih mreža). U Hrvatskoj egzistira preko 1,444 službenih Facebook stranica koje imaju ukupno 14,678,096 korisnika, pri čemu u zemlji ima nešto više od 1,452,000 korisnika. Najviše korisnika imaju stranice društvenih mreža Hrvatske turističke zajednice, 24sata, te Puta oko svijeta (Netokracija, 2012)[5].

Društvene mreže promijenile su društvo i način komunikacije. Razna istraživanja pokazuju da korisnici četvrtinu vremena provedenog na internetu provedu na društvenim mrežama i blogovima (Kirkpatrick, 2011)[6]. Zanemaruje se i elektronička pošta, jer Facebook integrira razne servise pomoću kojih se može dijeliti sadržaj. Preko društvenih mreža raste konzumacija filmova, glazbe, vijesti, te je odličan medij za oglašavanje i reklamiranje tvrtki, proizvoda i usluga.

Korisnik može jednostavno, brzo i besplatno doći u doticaj s prijateljima, poznanicima i obitelji čak i ako oni žive u drugim državama ili kontinentima. Moguće je pratiti što se događa s njima i njihovim obiteljima. Facebook stvara osjećaj pripadnosti. Olakšan je prijenos informacija i podataka kako u privatnom tako i u profesionalnom svijetu. Facebook se i koristi kao besplatan alat za promociju glazbenika, političara, poduzeća i drugih. Koliko god nas društvena mreža povezuje, toliko nas i razdvaja.

III. ANALIZA DRUŠTVENIH MREŽA U HRVATSKOJ

U razdoblju od lipnja 2010. do listopada 2010. godine provedeno je istraživanje o korištenju društvenih mreža u svrhu oglašavanja. U istraživanju je sudjelovala većinom populacija koja se bavi ili će se baviti oglašavanjem putem interneta. Anketirano je 300 ispitanika kroz 16 područja (pitanja), a obrađena će biti ona koja su relevantna za tematiku.

Tabela 6 – Zastupljenost društvenih mreža u Hrvatskoj

Društvena mreža	Zastupljenost
Facebook	43%
Youtube	28%
Flickr	13%
LinkedIn	9%
Twitter	7%

Najkorištenija društvena mreža u Hrvatskoj je Facebook (43%), što je činjenica koja prati svjetski trend. Velika količina informacija dovela je do toga da korisnici po nekoliko puta dnevno posjećuju društvene mreže, kako bi saznali nove događaje i pogledali što su objavili njihovi prijatelji. Većina korisnika (52%) još uvijek društvenim mrežama pristupa od kuće, ali zanimljiv je podatak da 20% korisnika pristupa putem mobilnih uređaja. Mobilne aplikacije svakako su olakšale komunikaciju putem društvenih mreža, jer se društvenim mrežama može pristupiti iz gotovo svakog dijela Republike Hrvatske. Većina kampanja koje provode kako operateri, tako i proizvođači mobilnih uređaja temelji se na tome da su uređaji kompatibilni s najpopularnijim društvenim mrežama.

Tabela 7 – Područja korištenja društvenih mreža u Hrvatskoj

Svrha korištenja društvene mreže	Zastupljenost
Pretraživanje i pronalaženje informacija	20%
Obrazovanje	7%
Održavanje kontakata	29%
Organizacije i planiranja društvenih događanja	17%
Oglašavanje	20%
Ostalo	7%

Nove generacije vrlo rijetko mogu odvojiti poslovni od privatnog života pa je slična situacija i u njihovom virtualnom životu gdje više od 40% ispitanika koristi društvene mreže poslovno i privatno. Budući da su društvene mreže novi trend, većina je ispitanika relativno kratkog staža na društvenim mrežama. Svakako komercijalizacija donosi to da gotovo svaka tvrtka kojoj je stalo do pozicioniranja na društvenim mrežama, nastoji potaknuti svoje uposlenike na aktivno korištenje društvenih mreža, što svakako povećava neposrednu komunikaciju s potencijalnim klijentima koji sve tražene informacije mogu dobiti direktno.

Društvene mreže još se uvijek najviše koriste za međusobno neformalno komuniciranje između korisnika. Svakako ne treba zanemariti ni udio korištenja u komercijalne svrhe, posebice jer on ima tendenciju rasta. Distribuiranje informacija putem društvenih mreža pokazalo se efikasnim, što je dovelo do toga da na što jednostavniji način dođemo do ciljane publike. Stavka u kojoj zaostajemo za svjetskim trendovima je obrazovanje. U SAD-u razna sveučilišta sudjeluju u zajedničkih projektima putem društvenih mreža ili imamo primjer knjižnica koje su veliki dio svoje građe objavili na društvenim mrežama.

Popularizaciji društvenih mreža pridonosi razvoj tehnologija pa tako osim što 20% korisnika objavljuje foto i video sadržaj na mrežama putem stolnih, a 45% korisnika putem prijenosnih računala, udio korisnika koji to čine putem mobilnih uređaja doseže čak 20%, dok u objavi materijala 68% imaju osobni i zabavni sadržaji, što je poveznica s mladom generacijom koju čini većina korisnika.

Tabela 8 - Svrha objavljivanja foto i video sadržaja na društvenim mrežama u Hrvatskoj

Svrha objavljivanja sadržaja	Zastupljenost
Osobni	32%
Edukativni	5%
Poslovni	19%
Komercijalni	8%
Zabavni	36%

Vezano uz objavu fotografije u komercijalne svrhe, 42% sadržaja vezana je uz prodajnu svrhu, 20% uz informativnu, 17% uz edukativnu dok 21% populacije ne koristi fotografiju niti video u komercijalne svrhe.

Interaktivne su mogućnosti (označavanje i komentiranje foto i video sadržaja) nešto čime su postignute velike mogućnosti u oglašavanju, jer su korisnici (84% od ukupne populacije) mogli prepoznati sami sebe u određenim kampanjama i sudjelovati u njima (Knoke, 2007)[7].

Jednostavna sučelja društvenih mreža, digitalnih fotoaparata te video kamera dovela su do toga sa korisnik ne treba napredno znanje o fotografiji i videu da bi se mogao njome služiti u svrhe oglašavanja na društvenim mrežama. Korisniku je dovoljno nekoliko poteza da snimljeni materijal prenese na društvenu mrežu bez potrebe znanja pojmova vezanih uz foto i video tehnologiju.

[7] Knoke, D. (14. 11 2007). Social Network Analysis

Nedostatak korištenja društvenih mreža u oglašivačke svrhe je što većini sadržaja određene stranice mogu pristupiti samo osobe s dozvolom odnosno prijatelji vlasnika te stranice. Ovaj se podatak može smatrati prednošću u kontekstu sigurnosti podataka.

IV. SIGURNOST I ZAŠTITA PRIVATNOSTI

Društvene mreže prikupljaju veliku količinu informacija o našim navikama koje su privatne, ali valja napomenuti da ih dobrovoljno dajemo. Razvojem interneta i društvenih mreža razvija se i Internet kriminal. Bez obzira radi li se o iskusnim korisnicima ili početnicima, svi su podložni krađi podataka, te mogu postati žrtve propusta društvenih mreža. Ljudi često odbijaju koristiti društvene mreže jer smatraju da se time ugrožava njihova privatnost. Otkrivanje osobnih podataka donosi rizik korištenja istih od strane zlonamjernih korisnika, koji mogu nanijeti veću ili manju štetu (ovisno o namjerama) nekom korisniku. Moguća je i krađa profila i zlonamjerno korištenje vjerodostojnosti koju donosi lažno predstavljanje. (Goldfarb, 2011)[8].

Problem sprječavanja neželjenih poruka koje se najčešće odnose na reklamiranje nerelevantnog proizvoda (spam) Facebook rješava uz pomoć Facebook Immunity Systema (FIS). Istraživanja su pokazala visoku učinkovitost ovog sustava, odnosno spamom se na ovoj mreži smatra 1% sadržaja.

Facebook je u početku bio više usmjeren na širenje nego na sigurnost. S vremenom i novim sigurnosnim prijetnjama, počelo se više pažnje pridavati tom problemu. Facebook Security je dostupan na http://www.facebook.com/security i namijenjen je edukaciji korisnika o sigurnosnim prijetnjama. te služi i da korisnici mogu prijaviti eventualne propuste, nove prijetnje ili tražiti pomoć. Facebook je ušao u partnerstvo s tvrtkama McAffe i Websense, koje su ponudile neke sigurnosne pakete specijalizirane za Facebook. Postoje još mnogi sigurnosni sustavi koji su nevidljivi običnom korisniku, dok su još mnogi u razvoju. Velik broj korisnika i količina interakcije na Facebooku, pogodna je za brzo širenje zloćudnog programa (engl. *Malware*), velikih količina neželjenih podataka i drugih načina zloupotrebe.

Korištenjem aplikacija i servisa koji su nezavisni od Facebooka, korisnik pristaje dijeliti svoje podatke. Takvi servisi moraju poštovati dogovor o pravima i odgovornostima. Servis se obavezuje da će koristiti samo one podatke koji su neophodni za rad programa, da će imati politiku privatnosti i da će korisnik moći izbrisati sve podatke. Ti se podaci neće dijeliti na oglašivačkoj mreži. Nitko ne može garantirati da servis neće prekršiti neko od pravila, te se može dogoditi da dođe do grešaka kod upravljanja podacima i od strane Facebooka. Tako prikupljeni podaci mogu se koristiti za krađu identiteta, lažno predstavljanje, uhođenja, industrijsku špijunažu i još mnogo toga (Prell, 2012)[9]. Usluga Google Adsense upravo na ovakav način prikuplja podatke te ciljano plasira reklame određenom korisniku u skladu s njegovim interesima.

V. ZAKLJUČAK

Korištenjem društvenih mreža tvrtke povećavaju konkurentnost na tržištu i poboljšavaju doseg svojih reklamnih kampanja kao i posjećenost korporativnih internet stranica. Političke stranke u Hrvatskoj prepoznale su potencijal interneta i društvenih mreža kao medija za promociju pa se tako dobar dio izbornih kampanja različitih političkih stranaka vodio preko društvenih mreža. Prvi potez nove vlade Zorana Milanovića bio je osnivanje odjela unutar službe za odnose s javnošću koji se bave objavljivanjem sadržaja i komunikacijom sa građanima putem društvenih mreža. Vlada Republike Hrvatske u prvih 50 dana od dana stupanja na vlast (23.12.2011.) uspjela je pridobiti 18.940 korisnika na društvenoj mreži Facebook i 6.000 korisnika na društvenoj mreži Twitter. (Socialnumbers, 2012)[10]

Na ovakav način tvrtke preko društvenih mreža mogu najlakše informirati javnost i dobiti povratne reakcije i prijedloge, što ovaj medij čini sredstvom dijaloga između ponuđača i potrošača. Korištenje društvenih mreža za firme i njihovu promociju postalo je uobičajeno u svijetu, a taj trend sve je izraženiji u Hrvatskoj i regijama oko nas. Riječ je o besplatnom alatu koji omogućuje brz i neposredan pristup postojećim i potencijalnim kupcima odnosno klijentima, kao i unaprjeđenje tvrtke. Tvrtke ističu kako se korištenjem društvenih mreža znatno poboljšava doseg njihovih reklamnih kampanja i posjećenost korporativne Internet stranice.

"Naše veze ne završavaju s ljudima koje poznajemo. Iza našega vlastitog vidokruga, prijatelji prijatelja naših prijatelja mogu pokrenuti lančane reakcije koje vremenom dolaze do nas,

Djeluje li laskanje?
O utjecaju snage poruke i pripisivanja identiteta altruistične osobe na odaziv sudionika u istraživanju putem interneta

Jelena Okroša*

* Filozofski fakultet/Odsjek za psihologiju, Zagreb, Hrvatska
jokrosa1@gmail.com

U reklamnim porukama česta je emocionalna nagrada obećanje željenog identiteta. Budućem korisniku može se učiniti privlačnim pripadanje skupini mladih urbanih vlasnika mobitela te mu se reklama tako i obraća: kao pripadniku opisane skupine. Cilj istraživanja je ispitati kako na odaziv u online istraživanju djeluje takvo pripisivanje identiteta u uvjetima slabih i jakih argumenata. U istraživanju je korišten pripisan identitet altruistične osobe. Hipoteza je će pripisan identitet djelovati u situaciji kada su u pozivu sudionicima na istraživanje putem interneta navedeni slabi argumenti o važnosti istraživanja i to tako da će odaziv istraživanju biti veći. U situaciji kada su u pozivu sudionicima na istraživanje putem interneta navedeni jaki argumenti neće doći do utjecaja pripisanog identiteta na povećanje odaziva. Odaziv istraživanju operacionaliziran je kao broj sudionika koji su upitniku pristupili te broj ispitanika koji su upitnik dovršili (od ispitanika koji su upitniku pristupili). Istraživanje je pokazalo da više studenata pristupa upitniku u slučaju kada poruka ne sadrži pripisani identitet, neovisno o kvaliteti sadržanih argumenata. Kod mjere dovršavanja upitnika pokazuje da u slučaju slabih argumenata više studenata dovršava upitnika kada je pripisan identiteta. U slučaju jakih argumenata više studenata dovršava upitnika kada identitet altruistične osobe nije pripisan.

UVOD

Često svjedočimo da reklame koriste sljedeću psihologijsku strategiju: nude emocionalnu nagradu u slučaju korištenja njihovog proizvoda te umjesto prikazivanja korisnosti proizvoda usmjeravaju se na identitet koji proizvod komunicira, a koji je poželjan potrošaču. Pozicioniranje proizvoda je strategija istraživanja tržišta u kojem se osobine proizvoda povezuju sa stavovima i idealima potrošača.

Pripisivanje socijalnog identiteta je varijabla koja se koristi i u istraživanju pomagačkog ponašanja (Fointiat, 2006). U istraživanjima „ Foot in the door “ paradigme dokazuje se da su ispitanici spremniji se odazvati velikom zahtjevu eksperimentatora, ukoliko su prethodno pristali na manji zahtjev. No, odaziv je još veći ukoliko se ispitanicima nakon što su se odazvali manjem zahtjevu uz zahvalu pripiše identitet pomagačke osobe (“Thank you. You’re being helpful.”) .

To je sukladno teoriji samopercepcije (Bem, 1972, prema Fointiat, 2006) : pripisivanje identiteta olakšava ispitanicima stvaranje slike o sebi u skladu sa kojom se ponašaju kada pristaju na veći zahtjev. Druga teorija koja nudi objašnjenje je teorija identifikacije akcije (Vallacher & Wegner, 1987). Po ovoj teoriji akcija ili čin mogu biti identificirani na više razina: od nižih razina koje odgovaraju na pitanje kako se akcija izvodi do viših koje odgovaraju na pitanje zašto se čini. Pripisivanje identiteta pomagača je po ovoj interpretaciji identifikacija čina pomaganja na višoj razini jer odgovara na pitanje zašto se pomoglo. Teorija pretpostavlja da viši identitet akcije ili čina osigurava dosljednost, to jest održavanje ponašanja u različito vrijeme i u različitim okolnostima.

Kako djeluje pripisivanja identiteta u persuaziji, procesu uvjeravanja kojemu je krajnji cilj formiranje, ojačavanje ili promjena stavova, uvjerenja, emocija, vrijednosti i/ili ponašanja što ga osoba ima prema nekom objektu drugoj osobi ili samoj sebi (Burgoon, Hunsaker i Dawson, 1994, prema Čorkalo, 1997)?

Aktualne teorije persuazije nazivaju se dvoprocesnim modelima persuazije jer objašnjavaju procese koji uključuju detaljnije razmatranje sadržaja poruke i aspekta objekta stava, ali i procese persuazije koji zahtijevaju malo kognitivnog napora (Aronson,Wilson i Akert, 2005). Model vjerojatnosti elaboracije (MVE) kao i heuristično-sustavni model elaboracije (HSM) objašnjavaju kada će primatelj poruke biti pod utjecajem logike argumenta u poruci, a kada pod utjecajem nevažnih, to jest perifernih obilježja u sadržaju i kontekstu poruke.

Heuristično sistematski model kao i MVE pretpostavlja da na niskim razinama motivacije prevladava obrada poruke bez ulaganja kognitivnog napora, to jest

heurističko procesiranje. Na višim razinama motivacije i sposobnosti, djeluje obrada uz ulaganje više kognitivnog napora, to jest sistematsko procesiranje, no heuristici, ili prečaca u zaključivanju, se koriste i dalje. To objašnjava hipoteza pristranosti HSM-a, po kojoj ako je sadržaj poruke nejasan ili mješovit, primjena heuristika može iskriviti sistematsko procesiranje poruke u smjeru koji primjenjeni heuristik implicira (Bohner, 2002) . U primjeru reklama ili pomagačkog ponašanja , nedovoljno uvjereni primatelj poruke dodatno će iskoristit pripisani identitet kao informaciju u prosudbi treba li djelovati sukladno poruci.

PROBLEM I HIPOTEZE ISTRAŽIVANJA

Problem ovog istraživanja je ispitati utjecaj snage poruke (različite kvalitete argumenata) i pripisivanja identiteta altruistične osobe na odaziv sudionika u istraživanju putem interneta. Hipoteza je da u situaciji kada su u pozivu sudionicima na istraživanje putem interneta navedeni slabi argumenti o važnosti istraživanja postojat će utjecaj pripisanog identiteta na odaziv istraživanju i to tako da će odaziv biti veći. U situaciji kada su u pozivu sudionicima na istraživanje putem interneta navedeni jaki argumenti prisutnost pripisanog identiteta neće povećati odaziv.

METODOLOGIJA

Nacrt

U istraživanju je upotrijebljen složen nacrt na nezavisnim skupinama 2 (jaki/ slabi argumenti) X 2 (sa pripisanim identitetom/ bez pripisanog identiteta). Zavisna mjera bila je odaziv sudionika, operacionaliziran kao proporcija studenta koji su upitniku pristupili te proporcija studenata koji su upitnik završili od svih studenata koji su upitniku pristupili.

Ispitanici

U istraživanju su sudjelovali studenti, korisnici mailing liste prve, druge, treće godine preddiplomskog studija te mailing liste prve godine diplomskog studija psihologije. Poruka je odaslana na ukupno 378 e-mail adresa od čega je 99 e-mail adresa sa liste prve godine, 100 e-mail adresa sa liste druge godine, 94 e-mail adresa sa liste treće godina te 85 e-mail adresa sa liste prve godine diplomskog studija.

Materijali i instrumenti

Persuazivna poruka

Persuazivna poruka upućivala je na važnost istraživanja načina učenja korištenjem jakih ili slabih argumenata odabranih nakon predispitivanja. U predispitivanju su kvalitetu argumenata o važnosti istraživanja načina učenja u procjenjivali studenti 2. godine diplomskog studija psihologije preko online upitnika dostupnog na stranici http://www.kwiksurveys.com.
Prvo predispitivanje sadržavalo je 29 argumenata. Ovisno o vlastitom prezimenu studenti su pristupali poveznici na jedan od dva upitnika koji su sadržavali iste argumente, ali prezentirane u dva različita redoslijeda. Kako bi se dobio veći raspon između jakih i slabih argumenata uslijedilo je dodatno predispitivanje sa upitnikom koji je sadržavao još 7 argumenata. Prvom su predispitivanju pristupila 27, a kasnijem 12 studenata.
Svaki od 36 argumenata prikazan je na zasebnoj stranici online upitnika. Studenti su trebali procijeniti na ljestici od 1 do 7 stupnjeva koliko je argument uvjerljiv pri čemu 1 značilo “argument je sasvim neuvjerljiv, slab i lako ga je pobiti”, a 7 značilo “argument je vrlo uvjerljiv, snažan i teško ga je pobiti”.
Na temelju tih procjena odabrano je pet slabih i pet jakih argumenata korištenih u formiranju jake i slabe persuazivne poruke. Prosječna procjena uvjerljivosti jakih argumenata iznosi 5.475 (*SD*= 0.172), dok prosječna procjena slabih iznosi 3.696 (*SD*=0.392). Razlika u procijenjenoj kvaliteti jakih i slabih argumenata statistički je značajna (t=9,17, df=8, p <0.01).
Pripisan identitet operacionaliziran je sljedećim rečenicama dodanim na kraju poruke sa argumentima, a prije poveznice na upitnik načina učenja: "Sudjelovanje u istraživanjima povezano je sa različitim mjerama altruizma (Crowley, 1998.). Unaprijed hvala na pomoći u istraživanju!".

Upitnik načina učenja

Studenti su mogli pristupiti online upitniku preko poveznice na stranicu http://www.kwiksurveys.com koja se nalazila na kraju poslanog e-maila. Čestice upitnika bile su namijenjene ispitivanju strategija učenja i organizacije vremena te su preuzete iz sljedećih upitnika:
1.Upitnika o načinu učenja - modificirana verzija (Bartulović i Biondić, 1986) namjenjenog ispitivanju učeničkih ponašanja koje obuhvaćaju aspekte bitne za postizanje rezultata u učenju.
2.Upitnika o procesima učenja (Schmeck, 1988) namjenjenog mjerenju četiri faktora učenja: dubine procesiranja, metode učenja, retencije činjenica i elaborativnih procesa.
3.Upitnika "Strategije osobne organizacije"(Drempetić , 2003).
4.Upitnika uspješnosti korištenja vlastitog vremena (DPP,1994)
(prema http://mjesec.ffzg.hr/webpac-cpi/) .
U konačnom je obliku upitnika ostalo 150 čestica nakon što su izbačene čestice neodgovarajućeg sadržaja poput pitanja namijenjenih isključivo ispitivanju obilježja srednjoškolskog obrazovanja te neodgovarajućeg formata poput pitanja otvorenog tipa. Ispitanici su odgovarali na skali od 1 do 5 pri čemu 1 znači "uopće se ne slažem" , a 5 znači "u potpunosti se slažem".
Prva stranica upitnika sadržavala je obavijest da zbog posebnosti mjerenja ispitanici nisu obvezni odgovoriti na sva pitanja, no poželjno je da odgovore na što više pitanja. Uslijedile su čestice prezentirane zasebno, kao čestica po stranici online upitnika. Na taj način ispitanici nisu mogli znati koliki je ukupan broj čestica u upitniku te koliko je vremena potrebno za ispunjavanje upitnika. Česticama nije prethodio redni broj.

Procedura

Istraživanje je provedeno krajem svibnja 2011. godine. Članovi svake skupina ispitanika, to jest godine studija, dobili su e-mail naslova "Molim vas, pročitajte" proslijeđen preko predstavnika godine na mailing listu godine studija. U e-mailu je nakon molbe za pomoć u istraživanju i definicije načina učenja, uslijedio je sadržaj različit za ispitanike ovisno o godini studija, to jest mailing listi kojoj pripadaju:

- Studenti prve godine studija dobili su poruku sa slabim argumentima o važnosti istraživanja načina učenja bez pripisanog identiteta.
- Studenti druge godine studija dobili su poruku sa jakim argumentima o važnosti istraživanja načina učenja sa pripisanim identitetom **.**
- Studenti treće godine studija dobili su poruku sa slabim argumentima o važnosti istraživanja načina učenja sa pripisanim identitetom .
- Studenti četvrte godine studija dobili su poruku sa jakim argumentima o važnosti istraživanja načina učenja bez pripisanog identiteta.

Na kraju e- maila je za sve skupine uslijedio poziv za sudjelovanje u istraživanju te poveznica sa upitnikom stilova učenja. Na prvoj stranici upitnika ispitanicima je dana uputa koja je glasila "Slijede pitanja namijenjena ispitivanju načina učenja. Upitnik je opsežan te niste obvezni odgovoriti na sva pitanja. Također, iako je što više odgovora poželjno, zbog posebnosti mjerenja svaki je ponuđeni odgovor koristan ."
Nakon upute uslijedile su čestice prezentirane zasebno, kao čestica po stranici upitnika. Kako je čestica bilo 150 , upitnik je zamišljen kao zamoran i za ispitanike nepredvidivog trajanja. Za popunjavanje kompletnog upitnika ispitaniku je bilo potrebno otprilike 20 minuta.
Ispitanicima je tjedan dana nakon poslanih e-mailova ponovno ponovo poslan e-mail u kojem je objašnjena prava svrha i problem istraživanja.

REZULTATI

Pristupanje upitniku

Kako bi se provjerilo između kojih uvjeta poruke različitog sadržaja je značajna razlika u pristupanju provedena je analiza varijance na proporcijama ispitanika koji su pristupili upitniku. To je učinjeno tako da je svaki ispitanik koji je pristupio upitniku dobio vrijednost jedan, dok je ostalim korisnicima mailing liste pripisana vrijednost nula. Na taj način dobiveni rezultati, to jest proporcije, prikazani su u tablici 1. Rezultati provedene 2X2 analize varijance (snaga argumenata X pripisan identitet) nalaze se u tablici 2.
Značajnim se pokazao glavni efekt pripisanog identiteta (F (1,374)= 15, 836, p <0,05) ; u uvjetima bez pripisanog identitete pristupa više sudionika upitniku (p=0,38 ili 38%) nego u uvjetima kada poruka sadrži pripisan identitet (p=0, 201 ili 20,1%). Glavni efekt snage argumenata kao ni interakcija snage argumenata i pripisivanja identiteta nisu se ispostavili značajnim (tablica 2).

Tablica 1
Proporcija ispitanika koji su pristupili upitniku te ispitanika koji nisu pristupili upitniku, ovisno o snazi argumenata i pripisivanju identiteta u poruci

Snaga argumenata	Pripisan identitet	*p*	*SD*	*N*
Slabi	Da	,192	,396	94
	Ne	,343	,477	99
	Ukupno	,269	,445	193
Jaki	Da	,210	,409	100
	Ne	,423	,497	85
	Ukupno	,308	,463	185
Ukupno	Da	,201	,402	194
	Ne	,380	,487	184
	Ukupno	,288	,454	378

Legenda: p=proporcija ispitanika koji su pristupili upitniku

Tablica 2
Rezultati 2X2 analize varijance za zavisnu varijablu proporcija ispitanika koji su pristupili upitniku

Izvor varijabiliteta	Suma kvadrata	Stupnjevi slobode	Prosječni kvadrat	*F*	*p*
Snaga argumenata	,229	1	,229	1,153	,284
Pripisan identitet	3,143	1	3,143	15,836	,000
Interakcija snaga *pripisan identitet	,089	1	,089	,450	,503

Dovršavanje upitnika

Kako bi se provjerilo postoje li razlike u dovršavanju upitnika provedena je analiza varijance na proporcijama ispitanika koji su dovršili upitnik. Svaki ispitanik koji je dovršio upitnik dobio vrijednost jedan, dok je ostalima ispitanicima koji su pristupili, no ne i dovršili upitnik, pripisana vrijednost nula. Na taj način dobiveni rezultati, to jest proporcije, prikazani su u tablici 3. Rezultati provedene 2X2 analize varijance (snaga argumenata X pripisan identitet) nalaze se u tablici 4.
Interakcija snage argumenata i pripisivanja identiteta je statistički značajna (F (1,374) = 4,168, p<0,05): kod slabih argumenata više ispitanika dovršava upitnik kada je pripisan altruistični identitet, dok u uvjetima jakih argumenata više ispitanika dovršava upitnik kada pripisanog identiteta nema. Glavni efekt snage argumenata kao ni glavni efekt pripisanog identiteta nisu se ispostavili značajnim

Tablica 3
Proporcija ispitanika koji su dovršili upitnik te ispitanika koji nisu dovršili upitnik od svih ispitanika koji su pristupili upitniku, ovisno o snazi argumenata i pripisivanju identiteta u poruci

Snaga argumenata	Pripisan identitet	*p*	*SD*	*N*
Slabi	Da	,722	,461	18
	Ne	,529	,507	34
	Ukupno	,596	,495	52
Jaki	Da	,429	,507	21
	Ne	,639	,487	36
	Ukupno	,561	,501	57
Ukupno	Da	,564	,502	39
	Ne	,586	,496	70
	Ukupno	,578	,496	109

Interakcija snaga *pripisan identitet	1,013	1	1,013	4,168	,044

DISKUSIJA

U slučaju mjere pristupanja upitniku provedeno istraživanje nije potvrdilo hipotezu o djelovanju perifernog znaka na povećanje odaziva u uvjetima slabih, ali ne i jakih argumenata. Istraživanje je pokazalo djelovanje efekta perifernog znaka i to tako da veći broj ispitanika pristupa upitniku u slučaju kada poruka ne sadrži periferni znak, neovisno o kvaliteti sadržanih argumenata. U slučaju dovršavanja upitnika hipoteza je potvrđena: pripisan identitet djeluje kod slabih argumenata na dovršavanje upitnika i to tako da više ispitanika dovršava upitnik ako je altruistični identitet pripisan. To se ne događa u uvjetima jakih argumenata kada više ispitanika dovršava upitnik kada pripisanog identiteta nema.

Mogući razlozi zašto više studenata pristupa upitniku u slučaju kada poruka ne sadrži pripisani identitet, neovisno o kvaliteti sadržanih argumenata su:

1) Razlika u početnoj motivaciji za pristupanje upitniku. Skupine u istraživanju su studenti različitih godina studija za što ima temelja vjerovati da djeluje na početnu motivaciju za sudjelovanje u istraživanju. Upravo su se studenti prve godine preddiplomskog (slabi argumenti i bez pripisanog identiteta) i prve godine diplomskog (jaki argumenti i bez pripisanog identiteta) odazvali u najvećem broju na istraživanje. Ovi rezultati potvrđuju pretpostavku da su prva godina preddiplomskog i prva godina diplomskog studija u početnoj motivaciji najviše zainteresirani za pristupanje.

2) Pretpostavka je da je pripisan altruističan identitet persuazivnu namjeru poruke učinio jasnijom i tako izazvao otpor kod sudionika. Efekt poruke na stavove je veći ukoliko namjera mijenjanja stavova nije očita (Petty i Cacioppo,1986, prema Aronson,Wilson i Akert, 2005). U slučaju očite persuazivne namjere, kod ispitanika se javlja otpor persuaziji i oni su potaknuti stvarati kontraargumente. Kako poruka apelira na izvođenje ponašanja, moguć je osjećaj sudionika da je njihova sloboda izvođenja traženog ponašanja ugrožena. Naime, na kraju poruke navodi se da je sudjelovanje u istraživanju povezano sa altruizmom, čime bi se ovo apeliranje na vrijednosti moglo shvatiti kao svojevrsna ucjena (“ Znači , ne pomognem li, manje sam altruističan/altruistična? “).

3) Duljina poruke može djelovati suprotno argumentima poruke . Naime, zbog osjećaj ulaganje napora u čitanje poruke koji je veći u slučaju duže poruke (sa pripisanim altruističnim identitetom), ispitanici su mogli odustati i od čitanja poruke do kraja i od sudjelovanja u istraživanju. Iako je tu moguć i učinak identiteta u skladu sa sadržajem poruke: dužina poruke kao heuristik može upućivati na važnost poruke, to jest važnost istraživanja načina učenja.

Kod mjere dovršavanja upitnika pokazuje da u slučaju slabih argumenata više studenata dovršava upitnika kada je pripisan identitet. U slučaju jakih argumenata više studenata dovršava upitnika kada identitet altruistične osobe nije pripisan. Ovi rezultati potvrđuju hipotezu koju smo očekivali zbog hipoteze o pristranosti HSM-a, po kojoj ako je sadržaj poruke nejasan ili mješovit, primjena heuristika (pripisanog identiteta) može iskriviti sistematsko procesiranje poruke u smjeru koji primijenjeni heuristik implicira (Bohner, 2002) . Alternativno objašnjenje nudi i hipoteza o raspoloženju kao informaciji (Schwartz, Bless, Bohner, 1991). Istraživanja opetovano pokazuju da ljudi u dobrom raspoloženju manje pažnje poklanjaju snazi argumenata te ih je lakše djelovati porukom na njihovo ponašanje ili stav. Razlog je što se ljudi u zaključivanju o poruci oslanjaju na svoje dobro raspoloženje kao informaciju o kvaliteti poruke. U ovom slučaju, postoji mogućnost da je laskanje ili pripisivanje identiteta posredno preko utjecaja na raspoloženje povećalo dovršavanje upitnika.

U slučaju mjere dovršavanju upitnika, nije dobiven značajan efekt pripisanog identiteta koji bi potvrdio početnu razliku u motivaciji: veću motivaciju studentata diplomskog studija i studenata prve godine studija.
Mjere pristupanja i dovršavanja poruke obuhvaćaju različita ponašanja: dok je pristupanje u većoj mjeri spontano ponašanje, dovršavanje je u većoj mjeri planirano ponašanje. U slučaju spontanih ponašanja stavovi predviđaju ponašanje jedino ako su jako pobudljivi (Fazio, 1990, prema Aronson,Wilson i Akert, 2005). Pobudljivost se odnosi na snagu asocijacije između objekta stava i vrednovanja objekta, a mjeri se brzinom izjašnjavanja o nekom objektu. Za pretpostaviti je različitu pobudljivost stava o važnosti istraživanja kod prve godine preddiplomskog studija koji navikli toliko često biti ispitanici, ali i kod četvrte godine studija kojoj slijedi vlastito istraživanje za diplomski rad. Kod planiranih ponašanja stavovi su prediktori ponašanja uz mogućnost izvođenja čina te prihvatljivost čina kod izvođaču značajnih osoba. Iz tog razloga je vjerojatnije da će djelovanje porukom na stav se očitovati na ponašanje ukoliko je ono planirano.
Najveći problem ovog istraživanja je upravo nedostatak informacije o početnoj motivaciji studenata različite godine. Naime, nemoguće je odijeliti negativan efekt pripisanog identiteta na pristupanje upitniku od djelovanja početne motivacija za sudjelovanje u istraživanju. Kako student ne bi posumnjali u obmanu istraživanja te da istraživanje umjesto načina učenja ispituje promjenu stava i ponašanje, studentima se nije u samom upitniku postavilo pitanje koliko su općenito zainteresirani za sudjelovanje u istraživanjima. Također kako bi to pitanje uslijedilo nakon e- maila sa porukom , moguće je da bi poruka djelovala i na taj odgovor. Ovaj nedostatak informacije o početnoj motiviranosti za istraživanje mogao se izbjeći na sljedećim izmjenama:

1) Umjesto različite poruke u e-mailu , svi student dobivaju e mail sa identičnim pozivom na sudjelovanje u istraživanju.

2) Na prvoj stranici upitnika slijedi poruka sa argumentima različite kvalitete i pripisanim identitetom ovisno o skupini , to jest godini studija

3) Slijedi uputa za rješavanje te pitanja upitnika.

4) Na taj način bi se kao mjera početne motivacije moglo iskoristiti pristupanje upitniku prije djelovanja persuazivne poruke.

Preporuke za daljnja istraživanja su:

1) Nepoznat identitet istraživača sudionicima. Osobno poznavanje istraživača djelovalo je uz sadržaj poruke na važnost istraživanja za student, pogotovu u slučaju studenata diplomskog studija.
2) Više od 150 pitanja. Kako bi se dobila kontinuirana mjera dovršavanje upitnika za obradu analizu varijance potrebno je više od 150 pitanja kako ispitanici ne bi dovršavali upitnik te bi mjera ponašanja bila kontinuirana i pogodnija za parametrijsku obradu .
Najznačajnija primjena ovih nalaza u praksi se odnosi na predtestiranje formulacija kojima se identitet pripisuje kako se u reklamnoj poruci ne bi postigao kontraefekt . Čini se da pripisivanje identiteta djeluje na način da povećava uvjerljivost poruke za ispitanike koji nisu početno odbijeni porukom sa pripisanim identitetom što je nalaz koji upućuje na važnost ispitivanja obilježja ciljane publike kojoj se poruka obraća kao što su početna motivacija i sposobnost za analiziranje poruke.

ZAKLJUČAK

U slučaju mjere pristupanja upitniku provedeno istraživanje nije potvrdilo hipotezu o djelovanju perifernog znaka na povećanje odaziva u uvjetima slabih, ali ne i jakih argumenata. Istraživanje je pokazalo djelovanje efekta perifernog znaka i to tako da veći broj ispitanika pristupa upitniku u slučaju kada poruka ne sadrži periferni znak, neovisno o kvaliteti sadržanih argumenata. U slučaju dovršavanja upitnika hipoteza je potvrđena: pripisan identitet djeluje kod slabih argumenata na dovršavanje upitnika i to tako da više ispitanika dovršava upitnik ako je altruistični identitet pripisan što se ne događa u slučaju jakih argumantata.

Razvoj modela e-škole kao dodatnog oblika nastave za djecu koja žive izvan Hrvatske

Tomislav Težak, Mario Dumančić
Učiteljski fakultet u Zagrebu, Savska cesta 77., Zagreb, Hrvatska
tom_tezak@hotmail.com mario.dumancic@ufzg.hr

Sažetak - U radu je prikazan model e-škole koji bi prvenstveno koristio djeci koja žive izvan Republike Hrvatske kao dodatni oblik nastave, a daljnjim razvojem bi bio primjenjiv učenicima u slabije naseljenim područjima RH i učenicima koji su djelomično ili u potpunosti onemogućeni u praćenju redovne nastave. Prijenos nastavnog procesa temelji se na sustavu učenja na daljinu posredstvom multimedije, a u radu su opisani primjenjivi alati za e-učenje na daljinu, osnovni „servisi" i sadržaji škole, oprema potrebna za rad škole i oprema potrebna za učenike škole. Cilj ovakve škole nije zamjena klasične škole i klasičnog oblika nastave nekom novom školom, već dopuna školskog sustava u područjima u kojima se redovnim putem nastava ili ne može održavati ili je otežana, a naglasak je na nastavi koja se održava u „realnom vremenu" bez obzira na udaljenost učitelja i učenika, te na niskim troškovima opreme koja je potrebna za praćenje nastave.

I. UVOD

E-učenje sa korištenjem interaktivnih multimedijskih nastavnih materijala je relativno uobičajeno u današnjem svijetu, ali školovanje na daljinu kao sustavnog oblika učenja predstavlja izazov.[1] Institucionalno provođenja obrazovanja koje zadovoljava sve pravne, planske i programske komponente koje ima uobičajena klasična škola do sada nije bila uobičajeno. Razvojem ICT tehnologije i multimedijskih sustava ovakav oblik škole na daljinu postaje ne samo moguć nego i vrlo sličan školovanju u klasičnoj školi.

Stručnjaci iz područja obrazovanja sagledavajući školu, školski sustav i tehnološke mogućnosti koje nam se u današnjem svijetu nude omogućuju razvoj ove ideja. Ovaj rad predstavlja ideju novog modela, ali na temelju ovog modela trebala bi se provoditi daljnja istraživanja koja bi pomogla u ostvarenju prave škole ove vrste. Na ideju ovakve škole došao sam nekoliko godina proučavajući e-učenje. U to vrijeme se na Internetu moglo pronaći vrlo malo o ovakvoj vrsti školovanja. Danas u SAD-u već postoji državna škola ovakvog tipa (e-school) što nam pokazuje koliko brzo se trendovi u modernom školstvu mijenjaju. [1]

U usporedbi s raširenijim načinima učenja na daljinu posredstvom IC tehnologije gdje se nastava ne odvija sinhronom komunikacijom i učenici sami odlučuju kada, gdje i koliko će učiti, model prikazan u ovom radu kao temelj ima sinhronu komunikaciju zbog toga da se što više približi klasičnom učenju jer su ciljana skupina učenici osnovnih škola koji nisu u mogućnosti pratiti nastavu u klasičnoj školi, ali što ne znači da model nije primjenjiv kod bilo koje dobne skupine[2,3].

II. PRIMJER POSTOJEĆIH VIRTUALNIH ŠKOLA

Primjer postojećih virtualnih škola e-škola posredstvom informacijsko komunikacijske tehnologije danas više nije rijetkost i postoje razni oblici e-učenja koji ne moraju obavezno podrazumijevati sinhronu komunikaciju učenika i učitelja. Model e-škole opisan u ovome radu daleko manje zastupljen u svijetu nego razni oblici neformalnog obrazovanja koji se održavaju oblikovani u e-učenje.[4]

Najpoznatija škola ove vrste je k12 koja je prihvaćena kao državna škola, a djeluje na području SAD. Drugo veliko područje koje koristi ovakvo školstvo je Australija, a u oba slučaja virtualne škole koriste stanovnici udaljenih područja ili učenici kojima je školovanje preko Interneta iz raznih razloga prihvatljiviji oblik nastave nego klasična škola.

K12 je u stvari sustav za učenje koji se provodi kroz „područne škole", a koji je uključen u američko javno školstvo, čime je sudjelovanje u ovoj školi potpuno zadovoljeno obveznost školovanja, a statusom javne škole (Public school), učenici imaju prava, obaveze i pogodnosti pri školovanju jednako kao u bilo kojoj američkoj javnoj školi. Ovaj sustav zapošljava preko 1600 učitelja i nastavnika i prisutan je u preko trideset država SAD-a (podatak od 26.11.2010.).[2]

Učenici ove škole nastavu prate putem osobnog računala (koriste komunikacijski alat Elluminate[3]), što znači da nemaju nikakve dodatne izdatke u smislu informacijsko komunikacijske tehnologije, a nastavne materijale, udžbenike, materijale neophodne za izradu pokusa, prezentacije za kućnu upotrebu, bojice za crtanje i slikanje, pa čak i mikroskope s preparatima dobivaju od matičnog školskog centra. Na kućnu adresu putem pošte dobivaju sve što će im biti potrebno u nastavi za određenu školsku godinu, čime se u stvari dolazi do toga da ovo nije klasična nastava potpomognuta računalnom tehnologijom, već je nastava putem računala dopunjena klasičnim oblikom knjiga, što opet dovodi do novog

[1] http://www.eschoolonline.com/

[2] https://www.eschooldata.com/login.asp

[3] http://www.elluminate.com/Services/Training/Elluminate_Live

oblika pojma blended learning, ali u „obrnutom smjeru“ nego što smo do sada navikli.[5]

III. PRIKAZ MODELA

Predložen je model e-škole kao dodatnog oblika nastave za djecu koja žive izvan matične zemlje, odnosno izvan Republike Hrvatske. Ovaj model bi se mogao pokazati vrlo korisnim u slučaju odlaska obitelji na privremeni rad u inozemstvo jer mnogi učenici po povratku, a uslijed različitosti u školskim sustavima koje pohađaju izvan naše zemlje, ne uspijevaju u cijelosti pratiti nastavni plan i program pa često dolazi do zaostataka ili potrebe za dodatnom nastavom.

Uspostavom ovakvog modela škole, učenici bi bili u mogućnosti povremeno ili svakodnevno uz redovnu nastavu koju prate u inozemstvu, pratiti i nastavu iz hrvatske škole koju prate njihovi vršnjaci u domovini, a po povratku iz inozemstva lakše bi nastavili školovanje.

Model se oslanja na predmete koji su specifični za hrvatsko školstvo kao što su u primarnom obrazovanju „Hrvatski jezik“ i „Priroda i društvo“, a daljnjim razvojem model bi mogao u potpunosti zamijeniti „klasičnu“ školu, te bi tako mogao biti koristan učenicima koji žive u udaljenijim i manje naseljenim prostorima naše zemlje, te bi na taj način doprinijelo sprječavanju raseljavanja stanovništva. Isto tako mogao bi biti koristan učenicima koji su zbog bilo kojih razloga (često zdravstvenih) spriječeni dolaziti u školu.

Tijekom rada istraživao sam učenje na daljinu s posebnim naglaskom na e-učenje, odnosno e-schooling, što je relativno novi pojam i u svijetu. Rad je napisan tako da kao jedan od prvih radova o e-schoolingu u našoj zemlji bude na neki način jedna vrsta početne točke odakle bi se u bliskoj budućnosti mogao istraživati ili graditi širi projekt e-škole, ali i novi, odnosno modificirani predmeti kojima su osnova temeljne znanosti (pedagogija, psihologija, logika, metodika) jer novi mediji donose i prilagodbu, odnosno novi pristup odgojno-obrazovnim znanostima.[6]

E-škola je jedan relativno novi pojam unutar e-učenja i učenja na daljinu, a koji je u stvari nadogradnja samog e-učenja težeći ka tome da se svi oblici klasične škole transformiraju u oblik e-učenje i time omogući školovanje učenika koji nisu u mogućnosti pratiti nastavu i školovati se kroz klasičnu nastavu i školovanje.

Drugim riječima e-školu bismo mogli definirati kao podvrstu e-učenja, u kojoj smo čitav sustav jedne škole preformulirali na informacijsko-komunikacijsku tehnologiju, a za razliku od drugih oblika e-učenja gdje se obavezno ne podrazumijeva provođenje formalnog obrazovanja i školskog sustava.

E-škola treba pružati materijalnu, komunikacijsku, nastavno-programsku, pedagošku i psihološku podršku učeniku u istoj mjeri kao i konvencionalna škola, s naglaskom na “živu” komunikaciju prema učeniku, a koja je potrebna iz više razloga. Prednosti su ovakve škole u usporedbi s uobičajenim informalnim učenjem ili neformalnim obrazovanjem oblikovanim kroz razne vrste e-učenja na daljinu: trenutačno ukazivanje na pogreške, uvid u razumijevanje odnosno nerazumijevanje nastavnog sadržaja, dosljedno i pravovremeno provođenje nastavnog plana i programa, sinhrona pomoć pri savladavanju novog nastavnog sadržaja, zorno prikazivanje nastavnih tema brzinom koja odgovara učenicima, kvalitetniju socijalizaciju s ostalim sudionicima u odnosu na druge modele e-learninga i ostalo, a što je najvažnije f2f komunikacija između učenika i učitelja.[7,8]

Ipak, tehnologija bi se trebala, koliko god je zastupljena, nalaziti u drugom planu jer učenik treba što manje pažnje posvećivati tehnologiji, a više sadržajima učenja. Drugim riječima, upotreba tehnologije od strane učenika treba se svesti na razinu svakodnevne upotrebe računala u svrhu zabave ili traženja informacija kakve učenik svakodnevno nalazi koristeći računalo.

Nastava se u školi predviđenom ovim modelom odvija putem video veze (stolne videokonferencije), u realnom vremenu i u živoj interakciji učitelja s učenikom ili učenicima, odnosno u međusobnoj interakciji učenika i time se omogućava privid razrednog okružja u kojem učitelj i učenici vode živi razgovor. Kvaliteta ovakvog načina učenja na daljinu je daleko bliža kvaliteti nastave u “realnom” razredu ili školi nego putem dopisne nastave (e-mail), putem snimljenih nastavnih programa na CD mediju ili bilo kojem nosaču informacija (uključujući i edukativne mrežne stranice) koje nazivamo e-learning, a gdje u stvari ne postoji živa komunikacija između učenika i učitelja, a time postoji daleko veća mogućnost motivacije učenika i prilagodbe rada trenutačnom stanju i znanju učenika u vrijeme održavanja nastave.

Ovaj način školovanja za sada je kod nas potpuno nepoznat u praksi, dijelom i zbog neprilagođenih zakonskih regulativa ovakvom školovanju, ali u svijetu ovakvi ili slični sustavi nisu nepoznanica.

IV. RAZRADA MODELA

Škola opisana modelom u ovom radu, trebala bi zadovoljavati potrebe ostvarivanja nastavnog procesa prema nastavnom planu i programu, a da u isto vrijeme ne zahtijeva posebna dodatna ulaganja od strane učenika u vidu IC tehnologije koja nije sastavni dio većine kućanstva (računalo, monitor, tipkovnica, pisač, skener). Uz to, rad na računalu ne bi smio zahtijevati posebnu edukaciju jer bi rad e-škole i programi morali biti razumljivi svakom prosječnom korisniku računala. To bi doprinijelo nesmetanom radu, odnosno praćenju nastave bez ometajućih faktora kao što su kompliciran ili nerazumljivi programi odnosno način rada koji izlazi iz okvira svakodnevnog korištenja hardversko-softverske tehnologije.[9]

Učenici bi putem Interneta i kućnog računalnog sustava primali informacije od učitelja s mogućnošću komunikacije u realnom vremenu s učiteljem i ostalim učenicima u “razredu”.

Učiteljsko računalo/oprema škole ima zadatak središnjeg računala gdje učitelj vodi nastavni sat s jednog mjesta, bez obzira na udaljenost učenika od učitelja. Učitelj na svojem računalu putem video veze vidi sve učenike, dok najveći dio ekrana zauzima nastavni sadržaj koji je u tom

trenutku predmet poučavanja i razgovora (pdf dokumenti, prezentacije, word dokumenti, fotografije, karte…). S učiteljskog računala moguće je odabrati uvid u rad pojedinog učenika, a moguće ga je odabrati i za prikaz ostalim učenicima.

Učitelj je u mogućnosti iz "e-školske e-biblioteke" odnosno bilo kojeg segmenta školskog repozitorija uzimati bilo koji dokument, prezentaciju, audio ili video isječak i prikazati ga učenicima, a isto tako ima mogućnost pisanja (white board) te učenicima objašnjavati nastavnu jedinicu na način koji je blizak nastavnom procesu u klasičnoj školi.[10,4]

Učeničko je računalo učenikovo sredstvo komunikacije prema učitelju i ostalim učenicima. Učenik na zaslonu računala vidi učitelja i ostale učenike, s time da veći dio zaslona zauzima prikaz učitelja, odnosno veći dio zaslona prikazuje sadržaj koji učitelj smatra najpotrebnijim u datom trenutku za održavanje nastave. Učenik nastavne materijale iz virtualne "biblioteke" preuzima samostalno ili na poticaj učitelja, a u nastavne materijale se mogu svrstavati svi materijali koji su trenutačno potrebni za praćenje nastave (radne listove), ili udžbenike i radne zadatke u pdf formatu ili u bilo kojem drugom formatu koji bi najbolje bio prilagođen nastavnom procesu. Time učenici prate nastavu, odnosno sadržaj koji je identičan nastavnoj literaturi koju prate i upotrebljavaju učenici u "realnoj" školi, a bez obzira na fizičku udaljenost, ali i obogaćen mogućnostima učenja i količini općih podataka dostupnim na Internetu.

Sva predavanja ostaju sačuvana na školskom poslužitelju tako da su učenici u mogućnosti pregledavati po želji predavanja i nakon videokonferencijske nastave.

Provjera znanja kao važna komponenta škole mogla bi se odvijati razgovorom putem videokonferencije (usporedba s klasičnom školom je ispitivanje "pred pločom"), a pismene provjere znanja se također mogu održavati kao u klasičnoj školi s razlikom da je ispit oblikovan kao web dokument, odnosno dokument koji je oblikovan u jednom od gotovih programa koji se nalaze na Internetu (Quizmaker programi) ili kao samostalno programirani ispiti u programima poput C++, Authorware…

Važno je napomenuti da je znanje potrebno temeljiti na informacijskoj pismenosti, drugim riječima potrebno je provjeru znanja provoditi u kombinaciji s nastavnim sredstvima (udžbenici, knjige, internetski izvori) gdje nestaje "opasnost od prepisivanja" pošto učenici moraju osim činjeničnog znanja imati znanje upotrebe literature i Interneta, a ispitna pitanja je potrebno oblikovati tako da odgovor nije moguće pronaći u samo jednom izvoru znanja. Podsjetimo li da je činjenično znanje samo jedna spoznajna domena znanja prema Bloom-u, dolazimo do spoznaje da je i veliki broj klasičnih školskih ispita u današnjoj školi nedostano, odnosno ne obrazuje učenike u smjeru koji vodi informacijskoj pismenosti.

V. KOMPONENTE ŠKOLE

Virtualna škola bi osim potreba koje zadovoljava realna škola trebala sadržavati i elemente koji se u realnoj školi promatraju u drugom planu, odnosno koji su sekundarni sadržaji, a u virtualnoj školi oni postaju neizostavni dijelovi škole. To su: Web stranica, E-mail , repozitorij nastavnih materijala i sadržaja, digitalni školski imenik, arhiva predavanja, whiteboard, listići/kvizovi, materijali i udžbenici u digitalnom i klasičnom obliku.

Ukoliko pretpostavimo da klasičnu školu čine učenici, učitelji i školski sadržaji kao što su razredi i školska knjižnica, prevedeno u virtualni svijet ponovno dobivamo učenike i učitelje, ali u ovom svijetu možemo dobiti i „pomagače" učitelja (virtualne agente/virtualne pedagoge), edukativne igre, "online" kvizove i radne listiće za provjeru i samoprovjeru znanja, opće informacije o školi, nastavi i nastavnim temama dostupne 24 sata dnevno te mogućnost snimanja i pohrane održanih predavanja tako da su učenici u mogućnosti "odgledati" sat ponovno nakon videokonferencijskog sata budu li imali potrebe za ponavljanjem nekog sadržaja.

Škola bi trebala imati i prilagođen nastavni plan i program koji se zbog prirode IC tehnologije razlikuje od programa u "realnoj" školi, ali ipak mora biti u skladu s propisanim nastavnim planom i programom, odnosno nastavnim kurikulumom propisanim od nadležnog Ministarstva.

Školska knjižnica ne mora biti samo knjižnica jer nam se u računalnom svijetu otvara mogućnost pohrane i prezentacije ne samo knjiga, već i filmova, glazbe, slika, fotografija, karata...ukratko svega što nam pomaže u nastavnom procesu i što koristimo na nastavi u razredu. Drugim riječima moguće nam je oblikovati repozitorij nastavnog sadržaja i nastavnih materijala koji bi sadržavao digitalnu biblioteku, videoteku, audioteku, fototeku, mape, ilustracije, pojmovnik, enciklopedije, arhive predavanja, a sve to s mogućnošću proširenja na nove sadržaje koji su stalno i besplatno ponuđeni na korištenje.[11]

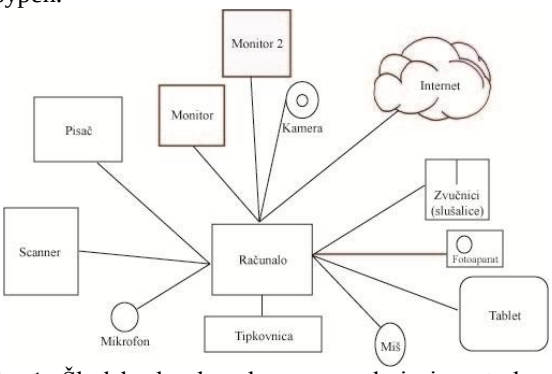
Sve nastavne materijale potrebno je preraditi za ovakav oblik nastave što iziskuje dosta vremena zbog velike količine materijala koji treba digitalizirati ili uz predložak klasičnih nastavnih materijala osmisliti i proizvesti nove materijale, ali kada se jednom uspostavi osnovni repozitorij, nadopuna novim materijalima može postati jednostavna, a zamjena s novim nastavnim sadržajima postaje moguća mnogo češće nego što je to slučaj u klasičnoj školi s tiskanim materijalima. Time se otvara mogućnost kvalitetnijeg pristupa učeniku i novim nastavnim sadržajima, a time i individualnom napretku učenika.

VI. OPREMA E-ŠKOLE

Računalna oprema škole ne bi trebala biti zahtjevna. Možemo govoriti o potpuno samostalnom sustavu gdje škola ima nezavisnu hardversko-softversku strukturu, odnosno rad škole i videokonferencija se oslanjaju na vlastiti informatičko/informacijski sustav, a školu je potrebno opremiti s računalnom opremom koja nije zahtjevna, prije bi se moglo reći da pripada u prosječnu kućnu računalnu opremu.

U ovom slučaju oprema škole je sljedeća: radno ("nastavničko") računalo za rad, poslužitelj za pohranu i

prijenos podataka, računalo za pohranu biblioteke, kvizova, udžbenika, pohranu održanih predavanja i ostalog sličnog materijala u elektroničkom obliku, skener, dva monitora, tipkovnica, miš, kamere, zvučnici, mikrofon, tablet s olovkom za pisanje Mousepen ili Easypen.[12]

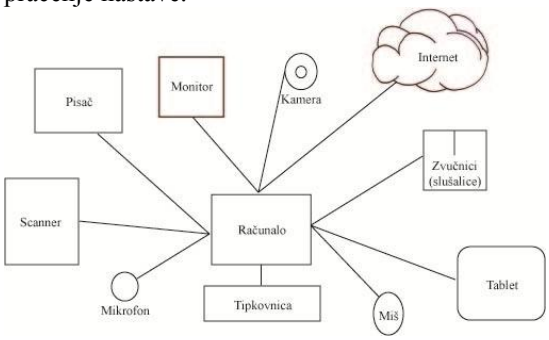


Slika 1: Školska hardverska oprema koja je potrebna za vođenje nastave

VII. UČENIČKA OPREMA ZA PRAĆENJE NASTAVE E-ŠKOLE

Kao što je prije rečeno, učenička oprema za praćenje nastave ne bi smjela biti niti skuplja, niti zahtjevnija od prosječne računalne opreme koja se nalazi u većini kućanstava, a moguća dodatna oprema bi se trebala odnositi na manje dodatke koji ne bi smjeli pretjerano opterećivati financije korisnika, odnosno roditelja učenika.

Učenička oprema za praćenje nastave trebala bi sadržavati: računalo, tipkovnicu, miš, monitor, printer, web kamera, mikrofon, zvučnici, tablet (Mousepen, Easypen ili slično pomagalo), potreban softver koji učenici imaju u svakodnevnoj upotrebi kao što su Internet pretraživači, ili besplatni programi koji omogućuju praćenje nastave.



Slika 2: Učenička hardverska oprema koja je potrebna za praćenje nastave

Softverski alati i programi potrebni za pripremu i održavanje nastave su uobičajeni programi i alati koji se nalaze u osnovnom Microsoft Office, Open Office ili nekom drugom paketu, a to su program za obradu teksta, slike, izradu prezentacija, program za obradu fotografije, zvuka ili filma, čitanje i izradu PDF dokumenata i videokonferencijski softver.

Sustav i učitelji moraju učenicima pružiti kvalitetu komunikacije koja je osnova svakog kvalitetnog odgojno-obrazovnog sustava, istu ili bolju nego što je uobičajena u klasičnoj školi.

Navedeni razlozi nameću pitanje veličine „razreda“ ovakve škole, a obzirom na to da manje učenika u razredu omogućava kvalitetniju komunikaciju s učenicima, lakše napredovanje i bolji uvid u učenikov rad, smatram da bi u istovremenoj komunikaciji, odnosno razredu trebalo biti do pet učenika. Istovremeno, istraživanja pokazuju da je učenje putem računala zamornije i da se lakše gubi koncentracija za praćenje nastave, a manji razred omogućuje posvećivanje više pozornosti svakom učeniku čime učenici ostaju motiviraniji.

Učitelj mora imati mogućnost vidjeti i čuti (audio, vizualno i pismenim putem) odnosno komunicirati pojedinačno i skupno sa svim učenicima istovremeno ili u odvojenim vremenima, sinkrono i asinhrono, zatim treba imati mogućnost određivati učenika koji će govoriti, a da ga ostali učenici čuju i vide, ali i da mogu pratiti njegovo izlaganje putem Whiteboarda, odnosno uvida u radni stol njegovog računala. Ovaj postupak bi u stvari trebao mijenjati klasičnu komunikaciju razgovora s jednim učenikom u klasičnom razredu, odnosno razgovora s učenikom „pred pločom“.[9]

ZAKLJUČAK

Današnji pristup školovanju općenito, a pogotovo školovanje putem stolnog videokonferencijskog sustava kakav je predviđen u ovom radu, osim prilagođenog samog nastavnog procesa i nastavnih materijala, iziskuje i prilagodbu temeljnih znanosti kao što su pedagogija, psihologija i metodika koje su, iako slične radu u klasičnom okruženju, ipak u nekoj mjeri izmijenjene zbog same prirode medija što znači da bi se u bliskoj budućnosti mogle razviti potpuno nove grane znanosti ili same samostalne znanosti koje su u današnjem svijetu nepoznanica. Neke od tih grana znanosti se u svijetu već i proučavaju u obliku pedagogije medija odnosno medijske pedagogije koja proučava odnos edukacije i novih medija općenito, ali za sada se još uvijek takvi predmeti kod nas ne poučavaju u redovnoj sveučilišnoj nastavi, a ukoliko smo usvojili termine e-učenje ili e-škola, uskoro bismo mogli usvojiti i termine e-pedagogija, e-metodika, e-psihologija.

Važno je osmisliti sustav, a tehnika ukoliko već ne postoji, biti će napravljena. U budućnosti bi se više trebalo pozabaviti edukacijom, radnim sadržajima, e-metodikom i ostalim segmentima školstva.

Drugim riječima, prvotna zamisao rada bila je obrada, odnosno oblikovanje škole s informatičke strane, ali tijekom razrade došao sam do zaključka da je u stvari informatička strana e-škole manje zahtjevna, odnosno programi i aplikacije koji su već postojeći i u upotrebi dovoljno su dobri, razvijeni i upotrebljivi za e-školu, ali s odgojno-obrazovne strane potrebnije je znanstveni rad usmjeriti ka proučavanju i prilagodbi te shvaćanju školstva u novom obliku, virtualnom svijetu koji koliko god bio sličan realnom svijetu, ipak ima velike razlike naspram klasičnog poimanja nastave i školstva.

Rad je obrađen kao opis škole koja zasigurno ne može zamijeniti „živi“ kontakt učenika i učitelja, već kao razrada školskog sustava koji dolazi do izražaja ukoliko ne postoji mogućnost „žive“ škole, a kako je ovo jedan od rijetkih radova u našoj zemlji koji se bavi ovakvim oblikom virtualne škole putem stolnog videokonferencijskog sustava, rad može biti poticaj za razradu i prihvaćanje ovakvog načina školovanja.

Isto tako sam naišao na pravno-birokratske prepreke koje bi u stvari trebale omogućavati napredak ovakvih projekata, ali isti ti propisi otežavaju ili čak onemogućuju rad ovakvog ili sličnog oblika škole što znači da bi i sa zakonodavne strane trebalo napraviti izmjene koje bi bile korisne za razvoj školstva i omogućavanje školovanja onima kojima je iz bilo kojeg razloga onemogućeno pohađanje redovne nastave u klasičnim školama na Hrvatskom književnom jeziku i s propisanim Nastavnim planom i programom koji je izdalo Ministarstvo.

Sažetak - U ovom radu želimo pokazati kako pojam forum nemoguće smjestiti i promatrati unutar jedne znanstvene discipline. Istraživanje u nastavku temelji se na presijeku tehničkih i socijalnih disciplina, budući da su Internetski forumi sami po sebi stvoreni su za dvosmjernu komunikaciju između korisnika. Komunikacija na forumima bitno ovisi kako o tehničkim predispozicijama foruma tako i o osobama koje forum vode, administratorima i moderatorima. Istraživanje za ovaj rad proveli smo forumu od studentskog zbora TVZ-a (forum.sztvz.hr) koji bi trebao biti središnje mjesto za razmjenu podataka između profesora i studenata. Kroz rad želimo naglasiti da web 2.0 tehnologija nije „potopila" forume, već im je dala novi uzlet i novu dimenziju. Kroz presjek foruma studenskog zbora TVZ-a želimo naglasiti kako je bitno da sve karike u nekoj zajednici moraju biti svjesne svoje uloge jer u protivnom može doći do odbojnog pristupa prema tehnologiji za komunikaciji u toj zajednici. Ovim radom želimo ukazati na činjenicu kako informacijska i komunikacijska tehnologija, putem koje se odvija dvosmjerna komunikacija, ima značajno mjesto i u tehničkim zajednicama jer su i one podložne odbijanju.

I. UVOD

Nagli porast upotrebe Interneta početkom 90tih godina prošlog stoljeća označava početak ekspanzije globalne komunikacije. Internet omogućava komunikaciju, stvaralaštvo i širenje novih znanja, pri čemu se pomiču granice onoga što se smatra vlastitim okruženjem [1]. Omogućava nam čitanje multimedijalnih dokumenata koji u sebi sadrže slike, tekst, glazbu, video, približio se malom čovjeku, kako bi mu olakšao svakodnevni život na razne načine, od jednostavnije poslovne komunikacije, pa sve do razonode. Kako se Internet širio tako su se i „apetiti" njegovih korisnika rasli. U početku grupne komunikacije na webu stvorile su se mailing liste, te News grupe koje su omogućavale korisniku da dok nije prisutan na Internetu sudjeluje u grupnim raspravama. Kako se telekomunikacijske infrastruktura i računalna tehnologija počela razvijati tako su se počele razvijati nove mogućnosti (ISDN). 1994 godine osnovana je World Wide Web Consortium (W3C), koji od tada kreira i održava WWW standarde koje se još nazivaju W3C preporuke. Te godine nastaju forumi preporukom W3C organizacije.

Forumi se temelje na raznim CMS (engl. Content management system) platformama. CMS sustav moguće je implementirati u bilo koji dizajn ili/i gotovu web stranicu. Korisniku omogućava automatizaciju prilikom promjene ili postavljanja sadržaja na Internet, odnosno umetanje i uređivanje sadržaja web stranica. Na tržištu se mogu pronaći komercijalni i besplatni CMS sustavi za upravljanje forumima. Najkorišteniji među njima su PHPBB, SMF, vBulletin. CMS povezuje grafičko sučelje s bazom podataka pomoću koje se upravlja na forumima. Dvije su vrste CMS-a kojega možemo naći na tržištu: slobodni i licencirani. Softver je slobodan ako zadovoljava sljedeće kriterije (Stallmanova podijela [2]):

- sloboda korištenja programa u bilo koju svrhu
- sloboda proučavanja načina na koje softver radi i prilagodbe na vlastite potrebe (nužan uvjet za to je pristup izvornom kodu)
- sloboda redistribucije kopija kako bi se moglo pomoći susjedu
- sloboda usavršavanja programa i javnog objavljivanja vlastitih poboljšanja u svrhu dobrobiti čitave zajednice (nužan uvjet za to je pristup izvornom kodu).

Navedeni sustavi služe za što lakše autoriziranje korisnika, za lakše praćenje novih tema na forumu, omogućuju indirektnu i direktnu komunikaciju među korisnicima. Pod indirektnu komunikacijom smatramo neke mogućnosti pojedinih CMS sustava, Mogućnost korisnika da izraze svoje trenutno stanje pored svog naziva profila, također omogućava drugim korisnicima da podrže ili da pokude drugog sudionika foruma bez pisanja teksta (pomoću pozitivnih i negativnih karma bodova, ili putem tipke THANKS), na taj način članovi mogu steći reputaciju pouzdanosti na nekom forumu.

Namjera ovog istraživanja nije bila napraviti digitalnu razdjelnicu između pojedinaca koji imaju i nemaju pristup informatičkoj opremi i na taj način kao rješenje našeg problema ponuditi rješenje putem uobičajenog pristupa gdje se digitalne razdjelnice svodi na statističko prebrojavanje osoba koje imaju pristup tehnologijama (Mason i Hacker [3]), u našem slučaju pristupa Internetu. Iz razloga što smo pretpostavili da svaki student informatike na TVZ-u može pristupiti Internetu na raznim lokacijama našeg veleučilištu.

Ovo se istraživanje temelji na metodologiji znanstvenika Van Dijka i Hackera iz razloga što su pokazali da gornja navedena metodologija daje tek ograničen opis problema „odbojnog" pristupa prema tehnologijama.

II. FORUM U DANAŠNJEM SVIJETU

Društvo u kojemu danas živimo često se naziva i „Internetskim" društvom. Zašto? Možemo promatrati koliko se poslova odnosno komunikacije odvija putem Interneta, od slanja obične elektronične pošte, pa sve do udaljenog upravljanja velikim industrijskim sustavima. Sve brži način života Upućuje nas na korištenje Interneta

pa se tako i privatna komunikacija odvija preko besplatnih društvenih mreža umjesto personalne komunikacije.

Nekada su stari stanovnici Rima svoj svakodnevni život provodili na trgovima (forumima), gdje su mogli slobodno izraziti svoje stavove i raspravljati o njima. Upućuje nas na korištenje Interneta pa se tako i privatna komunikacija. Web forumi su mjesta gdje svaki korisnik foruma može iznijeti svoje mišljenje o nekoj temi, ali pritom pazeći da ne povrijedi drugog sudionika rasprave, kao i da ne prekrši neke osnovne oblike međuljudske komunikacije. Forumi kao dio Interneta, ne bi smjeli zamjenjivati socijalnu ulogu društva, oni bi trebali poslužiti samo kao mjesto gdje ljudi mogu naći korisne podatke, ili činjenice koje bi mogle poslužiti za daljnju raspravu.

Nakon „nastajanja“ pojma Web 2.0 kojega su 2004. godine osmislili O'Reilly i Dougherty. Pojam Web 2.0 zapravo je samo ujedinio pojmove koji su nastali razvojem novih web servisa koji omogućuju korisniku da interaktivno uređuje i stvara sadržaj Internet stranice u svom Internet pregledniku. Tablica 1 prikazuje vezu između pojmova vezanih za Web 1.0 i Web 2.0. Također web 2.0 teži, odnosno želi stvoriti što interatktivniju virtualnu zajednicu od pojedinih internetskih stranica.

Iz tablice je vidljivo da se pojam „forum“ ne pojavljuje već se pojmovima navedenim u tablici može tumačiti internetski forum. Kada poželimo Internet forume pridodati pojmu starog (Web 1.0) ili novog (Web 2.0) možemo uočiti da to nije tako jednostavno iz razloga što Internet forumi sadržavaju značajke jednog i drugog „weba“ . Tako i sve daljnje podijele koje ćemo spomenuti u daljnjem radu ne možemo jasno definirati kroz samo jednu podjelu, odnosno ne možemo forume sagledavati samo iz jednog aspekta jer smatramo da proučavanje Internet foruma mora biti transdisciplinarno. Forume ćemo sagledat kroz njihov unutarnji presjek. Presjek foruma biti će prikazan kroz podjele po vidljivosti sadržaja, uloge korisnika te njihove socijalne odnose kroz koje tražimo problematiku ovog rada na temelju Van Dijakove i Hackerove metodologije.

Tablica 1 Usporedba Web 1.0 i Web 2.0 tehnologije

Web 1.0	Web 2.0

HTML	XML
Osobne stranice	Blogovi
Predavanja	Konverzacija
Objavljivanje sadržaja	Dijeljenje i sudjelovanje u sadržaju
Encarta	Wikipedia

III. PODJELA FORUMA

Na Internetu nalazimo brojne forume. Neki portali sa vijestima omogućavaju komentiranje dnevnih novosti putem komentara ispod novinarskih članaka, koji su zapravo dio foruma, i kojima mogu pristupiti svi čitatelji tog portala što je direktna posljedica sa „upotrebom“ Web 2.0 tehnologije. Dok sa druge strane postoje forumi kojima ne možemo pristupiti bez prethodne registracije naših podataka, te stvaranje forumskog identiteta (proces registracije novih korisnika).

A. Podjela prema vidljivosti sadržaja

Forume možemo podijeliti u tri temeljne skupine: **javne** koji omogućavaju raspravu vidljivu svim posjetiteljima, **polu-javne** koji omogućavaju raspravu te čitanje foruma samo korisnicima tog foruma; a vanjski sudionici mogu samo čitati rasprave, te **privatne** u kojima nije niti moguće vidjeti otvorene rasprave.

Na prikazanim slikama zamjećujemo razliku u broju vidljivih kategorija na privatnim (a) i polu-javnim (b) forumima.

Naše istraživanje stručnog rada radili smo na primjeru polu-javnog foruma forum.stvz.hr koji radi na plaćenoj vBulletin tehnologiji, te foruma forum.tvzino.net koji se bazira na SMF-u koja je tehnologija otvorenog koda te u skladu sa tim njegovo korištenje je besplatno. Na našem veleučilištu točnije na smjeru informatike dogodio se jedan vrlo zanimljiv „fenomen“. Većina veleučilišta i sveučilišta okuplja svoje studente na službenim polu-javnim forumima, koji pružaju budućim,

a. Polu-javni forum

b. Privatni forum

te sadašnjim studentima razne za njih korisne informacije. Forumi u današnjem e-obrazovanju igraju sve veću ulogu jer mogu poslužiti za direktnu komunikaciju između profesora i studenta, zapravo putem foruma se postiže dvosmjerna komunikacija koja prema većini suvremenih istraživanja pridonosi stjecanje više znanja samom studentu. Forum TVZ-a je pod okriljem studenskog zbora, koji bi trebao na sebe preuzeti tu ulogu. No spletom različitih okolnosti poput hakerskih napada na forum koji su se dogodili te tako uništili postojeće baze podataka, koje su za sobom povukle tada aktivne rasprave na forumu. Pa sve do nemogućnosti prilagodbe foruma korisnicima koji su ujedno i studenti. Tako se dogodilo da se informatički dio foruma odcijepio u privatni forum održavan isključivo od strane studenata informatičkog smjera. Taj privatni forum kod registracije novih korisnika zahtijeva jedinstvene parametre popu jedinstvenog broja akademskog građanina koji će autentificirati studenta informatike na TVZ-u. Tako i mnogi drugi privatni forumi traže neki jedinstveni parametar za registraciju. Ovakve se stvari rade se iz jednostavnog razloga, da bi korisnici takvog foruma mogli nesmetano komunicirati sa svojim žargonom, te tako pojednostavili buduće rasprave.

B. Podjela prema otvorenosti koda (plaćeni i besplatni)

Hakerski napadi na forum forum.sztvz.hr namjerno smo naveli iz razloga što su se oni desili prije mnogo godina, te sa nakon toga opet zajednica obnovila ali samo u manjem obujmu. Taj napad je trajno sa foruma obrisao sve dosadašnje rasprave, članove, te razne materijale koji su se nalazili na njemu. Još uvijek u našem društvu stoji percepcija da je softver koji platimo sigurniji od besplatnog softvera. Kao što možemo vidjeti iz ovog primjera da plaćeni softver odnosno u našem slučaju licenca za CMS forume (vBulltetin) ne mora nužno i značiti najsigurniju i najbolju opciju zaštite.

U današnje vrijeme razlika između plaćenih i besplatnih CMS-a gotovo da i nema (u razmatranje smo uzeli vBulletin i SMF). Oba navedena CMS-a sadržavaju mnoštvo dodataka za unaprjeđenje foruma, mnoštvo alata da se korisnicima olakša rad na forumu. Usudio bi se napisati da je momentalno besplatni CMS bolji u smislu zaštite i prilagodbe foruma po mjeri određene zajednice.

Smatramo da bi studenski forumi trebali koristiti besplatne CMS-ove za foruma, iz razloga što takav pristup omogućuje da studenska zajednica stvori sebi neovisan sustav namijenjen samo za svoju upotrebu, te također iz razloga što bi se sredstva za plaćanje licence mogla iskoristiti u druge svrhe (svrhe promocije foruma, uzimanje boljeg jačeg i većeg servera).

C. Mane društvene mreže nad forumom

Dolazimo do pitanja zašto da koristimo besplatne CMS-ove kada su mogućnosti društvenih mreža (Web 2.0) daleko naprednije, na prvi pogled mogli bismo zaključiti da prelaze mogućnosti foruma. U našem razmatranju zaključili smo da prelazak naše zajednice, odnosno korištenje društvenih mreža stvara mnogo problema. Razmotrili smo društvenu mrežu Facebook (facebook.com). Prvi problem do kojega dolazimo je problem narušavanje privatnosti. Svaki korisnik na društvenoj mreži posjeduje neke osobne stvari (fotografije, statuse…) koje možda ne želi podijeliti sa ostalom zajednicom koja sa njime studira, a na društvenim mrežama ne postoji „potpuna“ privatnost, jer je zadatak društvenih mreža stvoriti zajednicu ljudi sa istim interesima. Sljedeći veliki problem događa se sa pohranjenim podacima koji su na toj društvenoj mreži, svi podaci, slike vlasništvo su te društvene mreže kada se nađu na njoj. Javlja se i problem kako napraviti sigurnosnu kopiju svih podataka i brzo i jednostavno se preseliti na neki drugi servis.

IV. KAKO INTERNET FORUM FUNKCIONIRA

Naše istraživanje temeljili smo na Van Dijkovoj i Hackerovoj [4] metodologiji koja navodi četiri razloga što informacijsku i komunikacijsku tehnologiju čini nepoželjnom među korisnicima:

1. Nedostatak osnovnoga digitalnog iskustva, odnosno mentalna prepreka koje uzrok može biti nedostatak zanimanja, strah od računala i neprivlačnost tehnologija.
2. Neposjedovanje računala i mrežnog pristupa, odnosio materijalna prepreka.
3. Nedostatak digitalnih vještina ili prepreka vještina uslijed nedovoljne lakoće korištenja tehnologija i nedostatka obrazovanja ili društvene potpore.
4. Nedostatak značajnijih prilika za korištenje ili prepreka korištenja

U nastavku ćemo prikazati zašto je neslužbeni forum (forum.tvzino.net) više posjećeniji od foruma studenskog zbora (forum.sztvz.hr). Radi lakšeg razumijevanje problematike objasniti ćemo sve slojeve od kojih se sastoji „život“ na navedenim forumima (proces registracije korisnika, tko su: administratori, moderatori, korisnici, rasprava).

A. Proces registracije

Kada se želimo priključiti nekom forumu, na način da možemo sudjelovati u raspravama, trebamo proći kroz proces registracije novih korisnika. Postupak pri kojemu moramo sebi odabrati nadimak (eng. nick) pod kojima ćemo objavljivati svoje komentare, zatim moramo unijeti svoju adresu elektroničke pošte (ona prvenstveno služi za slučaj da korisnik zaboravi lozinku, te zbog jednostavnosti određivanja koji budući članovi uopće mogu pristupiti procesu registracije (putem domene pošte)) te moramo pročitati i prihvatiti pravila foruma na kojega se registriramo. Ovakav postupak je nužan iz tri razloga:

1. Kako bi mogli iskoristili puni potencijal CMS aplikacije
2. Da bi bili u mogućnosti kontrolirali sadržaj i promet na forumu
3. U slučaju nekog incidenta (vrijeđanja drugih korisnika, neprimjereno ponašanje za forum…)

izolirali problematičnog korisnika koji bi mogao nanijeti štetu našoj zajednici.

Odabrani nadimak na forumu pruža svakom korisniku da bude anoniman, te da se tako osjeća sigurnije. Odnosno da korisnici mogu lakše iskoristiti mogućnost slobode govora bez ikakvih osuda u stvarnom (realnom) životu.

B. Administrator

Administrator foruma je osoba koja je pokrenula inicijativu za stvaranje nekog foruma. Ona se pobrinula za odabir najbolje CMS aplikacije koja će se prilagoditi potrebama zajednice. Administrator određuje početni izgled foruma, kao i početne grupe rasprava u kojima će ostali korisnici sudjelovati. Administrator odlučuje koji korisnici imaju pristup određenom sadržaju, to znači da svi korisnici ne moraju vidjeti sve teme za raspravu, te dolazimo da svi korisnici nemaju jednaka „prava“ na forumu. Upravo „prava“ pojedinog korisnika na forumu su najveći problem sa kojime se susreću administratori. Administratori ne mogu procijeniti koji korisnik može pružiti kvalitetniji sadržaj, a koji je došao nanijeti štetu toj zajednici.

Ovdje se postavlja pitanje gdje je nestalo građanstvo. Uz pojam građanina najčešće se vežu epiteti „dobri“, „aktivni“, „odgovorni“. Današnje Internetsko društvo sve više gubi navedene epitete te se sve više marginizira, odnosno građani su postali nevidljivi. Ako se građanin pojavi u obliku administratora koji želi svim korisnicima foruma pružiti jednake uvijete za slobodu govora to nije u mogućnosti napraviti objektivno jer svaki građanin, pa tako i administrator ima svoja moralna načela

Ako administrator uoči neki incident na forumu može na korisnika usmjeriti određene mjere kako bi on shvatio da takvo ponašanje nije prihvatljivo. Prilikom počinjenja incidenta korisnik se ne mora nužno udaljiti se foruma. Administrator može navesti i neke druge mjere koje mu dopušta CMS sustav da bi upozorio člana foruma da njegovo ponašanje nije u skladu sa pravilima ponašanje. Takve mjere mogu biti pismeno upozorenje putem privatne poruke, može biti zabrana pristupa određenoj temi sve do udaljavanje korisnika sa korisnika na određeno ili ne određeni vremenski period. Ovakve mjere ovise o mogućnostima prilagodbe CMS sustava (za tu namjeru bolji su besplatni sustavi iz razloga što su oni rađeni po mjeri zajednice).

Uloga administratora na nekom studenskom forumu gdje dolaze nove generacije (npr. novo upisana generacija brucoša) bila bi da njima osigura ravnopravnu raspravu u svim temama i to na način da na jednom mjestu (npr. iz arhive foruma) mogu pogledati ono što studente zanima iz prošlih generacija, te da napravi nove teme za nove generacije. U slučaju da se ne postupi kako je napisano može doći do organizacijskih problema otvaranja novih tema, odnsno dolazi do nemogućnosti moderiranja (prevelika količina rasprave, koju nisu pratili novi moderatori). Također korisnik gubi kreativnosti (želju) za sudjelovanje u tako velikim i neuređenim raspravama. Administrator se mora pobrinuti da novi korisnik foruma ima iste uvijete za raspravu kao i korisnici koji su se na forum registrirali prvih dana početka rada foruma.

U slučaju foruma forum.sztvz.hr, administratori nisu bili fleksibilni, što se tiče novih ideja za forum. Administratori foruma nisu dozvolili korisnicima da oni kažu kako je njima najpraktičnije i najpreglednije koristiti forum. Stoga je forum počeo gubiti na popularnosti među studentima. Sa druge strane dogodilo da si se studenti informatike međusobno organizirali bez studenskog zbora, što je za sobom povuklo neke pozitivne i negativne posljedice za tu zajednicu. Administratori navedenog foruma nisu vršili promociju foruma odnosno nisu upoznavali brucoše da forum postoji, a to je sve rezultiralo naglim padom broja novih komentara i izostanak novih korisnika.

Administratori su glavne karike u opstanku foruma, moraju biti što bolje upoznati sa situacijom na forumom ali je naprosto nemoguće da jedna osoba prati sve članove i sve otvorene rasprave. Oko takvih stvari administratoru pomažu moderatori.

C. Moderator

Kako u svakoj raspravi u kojoj sudjeluju barem dvije osobe sa različitim gledištima na moguće rješenje situacije, može doći do sukoba, te je potrebna jedna osoba koja će voditi (moderirati) raspravu u dobrom smjeru. Također ista situacija događa se na web forumima. Na forumima također postoje moderatori koji usmjeruju raspravu u konstruktivnom smjeru, te se brinu da nitko u toj raspravi ne bude zakinuti, uvrijeđen.

Moderator može postati svaki korisnik foruma. Takav korisnik mora se istaknuti svojom kvalitetom otvorenih tema za raspravu sa drugim korisnicima, što kvalitetnijim diskusijama, te drugi angažmani na forumu i sa takvim zalaganjem je zadobio povjerenje administratora koji mu može omogućiti moderatorske odnosno uredničke ovlasti na dijelu foruma gdje je taj član pokazao interes. Moderatori aktivno sudjeluju u raspravama u jednom djelu foruma, te znaju kako voditi primijenjene diskusije na određenu temu. Oni trebaju voditi raspravu u pravom smjeru, te joj ne dopustiti da se rasprava ne pretvori u razgovor od dva sudionika. Također je njegova uloga da uvredljive sadržaje, bilo u obliku teksta, slike ili neki treći oblik trenutno ukloni. Ovaj način rada moderatora pomalo izgleda na cenzuru teksta, no sa druge strane to je jedino sredstvo sa kojim moderator može najbrže djelovati, da se neka konstruktivna rasprava ne pretvori u svađu. Kada moderator uoči neku nepravilnost na forumu, on upozorava administratora za nju. Također sve bitne odluke vezane za nekog korisnika foruma obavljaju se unutar vodstva (eng. Crew) kojega sačinjavaju svi moderatori i administratori. Dio foruma gdje se vrše ovakve odluke nevidljiv je ostalim članovima. Kod nekomercijalnih foruma, odnosno forume koje financiraju korisnici putem donacije odluke koje se tiču svih članova idu na javnu raspravu, te se nakon rasprave uvijek dogodi da ima više mogućih ishoda; u takvim slučajevima se postavlja javna anketa koja traje neki određeni dogovoreni vremenski period. Nakon što završi taj

vremenski period, odluka sa najvećim brojem glasova stupa na snagu, te vrijedi za sve korisnike.

Moderatori bi trebali biti što više neovisni od administratora, na način da administrator ne dovodi sebi pogodne administratore, nego odabire najkvalitetnije članove foruma. Što je ponekad kod stvaranja novog foruma malo teže ostvariti, jer svi članovi kreću od nule, u tom slučaju administrator bi trebao obavljati moderatorsku ulogu.

Na forumu forum.sztvz.hr dogodila se situacija da su većina moderatora bili kolege iz studenskog zbora, oni su sa svojom položajem „uzeli“ posao moderatora na foruma, što u krajnjem slučaju nije rezultiralo kao najoptimalnije rješenje, to vidimo po broju novo stvorenih tema u posljednjih par godina. Također moderatori nisu ažurirali potrebne teme relevantne za korisnika foruma. U konkretnom slučaju, teme od pojedinih predmeta nisu bile pripremljene za novu generaciju, odnosno nisu stvoreni uvjeti za kvalitetnu novu raspravu novim članovima.

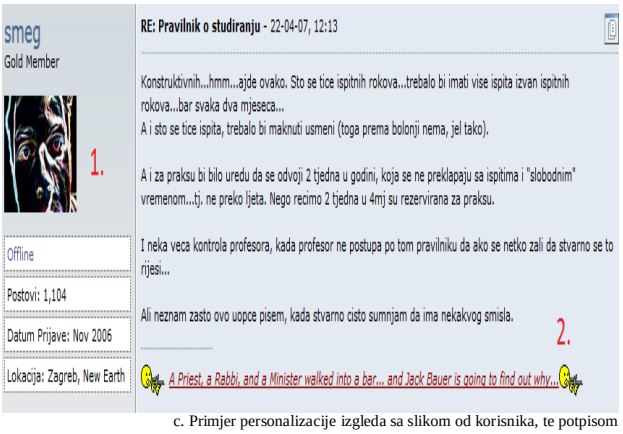
Glavni cilj moderatora nije da guši raspravu te da radi listu neželjenih korisnika koji svoju slobodu pisanja iskorištava na način da našteti drugom korisnika, već da svim korisnicima omogući da se osjećaju jednakim, da se ne dogodi situacija da za nekog korisnika vrijede pravila foruma, a da za drugog korisnika ne vrijede.

D. Korisnici

Pojam korisnika definirali smo kao svakog člana foruma koji je prošao proces registracije, bilo to na javnom, polu-privatnom, privatnom forumu. Svi korisnici na forum su pristupili samovoljno, bez ikakve prisile, pa sa tim načelom od njih se smatra da se korektno ponašaju po prihvaćenim pravilima foruma. Također osim napisanih norma i pravila postoje i ona ne pisana, kao što postoje kod personalne komunikacije i rasprave. Ova rečenica se ne može uzeti u doslovnom smislu. Dok razmatramo tu rečenicu, moramo razmisliti što je za nas etično. Sama etika je nauka o moralu, a što je moralno za pojedinog korisnika ne mora biti i za ostale korisnike foruma. Korisnici koji pristupaju određenom forumu, imaju neke sličnosti, odnosno slične poglede na teme foruma. Oni se nalaze na forumu jer možda samo žele javno negodovati pod krinkom anonimnosti, žele pomoći forum zajednici jer su nekada dobili pomoć, ili neka sasvim treća nakana.

Svaki korisnik je na početku registracije na forum odabrao svoj nadimak, pod kojime će objavljivati svoja pitanja, komentare. Kod same registracije najčešće se ne pregledavaju nadimci ali ako je za nekoga takav naziv uvrjedljiv slobodno se može požaliti nekom od vodstva foruma, da se nastala situacija riješi.

Većina CMS aplikacija za forume omogućava da svaki korisnik može upotrebljavati određenu sliku (c, 1.) (eng. avatar) koja se prikazuje ispod korisnikovog nadimka svaki put kada pošalje poruku. Osim slike koju korisnik želi postaviti u većini slučajeva korisnik može koristiti potpis(c, 2.). Potpis se također pojavljuje kada korisnik napiše poruku na forumu. U potpis se može navesti neki kratki tekst ili nekakva slika.



c. Primjer personalizacije izgleda sa slikom od korisnika, te potpisom

Korisniku foruma pruža se mogućnost da iznosi slobodu govora na odgovorni način. Zapravo svakom korisniku je dana šansa da pokaže ono najbolje od sebe, te da sebe predstavi u najboljem izdanju ili da sebe predstave onakve kavi nisu u svom privatnom životu. Mi ne možemo znati tko se „skriva“ ispod određenog naziva nekog profila, ne znamo da li on nama pristupa zato da bi nam pomogao ili da bi nam još više naštetio. Ovakvu tezu možemo iznijeti za bilo kakav oblik komunikacije sa nepoznatim osobama; čak i ako koristimo digitalni potpis, nitko nam ne može garantirati da je sa druge strane „žice“ pouzdana osoba. Važno je napomenuti da imamo različite vrste korisnika na web forumima. Jedna grupa korisnika je stalno aktivna u pisanju novih tema, sudjeluju u raznim raspravama. Druga skupina korisnika zna pročitati većinu rasprava, ali i ne sudjelovati u njima. Dok je treću skupinu korisnika možemo svrstati u ekstremne korisnike, ili su preaktivni (potiču nepotrebne rasprave, i pišu odgovore ne vezane uz temu (eng. spam)), a drugi su korisnici u potpunosti neaktivni te samo čitaju forum na način da vide što ima novoga u njihovoj virtualnoj zajednici.

U našoj studenskoj zajednici forum igra jednu važnu. Iako se to ne bi dalo zaključiti zbog zamrlosti foruma forum.sztvz.hr na nekim smjerovima. Pogotovo iz razloga što je najlakša i najbrža komunikacija preko Interneta, a još k tome forumi su slobodni mediji koji mogu poslužiti za raspravu vezanu za pomoć u svladavanju gradiva i za studenska pitanja. Baš suprotno od toga neki smjerovi vode jako uspješne forume, dok drugi to vode manje uspješno. U ovom slučaju studenti su mogli birati hoće li pristupiti polu-javnom forumu koji je pod okriljem studenskog zbora, ili privatnog foruma kojega vode studenti.

Korisnici su zapravo smisao foruma, zbog njih forum postoji ali također oni čine živu virtualnu zajednicu. Forum možemo zamisliti kao jednu veliku kuglu u kojoj su svi korisnici jednako udaljeni od središte kugle. Svi korisnici imaju pravo na izražavanje svoga mišljenja ali to izražavanje ne smije vrijeđati niti jednog drugog korisnika.

E. Rasprava

Korisnici na forumu komuniciraju putem rasprava u pojedinim temama. Razni korisnici imaju potrebu iznijeti različito mišljenje u toku rasprave. Tako neki korisnici

pridonose raspravi sa činjenicama, neki sa iskustvima iz svog života, neki korisnici postavljaju pitanja…

Da bi se rasprava uopće razvila korisnik mora napraviti raspravu (eng. topic), te joj dodijeliti neki naziv i postaviti je u pravi dio foruma. Ako korisnik postavlja tmu vezanu o nekom predavanju na određenom kolegiju, neće tu temu staviti u dio foruma koji je napravljen da se diskutira o studenskim problemima. U takvom slučaju moderator je dužan što prije smjestiti temu u odgovarajuću kategoriju da bi ostali korisnici mogli lakše pristupiti toj temi. Nakon što je otvorena rasprava ostali korisnici procjenjuju potrebu da se oglase u toj raspravi. Odnosno na svakom korisniku je odabir želi li on sudjelovati u toj temi ili ne.

U raspravama se redovito primjenjuje žargon (eng. *slang*) pojedine zajednice, koji je prilagođen za upotrebu na Internetu. Komunikacija na forumima može se vršiti sa skraćenicama koje razumije samo manji dio ili cijela zajednica. Takve skraćenice se koriste da bi korisnici sa što manje riječi mogli opisati što više svojih misli. Sa takvim načinom komunikacije zajednica se pokušava odmaknuti od tradicionalne komunikacije koja podliježe raznim pravilima za pisanjima. Zajednica kroji svoje norme i pravila za sebe uzima samo ono što je dobro za nju. Na taj se način smanjuje mogućnost za vrijeđanjem članova koji posjeduju drugačiji vokabular od većine korisnika na forumu. Kao i u svakoj raspravi postoje neka pravila, u svakodnevnom životu vodimo se po društveno propisanim normama[5]od kojih su neke i dio bontona. Pošto se sva pravila iz svakodnevnog života ne mogu primijeniti na Internet komunikaciju tako za komunikaciju na Internetu postoji internetski bonton (eng. netiquette). Za uspješnu komunikaciju na forumima, pa tako i Internetu preporuka je da se prouči Internet bonton.

Davši kratki presjek kroz slojeve foruma radi upoznavanje sa problematikom rada, želimo objasniti zašto smo koristili navedenu metodologiju dvaju autora. U razmatranje nismo uzeli prva dva nedostataka koje su naveli: nedostatak osnovnog digitalnog iskustava, te neposjedovanje računala. U istraživanju smo ih ostavili malo postrani iz razloga što smo istraživali forume koje koriste studenti informatike te smo zaključili da studenti studiraju područje informatike te da samim time imaju računalo i mrežni pristup. Kroz sljedeće dvije točke u njihovoj metodologiji o nepoželjnosti korištenja informacijskih i komunikacijskih tehnologija koje se odnose na nedostatak društvene potpore i nedostatak značajnih prilika za korištenje. Želimo istaknuti da su to dva glavna razloga zašto je forum.sztvz.hr izgubio na važnosti u zajednici studenata smjera informatike. Kao nedostatak društvene potpore naglasiti ćemo nebrigu studenata za studente. Nedostatak značajnih prilika za korištenje stvorio se kao posljedična veza nakon nedostatka društvene potpore.

V. ZAKLJUČAK

Istraživanjem smo željeli ukazati na potrebu da svaka zajednica, pa tako i zajednica studenata informatike mora imati neku živu „virtualnu“ zajednicu, koju će cijeniti studenti i profesori. Važan čimbenik koji je izostao kod foruma studenata informatike na TVZ-u je društvena potpora. Društvena potpora ima jednaku težinu kao i tehničke mogućnosti bilo plaćene ili besplatne licence za forum. Forum otvorenog koda omogućili bi studentima informatike veću društvenu potporu na način da bi svaki student mogao pridonijeti razvoju i unapređenju foruma uz pomoć profesora. Na takav način razvila bi se komunikacija između studenta i profesora te bi se unutar svakog studenta javila potreba da još više pridonese razvoju zajednice koje funkcionira na dijalogu.

Abstract - In this paper we present a method for real-time detection of human fall from video for support of elderly people living alone in their homes. The detection algorithm has four steps: background estimation, extraction of moving objects, motion feature extraction, and fall detection. The detection is based on features that quantify dynamics of human motion and body orientation. The algorithms are implemented in C++ using the OpenCV library. The method is tested using a single camera and 20 test video recordings showing typical fall scenarios and regular household behaviour. The experimental results show 90% of human fall detection accuracy.

I. INTRODUCTION

Thanks to the increase of the general standard of living and improving health care in developed countries in the past 50 years, life expectancy lengthened by 30 years, and thus increased the percentage of elderly in the general population. According to the census of 2001. year, people over 65 make up 14.35% of the population. Different studies have shown that it is in social and financial interests to enable older people to remain living at their own homes as long as possible.

Fear of a fall is one of the most prominent reasons why elderly people tend not to live alone. There are around 60000 reported falls per year, causing the cost of treatment of 400 million dollars. The risk for serious injuries is increased if the person remains unconscious or immobilized after the fall because of their inability to call for help. Because of this, devices that automatically detect the fall are in the focus of interest. Their goal is to shorten the time between the fall and the arrival of aid, increasing the likelihood of successful treatment, as well as reducing the cost of treatment. There are devices that detect the decrease in the acceleration and its direction, while some use the gyroscope to determine the position of the person's body. But the biggest drawback of such technology is that these devices are awkward and uncomfortable to wear and require frequent battery changes.

Intelligent video surveillance is the simplest way of detecting the fall and timely acquiring aid. Cameras can be installed in each room in the house and, beside the detection of falls, can be used for other purposes, such as ensuring homes of unwanted guests by serving as an alarm system. The goal of this project is to build a computer vision system which uses surveillance cameras and a video analysis method to detect a fall in the room. The project aims to detect the fall of a person in a room using one or more surveillance cameras. The cameras are connected to the computer which performs real-time processing and analysis of acquired video and shows the actual video footage. The fall detection event will be used to alarm the family and/or appropriate emergency services.

II. PROBLEM DESCRIPTION

There are many problems that occur in the automatic detection of falls using video surveillance cameras (selecting an optimum resolution of a video, changing of room lighting conditions cause difficulties in image processing, activities that people do every day with certain movements that resemble the fall). Therefore, it is almost impossible to build a video system with a 100% detection accuracy. Our goal is to build a system that will accurately detect falls in at least 85% of cases.

One of the first problems is the selection of surveillance cameras. Video recordings taken with expensive, high quality cameras (e.g. Axis network video cameras) contain the high level of video compression (e.g. MPEG4) that can generate a non-existent objects in the picture. If the room is illuminated by natural light, change of night and day, weather conditions and artificial lighting will significantly affect the changes in light. These changes should be taken into account while separating moving objects from a static background. In addition to these changes in light, changes in the background may occur due to short-term movements of objects that comprise for example shifting chairs or relocation of a book. Such facilities must be integrated into the background. Therefore it is best to dynamically build a background during certain time intervals. Another problem with the lighting is the occurrence of reflection (the colors are usually lighter than usual) and the shadow of moving objects (the colors are darker than usual). They can cause a problem if they are detected as moving objects. Generally, the biggest problem in the segmentation will be insufficient contrast and diversity between the person and the background, for example, a person in a white dressing gown walking in front of a white wall or a colorful object moving in front of a crowded and textured background.

In these cases, the person will blend with the background and his/her fall will not be detected. Another

significant problem is camera position. Large items that are in the room, such as furniture (wardrobe, bar, sofa, table, etc.) may block the view of some parts of the rooms.

In case a person falls behind something large, the fall will not be detected. Also, in the irregularly shaped or very large rooms, one camera is not enough to cover the desired area and those outside the camera's sight will not be recorded.

In the fall detection we use the method in which the silhouette of a person is described using an ellipse whose parameters are measured and calculated over time. In the event of a fall, the ellipse will change its shape, parameters will take on values characteristic for a fall, and the fall will be detected. However, some activities such as squat, lying, suction, stretching, exercise, etc. can have similar parameter values. In such situations, a totally different activity can be mistaken for a fall.

The algorithm for the fall detection is designed to measure the parameters and detect a fall of the largest object that moves. This is because smaller areas often do not represent people, but errors in the segmentation of the background or temporarily moved objects from the background. In case there is more than one person in the room at the same time, the system will detect a fall of only the largest of them. But this is not a problem because others present can provide assistance without signaling the system.

III. System Architecture

The main goal of the project is fall detection using surveillance video cameras. The camera should be placed in the corner of the room, so it's field of vision could capture the entire room. The fall detection consists of several basic activities: separating moving objects from the background, calculating the parameters for these areas and finally, fall detection itself.

A. Background Subtraction

Moving objects are extracted from the motionless background using an OpenCV algorithm BackgroundSubtractorMOG2 described in [1]. The algorithm uses Gaussian mixture model, as it proved to be very effective in previous work. A background model is created to monitor the difference between foreground and background pixels. Each pixel that does not fit into this model is considered a foreground pixel, part of a moving object. Additional parameters are adjusted to gain a better image for further analysis. The result is a series of binary images in which pixels with zero value represent the background (black areas), and pixels with the value equal to one are moving object (white areas).

B. Elliptical Approximation of an Object

Fall detection is based on the movement coefficient and human shape deformation. An ellipsoid contour is superimposed over the human shape to follow changes more easily. All bodies are outlined in the binary image using the OpenCV findContours function. Then, using the function contourArea, the largest contour is singled out. The largest contour in the figure represents a human. Finally, the function fitEllipse calculates the ellipse that fits best a set of contour points. It returns an ellipse defined by its center (x, y), orientation (angle θ) and lengths of large (a) and small (b) axis. The best approximation of an ellipse is obtained using the least squares method which minimizes the square error of approximation.

C. Movement Coefficient

Motion History Image (MHI) is used to calculate the movement coefficient. It shows recent motion in the image. Motion history is updated as following:

$$\text{mhi}(x, y) = \begin{cases} \text{timestamp}, & \text{foreground}(x, y) \neq 0 \\ 0, & \text{foreground}(x, y) = 0 \text{ and } \text{mhi} < (\text{timestamp} - \text{duration}) \\ \text{mhi}(x, y), & \text{else.} \end{cases}$$

Foreground is the result of a background subtraction. Timestamp represents the current time in milliseconds or other units. Each pixel in the MHI where the movement occurred at the point of time takes the value of timestamp. If there is no action at that point of time the value of MHI remains intact. Duration represents the maximal interval of the motion track in the same units as timestamp. Every value that is lower than the difference between timestamp and duration is set to zero.

The more recent moving pixels are seen brighter in the MHI image. To quantity the motion of the person we have to calculate the movement coefficient, C_{motion}, using the formula:

$$C_{motion} = \frac{\sum_{pixel(x,y)} mhi(x, y)}{\sum_{pixel(x,y)} foreground(x, y)}$$

This coefficient is scaled to a percentage of motion. Value zero means that there is no movement and value equal to one corresponds to full movement.

D. The Algorithm

Fall detection algorithm consists of three steps, as shown in Figure 1. The first step is movement coefficient analysis. Value larger than 0.8 indicates possible fall. Sudden movements or walk perpendicular to the camera can also result with high movement coefficient, so it is necessary to check other parameters to distinguish fall from normal movement.

The second step of the algorithm is human shape analysis. When a person falls, there is a sudden change of orientation and ratio of major and minor axes of the ellipse which approximates that person. In that case the value of standard deviation of the angle σ_θ and standard deviation of the axes ratio $\sigma_{a/b}$ will be high. When person walks around the room, those values will be low. A large amount of movement is considered to be a fall if σ_θ is larger than 15° and $\sigma_{a/b}$ larger than 0.9.

The last step of the algorithm is used to check whether the person remains motionless on the floor for a few seconds after falling. The coefficient of movement has to be less than 0.2 between the twentieth and the thirtieth video frame from the suspected fall time. This corresponds to interval from 0.83 to 1.25 seconds after the

fall and it means that observed object is no longer moving. Standard deviation of the y - coordinate of the center of the ellipse which approximates the object, σ_y, is always calculated for the last ten video frames. Over the next ten images since the fall, the standard deviation σ_y has to be larger than one eighth of the number of pixels per image width. This means that there has been a shift of the object in y - axis.

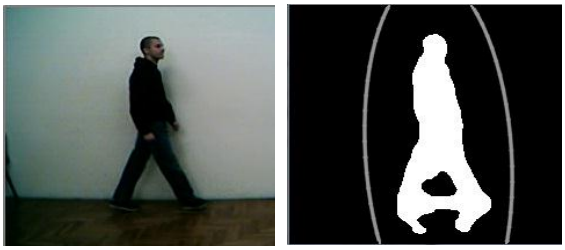
Figure 4. Motion history image

IV. RESULTS

All algorithms implemented in the project were written in C + + using the OpenCV library. It allows the system to work in real time using a webcam. The system supports the monitoring of only one camera.

Twenty different shots were used for testing the fall detection algorithm. The most images show everyday situations when people stay in room. Since the algorithm works by calculating the movement coefficient and ellipse approximation of the object, the key test specimens are those in which a person is doing sudden movements, jumping, sitting or lying down. The algorithm has successfully detected a fall in eighteen test samples which shows an efficiency of 90%. Two sections that are used to detect the fall (movement coefficient and ellipse parameters) successfully collaborate and complement their individual shortcomings. One of the examples that illustrate this is the situation where a person is lying down.

The change in the ellipse condition is met but the amount of movement is insufficient, which avoids the false fall detection. Out of twenty different video sequences, the algorithm did not show a satisfactory result for two. The first video sequence shows the situation of a person who is completely still and after some time immediately falls. In the second shot, the person falls while entering the frame. Algorithm does not work properly in these situations because it fails to calculate the corresponding movement coefficient. This is the result of an insufficient number of frames in which a person is not blended in the background.

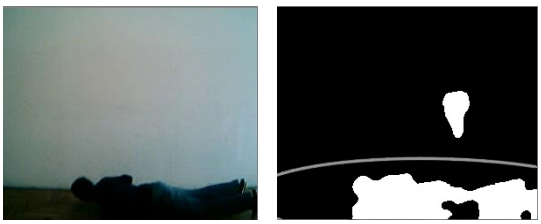


C_{motion} = 0.71, σ_{θ} = 2.49, $\sigma_{a/b}$ = 0.38

Figure 5. Walking – values of parameters are low

C_{motion} = 0.29, σ_{θ} = 4.43, $\sigma_{a/b}$ = 0.23

Figure 6. Sitting – angle deviation is high but rest parameters are low



C_{motion} = 0.9, σ_{θ} = 51.97, $\sigma_{a/b}$ = 0.91

Figure 7. Fall – all values are high

V. CONCLUSION

In this paper, we present a method for automatic fall detection using a system of camera for video surveillance. The developed method allows real time fall detection using the original algorithm. The algorithm has several stages that are performed sequentially. An output signal, which informs whether a person has fallen or not, is obtained by analysing the parameters. Applications other than the basic, can be, with some upgrades, multiple. One of the uses could be that the system is connected to a local health center in order to give the staff an insight into the situation and, if necessary, send assistance to people who have fallen. In order for the system to be used for commercial purposes, it is necessary to see how it behaves with a wider range of conditions and circumstances that can occur in households which would use it. This way the percentage of successful operation of the system remains high.

Although this algorithm gives satisfactory results and works relatively good in real time, there is still room for improvement. Given that all the test specimens are recorded under controlled conditions, which primarily refers to the constant illumination of the room and significant difference in the colors of the person's clothing and the background. The upgrade should primarily be performed on the background subtracting algorithm to make the whole algorithm become more robust.

Because of the complexity of the used functions, more time is required for calculating data, making the system run a little slower in real time. The first step in solving this problem is to find the section of code that is running the longest. If possible, this piece of code should be optimized and its execution time reduced.

Another way of solving this problem is to divide the algorithm into logical units that perform a specific job. Each unit gets its own thread, which deals with a specific task. All threads operate in parallel. Such a way of using thread parallelism is called a pipeline. Ideally, if all threads perform tasks that are approximately the same duration, the parallelism will be maximized.

Additionally, the system can be expanded in a way that it can monitor multiple cameras. Then cameras could be placed in every room of the house, and the system could be used for commercial purposes.

LightDesk - sustav za računalnu interakciju visoke rezolucije baziran na infracrvenom raspoznavanju oblika

Alan Divjak i Marko Maričević
Grafički fakultet Sveučilišta u Zagrebu, Zagreb, Hrvatska
alan.divjak@grf.hr, marko.maricevic@grf.hr

Sažetak - LightDesk je sustav za prikaz slike visoke rezolucije sa mogućnošću digitalnog crtanja, slikanja i generalne računalne interakcije, jednostavnog dizajna i niske cijene. Temelji se na višestrukoj pozadinskoj digitalnoj projekciji i raspoznavanju oblika, te se u radu ponaša poput LCD grafičkog tableta. Interakcija se vrši pomoću mehaničke olovke napravljene pomoću 3D tiska sa integriranim infracrvenim osvjetljenjem, a raspoznavanje nagiba i pritiska olovke ostvaruje se preko raspoznavanja slike koju snima pet infracrvenih kamera ugrađenih u sustav. Uz radni prostor rezolucije 3840*1600 piksela i dijagonale 135 cm (53 inča), te prepoznavanje 512 razina pritiska i promjenu nagiba od 0.5 stupnjeva, sustav omogućava iznimno visoku razinu produktivnosti u primjenama poput 3D grafike, animacije i vizualizacije, CAD-a, CAE-a, te obrade slika i videa. Korištenjem inovativnih rješenja za prepoznavanje interakcije olovke sa radnom površinom u kombinaciji sa ergonomskim dizajnom, stvoren je sustav koji je iznimno ugodan za korištenje, te pruža veliku slobodu i lakoću korištenja modernih računalnih aplikacija koje zahtijevaju preciznost pri izradi sadržaja. Ovaj rad prvenstveno demonstrira kako je moguće pomoću komercijalno dobavljivih komponenti i 3D tiska stvoriti sustav koji performansama i cijenom predstavlja iznimno primamljivu opciju za prikaz slike i interakciju sa računalnom.

I. Uvod

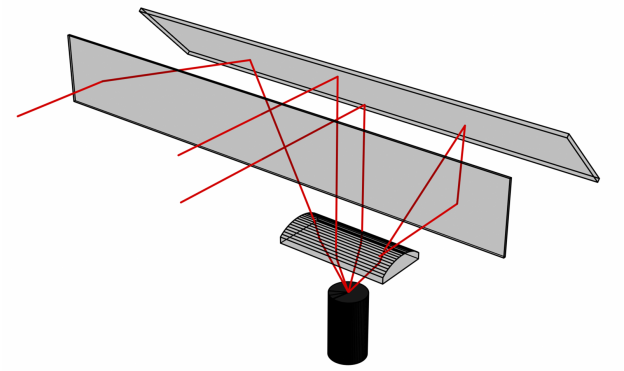
Stvaranje digitalnog sadržaja (Digital Content Creation- DCC) danas je postalo svakodnevica za veliki broj korisnika računala. Poslovi poput digitalne obrade fotografija i videa, računalnom potpomognutog dizajna i inženjeringa, 3D računalne grafike, vizualizacije, animacije i digitalnog crtanja danas su postali iznimno uobičajeni i rašireni, bilo da se radi o profesionalnom ili osobnom korištenju. Zajednička karakteristika tih i sličnih poslova je da su vrlo specijalizirani i kompleksni, te stavljaju velike zahtjeve na osobu koja ih obavlja, posebice u smislu količine znanja ili vremena koje zahtjevaju. Nadalje, računalne aplikacije pomoću kojih se ti poslovi obavljaju predstavljaju neke od najkompleksnijih softverskih proizvoda ikad napravljenih. Također, karakteristično je da je sama priroda posla takva da zahtjeva vrlo prirodnu i fluidnu interakciju sa aplikacijama, u mnogo većoj mjeri nego što je slučaj, primjerice, sa DTP-om, programiranjem, web dizajnom, itd... Glavni razlog ovome je što je neposredna interakcija i generiranje sadržaja u samoj srži stvaranja digitalnog sadržaja. Crtanje se izvodi direktnim radom na digitalnom platnu, modeliranje unutar virtualnog 3D prostora, retuširanje na digitalnim fotografijama... Iz svega rečenog, očito je da DCC predstavlja jedno specijalizirano područje korištenja računala po pitanju interakcije te koje bi imalo koristi od specijaliziranog hardvera za interakciju. Ovu izjavu potvrđuje činjenica da već duže vrijeme postoje uređaji koji olakšavaju rad u DCC-u, ubrzavaju proces stvaranja sadržaja, te podižu ergonomske standarde iznad onih koji nude tipkovnica i miš. Vjerojatno najpoznatiji takav uređaj predstavlja grafički tablet koji omogućuje interakciju sa računalom pomoću olovke i podloge po kojoj se crta. Grafički tableti pružaju iznimno prisan osjećaj interakcije sa sadržajem iz razloga što je držanje i upotreba olovke sama po sebi prirodna, jednostavna i ergonomski prihvatljiva radnja. Korak dalje predstavljaju LCD gafički tableti gdje je u podlogu integriran LCD ekran, tako da koristnik zaista ima osjećaj kao da radi na najprirodniji mogući način; crtanje na interaktivnom listu papira. Uređaji poput grafičkih tableta poznati su svakom tko se bavi poslom vezanim uz DCC, ali malo tko posjeduje takav uređaj, pogotovo neki koji spada u višu ili profesionalnu klasu. Naravno, razlog je u cijeni. Što zbog tržišne dominacije određenih proizvođača, a što zbog generalno nerealno visokih cijena sve opreme koja ima oznaku "profesionalno", cijena uređaja više kategorije takva je da je izvan dometa prosječnih korisnika. Kada se govori o LCD grafičkim tabletima, jasno je da je riječ o (barem trenutno) ultimativnom načinu interakcije sa sadržajem- jednostavno ne postoji direktniji i precizniji način rada. Nažalost, takav profesionalni hardver predstavlja popriličnu investiciju, s obzirom da je riječ o vrhunskom proizvodu koji predstavlja vrh ponude grafičkih tableta. Ilustrativno, cijena 24-inčnog LCD tableta Cintiq 24HD, renomiranog proizvođaća Wacom-a, sa WUXGA rezolucijom iznosi nešto preko 20,000 kuna u vrijeme pisanja ovog rada.

Ovaj rad bavi se daljnjom razradom same ideje LCD grafičkog tableta, te prikazuje evoluciju koncepta uz primjenu inovativnih tehnologija i tehničkih rješenja. Ostvarena je simulacija rada grafičke olovke, te je prikazan algoritam za prepoznavanje interakcije grafičke olovke i podloge, te je izvršena simulacija kako bi se pokazalo koliko kvalitetno algoritam zaista radi. Krajnji

cilj je stvoriti sustav koji omjerom perfomansi i cijene prestavlja iznimno primamljivu alternativu današnjim LCD tabletima.

II. TEHNIČKE KARAKTERISTIKE

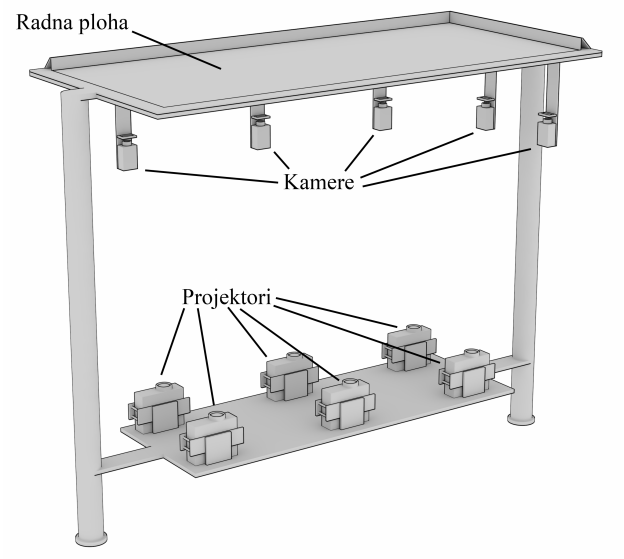
Da bi se smatrao relevantnim i uspješnim, LightDesk sustav mora zadovoljiti određene zahtjeve: visoka rezolucija, velika radna ploha, iznimna kvaliteta slike, precizna detekcija pozicije olovke, raspoznavanje 512 razina pritiska, te raspoznavanje nagiba od minimalno 0.476°. Sustav se sastoji od projekcijske plohe koja je sastavljena od polikarbonatne ploče, na čiju je donju stranu nanesen film za stražnju projekciju Vikuiti, tvrtke 3M. Dimenzije radne plohe iznose 120*50 cm, uz omjer stranica 2.4:1. Projekcijska ploha uglavljena je sa gornje strane u kruti polikarbonatni okvir debljine. Sa gornje i lijeve strane okvira nalaze se kućišta koja sadrže inracrvene kamere i pripadajuću optiku. Ispred svake kamere nalazi se kombinacija pravokutne cilindrične plankoveksne leće, zrcala i cilindrične plankonveksne Fresnelove leće nanesene na staklenu podlogu. Ovaj optički sustav, prikazan na slici 1., ponaša se kao telecentrični objektiv [1], odnosno, pruža ortogonalnu projekciju scene koju kamera snima. Ispod okvira nalazi se kučište koje sadrži projektore.



Slika 1. Optički sustav kamere

A. Visoka rezolucija

Projekcija visoke rezolucije nudi iznimno puno radnog prostora. Rad u modernim aplikacijama sa mnogo izbornika ili slikama velike rezolucije idealni su primjeri zašto je prikaz visoke rezolucije ključan u podizanju produktivnosti. Osim sposobnosti prikaza visoke rezolucije, kvaliteta slike je također vrlo važan čimbenik doživljaja. Prikaz slike postiže se pomoću šest LED projektora "pico" formata. Projektori korišteni u sustavu imaju rezoluciju 1,280*800 piksela, omjer slike 16:10, svjetlosni tok 300 lumena i deklariranu trajnost od 50.000 sati. Korištenjem šest takvih projektora ostvarena je ukupna rezolucija od 3,840*1,600 piksela ili 6.14 milijuna piksela, uz ukupni svjetlosni tok od 1800 lumena. Kako bi računalo uopće moglo dati izlazni signal na šest projektora, koristi se AMD Radeon 6950 grafička kartica sa Eyefinity tehnologijom koja ima upravo šest video izlaza. Ova rezolucija u usporedbi sa Cintiq 24HD tabletom pruža 2.66 puta veći broj piksela, te 3.57 puta veću radnu površinu). Projektori su smješteni u kučištu ispod projekcijske površine. Pozicionirani su tako da je projekcija svakog od njih okomita na projekcijsku površinu. Razlog ovome su ograničene mogućnosti keystone sustava projektora "pico" formata. Smještaj projektora i ostalih kompnenata prikazan je na slici 2. koja predstavlja grubu ilustraciju cijelog sustava.

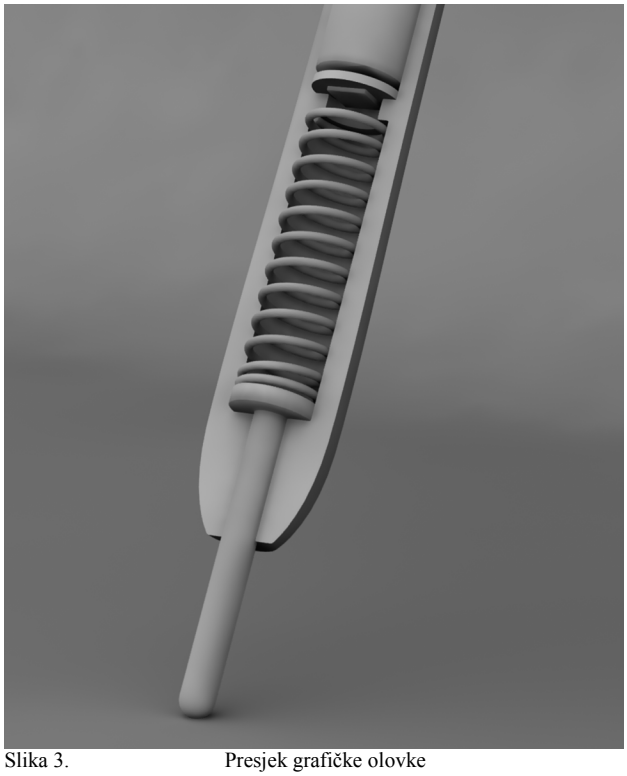


Slika 2. Ilustracija cijelog sustava

U idealnom slučaju, projektori bi se smjestili u jedan red pomaknut prema stražnjoj strani sustava i potom rotiranjem i popravljanjem kuta projekcije pomoću keystone sustava poravnali na projekcijskoj površini. Nažalost, pošto je potrebno iznimno precizno poravnavanje na razini piksela, trenutno jedino rješenje je postavljanje projektora na prikazane pozicije.

B. Grafička olovka

Grafička olovka je osnovni alat za interakciju sa LightDesk-om. Olovka je ergonomski oblikovana, dimenzija 160*16 mm. Vrh olovke ulazi u tijelo pod opterećenjem, a razina pritiska dobiva se računalnom analizom slike i raspoznavanjem oblika [2][3] iz toga koliko je vrh olovke ušao u tijelo. Opterećenje, razina pritiska i ulazak vrhe olovke su međusobno linearno zavisni, pošto otpor pruža linearna opruga. Različite razine otpora mogu se jednostavno postići promjenom opruge. Pošto se prepoznavanje pritiska bazira na vizualnom raspoznavanju, vrh olovke napravljen je od poluprozirne plastike. U tijelu olovke nalazi se infracrvena LED dioda koja svijeti kroz vrh olovke. Kamere koje detektiraju kretanje, pritisak i nagib olovke imaju uklonjeni infracrveni filter i dodan filter neutralne gustoće [4]. Ovime se postiže da kamere vide samo vrh olovke kao vrlo svijetli objekt, dok je pozadina crna, bez obzira u kojim svjetlosnim uvjetima se LightDesk nalazi. Za ovo postoje dva razloga. Prvi je da se na ovaj način iznimno olakšava raspoznavanje oblika, te se može primjeniti jednostavniji, brži i efikasniji algoritmi za analizu slike, a drugi je da uređaj radi u spektru koji korisniku ne odvlači pažnju. Presjek radnog dijela grafičke olovke prikazan je na slici 3.



Slika 3. Presjek grafičke olovke

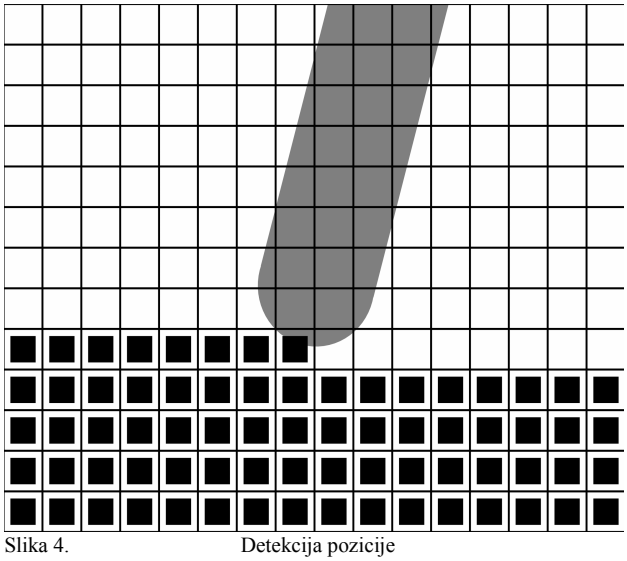
C. *Visoka preciznost*

Po dubini sustava, radnu plohu pokrivaju dvije kamere, te je ukupna rezolucija detekcije 3,840 piksela, uz preciznost detekcije pomaka vrha olovke od 0.13 mm. Po širini sustava, radnu plohu pokrivaju tri kamere, te je ukupna rezolucija 5,760 piksela, uz preciznost detekcije od 0.208 mm. Vertikalnu detekciju pokriva 1,080 piksela, uz preciznost od 0.0231 mm. S obzirom na smještaj kamera, može se reći da je površina LightDesk-a podjeljena u šest sektora, od kojih svaki pokrivaju dvije kamere.

II. Teorija

A. *Detekcija pozicije*

Način rada detekcije prikazan je na slici 4.

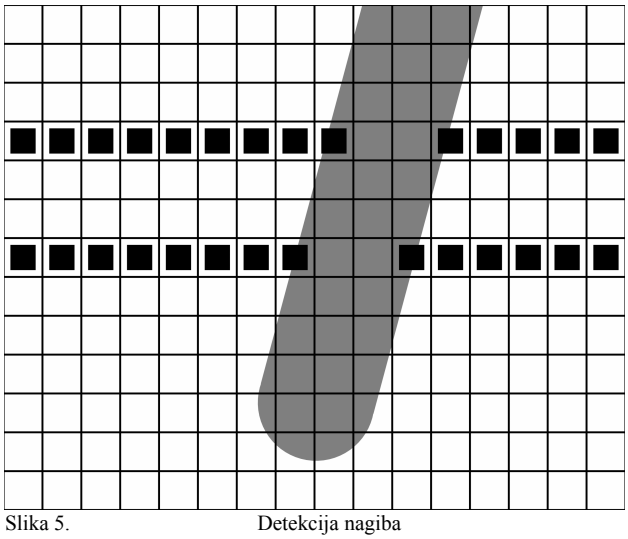


Slika 4. Detekcija pozicije

Algoritam za detekciju pozicije je jednostavan. Za svaki sektor kreće se sa analizom od donjeg prema gornjem redu, s lijeva na desno, dok se ne naiđe na bijeli piksel. Kako bi se potvrdilo da detektirani piksel zaista pripada vrhu olovke, a ne šumu ili nasumičnoj detekciji, analizira se deset piksela vertikalno. Ukoliko je 80% piksela bijelo, smatra se da detektirani piksel pripada vrhu olovke. Pošto kamere snimaju sektor preko telecentričnog sustava, X i Y pozicija vrha olovke dobiju se lako iz pozicije stupca u kojem se nalazi detektirani piksel.

B. *Prepoznavanje nagiba*

Nagib olovke predstavlja značajnu komponentu upotrebljivosti tableta, Jednako kao što se i klasičnom olovkom postižu različiti efekti sjenčanja kada se crta pod nagibom, tako se i sa grafičkom olovkom tableta postiže niz efekata. Algoritam prepoznavanje nagiba nadograđuje se na detekciju pozicije vrha olovke, te je prikazan na slici 5. Ukoliko se vrh nalazi više od 10 mm od radne površine sustava, algoritam se ne izvršava. Prepoznavanje počinje detekcijom piksela u redovima koji se nalaze 4 i 12 mm iznad piksela koji je definiran kao vrh olovke, s lijeva na desno. Kada se naiđe na bijeli piksel, vrši se provjera sljedećih 10 horizontalnih piksela kako bi se potvrdilo da bijeli piksel pripada vrhu olovke. Ukoliko je 80% piksela bijelo, detektirani piksel se prihvaća kao rub vrha olovke. Zatim se postupak ponovi za iste redove, ali se desna na lijevo. Ovime se dobivaju četiri točke koje definiraju rubove vrha olovke u dva reda. Zatim se nalazi srednja točka između dvije rubne točke jednog reda. Sada se može konstruirati pravac koji prolazi kroz dvije središnje točke, a koji prolazi kroz os vrha olovke. Pošto se dobiju dva pravca iz slike dvije kamere, stereometrijskim izračunom dolazi se do nagiba olovke naspram radne površine sustava. Preciznost prepoznavanja nagiba varira od 0.298º do 0.476º, ovisno o nagibu olovke. Usporedba sa Cintiq 24HD tabletom nije moguća jer podatak o preciznosti detekcija nagiba ne postoji.

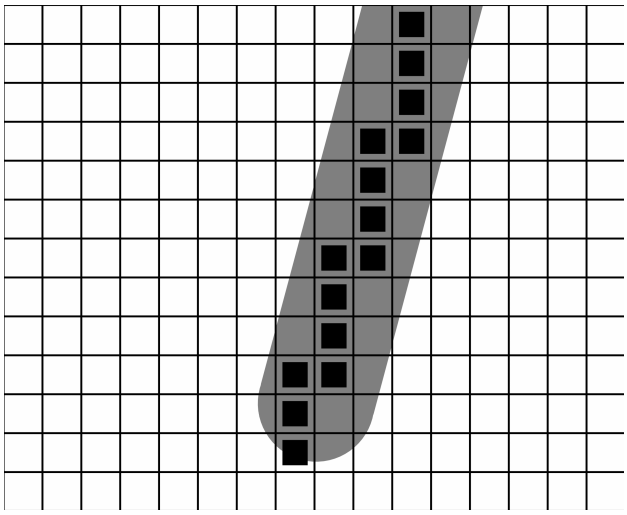


Slika 5. Detekcija nagiba

C. *Raspoznavanje pritiska*

Razina pritiska igra vrlo značajnu ulogu u poslovima poput digitalnog crtanja i modeliranja ili retuširanja i obrade fotografija. Uobičajen broj razina pritiska koje

tablet raspoznaje iznosi 512 ili 1024 razina. Iznimnka je Cintiq 24HD koji prepoznaje 2048 razina pritiska. LightDesk prepoznaje 512 razina pritiska, što predstavlja dobar kompromis za sustav koji nije primarno dizajniran za potpuno umjetničku ili grafičku primjenu, već kao sustav za generalnu interakciju sa DCC aplikacijama. Raspoznavanje razine pritiska postiže se pomoću iskorištavanja konstruiranog pravca kroz os vrha olovke, dakle temelji se na prepoznavanju nagiba. Algoritam jednostavno detektira broj bijelih piksela duž pravca, kao što je prikazano na slici 6. Iz broja piksela poznata je dužina vrha olovke. Kontrakcija dužine proporcionalna je pritisku, te se tako dobiva razina pritiska. Maksimalna rezolucija raspoznavanja pritiska iznosi 765 razina, ali je interno ograničena na 512 razina.



Slika 6. Detekcija pritiska

D. Optimizacija

Sustav koristi pet kamera rezolucije 1920*1080 piksela uz brzinu snimanja od 60 slika u sekundi. S obzirom da se analiza slike mora odvijati u stvarnom vremenu [5] kako bi se očuvao doživljaj interaktivnosti, a kamere generiraju preko 622 milijuna piksela u sekundi, potrebno je uvesti određene optimizacije. Osnovna je praćenje samo jednog sektora gdje se vrh olovke trenutno nalazi i konstruiranje pomičnog okvira oko težišta vrha olovke, Ukoliko se uzme u obzir maksimalna brzina pomicanja ruke za vrijeme korištenja sustava, određena eksprimentalnim putem, a koja iznosi 3.2 m/s, moguće je odrediti minimalnu širinu okvira iz kojeg vrh olovke neće izaći za vrijeme od 1/60 sekunde. Na taj način se osigurava da je praćenje vrha olovke uvijek moguće. Sliku je potrebno analizirati za poziciju, nagib i pritisak.

E. Cijena sustava

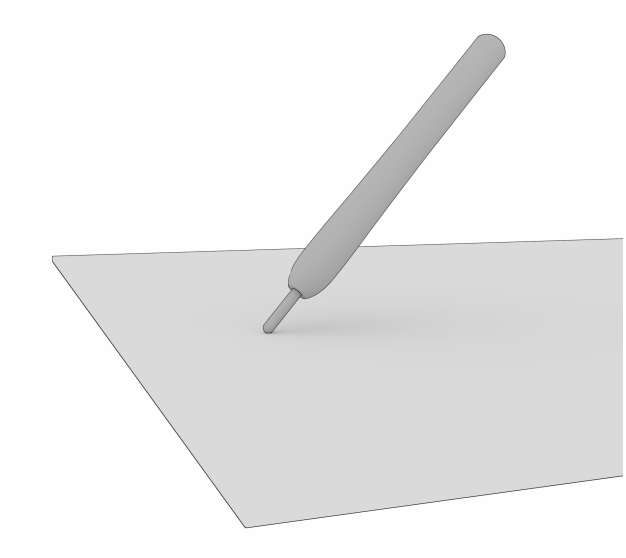
U tablici 1. nalazi se procjena ukupne cijene LightDesk sustava.

TABLICA 1. CIJENA KOMPONENATA I SUSTAVA

Komponenta	**Cijena**
Polikrarbonatna ploča	920 kn
Polikarbonatni okvir	650 kn
Aluminijski okvir	1,100 kn
Pet kamera	3,170 kn
Pet setova optike	1,750 kn
3D tisak grafičke olovke	650 kn
Šest projektora	11,200 kn
Ukupni manji dodatni troškovi	1,210 kn
Ukupno	**20,650 kn**

III. SIMULACIJA

Napravljena je simulacija kojom se promatra brzina i kvaliteta prepoznavanja vrha olovke. Generirano je pet 10-minutnih video zapisa koji formatom i izgledom simuliraju ortogonalni pogled koji imaju kamere sustava. Video zapisi predstavljaju snimku korištenja LightDeska, te su generirani unutar aplikacije Lightwave 10.1 3D, renomiranog alata za izradu 3D grafike tvrtke NewTek. Unutar Lightwave-a modelirana je precizna kopija radne plohe LightDesk-a i pripadajuće grafičke olovke. Zatim je definirano pet virtualnih kamera koje karakteristikama odgovaraju stvarnim kamerama. Izgled postave 3D scene vidljiv je na slici 7.



Slika 7. Grafička olovka na radnoj plohi

Tada je na temelju promatranja korisnika koji korištenjem Wacom Cintiq 24HD tableta obavlja uobičajene zadatke crtanja, modeliranja i retuširanja rekreirano kretanje olovke po 3D modelu LightDeska, te je pomoću pet virtualnih kamera renderirano pet video zapisa ponašanja vrha olovke. Kako bi se osiguralno da izgled infracrvenog vrha olovke izgleda jednako kao i u stvarnosti, napravljena je simulacija izgleda olovke u Maxwellu. Materijal vrha, te snaga i karakteristika IC LED diode modelirani su fizikalno točno. Izgled dobiven simulacijom prebačen je i mapiran na virtualnu olovku u Ligthwave-u. Dobiveni video zapisi analizirani su pomoću predloženih algoritama za detekciju, a koji su ostvareni kao program u Python programskom jeziku.

IV. Rezultati

U drugoj simulaciji generirano je ukupno 50 minuta video zapisa, 180,000 frameova i $373*10^9$ piksela. U sekundi se generira $622*10^6$ piksela, a optimizacijama je postignuto da je prosječan broj analiziranih piksela u sekundi samo 3.3 milijuna. Rezultati pokazuju kako optimizacije smanjuju broj obrađenih piksela za 99.47%, te da niti u jednom frameu nije počinjena greška pri prepoznavanju vrha olovke. Također, na testnom sustavu iz 2008. godine koji se sastoji od dva četverojezgrena Intel Xeon E5462 procesora sa 10 GB RAM-a, maksimalna brzina obrade iznosi 224.11 milijuna piksela u sekundi, što znači da se algoritam bez problema izvršava u stvarnom vremenu, te zauzima samo 1.47% računalnih resursa.

V. Zaključak

Rezultati simulacije pokazuju kako je implementacijom jednostavnih i inovativnih algoritama stvorena osnova za stvaranje sustava za računalnu interakciju koji performansama može uspješno parirati komercijalno dobavljivim rješenjima. Kombiniranje infracrvenih karakteristika grafičke olovke i telecentrične optike ostvaruje iznimo robusno i procesorski nezahjevno rješenje za raspoznavanje pozicije, nagiba i pritiska grafičke olovke, te predstavlja temeljnu tehnologiju za daljni razvoj sustava. Iako ovaj rad predstavlja samo jedan u nizu koraka potrebnih kako bi se izradio potpuni prototip sustava, postavlja jake temelje na kojima se mogu razvijati nove, inovativne tehnologije i pristupi računalnoj interakciji.

Detection of Commercials in Video Content Based on Logo Presence Without Its Prior Knowledge

Nikola Banić
University of Zagreb, Faculty of Electrical Engineering and Computing
Unska 3, 10000 Zagreb, Republic of Croatia
E-mail: nbanic@gmail.com

Abstract – Among many methods for commercial detection in TV video content the most precise and most used one in software today is the method of recognizing logo presence, and freeware as well as shareware shoftware using it usually needs some data about the channel logo. In this paper a commercial detection method is described which is also based on logo recognition, but without need of any prior knowledge of logo data like shape, position or colors. Applying the method on several test videos showed a 100% recognition of commercial presence and about 80% of correct determination of the begin and the end of commercials whereby videos with noise were also used.

I. INTRODUCTION

Video content of television channels is for a long time available over television sets and as such it is quite long a part of everyday life. As there are with time more and more new television channels, there is also a greater ofer of content, but as most of these new channels are private ones, they are mostly financed by broadcasting commercials and so their regular program is often interrupted. These commercials may become a bigger problem if a particular content, a movie for example, is being saved to a data storage device for later usage, because they're not a part of the original content and so the need to remove them occurs. It is good to notice that exactly because of the fact they are not a part of original content, they have different properties which are observable to humans.

The question is what these properties are and to what level of complexity can their detection be automatized. A more interesting question is which of these properties has the greatest discriminating power of regular program, and what combinations are preferable.

There are more commercial detection methods and it's worth to mention these: monochrome frames detection, hard cut detection, action detection, logo presence recognition.

By using the first three of them, [1] achieved an over 93% successful commercial recognition, however the problem with these methods is that they cannot be applied to all channels nor to all boundaries between commercials and regular program due to the each channel's technical characteristics and many special cases of the mentioned boundaries, and some of the methods are only proposed [3].

As far as it concerns recognizing known commercials, there is the problem of updating the commecrial database due to the continuous emergence of new commercials which is the main disadvantage of these method, although the method itself is easy to carry out and is effective.

There are also methods based on recognizing commercial block introduction jingles, recognizing black strips above and under movie frames, recognizing older movies mono sound, recognizing loudness level differences, tracking content encoding differences and recognizing static text [6][7][8].

The method implemented in more freeware and shareware programs like NoAd, NoAd2, CommScan and mythcommflag is the method of logo recognizion which achieves high accuracy. As these programs mostly need prior data on the channel's logo and therefore the data on the channel itself, it is naturally to raise the question about possible application of this method without knowledge of mentioned data, that is, if all logos have some common features discriminative enough to make them recognizable in most cases.

After looking at different commercial detection methods it is possible to conclude several key facts:

- there are more commercial detection methods of varying quality,
- implemented solutions are mostly based on one or two of these methods,
- the most used method is logo recognition,
- the logo recognition method only assumes absence of logo during commercial block,
- the main problem is precise determination of begin and end of a commercial block.

In this paper one such method with two main characteristics to recognize commercials via logo absence and not to need any prior data on logo is described. The method was implemented using free tools and after being tested it recognized all commercials and determined their boundaries with over 80% accuracy.

II. DATA EXTRACTION

Before describing the method itself, it would be good to describe the extraction of needed data and to describe its processing afterwards. As the method is directed at the logo, there is need for only some data from video content.

The data needed to be extracted from frames and to be processed further refers to edges and color distribution of single frames whereby edges are needed to search for the logo, and the color distribution is used to detect hard cuts [9]. In order to extract the described data, two auxillary methods are used of which the first one detects edges by indicating their sharpness, while the second one determines distribution of groups of several colors together.

A. Edge detection

In order to process edges, they are first found using an edge detection method. Due to its simplicity and usage in [6] the Sobel operator was chosen whose result is a grayscale image of the same dimensions as the input frame and whose pixels are the more brighter the sharper edge they are a part of [5]. This calculation is performed by knowing the 8-fold adjacency of each pixel as it is shown on Figure 1.

Now we define two matrices which we then use as Sobel operator:

$$X = \begin{bmatrix} -1 & -2 & -1 \\ 0 & 0 & 0 \\ 1 & 2 & 1 \end{bmatrix} \quad (1)$$

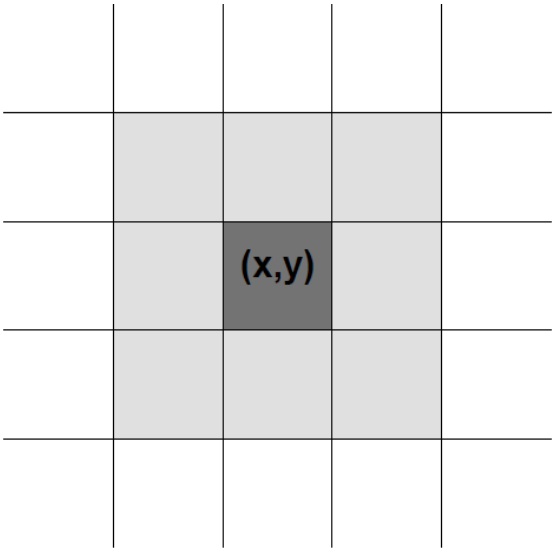

Figure 1. 8-fold adjacency of the pixel (x, y).

$$Y = \begin{bmatrix} -1 & 0 & 1 \\ -2 & 0 & 2 \\ -1 & 0 & 1 \end{bmatrix} \quad (2)$$

If we use I to denote the initial frame image and S the result image, we can calculate the value of each pixels of S at position (x, y) using the following formula:

$$S_{x,y} = \sum_{i=0}^{2}\sum_{j=0}^{2} I_{x+i,y+j} \cdot \left(X_{3-i,3-j} + Y_{3-i,3-j}\right) \quad (3)$$

After applying (3) on frame images we get images with clear edges as can be seen on Figure 2.

B. Determining color groups distribution

When determining color groups distribution, for each pixel first we only take two most significant bits of each of three RGB value components, that is, six bits per pixel which leads to 64 possible combinations so that every of 2^{24} RGB combinations maps to one of 64 and so we get color groups whose appearances are now counted. The procedure is accurate enough even if we skip some pixels and iterate for example through x and y axis with a step of 2 which speeds up the implementation, and gives almost the same results as iterating over all pixels. This is easy to explain because there are often many similar points grouped together and skipping over some of them makes no big difference and this skipping is the only variation to the procedure described in [1].

III. COMMERCIAL DETECTION METHOD

The whole method is composed from more logically separated phases which are connected in the way that the result of each phase depends on the result of the previous

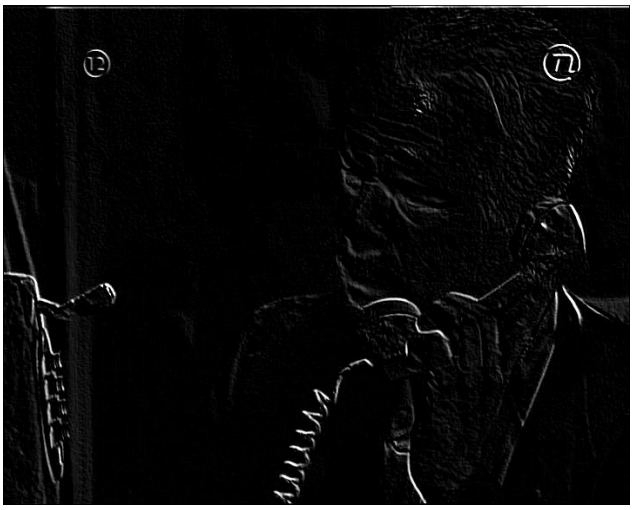

Figure 2. Edges detected using the Sobel operator.

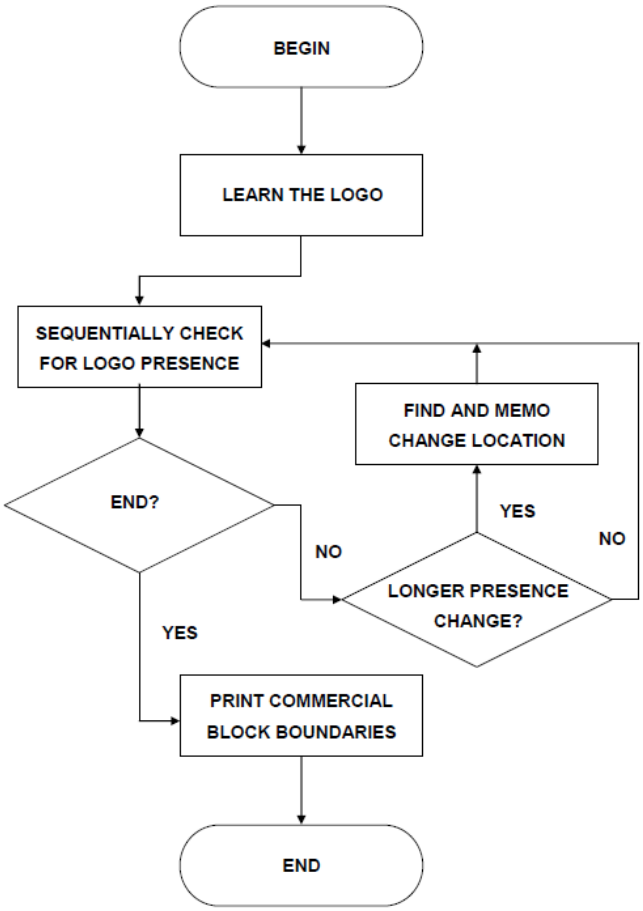

Figure 3. Flow chart of main phases of the whole method.

phase. A simple sketch of the whole method is shown on the flow diagram on Figure 3.

A. *Learning the logo*

Learning the logo comprises of learning the positions of sharper logo edges points. The basic assumption is that the video content does not begin with a commercial block, but with regular program, that is, it is assumed that the logo is present for a certain beginning time and in the test implementation this time amounted to 10 first seconds. The initial assumption is also that all pixels in upper left and right image corner represent potential logo pixels and each of them is assigned a tolerance value whose meaning is about to be described. By upper left and right corner we understand the rectangular areas with height of 15% of that of the image, and width of 20% of that of the image. It is also good to exclude several top and bottom lines due to the possible presence of multiple kinds of noise there. During the next few seconds of video content (in test implementation 10 seconds were used which amounted to 250 frames under assumption of 25 frames per seconds) each pixel of the Sobel processed image is checked for detecting sharp edges. If the value calculated for a pixel is under a prior defined threshold, the tolerance value for that pixel is decreased and if it in one point reaches 0, the point is excluded from the list of potential logo edge points.

The next step is getting rid of the pixels in whose adjacency no more than an in advance set number of points is to be found. Even though a square region of every candidate pixel is needed to be checked, this problem can be efficiently solved by placing the pixel positions into a double Fenwick tree that makes the complexity of later queries to be $O((\log n)^2)$ [4]. At the end it is possible that both the left and the right corner contain static sharp edge pixels. After aforementioned time there are only points in the list left that represent static sharp edges in the corner regions, but not all of them necessary represent logo edges. Assuming well that the logo makes the larger part of the static points, the pixels in the left and right upper corner are counted and the pixels of the side with less pixels are simply thrown away from further procedure and as a result we get images like the one shown on Figure 4 which shows the result of applying the described procedure on Figure 3.

Now the main part of learning the logo edges is complete. The main problem of this phase is that the edges largely depend on the video beginning because the logo differs more or less from the background depending on what content is shown at a time so the greater the difference, the better the learned edges. There is also the possibility for logo to change its position in later parts of video content and such a situation could be treated as logo absence and therefore it is necessary to perform new edges learning.

B. *Subsequent logo learning*

Due to the problems described at the end of the previous chapter, all the time a subsequent logo learning is performed, which however is not shown on the flow chart, because in a lot of cases it is not necessary, but in the whole procedure it is important in some places. Subsequent learning is performed so that on every consecutive 250 frames the aforementioned algorithm of logo learning is applied. The results of subsequent learning are taken iff the following conditions are met:

- from the currently used logo positions it is concluded that the logo is not present,
- last three results of subsequent learning found a new logo,
- the number of pixels in new learning result is not

Figure 4. Edges related to the logo.

less than one third of currently used pixels,

- the center of all new pixels is not to much away from the center of the currently used pixels.

The reason for the first condition is the fact that the need for new logo pixels occurs only if old ones no more point to the correct logo edges and direct consequence is apparent logo absence even if this is not the case. The second conditions demands that the existance of the logo on another position is a real, and that there is currently no commercial during which there is no logo shown, or no such short period occured during which the logo is purposely hidden. The third condition assures the new learned pixels do not form something else smaller than the logo or even no logo at all, and the fourth condition takes into consideration the fact that new logo pixels do not differ to much in their positions from the current ones which was experimentaly shown to be correct.

It is also possible to adopt new logo knowledge when it simply gives sharper edges then the current one thereby improving overall commercial recognition.

C. *Checking the logo presence*

The first step of checking the logo presence on a frame is to calculate value of Sobel operator in all previously determined logo edge pixels. After that the mean value of all pixels is calculated and it is compared to a threshold value, and if it is greater than the value, it is to conclude that the logo is present on the current frame.

D. *Significance of the logo absence*

Even though the logo absence is the main indicator for commercial detection, not every logo absence should be characterized as a commercial presence. It is possible that the current part of the video content is of lower quality so it contains noise, it is also possible that the background is very similar to the logo so the boundaries are not sharp enough after applying the Sobel operator, and it is also possible that the logo was purposely removed for a few seconds by the channel itself for showing some informations or for some other puspose. Such absences are not significant, that is, they do not represent a commercial and they need to be ignored.

The method gives significance to the logo absence only if the absence lasts for a defined amount of time (10 seconds in test implementation) because in most cases it can then be concluded that we are really dealing with a longer logo absence which most probably means the beginning of the commercial block and only in that case the presence status change can be called significant.

The same procedure goes for logo presence as well because not all of its presence has to be a longer one so it has to be treated in the same way as is absence.

E. *Determination of commercial block boundaries*

The first main condition for existence of commercial block boundaries (beginning or end) is a significant change in logo presence. After this change has been detected, the next step is to determine the exact frame when the commecrial block started, that is, where the switch of presence to absence in the case of beginning of commercial block and of absence to presence in the case of end of commecrial block accured.

This part is relatively simple because after a significant change in logo presence is detected, it is only necessary to get back to the place where it was first noticed before being taken as a significant.

However, during the next steps several problems can arise and they need to be examined by cases.

First case shown on Figure 5 illustrates an ideal change of presence where there is no doubt about exact point of the boundary and the fact that we have a boundary.

Second case shown on Figure 6 is a more bit complicated and it shows one presence type bordered by two equivalent presence types. In such a case there is no sense of taking about a commercial block boundary; it is more probable that some of aforementioned events caused this case. Third case shown on Figure 7 is very similar to the second one and is therefore not explained.

Fourth case shown on Figure 8 is very similar to the first one with the difference of several insignificant presence types between two different significant presence types. Here we can also speak of a commercial block boundary.

Except for the condition which is met when a significant logo presence change occured, we have to introduce a second condition as well, which is met when the first next significant logo presence is different from the previous significant one. The next question is whether the boundary is on the end of the first of the significant presences or at the beginning of the second one. After a greater number of experimental tests it is easily to conclude that in most cases the boundary is to be placed at the end of the first significant state, that is, at the beginning of the sequence of insignificant logo presences.

IV. EXPERIMENTAL RESULTS

A program implementation of the described method developed using C++ on Linux operating system was

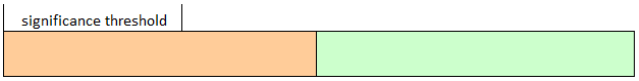

Figure 5. Two adjacent significant types of logo presence..

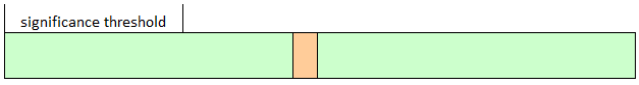

Figure 6. Insignificant logo presence type bordered by two equivalent significant logo presence types.

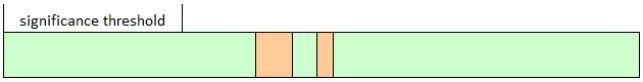

Figure 7. More consecutive insignificant logo presence types bordered by two equivalent significant logo presence types.

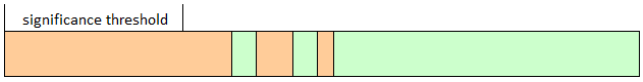

Figure 8. More consecutive insignificant logo presence types bordered by two unequivalent significant logo presence types.

tested on four Croatian TV channels of Nova TV, RTL TV, RTL 2 TV and Doma TV whose logos mostly cover all different properties of logos mentioned in [2]. The video test base was formed by recording channel content at random chosen times so as to contain movies, various shows and the commercials and all videos were later deleted in order to protect copyrights. The testing itself can be split in more principle components: testing of logo recognition, testing of commercial recognition and testing of boundary determination. In the following text every mentioning of the program referrs to the implementation.

A. Logo recognition

Assuming the video had a good starting quality, the program almost always recognized the logo at various times during the rest of video and only two cases presented some problems:

- the background color mathes the logo color
- and the logo suddenly changes its position.

In the first case a simple problem is encountered where there are no sharp edges to detect, but as most logos are white or transparent, such cases are not so often.

The second case is much more dangerous because the old knowledge of edge positions is of little value for further edge recognition. The problem complicates further when the logo size changes as well as the position so a simple translation is not enough. The problem is solved by applying new learning as it was described, but as long as new pixel positions are not learned, data processing will be erroneous when deciding about logo presence significance.

B. Commectial recognition

Due to the fact that a commercial never contains the logo of the channel, the program always recognized all commericals if they were longer than 10 seconds which was always the case and taking that in consideration the commercial recognition was 100%. The problem was in the false positive cases when there was no commecial, but this cases were relatively rare and their causes were described in the previous chapter.

C. Commercial block boundaries

Experimental results of boundary detection on 10 chosen commercial blocks on different channels, that is, testing 20 boundaries, looked like this:

- 12 boundaries were recognized correctly
- 4 boundaries were recognized at a distance of no more than 50 frames from their original position
- 4 boundaries were recognized at a distance of more than 50 frames from their original position

It is important to mention that several cases of correct boundary recognitions included selecting one of consecutive monochrome frames which is however a legal choice since the frames have no special program affilition.

The boundaries which were recognized within 50 frames of their original position still represent a good result as we are talking of less than 2 seconds of real program. This cases occured mostly when hard cuts were not as hard as expected or they occured at unwanted positions.

The more failed boundary recognitions are a result of several unfavorable conditions being met at once and the method was in most cases deemed to fail.

D. Additional results overview

The used video contents surely do not represent all possible program types, but at the same tame, they do a large part of them. It must be mentioned that the accuracy of commercial recognition varies from channel to channel and the principle reasons for that are:

- not all logos equally hard to learn,
- different channels have different ways of logo removing and returning behaviour,
- the commecrial policy differs from channel to channel
- and some channels change position and size of their respective logos during different broadcast material.

For example, it was much easier to learn Nova TV or RTL TV logo then the one of Doma TV or RTL 2 TV which means that the detected edges contained much more pixels and were therefore easier to find in other frames.

As far as it concerns the second mentioned point, some channels remove their logos gradually, some do it instantly, some do it about 10 frames before the commercial block, some on the boundary itself and it is easy to see why this is a source of recognition problems.

Another problem is that in the policy of some channels there is no logo removing when the channel has so to say self-commercials about future broadcasting and such content is therefore not labeled as a commercial, even though it has some similar properties with them.

The last point concerns position and size changing of the logo. This is not something that happens on every channel, but only on some of them and when such an event occurs, new learning has to be applied as it was described before.

V. CONCLUSION

Commercial recognition within video content is a subject for which solutions exist for some time, but they are still not on the level which would be hard to improve. Logo recognition is most certainly the most spread way to deal with the problem and most implementations use it in their handling. Even though prior data knowledge represents a great advantage for a single channel, the same data can be learned from the content which grants a great independence to the implementation using such learning, keeping at the same time a good discriminative power which is easily shown experimentaly. The main advantage of the described method is the possibility of using it without knowing any prior data knowledge and its

robustness to noise and small changes in logo size and position during time.

***Abstract*—User authentication based solely on user's password is the most commonly used method, but with several known issues. With the growing number of Internet users, most of whom are not familiar enough with security threats, as well as growing significance of their on-line activities, stolen passwords are becoming a major security problem. We argue that an additional, non-intrusive level of security can be achieved by analysing keystroke dynamics. A system was developed which uses an artificial neural network to discriminate between a genuine user and an impostor with a high success rate.**

I. Introduction

The increasing need for additional security measures in computer systems, online as well as offline, has motivated the research of various authentication techniques. As a non-intrusive and cheap (it requires no additional hardware) authentication technique , the analysis of the user's keystroke dynamics has been researched since 1980. [1].

This work focuses on building a system that would successfully store the typing dynamics of various users' passwords and could be used to provide an additional authentication layer besides the standard password protection. The decision about the user's identity is reached based on an artificial neural network output. The artificial neural network is trained on known pairs of users and passwords, as well as "impostor" samples in order to learn how to discriminate between a genuine user and an impostor. A separate neural network is constructed for each user–password pair.

The rest of the paper is structured as follows: The next section (section II) is a short introduction into recent works on the subject. An overview of the method and the application implemented for data retrieval can be found in section III-A. The structure and the training proces of the neural network is explained in section III-B. The description of the testing process and achieved results follows in section IV. A conclusion is given in section V.

II. Related work

Keystroke dynamics are biometric features from the category of *behavioral* features. While the *physiological* features (e.g. face, eye patterns, fingerprints) do not vary much along time, behavioral features may vary greatly even between two consecutive samplings [2] due to both controllable actions and unintentional psychological factors [3]. This temporal instability of behavioral features is common to static and dynamic hand signatures and keystroke dynamics, while voiceprints (especially made of the same uttered text) show an additional level of stability [2]. It is, thus, understandable that the authentication techniques based on analysing behavioral features are not yet as accurate as the techniques analysing the physiological features [4]. While not as accurate as physiological features, additional security layers including behavioral features are better accepted by the users because of the non-intrusive ways of data collection. Another advantage of security systems based on behavioral features is that they are easier to implement [4].

Two main directions of researching authentication based on keystroke dynamics include the analysis of the (usually pre-determined) written text [1], [2], [3], [5] or the analysis of a specific short text sample (e.g. personal name or password). If authentication was based on continuous typing (written text), it is usually language dependent: in [3], user reference profiles are constructed from the keystroke latencies and durations of the top n most frequent features of the pattern vectors corresponding to most common letter pairs and triplets in the English language. In [5], a similar technique is used, extraction features for most common English words instead of letter pairs.

Various techniques have been used in analysing the keystroke dynamics of a short text sample, and an overview with a detailed analysis of many of the techniques proposed in various works can be found in [6]. The paper [6] compares the proposed techniques based on *equal-error rate* and *zero-miss false-alarm rate*. While some papers focus on exploiting a single classification technique, there are examples of using a combination of multiple methods to identify users based on keystroke dynamics: in [7], a Genetic Algorithm approach is used for randomized search in combination with SVM as a base learner in the wrapper approach, while [4] uses a fusion of numerical methods with good performance properties that require a low training data volumes in the learning process and are easy to implement. Examples of user classificators based on a single classification technique include the rough set approach proposed by [8], statistical methods such as Naive Bayes classifier explored in [5] and an artificial neural network approach using autoassociative Multilayer perceptrons used by [9]. While the approach to collecting the training data is similar in most of the related works, approach to classification used in this work shows most similarities to the approach used by [9]. While most other approaches to classification and recognition strive to develop a mathematical model that corresponds with measured data and model a system based on the calculated model, artificial neural networks work directly

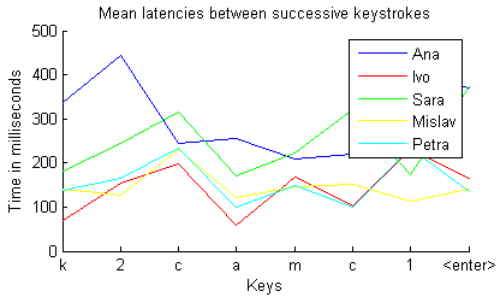

Fig. 1: Mean interkey times

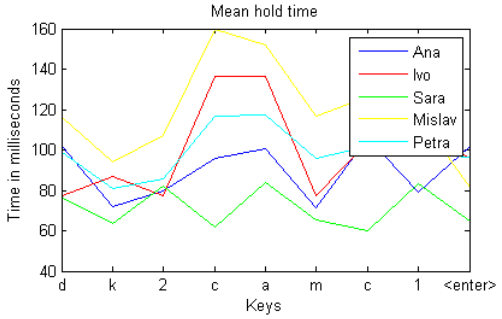

Fig. 2: Mean hold times

with the measured data implicitly storing the model [10]. Many different topologies (e.g. single and multi-layer feedforward networks, recurrent networks, lattice structures) and perceptron activation functions (e.g. linear, step function, sigmoid function) allow the neural network to successfully model various mathematical models of input data correlations. We further argue that artificial neural networks are especially suitable for problems where data correlation can be easily observed from various input data visualizations but a mathematical model is not trivial to calculate. Since analyzing user keystroke dynamics is just such type of problem, an assessment of user authentication system based on artificial neural networks is given.

III. Approach

A. Collection of the training data

To successfully implement the proposed system, data from various user–password pairs had to be collected and the features extracted. An application for this purpose was implemented in *C#*. The neural network training process and classification of new data, implemented in *Matlab* (cf. section III-B) was later built into the *C#* data retrieval application, allowing for the same application to be used for the live testing of the constructed neural network.

The implemented application allows to set up various user–password pairs before the beginning of the data collection process. Features for the training and testing input vectors are then extracted only from correctly–typed passwords. Features extracted from a single password are *interkey* and *hold* times. Interkey times represent the time difference between successive keystrokes while hold times correspond to the duration of a certain keypress. We include the information about a *<enter>* keypress that occurs after typing in the password to obtain one addition interkey and hold time. This way, a single 8-character-long password is represented by a 17-features-long feature vector. Similar features have been used extensively throughout other keystroke dynamics works and can be seen in [7], [5], [2], [9]. Some authors also define *Flight time* as the time between the release event of one key and the next keypress event. Since Flight time can be constructed as a linear combination of interkey and hold times, we argue that they are irrelevant in the neural network approach since the Network naturally works with linear combination of it's inputs. A visual proof that interkey and hold times provide discriminatory features describing user passwords can be seen on Figures 1 and 2 representing mean values for interkey and hold times for 5 different users.

The chosen passwords are not full English words, but rather a (semi)-random set of eight lower-case letters and numbers. That way, the passwords resemble real user passwords, while eliminating the need for an extra keypress of the shift key by omitting the upper case letters and special characters from the passwords to allow more fluent typing.

Ideally, multiple password input attempts should be taken over a long period of time. Because of the time restrictions, most of the data from a user is collected in a single session. The problem with this approach is that the user "learns" the passwords over several repeated tries, and thus the latter feature vectors contain smaller measures because of the user's faster typing. For this reason, the data used as input and testing data from which the main part of the results is obtained is collected in such a way that:

- between 100 and 200 password samples from a single user represent the *real* user samples
- around 15 password samples from every other user together form the *imposter* samples.

Additionally, each real user rehearsed typing his or her password before his data-collecting session to better reflect the fact that most users type their passwords quite often. On the other hand, imposter users did not practice typing other users' password before the session. The number of different user-password samples can be seen in Table I, with the *real* user-password combinations shown on the main diagonal.

Another imperfection in the data collection method was that different users used different keyboards in the process. While some other works argue that it is better to collect data in a strictly controlled environment (single keyboard previously unused by the subjects) [6], [2], [7], our premise is that the data typed from the user's usual keyboard better reflects the real life password typing situations. The real user will most often type in his or her password from a familiar environment (e.g. home/office computer) as will the impostor (e.g. in case of online attack). The premise can be justified by the works of [5] or [9] where the emphasis is not on the users typing in the same environment.

B. Topology and training process of the artificial neural network

In addition to the *C#* application used for collecting data and live testing of the trained Network (cf. section III-A), a *Matlab* application was developed to train the neural network (using *Neural Network Toolbox*) and gather network performance data.

To train the neural network for a single user-password combination (represented by a single column in Table I), the data is separated in two files: one containing the real user's input information, and one with the data collected when all other users attempted to type the same password. As 10-*fold cross-validation* has been used in estimating the performance of the neural network, the data used as a learning set in each iteration consists of 90% of the all the available password samples for a single user as well as 90% of the imposter data. The remaining 10% of the data is later used in testing, with the results of the performance data presented in section IV. The goal is for the Network to accept all the real user's inputs and reject all the imposters' attempts in typing the password.

The chosen topology of the artificial neural network is a *feedforward neural network*. This topology does not contain any directed cycles in perceptron connections, as opposed to the recurrent neural networks. Due to the complexity of the model, we believe that a single-layer perceptron network would not be able to learn the required model. Instead, a *multilayered perceptron* is used. MLP consists of a group of neurons, organized in layers. The input and output layers connect the neural network to the outside world (i.e. inputs and outputs). Except for these two layers, there is at least one more hidden layer. The hidden layer neurons are not directly accessible, and are used to implicitly store the model of the input data [10]. Models of a single neuron and a MLP can be seen on Figures 3 and 4 respectively. The decision about the number of the layers, as well as the number of neurons in each layer is left to the designer of the network. This choice often relies on the specific problem requirements as well on the experience of the neural network designer. For this problem, an artificial neural network with 3 hidden layers has been constructed, with 8, 12 and 8 neurons in the hidden layers. The choice to use three hidden layers was made empirically. Our testing showed that when using less than three hidden layers, the neural network shows poor generalization qualities, e.g. the decision making process is heavily based on comparison of total password type times. Such a neural network could easily give false positive outputs for an imposter mimicking a slow-typing user by typing in an equally slow pace. On the other hand, using a greater number of layers did not significantly improve authentication accuracy, while the training and execution times were prolonged for such a Network.

Explicit storage and learning of the input data model is done using *backpropagation algorithm* which works in two phases: *forward* and *backward* phase.

The first, forward phase includes input samples represented as information signals which are moving in the forward direction, from the input nodes, through the hidden layers, towards the output nodes. During this process, the output of each neuron is determined by applying an activation function using on a sum of the weighted inputs and a bias factor specific to the current neuron:

$$\rho(v) = \frac{1}{1 + e^{-v}},$$

where v represents the weighted sum. The signals are propagated through the network all the way to the output layer. The forward pass ends with the computation of an error signal of the single output neuron as the difference between the desired and produced output:

$$e = d - y,$$

where d is the desired output, and y is the actual output given by the network.

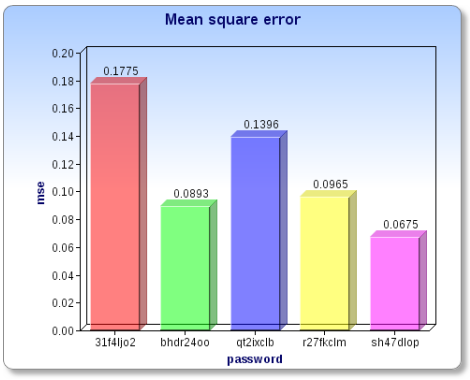

Fig. 5: Mean Square Error distribution among the users after the completion of the neural network learning phase

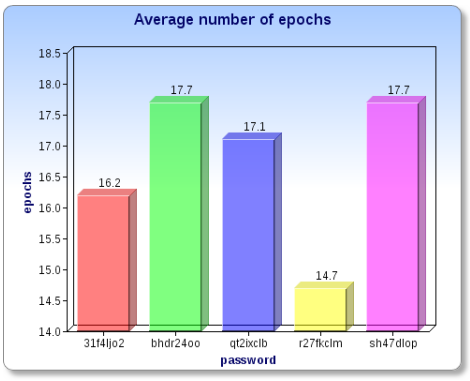

Fig. 6: Average number of epochs per user in the training phase of the neural network

The second phase propagates the error signal in the backward direction, from the output layer, towards the input layer. A local gradient is calculated for each neuron. Using the delta rule, adjustments are then applied to the weight and bias parameters of every neuron to minimize the error in a statistical sense:

$$\Delta w_{ji}(n) = \eta \delta_j(n) y_i(n),$$
$$w_{ji}(n+1) = w_{ji}(n) + \Delta w_{ji}(n),$$

where η is the constant of the learning process, $\delta_j(n)$ a local gradient in the neuron j and $y_i(n)$ input to the jth neuron.

After adjustment of all the weights in all the layers, ending with the input layer, a new sample is presented to the network. Presentation of the pairs continues in a random order to ensure a stochastic weight space optimization. As the training of the perceptron is implemented using a pre-existent *Matlab* function, a Mean Square Error criteria was used for an internal quality measure. Training stops when the internal quality measure ensures sufficiently small error rate to assure good generalization properties of the neural network. Empirically chosen threshold for the Mean Square Error was 0.2, while the final Mean Square Error for a single user varied depending on the discriminatory qualities of the input data. The average Mean Square Error for all the users was 0.1141, while the exact numbers are shown graphically in Figure 5. Number of epochs needed to achieve these results is shown in Figure 6 with the average number of epochs

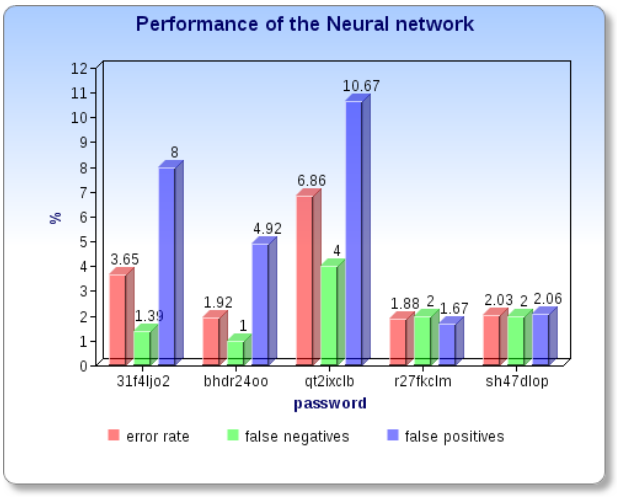

Fig. 7: A graphical representation of the data presented in Table II

through all the users equal to 16.68.

Internally, the goal values are 1 for accepting the input feature vector, and -1 for rejecting it. The Networks outputs are real values in the range $[-1, 1]$. The quality of the neural network outputs for different thresholds for rejecting the input is presented along with other results in section IV.

IV. Testing and Performance of the *ANN*

Performance of the neural network was measured using 10-*fold cross-validation* technique as previously mentioned in III-B. This method divides the input set randomly in to 10 equal portions, separately for the real user samples and the imposter samples. In each of the 10 iterations of the testing process, a different portion of the input set is chosen as a *validation set*, while the remaining 90% is used as the *learning set* for the iteration. The Network performance is then estimated as a mean of performance values obtained in each iteration.

Testing of the neural network was done for five different user-password combinations. The input set, already described in section III-B which can be seen in Table I, consisted of between 100 and 200 feature vectors obtained from the real user, as well as between 60 and 100 feature vectors from the imposter user samples.

The results of the 10-fold cross-validation process are presented in Table II with a graphical representation in Figure 7.

The rate of *false negative* detections (i.e. samples belonging to the real user that have been rejected) is in most cased lower then the rate of *false positive* samples (i.e. accepted imposter samples). The reason for this is that while the Network tries to divide the feature-space in to two classes, *real* and *imposter*, only the feature vectors belonging to the *real* users class are localized in the feature space. Number of samples belonging to the imposters is significantly smaller than the number of the real samples contributing to better classification of the *real* samples and more misses when classifying the *imposter* samples. It can also be observed that our results

Password	# real user samples	# imposter samples	error rate	false negative rate	false positive rate	F1-measure

are comparable to the results presented in the works using similar performance measures [9], [3].

For the main part of the testing process, a threshold of 0 was used to determine between real user's and imposter samples. To determine the impact of the threshold on the quality of the neural networks explicit model, performance of the Network with only two users typing the same password is examined. The number of samples per user is also greater, with the database consisting of around 400 samples from each user.

The impact of the threshold on the F1-measure can be seen on Figure 8. Figure 9 shows the average number of false positives and false negative samples with different threshold values. Different *equal-error* rates (i.e. the point where the number of false positive and negative samples is equal) and different maximums of the F1-measure in the Figures suggest that the threshold should be considered individually for each user, perhaps as a separate output parameter of the artificial neural network.

The application developed in *C#* also allows live testing of a trained neural network and demonstration of usability of the developed classifier. While training the artificial neural network for recognizing one user-password combination against 5 different imposter users takes from 10 to 15 seconds, once trained, the Network's outputs are obtained instantaneously.

V. Conclusion

It can be concluded from the results presented in the section IV that keystroke dynamics analysis holds big potential as an authentication method, but the methods used in the process have to be improved before it can be used as an independent security measure. The results also indicate that while artificial neural networks show good performance in this situation, as well as potential for improvement, there are some drawbacks to this approach. In the real-world situation, training the Network with "imposter" samples would require for a user to repeat his password to several individuals whose samples will be used for training of the Network. Also, there is only a limited number of samples (and people) available as the "imposter" samples, while in the real world, there is an infinite number of possible imposters.

The application developed for collecting data and live testing the trained neural network is implemented modu-

larly, and as such can be used in the future with any neural network keystroke dynamics system, as well as any other implementation of a similar system.

While the developed application implements the functionality of adding a new user to an existing system, for each new user the samples for the user as well as the imposter have to be presented to the system. This is due to the fact that the current implementation creates a separate neural network for each user in the database. To improve the systems scalability as well as avoid the need for imposter samples, a different architecture of a neural network could be attempted. This could be achieved by training the Network with only the real user samples and having multiple output neurons, each corresponding to a particular user.

GRATITUDE AND THANKS

The authors of the paper would like to thank everyone who contributed to this paper with providing the input data required for performance analysis.

Abstract - The purpose of this paper is to introduce and quickly make a reader familiar with OpenCV (Open Source Computer Vision) basics without having to go through the lengthy reference manuals and books. OpenCV is an open source library for image and video analysis, originally introduced more than decade ago by Intel. Since then, a number of programmers have contributed to the most recent library developments. The latest major change took place in 2009 (OpenCV 2) which includes main changes to the C++ interface. Nowadays the library has >2500 optimized algorithms. It is extensively used around the world, having >2.5M downloads and >40K people in the user group. Regardless of whether one is a novice C++ programmer or a professional software developer, unaware of OpenCV, the main library content should be interesting for the graduate students and researchers in image processing and computer vision areas. To master every library element it is necessary to consult many books available on the topic of OpenCV. However, reading such more comprehensive material should be easier after comprehending some basics about OpenCV from this paper.

I. INTRODUCTION

Computer Vision is the science of programming a computer to process and ultimately understand images and video, or simply saying making a computer see [1]. Solving even small parts of certain Computer Vision challenges, creates exciting new possibilities in technology, engineering and even entertainment. In order to advance vision research and disseminate vision knowledge, it is highly critical to have a library of programming functions with the optimized and portable code, and hopefully available for free. This was an original goal of Intel team back in 1999 when OpenCV (Open Source Computer Vision Library) was officially launched. Since then, a number of programmers have contributed to the most recent library developments. The latest major change took place in 2009 (OpenCV 2) which includes main changes to the C++ interface. The newest library release can be found on the OpenCV official website [2]. Nowadays the library has >2500 optimized algorithms. It is extensively used around the world, having >2.5M downloads and >40K people in the user group. OpenCV can be used in academic and commercial applications as well, under a BSD license [3]. To master every OpenCV library element it is necessary to consult many books available on the topic of OpenCV. Nevertheless, reading such more comprehensive material should be easier after comprehending a basic idea about OpenCV from this paper. In fact to make it even more convenient, the text presented here intentionally closely follows one of the most recent OpenCV sources [4].

II. BASIC LIBRARY STRUCTURE AND FEATURES

OpenCV library (since version 2.2) is divided into several modules, where each module can be understood, in general, as being dedicated to one group of computer vision problems. All the classes and functions are defined within the name space *cv*. Therefore to access them we can either precede the main function definition by the declaration *using namespace cv;* or prefix OpenCV class and function names by namespace specification *cv::*. The main object is of class *Mat*. As implicated by the class name it is essentially a matrix holding pixel values of some image and, in addition, a number of attributes about an image. In the simplest case an image can be created as *cv:: Mat image*;, creating an image of size 0 by 0. Perhaps the most important member variable of *image* object is *data* where *image.data* member is actually a pointer to the allocated memory block that contains the image data (in this trivial case it would be *image.data*=0). Alternatively during a creation of *Mat* object we can explicitly specify an initial size and the type of each matrix element. This type specifies, for example, signed 1-byte pixel image values (*CV_8U*), or three channels for a color image (*CV_8UC3*), or even 32-bit/64bit floating point numbers (*CV_32F*).

Once an object of class mat is defined, a nice feature about it (not present in the early versions of OpenCV) is that a memory allocation/deallocation takes place automatically. For instance, a memory automatically allocated during the image read out into some object, will be also automatically released once the corresponding object goes out of scope.

Another important thing is that *Mat* class implements the reference counting and shallow copy. Hence, when an image is assigned to another one, the image data itself is not copied and both images point to the same memory block (this also applies to images passed by/returned by value). However, since reference count is supported, a memory allocated for image (pixel) data itself will be released only when all of the references to the image are destructed.

In the versions prior to OpenCV 2, C like functions and structures were used (still can be though) and the main structure was *IplImage*. Although there is a convenient way to convert *IplImage* structure into *cv::Mat* object, it is highly recommended to avoid this deprecated data structure.

III. ACCESING PIXEL VALUES

The basic image content is made of picture elements known as pixels. Consequently, an efficient pixel

processing is of high importance since images can easily have tens of thousands of pixels. Since a matrix is a basic data structure in OpenCV, it seems reasonable that each element of the matrix represents one pixel. However for a gray level image, pixel values themselves are typically unsigned 8bit values, whereas for a color image three such 8bit unsigned values are used per pixel to describe three primary colors, i.e. channels (Red, Green and Blue; actually OpenCV uses BGR channel order). In more general sense, OpenCV allows to create matrix of various value types (as described earlier) and it is important to note that certain operations (pixel processing) can be applied only on the certain matrix types. Moreover, certain image processing could be more effective if appropriate color space is chosen [5].

In order to access each individual matrix element essentially we just need to specify row and column, but the way we actually do it can influence code mostly in terms of performance efficiency and clarity. One of the access method is to use method *at(int x, int y)*. However, in this case the type returned must be known at compile time and, consequently, *at* method is implemented as a template method. For example, accessing pixel on coordinates (j, i) of some *Mat* object *image* and where returned type is 8bit unsigned value, can be written as *image.at<uchar>(j, i)*. Note that *at* method does not perform any type conversion and it is a programmer's responsibility that specified type matches the actual one in the matrix. For color images a syntax is somewhat more complex since in that case we actually retrieve a vector of three 8bit values: *image.at<Vec3b>(j, i)*[channel]. *Channel* determines one of the three color channels.

Specifying a returned type as a template argument for each call may be cumbersome. In case an image type is *a priory* known we can use *Mat_class* which is a template subclass of *Mat* class. Now we specify matrix type only once at the object creation and later on we just use *operator()* to access individual pixel values, e.g. *Mat_<uchar> im2=image; im2(101,303)=0;*.

Accessing pixel elements with a pointer generally provides a more efficient code, frequently at cost of more cumbersome syntax. Fortunately, OpenCV offers *ptr* method which simplifies a pointer arithmetic by directly giving an address of an image row *j*, e.g. *uchar* data=image.ptr<uchar>(j);*

We can also access pixel simply using traditional pure low level pointer arithmetic. Considering that the image data is contained into memory block of unsigned chars, we can retrieve the address of the first element in this block, i.e. *uchar * data=image.data;*. Now obtaining the address of the pixel at row *j*, column *i* we should write *data=image.data+j*image.step+i*image.elemSize();*
where *elemSize* returns number of bytes occupied by one pixel, *step* is the actual number of bytes per one row. Namely, for efficiency reasons the length of rows in bytes is often not necessarily equal to the theoretically excepted number equal to image width in pixels × number of bytes occupied by one pixel. Rather the rows are padded with few extra pixels in order to be multiples of 4 or 8. Certainly these extra pixels are neither displayed nor saved. On the other hand, in case the image is not padded with extra pixels at the end of each row, it is interesting to note that an image can be seen as one dimensional array of *Width×Height* pixels. We can take advantage of this continuity by scanning the image pixels within a single loop, which in turn can yield a more efficient code (particularly in cases when several smaller images are scanned simultaneously in the same loop). Whether or not image has been padded a convenient method *isContinous* can tell us.

Looping over data collection in object oriented programming is frequently done using iterators (a special class which hides how iteration over each element is specifically done for each data collection). Similarly as the Standard Template Library (STL) has an iterator class associated with each of its data collection classes, OpenCV provides *Mat* iterator class, which is compatible with standard iterators found in the C++ STL. Since iterators scan pixels of certain type, we need to declare iterator using template where we define a specific type to be known at compile time, e.g. *MatIterator_<Vec3b> it;* Nice thing about iterators is that no matter what collection is scanned it follows always the same pattern. We conclude that in principle, using iterators, similarly as *at* method, has the main objective to make the code less error-prone. However, working directly with pointer provides usually more time efficient code.

To combine images using arithmetic operators, OpenCV provides numerous functions which names by themselves reveal their purpose, e.g. *add, absdiff, multiply, divide, bitwise_and* etc. Note that in all cases function *saturate_cast* is used to assure the results within a defined pixel value domain. Optionally, we can include a mask in a function call where a particular operation will be executed only on pixels for which the mask value is not null. In addition, input images have to have the same size and type, only the output image will be re-allocated if it does not match the input size. Alternatively, we can use the usual C++ operators which are overloaded in OpenCV. Occasionally, it is necessary to work only on the particular image channel (plane). *split* function will copy the three channels of a color image into three distinct instances. A reverse action to combine a color image from three 1-channel images is done via *merge* function.

IV. MAIN ALGORITHMS AND METHODS

In the above we have briefly described some of the main engine features used for OpenCV implemented processing techniques and methods. Below we try to mention several OpenCV image processing techniques and algorithms which are known to be widely used too.

The concept of image histograms is well explored for image analysis. A histogram is a table showing a number of pixels having a given value in an image (occasionally a set of images). Histogram entries are called bins. OpenCV function which computes histogram is *calchist()*. To enhance image contrast perhaps the first idea would be to spread an original narrow range of intensities on a full available range (i.e. linear stretch). However, sometimes the real problem is that some

intensities are used more frequently than others, which is readily visible from the histogram intensities distribution. Based on the idea that a good quality image should make (almost) equal use of all available intensities, the concept of histogram equalization is brought up, which tries to make image histogram as flat as possible. This is a task of OpenCV *equalizeHist()* function. Besides, the intensities distribution can be understood as the probabilities that some pixel will have a particular value. This constitutes a base to detect specific image content using a histogram back projection. This back projection replaces each pixel value in an input image by its corresponding probability read in the histogram, eventually yielding a probability map. Furthermore, this probability map can be used to detect an object on the image utilizing a mean shift algorithm [6]. It is an iterative procedure which locates the local maxima of a probability function by finding the weighted centroid of the data point inside a predefined window. The algorithm then moves the window center to the centroid location and repeats the procedure until a window center converges to a stable point. The mean shift has been extensively used for visual tracking. In addition, a more advanced version where the size and the window orientation can change is implemented as well under the name CamShift algorithm [7].

Morphological operations are operations where the value of each pixel in the output image is based on a comparison of the corresponding pixel in the input image with its neighbors. By choosing the size and shape of the neighborhood (i.e. a structuring element), we can construct a morphological operation that is sensitive to specific shapes in the input image. A structuring element has an origin (usually at the center of the structuring element) which is aligned with a given pixel. The most fundamental morphological operators are erosion (the output pixel value is the minimum value of all the pixels in the input pixel's neighborhood) and dilation (the output pixel value is the maximum value of all the pixels in the input pixel's neighborhood). Morphological filters are usually applied on the binary images. Assuming that foreground (objects) is white and background is black, an erosion operation will reduce the object size whereas a dilatation will increase the object size. Combining dilation followed by erosion, with the same structuring element, defines a closing operation. The idea is to connect together the object components erroneously fragmented into smaller pieces (this would be a task of dilatation step, while the subsequent erosion step is to undo a previous dilatation effect for the very small objects which are most likely noise and thus meant not to be a part of any object). Similarly, combining erosion followed by dilation, with the same structuring element, defines an opening operation. Here, the idea is to remove (erosion part) a small objects (all of the ones too small to contain a structuring element) presumably introduced by the image noise. Since this erosion also shrunk the valid objects to undo this effect, opening operation also assumes a subsequent dilatation. In fact, closing and opening are usually applied in the sequence (e.g. during object detection). Alternatively, the opening can be applied before closing if priority is noise filtering, but possibly at the price of eliminating some (smaller) fragmented objects as well, before they have chance to be defragmented. It should be also noted that applying the same opening (closing) on an image several times has no additional effect on the result acquired after its first application. Morphological filters can be used to detect lines and corners also ([8], [9]). In the first case, this procedure essentially comes down to differencing dilated and eroded image. In the second case, in addition to the mentioned image differencing, an appropriate structuring element has to be chosen such to emphasize only the corner points and to leave straight edges unaffected.

Instead of observing distribution of image gray-level intensities, we can study the frequency of intensity variations. This point of view is referred as the frequency domain and allows a processing pallet aimed at image frequency filtering. A frequency domain analysis decomposes an image into its frequency content from the lowest to the highest frequencies. Such decomposition is often undertaken using Fourier or Cosine transform. Under the frequency analyses framework context a filter is an operation that amplifies/removes certain bands of frequency. OpenCV offers *blur()* function which smoothes the image by replacing each pixel by the average value computed over rectangle neighborhood. Hence, *blur()* function is a low-pass filter. A considered neighborhood in the form of mask is also called a kernel, and mathematically this operation is named convolution. More advanced function use allows filtering not only with a rectangle window, but with some other shapes e.g. Gaussian. Low-pass filtering is routinely used prior to image down sampling by some factor N. Without it, i.e. simply just discarding every N column and row would cause effect known as aliasing. Visually it manifests as jagged image distortions and it is caused by the fact that image is simply too small to represent fine textures i.e. high frequencies. This is why filtering out high frequencies is necessary prior to down sampling itself. Unfortunately, up sampling the down sampled image will not recover exactly the original image. In any case, this down/up sampling operations are often used to create image pyramids, a data structure built for certain efficient analyses, e.g. an object detection on smaller size image first, followed by the refined search on the higher resolution images. Median filter is another OpenCV implemented filter option (*medianblur()*) aimed at removing outlier noise (e.g. salt and paper type of noise) where pixel values are replaced by the median of all neighborhood considered pixels. We note that a median filter although very helpful in preserving the sharpness of edges, it also washes out the texture in uniform regions.

Sometimes the idea is to amplify high frequency instead of attenuating it. This is the case when using directional filters to perform edge detection where image intensity gradient (composed of first order derivates in two orthogonal directions) is computed. Alternatively, a high pass linear filter can be based on the (sum of) second order derivates, i.e. the Laplacian filter. Here, the edge is determined by zero crossing of the Laplacian function, were in principle we scan the Laplacian image and detect the change of sign for two neighborhood pixels. Thresholding the gradient magnitude and/or change of Laplacian around zero, we conveniently acquire the image edge map. However, choosing the right threshold

for edge detection is not a trivial task and some more advanced edge detectors actually use two thresholds, e.g. Canny [10]. The Canny operator is generally based on one of the gradient operators (e.g. Sobel). On such gradient image we first apply separately low and high threshold, producing low and high threshold edge map respectively. The idea is to combine those two edge maps in a way that from the low threshold edge map we keep only those points with a continuous path linked to some edge point on the high threshold edge map. Consequently, the Canny edge detector should yield a good compromise allowing good quality contours.

The Hough transform is another popular algorithm implemented in OpenCV, aimed at detecting lines, but extendable for some other image structures as well ([11], [12]). The Hough transform usually takes as input edge pixel map. The idea is to parameterize a particular image structures with a certain number of parameters. In the case of line *N=2* parameters suffice. Next, *N* dimensional accumulator is constructed where each entry represents an image structure (line) with a particular set of parameters. Considering one point of input image we search all lines that pass through this point. The entries of the accumulator corresponding to the found line parameters are then incremented. Evidently when the same line passes through many points, a corresponding accumulator entry will be high and this line can be considered as significant.

Assuming an image has a distinguishing points, it is possible to detect them using interest point (also known as keypoints or feature points) detectors. Corners are one of the most common feature points. OpenCV offers an implementation of Harris corner detector ([13], [14]). A corner being the junction of two edges is a two-dimensional feature. Based on that fact, Harris detector looks at the rate of intensity change (characterized by a covariance matrix) around some point and obtains the maximal average intensity change for some direction. Next, it checks if average intensity change in the orthogonal direction is also high, then we have a corner.

A faster corner detector than Harris is offered in the form of FAST (Features from Accelerated Segment Test) algorithm [15]. It avoids a computation of image derivates by examining a circle of pixels centered around some candidate point. In more detail, if an arc of contiguous pixel points (all having intensities significantly different from the center point) of length greater than 3/4 of the circle perimeter is found, then a corner is declared.

Even more advanced keypoint detectors are designed to be scale invariant. This is particularly advantageous if we try to match the same feature from two images taken at a different distance from the object. Evidently, using a fixed size neighborhood for matching would be hard since the scale change will prevent intensity patterns from matching. OpenCV implemented the scale invariant SURF (Speeded Up Robust Features) keypoint detector [16]. SURF computes the image derivates on different scales (image resolutions). Given some image point, at one scale filter response will reach its maximum. If this maximum is at least a minimum value supplied as an algorithm input, a key point (i.e. a scale invariant feature) is declared. SURF actually uses a Hessian matrix to detect corners at image points with high local curvature, and at different scales. Thus, a scale invariant feature is declared when Hessian matrix determinant reaches its local maximum at certain scale and given pixel location. SURF approximates Gaussian kernels in order to speed up a computation. In addition, OpenCV implements a somewhat slower alternative, but considered more accurate, SIFT (Scale invariant Feature Transform) which uses Laplacian filer response instead of Hessian determinant [17].

Feature detectors are usually used for feature matching across different images and this normally requires definition of featured descriptors as N dimensional vectors that describe a feature point. The goal is to make descriptors invariant to change in lightening and to small perspective deformations. OpenCV provides function to compute SURF feature descriptors based on previously computed feature points. It allows additionally comparing feature descriptors from different images and finding eventually the best match for some feature. In turn, matches can be used to solve many task in 3D reconstruction, visual tracking, image registration etc.

A digital camera is a device that captures a 3D scene onto a 2D plane. Related to, it is a camera calibration procedure which aims to find function parameters describing a projection of 3D point onto 2D image plane [18]. OpenCV offers functions which based on the so called calibration images computes those parameters. In turn, two or more calibrated cameras allow a reconstruction of 3D point using only its correspondent image coordinates. The relation between two cameras is neatly captured through the concept of epipolar geometry and fundamental matrix. It simplifies corresponding image point search between two cameras, relating some image point of one camera with the corresponding line on the other camera, on which a corresponding image points is somewhere too. Therefore, OpenCV computes the fundamental matrix as well. Moreover, OpenCV supports a robust two view feature matching based on the fundamental matrix computation during a random sample consensus strategy. Finally, there is a relation relating two cameras views differing only by some rotation or equivalently if we consider projection of 3D planar points on cameras' images. In that case image points of two cameras are related by the so called homography matrix. This matrix OpenCV computes simply from a set of matched points between two cameras. Such homography is particularly useful in creating, for instance, panoramic images.

OpenCV offers advanced video analysis on video sequences too. Besides basic operations such as reading/viewing/writing video sequences, extracting individual frames etc. a typical two tasks are the foreground extraction and object tracking [19]. It is essential to note though that in order for OpenCV to open a specified video file, the corresponding codec must be installed on the computer. Besides, there is a possibility to read directly the video stream of a connected camera.

A point tracking in the current frame is based on the search around point's position in the previous frame. In general a point tracking algorithm is as follows. Firstly, a certain number of features are detected in the initial frame. It is assumed that an intensity of the feature point has not changed from one frame to the next one, which holds for some small displacements (u, v). Thus, it is possible to derive a feature intensity expression in the frame (t+1) as a function of an intensity in the current frame t and assumed displacement (u, v). This leads to famous Lukas-Kanade tracking algorithm [20]. It further assumes that displacement of all points in the neighborhood is the same which leads to over-determined set of equations to compute (u, v). Once OpenCV finds (*calcOpticalFlowPyrLK()*) output positions, normally we keep for further tracking only those points which have significantly moved by some amount of pixels. If by the time, the actual number of tracked points significantly decreases, it is recommended to add new feature points Note that we normally do that only in the initial frame and in the very next one we expect to find only points which actually moved and are therefore worth of tracking in the subsequent frames. When extracting a foreground from a background it is useful to compute a background dynamically (i.e. for each frame a background is updated) rather than to work with the same background image appearance throughout the process [21]. This can be accomplished by computing a so-called running average.

V. EXPERIMENTS

We demonstrate the library performance on the passive stereo matching. Stereo matching is the process of taking two or more images and estimating a 3D model of the scene by finding matching pixels in the images and converting their 2D positions into 3D depths. In more detail, for a given image location on the first (left) image (x_L, y_L), stereo matching algorithms try to find a disparity value *d* which will yield a correspondent image location on the second (right) image (x_R, y_R) [1]. If camera pair images are rectified [22], the following condition holds: $x_R=x_L$, $d=y_R-y_L$. As a rule there are two approaches available for the matching: area based and feature based [23]. Area based algorithms are typically further classified on the local and global optimization algorithms [24]. OpenCV has an implementation of both local and global approach, which theoretical details are beyond of this paper scope. However, we do compare OpenCV performance with the state of the art algorithms implementations using the well known Middlebury Stereo Evaluation test bed [25]. It is a globally recognized site which has an image data base utilized for the algorithm performance test in many, many published work. One of the most popular test images are perhaps Tsukuba, Venus, Cones and Teddy (see [25] for more details). The ground truth values for the pixels disparities are available also from [25]. Table I and Table II represents, for the mentioned images, a percentage of relative errors rates for the computed disparity where an estimated disparity is considered correct if it is within a ground truth disparity ±1. In terms of global methods (Table I), OpenCV demonstrates somewhat worse results. Still, we note two crucial things. Global methods are known to assume a number of threshold parameters and frequently require some experimenting before optimal ones are found for a specific image. This is what was basically done in referred work against which we compared OpenCV. Therefore, a parameter set for one image may perform quite badly for another. On the other hand, we have here used OpenCV implementation using its default parameters, i.e. the ones chosen automatically as best ones from the code itself. We feel this is a fair manner of testing since many practical users would like to use OpenCV functions with as few experiments and adjustments as possible. Thus, form this perspective we can say that OpenCV performs quite well. In terms of local methods (Table II) OpenCV implementation is side by side with the best known methods, again without any a priory manual parameter adjustment for some specific image.

Table I Performance in terms of accuracy for top ranking methods, as evaluated by Middlebury stereo site [25], which employ a significant additional processing in the form of (global) optimization and/or color segmentation.

Method	Tskuba	Venus	Teddy	Cones

VI. CONCLUSION

The purpose of this paper is to quickly make a reader familiar with OpenCV basics without having to go through lengthy reference manuals and books. Given the total number of OpenCV implemented algorithms (~thousands) and possible challenges in Computer Vision in general, it was normally beyond the scope of this paper to go in depth about every possible OpenCV detail. Actually, some more advanced topics, such as the use of GPU accelerated codes, were not even mentioned. However, the paper did present many basic and popular Computer Vision algorithms, along with many key references for an interested reader to pursue further details. The shown content should raise the interest and strengthen the awareness about OpenCV among the graduate students and researchers in image processing and computer vision areas as a whole, who may not to be

aware of it yet and/or its practical users. It is important to note that OpenCV is considered by many to be side by side with many commercial image processing packages, and yet it is an open source tool. Furthermore thanks to the fact that OpenCV keeps evolving is an additional guarantee that it will advance research in vision and promote the development of rich, vision-based CPU-intensive applications.

Abstract - Defect pixels are a common occurrence in digital camera sensors, either resulting from the manufacturing process or developing over time. Though low in quantity, they are very noticeable and can destroy the perceived quality of the images. This paper presents a method for detection and correction of defect pixels in images generated by a Bayer mosaic image sensor. We propose an online and adaptive algorithm, which analyzes the images retrieved from a Bayer array sensor on a pixel by pixel basis. We consider the values of adjacent pixels to determine if the current pixel is possibly defective, which is either confirmed or refuted by repeating the analysis in subsequent frames. For the confirmed defective pixels, interpolation is performed to restore the image quality. The algorithm is implemented on a FPGA logic device, suitable for very high frequency operation required to correct defect pixels in images produced by high definition (HD) cameras.

I. Introduction

Camera sensors can develop defect pixels either during manufacturing process or in the field during the sensor usage. In manufacturing this may be due to the non uniform temperature in the production unit, impurities in the chemicals used during the sensor etching, etc [1]. These pixels are usually detected in production process and sensor is either discarded or defect pixel locations are written to one-time-programmable memory. A greater problem is the appearance of defect pixels developed in the field. It is shown [2] that four different DSLR cameras have developed from 7 to 14 defect pixels. The tested cameras were 0.5 to 5 years old and the growth rate of defect pixels was estimated to be about 0.082 defects per 1000 pictures per megapixel. These were professional and semiprofessional digital cameras and one can presume that growth rate in consumer digital cameras is even larger.

Pixel defects can usually be divided into three main groups: stuck high (hot), stuck low (dead or cold) or noisy. Stuck high pixels are those which produce output values much higher than expected from its surrounding neighbors, even until the point of saturation of the value. Stuck low pixels are pixels whose values are much lower than expected from neighboring pixels and the value may even be completely low. Noisy pixels are the pixels whose values are different by a certain degree than its surrounding neighborhood, usually by a small factor [3], [12], [13].

Although camera sensors develop small number of defective pixels, they are very noticeable and must be dealt with. Algorithms for detecting and correcting defect pixels are typically implemented in either ASIC or a digital computer. Implementation in the ASIC technology is generally very expensive, especially for small series, while a standard digital computer may not have enough performance to successfully perform the task. A new and popular solution for small device series and a custom camera pipeline is to use an FPGA logic device. An FPGA can be used as a platform for the implementation of an entire camera pipeline (defect pixel correction, demosaicing, auto white balance, auto exposure, gamma correction etc.).

In this paper we present an algorithm and core for defect pixel correction. Previous methods are shown in Section II. Algorithm description is provided in Section III. Section IV outlines implementation in VHDL and synthesis for FPGA. Our algorithm is compared to a different state-of-the-art algorithm. The results and discussion can be found in Section V.

II. Related work

Common approaches to correction of defect pixels can roughly be divided into two groups: online and offline methods.

A. Offline methods

Offline methods use analysis on many consecutive images to get locations of defective pixels. This is usually done as a calibration process either with external equipment or with circuitry integrated directly on the sensor chip. The commonly used method consists of a simple repetition of images and observation of which pixels remain unchanged. The resulting list of pixels (defective pixel map) is stored in a non-volatile, one time programmable memory which is then integrated into the sensor chip to allow correction of the defected pixels before outputting the result [3]. Such factory based methods do not permit detection of defections created

during the field use of the sensor. In one of the popular offline methods, the sensor is illuminated with a flat image (image with no variations in light intensity). This image must be sufficient to cause all of the pixels to be saturated. A pixel is deemed defective if it is not saturated [4]. Fossum, Doudoumopolous and Panicacci propose a system for detection of malfunctioning bad areas of the sensory imaging parts directly by testing of individual sensory elements (sensels) in the chip system with reference voltages and currents [5]. Those methods also require special calibration procedures so that the defect pixels can be stored into the defect pixel map. An imaging system would require sensors to undergo maintenance, and would not be able to correct defects immediately after their appearance which makes it far from ideal for field usage.

B. Online methods

Online algorithms are another group of methods of defect pixel correction. These methods allow the continuous detection and correction of pixels without the need for storing of pixels in memory. Each frame is processed independently and the defect pixels are determined for each new cluster of pixels. Application of online methods is limited by the need of small size and high speed calculations to allow the stream of data to be processed in time. Online algorithms usually compare a pixel with its neighboring pixels to determine possible defectiveness. The defective pixel is typically immediately corrected. Conventional online approach suggests using frame buffers for detection and storing of the defect pixel locations, and using horizontal neighbor interpolation for correction [6], [7]. Those methods are tailored for simple and efficient implementation in hardware.

Modern online methods use numerous image lines and relatively complex calculations. In a particular adaptive pixel defect correction [8], gradient is calculated on 7x7 image patch. Defective pixels are detected based on the gradient and image edge vectors. Defective pixels are finally interpolated using linear interpolation. Other approaches [9] and [10] use a system with two threshold values, minimum and maximum, determined from an array of surrounding pixels. A pixel is established to be defective if its value is above maximum or below minimum. Kakarala [11] suggests combined demosaicing and defective pixel correction using a threshold calculated from the gradient of neighborhood pixels in different color planes.

Nagatsuma [12] proposes a detection and correction algorithm which consists of a two-step cycle of determining the defect pixels. In the first step it calculates the presumed threshold for the neighborhood of targeted pixel within its color plane, while in the second step it applies that threshold on the targeted pixel. When detected, a defective pixel is corrected by interpolating its value. All above mentioned online algorithms have in common that they do not depend on past images to determine defectiveness of pixels. Only the current frame is analyzed in order to keep simplicity and effectiveness of the algorithm, which additionally removes the requirement for the use of memory elements. It does however introduce a certain degree of error in finding defective pixels, alongside the possible detection of false positives.

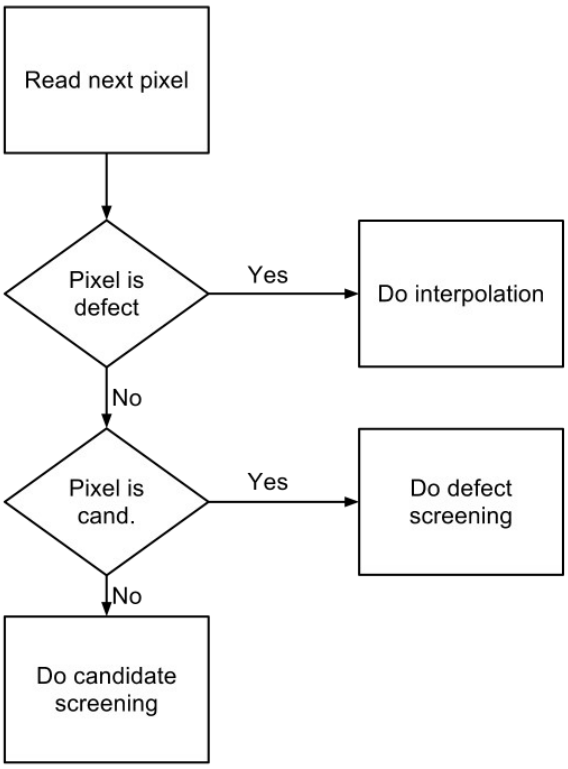

Figure 1. Flowchart diagram of algorithm

III. ALGORITHM

The described algorithm is specifically designed to be implemented in FPGA logic devices, and used in conjunction with a Bayer mosaic image sensor. As the input from the camera sensor it receives a standard video horizontal scan. The data is input pixel by pixel, along with typical control signals (horizontal and vertical sync and pixel valid). Incoming pixels are stored into a line buffer which outputs the last five lines received from the image sensor in parallel. Its output is a Bayer mosaic image with corrected pixels.

This algorithm is both online and offline. The most recent image is analyzed to find possible defects, and a sequence of images is analyzed to confirm the defectiveness of the possible defects.

A. Interpolation

The coordinates of defective pixels are stored into a separate memory which is checked for every incoming pixel to determine if it is already pronounced as defective. Interpolation is performed only when a pixel is confirmed to be defective. A rather straightforward interpolation technique is used; the value of the central pixel in a 5x5 grid is replaced with the average value of the adjacent pixels of the same color in the grid. This method is determined to be performing in a satisfying

fashion and it is time and space saving because of its use of only one multiplication element.

B. Detection

The detection algorithm can be divided into two main functional parts. In the first part, called "candidate screening", the value of the current pixel is compared to the average value of the adjacent pixels. If the difference of the two values is greater than a defined threshold, the current pixel is proclaimed possibly defective and its value and coordinates are saved into the candidate memory. The second part of algorithm, called "defect screening", confirms or refutes the defectiveness of candidates declared in the first part. When the current pixel is declared a candidate, its current value is compared to its previous value, which is read from the candidate memory. If the absolute difference of values exceeds a configurable threshold, then the time parameter of the candidate is incremented and saved back into candidate memory. The value of the time parameter indicates the number of frames in which the value of the pixel did not change more than a value set by a pre-defined threshold. If the pixel remains unchanged in subsequent frames sufficiently for the time parameter to exceed a certain threshold ("time threshold"), the pixel is confirmed defective and saved into the defect pixel memory. It is possible (depending on parameter values) that a correct pixel is confirmed defective and saved into the defect memory. This event is called a "false positive" detection. To prevent false positive detections from affecting image quality, the defect pixels are periodically removed from the defect memory and saved into the candidate memory for rechecking.

IV. Implementation

The described algorithm is implemented in VHDL hardware description language, and is targeted for a FPGA logic device. Simulation and synthesis of the implementation is performed using the Lattice Semiconductor Diamond design software suite, version 1.3.

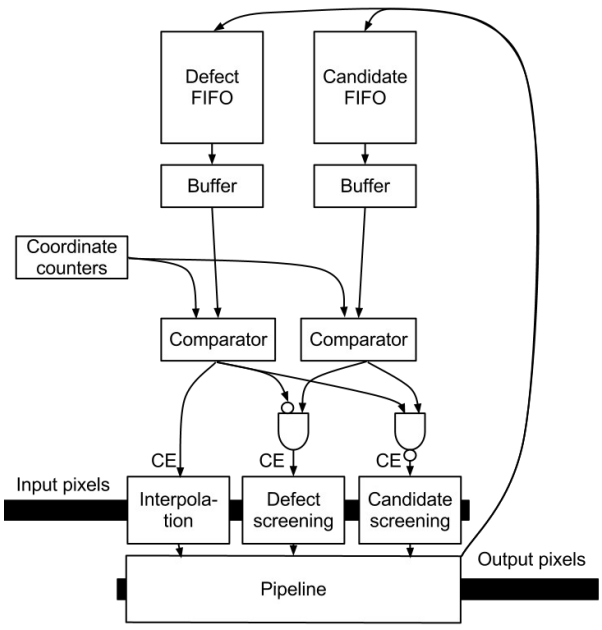

Figure 2. Functional architecture of core

Table I. Synthesis report

FPGA Family	Registers	LUT4s	EBR	Max. freq	Logic levels
ECP2	1018	1332	8	108 MHz	6

A. Line buffer

The line buffer is a component which stores the incoming sensor pixels into a temporary memory, filled line by line. After receiving five lines of pixels of a single frame, the buffer outputs the pixels in such way that the next stage of the pipeline receives the lines of the image at the same time together with correctly delayed and aligned control signals.

B. Core algorithm

The core algorithm architecture is shown in Fig 2. The coordinate counters count the current pixel coordinates and update their value every clock cycle in order for their values to be compared with the pixel coordinates read from either the defect or candidate memory, both implemented as a FIFO queue. When a pixel is read from sensor it goes through three stages.

First, the pixel is checked if it was already declared defective, in which case the interpolation is performed. When the current coordinates are equal to the coordinates read from the defect FIFO, the current pixel is considered defective and the interpolation process is enabled. The FIFO structure removes the need to iterate and search through the complete list of defective pixels, because the output of the list is sequentially ordered. During the interpolation, the adjacent pixels of the same color are input into the calculation pipeline, the output of which is the interpolated value.

If the pixel had not been found defective and consequently not interpolated, it enters the second stage of algorithm, which is the detection part. In the detection part, the current coordinates are verified to be equal to the coordinates read from the candidate FIFO memory which contains the lists of possible, but yet unconfirmed defective pixels. If the coordinates match, defect screening is enabled. In defect screening, the previous value and the time parameter of the pixel is loaded from the candidate FIFO. If the difference between the current pixel value and the previous value does not exceed a defined threshold (to cancel effects of noise), the value of the time parameter is incremented. When the value of the time parameter exceeds the threshold, the pixel is declared defective and saved into defect FIFO memory.

Finally, if the current coordinates are not equal to the coordinates read from the defect FIFO or the candidate FIFO, a third stage called candidate screening is performed. The pixel is analyzed and compared with the average of the neighboring pixels of the same color. If the difference is greater than a certain threshold, the pixel is declared a candidate for defection and stored into the candidate FIFO memory.

Figure 3. First row, original images, second row, demosiaced without correction, third row, corrected and demosaiced

The pipeline consists of a ladder adder and a multiplier, combined with additional control logic. Both the interpolation and candidate screening stages use the same pipeline resources (the adders and multiplier), conserving space in the implementation process.

C. Synthesis

Synthesis is performed for Lattice Semiconductor ECP2 FPGA and is performed in Lattice Diamond software. The synthesis report generated for the implementation is given in Table 1. One can see that the implementation satisfies the general standards or the FPGA style circuitry.

V. Experimental results

The core was simulated with specifically designed video sink and source behavioral components. The input of the video source component was an image [14] with additive noise, and the output of the sink component was a file containing the resulting images. The density of defective pixels in the input was approximately 0,5 %. We compared our algorithm with an online algorithm [10]. Images were first converted into a Bayer pattern format and then corrected with both algorithms. At last, demosacing was done using the Matlab function "demosaic". The results were compared with CPSNR quality measure. Although our primary concern in design was the area and speed optimization for implementation in an FPGA device, our algorithm has shown good performance. It outperforms Li and Randhawa [10] algorithm by approximately one decibel in every

Figure 4. Example of defect pixel correction, from up to down, from left to right : original, converted into Bayer patern, with 0.5 % defect pixel density, demosaiced with defectivce pixels, defects corrected, defect corrected and demosaiced

TABLE II. CPSNR (dB) IMAGE QUALITY RESULTS FOR 0.5% DEFECT PIXEL DENSITY

Image	Li and Randhawa	**Proposed algorithm**	Without correction
Fig. 3, left	29.77	**30.73**	26.11
Fig. 3, center	34.34	**35.82**	17.73
Fig. 3, right	31.63	**32.64**	27.88

performed test. It is important to emphasize that [10] is an online algorithm and does not use the previous images to find a defect. It is also more computationally complex; for interpolation and detection it applies cubic interpolation from four directions and employs a 10x10 pixel neighborhood, compared to the 5x5 neighborhood of the described algorithm.

VI. CONLUSION

In this paper we propose a combination of an offline and online method for defective pixel correction. The method uses the current image to find the possibly defective pixels, which are confirmed or discarded by repeating the analysis on successive frames. We find that this type of algorithm performs well on FPGA logic device because of the availability of small embedded memory and logic resources. The method was compared to a different defective pixel correction method. The comparison results show that our method was able to remove defective pixels with minimal color artifacts while producing images with superior CPSNR image quality measure.

ACKNOWLEDGMENT

Special thanks go to the company Mikroprojekt d.o.o. under which guidance this paper was created, and which provided the necessary tools and equipment for the research. Luka Mijatović and Hrvoje Dean also thank Professor Hrvoje Džapo of University of Zagreb for his encouragement and assistance in creating this paper, as well as advices on technical issues.

Emocionalni dizajn: važnost emocija u procesu izrade web stranica

Ivan Grbavac *, Nikola Marangunić ** i Andrina Granić **

Prirodoslovno-matematički fakultet/Odjel za informatiku, Sveučilište u Splitu

Sažetak - U radu se ističe važnost emocija u procesu dizajna web stranica. Općenito prilikom dizajniranja bilo kojeg predmeta, važno je dizajn obogatiti onim „nečim“ što će kod korisnika izazvati pozitivne emocije. Naime, proizvod koji budi pozitivne emocije, pruža užitak korištenja te pozitivna iskustva korisnika. Važno je da dizajn svojim izgledom i pruženom funkcionalnošću implicira pozitivna iskustva koja se reflektiraju na korisnikovu ponovnu želju za korištenjem istog ili nekog sličnog proizvoda. Biološki gledano, dizajnom je važno zadovoljiti tri nivoa procesuiranja u mozgu: visceralni, bihevioralni i misaoni. Tek se u tom slučaju dizajn smatra uspješnim. U prvom dijelu rada opisuju se tri nivoa procesuiranja, njihova veza s emocijama kao i bitni aspekti o kojima prilikom dizajniranja treba voditi računa. U drugom dijelu rada donose se rezultati istraživanja u kojem se uspoređuju dvije web stranice sličnog sadržaja i funkcionalnosti, ali bitno različitog dizajna. Pretpostavka je da će web stranica koja je „ljepše“ dizajnirana kod korisnika (iskusnih i manje iskusnih) izazvati više pozitivnih emocija, te da će ujedno biti procijenjena lakšom i jednostavnijom za korištenje. Statističkom obradom dobivenih rezultata pokazalo se da su pretpostake istraživanja potvrđene, te da se rezultati mogu pripisati utjecaju boljeg ili lošijeg dizajna na procjenu emocionalnog odgovora korisnika kao i utjecaja na procjenu funkcionalnosti zadanih web stranica.

I. UVOD

U današnje vrijeme važnost dobrog i uspješnog dizajna zaista je velika. Sve što nas okružuje rezultat je procesa dizajniranja, bilo da se radi o ručnom satu, šalici iz koje pijemo ili stolici na kojoj sjedimo. Dizajn tih predmeta treba biti takav da ih ljudi sa zadovoljstvom uvijek iznova koriste. Koliko je važno da nam predmeti koji nas okružuju pružaju pozitivno iskustvo korištenja, isto toliko je važno i da web stranice koje svakodnevno posjećujemo budu u skladu s našim očekivanjima što se tiče njihovog izgleda ali i upotrebljivosti (eng. usability). Upotrebljivost kazuje koliko se lako i jednostavno koristi funkcionalnost određenog proizvoda ili usluge. Termin se odnosi podjednako na korisnička sučelja operacijskih sustava, računalnih programa ali i web stranica (eng. web usability) koje susrećemo na osobnim računalima ili mobilnim telefonima [1].

Internet je danas kao medij vodeći način komunikacije i pružanja informacija, a upravo web stranice su ogledalo područja koje predstavljaju, bilo da je riječ o ozbiljnom poslu ili zabavi. Svaki dizajn, pa tako i onaj web stranica, mora kod korisnika izazvati pozitivne emocije jer one uzrokuju pozitivno raspoloženje. Uspješan i dobar dizajn ne smije frustrirati, nego stvarati osjećaj ugode i zadovoljstvo (ponovnog) korištenja.

Pojam emocionalnog dizajna podrazumijeva udovoljavanje korisnikovim potrebama i izazivanje pozitivnog iskustva korištenja, što vodi ka dizajnu koji je usmjeren korisniku.

Prvi dio rada govori o emocijama i tri nivoa procesuiranja u mozgu koja su zaslužna za sve naše aktivnosti. Prema tome, u cilju realizacije uspješnog dizajna, važno je da proces dizajniranja obuhvati sva tri nivoa procesuiranja. Norman [2] napominje da korisnici prilikom korištenja dva predmeta koji imaju iste mogućnosti i podjednaku funkcionalnost, uvijek smatraju funkcionalnijim onaj predmet koji je „ljepše“ dizajniran i čiji im se izgled više sviđa.

Događa li se isto i s web stranicama? Odgovor na navedeno pitanje pokušat će se pružiti u drugom dijelu rada gdje se opisuje istraživanje u kojem se uspoređuju dvije različito dizajnirane web stranice sličnog sadržaja i funkcionalnosti. Pretpostavlja se da će korisnici smatrati funkcionalnijom i lakšom za korištenje onu web stranicu koja je „ljepše“ dizajnirana jer će ona kod njih izazvati više pozitivnih emocija. U radu se iznose rezultati empirijskog istraživanja i njihova interpretacija.

II. UTJECAJ POZITIVNIH I NEGATIVNIH EMOCIJA

Emocije su stanja koja određuju čovjekovo raspoloženje. One traju dosta kratko, za razliku od raspoloženja koje traje puno duže. Pozitivne emocije uzrokuju pozitivno raspoloženje, a negativne emocije negativno, te je upravo zbog toga važno da ljudi češće dožive neku pozitivnu emociju [3].

Emocije i raspoloženja, koji su prisutni kod ljudi u određenim trenucima, zapravo određuju njihovo ponašanje i njihovu razinu tolerancije prema drugim ljudima ili prema određenim predmetima s kojima stupaju u interakciju. Dok se osoba osjeća ugodno puno učinkovitije razmišlja i razmatra mnogo više alternativnih rješenja problema koji se nalazi pred njom. Dobro

raspoložene osobe su mnogo kreativnije i motiviranije od osoba lošeg raspoloženja. Za razliku od osoba koje su dobro raspoložene, one nešto lošijeg raspoloženja pri rješavanju određenog problema koncentriraju se isključivo na taj problem; žele ga što prije riješiti, ne žele dodatno razmišljati i potražiti možda neka bolja ili prikladnija rješenja. Na naše raspoloženje utječe mnogo različitih faktora, od vremenskih uvjeta, hrane, dužine spavanja, okruženja, pa sve do predmeta koje svakodnevno koristimo. Ukoliko su predmeti loše dizajnirani, kod osoba će izazvati negativne emocije, osoba će se loše osjećati te neće biti zainteresirana za njihovo korištenje.

Slično je i sa web stranicama. Danas je jako veliki broj korisnika interneta, te ukoliko „otvore“ loše dizajniranu web stranicu vjerojatno je neće htjeti koristiti jer će je doživjeti kao kompliciranu i tešku za korištenje. Međutim, možda konkretna web stranica samo „nije lijepa“. Važno je istaknuti da će osoba/korisnik isti proizvod s istom funkcionalnošću percipirati kao puno bolji ako je on privlačniji izgledom i ako kod korisnika budi pozitivne emocije. Zbog toga je bitno da se svakim dizajnom izazove neka pozitivna emocija kako bi privukla korisnika na prvi pogled.

III. DIZAJNIRANJE ZA TRI NIVOA PROCESUIRANJA

Reeve [4] navodi da u ljudskom mozgu postoje tri različita nivoa procesuiranja informacija iz kojih proizlaze neke ljudske osobine: visceralni, bihevioralni i misaoni nivo.

Na *visceralnom nivou* procesuiranja informacija u mozgu se događaju stvari koje čovjek radi nesvjesno. Mozak je na visceralnoj razini najjednostavniji i veoma je osjetljiv. Visceralni nivo nije u stanju razmišljati, zaključivati i uspoređivati različite situacije. Ljudi prirodno vole kada im je toplo, vole jednostavne i skladne melodije, milovanje, maženje, nasmijana lica, tople boje, dok ne vole visine, iznenadne glasne zvukove, ekstremnu vrućinu i hladnoću. Kada čovjek percipira nešto kao lijepo, to dolazi izravno iz visceralnog dijela mozga. Upravo zbog toga važno je dizajnirati predmete na način da oni privuku korisnika na prvi pogled. Načela dobrog visceralnog dizajna su: korištenje svijetlih, visoko zasićenih boja, oblih linija, lijepih zvukova i slično. Ako dizajn sadrži ove komponente on će za korisnika biti atraktivan i privlačan, a dizajniranje za visceralni nivo uspješno.

Sljedeći nivo procesuiranja informacija u mozgu je *bihevioralni nivo*. Taj nivo je također nesvjestan i on je zaslužan za neke stvari koje svakodnevno radimo a da o njima ne razmišljamo. Kada pričamo ne razmišljamo o pokretu naših usana, kada hodamo ne razmišljamo o tome kako podižemo noge, kada jedemo ne razmišljamo kako žvačemo hranu. Bihevioralni dizajn se zapravo odnosi na sve ono što ima veze s upotrebom određenog predmeta. Mi želimo da nešto funkcionira na ispravan način i ne želimo razmišljati kako se upotrebljava. Jednostavno predmet bi sam trebao upućivati na svoje korištenje. Za dobar bihevioralni dizajn ne igra ulogu izgled predmeta, važno je da je predmet jednostavan i lak za korištenje (upotrebljiv), razumljiv i funkcionalan. Svaki proizvod mora ispunjavati svrhu onoga za što je namijenjen, inače bihevioralni dizajn takvog predmeta nije uspio. Primjerice, ako sat ne pokazuje točno vrijeme, tada nije važno to što je estetski privlačan. Zakazale su njegove glavne funkcije i ne može se smatrati uspješnim.

Misaoni nivo procesuiranja informacija je jedini kojega smo svjesni. Kod odluke o kupnji nekog predmeta razmišljamo o tome koliko nam je potreban, a ne samo da li nam se sviđa. To znači da smo donijeli misaonu odluku. Za misaoni dizajn je najvažniji sveukupan dojam koji na njega ostavlja proizvod ali veoma važnu ulogu igra i pozitivno iskustvo korištenja. Važno je da nas nešto privuče na prvi pogled, da je funkcionalno i upotrebljivo, te da imamo pozitivna iskustva korištenja takvog ili sličnog proizvoda. Tek ako neki predmet zadovoljava sve ove komponente možemo reći da je njegov misaoni dizajn uspio. Na misaonoj razini manji nedostaci jednog aspekta mogu biti zanemareni ako je korisnik u cjelini zadovoljan s proizvodom.

U skladu s navedenim, za dobar dizajn je veoma važno da budu zadovoljeni visceralni, bihevioralni ali i misaoni nivo procesuiranja u mozgu.

IV. ISTRAŽIVANJE UTJECAJA EMOCIONALNOG DIZAJNA NA KORISNIKE WEB STRANICA

Cilj provedenog istraživanja bio je ispitati kako različit dizajn dvije web stranice utječe na procjenu emocionalnog stanja i osobnog zadovoljstva skupine korisnika. Pretpostavka je da će modernije dizajnirana web stranica od strane korisnika biti procjenjivana ljepšom ali i jednostavnijom za korištenje. Pokazati će se na koji način dizajn dviju web stranica sličnog sadržaja može kod korisnika izazvati različite emocije, osjećaj veće lakoće korištenja i pružanja bogatije funkcionalnosti one web stranice koja je ljepše dizajnirana. U istraživanju su se koristila dva upitnika; Upitnik emocionalnog odgovora i Upitnik osobnog zadovoljstva. Ispitivane su razlike u procjenama dviju web stranica različitog dizajna od strane dvije skupine korisnika (iskusnih i neiskusnih u korištenju interneta) kao i korelacija odgovora dobivenih iz dvaju korištenih upitnika.

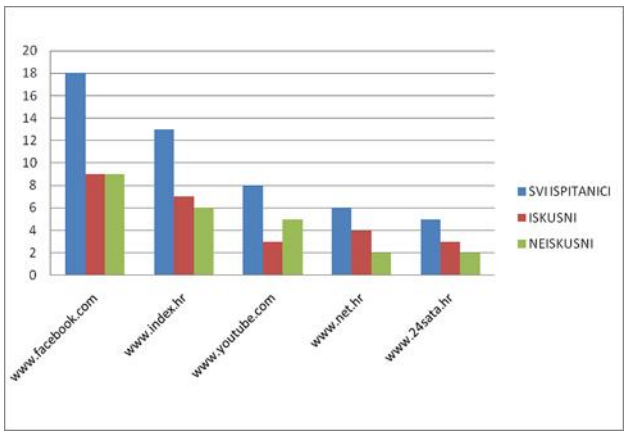
A. Sudionici

U istraživanju je sudjelovalo 30 korisnika, od toga 16 muškaraca (53%) i 14 žena (47%), starosti od 17 do 56 godina. Najviše korisnika bilo je od 21 do 24 godine starosti, njih čak 43%. Stupanj obrazovanja sudionika kretao se od osnovne škole (6%) do fakultetske razine (17%) s tim da je najviše sudionika bilo sa završenom srednjom školom (77%). Sudionici su odabrani slučajnim odabirom kako bi reprezentirali široki raspon populacije, tj. kako bi proporcionalno bili zastupljeni po spolu, dobi, stupnju obrazovanja i iskustvu u korištenju računala i interneta. Ispitalo se također koliko su vremena sudionici koristili računalo i internet u proteklih godinu dana. Polovica sudionika koristila je računalo 8 sati tjedno dok je njih čak 40% koristilo internet samo nekoliko sati mjesečno. Na osnovu ovih rezultata korisnici su bili podijeljeni u dvije skupine: iskusni i neiskusni. Iskusnima su se smatrali svi oni korisnici koji su koristili internet

najmanje 2 do 4 sata dnevno, a neiskusnima oni koji su ga koristili manje od 2 sata dnevno ili je njihovo korištenje interneta obuhvaćalo samo pojedine stranice. Usporedbom stranica koje su korisnici navodili da najčešće posjećuju, dobiveno je da je www.facebook.com najposjećenija stranica (60% korisnika) kojeg slijedi www.index.hr (43% korisnika). Slika 1 prikazuje i ostale najposjećenije web stranice od strane sudionika.

Velika većina iskusnih korisnika koristi računalo više od 8 sati tjedno (njih čak 93%), dok ga neiskusni korisnici najviše koriste 4 do 6 sati tjedno. Korištenje računala detaljnije je prikazano u Tablici 1.

Velika razlika vidljiva je između dvije skupine i u korištenju interneta. Čak 53% iskusnih korisnika koristi internet više od 4 sata na dan. Kod neiskusnih korisnika situacija je suprotna, njih 80% koristi internet samo nekoliko sati mjesečno (vidi Tablicu 2).



Slika 1. Najposjećenije web stranice od strane sudionika

TABLICA I. TJEDNO KORIŠTENJE RAČUNALA ISKUSNIH I NEISKUSNIH KORISNIKA

Korisnici	**< 2 sata**	**2-4 sata**	**4-6 sati**	**6-8 sati**	**> 8 sati**
neiskusni	20%	13%	40%	20%	7%
iskusni	0%	0%	1%	6%	93%

TABLICA II. KORIŠTENJE INTERNETA ISKUSNIH I NEISKUSNIH KORISNIKA

Korisnici	**< 2 sata na mjesec**	**> 2 sata na mjesec**	**< 2 sata dnevno**	**2-4 sata dnevno**	**> 4 sata dnevno**
neiskusni	7%	80%	13%	0%	0%
iskusni	0%	0%	0%	47%	53%

B. Instrumenti

Sudionici istraživanja su koristili dvije web stranice. Jedna web stranica je bila *www.narodni.hr* (vidi Sliku 2). Ona je bila primjer dobrog, „emocijama obojenog" dizajna, te se pretpostavilo da će je kao takvu korisnici procijeniti boljom i lakšom za korištenje.

Druga web stranica je bila *www.radiodalmacija.hr* (Slika 3). S obzirom da navedena stranica nije jasno i nedvosmisleno ukazivala na svoju namjenu, da je pretrpana s raznorodnim sadržajem, te da kao takva nije dobro dizajnirana, pretpostavilo se da će je i sudionici procijeniti lošije nego prethodnu stranicu.

Za procjene dviju navedenih web stranica korištena su dva upitnika. *Upitnik emocionalnog zadovoljstva* sastoji se od 8 tvrdnji, pri čemu svaka tvrdnja odgovara određenoj emociji: tuzi, zabrinutosti, iritaciji, očekivanju, iznenađenju, povjerenju, sviđanju i sreći [5]. Upitnik se sastoji od slijedećih tvrdnji:

1) Izgled web-stranice pobuđuje u meni osjećaj tuge.
2) Osjećam se zabrinuto dok promatram web-stranicu.
3) Pojedini dijelovi web-stranice posebno su mi iritantni.
4) Web-stranica je ispunila moja očekivanja.
5) Web-stranica je bila pravo iznenađenje za mene.
6) Promatrajući web-stranicu u meni se javlja povjerenje u ono što ona prezentira.
7) Sviđa mi se dizajn web-stranice.
8) Web-stranica pobuđuje u meni osjećaj zadovoljstva.

Razinu slaganja s navedenom tvrdnjom, korisnici su morali procijeniti na Likertovoj skali od 5 stupnjeva, gdje ocjena 1 označava da se uopće ne slažu, 3 da se niti slažu niti ne slažu, a 5 da se u potpunosti slažu s navedenom tvrdnjom. Ovim upitnikom se procjenjuje koje emocije pojedina web stranica izaziva kod korisnika.

Slika 2. Prikaz web stranice www.narodni.hr

Slika 3. Prikaz web stranice www.radiodalmacija.hr

Drugi korišteni upitnik bio je *Upitnik osobnog zadovoljstva* [6] koji sadrži 10 tvrdnji koje se odnose na korisnikovu percepciju funkcionalnosti i lakoće korištenja web stranice. Upitnik se sastoji od slijedećih tvrdnji:

1) Želio/željela bih često koristiti web-stranicu.
2) Web-stranica mi se čini nepotrebno kompleksna.
3) Web-stranicom se lako koristiti.
4) Mislim da bi mi trebala tehnička pomoć da bi mogao/mogla koristiti web-stranicu.
5) Razne funkcije web-stranice su u njoj dobro integrirane.
6) Mislim da ima previše nedosljednosti na web-stranici.
7) Čini mi se da većina ljudi može vrlo brzo naučiti koristiti web-stranicu.
8) Mislim da je web-stranica vrlo nezgrapna za korištenje.
9) Tijekom rada osjećao/osjećala sam da je web-stranica pouzdana za korištenje.
10) Prije boljeg korištenja web-stranice morao/morala bih još dosta naučiti o njoj.

Procjena se također određuje na Likertovoj skali od 5 stupnjeva. Ovaj upitnik pokazuje koliko se korisnicima pojedina web stranica čini funkcionalnom i lakom za korištenje te koliko su korisnici zadovoljni dizajnom stranice.

C. Postupak

Provedeno istraživanje sastojalo se od tri dijela. Korisnicima je dana uputa za sudjelovanje u kojoj su detaljno opisana sva tri dijela istraživanja. Upute, kao i odgovarajući upitnici su korisnicima poslani elektroničkom poštom (e-mailom). U prvom dijelu korisnici su ispunili ulazni upitnik pomoću kojeg su dobiveni njihovi opći podaci na temelju kojih su podijeljeni u dvije grupe (iskusne i neiskusne u korištenju interneta).

U drugom dijelu korisnicima je dana uputa da posjete web stranice radio Dalmacije [7] i Narodnog radija [8] te da kroz 5 do 10 minuta pregledaju sadržaj navedene stranice. Polovica korisnika je prvo pregledavala web stranicu *www.radiodalmacija.hr*, pa onda *www.narodni.hr*, a druga polovica obrnuto. Rotacije su provedene da bi se utjecaj slučajnih faktora podjednako podijelio na obje eksperimentalne situacije. Nakon pregledavanja određene web stranice, sudionici su trebali popuniti Upitnik emocionalnog odgovora i Upitnik osobnog zadovoljstva u kojem su procijenili kakav emocionalni utisak ostavlja zadana web stranica, koliko je laka za korištenje i koliko je prilagođena korisniku. Sudionici su svoje rezultate poslali e-mailom natrag eksperimentatoru koji je rezultate zabilježio u odgovarajući protokol.

D. Rezultati

Primjenom adekvatnih statističkih postupaka u skladu s navedenim ciljem istraživanja, dobiveni su sljedeći rezultati. Rezultati deskriptivne statistike koja uključuje aritmetičke sredine (M) i standardne devijacije (SD) rezultata dvije skupine korisnika iz dva upitnika (emocionalnog odgovora – emo, te subjektivnog zadovoljstva – sus), zajedno s brojem korisnika (N) prikazana je u Tablici 3.

Nadalje, Tablica 4 prikazuje aritmetičke sredine (M) i standardne devijacije (SD) rezultata u cijelom uzorku korisnika (N). U cilju ispitivanja razlike u procjenama dviju stranica od strane dvije skupine korisnika (iskusnih i neiskusnih u korištenju interneta), primjenom t-testa za nezavisne uzorke (Tablica 5) dobivena je statistički značajna razlika u procjenama stranice www.radiodalmacija.hr u upitniku emocionalnog odgovora ($t = 3,79$; $df = 28$; $p < 0,01$). To znači da je navedena stranica kod neiskusnih korisnika izazvala više pozitivnih emocija nego kod iskusnih (jer su imali veći rezultat u Upitniku emocionalnog odgovora od iskusnih, što je vidljivo iz Tablice 3). S obzirom da se pretpostavilo da će bolje dizajnirana stranica kod korisnika izazvati pozitivnije emocije, navedeni se rezultat može objasniti time da korisnici koji manje koriste internet nemaju jednaku referentnu točku (subjektivnu vrijednost ili pojam dobre/loše web stranice temeljem koje rade usporedbu) kao iskusni korisnici.

TABLICA III. DESKRIPTIVNA STATISTIKA REZULTATA ZA DVIJE SKUPINE KORISNIKA

Upitnik	Korisnici	N	M	SD
emoDalm	iskusni	15	10,40	4,733
	neiskusni	15	17,33	5,273
emoNar	iskusni	15	25,67	2,743
	neiskusni	15	22,73	4,758
susDalm	iskusni	15	40,83	16,894
	neiskusni	15	59,50	16,207
susNar	iskusni	15	83,33	9,433
	neiskusni	15	70,33	14,816

Navedeno je rezultat manjka iskustva u korištenju različitih internetskih sadržaja, tj. poznavanja manjeg broja internetskih stranica s kojima mogu usporediti zadanu stranicu. Rezultat toga može biti dobivena značajna razlika u procjenama iskusnih i neiskusnih korisnika.

Nadalje, dobivena je statistički značajna razlika u procjenama stranice www.narodni.hr u upitniku emocionalnog odgovora od strane iskusnih i neiskusnih korisnika ($t = 2,07$; $df = 28$; $p < 0,05$). To znači da je web stranica izazvala pozitivnije emocije kod iskusnih korisnika nego kod neiskusnih, što je u skladu s očekivanjima. Naime, s obzirom na veće iskustvo, oni koji više koriste internet jasnije su doživjeli razliku u dizajnu i u skladu s time iskazali pozitivniji emocionalni odgovor, za razliku od onih neiskusnih kod kojih je ta razlika manje izražena. Drugi korišteni upitnik bio je Upitnik subjektivnog zadovoljstva korisnika. Primjenom t-testa za nezavisne uzorke dobivena je statistički značajna razlika u procjenama dviju stranica. Web stranica www.radiodalmacija.hr je procijenjena funkcionalnijom i lakšom za korištenje od strane neiskusnih korisnika nego od strane iskusnih ($t = 3,09$; $df = 28$; $p < 0,01$). S druge strane, web stranica www.narodni.hr je procijenjena učinkovitijom od strane iskusnih korisnika ($t = 2,87$; $df = 28$; $p < 0,01$).

Promatrajući prosječne vrijednosti rezultata korisnika vidljivo je da neiskusni korisnici imaju manju razliku u procjenama učinkovitosti i funkcionalnosti dvije stranice. Manjak iskustva rezultira time da im je potrebna približno jednaka pomoć u korištenju obje stranice. Nadalje, jednako im je važna prilagođenost i jasnoća upotrebe stranice bez obzira na dizajn. S druge strane, iskusni korisnici su imali veću razliku u procjenama dviju web stranica, s tim da su stranicu www.narodni.hr procjenjivali funkcionalnijom i prilagođenijom korisniku.

Pretpostavlja se da je dizajn stranice kod iskusnih korisnika više utjecao na njihove procjene. Poznavanje velikog broja internetskih stranica omogućilo im je lakšu usporedbu sa zadanom stranicom. Bez obzira što im je kod većine internetskih sadržaja potrebna mala pomoć, mogli su jasno odrediti za što bi im, da imaju manje iskustva, trebala veća pomoć. Sve navedeno rezultiralo je jasnijim razlikama u procjenama iskusnih i neiskusnih korisnika.

U cilju ispitivanja razlike u procjenama dvije web stranice za cijeli uzorak korisnika primjenom t-testa za zavisne uzorke (Tablica 6) dobivena je statistički značajna razlika u upitniku emocionalnog odgovora ($t = 7,69$; $df = 29$; $p < 0,01$). Korisnici su u prosjeku procjenjivali web stranicu www.narodni.hr kao onu koja kod njih izaziva pozitivniji emocionalni odgovor od web stranice www.radiodalmacija.hr. Primjenom istog statističkog postupka, dobivena je statistički značajna razlika u procjenama dviju web stranica u Upitniku subjektivnog zadovoljstva korisnika. Naime, korisnici su u prosjeku bili zadovoljniji, odnosno procjenjivali su funkcionalnijom web stranicu www.narodni.hr. Dobiveni rezultati su u skladu s očekivanjima da će bolji dizajn izazivati pozitivnije emocije te biti procijenjen učinkovitijim i prikladnijim.

U cilju ispitivanja veličine povezanosti procjena korisnika u dvama upitnicima korišten je Pearsonov koeficijent korelacije te je dobivena statistički značajna povezanost kako za web stranicu radio Dalmacije ($r = 0,60$; $df = 28$; $p < 0,01$), tako i za Narodni radio ($r = 0,38$; $df = 28$; $p < 0,05$). Korisnici su, dakle, funkcionalniju i prilagođeniju stranicu procjenjivali i kao onu koja izaziva pozitivnije emocije.

Na temelju dobivenih rezultata vidljivo je da su pretpostavke istraživanja potvrđene te da se rezultati mogu pripisati utjecaju boljeg ili lošijeg dizajna na procjene emocionalnih odgovora korisnika kao i utjecaja na procjenu funkcionalnosti zadanih web stranica.

V. ZAKLJUČAK

Prilikom dizajniranja web stranica važno je uzeti u obzir tri nivoa procesuiranja informacija u mozgu koja su zaslužna za sve što radimo. Radi se o visceralnom, bihevioralnom i misaonom nivou. Osim što web stranica mora biti funkcionalna, te ispunjavati svoju svrhu, ona mora sadržavati i one elemente dizajna koje ljudi intuitivno i prirodno vole, te koji kod njih izazivaju pozitivne emocije. Ako izgled web stranice privuče korisnika na prvi pogled, te ako njezino korištenje rezultira korisnikovim pozitivnim iskustvom, tada će je zasigurno ponovno poželjeti koristiti. Visceralni dizajn je ključan, budući je provedeno empirijsko istraživanje pokazalo da ona web stranica koja ljepše izgleda i koja kod korisnika budi pozitivne emocije, ostavlja dojam bogatije funkcionalnosti, te lakoće i jednostavnosti korištenja. U slučajevima kada web stranica udovoljava najvažnijim zahtjevima dobrog dizajna (lijep izgled, funkcionalnost i pozitivno iskustvo korištenja) može se kazati da je njezin dizajn u potpunosti „uspio“. U navedenom kontekstu evidentna je važnost emocionalnog dizajna. Naime, područje emocionalnog dizajna bavi se istraživanjima koja, u cilju udovoljavanja korisnikovim potrebama i izazivanju pozitivnog iskustva korištenja, vode ka korisniku-usmjerenom dizajnu.

ZAHVALA

Istraživanje čiji su rezultati prezentirani u radu realizirano je okviru znanstveno-istraživačkog projekta 177-0361994-1998 *Upotrebljivost i prilagodljivost sučelja inteligentnih autorskih ljuski* financiranom od strane Ministarstva znanosti, tehnologije i sporta Republike Hrvatske.

smarkovi@fesb.hr, jmusic@fesb.hr, mirjana@fesb.hr

Abstract - While uncalibrated image based visual servoing is traditionally used in robotics, in the paper we propose its application on the problem of automatic control of balancing beam with two thrusters, one at each end. Classical approach to the problem is application of PID regulator or LQR (linear quadratic regulator). Our proposal has several important advantages over these classical approaches: knowledge of exact mathematical model is not needed, no issues with observability and controllability, no need for regulator parameter identification, no calibration is needed. In the paper we propose application of Broyden and population algorithms within image based visual servoing framework for control and stabilization of balancing beam and test it in simulation environment. Obtained results are analyzed and compared to results obtained with PID. Several improvements and possible future research directions are proposed and discussed.

I. INTRODUCTION

Visual servoing in robotics [1,2,3,4,5] has received a lot of attention in the last decade since associated theory has reached a level of development where excellent results can be achieved even for most complex systems/problems. Particularly interesting category of visual servoing is uncalibrated model free image-based visual servoing due to its low cost and simplicity [4,5]. Here, the term *image-based* signifies that error signal is not defined in 3D world coordinate frame but rather directly in image space/plane while term *model free* indicates that no kinematic or dynamic model of the system under consideration is needed. The final term, *uncalibrated* indicates that no camera calibration is needed. Specified advantages, which are possible only with estimation of total Jacobian matrix (which includes both the image and system Jacobian matrix), significantly facilitate practical applications of visual servoing. Nevertheless, real-time Jacobian matrix estimation is usually extremely difficult and computationally demanding task due to matrix nonlinearity, high dimensionality, time-varying elements and ill-conditioning [5,6]. Thus, several characteristic approaches to the problem, usually based on optimization techniques with least square methods, were developed. These include Broyden method [1,2,3,4,5,6,7], Piepmeier method [3,5], Kalman filter and more recently particle filter [5] and population-based method [4,5]. Due to iterative nature of the algorithms only knowledge of Jacobian matrix from the previous time instance as well as current measurements (i.e. image coordinates and system states) is required to estimate Jacobian matrix for current time instance. It should be noted that calibration and/or dynamic model would improve accuracy of visual servoing but at the same time some of previously mentioned desired properties (guarantying simplicity and low-cost) would be lost. All of previously mentioned characteristics of uncalibrated model free image-based visual servoing make it appropriate for application in automatic control of number of systems which include some of the classical control problems. One of them is beam and ball problem with its nonlinear and unstable open-loop characteristics. Since the ball cannot be controlled directly but only by means of beam rotation this problem is often considered benchmark problem [8,9] for testing of control algorithms and is thus appropriate and important model for teaching control engineering. Thus it is surprising that only several such applications can be found in available literature [8,9,10] with the remark that in some of them [9] computer vision was only used as a sensor for some other control scheme with calibration for added precision. Classical approach to solving this problem is to either mathematically model the system and then linearize it around working point applying linear quadratic regulator (LQR) [11] or using PID regulator [8] and associated parameter estimation algorithms which do not guaranty optimality of the solution in respect to measurement error. Additional control schemes like fuzzy control [12], state observers [13] and phase lead compensation [14] are also used.

Since the developed control scheme and visual servoing algorithms are intended for education purposes, in the paper a simplified and slightly altered control problem is considered in order to be more accessible to undergraduate control engineering students. The problem is now formulated as stabilization of balancing beam (without the ball) in the desired orientation which can be static or dynamically changing. The beam was built with two thrusters (one at the each end of the beam) as can be seen in figure 1. Thrusters act as actuators and provide necessary forces to achieve control effect. But before the control scheme can be implemented, simulation trials should be carried out in order to verify applicability of visual servoing to the control problem as well as test for various situations in a secure environment and controlled conditions. This is the main focus of the paper. We note that because of very simple plant it is not expected that visual servoing will produce better results when compared to classical approaches. Full advantages of visual servoing can be expected for more complex systems. The remainder of the article is organized as follows.

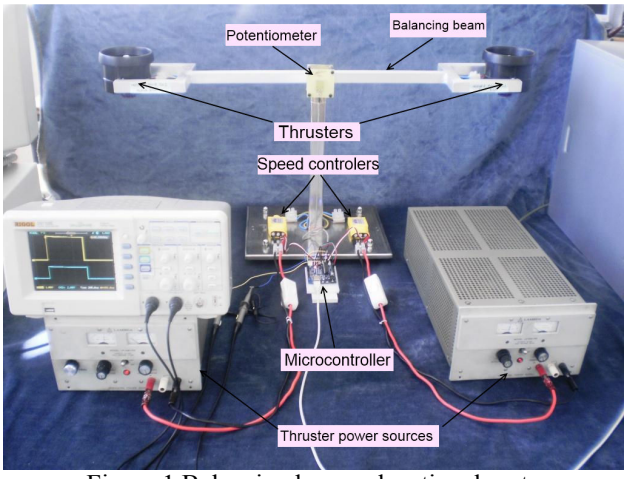

Figure 1 Balancing beam educational system

Section 2 describes Jacobian matrix estimation algorithms as well as standard PID regulator. Section 3 presents developed simulation model using object oriented approach with Modelica and Dymola. Section 4 summarizes and discusses obtained simulation results while section 5 contains conclusions and directions for possible future research and implementation.

II. ALGORITHMS

The visual servoing problem can be solved using quasi-Newton methods [4,6], which consider at each iteration the linear model of form:

$$L_k(x, B_k) = F(x_k) + B_k(x - x_k) \tag{1}$$

where $F(x_k)$ is a continuously differentiable function, and $B(x\text{-}x_k)$ is the function estimate at previous instance.

A. Broyden algorithm

Broyden [7] proposed the most successful class of quasi-Newton methods based on the secant equations, imposing the linear model to exactly match the nonlinear function at iterates x_k and $x_{(k+1)}$ i.e.

$$\begin{aligned} L_{k+1}(x_k) &= F(x_k) \\ L_{k+1}(x_{k+1}) &= F(x_{k+1}) \end{aligned} \tag{2}$$

Subtracting these two equations and defining the difference as $y_k = F(x_{k+1}) - F(x_k)$ and $s_k = x_{k+1} - x_k$ as the step representing the difference between two consecutive points at which the function has been observed, we obtain the classical secant equation

$$y_k = B_{k+1} s_k \tag{3}$$

If the dimension *n* of y_k is strictly greater than 1, there are an infinite number of matrices satisfying (3). The "*least-change secant update*", proposed by Broyden, includes following steps

- minimize $\|B_{k+1} - B_k\|$
- use constraint expressed with (3)

which, after some mathematical manipulations, lead to

$$B_{k+1} = B_k + \eta \frac{(y_k - B_k s_k)}{s_k^T s_k} s_k^T \tag{4}$$

Parameter $\eta \in \langle 0,1 \rangle$ is introduced to control Jacobian update rate and to prevent singularity of matrix B_i [4]. Broyden method has proved successful in number of applications but is sensitive to noise [1,2,3,4,5,6].

B. Population-based algorithm

Recently, "population based" generalization of Broyden update, has been recommended [4,5] in order to improve robustness and stability where at each iteration, the finite population of iterates $x_0 \ldots . x_{k+1}$ is maintained. The method also belongs to quasi-Newton framework, with B_{k+1} computed as

$$B_{k+1} = \arg\min_J \left(\sum_{i=0}^{k} \left\| \omega_{k+1}^i F(x_i) - \omega_{k+1}^i L_{k+1}(x_i, J) \right\|_2^2 + \right. \\ \left. + \left\| \Gamma J - \Gamma B_{k+1}^0 \right\|_F^2 \right) \tag{5}$$

where $B_{k+1}^0 \in \Re^{n \times n}$ is an a priori approximation of B_{k+1}. The role of the second term in equation (5) is to overcome the under-determination of the least-square problem based on the first term and also to control the numerical stability of the method. The matrix contains weights associated with the arbitrary term B_{k+1}^0, and the weights $\omega_{k+1}^i \in \Re^+$ are associated with the previous iterates. Equation (5) can be rewritten in matrix form as

$$B_{k+1} = \arg\min_J \left\| \left(J(S_{k+1} I_{n \times m}) \begin{pmatrix} \Omega & 0_{k \times n} \\ 0_{k \times k} & \Gamma \end{pmatrix} - \begin{pmatrix} Y_{k+1} & B_{k+1}^0 \end{pmatrix} \begin{pmatrix} \Omega & 0 \\ 0 & \Gamma \end{pmatrix} \right\|_F^2 \tag{6}$$

where $\Omega \in \Re^{k \times 1}$ is a diagonal matrix with weights ω_{k+1}^i on the diagonal for i=0,…,k. Now the following update equation is obtained

$$B_{k+1} = B_{k+1}^0 + (Y_{k+1} - B_{k+1}^0 S_{k+1}) \Omega^2 S_{k+1}^T (\Gamma^2 + S_{k+1} \Omega^2 S_{k+1}^T)^{-1} \tag{7}$$

where $Y_{k+1} = (y_k, y_{k-1}, \ldots, y_0)$ and $s_{k+1} = (s_k, s_{k-1}, \ldots, s_0)$. Update equation (7) exhibits good properties for $B_{k+1}^0 = B_{k+1}$ and its local convergence has been proved [4]. The weight ω_{k+1}^i captures the relative importance of each iteration in the population, and the matrix Γ captures the importance of the arbitrary terms defined by B_{k+1}^0 for the identification of the linear model. The weights have to be finite and Γ must be such that $\Gamma^2 + S_{k+1} \Omega^2 S_{k+1}^T$ is safely positive definite. To ensure this, we have found that it should be defined trough simulations as a small positive constant [4].

Population method exhibit faster convergence and a greater robustness than quasi-Newton methods (e.g. Broyden).

C. PID regulator

PID controller is one of the oldest control schemes. It is used to achieve desired system response in terms of steady state error, overshoot, time of overshoot and/or rise time. Its effects on measurement error (difference between desired and actual beam angle value) are threefold: proportional (P), integration (I) and derivational (D). It should be noted that in the paper the term PID refers to ideal parallel realization. Ideal means that D term is ideal which cannot be realized practically due to noise issues, while parallel refers to the fact that angle error signal is simultaneously fed to all three terms and the final output is their summation. The equation describing behavior of PID used in the paper is

$$u(t) = K_p e(t) + K_I \int e(t)dt + K_D \frac{de(t)}{dt} \qquad (8)$$

where u(t) is PID output, e(t) is error signal, K_p proportional constant, K_I integration constant and K_D derivative constant. There are several methods which help in determining these constants (ultimate cycle method, Cohen-Coon method and Ziegler-Nichols method) but none of them can guarantee optimal selection of parameters thus human intervention is needed based on the knowledge of effects which individual PID terms have on system response. In the paper we adopted the following approach: proportional term was increase to the level that steady state error was small enough while at the same time keeping system stable. Then integration term was corrected to further eliminate the error and decrease raise time. Finally, derivative constant is corrected to reduce and/or eliminate overshoot and settling time.

III. SIMULATION

A. Modelica-Dymola model of balancing beam

Modelica-Dymola modeling and simulation environment was chosen for this experiment because it does not require knowledge of mathematical model to build a simulation model. This can be achieved because Modelica is object oriented language used for acasual modeling, as opposed to some other widely used simulation environments (like Simulink) that use casual modeling. In acasual modeling state equations are written in neutral form without consideration for computational order, while in casual modeling computational order needs to be considered. Commercially available programming environment based on Modelica language which enables simple and easy graphical user interface based programming is Dymola from Dynasim. Dymola offers wide range of features such as: acasual modeling, reusability, hierarchical structure of models, symbolic and numerical solving of system equations, algebraic loop solving, hybrid system modeling, 3D animation of modeled system, etc. Important feature of Dymola is Dymola-Simulink interface. The DymolaBlock in Simulink is shielded around an S-function MEX block i.e. the interface to the C-code generated by Dymola for the Modelica model. This enables us to take advantage of both programming environments: modeling in Modelica-Dymola without the need to develop mathematical model and simulation in Simulink where full potential of Matlab can be used.

Designed Modelica-Dymola model of balancing beam can be seen in figure 2 where world icon is not a part of physical model, but rather the requirement of Modelica. BodyBox1 and BodyBox2 present the beam, while BodyBox3 is necessary for connecting these parts to revolute joint which is in turn connected to BodyBox4 which presents the vertical pillar on which the beam system is suspended. In order to know the system state at given time instance two sensors were added to the model (although it should be noted that the same result can be achieved with only one sensor). This is illustrated in figure 3. Upper sensor measures relative angle of the balancing beam in respect to horizontal, while lower sensor measures angular velocity. These quantities present balancing beam model output. It should be noted that same quantities are readily available in real world system through potentiometer measurements which is attached to the revolute bearing (figure 1).

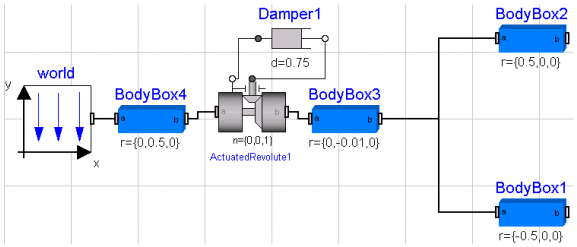

Figure 2 Modelica-Dymola balancing beam model

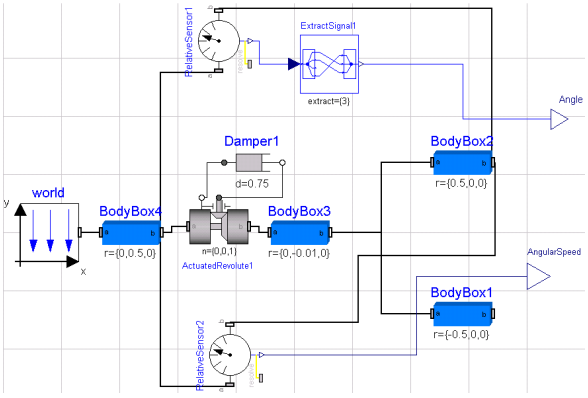

Figure 3 Modelica-Dymola model with angle and angular rate sensors

Since system under consideration has thrusters as actuators for realization of desired control actions it was necessary to include resulting force into the model as is shown in figure 4.

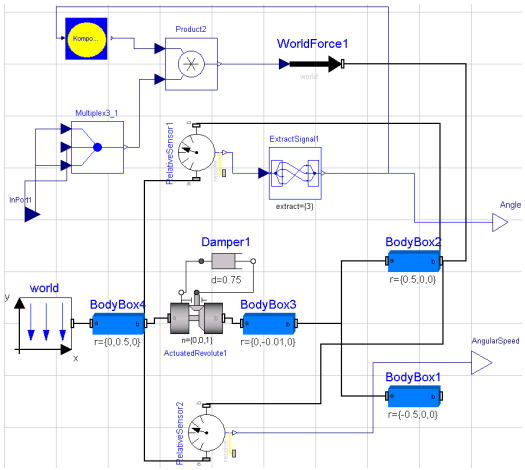

Figure 4 Complete Modelica-Dymola model of balancing beam system

In simulation force acting on only one end of the beam was used since it could obtain both the positive and negative values. In real world system (figure 1) two thrusters (one mounted at each end) are used since they can produce only positive forces. Necessary blocks were added in order to ensure that force acting on the beam is always perpendicular to it so to correspond to real world situation (top of figure 4). In practical application there exists a nonlinear relation between force exerted by thrusters and propeller which needs to be considered. In simulations we assumed that the force control loop is achieved. Also camera model shown in figure 5 was added so that desired angle (input to the model) was firstly transformed into x and y coordinates of beam's end. In the figure this is represented by yellow square. Note that two such squares are present in the figure: upper one executes described operation for actual beam position while the lower one executes it for desired position. This is also the case for all other squares in the figure. Next, red square transforms beam's end coordinates into camera coordinate frame using homogenous matrix. Translation of 1.5 m along z axis and constant rotation of 15° around x axis is assumed for this step.

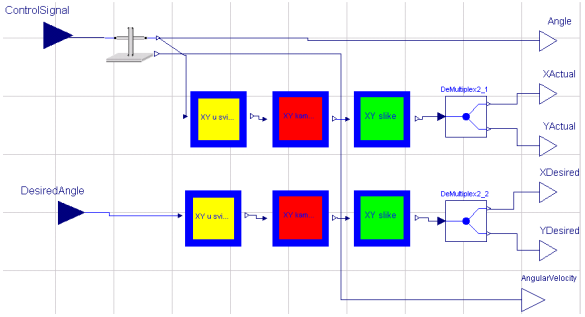

Figure 5 Inclusion of camera model in Modelica-Dymola

Finally, green square transforms coordinates from camera coordinate frame into image plane coordinate frame using known camera parameters such as focus (data from real camera were used). Final model thus has 2 inputs (desired angle and force control signal) and 6 outputs (current angle and angular velocity, desired and actual x and y coordinates in image plane) as can be seen in figure 5.

B. Simulink model for control application

Modelica-Dymola programming environment offers possibility of exporting built model in the Simulink-Matlab environment where more in-depth analysis and data presentation can be achieved. Thus Simulink model with imported Dymola-Modelica was constructed as can be seen from figure 6. The figure contains five distinct parts highlighted by different colors. Blue part named "*Desired angle*" contains source blocks which produce static or dynamic angle trajectory depending on manual switch position. This angle defined in degrees is then transformed by simple gain into radians which are required for proper functioning of other simulation blocks. Red square labeled "*Dymola model*" contains imported Modelica-Dymola model described in preceding section and presented in figure 5. Green markings on figure 6 highlight visual servoing part of simulation. Here, feature vector containing current angle value as well as current and desired x and y image plane coordinates is fed via multiplexer into two blocks (Level-2 M file S-Functions), one containing Broyden algorithm code and other population-based method. Although both M-files are executed simultaneously during simulation only one output selected with multiport switch is forwarded to proceeding blocks for calculation. Output from selected M-file is estimated Jacobian matrix (in our case it is actually a 2x1 vector). This estimation is inverted and multiplied with error vector containing difference between actual and desired image plane coordinates of balancing beam end. Output from this part of simulation is (required) angular velocity for next time step. Required angular velocity is then fed into yellow part of simulation scheme which is responsible for transforming it into required force acting on balancing beam. In order to achieve this in simulation, simplified mathematical model based on Euler-Lagrange mechanics was derived

$$F = \frac{m \cdot g \cdot d}{l} \sin\phi - \frac{I}{l}\alpha \qquad (9)$$

where m is total beam mass (without thrusters), g gravity constant, d distance of beam's center of mass from rotation axis, l half the length of the beam, I is beam's moment of inertia, ϕ current angle in respect to Earth surface, α is angular acceleration and F applied force. Since angular acceleration is not readily available from the model we used the following equation

$$\alpha = \frac{\dot{\phi}_2 - \dot{\phi}_1}{\Delta t} \qquad (10)$$

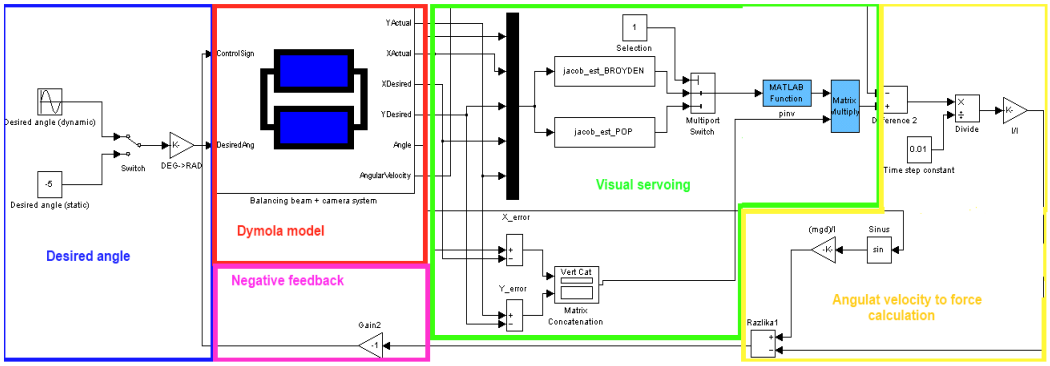

Figure 6 Complete Simulink simulation scheme for visual servoing

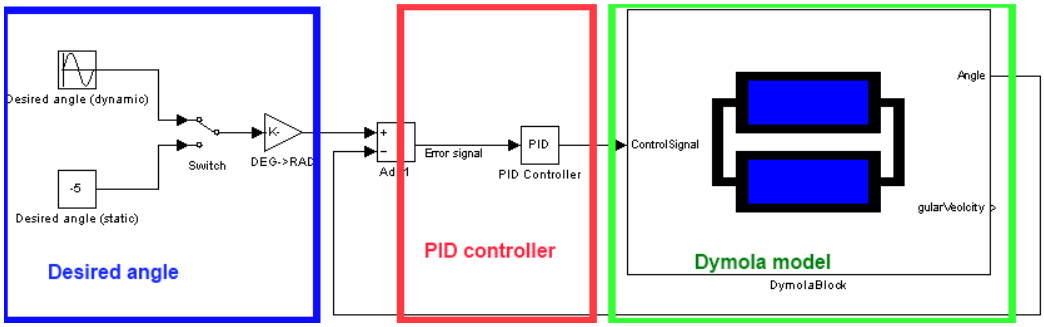

Figure 7 Complete Simulink simulation scheme for PID regulator

where Δt is simulation time step, $\dot{\phi}_2$ is desired angular velocity (output from visual servoing) and $\dot{\phi}_1$ is current angular velocity (Modelica-Dymola output). It should be noted that in real application simplified mathematical model might not be sufficient but system identification can be applied. Generated force signal is inverted in purple square because of negative feedback and if needed is multiplied with constant gain (P controller).

For PID controller the same scheme could not be used due to different Modelica-Dymola model (no need for camera model) and no need for angular velocity/force conversion. Simulation scheme for PID regulator is depicted in figure 7 containing three main parts. Part in blue square is the same as in case of visual servoing while red square highlights ideal parallel PID regulator with angle error as input and force control signal as output. Green square pertains to Modelica-Dymola model which is different from visual servoing case and is depicted in figure 4. Please note that angular velocity output still exists in Dymola model but is not used in simulation.

IV. RESULTS AND DISCUSSION

Simulation experiments were achieved for two cases: static and dynamic target position. For each of the two cases Broyden and population algorithms were applied as well as standard PID controller. Broyden method parameter η was set to 1, while population size was set to 50. PID regulator was tuned so that its response was quick: K_p was set to 30, K_I to 3 and K_D to 5. It should be noted that in visual servoing case desired target position was defined as coordinates in camera image plane while for PID this could not be done (since no camera is required) thus target position was defined as balancing beam angle. For comparison reasons angle results will be presented for both the static and dynamic case. Comparison of obtained results for static case are presented in figure 8.

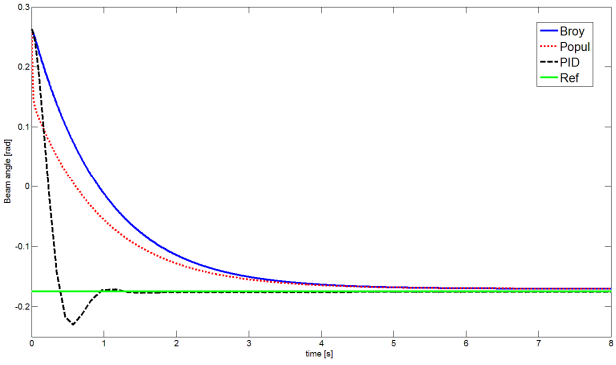

Figure 8 Simulation results for static target

As can be seen from the figure all of the methods successfully converge to desired target position (-10°) from the initial position (15°). Visual servoing methods are somewhat slower in their response with 0.235° steady state error for Broyden and 0.246° for population method but with no overshoot. On the other hand, PID response is faster with somewhat smaller steady state error (0.057°) when compared to visual servoing methods but has overshot of 12.4% which might present a problem for certain applications. PID regulator could have been tuned differently to have slower response with smaller overshoot or even leaving out the D term which would altogether eliminate the overshot (but it would then be PI controller). This might be a valid approach in practical

implementation since D term cannot be implemented in ideal form and is sensitive to noise prompting the use of filtering algorithms such as low-pass filtering or median filtering. Figure 9 presents the dynamic target case. From the figure conclusion that PID performs better than visual servoing methods can be made.

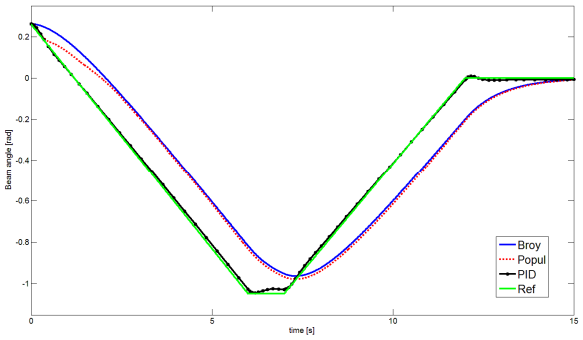

Figure 9 Simulation results for dynamic target

But that would be only a partial conclusion. As was concluded for static case PID controller exhibits faster response time thus it better (or more quickly) tracks the target orientation then visual servoing. Also because of quick response and overshoot in static case it exhibits more sensitive behavior to abrupt changes in desired angle signal. If figure is analyzed in more detail it can be seen that visual servoing methods also track target with good agreement but with almost constant lag. This again is in agreement with static case were asymptotical response was observed. Improved response might be obtained if instead of simple gain (P term) in feedback loop (purple square in figure 6) some other block (PD term) was used or speed of desired trajectory lowered. Better insight into the issue can be provided by figure 10 which presents same results but in camera image plane. In the figure time is implicitly included thus lag induced error is not visible. Visual servoing methods performance now looks better since it tracks desired trajectory very closely so that they can be hardly distinguished (for better visibility additional markers with colors corresponding to appropriate methods are included: x for population and dot for referent signal).

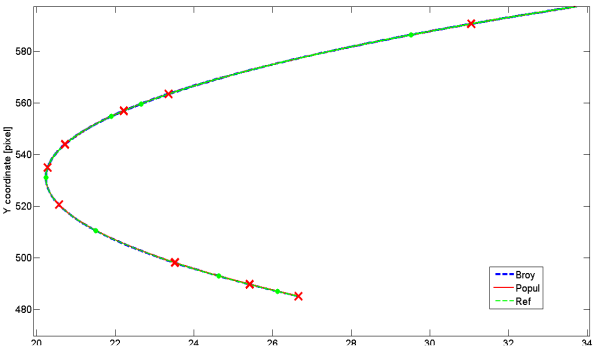

Figure 10 Enlarge portion of image plane for dynamic target tracking in visual servoing

It should be noted that some of other standard approaches like LQR might exhibit significantly degraded performance then PID since they rely on model linearized around working point which is constantly changing. Also although Broyden and population algorithm results are very similar with population method having slightly better response but with significantly higher computational requirements we expect significantly larger degradation of Broyden performance (due to noise sensitivity) then population based method in practical application as was observed in [4].

V. CONCLUSIONS

In the paper application of model free uncalibrated visual servoing was applied to a problem of balancing beam stabilization and trajectory following. PID controller was used for comparison purposes as standard solution. Obtained results validated the proposed approach with good agreement with desired signals both in static and dynamic case (where certain amount of constant lag was present). In static case errors were as follows: 0.057^0 for PID regulator, 0.235^o for Broyden algorithm and 0.246^o for population based method. Future development of the approach might include application of other estimation algorithms like Kalman and Particle filter in the visual servoing loop especially for more complicated systems under automatic control, application to real world balancing beam and extension to ball and beam problem.

Abstract – **Building scalable applications or improving scalability of existing ones is important and not an easy task to perform. Although every application is unique, they can be categorized in several classes. Similar solutions may be applied when scaling applications which belong to the same class. This paper covers five different techniques for scaling read-heavy web services delivering small amount of data for each request. The techniques analyzed include database scaling, horizontal and vertical architectural scaling, as well as two caching techniques [2]. The service is Ruby on Rails [6] based, but similar approaches may be applied when using other technologies. Advantages and disadvantages of each method are presented, as well as several suggestions related to further research on this topic.**

I. Introduction

Web services are encountering large challenges with growth of Internet. Technically, the most demanding task is to build a complete system which can handle tens or even hundreds of thousands requests per minute. This encompasses building a system as a whole: including hardware, operating systems, application code and database system. The system built must offer reliable and fast service for end users. Words "reliable" and "fast" highly depend of the application type. Some applications may not require fast response (complex data mining and reporting) or high reliability (personal blog); however, it does not mean it should be completely neglected. One weak spot can mean weakness of an entire system, and cause system malfunction.

Many applications are encountering scalability issues, representing a problem with no unique solution. As a result, every system must be built according to specific requirements, yet some guidelines must be given for every application class. The system architecture can be completely changed in order to make an application scalable. Most systems are built using combination of techniques analyzed in this paper.

Provided results analysis may be taken in consideration when building similar read-heavy applications. They could save significant amount of time when trying to find optimal working environment for some applications. Also, they can provide good basis for further research by fine tuning the parameters mentioned in the later chapters.

II. Benefits From Scaling

Many web applications have large underlying infrastructure enabling them to satisfy above mentioned requirements. Most of them have large clusters or even distributed ones with complex custom load balancers [8]. However, system as a whole must be built so it can use raw computing power given by cluster nodes. That means that network infrastructure and operating system or systems must provide good basis for further system enhancements [10]. Companies must decide whether to use horizontal or vertical scaling. Most of them choose hybrid variant that includes the use of both. The extent in which each method is used depends on application requirements.

While vertical scaling implies that existing machine is upgraded or a new one bought, horizontal scaling means that more machines are added and the job is split between them. It is harder to program because communication and synchronization over the network must be considered.

Horizontal scaling is always better when it comes to reliability [3]. Horizontal scaling is suitable for applications in which communication would not significantly increase execution time. Vertical scaling is preferred from software point of view, due to easier programming of such machine whose performance is not affected by other factors, such as network bandwidth and latency. The problem with this approach is that a single machine means single point of failure, and if it fails, the whole system fails [12]. Different mechanisms can be built in this kind of system to prevent failure, but it is the risk of failure is still higher in comparison to horizontal scaling.

From reliability point of view, horizontal scaling is often better because more machines are doing the same work and they can be configured in such manner to provide redundancy, so there are more than one replica of data and software. If one point fails, work can be distributed so that the end users do not notice the failure. These systems are fairly complex and need to provide mechanisms for load balancing for work distribution and mechanisms for data replication. As such, they represent a problem. There is also a need to minimize communication between the systems so it does not take many resources in comparison to raw processing power provided by machines on the system.

III. Scaling Scenarios

This document covers five scaling scenarios. Scaling is performed on web service for courseware application. The goal of the application is to provide multiple elements which facilitate learning and administration activities. The core of the application are report generators which give necessary data for faculty administration. The most read-heavy reports are based on several students' scoring elements. The report

contains about 3000 queries to the database, and most of them are very small and return about 10 bytes of data. Service is RESTful [16], and average size of HTTP body of the response is 15-20 bytes. Whole database size is around 10 MB. Experiments are performed on MySQL database [11] with few different configurations. In standalone and replication configurations, MySQL uses InnoDB [15] storage engine, and in cluster configuration [1] it uses NDB [14] storage engine. While web service provides the data by accessing database and serializing it to JSON [13] format, front-end of the application takes the data from that service, and displays data to end user.

Two machine types were used to measure performance of this kind of application. First machine is Intel Pentium IV working on 2 GHz with 1486 MB of free main memory. It also has 7200 rpm hard drive with 32 MB buffer size. Second machine has Intel Core 2 Duo E8500 processor working on 3.16 GHz with 4 GB of main memory and the same hard drive as previous machine. All systems had Ubuntu Linux 11.10 installed.

Database is given 100 MB of main memory to store its buffer. Database is relatively small in comparison to this buffer size, so it is an assumption that MySQL database engine will store entire database in RAM, decreasing access time.

Client machine is located in the same network. It is used to simulate one or more user requests for the web page where report is generated. Each user makes two requests, which makes about 6000 service requests per user. Users request the page at random time, but all within 30 seconds from the beginning of the experiment. Number of users is gradually increased, so performance increase/decrease can be measured depending on their number.

Several approaches to horizontal scaling are presented. They are trying to achieve better load distribution across multiple machines. Vertical scaling approach is relatively simple: more powerful machine means that more work is done in less time.

All computers were interconnected by 100Mbps Ethernet network.

Front-end load balancer [4] performance experiments were performed on Pentium IV machines. In single machine experiment back-end, front-end and the database were located on a single machine and there was no need for network communication. Front-end uses data provided by back-end and the back-end communicates with the database to get data it needs to operate.

This scenario involves multiple machines where front-end is located on a single machine and there were several back-ends. A hybrid (master-master-slave) database replication was set. There were two master nodes as well as multiple slave nodes. This service is not write-heavy, so two master nodes are used to accomplish fault tolerant system. Slave nodes were used only for read operations. One back-end software was placed on each slave machine, so the back-end has local access to the database. Front-end has done the load balancing between these back-ends. Number of back-ends was gradually increased to demonstrate its influence on system performance. Only read operations were taken to consideration; however, when the number of machines was increased the number of transactions also increased, and replication speed was getting slower, making it a point which needs to be considered when building a real system. This is shown in Figure 1.

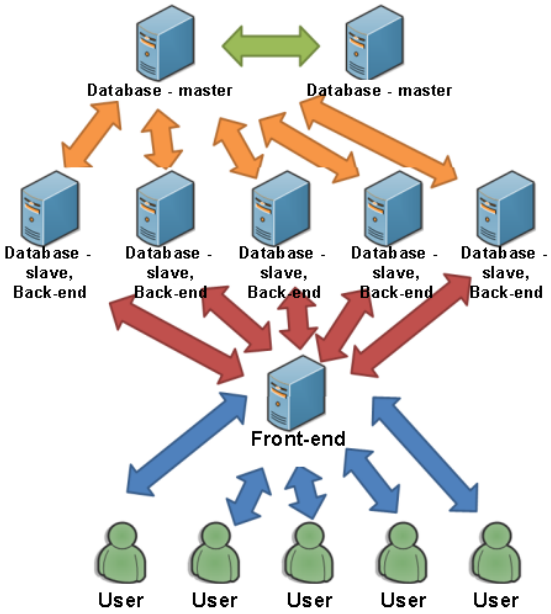

Figure 1: Front-end load balancer scenario configuration

Database load balancer experiment scenario (Figure 2.) was performed on the same machines, but with only one front-end and only one back-end. Back-end accesses load balanced MySQL cluster, and then serializes the data. Number of nodes in MySQL cluster was increased and performance experiments were done accordingly.

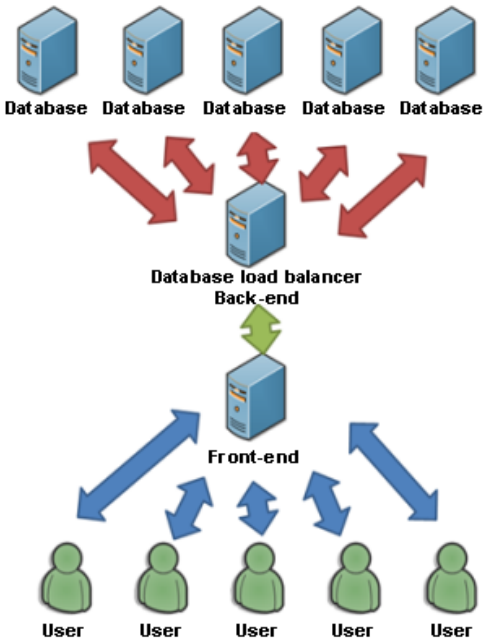

Figure 2: Database load balancer scenario configuration

Vertical scaling experiment scenario includes running application on a more powerful machine. Database, back-end and front-end were placed on the same machine.

Disk caching and memory caching experiment included caching mechanisms. Both experiments were done on Intel Core 2 Duo machine. Disk experiment was done by caching the back-end responses on the disk, and memory used caching the same responses in main memory. These caching mechanisms were provided by Ruby on Rails framework [5] and its ActiveRecord component [9].

In every case, a timeout was set to 600s, so every response time longer than 600s was aborted and it was not shown on the diagram.

IV. Experimental Results and Analysis

A. Single machine experiment

Single machine experiment results were taken as reference point for all others. Response times with one, two and three users were less than the timeout, while others were not, so they were not showed on the diagram. Results are shown in Figure 3.

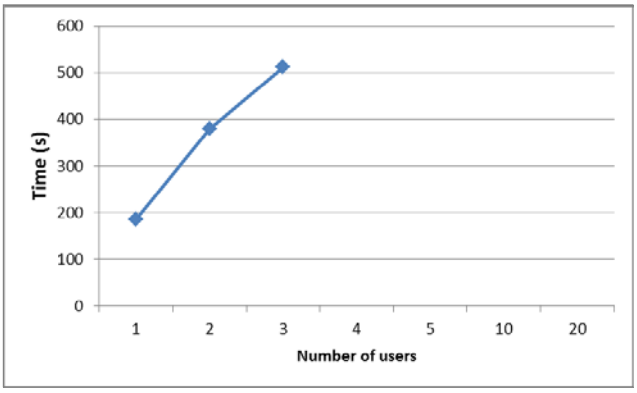

Figure 3: Response times in single machine experiment

B. Experiment with front-end load balancing

These experiment results were analyzed regarding two aspects: increasing number of users and increasing number of back-ends. The results for one user indicate that time were considerably slower than on a single machine, which means that the single machine was under maximum working load. After that, the load was distributed on more than one computer and certain amount time was spent on load balancing and communication. Communication was not efficient because influence of network latency prevails over bandwidth in case of small chunks of data produced by the service. Bandwidth in this experiment and the next one did not exceed 15kBps. As the number of requests increased, response time increased as well. The machine became fully loaded and requests had to wait for execution for longer period of time. Execution time increase rate was lower and network latency time was less expressed. That caused less steep line on the Figure 4. Experiment with three machines used as back-ends have shortest response time due to additional load due to load balancing. Other response times were not shown due to timeout.

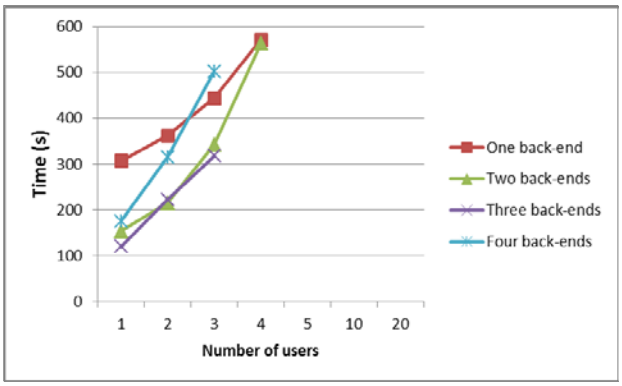

Figure 4: Response times in front-end load balancing experiment

C. Experiment with database load balancer

Experimental results with database load balancer (Figure 5.) showed that response time increased compared to previous results. Explanations might be the time lost on MySQL load balancing, network latency when performing SQL queries and delivering web service messages. Single back-end had to do all the data requests and serialization and became the bottleneck in the system. The communication turns out to be the bottleneck [7] because previously mentioned SQL queries were returning several bytes of data in average. These chunks of data were smaller than the data serialized in JSON format. That emphasized the network latency.

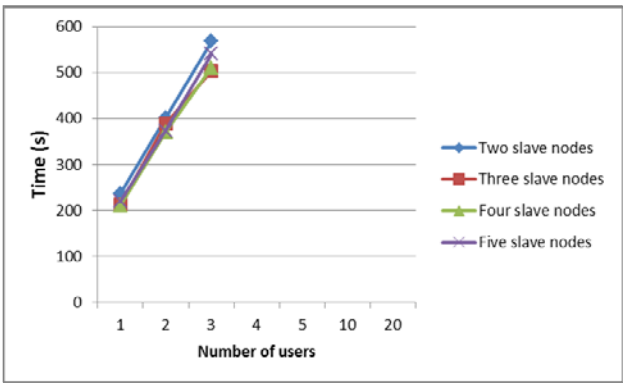

Figure 5: Response times in database load balancing experiment

D. Vertical scaling experiment

Vertical scaling experiment (Figure 6.) showed that vertical scaling for this type of problem is far better than horizontal, since no time is wasted on data transfer over the network. It took longer when the same amount of data was

transmitted in small packages than in large ones. This machine's processor was dual core. This is useful when dealing with large number of parallel requests, because modern applications and database systems have good mechanisms of using multi-core processors and multi-threading support.

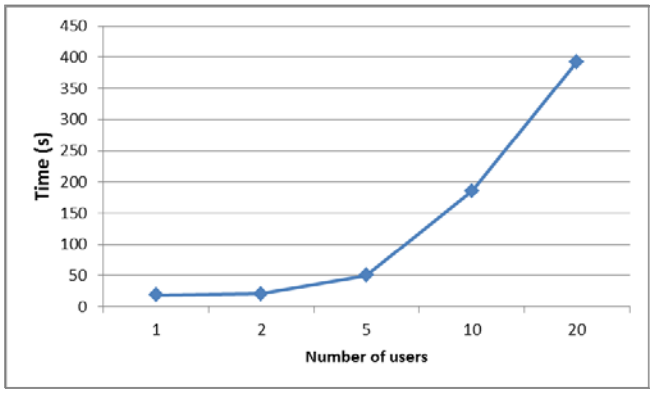

Figure 6: Response times in vertical scaling experiment

E. Disk caching experiment

Caching small chunks of data on disk did not appear to be efficient. This approach was used in disk caching experiment and it showed much worse results than without cache, especially with large number of requests. This happens because most of the time spent getting data from the disk was due to disk latency, and transfer itself lasted much shorter. On the other hand, database systems hold large amounts of data in main memory, up to the amount stated in configuration files. The data retrieval and serialization time was much shorter than data retrieval from the disk. Results are shown in Figure 7.

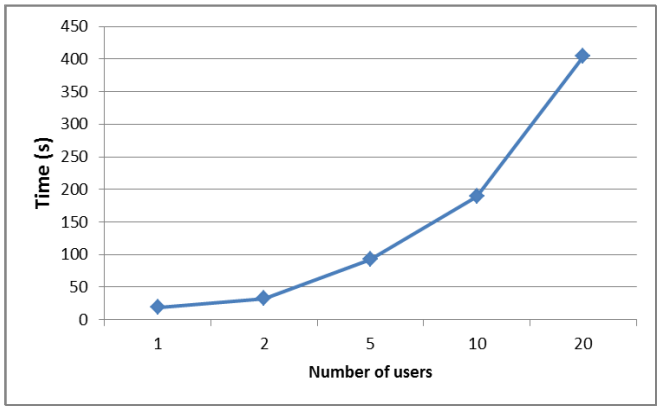

Figure 7: Response times in disk caching experiment

F. Memory caching experiment

The last experiment results (Figure 8.) prove that scaling of the application should start from application logic and software optimization mechanisms, followed by scaling with additional or better hardware. The goal should be to improve application's performance on current system before trying to scale – benefit from hardware upgrade. Many aspects should be considered, such as cost of these optimizations and time of for these optimizations. This experiment results showed six to eight times better performance when caching web service results in main memory compared to the scenario without the caching.

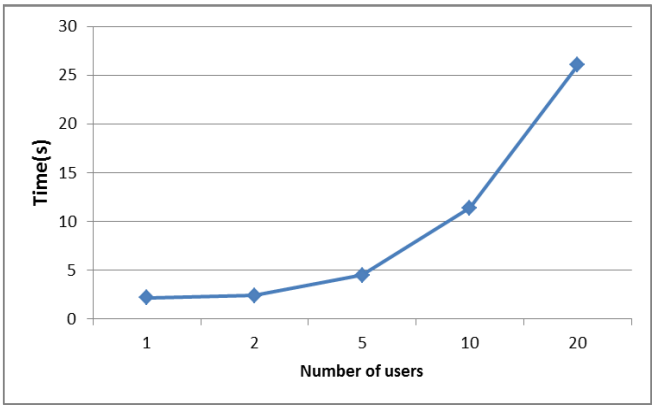

Figure 8: Response times in memory caching experiment

V. Additional Considerations

Limiting factor for horizontal scaling was 100Mbps network. For network traffic produced by this type of web service, key problem was network latency having considerable influence on whole system performance**.** This type of application would benefit from using higher speed network with lower latency, especially when building network based on fiber optics.

Database configuration used for these experiments did not differ much from default setup. The only thing changed was buffer size and network settings. Many databases require specific setup for hardware they are running on, so there is probably some space for performance increase with fine tuning the database settings.

Database and application load balancers contribute to system performance. It brings one more layer being used and it can consume large amount of resources if it is not implemented properly. They might have been weak spot in horizontal scaling if not being used properly.

Only performance aspects were analyzed in this paper. Although horizontal scaling gives much better results when it comes to performance, vertical scaling provides better reliability.

Master-slave replication used in front-end load balancer experiment, as well as in cluster environment in database load balancer experiment is suitable for read operations. When it comes to write operations, negative side effects can be

produced because all nodes have to receive all the information, and that is time consuming.

VII. Conclusion

Making scalable application must be well planned and considered from the beginning of application lifecycle. Before considering horizontal and vertical scaling, it is good practice to better utilize the currently available resources. Experiments were performed on read-heavy web service delivering large number of small packages. The results showed large performance improvement from vertical and very little performance benefits from horizontal scaling. The best results were accomplished with smarter programming method like caching web service responses in main memory. Response times were six to eight folds better. Even better results would be expected after combining these three elements. Real system configuration should be based on assessment for every application. Each application is unique in its design and methods stated above should be combined accordingly.

Design and Implementation of Fuzzy Controller on Embedded Computer for Water Level Control

Senka Krivić, Muhidin Hujdur, Aida Mrzić and Samim Konjicija
Faculty of Electrical Engineering, Department of Automatic Control and Electronics, Sarajevo, Bosnia and Herzegovina
krivic.senka@gmail.com, hujdur.muhidin@gmail.com, amrzic@gmail.com, skonjicija@gmail.com

Abstract - The paper deals with one of frequently encountered tasks in process industry - water level control. Proportional Integral Derivative (PID) control is often used for this purpose. Since control parameters of PID controller are fixed and tank system is inherently nonlinear, PID controller should not be used on wider level range. Therefore, this paper analyzes the effectiveness of water level control using fuzzy controller. The fuzzy controller is implemented based on mathematical model of tank and using MATLAB. The controller is implemented on Friendly ARM - embedded computer. Arduino board is used as an acquisition board for collecting sensor data from tank system Festo Didactic DD 3100 and as a PWM signal generator for water pump control. Experimental results confirm that the fuzzy control system has good adaptability in comparison with PID and provided satisfying results.

Keywords: fuzzy, Sugeno, PID, embedded system, microcontroller, tank, water level control, nonlinear system

I. Introduction

In certain industry branches (e.g. food, pharmaceutical, chemical etc.) the problem of water level control is very often encountered. The main objective of controller in this case is maintaining different setpoint water levels, mostly, in real time environment.

The traditional approach to this problem using PID controllers is not fully convenient when it comes to dealing with nonlinearity of tank systems and their complexity in industry [1][2]. These problems can be successfully dealt with using fuzzy control [3-5]. Based on expert knowledge and experience, control implementation is therefore simplified, and it can be achieved without complex mathematical modeling [6][7]. Since the water level controller is often a part of complex control system, the controller should have a communication interface which allows it to be incorporated and integrated with centralized control system. Different communication interfaces makes it suitable for use in already existing control systems, without changing communication protocols and interfaces.

Taking all this into account, this paper deals with implementation of PID and fuzzy water level controller using embedded computer and comparison of these controllers on laboratory tank model Festo DD3100.

The paper is organized in six sections. Section II describes implemented control system. In subsection A of section III, mathematical model of tank system is given. Subsection B of section III deals with system identification, while Section IV describes the PID and fuzzy controller implementation. The experimental results are shown in Section V, and conclusion is given in Section VI.

II. System Description

Figure 1 shows the block scheme of implemented control system.

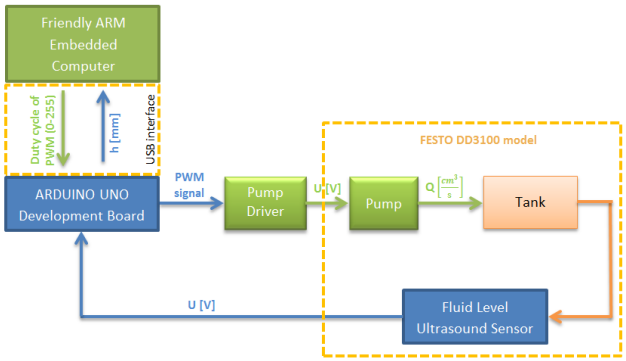

Figure 1. System structure

The PID and fuzzy controllers are implemented in application developed for Friendly ARM [10], which allows user to set desired water level and to select the type of controller (PID, or fuzzy). It also displays measured water level. Regardless of controller type, controller input (or one of the inputs) is measured water level expressed in millimeters, and its output is duty cycle of pulse width modulatied signal, expressed in 8 bits digital form proportional to percentage of duty cycle. The Figure 2 shows the implemented system.

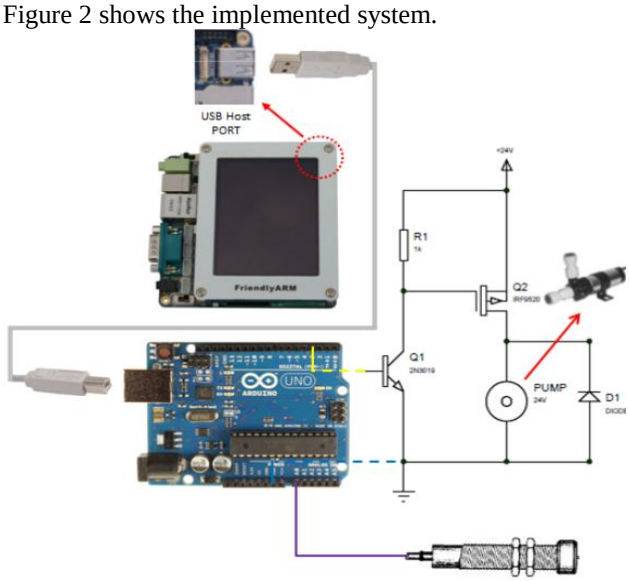

Figure 2. Implemented system

Both, controller input and output are exchanged with Arduino Uno Development Board [11]. Arduino is used as an acquisition input/output card for Friendly ARM. Arduino and Friendly ARM are connected using USB interface.
The PWM signal is used for triggering of pump driver [8] which generates a voltage signal used for pump control. Measurement of water level is done using ultrasound sensor and analog to digital and voltage to water level conversion on Arduino.

III. System Identification and Modelling

A. Mathematical modeling

The structure of the liquid volume in horizontal tank and its geometrical parameters are shown in Figure 3.

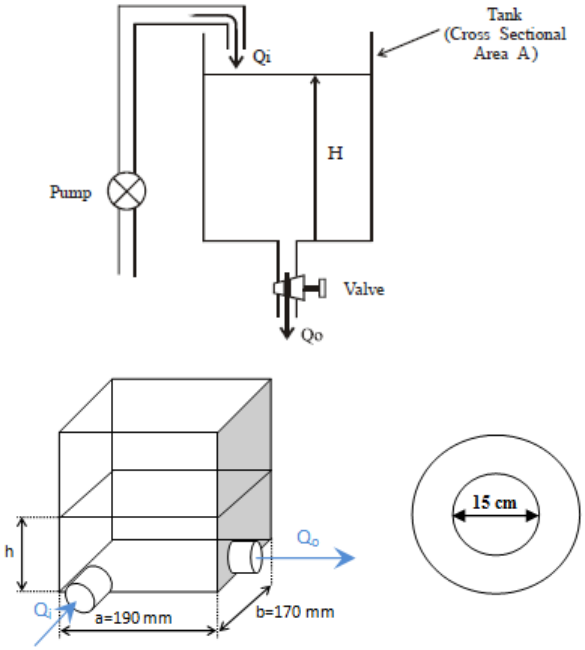

Figure 3. Single tank water level system

The system model is determined by relating the flow Q_i into the tank to the flow Q_o leaving through the valve at the tank bottom. Using a balance of flows equation on the tank, it is possible to write:

$$Q_i(t) - Q_o(t) = A\frac{dh(t)}{dt} \tag{1}$$

Where A is the cross sectional area of the tank and h is the height of the water in the tank.
The Bernoulli's equation can be adapted to a streamline from the surface to the orifice as:

$$gz_1 + \frac{p_1}{\rho} + \frac{v_1^2}{2} = gz_2 + \frac{p_2}{\rho} + \frac{v_2^2}{2} \tag{2}$$

Equations (1) and (2) refer to two different points in the flow, first being upstream of second point. v is the local velocity of the water, g represents the local acceleration of gravity, p the pressure and z the vertical height of the point.
If Bernoulli's equation including loss is applied to single tank system shown on Figure 3, h is calculated as:

$$h = \frac{v^2}{2g} + \Delta h \tag{3}$$

Where, h represents height of the water in the tank, $h = z1 - z2$. Loss to the system Δh can be written as

$$\Delta h = \frac{v^2}{2g}\left(\xi_t + 2\xi_k + \xi_i\frac{1}{d}\right) \tag{4}$$

Where, ξ_k is the local loss coefficient of the curved tube, ξ_i is the local loss coefficient at the entrance of the tube, ξ_t is the resistance coefficient, l is the length of the discharge pipe and d is the diameter of the discharge pipe. Combining (3) and (4) h becomes:

$$h = \frac{v^2}{2g}\left(1 + \xi_t + 2\xi_k + \xi_i\frac{1}{d}\right) \tag{5}$$

The flow Q_o leaving through the valve at the tank bottom is given by

$$Q_0 = \frac{d^2\pi}{4}v \tag{6}$$

Using (6) and (5), the flow Q_o can be expressed as

$$Q_0 = C\sqrt{2gh} \tag{7}$$

where

$$C = \frac{d^2\pi}{4}\frac{1}{\sqrt{1 + \xi_t + 2\xi_k + \xi_i\frac{1}{d}}} \tag{8}$$

Combining equations (7) and (1), gives

$$A\frac{dh(t)}{dt} + C\sqrt{2gh} = Q_i(t) \tag{9}$$

C is called the discharge coefficient of the valve. This coefficient takes into account all water characteristics, losses and irregularities in the system.
Equation (9) represents mathematical model of system.

B. System identification

In this section, nonlinear system model described with (9), will be approximated by the integrator and time delay model. The tank model, Festo Didactic DD3100 is shown on Figure 4.

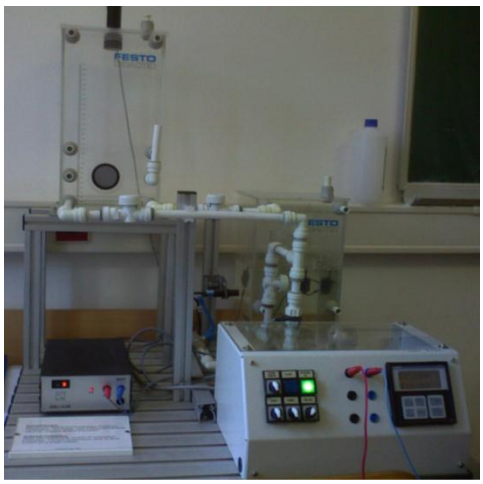

Figure 4. Festo Didactic DD3100 tank model

In order to identify the tank model, step of maximum pump voltage was applied until the water level reached 12,5 cm, starting from water level of 9,5 cm. System response is shown in Figure 5.

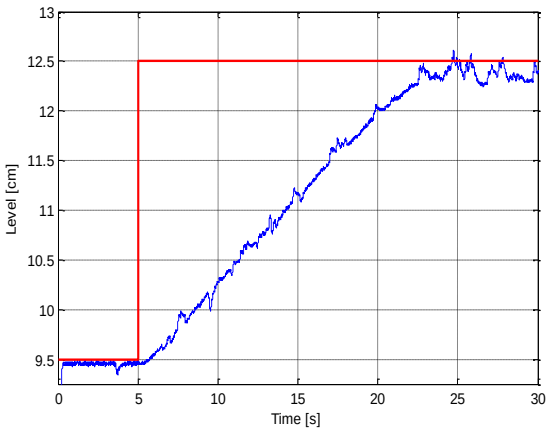

Figure 5. System response

Identification process provided following transfer function.

$$G_{ob}(s) = \frac{0{,}1553}{s} \cdot e^{-0.19s} \qquad (10)$$

The transfer function of approximated system was used for simulation and tuning of PID and fuzzy controller inside Matlab/Simulink program package. [9]

IV. Controller Implementation

A. PID controller implementation

The design of PID controller based on approximate model was done using Matlab/Simulink. Control parameters (gain/proportional band, integral gain/reset, derivative gain/rate) were adjusted to their optimum values for the desired control response (reaching the operating point of 12.5 cm) using Ziegler-Nichols Method. Following values of PID controller parameters were obtained: Kp = 2, Kd = 0.001, Ki = 0.005. The system discretization was conducted with sample time of Ts = 10ms.

B. FUZZY controller implementation

Two Sugeno fuzzy controllers were designed based on mathematical model and also using Matlab/Simulink. Simulink model shown on Fig. 6 was used for testing fuzzy controller performance.

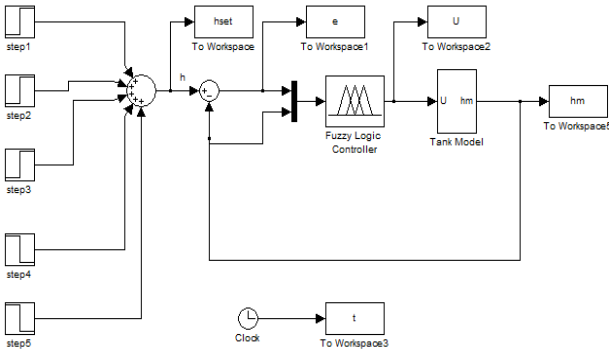

Figure 6. Simulink model used for fuzzy controller testing

Since the tank system is nonlinear and water drainage is correlated with water level, two possible inputs for fuzzy controller can be taken into account – error and current water height. In order to analyze the influence of using measured water level as controller input, two types of fuzzy controller were implemented

1. one input fuzzy controller with error as input
2. two inputs fuzzy controller with error and current water height as inputs

The Sugeno model was used, since it is computationally efficient and works well with optimization and adaptive techniques. This makes it popular for control problems, in particular for dynamic nonlinear systems [7]. Properties of Sugeno type for both controllers are given in Table I.

TABLE I. FIS (FUZZY INFERENCE SYSTEM) PARAMETERS

FIS TYPE	Sugeno
AND method	prod
OR method	max
Defuzzyfication	wtaver

In case of one input fuzzy controller, the error is calculated by taking the difference between referent and current water level. Chosen error memberships functions are shown on Fig. 7.

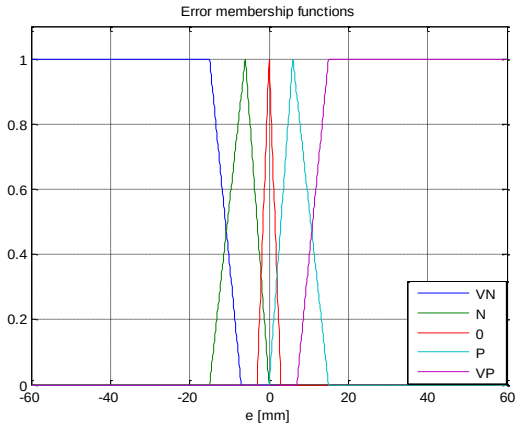

Figure 7. Membership functions of one input fuzzy controller

Output Membership functions represent voltage value. Output values are: 0, 4, 6, 12 and 24. Output MFs are shown on Fig. 8.

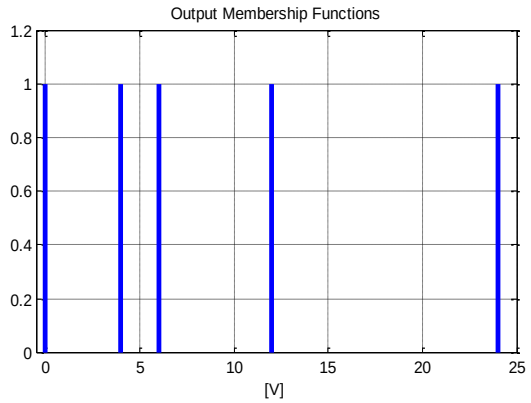

Figure 8. Output membership functions of one input fuzzy controller

The final output of the system is the weighted average of all rule outputs, computed as

$$FINAL\ OUTPUT = \frac{\sum_{i=1}^{N} w_i z_i}{\sum_{i=1}^{N} w_i} \qquad (11)$$

where N is the number of rules [7]. In this case the number of rules N is 5. These rules are shown in Table II.

TABLE II. RULE BASE FOR ONE INPUT FUZZY CONTROLLER

If e is VN	Output voltage is 0V
If e is N	Output voltage is 4V
If e is 0	Output voltage is 6V
If e is P	Output voltage is 12V
If e is VP	Output voltage is 24V

Labels in Table II and Figure 7 are as follows: VN=Very Negative; N=Negative; 0=Small; P=Positive; VP=Very Positive.

Inputs for two inputs fuzzy controller are current water level and error, calculated as a difference between referent and current water level. Chosen memberships functions are shown on Fig. 9.

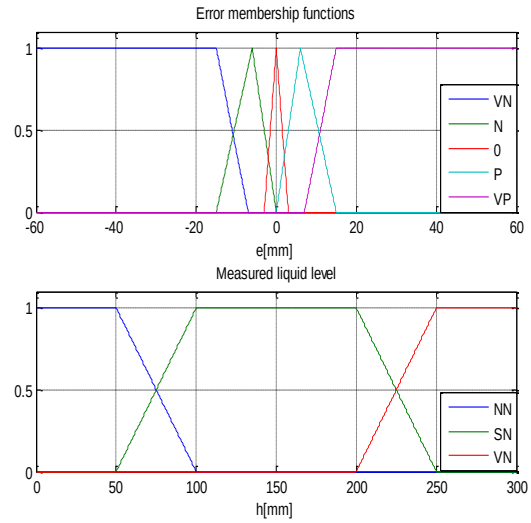

Figure 9. Membership functions of two inputs fuzzy controller

Output membership functions represent voltage value and they are shown on Fig. 10. Output values are: 0, 3, 4, 5, 6, 7, 10, 12, 13 and 24.

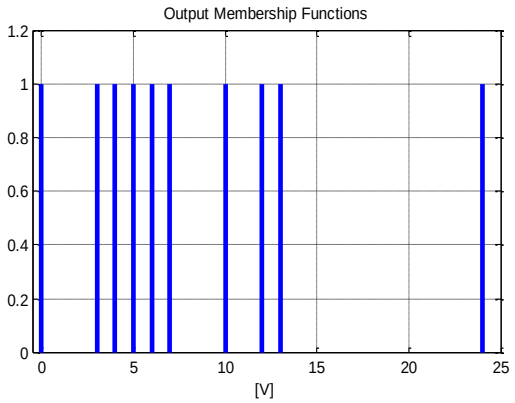

Figure 10. Output membership functions of two inputs fuzzy controller

The final output of the system is represented with weighted average of outputs of all rules, computed as in equation (11). In this case the number of rules N is 11. Rule mapping is shown in Table III.

TABLE III. RULE MAPPING FOR TWO INPUTS FUZZY CONTROLLER

		Error				
		VN	**N**	**0**	**P**	**VP**
Height	**NN**	0	4	5	10	24
	SN	0	3	6	13	24
	VN	0	0	7	24	24

Labels in Table III. and Figure 9 are as follows: VN=Very Negative; N=Negative; 0=Small; P=Positive; VP=Very Positive, NN=Low Height, SN=Medium Height, VN=High Height.

V. EXPERIMENTAL RESULTS

Controllers were first designed using Matlab and tested using Simulink model, based on mathematical model of tank. Functions that represent controllers were then created in programming language C. For more user-friendly usage of these functions, GUI application was created. Simple GUI is designed using QT Designer for Friendly ARM mini 2440. The GUI application is shown on Figure 11.

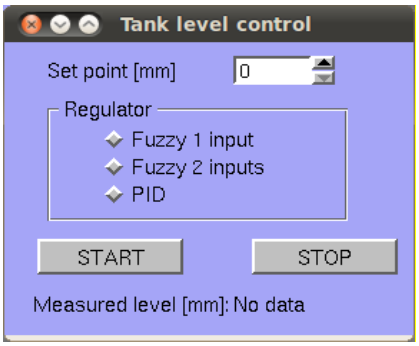

Figure 11. GUI application for ARM mini 2440

All control and measured data is collected and placed into files. Change of controllers type and set level is possible during control. For demonstration of controllers

effectiveness and their comparison, same step sequence for each controller is used. Collected data and control errors for controllers are shown on Figures 12 - 15.

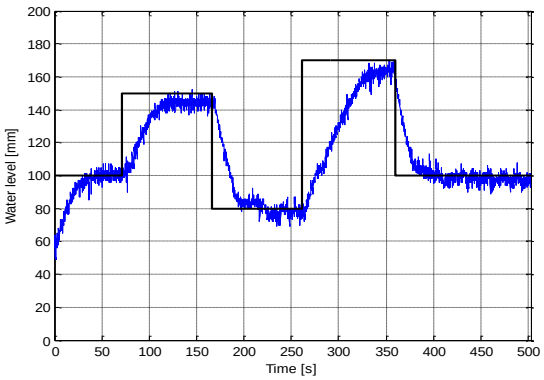

Figure 12. System response on step sequence (PID controller)

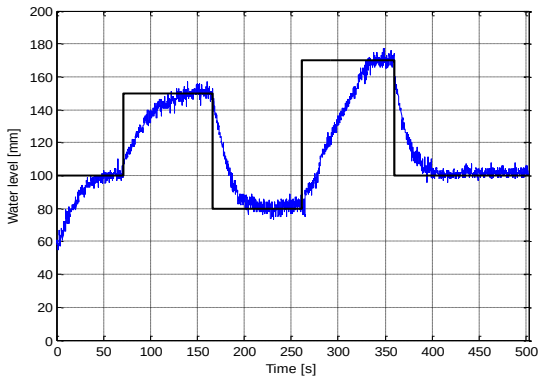

Figure 13. System response on step sequence (one input fuzzy controller)

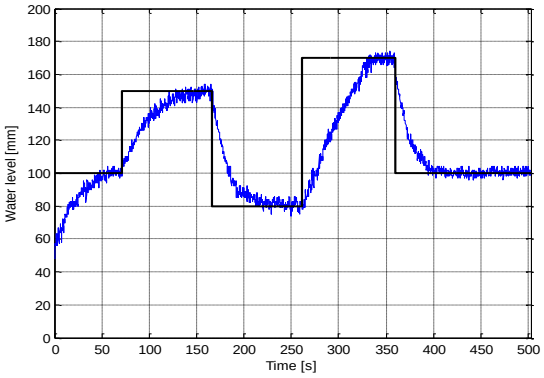

Figure 14. System response on step sequence (two input fuzzy controller)

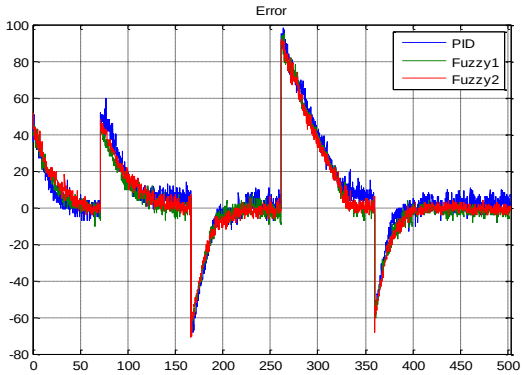

Figure 15. Control errors for different controllers

Based on experimental results, the control error and oscillations around stationary states for both fuzzy controllers were smaller, compared to PID controller. The fuzzy controllers provide better results on wider ranges of water level setpoints. The two input fuzzy controller did not provide significant improvements compared to one input fuzzy controller, although some improvements were achieved in terms of amplitude of oscillations around stationary states.

VI. Conclusion

By implementing fuzzy and PID controllers for water level control, in form of application for Friendly ARM embedded Computer, user-friendly solution was offered. This solution can be used separately or as a part of already existing control system. The use of fuzzy controller is fully justified by experimental results due to nonlinearity of tank model.

This paper can be used as a base for future work involving different fuzzy controller structures and control techniques for water level control. Future work may also include development of centralized control system for process industry, using on-board controllers and integrating them into one system.

Abstract - **This paper describes the calibration procedure of a CCD digital camera based on the perspective projection method. The idea of this method is to calibrate the camera in order to extract precise three dimesional information from the images so that they can be used for the computer vision and similar applications which take the images acquired from the camera as an input. The image capturing proccess reduces the dimensions of data from three to two. The camera calibration procedure determines which light source is associated with each pixel on the resulting image. Since the camera used in the process is a complex CCD camera, errors resulting from the misaligned lenses and deformations in their structures result in more complex distortions in the acquired image. In order to associate the points in the cameras image space with the locations in a 3D world space the camera projection matrix consisting of the estimated intrinsic and extrinsic parametars is calculated. The calibration process is comprised of capturing calibration images and processing them in order to get the intrinsic and extrinsic camera parameters. The results of the calibration are tested using the test images captured with the same camera. The calibration process was implemented using a MATLAB software package.**

Keywords: calibration, CCD camera, perspective projection method, pixel error, intrinsic parametars, extrinsic parametars

I. INTRODUCTION

The CCD (charge-coupled device) is a device for movement of the electrical charge, usually from within the device to an area where the charge can be manipulated, for example conversion into a digital value. CCD cameras are used in scientific and profesional applications where high-quality image data is required. [1-2]

The CCD image sensors consist of an array of light sensitive photodiodes. This array can be rectagular or poligonal. Photoactive region of CCD is an epitaxial layer of silicon. Besides it there is a transfer region comprised of an array of shift registers. It's role is to transfer the charge from the active region to the processing part of the camera. First, the picture is projected through the lens onto the photoactive region. This results in the electrical charge accumulation in the photoactive region proportional to the light intensity. Depending on the type of the CCD sensor the charge is moved along the transfer array towards the charge amplifier which converts the charge into voltage. The voltage is then digitalized before processing if the application is digital. In analog applications the voltage is imediately processed. [2]

The CCD sensor can be implemented in several different architectures. Most common ones are full-frame, frame-transfer and interline. Difference between them is in their approach to problem of shuttering. Full-frame architecture does not have an electronic shutter so mechanical must be implemented. Frame-transfer architecture has a double silicon surface. Half of the surface is used to capture the image. The other half is covered with an opaque mask and is used to temporarely store the image before processing. The image is slowly read from the storage area while the new image is being exposed. Interline architecture masks every other column of the sensor so the image can be stored. This architecture enables fast transfer of information but the fill factor is reduced to 50%. The Fill Facator can be increasd to 90% by adding microlences to deflect the image to the active region. [3]

Camera calibration has always been the most important component in designing computer vision applications. It is also used in the applications of stereo vision where the camera projection matrices of two cameras are used to calculate the real 3D coordinates of a viewed point. Camera calibration is the process of extraction of 3D metric information from the images. The goal of calibration is to convert the coordinates of a 3D object into the 2D image coordinates. In camera capturing, the light from the environment focused on the object is also captured (light from a 3D scene is stored on a 2D image). Each pixel on the image is associated with the incoming light, and the errors resulting from the misligned lenses can result in a more complex distorsions in the final image. The projection matrix is composed of the intrinsic and extrinsic parameters and there is a few methods for extracting these parametars. The simplest and the most used method is the perspective projection method, and in this paper is described the whole process of the calibration. [4]

This paper is organized as follows: Methodology of calibration procedure using perspective projection method is described in Section II. Results of calibration iterations as well as discussion of these results is given in Section III. Finally, Section IV discusses the entire work in general and gives some conclusions.

II. METHODOLOGY

The work in this paper is essentialy the calibration procedure of a Cannon's VC-C50i CCD camera. The calibration itself is carried out using a computer with the MATLAB high-level technical computing language installed. Since the camera is analog it requires a frame grabber if the images are to be processed by a general purpose PC. Connection between the camera and the computer was established via the frame grabber (shown on Figure 1). After the camera was connected to the computer a set of 20 monochrome test images was taken. Test images featured a planar checkerboard grid differently oriented in the each image (shown on Figure 2). The planar checkerboard grid is a common tool used in a camera calibration procedure. The main tool in the calibration procedure is the Camera Calibration Toolbox developed by Jean-Yves Bouguet. It features an algorithm that uses the extracted corner points of the checkerboard pattern to compute a projective transformation between the image points of the n different images. Afterwards, the camera intrinsic and extrinsic parameters are recovered using a closed-form solution, while the third- and fifth order radial distortion terms are recovered within a linear least-squares solution. A final nonlinear minimization of the reprojection error, solved using a Levenberg-Marquardt method, refines all the recovered parameters.

First the images are loaded into the toolbox so that the grid coners can be extracted. The corner extraction engine includes an automatic mechanism for counting the number of squares in the grid. This tool is especially convenient when working with a large number of images since the user does not have to manually enter the number of squares in both x and y directions of the pattern. On some very rare occasions however, this code may not predict the right number of squares. In order that the algorithm can extract the corners the edges of the checkerboard must be marked. It is necesary to accurately mark the four corners, at most 5 pixels away from the corners. Otherwise some of the corners might be missed by the detector. Afterwards it is necesary to enter the dimensions of the each grid. The image corners are then automatically extracted to an accuracy of about 0.1 pixel. Sometimes, the predicted corners are not quite close enough to the real image corners to allow for an effective

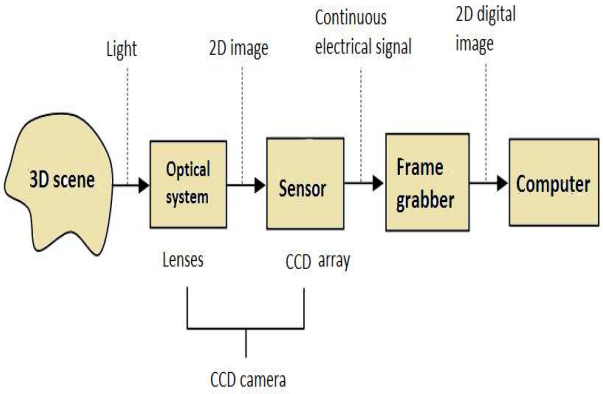

Figure 1. Conection between camera and computer

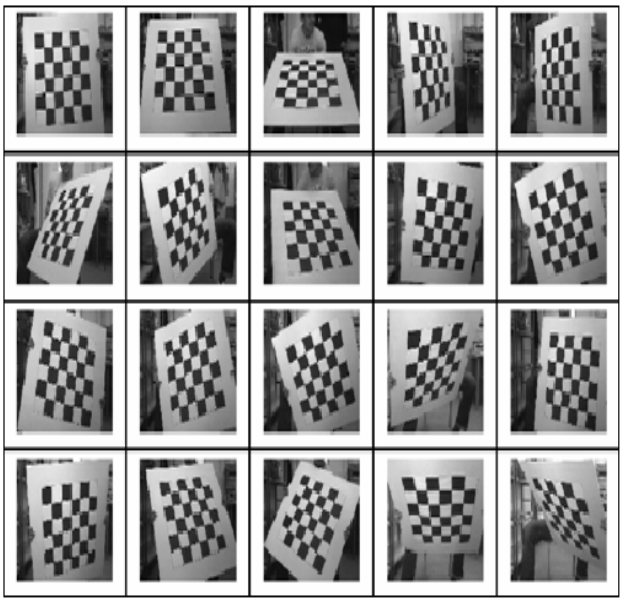

Figure 2. Images used in calibration process

corner extraction. In that case, it is necessary to refine the predicted corners by entering a guess for lens distortion coefficient.

In case of larger image distortion a guess for the first order lens distortion coefficient kc can be entered manually. The process of corner extraction can be repeated as many times as it is necesary to get the satisfactory prediction. If lens distortions are too high the manual corner extraction should be performed after the automatic corner extraction has been done. This method of a corner extraction is extremely time consuming and should be used as last resort when everything else fails.

After the corner extraction calibration is performed in two steps: the initialization and the nonlinear optimization. The initialization step computes a closed-form solution for the calibration parameters based not including any lens distortion. The non-linear optimization step minimizes the total reprojection error in the least squares sense over all the calibration parameters. In our case we have 129 parameters to be optimized: 9 DOF (depth of field) for intrinsic parameters and 120 DOF extrinsic parameters. It should be mentioned that intrinsic parameters are: the focal length, the principal point and the distortion coefficients. The optimization is done by the iterative gradient descent with an explicit computation of the Jacobian matrix. After the first calibration the algorithm provides the calibration parameters and the calibration results. The calibration parameters are provided after the initialization and the calibration results are given after the optimization. A number of iterations is needed to reach the optimum. The rate of convergence depends on the quality of the inital guess for the parameters computed by the initialization procedure. After the first calibration the reprojection error is still too large to make a judgement on the complexity of the model. This is mainly because some of the grid corners were not very precisely extracted for a number of images. After the examination of the error plot, it can be seen that the reprojection error is very large across a large number

of figures. The reason for that is that we have not done a very careful job at extracting the corners on a number of highly distorted images. This can be rectified by recomputing the image corners on all images automatically. The optimization now starts from the previous calibration result and a fewer iterations then previously were nedeed to reach the optimum. Results can be improved even further if diferent window sizes for the corner finder are used on highly distorted images. This can be done in the next calibration step.

On the end images were undistorted using the calculated extrinsic and intrinsic parameters.

III. RESULTS AND DISCUSION

After the first calibration was performed parameters were calculated in two following steps: after the initialization and after the optimization. In both steps following parameters were calculated: focal length, principal point, skew, distortion and pixel error, and they represent the intrinsic parameters of the camera. The focal length in pixels is stored in the 2x1 vector **fc**. The principal point is also stored in the 2x1 vector **cc**. The skew coefficient defining the angle between the x and y pixel axes is stored in the scalar **alpha_c**. The image distortion coefficients (the radial and the tangential distortion) are stored in the 5x1 vector **kc**.

Calibration parameters after initialization:

Focal Length: $fc = [917.42218 _ 917.42218]$

Principal point: $cc = [401.50000 \quad 282.500\ ]$

Skew: $alpha_c = [0.00000] \Rightarrow$ angle of pixel = 90.0000 degress

Distortion:
$kc = [0.00000 \quad 0.00000 \quad 0.00000 \quad 0.00000 \quad 0.00000\ ]$

Calibration results after optimization (with uncertainties):

Focal length:
$fc = [915.09675 \quad 922.46410\ ] \pm [5.34774 \quad 5.73476\ ]$

Principal point: $cc = [393.00968 \quad 227.50408\ ] \pm [10.35084 \quad 9.87906\ ]$

Skew: $alpha_c = [0.00000] \pm [0.00000] \Rightarrow$ angle of pixel axes $= 90.00000 \pm 0.00000$ degrees

Distortion:
$kc = [-0.11927 \quad 0.21166 \quad -0.00951 \quad -0.00312 \quad 0.00000] \pm [0.04414 \quad 0.29631 \quad 0.00302 \quad 0.00304 \quad 0.00000]$

Pixel error: $err = [0.61727 \quad 0.74773\ ]$

Observe that only 20 gradient descent iterations are required in order to reach the minimum. The reason for that fast convergence is the quality of the initial guess for the parameters computed by the initialization procedure.

The reprojection error is still too large to make a judgement on the complexity of the model. This is mainly because some of the grid corners were not very precisely extracted for a number of images. As it was described in the Methods section the reprojection error was reduced by conducting three more consecutive calibrations and reprojections of the grids. These projections are computed based on the current intrinsic and extrinsic parameters. After these steps we got following parameter values:

Focal Length: $fc = [913.49376 \quad 921.60192\ ] \pm [1.50531 \quad 1.61318\ ]$

Principal point: $cc = [393.65084 \quad 232.70717\ ] \pm [2.91469 \quad 2.77715\ ]$

Skew: $alpha_c = [0.00000\ ] \pm [0.00000\ ] \Rightarrow$ angle of pixel axes $= 90.00000 \pm 0.00000$ degrees

Distortion:
$kc = [-0.13214 \quad 0.39384 \quad -0.00938 \quad -0.00309 \quad 0.] \pm [0.01276 \quad 0.08875 \quad 0.00087 \quad 0.00089 \quad 0.00000\ ]$

Pixel error: $err = [0.19534 \quad 0.19198\ ]$

These results were saticfactory. It can be observed that the pixel error is greatly reduced during the calibration process. This reprojection error is shown in the from of color-coded crosses on Figure 3. This analysis is very useful in cases where the corners have been badly extracted on one or several images, because it shows where the error is large. Next, the rotations and the translations of extrinsic parameters were calculated and they are given in the following section.

Translation vector:
$Tc_ext = [-269.983575 \quad -74.307502 \quad 1712.849480\ ]$

Rotation vector:
$omc_ext = [1.902719 \quad 1.757589 \quad -0.043652\ ]$

Rotation matrix:

$$Rc_ext = \begin{bmatrix} 0.147023 & 0.931663 & 0.332249 \\ 0.914020 & 0.000430 & -0.405668 \\ -0.378089 & 0.363325 & -0.851495 \end{bmatrix}$$

Pixel error: $err = [0.27080 \quad 0.34822\ ]$

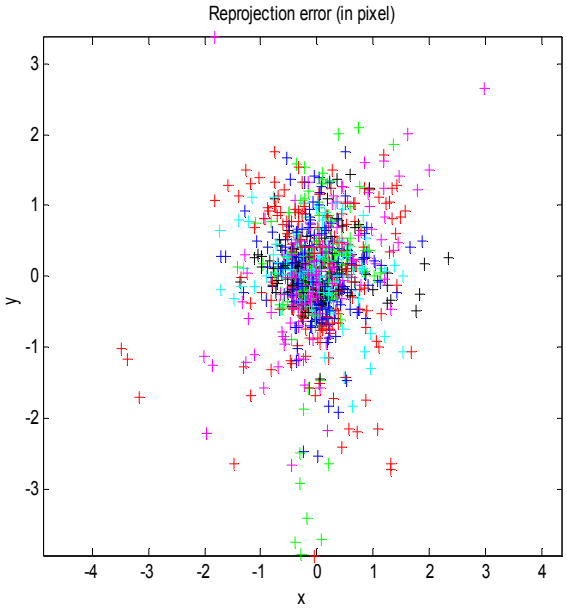

Figure 3. Reprojection error

The extrinsic parameters (the relative positions of the grids with respect to the camera) are then shown in a form of a 3D plot shown on Figure 4. On this figure, the frame (O_c,X_c,Y_c,Z_c) is the camera reference frame. The red pyramid corresponds to the effective field of view of the camera defined by the image plane. On Figure 5, very camera position and orientation is represented by a green pyramid.

In order to make a decision on the appropriate distortion model to use, it is sometimes very useful to visualize the effect of distortions on the pixel image, and the importance of the radial component versus the tangential component of distortion. Figure 6. shows the impact of the complete distortion model (radial and tangential) on each pixel of the image. Each arrow represents the effective displacement of a pixel induced by the lens distortion.

Focal Length	= (910.838, 918.471)	+/- [2.188, 2.391]
Principal Point	= (403.098, 232.791)	+/- [4.625, 4.589]
Skew	= 0	+/- 0
Radial coefficients	= (-0.1446, 0.4438, 0)	+/- [0.02556, 0.2202, 0]
Tangential coefficients	= (-0.009204, -0.0004129)	+/- [0.001421, 0.00141]

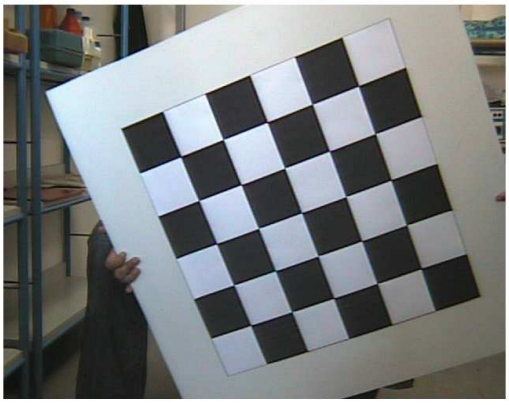
Figure 8. Radial Component of the Distortion



Picture 9. Original image (with distortion)

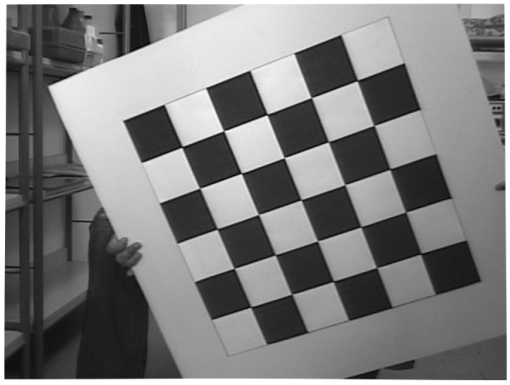


Figure 10. Undistorted image

The tangential component of distortion model is shown on Figure 7. On this picture, the maximum induced displacement is 2.5 pixels (at the upper left corner of the image). Figure 8. shows the impact of the radial component of distortion. This figure is very similar to the full distortion plot, showing the tangential component could very well be discarded in the complete distortion model. The cross indicates the center of the image, and the circle the location of the principal point.

In the last step we generated the undistorted version images that we used in the calibration process with the pre-computed intrinsic and extrinsic parameters. The following two figures shows the original image (with distortion) and the undistorted version of that image.

IV. CONCLUSION

This paper was written to show the process of camera calibration using the method of perspective projection. Since cameras are increasingly more used in scientific application as well as in the applications requiring precise visual informations, effective calibration of such cameras is getting ever more important. In the paper the perspective projection method has shown to be very effective calibration tool if used in conjuction with a digital computer. Computer is used to numericaly calculate all the required extrinsic and intrinsic parameters. The entire procedure is relativly simple if the appropriate program is used. In this case MATLABs Camera Calibration Toolbox was used to conduct the calibration and to undistort the images. Of course, if neccesary, user can generate his own calibration program too.

Procedure required several iterations of the calibration procedure itself in order to yield satisfactory results. During these steps the pixel error was reduced several times. It is worth mentioning that because of the high quality of the camera the initial pixel error was very small to begin with.

A Hybrid Ant Colony System approach for solving Capacitated Vehicle Routing Problems with Time Windows

Filip Boltužić and Alen Rakipović
Faculty of Electrical Engineering and Computing
Unska 3, 10000 Zagreb, Croatia
filip.boltuzic@fer.hr alen.rakipovic@fer.hr

Abstract – The Capacitated Vehicle Routing Problem with Time Windows represents a common problem. First, the problem is defined mathematically and an example of such a problem is shown. In short, the problem itself is a mixture of the Traveling Salesman Problem and the Bin Packing Problem. A possible solution to the problem is demonstrated, as well as the fitness criteria of the problem. The Ant Colony System algorithm is used to solve the problem. A modification of the original Ant Colony System Meta-heuristic is introduced. The heuristics used to improve the basic ACS algorithm are the Savings heuristic, Wait heuristic and the Route Size heuristic. Also, a few local search methods are used, such as 2*opt and Route Elimination local search. Finally, the result of applying the algorithm to a problem instance is discussed.

I. INTRODUCTION

The Vehicle Routing Problem has been introduced by Danzig and Ramser in 1959 [1]. It was defined as a transportation and a distribution problem. Basically, the problem is to distribute some goods using a number of vehicles to the clients which have specified locations (often defined as two-dimensional coordinates). Since the VRP problem is NP-hard, the solving method will be heuristics. Heuristics can give valid solutions without specifically regarding the problem instance. In this paper a modification of the original VRP is described. It is the Capacitated Vehicle Routing Problem with Time Windows (CVRPTW). The mathematical definition of the problem can be found in [7].

To solve the problem we introduce a few modifications to the basic Ant Colony System algorithm [3]. The goal of the algorithm is not only to produce very good solutions, but to determine the algorithm behaviour in regard to the given problem. By extracting knowledge from the algorithm performance new improved heuristics can be designed. Solving a problem without realizing why the algorithm behaves in the way that it does is a usual setback with metaheuristics (e.g. genetic algorithm). Our goal is to recognize the advantages and disadvantages of using specified heuristics.

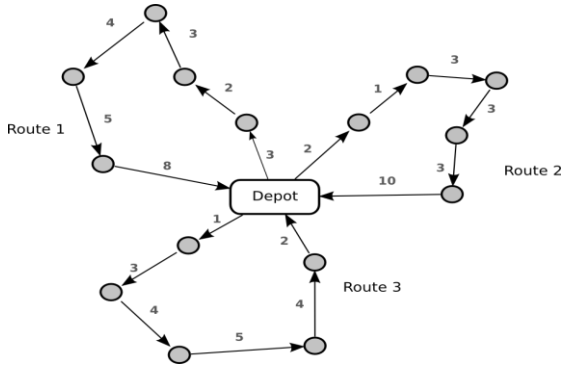

Figure 1 Simple route example

II. THE CAPACITATED VEHICLE ROUTING PROBLEM WITH TIME WINDOWS

The Vehicle Routing Problem is a combinatorial problem which can be modeled as a graph $G(V,E)$[4] with vehicle set $K=\{k_1..., k_k\}$ where the **input** parameters are:

- V – list of clients
- v_{ij} – boolean *1* for connection between i and j, otherwise *0*
- *0* –source depot index
- dem_i –amount of demand of client i
- s_i – time needed to service client i
- tl_i –earliest time of arrival to client i
- tu_i – latest time of arrival to client j
- c_{ij} – cost (time) of going from i to j
- k_k – capacity of vehicle k
- d_{ij} – distance between client i and client j

These terms above describe all the information neccessary to describe the problem. In order to cover the entire solution space data must exist for each parameter and each possible index i, j and k. [4]

The solution to the problem, in other words, the **output** is a list of routes for each of the used *k* trucks. Every single truck has its own route where the order of visiting clients is defined. The subject of optimization is to find [4]:

$$fitness_vehicles = \min|K| \quad (1)$$

$$fitness_length = \min \sum_{k\in K}\sum_{i\in V}\sum_{j\in V} v_{ij}^{k} c_{ij} \quad (2)$$

and thus satisfy [4]:

$$\sum_{k\in V}\sum_{j\in V} v_{ij} = 1, \forall i \in V \quad (3)$$

$$\sum_{i\in V} v^{k}{}_{ij} - \sum_{i\in V} v^{k}{}_{ji} = 0, \forall i \in V, \forall k \in K \quad (4)$$

$$\sum_{i\in V} v_{0j}^{k} = 1, \forall k \in K \quad (5)$$

$$\sum_{i\in V} v_{j,0}^{k} = 1, \forall k \in K \quad (6)$$

Once again, *V* denotes the set of clients and *K* stands for the set of trucks. These formulas make it clear that we want to find the minimal number of vehicles used to create such routes that the sum of lengths for each route is minimal. Every client is visited exactly once and each vehicle route starts and finishes with the source node.

If viewing the problem from a visited node *i*, the cost of visiting a node *j* from node *i* is defined as:

$$t_{ij} = ceil(\max(tl_j, t + s_i + d(i,j)), \quad (7)$$

where *t* is the total time. This cost can be regarded as the wait time because it gives us the information when the node *j* can be visited.

A. Fitness criteria

We can see that capacity is added as a constraint which means that every vehicle has a certain capacity of goods that it can load. This feature can be related to the Bin Packing Problem.

The other constraint are the Time Windows. This means that each client can be visited in a specified time in order for the solution to be valid. Solving the problem with just this constraint would be similar to the Traveling Salesman Problem with Time Windows.

If viewing the CVRPTW problem as a combination of the Bin Packing Problem and the Traveling Salesman Problem two different fitness criteria can be recognized:

- Total length of all the tours
- Total capacity of all the vehicles.

So, the problem criteria have to be optimized in a specified order. In the rest of the paper the priority is the number of vehicles. In addition, the total length is used to sort solutions with the same number of vehicles.

```
Initialize the ACO parameters;
Initialize number of ants;
while not end-condition do

        ant k selects a node with
        probability;
      end while
   end for
Local search procedure;
Update-pheromone-trails;
end while
```

Figure 2 Ant Colony Optimization Pseudocode

III. Ant Colony Optimization

The Ant Colony Optimization was initially described in [3]. It was originally designed to be used for solving problems such as the Travelling Salesman Problem. It has been shown that the algorithm is quite adaptable to other problems and that various heuristics can be implemented in the algorithm so that it can deal with a large problem set. An example of applying the algoritm to protein folding can be found in [5]. The pseudocode [3] is displayed in Fig. 2.

IV. Hybrid Ant Colony System Algorithm

This section will describe the algorithm used to solve the defined problem. The basic Ant Colony Optimization is a well know method [3] originally designed to be used for solving problems such as the Traveling Salesman Problem. It has been shown that the algorithm is quite adaptable to other problems and that various heuristics can be implemented in the algorithm so that it can deal with a large problem set.

The modification needed to make the ACO algorithm Ant Colony System was to introduce parallelism. This was done the same way as it is done with solving the TSP [4], but the chosen starting points were those whose time of arrival was valid at the beginning moment ($tl_i=0$). In this way an ant is layed in each of the clients so the initial solutions are more different.

The original construction rule for choosing a new client is [3]:

$$p_{ij} = \frac{(\tau_{ij})^{\alpha}(\eta_{ij})^{\beta}}{\sum_{u\in V}(\tau_{iu})^{\alpha}(\eta_{iu})^{\beta}} \quad (8),$$

where:

- p_{ij} is the probability of transition between vertices *i* and *j*
- α determines how important is the pheromone trail
- β determines how important is the distance to client
- η_{ij} is the distance between clients
- τ_{ij} is the pheromone strength

A. Wait Heuristic

The simplest way to introduce a new heuristic in the Ant Colony System algorithm is to simply add a new component in the construction rule. With wait heuristics we want to favour the client which has the minimal wait time. The formula for the actual time of arrival has been defined in (6). We also possess the earliest time of arrival to client *j*. Hence we build the Wait heuristic as:

$$\omega_{ij} = \frac{1}{tl_j - t_{ij}}. \qquad (9)$$

If the values are equal the denominator is set to 1 to avoid zero division.

B. Savings heuristics

Often two distant nodes are put in the same tour which means that a vehicle spends a lot time just by travelling between them. To minimize this a simplified clustering of the client locations is performed. For each node a savings measure is taken so that the algorithm evaluates wheter it is better to put the nodes in the same, or different routes. If we take some client nodes *i* and *j* we can calculate the savings value as:

$$\gamma_{ij} = d(i,0) + d(0,j) - d(ij)g + f\left|d(i,0) - d(j,0)\right|, \qquad (10)$$

where *g* and *f* are algorithm parameters which determine what distance will have a bigger impact to the heuristic output.
This formula considers distances between the source (index 0) and the clients *i* and *j*, as well as the distance between them. With this formula the value γ stores a measure which illustrates whether it is more beneficial to go home to the source, or to continue the route with the next client *j*.

C. Route Size heuristics

Bigger routes will take up more clients and therefore use less vehicles. So, another heuristic value is introduced which will help to create longer routes. Apart from the pheromone trail which evaluates only the solution, a route size pheromone is made. The best ants will add some pheromones on the longest trails. The amount of added pheromones is equal to the trail length of a specific tour. So, the update is done:

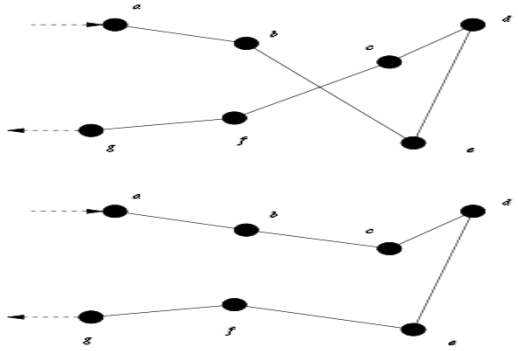

*Figure 32*opt heuristics*

$$\delta_{ij}^{\ k} = \delta_{ij}^{\ k} + \sum_{i \in V} v_{ij}, \forall k \in K. \qquad (11)$$

D. 2*opt Local Search

The 2*opt Local Search method is a well known method[6] often used for solving the TSP. Here we use it for a similar reason, and that is to additionally reduce the route sizes. Fig. 3 shows how 2*opt works. We determine some solutions (implemented as 5% best ones) and attempt to improve them with this local search.

E. Route elimination Local Search

Case has shown that some routes in the solution are very long and some a extremely short. To counter this, the Route elimination Local Search was implemented. This local search traverses through small routes and attempts to add them to other routes. The goal of this local search is to merge tours, hence producing solutions using less vehicles in total.

F. Complete algorithm

In fig. 2 the basic ACO is shown. The Hybrid Ant Colony System Algorithm is an upgrade of the algorithm desribed in the figure. When each ant constructs the solution it chooses a next node using the (12) formula, whereas it is done using (8) in the basic ACO algorithm. Also, the local search methods described in D and E are executed consequently: first route elimination, then 2*opt. Last, but not least, the ants are sent initialized to work in parralel as described in IV.

If we change the basic ACO algorithm with these modifications we get the Hybrid ACS. The pseudocode of the Hybrid ACS is extremely similar so we will not write it separately.

V. EXPERIMENTATION AND RESULTS

The final algorithm with all added heuristics has a construction rule defined by:

$$p_{ij} = \frac{(\tau_{ij})^{\alpha}(\eta_{ij})^{\beta}(\omega_{ij})^{\theta}(\gamma_{ij})^{\lambda}(\delta_{ij})^{\psi}}{\sum_{u \in V}(\tau_{iu})^{\alpha}(\eta_{iu})^{\beta}(\omega_{iu})^{\theta}(\gamma_{iu})^{\lambda}(\delta_{iu})^{\psi}} \qquad (12)$$

The update rule of pheromone trails remain the same as defined in the original algorithm, as well as the rest of the part which was not specifically explained so far.

Since there are a lot of parameters in this algorithm we will enumerate them:

- α – fitness pheromone strength
- β – relevance of relative distance
- θ – relevance of wait heuristics
- λ – relevance of savings heuristics
- ψ – route size pheromone strength
- f – importance of the distance between the source and each of the clients
- g – importance of the distance between two selected clients

The total fitness of a single solution (the one used for pheromone updating) is calculated as:

$$f = \frac{fitness}{worst(fitness)} + |K| \quad (13)$$

This is used so that we can favor the number of vehicles used over the total distance traveled. The experiments were done on a personal laptop computer with a *2.00* GHz processor and *4 GB* of RAM. In the experiments specific parameters were chosen based on personal opinions. The table with results is shown in table 1. Since more computers weren't available all the tests were done with a well prepared test case with a hundred clients. The step between parameter values was set to the value *0.5*. When one parameter was changing others were fixated to the value *1*, so it is important to note that this is not a real extensive Cartesian product testing. Once again, all other parameters were set to the recommended values [3][4]. The execution time was 2 minutes.

The results which can be viewed in table 1 can indicate a few things. First, we can notice that the best and worst values are often upper or lower bounds of the testing range that was explored. This means that further testing could give us more material for analysis.

It has been shown that the most influental parameter to the testing is the relevance of relative distance β. The table shows that modifying this parameter can produce very good solutions when well tuned. On the contrary the route size parameter δ has shown little influence in the solution quality making.

Generally speaking the results are satisfactory. The algorithm has shown that it can quickly produce very good solutions, which have proven to be local optima in most cases, since an extensive experiment has been contuced to get to know the used problem instance better. The most important heuristics has shown to be the distance between clients, which could mean that similar results would have been generated using the basic ACO algorithm since it is the only heuristic used in that algorithm. Other algorithms [8] have also proven to be effective in solving the problem, better than this algorithm, according to the Solomon benchmark[10].

The local search methods have proven to be very useful in incrementing the solution fitness. Applying the 2*opt heuristics to many solutions has proven to be a bad idea, producing several local optima, but applying the Route Elimination to more than a few solutions has proved to be very good strategy.

VI. CONLUSION

The implementation of the Hybrid Ant Colony System Algorithm has proven successful in solving the Capacitated Vehicle Routing Problem with Time Windows. Testing of the algorithm was not simple since the algorithm has a lot of parameters which means proper thourough testing is quite time consuming. This is a part which can definitely be improved in order to understand the behavior of the algorithm. This would enable us to create an adaptive algorithm which could set its own parameters according to the given problem.

The algorithm design was shaped in regard of the problem. It's behavior was satisfiable because the problem was carefully studied and examined before creating the modifications. Like all heuristics, it is most likely that the algorithm performance varies in different problem enviroment.

To sum up, the main advantages of the designed and implemented Hybrid Ant Colony System algorithm are good performance on the CVRPTW problem, easy upgrading of the solving heuristics and understandable behavior. In our opinon the main disadvantage would be high computational complexity and the inability to apply the algorithm to larger problem set. If we compare our algorithm to the GA we can clearly see that it does a lot of calculating in each iteration in order to handle a problem efficiently. Also, it takes more time to adapt the algorithm to a newly introduced problem.

The algorithm has proven succesful in solving the problem, but there more efficient ones have been produced. Further heuristics modifications could change this, as well as extensive testing of the algorithm performance.

Android application for sending SMS messages with speech recognition interface

Sanja Primorac and Mladen Russo
FESB, University of Split, Croatia
sprimora@fesb.hr

Abstract - Voice SMS is an application developed in this work that allows a user to record and convert spoken messages into SMS text message. User can send messages to the entered phone number or the number of contact from the phonebook. Speech recognition is done via the Internet, connecting to Google's server. The application is adapted to input messages in English. Used tools are Android SDK and the installation is done on mobile phone with Android operating system. In this article we will give basic features of the speech recognition and used algorithm. Speech recognition for Voice SMS uses a technique based on hidden Markov models (HMM - Hidden Markov Model). It is currently the most successful and most flexible approach to speech recognition.

I. INTRODUCTION

Mobile phones have become an integral part of our everyday life, causing higher demands for content that can be used on them. Smart phones offer customer enhanced methods to interact with their phones but the most natural way of interaction remains speech.

Market for smart mobile phones provides a number of applications with speech recognition implementation. Google's Voice Actions and recently Iphone's Siri are applications that enable control of a mobile phone using voice, such as calling businesses and contacts, sending texts and email, listening to music, browsing the web, and completing common tasks.

Both Siri and Voice Actions require an active connection to a network in order to process requests and most of Android phones can run on a 4G network which is faster than the 3G network that the iPhone runs on. There is also an issue of availability, Voice Actions are available on all Android devices above Android 2.2, but Siri is available only for owners of the iPhone 4S. The Siri's advantage is that it can act on a wide variety of phrases and requests and can understand and learn from natural language, whereas Google's Voice Actions can be operated only by using very specific voice commands.

In this work we have developed an application for sending SMS messages which uses Google's speech recognition engine. The main goal of application Voice SMS is to allow user to input spoken information and send voice message as desired text message. The user is able to manipulate text message fast and easy without using keyboard, reducing spent time and effort. In this case speech recognition provides alternative to standard use of keyboard for text input, creating another dimension in modern communications.

II. ANDROID

Android is a software environment for mobile devices that includes an operating system, middleware and key applications [1]. In 2005 Google took over company Android Inc., and two years later, in collaboration with the group the Open Handset Alliance, presented Android operating system (OS).

Main features of Android operating system are:

- Enables free download of development environment for application development.
- Free use and adaptation of operating system to manufacturers of mobile devices.
- Equality of basic core applications and additional applications in access to resources.
- Optimized use of memory and automatic control of applications which are being executed.
- Quick and easy development of applications using development tools and rich database of software libraries.
- High quality of audiovisual content, it is possible to use vector graphics, and most audio and video formats.
- Ability to test applications on most computing platforms, including Windows, Linux…

The Android operating system (OS) architecture is divided into 5 layers (fig. 1.). The application layer of Android OS is visible to end user, and consists of user applications. The application layer includes basic applications which come with the operating system and applications which user subsequently takes. All applications are written in the Java programming language.

Framework is extensible set of software components used by all applications in the operating system. The next layer represents the libraries, written in the C and C + + programming languages, and OS accesses them via framework.

Dalvik Virtual Machine (DVM), forms the main part of the executive system environment. Virtual machine is used to start the core libraries written in the Java

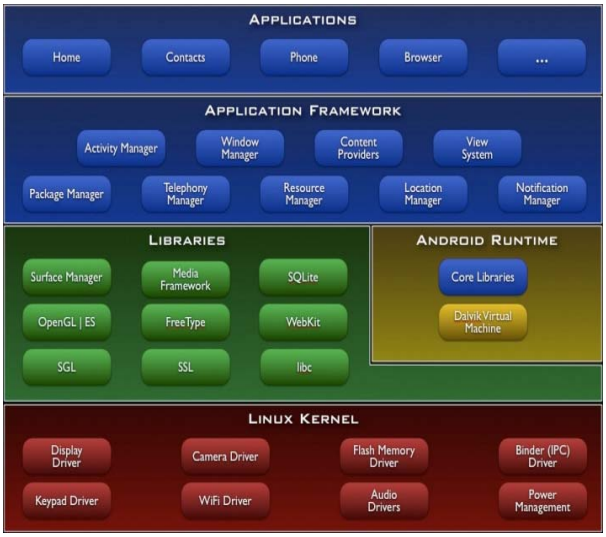

Figure 1. Structure of Android operating system [1]

programming language. Unlike Java's virtual machine, which is based on the stack, DVM bases on registry structure and it is intended for mobile devices.

The last architecture layer of Android operating system is kernel based on Linux OS, which serves as a hardware abstraction layer. The main reasons for its use are memory management and processes, security model, network system and the constant development of systems.

There are four basic components used in construction of applications: activity, intent, service and the content provider. An activity is the main element of every application and simplified description defines it as a window that users see on their mobile device. The application can have one or more activities. Main activity is the one that is used as startup. The transition between the activities is carried out in a way that launched activity calls a new activity. Each activity as a separate component is implemented with inheritance of Activity class. During the execution of applications, activities are added to the stack, currently running activity is on the top of the stack. An intent is a message used to run the activities, services, or recipient's multicast. An intent can contain the name of the components you need to run, the action which is necessary to execute, the address of stored data needed to run the component, and component type. A service is a component that runs in the background to perform long-running operations or to perform work for remote processes. One service can link multiple applications and service is executed until a connection with all applications is done. A content provider manages a shared set of application data. Data can be stored in the file system, a SQLite database, on the web, or any other persistent storage location which application can access [1]. Through the content provider, other applications can query or even modify the data (if the content provider allows it).

III. SPEECH RECOGNITION

Speech recognition for application Voice SMS is done on Google server, using the HMM algorithm. HMM algorithm is briefly described in this part. Process involves the conversion of acoustic speech into a set of words and is performed by software component. Accuracy of speech recognition systems differ in vocabulary size and confusability, speaker dependence vs. independence, modality of speech (isolated, discontinuous, or continuous speech, read or spontaneous speech), task and language constraints [2].

Speech recognition system can be divided into several blocks: feature extraction, acoustic models database which is built based on the training data, dictionary, language model and the speech recognition algorithm. Analog speech signal must first be sampled on time and amplitude axes, or digitized. Samples of speech signal are analyzed in even intervals. This period is usually 20 ms because signal in this interval is considered stationary.

Speech feature extraction involves the formation of equally spaced discrete vectors of speech characteristics. Feature vectors from training database are used to estimate the parameters of acoustic models. Acoustic model describes properties of the basic elements that can be recognized. The basic element can be a phoneme for continuous speech or word for isolated words recognition. Dictionary is used to connect acoustic models with vocabulary words. Language model reduces the number of acceptable word combinations based on the rules of language and statistical information from different texts.

Speech recognition systems, based on hidden Markov models are today most widely applied in modern technologies. They use the word or phoneme as a unit for modeling. The model output is hidden probabilistic functions of state and can't be deterministically specified. State sequence through model is not exactly known. Speech recognition systems generally assume that the speech signal is a realization of some message encoded as a sequence of one or more symbols [3]. To effect the reverse operation of recognizing the underlying symbol sequence given a spoken utterance, the continuous speech waveform is first converted to a sequence of equally spaced discrete parameter vectors. Vectors of speech characteristics consist mostly of MFC (Mel Frequency Cepstral) coefficients [4], standardized by the European Telecommunications Standards Institute for speech recognition. The European Telecommunications Standards Institute in the early 2000s defined a standardized MFCC algorithm to be used in mobile phones [5].

Standard MFC coefficients are constructed in a few simple steps. A short-time Fourier analysis of the speech signal using a finite-duration window (typically 20ms) is performed and the power spectrum is computed. Then, variable bandwidth triangular filters are placed along the perceptually motivated mel frequency scale and filter-bank energies are calculated from the power spectrum. Magnitude compression is employed using the logarithmic function. Finally, auditory spectrum thus obtained is decorrelated using the DCT and first (typically 13) coefficients represent the MFCCs.

These vectors of speech characteristics are called observations and used in further calculations. To develop an acoustic model, it is necessary to define states. In

continuous speech recognition, each state represents one phoneme. Under the concept of training we mean the determination of probabilities of transition from one state to another and probabilities of observations. Iterative Baum-Welch procedure is used for training [6]. The process is repeated until a certain convergence criterion is reached, for example good accuracy in terms of small changes of estimated parameters, in two successive iterations. In continuous speech the procedure is performed for each word in complex HM model. Once states, observations and transition matrix for HMM are defined, the decoding (or recognition) can be performed.

Decoding represents finding of most likely sequence of hidden states using Viterbi algorithm, according to the observed output sequence. It is defined by recursive relation. During the search, n-best word sequences are generated using acoustic models and a language model.

IV. MAIN PARTS OF THE PROJECT

A. *VoiceRecognitionActivity class*

VoiceRecognitionActivity is startup activity defined as launcher in AndroidManifest.xml file. REQUEST_CODE is static integer variable, declared on the beginning of activity and used to confirm response when engine for speech recognition is started. REQUEST_CODE has positive value. Results of recognition are saved in variable declared as *ListView* type.

Method onCreate is called when activity is initiated. This is where the most initialization goes: setContentView (R.layout.voice_recognition) is used to inflate the user interface defined in res > layout > voice_recognition.xml, and findViewById(int) to programmatically interact with widgets in the user interface. In this method there is also a check whether mobile phone, on which application is installed, has speech recognition possibility. PackageManager is class for retrieving various kinds of information related to the application packages that are currently installed on the device. Function getPackageManager() returns PackageManager instance to find global package information. Using this class, we can detect if the phone has a possibility for speech recognition. If a mobile device doesn't have one of many Google's applications which integrate speech recognition, further work of this application Voice SMS will be disabled and message on the screen will be "Recognizer not present". Recognition process is done trough one of Google's speech recognition applications. If recognition activity is present user can start the speech recognition by pressing on the button and thus launching startActivityForResult (Intent intent, int requestCode). The application uses startActivityForResult() to broadcast an intent that requests voice recognition, including an extra parameter that specifies one of two language models. Intent is defined with intent.putExtra (RecognizerIntent. EXTRA_LANGUAGE_MODEL, RecognizerIntent.LANGUAGE_MODEL_FREE_FORM). The voice recognition application that handles the intent processes the voice input, then passes the recognized string back to Voice SMS application by calling the onActivityResult() callback. In this method we manage result of activity startActivityForResult. Received result *Data* is stored in ListView variable and shown on the screen (Fig. 2.).

Interface setOnItemClickListener registers a callback to be invoked when an item on ListView widget has been clicked. Method OnItemClick enables control over statement that user selected from the list. Method contains definition of new Intent and user is transferred into interface for writing SMS (fig. 3.). Selected text is transferred from VoiceRecognitionActivity to SMS activity with putExtra (String name, String data) label. The first parameter is a string "key" and the second is the selected text.

B. *SMS class*

In onCreate method label setContentView (R.layout.sms) opens new user interface. Command final String message1 = getIntent().getExtras().GetString ("Key") retrieves the data associated with the string "key" which in this case is selected text from recognition

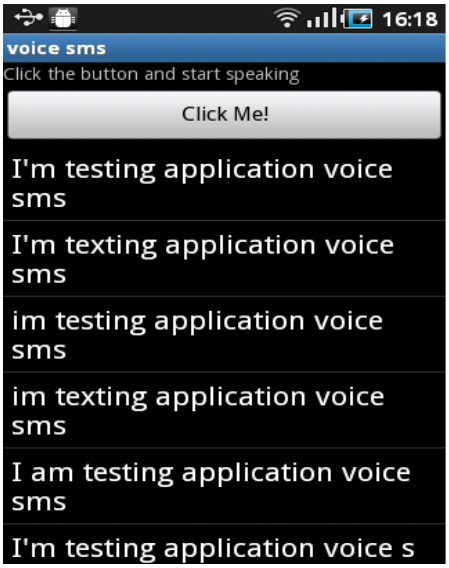

Figure 2. Testing

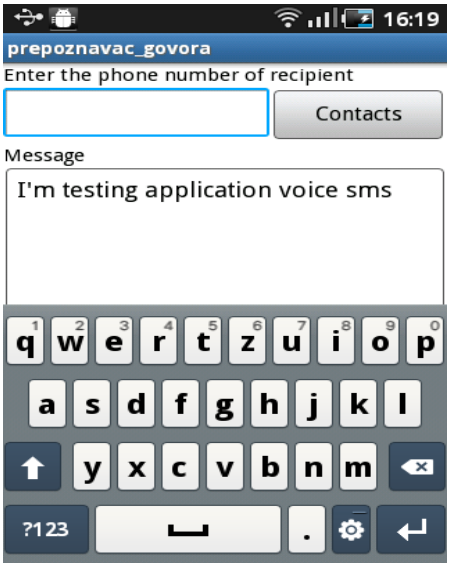

Figure 3. Interface for sending SMS

activity. The text is entered in the space for writing messages and displayed on the screen. By clicking the Send SMS button application checks whether the message and the number of recipient are entered. If result of check is negative, message "Please enter phone number and message" is shown. Otherwise, method sendSMS is called to perform sending of message. When cursor is positioned in the space for recipient number, button for contacts opens. Button attribute visibility is changed from default *gone* to *visible*. Pressing the button the command that allows you to display the contact numbers stored on mobile phone, label Intent forContacts new Intent = (Intent.ACTION_PICK, ContactsContract.Contacts.CONTENT_URI) startActivityForResult (forContacts, REQUEST_CODE) is executed. After selecting desired contact, message can be sent.

C. XML files

Application consists of two different interfaces. When the user runs application screen is defined in voice_recognition.xml. The linear arrangement of elements allows adding widget one below another. Width and height are defined with *fill_parent* attribute, which means to be equal as parent (in this case the screen).

The second interface, defined within sms.xml file, is displayed when the user chooses one of offered messages.

AndroidManifest.xml realizes installing and launching applications on the mobile device. Every application must have an AndroidManifest.xml file (with precisely that name) in its root directory. The manifest presents essential information about the application to the Android system, information the system must have before it can run any of the application's code. It defines the activities and permissions required for the application. Permissions are used to remove restrictions that prevent access to certain pieces of code or data on mobile device. Each permit is defined by a special label. If application needs data with distrait if must seek the necessary authorization. The syntax is: <uses-permission android:name= "Unique name of permission"> </ uses-permission>.

Every activity must be named in manifest. Name is used as a parameter that is passed to the constructor of intent which is used to start desired activity. Activities can have different <category> attribute. VoiceRecognitionActivity.java is the main class and its onCreate method is executed at application startup. The category tag is specially defined String that describes this feature of activity with keyword *Launcher* while other classes are marked with keyword *Default*.

AndroidManifest.xml has to include permission to send and receive messages, to access Internet and permission to access the list of contacts from the phonebook.

Permissions are:

- android.permission.INTERNET.
- android.permission.SEND_SMS.
- android.permission.RECEIVE_SMS.
- android.permission.READ_CONTACTS.

V. APPLICATION FUNCTIONALITY PRINCIPLE

Application Voice SMS integrates direct speech input enabling user to record spoken information as text message, and send it as SMS message. After application has been started display on mobile phone shows button which initiate voice recognition process. When speech has been detected application opens connection with Google's server and starts to communicate with it by sending blocks of speech signal. Simultaneously the figure of waveform is generated on the screen.

Speech recognition of the received signal is preformed on server. Google has accumulated a very large database of words derived from the daily entries in the Google search engines well as the digitalization of more than 10 million books in Google Book Search project. The database contains more than 230 billion words. If we use this kind of speech recognizer it is very likely that our voice is stored on Google's servers. This fact provides continuous increase of data used for training, thus improving accuracy of the system.

When process of recognition is over, user can see the list of possible statements. Process can be repeated clicking on the button *Click Me!*. Pressing the most accurate option, selected result is entered into interface for writing SMS messages.

Interface for writing SMS messages has all standard features. User can correct text and input recipient number in the empty textbox. Button *Contacts* opens interface with contact numbers from mobile phone and enables user to chose phone number on which message will be sent after pressing button *Send.* Customer receives response in a little cloud (toast) if message has been sent.

VI. CONCLUSION

With the development of software and hardware capabilities of mobile devices, there is an increased need for device-specific content, what resulted in market changes. Speech recognition technology is of particular interest due to the direct support of communications between human and computers. The integration of the speech recognition in mobile devices enables easier and faster use of smart phones. Use of such systems opens countless possibilities. Besides to facilitating the manipulation for current users of mobile devices, the market is opened to a whole new range of people who might use these technologies. The elderly, and persons with various disabilities, would have the opportunity to participate in the technological present and feel the benefits of smart phones.

Using the speech recognizer, which works over the Internet, allows much faster data processing. Another advantage is the much larger databases that are used. Many believe that this mode is a big step for speech recognition technology. The accuracy of the system has significantly increased and become more accessible to everyone. We have been given a possibility to manage mobile devices without installing complex software for speech processing, resulting in memory savings. A lack of application Voice SMS is its adaption only for English language, and the need for permanent Internet connection.

The objective for the future is development of models and databases for multiple languages which could create a foundation for everyday use of this technology worldwide.

The main goal of application is to allow sending of text messages based on uttered voice messages. Testing has shown simplicity of use and high accuracy of data processing. Results of recognition give user option to select the most accurate result. Further work is planned to implement the model of speech recognition for Croatian language.

A Robust Hand Detection and Tracking Algorithm with Application to Natural User Interface

Benussi Toni, Jurić Darko
University of Zagreb, Faculty of Electrical Engineering and Computing
Unska 3, 10000 Zagreb, Croatia

This paper describes a system for hand detection and tracking which is used to implement a natural user interface which allows controlling the computer with hand movements and gestures. Different image processing and computer vision techniques were used in the realization of this system. The main components of the system are a skin detector based on histograms whose results have been improved with background subtraction and a clustering algorithm, an open hand detector and a subsystem for object tracking with a flock of features algorithm. The system has proved to be very robust to different background and lightning conditions and can be used in a wide array of multimedia and desktop applications.

I. INTRODUCTION

There are domains in human-computer interaction where classic interfaces like keyboards and mice show an absence of flexibility and freedom while giving input to the computer. One of the possible solutions in these domains is the use of natural user interface (NUI). The idea of this paper is to explore the possibility of implementing a natural interface with just a regular camera, without the use of specialized sensors and devices, as in most commercial implementations.

Specifically this NUI is designed to use human hand gestures as an "input device". The advantage of this approach is a much wider array of possible applications and the independence of the recognition procedure regarding the device on which it is performed as it can be used on any computer equipped with a web-cam.

The basic requirements such a system must satisfy are the capacity to operate in real time and robustness to different background and lightning conditions.

There are several approaches to hand detection, recognition and tracking. The most frequently used ones are based on color because of its distinctiveness as a pixel attribute. The paper (1) relies on color segmentation where the biggest skin region represents a hand. In (2) only simple background is considered where the color histogram can be modeled to contain large spike representing skin color pixels. A color based hand tracking without colors similar to the skin appearing in the background is discussed in (3). (4) relies on color distributions which tolerates noise (e.g. chosen non-skin regions) but it requires techniques for elimination non hand regions. Those processes are based on only one criterion and are not robust enough especially when skin color-like objects are present in the background, thereby this paper uses several detection criteria to overcome this problem.

The hand detection and tracking process is divided in several steps that will be further explained in the paper. The first step is to detect image regions that represent the skin. For this purpose a prepared distribution of skin color under different lighting conditions is used, which was obtained as a result of (5). With this distribution the probability of belonging to the skin region or the background region is computed for each image pixel. Skin regions obtained in this way do not cover all the skin pixels present in the image, so a clustering algorithm is used to enhance the results of skin detection. As a result of these two steps compact sin regions are obtained. The next step is to determinate which skin region corresponds to the hand. This procedure is based on the morphological characteristics of the hand. When the hand has been successfully detected and localized this information is used to initialize the tracking process based on the flock of features algorithm. In the end, as an example of the potential applications of this system an algorithm was added that detects whether the hand is open or closed, which can be used for example to control the mouse pointer on a computer. The whole procedure is shown schematically.

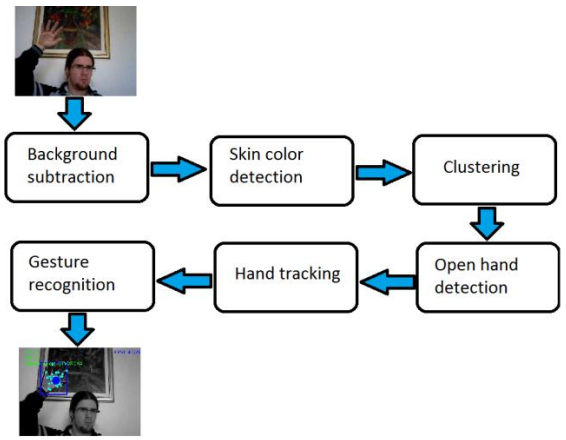

Figure 1. Schematic representation of the system.

II. BACKGROUND SUBTRACTION

A background subtraction algorithm based on local histograms was suggested in (6) and (7). In the first paper color was used as a feature, but it has proven to be susceptible to changing light conditions, so gradient orientation was introduced as a new feature in the second paper.

A. Algorithm

The image is divided into cells that can overlap each other. The best results are obtained with 8x8 or 12x12 cell size. For each cell the histogram is calculated in the following way.

The gradient magnitude and gradient orientation images are calculated first. Gradient orientation results for each cell are used to determinate to which column of the histogram each gradient result belongs. Good results are achieved by using 8 columns and angles from [0..180°]. The gradient magnitude is added to the selected column. As a pixel can belong to a border of a histogram column a better variant is to use the Gaussian membership function on the gradient orientation so that the value of each pixel affects also adjacent columns.

$$G_j^O(O_k) = \frac{K_j^O}{2\pi\sigma_O}\exp(-\frac{(O_k-O_j)^2}{2\sigma_O^2})$$

, where O_k is a orientation histogram column, O_j the column in relation to which the result is calculated. K_j^O is a normalization constant, and σ_O is defined empirically based on the camera noise.

To increase the cell tolerance to small displacements in the image another Gaussian function is applied, but this time in the spatial domain to favor the central pixels of the cell:

$$G_l^S(S_k) = \frac{K^S}{2\pi\sigma_S}\exp(-\frac{(x_k-x_l)^2+(y_k-y_l)^2}{2\sigma_S^2})$$

where the coordinate $S_k(x_k, y_k)$ is the central coordinate of the cell, and (x_l, y_l) is the coordinate for which the result is being calculated. After the introduction of these improvements the value of a histogram column is calculated as the sum of products of Gaussian functions.

$$h_j = \sum_{k=1}^{n^2} G_l^S(S_k)\, G_j^O(S_k)$$

Histograms are normalized so that the area of each histogram is equal 1. Comparison is performed by calculating the *Bhattacharyya distance*.

$$P_l = \sum_{j=1}^{n_h} \sqrt{h_j^{H_1} h_j^{H_2}}$$

During the implementation was noticed that it's better to use the Euclidean distance instead, as the *Bhattacharyya* distance doesn't take into account the possibility that one of the gradient histograms is equal 0. This can happen for uniform cells where the gradient magnitudes are equal 0.

B. Performance improvements

It is necessary to choose a cell size for the algorithm and by choosing smaller or bigger cells inevitably there is a trade-off between robustness to noise, computation time and accuracy. An improvement of the original algorithm is suggested in (8). The integral image of the histogram is calculated and bigger cell size is used. Unchanged cells are discarded and the other ones are recursively divided to the desired level.

III. SKIN COLOR CLASSIFICATION BASED ON HISTOGRAMS

A brief description of the histogram construction and classification process used in (5).

A. Histogram construction

Images containing skin segments and those that don't have been divided and the skin segments were labeled manually.

Two histograms are constructed, one from the labeled skin pixels and one from all the other pixels. It's not necessary to model 256 columns for each channel. A common procedure is to perform a histogram quantization to 32 columns per channel. One of the best results was obtained while using such a quantization.

B. Classification

The classification is performed by calculating the probability:

$$P(rgb|skin) = \frac{s(rgb)}{N_s}$$

where *s(rgb)* is the number of pixels in the *rgb* column of the skin distribution histogram. N_s is the total number of pixels in the skin distribution histogram.

$$P(rgb|\neg skin) = \frac{n(rgb)}{N_n}$$

where *n(rgb)* is the number of pixels in the *rgb* column of the non-skin distribution histogram. N_n is the total number of pixels in the non-skin distribution histogram.

A pixel is classified as skin element if the ratio between these 2 probabilities is greater than a defined threshold. By changing the threshold we get more false positives and less false negatives or vice versa. The used threshold is based on the ROC curve.

$$\frac{P(rgb|skin)}{P(rgb|\neg skin)} \geq \theta$$

The results were about 80% correctly classified pixels with 8.5% false positive responses or 90% correctly classified pixels with 14.2% false positive responses.

Mixture of Gaussian functions generated from the histograms yield slightly worse results than the actual histograms.

C. Implementation

The concrete histograms were taken from (9). Because the mixture of Gaussian yielded worse results without giving any noticeable performance improvements original histograms were used directly to classify skin pixels.

The histogram was constructed from 14,985,845 skin color pixels and 304,844,751 pixels that didn't belong to human skin.

IV. SKIN COLOR CLASSIFICATION BASED ON CLUSTERING

This algorithm was designed as a color based tracking algorithm in (10) and (4), but in this paper it was used to improve the results of the histogram based skin color classification.

A. Description

The user selects the regions of the objects he wants to track. The algorithm chooses the first pixel and calculates the Euclidean distance between the chosen pixel vector and the weights vector of the cluster. If the distance is smaller than the defined threshold the pixel is added to the cluster and the number of elements of the cluster is increased by 1. If the distance is bigger than the threshold a new cluster is generated and the weights of the pixel become the initial weights of the cluster. The number of elements of the cluster is set to 1.

Pixel color is expressed in the L*a*b* color space. For the classification purposes only components a* and b* are used.

The initialization or the selection of the learning samples is done manually or by some other technique, like in this case with histogram based classification.

Other objects in the scene can be of the same color as the tracked object. In the original paper false positive results were eliminated selecting the biggest connected region as the tracked object.

B. Variations in cluster weights computation

The first pixel associated with the cluster determines its weights. Another tested approach uses the mean of the cluster elements to determine the weights which is computed every time a pixel is added to the cluster. The third approach changes the weights based on the last pixel added to the cluster. All approaches refer to the learning phase of the clustering algorithm. No significant changes in classification quality were observed with the second and third approach so the simplest first variant was used.

C. Other color spaces

The following color spaces were tested: L*a*b, RGB, Ycc, HSV. Neither yielded significantly better results compared to the others. Some show less correctly classified skin pixels with less false positives or vice versa.

The only noticeable differences are in the threshold values. Some color spaces (like HSV, L*a*b*) which group skin colors more densely require a lower threshold, while others (like RGB) require a higher threshold. The tolerance to particular colors is also different between color spaces.

Changes in illumination are not necessarily a result of external sources, but can be the result of refocusing and the camera contrast corrections which we could not affect.

There are differences in tolerance to illumination changes between color spaces. This can be observed when the object moves away from the camera (it usually becomes darker). L*a*b can cope successfully with this problem while for example RGB and Ycc cannot.

Figure 2. Classification for L*a*b* color space. The first line represents the initialization of the algorithm with the region inside the green rectangle. The lower line represents an example of classification. There are plenty false responses and there is intolerance to the seemingly slight color change caused by light condition changes (wrong classified regions inside the palm area).

D. Discarding of clusters

An approach to discard clusters with low pixel count was tested. The results have proven to be worse in regard to correctly classified pixels so this approach was rejected as ineffective.

E. Implementation

The number of clusters is often bigger then 40 and an implementation that stored the clusters directly into data structures would be computationally demanding and inappropriate for real time applications. Instead in the initialization step a field of 256*256*256 elements is

created to cover the entire color space and all the distances [0..border] are computed as sums of absolute values of differences so that integers can be used for better performance. After this initialization step the classification is made simply by using this 3-dimensional field as a look-up table with precomputed distances. In this way the computational requirements have been drastically decreased. The number of clusters doesn't affect the performance of the algorithm.

F. Conclusion

Although it was originally intended for object tracking, because of the poor classification results it's not possible to separate the desired object from the background. However it can be used to improve the results of histogram based classification. Clusters are initialized around each of the colors classified as skin elements. By expanding skin regions with color clustering an error is introduced, but also it has proven to increase the ratio of correctly classified pixels in relation to the total number of pixels marked as skin elements.

V. OPEN HAND DETECTION

Different approaches are mentioned in literature to solve the problem of recognizing hand shape for the purpose of monitoring and recognizing hand gestures. These approaches include the use of Viola-Jones detection and model based localization (11), principal component analysis (PCA) and Fourier descriptors usage (2), self-organizing maps (3), and simple approaches based on tracking using a skin color classification (12).

In this paper a different approach is used that tends to take maximum advantage of the results obtained using the previously described algorithms for skin detection that gave the solution as a set of objects in the image identified by skin color. The number of such objects can be over a few and they are mainly the consequence of the presence of other skin color regions other than the hands, such as the head or elements of the background of similar color.

The basic idea is to recognize the hand based on its shape which is very distinctive. For a description of the shape of a hand, we used its most prominent morphological feature, the presence of fingers as distinct protruding formations. To detect the presence of fingers a method from the *OpenCV* library is used that calculates convexity defects, or dents in an object for which the object is not convex. Such a defect is described by its start and end point, the deepest point in the recess and the depth of the recess which is equal to distance of the deepest point of the line connecting the start and the end point. The occurrence of such defects in the context of a hand does not directly describe the fingers, but the gaps between fingers as shown in Figure 3.

As seen in Figure 3 in the case of a hand there are potentially more defects than the recesses between fingers and other objects can have such defects. However for the gaps between fingers it is characteristic that convex defects have a relatively large depth versus the distance between start and end point of defects. Therefore, a criterion for identifying gaps between fingers is used which rely on the assumption that the gaps must be convex defects with a depth equal to at a least half the distance between the start and the end point.

Another problem that arises is the possibility that due to imprecise skin detection the boundary of the hand and other skin areas is quite uneven, which can cause a lot of small convexity defects that can lead to false recognition of gaps between the fingers that do not actually exist. This problem is resolved by an additional criterion that requires the convexity defects to be sufficiently deep compared to the total perimeter of the observed object.

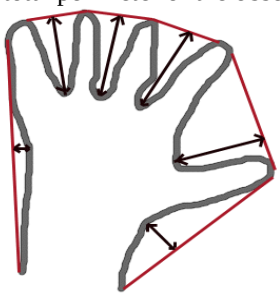

Figure 3. An example of convexity defects on a hand..

Of course, in the case of the hand we expect that the number of convexity defects that correspond to gaps between the fingers to be 4, but just in case we tolerate the possibility that there is only 3 if one finger is not successfully detected in earlier stages.

The last stage of the algorithm for hand shape recognition needs to determine which among all the objects in the picture is really the hand in case there are multiple objects that meet the criteria described above. For this purpose, using the fact that all the gaps between fingers have roughly similar depths, the object that satisfies the criteria described before and has the highest ratio of depth of the shallowest and deepest convexity defect is declared as the hand.

In addition to speed up the process of finding the object corresponding to a hand all skin colored objects which surface area is less than 1000 pixels are ignored because they are very small (using the resolution 320x240 and 640x480 these objects can take up about 1.3% and 0.3% of a surface of an image), and it is difficult to properly track and almost impossible to reliably recognize any gestures that such object represent.

A. Testing the hand detection

The images from two video clips in 320x240 resolution which are obtained from a web-cam built into a laptop are used for testing. The first video clip contains 470 images while the second clip contains 276 images. The video clips contain a hand that moves in a scene with different backgrounds and different lighting conditions. For the entire set of images several measurements have been calculated: the number of images in which the hand has been successfully identified, the number of images where have been no successful identification and the number of images which contain false-positive

identifications. The test results are shown in the table.

The purpose of hand detection is tracking initialization, thereby it is not essential to detect the hand in each image in a video sequence, it is sufficient to detect the hand in a reasonable period of several seconds so the tracking could begin as soon as possible. Therefore, we believe that the obtained results are more than satisfactory because the performance of the hand detection procedure is good enough to ensure that the tracking begins almost at a same time when the video file loads, and a very small number of false positive detections ensures that the hand is tracked instead of a similar object in the scene.

	Video 1 (470)	Video 2 (276)	Total(746)
Successful hand recognition rate	79.1%	76.1%	78.0%
Unsuccessful hand recognition rate	19.8%	23.9%	21.3%
False-positive hand recognition rate	1.1%	0.0%	0.7%

Table 1. The test results of hand detection

VI. OBJECT TRACKING

There are various algorithms to track objects that are based on some specific characteristic usually color: classification based on color (4), color histograms: modified Camshift (13). The approaches that are based on particle algorithms have proven to be particularly good like Condesation (14). This approach takes into account the gradient, but has the disadvantage that rapid object shape changes are not supported.

Hand tracking is a difficult problem because it must take into account changes in shape, size and sudden and rapid movements. We have taken and modified an algorithm that takes into account all the above, and it is a representative of particle algorithms. It combines different features (color and gradient) which proved to be crucial for the successful tracking of these types of objects.

A. *Original algorithm*

The paper (15) developed an algorithm based on particle approach. Each particle uses two types of features. The first is the KLT feature while the other takes into account the image pixels belonging to the skin. KLT features are named according to the three authors: Canade, Lucas and Tomasi. In combination with images obtained by reducing the size of an original image (image pyramid) they can be efficiently identified; it has been shown that they are robust to noise in the image. If the correlation between the found and the searched feature is smaller than a defined threshold particle is considered lost.

An image with identified skin regions is the input parameter of the algorithm. Not only each particle must be in an area that belongs to a certain color, but it also must satisfy two rules regarding distance. None of the particles should be too close to other particles, and none of the particles should be too far from other particles. The analogy of the birds flight is used where birds keep together, but at a certain distance.

Tracking is initialized by selecting a certain number of particles that satisfy the above conditions. A fixed number of KLT features is generated ($k*n$), where k is an empirical factor. The best number of particles (n) is chosen according to skin color. The locations of existing particles are updated as KLT features. The algorithm uses a search window with image reducing by levels (image pyramid). Particles that are not found or do not meet the criteria are reallocated to meet these conditions. The center is calculated as the mean value.

B. *Tracking initialization*

Instead of using raw probability map, that map is thresholded. It is experimentally determined that skin color values change a lot during rapid hand movements or with mild light changes but the most common reason is video quality. In these cases the algorithm can lose the tracked object. Thresholding reduces constant fluctuations between pixel values.

Tracking is initialized by selecting a certain number of particles that satisfy the above conditions. Initially the particles are selected according to the obtained KLT features. These selected particles are filtered to meet the conditions of minimum distance between two particles and belonging to the skin which is determined by the input skin color image. The number of particles that are removed is compensated by randomly chosen ones that satisfy the conditions.

C. *Object tracking*

Locations of existing particles are updated as KLT features. The algorithm uses a search window of 3x3 pixels with 5 levels of image pyramid. Particles that are not found or do not meet the criteria are removed.

Before computing the center, the outermost particles are temporary removed in order to achieve higher accuracy of center computing. The center is calculated as the mean value because the center shifts, while losing and adding particles are smoother and smaller than the shifts of the median value.

The contour of the object is updated which is derived from the skin color image, and as a contour which contains the calculated center. The original algorithm contains a maximum distance, thereby is not possible to track objects of an arbitrary size therefore in a modified version of the algorithm p outermost particles are taken. A part of such particles is removed, and some are reallocated at half the distance between the old location of a particle and the calculated center. Such reallocated particles do not have to meet all conditions, but they will nevertheless be removed in the next iteration. By removing and reallocating the particles the selection of closer points is enforced, thereby the stability of the

tracking is increased because the likelihood that the observed object is lost due to particle transferring to another object that has strong edges is decreased.
Compensation of particles is done by randomly selecting new ones that meet the defined conditions. The number of attempts to find a new location for each particle is set in advance. It is shown that it is not necessary to look each time for new particle locations as KLT features because a particle is placed on such a spot by the algorithm itself after a few iterations. Another reason is the performance loss that would occur using such reinitialization.
The figure below shows the tracked object which is marked by a blue rectangle and a black colored contour.

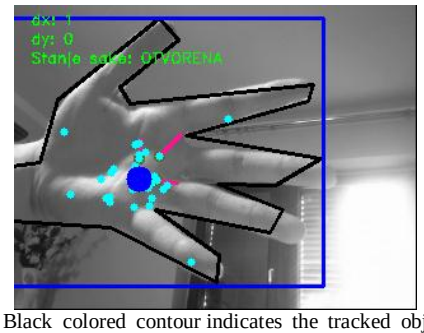

Figure 4. Black colored contour indicates the tracked object; a dark blue circle is its center, while light-blue circles indicate the particles. Pink lines symbolize reallocation of particles.

D. *Object loss*

The tracked object can be lost due to object disappearance, poor quality of skin color image and because of sudden movements. Short transition of another object over the tracked one is tolerated in most cases.
An object is considered lost if the center cannot be calculated due to lack of particles. In this case the center is not updated but retains the last known position, thereby the lost object must be restored to its previous position to re-start tracking. The old center is marked in the image if the object is lost.

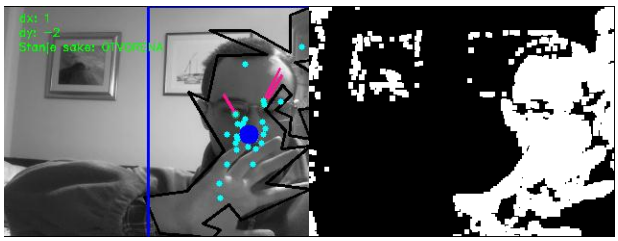

Figure 5. Migration of particles on adjacent object due to presence of objects of similar color.

VII. HAND STATE RECOGNITION

The paper (16) recognizes the state of the hand in the way that an image of the hand is binarized and the vertical and the horizontal projection is determined. Hand gesture is determined by obtained functions.

Somewhat more robust method (17) is proposed to recognize different hand gestures in a way that the image of the hand is binarized and the center of gravity is determined. After that for one or more circles which have smaller radius than the circle which surrounds the hand number of crossings with a hand is calculated. The number of crossings minus one (because of the arm) denotes the number of fingers. This feature is invariant to rotation, translation and scaling.

A. *Implementation*

Due to lower camera quality and possibility of fast hand movements the contours of the hand is averaged and is difficult to distinguish a greater number of gestures. Therefore, only the main idea is taken, which is that the number of fingers is determined by the number of intersections with the circle. However, if a person does not cover his wrist the center of the gravity can be driven out and the classification would not be correct.

Therefore, it is implemented as follows. The part of the algorithm for open hand detection that counts convex defects has been reused. If the number of defects is larger than a predefined threshold the hand is considered to be open otherwise it is considered closed. These are the only supported states. Recognition has proved robust even with a smaller presence of noise.

VIII. CONCLUSION

This paper describes a system that achieves a natural interface just with a simple web-camera as input device. The realization of such a system has proved to be a quite complex problem and for its successful implementation it was necessary to combine a number of different techniques and algorithms described in this paper. The system has proven quite successful in fulfilling its tasks in case those good working conditions are insured (good illumination and static background). In the case of a background which has very similar color as the skin, or in case of inadequate illumination, system performance significantly decreases. The main problem is the high sensitivity of the image as a source of information regarding shooting conditions, and it is very difficult to build a system that would be robust enough to ensure proper operation in every possible scenario of application.

Therefore, we believe that the use of advanced specialized sensors which are installed in such commercial systems is justified, and that without further progress in the field of computer vision it's not possible to completely replace traditional interfaces with natural interface in applications that require high-precision control.

Recommendation of YouTube Videos

M. Brbić, E. Rožić and I. Podnar Žarko
Faculty of Electrical Engineering and Computing (FER), Zagreb, Croatia
firstname.lastname@fer.hr

Abstract - YouTube is a huge video-sharing service with hundreds of millions of users and hundreds of thousands of videos being uploaded every day. Thus, recommendation of YouTube videos to a single user is a challenging problem which cannot be solved by simply reusing the prevailing recommendation methods.

The paper presents a specific recommendation algorithm for YouTube which relies on the data retrieved through the YouTube Data API. A cloud-based application integrates the proposed algorithm and offers a web interface to end users. The paper presents a preliminary analysis of the recommendation quality and lists YouTube Data API limitations which influence the design of recommender systems for YouTube videos.

I. INTRODUCTION

Recommender systems and algorithms stem from fields such as cognitive science, approximation theory, information retrieval and forecasting theories. In the mid-1990s recommender systems have become an independent research area and today we can classify recommender algorithms in three basic categories: content-based recommendations, collaborative recommendations and hybrid approaches [1].

Content based recommendations predict future user actions and preferences based on their past actions. Collaborative recommendations try to find similarities between a user and other users who have already used the system, and based on past actions of similar users recommend some content which might be interesting to the user. Hybrid systems combine both approaches to offer better recommendation performance.

Recommendation algorithms depend widely on the available data set which captures past user behavior, similarities between the data and also on context such as time of year or user's current location. Collaborative recommendation systems typically produce their recommendations based on user and item information while taking into account user context. Thus, the two-dimensional User×Item matrix which shows which items have been consumed by all system users in the past is extended to multidimensional space to take context information into consideration. The easiest way to solve the problem related to context and avoid extending the matrix to multidimensional space is reduction-based recommendation proposed in [2]. Reduction based recommendation uses only ratings that correspond to the specified context and reduces greatly the input dataset.

YouTube recommendation is a specific problem which cannot be solved by simply reusing existing recommendation methods. There are about 485,000,000 videos in repository [4] and that number is growing every minute. Approximately, 48 hours of video are uploaded every minute, resulting in nearly 8 years of content uploaded every day [5]. A large number of users and great dynamicity of YouTube content represent special challenges to recommender systems. Moreover, YouTube gives limited access to user and video information through the YouTube Data API which represent another major difficulty. For example, it is not possible to access a viewing history for a user but it is possible to find out which videos a user has added to his/her favorites or uploaded over time and also which videos a user has rated positively (within the last 60 days [6]. By reusing such data, a User×Item matrix would be almost a zero matrix because the probability that two users have added the same video to their favorites is very small. Therefore, the standard collaborative recommendation methods are not applicable. The problem with content based approaches is that almost every user has a set of videos (his favorites and likes) which is too small, and if a recommender systems would use such small amount of information regarding a user to find the right video from the set of millions of videos in the YouTube repository, the resulting recommendation quality would be extremely poor. Therefore, we propose a different approach which is specific for YouTube recommendation.

In this paper we describe our algorithm and initial experimental evaluation of our algorithm. The paper is organized as follows: In Section 2 we present our algorithm and the idea behind it. Section 3 describes the implementation of the algorithm and related technologies. Section 4 preliminary evaluation results of the recommender system while Section 5 closes the paper with conclusions and lists possible system improvements.

II. ALGORITHM DESCRIPTION

Since we have concluded that a content-based approach is simply inapplicable for YouTube recommendation in any form because of the lack of usable information about a user, we have decided to find another criterion to identify similar users for a target user U for whom the recommendation is made. Of course, the limitation is the aforementioned set of data that we have access to via the YouTube API.

We can get a list of user's friends, but recommendation of videos that his/her friends have liked in the past is probably not a good solution for many reasons. The user does not have to share the same taste as his friends, and it is likely that the user will share videos with his friend who have the same taste as he/she (YouTube has an option

share) while a large number of users do not have many friends on YouTube. Thus, as users that are most similar to user U (his related users), we have decided to choose those users that have uploaded videos which user U has rated positively or added to favorites. The assumption is that if user U has liked a video which the user R has uploaded in such a degree that he added that video to favorites or rated it positively, the user U will probably also like other videos which user R uploads, rates positively or adds to his favorites. This assumption is similar to the follower effect which is characteristic for Twitter, where user U is the follower of user R. However, we have realized that this assumption could be valid only for those videos that are in the same category as the video which user U likes. For example, if user U liked a music video which user R uploaded, it is likely that user U and user R have the same taste in music. However, we cannot make any assumption about the interests of user U in other categories like sports or entertainment compared to user R.

The first step of the algorithm finds all videos that user U has liked or added to favorites in the past, and then it identifies the users that have uploaded those videos and the categories of those videos. Those are the related users of user U. This information is stored for every user and is updated at each subsequent rerun of the algorithm (login to the system or request for a recommendation). The information is stored per each user as a Related_user×Category matrix which gives the number of videos from a given category which user U has liked or added to favorites from a related user. Since the matrix will most probably be very scarce (it seems very unlikely that one user will be related to another in more than one or two categories) it is most appropriate, in our opinion, to use a data structure like a map (dictionary) to store it.

The second step of the algorithm finds all the videos that the related users of a user U have liked, added to favorites or uploaded in the same category which relates the two users. Those videos are considered to be of interest to user U. It is obvious that the recommendations will be better for more active users i.e. users with greater number of related users. The assumptions are that the users who upload videos are active YouTube users, as it is often the case with such users, and that user U has videos that he/she added to favorites or has positively rated.

Finally, after obtaining videos of all related users which represent potential recommendations, we have to rank them. For that we have decided to use the information about the number of views of each video (*viewCount*) and the number of times a video had been positively (*likeCount*) or negatively (*dislikeCount*) evaluated. That information represents, in a way, the recommendation of the whole YouTube community. We also took into account two parameters that are specific for our algorithm. Those are the *appearanceNumber* and *userFactor*. All parameters used for ranking of the videos are summarized in table 1.

For the purpose of ranking we take the logarithm of the number of views of a video to get an order of magnitude because the number of views of a video spans from several tens to several hundreds of millions and we wanted it to have a relatively equal part in the ranking process as the other parameters. The overall assessment of a video we decided to punish according to the proportion of negative evaluations of the video. We found empirically that it is desirable for better results to attenuate the impact of that portion and therefore we decided to take the square root. If that is not done then videos with very few views and even fewer ratings, all of which are positive, are ranked very high. That is not really good because there are a lot of such videos which are liked by close friends and acquaintances, but few others would find them interesting.

If more than one related users have added the same video in their favorites or liked it, extra weight is given to the video in the ranking process. This is represented by the *appearanceNumber* parameter. For example, if a video appears in the potential recommendations of two related users then the *appearanceNumber* of that video is set to 2. However, a situation in which the *appearanceNumber* is greater than 1 will be very rarely satisfied because the probability that two or more related users in a limited period of time have added to favorites or positively rated the same video (among all the videos on YouTube) is very small. The *userFactor* is the information that is held by the Related_user×Category matrix, i.e. it is the number of times user U liked or favorited a video from a related user in a specific category. Since the *userFactor* is less significant than the *appearanceNumber* and is much more likely to be greater than 1 we attenuated the value of *userFactor* by using the square root.

TABLE 1. – RANKING PARAMETERS

Parameter name	Parameter description
viewCount	number of views of the YouTube video
likeCount	number of positive ratings (likes) of the YouTube video
dislikeCount	number of negative ratings (dislikes) of the YouTube video
userFactor	the number of times the user liked or favorited a video in the same category as this video that the related user, in whos activity this video was found, uploaded
appearanceNumber	the number of times this exact video is recommended in the current recommendation (usualy one)

The final formula used for ranking videos identified as potentially interesting to a user is the following:

$$\text{rating} = \frac{\log(\text{viewCount})}{\sqrt{\frac{\text{dislikeCount}}{\text{dislikeCount}+\text{likeCount}}}} \cdot \sqrt{\text{userFactor}} \cdot \text{appearance Number} \quad (1)$$

where rating is a score given to each video.

In cases when the *dislikeCount* is equal to zero it is necessary to make a correction of its value. We found empirically that in this case it is desirable to set the value

of the *dislikeCount* to one. If a video is really good and has a large number of positive ratings and a large number of views then adding a one dislike to such video will not have a major impact on its overall rating. If a video has a small number of positive ratings and a small number of views this will greatly reduce its rating, but this effect is positive because we usually don't want to recommend such a video (obviously this video is interesting to a small group of people, and therefore it is not likely that it will be interesting to user U).

III. IMPLEMENTATION

The recommender system is implemented as a web-application[1] written in the Java programming language on the Google App Engine cloud computing platform [7] using YouTube Data API libraries for extracting required data sets from YouTube.

The user interface enables the user to enter his/her YouTube username and choose among two options – make a new recommendation or view past recommendations.

When a user makes the first request for a recommendation, the application contacts YouTube and gets all the favorite videos of that user and all the videos that he liked (rated positively) as far in the past as the YouTube API will let it or keeps track itself (60 days). The information about the users who uploaded those videos and the categories of those videos are extracted and stored in the Google App Engine datastore as RelatedUser entities which represent the Related_user×Category matrix for that user. Also, a User entity is stored containing the username and the date and time of the last recommendation request for that user. Every subsequent time that same user makes a recommendation request the application retrieves from YouTube only the activity (liked and favorite videos) from the last time the user made a recommendation request and updates the Related_user×Category matrix for that user, i.e. updates some and adds new RelatedUser entities if necessary.

After all the related users and corresponding categories for a user are found the application contacts YouTube again and retrieves all the videos the related users have liked, added to favorites or uploaded (in the right category) since the last recommendation request of the user using the application (or 14 days if first use). First the *appearanceNumber* and *userFactor* parameters for each video are set and then the rating for each video is calculated by the algorithm formula. The videos are then sorted by the calculated rating in a descending order and the first 25 are taken as the recommendation.

Before the recommended videos are shown to the user a Recommendation entity is made with two parameters: time and date of its making and the time span it took for recommendation. Also, for each of the recommended videos a RecommendedVideo entity is made which are all put as children of the just made Recommendation entity and which hold information about the videos that were recommended. That is needed for users to be able the see their past recommendation and more importantly for the application to be able to note if the recommended video has been clicked on by the user it was recommended to.

If the user chooses on the main page to view his past recommendations the application simply gathers information about the past Recommendation entities of that user and presents them to the user in the form of the time the recommendation was made and the time span it was made on. If a user clicks on one of them the past recommendation is shown in its exact original form. The application simply does that by finding the relevant RecommendedVideo entities in the datastore.

Whenever a user of the application clicks on a recommended video the link does not take him directly to the URL of the video. Instead it takes him to a separate URL on the application on which operates a servlet that takes the information from the GET request and based on them retrieves the relevant RecommendedVideo entity from the datastore. It gets the real URL of the video from the retrieved RecommendedVideo entity but before it redirects the user to that URL it marks the entity (or rather the video that the entity represents) as clicked and puts it back in the datastore. In that way the usage of the application can be easily tracked and some simple tests of quality of the recommendations can be made.

IV. RESULTS

In order to view the results objectively the reader should know that the collected data for the evaluation of the algorithm was collected from very similar people in very similar circumstances and should also be aware of the fact that we made a small improvement on the algorithm at the time of testing which we believe improves the quality of the recommendations greatly. At first the maximum amount of time (60 days) of recent activity of related users was used for the first recommendation. We realized that because of that the first recommendation will have a great chance of having high ranked videos that the user had already watched and that it will divert the user from using the application again. So we decided to reduce the time span for that first recommendation to 14 days, a time period we considered long enough to generate sufficient videos and yet short enough for those videos to be recent. Because of that the data collected after the change will be presented separately.

The application was used by a total of 113 users. Of those 113 users 29 have no related users and were thus useless for the algorithm. There are two reasons why a user would have no related users. The first is the obvious one – the user has no favorites and has not rated any video in the 60 days prior to using the application and the second is that the user's YouTube profile is private. Those 29 users are not taken into further account; all calculations are made on the remaining 84.

The average number of related users over all users is 15.86. It is interesting to observe the average number of related users of only the users who have made more than one recommendation and those who have made only the first and never came back. The average number of related users of the users that made only one recommendation is 14.84 while the average number of related users of the

[1] http://givemeclips.appspot.com

users that made 2 or more recommendations is 27.92. This is a strong indication that users with more related users get better recommendations.

Of the 84 valid users 7 had very few (1 to 3) and apparently very inactive related users because no videos were recommended to them. If we disregard those 7 users we are left with 77 users of which 13 have returned after making the first recommendation, which is 16.88%. If we now separate those 77 users by the time span of their first recommendation (60 and 14 days i.e. before and after the change) we get a group of 52 and a group of 25 users respectively. Of those 52 users that made the first recommendation before the change to the application 7 returned after the first recommendation, which is 13.46%. Of the other 25 users 6 returned, which makes 24%. This clearly indicates that the change to the application/algorithm was a positive one.

Since the first recommendations are a bit different than the others because they cover a longer time period and often recommend a lot more videos, at least in the small dataset we have gathered, we decided to analyze them separately.

The average number of videos per recommendation for all recommendations is 18.10 and the average number of visited videos per recommendation is 1.69. For only the first recommendations that were made on a 60 day time span those averages are 22.96 and 1.60. For only the first recommendations that were made on a 14 day time span those averages are 17.36 and 1.36, which is expected. The most interesting results are the averages for the recommendations that were not the first. They have a lot lower average of videos per recommendation, only 9.44, but also a quite higher average of visited videos per recommendation - 2.18. This could be interpreted as an indicator that, although later recommendations have fewer videos those videos are more interesting. That is consistent with the idea behind this algorithm which is to recommend videos that the user would normally run into very hard because they are not very popular yet or got lost in the sea of videos, but that are interesting to the user because of his/hers specific interests.

The collected data is also used for evaluation of the ranking formula (1). The most visited video is the first video i.e. the best ranked video. The first video of a recommendation was selected 33 times in 104 recommendations and out of 175 videos selected in total. Top 5 videos were selected a total of 83 times, and top 10 videos a total of 118 times. That means that 47.4% of all selected recommended videos were ranked among top 5 and 67.4% among top 10 videos in a recommendation. These results indicate that better ranked videos are in fact more interesting to the user and that the use of formula (1) is justified.

V. DISCUSSION AND CONCLUSION

In this paper a recommendation algorithm for YouTube was presented which relies on the data retrieved through the YouTube Data API. This algorithm finds all YouTube users who uploaded videos which the target user has liked or added to favorites and categories of these videos and then stores that information in a Related_user×Category matrix. The algorithm then finds the videos which those related users had recently uploaded, liked or added to favorites and that are of the corresponding category and ranks them using formula (1) to form a recommendation.

Our recommendation algorithm depends a lot on the activity of the related users or the user itself. If a user is not very active on YouTube and has a few related users, the recommendation will most probably not work very well for him/her. This problem is a consequence of the limited information that we can obtain using YouTube Data API.

A definite specificity of the algorithm is the amount of the recommended videos. Since they are generated from the recent activity of the related users there will be only a small amount of them on a day-to-day basis, unless, of course, a user has a huge amount of related users. But from the testing that we managed to do in this short period of time the amount of related users ranges from just a few to a maximum of 45. The problem lies in the fact that most people just watch YouTube videos. A very large amount of them do not even have user accounts, and a lot of others use them very rarely and for specific purposes (music playlists, etc.). Average YouTube users rarely rate (click LIKE) on a video they like. That is obvious from simply observing the number of view counts on YouTube videos in contrast to the number of ratings. On the other side, for users that do have accounts and do rate videos occasionally, when they really like something, this recommendation algorithms makes a really personally tailored recommendation made of videos that will not show up that easily on their standard YouTube recommendation. Thus our algorithm can be used in cooperation with a more standard recommendation like e.g. the YouTube official recommendation which can recommend extra videos when our algorithm cannot find a sufficient number of videos[2].

There is a possibility to expand the algorithm so that it always generates enough recommended videos. This could be done by making the algorithm recursive in a manner that the related users of the related users of a user can be found and their activity checked. In our opinion this would be unscalable network-wise because all that activity generates traffic to and from YouTube. But if the algorithm would be run on YouTube servers directly that could be a possible solution.

Of course, that would then solve the biggest setback of the whole problem of recommending YouTube videos and that is the limitations of the information that can be retrieved from YouTube. The biggest limitation of all for this algorithm in its current form is the inability to catch events like negative ratings. For example, a user rates a video positively and because of it gets a related user. The user then gets a recommendation based on that related user and rates a video negatively. The related user that was responsible for that negative rating should be removed from the related users list. But that information is not retrievable. One possible, indirect way to solve this problem is to remove from the related users list those

[2] The YouTube official recommendation for a user is retrievable by YouTube Data API.

related users that are responsible for recommended videos that the user clicks on very rarely or never in the recommendations presented to him.

Due to all the limitations we must conclude that recommending YouTube videos in this kind of manner can hardly be a substitution for the official YouTube recommendation since it lacks information and speed because of the way the information that can be retrieved is retrieved. But we believe that this is a good new way to look at recommendation problems in services with similar characteristics as YouTube, which are very dynamic, and we argue that our idea of finding related users and generating a user specific reduced User×Item matrix has potential which would be worth exploring by implementing it on a real system with immediate access to all relevant information.

***Abstract*—Multi-core processors offer a growing potential of parallelism but pose a challenge of program development for achieving high performance in applications. This paper presents a comparison of the five parallel programming models for implementing parallel programs in C++ on multi-core computer systems. The models under consideration are Intel®'s Thread Building Blocks (TBB), OpenMPI, Intel®'s Cilk™ Plus, OpenMP and Pthreads. For demonstration purposes multiple parallel implementations of an algorithm for matrix multiplication suitable for parallelization were created. The main goal of this paper is a comprehensive comparison of chosen models with respect to the following criteria: performance and coding effort required.**

Index Terms—Parallel programming, Pthreads, OpenMP, TBB, Cilk++, OpenMPI

I. INTRODUCTION

Multiprocessor computer systems are now widely available, with all of the processors shipped by manufacturers being multi-core based designed[1]. The current trend towards more processor cores instead of higher clock speeds can be attributed to the physical limitations of modern processor designs [2], [3]. This has serious implications for the design and development of applications as writing and debugging parallel software is difficult and requires more expertise than sequential programming [3]. However, it is vital that programmers become proficient in writing parallel code so that we can harness the parallel power available in multi-core computer systems.

Various tools and libraries which help programmers make the transition from sequential to parallel programming are available. These include the compiler directive based OpenMP [9] and Thread Building Blocks [12], which is a high-level library providing parallel constructions and optimized parallel algorithms [4], [1], [2], [5]. Additionally, lower-level libraries such as Pthreads provide more control, but require the programmer to manage threads explicitly [6], [7].

Other parallel and performance tools include Intel® Integrated Performance Primitives (IPP), Intel® Math Kernel Library (MKL), Microsoft® Parallel Patterns Library (PPL).

This paper aims to evaluate the performance and code characteristics of the selected five parallel libraries for the parallelization of an algorithm for matrix multiplication. The various parallel implementations are compared on program elapsed time and speedup. Code characteristics such as effort required (measured in lines of code added or changed) and total number of lines will be compared.

II. RELATED WORK

To support parallelization available from multiple CPU cores software has to be able to spread its workload across multiple processors. On shared memory multiprocessors system, such as those based on multi-core CPU-s, this is typically achieved using multi-threading, although other techniques such as message passing can be employed. It might seem that if a little threading is good, then a lot must be better. In fact, having too many threads can bog down a program. The impact of having too many threads comes in two ways. First, partitioning a fixed amount of work among too many threads gives each thread too little work that the overhead of starting and terminating threads swamps the useful work. Second, having too many threads running incurs overhead from the way they share finite hardware resources.

A good solution is to limit the number of runnable threads to the number of hardware threads. Algorithms that were developed used two threads.

A. Shared memory based parallel programming models

A diverse range of shared memory based parallel programming models are developed up to now. They can be classified into mainly three types as described below. [8]

1) Threading models: These models are based on the thread library that provides low-level library routines for parallelizing the application. These models use mutual exclusion locks and conditional variables for establishing communications and synchronization between threads. Threading models are suitable for applications based on the multiplicity of data and they provide a very high flexibility to programmer.

2) Directive based models: These models use the highlevel compiler directives to parallelize the applications. These models are an extension to the thread based models. The directive based models takes care of the low-level featureslike partitioning, worker management, synchronization and communication among the threads. The main advantages with directive models are that it is easy to write parallel application and programmer doesn't need to consider issues like data races, false sharing, deadlocks.

3) Tasking models: models are based on the concept of specifying tasks instead of threads as done by other models.

This is because tasks are of short span and more lightweight than threads. One difference between tasks and threads is that tasks are always implemented at user mode.

B. *Programming Models Evaluated*

This section describes the parallel programming models that are evaluated in this paper.

The models evaluated are:
Pthread as threading model
OpenMP as directive based model
TBB and Cilk++ as task based model
MPI as both distributed and shared model

1) Pthreads: Portable Operating System Interface (POSIX) threads are an interface with a set of C language procedures and extensions used for creating and managing threads. [6] They can be easily extended to multiprocessor platforms and are capable for realizing potential gain in performance of parallel programs. It is raw threading model that resides on a shared memory platform leaving most of the implementation details of the parallel programs and more flexible to devel oper. Pthreads has very low-level of abstraction and hence developing the application in this model is hard from the developer perspective. With Pthreads the parallel application developer has more responsibilities like work load artitioning, worker management, communication and synchronization and task mapping. It defines a very wide variety of library routines categorized according to the responsibilities presented above.

2) OpenMP: Open Message passing or Open specification for multiprocessing is an application program interface, which defines a set of program directives, Run time library routines and environment variables that are used to explicitly express direct multi-threaded, shared memory parallelism. [9] It can be specified in C/C++/FORTRAN. OpenMP stand at high-level of abstraction which eases the development of parallel appli cations from the perspective of the developer. OpenMP hides and implements by itself the details like work load partitioning, worker management, communication and synchronization. The developers only need to specify the directives in order to parallelize the application. OpenMP is not widely used as Pthreads and is not emerged as a standard. The flexibility with this model is less compared to Pthreads.

3) TBB: Threading building blocks is a parallel programming library developed by the Intel Corporation. [12] It offers a very highly sophisticated set of parallel primitives to parallelize the application and to enhance the performance of the application on many cores. Intel's threading building blocks is a high-level and supports the task based parallelism to parallelize the applications; it not only replaces the thread ing libraries, but also hides the details about the threading mechanisms for performance and scalability. Intel's TBB relies on offering the scalable data parallel programming which is much harder to achieve by making use of the performance as the number of processor cores increases. Threading building blocks is a library that supports the scalable parallel program ming by using the C++ code and does not require any special languages or compilers. The underlying library is responsible for mapping the tasks on to the threads in an efficient manner. As a result TBB enables you to specify parallelism more efficiently than using other models for scalable data parallel programming. In general as one goes deep into the TBB parallel programming model it is hard to understand the model and in some cases increases the development time this is because TBB stands at a high level of abstraction.

4) Cilk++: This is a task based parallel library. [11] It facilitates the fastest development of the parallel applications by just using the three Cilk++ components and a runtime system that are capable of extending to the realms of the parallel programming. It is based on the C++. It is well suited for problems based on the divide and conquer strategy. Recursive functions are often used that are well suitable for the Cilk++ language. The Cilk++ keywords identify function calls and loops that can run in parallel. The Intel's Cilk++ runtime schedules these tasks to run efficiently on the available processors. Eases the development of the applications by imposing the developer to create tasks and also enables to check for the races in the program.

5) MPI: The Message Passing Interface Standard (MPI) is a message passing library standard designed to function on a wide variety of parallel computers.[10] Interface specifications have been defined for C/C++ and Fortran programs. While all other evaluated models work only on symmetric multiprocessing (SMP) systems, MPI works on both SMP and distributed memory systems. It is portable, there is no need to modify source code when porting application to a different platform that supports (and is compliant with) the MPI standard. MPI uses objects called communicators and groups to define which collection of processes may communicate with each other. Most MPI routines require specifying a communicator as an argument. Within a communicator, every process has its own unique, integer identifier assigned by the system when the process initializes, called rank. Ranks are used by the programmer to specify the source and destination of messages.

Table 1 shows comparison of five tested parallel programming approaches based on several criteria such as type of parallelism they are support, complexity, compiler and environment support they require.

TABLE I. COMPARISON OF FIVE PARALLEL PROGRAMMING LANGUAGE

Implementation	TBB	OMP	PThrd	Cilk	MPI
Task level parallelism	+	+	-	+	+
Data decomposition support	+	+	-	-	-
Complex parallel patterns	+	-	-	+	+
Broadly applicable generic parallel patterns	+	-	-	-	+
Scalable nested parallelism support	+	-	-	-	+
Built-in load balancing	+	+	-	+	-
Affinity support	-	+	+	-	+
Static scheduling	-	+	-	-	-
Concurrent data structures	+	-	-	-	-
Scalable memory allocator	+	-	-	-	+
I/O dominated tasks	-	-	+	-	+
User-level synchronization primitives	+	+	-	-	+
Compiler support is not required	+	-	+	+	-
Cross OS support	+	+	-	+	+

III. PROBLEM DEFINITION

The approach takes focus on experimentation and benchmarking. The algorithm for matrix multiplication was chosen for this simple demonstration of the tools as it provides a best-case scenario for parallelization. As the workload is easily distributed, any overheads introduced by the parallel tools should be made apparent when comparing the performance of the tools.

IV. MATRIX MULTIPLICATION PARALLELIZATION

Matrix multiplication is binary operation that takes a pair of matrices and produces another matrix. If A is an m-by-n matrix and B is an n-by-p matrix, then their matrix product AB is given by:

$$[A,B]_{i,j} = A_{i,1}B_{1,j} + A_{i,2}B_{2,j} + \ldots + A_{i,n}B_{n,j} = \sum_{r=1}^{n} A_{i,r}B_{r,j},$$

where $1 \le i \le m$ and $1 \le j \le p$.

After an examination of sequential algorithm for matrix multiplication, it is clear that the main part of the work is carried out within three for loops. First two loops are for initialization of matrices, and third one, nested loop, does the multiplication. As such, the primary focus of parallel optimization effort is on making the loop iterations run in parallel. However, a precaution has to be taken to ensure that it is safe and that no race condition are introduced in parallel implementation of the algorithm. It is evident from the structure of initialization loop and outer multiplication loop that there are no data dependencies between loop iterations, unlike the inner loops which have several dependencies. This allows an implementation without use of locks, there is no chance of deadlock. The first parallel implementation was carried out using Pthreads. OpenMP, TBB, Cilk++ and MPI implementations were devised and tested afterwards.

A. *Pthreads*

Pthread implementation is somewhat harder then OpenMP, TBB and Cilk implementations as it is programmers job to manage threads creation and scheduling. When implementing parallelism using Pthread four threads were used. The iteration space is then distributed evenly between threads.

```
void *Multiply(void *ptr)
{
    int rowsperprocess = size / THREADS;
    int id = (int) ptr;
    ...
    startpoint = (id - 1) * rowsperprocess;
    if (id == THREADS)
        endpoint = startpoint + rowsperprocess + (size
            % THREADS);
    else
        endpoint = startpoint + rowsperprocess;
    ...
    for (i = startpoint; i < endpoint; i++)
    for (j = 0; j < size; j++)
    {
        for (k = 0; k < size; k++)
        c[i][k] += a[i][j] * b[j][k];
    }

}
```

Listing 1. Matrix multiplication source code using Pthread

B. *OpenMP*

OpenMP implementation uses simple pragma directives for compiler. Listing bellow shows how omp parallel for directive has been used to provide parallelization of loop execution.

```
...
#pragma omp parallel for default(none) shared(a,b,c)
    for (int i = 0; i < size; ++i) {
        for (int j = 0; j < size; ++j) {
            for (int k = 0; k < size; ++k) {
                c[i][j] += a[i][k] * b[k][j];
            }
        }
    }
...
```

Listing 2. Matrix multiplication source code using OpenMP

C. *TBB*

Thread Building Blocks implementations requires more extensive modification to the original code to implement parallelism. Due the fact that TBB follows object oriented model, multiplication work was implemented in its own class

```
...
class Multiply
{
public:
    void operator()(blocked_range<int> r) const {
        for (int i = r.begin(); i != r.end(); ++i) {
            for (int j = 0; j < size; ++j) {
                for (int k = 0; k < size; ++k) {
                    c[i][j] += a[i][k] * b[k][j];
                }
            }
        }
    }
};
...
```

Listing 3: Matrix multiplication source code using TBB

”Blocked range” represents range over which to iterate. The call of multiply function is replaced with a call to the TBB ”parallel for” template.

D. *Cilk++*

Similar to TBB implementation, in Cilk++ implementation outer loop was parallelized using ”cilk for” keyword and no other modifications are needed. ”Cilk for loop” is replacement for the normal C/C++ for loop that permits loop iterations to run in parallel. The compiler then converts a loop body to a function that is called recursively using a divide and conquer strategy.

```
...
cilk_for (int i = 0; i < size; ++i) {
        for (int j = 0; j < size; ++j) {
            for (int k = 0; k < size; ++k) {
                c[i][j] += a[i][k] * b[k][j];
            }
        }
    }
...
```

Listing 4: *Matrix multiplication source code using Cilk++*

E. *MPI*

MPI implementation of matrix multiplication algorithm requires significant code modification, while data transfer to workers and work partitioning have to be done manually. Also, many index calculation and handling the remaining work when the amount of work is not divisible by the number of workers bring more difficulties for programmers.

```
int main(int argc, char* argv[])
{
    int rank, nproc;
    int istart, iend;

    MPI_Init(&argc, &argv);
    MPI_Comm_size(MPI_COMM_WORLD, &nproc);
    MPI_Comm_rank(MPI_COMM_WORLD, &rank);

    if (rank == 0) {

        for (int i = 0; i < size; ++i) {
            for (int j = 0; j < size; ++j) {
                a[i][j] = (float)i + j;
                b[i][j] = (float)i - j;
                c[i][j] = 0.0f;
            }
        }
    }

    MPI_Bcast(a, size*size, MPI_FLOAT, 0,
        MPI_COMM_WORLD);
    MPI_Bcast(b, size*size, MPI_FLOAT, 0,
        MPI_COMM_WORLD);
    MPI_Bcast(c, size*size, MPI_FLOAT, 0,
        MPI_COMM_WORLD);
    istart = (size / nproc) * rank;
    iend = (size / nproc) * (rank + 1) - 1;

    multiply(istart, iend);

    MPI_Gather(c + (size/nproc*rank),
               size*size/nproc,
               MPI_FLOAT,
               c + (size/nproc*rank),
               size*size/nproc,
               MPI_FLOAT,
               0,
               MPI_COMM_WORLD);

    if (rank == 0) {
        if (size % nproc > 0) {
            multiply((size/nproc)*nproc, size-1);
        }
    }

    MPI_Finalize();
    return 0;
}
```

Listing 5: Matrix multiplication source code using MPI

V. RESULTS

To compare Pthreads, OpenMP, TBB, Cilk++ and MPI, multiple implementation of matrix multiplication algorithm were developed. These implementations were then tested and information about execution time and speedup were collected. These results are elaborated in Section V-A. Section V-B elaborates code characteristics (measured in lines of code added or changed) for each model.

Testing was performed on a dual-core (Intel CoreTM2 Duo Processor T6500 (2M L2 Cache, 2.10 GHz, 800 MHz FSB)) system with 4GB DDR2 800MHz RAM, running Ubuntu 10.10. Software versions are as follows: GCC 4.2.4 (Cilk Arts build 8503), TBB 4.0, OpenMPI 1.4.4, Boost 1.42 and OpenMP 3.0.

A. *Matrix multiplication Performance Analysis*

For benchmarking purposes 11 data sets were created, in creasing matrix size from 1000 to 2000 using step 100. Then these data sets were applied to each algorithm. To ensure that benchmarking process is consistent each developed algorithm was rerun 30 times and calculate average time of execution.

The first performance comparison of interest is time consumption.

Fig. 1. demonstrates that all tested models show significant improvements in decreasing execution time compared to sequential execution. While it may appear that OpenMP per forms poorly when compared to Cilk++ and TBB, it must be noted that matrix multiplication algorithm is embarrassingly task-parallel problem that is more suited to Cilk++ and TBB, which are task-parallel models, whereas OpenMP is better suited to data-parallel problems and may prove easier to implement and perform better when faced with data-parallel problems.

Fig. 2. shows speedup of the various implementations and confirm previous observation that task based models utperform directive and thread based ones.

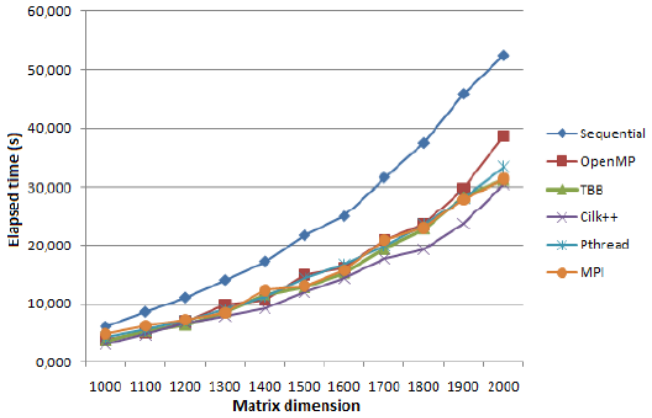

Fig. 1: Performance of Sequential vs. Parallel Matrix Multiplication using OpenMP, TBB, Pthread, Cilk++ and MPI

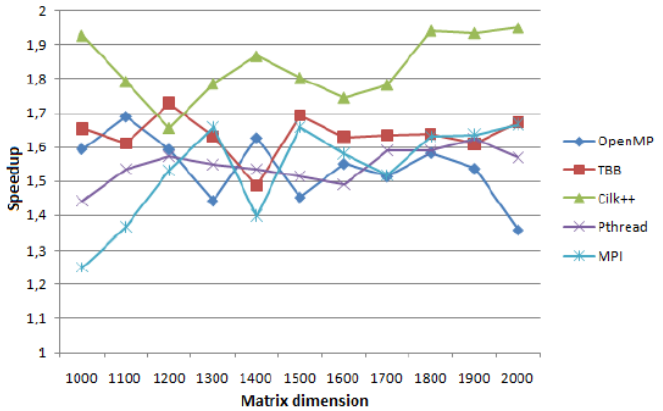

Fig. 2: Speedup trends of Parallel Matrix Multiplication using OpenMP, TBB, Pthread, Cilk++ and MPI over Sequential Implementation

B. *Matrix Multiplication Code Analysis*

For code characteristic comparisons, the number of lines of code (LOC) for each implementation as well as the number of modified lines (LOC) were compared over the original sequential version and shown in Table II. OpenMP and Cilk++ require only a single additional line. TBB requires significantly more code modification, but not nearly as much as Pthread, since TBB library handles thread management.

TABLE II. CODE MODIFICATION DATA

Implementation	Lines	Modified
Sequential	30	-
OpenMP	31	1
Pthread	62	33
Thread Building Blocks	45	12
Cilk++	30	1
OpenMPI	75	24

As expected Pthread implementation required most code modification since it is programmers responsibility to create, assign and synchronize threads. Significant code modification is presented in MPI because data transfer to workers and work partitioning have to be done explicitly.

VI. CONCLUSION

Choosing the best model when developing parallel software application depends on multiple factors. The key factors are development environment and complexity of the problem. Pthreads programming model introduces much more complex ity within the code than OpenMP, TBB, Cilk++ and even MPI, making it more challenging to develop. One of the benefits of using TBB, OpenMP or Cilk++ when appropriate is that creating and managing the threads are handled automatically. Even though OpenMP's trivially simple implementation make it reasonable choice for implementing parallelism, as this paper showed, it is better to consider other models when problem is of task-parallel nature. TBB requires significantly more effort to implement, but it provides more control and is better equipped to handle other problems such as task-parallel processes, while still maintaining respectable performance improvement when using parallel for on data-parallel loops. MPI implementation requires most effort and expertise to implement effectively. One of the advantages of MPI model over other four is that MPI can be used both on shared memory systems and distributed memory systems.

Abstract - **This paper presents results of performance comparison of simulated annealing algorithm execution on central processing unit (CPU) and Graphics Processing Unit (GPU) that uses Compute Unified Device Architecture (CUDA). Algorithm used for measurement is a meta-heuristic embarrassingly parallel algorithm based on idea of material crystallization process when temperature is being increased to melting point and then decreased to minimum pre-defined value. Algorithm was implemented for quad-core CPU using C and on CUDA enabled GPU using C for CUDA. Execution time was used as criteria for performance comparison and was measured in two scenarios: fixed number of points with number of threads as a parameter and vice versa. Results of measurements were analyzed and presented.**

Keywords: simulated annealing algorithm, thread, CUDA, GPGPU

I. INTRODUCTION

Primary purpose of graphic cards was to help users while viewing content on personal computer, but with growth of users' needs, developers improved graphic cards to be able to process large amounts of data. This means that graphic cards are used not only to do graphic, but also non-graphic calculations [1].

CUDA is hardware and software architecture for issuing and managing computations on the GPU as a data-parallel computing device without the need of mapping them to a graphics API [1]. Software developers, scientists and researchers are finding broad-ranging uses for CUDA, including image and video processing, computational biology and chemistry, fluid dynamics simulation, computed tomography image reconstruction, seismic analysis, ray tracing, and much more. This paper shows how much performance can be gained with CUDA when working with simulated annealing algorithm.

Simulated annealing algorithm is metaheuristic algorithm based on material crystallization process while temperature is being increased to the melting point and then decreased to the minimum pre-defined value.

The most important fact about this algorithm is that, comparing to the local search, it successfully manages not to fall in local extrema, but it finds the global extrema of concrete problem. This algorithm was developed by Scott Kirkpatrick, C. Daniel Gelatt and Mario P. Vecchi in 1983 [1].

While temperature increases the material starts to melt causing its crystal structure to change and rearrange. Then, while decreasing the temperature material's crystal structure is getting its better schedule with corrected former defects. There are few elements important for algorithm implementation: number of iterations, number of repetition for same value of temperature, initial point, function (problem being solved) and how new points are taken. In every iteration new potential solution is examined and value of function is calculated for that potential solution. Then that value is compared to previous best value of function; if the new value is better it is being set to the best value and point at which function has that value is set to be current best solution. But if the value is not better than that point can be taken with some probability. This enables the algorithm to leave local extrema. Total number of iterations is product of the number of iterations and the number of repetition for same value of temperature [2].

II. PERFORMANCE MEASURMENT

First, the algorithm was implemented using Matrix Laboratory (MATLAB). Then, two versions of algorithm were implemented: C and CUDA C. Both versions were based on a MATLAB version so that the implementation of versions wouldn't affect the results. Hardware setup used for measurement of C version is Intel Core 2 Quad CPU Q6600. Hardware setup used for measurement of CUDA C is shown in table 1.

Name	GeForce G 103M
Compute capability	1.1
Clock rate	16 MHz
Total global memory	464.5 MB
Total constant memory	64 KB
Texture Alignment	256
Multiprocessor count	1
Shared memory per multiprocessor	16 KB
Registers per multiprocessor	8192
Threads in warp	32
Max threads per block	512
Max thread dimensions	(512, 512, 64)

Table 1: Hardware setup used for measurment of CUDA C implementation

A. Parallelism on quad-core processor

Before running the algorithm on CUDA, a C application was created to implement the same algorithm for profiling on a quad-core processor. A quad-core Intel processor was used for this performance analysis with Visual Studio 2010. Performance analysis window contains three key elements: CPU Utilization, Threads and Cores. Tests were performed three times and they were nearly the same in each run. During the test runs there were no applications running in the background, only operating system processes. All figures show results from the first test. CPU Utilization screen shows the usage of logical cores in processing of the current task. Threads screen shows detailed information about every running thread, such as its execution time and state. Cores screen shows the representation of threads on specific logical cores.

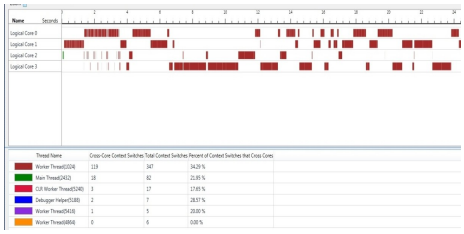

Figure 1. Execution of one thread between cores

In order to gain better utilization of processor, problem space was divided into discrete sets whose elements are starting points. Depending on number of threads started by main application, each thread had a same number of starting points to examine.

While using only one thread on four cores, the execution time was 28 seconds. That is inefficient, because while only one core is used, the other cores are idle which is resource-wasting (figure 1). The same application took about 15 seconds to finish its execution using two threads, which is a good improvement over the first case but there is still room for more, because there are still two cores left idle. The two assigned threads are evenly used on all four cores, but there is a lot of empty space in-between. Also, some time is spent on the overhead (thread synchronization, context switching).

Four-threaded application gives much better results, and it terminates after 10 seconds. It is not a quadruple improvement, but it's still a significant improvement (76%). Now more time is spent on preemption processes (cache misses, end of quantum) and overhead, but the cores are used more evenly, with less wasted resources. Because every thread runs (mostly) on its own core, this means less context switching.

Is it possible to achieve more speed with more threads than cores? The answer is yes. The same application running on 8 threads gave slightly better performance (9.1 seconds), which is not remarkably better, but still better, because of greater thread usage. If every thread was used 100% in the application, it would be safe to say that the optimal number of threads for a quad-core processor is 4. But since some of the time threads have to wait for execution because of cache misses, I/O operations and system processes, that means better performance can be achieved with more threads, so when all four threads are busy, the fifth can run and avoid unnecessary waiting (figure 2). Of course, the number of threads has its limit. In this particular application, 32-threaded application gave the best results (8.93 seconds). From now on, increasing the number of threads will give weaker results because of the overhead.

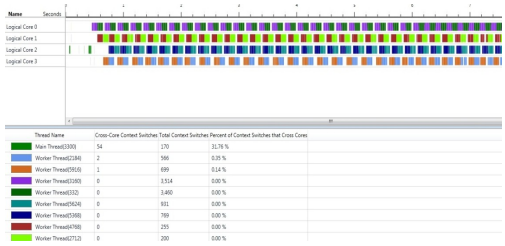

Figure 2. Execution of eight threads between cores

In conclusion, the best way to create a multi-threaded application with good performance is trial and error approach. There is neither universal parallel machine nor parallel application, and these considerations can be used as a rule of thumb, but not as definite solutions. Different algorithms will perform differently so it is essential to analyze the CPU usage and program performance on different number of threads in order to find the best possible solution.

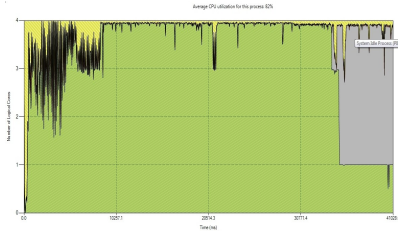

Figure 3. CPU utilization when using 50 000 points

Second measurement was using fixed number of threads while changing the number of starting points. By using different number of starting points there was a significant improvement in CPU utilization. Figure 3 and Figure 4 show the difference in CPU utilization when using 50 000 starting points and 500 000 starting points (green area represents algorithm execution and gray area represents idle processes). CPU utilization when using 50 000 starting points was 82% and when using 500 000 starting points it was 96%.

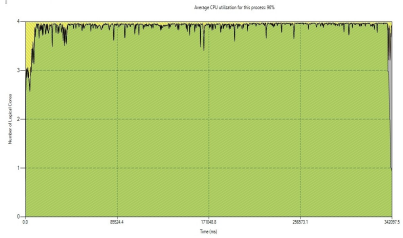

Figure 4. CPU utilization when using 50 000 points

B. *Parallelism on CUDA enabled card*

Even though CUDA architecture is promising good ground for parallel execution there are some factors that need to be considered while developing CUDA applications. Sometimes these factors can be considered as constraints of graphic cards.

In order to achieve better performance in data processing, data which is processed should be kept closer to the processing units. On CPU, performance is improved when the data is kept in cache but the size of cache is limiting factor. Graphic cards with CUDA architecture don't support caching. All the data that is processed is kept in graphic cards memory. Data is copied from RAM to graphic cards memory which is a slow process because of the bus latency. Main memory on graphic cards can be main bottleneck because of speed and its capacity. Executing kernels (part of code that is executed on graphics card) with smaller chunks of data can be one solution but not best because of the overhead in communication with main memory.

In addition to limit with capacity of main graphic card memory (global memory), limiting factor can also be number of registers used by a thread. Number of variables and intermediate results in kernel functions should be arranged in a way which will reduce need for using too many registers. Lack of registers causes overhead which consist on reading and writing data from and to shared and global memory.

In order to get maximum utilization of graphic cards, one of the biggest factor is number of threads generated per kernel call. Figure 7 shows the impact of number of threads on execution time. Significant speedup is achieved generating more than 100 threads per kernel call. Reducing number of threads is causing less speedup and longer execution time.

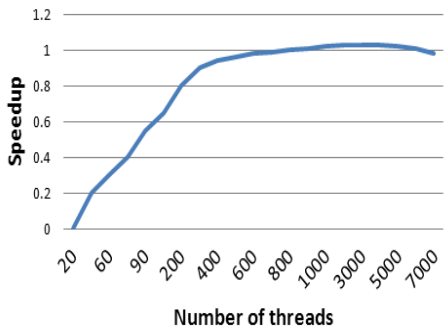

Figure 5. Speedup affected by the number of threads

In Figure 5, it's important to highlight that number of starting points is kept constant while the number of threads is increased. Speedup is based on execution time of (current number of threads)./(previously selected number of threads).

This experiment was repeated for different number of starting points that needs to be examined. In simulated annealing, and in other metaheuristic algorithms, number of starting points is very important for faster search through problem space. In this application, number of starting points and number of threads was also increased. Results are displayed in Figure 6.

Running small number of threads for small data set that needs to be processed, doesn't make any difference. On large data sets execution time can be reduced by increasing number of threads started with kernel call as can be seen on figure 8.

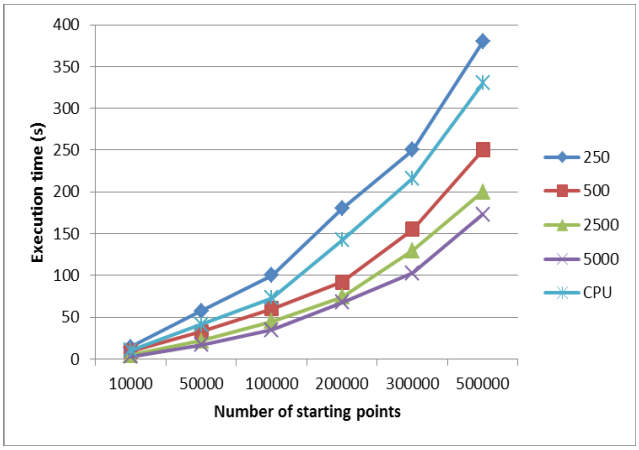

Figure 6. Comparison of CPU execution and GPU with different number of threads(color) and different number of starting points

III. RESULTS

Even though the CPU on which test were executed has a modern processor, results of tests show that faster data processing was made while using graphic card. Faster execution of CUDA powered application was accomplished with consideration of constraints with which graphic cards and programs executing on graphic cards are faced.

Better performance, as it can be seen on Figure 6, are achieved on graphic card because of the way graphic card handles threads. On graphic card there is no context switching. Threads are organized in warps (groups of 32 threads executed simultaneously) and next warp of thread is executed when previous warp finishes its execution. On the other hand, operating system is constantly switching threads on cores which causes additional overhead.

IV. CONCLUSION

While executing a program on a processor, the handler of execution is operating system. The operating system is in charge of assigning a time interval to the program. Time interval given to application depends on priority of applications and load of the system. If the application has a higher priority, its time interval can be higher. Therefore, it is difficult to ensure that all processing time will be assigned to the application that is being executed.

Threads that application runs are distributed among processors in an interchangeable schedule so that every thread gets a certain time interval in which it can execute. This can sometime increase the execution time because of too much context switching.

Unlike on CPU, threads on GPU don't interchange until they are completely finished. After the first group on streaming

processors is finished the second one runs and that process is repeated for the next group.

Modern GPU-s use more streaming multiprocessors so groups of threads are distributed among processors and they can achieve better parallelism.

A partially limiting factor is small amount of memory available on a graphics card. Because of that, it is important to divide the problem on a smaller number of problems and execute them on a graphics card.

CUDA-supported graphics cards will run a large number of threads. These threads differ from processor threads because it takes less time to create them. For that reason these threads are not reused for different operations.

V. FURTHER RESEARCH

Further research will include comparing execution of the same algorithm on a cluster of computers and on a cluster of graphic cards. Cluster of GPUs can consist of multiple graphic cards connected to one computer or of cluster of computers with one or multiple GPUs connected to the each of the computers.

Abstract – This paper describes the procedure and the results of measuring the speed of processing arrays on 1, 2, or 3 hosts, connected in LAN. The measurement scenario was based on having the fixed processing time for each array member in all cases. Also, processing each array member is individual from processing others. For gaining control data, the array was processed on only one host. Afterwards, the array was split in two and three equal pieces for processing on two and three hosts, respectively. The communication between the hosts was established by using socket programming techniques in .NET. The results were impressive because the speed-up in some cases was almost linear.

Key words – Parallelism, LAN, array operations, server-client application, socket programming.

I. INTRODUCTION

In this paper, measurements have been conducted on whether or not it is possible to parallelize data processing by assigning equal pieces of array to the hosts in LAN. For the measurements purposes, the server-client application was developed in .NET framework, and was used for processing different sizes of arrays on different number of hosts on the network. Socket programming is a technique used for communication between server and client on LAN.

Nowadays LAN is the most used way of connecting hosts. There are many reasons for that. It is easy to set; the needed equipment is cheap and available in almost every tech shop. Mostly, LAN is used for sharing data and playing games, but why would not it be used for processing data on multiple hosts? It is known that clusters offer higher performance than ordinary PCs, but usually, these are not available for everyday use. In case of LAN, everyone has an opportunity to meet performance boost for reasonable amount of money, which can be used to solve their problems faster.

Even when all the necessary hardware for achieving parallelized processing is available, it is hard to parallelize the processing of data, because not all problems allow parallelization. It is a known fact that reaching linear speed-up by parallelizing processing is practically impossible. Array processing is the most representative example that can be used to explain the parallelization of data processing. Splitting the arrays in equal pieces and processing them on more than one host at a time is a typical example of parallel data processing. Ideal parallelization can be achieved when using such arrays where processing each and every single member is independent, meaning that operation done on one value in array does not affect others. This also means that those arrays are easier to split in pieces and to assign them to more than one hosts to be processed.

For small companies who deal with large amounts of data, this can be useful for operations affecting all data. Their work usually does not require the use of supercomputers or any other special equipment. One of the practical applications can be a big supermarket with millions of articles. For example, if they wanted to set a fixed discount for all the articles, they could do it by applying the same operation on all the articles in the database.

II. MEASURING PROCEDURES

Two applications have been used for the measuring: client application and server application.

Client application is the main application used first of all for generating random integers (6 digits each), which form an array of integers. Then, the client application either does all the work alone or splits array in two or three pieces, one piece for itself, others for other hosts (hosts running server application). After receiving processed data from all the server hosts, the client application puts together all the array pieces to form resultant array.

Server application is used for processing data and returning it to client host. Both applications were developed in .NET platform, specifically in Visual C#. All the hosts in the network were connected in 100 Mbps LAN. After the client application sends a piece of array to the server application, the server application processes it and returns the data back to the client application.

In order to be able to neglect the slight differences between the hosts' performances, no specific algorithm

was used for processing data. Instead, a simple function, that "sleeps" for 1 millisecond for each array member was made. Additionally, it makes a simple change of value, just for measuring purposes. The source code for this function follows:

```
private void process(ref List<int> array)
{
   for (int i = 0; i < array.Count; i++)
   {
      Thread.Sleep(1);
      array[i] = 222222;
   }
}
```

Source code 1. The function that simulates such processing where each array member takes 1 millisecond to process.

The client application connection to the server host is implemented by using *TcpClient* class. The example of the source code that connects to one server host follows:

```
TcpClient tcpclnt1 = new TcpClient();
tcpclnt1.Connect("192.168.1.70", 8001);
```

Source code 2.Connectig to the host.

In the server application *TcpListener* class was used to listen and wait for the connection from the client host, with the help of the timer (.NET control). The short source code follows:

```
TcpListener tcpl;
tcpl = new TcpListener(ipaddress, 8001);
tcpl.Start();
```

Source code 3. Waiting for connection.

The source code used for sending data to the server application is the following (The example shows one third of the array *list* being sent byte by byte to the server. The variable *dim* represents the array length):

```
ASCIIEncoding asen = new ASCIIEncoding();
byte[] ba;
Stream stm;
for (int i = 0; i < dim / 3; i++)
{
   ba = asen.GetBytes(list[i].ToString());
   stm = tcpclnt1.GetStream();
   stm.Write(ba, 0, ba.Length);
}
```

Source code 4.Sending data to hosts.

Receiving data is implemented by using the timer (.NET control) which listens to the specific TCP port and receives data when triggered. The source code follows:

```
If (tcpclnt1.Available > 0)
{
   Stream stm2 = tcpclnt1.GetStream();
   byte[] b = new byte[100000000];
   int a = stm2.Read(b, 0, 100000);
}
```

Source code 5. Receiving data.

Sending data back to client host (after processing) within the server application is slightly different than sending data from client. The loop used for returning processed piece of original array (again byte by byte) follows:

```
for (int i = 0; i < array.Count; i++)
{
   byte[] ba;
   ASCIIEncoding asen = new ASCIIEncoding();
   ba = asen.GetBytes(array[i].ToString());
   sck[0].Send(ba);
}
```

Source code 6. Sending data back to client host.

Six measurements were done with different scenarios:

- First scenario was using only client application, i.e. processing only on one host. These were the control results.
- The second scenario was based on using 2 hosts, which were connected through LAN as described before. One of them was client, another was server host.
- Third scenario was using three hosts (one of them was host, the other two being servers), which were connected through LAN.

In general, each host had a task to change all members of array to one specified number (included in the function *process*). Expected speed of processing the array on one host could roughly be calculated as Sleep time multiplied by Array size. For the latter two scenarios, additional time is needed for transferring the data to and from the server hosts. However, the data processing time is expected to be significantly decreased, depending on the number of hosts. All the measurements were conducted by using the following array sizes (expressed in numbers of integers in array): 80 000, 100 000, 200 000, 500 000, 1 000 000, 5 000 000.

III. RESULTS AND ANALYSIS

Table 1. Results of all the measurements in all the scenarios.

Number of integers in an array	Total size of array in MB	Number of hosts	Time in seconds	Percentage of time spent compared to one host
80000	0.3052	1	82.3467	100.00%
80000	0.3052	2	46.3637	56.30%
80000	0.3052	3	37.8402	45.95%
100000	0.3815	1	100.0217	100.00%
100000	0.3815	2	57.2003	57.19%
100000	0.3815	3	43.1585	43.15%
200000	0.7629	1	220.5906	100.00%
200000	0.7629	2	120.1589	54.47%
200000	0.7629	3	113.2515	51.34%
500000	1.9073	1	575.3279	100.00%
500000	1.9073	2	297.2694	51.67%
500000	1.9073	3	235.3525	40.91%
1000000	3.8147	1	1122.8102	100.00%
1000000	3.8147	2	575.3639	51.24%
1000000	3.8147	3	452.8699	40.33%
5000000	19.0735	1	6363.9497	100.00%
5000000	19.0735	2	3187.3917	50.09%
5000000	19.0735	3	2311.2192	36.32%

As it is clearly visible from the Table 1, regardless of the number of integers in array, the percentage of the gained speed-up was close to a constant in all cases. The cause of the slight variations is other activity on the network during the measurements or some other processes taking processor time on one of the hosts during the measurements. Neither of these was at such level that it could affect the results of the measurements significantly.

Also, the important result was that, taking into consideration the "Percentage of time spent compared to one host" column from Table 1, the speed-up goes further away from linear as the number of hosts increase. Optimal situation would be that 50% and 33% of the time needed to process the array on one host is needed for processing the same array on two and three hosts, respectively.

If faster LAN was used in the measurements, the results would have been even better, i.e. closer to ideal (but never equal).

The following figures show the processing time ratio between the measurements with 1, 2 and 3 hosts for all the measurements conducted.

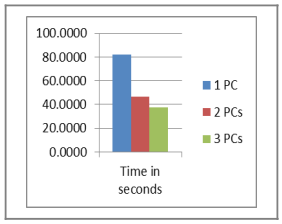

Figure 1. Processing time for 80 000 integers in array.

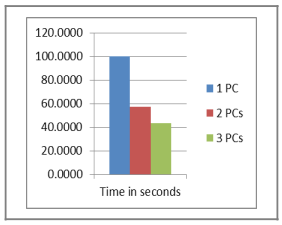

Figure 2. Processing time for 100 000 integers in array.

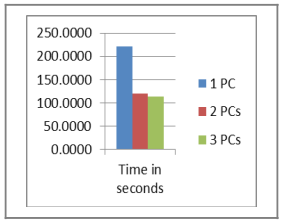

Figure 3. Processing time for 200 000 integers in array.

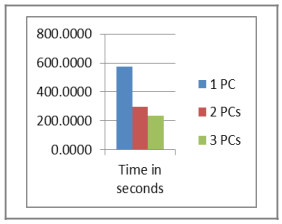

Figure 4. Processing time for 500 000 integers in array.

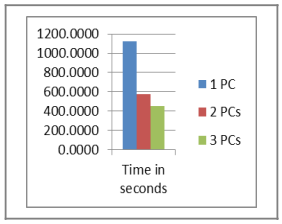

Figure 5. Processing time for 1 000 000 integers in array.

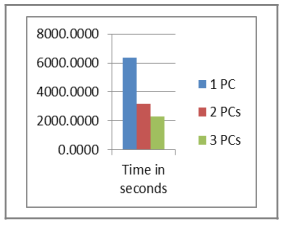

Figure 6. Processing time 5 000 000 integers in array.

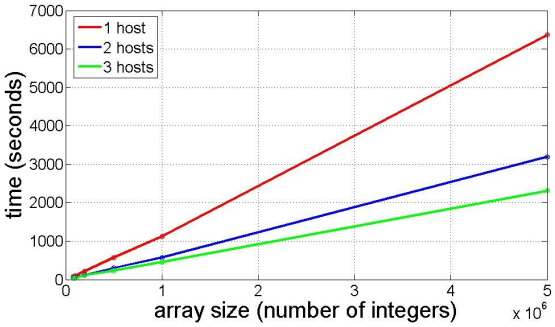

Figure 7. Experimental results on a single figure.

The figures 1-6 show that, in each case, significant speed-up was gained as the number of hosts in the network increases.

Figure 7 shows the experimental results for all the measurements on a single figure.

IV. Conclusion

For sequential operations on arrays (where processing of each individual array member is independent), this method of increasing performance by using socket programming is more than useful and efficient. The speed-up was very close to linear, for the measurements described in this paper.

Generally, the latency and a throughput of a network were important parameters here, apart from the individual specifications of the hosts (All the hosts had 100Mbps LAN adapter, Intel dual or quad core processors – x64, 64 bit operating system and 4 GB of RAM.) and the complexity of the processing each array member. Additionally, sending data could not have been parallelized, at least not by using common of-the-shelf hosts (because they have only one ethernet adapter). This means that different data cannot be sent to different hosts in network at the same time.

Because of socket programming techniques the source code was very simple (a little more than 200 code lines in both applications).

The biggest advantage of this method of parallelization is the simplicity of implementation, and the fact that there is no need for any additional hardware apart from what most of the households worldwide have today, needless to say companies.

The aim of the measurements conducted was to show that parallelizing using socket programming in LAN is possible, useful, and easy to implement.

The results showed that, in average, the time taken to process the array was 53.49% (when using two hosts) and 43.00% (when using three hosts) of the time that took the same array to be processed on one host only.

***Abstract*—In order to obtain 360 degree panoramic displays, tiled video projections are often used. In this paper we present a system for cylindrical 360 degree panoramic projection based on a client-server architecture. The system performs following actions: projector calibration, image transformation and video playback. To perform above actions several problems have to be addressed. Calibration of multiple projectors is based on computing of spatial relations between cylindrical projecting surface and each projector. We do this by photographing the projected chessboard pattern of each projector using a camera with fish-eye lens. The photograph first has to be unwrapped into a rectangle shaped texture. After that, the relation between original chessboard corners and corners on the photograph has to be found. Using these corners the image transformation function has to be interpolated. The transformation of image to be projected is done using this function and also includes lightning correction to achieve smooth transitions between each projector image. If playing video, videos from all projectors have to be synchronized. In the current client-server architecture, a server performs semiautomatic projector calibration, files and configuration distribution to clients and has the ability to off-line create images for each projector. Each client handles storage, showing of already prepared images and playback and real-time transformation of videos. The projector calibration is done using Matlab, whilst the playback and real-time transformation of video is done using custom made software written in C++ and OpenGL.**

I. Introduction

Tiled displays are an emerging technology for constructing large scale displays that can be used for many purposes. Our primary purpose was to display 360° panoramic movies on cylinder that can be seen by many viewers at the same time. This technology can also be used to create large tiled projection displays in order to display some information, for example in control rooms or in situations where a lot of data needs to be displayed. When designing a system for multiple projector-based tiled video playback there are a number of problems. First of all, the system needs to stay synchronized during the video reproduction. Second, the angle of projectors to the projection plane needs to be taken into account, and the projectors need to be calibrated. Finally, video that is to be reproduced needs to be cut and regions where projections overlap need to be adjusted to achieve a seamless transition between two displays. In the rest of the paper we present a method for solving these problems. The rest of the paper is organized as follows: In section II we give a short overview of previous work in the same field, in section III we describe the calibration process, in section IV we discuss some implementation details and finally in section V we give conclusion with short discussion.

II. Previous work

There are several systems for multiple projector panoramic visualization. In [1] a projector-based tiled display system is described. In that paper, a system for precise alignment of projectors is described and used instead of software image transformation. In [2] a novel technique to calibrate multiple casually aligned projectors on piecewise smooth vertically extruded surfaces is described. The system described on website [3] uses projectors to make 360° spherical projection. This system is used for representational purposes on some events.

In our paper, we describe a system which uses six projector to achieve a 360° panoramic projection onto a cylindrical projection plane. The system calibration is done using a single fish-eye lens camera. The projectors being used are commodity projectors available for everyone.

III. System calibration

System calibration is the most important part. It is written in *Matlab* and consists of several steps: calibration patterns acquisition, canvas unwrapping, corner detection and brightness correction.

A. Calibration patterns acquisition

The first step of calibration is to capture the images of the system using a fish-eye lens camera. The camera has to be placed in the center of the system and directed upwards. This is required in order to get better pictures for calibration. Before taking pictures of calibration patterns, we take a picture of a white image projected from one of the projectors. We require this for searching the canvas area in the picture. The example photograph is shown in figure 1. The calibration patterns projected from each projector is a 13x11 white-black chessboard. The upper-left chess field is white. The pattern resolution is equal to the resolution of projector being used, in our case 1280x800. The example photograph of the calibration pattern is shown in figure 3.

B. Unwrapping the canvas into a texture

The next step is to unwrap the canvas from captured pictures of calibration patterns into a texture. To make this possible, we first have to detect the canvas edge and the canvas area. The canvas area detection starts with a simple threshold of

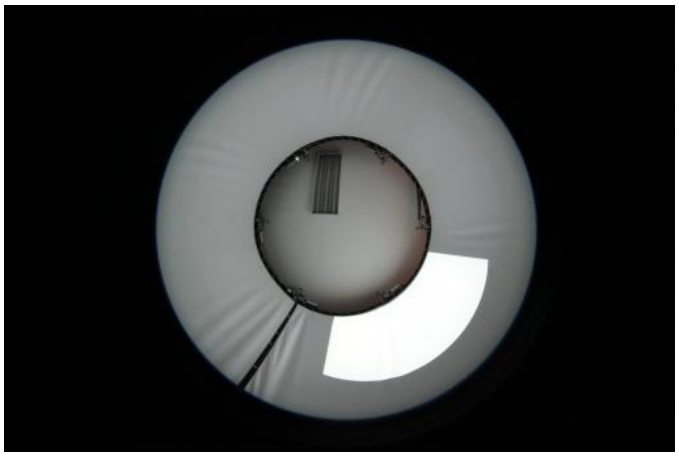

Figure 1. The photograph of the white image projection

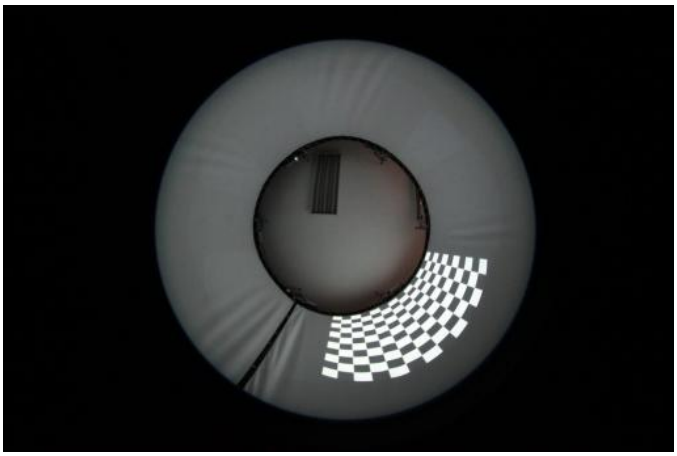

Figure 3. The photograph of the calibration pattern projection

the gray image. Afterwards, we remove small objects with morphological operators and the biggest blob is then selected as a canvas area. The example of detected canvas is shown in figure 2.

Using simple edge detection methods we detect the canvas edge, as shown in figure 4. After detecting the canvas edge and area we need to find the circles that define the inner and outer edge of the canvas. We use the Hough transformation to achieve this. We also need to find the initial azimuth to be able to unwrap the canvas. In order to find the initial azimuth for small circle, we first generate a marginally larger circle and subtract the canvas edge from the generated circle. Thus we get an image that only contains a little object. We the find the center of this object and construct a line through this center and the center of the small circle. Finally, we find the angle between the constructed line and the reference line that defines the azimuth of 0°. We do the same for searching the initial azimuth for large circle, except that we first generate a marginally smaller circle and subtract the canvas edge from it in order to find a little object.

If we simply use these circles for unwrapping the canvas, we will get bad results because circles on figure 4 are actually not circles. In order to get a precise unwrapping of the canvas, we need to find the exact curve that describes the edge. We do this by first defining the size of the texture and then use the horizontal size to define the number of sampling point of that curve. We sample the curve in the following way: for each sampling point of the circle found in previous step we select the small number of pixels around this point. Then we fit a parabola onto a white pixels in selected region and find the intersection between this parabola and the line that connects the point on the circle and the center of the circle. We have to do this for both small and large circle so that we get endpoints defining the real canvas edge. The results of this procedure can be seen in figure 5.

While unwrapping the canvas we have to face a fish-eye lens correction problem: the camera sampling of image is non-linear when using fish-eye lens. We correct this by postulating that the lower edge of the canvas is inclined 60° from camera optical axis and assuming that aforementioned camera sampling is tangent. Then, by applying an inverse function we correct the lens distortion and finally sample the image using

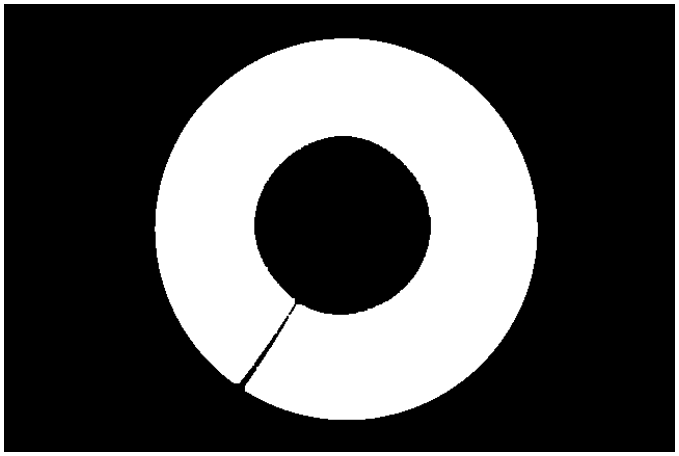

Figure 2. Detected canvas area

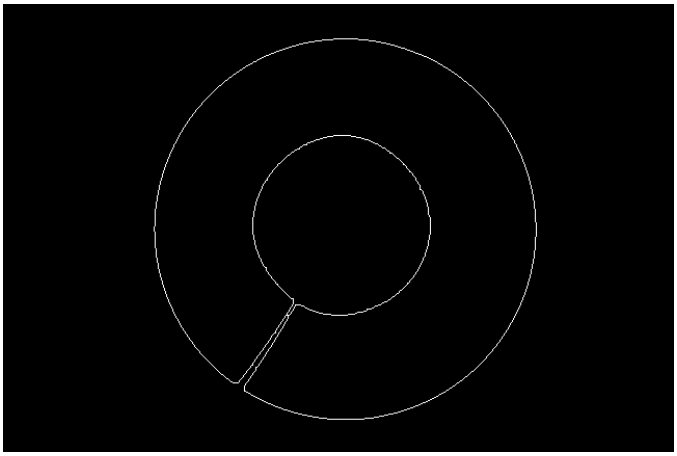

Figure 4. Detected canvas edge

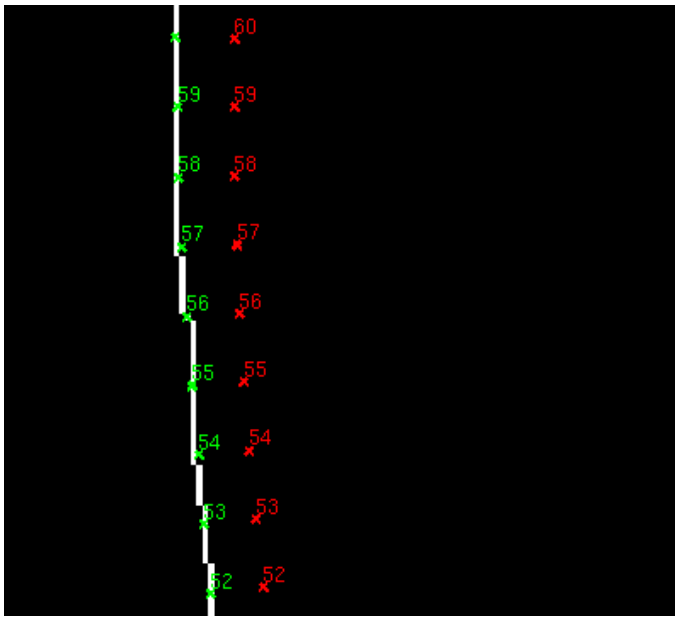

Figure 5. The original small circle sampling points (red) and fitted exact edge curve sampling points (green)

Figure 6. The unwrapped texture of the calibration pattern projection

bilinear interpolation. The unwrapped texture can be seen in figure 6.

C. Corner detection on calibration patterns

The whole point of calibration is to find the pairs of points in which the first point is the corner point in the original chessboard image and the second point is corresponding point on the unwrapped texture of the projected chessboard. Therefore, we have to find the corners in the unwrapped texture. First, we do an automatic corner detection using various functions integrated in *Matlab*. Afterwards, we correct the position of detected points by hand. The result of this step is shown in figure 7. Those corner pairs are used for bilinear interpolation of map used for transforming the panoramic picture that is to be projected into image for each projector.

Figure 7. Detected and hand-optimized corners of projected calibration pattern

D. Brightness correction

As can be seen on figure 8, the image brightness correction is required in order to have uniformly bright picture across the whole projection. The problem is that in the overlapping area two light sources are lighting on the same point, thus making this point brighter. Therefore, the projected picture is brighter in the overlapping area as shown in figure 9. In order to prevent this, we have to reduce the image brightness in the overlapping area. We reduce the brightness by following a

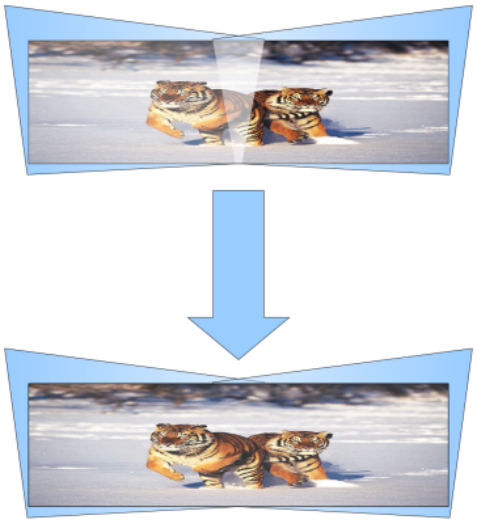

Figure 8. Brightness correction of images in overlapping area

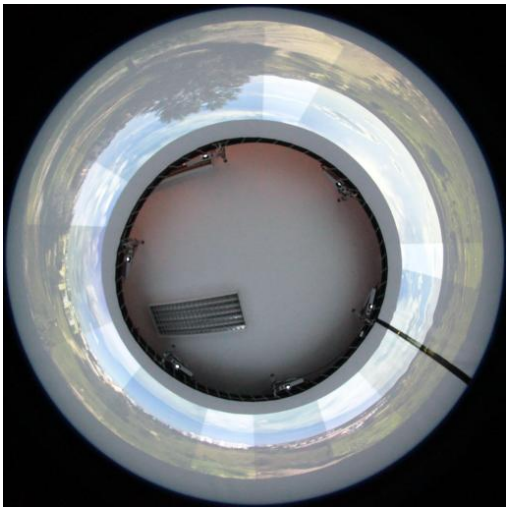

Figure 9. Projection without brightness correction

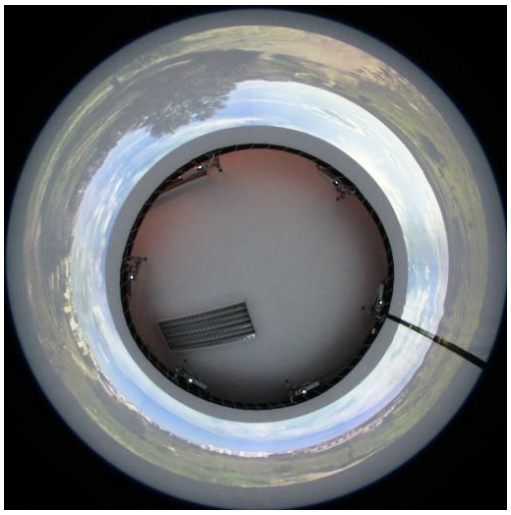

Figure 10. Projection with brightness correction

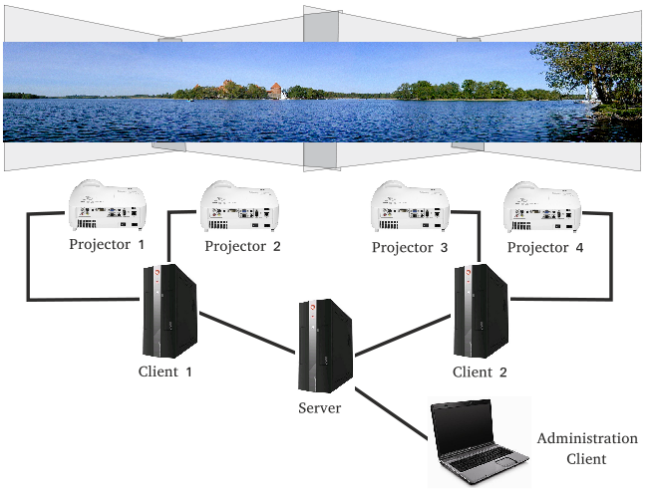

Figure 11. System architecture

Gaussian curve, i.e. at the beginning of the overlapping area we set the brightness to maximum, and at the end of the picture to minimum. For each pixel in the image we know its distance from the edge of the picture x, the beginning of the overlapping area x_{g1} and the end-coordinate of the picture x_{g2}, i.e. the horizontal size of the image. The brightness of the pixel is then calculated with the expression (1).

$$I = e^{\frac{-(x-x_{g2})^2}{(x_{g1}-x_{g2})^2}} \quad (1)$$

With this method in overlapping area the brightness of first image is exponentialy dropping and the brightness of the second image is exponentialy rising thus making the projected image uniformly bright, as shown in figure 10.

IV. Implementation

A. Network Communication

System for multiple projector-based tiled video playback is designed in a distributed manner, utilizing several key components that act like a single system when properly initialized and synchronized. Whole system communicates over Ethernet Local Area Network (LAN) using TCP/IP protocol. Components that build the system are the main server, which handles administrators' and clients' requests and messages, the administrator client, who sends requests, and regular clients, to which multiple projectors are connected. These are software components, which can be run in a wide array of hardware configurations and one of possible configurations is shown in figure 11. This architecture was chosen because it could be built using inexpensive hardware like several modern low-end PCs instead of using specialized hardware. The server component is designed to be the central point of the system. Its main purpose is to relay messages between clients and to synchronize the whole system. Server is a multithreaded system that can support arbitrary number of clients. When a client connects to the server it's assigned a unique id that is kept until next server restart. Server spawns two new threads each time a new client connects to it. One thread is for reading from the network socket, and the other is for writing to it. Each thread has its own message queue. When the client sends requests, they are placed in the input queue, and when the server sends the replies, they are placed in the output queue. The server has a processing thread that reads from clients' input queues, processes the request, and writes to a specific output queue. Depending on the port to which the connection was made, the server decides whether the incoming connection is from an administrator client or a regular client, and acts accordingly. Clients implement a similar architecture but much simpler because they only need to communicate over one network connection. The administrator client is the main control component in the system and directly interacts with the user. It's used to send requests for image displaying, video playback, pausing and stopping.

B. Video playback

In order to playback video, we require an ability to synchronize video playback and an ability to geometrically transform and correct the brightness of each video frame in real time. The real time image transformation is done on GPU using OpenGL. We first initialize GPU by sending the points obtained from calibration process to GPU. The coordinates of each point are defined with the position of the corner in original chessboard, and the texture coordinates of the same point are defined with the position of the corner in the unwrapped chessboard projection, as described earlier. The blend mask obtained from brightness calibration step is used as a light map in the rendering process.

To be able to synchronously start the playback we first have to synchronize the clocks of all clients and the server using NTP protocol. This is also needed because all events in the system must happen almost simultaneously on all machines. Whilst starting the video playback, the administrator client sends the command to start the playback and the time stamp at which the playback should be started to all clients. When a

client receives this command it prepares video for playback and waits for the clock. When the received time stamp is reached, the client start the playback. Thus, if we assume the clock synchronicity between all clients, the playback will start on all clients in the same moment.

Video reproduction is a time-sensitive process, so minimal deviation in performance of clients could lead to loss of synchronicity between clients and their video playback. Therefore, we need to guarantee that if the playback is started synchronously, it stays synchronized all the time during playback. To achieve this, each client renders video frames as fast as possible and on each draw event it calculates the exact frame number that should be shown. Thus, it is common to draw one frame multiple times, or not to draw a frame at all.

V. Conclusion

We have presented an overview of the tiled displays system. Our primary purpose was to display 360° panoramic movies that can be seen by many viewers at the same time. This technology can also be used to create large 360° tiled projection displays in order to display some information, for example in control rooms or in situations where a lot of data needs to be displayed. Current implementation of the system performs computationally intensive video processing on GPUs. The system development has been done on several platforms including Matlab, C++ and OpenGL.

This is an interesting project and there are several opportunities that could expand the system's base functionality. For example, we could use Google Street View for interactive walk through streets.

***Abstract*—For the surveillance of the large interior spaces it is often necessary to use multiple cameras. This paper deals with the tracking of an individual using multiple cameras with partially overlapping views. To implement such a system it is necessary to preprocess recordings, detect a person in motion and find the contact point between person and floor. It is especially important to consider the situation in which a person is in the folded multi-camera field of view. Last step is making homographic transformation of a point where person contacts the ground in observed space. System performance was measured on artificially generated recordings of a person moving through halls. It utilizes views with cameras from four different locations. Implemented application runs fast enough for use in systems that operate in real time.**

I. Introduction

Object motion tracking (especially people tracking) using cameras has an important role in various forms of of surveillance systems. Because of the limited view, and limited operating angle of cameras, often is necessary to use multiple cameras with partially overlapping views, which combined can monitor whole area of the interest. Such systems usually generates collection of separated videos, each covering a certain part of the supervised area. A person responsible for supervision must watch and analyze all videos in order to monitor persons moving in the controlled area. There are numerous problems with the object tracking using multiple cameras and here we list some of them. The human capacity for simultaneous multiple video monitoring is limited. Also, an object located at the point with overlapping visual fields of two or more cameras appear simultaneously on several different views, and this further complicates tracking. Therefore, there is a need to develop computer systems that can analyze videos sent from multiple cameras simultaneously, and present the information to user in convenient and easy understandable form.

In the experiment in this paper we use several fixed cameras placed in the area of interest, so that the observed object is always in the field of view at least of one camera, provided the object is within supervised area. Cameras views partially overlaps so they completely cover the entire area of interest. Multiple views of the object obtained with several different cameras is analyzed and the system generates objects trajectory on the ground plan of the supervised area.

The next section describes related work in this area. The main part describes the procedure for monitoring a person, image preprocessing, detection of person in motion, finding the lowest point of the moving person, homographic mapping, and system testing. The last chapter contains a brief conclusion of this paper.

II. Related work on multiple camera surveillance systems

There are several related papers dealing with the similar problems as in our work and they will be briefly described here. [1] used only relative camera calibration, while the correspondence of two views has been established using a set of feature points in Bayesian network. As the features they only used points of the upper half of the body to minimize the differences between different perspectives. In addition to the previously described features, as additional geometrical property they used the estimated height of the person moving in view of each camera. Following the moving object trajectory system is able to discover that the person is near the edge of the area which is observed with the camera, and at that point system choose another camera that best covers the area in which a person enters.

Unlike the previously described work, in [2] cameras had to be pre-calibrated in order to system work properly. The system is then based on the information about the position and orientation of the camera and it is able to calculate the 3D coordinates of the monitored person. To establish a correspondence between views of two overlapping cameras, information on the volume (voxel occupied by the moving person) is used. This is possible because regardless of the perspective from which object is observed (ie, to the camera from which we look at a person) it will always occupy the same voxels in the space. The paper [3] used a different approach than the above.

Specifically, in this article any information about the camera calibration and position in observed area was not used. The camera position in space is calculated based on the observation of trajectories of moving object in the space. Trajectories

obtained from different camera views were randomly mapped one to another, ie. for a pair of two camera views homographic mapping is calculated (homography that match one view to another). This approach provides multiple homgraphies, and, from the statistic theory, the right one is the one which appears most often. Namely, even if there are more inaccurate than accurate homography, inaccurate homography will have different orientations, ie. they will be different, while the correct homography should be very similar to each other.

Object tracking (people, vehicles) is possible even when there is no overlap between camera views. Then, of course, will not be possible to reconstruct the complete trajectory of a moving person, because there are parts of space that are not covered at all by any camera. This problem is considered in [4] where the goal was to obtain the broken path of the object in the view of some cameras. The solution also used Bayesian formulation of probability, and the camera position and possible trajectories were required to be known in advance.

III. Description of tracking method

The process of monitoring person's movement through the corridors consist of several steps. Video footage from cameras are handled as a series of images over which several operations are applied. A series of operations are carried out cyclically for each camera and the person's position is updated on a corridor plan.

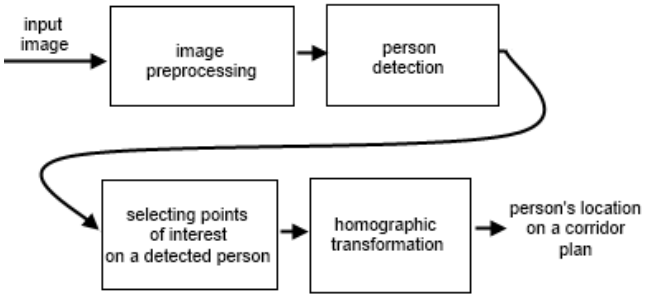

Figure 1. The process of object detection and tracking

A. Image preprocessing

The first step of tracking method is image preprocessing procedure, in order to emphasize the image elements essential for further processing and to remove the noise. Procedure consists of converting images to monochrome, averaging and normalization of the histogram. Using monochromatic image any further operations are quite simple, yet there is no loss of information that are required for person's movement detection. Image averaging removes noise that may occur during signal transfer or other external disturbances. The next technique used to improve image is the normalization of histogram. Using this process, histogram is modeled so that values conform to uniform distribution which contributes to a better image quality.

B. Person's movement detection

Detection of person on the move is performed by subtracting values of static scene model from the current image from the camera. Scene is modelled by weight averaging previous input images, using the following expression:

$$M_{k+1}(x,y) = \alpha \cdot M_k(x,y) + (1-\alpha) \cdot I(x,y),$$

with symbols:

- M_{k+1} scene model in next step,
- M_k scene model from previous step,
- α parameter used for determining contribution of image to the current scene model
- I current input image.

Using static scene model M makes movement detection method more resistant to the noise that appears in the image. Stationary parts of an image have similar values in the scene model and in each input image, which is why by subtracting these components we get values close to zero. Parts of the image that contain person in movement are different from the scene model. By subtracting these values and taking the absolute value, the result is image on which moving parts have higher values then the static ones. After subtracting with scene model and taking absolute values, the image is converted into a binary with a certain threshold value (which may not be in the middle of the intensity range) to obtain a mask of objects that are in motion.

C. Determination of the lowest moving point

After determining the moving parts of an image, next step is to determine the point of an object that is in the floor level. It will be used later to define the position of the person on the corridor plan. The moving parts of image which are identified in the previous step are bounded with rectangles. Y coordinate of the requested point is lower edge of the lowest bounding rectangle. X coordinate of the point is calculated as the mean value of X coordinates of centers of every bounding rectangle in the image. Figure 2 shows bounding rectangles on image with detected moving parts.

D. Homographic transformation

Homography or projection transformation is invertible transformation which has the property of preserving collinearity and cross ratios of quadruples of points. Formally, it is a composition of two perspective projections and describes the change of points location of the observed objects with the changing position of the observer. In our case, homography transforms the point of an object from the camera field of view to the point on the corridor plan.

Illustration of the homography transformation is shown on figure 3.

In order to compute the transformation, it is necessary to determine transformation (homographic) matrix H that maps points of the plane Π to points of the plane Π', so that point p'

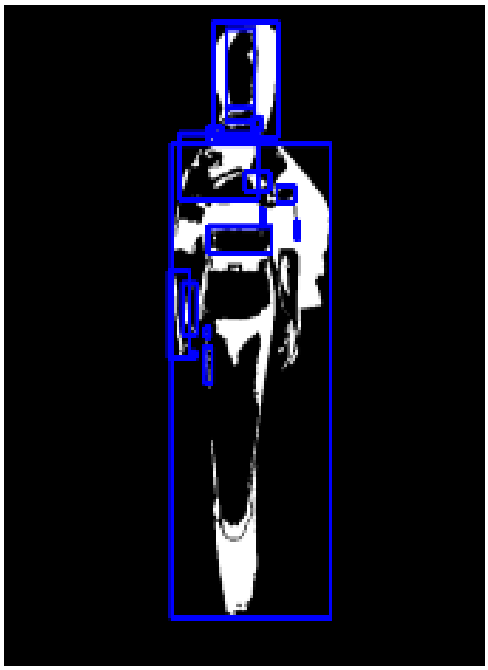

Figure 2. Detection of moving parts

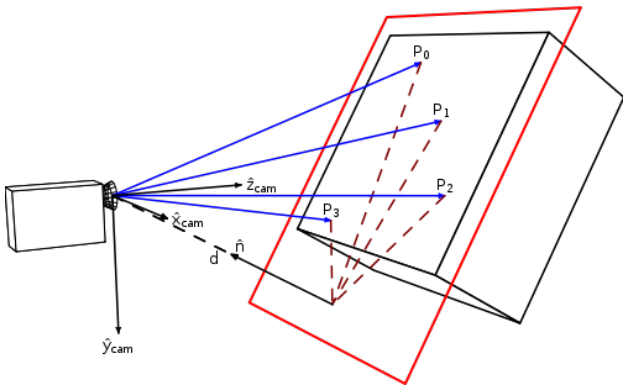

Figure 3. Ilustration of homography

is obtained from the point p by using the expression: $p' \approx Hp$. Note that p' and Hp are not numerically equal and they can differ by a scale factor. However, they have the same direction, and, hence $p' \times Hp = 0$. Also, points p and p' are homogenous vectors of size 3×1, and H is 3×3 matrix.

Writing the ith row of H as h_i^T, we have:

$$Hp = \begin{bmatrix} h_1^T p \\ h_2^T p \\ h_3^T p \end{bmatrix}$$

We can write:

$$p' \times Hp = \begin{bmatrix} y' h_3^T p - w' h_2^T p \\ w' h_1^T p - x' h_3^T p \\ x' h_2^T p - y' h_1^T p \end{bmatrix}$$

Since $h_j^T x_i = x_i^T h_j$, the system of equations can be written in terms of the entries of H as:

$$\begin{bmatrix} 0^T & -w'p^T & y'p^T \\ w'p^T & 0^T & -x'p^T \\ -y'p^T & x'p^T & 0^T \end{bmatrix} \begin{bmatrix} h_1 \\ h_2 \\ h_3 \end{bmatrix} = 0$$

Those equations have the form $A_i h = 0$ where A_i is a 3×9 matrix and h is a 9×1 vector. Note that A_i has rank of 2. Stacking up the equations for all four points we have $Ah = 0$ where A is 12×9 matrix of rank 8. Vector h is given by the last column of V where $A = U\Sigma V^T$ is singular value decomposition (SVD) of A. From h we obtain homographic matrix H.

Points p, p' and homographic matrix H have the following format (points are given in homogeneous coordinates):

$$p = \begin{bmatrix} x \\ y \\ 1 \end{bmatrix} \qquad p' = \begin{bmatrix} kx' \\ ky' \\ k \end{bmatrix} \qquad H = \begin{bmatrix} h_{11} & h_{12} & h_{13} \\ h_{21} & h_{22} & h_{23} \\ h_{31} & h_{32} & h_{33} \end{bmatrix}$$

To calculate the position of a point in the corridor plan it is necessary to determine homographic matrix. For that it is necessary to have at least four correspondent pairs of $2-D$ points ($p_i \leftrightarrow p_i'$) that are in the same plane and are not collinear, in this case in the plane of the floor.

For the required points were taken corners between two walls and the corridor floor, because their transformed coordinates can be easily determined on the 2D corridor plan. Homographic matrices are calculated separately for each camera.

Below are given examples of a such matrix, points from input image and obtained transformed points on the corridor plan. Input and output point coordinates are expressed in pixels.

$$H = \begin{bmatrix} -1.74 & -0.86 & 719.25 \\ 0 & -12.53 & 1938.16 \\ 0 & -0.02 & 1.00 \end{bmatrix}$$

Four input points:

$$p_1 = (212, 600)$$
$$p_2 = (354, 156)$$
$$p_3 = (667, 600)$$
$$p_4 = (440, 156)$$

Transformed points:

$$p_1' = (16, 535)$$
$$p_2' = (16, 8)$$
$$p_3' = (92, 535)$$
$$p_4' = (92, 8)$$

E. Determination of the position on corridor plan

For every camera that detected movement, the lowest point of moving object is calculated. Then by multiplying that point with corresponding homographic matrix its position on the corridor plan is determined. If the resulting position deviates from the previous position of the person, it is ignored.

Otherwise it is taken together with correct positions from other cameras. The new position of the person is calculated as the mean of the last three received information about the position.

IV. Recordings for system test and evaluation

In order to create the system first was necessary to obtain recordings for system testing. We have considered a number of ways to obtain needed materials. One option was to record the materials in real word building, but unfortunately we did not have adequate space to set up the experiment with adequate number of cameras.

Another approach was to make a model of the corridor system (Figure 4), and in such an environment to make recordings of the moving object through the corridors of the building. This approach we tried out on a small model consisting of three corridors, and we placed three cameras inside it. The moving object in this simulation was a ball, and we used *Basler* cameras. The obtained recordings were relatively poor quality due to inadequate lighting and the look of footage was quite unrealistic due to the poor geometry of space (the camera lens was almost a half wide of corridor, which resulted in unrealistic perspective of captured materials).

Figure 4. Corridor model with three cameras

Finally we get the final recordings by creating a computer model of corridor network, and capturing animated simulation of moving persons through the corridors. Corridor network consists of 4 corridors housing a four cameras, which almost completely cover the area. Specifically, there are two dead angle areas, which were located below the two cameras that are located at the very ends of the corridors. A virtual model itself and simulation of the moving person was made using *Autodesk 3ds MAX*. The simulation duration was minute and 8 seconds, and the rendering of that material took about 4 hours on a PC with *Intel Core2Duo* processor running at 1.8 GHz.

A. Corridor configuration

Image of the corridor configuration which is used for system development and evaluation is shown on the figure 6.

Image shows the floor plan of the building with four corridors. In order to adequately cover the monitored area, it was necessary to set up a minimum of four cameras, each covering one corridor of the building. Camera positions are marked in the figure with camera icons. However, as mentioned earlier, in this configuration there are two dead angles, and they are located at the very ends of the corridor under the camera C1 and C4. The problem could be solved by installing additional cameras on the other ends of the corridors, opposite to the cameras C1 and C4, but we believe that using an additional camera is not necessary. The blind spots are located at the very ends of the corridors, and therefore is not possible to lose important information about the tracked person (from the non-visible area person has only one way to move into the building, and this way is covered with a camera).

V. Results

The system for objects tracking using multiple cameras has been developed in C++ language using openCV [5], library for real-time computer vision. The developed system works in real-time, and is able to draw the trajectory of a moving object on the ground plan of the supervised area. In addition, the system marks the camera views when the supervised object is moving in the camera's view. Image 5 shows the four cameras view, while the image 6 shows the floor plan of the supervised space.

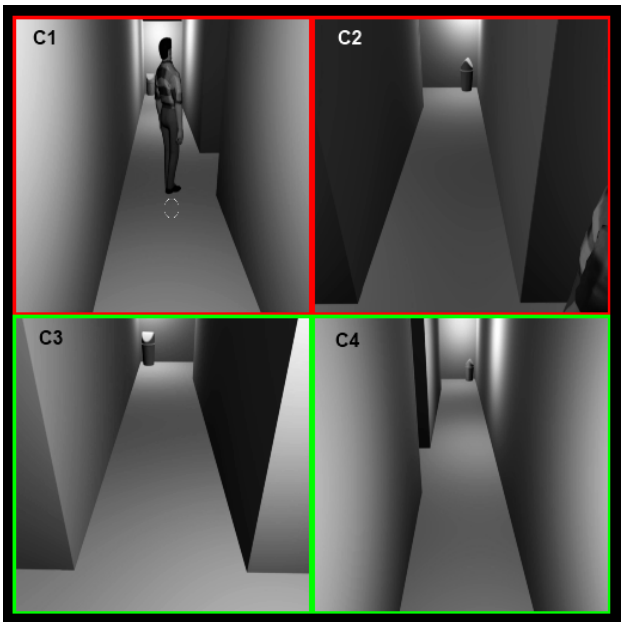

Figure 5. Four-camera views

On the first image cameras C1 and C2 view is marked with red frame-border which indicates that moving object is in the view of this two cameras. In the second image line shows the moving person trajectory, while the current person position is marked with dot on the end of trajectory.

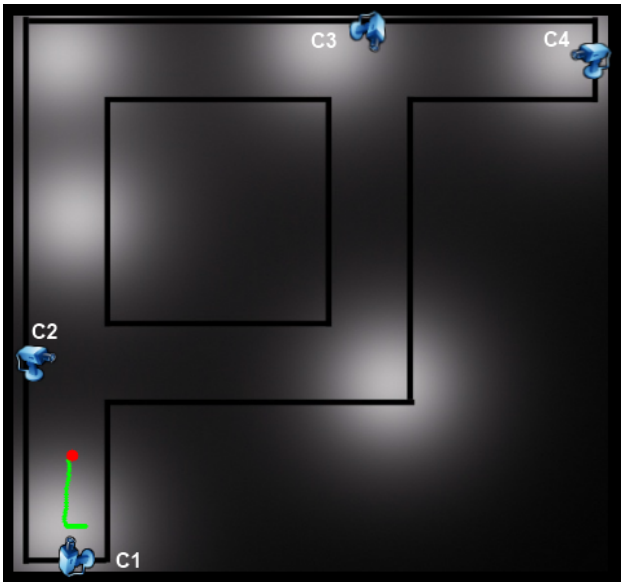

Figure 6. Corridor plan view

VI. Conclusion

This paper describes a system for monitoring large areas in the interior of a building, using multiple surveillance cameras. The process consists of image preprocessing, person's movement detection, determining the point of contact with the ground and using homography to determine the position in 2D space plan. The footage from the model of the area and recordings obtained from the virtual 3D model are used for system testing. The actual model has not proved successful due to poor recordings quality. The test results by using virtual model are satisfactory and the person's movement can be monitored on the area plan. Possible future work on the system would include testing in real situations with surveillance cameras.

***Abstract*—Financial market turmoil is a new normal today and modern computer science is partialy responsible for this. In this paper we try to show that modern fincancial markets are informationally efficent. In order to show this attribute of financial markets we use a neural network and test it against the S & P 500 stock index. We train our neural network using index information from past in order to predict the future value of the index. We compare the results of neural network based index prediction and a simple buy & hold strategy. Based on this comparison we make a decision about validity of the market efficiency hypothesis. Finally we present some possible improvements to our solution of this problem.**

I. Introduction

In times of swift technological advancements, we are witnessing a great financial crisis that shakes our world and has great influence on our lives. Of course, the main reason for emerging of the crisis is the insatiable human greed combined with the existence of various exotic financial instruments. Those financial instruments have had different role at the time of their creation - risk protection. Unfortunately, today those are used in speculative means and people who use those instruments are often unaware of the risks of using those instruments.

Computers are today everywhere and they are irreplaceable part of our world. Computer systems for automatic trading have very special role in financial markets today. They are able to generate buy and sell order signals on stock market independently of broker. Such computer systems create over 80% of financial transactions on American stock markets today. In designing such systems artificial neural networks have a important role because they have the ability to adapt for solving various problems. They are often used as a part of a bigger computer system that collects technical and fundamental parameters and decides whether to buy or sell securities in real time.

This paper is organized as follows: in section II we give the introduction to the problem and give an overview of previous work in the same field. In section III we describe our method for tackling the problem described in section II. In section IV we comment our results and finally in section V we conclude and give some proposals for improving our method.

II. Problem definition

In this paper we are not trying to use artificial neural networks for financial market trend prediction. Actually, we are trying to test the correctness of efficient market hypothesis. The financial market is informationally efficient if stock values on market react on new information quickly and rationally. Therefore, efficient markets are those markets in which today's stock price is based on all past and present information.

In general, we can define three levels of efficiency: the weak, semi strong and strong market efficiency. We are interested in weak efficiency and we say that market is weak efficient if current stock price includes all past information, such as past values and trade volumes. Therefore, if a market is weak efficient then it is not possible to predict stock value trend based on past data and use this information to gain above-average returns. When saying above-average returns, we think of returns that are larger than returns of a simple buy & hold strategy. It is important to say that it is not possible to achieve above-average returns in the long run, while in a shorter period it is possible to achieve much larger or smaller returns than average.

According to some research, such as [1] and [2], it is apparent that developed financial markets are weak or semi strong efficient. Even though this principle is true, it has been shown in some papers that artificial neural networks can achieve better returns than market, but it is always doubtful whether the observed time interval is representative [3]. In [1] it has been tried to show that using technical analysis, i.e. using pattern searching in past data, it is not possible to achieve above-average returns on American stock markets. In [2] it has been tried to show that developed European financial markets are efficient. On the other hand, in papers [4] and [5] is has been shown that technical analysis makes sense in developing markets.

Our method is similar to mentioned methods with the difference that we are not using a technical indicator, such as MACD, Bollinger Bands, Fibonacci or similar, but we are using only data that are presented to artificial neural network which has to find a potential stock value trend rule. It is important to mention that the market efficiency tests are often based on stock indices and not on specific stock value. Thus, S&P 500, DJIA, Nasdaq, Nikkei 225, Dax, Cac, USD/EUR rate or similar widely known liquid indices are often used.

III. Realization

A possible implementation of computer system for automatic stock trading could use various types of artificial

neural networks, of which every has its own advantages and disadvantages. We have chosen a feed forward multi-layered neural network, as it is simple and easy understandable, but has very good properties. We have implemented our system using *Matlab* because most of the functions we needed were already implemented in it. That has made this project much easier to work on.

After choosing the type of neural network to use, we had to define how to train the network, what to use as an input to the network, how to interpret the output of the network, how many hidden layers to use and how much neurons should be in every layer of the network. This is a common problem when using artificial neural networks because there are many parameters that needs to be chosen, which greatly influence on the final result of solving the problem. In order to clearly explain why we have chosen some parameters as we did, we first have to explain our trading strategy.

Our goal is to predict the tomorrow's stock value based on data from the past and the present. If we predict that the stock will rise, then we will buy it. On the other hand, if we predict that the stock price will decline, then we will take a short position. This position is opposite to buying a stock. We borrow a certain amount of stocks from a broker and sell them, but we are obligated to return the stocks to our broker at some point in future. As we have sold stocks, at some moment we will have to buy them back. Of course, it suits us if the stock price declines because then we will be in position to buy the stock at a lower price and gain a profit equal to the difference between the selling and buying price. Clearly we can lose money if the stock price rises. The short position method is very common on developed financial markets. When we choose the position to take, we can simply calculate our profit using a tomorrow's stock value when it becomes known. Since we work with the past data, it is clear that we know those values. We make choices every day so we are able to calculate profit for each day.

After we have explained our trading strategy, we have to explain the network parameters. Let us begin with the simplest things: inputs and outputs of the network. The input in our network could be an average S&P 500 index value for predetermined number of past days. As we mentioned earlier, it is important to use index that represents the market as a whole, and S&P 500 is an index of 500 most important corporations divided in 10 different groups. This index is an excellent representation of American financial market. The average index values have been downloaded from *finance.yahoo.com* for period from 5th July 1950 to 8th December 2011. This broad range of days and index values is shown on figure 1. Since the range of index values is very broad, it could represent a problem if we use the index value directly as a input to network. At first, we tried to solve this problem by scaling the input data. Although this has partially improved the results, at the end we have decided to take a different approach. We have decided to put relative changes of index values from past as our input and we did not have problems with this approach because past changes are mainly of equal dimension (in percents). The amount of past days to use for network training can be arbitrarily changed, and we have empirically determined that using 40 days gives good results.

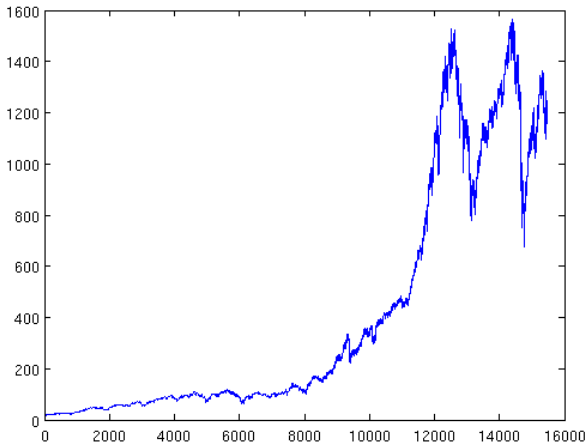

Figure 1. S&P 500 index trend

As we have said that we need to predict the index value for tomorrow, the output of the network could be the predicted index value. But the exact value prediction is not so important because all we want to know is whether the index will be higher or lower than today. Therefore, in sake of simplicity, the network output will be the indication whether the stock will rise or fall. We could use two neurons in the exit layer of the network in which one neuron would designate the rise and the other fall of the index. The final decision would then be based on comparison of those two output values. But again for the sake of simplicity, we have chosen to use only one neuron in networks exit layer. The output value of that neuron close to one marks a rise of index, and the output value close to zeros marks a fall of index. We have also tried to use a network with two neurons in exit layer of the network, but results were not better than using a simpler network with only one neuron in the exit layer, even though that network required more time to train and was slower in exploitation.

Number of training samples was not a problem since we had more than 15000 samples for training and model evaluation. We needed to decide how much and which samples would be used for learning, and how much and which samples would be used for testing the network. We have striven to make this procedure as simple and flexible as possible, so we have added a possibility to choose how much samples we want to use for training. In final version, we have decided to use 100 training samples. Except this parameter, we have to set a parameter that tells us for how much days so trained network is "valid", because after we train the network once it makes no sense to use the same network for 40 years, but we have to retrain the network e.g. each 200 days on fresh data because the market and its rules are constantly changing. The extreme case is retraining the network every day, but this is very computationally intensive.

Except mentioned parameters, we also had to define the maximum allowed mean squared error and maximum number of iterations during training. Those parameters are sometimes very difficult to determine, but as we used Levenberg-Marquardt [6] algorithm for training the network, we have empirically chosen the maximum of 500 iterations for network training as enough. We have also chosen the maximum allowed mean squared error of 0.01. Those parameter satisfied us, although they are easily changeable. The selection of some parameters will be commented in further text.

IV. Results

Since our goal was to determine whether the financial markets are informationally efficient, we had to check this. In order to check this, we had to show that neural network cannot beat a simple *buy & hold* strategy on average. In figure 2 we can see a period of 1000 days in which the strategy of our neural network has shown to be much better than a buy & hold strategy. We can see that the the buy & hold strategy would give us only 10% profit, whilst our neural network achieved 50% profit. We can see that the difference is really big and in that period it would be profitable to invest according to our neural network's signals. But we cannot immediately

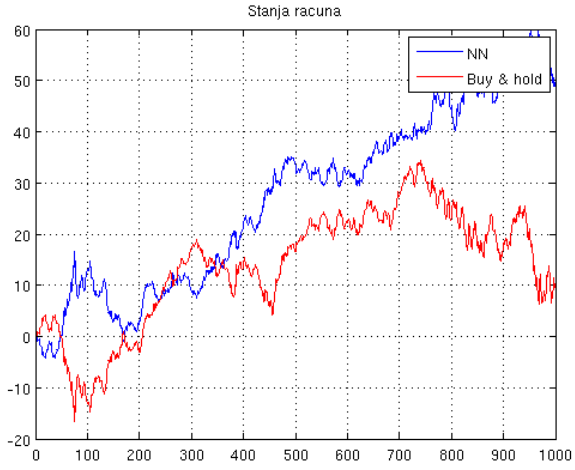

Figure 2. Neural Network vs *buy & hold* trend

conclude that our neural network has shown that market is not efficient. If we take a look at figure 3, we can see a completely different story. We can see that our neural network achieved quite a bad result compared to a buy & hold strategy. Our neural network has achieved only 30% profit, whilst simple buy & hold strategy achieved more than 120% profit, that is four times better result. This result is similar to the previous one, but this time in favor of buy & hold strategy.

As we have shown that each strategy can beat the other one in some period, we should also show a period in which both strategies perform equally. Such a 1000-day period is shown in figure 4.

Remember that efficient market hypothesis says that it is not possible to achieve profits that are above-average, but only in

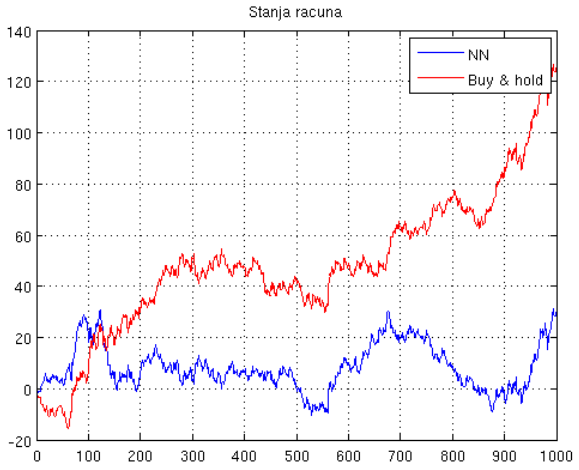

Figure 3. Neural Network vs *buy & hold* trend

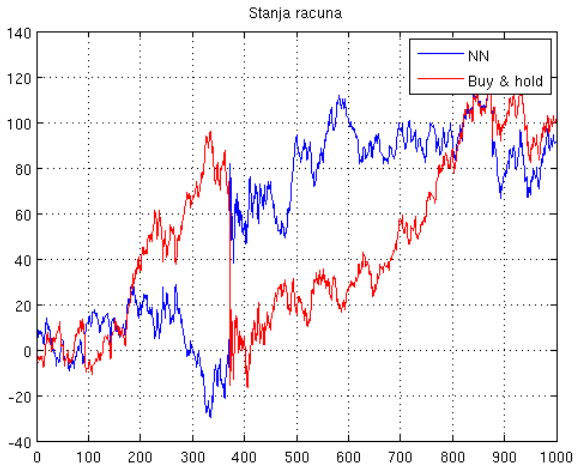

Figure 4. Neural Network vs *buy & hold* trend

average. It is not defined how long that period has to be. Of course, we need to observe average values so we have taken a period of almost 20 years and as shown in figure 5, we achieved below-average results compared to a simple buy and hold strategy.

If we observe even larger period of more than 50 years, we can see that in some sub-periods our neural network achieves better results than buy & hold strategy, but in the end the buy & hold strategy achieves much better result, as shown in figure 6.

Beside those results it is necessary to observe a distribution of daily profits. For the longest period, this distribution is shown in figure 7. We can notice that changes are bigger at the end of period because the index values are higher, but the amount of correctly predicted trends is roughly equal to the amount of incorrectly predicted trends. It is possible to calculate some statistical properties i.e. the amount of correctly predicted trends. The amount of prediction of rising the value

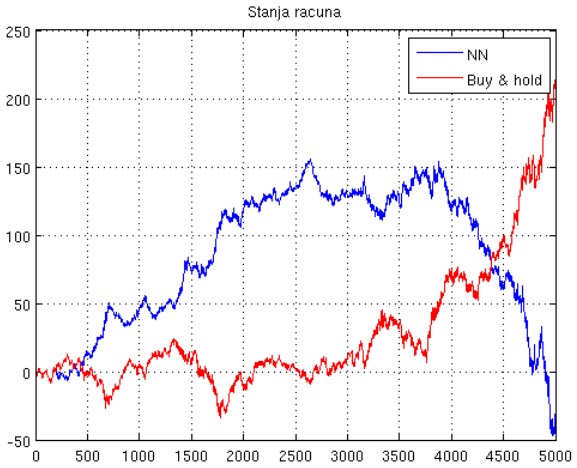

Figure 5. Neural Network vs *buy & hold* trend

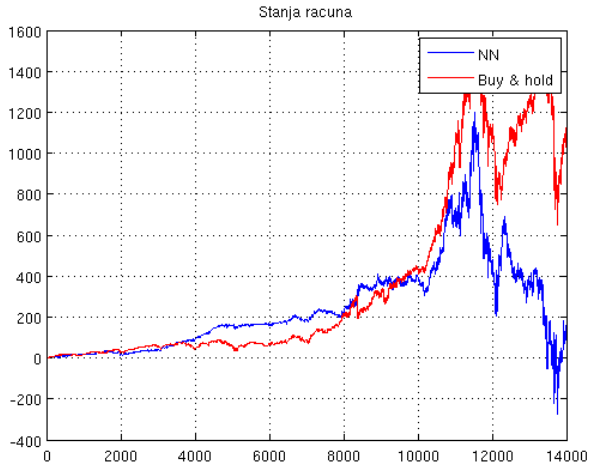

Figure 6. Neural Network vs *buy & hold* trend

when the value really rose was 5204, the amount of falls when the fall was predicted was 2040, the amount of falls when the rise was predicted was 4592 and the number of rises when the fall was predicted was 2164. Similar data can be obtained for other periods on which tests were performed. According to this data, the accuracy of trend prediction is 0.5174, which is similar to other research in this field. This number is marginally larger than 0.5 which means that trend prediction is hardly better than making a decision based on throwing a coin. As the result is marginally better that 0.5, we could conclude that market has partially predictive property.

V. Conclusion

In this paper we have shown how to make an artificial neural network that has a goal to predict the trend of the S&P 500 stock index based on past information, such as past value changes. The goal was to show that financial markets are informationally efficient and therefore it is not possible

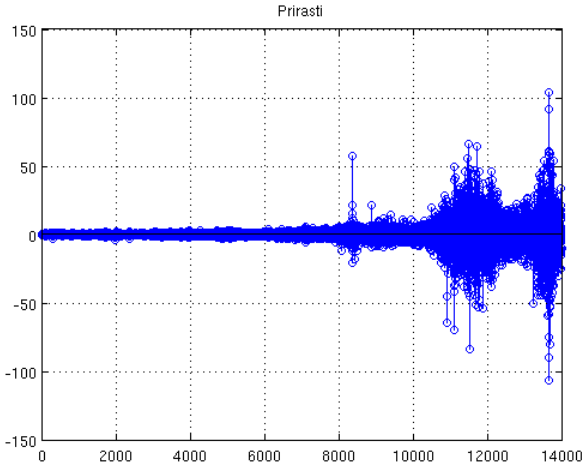

Figure 7. Neural Network's daily profits

to determine the future trend based on past information. On some examples we have shown that this property is valid for long periods of time, whilst in shorter periods it is possible to achieve above-average returns. Those results are widely known and they are similar to other research in this field. But it is always important to observe certain time periods because in one of our examples our neural networks achieved better results than simple buy & hold strategy for more than 20 years. This cannot be a proof that using neural networks one can predict the market trend because there was a period in which a buy & hold strategy has shown to be a better strategy.

Apart from our approach, it is possible to use additional parameters such as trade volumes, fundamental data, macroeconomic data, exchange rates, country's debt costs [7], etc. It is also possible to make the decision making process more robust by basing a decision to buy or sell a security on outputs of multiple neural networks that have different parameters [3].

Abstract - Preventing and controlling of epidemics in human or computer networks is a top problem. This paper presents an implementation of the algorithm that simulates the epidemic spreading in networks, using CUDA (*Compute Unified Device Architecture*) technology. Spreading of the epidemics over the network is modeled by a discrete SIR (*Susceptible - Infected - Recovered*) model. This implementation enables selection of starting node and monitoring the epidemic spread in each cycle. In comparison to a common CPU implementation, the CUDA implementation achieves about 10x faster execution time, which is of high significance to running tests on larger networks. The implementation was tested on real social networks consisting of more than 5 million nodes. Hence, we belive this implementation can have a practical value in analysis of the epidemic spreading over large networks.

I. INTRODUCTION

Very often it is convenient to represent a certain population as a network where nodes represent individuals and links represent connections between them. SIR *(Susceptible – Infected – Recovered)* compartment model is used for monitoring epidemic spread in network where each individual in population can belong to the one of three compartments. Those compartments are Susceptible(consisting of individuals who can get infected), Infected(consisting of individuals who are infected and can infect others) and Recovered(holding individuals who have recovered and are immune). Realistic epidemic simulations (EpiFast [1], EpiSims [2] and EpiSindemics [3]) are widely used in public health studies. Naive SIR[5] and FastSIR[5] algorithms are CPU implementations we are trying to outperform in this paper. When dealing with extremely large networks it is crucial to achieve a reasonable execution time of a conducted simulation and that is where parallel algorithms become important.

CUDA *(Compute Unified Device Architecture)* is a parallel computing architecture developed by Nvidia. It is a computing engine in Nvidia GPUs *(Graphics Processing Units)* that is accessible to software developers through different programming languages, including C which was used for implementing this algorithm. CUDA gives developers access to the virtual instruction set and memory of the parallel computational elements in CUDA GPUs which that way become accessible for computation like CPUs. Unlike CPUs however, GPUs have a parallel throughput architecture that emphasizes executing many concurrent threads slowly, rather then executing a single thread very quickly. Such behavior enables solving certain problems much more time-efficient than by usual CPU approach. Main precondition that problem must conform in order to achieve that is that it is possible to divide it into large number of smaller problems that can be solved independently and thus executed concurrently.

We define network as undirected and non-weighted graph G(*N, L*) (*N*-set of nodes, *L*-set of links). Link (*u, v*) exists only if two nodes are in contact during epidemic time. We also assume that the network during epidemic process is static. To simulate epidemic propagation through network, standard stochastic SIR model is used. In this model each node at some time can be in one of the following states: susceptible (*S*), infected (*I*) and recovered (*R*). A discrete time model is used. Time needed for the epidemic to stop spreading defines one epidemic simulation.

In chapter Results we present speedup achieved over NaiveSIR and FastSIR on specific test case. In Methods is presented the general idea behind implementation. The last chapter (Discussion and conclusion) proposes ideas for eventual further research related to this paper.

II. RESULTS

Purpose of this chapter is to show execution time in comparison to Naive SIR and FastSIR algorithms. Tests were conducted on server with Nvidia 570 GTX GPU and Intel Core2 6400@2.13 GHz with 4 GB RAM.

LiveJournal is a free online community with almost 10 milion members. LiveJournal allows members to maintain journals and it allows people to declare which other members are their friends. Network representing friendship relations of this population (nodes represent users and links represent friendships) is used for the following test case. Results for Live Journal network[6] consisting of 5 milion nodes and 50 milion links are shown in Table 1.

TABLE I. RUNNING TIME IN SECONDS FOR 2000 SIMULATIONS FOR LIVE JOURNAL NETWORK

q	p = 0.2			p = 0.5			p = 0.8

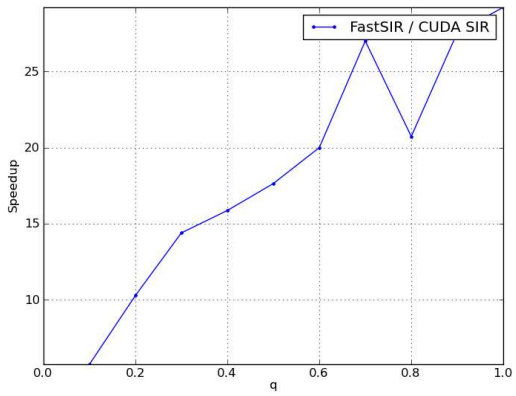

Figure 1. Running time ratio for FastSIR and CUDA algorithm. Parameters: 2000 simulations, p = 0.2, q = 0.1 to 1

The running time ratio for FastSIR and CUDA algorithm is especially interesting. The achieved speedup ranges from 5 to almost 30 times in some cases.
On average, CUDA algorithm is about 16 times faster than FastSIR for LiveJournal network. Figure 1. shows calculated ratios for different choices of *p* and *q*.

III. METHODS

At the beginning of each epidemic simulation all nodes from graph G are in susceptible state except arbitrary single node, which is initially infected with epidemic parameters *p* and *q*. Epidemic parameter *p* is a probability that the infected node *u* infects adjacent susceptible node *v* in one discrete time step. Epidemic parameter *q* is a probability that the infected node recovers in one discrete time step. At the end of an epidemic simulation all nodes can be in one of two following states: susceptible or recovered.

In each step of simulation every infected node tries to infect its neighbors with probability *p* and then tries to recover with probability *q*. Simulation continues until each node is either susceptible or recovered. So far, these actions have been executed sequentially, both serving infected node and spreading infection to its neighbors. Having that in mind, it is possible to notice that this algorithm exposes its parallel nature on two levels: it is possible to serve multiple infected nodes simultaneously and for each infected node its neighbours can also get infected simultaneously. Executing algorithm in this manner does not affect final result in any way.

The simplest case where *p* and *q* are equal to 1 translates our problem to well known BFS (*Breadth First Search*). Also, in general case where *p* and *q* are arbitrary values from [0, 1] the algorithm resembles BFS, only with different propagation conditions. That is why implementing BFS on CUDA is a great step to final algorithm for epidemics spreading. GPUs have shown promising results in accelerating computationally challenging graph problems but their performance depends heavily on the structure of the graph. When graph has highly irregular structure, as most real-world graphs tend to, it can significantly slow down the program execution. CUDA BFS[7] algorithm upon which we built our solution quite successfully addresses this problem. The main idea is to assign a group of threads to each group of nodes. A thread group sequentially takes nodes from its node group and then simultaneously tries to infect all neighbours. In this way two-level parallelization is achieved. Although it may seem more efficient to assign thread group to single node and evade sequential „walk“ through group of nodes, in real CUDA system it would result with too many inactive threads causing underutilization and therefore slowing the performance.

In this implementation graph is represented as an adjacency list rather than adjacency matrix which would waste a lot of space for sparse graphs. Also, we always access all of the neighbors and do not need to know if the two specific nodes are linked or not. Further optimization of this representation is achieved by packing all adjacency list into a single large array making it more convenient to store and use on GPU. In this way, a graph is being held in two arrays, *N* and *L*. Array *N* represents nodes of graph where each node points to the starting position of its own adjacency list in *L*. Array *L* holds all adjacency lists merged sequentially. Each element in *N* corresponds to the starting index of its adjacency list in *L* except the last one, which serves as a marker to indicate the length of the links array. Each element in *L* refers to a node in *N*. The described data structure is also known as compressed

sparse row (CSR) in sparse – matrix computation domain [4]. It is visualized by Figure 2.

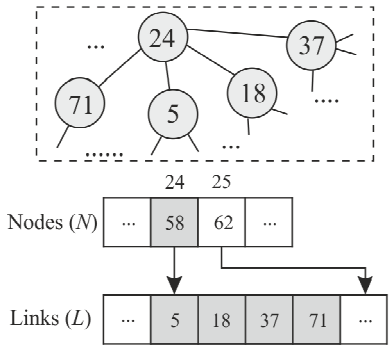

Figure 2. Graph data structure used in the implementation

Before starting the simulation part of the algorithm, random number generator (RNG) has to be initialized for each thread. RNGs are used to implement probabilites given by p and q. If number generated from interval [0, 100] is smaller than given probability multiplied by 100 it is considered that the modelled event occured. CUDA provides its own library for generating random numbers and it is advised that each thread uses only its own generator to evade possible determinism. The following two procedures, loading network from file and initializing an array of RNGs, have to be executed every time the program is started. Time needed depends on the size of network and CPU used in system, in our test case for LiveJournal it took about 20 seconds. Once network is loaded into RAM and RNGs are initialized an arbitrary number of independent simulations can be executed, so the amount of time spent for those two steps can usually be ignored due to large number of conducted simulations.

The simulation is executed in steps, where for each step a suitable CUDA function is called. Between two steps CPU analyses information about current state in the network and makes decision which CUDA function to call next. Each node is assigned a certain level. If a node has level of n, it means it has been infected in the n-th step of simulation. Node levels are stored in the array *Levels*. If the node is not infected, its level is considered to be infinite. Node that is chosen to be the source of infection has level of 0. Figure 3. is showing an example of the first three steps of epidemic spread, presuming p is 1. Node marked in red is the source. In the first GPU call only one node has to be served. Depending on whether the red node has recovered or not in the second step of algorithm four or five nodes are ready to spread an infection further. Blue nodes have level of 1, green have level of 2 and yellow level of 3.

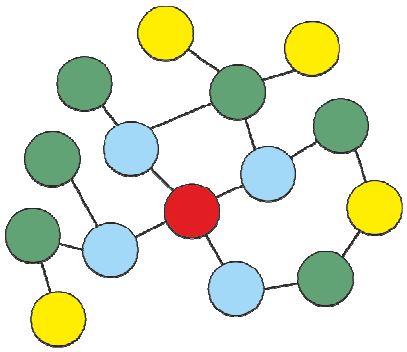

Figure 3. Steps in epidemic spread, red node is source, p equals 1

CUDA function which operates on GPU alternates two phases: SISD (*Single Instruction Single Data*) and SIMD (*Single Instruction Multiple Data*) phase. As mentioned before, threads are split into groups which are then assigned to equal groups of nodes, including corresponding parts of arrays *Levels* and *N*. In SISD phase all threads in a thread group execute the same instruction on the same data assuring there is no divergence slowing the performance. Additionally, in this phase each thread group copies its portion of data from slow global to fast shared memory. Acessing global memory in CUDA architecture takes around 300 cycles while access to shared memory takes only few[8]. In SISD phase all threads in a group loop sequentially through assigned nodes. If currently inspected node is infected SIMD phase is applied to its neighbours. In SIMD phase threads in a group execute the same instructions but on different data. In this case array holding neighbours is being served simultaneously by the whole thread group. Thread divergence is present in SIMD phase, but due to nature of problem it cannot be evaded. Figure 4. depicts this process more clearly.

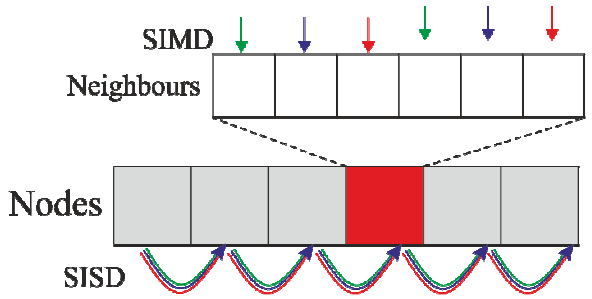

Figure 4. SISD and SIMD phases alternating during algorithm execution

Example in Figure 4. presumes thread group of size 3 and number of nodes assigned to thread group to be 6. Only the fourth node is infected. All three threads are in SISD phase until they reach the infected node, when SIMD phase is initiated. Threads split and each one tries to infect different neighbour. After all neighbours of infected node have been served (tried to get infected), the algorithm returns to SISD phase. Another problem is determining optimal sizes for a thread group and assigned group of nodes. Thread group size is partially determined by certain architectural traits of underlying CUDA system (should be multiplier of 8), but both parameters mostly depend on structure of the given network. So far, we have

determined optimal parameters purely experimentally, but it would be interesting to see if they can be predicted from input network characteristics.

In case when q is very small and p high, network quickly comes to a state where infected nodes do not have any susceptible neighbours. In that particular case it is redundant to spend time on visiting each neighbour of infected node just to find out none of them is susceptible. When this state occurs in network algorithm recognizes it and changes its behavior by calling another CUDA function, which assigns only one thread to each infected node. Neigbhours are not visited at all since none of them is susceptible and the only job to be done is trying to heal the node with probability q.

When there are no more infected nodes left, simulation is finished. It is possible to reconstruct epidemics spread from *Levels* which holds moment of infection for each node.

IV. DISCUSSION AND CONCLUSION

In this paper we presented general idea behind parallel implementation of the SIR algorithm for simulating epidemic spread in networks. It is shown it is possible to achieve significant speedup up to 30 times, especially on very large networks. In future work it would be interesting to see visualization tool for monitoring progress of simulation step by step. Additional speedup could be achieved by using multiple GPUs for calculations and MPI could be used for running more simulations at the same time. Current SIR model could be broadened by adding new events to network, like disappearing link or dynamical changes of p and q in order to represent population more realistically.

Dijkstra's shortest path algorithm serial and parallel execution performance analysis

Abstract - This article introduces the problem of parallelization of Dijkstra's algorithm, a well known algorithm for computing single-source shortest path in a graph. Dijkstra's algorithm can be applied to graphs with a various number of vertices and edges. Dijkstra's shortest path algorithm is implemented and presented, and the performances of its parallel and serial execution are compared. The algorithm implementation was parallelized using OpenMP (Open Multi-Processing) and OpenCL (Open Computing Language) standards. Its performances were measured on 4 different configurations, based on dual core and i5 processors. The experimental results prove that the parallel execution of the algorithm has good performances in terms of speed-up ratio, when compared to its serial execution. Finally, the results show that, because of Dijkstra's algorithm in itself is sequential, and difficult to parallelize, average speed-up ratio achieved by parallelization is only 10%. This proves to be a huge disadvantage of this algorithm, because its use is widespread, and enhancing its performance would have great effects in its many uses.

Keywords - Dijkstra algorithm; single source shortest path; parallel algorithm; OpenMP, OpenCL

I. INTRODUCTION

With the development of computer and information technology, the research about graph theory get a wide range of attention, and a variety of graph structures and algorithms have been proposed [2].

The shortest path algorithm is always a research hotspot in graph theory and it is the most basic algorithm. For example, shortest path algorithm is used to implement traffic engineering in IP networks and to improve Intelligent and Transportation Systems. But for that kind of algorithm it is very difficult to improve its performance.

Currently the algorithms for the serial shortest path optimization have reached the time limitation. Therefore the parallel computation is an efficient way to improve the performance. By putting some constraints on the data and taking the advantage of the hardware, the performance of the algorithms can be significantly improved.

In this article, firstly you can find a definition of the Dijkstra's algorithm for computing single-source shortest path in a graph, and then there is a parallel algorithm given to solve the shortest path problem of the single source graphs, where one implementation of single source shortest path algorithm executed on dual-core and i5 processor with OpenMP, and one with OpenCL. Finally we can find through experiments that parallel algorithm used in this article is has better performance than the serial one.

II. DIJKSTRA'S ALGORITHM

Dijkstra's algorithm finds the length of an shortest path between two vertices in a graph.

The algorithm works as follows:

1. Choose the source vertex
2. Define a set S of vertices, and initialise it to emptyset. As the algorithm progresses, the set S will store those vertices to which a shortest path has been found.
3. Label the source vertex with 0, and insert it into S.
4. Consider each vertex not in S connected by an edge from the newly inserted vertex. Label the vertex not in S with the label of the newly inserted vertex + the length of the edge.

But if the vertex not in S was already labeled, its new label will be min(label of newly inserted vertex + length of edge, old label)

5. Pick a vertex not in S with the smallest label, and add it to S.
6. Repeat from step 4, until the destination vertex is in S or there are no labeled vertices not in S.

If the destination is labeled, its label is the distance from source to destination. If it is not labeled, there is no path from the source to the destination.[6]

III. EXPLANATION OF SERIAL DIJKSTRA ALGORITHM

In this algorithm, two sets are maintained: D for all discovered nodes and U for undiscovered nodes. At first, D contains only the starting node s, use d(v) to denote the current estimated best distance from s to v, which is his neighbor. Initially all v except s has d(v)=infinity. Set D

grows by adding the node with minimal estimated distance from U into D, and update the current distance of the neighbor nodes of the newly added node, and repeat this procedure until all nodes are in D.

IV. EXPLANATION OF PARALLEL DIJKSTRA ALGORITHM

There are two parallelization strategies - execute each of the n shortest path problems on a different processor (source partitioned), or use a parallel formulation of the shortest path problem to increase concurrency (source parallel). Using n processors, each processor Pi finds the shortest paths from vertex Vi to all other vertices by executing Dijkstra's sequential single-source shortest paths algorithm.
It requires no interprocess communication (provided that the adjacency matrix is replicated at all processes). In this article it is used formulation of Dijkstra's algorithm using OpenMP. An OpenMP application begins with a single thread, the master thread. As the program executes, the application may encounter parallel regions in which the master thread creates thread teams (which include the master thread). At the end of a parallel region, the thread teams are stopped and the master thread continues execution. Since OpenMP is primarily a pragma or directive based standard,it can be easily combine serial & parallel code in a single source. By simply compiling with or without the /OpenMP compiler, it can turn OpenMP on or off. Code compiled without the /OpenMP simply ignores the OpenMP pragmas which allows original serial execution.

Figure 2. Part of code where OpenMP pragmas was used, wg represents weighted graph which contains weights of paths between nodes and vid.size() is size of vector with all nodes in graph

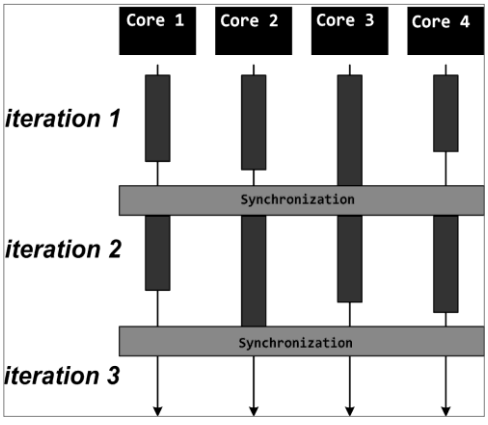

Figure 3. Example of iterations during execution of parallelized Dijkstra's algorithm on four processors using OpenMP

V. EXPLANATION OF IMPLEMENTATION OF DIJSKTRA'S ALGORITHM

The first step in running Dijkstra's algorithm on GPU (Graphics Processing Unit) is to create a graph data structure that is efficiently accessible by the GPU. The graph is composed of vertices and edges that connect vertices together. Each edge has a weight value associated with it that typically measures some cost in traveling across that edge. In this case, the edge weights were determined by the curvature function as curvature values were minimalized in traveling across the mesh. Each execution of Dijkstra will output an array the size of the number of vertices in the graph with the total cost of the shortest distance from the source vertex to each vertex in the graph.
The first kernel (functions that execute on OpenCL devices) that is queued to OpenCL for each source vertex is simply responsible for initialization of buffers. This was done using a kernel rather than on the CPU to reduce the amount of data transferred between the CPU and GPU.
The algorithm itself is broken into two phases. This is necessary because synchronization isn't possible outside of local work-groups in OpenCL, and this would be required to execute the kernel algorithm in a single phase. The first phase of the algorithm visits all vertices that have been marked and determines the cost to each neighbor. If the current cost plus the new edge weight is less than what is currently stored in function, then that new cost is stored for the vertex. The second phase of the algorithm checks to see if a smaller cost has been found for each vertex and, if so, marks it as needing visitation and updates the costArray.
In order to leverage multiple compute devices, the workload needs to be partitioned. The approach taken in this implementation is to partition the number of searches across the available compute hardware. The application detects the number of GPU and CPU devices and splits the workload across the devices.
Each of the kernels is written to process one vertex at a time and it was implemented by workload portioning.
In the case CPU device is selected from the initial menu when execution starts, the OpenCL implementation will multithread the implementation across the available cores.

VI. EXPERIMENTAL RESULTS AND ANALYSIS

The experimental environments for analyzing the performance of algorithms in this article were as follows:

Configuration 1:
Processor: Intel(R) Core(TM) i5 CPUM460 @ 2.53GHz 2.53GHz
GPU: AMD Radeon HD 6500M/5600/5700 series

Configuration 2:
Processor: Intel(R) Pentium(R) Dual CPU T2390@ 1.86GHz 1.87GHz
GPU: Intel® GMA X3100

Configuration 3:
Processor: Intel Celeron Dual Core CPU T1500 @ 1.86GHz 1.86GHz
GPU: Intel GMA X3100

Configuration 4:
Processor: Intel(R) Core(TM)2 Duo CPU T5760 @ 1.80GHz
GPU: Mobile Intel(R) 965 Express Chipset Family

Execution speed was compared for those algorithms: sequential one, the parallel one, and the parallel one made for OpenCL.
They are all implemented and tasted on processors (dual core and i5). As it can be seen from the graphs on Figure 4., parallel version seems to perform better than the sequential one when the number of nodes becomes larger than 3000.

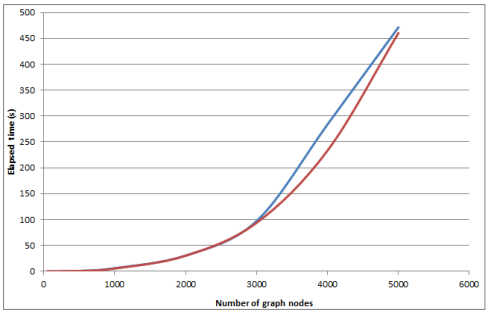
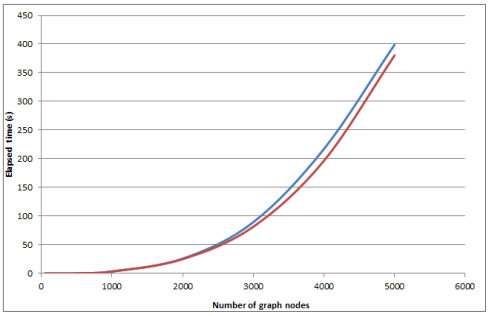
4.b



4.c

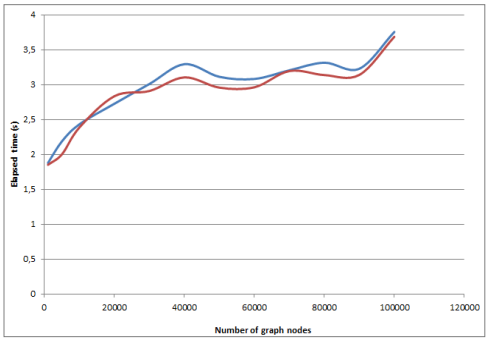


4.d

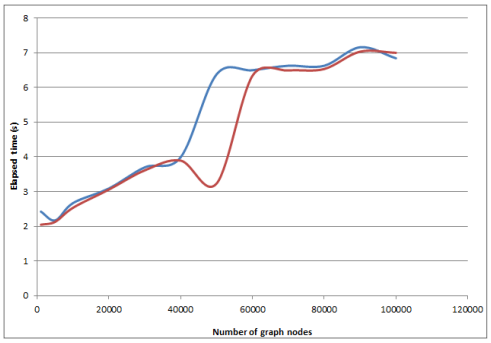
4.e

Figure 4. The comparison of execution time in algorithms (parallel and sequential) running on a different machines: 4.a: Configuration 1, 4.b: Configuration 2, 4.c: Configuration 3, 4.d: Confituration 4, 4.e: Legend

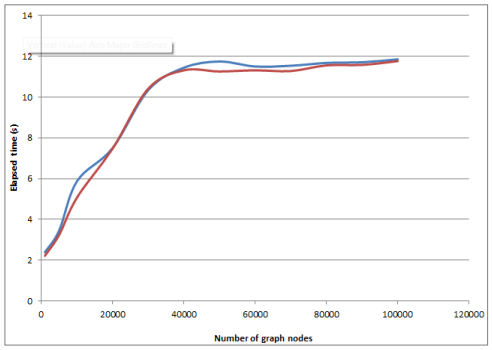
As can be seen from Figure 4, for weighted graphs, parallel algorithm has better performance than the sequential one, but these performance also depends on which machines was this tested, where the best performance were on i5 processor.



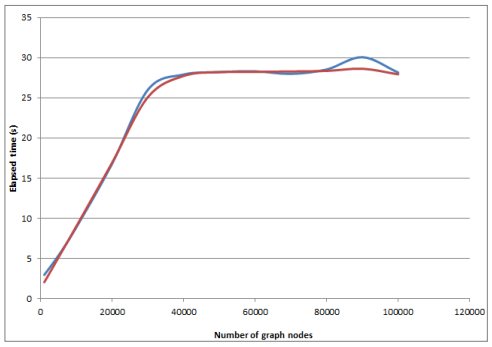
5.a



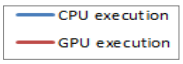
5.b



5.c



5.d



5.e

Figure 5. The comparison of execution time in algorithms (parallel one made for OpenCL and sequential one) on Configuration 1; 5.a: 5 edges per node, 5.b: 10 edges per node, 5.c: 20 edges per node, 5.d: 50 edges per node, 5.e: Legend

As can be seen from the collected performance data, the number of edges per node affect the performance. On figure 5. It can be seen that the performance on GPU are better than the one on CPU, but when the number of edges per node is bigger than 10, as shown on figure 7. and 8. the performances are almost the same. That means that for the different values of vertices the speed-up ratio of our parallel algorithm keep basically unchanged.

VII. CONCLUSION

Parallel programming is a very intricate, yet increasingly important task as we have entered the multicore era and more cores are made available to theprogrammer. Althou gh separate applications or independent tasks within a sin gle application can be easily mapped on multicore platfor ms, the sameis not true for applications that do not expos e parallelism in a straightforward way. Dijkstra's algorith m is a challenging example of such an algorithmthat is dif ficult to accelerate when executed in a multithreaded fash ion. It is very important to have in mind the two major iss ues inherent to Dijkstra'salgorithm: limited explicit parall elism and excessive synchronization. Dijkstra's algorithm does not readily lend itself to parallelization mainly beca use itrelies on priority queue. Because evaluating the vert ex at the head of the priority queue may change the order of elements remaining within the priorityqueue, it is not n ecessarily correct or efficient to evaluate more than the he ad of the priority queue on each iteration.

There are several possible reasons why the more advanced parallel execution of Dijkstra's algorithm wasn't as fast as expected. One of the reasons could be that the code used may be inefficient. Another possibility is that, for a small amount of nodes, more time could be spent on parallelization and synchronization then it is spent on execution of code as sequential.

There are several areas in which this article could be exte nded with further work. Overcoming issues such as utilizing shared memory, avoiding branches, choosing appropriate data structures and designing algorithms correctly are the key to success with parallelization of Dijkstra's algorithm.

Some problems appear to be inherently sequential, and are difficult, if not impossible, to implement in parallel. Unfortunately, one of these problems is Dijkstra's algorithm. This is actually the main problem for the implementation of its parallelization.
