mipro 2015

organizer upro

38th international convention

May 25-29, 2015, Opatija – Adriatic Coast, Croatia

Lampadem tradere

mipro - path to knowledge and innovation

mipro proceedings

My profession.
My organization.
My IEEE.

Discover the benefits of IEEE membership.

Join a community of more than 365,000 innovators in over 150 countries. IEEE is the world's largest technical society, providing members with access to the latest technical information and research, global networking and career opportunities, and exclusive discounts on education and insurance products.

MIPRO 2015

38th International Convention

May 25 - 29, 2015
Opatija, Croatia

Proceedings

Conferences:

Microelectronics, Electronics and Electronic Technology /MEET

Distributed Computing, Visualization and Biomedical Engineering /DC VIS

Telecommunications & Information /CTI

Computers in Education /CE

Computers in Technical Systems /CTS

Intelligent Systems /CIS

Information Systems Security /ISS

Business Intelligence Systems /miproBIS

Digital Economy and Government, Local Government, Public Services / DE-GLGPS

MIPRO Junior - Student Papers /SP

Edited by:
Petar Biljanović

CONTENTS

LIST OF PAPER REVIEWERS

LIST OF AUTORS

FOREWORD

MICROELECTRONICS, ELECTRONICS AND ELECTRONIC TECHNOLOGY

INVITED PAPER

State-of-the-Art Semi-Classical Monte Carlo Method for Carrier Transport in Nanoscale Transistors 5
P. Palestri, E. Caruso, F. Driussi, D. Esseni, D. Lizzit, P. Osgnach, S. Venica, L. Selmi

PAPERS

Preparation and Characterization of SERS Substrates: from Colloids to Solid Substrates 15
L. Mikac, M. Ivanda, M. Gotić, D. Ristić, V. Đerek, H. Gebavi, P.G. Gucciardi, S. Trusso, C. D'Andrea

The Conductivity and TEMF of MoS_2 with Mo_2S_3 Additive 18
G.E. Yakovleva, A.S. Berdinsky, A.I. Romanenko, S.P. Khabarov, V.E. Fedorov

Strain-Sensing Element Based on Layered Sulfide $Mo_{0.95}Re_{0.05}S_2$ 21
V.A. Kuznetsov, A.S. Berdinsky, A.Y. Ledneva, S.B. Artemkina, M.S. Tarasenko, V.E. Fedorov

Electrical Properties of Composite Silicon Thin Films 25
V. Tudić

Impact of Different Gate Insulator Materials on the Electron Mobility in Ultra-thin (100) InGaAs-on-insulator MOS Devices 31
S. Krivec, M. Poljak, T. Suligoj

Impact of the Emitter Length Scaling on Electrical Characteristics of Horizontal Current Bipolar Transistor with Single Polysilicon Region 37
M. Koričić, J. Žilak, T. Suligoj

Optimization of Floating Guard Ring Parameters in Separate-Absorption-and-Multiplication Silicon Avalanche Photodiode Structure 43
I. Janeković, T. Knežević, T. Suligoj, D. Grubišić

Low-Power Low-Voltage CMOS Analog Signal Processing Circuits Using a Functional Core 48
C. Popa

Multifunctional Circuit Using Improved Performances Linearization Technique 52
C. Popa

Design of a High-Voltage Differential Amplifier Based on Stacked Low-Voltage Standard CMOS with Different Input Stages 56
S. Pashmineh, D. Killat

Opamp Based Bandgap Voltage Reference in 130 nm: Design and Schematic Level Simulation 62
A. Pajkanović, V. Malbaša

Design of a Power Supply and Voltage References for a Wirelessly Powered ADC in 0.18-µm CMOS 68
N. Bako, Ž. Butković, A. Barić

RFID UHF Protocol Implementation in Distributed Sensor Networks 74
I. Broz, N. Bako, Ž. Butković, A. Barić

Temperature Dependence of Injection-Locked Fabry-Pérot Laser Emission in WDM-PON Architectures 80
M. Šprem, D. Babic, M. Bosiljevac, Z. Šipuš

Fiber-Optic Vibration Sensor for High-Power Electric Machines 85
B. Igrec, M. Bosiljevac, S. Rudan, Z. Šipuš, D. Babić

Comparison of Electrical and Electromagnetic Properties of a Planar Inductor 89
J. Kundrata, A. Barić

Effects Influencing Repeatability of Direct Power Injection Measurements 93
F. Fajdetic, M. Mikic, T. Mandić, A. Barić

SPICE Analysis of RL and RC Snubber Circuits for Synchronous Buck DC-DC Converters 97
R. Blečić, R. Gillon, B. Nauwelaers, A. Barić

Dual-channel Programmable Precise Time-delay Pulse Signal Generator for Synchronous DC-DC Converter Applications 104
F. Hormot, J. Bačmaga, A. Barić

Effect of Dead Time and Semiconductor Device Voltage Drops of Output Voltage of Multilevel Converters 109
I. Mrčela, V. Šunde, M. Kovačić

Model of Three Level Neutral Point Clamped Converter (NPC) for Grid Connected Photovoltaic Systems 116
M. Novak, V. Šunde, Ž. Jakopović

Fast Development of a DSP-Based Control of Three-Phase Four-Leg Inverter for Auxiliary Power Supply Converters Using Hardware-in-the-Loop 121
I. Musulin, J. Babić, Ž. Jakopović

Noise Improvement Using SC Filters 127
I. Volarić, N. Stojković, S. Vlahinić

Phase Demodulation of Magnetic GMR Signal for Virtual Sensing Applications by using Hilbert Transform 133
M. Adnan, D. Hammerschmidt, M. Huemer

Thin-film CIGS Solar Modules for Design Driven Applications in the Frame of the FP7 NMP Project SolarDesign 137
W. Brenner, N. Adamović

Measurement System for Object Detection Based on Multielectrode Capacitive Sensor 143
D. Ćika, T. Martinović, H. Džapo

IBMS - Intelligent Building Management System Framework 149
S. Tepić, P. Pejić, J. Domšić, H. Mihaldinec, H. Džapo

A Hybrid Local Method for Stereo Correspondence Based on Three-Dimensional Recursive Search 155
M. Rožić, M. Đonlić, T. Pribanić

Two Approaches to Derive Approximate Formulae of NILT Method with Generalization 161
L. Brančík, N. Smith

Laboratory Exercise for Class B/AB Power Amplifier 167
Ž. Stojanović, S. Stojanović, I. Činikas

Integration of High-Level Synthesis to the Courses on Reconfigurable Digital Systems 172
I. Skliarova, V. Sklyarov, A. Sudnitson, M. Kruus

DISTRIBUTED COMPUTING, VISUALIZATION AND BIOMEDICAL ENGINEERING

PAPERS

DISTRIBUTED COMPUTING

Cloudflow – A Framework for MapReduce Pipeline Development in Biomedical Research 185
L. Forer, E. Afgan, H. Weißensteiner, D. Davidović, G. Specht, F. Kronenberg, S. Schönherr

Science Gateway for Distributed Multiscale Course Management in e-Science and e-Learning - Use Case for Study and Investigation of Functionalized Nanomaterials ... 191
Y. Gordienko, S. Stirenko, O. Gatsenko, L. Bekenov

Evaluation of POS Scheduling Algorithm for Distributed Computing Environment . 197
A. Shamakina, L. Sokolinsky

Performance evaluation on a Grid platform 201
A.A. Banka, M.A. Dedmari, M.T. Masoodi

Synergy of Volunteer Measurements and Volunteer Computing for Effective Data Collecting, Processing, Simulating and Analyzing on a Worldwide Scale..... 206
N. Gordienko, O. Lodygensky, G. Fedak, Y. Gordienko

Sucssessfull Implementation of L3B: Low Level Load Balancer 212
K. Cvetkov, S. Ristov, M. Gusev

Scalable and Parallel Machine Learning Algorithms for Statistical Data Mining - Practice & Experience..... 217
M. Riedel, M. Goetz, M. Richerzhagen, P. Glock, C. Bodenstein, A.S. Memon, M.S. Memon

Decomposition of Natural Join Based on Domain-Interval Fragmented Column Indices..... 223
E. Ivanova, L. Sokolinsky

Theoretical and Statistical Evaluation for Approximate Solution of Large, Over Determined, Dense Linear Systems 227
Ž. Jeričević, I. Kožar

DARIAH Meta Hosting: Sharing software in a distributed infrastructure 230
J. Rybicki, B. von St. Vieth

Building and Provisioning Bioinformatics Environments on Public and Private Clouds..... 236
E. Afgan, K. Krampis, N. Goonasekera, K. Skala, J. Taylor

Gathering Useful Programming Data: Analysis and Insights from Real-time Collaborative Editing **242**
M. Rantala, J. Soini, T. Kilamo

Microservices Validation: Mjolnirr Platform Case Study **248**
D.I. Savchenko, G.I. Radchenko, O. Taipale

Four Level Provenance Support to Achieve Portable Reproducibility of Scientific Workflows **254**
A. Bánáti, P. Kacsuk, M. Kozlovszky

Using the P-TOSCA Model for Energy Efficient Cloud **258**
B. Ivanovska, S. Ristov, M. Kostoska, M. Gusev

Achieving Dynamic Workflow Management System by Applying Provenance Based Checkpointing Method **263**
E. Kail, P. Kacsuk, M. Kozlovszky

Operating System Impact on CPU and RAM Utilisation when Introducing XML Security **267**
S. Ristov, M. Gusev

Evaluating the Impact of the Number of Processor Cores, Cache Memory and Threads During the Parallel Execution of Programs **272**
F. Dika, V. Xhafa

Performance Analysis of a New Cloud e-Business Solution **276**
K. Kolić, M. Gusev, S. Ristov

Interoperable Job Execution and Data Access through UNICORE and the Global Federated File System **282**
S. Memon, M. Riedel, C. Koeritz, A. Grimshaw

Multi-stream 2D Frequency Table Computation on Dataflow Architecture **288**
P. Škoda, V. Sruk, B. Medved Rogina

Porting an N-tier Application on Cloud using P-TOSCA: A Case Study **294**
M. Kostoska, A. Donevski, M. Gusev, S. Ristov

Cloud Portability Standardisation Overview **299**
E. Markoska, I. Chorbev, S. Ristov, M. Gusev

In-Situ Anonymization of Big Data **305**
T. Križan, M. Brakus, D. Vukelić

VISUALIZATION SYSTEMS

A GPU-based Simultaneous Real-Time EEG Processing and Visualization System for Brain Imaging Applications **315**
Z. Juhasz, G. Kozmann

Web Portals for Visualizing and Searching Spatial Data..... 321
L. Bećirspahić, A. Karabegović

Prototyping of Visualization Styles of 3D Scalar Fields Using POV-Ray Rendering Engine..... 328
J. Opiła

Freeform Spatial Modelling Using Depth-sensing Camera..... 334
M. Volarević, P. Mrazović, Ž. Mihajlović

Seismic Data Visualisation..... 340
M. Ivančić, Ž. Mihajlović, I. Ivančić

Situation and Location Awareness in Harsh Environment..... 344
M. Kozlovszky, D. Zavec Pavlinić, A. Oder, G. Fehér, P. Bogdanov

Error Correcting Codes and Their Usage in Steganography and Watermarking..... 349
H. Kostadinov, N.L. Manev

Model for Calculation of Post Service Efficiency by Using GIS..... 353
M. Kranjac, U. Sikimić, M. Vujaković

Generalization of Hypersphere Function..... 359
D. Letić, I. Berković

Visualization and Multimedia Presentation of Cultural Heritage..... 364
S. Rizvić, V. Okanović, A. Sadžak

Using Entropy Information Measures for Edge detection in Digital Images 368
D. Sušanj, V. Tuhtan, L. Lenac, G. Gulan, I. Kožar, Ž. Jeričević

BIOMEDICAL ENGINEERING

Wireless Electrocardiographic Monitoring in Veterinary Medicine..... 375
M. Brložnik, V. Avbelj

Software for Acid-Base Status Disorders Management 379
M. Mandžuka, E. Begić, Z. Begić, D. Bošković

Impact of Electrode Misplacement on the Accuracy of 12-lead ECG Synthesized from Differential Leads..... 384
I. Tomašić, R. Trobec, A. Rashkovska, M. Lindén

Extranodal Pacemaker Activity During Sleep - a Case Study of Wireless ECG Sensor Data..... 389
V. Avbelj

A New Color Assessment Methodology using Cluster-based Features for Skin Lesion Analysis 392
M.J.M. Vasconcelos, L. Rosado, M. Ferreira

Automatic Adaptation of Filter Sequences for Cell Counting 398
U. Čibej, J. Lojk, M. Pavlin, L. Šajn

Assessing Blood Pressure Unobrtusively by Smart Chair 404
D. Zazula, J. Kranjec, P. Kranjec, B. Cigale

Towards Noninvasive Bioimpedance Sensor Design Based on Wide Bandwidth Ring Resonator 409
M. Pavlin, F. Novak

Exploring Bacterial Biofilms with NAMD, a Highly Scalable Parallel Code for Complex Molecular Simulations 412
D. Tomić

Information System of the Institute for Blood Transfusion of Montenegro 417
A. Balota

TELECOMMUNICATIONS & INFORMATION

PAPERS

TELECOM MARKET AND REGULATIONS

Effective Strategies for Implementation of Customer Experience Management in MSPs in Bosnia and Herzegovina 429
N. Banović-Ćurguz , D. Ilišević

Regulatory Aspects of Child Online Protection 435
S. Hadžović, D. Šerval, S. Kovačević

Architecture and Functionality in M2M Standards 439
M. Ptiček, V. Čačković, M. Pavelić, M. Kušek, G. Ježić

Metodologija procjene kapaciteta RF spektra za potrebe implementacije mobilnih servisa u periodu do 2020. godine sa primjenom u BiH 445
A. Džebo, A. Krivošić

Uloga kvalitetnog dizajna poslovnih procesa u složenom okruženju telekomunikacijskog tržišta 450
D. Markulin, K. Musa

SERVICES

Semantic Approach to Accommodation & Booking Related Web Services 459
I. Pavković, I. Štajduhar

Voice over Wi-Fi **465**
D. Bilajbegović

An Example of Real Time QoE IPTV Service Estimator **468**
N. Goran, M. Hadžialić

Primjena mobilnih komunikacijskih tehnologija sa svrhom unapređenja usluga javnog prijevoza **472**
M. Dujak, Z. Civadelić, K. Vidović, P. Miletić

SIMULATIONS AND MEASUREMENTS

Computer Modeling and Simulation of Teletraffic Models for 5G Networks **479**
E.P. Ivanova, T. Iliev, G. Mihaylov, I. Stoyanov, F. Tsvetanov, E. Otsetova, D. Radev

Simulation of a Quasigroup Error-Detecting Linear Code **483**
N. Ilievska, D. Gligoroski

An Integrated Remotely Controlled Oceanographic Measuring Station **489**
H. Kalinić, D. Jelavić, D. Ivanković, J. Bašić, S. Muslim, S. Marasović, V. Dadić

Role of Performance Measurements in Process of Migration to IP Mobile Backhaul in 3G Networks **494**
D. Ilišević, N. Banović-Ćurguz

Comparative Analysis of GSM Coverage Prediction with Measurement Results for Urban Areas Using Statistical Nonparametric Mapping **499**
H. Lučkin, E. Lučkin, M. Škrbić

SOFTWARE ENGINEERING & DATA MANAGEMENT

Software Defined Networking Demands on Software Technologies **507**
T. Galinac Grbac, C.M. Caba, J. Soler

Data Collection for Software Defect Prediction – an Exploratory Case Study of Open Source Software Projects **513**
G. Mauša, T. Galinac Grbac, B. Dalbelo Bašić

Trendovi u izgradnji podatkovnih centara u Hrvatskoj **520**
M. Galac, D. Valenčić

Data Storage and Analysis System for Conducting Biotechnological Experiments **528**
D. Spahić, G. Mauša, S. Kraljević Pavelić, T. Galinac Grbac

CLOUD SYSTEMS

Automatizacija postavki mreže u *Cloud* sustavima preko samouslužnih portal..... 537
M. Maras, T. Kosanović

Data Storage and Synchronization in Private Cloud 541
D. Hodanić, N. Vrkić, M. Tomić

Testing in the Private Cloud 546
T. Pavić, I. Vrbovčan, M. Šoša Anić

NETWORKS & NETWORKS PERFORMANCE

The Methodology for the Optimal Choice of Access Technologies 553
Ž. Božinović, N. Hadžiahmetović

An Open Source TCP/UDP-Based Network Probing Tool for Real-Time Packet Loss Estimation 559
A.F. Khalifeh, A. Abbad, K.A. Darabkeh

Improvements in Failure Detection for Emergency Service Centers in IMS Network 564
I. Krevatin, Ž. Presečki, M. Gudelj

BER Analysis in Relay-Based DF Cooperative Diversity Systems with Relay & Destination Interferers 569
A.M. Magableh, M.F. Al-Mistarihi, R. Mohaisen, A.H. Sharaqa

Outage Probability Analysis in Relay-Based DF Cooperative Diversity Systems with Relay & Destination Interferers 574
R. Mohaisen, M.F. Al-Mistarihi, A.M. Magableh, A.H. Sharaqa

Closed Form Expression of Outage Probability in DCSK Cooperative Communication Systems over Nakagami-m Fading Channels 580
M.F. Al-Mistarihi, A.M. Magableh, M.M. Al-Khasawneh

Outage Probability of Dual-Hop Amplify-and-Forward Cognitive Relay Networks under Interference Power Constraints over Nakagami-m Fading Channels 584
M. Shurman, M.F. Al-Mistarihi, M. Alhulayil

Outage Probability of Amplify-and-Forward Underlay Cognitive Relay Networks with Selection Diversity over Nakagami-m Fading Channels 589
M. Alhulayil, M.F. Al-Mistarihi, M. Shurman

ENVIRONMENTAL PROTECTION

Simulation of Energy Efficient Telecommunication Network 597
G. Dimić, J. Seljan, D. Šimunić

Environmental Sustainability of Information and Communication Technologies for Advanced Metering and Home Area Networks 601
V. Mujan, S. Aleksić

Aspects of Remote Monitoring and Recording System of Non-ionizing Electromagnetic Radiation 607
D.S. Šuka, M.I. Simić, P.V. Pejović

Energetic Self-Regulation of eWALL System 612
Ž. Martinović, D. Budić, D. Šimunić

Investigation of Electromagnetic Compatibility of High Frequency Polymer-Welding Machines 617
L. Iliev, I. Stoyanov, T. Iliev, E.P. Ivanova

Energy Consumption Analysis of Real Metro-optical Network 621
J. Lorincz, E. Mujarić, D. Begušić

Doprinos informacijsko-komunikacijskih tehnologija smanjenju emisija CO_2 627
M. Berković, A. Kosovac

TELECOM INFRASTRUCTURE

A Low Energy Computer Infrastructure for Radio VOIP Supported Communication and SDR APRS in Education and Disaster Relief Situations 637
K. Hajdarević, S. Konjicija

Evaluation of Software Defined Radio Systems for Smart Home Environments 643
I. Vitas, D. Šimunić, P. Knežević

Smartwatch as a Remote Server Monitoring Device: Implementation and Interaction Design 647
A. Vega, S. Ljubić

Improving City Infrastructure Resilience Capacity: Water-supply Network Case Study 653
O. Jukić, I. Heđi, I. Špeh

Elektronička komunikacijska infrastruktura u zgradama 658
J. Bajt

ALGORITHMS & PROTOCOLS

Integrating Extreme Programming with Software Engineering Education 667
J.J.Y. Chen, M.M.Z. Wu

Sensors Definitions and Positioning for Load Balancing Algorithms 673
B. Radojević, M. Žagar, I. Golub

Design of the BCJR Decoding Algorithm with Reduced Space Complexity 678
D. Spasov

Towards a Self-organizing Sensor Network: An Algorithm 682
J. Seljan, D. Šimunić, G. Dimić, B. Vrandečić

Static Cluster and Dynamic Cluster Head (SCDCH) Adaptive Prediction-Based Algorithm for Target Tracking in Wireless Sensor Networks 686
M.A. Wahdan, M.F. Al-Mistarihi, M. Shurman

New Efficient On-Demand Multicast Routing Protocol over Mobile Ad hoc Networks 691
K.A. Darabkeh, O.A. Alsukour

Implementation of a HMIPv6 Extension in the INET and xMIPv6 Simulation Framework with Dynamic MAP Discovery for OMNeT 4.x 695
E. Kadušić, M. Škrbić, N. Živić, A. Žgalj, A. Hantalašević

NEW METHODS & SOLUTIONS

Matrix Inversion in the Design of Active Queue Management Mechanisms 703
P. Mrozowski, A. Chydzinski

An Overview of Various Types of Waveguide Grating Based Demultiplexors in WDM Systems 709
J. Tóth, Ľ. Ovseník, J. Turán

A Powerful Early-based Video Discarding Policy 714
K.A. Darabkeh, A.M. Awad, A.F. Khalifeh

Mobile Node Localization Using Infrared Angle of Arrival Sensor 719
D. Frantal, D. Arbula

A Profile- and Community-Driven Book Recommender System 724
I. Petrović, P. Perković, I. Štajduhar

Extending LARIS with Session Types: A Case Study in the Railway Interlocking ... 729
T. Kiss, F. Craciun, B. Parv

Monitoring Cerebral Processing of Gustatory Stimulation and Perception Using Emotiv Epoc 736
G. Madhale Jadav, M. Vrankić, S. Vlahinić

People Tracking Using Synthetically Generated Depth Maps 739
L. Vretenar, K. Lenac

Virtualizacija mrežnih funkcija u telekomunikacijama 745
O. Lovaković

COMPUTERS IN EDUCATION

PAPERS

The Relations Between Cultural Dimensions and Quality of Communication in Education 753
B. Grobenski, V. Vidaček-Hainš

Collaboration, Distribution and Culture – Challenges for Communication 758
H. Jaakkola, J. Henno, B. Thalheim, J. Mäkelä

Project- and Product-Oriented Course 766
J. Henno, H. Jaakkola, J. Mäkelä

Personalization of e-tivities using Web 2.0 tools and ELARS (E-learning Activities Recommender System) 770
J. Mezak, N. Hoić-Božić, M. Holenko Dlab

Model of Information System for Recognition of Non-Formal and Informal Learning in Higher Education 775
M. Balković, G. Đambić, Z. Jančić

Computer Game Angry Birds in Teaching Physics 781
D. Robič, R. Repnik

Towards Blended Learning: A Case Study 786
P. Linna, H. Keto, T. Mäkinen

The use of HILL Online e-learning Environment in Language Teaching 791
M. Linna, A. Valo

Information Literacy Assessment at the University of Zagreb: an Undergraduate Students' Perspective 796
M. Pavlovski, I. Dunđer

Tiny Operating System Kernel for Education Purposes 801
S. Ribić, A. Salihbegović

Usage of Compulsory Content in Secondary School Education 807
R. Barišić

Online Learning Efficiency in the Humanities 811
S. Gartner, M. Krašna

Designing m-learning Materials for Language Learning 816
D. Pukšič, M. Krašna

Comparison of ICT in Education Between Slovenia and Serbia 822
M. Popović, D. Cvetković, M. Krašna

The Application of Formative E-Assessment Data in the Final Exam Results Modeling Using Neural Networks 827
J. Gamulin, O. Gamulin, D. Kermek

Knowledge Generating House – a Tool for Education Based on Open Innovation Principle 832
I. Korobaničová, D. Paľová, N. Urbančíková

FASTER Platform – an On-Line Tool for EU Accountants Education 838
D. Paľová, M. Vejačka

User Knowledge Development in the Field of Electronic Services and Their Security in Slovakia 844
M. Vejačka, J. Bucko

A Course in Digital System Design using Unified E2LP Platform 850
I. Kaštelan, N. Pjevalica, M. Temerinac

Improving education experience with Augmented Reality (AR) 856
B. Kraut, J. Jeknić

Introduction of the Automated Assessment of Homework Assignments in a University-level Programming Course 862
M. Poženel, L. Fürst, V. Mahnič

Informatics Education and Requirements of Current Practice 868
L. Révészová

Integrating Learning Management System and Faculty Information System –Service Oriented Approach 874
P. Bjeljac, I. Zečević, B. Perišić

Evaluating the Effect of the Automatic Assessment Introduction in the ADS1 Course Practical Work 879
I. Rožanc, J. Mihelič

Conceptual Design, Development and Analyses of "E-Learn SEEU" Model and Framework 885
B. Fetaji, M. Fetaji, O. Rakipi, M. Ebibi

Hands-on System Programming Labs & Projects Based on E2LP Platform 891
B. Kordić, V. Marinković, M. Popović, I. Kaštelan

Wiki-based Books as Alternatives to Printed University Publications 895
M. Sakal, P. Tumbas, P. Matković, V. Pavličević

Analysis of Learning by Doing in the Creation of Instructional Video in Teaching Optics 901

FOREWORD

The *38th International ICT Convention MIPRO 2015* was held from 25th until 29th of May 2015 in Opatija, the Adriatic Coast, Croatia. The Convention consisted of nine conferences under the titles: *Microelectronics, Electronics and Electronic Technology (MEET), Distributed Computing, Visualization and Biomedical Engineering (DC VIS), Telecommunications & Information (CTI), Computers in Education (CE), Computers in Technical Systems (CTS), Intelligent Systems (CIS), Information Systems Security (ISS), Business Intelligence Systems (miproBIS), Digital Economy and Government, Local Government, Public Services (DE/GLGPS)*. A special conference was dedicated to works of the students: *MIPRO Junior-Student Papers (SP)*.

The papers presented on these conferences are contained in this comprehensive Book of Proceedings. All the papers were reviewed by an international review board. The list of reviewers is contained in the Book of Proceedings. All the positively reviewed papers are included in the Book of Proceedings. These papers were written by authors from the industry, scientific institutions, educational institutions, state and local administration.

The convention was organized by the Croatian ICT Society MIPRO with the help of numerous patrons and sponsors to whom we owe our sincere thanks. We specially single out our gold sponsors Ericsson Nikola Tesla, T-Croatian Telecom and Končar-Electrical Industries and silver sponsors HEP–Croatian Electricity Company and InfoDom. Our bronze sponsors are Hewlett Packard, IN2, Transmitters and Communications and Storm Computers.

To all who helped organize the 38th International ICT Convention *MIPRO 2015* as well as editing of this Book of Proceedings we extend our heartfelt thanks.

INVITED PAPER

State-of-the-art semi-classical Monte Carlo method for carrier transport in nanoscale transistors

palestri@uniud.it

Abstract - We review the Monte Carlo method to model semi-classical carrier transport in advanced semiconductor devices. We report examples of the use of the Multi-Subband Monte Carlo method to simulate MOSFETs with III-V compound semiconductor channel. Monte Carlo transport modeling of graphene-based transistors is also addressed.

I. INTRODUCTION

The models implemented in commercial TCAD tools for semiconductor devices are derived from the Boltzmann Transport Equation (BTE) under assumptions that make them inaccurate when applied to nanoscale devices (L_G<100 nm), or to the study of hot carriers.

Exact numerical solutions of the BTE via the Monte Carlo (MC) method have been used since the 60s and the 70s to analyze uniform transport in semiconductors [1]. Monte Carlo simulators describe the carrier motion as a sequence of "free-flights" (i.e. collision-less motion according to Newton's law) interrupted by scattering events, which abruptly change the particle's momentum. The simulation is statistical in the sense that the duration of the free-flight, the selection of the scattering mechanism and of the state-after-scattering are randomly chosen according to the respective probability density functions.

During the 80s, MC models have become increasingly complex by including full-band descriptions of the E(**k**) relation and achieving the capability to describe realistic 2D devices [2],[3]. During the 90s, full-band MC simulators evolved by including comprehensive sets of scattering mechanisms and by improving the numerical efficiency. Mutual agreement between MC simulators developed by different groups was consolidated [4] and a wide range of successful applications to the study of I-V, RF and reliability properties of scaled MOSFETs [5][6], BJTs [7] and non-volatile-memories [8] was reported.

Quantization effects have become more and more relevant in scaled MOSFETs, and quantum corrections have been proposed for semi-classical MC simulators starting from the year 2000 [9]-[12]. These corrections describe the electrostatic effects due to the displacement of the inversion charge from the channel/dielectric interface, and sometimes also for the valley splitting [13]. However, other important aspects related to the quantized nature of the carrier gas (e.g. scattering rates modulated by size- and bias-induced quantization, strong degeneracy of the carrier gas) are not captured by these corrections. These limitations led to the development of the Multi-Subband Monte Carlo (MSMC) approach.

This paper reviews the main features of the MSMC method and reports sample applications to the study of MOSFETs with III-V channel materials and comparison with full-quantum transport simulations. The use of the MC method to study graphene-based devices is reported too. We thus demonstrate that the MSMC method is a very powerful and useful technique to assess the potential of new, technology-boosted, MOSFET architectures.

II. THE MULTI-SUBBAND MONTE CARLO APPROACH

The MSMC methodology has been initially proposed in [14]. Since then, MSMC simulators have been developed by various groups [15]-[20]. A typical simulation flowchart is reported in Figure 1.

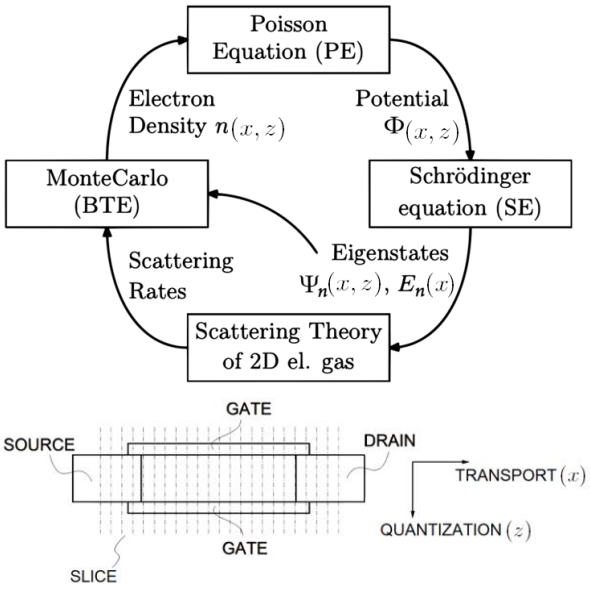

Figure 1 Top: Flowchart of a MSMC simulator; Bottom: sketch of a double-gate MOSFET with indication of the slices normal to the transport direction where the 1D quantization problem is solved.

The simulation proceeds as follows [21]. Starting from an initial guess of the 2D potential profile, the device is divided in sections along the channel (x) direction. In each section, the 1D Schrödinger equation (SE) is solved for all relevant valleys. The discrete energies levels in each section are used to build subband profiles along the

channel; the derivative of the subband energy along *x* provides the driving force to move particles in the MC simulation module. The solution of the SE also provides the wave-functions that are used to compute the scattering matrix elements for intra- and inter-subband transitions and, at a later stage, the charge distribution in the direction normal to transport.

Scattering rates and subband profiles feed the MC transport module that solves the multi-subband BTE [21]; the particle state contains only the position along the channel and the 2D wave-vector in the transport plane (normal to quantization). In other words, the MC module computes, for each subband and at each position, the occupation probability of the k-states in the transport plane. During the MC step, scattering events are rejected based on the availability of the final state [22], in order to enforce Pauli's principle that is of paramount importance to obtain accurate Fermi-Dirac occupation in highly doped regions at equilibrium and to account for the strong degeneration of the inversion channel. At the end of the MC step, the electron concentration profile is available. Then, the solution of the 2D Poisson equation provides a new estimate of the potential. The procedure is iterated until convergence is reached, i.e. until the drain current update among iterations is less than a few %.

In this paper, we show results using the MSMC tool developed at the University of Udine over the last 10 years. The simulator has been initially developed for silicon MOSFETs (bulk or SOI) [20]. Local phonon, Coulomb and surface roughness scatterings are commonly regarded as the dominant collision mechanisms in these devices. Only Δ valleys are relevant, and their weak non-parabolicity can be accounted for in the calculation as a correction of the in-plane dispersion relation, resorting to the conventional Effective Mass Approximation (EMA) when solving the 1D Schrödinger equation. Screening of the scattering events has been implemented following either the scalar or the matrix dielectric function approach [23]. Extension of the model to sSi [24] and Ge [25] required a more flexible treatment of multiple sets of valleys (CB minima) with arbitrary energy shift and inter-valley phonons. Alloy scattering was then added to enable the simulation of SiGe channels [26]. Furthermore, specific scattering models were added to simulate MOSFETs with high-k dielectrics [27]; in particular, remote polar phonon scattering (i.e. the scattering potential induced in the channel by the polar phonons in the dielectric) and remote Coulomb scattering (scattering induced by fixed charges in the gate stack). Models for metallic source and drain were also developed as described in [28]. Among possibly relevant but still missing scattering mechanisms, it is worth to mention that so far we do not include long-range Coulomb interactions [29][30] whose effect on the current of short MOSFETs is still debated [31].

The multi-valley energy relation and the wide variety of scattering mechanisms allow extending the use of the MSMC model to III-V MOSFETs. Due to the highly defective interfaces of III-V semiconductors, a model for interface states has been recently implemented [32]. Generation of e-h pairs by band-to-band tunneling have been added to enable the simulation of tunnel-FETs [33].

A MSMC for pMOSFETs has been developed too [34][35].

The rich portfolio of physical effects and scattering mechanisms increases the computational burden. In spite of this, competitive execution times and remarkably good numerical efficiency was achieved thanks to optimization and parallelization of the code [36].

III. Applications of MSMC transport modelling to III-V channel MOSFETs

As mentioned in the previous section, the MSMC method was initially developed for group IV semiconductors. Its extension to III-V compounds required additional models for polar phonon scattering [21] and interface states [32] and a quantization model taking into account the strong non-parabolicity of the Γ valley [37] and the layered structure of the channel.

The non-parabolic quantization model of ref. [37] not only corrects the subband energies, but also modifies the in-plane E(**k**) relation. As a result (see Figure 2), when the well thickness decreases, the effective mass (i.e. the inverse curvature of the E(**k**) relation) of the lowest subband increases. This result is consistent with the accurate quantization models based on DFT, tight-binding or k·p calculations [38].

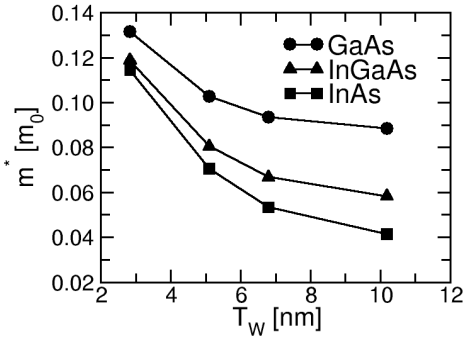

Figure 2: Effective mass (calculated from the inverse curvature of the in-plane E(**k**) of the lowest subband) vs. well thickness for different III-V compounds. The model of Ref.[37] has been used to account for the non-parabolicity of the Γ valley.

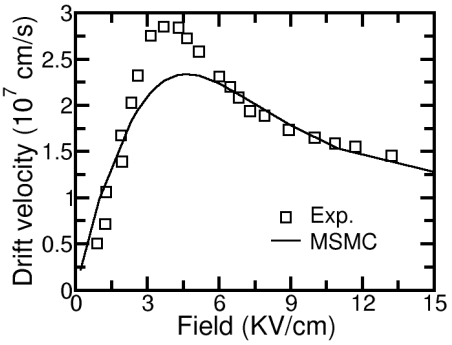

Figure 3: Comparison between simulated and measured [39] velocity-field curves in bulk $In_{0.53}Ga_{0.47}As$.

One of the advantages of the MC method is that it handles equally well long and short channel devices. The former are important for calibration purposes. As an example, Figure 3 compares the simulated and experimental velocity-field curves for bulk $In_{0.53}Ga_{0.47}As$

(the bulk structure is simulated in the MSMC as a thick well considering a large number of subbands), whereas Figure 4 compares MSMC results and measured mobility in $In_{0.53}Ga_{0.47}As$ inversion layers. The results in Figure 3 validate the bulk band structure and the phonon and alloy scattering models, whereas Figure 4 was used to calibrate the parameters of the surface roughness model. We employ here the "standard" linear model for surface roughness [43]. A more rigorous non-linear model has been developed [44][45] and is being implemented in the MSMC.

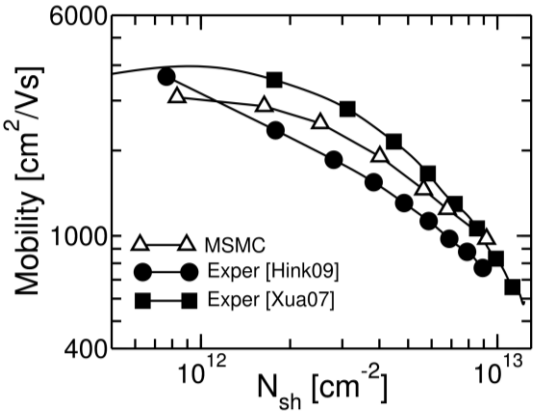

Figure 4: Comparison between simulated and measured [40][41] low-field mobility in bulk $In_{0.53}Ga_{0.47}As$ MOSFETs.

After calibration on long channel devices, the MSMC has been used to simulate the current drive of short channel III-V nMOSFETs [46],[42]. An example of transfer characteristics is reported in Figure 5 for a device with L_G=14nm, designed according to the ITRS roadmap for HP devices. These calculations account for all the relevant scattering mechanisms, namely: local and remote polar phonons, surface roughness, alloy scattering, intra- and inter-valley non-polar acoustic and optical phonons. Interface states have not been considered in these simulations. The on-current of the $In_{0.53}Ga_{0.47}As$ device is larger than in silicon but comparable to the one of highly strained (2GPa) silicon. The subthreshold swing is also improved in $In_{0.53}Ga_{0.47}As$ as discussed in details in [46].

The analysis of the internal variables in Figure 6 helps us understand the differences between $In_{0.53}Ga_{0.47}As$ and sSi channel. The profile of the first subband energy along the channel (right axis) shows that, due to the low density-of-states, the electron gas in the source and drain regions is strongly degenerate in $In_{0.53}Ga_{0.47}As$. The screening length of a highly degenerate electron gas is much longer than in a weakly degenerate one (as is the case of sSi, where the subband energy in the source and drain is close to the Fermi levels). As a result, the potential induced by the gate bias penetrates much deeper inside the source and drain in the $In_{0.53}Ga_{0.47}As$ device than in the sSi one. The "effective length" of the $In_{0.53}Ga_{0.47}As$ device is thus larger than in the sSi one [46] and this explains the better SS.

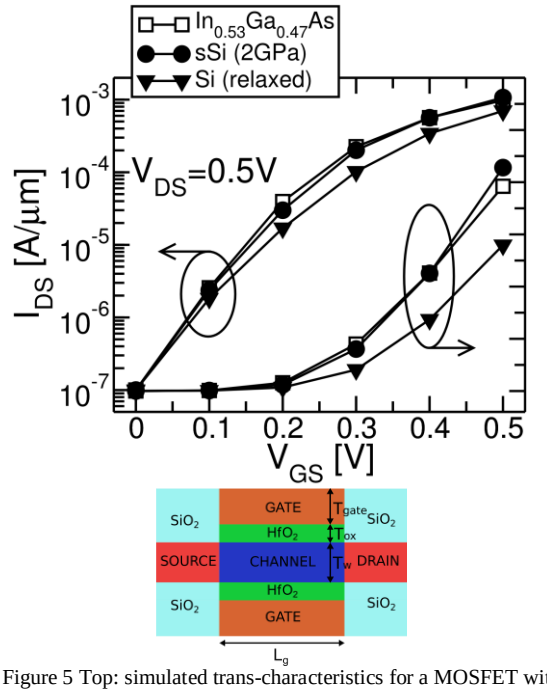

Figure 5 Top: simulated trans-characteristics for a MOSFET with L_G=14nm considering different channel materials. T_{OX}=4nm. The volumetric gate thickness is T_{GATE}=4nm. TW=5nm. The device is sketched in the lower panel. The source and drain junctions are abrupt and perfectly aligned to the gate edge.

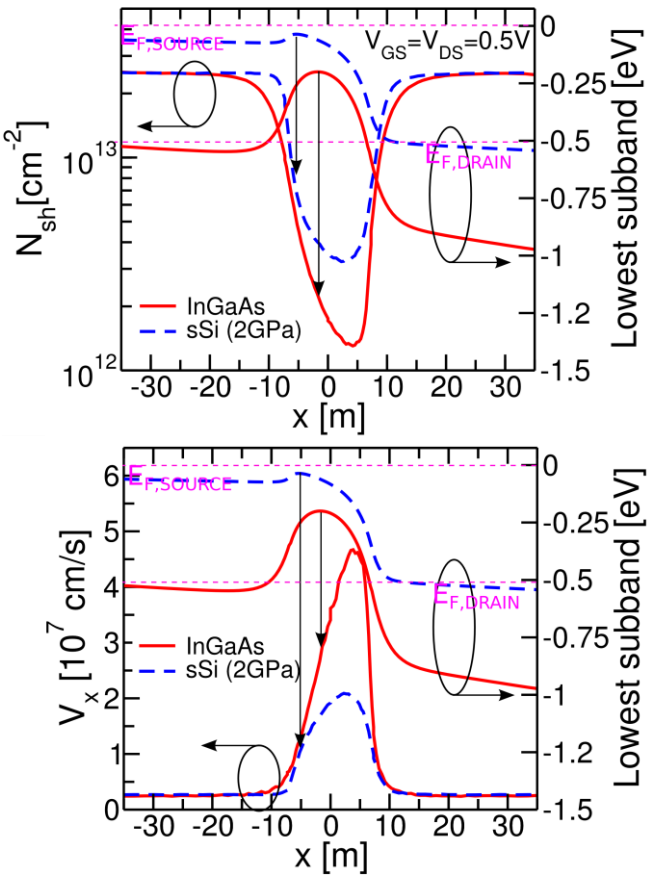

Figure 6: Internal quantities (subband profile, inversion density and average velocity) for the device of Figure 5 considering sSi and InGaAs channels. The energy reference (E=0) is the Fermi level in the source contact.

The inversion density profile ($N_{sh}(x)$, Figure 6, top graph) is, as expected, lower in $In_{0.53}Ga_{0.47}As$ than in sSi, due to the lower density of states. Conversely, the average velocity profiles along the channel (bottom graph) show that V_x is larger in $In_{0.53}Ga_{0.47}As$ than in sSi due to the lower effective mass in the transport direction. In particular, the velocity at the injection point (maximum of the potential barrier, indicated by the vertical arrows in Figure 6) is larger by a factor of about three, and this compensates the lower inversion charge, so that the current is almost the same in the two devices. The digital switching time can be estimated from the static simulations [46] and it is 0.327ps for the $In_{0.53}Ga_{0.47}As$ device vs. 0.362ps for the sSi one. This means that the charge modulation in the S/D regions due to the low DoS almost compensates the larger injection velocity of $In_{0.53}Ga_{0.47}As$.

IV. SEMI-CLASSICAL MC VS. FULL-QUANTUM MODELS

The MSMC describes quantization normal to the transport direction in a rigorous way. On the other hand, transport from source to drain is semi-classical, i.e. electrons are treated as point particles obeying Newton's law. This means that phenomena such as source-to-drain tunneling, that is relevant in the sub-threshold region of short channel devices are not accounted for. To overcome this limitation, following the effective potential approach already used for quantum corrections in semi-classical MC [9], we have proposed the subband smoothing procedure sketched in Figure 7 [47]: convolution between the subband profile and a Gaussian (envelope) function mimics the distributed nature of the electron wave-packet. In other words, the electron "feels" an average of the driving force in its surroundings, but it is still treated as a point particle in the MC transport core. The Gaussian shape is assigned to the electron when solving the Poisson equation [47].

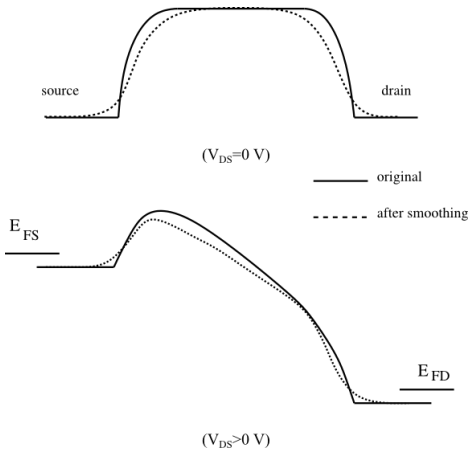

Figure 7 Sketch of the subband smoothing procedure applied in the MSMC. At low V_{DS} the smoothening leads to more penetration of the electrons from the S/D into the channel. At V_{DS}>0, the top of the potential barrier at the injection point is lowered: the enhanced thermionic emission mimics the source-to-drain tunneling.

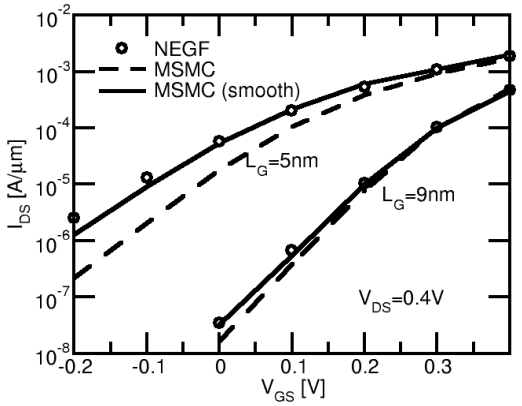

Figure 8 Comparison between MSMC and NEGF [48] simulations for Si MOSFETs with different gate length. Double-gate devices with 3nm film thickness and 0.9nm EOT.

The only parameter of this model is the standard deviation of the Gaussian function. Figure 8 compares the MSMC results with and without subband smoothening with NEGF results obtained by using "nanomos" [48]. Silicon MOSFETs are considered. A single value of 1.1nm for the standard deviation of the Gaussian function allows the MSMC to reproduce the NEGF results for devices down to 5nm gate length. Applicability of this approach to III-V channel MOSFETs is under investigation.

V. MONTE CARLO MODELING OF GRAPHENE DEVICES

Due to the large mobility and its monoatomic thickness [49], graphene has been widely investigated as material for electron devices, either as a replacement of the silicon channel in FETs or as part of alternative device structures able to exploit the graphene unique features.

Although quantum-mechanical effects are very relevant in graphene due to its gap-less nature and to the long coherence length, semi-classical transport and MC methods have been used as well to predict device performance, as shown in the following two examples.

A. Graphene FETs (GFETs)

The MC method has been used by several authors studied dissipative transport in GFETs [50]-[54]. When considering graphene foils, band-to-band-tunneling (BTBT) must be taken into account [52],[54] in order to describe the strong ambipolarity of the devices. We have shown in [54] that a simple local BTBT model is adequate to reproduce more accurate NEGF calculations.

As explained above, where we showed results for III-V MOSFETs, one of the main advantages of the MC approach is that the same model can be used for long channels (for calibration purpose) as well as for short channels (to predict the performance of ultimately scaled devices). In this spirit, Figure 9 compares MC simulations and experiments for mobility in graphene nano-ribbons. Here the dominant scattering mechanisms are edge roughness and remote polar phonons from the insulator [53]. A more extensive comparison for different

charge sheet densities and temperature can be found in [53].

Note that MC simulation of graphene foils does not require the MSMC approach, since there is no quantization-induced subband splitting. On the other hand, it also differs from a conventional 3D semi-classical MC since the k-space is 2D. Nano-ribbons, instead, may demand the description of quantization in the ribbon width [55]. In Figure 9, however, we use a 2D model with a ribbon width dependent energy dispersion relationship [51].

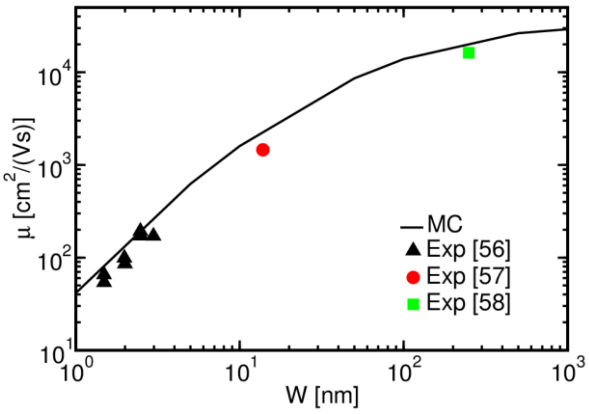

Figure 9: Simulated mobility as a function of the graphene ribbon width (W). Experiments are reported for comparison [56][57][58]. The simulated sheet charge density is low (10^{11}cm^{-2})

Having verified the correctness of the band structure model and of the scattering mechanisms in long channel devices, we have then run MC simulations of short channel devices. Sample results are illustrated in Figure 10 for a 50 nm long graphene FET. BTBT is responsible for the non-saturating output characteristic (circles): in fact, the simulation without BTBT (triangles) exhibits well behaved current saturation at large V_{DS}. The inclusion of scattering (filled circles) significantly reduces the current compared to ballistic transport.

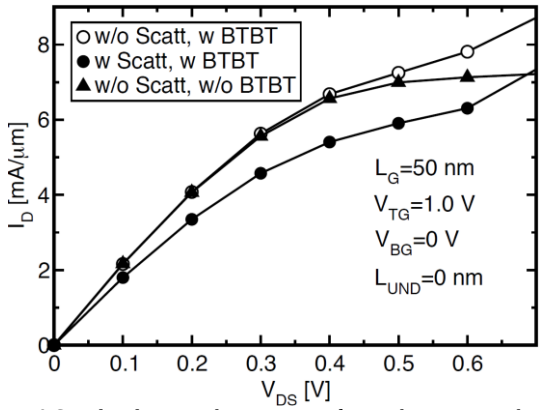

Figure 10 Simulated output characteristic of a graphene FET with 50nm channel. The top dielectric is 5nm of Al_2O_3, with the substrate consists of 300nm of SiO_2.

B. *Graphene Base Transistor (GBT)*

Ambipolarity strongly limits the performance of graphene FETs both in the digital (large off-current) and in the analog (high output conductance) domains [59]-[61]. For this reason, new device concepts exploiting graphene have been proposed. A relevant example is the Graphene Base Transistor (GBT) [62]-[64], sketched in Figure 11. A graphene base controls the tunnel injection of electrons from the (metal of silicon) emitter to an emitter/base insulator (EBI). The carriers then go through the graphene base, enter the conduction band of the base/collector insulator (BCI) and are eventually collected by the metal "collector".

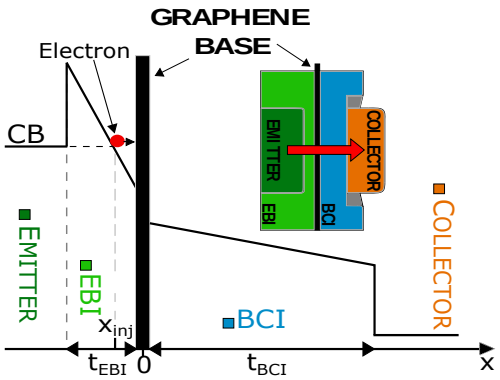

Figure 11: Conduction band diagram of the GBT. Electrons are injected in the EBI conduction band at x_{inj}. The inset shows the GBT structure.

Modeling the GBT mainly involves calculating tunneling currents [65]-[67] since this is the current limiting mechanism. Nevertheless, the MC approach has been useful to describe dissipative transport in the conduction band of the EBI and BCI layers and the energy distribution of the carriers. As an example, Figure 12 reports the average velocity (top) and the concentration profile (bottom) in a template GBT. The model considers electron scattering with the phonons of the dielectric (polar optical and non-polar acoustic) [68], and a non-parabolic description of the conduction band. We see that the velocity and concentration profiles in the BCI are essentially constant. This information was used to derive simplified electrical models to simulate the GBT under high injection conditions [67].

The MC simulation also provides the fraction of the electrons entering the BCI conduction band that are back-scattered into the base. These electrons are most likely captured by the graphene layer and contribute to the base current. Consequently, back-scattering in the BCI sets an upper limit to the common base current gain $\alpha_F = I_C/I_E$ (see values in the legend of Figure 12). According to our results, the simulated α_F is much higher than the experiments [63] (mainly because the assumption that the graphene base is fully transparent to electrons arriving from the EBI is not verified), but, nevertheless, small enough to pose a serious limitation to the device performance.

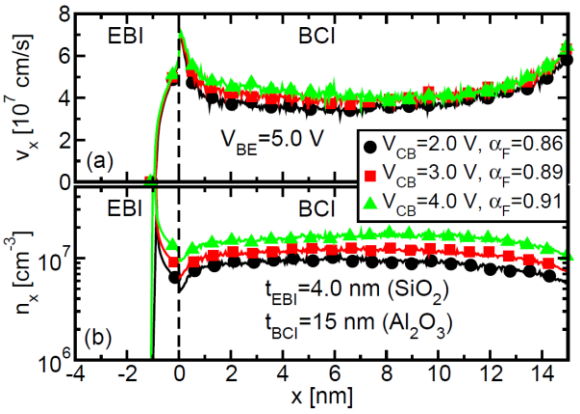

Figure 12 Average velocity v_x (a) and electron concentration n_x (b) along the GBT for a few values of V_{CB}. The concentration is low since the injected current is a few A/m^2.

VI. CONLUSIONS

In this paper, we have reviewed the Monte Carlo method for carrier transport in electron devices. Applications to MOSFETs with III-V channels and to graphene devices have been reported. This demonstrates that MC transport models are versatile tools, well suited to help in the assessment of the performance of modern nanoscale devices, and to support researchers in the evaluation of new materials and device architectures.

Compared to the conventional drift-diffusion model used in commercial TCAD, modern MSMC transport techniques provide a much more rigorous description of far-from-equilibrium transport and of carrier quantization. Compared to full-quantum transport methods, they can handle larger devices, allowing for an easier calibration with experimental data, and a more efficient and complete treatment of scattering. However, comparison between MC and full-quantum transport simulators is of paramount importance to verify and calibrate the many model ingredients; e.g., the quantization model with non-parabolic corrections used for III-V MOSFETs [38], the subband smoothening procedure [47] and the BTBT model for graphene [54].

Abstract. – Surface enhanced Raman spectroscopy is an important technique for detection of wide number of analytes. Today, there is a growing need for the development of stable, sensitive, reproducible and portable SERS-active substrates for use in different fields. Some of the most extensively used SERS substrates are metal colloids. However, the use of the colloid solutions for SERS deals with important issues, like stability and reproducibility. Other popular types of substrates are rough or nanoporous surfaces, such as porous silicon, coated with noble metals. Porous silicon (pSi) is a semiconducting material typically obtained by electrochemical etching in hydrofluoric acid (HF). Due to its high surface-to-volume ratio pSi is an interesting material for photonic and sensing devices, drug delivery systems as well as for use in SERS. In this paper, attempts are made to prepare a stable and uniform noble metal colloidal solution as well as solid substrate using porous silicon (pSi) with deposited silver and gold nanostructures. SERS substrates obtained by different methods are evaluated for SERS efficiency using methylene blue and rhodamine 6G (R6G) at 514.5 and 633 nm. The prepared substrates showed good stability and reproducibility. For some substrates the concentrations detected were below nanomolar range.

I. INTRODUCTION

Raman spectroscopy is an important technique for identification as well as for structural characterization of wide number of analytes. Raman scattering is known to be a very inefficient process due to its low scattering cross-section. In order to improve the sensitivity of the process, surface enhanced Raman spectroscopy (SERS) has been used for several decades [1]. A lot has been written about the mechanism of the SERS but it is now widely accepted that there are two main factors affecting SERS: electromagnetic and chemical [2, 3]. In the electromagnetic mechanism, the laser light excites collective oscillations of the surface electrons in a metal which results in the enhancement of the local electromagnetic field. The molecule which is near the metal surface or adsorbed to it, experiences this enhancement and as a result the intensity of the Raman scattered light is enhanced. In the chemical mechanism, the polarizability of the molecule adsorbed on the metal surface increases. The total Raman signal enhancement is the product of both processes. Silver and gold are very good for fabrication of SERS substrates because of intense surface plasmon absorption in the visible region of the spectra.

Today, there is a growing need for the development of stable, sensitive, reproducible and portable SERS-active substrates for use in different fields. Some of the most extensively used SERS substrates are metal colloids [4, 5] because of their simplicity of preparation (in-situ reduction methods) and strong Raman enhancement. However, the use of the colloid solutions for SERS deals with important issues, like stability and reproducibility [6]. Nanostructures can also be fabricated electrochemically [7] and with methods that allow high organization in the structure, like lithography methods [8-10] and Langmuir-Blodgett technique [11]. Other popular types of substrates are rough or nanoporous surfaces, such as porous silicon, coated with noble metals [12]. Porous silicon (pSi) is a semiconducting material typically obtained by electrochemical etching in hydrofluoric acid (HF) [13, 14]. After the etching, material is consisted of a network of pores with different diameters and depth, depending on the etching conditions. Due to its high surface-to-volume ratio this is an interesting material for photonic and sensing devices, drug delivery systems as well as for use in SERS [15-18].

II. MATERIALS AND METHODS

The metal colloidal solutions were prepared using chemical reduction method. Ascorbic acid, tri-sodium citrate and ice-cold sodium borohydride were used was as reducing agents and citrate was used as stabilizer.

Silicon wafers (100) of p-type (boron-doped), with a resistivity of ~20 Ωcm and 525±25 μm thickness, were cut into ~2.5 x 2.5 cm pieces and degreased by sonication in acetone and ethanol and rinsed with ultra pure water. Electrochemical experiments were performed with home-made two-electrode Teflon cell in 12 %wt hydrofluoric acid solution. The constant current densities used were 4 and 10 mA/cm^2 for 15 or 30 minutes in 12 wt% HF acid. Silver was deposited on the surface of pSi by immersing the pSi

samples in 0.01 and 0.001 M aqueous silver nitrate ($AgNO_3$) solution, by drop casting or by pulsed laser ablation.

The absorption optical spectra of silver samples were recorded using UV–Vis–NIR spectrophotometer (UV-3600, Shimadzu). All the spectra were recorded at room temperature.

The morphology of silver nanoparticles was investigated with Jeol JSM 7000F field emission scanning electron microscope (FE SEM) coupled with Energy-dispersive spectroscopy (EDS). The particle size distribution was determined from corresponding SEM micrographs using ImageJ program and modified level set algorithm.

Surface-enhanced Raman spectra were recorded by Horiba Jobin Yvon HR800 and T64000 micro Raman systems. The exciting lines were 514.5 (Ar laser) and 632.8 (He-Ne laser). In order to reduce the photo degradation of the analyte, filters were used, and the laser excitation power was kept low. Prior to recording the Raman spectra, the samples were soaked in aqueous solutions of testing molecules at different concentrations for 30 minutes. As testing molecules pyridine, rhodamine 6G (R6G) and methylene blue (MB) were used.

III. RESULTS AND DISCUSSION

A. SERS in colloidal solutions

A series of silver colloids was prepared by using different reducing agents. They were investigated with respect to nanoparticles morphology and SERS activity [19]. The silver particles with 10–40 nm size and spherical shape were prepared by reducing silver nitrate with citrate, ascorbic acid and $NaBH_4$ in the presence of stabilizing agents. Thus obtained silver nanoparticles were used as SERS substrates with pyridine as analyte. The best enhancement of the Raman signal was achieved when sodium borohydride (0.1M) was used as aggregating agent in citrate reduced silver colloid (Fig. 1). The SERS enhancement factors for pyridine were calculated taking into account the number of molecules on the silver nanoparticles in laser activation volume and for the best results was estimated to be of the order 10^6.

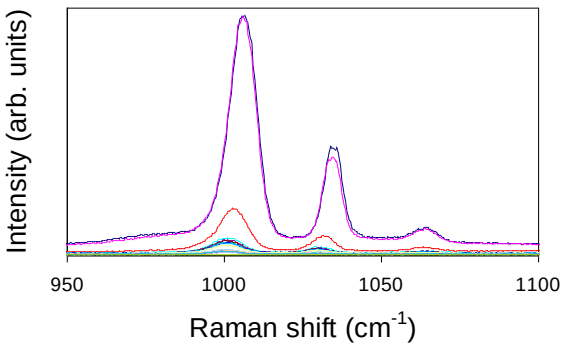

Figure 1. SERS spectra of pyridine in citrate-reduced Ag colloid sample recorded one after another during 25 minutes after addition of 0.1M $NaBH_4$ (the highest peak represents the longest time) [19].

B. SERS in solid substrates.

The electrochemical etching of silicon samples for both current densities and etching times resulted in the formation of macro pores with ~1 μm width and variable lengths. The etched samples were coated with noble metals in several ways: a) immersion in $AgNO_3$ solution, b) drop casting silver colloidal solution and c) laser ablation with silver and gold. The formation of the silver layer in all cases could be confirmed visually. A SEM micrographs of the SERS substrates obtained by immersion of pSi etched 30 min at 4 mA/cm^2 in 0.01 M $AgNO_3$ solution reveal that the silver layer is composed of homogeneously distributed nanoparticles that cover the surface leaving the macro pores open. The average size of the nanoparticles is around 100 nm but there are also some aggregates. On the SEM micrograph of the pSi with drop casted silver colloidal solution micron scale agglomerates of silver nanoparticles formed at the entrances of the pores are observed. The average size of the single silver nanoparticles is around 80 nm, but some smaller particles are present as well. The mean silver particle size on macroporous Si surface for both silver ablations and gold ablation was calculated to be in the range from 20 to 40 nm.

The efficiency of pSi templates with metal nanoparticles was tested using dye molecules, methylene blue and rhodamine 6G at different wavelengths.

In the case of immersion of pSi sample in silver nitrate solution the lowest R6G concentration detected at 514.5 nm was 10^{-9}M (Fig. 2). When silver colloidal solution was applied to pSi template, the lowest R6G concentration that was detected was 10^{-8}M. Considering samples ablated with silver and gold, R6G was detected only in one sample to the concentration of 10^{-8}M.

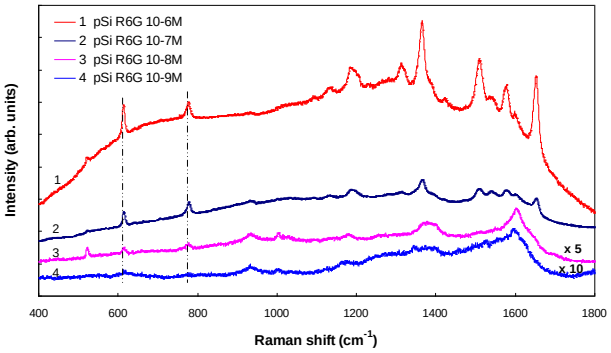

Figure 2. SERS spectra of of rhodamine 6G (concentrations 10^{-6}, 10^{-7}, 10^{-8} and 10^{-9} M from top to bottom) on Si (4 mA/cm^2; 30 min) with silver obtained by immersion plating; excitation line 514.5 nm; laser power 1 mW; accumulation time 10s.

Using 633 nm laser wavelength and MB the most pronounced SERS activity gave pSi samples ablated with 45000 pulses. For these samples nice spectra for 10^{-10}M concentration of MB were obtained (Fig. 3). The detection

limit of 10^{-10}M was also reached for 4 mA/cm^2 - 15 min pSi sample, silver ablated with 30000 pulses. For the gold ablated pSi samples, the lowest concentration detected was barely 10^{-8}M.

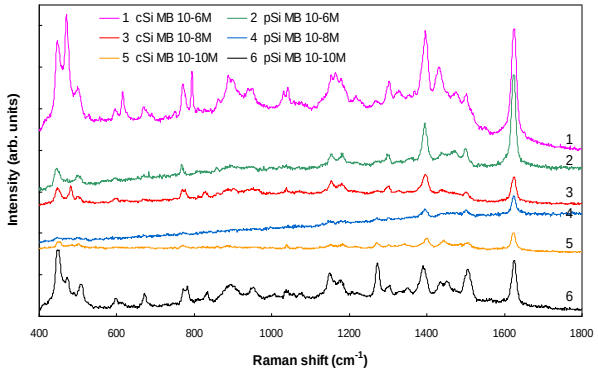

Figure 3. Raman spectra of methylene blue (concentrations 10^{-6}, 10^{-8} and 10^{-10} M from top to bottom) on macroporous Si (4 mA/cm^2; 30 min) and crystal Si (cSi) samples ablated with silver (45000 pulses); excitation line 633 nm; laser power 6µW; accum. time 10s.

IV. CONCLUSION

In conclusion, stable and reproducible SERS substrates were successfully prepared with different methods. First, silver colloids were used as SERS substrate with pyridine as analyte. The SERS enhancement factors for pyridine were estimated to be of the order 10^6. Second, porous silicon produced by anodisation of p-type silicon in hydrofluoric acid was used as a template for Ag and Au depositions. The SERS efficiency of the different pSi substrates was evaluated in terms of limit of detection (LOD) using methylene blue (MB) and rhodamine 6G (R6G) as probe molecules, and laser excitations at 514.5 and 633 nm. LODs below the nanomolar range are reproducibly obtained. Porous silicon proved to be a good base for the preparation of SERS substrates.

Abstract - Transition-metal chalcogenides are prospective thermoelectric materials. One of them is a molybdenum disulfide MoS_2, which has a layered structure. MoS_2 has a good potential to have a high value of thermoelectric quality factor due to a high value of thermo-EMF and low value of thermal conductivity. But a low value of its electrical conductivity suppresses the thermoelectric quality factor ZT on the level of 0.1 at high temperatures. Present work shows the influence of metal addition to MoS_2 on electrical conductivity and Seebeck coefficient (SC) of final mixture. Mo_2S_3 was chosen as a metal addition. Mo_2S_3 has an electrical conductivity of 330 S/m and thermo-EMF of 10 μV/K at 300K. Bulk powder samples of MoS_2 with addition of 3, 6, 10, 30 and 60 wt% Mo_2S_3 were studied. An electrical conductivity of samples was measured in temperature range: 77 K – 423 K. All samples have shown semiconductor hopping conductivity with variable hopping length. The SC was measured in the temperature range of 300K - 500K. The addition of Mo_2S_3 decrease SC from 300μV/K to 75μV/K.

I. INTRODUCTION

Thermoelectric materials have a great interest for study. Environmental problems associated with non-renewable natural resources and environmental pollution are the cause of such interest [1].

The effectiveness of a thermoelectric material is characterized by dimensionless thermoelectric quality factor ZT, which is calculated by the formula "(1)".

$$ZT = S^2\sigma T/\lambda, \quad (1)$$

where S – Seebeck coefficient, σ – electrical conductivity, λ – thermal conductivity, T – temperature [2].

The search of new materials with high ZT consists of research of completely new composite materials.

Thermoelectric materials have a different temperature range where the quality factor reaches its maximum. Therefore thermoelectric materials are classified as low, middle or high temperature materials according to a temperature range with a highest value of quality factor.

Such materials as transition-metal chalcogenides are of great interest in recent time. One of the brightest representatives of such materials is a molybdenum disulfide. Molybdenum disulfide has its own distinctive electronic, optical and catalytic properties [3].

Molybdenum disulfide has a layered structure. Single-layer in disulfide molybdenum is a two-dimensional quasi-crystal, which consists of close-packed layer of molybdenum in between of two close-packed layers of sulfur S-Mo-S. Layers are held together due to weak Van der Waals forces, whereas atomic structures of layers are tied together by strong covalent forces. This material is structurally similar to graphene and hexagonal boron nitride (h-BN) [4].

Recent reports demonstrated thermopower of MoS_2 in a range of 600 to 700 μV/K at a high temperature. Electrical and thermal conductivity of MoS_2 have different values in a various sources. The value of the electrical conductivity is in a range of 0.01 to 10 S/m at room temperature. The value of thermal conductivity is in a range of 0.1 to 1 W/(m*K) [5-7].

Molybdenum disulfide has a potential to have a high value of thermoelectric quality factor due to high value of thermo-EMF and low value of thermal conductivity. But the low value of electrical conductivity suppresses its thermoelectric quality factor on the level of 0.1 at high temperatures [8].

Present work shows the influence of metallic addition to molybdenum disulfide on its electrical conductivity and Seebeck coefficient. Molybdenum(III) sulfide Mo_2S_3 was chosen as a metallic addition. Mo_2S_3 has an electrical conductivity of 330 S/m and thermopower of 10 μV/K at room temperature.

II. EXPERIMENTAL

A. Preparation of sample

MoS_2 and Mo_2S_3 were synthesized by a standard high temperature ampule method using high purity elements in stoichiometric ratio. The composite samples are prepared by means of intimately mixing molybdenum disulfide with 3, 6, 10, 30, 60 wt% Mo_2S_3.

The powdered composite materials were pressed to obtain 12 mm in diameter pellets-shape samples. The samples shape was further trimmed to rectangular form for study of thermoelectric and electronic properties. Such shape of the samples was obtained by means of diamond cutter. The ohmic contact to the samples was obtained using silver paste.

B. Electrical properties

The samples under study have n-type conductivity. Seebeck coefficient of the samples was measured at the temperature range of 300 to 500 K. The results on Seebeck coefficient are presented in Fig.1.

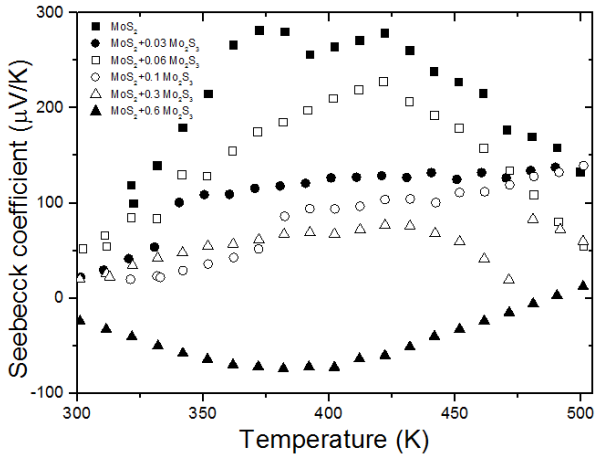

Figure 1. The Seebeck coefficient as function of temperature.

Seebeck coefficient of pure molybdenum disulfide has value of 100 to 300 μV/K over a temperature range of 300 to 500 K. It is observed that Seebeck coefficient is decreased with introduction of Mo_2S_3 to the MoS_2. Introduction of 60wt% of Mo_2S_3 has the highest effect on the Seebeck coefficient of the composite. At 60wt% of Mo_2S_3 Seebeck coefficient became negative which means than composite changed its conductivity to p-type.

Electrical conductivity was measured at the temperature in the range of 77 to 500 K. The measured results are displayed in Fig.2.

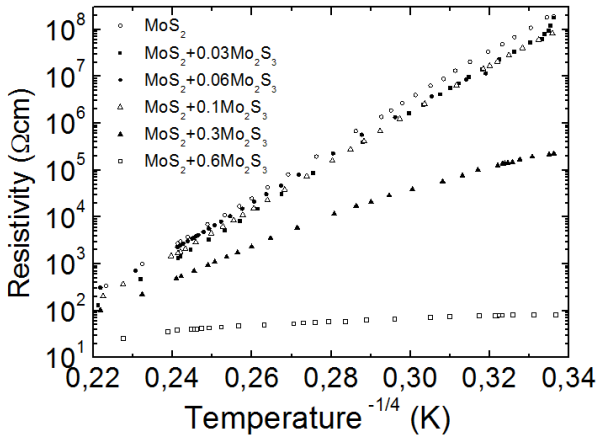

Figure 2. The resistivity as function of temperature.

The results of electrical conductivity measurement showed that the samples with addition of 60wt% of Mo_2S_3 have a higher electrical conductivity. The results are proved by the fact that Mo_2S_3 is a metal with high electrical conductivity. The results in Fig.2 clearly shown, that MoS_2 sample itself as well as all sample with Mo_2S_3 additive demonstrated 3D hopping conductivity with variable range hopping .

Thus all the samples belong to family of materials, where hopping conductivity with variable range hopping (VRH) is realized. Such type of conductivity was discussed by Mott in 1968 [9]. According to Mott's law, the resistivity varies with temperature by the formula "(2)".

$$\rho(T)=\rho_0 \cdot \exp[(T_0/T)^{1/4}] \quad (2)$$

where ρ_0 is the resistivity at infinite temperature and T_0 is the characteristic temperature

Thermoelectric power factor of the samples was calculated by the formula "(3)".

$$P = S^2\sigma \quad (3)$$

where S – the Seebeck coefficient, σ – electrical conductivity.

The results of the thermoelectric power factor calculation are presented in Fig. 3. One can see that addition of 60wt% Mo_2S_3 dramatically changes the thermoelectric power factor in comparison with MoS_2, e.g. thermoelectric power factor increased in 3.5 times in the average range of the temperatures. The smaller additions of Mo_2S_3 show the trend in decreasing of thermoelectric power factor.

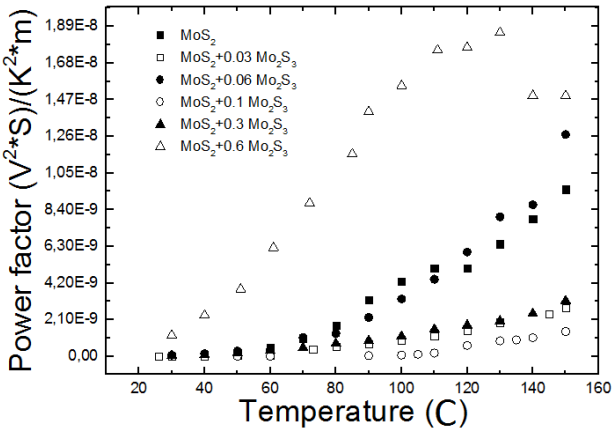

Figure 3. The power factor as function of temperature.

III. CONLUSION

We have measured MoS_2 pellet-shape pressed samples with different amount of Mo_2S_3 additive for analysis of TEMF and conductivity. It was shown that addition of Mo_2S_3 decreases Seebeck coefficient from 300μV/K to 75μV/K. The addition of 60wt% Mo_2S_3 gives the advantage in thermoelectric power factor.

It was shown that all samples have disordered structure with 3D hopping type of conductivity with variable hopping length. It was also shown that the temperature dependence of the samples omit Mott's law. By the variation in MoS_2/Mo_2S_3 composites is possible to change thermoelectric and conductive properties by controlling of Mo_2S_3 contents.

Abstract – The work presents a study of piezoresistive effect of thin films of rhenium-doped molybdenum disulfide of composition $Mo_{0.95}Re_{0.05}S_2$ possessing layered structure of 2H-MoS_2 type. The compound was synthesized by high temperature ampoule method using stoichiometric mixture of elements. The thin films were formed by spraying colloidal dispersion produced by liquid exfoliation of solid phase in mixed solvent EtOH/H_2O. The phase $Mo_{0.95}Re_{0.05}S_2$ is semiconductor with effective activation energy of about 150 meV estimated from temperature dependences of resistance of the films. The dependence of resistance on deformation is presented. It has almost linear type and good reproducibility during a sinusoidal alternating load of 0.12% deformation amplitude. The strain gauge factor of 12 and 24 was obtained depending on preparation details from room temperature measurements using a beam of uniform strength (in bending).

I. Introduction

The piezoresistive effect is a change in the electric resistance of materials when mechanical strain is applied. The piezoresistive effect is pronounced one for semiconductors: for example, strain gauge factor of even polycrystalline and amorphous silicon can vary from -30 to +40, about a third that of single-crystal silicon, that are an order of magnitude larger than those observed in metals [1, 2]. Very high strain gauge factor of semiconductors determine heightened interest of investigators to new semiconductor materials.

MoS_2 is a bright representative of the layered family of transition metals dichalcogenides (TMDC) possessing semiconducting electronic properties as well as high thermal and mechanical stability [3]. The properties of 2H-MoS_2 were studied on the bulk state, but recently, a series of publications was devoted to exfoliated samples – nanosheets, mono- and bilayer MoS_2 that make them attractive for flexible electronic applications [4-7]. Because pure MoS_2 is characterized by rather high resistivity, in our work we used rhenium-doped sulfide $Mo_{0.95}Re_{0.05}S_2$. We showed recently [8] that substitution of 5-15% of molybdenum atoms by electron-rich rhenium ones results in changes of resistivity compared to non-substituted MoS_2. For instance, pressed powder sample of composition $Mo_{0.95}Re_{0.05}S_2$ revealed significant drop in the resistivity (by c.a. 10^4 times) and decrease of Δ_{eff} (the logarithmic derivative of electrical resistance with respect to the inverse temperature) in 4 times down to 0.086 eV at 300 K.

In this work we study a piezoresistive effect of $Mo_{0.95}Re_{0.05}S_2$ film samples prepared from its colloidal dispersion. The resistance temperature characteristics of the samples were measured as well.

This work was supported by the Russian Science Foundation (Grant № 14-13-00674).

II. Experimental

A. Preparation of $Mo_{0.95}Re_{0.05}S_2$ film samples

$Mo_{0.95}Re_{0.05}S_2$ was synthesized by high temperature ampoule method from stoichiometric mixture of Mo/Re/S and characterized by X-ray powder diffraction method. Thin films were formed by filtering of the $Mo_{0.95}Re_{0.05}S_2$ colloidal dispersion that was produced by exfoliation of solid phase in mixture solvent (45% EtOH + 55% H_2O) under ultrasonic treatment (Fig. 1). The XPD patterns of bulk material and thin film were indexed in hexagonal sp. gr. P63/*mmc* (No. 194), as 2H-MoS_2.

The particle sizes forming colloidal dispersions were of few layers thick with lateral dimensions of 50-200 nm (see Fig. 2). Six samples (from **1s** to **6s**, Table 1) for measuring the dependences of resistance on strain were prepared by spray method using preheated to 200°C steel beams coated with the polymer glue VL-931. Herewith **5s** and **6s** were influenced in situ with the ethanol-water solution in an attempt to form homogeneous films, because the films' forming usually proceeded with forming of bottom layers and islands not more than 0.3 mm in lateral dimension placed onto the layers. Such forming is distantly similar in growth to Stranski-Krastanov mechanism [9]. The beams with the samples were dried in air at 60°C for 3 hours. The samples **3s** – **6s** were covered with the polymer glue at room temperature followed by 80°C and 120°C dryings.

B. Resistance-strain measurements

A beam of uniform strength (in bending) was chosen for studying the piezoresistive effect (see Fig. 3). The feature of the beam lies in invariable strain ε throughout the trapezoidal section of the beam [10]. The beams were

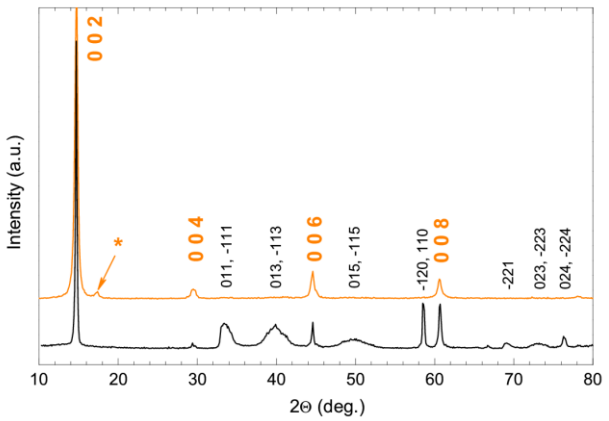

Figure 1. X-ray powder diffractogramms of bulk $Mo_{0.95}Re_{0.05}S_2$ (bottom line) and $Mo_{0.95}Re_{0.05}S_2$ film formed by filtering (upper line)

made of spring steel: thickness h = 0.5 mm; Young modulus E = $2.15 \cdot 10^{11}$ Pa; Poisson ratio μ = 0.3; linear temperature expansion coefficient α = $12.3 \cdot 10^{-6}$ K^{-1} (from 293 K to 393 K). The beams themselves had the following dimensions: the length of the place pinched – 12 mm; the width – 12 mm; the length of the trapezoidal section (section of uniform strain) – 43 mm; the length of the narrow part – 25.5 mm; the total length – 80.5 mm; the distance from the pinched line to the vertex of the triangle – 66 mm. The beams were bent by the pusher as it is shown on Fig. 3.

The dependences of resistance on strain in loading and unloading regimes as function of relative resistance variation on strain of the samples are shown in Fig. 4. The dependences for all samples are of similar shapes. One can see that the curves received are almost linear and the strain gauge factors for **1s** – **4s** and **5s** – **6s** samples have the same values within the error.

The strain gauge factor was defined as slope of connecting line between the two extreme values (values of relative resistance at the positive and negative strain maxima) by a well-known formula [11]:

$$K = \frac{\Delta R / R_{\varepsilon(\min)}}{\varepsilon}, \qquad (1)$$

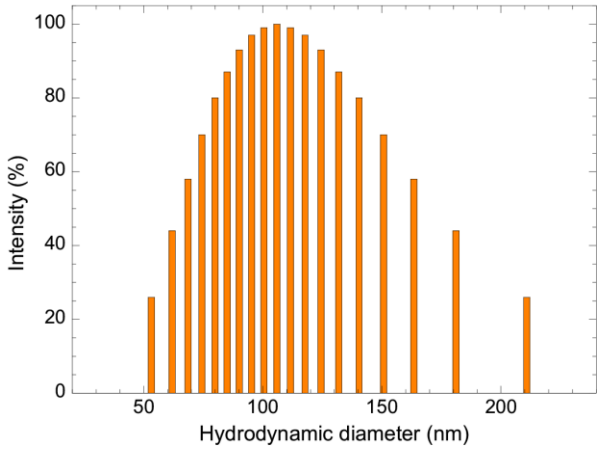

Figure 2. The size particles distribution in colloidal dispersion of $Mo_{0.95}Re_{0.05}S_2$ / 45% EtOH + 55% H_2O

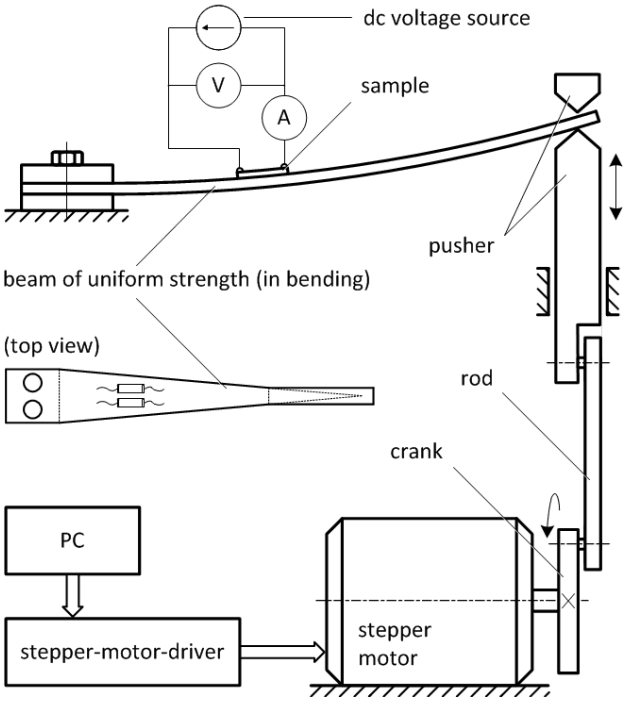

Figure 3. The device for measuring a strain gauge factor and for endurance test

where $\Delta R = R_{\varepsilon(\max)} - R_{\varepsilon(\min)}$; $\varepsilon = \varepsilon_{\max} - \varepsilon_{\min}$ – the strain leading to change of resistance ΔR; $R_{\varepsilon(\max)}$ and $R_{\varepsilon(\min)}$ are resistances at $\varepsilon_{\max}$ and $\varepsilon_{\min}$, respectively. To obtain the strain gauge factors the beams were loaded with the deflection increments about 2 mm. The strain values were calculated by ANSYS software.

The slope difference received for all samples might have appeared because of some reasons. First one probably is different forming technique, especially for **5s** and **6s** samples. The second reason may be various thicknesses of insulating bonding glue. Finally, the third reason may be that the samples **1s** and **2s** had not a covering in contrast to the other ones. In spite of the above-stated, one can see that neither the covering nor the possible glue thicknesses difference have affected the strain gauge factor, as the factors for **1s** – **4s** have the same values within the error (see Table 1). But at the same time the additional treatment of films of **5s** and **6s** samples has changed the sensitivity, and it will be discussed in the next subsection.

One can see the hysteresis for each sample in Fig. 4. The hysteresis may be concerned mainly with residual resistance changes due to geometrical and structural changes of the films in plastic strain range of them. One more reason may be hysteresis in the glue. The hysteresis for **5s** and **6s** samples may be essentially due to low accuracy rate because of their high resistances.

The error of the strain gauge factors was evaluated by the formula (2):

$$\Delta K = \sqrt{\sum_i \left(\frac{\partial K}{\partial X_i}\right)^2 \Delta X_i^2}, \qquad (2)$$

where X_i – are the current and voltage accuracy specifications of the measuring instruments used and strain accura-

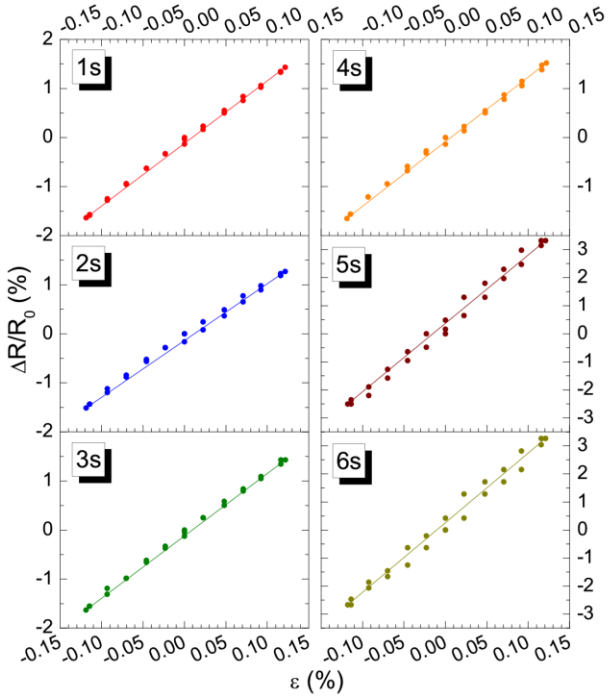

Figure 4. Resistance-strain characteristics of all samples at room temperature

cy. But at the same time, the errors for **3s** – **6s** were evaluated without considering of additive error of the current meter. The result is the strain gauge factor equal to 12.5±1.6 and 24.4±1.4 for **1s** – **4s** and **5s** – **6s** samples, respectively, with linear resistance-strain curves.

To examine the samples for endurance the beams were bent by sinusoidal alternating load of 0.12% deformation amplitude with 3 Hz the oscillation frequency. The samples were tested after 10, 30, 100, 300,… up to 100'000 load cycles [11]. The dependences of the strain gauge factors on the number of load cycles are shown in Fig. 5. As one can see there are not significant degradations of K along the range of number of cycles within the errors.

The piezoresistive effect of semiconductor and metallic resistors is related to changes of specific resistivity and geometric parameters respectively [1]. We cannot discuss here with confidence what makes the considered films sensing on strain because it requires an additional investigation which has not been carried out yet. The films of the samples consist of nanoparticles separated by insulating gaps and these films may be considered as disordered material. So we suppose the piezoresistive effect of the films may be concerned with a change of these gaps.

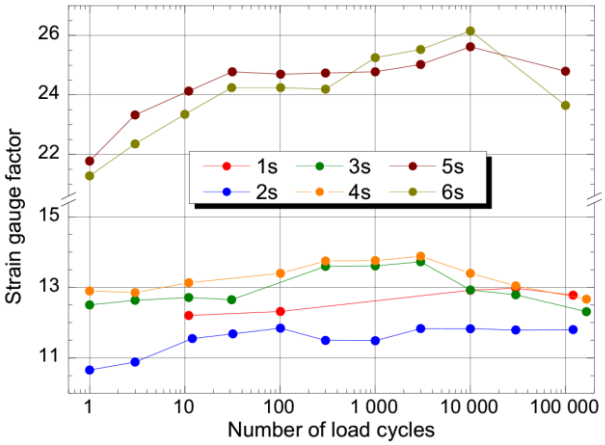

Figure 5. Dependences of the strain gauge factors on the number of load cycles. The oscillation strain amplitude is equal to 0.12%; the oscillation frequency is 3 Hz; $T \approx 296$ K

C. *Resistance temperature characteristics of the films*

To characterize the samples and especially the insulating gaps the temperature dependences of resistance of the samples have been measured (Fig. 6). These plots show that $R(T)$-dependences obtained are typical for semiconductors. The temperature dependences of resistance of **1s** and **2s** samples were measured over the range of temperature from 296 K to 453 K, but the dependences of the other samples were measured just to estimate the values of effective activation energies. The energies are defined as $\Delta_{eff} = d\ln(R)/d(1/T)$. The result values are shown in Table 1.

The greater effective activation energies of **5s** and **6s** samples correspond to larger average lengths of the insulating gaps between the particles in the films, as lengths of the insulating gaps in disordered material are characterized by energy barriers for electron tunneling [12-15]. Such difference in the energies may be also due to a deviation of average orientations of the nanoparticles relative to the beams surfaces that might be induced by the

TABLE I. SAMPLES' PARAMETERS

Sample	1s	2s	3s	4s	5s	6s
d, μm thickness	1.2	1.1	0.7	0.7	0.7	0.7
Covered with the polymer glue	–	–	+	+	+	+
Additional treatment with the solvent	–	–	–	–	+	+
$a \times b$, mm a – length between contacts b – width of the samples	2.0×2.6	2.5×2.5	8.3×2.5	8.5×2.5	7.7×2.5	7.8×2.5
Shape factor, a/b	0.77	1.00	3.32	3.40	3.08	3.12

K strain gauge factor	12.3±1.3	11.8±1.7	12.7±1.1	13.1±1.1	24.7±1.4	24.2±1.4
Δ_{eff}, meV effective activation energy	150	153	147	148	167	177

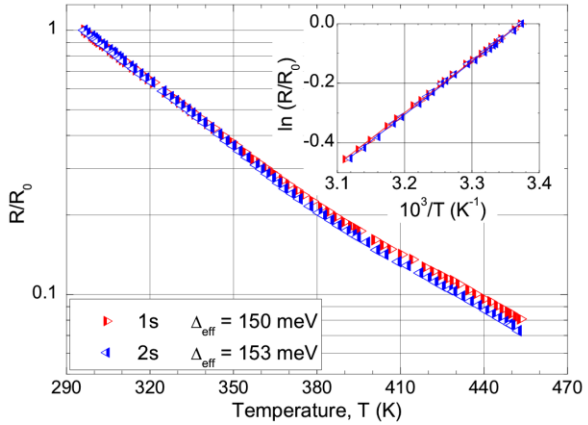

Figure 6. Resistance temperature characteristics of **1s** and **2s** samples

treatment of the samples **5s** and **6s** with the ethanol-water solution.

It is most likely in our case that just the orientation of the particles affected the factors, as electrical properties of layered materials strongly depend on crystal orientation (perpendicular and parallel to the *c* axis) [16]. Influence of the lengths of the insulating gaps on the factors is less likely than that of the orientation, because **5s** and **6s** have the different effective activation energies estimated and at the same time the same values of the factors within the error (see Table 1).

It is clear that the preparation details influence the properties of the resulting films including the strain sensitivity. We prepared six samples by spraying with different preparation details, but only the additional treatment of films of **5s** and **6s** samples has affected the strain gauge factor having made it higher. Anyway it needs an additional investigation.

III. Conlusion

The $Mo_{0.95}Re_{0.05}S_2$ thin films prepared by spraying colloidal dispersion have the strain gauge factors equal to 12 and 24 depending on the preparation details. The factor can be tuned by an additional treatment of films structure with the solvent.

Acknowledgment

The authors thank to Aleksey S. Cherkaev and Mikhail A. Chebanov (Novosibirsk State Technical University) for suggestions to measurements and calculating the beam strain by ANSYS software, respectively.

vladimir.tudic@vuka.hr

Abstract - Amorphous-nano-crystalline silicon composite thin film (a-nc-Si:H) sample were synthesized by Plasma Enhanced Chemical Vapor Deposition technique. The electrical properties of thin film and measurement of DC conductivities were accomplished using Dielectric spectroscopy (Impedance Spectroscopy) in wide frequency and temperature range. In analysis of impedance data, two approaches were tested: the Debye type equivalent circuit with two parallel R and CPE (constant phase elements) and modified one, with tree parallel R and CPE additionally interpreting crystal boundary effects. It was found that the later better fits to experimental results properly describing significant composite structure and crystal boundary dielectric effect with arbitrary hydrogen concentration indicating presence of strain. The amorphous matrix showed larger resistance and lower capacity than nano-crystal phase. Also it was found that composite silicon thin film cannot be properly describes by equivalent circuit only with resistors and constant phase elements in serial relation.

I. INTRODUCTION

It is natural that vast interest activation about silicon experimental and theoretical resources has been devoted to understanding its properties. Concerning third generation silicon thin film solar cells, its layers and device applications move inexorably to shorter length scales interface and surface characteristics gain in great importance. In analyze of silicon thin film properties it is desirable to explore the nature of chemical bonding not only the interface and surface of silicon layers but already include both static structural properties and kinetic aspects of its composites. A dark conductivity property of silicon thin film implies both aspects: static throe structural ordering issues and kinetic or dynamic properties revealed by impedance spectroscopy throe electrical properties.

The composite a-nc-Si:H thin films is mixed-phase material consisting of silicon nanocrystals embedded in amorphous silicon (a-Si:H) matrix. It has been the subject of intense research for variety of applications due to their unique optical and electrical properties [1]. Electrical and optical properties of a-nc-Si:H can be controlled by silicon nanocrystals size distribution and ratio of amorphous/nanocrystalline volume contribution. Measurements of the optical properties and structural analysis in previous published papers [2] showed that the spectral distribution of the absorption coefficient, in a wide range of crystal to amorphous fractions, can be maintained close to pure amorphous silicon in the visible part of the spectrum and showed square dependence on the photon energy. The average optical gap was larger for smaller nano-crystals and a higher crystal fraction *X*c just confirming the quantum size effects that correspond to quantum dots [3, 4].

Impedance spectroscopy (IS) has been widely used in last couple of years as a powerful technique for the study of the dielectric and conductivity behavior of ferroelectrics, ceramics, crystalline bulk and composite-crystalline silicon thin films [5, 6].

Because of silicon thin films composite form which is primarily characterized by the crystal fraction *X*c and crystal grains sizes, it is necessary to understand effects of complex micro structural features on the overall electrical properties of thin films. The resistance and capacitance of crystals grains and grain boundaries, which is frequency and temperature dependent, can be evaluated from IS spectra. This technique for determination of the starting values for the basic equivalent electrical circuit were used in the fitting procedure of experimental impedance data with simulated data in order to select most appropriate equivalent circuit. This technique enables us to separate the real and imaginary component of the complex impedance and related parameters, and hence provides information of the structure-property relationship in the rated sample.

The sample examined by IS technique with composite structures with presence of crystals grains and grain boundaries embedded in matrix demonstrate complex impedance common in the event of two phase materials with different conductivity or permittivity. At high temperatures may occur two successive semicircle arcs mostly as a rule. These properties can conventionally be displayed in a complex plane plots (Nyquist diagram) in terms of the same formalism, refer to [5, 7].

The micro-structural properties revealed by techniques like grazing incidence X-ray diffraction (GIXRD) described in [4], Raman spectroscopy (RS) or X-ray powder diffraction (XRD) [2] are fundamental in composite silicon thin films investigations but the correlation between microstructure and electrical properties is not always obvious or straightforward. Electrical properties may vary in intrinsic material and are intensive to minor variations in structure and composition or whether the properties are extrinsic since they could vary dramatically if impurities are present, especially if impurities to the grain boundaries [8]. Thanks to impedance spectroscopy and appropriate data analysis it is

possible to characterize the different electrically active regions in a material, qualitatively by demonstrating their existence and quantitatively, by measuring their individual electrical properties. Identification and adoption of the most appropriate equivalent circuit for representation of the electrical properties is essential as a further step towards proper understanding sample properties. It has to be done in materials that are electrically particularly heterogeneous and where the impedance response of one part of sample overlaps, in frequency domain, with the response of other regions, giving rise to a composite response. Therefore, from an equivalent circuit model analysis the responses of the different regions may then be deconvoluted and characterized separately. The adequate model subsumes that are acquired simulation results have to be consistent with experimental data. This is, in most cases, based on designers experience on various equivalent circuit modeling.

II. MATERIALS CHARACTERIZATION

A. Experimental

Sample of amorphous-nano-crystalline thin film with a thickness of 100 nm were deposited by the PECVD method using radio frequency glow discharge in a capacitively coupled parallel plate reactor, as described earlier (Gracin, Thin Solid Films). Used gas mixtures consisted of 5% silane and 95 % hydrogen and the substrate was glass.

The electrical conductivity of the thin film was measured by impedance spectroscopy (Novocontrol Alpha-N dielectric analyzer) in the frequency range 0.01 Hz – 10 MHz and in the temperature range -100–120 ^{o}C. For the electrical contact, two gold electrode pads separated by 4 mm were sputtered on the sample surface using SC7620 Sputter Coater, Quorum Technologies. The impedance spectra were analyzed by equivalent circuit modelling using the complex non-linear least squares fitting procedure.

B. Measurement Data

Typical GIXRD data for measured sample titled G01 is described in previous paper [4]. The volume fraction of crystalline/amorphous phase, estimated from the ratio of integrated intensities under crystalline diffraction peaks and broad amorphous contributions, was about 30%. The average crystal size was estimated from the width of crystalline peaks using Scherrer formula assuming that the size broadening due to strain could be neglected comparing to the size broadening. In that way obtained values are the same as estimated from HRTEM micrographs just verifying the procedure.

III. EQIVALENT CIRCUIT MODEL

There are various approaches to model non-ideality of electronically conducting materials such as amorphous nano-crystalline materials. Since non-ideality of impedance response in silicon samples are observed, introduction of CPS is mainly instead of ideal capacity used in equivalent circuit modeling. Equivalent circuit model described in earlier paper [9] consisted of to two R_1||CPE$_1$ and R_2||CPE$_2$ parallel elements in serial connection had provided correct picture and adoptable results. Calculated values adopted in fitting procedure represents well defined model with good alteration with experimental IS curves and defined equivalent circuit elements. But for better alteration of experimental results an improved equivalent circuit model must be presented to include proven strain in matrix according to arbitrary hydrogen concentration and therefore evidenced of crystal boundary effect – different dielectric region and prove of existing potential barrier. In that case an additional component will be added to basic structure and final impedance $\dot{Z}$ of modified complex equivalent circuit can be calculated according to literature [7] as:

$$\dot{Z} = \frac{A_1 R_1 (j\omega)^{n1}}{R_1 + A_1 (j\omega)^{n1}} + \frac{A_2 R_2 (j\omega)^{n2}}{R_2 + A_2 (j\omega)^{n2}} + \frac{A_3 R_3 (j\omega)^{n3}}{R_3 + A_3 (j\omega)^{n3}}, \quad (1)$$

Where $\dot{Z}(\omega) = \dot{Z}_1 + \dot{Z}_2 + \dot{Z}_3$ is impedance of tree R||CPE parallel elements in serial connection representing mixed-phase material with notable crystal boundary effect between phases and therefore different structural and individual electrical properties. Figure 1 shows a sketch of a a-nc-Si:H film where region 1 corresponds to the amorphous, region 2 to the nano-crystal and region 3 to the crystal boundary interface components.

Other formalisms as complex admittance $\dot{Y}(\omega)$, complex permittivity $\dot{\varepsilon}(\omega)$ complex modulus $\dot{M}(\omega)$ are describe and given in previous paper [7]. The relationship between them is given as

$$\dot{Z}(\omega) = 1/\dot{Y} = \dot{Y}^{-1}, \; \dot{M}(\omega) = 1/\dot{\varepsilon} = \dot{\varepsilon}^{-1} \quad (2)$$

And

$$\dot{M}(\omega) = j\omega C_0 \cdot \dot{Z}, \quad (3)$$

Where omega is angular frequency $(\omega = 2\pi f)$, $C_0 = \varepsilon_0 A / d$ presents the capacitance of the measuring cell in vacuum without presence of sample where A is cell area and d is plate distance or sample thickness, respectively. Capacitance C_0 of a condenser with the geometry of the sample is calculated $C_0 = 6.95 \cdot 10^{-15}$ F.

Serial resistor R_s presenting measuring electrode resistance reasonable can be excluded in presented equivalent circuit model since its parameter is a few orders of magnitude less in comparison to sample DC resistance. Therefore its influence in numerical analysis can be negligible. Capacitance C_0 of a condenser with the geometry of the sample is also excluded in many discussions made in previous papers analyze [9-11]. However in presented modified equivalent circuit model calculated value C_0 is presented with equivalent capacity named C_1 and as a notable capacitive value it is taken in the consideration in fitting procedure. As a result of fitting steps C_1 will be evaluated as well.

All paper IS data are publish according to courteously from Ruđer Bošković Institute, Zagreb.

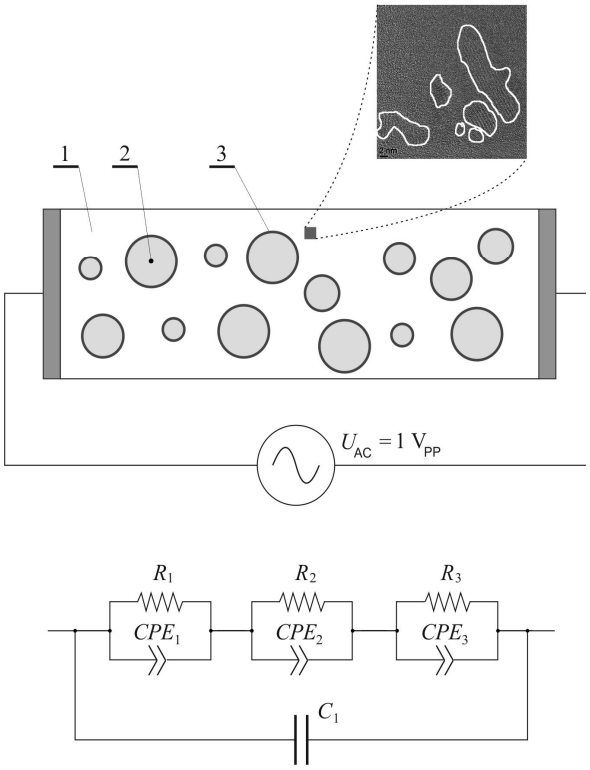

Figure 1. Sketch of the different components contributing to dark conductivity of composite sample connected to AC voltage and equivalent circuit model formed by impedances in series; 1–a-Si:H phase, 2–nc-Si:H phase, 3–Crystal boundary phase.

IV. EXPERIMENTAL RESULTS

Amorphous-nanocrystalline composite silicon thin film named G01 have been investigated in the frequency range 0.01 Hz – 10 MHz using 80 steps and $1V_{pp}$ of modulation in the temperature range from -100 °C to 120 °C . Experimental impedance data of named sample shows semicircle arcs in tree temperature cases: 80 °C , 100 °C and 120 °C [9]. Interpreting the results of AC IS experiment to give information on electrical properties (DC conductivity) or microstructure picture as existence of phases, especially for complex materials like a-nc-Si:H requires a kind of complex approach.

Predominate opinion interprets experimental IS results of composite silicon thin film in terms of series or parallel combinations of resistors and capacitors and special elements like the CPE. It is not proven jet that the complex topology of real nano-structures can be described by using other elements in combination with R-CPS series and parallel ideas. Physically is not possible to consider the complex microstructure as either a parallel or a series arrangement of phases. Rather, since the current must flow according to some arbitrary frequency through amorphous lower-conducting phase in some percolation effective path and through higher-conducting nanocrystalline phase, there is a degree of tortuosity present, which gives a more complicated, IS response. This anisotropic structure influences electronic transport, since carriers flowing between crystals (conduction path in Figure 2) will encounter more crystals boundaries then when flowing throe high resistance a-Si:H matrix.

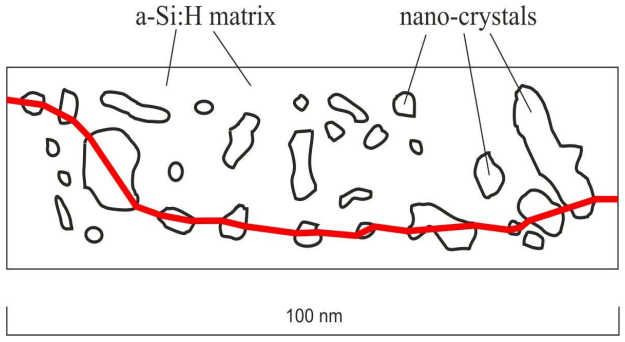

Figure 2. Geometrical model of sample G01structure derived from HRTEM [9]. Red line represents arbitrary conduction path - effective current path on some arbitrary frequency throe composite structure.

The total resistance of the circuit can easily be read from the $Z''(Z')$ curve. The presented spectrum allows clearly determination only dominant resistance amorphous phase R_1 at the beginning of the fitting procedure. Different relaxation time or time constants are detected based on peaks plots of $Z'' = \log(f)$ and electric modulus $M'' = \log(f)$, $(1/\omega_{max})_1 = \tau_1 = A_1 R_1$ and further on [7]. $-Z''$ and M''/C_0 plotted versus frequency f show two peaks for thin film sample G01. Since $-Z''_{max}$ correspond to R_2 and M''/C_0 correspond to $1/2C_1$, the conductivity and the capacitance values were determined [6, 7].

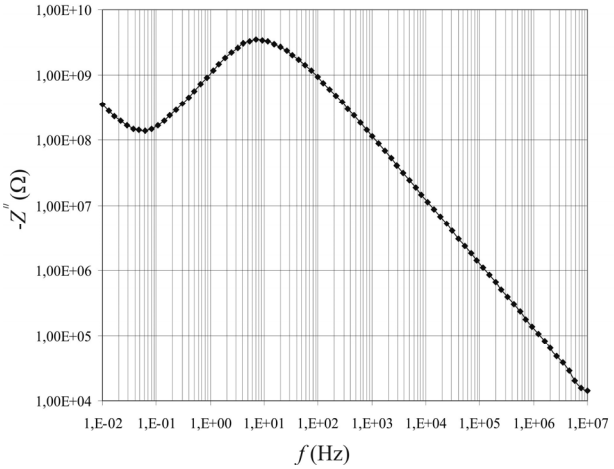

Figure 3. $-Z''$ plot versus frequency (f) of a-nc-Si:H sample G01 at temperature 120 °C .

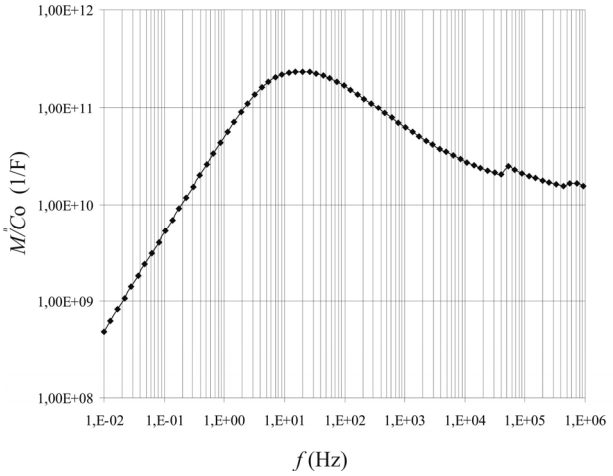

Figure 4. M''/C_0 plot versus frequency (f) of a-nc-Si:H sample G01 at temperature 120 °C .

Depending on the frequency one of the components dominates in serial connection giving us possibility to obtain its resistance R and CPE value - capacitance A.

It is possible that inclusion geometry capacitance of metal-contact interface and porous oxide influence contact/film layer also contributes to determining complexity of arcs in the impedance spectrum, and not just materials series or parallel character. But this influence is not discussed of this study.

In the IS data the dominant amorphous phase is presented by parallel R_1 and CPE_1 element and evaluated with data from Table I, especially amorphous resistance R_1=7.27 GΩ and amorphous capacitance A_1=1.5 pF as it was shown earlier in [9]. Calculated capacitance of A_1=1.25 pF from theoretical relation M''/C_0 which corresponds to value $1/2C_1$ is in good agreement with calculated one. Exponent index n_1 as no-ideality index of impedance semicircle arcs at investigated temperature 120 °C is calculated as 0.937. This index points up the inhomogeneous amorphous structure reach of dangling bonds and hydrogen atoms earlier revealed by techniques like grazing incidence X-ray diffraction (GIXRD).

Nanocrystalline-phase resistance R_2=0.877GΩ is order of magnitude lower than amorphous resistance as expected. Additional nc-Si:H phase capacitance A_2 evaluated as 3.4 pF (shown in Table II) can be expressed only according to M''/C_0 , $M'' = f(M')$ and $M'' = \log_{10}(f)$ plots. This capacitance suggests existence of second present phase: reach nanocrystalline phase. Its existence is previously evaluated thru volume fraction index Xc=33 % [11, 12]. Consequently this is not just one particular crystal size or distribution influence to overall capacitance. Nanocrystalline phase calculated capacitance A_2 =3.4 pF of a-nc-Si:H sample suggests complex connection of nano-sizes individual crystals whit substantially higher capacity than amorphous phase (A_1=1.5 pF). Furthermore, no-ideality index n_2 is calculated as 0.89. This value reveals reach capacitive nature of its phase sins its value is significantly lower than one.

TABLE I. CALCULATED VALUES EXTRACTED FROM EXPERIMENTAL IMPEDANCE DATA

Impedance plot data	Data index / units	Values
Total equivalent resistance	R_p / GΩ	8.11
Specific sample resistance	ρ_p / Ωm	811
Specific sample conductivity	σ_p / μScm^{-1}	12.33
Amorphous-phase resistance	R_1 / GΩ	7.27
Amorphous-phase specific resistance	ρ_1 / Ωcm	72700
Amorphous-phase specific DC conductivity	σ_1 / μScm^{-1}	13.85
Amorphous-phase dark pre-factor	σ_{01} / kScm^{-1}	12.2
log (freq.) plot maximum	$\log_{10} f_{2max}$ (Z)	0.875
Frequency maximum	f_{1max} / Hz	7.499
Amorphous-phase Relaxation time	$1/\omega_{1max}$ / sec.	0.0212233
Amorphous-phase non-ideality index	n_1	0.937
Amorphous-phase capacitance	A_1 / pF	1.5
Fitted Measuring cell capacitance	C_1 / pF	0.005

TABLE II. CALCULATED VALUES EXTRACTED FROM EXPERIMENTAL MODULUS DATA

Modulus plot data	Data index / units	Values
Nanocrystalline-phase resistance	R_2 / GΩ	0.877
Nanocrystalline-phase specific resistance	ρ_2 / Ωcm	87.7
Nanocrystalline-phase specific DC conductivity	σ_2 / μScm^{-1}	114.2
Nanocrystalline-phase dark pre-factor	σ_{02} / kScm^{-1}	304
log (freq.) plot maximum	$\mathrm{Log}_{20} f_{1max}$ (Z)	1.25
Frequency maximum	F_{2max} / Hz	17.78
Nanocrystalline-phase Relaxation time	$1/\omega_{2max}$ / sec.	0.00895
Nanocrystalline-phase non-ideality index	n_2	0.89
Nanocrystalline-phase capacitance	A_2 / pF	3.4
Boundary-phase resistance	R_3 / GΩ	0.013
Boundary-phase capacitance	A_3 / pF	2
Boundary-phase non-ideality index	n_3	0.83

Based on introduced improved equivalent circuit model which consists of three R||CPE elements, existence of additional capacitance A_3=2 pF suggests presence of third dielectrically phase in investigated composite material. More likely it is a boundary effect of existing potential barriers arising from the resulting space charge layer at the silicon crystals boundaries crowded with hydrogen atoms. Also another parameter which proves the specific material dielectrically properties is no-ideality index of this phase – n_3. In fitting procedure it is estimated as 0.83. This index clearly indicates different dielectric properties of its phase - more likely a quarter of nanometer wide boundary regions around formed silicon crystals formed by hydrogen atoms and therefore a weak dangling bonds presence. Another evidence of different dielectric region inherent as silicon crystals boundaries can be annotate throe boundary phase resistance R_3. Evaluated value R_3=13 MΩ is significantly lower then amorphous resistance R_2=877 MΩ proving thin hydrogen dielectric layer. Also, effective capacitance of measuring electrodes is fitted as $C_1 = 5 \cdot 10^{-15} F$ despite of its nominal value $C_0 = 6.95 \cdot 10^{-15}$ F as result of the sample geometry calculation published in [9]. It means that equivalent capacity of measuring electrodes is little bit smaller than expected. It is also prove of effective current path between electrodes despite of its geometrical shape.

It is common opinion that hydrogen presence in this region can be overcome by thermal treatment - annealing. These phenomena can be noted according to hydrogen atom redistribution in porous matrix and weak dangling bonds crystal boundary regions and predictable structural change phenomena in composite silicon thin films described elsewhere [13, 14].

All calculations based on experimental data and fitting curves on impedance and modulus data according to equations (1), (2) and (3) are shown in TABLE I and TABLE II.

V. CONCLUSION

The electric properties of amorphous-nanocrystalline silicon composite thin film were studied in a wide frequency range at different temperatures. The impedance response of a-nc-Si:H sample G01 were interpreted in terms of model of equivalent circuit with tree parallel R and CPE elements connected in serial. By the analysis of equivalent circuit impedance, combined with the analysis of experimental data of electrical modulus, it was possible to extract the resistance and capacitance contribution of all regions to the overall electrical properties of silicon composite thin films. Better model of equivalent circuit is established in the fitting process of experimental impedance data. Multi-arc behavior of experimental results had proved presumption of multi-phase existence, series arrangement of dominant amorphous and nanocrystalline phase with clearly evidence of crystal boundary effects. The non-ideality parameter $n_2 = 0.89$ highlights the capacitive nature of composite structure reach of nano-crystals embedded in amorphous matrix while another index $n_3 = 0.83$ highlights different dielectric properties of boundary regions around formed silicon crystals. The amorphous phase resistance is higher than the same of nano-crystals while a-Si:H capacitance is smaller than capacitance in nc-Si:H phase. Impedance peak against frequency is proportional to the resistance of the composite material, while the peak of electrical modulus against frequency is inversely proportional to the existing capacitance, determining equivalent circuit parameters.

So far, the observed additional specificity in the electrical and structural properties can be explained as a consequence of hydrogen effusion and redistribution in the porous film forming boundary regions around crystals with arbitrary concentrations. The analysis of the IS data confirmed that crystals and its boundary effect has great contribution in the silicon thin film sample resistance and therefore consequently its conductivity.

However, the goal of this work is quite ambitious in its choice of equivalent circuit model to be represented, and the simplicity of model investigated here may prove to be a limitation on its ultimate quantitative success. In any case, a detailed comparison of dynamical results extracted from a well-defined model, such as one derived here, and carefully measured experimental properties on acceptable temperatures will inevitably lead to a deeper understanding of silicon-hydrogen surface chemistry, interactions and coexistence in silicon thin films.

***Abstract* - In this paper, we studied the influence of the parameters of technologically relevant dielectrics (SiO_2, Al_2O_3 and HfO_2) and channel thickness downscaling on the electron mobility in InGaAs-on-insulator channels with (100) surface orientation. The study of mobility properties is enabled by a self-consistent Schrödinger-Poisson solver that is coupled with a scattering simulator based on the momentum relaxation time approximation, in order to calculate the scattering rates of electrons with acoustic, optical, remote and polar phonons, surface roughness, Coulomb impurities and alloy disorder. Simulations revealed that SiO_2 is the optimum gate dielectric material irrespective of the body thickness, followed by Al_2O_3 or HfO_2, depending on InGaAs-to-oxide surface roughness.**

Keywords* - *InGaAs-on-insulator; ultra-thin body; mobility; scattering; (100); SiO_2; Al_2O_3; HfO_2.

I. Introduction

III-V channel MOS devices draw attention due to high electron mobility and acceptable band gap. $In_{0.53}Ga_{0.47}As$, as a member of that group of materials, is one of the candidates for low-power and high-frequency CMOS applications [1]. On the other hand, InGaAs has a high dielectric constant, which makes it more susceptible to short-channel effects (SCEs). Consequently, to suppress SCEs, ultra-thin body (UTB) structures have to be employed [2-4]. The InGaAs band gap of 0.75 eV is lower than in silicon, but high enough to results in acceptable band-to-band tunneling, and consequently OFF-state current consumption. Due to scaling of bulk CMOS, the gate oxide thickness was reduced well below 5 nm, causing leakage currents due to tunneling, which lead to a high power consumption and a reduced device reliability [5]. Therefore, SiO_2 was replaced by high-*k* materials, such as Al_2O_3 and HfO_2, which provide the same capacitance as SiO_2 but with thicker oxide layers, thus eliminating the associated leakage effects [6].

This work is sponsored by the Croatian Science Foundation under the project „High-performance Semiconductor Devices for Wireless Circuit and Optical Detection Applications" (contract no. 9006)

Recently, first demonstration of InGaAs-OI with wafer size scalability up to Si wafer size of 300 mm and larger, with Al_2O_3 as gate (GOX) and buried (BOX) oxide has been reported [7]. The experimental data has shown the high electron mobility of 1700 cm^2/Vs and mobility enhancement as much as 3× against Si MOSFETs. Based on this measurement, we present in this paper the results of physics-based modeling of electron mobility in ultra-thin body (100)-oriented InGaAs-OI devices with technologically relevant materials (SiO_2, Al_2O_3 and HfO_2) as gate dielectrics. Electron mobility in UTB InGaAs-OI is investigated by examining the impact of body thickness (T_B) downscaling and of all relevant scattering mechanisms, especially the mechanisms that are inherently present in those materials, such as soft-phonon scattering. The goal is to reveal the optimum device structure considering different gate dielectric materials.

II. Physics-based Mobility Modeling

InGaAs has complex bandstructure consisting of Γ, Δ and *L* energy valleys, just like other III-V compound semiconductors. Regardless of the fact that Γ valley has the lowest conduction band energy, the energy difference between valleys is rather small which means that Δ and *L* valleys can also be filled in strong inversion. Therefore, the electrons from all three valleys are included in simulations. The equi-energy ellipsoid related to each valley is generally described with transversal (m_t) and longitudinal (m_l) effective mass. Knowing m_t and m_l, we can calculate confinement (m_z), density-of-states (m_d) and conductivity masses (m_c) based on expressions reported in [8]. By employing T_B-dependent effective masses [9] and nonparabolicity factors $\alpha_\Gamma = 1.1$, $\alpha_\Delta = 0.55$, $\alpha_L = 0.44$, the bandstructure effects appearing in extremely thin III-V devices are taken into account.

Using the self-consistent Schrödinger-Poisson solver, eigenstates and eigenfunctions of 2-D electron gas (2DEG) in the sub-20 nm-thick InGaAs channel are calculated. The solver is coupled with a scattering rate simulator that is based on the momentum relaxation time approximation (MRTA) [9, 10]. The scattering mechanisms included in

TABLE I. PARAMETERS OF POLAR PHONONS IN DIELECTRICS EXAMINED IN THIS PAPER. DATA IS TAKEN FROM [9].

Parameter	SiO_2	Al_2O_3	HfO_2
ε_0	3.9	12.53	22
ε_{int}	3.05	7.27	6.58
ε_∞	2.50	3.20	5.03
$\hbar\omega_{TO1}$ [meV]	55.60	48.18	12.40
$\hbar\omega_{TO2}$ [meV]	138.10	71.41	48.35

our model are: non-polar acoustic and optical (NPP), polar optical (POP), surface optical phonons (SOP), which must be taken into account when using high-k materials as dielectrics [11]; surface roughness (SR) scattering using Prange-Nee approximation with wave-functions that penetrate into the GOX and BOX layers; Coulomb (CO) scattering which includes scattering with ionized impurities (N_{II}) and interface charge (N_{int}); and alloy disorder (AD) scattering. Equations for each of the scattering mechanisms can be found in [9], accept for SOP scattering. For the intravalley scattering of electrons by SOPs from the i-th to j-th subband in valley v, the matrix element is given by [12]:

$$M^{i,j}_{SO,s}(q) = 4\pi^2 e^2 \left[\left| \int_0^\infty \Psi_i(z)\, \Psi_j(z)\, \varphi_{FI,s} dz \right|^2 + \left| \int_0^\infty \Psi_i(z)\, \Psi_j(z)\, \varphi_{FI,s} dz \right|^2 \right], \quad (1)$$

where $\Psi_{i,j}$ are normalized wave-functions, $\varphi_{FI,s}$ and $\varphi_{BI,s}$ are scattering potential induced by SO phonons at the front and back interface defined as [12]:

$$\varphi_{FI,s} = \left[\frac{\hbar\omega_{SO,s}}{2\pi\varepsilon_S q} \right]^{1/2} e^{-qz},$$
$$\varphi_{BI,s} = \left[\frac{\hbar\omega_{SO,s}}{2\pi\varepsilon_S q} \right]^{1/2} e^{-q(T_B - z)}, \quad (2)$$

where q is a wave-vector and s denotes one of the two SO modes included in the model. Phonon energies are weakly dependent on the wave-vector and are given by [12]:

$$\hbar\omega_{SO,1,2} = \left[\frac{\varepsilon^{(ox)}_{0,i} + \varepsilon_{InGaAs}}{\varepsilon^{(ox)}_{i,\infty} + \varepsilon_{InGaAs}} \right]^{1/2} \hbar\omega_{TO,1,2}, \quad (3)$$

where $\hbar\omega_{TO,1,2}$ are the energies of the bulk oxide optical modes, ε_0 is static dielectric constant, ε_∞ is high-frequency value for dielectric constant and ε_{int} is dielectric permittivity at intermediate frequency between $\omega_{TO,1}$ and $\omega_{TO,2}$. The values of parameters mentioned above for dielectrics of intrest are listed in Table I. Knowning the matrix element, the scattering rate is obtained by Fermi Golden rule [10]. Since multiple scattering mechanims were included in the model, total scattering rate for each subband in each valley is obtained by summing up the contributions from all mechanisms in order to find subband mobility using the Kubo-Greenwood formula [10]. The total mobility is calculated by summing up all obtained subband mobilities weighted by the corresponding subband carrier densities [9].

TABLE II. MATERIAL AND SCATTERING PARAMETERS USED IN SELF-CONSISTENT SCHRÖDINGER-POISSON AND MRTA MOBILITY SIMULATIONS.

Bulk Effective Masses			
Material		GaAs	InAs
Valley	Γ	$m_l = m_t = 0.067$	$m_l = m_t = 0.023$
	Δ	$m_l = 1.90$, $m_t = 0.19$	$m_l = 1.90$, $m_t = 0.19$
	L	$m_l = 1.90$, $m_t = 0.075$	$m_l = 1.90$, $m_t = 0.075$
Bandstructure and Scattering Parameters			
$E_\Gamma = 0.75$ eV, $E_\Delta = 1.33$ eV, $E_L = 1.21$ eV $D_{AP,\Gamma} = 7$ eV, $D_{AP,\Delta} = 9.2$ eV, $D_{AP,L} = 9.0$ eV $E_{OP} = 32$ meV, $D_{OP} = 10\times10^8$ eV/cm $E_{POP} = 32$ meV, $\varepsilon_0 = 13.94$, $\varepsilon_\infty = 11.64$ $v_{s,T} = 2974$ m/s, $v_{s,L} = 4253$ m/s, $\rho = 5506$ kg/m^3 $a = 5.868$ Å, $V_0 = 0.5$ eV, $N_{II} = 4\times10^{15}$ cm^{-3}			
InGaAs-insulator Interface Parameters			
$L = 2.6$ nm, $\Delta = 2.3$ nm, $N_{int} = 6.5\times10^{12}$ cm^{-2}			

III. MODEL CALIBRATION

The calibration of the model is carried out on the experimental data for 9 nm-thick InGaAs-OI MOSFET from [7] with 10 nm thick Al_2O_3 as gate oxide (T_{ox}) and Al_2O_3 as buried oxide (T_{BOX}) by keeping the material and phonon scattering parameters fixed, while adjusting interface charge density (N_{int}) and surface roughness parameters. Fig. 1 shows good agreement between simulation and experiment for InGaAs channel between 10 nm thick Al_2O_3 gate oxide and 15 nm thick Al_2O_3 BOX, which proves that all relevant scattering mechanisms are taken into account in the model. The discrepancy between the simulated and experimental mobility at higher N_{inv} is attributed to strong carrier screening included in the model.

In order to match the experimental data $N_{int} = 6.5\times10^{12}$ cm^{-2}, $\Delta = 2.3$ nm and $L = 2.6$ nm were used for both interfaces. Other parameters used in simulations are listed in Table II. Rather high values of surface roughness scattering parameters (Δ and L) are extracted due to the fact that only intra-subband matrix elements are used for modeling the surface roughness scattering. Effective masses required for solving Schrödinger-Poisson system are obtained by linear interpolation from GaAs and InAs effective masses. Since the initial fitting of the model was performed for 9 nm thick InGaAs-OI device, additional simulations for body thickness up to 30 nm were performed to examine mobilities for thicker body devices. Fig. 2 shows total electron mobility dependence on inversion charge density for body thicknesses from 5 to 30 nm with Al_2O_3 as gate oxide and BOX material. Also, as the body thickness is decreased, mobility is decreasing too, e.g. at $N_{inv} = 2\times10^{12}$ cm^{-2}, the decrease is equal to 84% and 38% at $N_{inv} = 10^{13}$ cm^{-2} when T_B scales down from 30 to 5 nm. The strong T_B-dependence in Fig. 2 is the result of strong volume inversion effect, resulting in a wide distribution of the inversion charge [9]. This effect is more pronounced for thicker devices. Wider distribution of the inversion charge is a result of light effective mass in Γ valley. For a thicker device, the steepness of the wave-function is smaller because of the light $m_{z,\Gamma}$ of InGaAs, whereas the light $m_{d,\Gamma}$ enables the filling of higher

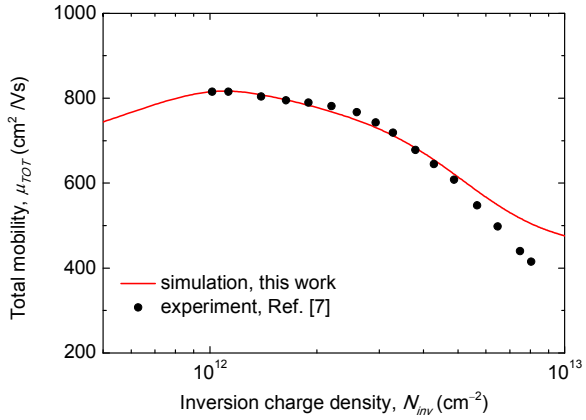

Fig. 1. Comparison between experiment and simulated electron mobility for (100)-oriented InGaAs-OI MOSFET with body thickness T_B = 9 nm, T_{ox} = 10 nm and T_{BOX} = 15 nm. Al_2O_3 is used as GOX and BOX material. Experimental data is taken from [7].

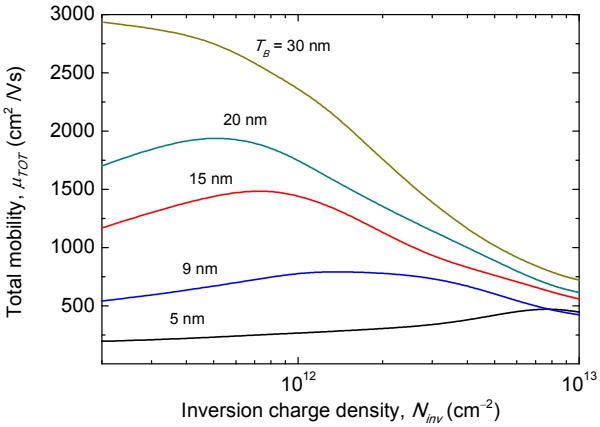

Fig. 2. Mobility in (100)-oriented InGaAs-OI MOSFET with T_B ranging from 5 to 30 nm. Al_2O_3 is used as gate oxide and BOX material (T_{ox} = 10 nm, T_{BOX} = 15 nm).

subbands in Γ valley. Due to the wider distribution and thin body, electrons experience scattering potential caused by SR and the interface charge of the bottom interface as well, although the device has single gate.

IV. Simulation Results and Discussion

The impact of using different gate dielectrics on the total mobility of the 20 nm-thick device is shown in Fig. 3. While performing simulations for different gate dielectrics, the channel material parameters and scattering parameters listed in Table II. were not modified. Depending on the type of material used as dielectric, different dielectric functions and electron affinities were used. That allows us to compare the influence of different gate dielectrics only by comparing their inherent characteristics. As shown in Fig. 3, the total mobility is significantly higher for the structure with SiO_2 gate dielectric compared to the structures with Al_2O_3 and HfO_2

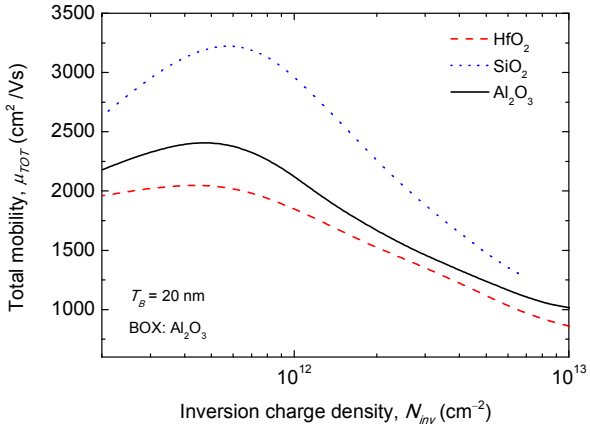

Fig. 3. Total electron mobility in (100)-oriented InGaAs-OI channel with different gate oxides and Al_2O_3 BOX for T_B = 20 nm.

as gate dielectrics. The difference is mostly pronounced at N_{inv} = 5×10^{11} cm^{-2}, where mobility of 3250 cm^2 /Vs for device with SiO_2 as gate oxide is 24% and 35% higher than mobility of devices where gate oxides are Al_2O_3 and HfO_2, respectively. Increasing the inversion charge density, the difference is smaller. At N_{inv} = 6×10^{12} cm^{-2}, mobility of the device with SiO_2 as gate oxide is 13% and 18% higher than mobility where gate oxides are Al_2O_3 and HfO_2, respectively.

The contribution of all scattering mechanisms on total mobility for each structure, is shown in Fig 4. In the case of SiO_2 as gate dielectric the mobility is dominantly determined by CO scattering at lower N_{inv}, as shown in Fig. 4. (b), while for the structures with Al_2O_3 and HfO_2, the scattering with SOP has a strong impact on the mobility both at lower and higher inversion densities (Figs. 4. (a) and (c)). The cumulative effect of CO and SOP scattering for the structures with Al_2O_3 and HfO_2 as gate dielectrics results in a slower increase of total mobility at lower inversion charge densities as compared to the structures with SiO_2 as GOX. The use of alternative high-*k* dielectrics with large difference between the static and optical permittivities, especially when used not only as gate dielectric, but also as buried oxide as in our case, increase the contribution of soft optical phonons scattering in the degradation of total mobility. As shown in Figs. 4. (a) and (c) for Al_2O_3 and HfO_2, respectively, SOP scattering has generally a stronger influence on total mobility in comparison with SiO_2 as a gate dielectric, where basically only SR and CO scattering determinate the total mobility. Also, stronger influence can be observed for HfO_2 because of lager difference in dielectric constants in comparison with Al_2O_3.

The scattering of electrons on surface roughness is more prominent for structures with high-*k* gate oxides, as can be seen by comparing Figs. 4. (a) and (b) with Fig. 4. (c). The explanation lies in the slope of the wave-function at semiconductor-insulator interface since this parameter determines the matrix element for defining

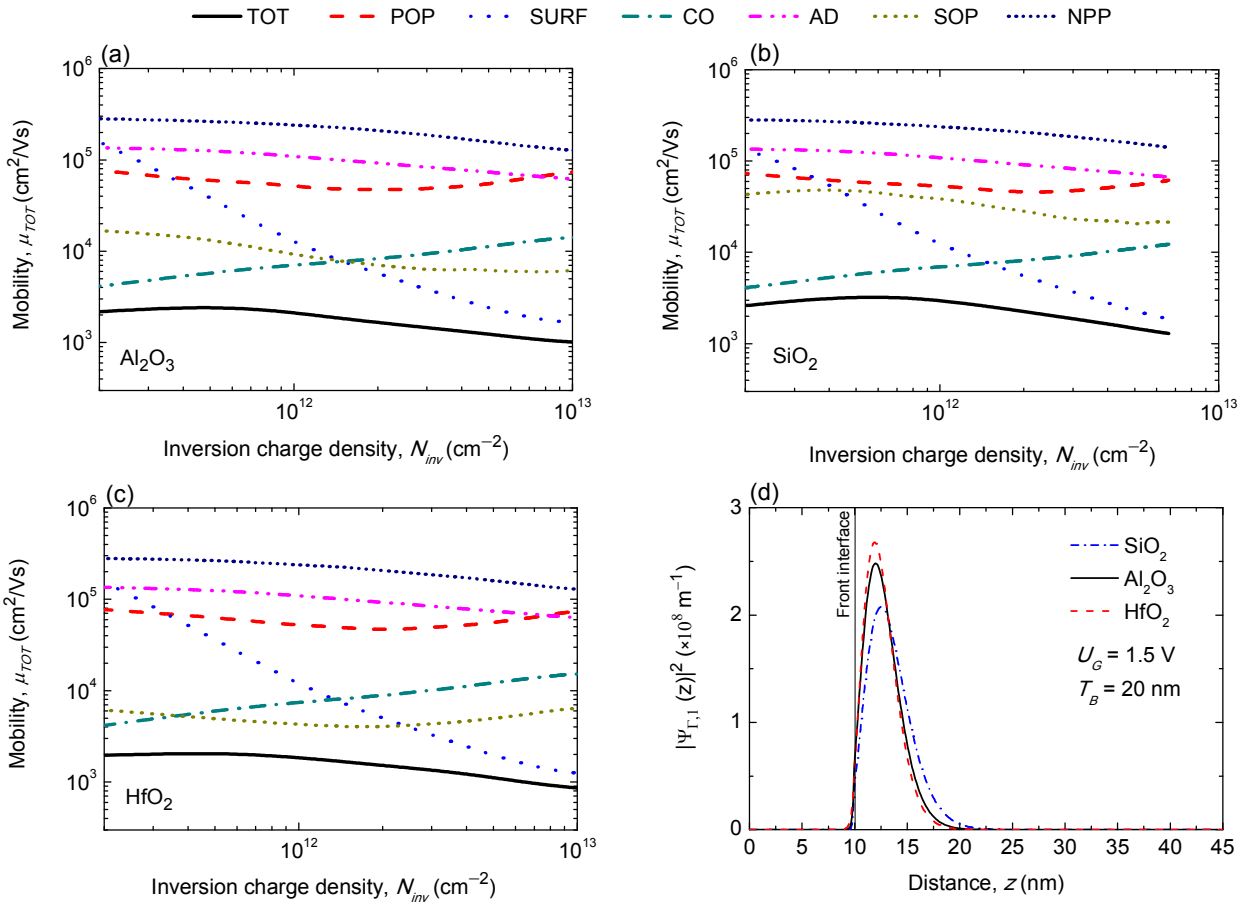

Fig 4. Dependence of mobility on inversion charge density in InGaAs-OI devices with: (a) Al_2O_3, (b) SiO_2, (c) HfO_2 as gate dielectric; (d) Γ-valley ground-state wave-function for $T_B = 20$ nm at $U_G = 1.5$ V for structures with different gate dielectric materials.

MRT in case of SR scattering [9]. Hence, Γ-valley ground-state wave-function for the structure with T_B = 20 nm at U_G = 1.5 V is shown in Fig 4. (d). The smaller wave-function slope at the front interface for the SiO_2-InGaAs-Al_2O_3 structure, in contrast to structures with high-k gate materials, is consequence of smaller dielectric constant. In general, from the flux continuity at the semiconductor-insulator interface we have:

$$F_s = \frac{\varepsilon_{ox}}{\varepsilon_s} F_{ox}, \qquad (4)$$

where $\varepsilon_{ox}, \varepsilon_s$ is the dielectric function and F_{ox}, F_s is the electric field in the oxide and the semiconductor, respectively. In accordance with (4), electric field exhibits a stronger influence in semiconductor when the gate insulator has a higher dielectric constant.

In Fig. 5, the effect of body thickness downscaling is reported for structure with Al_2O_3 as gate dielectric and BOX, i.e. the structure that was used to calibrate the model. Total electron mobility is extracted for three inversion charge density values ranging from $N_{inv} = 10^{12}$ cm^{-2} to relatively strong inversion $N_{inv} = 6\times10^{12}$ cm^{-2}. As the body thickness is scaled down, total electron mobility decreases for all three values of inversion charge density. The decrease of mobility is mostly pronounced for a weak inversion, and least for strong inversion. For the strong inversion, a sharper drop of mobility is visible for $T_B < 6$ nm.

Qualitatively, the explanation of that behaviour can be found by examining the properties of electron wave-functions in the channel. For this purpose, Γ-valley

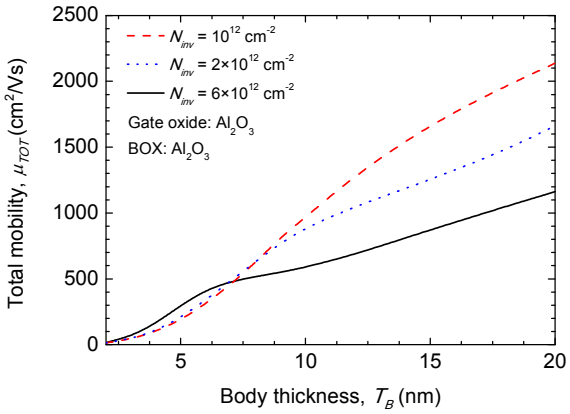

Fig. 5. Dependence of total electron mobility on body thickness for different inversion densities. Al_2O_3 is used as GOX and BOX.

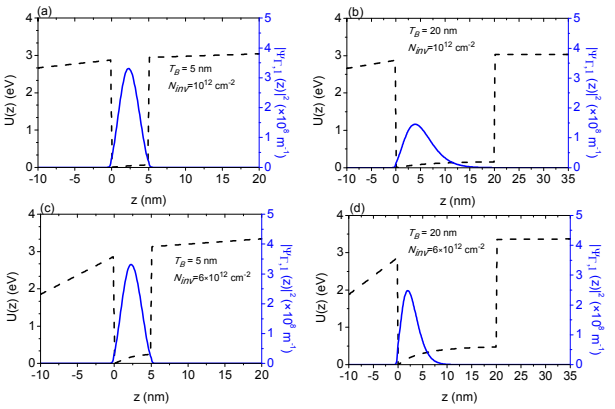

Fig. 6. Potential profiles and Γ-valley ground-state wave-functions for $T_B = 5$ nm [in (a) and (c)] and $T = 20$ nm [in (b) and (d)]. For each T_B, two cases are shown, i.e. for N_{inv} of 10^{12} cm^{-2} and 6×10^{12} cm^{-2}. Al_2O_3 is used as GOX and BOX.

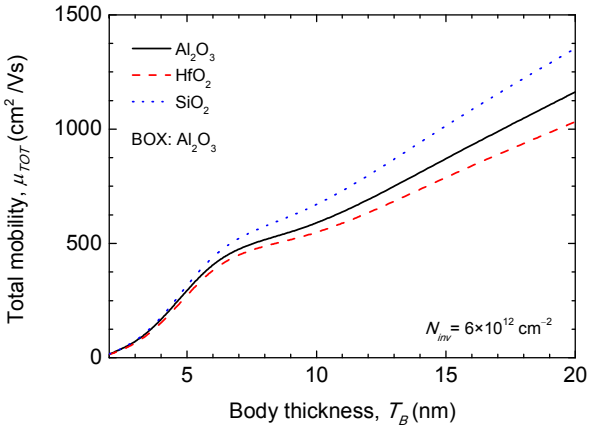

Fig. 7. Dependence of total electron mobility in InGaAs-OI devices on body thickness for different gate oxides at $N_{inv} = 6\times10^{12}$ cm^{-2} ($\Delta = 2.3$ nm, $L = 2.6$ nm).

ground-state wave-functions are shown in Fig. 6 for T_B of 5 and 20 nm, at $N_{inv} = 10^{12}$ cm^{-2} and $N_{inv} = 6\times10^{12}$ cm^{-2}. In weak inversion, due to less pronounced field-induced quantization, the Al_2O_3-InGaAs-Al_2O_3 quantum well acts more like a square well with finite walls as shown in Figs. 6. (a) and (b). As seen in Fig. 6. (b), the wave-function spreads more into the channel resulting in an increased sensitivity of scattering mechanisms to body thickness. In strong inversion (N_{inv} = 6×10^{12} cm^{-2}), the field-induced confinement is dominant and the wave-functions are positioned closer to the top interface. Thus, the impact of body thickness downscaling is less pronounced which can be seen in Figs. 6. (c) and (d).

Fig. 7 shows dependence of total mobility extracted at $N_{inv} = 6\times10^{12}$ cm^{-2} in InGaAs-OI devices on body thickness for different materials as gate dielectrics. For $T_B < 6$ nm, a sharp decrease of mobility can be observed for every examined structure. Also, for body thicknesses less than 6 nm, the values of mobility for each structure are approximately the same. Since SR scattering parameter Δ is equal to 2.3 nm, which is comparable to body thickness in this range, SR scattering is a dominant scattering mechanism defining mobility for T_B < 6 nm for each structure. As body thickness increases, mobility difference between structures is more pronounced, especially between structures with SiO_2 as gate dielectric in comparison to other two structures. The reason for this is a weaker influence of SOP scattering for higher T_B for device with SiO_2 as gate dielectric compared to the other two structures. Total mobility for the structure with SiO_2 as gate dielectric at $T_B = 6$ nm is 450 cm^2/Vs which is 8% and 13% higher than total mobilities of structures with Al_2O_3 and HfO_2, respectively. Moreover, total mobility for the structure with SiO_2 as gate dielectric at $T_B = 15$ nm is 1017 cm^2/Vs which is 14% and 22% higher than total mobilities of the structures with Al_2O_3 and HfO_2, respectively. Also, due to the stronger influence of SR scattering for device with HfO_2 as gate dielectric, mobility for that device is lower than mobility for device with Al_2O_3 as gate dielectric. With body thickness increasing, the difference between these two mobilities is increasing following the SR scattering limited mobility trend.

The impact of all scattering mechanisms for different structures is reported in Fig. 8. For every structure, the SR scattering dominantly determines the total mobility, especially for extremely thin bodies (T_B < 6 nm). Dominant influence of SR scattering is expected because of choosing quite high values of SR scattering parameters (Δ and L) already explained in Section II. The second relevant mechanism, particularly for structures with Al_2O_3 and HfO_2 as gate dielectrics is SOP scattering. Since the scattering potential of the SO phonons is defined with exponential function for front and back interface (2), thus a considerable body thickness dependence is expected, as can be seen in Fig. 8.

Assuming a smaller Δ that could be achieved in modern III-V manufacturing, the total mobilities for each structure are obtained and reported in Fig. 9. Compared to the results for higher values of Δ (see Fig. 7), mobility difference between structures with SiO_2 as gate dielectric in comparison to the other two structures is more pronounced. Also, mobility for HfO_2-InGaAs-Al_2O_3 device has slightly higher values of mobility for T_B

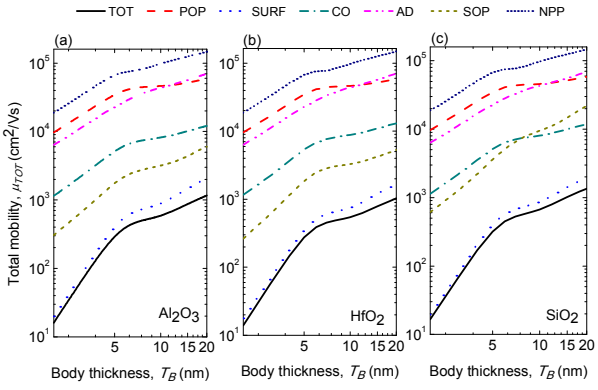

Fig. 8. Impact of different scattering mechanisms in InGaAs-OI devices with Al_2O_3 as BOX and different gate oxides at $N_{inv} = 6\times10^{12}$ cm^{-2} ($\Delta = 2.3$ nm, $L = 2.6$ nm).

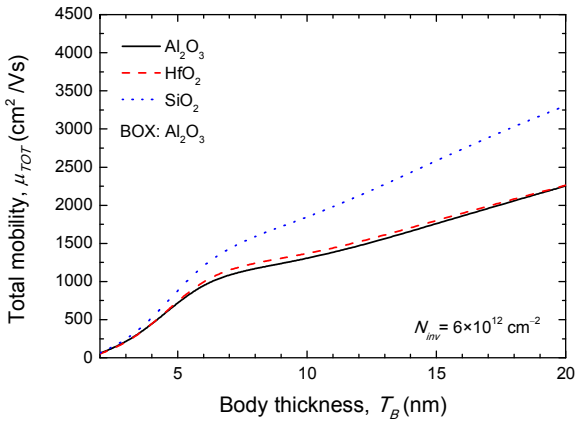

Fig. 9. Dependence of total electron mobility in InGaAs-OI devices on body thickness for different gate oxides at $N_{inv} = 6\times10^{12}$ cm^{-2} with decreased influence of SR scattering ($\Delta = 1$ nm, $L = 2.6$ nm).

between 6 and 15 nm in comparison to mobility for Al_2O_3-InGaAs-Al_2O_3 device. With smaller Δ, total mobility for structure with SiO_2 as gate dielectric at $T_B = 6$ nm is 1223 cm^2/Vs thus 21% and 17% higher than total mobilities of structures with Al_2O_3 and HfO_2, respectively. Additionally, the total mobility for SiO_2-InGaAs-Al_2O_3 device at $T_B = 15$ nm is 2589 cm^2/Vs which is 32% and 31% higher than total mobilities of the structures with Al_2O_3 and HfO_2, respectively.

As shown in Fig. 10, for the structures where Al_2O_3 and HfO_2 are gate dielectrics, mobility is dominantly determined both with SOP and SR scattering. Cumulative effect of these two scattering mechanisms at lower N_{inv} and effect of SOP scattering at higher N_{inv} are producing more pronounced mobility difference in comparison with the mobility of SiO_2-InGaAs-Al_2O_3 device where total mobility is still determinated only by SR scattering. Higher mobility for device with HfO_2 as gate dielectric compared to Al_2O_3-InGaAs-Al_2O_3 device is result of stronger influence of SOP scattering and weaker influence of SR scattering for $T_B > 6$ nm.

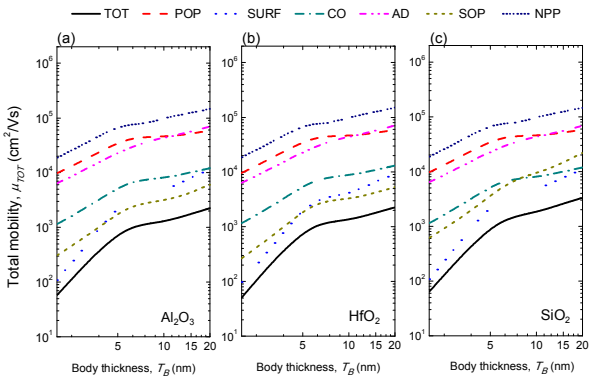

Fig. 10. Impact of different scattering mechanisms in InGaAs-OI devices with Al_2O_3 as BOX and different gate oxides on body thickness at $N_{inv} = 6\times10^{12}$ cm^{-2} with decreased influence of SR scattering ($\Delta = 1$ nm, $L = 2.6$ nm)

V. Conclusion

In this paper, the results of physics-based modeling of electron mobility in InGaAs-OI devices with technologically relevant gate dielectrics (SiO_2, Al_2O_3 and HfO_2) are presented. With body thickness downscaling, the total electron mobility decreases monotonically in all the examined structures and for all values of inversion charge density. The simulations have shown that SiO_2 is the optimum gate dielectric material in terms of carrier transport as it exhibits the highest mobility values in the entire T_B range investigated in this work. For $T_B > 6$ nm, mobility difference between the SiO_2-InGaAs-Al_2O_3 devices and alternative structures is more pronounced due to a weaker influence of SOP scattering resulting in mobility of 450 cm^2/Vs for SiO_2-InGaAs-Al_2O_3 device at $T_B = 6$ nm (8% and 13% higher than in structures with Al_2O_3 and HfO_2 as gate oxide, respectively). Assuming smaller Δ, mobility difference between structures with SiO_2 in comparison to the other two structures is even more pronounced due to the cumulative effect of SOP and SR scattering in devices with high-k oxide materials. The resulting mobility is 1223 cm^2/Vs at $T_B = 6$ nm for SiO_2-InGaAs-Al_2O_3 structure, i.e. 21% and 17% higher than in devices with Al_2O_3 and HfO_2, respectively.

Impact of the Emitter Length Scaling on Electrical Characteristics of Horizontal Current Bipolar Transistor with Single Polysilicon Region

Abstract - Emitter length scaling of HCBT with single polysilicon region is investigated by 3D device simulations with the emphasis on the high frequency characteristics. It is shown that collector current and junction capacitances have linear dependence on the emitter length. Collector resistance can be represented by two components which appear in parallel, one that scales proportionally with the emitter length and a constant part which describes lateral portion of the extrinsic transistor. Cut-off frequency is improved for small emitter area devices due to current spreading in the collector region which reduces the current density and causes the base push-out at higher collector currents. The effect cannot be captured by scalable transistor model and separate set of model parameters is needed for transistors with very small emitter size.

I. INTRODUCTION

Scalability of transistor models used in circuit simulators is a highly desirable property. With the technology progress and scaling, small geometry effects arise requiring separate set of model parameters for devices of different scale, often referred to as parameter binning. This modeling approach is implemented in modern circuit simulators and is found as an option in all models suitable for submicron CMOS technologies such as BSIM3 [1] and BSIM4 [2].

Horizontal Current Bipolar Transistor (HCBT) is a lateral bipolar transistor which is integrated with standard 180 nm CMOS with small number of additional process steps [3]. Low-cost and high-performance characteristics make HCBT suitable for fabrication of RF circuits for wireless applications. RF mixer reported in [4] was designed by using Gummel-Poon model extracted for unit size single polysilicon region HCBT [5]. Unit transistors were added in parallel where higher collector current drive was required. HCBT emitter is defined by polysilicon etching process and its height is given by the technology. Therefore, the collector current in the circuit design can be tuned by changing the emitter length or by adding transistors of unit size in parallel, the former being the more flexible solution. In order to address the ability to make scalable HCBT models, impact of lateral scaling of the emitter length and lateral portion of the extrinsic transistor is investigated by 3D device simulations.

This work has been supported by the Croatian Science Foundation under the Project no. 9006.

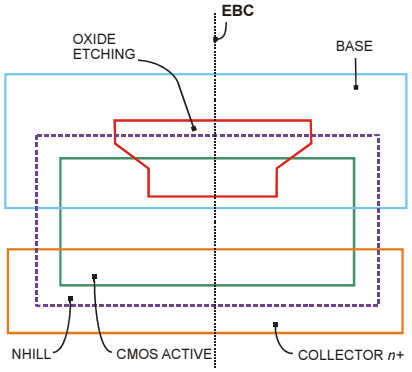

Fig.2. Lithography masks important for the fabrication of HCBT.

II. DEVICE STRUCTURE

3D model of the single polysilicon region HCBT used in the simulations is presented in Fig. 1 and the lithography masks important for the fabrication of the HCBT regions are shown in Fig. 2. HCBT is fabricated in silicon island defined by the CMOS shallow-trench-isolation (STI) using a *CMOS active* mask (Fig. 2). Intrinsic collector marked as *n*-hill in Fig. 1 is defined by dedicated implantation using a *nhill* mask (Fig. 2). Extrinsic base is implanted on the top surface of the silicon island using a *base mask* (Fig. 2) and is extended laterally across the whole active area to accommodate for mask misalignment. Emitter trench is defined by oxide wet etching using an *oxide etching mask* (Fig. 2), which has to be narrower than the CMOS active exposing only a

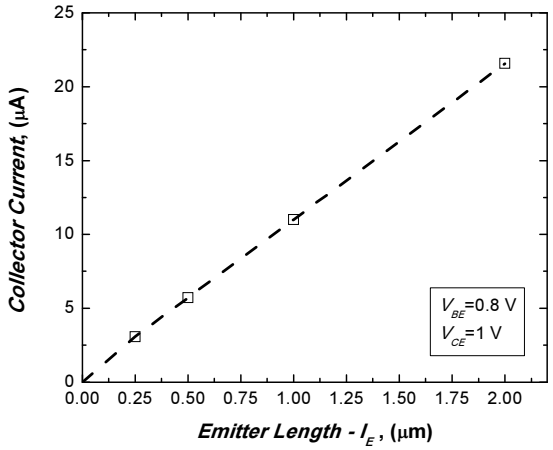

Fig.4. Simulated collector currents (I_C) for different emitter length (l_E) at V_{BE}=0.8 V and V_{CE}=1 V. Dashed line presents linear interpolation of simulated results showing linear scaling of I_C with l_E.

portion of STI sidewall, where intrinsic transistor is fabricated. The intrinsic base is fabricated by angled ion implantation using the *base mask* again (Fig. 2). Implant is done on the sidewall exposed by oxide etching with the remaining oxide serving as a hard mask, self-aligning the intrinsic base to the shape of the trench. The emitter is fabricated by deposition and etch-back of *in-situ* doped amorphous-silicon, which crystallizes during the emitter drive-in annealing. In this way, the emitter and the intrinsic base are self-aligned resulting in the state-of-the-art electrical performance. Transistor has a very small emitter height (h_E in Fig. 1) of around 80 nm, which is considerably smaller than the minimum lithography resolution. Due to the small h_E, one-sided base contact can be tolerated achieving the maximum oscillation frequency (f_{max}) comparable to the best reported vertical-current bipolar transistors with implanted base [6]. An extrinsic collector (i.e. collector contact region) is formed during CMOS source/drain implantation by using a *collector n+* mask, which is available from the CMOS.

Since the emitter trench has to be narrower than the active region, a certain lateral overlap of the extrinsic base with respect to the intrinsic base exists (bo in Fig. 1). The emitter trench defines the emitter length (l_E), which can be changed in the circuit design in order to tune the transistor operating current. These two parameters are changed by the lateral scaling. Additional geometrical parameters that can be changed by transistor mask layout are an extrinsic base width (w_{bext}) and a distance between the extrinsic base and the collector contact region (d_c). These parameters should be kept as small as possible since w_{bext} affects collector-base capacitance (C_{jBC}) and d_c affects collector series resistance (R_C). The lower limit is set by the formation of reliable base contact in case of w_{bext} [7] and by the base-collector junction breakdown in case of d_c. Geometrical parameters are summarized in Table 1. All doping profiles in the transistor are defined as analytical Gaussian profiles. Vertical collector doping profile is a steep profile reported in [8], which is optimized for maximum f_TB_{VCEO} product. It should be noted that the intrinsic base profile in fabricated devices is steeper than the Gaussian resulting in slightly higher cut-off frequency (f_T) obtained by the measurements reported in [8] compared to the simulations presented in this paper. Nevertheless, the results are within 20 % margin and only relative comparison of simulation results was important for this study. Since the transistor is symmetrical with respect to the middle of the emitter (*EBC* line in Fig. 2), only half of the transistor is simulated in order to save computational time.

III. ANALYSIS OF ELECTRICAL CHARACTERISTICS

Simulated Gummel characteristics for the structure with l_E=1 μm and bo=0.3 μm at V_{CE}=2 V are shown in Fig. 3. Scaling of the collector current (I_C) is investigated by simulating transistors with different l_E and bo=0.3 um and with the same terminal voltages applied, i.e. at V_{BE}=0.8 V and V_{CE}=1 V. Results are represented by symbols in Fig. 4. Dashed line shows the linear interpolation of simulated points indicating linear scaling of I_C with the l_E.

Simulated cut-off frequency (f_T) for structures with different l_E and bo=0.3 μm are shown in Fig. 5. It can be seen that maximum value of f_T falls from 31.2 GHz to 28.3 GHz or by 9.3 % if l_E is increased from 0.25 μm to 2 μm. It can also be observed that maximum f_T settles to constant value for larger l_E. For example, if l_E is increased from 1 to 2 μm, f_T is reduced by only 2 %. Additionally, peak f_T value is shifted to higher collector currents for structures with larger l_E, which is expected since fall-off of f_T is caused by the Kirk effect [9] which starts at the certain collector current density. Cut-off frequency depends on the time constants associated with the charges stored in the transistor regions and is given by [9]:

$$\frac{1}{2\pi f_T} = \tau_F + \frac{kT}{I_C}\left(C_{jBE} + C_{jBC}\right) + \left(R_C + R_E\right)C_{jBC} \qquad (1)$$

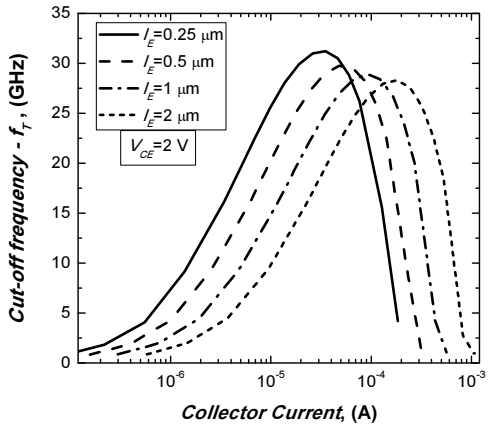

Fig. 5. Simulated cut-off frequency (f_T) dependence on collector current for structures with different emitter length (l_E) and base overlap bo=0.3 μm.

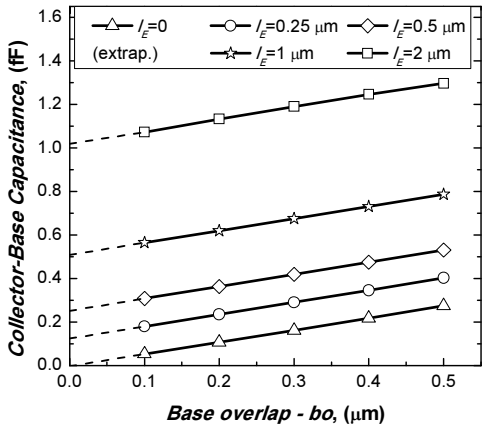

Fig.7. Extracted collector-base junction capacitance for structures with different base overlap(bo) and emitter length (l_E). Extrapolated values for l_E=0 are added to demonstrate linear scaling of capacitances.

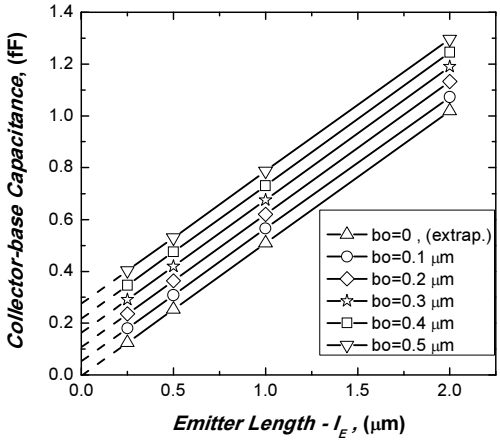

Fig.6. Extracted collector-base junction capacitance for structures with different emitter length (l_E) and base overlap(bo). Extrapolated values for bo=0 are added to demonstrate linear scaling of capacitances.

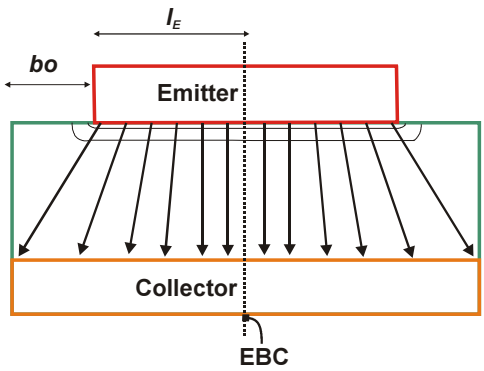

Fig. 8. Current spreading in the collector. Due to larger collector length (l_E+bo) compared to the emitter length (l_E) current spreads laterally. The effect is more pronounced for transistors with smaller l_E. Cross-section parallel to wafer surface is shown. Parameters l_E and bo of simulated half-structure are marked for reference.

where τ_F is forward transit time consisting of base and base-collector depletion region transit times, C_{jBE} and C_{jBC} are base-emitter and base-collector depletion region capacitances and R_C and R_E are collector and emitter series resistances, respectively. Since the intrinsic doping profiles are the same in all simulated structures, the forward transit time should be the same for all of them. In order to address influences of terms in (1), C_{jBC} and R_C are extracted from the simulated electrical characteristics of HCBT structures with different geometries. The emitter length (l_E) and the extrinsic base overlap (bo in Fig. 1) are varied in simulations.

C_{jBC} is extracted from AC simulation performed at low frequency (f=50 MHz) at the bias point with V_{BE}=0.8 V and V_{CE}=2 V. The dependence of C_{jBC} on l_E and bo are shown in Figs. 6 and 7. The results are shown twice in order to demonstrate that capacitances scale linearly both with l_E and bo. Also, extrapolated C_{jBC} for bo=0 (in Fig. 6) and l_E=0 (in Fig. 7) are shown to demonstrate that capacitance extrapolate to zero when both bo and l_E tend to zero. As a result we can conclude that C_{jBC} scales linearly with lateral dimensions and that the same behavior can be expected for C_{jBE}. Therefore, the second term in (1) is the same for all structures regardless of l_E since both I_C (see Fig. 4) and C_{jBC} (Figs. 6 and 7) rise linearly with l_E. Component R_EC_{jBC} from the third term in (1) is very small since R_E is order of magnitude smaller than R_C. Furthermore, R_E depends on the emitter polysilicon sheet resistance and scales linearly with l_E, similar as in case of integrated resistors. Therefore, component R_EC_{jBC} should be independent on l_E, since C_{jBC} rises and R_E falls linearly with l_E. On the other hand, R_C cannot be expected to scale linearly with l_E since electrons can spread when they leave collector-base depletion region and enter the neutral collector (see Fig. 8). This depends on the relative difference in collector and emitter length [10]. The collector length is equal to l_E plus bo. For smaller l_E and larger bo, the collector current spreading should be more pronounced. R_C is extracted from the saturation region of the output characteristics [11] of simulated HCBT structures with different l_E and bo. Results are shown in

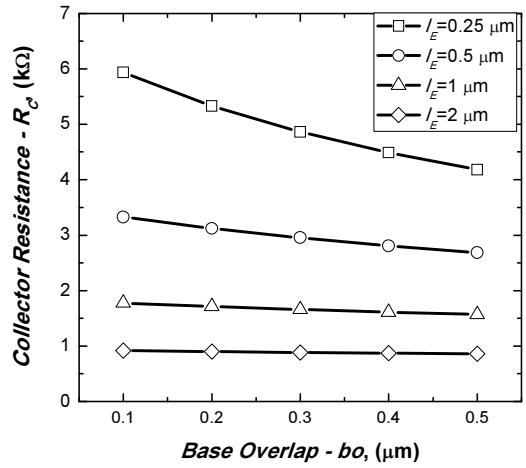

Fig. 9. Extracted series collector resistances (R_C) for structures with different overlap(bo) and emitter length (l_E).

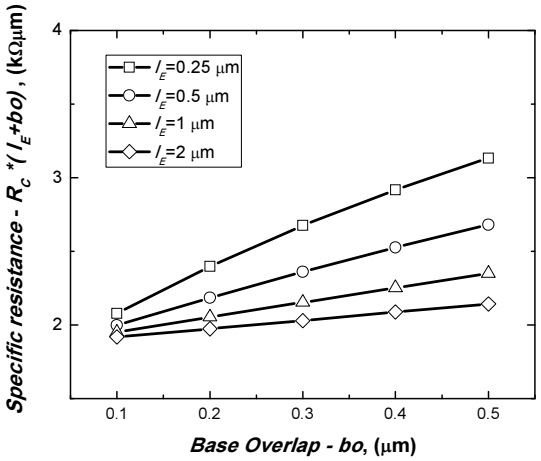

Fig. 10. Calculated collector specific resistance for structures with different overlap(bo) and emitter length (l_E).

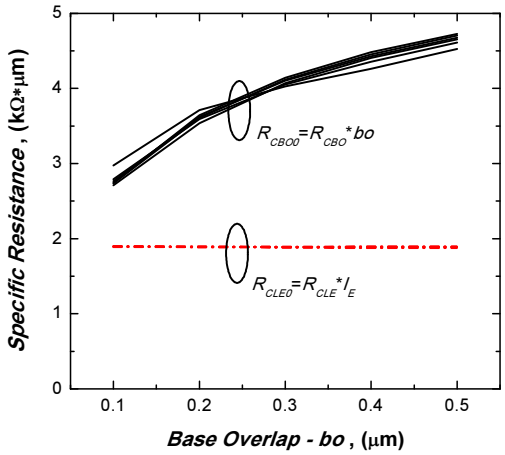

Fig. 11. Calculated collector specific resistance components for structures with different overlap (bo). Resistances are calculated by solving 6 sets of two equations obtained by permuting equations (3) for different l_E. There are 6 curves for R_{CLE0} basically overlapping.

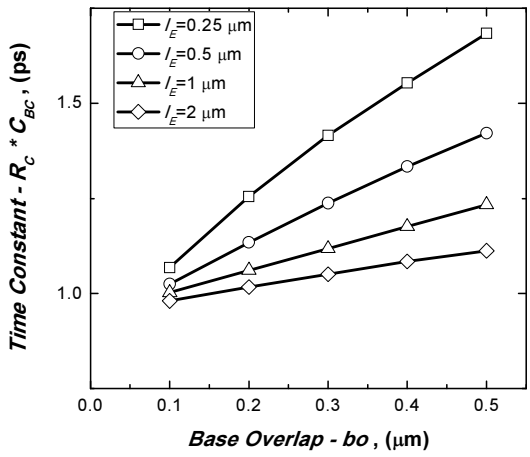

Fig. 12. Transistors' R_CC_{jBC} time constants calculated from the extracted transistor parameters for structures with different base overlap(bo) and emitter length (l_E)

Fig. 9. It can be seen that R_C doesn't have linear dependence on bo, which is more pronounced for transistors with small l_E.

This is confirmed by plotting specific collector resistance (in Fig. 10), calculated as a product of the extracted R_C and the collector length (l_E+bo). Since the lines are not flat, dependence of R_C on l_E+bo is not linear. It can also be seen that lines representing specific resistance are tending to a single point if bo tends to zero. This means that component of collector series resistance arising from the portion of collector overlapped by the emitter window (defined by l_E), scales linearly with l_E. The non-linear dependence of R_C on l_E+bo arises from the nonlinear dependence of the R_C component determined by the bo overlap of collector. Therefore, R_C could be decomposed into two components, R_{CLE} which scales linearly with l_E and R_{CBO} which has a non-linear dependence on bo. Those two components appear in parallel and a set of equations for different l_E and fixed bo can be written as:

$$\frac{1}{R_{Ci}} = \frac{1}{R_{CLEi}} + \frac{1}{R_{CBO}} \tag{2}$$

where we have assumed that component R_{CBO} is the same for all structures with the same bo and different l_E. Next, since we postulate that R_{CLE} scales linearly with l_E, we can write:

$$\frac{1}{R_{Ci}} = \frac{l_{Ei}}{R_{CLE0}} + \frac{1}{R_{CBO}} \tag{3}$$

where R_{CLE0} is specific resistance. We have extracted R_{Ci} of 4 simulated structures with 4 different l_{Ei} and we can write i=4 equations. There are only two unknowns (i.e. specific resistance R_{CLE0} and resistance R_{CBO}) and the system is redundant since we can construct 6 sets of two equations by permuting those 4 equations. Solutions of all 6 sets for each bo are shown in Fig. 11. It can be observed that specific resistances R_{CLE0} calculated from all 6 equation sets overlap, showing that the same result is

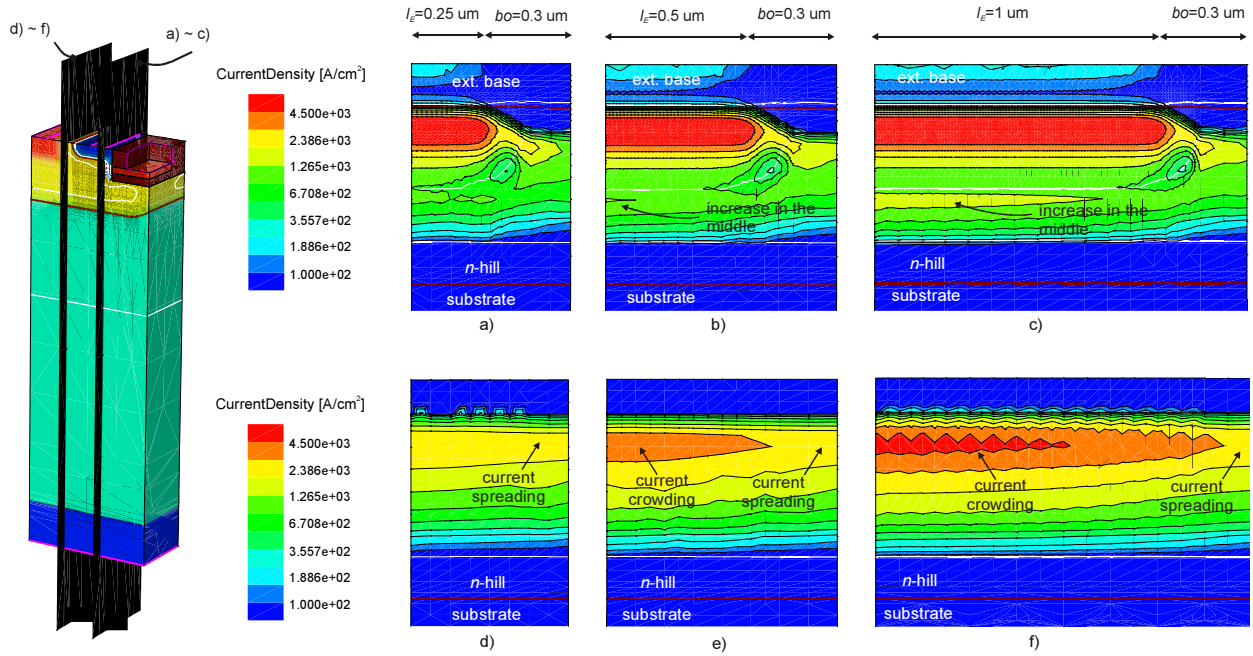

Fig.13. Current density at cross sections across base-collector depletion region (a~c) and close to the collector contact region (d~f). 3D model with marked cross-sections is given for reference.

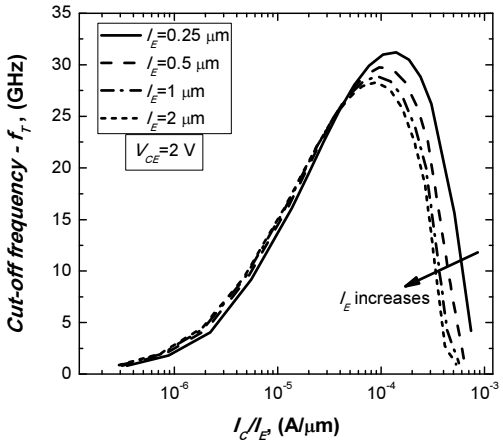

Fig. 14. Simulated cut-off frequency (f_T) dependence on collector current normalized to the emitter length (l_E) for structures with different emitter length (l_E) and base overlap bo=0.3 μm.

obtained for any combination of l_E meaning that R_{CLE0} specific resistance component is constant and independent on l_E. Therefore the assumption that R_{CLE} scales linearly with l_E is valid since it fits well to simulated data. Furthermore, the lines representing R_{CLE0} are flat indicating linear scaling of R_{CLE} resistance component with l_E regardless of bo. The results obtained for specific resistance R_{CBO0} component are calculated as a product of R_{CBO} obtained as a solution from the 6 equation sets with bo. Results also overlap within reasonable margin indicating that it is independent on l_E, but dependence on bo is non-linear. This leads us to the conclusion that in order to obtain scalable model, R_C can be modeled by two components - R_{CLE} which scales linearly with l_E and R_{CBO} which is independent on l_E and is constant for fixed bo.

Time constant R_CC_{jBC} calculated from extracted R_C (Fig. 9) and C_{jBC} (Fig. 6 and 7) is shown in Fig. 12. The largest time constant is observed for transistor with smallest l_E. This is contrary to the highest f_T result from Fig. 5 meaning that R_CC_{jBC} is small enough for all simulated structures and that it has minor influence on f_T compared to other terms in (1). It can also be seen that as bo increases, R_CC_{jBC} increases for all structures meaning that the increase of C_{jBC} is stronger than the decrease of R_C, which can be observed as a saturation of extracted R_C in Fig. 9 in case of larger bo.

In order to identify the reason for improved f_T of small l_E transistors, current distributions in the intrinsic base-collector depletion region and near the collector contact region are plotted for structures with different l_E at the same bias point (i.e. V_{BE}=0.8 V and V_{CE}=2 V). The results for transistors with l_E=0.25, 0.5 and 1 μm are shown in Fig. 13. For transistors with larger l_E increase of current in a cross-section close to the intrinsic base-collector junction (Fig. 13a~c) appears below the white line which marks the depletion region edge. This means that portion of current is pushed downwards. In case of smaller l_E transistors, this increase is not observed meaning that current spreads laterally. This is also observed in a cross section close to the collector contact region (Fig. 13d~f) where we can see that for larger l_E, region of higher current density appears near the middle of the transistor. This increase of the current density can cause the onset of base push-out (i.e. Kirk effect) and reduce the maximum f_T. To confirm this, the results from Fig. 5 are plotted against collector current normalized to l_E in Fig. 14. Since current is scaled linearly with l_E (see Fig. 3) we can conclude about local current density from the onset of

Kirk effect. It can be observed that peak f_T is shifted to smaller normalized I_C/l_E for structure with larger l_E. f_T fall-off and therefore Kirk effect starts earlier meaning that local current density is higher. Current spread for small l_E is more pronounced and current density is locally reduced causing the Kirk effect at larger I_C/l_E.

IV. CONCLUSION

Impact of the emitter length scaling of HCBT with single polysilicon region is investigated by 3D device simulations. The collector current and junction capacitances have linear dependence on the emitter length. Collector resistance can be modeled by the parallel combination of the constant resistance representing the extrinsic transistor and the one seen from the emitter window, which scales linearly with the emitter length. Cut-off frequency (f_T) of HCBT with single polysilicon region is improved for transistors with small emitter length. Current spreading in the collector reduces the collector current density and postpones the onset of base push-out to higher collector currents. It was shown that f_T is improved by approximately 10 % compared to long emitter devices. From the perspective of device modeling this imposes the constraint on the usage of HCBT models in circuit simulator. Separate set of model parameters should be given for transistors with small emitter length.

Abstract - In this paper, the effect of the floating guard ring (FGR) parameters, such as number of FGRs and the distances between the FGRs, on the prevention of the breakdown at the multiplication layer edge for a given avalanche photodiode (APD) structure has been analyzed. Four structures are examined: APD without FGR and APDs with one, two and three FGRs. The width and depth of the boron-doped FGRs is 1 µm with peak concentration of 10^{18} cm^{-3}. The intrinsic breakdown voltage in the active region of the APD is 371 V and the epitaxial layer is fully depleted at 14 V. The breakdown occurs in the active area of the APD structure by using three FGRs. The optimal position of three FGRs are determined and the breakdown voltage of 409 V is achieved at the multiplication edge, which is higher by 38 V than in the active region. In contrast, the edge breakdown voltage is 170 V, 270 V and 348 V for structures without floating guard rings, with one FGR and with two FGRs, respectively. Spectral responsivity of the structure is analyzed in the range of 400 to 1000 nm showing that such APD can be effectively used for detection of the visible light.

I. INTRODUCTION

Avalanche photodiodes (APDs) are commonly used devices for photon detection in optical communication systems because of their high gain, high sensitivity and high quantum efficiency [1], [2]. Additionally, the APDs are also exploited in laser systems, ceilometers and astronomical observations. Mostly exploited structures are beveled edge diode, reach through diode and guard ring diode [3]. The diodes with guard rings are compatible with planar technologies such as CMOS [3], which make them attractive for numerous applications.

Separate-absorption-and-multiplication (SAM) APDs with thin pn-junction have lower noise and higher operating speed as compared to APDs with a single absorption-multiplication region [4]. SAM APD structures have an accumulation region with low electric field with the main purpose of photon absorption, and a multiplication region with high electric field, where the avalanche multiplication occurs [4].

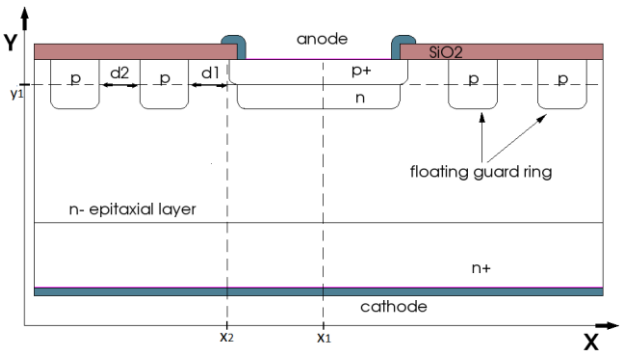

Figure 1. Cross section of simulated APD.

SAM APDs have a lower multiplication noise because either holes or electrons are causing impact ionization. Multiplication gain is not uniform and it depends on the wavelength of the incoming radiation.

APD structure has to be carefully designed such that the highest impact ionization is located in the active part of the device, where the incident radiation is absorbed. The critical part of the photodiode structure is the multiplication layer edge, where the premature breakdown can occur. The built-in electric field is higher at the edge of the multiplication region due to junction curvature, which can increase the noise of the APD, reduce the gain, and also reduce the desired breakdown voltage (V_{BR}). There are several techniques used to solve this problem, including metal plates located above the diode [5], shallow trench isolation (STI) [6], diffused guard rings and floating guard rings [6], [7]. Adding the guard ring close to the multiplication region edge will decrease the electric field near the multiplication junction, due to the reduced curvature, which will increase the local breakdown voltage. Choosing the optimum parameters of the FGRs such as the number of guard rings, position and the doping profile is critical. The goal of the optimization of the floating guard ring parameters is that the breakdown voltage of the multiplication region edge should be higher than the breakdown voltage of the active part of the structure. It must be kept in mind that the number of the

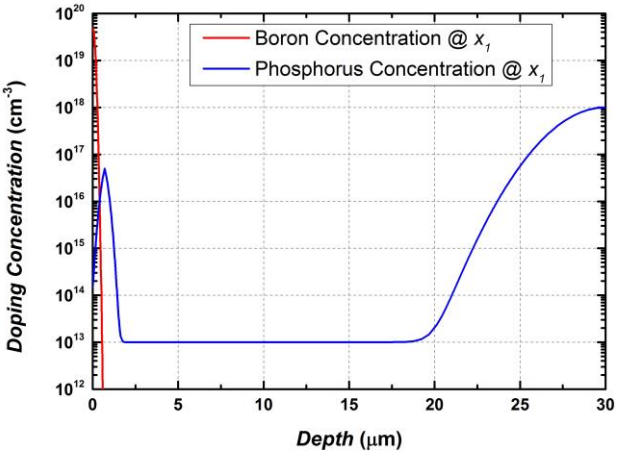

Figure 2. Doping profile in the active area part of the APD structure at the lateral distance of 75 μm (x_1 in Fig. 1).

FGRs should be minimal since every FGR adds a "dead region" to the whole photodiode structure, leading to a smaller photon absorption efficiency due to lower fill factor.

In this paper, we analyze how the change of the FGR parameters such as the number of FGRs and the distances between the FGRs prevents the breakdown at the multiplication region edge for a given APD structure. Four structures are analyzed: structure without FGR and structures with one, two and three FGRs. The optimal position and the parameters of FGRs are determined using the device simulation software. The spectral responsivity of the proposed structure is also analyzed.

II. APD STRUCTURE

Cross section of the simulated silicon photodiode is shown in Fig. 1. All the simulations have been performed using Sentaurus TCAD software [8]. Active part of the APD consists of the highly doped boron region with the thickness of 0.4 μm and the peak doping concentration of $5 \cdot 10^{19}$ cm^{-3} at the surface. Multiplication region is formed by defining an n-type Gaussian doping profile with the peak concentration of $5 \cdot 10^{16}$ cm^{-3} at the depth of 0.7 μm. Consequently, the pn-junction depth is 0.4 μm. Epitaxial layer is defined as uniformly doped layer with the concentration of 10^{13} cm^{-3}. Back side of the APD is doped by phosphorus with the peak concentration of 10^{18} cm^{-3}. Doping profile in the active part of the structure is shown in Fig. 2. Dimensions of the structure cross-section are 150 x 30 μm.

III. ELECTRICAL SIMULATIONS

Electrical simulations are performed using the following physical models. *Masetti* model for mobility degradation due to the impurity scattering is used. *Canali* model is used to simulate carrier velocity saturation due to high electric field. The *Slotboom* model is used for the bandgap narrowing model. Three generation-recombination models are used in the simulations: *SRH*, *Auger* and *van Overstraeten-de Man* for modeling the impact ionization generation [9].

The APD structure described in the section II has V_{BR} of 170 V. Comparison of the electric field at the edge of the multiplication region and in the active part of the structure is shown in Fig. 3. The electric field at the edge is higher than the electric field in the active part of the structure due to the junction curvature and a higher electric field. Consequently, the breakdown occurs at the edge of the multiplication region, leading to a higher optical sensitivity at the edge instead in the active region and preventing photogenerated carriers from obtaining sufficient energy in multiplication region, which could limit the gain.

The V_{BR} of the active region is obtained by 1D simulations of the intrinsic part of APD and equals 371 V, which is considerably higher than V_{BR} of 170 V resulting from 2D simulations. In order to improve APD characteristics and achieve the breakdown in the multiplication region, in the value obtained by 1D simulations, the guard rings should be added to the periphery of the structure. In this work we used the

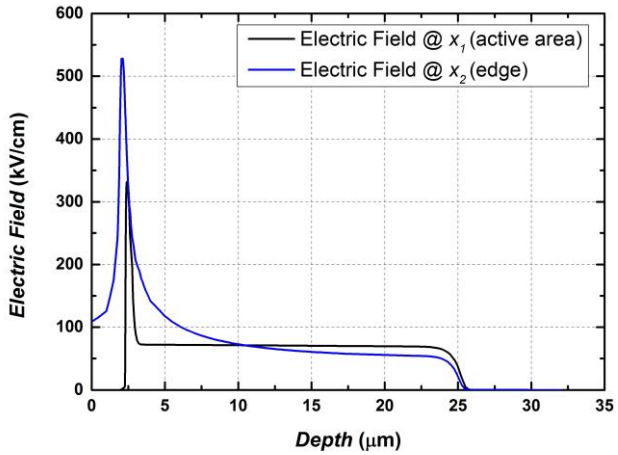

Figure 3. Electric field in the center of the active part of the structure (black line) and at the edge of the multiplication region (blue line) of the photodiode at the reverse bias V_D = 170 V.

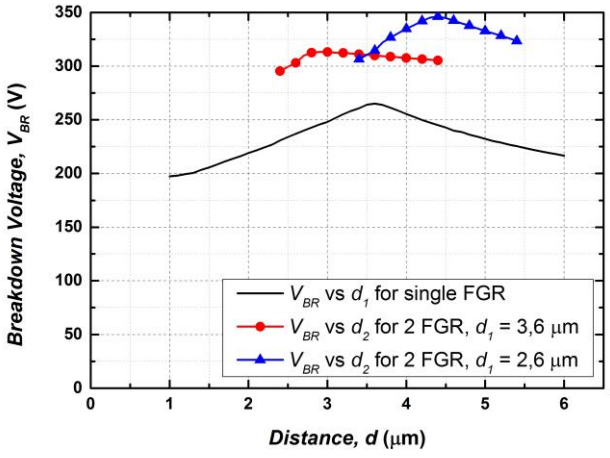

Figure 4. Breakdown voltage vs distance between the FGR and the multiplication region (black line) and breakdown voltage vs. the distance between the FGRs for d_1 = 3.6 μm (circles) and d_1 = 2.6 μm (triangles).

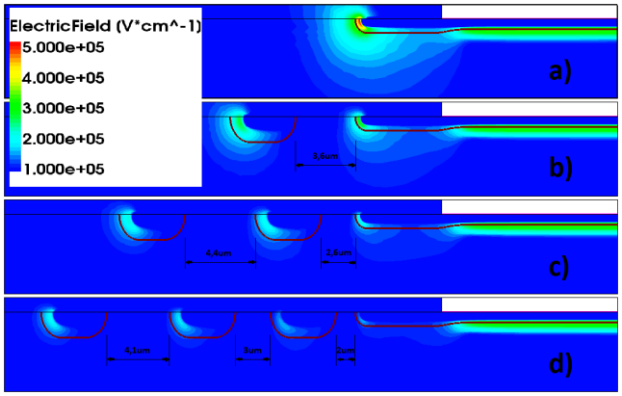

Figure 5. Electric field distribution at V_D = 160 V for the structure (a) without FGR, (b) with single FGR, (c) with two FGRs and (d) with three FGRs.

floating guard rings. The on-mask width of the FGRs is 1 µm, the junction depth is 1 µm, whereas the surface concentration is 10^{18} cm^{-3}.

Firstly, the addition of a single FGR to the periphery of the structure will be analyzed. In order to achieve the highest V_{BR}, the position of the first FGR has been varied with respect to the edge of the multiplication region (d_1). The maximum value of V_{BR} of 270 V is achieved for d_1 of 3.6 µm. For d_1 < 3.6 µm, the breakdown occurs at of the periphery of the FGR. For d_1 > 3.6 µm, the breakdown occurs at the edge of the multiplication region.

The next step is the addition of another FGR since only one FGR was unable to prevent the premature breakdown. The distance of the second FGR with respect to the first FGR (d_2) is also varied to determine the maximum V_{BR}. After adding the second FGR, it is necessary not only to find the optimal position of the second FGR, but also the optimal position of the first FGR. The highest V_{BR} of 348 V is achieved for d_1 = 2.6 µm and d_2 = 4.4 µm, which is still below the V_{BR} in the active region obtained by 1D simulation. Breakdown voltage versus the FGRs distances is depicted in Fig. 4. For the structure with two FGRs, choosing d_1 at the maximum V_{BR} does not result with the highest V_{BR} for varied d_2. As already mentioned, the position of the first

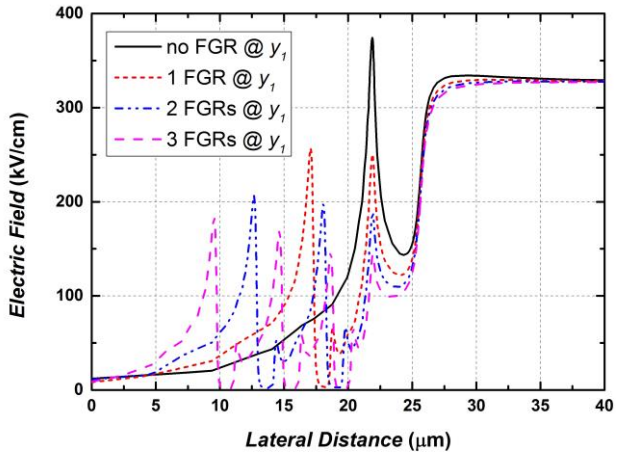

Figure 6. Electric field distribution at the edge of the multiplication region at the depth of 0.4 µm, V_D = 160 V.

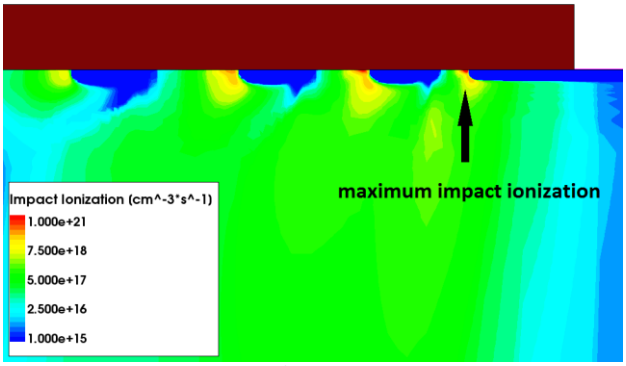

Figure 7. Impact ionization of the structure without multiplication region with three FGRs, d_1 = 2 µm, d_2 = 3 µm, d_3 = 4.1 µm. V_D = 409 V.

FGR needs to be optimized as well to achieve the highest V_{BR}. Finally, the third FGR has been added to the structure. The distance between the third FGR and the second FGR (d_3) is also varied to determine the maximum V_{BR}. After the optimization of d_1, d_2 and d_3, the highest breakdown voltage of 409 V has been achieved for the parameters d_1 = 2 µm, d_2 = 3 µm and d_3 = 4.1 µm. In order to reach the breakdown at the edge, higher than V_{BR} in the active region, such simulations has to be performed without the multiplication region in the active part of the structure. Distribution of the electric field for structures without FGRs, and with one, two and three FGRs at V_D = 160 V is depicted in Fig. 5. For the structure without FGRs, the electric field at the edge is larger comparing to the electric field in the multiplication region. In the structure with a single FGR the electric field is distributed between the FGR and the edge of the multiplication layer resulting in the reduced peak value. However, for lower V_D, the electric field increases faster at the edge of FGR as compared to the electric field in the multiplication region. Eventually, the breakdown will occur at the same place. Adding the second FGR causes the electric field to spread over the FGRs more uniformly, which decreases the field at the edge of the multiplication region. By adding the third FGR, the electric field has the highest value in multiplication region, while the field at the edge is redistributed between the FGRs. By adding FGRs, a better electrical isolation in photodiode's periphery is achieved, which means that the current is directed toward the active area of multiplication region. Electric field distribution at the depth of 0.4 µm, where its peak in the multiplication region is expected, is

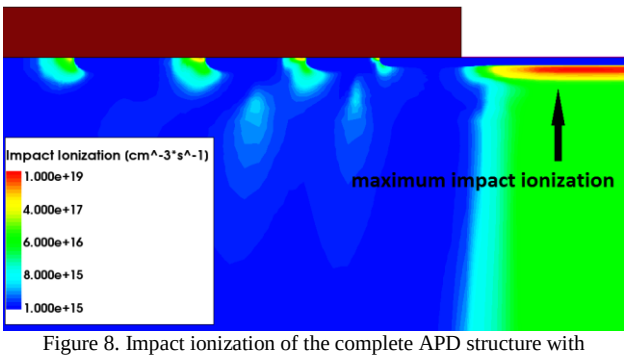

Figure 8. Impact ionization of the complete APD structure with multiplication region. V_D = 371 V.

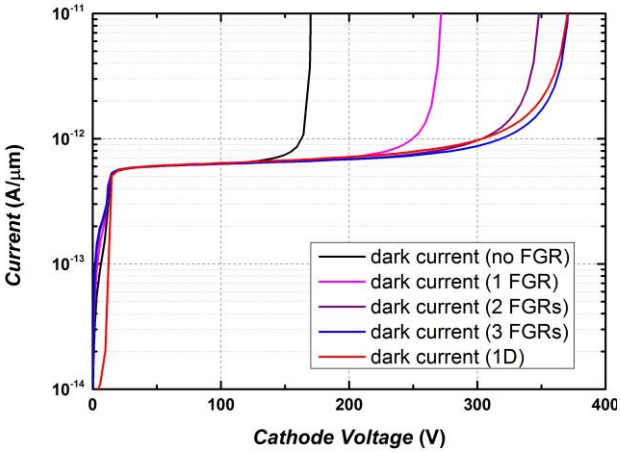

Figure 9. I-V characteristics of the structures without and with one, two and three FGRs.

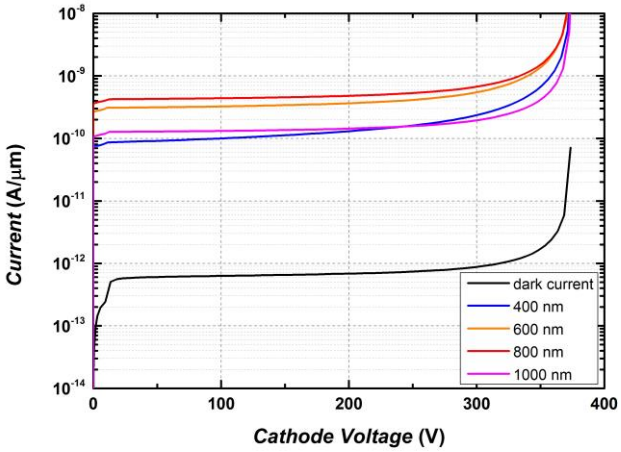

Figure 10. I-V characteristic of the optimized structure with three FGRs for different wavelengths. Light source intensity is 10^{-3} W/cm^2. TMM model is used in the simulations.

shown in Fig. 6. The diode voltage is V_D = 160 V, which is below V_{BR} of the structure without FGRs. Although the electric field at the edge of the multiplication region and guard rings does not have the maximum value at a given depth, it can be observed how FGRs reduce the electric field. Impact ionization at V_D = 409 V of the optimized structure with three FGRs and without the multiplication region is depicted in Fig. 7. Maximum impact ionization is at the edge of the structure, showing the location of the breakdown. The breakdown for structure without FGRs occurs at the same place. The V_{BR} at FGRs is 38 V higher than the V_{BR} of the multiplication region. Such a difference should be sufficient to compensate the process variations in reality.

Impact ionization for the structure with multiplication region is shown in Fig. 8. By adding the multiplication region, the maximum impact ionization is now shifted to the active part of the structure indicating the position of the breakdown. The I-V characteristics for the aforementioned structures are shown in Fig. 9. I-V characteristics show that the full depletion of the structure is at V_D = 14 V. Also, the increase of dark currents in the structures with added FGRs is negligible. The simulations were performed neglecting the silicon/oxide interface traps.

IV. OPTICAL SIMULATIONS

The optical simulations have also been performed for the optimized structure with 3 FGRs. Light source with intensity of 10^{-3} W/cm^2 and with varied wavelengths is assumed. The I-V characteristics of the dark and illuminated structures are shown in Fig. 10. Wavelengths of the light source are 400 nm, 600 nm, 800 nm and 1000 nm. In simulations silicon band gap is taken into account for describing how many of the absorbed photons are converted to generated electron-hole pairs. Wavelength dependent refractive and absorption index has been used. An illumination window is defined only over the active area. The gain dependency on diode voltage is depicted in Fig. 11 for APD illuminated with wavelength of 600 nm and light source intensity of 10^{-3} W/cm^2.

The avalanche multiplication does not have a significant impact on the APD performance for voltages below 350 V. The higher diode voltages cause a higher impact ionization and a higher internal gain of the structure caused by the avalanche multiplication. In the subsequent optical analysis, the diode is biased at 372.26 V, which corresponds to the gain of 50.

Spectral responsivity of the optimized APD structure for gain of 50 is shown in Fig. 12 using two simulation models. Black curve represents responsivity simulated with model where only the Beer-Lambert law for light absorption is included. Responsivity has values over 20 A/W for wavelengths from 415 to 830 nm, which means that the analyzed structure can be effectively used for detection of visible spectrum light. Red curve represents responsivity with simulated Transfer Matrix Method (TMM) model, where the reflection, transmission and total absorption is included in the simulations. This gives more realistic model for the optical detection. Responsivity with the TMM model is 35% lower compared to the first model at the wavelength of 600 nm. This can be improved if an anti-reflecting coating is applied on APD surface.

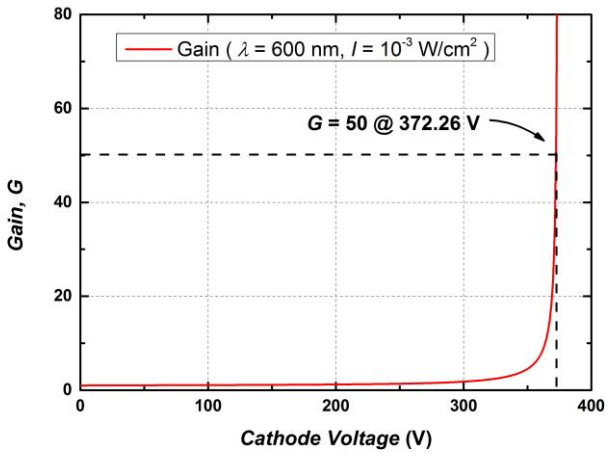

Figure 11. Gain vs the diode voltage for illuminated APD. Light source intensity is 10^{-3} W/cm^2 and the wavelength is 600 nm.

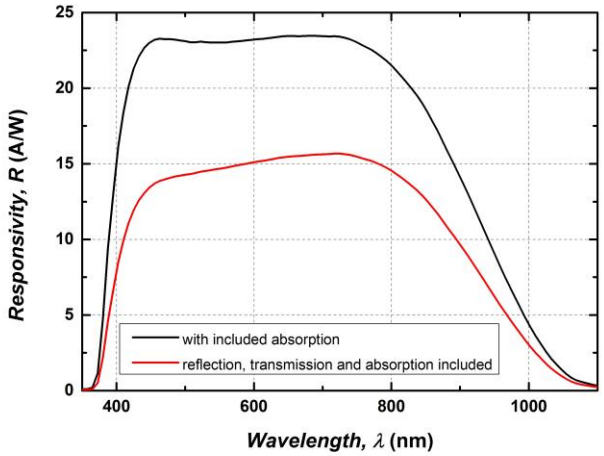

Figure 12. Spectral responsivity of the structure at V_D = 372.26 V for light source intensity of 10^{-3} W/cm^2.

V. CONCLUSION

It has been shown in the paper that APDs can suffer from premature breakdown at the edge of multiplication region. For that reason it is necessary to implement guard rings around photosensitive area. Edge breakdown has been successfully prevented by using three floating guard rings. After adding FGRs, the highest value of breakdown voltage of 409 V is achieved for structure without multiplication region and with the parameters d_1 = 2 µm, d_2 = 3 µm and d_3 = 4.1 µm. The breakdown of APD with the multiplication region is 371 V as predicted in 1D model, and it occurs in the multiplication region. The optical responsivity dependency on wavelength has shown that the simulated structure is suitable for the visible light detection.

Low-Power Low-Voltage CMOS Analog Signal Processing Circuits Using a Functional Core

Cosmin Popa
Faculty of Electronics, Telecommunications and Information Technology
University Politehnica of Bucharest
e-mail: cosmin_popa@yahoo.com

Abstract **- The paper presents an original approach of designing analog signal processing circuits, based on the re-using of the same functional core for implementing a multitude of circuit functions: signal gain with theoretical null distortions, signal squaring, voltage multiplying with very good linearity and simulation of a perfect linear resistor with both positive and negative equivalent resistance. The great advantages of the increased modularity and controllability and of the reduced design costs represent an immediate consequence of the multiple functions realized by the proposed structures. Because the most important circuit complexity is concentrated in implementing the core of the multifunctional structure, both circuit area and power consumption per each realized function can be strongly reduced using this method, especially for multifunctional structures that are able to implement an important number of functions. The overall error of the linear designed computational structures is *0.4%* and the approximation error for the squaring circuit is *0.27%*, in the condition of a low-voltage low-power operation (a supply voltage of *1.5V* and a medium current consumption of *50μA* for each implemented circuit function).**

Keywords - analog signal processing, functional core, linearity, multifunctionality, low-voltage low-power operation

I. INTRODUCTION

Analog signal processing (ASP) structures are extensively used in the latest VLSI designs. Even their capability of generating circuit functions is very wide, most of these functions are developed starting from a relatively limited number of primitive functions. From this point of view, it could be identified two important classes of ASP structures: with linear and nonlinear behavior. The nonlinear components from the operation of an ASP structure are usually related to polynomial functions or, in most cases, to squaring function (because of the extensively use of the squaring characteristic specific to a MOS transistor biased in saturation).

We will present in this paper an intuitive design of ASP circuits that is able to generate using an original method a multitude of linear and nonlinear circuit functions.

An important goal in ASP is represented by the possibility of reusing the same functional core for implementing a multitude of circuit functions, the increased modularity that could be achieved being reflected in an important reduction of the design costs per implemented function.

The proposed ASP circuit realizes the following circuit functions:

- Signal gain with theoretical null distortions using a transconductance amplifier circuit;
- Signal squaring with increased accuracy using a squaring circuit;
- Simulation of a perfect linear resistor with both positive and negative resistance using an active resistor circuit;
- Voltage multiplying with very good linearity using a multiplier circuit.

The transconductance amplifier is an important stage in VLSI designs, having many applications in a large area of high-performances analog/mixed ICs, such as operational amplifiers, voltage comparators, voltage regulators, video amplifiers, modulators and demodulators or A/D and D/A converters. The linearity of the circuit is limited because of the squaring characteristic of MOS transistors biased in saturation, being possible to achieve a relatively good linearity only for a limited input voltage range. Thus, the transconductance amplifiers require the implementation of a linearization technique for decreasing the superior-order nonlinearities and for increasing the maximal range for the input voltage amplitudes. There were reported in literature many techniques [1]-[4] for improving the MOS transconductance amplifier linearity.

Squaring circuits [5]-[8] are very important CMOS analog signal processing structures, finding multiple applications in analog and mixed-signal designs. Their implementations are relatively simple using the squaring characteristic of the MOS transistor biased in saturation.

CMOS active resistors [9]-[18] are widely used in VLSI analog designs for replacing the large value passive resistors, having the great advantages of the controllability of the equivalent resistance. Amplitude control in low distortion oscillators, voltage controlled amplifiers and active RC filters represent their usual utilisation domains. The first generation of MOS active resistors [11], [12] exploits the quasi-linear characteristic of MOS transistors working in the linear region. The disadvantage of this approach of designing active resistor structures is that the circuit operation is inherently nonlinear and the distortion components depend on MOS technological parameters. An improved method for obtaining CMOS active resistors exclusively uses MOS transistors biased in saturation. A multitude of linearization techniques [12]-[17] have been implemented in order to minimize the nonlinearity of active resistor circuits. The active resistor structures offer the

possibility of obtaining a controllable negative equivalent resistance, finding very large domains of applications.

Multiplier circuits represent intensively used blocks in telecommunication applications, medical equipments, hearing devices and disk drives. In order to improve the linearity of a classical multiplier structure, specific techniques [18]-[21] have been reported in literature.

II. THEORETICAL ANALYSIS

A. Design of the functional core

A functional core represents a computational circuit having a reasonable complexity that is able to generate a multitude of circuit functions.

The most important advantage of the proposed method of designing analog signal processing circuits using a functional core is related to the multifunctional capability. As the most important design effort is concentrated for improving the performance of the functional core (which is common for all the implemented circuit functions) and because this core has the largest complexity, all designing costs per each implemented function will be strongly reduced comparing with classical approaches of designing analog signal processing circuits. Additionally, the power consumption for an implemented function can be reduced because the functional core consumes the most important power of the circuit.

The proposed implementation of the functional core is presented in Fig. 1. It consists in a differential amplifier, having a composing MOS transistor biased at a constant reference current, I_O.

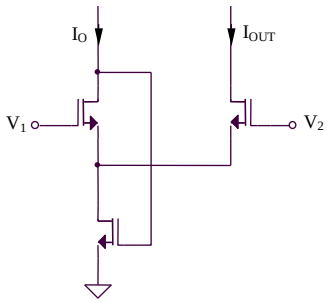

Fig. 1. Functional core

The differential input voltage of the functional core can be expressed as follows:

$$V_1 - V_2 = V_{GS}(I_O) - V_{GS}(I_{OUT}). \quad (1)$$

Biasing in saturation all MOS transistors from Fig. 1, it results:

$$V_1 - V_2 = \sqrt{\frac{2}{K}}\left(\sqrt{I_O} - \sqrt{I_{OUT}}\right). \quad (2)$$

The expression of the functional core output current will be:

$$I_{OUT} = I_O - \sqrt{2KI_O}(V_1 - V_2) + \frac{K}{2}(V_1 - V_2)^2. \quad (3)$$

The advantage of this implementation is given by the availability of both linear and squaring terms with respect to the differential input voltage variable, $V_1 - V_2$.

B. Design of a linear transconductance amplifier

In order to obtain a linear transconductance amplifier, two parallel-connected functional cores from Fig. 1 will be used, resulting the transconductance amplifier circuit presented in Fig. 2.

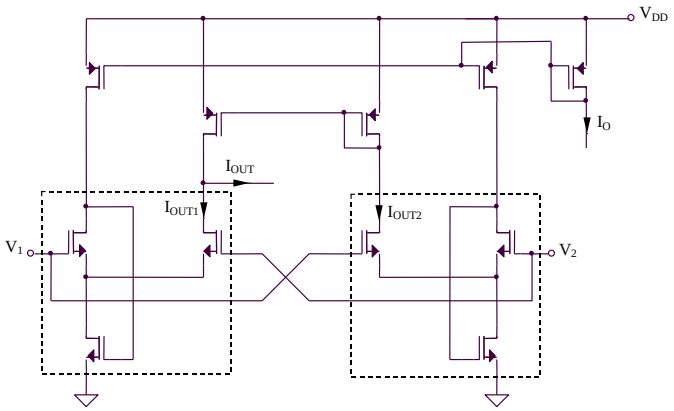

Fig. 2. Transconductance amplifier

The expressions of I_{OUT1} and I_{OUT2} currents are:

$$I_{OUT1} = I_O - \sqrt{2KI_O}(V_1 - V_2) + \frac{K}{2}(V_1 - V_2)^2 \quad (4)$$

and:

$$I_{OUT2} = I_O + \sqrt{2KI_O}(V_1 - V_2) + \frac{K}{2}(V_1 - V_2)^2. \quad (5)$$

The output current of the transconductance amplifier will be expressed by:

$$I_{OUT} = I_{OUT2} - I_{OUT1} = \sqrt{8KI_O}(V_1 - V_2). \quad (6)$$

illustrating a linear dependence of the I_{OUT} output current on the $V_1 - V_2$ differential input voltage.

C. Design of a squaring circuit

The squaring function can be obtained using the last term from the expression (3) of the functional core output current. Considering the sum of I_{OUT1} and I_{OUT2} output currents from Fig. 3, expressed by (4) and (5), the linear term with respect to the differential input voltage will be cancel out:

$$I_{OUT} = I_{OUT1} + I_{OUT2} - 2I_O = K(V_1 - V_2)^2. \quad (7)$$

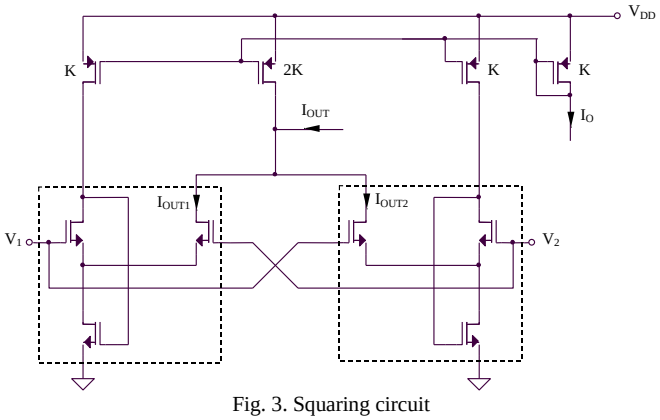

Fig. 3. Squaring circuit

D. Design of a linear multiplier circuit

The original idea for obtaining the multiplying function (Fig. 4) is to use an anti-parallel connection of two functional cores from Fig. 1, M1-M3 and M4-M6, respectively. The I_{O1} and I_{O2} currents are generated using two parallel-connected differential amplifiers, M7-M10.

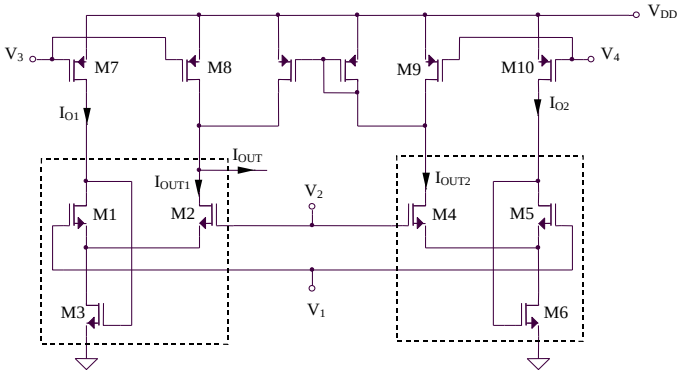

Fig. 4. Multiplier circuit

The expressions of I_{OUT1} and I_{OUT2} output currents are:

$$I_{OUT1} = I_{O1} - \sqrt{2KI_{O1}}(V_1 - V_2) + \frac{K}{2}(V_1 - V_2)^2 \qquad (8)$$

and:

$$I_{OUT2} = I_{O2} - \sqrt{2KI_{O2}}(V_1 - V_2) + \frac{K}{2}(V_1 - V_2)^2, \qquad (9)$$

while I_{OUT} current can be expressed as follows:

$$I_{OUT} = (I_{OUT2} - I_{O2}) - (I_{OUT1} - I_{O1}) = \\ = \sqrt{2K}\left(\sqrt{I_{O1}} - \sqrt{I_{O2}}\right)(V_1 - V_2) \qquad (10)$$

Replacing the squaring dependencies of I_{O1} and I_{O2} currents on the source-gate voltages of M7-M10 transistors, it results:

$$I_{OUT} = K(V_1 - V_2)(V_4 - V_3). \qquad (11)$$

E. Design of linear positive and negative active resistor circuits

In order to simulate an active resistor circuit with improved linearity, the proposed method is to consider two functional cores from Fig. 1 and to pass between the input terminals the difference of their output currents, $I_{OUT2} - I_{OUT1}$, expressed by (6) (Fig. 5). Because of a linear current-voltage characteristic, it is possible to define an equivalent resistance between V_1 and V_2 as follows:

$$R_{ECH} = \frac{V_1 - V_2}{I_{OUT2} - I_{OUT1}} = \frac{1}{\sqrt{8KI_O}}. \qquad (12)$$

The equivalent resistance can be controlled by the I_O reference current.

Changing the sense of the current passing between the input terminals (Fig. 6), it is possible to obtain a controllable negative equivalent resistance:

$$R_{ECH}' = \frac{V_1 - V_2}{I_{OUT1} - I_{OUT2}} = -\frac{1}{\sqrt{8KI_O}}. \qquad (13)$$

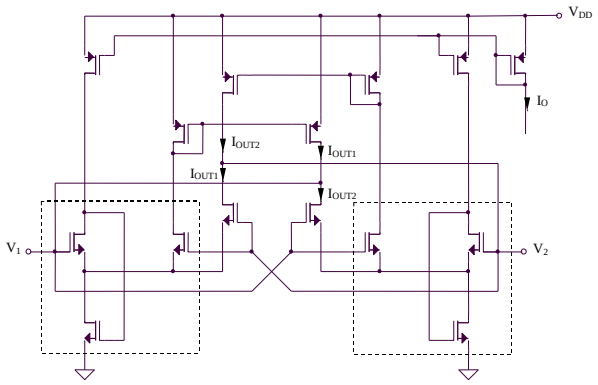

Fig. 5. Active resistor with positive equivalent resistance

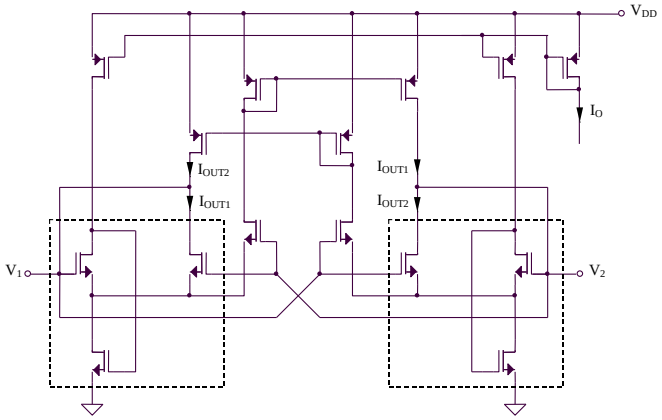

Fig. 6. Active resistor with negative equivalent resistance

III. SIMULATIONS

The simulation of the transconductance amplifier transfer characteristic (6) is presented in Fig. 7, illustrating an excellent linearity (a simulated linearity error of *0.4%*).

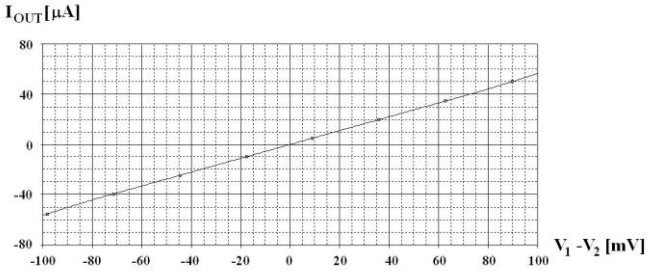

Fig. 7. Simulated transfer characteristic of the transconduactance amplifier

The simulation of the squaring circuit characteristic (7) is presented in Fig. 8, resulting a simulated approximation error $\varepsilon = 0.27\%$.

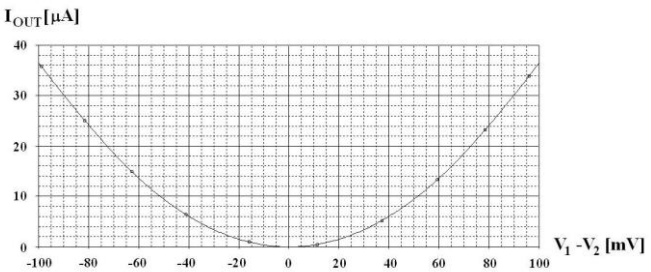

Fig. 8. Simulated characteristic of the squaring circuit

The simulations were made using SPICE, for a 0.35 μm CMOS process.

IV. CONCLUSIONS

An original design technique for obtaining analog signal processing circuits able to generate a multitude of circuit functions has been presented. The paper analyses and implements a large number of analog signal processing circuits, exploiting the specific characteristic of a single functional core. In this way, it is possible to obtain, with minor changes in the design, five important functions: signal gain with theoretical null distortions, signal squaring, voltage multiplying with very good linearity and simulation of a perfect linear resistor with both positive and negative equivalent resistance. As a consequence of the multiple functions implemented using the same functional core, the proposed structure presents the advantages of an increased modularity and controllability and of the associated reduced design costs. Comparing with similar designs from literature, the linearity of the proposed structure is strongly increased by implementing original techniques, while the circuit complexity per function is reduced as a result of the proposed multifunctionality. The linear designed computational structures has an overall error of 0.4%, while the proposed squaring circuit has an approximation error of 0.27%, all of them being designed for a low-voltage low-power operation (the supply voltage is 1.5V and the medium current consumption for each implemented circuit function is 50μA).

Abstract **- Original low-power low-voltage multifunctional structure with improved performances will be presented, allowing to implement (with minor changes in the design) two important functions: signal gain with theoretical null distortions and voltage multiplying with very good linearity. The great advantages of the increased modularity and controllability and of the reduced design costs associated represent an immediate consequence of the multiple functions realized by the proposed structures. The linearity is strongly increased by implementing original techniques, while the silicon occupied area per function is reduced as a result of the proposed multifunctionality. The structures are supplied at $\pm 3V$, presenting a very good linearity (in the worst case, $THD<0.4\%$ for differential amplifiers and $THD<0.5\%$ for multiplier), correlated with an extended range of the input voltage (at least $\pm 0.5V$).**

Keywords - Linearity, multifunctionality, computational circuits, VLSI design

I. INTRODUCTION

An important goal in VLSI designs is represented by the possibility of a multiple use for the same cell, the increased modularity that could be achieved being reflected in an important reduction of the design costs per implemented function.

The differential amplifier is an important stage of a large area of applications, including high-performances analog/mixed ICs, such as operational amplifiers, voltage comparators, voltage regulators, video amplifiers, modulators and demodulators or A/D and D/A converters. The linearity of the circuit is relatively poor because of the fundamental nonlinear characteristic of MOS transistors, resulting the possibility of achieving a relatively good linearity only for a restricted input voltage range (the amplitude of the input voltage for the classic differential amplifier using MOS transistors in saturation have to be below a few hundreds of mV). In conclusion, it results the necessity of implementing a linearization technique for decreasing the superior-order nonlinearities of the MOS differential stage and for increasing the available range for the input voltage amplitudes. It exists in literature many circuit techniques used to improve the MOS differential amplifier linearity. It was presented in [1], [2] a third and fifth-order harmonics cancellation with good results and a relatively simple circuit implementation.

A constant-sum of the gate-source voltages circuit connection was described in [3] and it allows an important reduction of the total harmonic distortions coefficient of the circuit. In [4], it was presented and implemented in CMOS technology a simple technique based on square-root circuits for improving the CMOS differential stage linearity, which compensates the quadratic characteristic of the MOS transistor in saturation.

Computational circuits and particularly multiplier circuits are important building blocks for telecommunication applications, medical equipments, hearing devices and disk drives. In CMOS technology, analog circuits based on the square-algebraic identity can be easily realized from the well-known square-law model of the MOS transistors in the saturation region. Based on this principle, several basic multiplier circuits have been developed [5]-[9], having the important disadvantage of a relatively poor linearity.

The original idea proposed in this paper is to use a linear CMOS differential amplifier for obtaining (with minor changes in the design) two important functions:

- The signal gain with theoretical null distortions;
- Voltage multiplying with very good linearity.

II. THEORETICAL ANALYSIS

A. Analysis of the classical MOS differential amplifier

The analysis of the large signal operation for the classical MOS differential structure (Fig. 1) can quantitatively evaluate the circuit's nonlinearity, being possible to determine the weight of each superior-order distortion introduced by the structure nonlinearity.

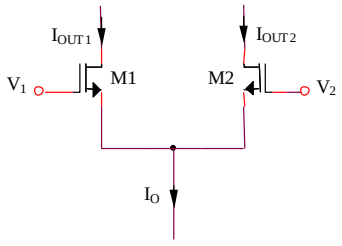

Fig. 1. Classical MOS differential structure

The output currents of the classical differential amplifier can be expressed as a function of the differential input voltage as follows:

$$(I_{OUT1})_{1,2} = \frac{I_O}{2} \pm \frac{I_O}{2}\sqrt{\frac{KV^2}{I_O} - \frac{K^2V^4}{4I_O^2}} \qquad (1)$$

so:

$$I_{OUT1} = \frac{I_O}{2} + \frac{I_O}{2}\sqrt{\frac{KV^2}{I_O} - \frac{K^2V^4}{4I_O^2}} \quad (2)$$

$$I_{OUT2} = \frac{I_O}{2} - \frac{I_O}{2}\sqrt{\frac{KV^2}{I_O} - \frac{K^2V^4}{4I_O^2}} \quad (3)$$

The differential output current will be:

$$I_{OUT2} - I_{OUT1} = -\frac{V}{2}\sqrt{4KI_O - K^2V^2} \quad (4)$$

The $(I_{OUT2} - I_{OUT1})(V)$ function is strongly nonlinear, the quantitative evaluation of the nonlinearity being possible using the Taylor series expansion. The Taylor series expansion of the transfer function (4) can be written as follows:

$$(I_{OUT2} - I_{OUT1})(V) = -K^{1/2}I_O^{1/2}V + \frac{K^{3/2}}{8I_O^{1/2}}V^3 + \frac{K^{5/2}}{128I_O^{3/2}}V^5 + \ldots \quad (5)$$

or:

$$(I_{OUT2} - I_{OUT1})(V) = a_1V + a_3V^3 + a_5V^5 + \ldots \quad (6)$$

a_k being constant coefficients with respect to V differential input voltage. So, as a result of squaring characteristics of MOS transistors biased in saturation, the classical MOS differential amplifier behavior is extremely nonlinear. The first term from (6) is linearly dependent on the input voltage, while the following two terms model the third-order and fifth-order nonlinearities of the differential structure. In conclusion, it is obviously the necessity of implementing a linearization technique for improving the performances of the classical MOS differential stage (good linearity for a relatively extended range for the amplitudes of the input voltage).

B. The analysis of the classical MOS Gilbert multiplier

The classical MOS Gilbert multiplier schematic is presented in Fig. 2. The differential output current of the circuit can be expressed as follows:

$$I_{OUT1} - I_{OUT2} = (I_{D1} - I_{D4}) - (I_{D2} - I_{D3}) \quad (7)$$

where:

$$I_{D1} - I_{D4} = (V_1 - V_2)\sqrt{\frac{KI_O}{2} - \frac{K^2}{4}(V_1 - V_2)^2 - \frac{K}{2}(V_3 - V_4)\sqrt{KI_O - \frac{K^2}{4}(V_3 - V_4)^2}} \quad (8)$$

and:

$$I_{D2} - I_{D3} = (V_1 - V_2)\sqrt{\frac{KI_O}{2} - \frac{K^2}{4}(V_1 - V_2)^2 + \frac{K}{2}(V_3 - V_4)\sqrt{KI_O - \frac{K^2}{4}(V_3 - V_4)^2}} \quad (9)$$

So, analyzing (7), (8) and (9) relations, it results that the classical MOS Gilbert multiplier presents an important nonlinearity.

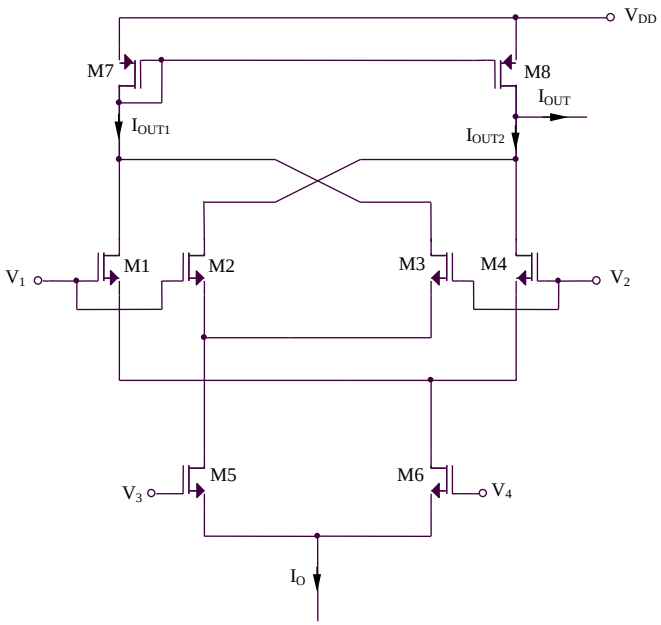

Fig. 2. MOS Gilbert multiplier

C. Improved linearity MOS differential structure

The original improved linearity MOS differential structure is proposed in Fig. 3. "SQ" block represents a squaring circuit, having the original implementation presented in Fig. 5.

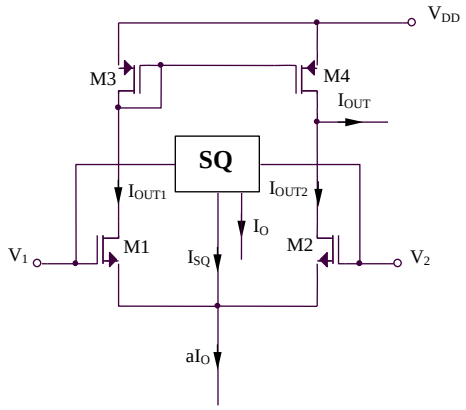

Fig. 3. Improved linearity MOS differential structure

The differential output current for this circuit has the following expression:

$$I_{OUT} = (V_1 - V_2)\sqrt{K(aI_O - I_{SQ}) - \frac{K^2}{4}(V_1 - V_2)^2} \quad (10)$$

In order to obtain a linear behavior of the proposed differential structure, the I_{SQ} output current of the squaring circuit "SQ" must be the sum of a constant term and a term proportional with the square of the differential input voltage:

$$I_{SQ} = bI_O - \frac{K}{4}(V_1 - V_2)^2 \quad (11)$$

b being a positive constant, depending on the particular implementation of the squaring circuit. Replacing (11) in (10), it results:

$$I_{OUT} = \sqrt{(a-b)KI_O}\,(V_1 - V_2) = G_m(V_1 - V_2) \quad (12)$$

$G_m = \sqrt{(a-b)KI_O}$ being the circuit equivalent transconductance.

D. Implementation of the squaring circuit "SQ"

The proposed method for designing the required voltage squaring circuit is based on a differential amplifier (Fig. 4) [9] having a controllable asymmetry between the geometries of its composing transistors. This difference between the aspect ratios of MOS transistors will introduce in the output currents of the differential amplifier a term proportional with the square of the differential input voltage.

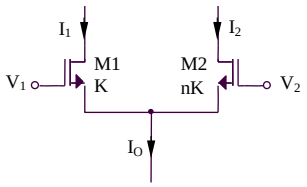

Fig. 4. Asymmetrical differential structure

The differential input voltage, V, can be expressed as:

$$V = V_{GS1} - V_{GS2} = \sqrt{\frac{2I_1}{K}} - \sqrt{\frac{2(I_O - I_1)}{nK}} \tag{13}$$

resulting:

$$\frac{K}{2}V^2 = I_1 + \frac{I_O - I_1}{n} - 2\sqrt{\frac{I_1(I_O - I_1)}{n}} \tag{14}$$

The expression of I_1 current can be obtained solving the following second-order equation, derived from (14):

$$I_1^2\left[\left(\frac{n-1}{n}\right)^2 + \frac{4}{n}\right] + \left(\frac{I_O}{n} - \frac{KV^2}{2}\right)^2 + I_1\left[2\frac{n-1}{n}\left(\frac{I_O}{n} - \frac{KV^2}{2}\right) - \frac{4I_O}{n}\right] = 0 \tag{15}$$

So:

$$I_1 = \frac{I_O}{n+1} + \frac{n(n-1)}{2(n+1)^2}KV^2 + \frac{nV}{(n+1)^2}\sqrt{2KI_O(n+1) - K^2nV^2} \tag{16}$$

and:

$$I_2 = I_O - I_1 = \frac{nI_O}{n+1} - \frac{n(n-1)}{2(n+1)^2}KV^2 - \frac{nV}{(n+1)^2}\sqrt{2KI_O(n+1) - K^2nV^2} \tag{17}$$

The complete realization of a voltage squaring circuit, based on the previous proposed method, uses a cross-coupling of two differential amplifiers having controllable asymmetries between their geometries, M1-M2 and M3-M4 (Fig. 5) [9].

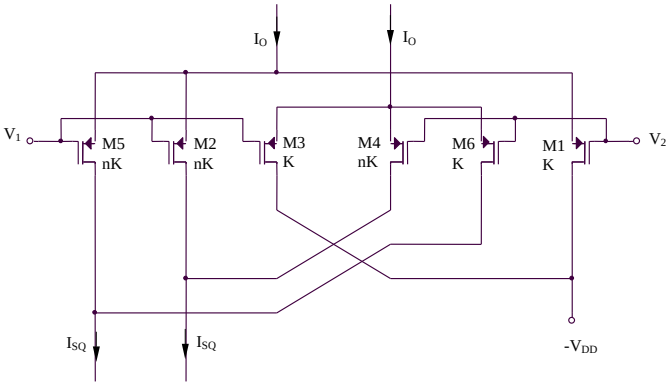

Fig. 5. Squaring circuit

Using (16) and (17), it results:

$$I_{SQ} = I_{D2} + I_{D4} = \frac{nI_O}{n+1} - \frac{n(n-1)}{2(n+1)^2}KV^2 - \frac{nV}{(n+1)^2}\sqrt{2KI_O(n+1) - K^2nV^2} + \frac{nI_O}{n+1} - \frac{n(n-1)}{2(n+1)^2}KV^2 + \frac{nV}{(n+1)^2}\sqrt{2KI_O(n+1) - K^2nV^2} = \frac{2nI_O}{n+1} - \frac{n(n-1)}{(n+1)^2}KV^2 \tag{18}$$

E. Improved linearity MOS multiplier circuit

The proposed multiplier circuit with improved linearity is presented in Fig. 6. The squaring circuit "SQ" has the previous presented implementation (Fig. 5).

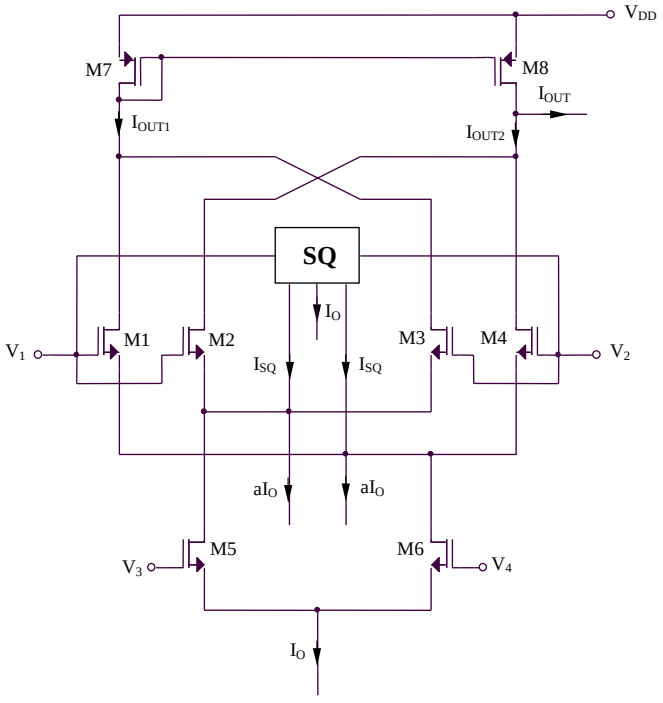

Fig. 6. Improved linearity multiplier circuit

The differential output current of the circuit shown in Fig. 6 can be expressed as follows:

$$I_{OUT1} - I_{OUT2} = (I_{D1} - I_{D4}) - (I_{D2} - I_{D3}) \tag{19}$$

The expression of the M1-M4 differential amplifier output current is:

$$I_{D1}-I_{D4}=(V_1-V_2)\sqrt{\begin{matrix}KI_{D6}+KI_O\left(a-\dfrac{2n}{n+1}\right)+\\ +K^2(V_1-V_2)^2\left[\dfrac{n(n-1)}{(n+1)^2}-\dfrac{1}{4}\right]\end{matrix}} \quad (20)$$

For obtaining a linear behavior of the multiplier, it is necessary that $\frac{n(n-1)}{(n+1)^2}=\frac{1}{4}$, resulting $n_{1,2}=1\pm\frac{2}{\sqrt{3}}$ and $a_{1,2}=\frac{\sqrt{3}\pm 2}{\sqrt{3}\pm 1}$. So, choosing these proper pairs (a_1,n_1) or (a_2,n_2), it results:

$$I_{D1}-I_{D4}=(V_1-V_2)\sqrt{KI_{D6}} \quad (21)$$

Similar conditions impose:

$$I_{D2}-I_{D3}=(V_1-V_2)\sqrt{KI_{D5}} \quad (22)$$

resulting:

$$I_{OUT1}-I_{OUT2}=\sqrt{K}(V_1-V_2)\left(\sqrt{I_{D6}}-\sqrt{I_{D5}}\right) \quad (23)$$

equivalent with:

$$I_{OUT1}-I_{OUT2}=\frac{K}{\sqrt{2}}(V_1-V_2)(V_3-V_4) \quad (24)$$

IV. CONCLUSIONS

An original low-power low-voltage multifunctional structure with improved performances was presented, allowing to implement (with minor changes in the design) two important functions: signal gain with theoretical null distortions and voltage multiplying with very good linearity. The great advantages of the increased modularity and controllability and of the reduced design costs associated represent an immediate consequence of the multiple functions realized by the proposed structures. Comparing with other similar designed reported in literature, the linearity is strongly increased by implementing original techniques, while the silicon occupied area per function is reduced as a result of the proposed multifunctionality. The structures are supplied at $\pm 3V$, they presenting a very good linearity (in the worst case, $THD<0.4\%$ for differential amplifiers and $THD<0.5\%$ for multiplier), correlated with an extended range of the input voltage (at least $\pm 0.5V$).

Abstract - This paper presents the design of a high-voltage differential amplifier using six different pre-input stage circuits to reduce high-voltage input levels to low-voltage signals. The proposed circuits are designed using 65 nm CMOS process technology with a nominal voltage of 2.5 V and a supply voltage of 5 V. The designs are based on stacked low-voltage standard CMOS transistors. The different pre-input stage circuits are compared to each other in terms of their circuit description, drawbacks, advantages and simulation results. The principle of the five designed pre-input stage circuits can be applied to higher voltage range input signals as well.

I. INTRODUCTION

The development of MOS technology scaling has increased the challenge of designing high-voltage circuits. A high-voltage integrated circuit is defined as a circuit with a supply voltage higher than the nominal voltage of its transistors. One method of designing these circuits is to use high-voltage compatible transistors [1]. Unfortunately, such transistors are technology dependent and not available in recently developed processes such as the 28nm TSMC technology. Another way of designing these high-voltage circuits compatible with scaled technologies is to use stacked low-voltage standard CMOS transistors [2]–[11].

Power management, which plays an increasing role in electronic systems for consumer, sensor and automotive applications, requires high-voltage circuits such as low-dropout voltage regulators or switching converters that use error amplifiers in the feedback loop. To meet all operating and load conditions, these amplifiers must operate with high-voltage input and output signals and high supply voltages. The objective of this paper is the design of a differential amplifier based on stacked low-voltage standard transistors without loading the input with a dc current.

This paper introduces the design of a high-voltage differential amplifier having a high-voltage input Vin_{HV} and a high supply voltage Vdd_{HV} of 5 V, which can be between 2.6 V and 5 V (= $2\times V_n$). The input voltages can vary between 0 V and Vdd_{HV}.

In order to keep the voltage between the terminals of each transistor within technology limits, the amplifier is designed using stacked low-voltage standard CMOS transistors (Fig. 1). The gate-terminals of the nMOS transistors *ML4* and *MR4* are regulated by input signals. Both transistors are low-voltage standard transistors. Therefore, to drive the amplifier, the input signals must not exceed the nominal voltage V_n, which is 2.5 V in this design. Pre-input stage circuits are needed to reduce the high-voltage inputs into low-voltage signals and, such a circuit is termed here as a **H**igh to **L**ow **V**oltage **L**evel **S**hifter (HLV-Level Shifter).

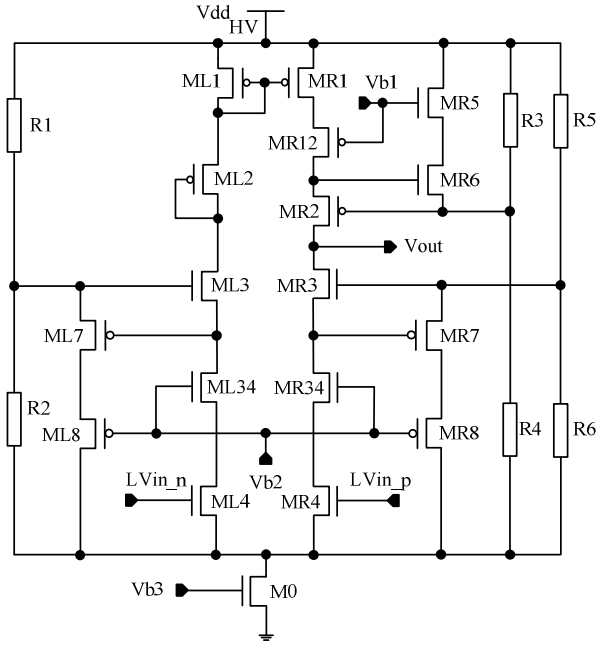

Fig. 1. The structure of the proposed high-voltage differential amplifier

This paper presents six different designs for a pre-input stage HLV-Level Shifter circuit. These designs are compared to each other in terms of their circuit description, drawbacks and advantages by simulation.

This work is organized as follows: Section II describes the proposed high-voltage differential amplifier and section III introduces six different designs of a pre-input stage to shift the level of high-voltage input signals of the proposed HV-differential amplifier down to a low voltage. Section IV presents the simulation results together with a comparison of the proposed HV-amplifiers using the different high to low input voltage converters. Finally, the conclusions are given.

II. SYSTEM DESCRIPTION

Fig. 1 shows the proposed high-voltage differential amplifier with single-ended output. The circuit is based on stacked low-voltage standard CMOS transistors.

The circuit is supplied with 5 V, which is twice the nominal voltage 2.5 V. To restrict the voltage between the terminals of every transistor to stay within the technology limits, both differential stages need to be based on at least 2-stacked CMOS transistors. Because of diverse gate-voltages, gate-drain and gate-source capacitances, the unregulated charge and discharge of stage-nodes can cause an overvoltage between the terminals of each transistor. To prevent this overvoltage, extra transistors *MR12*, *ML34* and *MR34* are included to the 2-stacked CMOS transistors (*MR1*, *ML1*, *MR2*, *ML2*, *MR3*, *ML3*, *MR4* and *ML4*), as can be seen in Fig. 1. The nMOS transistors *MR4* and *ML4* are controlled by low-voltage input signals.

When the input signal V_{LVin_p} is low enough to turn off the transistor *MR4*, the pull-down nodes of the right stage(drain nodes of *MR3*, *Mr34* and *MR4*) become charged, causing *MR7* to turn off. In this case, the gate of *MR3* is regulated only by the voltage divider of *R5* and *R6*, which turns it off. With a high input signal, the gate-source of *MR3* starts discharging and the pMOS transistor *MR7* turns on. As a result, the gate voltage of *MR3* decreases in order to maintain its gate-drain and gate-source voltages within the technology limit, as will be shown in section IV, Fig. 8 and 9.

In a similar way, the nMOS transistor *ML3* is regulated by the pMOS *ML7* and the voltage divider consisting the resistors *R1* and *R2*. The pMOS transistor*MR6* and the voltage divider consisting of resistors *R3* and *R4* control the pMOS transistor *MR2*. The transistors *MR12* and *MR5* are regulated by the reference voltage *Vb1* in order to avoid the overvoltage.

The designed differential amplifier is regulated by the input signals, which are fed to the gate terminals of both low-voltage nMOS transistors *MR4* and *ML4*. With regard to the technology limit, the input signals have to be equal to or less than the nominal voltage *Vn* (2.5 V).

Therefore, a pre-input stage circuit is required to reduce both high-voltage inputs into low-voltage signals. In the next section, the design and comparison of six different **H**igh into **L**ow **V**oltage Level Shifter (HLV-Level Shifter) pre-input stage circuits are presented.

III. DESIGN AND COMPARISON OF PRE-STAGE INPUT CIRCUITS

A. HLV-Level Shifter A

Fig. 2 demonstrates a level shifter, which is based on a voltage divider. The circuit contains two resistors *Rx* and *Ry* whose values are determined according to the high voltage input signals. However, this method has two major disadvantages; the voltage divider draws a current from the input, the dynamic range is reduced, and the signals are subject to resistor variations.

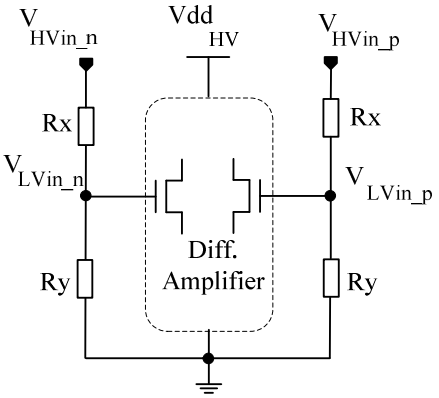

Fig. 2. HLV-Level Shifter A

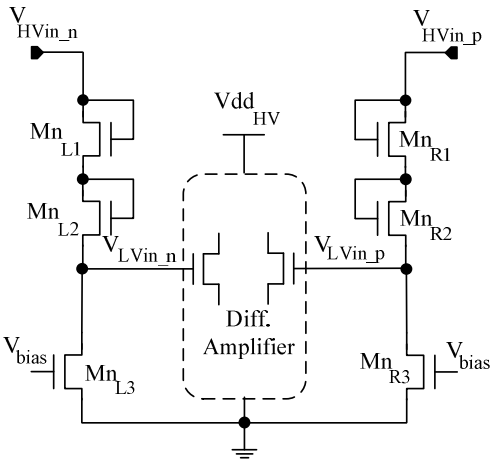

Fig. 3. HLV-Level Shifter B

B. HLV-Level Shifter B

Fig. 3 shows the second HLV-Level Shifter. To stabilize and reduce variations of the shifted voltage, nMOS transistors are used rather than resistors as found in HLV-Level Shifter (A). The node between the two series-connected nMOS diodes (*Mn1* and *Mn2*) and the nMOS transistor Mn3 generates the required low input voltage for the proposed differential amplifier. The transistor *Mn3* is biased by a reference voltage *Vbias*.

To reduce a higher voltage input signal in the range of $(N–Vn)\times Vn$ to $N\times Vn$, it would be necessary to have $2\times(N–1)$ nMOS diodes connected in series.

This level shifter has the same disadvantage as HLV-Level Shifter (A), as the input source must feed a current through the nMOS transistor *Mn3*, whose source is ground connected.

C. HLV-Level Shifter C1 using current mirrors

Fig. 4a shows the design of a new HLV-Level Shifter using current mirrors. The circuit generates low-voltage signals from high-voltage inputs in two processes: (1) converting the voltage V_{HVin} to the current I_1 (V/I-converter) and (2) the mirrored current to the voltage V_{LVin} (I/V-converter). The circuit is supplied by a low-voltage Vdd_{LV}, which is equal to the nominal voltage (2.5 V). On the first path of each side, the circuit contains a resistor *R*, which is connected in series with a gate-drain connected nMOS transistor Mn_{R3} (Mn_{L3}). Due

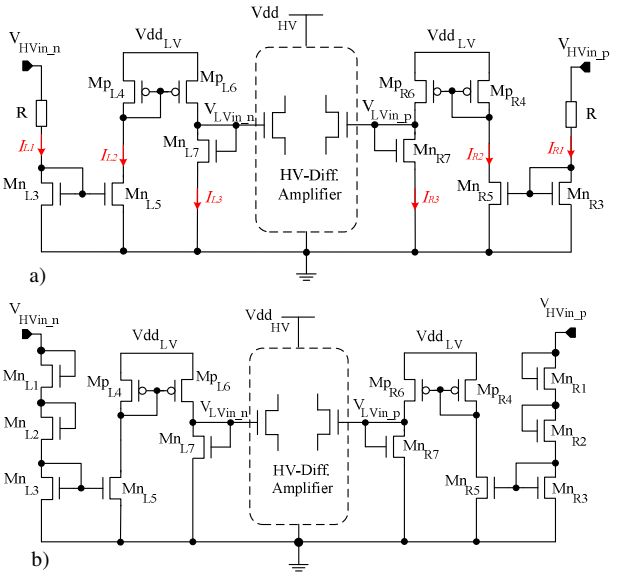

Fig. 4. HLV-Level Shifter a) C1 b) C2

to the two current mirrors, the current I_1 generated from the HV-signal through the resistor R, is mirrored in the second path (I_2) and in the third path (I_3). The generated voltage V_{LVin} is the required voltage for the proposed differential amplifier:

$$I_3 = \frac{W_6 \cdot L_4}{W_4 \cdot L_6} \cdot I_2 = \frac{W_5 \cdot L_3}{W_3 \cdot L_5} \cdot I_1 \quad (W_6 = W_4, L_6 = L_4) \qquad (1)$$

$$Vg_{Mn7} = V_{LVin} = \sqrt{\frac{2 \cdot I_3}{\beta}} + V_{nTh} \qquad (2)$$

The equations (1) and (2) show that V_{LVin} is generated by a current I_1, which depends on the high voltage input and the resistor R. However, the disadvantage of this circuit is that the input is loaded by a current.

Fig. 4b shows an improved circuit of this HLV-Level Shifter (C1). To avoid fluctuations of the resistors, two gate-drain connected nMOS transistors are used in series instead of the resistor R. An additional drawback of both level shifters (C1 and C2) is that the generated signal V_{LVin} is limited to the threshold voltage of Mn7, as can be obtained from (2).

To avoid input loading HLV-Level Shifters D, E and F have been designed.

D. HLV-Level Shifter D

Fig. 5 shows a HLV-Level Shifter using a common-drain stage. The high-voltage input signal, which varies between 0 V and 5 V controls the gate of the nMOS transistor *MnR* (*MnL*). The supply voltage of this circuit is 2.5 V. When the gate-source voltage of the nMOS exceeds the threshold voltage, the node between the transistor *Mn* and the resistor R_{R1} (R_{L1}) starts to charge from 0 V until 2.5 V, which can then be applied to the inputs of the proposed HV-differential amplifier. The disadvantage of this method is that a high-voltage input signal with only a short range of 5 V can be applied (Table 1), otherwise an overvoltage between the transistor's node would occur.

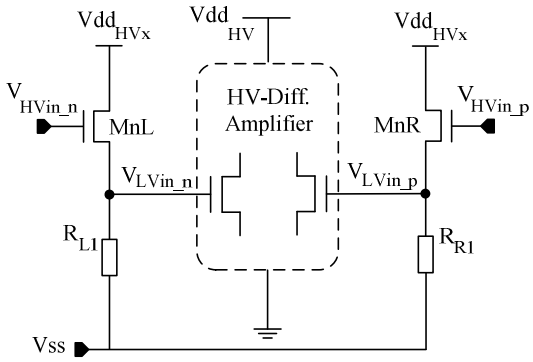

Fig. 5. HLV-Level Shifter D

TABLE 1. The voltage range of the HLV-Level Shifter D (V)

Vdd_{HV}	Vss	V_{HVin}		Vdd_{HVx}	V_{LVin}	
		min.	max.		min.	max.
5.0	0	0.0	5.0	2.5	0.0	2.5
7.5	2.5	2.5	7.5	5.0	2.5	5.0
10.0	5.0	5.0	10.0	7.5	5.0	7.5
$N \times V_n$	$Vdd_{HV} - 5$	$(N-1) \times V_n$	$N \times V_n$	$(N-1) \times V_n$	$(N-2) \times V_n$	$(N-1) \times V_n$

To keep the gate-source voltage (Vgs) of *Mn* in the range of technology limit (2.5 V), Vss in Fig. 5 has to be the minimum value of the input signal V_{HVin}, as can be seen in (Table 1). The problem is that the source node of *Mn*, which generates the low-voltage input signal V_{LVin}, can be charged when Vgs of *Mn* exceeds the threshold voltage.

E. HLV-Level Shifter E

To extend the range of the applied high input voltage for the HLV-Level Shifter D of Fig. 5, an extra nMOS transistor *MnL1* (*MnR1*) is included in series between the input transistor *MnL2* (*MnR2*) and the supply voltage node Vdd_{HV} in Fig. 6 To maintain the voltage between the terminals of each transistor in the range of technology limit, the gate voltage of *Mn1* needs to be varied from 2.5 V according to the high-input signal V_{HVin}. Therefore, a second stage containing series-connected pMOS transistors (*Mp1*, *Mp2* and *Mp3*) is designed to each side of the circuit in Fig. 6. This stage also has a supply voltage of Vdd_{HV} (5 V). The gates of *Mp2* and *Mp3* are controlled by the nodes of the first stage according to the high-voltage input signal V_{HVin}.

The gate of *MP1* is biased by a reference voltage of 2.5 V to maintain the gate-source voltage of *Mp2* in the range of 2.5 V, as can be expressed with the following equations:

$$I_{Mp1} = \frac{\beta}{2}(|Vgs_{Mp1}| - |V_{pTh}|)^2 = I_{MP2} \qquad (3)$$

$$Vgs_{Mp1} = 2.5\,V \approx Vgs_{Mp2} = Vg_{Mn1} - V_{LVin} \qquad (4)$$

Due to this, the gate voltage of *Mn1* is shifted to the gate of *MP2* (V_{LVin}) about 2.5 V. In the on-state, the transistor *Mp2* operates in both regions (saturation and triode), therefore its gate-source voltage cannot be exactly 2.5 V, as can be seen in the simulation results in Fig. 11a.

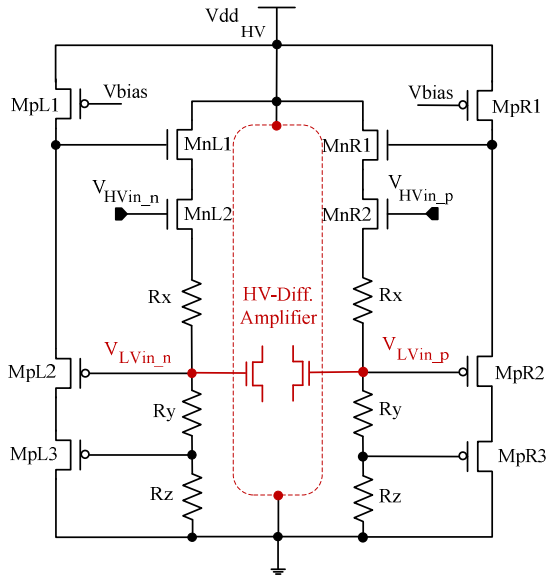

Fig. 6. HLV-Level Shifter E

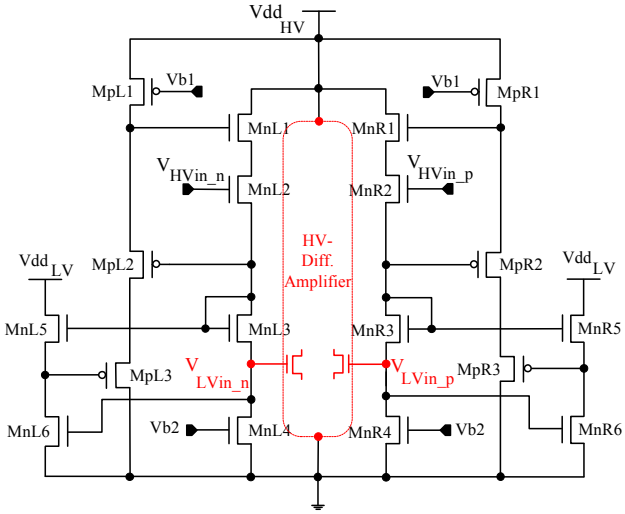

Fig. 7. HLV-Level Shifter F

For a higher input voltage ($N \times Vn$), ($N–1$) nMOS transistors are needed to be connected in series to the input nMOS transistor *Mn2*.

F. HLV-Level Shifter F

However, HLV-Level Shifter (E) suffers from fluctuations of the resistors. Fig. 7 shows an optimized HLV-Level Shifter using two nMOS transistors with *Mn4* and gate-drain connected *Mn3*, instead of the resistors. The node voltage between both transistors (Mn3 and Mn4) is not low enough to drive the pMOS transistor Mp3 of the second stage. Therefore, the third stage containing series-connected nMOS transistors (*Mn5* and *Mn6*), which forms the current mirror *Mn3* and *Mn4,* is designed. The node between both transistors *Mn5* and *Mn6* provides a voltage for the gate of *Mp3* of the second stage according to the high-voltage input signal.

IV. SIMULATION RESULT

The simulation results in Fig. 8 show the dc and transient voltage characteristics of *MR3* and *MR34* for the proposed HV-differential amplifier (Fig. 1). The pMOS transistor *MR7* and the voltage divider (*R5* and *R6*) control the gate of *MR3* according to the input signal. In the off-state, the gate voltage is about 4.5 V and in the on-state approx. 2.45 V. The dc voltage characteristics of the pull-up nodes according to the high-voltage V_{HVin}, the low-voltage input V_{LVin} and the output V_{out} can be seen in Fig. 9. The transistors *MR6*, *MR7* and the voltage dividers (*R5*, *R6*) and (*R3*, *R4*) control the right-hand stage of the proposed differential amplifier and maintain the voltage between the terminals of each transistor to be within the technology limit with 5% tolerance using extra transistors *MR12*, *MR5*, *MR34* and *MR8*.

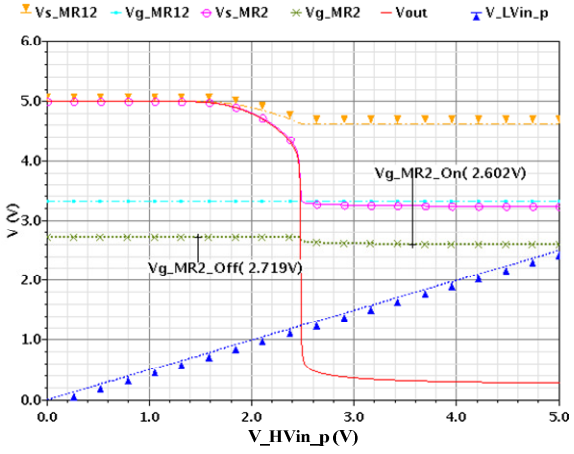

Fig. 9. Voltage characteristics of the pull-up nodes (right-stage of the diff. amp.) vs. V_{HVin_p}

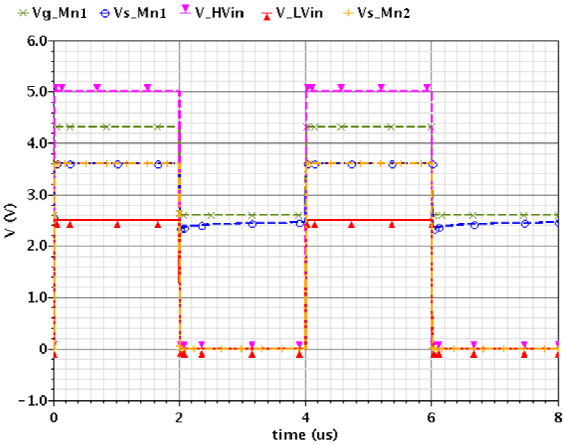

Fig. 10. Node voltage characteristics of HLV-level shifter E

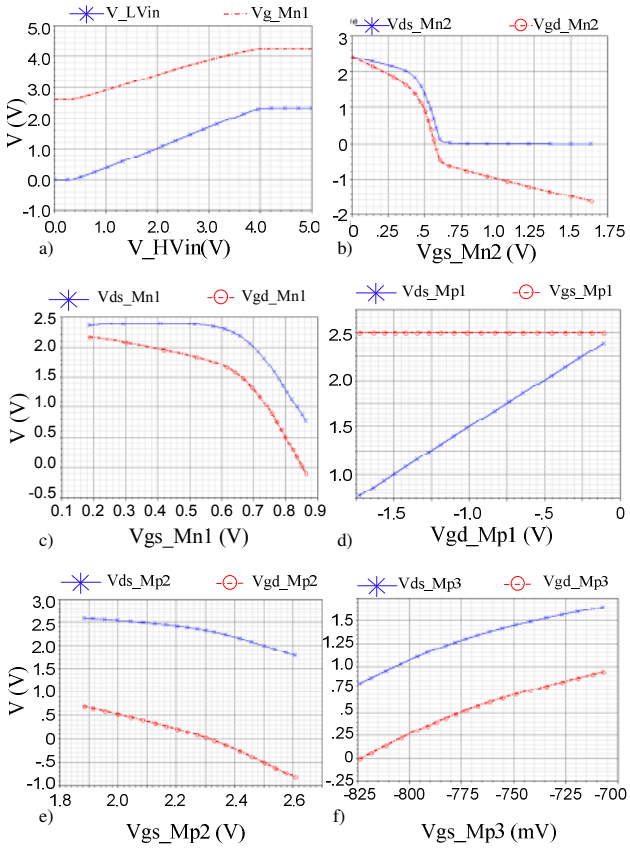

Fig. 11. a) voltage characteristics of Vg_{Mn1} and V_{LVin} vs. V_{HVin}
b)-f) voltage between transistors' terminals (HLV-Level Shifter E)

Fig. 10 demonstrates the node voltage characteristics of the transistors *Mn1* and *Mn2* for the HLV-Level Shifter (E). The HV-input signal V_{HVin} is a square-wave and varies between 0 V and 5 V. The gate voltage of *Mn1* is generated by the second stage (*Mp1*, *Mp2* and *Mp3*) and varies between 4.3 V and 2.6 V to keep the voltage between the terminals of each transistor within the technology limit. The generated desired input signal V_{LVin} varies between 0 V and 2.5 V.

The characteristic of the gate voltage of *Mn1* generated by the second stage can be seen in Fig. 11a according to V_{LVin}, which is generated by the first stage and controls the gate voltage of *Mp2*.

The simulation results in Fig. 11 b-f and 12 show that the voltage between the terminals of each transistor for HLV-Level Shifters (E and F) is within the technology limit with 5% tolerance.

Fig. 13 shows that the first three HLV-Level Shifters (A, B and C1/C2) lose input current. In comparison, the first level shifter is more favorable because of its lower current loss (max. 5 µA).

Fig. 14 demonstrates the generated voltages of the designed HLV-Level Shifters, which are less than or equal to the nominal voltage of 2.5 V. According to the generated LV-signals, the output of the proposed HV-differential amplifier can be charged and discharged between 0 V and 5 V.

Table 2 gives a comparison between delays, rise (*RT*) and fall (*FT*) times of the HV-amplifier output voltage with all designed HLV-Level Shifters. The HLV-LS A dissipates less current than the other two level shifters (B and C), but the output of the proposed amplifier using this level shifter has the highest delay, rise (*RT*) and fall times (*FT*). With HLV-Level Shifter (F), the output has a satisfied delay, rise and fall times in comparison to the other level shifters. Transistor dimensions and resistor values of the designed circuits are given in Table 3.

V. CONLUSION

In this paper, a HV differential amplifier is presented with a supply voltage of 5 V. As the design uses standard transistors with nominal voltage of 2.5 V, low input voltages are required. Six types of pre-input stage circuits are designed for reducing the high-voltage signal down to the nominal voltage. Five of the presented HLV-Level Shifters (A, B, C, E and F) are extendable for use with higher input voltages. The first three HLV-Level Shifters (A, B and C) draw an input current. When comparing input current, delays, rise and fall times of the HV-amplifier output with the different level shifters, it is concluded that the HLV-Level Shifter Type-F is the most favorable due to low delay, rise and fall times without loading the input with a dc current and without the need of resistors.

The presented HV-differential amplifier and the pre-input stage HLV-Level Shifter circuits are technology independent and can be used with every process technology.

***Abstract*—A bandgap voltage reference circuit employing an operational amplifier is designed using the unified current-control model transistor model and 130 nm CMOS standard process. Schematic level simulations in Cadence Design System Spectre Simulator show temperature variation of the output voltage within 0.40 mV over a temperature range of 165 K (from - 40°C up to 125°C) in the nominal case, i.e. 1.06 ppm/°C. The supply voltage (3.3 V) change of ±10 % causes a disturbance in the output voltage of only 2.37 mV, i.e. 0.10 % of the output nominal value. The process variations, examined through corner and Monte Carlo analysis, are also presented and discussed.**

Keywords-CMOS, integrated circuits, bandgap, voltage reference, temperature stability

I. Introduction

In this paper we continue the development of a process, voltage and temperature (PVT) stable bandgap voltage reference, started in [1]. Namely, the design of DC current and voltage sources internal to the chip is an essential step in monolithic integrated circuits design, because the performance of nonlinear analog components depends strongly on the current flowing through them, i.e. biasing conditions. The task that these references should accomplish is to properly bias analog components of integrated circuits. Among a variety of solutions, efficient, simple and easy-to-design structures are the priority. These reference circuits should be autonomous when the supply voltage is switched on. Further, they should be based on intrinsic physical properties or on reproducible technology parameters [2], [3].

A PVT invariant reference voltage within an integrated circuits brings stable biasing conditions. A circuit showing promising results in the domain of temperature stability was demonstrated in [1]. Nevertheless, the supply voltage variance consequences were not tackled as successfully in the same circuit. Therefore, the main motivation for this work is obtaining a circuit with a better response to the supply voltage variations.

Since the simplest possible topology employed in [1] was only able to provide temperature stability to an acceptable degree (compared to similar circuits found in literature [1]), a somewhat more complex circuit is synthsized in this paper. Namely, the bandgap voltage reference is designed using the unified current-control model (UICM) of MOSFET [3] and the topology is based on an operational amplifier [3], [4]. The circuit is simulated using the Cadence Design System Spectre Simulator in 130 nm CMOS standard process. The schematic level simulation results show temperature variation of the output voltage within 0.40 mV over a temperature range of 165 K (from - 40°C up to 125°C) in the nominal case, i.e. 1.06 ppm/°C. The supply voltage (3.3 V) change of ±10 % causes a disturbance in the output voltage of only 2.37 mV, i.e. 0.10 % of the output nominal value. Besides the achieved goal of improving the supply voltage stability, the temperature stability is also improved. Such advances of the circuit characteristics are paid by higher power consumption and larger chip area. The process variations, examined through corner and Monte Carlo analysis, are also presented and discussed.

II. Model Used

The design methodology is based on the UICM model [3], [5]. It is a current-based MOSFET model that uses the concept of inversion level. According to the UICM model, the drain current can be split into the forward (I_F) and reverse (I_R) currents:

$$I_D = I_F - I_R = I_S(i_f - i_r), \tag{1}$$

where I_S is the normalization specific current, and i_f and i_r are inversion levels, forward and reverse, respectively. The forward and reverse currents depend on the gate to source and gate to drain voltages, respectively. If the transistor operates in saturation, we have:

$$I_F \gg I_R, \text{ thus: } I_D \approx I_F = I_S \cdot i_f. \tag{2}$$

The normalization current is a function of the technology:

$$I_S = \frac{\mu C_{ox} \phi_T^2 n}{2} \frac{W}{L}, \tag{3}$$

where μ represents the charge mobility, C_{ox} gate-oxide capacitance per area, ϕ_T thermal voltage, n slope factor and W/L transistor aspect ratio.

The inversion level value signifies the transistor operation region in the following way: if $i_f < 1$, the transistor operates in weak inversion and if $i_f > 100$ the transistor operates in strong inversion region. If $1 < i_f < 100$, the transistor operates in moderate inversion region.

According to this model, the voltage and current are related in the following manner [3]:

$$\frac{V_P - V_{S(D)}}{\phi_T} = \sqrt{1 + i_{f(r)}} - 3 + \ln\left(\sqrt{1 + i_{f(r)}} - 1\right), \quad (4)$$

where V_P is the pinch-off voltage, given as the difference of the gate potential and the zero bias threshold voltage (modified by the slope factor):

$$V_P \approx \frac{V_G - V_{T0}}{n}, \text{ if } V_G \approx V_{T0}. \quad (5)$$

Further detailed description of the model can be found in [3] and [5].

III. Bandgap Voltage Reference Theory of Operation

A bandgap voltage reference operation is based on adding two voltages having equal and opposite temperature coefficients, i.e. a voltage proportional to absolute temperature (PTAT) and a voltage complementary to absolute temperature (CTAT) [3], [4]. The logic behind this idea is to cancel out the temperature dependence, so that the output voltage, i.e. reference voltage is independent of temperature variation.

The reference voltage, V_{REF} we can write as:

$$V_{REF} = \alpha \cdot V_{CTAT} + \beta \cdot V_{PTAT}. \quad (6)$$

where α and β are coefficients of proportionality.

The temperature coefficient of a voltage is numerically expressed by the first derivative of that voltage as a function of temperature. Thus, in order to accomplish that V_{REF} is independent of temperature, its derivative needs to be zero:

$$\frac{\partial V_{REF}}{\partial T} = \alpha \frac{\partial V_{CTAT}}{\partial T} + \beta \frac{\partial V_{PTAT}}{\partial T} = 0. \quad (7)$$

To achieve this, a CTAT and a PTAT voltages need to be designed and, then, the coefficients α and β need to be set in such a way that slopes of these two voltages are equal.

The easiest way to obtain a CTAT voltage is the forward-biased pn junction - a diode. The diode current is given by [3]:

$$I_D = I_S \cdot e^{\frac{V_D}{\phi_T}}, \quad (8)$$

where I_S represents a diode saturation current and V_D is the diode voltage. From this relation, we extract the diode voltage as:

$$V_D = \phi_T \ln\left(\frac{I_D}{I_S}\right). \quad (9)$$

The two members comprising the expression for the diode voltage are of opposite temperature coefficient, but the PTAT (the thermal voltage) is negligible when compared to CTAT (the logarithm expression). The diode voltage is a CTAT in its nature [3], [4]. The temperature coefficient of the diode voltage can be calculated around -1.5 mV/K at room temperature [1].

To obtain a PTAT voltage, a pn junction is again used, i.e. several pn junctions are used. Namely, the idea is to subtract two V_D voltages, thus canceling the CTAT members and extracting the thermal voltage, i.e. the PTAT member. Such an effect can be obtained if there are different currents flowing through physically identical pn junctions, Fig. 1. Assuming an array of n identical diodes (Fig. 1), according to (9), the voltage of each one of them is given as:

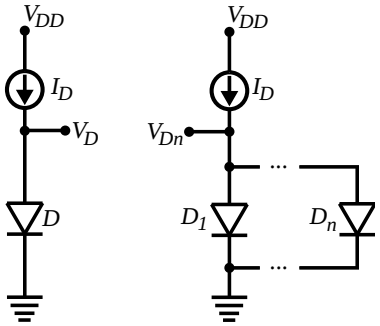

Figure 1. A PTAT voltage can be obtained as the difference of V_D and V_{Dn}

$$V_{D1} = V_{D2} = ... = V_{Dn} = \phi_T \cdot \ln\left(\frac{I_D}{n \cdot I_S}\right). \quad (10)$$

Observing the difference of V_D and V_{Dn}, yields:

$$\begin{aligned} V_D - V_{Dn} &= \phi_T \cdot \ln\left(\frac{I_D}{I_S}\right) - \phi_T \cdot \ln\left(\frac{I_D}{n \cdot I_S}\right) \\ &= \phi_T \cdot \ln(n), \end{aligned} \quad (11)$$

which means that this voltage difference is PTAT in its nature.

The subtraction can be performed by inserting a resistor, as shown in Fig. 2. The voltage over R_1 is given as:

$$V_{R1} - V_{Dn} = I_D \cdot R_1. \quad (12)$$

If V_D and V_{R1} are equal, we can write:

$$V_{R1} - V_{Dn} = I_D \cdot R_1 = \phi_T \cdot \ln(n). \quad (13)$$

Therefore, in order for this idea to work, the current generators in Fig. 2 must be replaced by a circuit which will make sure that $V_D = V_{R1}$. In this circuit, the current I_D is completely determined by the resistor R_1.

The temperature coefficient of $V_{R1} - V_{Dn}$ is that of the thermal voltage:

$$\frac{\partial \phi_T}{\partial T} = \frac{k}{q} = 86.25 \frac{\mu \text{V}}{\text{K}}. \quad (14)$$

In this paper the negative feedback connected operational amplifier is employed to provide equal voltage levels at points V_D and V_{R1}. Namely, if an operational amplifier is in negative feedback configuration its inputs are considered to be at the same voltage level [3], [4]. Thus, the ideal current generators in Fig. 2 are replaced by the adequate circuit, shown in Fig. 3.

Now, both CTAT and PTAT voltages are provided, even though of unequal temperature coefficients. This issue is solved by setting the coefficients of proportionality, α and β, in the

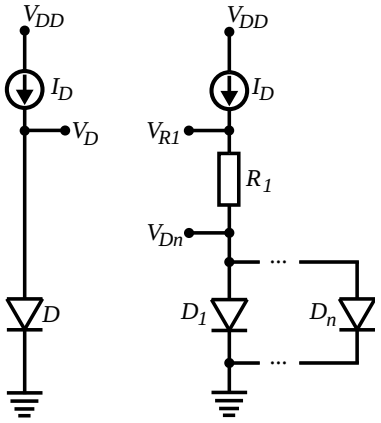

Figure 2. To obtain a PTAT, voltages V_D and V_{R1} must be equal

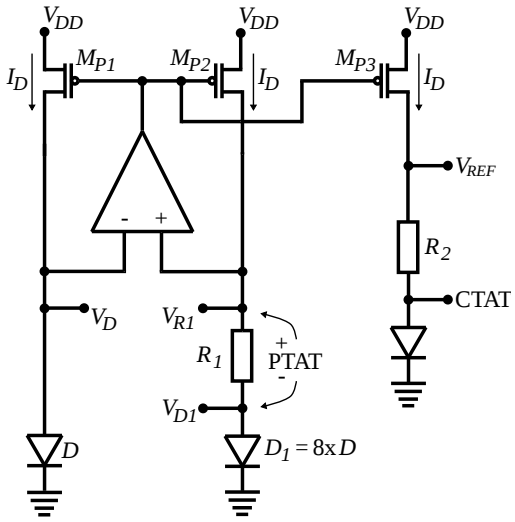

Figure 3. Proposed circuit schematic

correct way. The last step is to sum these two voltages so that the whole circuit yields an output voltage constant to temperature variation. The easiest way to sum voltages is to simply connect them in series. This is what the third branch in Fig. 3 actually does. Namely, the output transistor, M_{P3}, copies the current from the current mirror. Thus, the voltage V_{REF} is given as:

$$V_{REF} = V_D + V_{R2} = V_D + I_D \cdot R_2. \tag{15}$$

From (13) we can write:

$$I_D = \frac{\phi_T \cdot \ln(n)}{R_1}, \tag{16}$$

which, used in (15), yields:

$$V_{REF} = V_D + \frac{R_2}{R_1} \cdot \ln(n) \cdot \phi_T. \tag{17}$$

Comparing this expression with (6), we realize the following identities: $V_{CTAT} = V_D$, $V_{PTAT} = \phi_T$ and $\alpha = 1$, $\beta = (R_2/R_1) \cdot \ln(n)$. Substituting according to these relations into (7), we obtain:

$$\frac{\partial V_D}{\partial T} + \frac{R_2}{R_1} \cdot \ln(n) \cdot \frac{\partial \phi_T}{\partial T} = 0. \tag{18}$$

Temperature coefficients of pn junction and thermal voltages are known from [1] and (14), respectively, whereas R_1, R_2 and n remain to be determined during circuit design.

IV. Circuit Design Using UICM Model

The operational amplifier and its design and operation are not discussed within this paper. It is further investigated in [6], while here only the important characteristics are given in Tab. I. The amplifier provides the open loop gain of 75 dB and gain-bandwidth product of almost 90 MHz, which means that we can assume equal voltage level at the input contacts, positive and negative, when the amplifier is in negative feedback configuration.

TABLE I. Operational Amplifier Characteristics

Parameter	Value
open loop gain A_{v0dB}	66 dB
bandwidth ω_{3dB}	40 kHz
gain-bandwidth GBW, ω_u	90 MHz
phase-margin PM	60°
input common-mode range maximum $ICMR+$	3 V
input common-mode range minimum $ICMR-$	1.3 V
slew rate SR	50 [V/μs]
power consumption P_{DD}	2.46 mW

The information on the input common-mode range of this amplifier influences further design of the bandgap voltage reference. Namely, for the operational amplifier to operate as intended, the minimum DC voltage at the input contacts is 1.3 V. Observing the schematic in Fig. 3, we conclude that the maximum voltage at the inputs is V_D, which is of the order of 0.75 V, therefore $V_D < ICMR-$. This means that the proposed schematic needs to be modified so that it allows somewhat higher voltages at the inputs of the operational amplifier. The simplest way is to add an additional diode for the two branches connected to the positive and the negative contacts, as shown in Fig. 4. Now, the voltage at the inputs is $V_D^{'} = 2V_D$, which is of the order of 1.5V, therefore $2V_D > ICMR-$.

Since the proposed schematic was modified, some of the equations given in section III also need to be modified. First of all, the DC voltage at the negative input of the operational amplifier is now:

$$V_D^{'} = 2V_D \tag{19}$$

while the voltage $V_{Dn}^{'}$ is given by:

$$V_{D1}^{'} = V_{D2}^{'} = ... = V_{Dn}^{'} = 2 \cdot \phi_T \cdot \ln\left(\frac{I_D}{n \cdot I_S}\right). \tag{20}$$

while the PTAT voltage is obtained by subtraction:

$$\begin{aligned} V_D^{'} - V_{Dn}^{'} &= 2 \cdot \phi_T \cdot \ln\left(\frac{I_D}{I_S}\right) - 2 \cdot \phi_T \cdot \ln\left(\frac{I_D}{n \cdot I_S}\right) \\ &= 2 \cdot \phi_T \cdot \ln(n), \end{aligned} \tag{21}$$

Assuming that $V_D^{'} = V_{R1}^{'}$, as discussed at the beginning of this section, the voltage over the resistor in the second branch is given by:

$$V_{R1}^{'} - V_{Dn}^{'} = I_D \cdot R_1 = 2 \cdot \phi_T \cdot \ln(n). \tag{22}$$

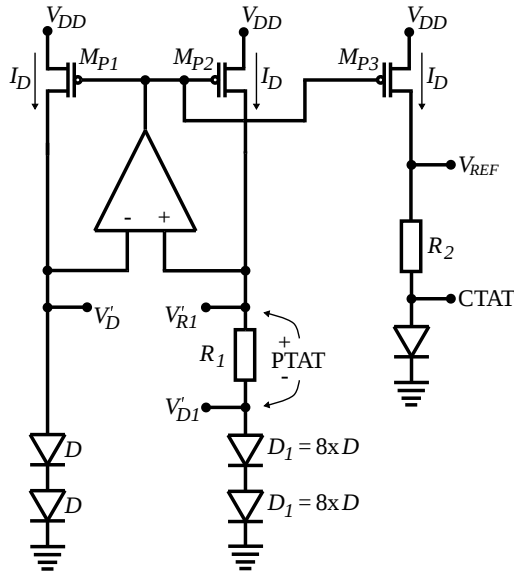

Figure 4. Modified circuit schematic

Finally, taking into account all the modifications, the output voltage previously given by 17 is now:

$$V_{REF} = V_D + 2 \cdot \frac{R_2}{R_1} \cdot \ln(n) \cdot \phi_T. \tag{23}$$

which means that now $V_{CTAT} = V_D$, $V_{PTAT} = \phi_T$ and $\alpha = 1$ and $\beta = 2 \cdot (R_2/R_1) \cdot \ln(n)$ The last equation to be modified is 18. Since in the third current mirror branch the number of diodes is not doubled, the first member of 18 remains as it is. The second member is modified as follows:

$$\frac{\partial V_D}{\partial T} + 2 \cdot \frac{R_2}{R_1} \cdot \ln(n) \cdot \frac{\partial \phi_T}{\partial T} = 0. \tag{24}$$

The remaining circuits components to be calculated are the transistors of the current mirror and the resistors. In order to calculate the needed values for all of the components shown in Fig. 3, certain parameters must be assumed. For a current mirror, it is of primary importance that all of the transistors be as equal as possible. Since mismatch is inversly proportional to the transistor size [7], larger transistor should be used - therefore, $W = 5$ μm. For the same reason, the number of parallel diodes in the second branch is chosen as $n = 8$. Namely, this means that there will be 18 diodes in the PTAT circuit, which can be positioned in two matrices of 3x3. In that way, matching conditions are better during the layout phase [4]. For the same reason, a somewhat larger resistor is chosen, $R_1 = 1$ kΩ.

The current mirror transistors MP1, MP2 and MP3 need to operate in saturation and in strong inversion. According to the UICM model, that means: $i_f \gg i_r$. To make sure that they will all remain saturated and in strong inversion in all cases, we assume $i_f = 800$ for all three of them.

Using the transistor model approximate parameters, it is possible to calculate the sheet normalization current:

$$I_{SHP} = \frac{I_S}{W/L} = \frac{\mu C_{ox} \phi_T^2 n}{2} = 13.4 \text{ nA}. \tag{25}$$

According to (16), the drain current, i.e. the current of each of the branches, is determined by the resistor R_1. After the modification of (16) in accordance with (19)-(23), it can be calculated as $I_D \approx 108\mu$A. Now it is possible to calculate the transistor ratio:

$$\frac{W}{L} = \frac{108 \cdot 10^{-6}}{800 \cdot 13.4 \cdot 10^{-9}} = 10.08 \approx 10, \tag{26}$$

which means that $L = 0.5$ μm.

The final unknown value of this circuit is the resistivity of R_2, which is determined from the temperature invariance condition, (24). Even though an approximate value for $\partial V_D/\partial T$ is already mentioned in section III of this paper, it varies significantly for each technology. Therefore, the actual value of this coefficient for this particular technology process is obtained through an experiment: a simple DC simulation yields $\partial V_D/\partial T \approx -1.2$ mV/K, for the range of temperatures from -40 up to 125°C.

Substituting now the obtained temperature coefficients and the rest of the known values in 24, we write an equation with only one unknown:

$$-1.2 \cdot 10^{-3} + 2 \cdot \frac{R_2}{10^3} \cdot \ln 8 \cdot 86.25 \cdot 10^{-6} = 0, \tag{27}$$

which provides a solution to the unknown value of the final circuit component, the resistor $R_2 \approx 3300$ Ω.

V. Simulation Results

Since we used approximate values for the calculations performed in section IV of this paper, some fine tuning is expected. After several iterations of simulations, these are the final parameter values of all the components used in circuit in Fig. 4 all transistor channel widths are 5 μm and all lengths are 0.5 μm, $n = 8$ $R_1 = 1$ kΩ and $R_2 = 2.28$ kΩ.

In the following simulations, the characteristics of the designed bandgap reference voltage circuit are demonstrated. First, the output of the circuit, i.e. the reference voltage, is shown as a function of temperature and of supply voltage. Then, process variations are simulated, observing the worst case scenarios through corner analysis and the statistical mismatch through Monte Carlo analysis. In the end, transient analysis is performed to show that the circuit's operating point is stable.

From Fig. 5 we see that the output voltage varies only ± 0.2 mV around the mean value of 1.14 V over a temperature range

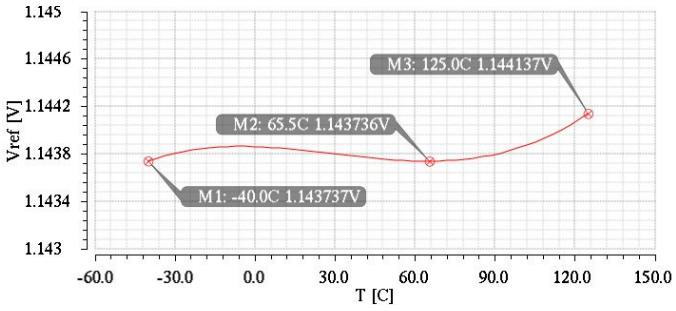

Figure 5. Temperature dependence of the output voltage at nominal supply voltage

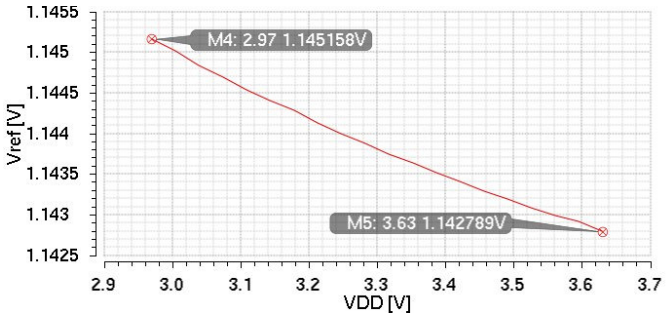

Figure 6. Output voltage dependence on the supply voltage

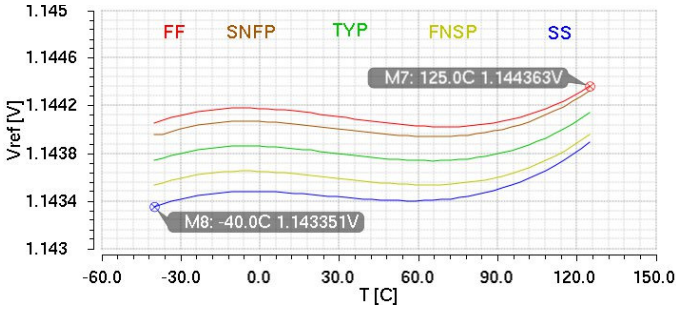

Figure 7. Corner analysis performed on top of the output voltage temperature dependence analysis

160 K wide, i.e. from -40 to 125 °C. This is an error of less than 0.02 % and of ≈1.06 ppm/°C.

Supply voltage variations are demonstrated in Fig. 6. The nominal value of V_{DD} is 3.3 V and here the circuit behavior at ±10 % is shown. The simulation results show that, with the supply voltage change from 2.97 V to 3.63 V, the reference voltage changes its value within the limit of ±1.18 mV around the mean value of 1.14 mV. Relative error is 0.1 %, i.e. 1.57 ppm/mV.

In Figs. 7-10 process variations of the circuit in question are analyzed. Corner and Monte Carlo analysis are performed on top of temperature (Figs. 7 and 9) and on top of supply voltage (Figs. 8 and 10) variation analysis. Through corner analysis, worst case scenarios are treated, showing that the maximum possible change of the output voltage taking into account both temperature and process variations is around 1 mV, which is ±0.04 %. Also, the maximum possible variation of the output voltage as a consequence of both supply and process variations is around 3 mV, i.e. ± 0.13 %.

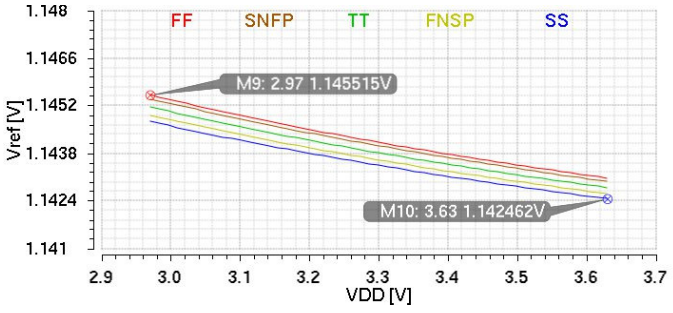

Figure 8. Corner analysis performed on top of a supply voltage analysis of the output voltage

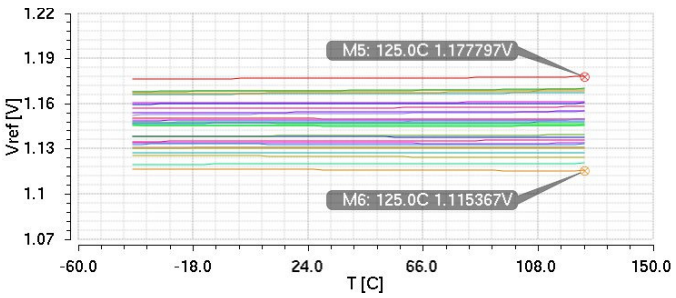

Figure 9. Statistical process variation observed through the Monte Carlo analysis of the temperature dependence of the output voltage

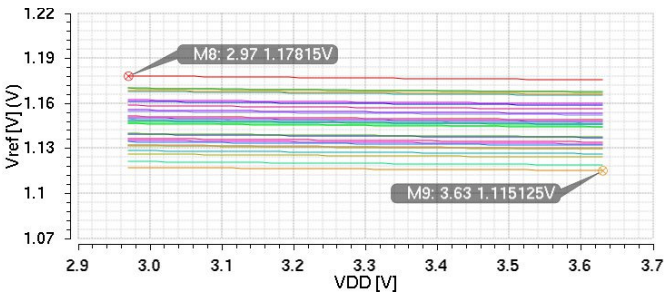

Figure 10. Statistical process variation observed through the Monte Carlo analysis of the output voltage dependence on the supply voltage

If the circuit operates correctly for 30 iterations of Monte Carlo simulation, there is 99 % probability that over 80 % of all possible component values operate correctly - according to the technology process documentation. Therefore, the statistical significane of 30 iterations is acceptable. In this paper, transistor mismatch is analyzed through Monte Carlo simulations, each with the mentioned number of iterations. The statistical analysis is performed on top of temperature (Fig 9) and supply power variation analysis (Fig. 10). In the first case (temperature and mismatch), the analysis shows the reference voltage maximum variation of 62.43 mV, i.e. ±2.72 %. When mismatch is analyzed over the supply voltage variation analysis, the output voltage maximum variation is 63.02 mV, i.e. ±2.75 %.

In Fig. 4 the start-up circuitry is ommited for simplicity. Nevertheless, in order for this bandgap voltage reference to work at the intended stable operation point, such subcircuit is mandatory. Further discussion on the start-up circuit can be found in [3]. In this paper, only the time domain analysis is given in Fig. 11, which shows that the circuit provides nominal output voltage within 62.5 ns.

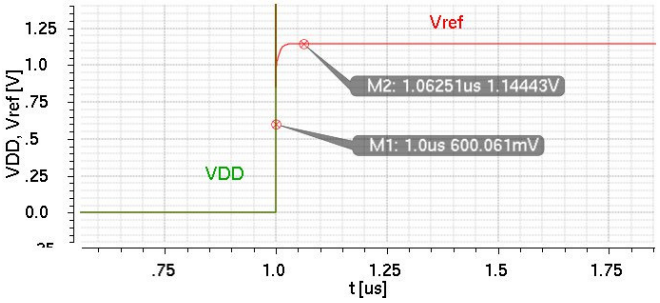

Figure 11. Time domain analysis, showing that the circuit starts-up in 112 ns

VI. Discussion

In Tab. II the characteristics of several circuits of the same purpose are compared. In [8] a bandgap voltage reference is implemented through a topology employing a current-voltage mirror instead of an amplifier, while in [9] a two-stage amplifier is used. These two are characterized by a somewhat larger temperature coefficient and lower power consumption, but at a narrower temperature range. Circuits presented in [10] and [11] show very weak variance of the reference voltage as a function of temperature over a wider temperature range. Also, these are characterized by higher power consumption, up to 1.3 mW. The topologies implemented use operational amplifier, with the addition of a 4-bit trimming circuit in [11]. The purpose of this additional circuit is to reduce the influence of the process variations.

The circuit presented in this paper shows the lowest output voltage temperature variation of the circuits in Tab. II, but it also shows the highest power consumption. There is an obvious trade-off between these characteristics, so increased power consumption is an expected price to pay for severly improved temperature coefficient of only 1.06 ppm/°C. One of the main goals of this research is the improvement of our work presented in [1]. Namely, in that paper a voltage bandgap reference based on a simpler topology is discussed. There, we concluded that the circuit shows satisfactory behavior concerning the temperature coefficient (11.5 ppm/°C), but also that its supply voltage caused output variation is not acceptable ($\pm$16.98 mV, i.e. 21.53 ppm/mV). The circuit presented in this paper is characterized by the improved performance. Namely, temperature variation is improved 10 times, while the supply voltagae caused variation is improved more than 13 times and it is 1.57 ppm/mV. Besides increased power consumption, this circuit is also characterized by a more complex topology and, consequently, higher demand for chip area.

The purpose of this comparison in no way is a claim which of the circuits is better, since each one of them is designed with the author having a different goal in mind, e.g. low power, higher stability or smaller chip area. The Tab II is given in order to point out that the results obtained within this paper are of the same order like those found in current literature.

TABLE II. Characteristics comparison

Circuits	Technology process [nm]	Supply voltage [V]	Temperature coefficient [ppm/°C]	Temperature range [°C]	Power [μW]
[1]	130	3.3	11.5	-40:125	600
[8]	350	2.5	12.1	5:95C	276
[9]	180	1.8	6.5	-20:90	150
[10]	130	3.3	5.5	-40:105	1300
[11]	180	1.8	2	-20:140	620
This work	130	3.3	1.01	-40:125	3710

VII. Conclusion

A temperature stable bandgap reference voltage circuit is presented in this paper. Concerning both temperature and supply voltage stability, this bandgap voltage reference represents an advancement compared to our previous work. On the other hand, power consumtpion is increased, since a more complex topology employing a separately developed operational amplifier is used. Process variation analysis performed (both corner and Monte Carlo) show that the output is influenced by the fabrication process. This characteristic remains to be worked upon during the layout phase, when more attention will be dedicated to device mismatch.

***Abstract*—A low power tag with integrated ADC designed in 0.18-μm CMOS process is presented. The tag extracts energy from electromagnetic waves and stores the charge on external capacitor. The stored charge is used to supply the tag circuitry: supply unit, current and voltage references and voltage regulators and ADC. The obtained referent voltage shows good stability over process, voltage and temperature variations. The mean value of the reference voltage is 485.8 mV and the standard deviation is σ= 7 mV in the temperature range -10° to 70°. The mean temperature coefficient (TC) is 7 ppm/°C and the standard deviation is σ_{TC}= 30 ppm/°C in the same temperature range.**

I. Introduction

In recent years there has been a growing interest in integration of sensing and telemetry to create wireless sensor networks. Integration of radio frequency identification (RFID) systems with sensors has potential usage in infrastructure and object monitoring, identification of harmful agents and implantable biomedical devices [1]. Also, wirelessly powered healthcare sensors enable continuous health monitoring [2], [3]. In such systems available power is limited because the energy is very often extracted from environment and used to supply chip (tag). One way of energy harvesting is harvesting from electromagnetic waves.

The key component in intelligent RFID systems is an analog to digital converter (ADC) because it has to provide high resolution and low power consumption [1]. The designers of a such ADCs are focused on lowering power consumption and increasing the ADC speed. The examples of a low power ADCs are presented in [1]–[5]. Very often generation and stability of reference voltage for the ADCs is challenging task because classic bandgap voltage references are not used in the tags due to low supply voltage of the the tags. The papers [1], [4] presents ADC but without reference and supply voltage while papers [2], [3] presents the whole chip with on-chip voltage references but it is not clear how the references are designed. This paper focuses on design of supply voltage and fully differential reference voltages generation for the fully differential 9-bit ADC presented in [5]. The proposed circuity are integrated with ADC and the proposed circuit (tag) is implemented in 0.18-μm CMOS process.

This paper is organized as follows. Section II presents the proposed circuit, Section III presents simulation results of the proposed circuits with ADC and Section IV brings the conclusion.

II. System description

Fig. 1 shows the block diagram of the proposed tag. The ADC is a 9-bit fully differential cyclic ADC with the following performance characteristics; the supply voltage range is from 1.4 to 1.8 V, the differential reference voltage is 500 mV and the typical common mode voltage is 700 mV. At the sampling rate of 10 kS/s the ADC consumes 7.4 μW from 1.4 V supply (current consumption is 5.3 μA). Input energy, extracted from electromagnetic waves, must be sufficient to ensure normal operation of the ADC under described conditions. The input impedance of the ADC is capacitive.

The tag powering strategy, which reduces required input power, is adopted from [6]. The RF/DC converter converts harvested RF energy to DC voltage V_{DD}. The charge needed to produce the voltage V_{DD} is stored in the external capacitor C_{STORE} and when the tag is active, V_{DD} is used as a supply for the rest of the tag circuitry. When V_{DD} is low, only voltage references are enabled so the tag consumes the minimal power. When V_{DD} exceeds targeted upper voltage limit V_{HIGH} the voltage detection unit will enable the rest of the tag circuitry (the tag is active). When the tag is active, the harvested energy stored in the capacitor is decreasing as the capacitor discharges reducing the supply voltage. At the low targeted voltage limit V_{LOW} the voltage detection circuit will turn off the circuitry so power consumption is minimal and the supply voltage will rise again. The designed tag operates in voltage range $V_{HIGH} - V_{LOW} \approx 0.4$ V so the tag circuitry has to be insensitive to supply variations.

A. Voltage detection and voltage limiter

Fig. 2 shows the voltage reference circuit, the voltage detection and power limiter circuit presented in [6]. A low-power voltage and temperature compensated voltage reference is presented in [7]. The circuit in Fig. 2 generates two 485 mV reference voltages which are insensitive to voltage and temperature variations. One is for the ADC (ADC_{REF}) and the other is for the voltage detector, voltage limiter and for voltage regulators (VDD_{REF}). The reference generation for

This work has been partly supported by the European Union from the European Regional Development Fund under the project Wirelessly powered microelectronic circuits for distributed sensor networks, project code RC.2.2.08-16, contracted through the Ministry of Science, Education and Sports of Croatia

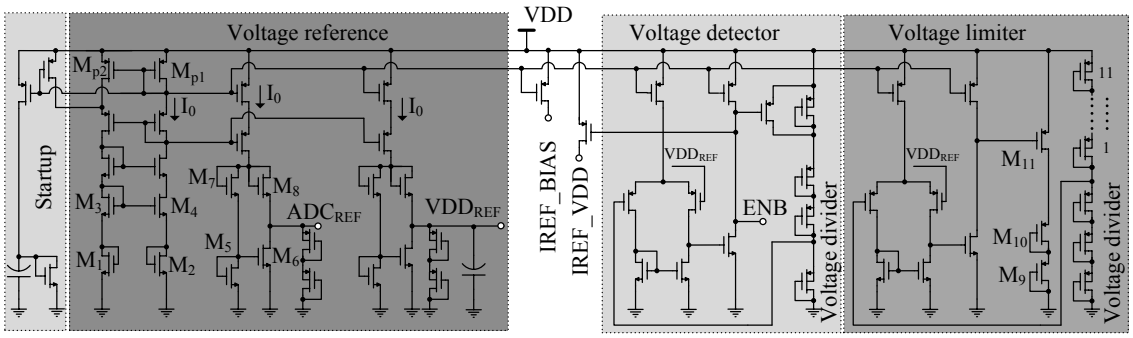

Fig. 2. Schematic of voltage detector circuit and voltage limiter.

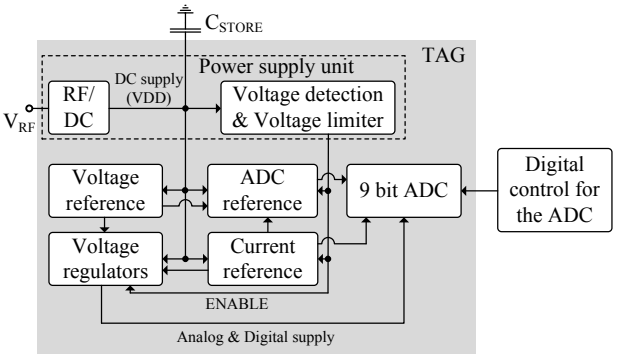

Fig. 1. Block schematic of implemented solution.

the ADC and for the supply is separated in order to avoid possible interferences generated by the voltage regulators.

The stability of the reference voltage depends on process parameters so Monte Carlo mismatch analysis is performed. The mean value of the reference voltage is 485.8 mV and the standard deviation is σ= 7 mV. The mean temperature coefficient (TC) is 7 ppm/°C and the standard deviation is σ_{TC}= 30 ppm/°C. The temperature coefficient is calculated in range -10 °C to 70 °C.

The voltage detector is a low power comparator with the hysteresis. Since the power consumption must be low, four pMOS transistors are used as a voltage divider instead of using large resistors. The transistors bulk and source terminals are shorted and each transistor has the same threshold voltage (i.e. same characteristics) so they are considered to be resistor with equal resistance. When V_{DD} exceeds high level V_{HIGH} = 1.94 V (4·VDD_{REF}) the comparator digital output ENB is set low. This signal enables the rest of the circuitry and the supply voltage $IREF\_VDD$ for current references so C_{STORE} discharges and voltage decreases. When the voltage reaches low level V_{LOW} = 1.455 V (3·VDD_{REF}), ENB is set high and the tag circuitry is turned off so C_{STORE} voltage rises. When V_{DD} is in range 1.455 V – 1.94 V the tag is active so the voltage hysteresis is 485 mV.

The voltage limiter detects if V_{DD} exceeded the breakdown voltage (2.2 V). When the voltage is too high the limiter will very fast turn on the transistor M_{11} and pull large current which will discharge the capacitor C_{STORE} and decrease V_{DD}. In order to prevent a short circuit V_{DD} - ground, two pMOS-based resistors are added (M_9 and M_{10}).

The consumption of the circuit from Fig. 2 must be as low as possible. The overall current consumption in voltage range from 1.4 V to 2 V is 60 nA in a typical case. The voltage reference circuit consumes 41 nA while voltage detection and voltage limiter consumes 12 nA and 7 nA respectively. The worst case consumption is 100 nA (fast corner, 70 °C).

Because very low current flows (15 nA) into the transistors $M_5 - M_8$ and the parasitic capacitances of the transistor gates are large, the reference voltages reaches 485 mV very slowly (the settling time is ≈500 μs). On the other hand ADC_{REF} must be stable before the comparator enables the tag circuitry. This can be achieved if ADC_{REF} is generated at the same time as, VDD_{REF}, so when the tag is enabled (ENB is low) ADC_{REF} has already settled at 485 mV.

B. Current references

Fig. 3 shows the current reference circuit. The circuit generates six current references of ∼100 nA for voltage regulators and for ADC references and one reference current of ∼150 nA for the ADC. The overall current consumption of the circuit is 1.2 μA. The stability of the reference current over temperature and voltage variations is not crucial because generated currents are used as reference currents for the operational amplifiers used in tag. It is only important that these currents are as low as possible due to the power consumption restriction. The current variations over temperature and voltage variations are shown in Fig. 4.

In order to minimize the current consumption the reference supply voltage $IREF\_VDD$ is disabled and the circuit is turned off when ENB is high. After ENB is set low $IREF\_VDD$ is equal to the voltage V_{DD}. The startup circuit is modified to ensure fast turn on. The parasitic capacitance C_p slows down start up and, after enabling the reference circuit, this capacitance charges with current $IREF\_BIAS$ which is generated in the voltage reference circuit. The transistor M_{s1} is always on because it is connected to V_{DD}. After enabling

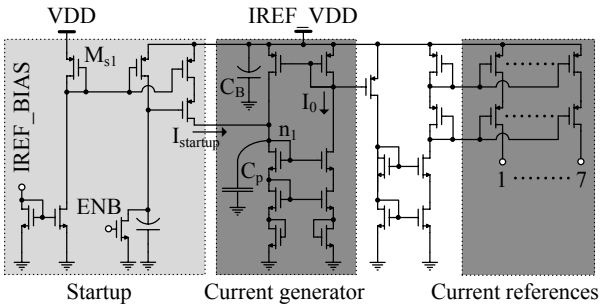

Fig. 3. ADC references.

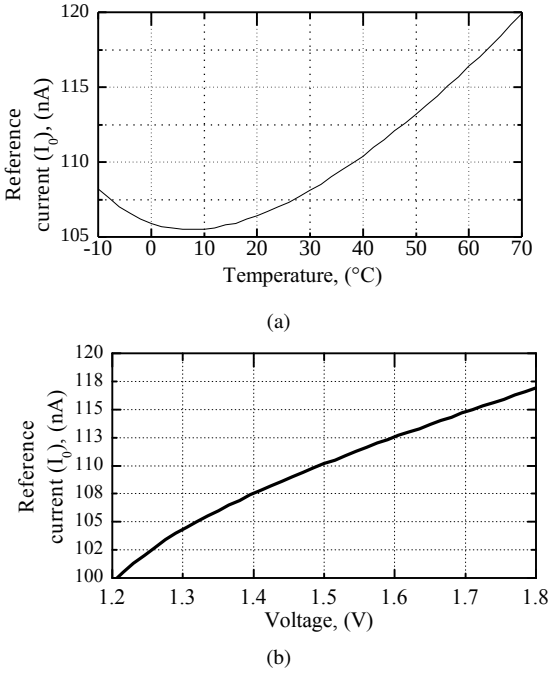

Fig. 4. Reference current variations as a function of temperature and supply voltage obtained by simulations. (a) Reference current variation as a function of temperature (b) Reference current variation as a function of supply voltage.

$IREF\_VDD$ the current $I_{startup}$ will quickly charge C_p and improve startup time.

C. ADC references

The ADC reference circuit is shown in Fig. 5. Input is the referent voltage REF_{ADC} and the outputs are three voltages V_{RHIGH}, V_{RMID} and V_{RLOW}. Three voltages are necessary because the ADC is fully differential. V_{RHIGH} and V_{RLOW} are high and low referent voltages while V_{RMID} is the common mode voltage. The voltage REF_{ADC} is first amplified 2 times so the voltage V_{REF} = 970 mV. V_{REF} is divided and then three reference voltages are generated. To reduce current consumption the feedback resistors should be large. The area is reduced because pMOS transistors M_{R1} and M_{R2} are used instead of resistors. The transistors have the same (W/L) ratio but consists of multiple devices to enable good matching. The overall (W/L) ratio is 1µm/8µm. The source and bulk terminals of the transistors M_{R1} and M_{R2} are shorted so the transistors have the same threshold voltage and resistance R_{DSon}. According to [8] the voltage V_{REF} is

$$V_{REF} = REF_{ADC}\left(1 + \frac{m}{n}\right) \quad (1)$$

where m is the number of transistors between the nodes V_{REF} and V_{FB} and n is the number of transistors between the nodes V_{FB} and ground. Since m=n=1 the voltage V_{REF}=V_{RHIGH} = 970 mV. Low reference voltage is V_{RLOW}= 485 mV and the common mode voltage is $V_{RMID} \approx$ 730 mV. The capacitors C_{R1}, C_{R2} and C_{R3} are blocking capacitors. Their task is to filter any interference which could couple from the power supply V_{DD}. Also, the buffers $OA_2 - OA_4$ prevents switching noise from the ADC during AD conversion.

The power consumption of the circuit is crucial so, in order to reduce power consumption, the operational amplifiers $OA_1 - OA_4$ are directly connected to V_{DD} without voltage regulators. This means that the amplifiers must have good power supply rejection ratio (PSRR). Besides PSRR the reference buffers $OA_2 - OA_4$ also must be capable driving capacitive loads since the ADC inputs are purely capacitive load. Because the ADC has 9-bit resolution the buffers open loop gain is A_{V0} = 60 dB. With 60 dB open loop gain voltage error at the output of buffers is less than 1/2 of differential nonlinearity (DNL) for a 9-bit resolution e.g. $V_{REFH} - V_{REF}$= 0.45 mV. During AD conversion for each bit the buffers must charge or discharge ADC input capacitors (the DAC capacitors) very fast and the reference voltages must settle before the conversion of the next bit starts. The settling time accuracy S is defined as $S = 2^{-b}$ where b is the number of bits [9]. Under assumption that the buffers are modelled as a single-pole systems the gain bandwidth (GBW) is given in [9]

$$GBW = -\frac{\ln S}{\beta T_S} \quad (2)$$

where β is the feedback factor of the closed-loop system (for buffers β=1) and T_S is the settling time. The setting time is defined by the speed of the ADC. The ADC output voltage settles within 2 µs so the buffers must settle much faster and T_S is chosen to be 0.5 µs. According to (2) for 9-bit resolution and T_S = 0.5 µs GBW is $\approx$ 2 MHz.

The classic Miller compensated amplifier has very low gain bandwidth (GBW) which depends on compensation capacitor C_C and it is not suitable for this application. Also the speed is limited by the slew rate. The amplifier presented in Fig. 6 is capable to source and sink large currents so the slew rate is not an issue although quiescent current of the amplifier is only 1 µA. The GBW can be improved if the amplifier is load compensated as the amplifier in Fig. 6.

Because of the small dimensions the amplifier offset is σ= $\pm$2.6 mV. Since the proposed ADC is fully differential circuit the buffers OA_2 and OA_4 from Fig. 5 are layouted close to each other. In this way the differential offset can be reduced.

The Table I presents the performance of the amplifier from Fig. 6 when C_C = 1.8 pF. The transient simulations confirmed that, when phase margin (PM) is 54°, the buffer amplifier

has no overshoots. Fig. 7 shows transient behaviour of differential reference voltage $V_{REF\_DIFF} = V_{RHIGH} - V_{RLOW}$ during AD conversion. During AD conversion the buffers OA_2 and OA_4 charges the ADC input capacitors so voltage V_{REF_DIFF} drops. The voltage settles to its nominal value of 485 mV within 0.5 μs which is enough for the ADC maximal conversion rate of 10 kS/s.

D. Voltage regulators

The ADC is insensitive to power supply variations but the voltage regulators are added to separate the digital and analogue supply. The ADC does not need state of the art regulators so the regulators, used in this design, are actually non-inverting amplifiers shown in Fig. 8. The amplifier gain is 3 so the output voltage voltage ($AVDD$ or $DVDD$) is $AVDD = 3VDD_{REF}$ ≈1.45 V. An operational amplifier used in the voltage regulators is the same amplifier which

is used for the ADC reference generation (Fig. 6). The pass element is the transistor M_{A5}. To save the area a pMOS transistors $M_{d1} - M_{d3}$ are used instead of resistors. The transistors have the same (W/L) ratio, but each transistor consists of two parallel devices to enable good matching. In order to track fast transition on $AVDD$ and $DVDD$ pins the feedback loop, which is formed by $M_{d1} - M_{d3}$, must have fast response time. The parasitic capacitance C_{pFB} slows loop performance so it must be reduced. This can be done by reducing (W/L) of $M_{d1} - M_{d3}$ so the transistor ratio is 1μm/2μm. The value of the blocking capacitor C_{B2} is 34 pF and it is implemented as an nMOS capacitor (MOSCAP). When load current varies in range 0 – 5.3 μA (maximal ADC current) the voltage $AVDD$ settles within 1 μs.

Table II presents typical performance of the designed regulator.

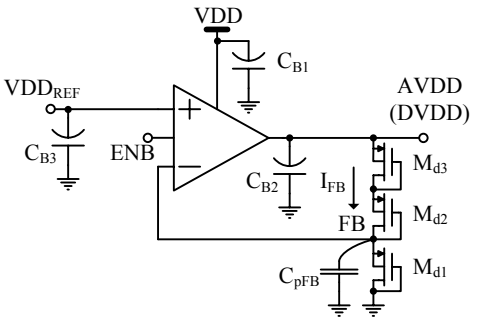

Fig. 8. The schematic of voltage regulators.

E. RF/DC converter

The schematic of RF/DC converter is shown in Fig. 9. The transistors are low threshold voltage nMOS transistors with the typical threshold voltage of 220 mV. The capacitors are metal–insulator–metal (MIM) capacitors. The converter must be able to deliver minimal DC output voltage of 1.94 V for the load current of 100 nA (load is the circuitry for voltage detection and voltage limiter) with minimum input amplitude. The optimal number of half-voltage rectifier stages (*N*), transistors size and capacitors value are obtained through simulation. The simulations have shown that for $W/L = 35\mu m/0.24\mu m$ (all transistors have the same dimensions), $C = 0.6$ pF (all capacitors have the same dimensions) and *N*=24.

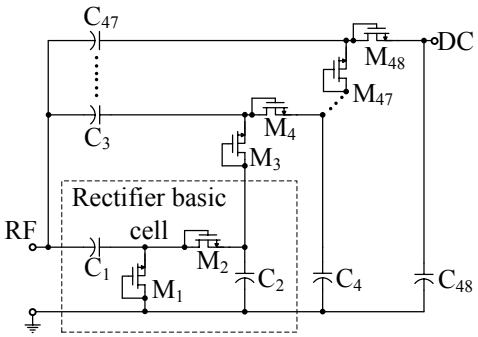

Fig. 9. Block schematic of implemented solution.

F. Tag implementation

The tag is implemented in a 0.18-μm CMOS process and occupies 0.96 mm^2 (1.2×0.8 mm^2) excluding pads. Fig. 10 presents the tag layout. Most of the area is occupied by the ADC and the ADC references. The blocking capacitors $C_{R1} - C_{R3}$, used in the ADC references (Fig. 5), are MiM capacitors. The capacitors consumes most of the reference area.

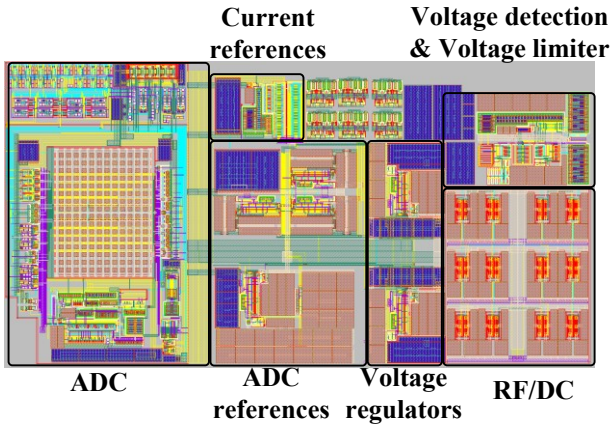

Fig. 10. Layout of the tag.

III. The Tag Performance Results

Fig. 11 shows generated voltage reference V_{REF_DIFF}, analogue and digital supply voltages $AVDD$ and $DVDD$.

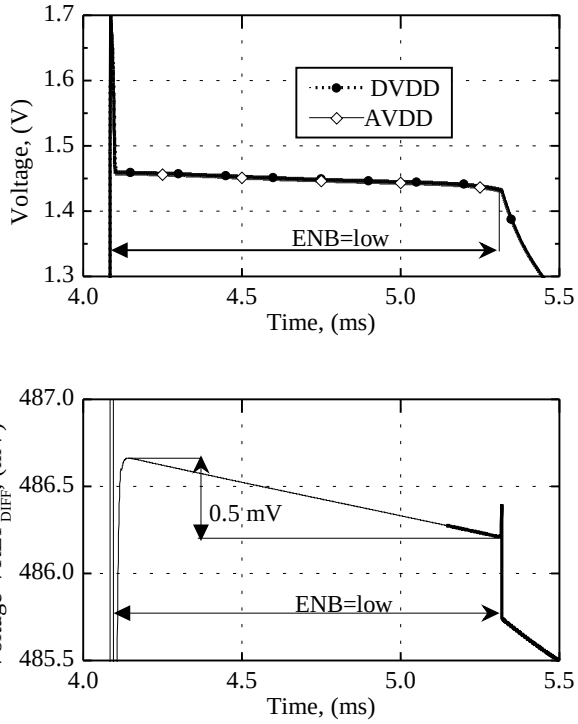

Fig. 11. The generated voltages $AVDD$, $AVDD$ and V_{REF_DIFF}

In order to speed up simulation time, RF signal amplitude is 300 mV while frequency is 900 MHz. The capacitance of the storage capacitor C_{STORE} is 11 nF. With this capacitance the tag is active 1.1 ms which is sufficient to ensure normal operation of the ADC (ADC conversion cycle is 80 μs). The digital signal ENB (active low) enables voltage regulators and voltage reference circuits. After the signal is set low the differential reference voltage V_{REF_DIFF}, analogue and digital supply voltages $AVDD$ and $DVDD$ are settled to final value after 40 μs. The supply voltages varies when the tag is active. This is because VDD_{REF} slightly changes as the supply voltage V_{DD} decreases.

A. The ADC performance results

In order to test performance of the whole tag, the ADC static and dynamic characteristics are simulated. The post layout simulations of the tag would be too complicated so only the ADC extracted parasitic parameters are included in simulations. Because of the same reasons the RF/DC verilog A model, presented in [10], is used instead of the transistor level model. The RF/DC verilog A model models the rectifier in time domain and it is easily implemented in circuit simulator and simulated with the rest of the tag circuitry. Compared with transistor level simulations the model achieves the simulation speed-up factor from 1080 to 3.84E6 times for a root-mean-square error (RMSE) below 4.8 mV.

Static characteristics are shown in Fig. 12. The simulated differential nonlinearity (DNL) is 0.075/-0.18 LSB and the integral nonlinearity (INL) is 0.22/-0.2 LSB which is the same

result as obtained in [5]. Dynamic characteristics are simulated for a full scale 1 kHz sine wave (V= 967 mVpp) and 10 kS/s sampling rate with included transient noise. The external capacitor C_{STORE} is 220 nF. With this capacitor the ADC can take 60 samples before the tag is off. Simulations with included transient noise are repeated 8 time which gives 480 samples. The signal spectrum is shown in Fig. 13. The spurious free dynamic range (SFDR) is 66 dB and signal-to-noise and distortion ratio (SNDR) is 52 dB.

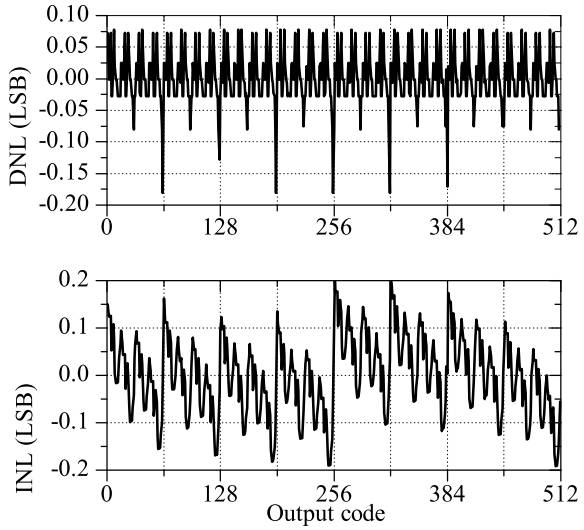

Fig. 12. Integral nonlinearity (INL) and Differential nonlinearity (DNL).

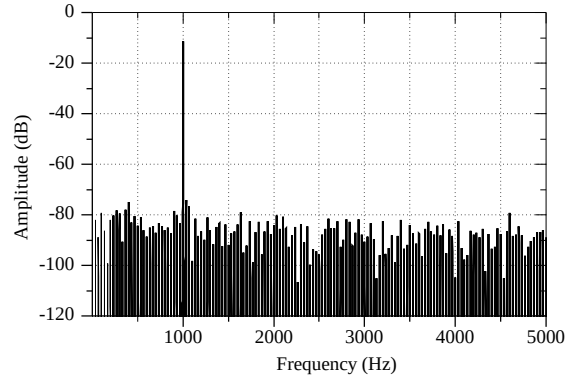

Fig. 13. FFT spectrum of 1 kHz input signal at 10 kS/s.

The maximal overall current consumption, including ADC, is 13 μA. The average power consumption is 22 μW. The most of the power is consumed by the ADC reference circuit (10 μW) and ADC (7.4 μW).

IV. Conclusion

This paper presents the design of power supply and voltage references for a fully differential 9-bit cyclic ADC. The supply, voltage references and ADC are integrated in tag. The tag extracts supply voltage V_{DD} from incoming electromagnetic waves. The supply voltage is stored in the external capacitor C_{STORE}. When the tag is active V_{DD} is used as a supply for the rest of the tag circuitry. The tag is on when V_{DD} exceeds the upper voltage level V_{HIGH} ≈1.94 V. When V_{DD} is lower than the lower voltage level V_{LOW} ≈1.455 V the tag is off. The generated reference voltage for the ADC and for the voltage regulators shows good stability over temperature and supply variations. The mean value of the reference voltage is 485.8 mV and the standard deviation is σ= 7 mV. The mean temperature coefficient (TC) is 7 ppm/°C and the standard deviation is σ_{TC}= 30 ppm/°C.

The tag performance is tested together with the ADC. The simulated static characteristic of the ADC, DNL and INL, are 0.075/-0.18 LSB and 0.22/-0.2 LSB respectively. Dynamic characteristics are following: the spurious free dynamic range (SFDR) is 66 dB and signal-to-noise and distortion ratio (SNDR) is 52 dB. The equivalent number of bits (ENOB) is 8.35. The overall power consumption is 22 μW.

Abstract - In today's market significant segment is taken by the applications using sensors to track physical events in the surrounding environment. Market raise is particularly related to the distributed sensor networks based on the wireless communications (like Internet of Things IoT devices). One of the hardest challenges in this field is associated with the power supply requirements. Battery operated electronics is limited by the battery capacity and battery lifetime. This paper proposes solution based on the RFID EPC-Gen2-protocol-based readers supplying power to the sensor nodes, consisting of the microelectronic circuit and the associated sensor. Besides the power, RFID protocol provides means of wireless communication, without the need for the battery supply on the sensor node side. Analogue circuits for receiving and demodulating RF ASK modulated signal from the reader, and transmitting back the signal to the reader using backscattering technique, are presented. Subset of the command protocol is implemented to support data communication including sensor identification through the unique ID code and sensor reading in the form of the digital word provided by the on-chip ADC. RTL description for digital control is developed in VHDL and synthesized. The prototype is processed in UMC Mixed-Mode/RF 180 nm technology.

I. INTRODUCTION

The main challenge in design of low cost, low power sensor nodes in wireless sensor networks is the power supply. RF communication takes the significant part of the power consumption and the time period before the battery requires replacement is often limited. Battery replacement requires human intervention and monitoring that raises the cost of the device and overall system. Sensor nodes without the battery supply, powered by energy harvesting are ideal for the sensor networks.

RFID standard EPC Gen2 [1] operating in the UHF range around 900 MHz (frequency range depends on the region) is present on the market for long time and is still mainly used for the identification of goods or people. The idea presented in this paper is to use standard RFID readers for powering and communication with the sensor nodes in the sensor network, with each node implemented as an integrated circuit (IC) with a sensor without the battery supply. The reader provides power to the IC and communicates according to the RFID protocol. The proposed IC in comparison with a regular RFID tag includes the on-chip ADC. It requires powering in the same way as the digital logic for the RFID communication. The ADC provides sensor reading and this binary data, sent together with the unique ID number of the sensor node, is sent to the reader, as the central place for gathering information from all the sensor nodes in the network.

This work has been partly supported by the European Union from the European Regional Development Fund under the project „Wirelessly powered microelectronic circuits for distributed sensor networks", project code RC.2.2.08-16, contracted through the Ministry of Science, Education and Sports of Croatia.

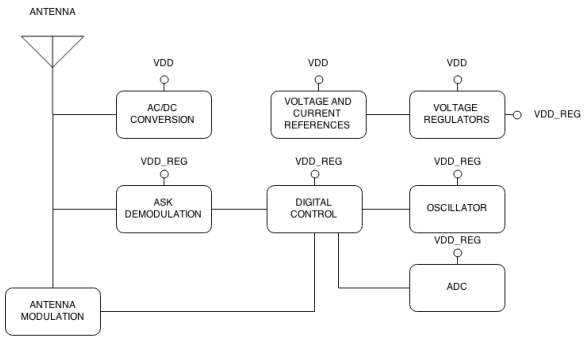

Figure 1. Block Schematic of Proposed IC Tag System.

IC tag system is composed of the energy harvesting module (AC/DC conversion), voltage and current references, voltage regulators, ADC, RF demodulator for the received signal (ASK demodulation), RF modulator for the transmit signal (antenna modulation), oscillator and the digital control logic for the protocol implementation. Fig. 1 shows the block schematic of the proposed system.

In this paper RF modules for modulation and demodulation and the digital logic for the RFID protocol are presented. Section II presents basic principles of the RFID communication and elaborates respective analogue and digital blocks for the protocol implementation. Section III provides the information about the prototype while the section IV gives the conclusion.

II. RF COMMUNICATION

A. *RF communication principle*

RFID system is always consists of the RFID reader and the tag. The tag is an IC chip that carries information that the reader fetches. The basic information is the unique identification number (ID) that directly identifies each tag and indirectly person or goods associated with the tag.

Depending on the power supply, tags can be active (battery supply for powering RF communication and digital logic), semi passive (battery supply for powering digital logic) and passive (no battery supply is provided, all power comes from RF signal harvesting) [2].

Readers and tags operate in different RF frequency bands: LF (125/134 kHz), HF (13.56 MHz) and UHF (880 – 960 MHz, 2.4 GHz) each with its own standard.

This paper presents a passive tag solution operating in UHF range 880 – 960 MHz based on EPC Gen2 protocol [2].

Passive tags don't use battery supply, so the complete power necessary for the RF communication, digital protocol operations and additional functions (in this case ADC conversion) must come from the energy harvesting of the RF signal. Energy must be stored during energy harvesting and the external capacitor is used for this purpose.

Passive tag doesn't incorporate any active RF modules due to limited power supply availability. Communication from the tag to the reader is provided using backscatter technique.

Backscattering is based on the following principle. Antenna on the tag side receives RF signal from the reader (forward link) that induces voltage on it and causes current to flow in antenna load (tag circuits). The principle of reciprocity says that every structure that receives an RF wave also transmits a wave. This transmission is proportional to the current induced in the antenna. This leads to the general principle of backscattering; by the changing antenna load it is possible to change the amplitude of an induced current causing the respective change of an amplitude of the transmitted wave (reverse link). The principle is displayed in Fig 2.

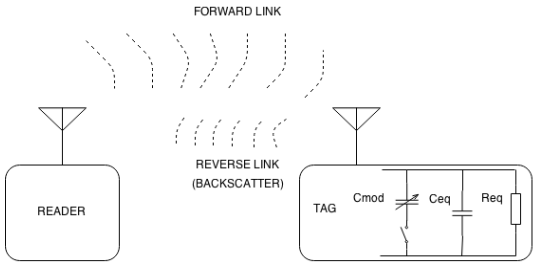

Figure 2. Reader – Tag Communication.

The tag impedance can be approximated by the parallel combination of the capacitor *Ceq* and the resistor *Req*. Resistor *Req* is equivalent to the tag power consumption, while *Ceq* capacitive load comes from the load of the AC/DC converter and the RF demodulation modules. The *Cmod* capacitance is the capacitor used for the modulation of the antenna load.

If the reader transmits RF signal with the constant amplitude, by changing antenna load it is possible to modulate backscatter signal as communication link from the tag to the reader. The largest backscatter signal is obtained when the antenna impedance is matched to the impedance of the tag on the transmitting frequency without connecting *Cmod* (switch in off state). If *Cmod* is connected in parallel to the tag impedance (switch in on state), matching is reduced and the backscatter signal has lower amplitude. This is the general principle which uses low power consumption from the tag side for establishing communication with the reader.

B. Modulation/demodulation

RFID Gen2 protocol defines three modulation types for RF signal communication: double sideband amplitude shift keying (DSB-ASK), single sideband amplitude shift keying (SSB-ASK) and phase reversal amplitude shift keying (PR-ASK) using a pulse interval encoding (PIE) format.

DSB-ASK modulation is chosen for the implementation of a reader to a tag communication due to simple solution for the demodulation of RF signal. RF signal in time domain is shown qualitatively in Fig. 3 (frequency of the RF signal is much higher than the periods of high and low amplitude, so transitions would not be visible in the correct time scale).

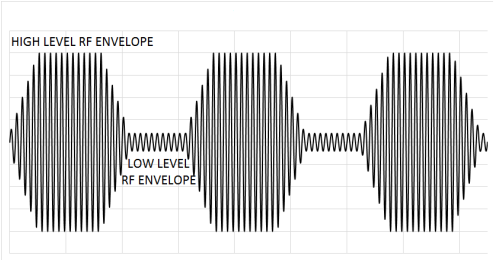

Figure 3. ASK Modulated RF signal.

RF signal is amplitude modulated with two states: the high state and the low state, represented by the high amplitude and low amplitude of the signal envelope. The low amplitude must be in the range from 0 to 20% of the high envelope amplitude according to the protocol.

Demodulation is performed by the envelope detector circuit and the comparator that extracts the RF envelope into pulse train digital signal [3]. This signal has to be decoded into the actual binary information.

Digital signal is encoded with PIE (Pulse Interval Encoding) format. Information about logical "0" and "1" is decoded from the ratio of periods of the high state and the low state according to the Fig. 4. All time intervals are expressed in "*Tari*" values defined by the standard which are in absolute values from 6.25 μs to 25 μs.

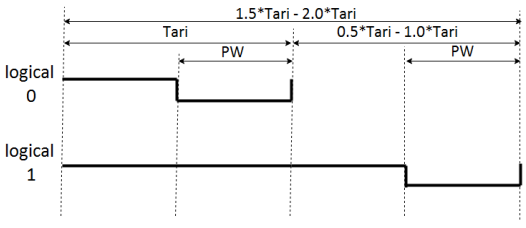

Figure 4. PIE encoding.

Extraction of the digital information is performed in the digital circuitry, by counting the periods of high and low states and calculating the ratio between these two values.

C. Envelope detector

The envelope detector circuit takes as the input the RF signal with the ASK modulation and generates digital signal with PIE encoding (PWM signal) as the output. The circuit consists of two main blocks: the rectifier circuit and the comparator with the circuit for the referent voltage.

The basic rectifier cell architecture is used for providing DC power and demodulation. The circuit of the voltage doubler cell is shown in Fig 5.

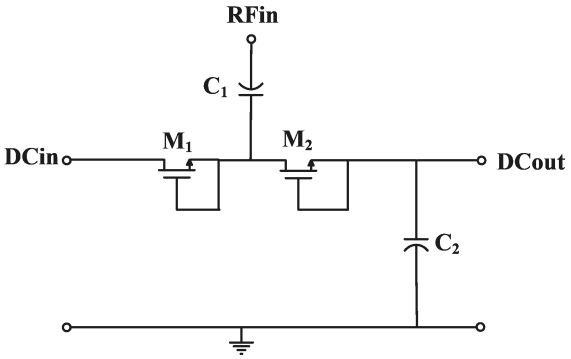

Figure 5. Voltage Doubler Cell.

This architecture is suitable for RFID applications due to its simplicity and re-usability in form of multiplication configuration (connection in series) for achieving larger output voltages.

In an RF signal period when the signal is negative and the *DCin* input is grounded, *M1* NMOS transistor connected as a diode is turned on and the capacitor *C1* is charged to (V_{pk} - V_{on}), where V_{pk} is peak RF amplitude and V_{on} is the drain source voltage of the transistor in on state. During this period the device *M2* is in off state and *C2* in disconnected from the RF signal.

In the positive signal period the device *M1* turns off while *M2* turns on. The capacitor *C2* is charged through the path *RFin*, capacitor *C1* and device *M2* (in on state), to the voltage defined in (1)

$$V_{C2} = V_{pk} + (V_{pk} - V_{on}) - V_{on} = 2*(V_{pk}-V_{on}). \quad (1)$$

Equation (1) is ideal, without taking into count RC time constant of equivalent resistance of diode-connected-devices and capacitors, effecting charging and discharging characteristics on the RF carrier frequency.

The basic voltage doubler cell can be connected in series by connecting the output *DCout* to the input *DCin* of the following stage. In that way the RF signal having the low amplitudes, by multiplication of the stages, produces the output with the voltage levels suitable for further analogue signal processing.

The basic voltage doubler cell is instantiated twice and in this configuration represents the low level cell in the hierarchy of the envelope detector module. The schematic is shown in Fig. 6.

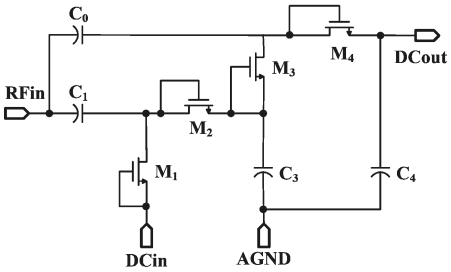

Figure 6. Envelope Detector Cell.

The cell is connected in series three times and the output of the last cell in the series is connected to the diode connected NMOS load, at the pin *ENV_ANA_OUT*, shown in Fig. 7.

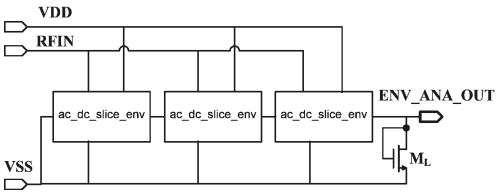

Figure 7. Envelope Detector Module.

The design challenge is to the optimize the design of the voltage basic voltage doubler cell and the NMOS diode connected load M_L to provide acceptable characteristics of these two parameters: timing of the PWM output signal (regarding rise and fall times) and the acceptable voltage level of the signal envelope to be used as the input in the following comparator stage.

The design trade-offs are needed in order to get optimal characteristics of the following requirements. RF signal amplitude at the input of the envelope detector restricted the voltage levels at the output. If higher capacitor values are used with the smaller amplitude of RF signal, higher voltages are achieved at the output. Higher capacitor values demanded NMOS devices with lower equivalent resistance in the voltage doubler cell to keep the timing constant inside acceptable values restricts by the protocol regarding rise and fall times. Communication from the reader to the tag can operate at *"Tari"* values down to 6.25 μs which is a limiting factor for the speed of the envelope detection. The rise and fall times are especially dependent on the dimensions of the NMOS connected load M_L at the output of the envelope detector module. When the NMOS load has lower equivalent resistance (higher width to length (W/L) ratios) to suit rise and fall time requirements, it also lowers the voltage level at the output (in the high envelope state) which limits the useful voltage range of the comparator stage.

Besides all this, the technology corners and temperature range significantly influences the circuit characteristics.

Extensive SPICE simulations are run across technology corners and temperature range from 0ºC to 85ºC and different levels of RF signal amplitudes from 250 mV to 450 mV. The circuit exhibits slowest response on slow corners and low temperatures and this is the worst case for the operation of the envelope detector.

The last stage before the digital control is the comparator stage which produces digital signal from the demodulated signal envelope.

The comparator stage consists of the comparator (Fig. 8) and the circuit for the referent voltage. Since the voltage and current reference block provides regulated power supply for the analogue and the digital circuits, the comparator stage was designed with defined supply voltage range and with the low power consumption as the priority demand. The reference voltage for the comparator is implemented as a simple voltage divider with diode-connected isolated NMOS devices with the bulk connected on the device source for each device separately. This eliminates body effect [4] for the devices and provides more precise voltage division.

The comparator uses a simple architecture of a differential pair and a buffer at the output [5]. It uses bias current of 200 nA. The comparator doesn't need to detect small differences of the input signal, so the offset is not an issue and differential pair transistors are relatively small devices. The input range of the signal is suitable for the NMOS type devices. The output buffer provides additional gain and driving strength for routing to the digital control logic.

The comparator in this application works with the signal transition at its input in the order of microseconds when the signal changes state. It results in the propagation time of the comparator of few hundred nanoseconds. The propagation time is in this case sufficient for the application. Digital logic, which counts the periods of the high state and the low state of the signal, is running on the system clock of 2 MHz, not synchronized with the demodulated signal coming from the envelope detection module. Therefore the transition of the comparator output signal can be detected in the worst case with the delay of almost 500 ns if the comparator changes state just after the clock transition. Tolerances defined by the EPC Gen2 protocol for the *"Tari"* value and the respective intervals of the high and the low signal state are loose, so the inaccuracy in the detection of the high and the low signal periods does not influence functionality.

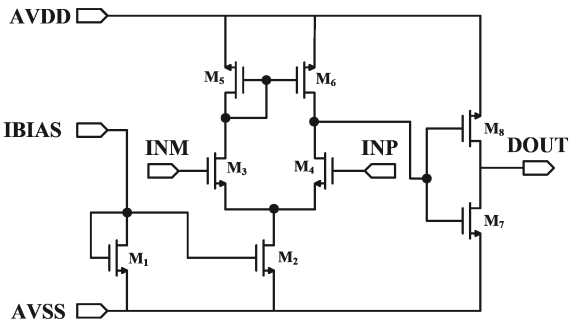

Figure 8. Comparator.

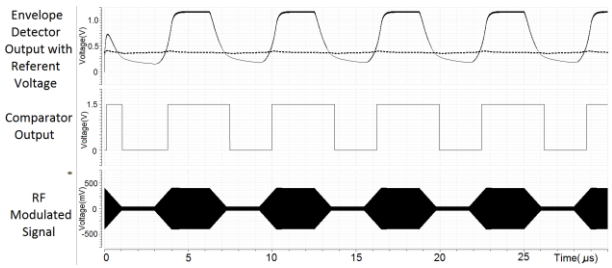

Figure 9. Envelope Detector Signal Waveforms.

The simulation results of the envelope detector circuit are shown in Fig. 9. RF signal is modulated with 400 mV amplitude in high state and 40 mV in the low state with the rise and fall time in accordance to the Gen2 standard. The analogue signal output of the envelope detector is displayed together with the referent voltage in the first waveform row. The referent voltage is around 400 mV, while the analogue signal spans from 100 mV for the low state to 1.2 V for the high state. The comparator output is in the second row. This digital signal is fed directly to the digital control logic for signal processing. The RF modulated signal is shown in the third row.

Simulations are run with the amplitude range of RF signal from 275 mV to 450 mV. The temperature range is from 0º C to 85º C and the technology process corners is used for slow, typical and fast case. The supply voltage is 1.5V. The results obtained by the simulations using these parameters fall into the allowed values defined by the protocol.

D. Layout

The layout was designed with the special care to the interferences that could experience analogue blocks from the RF. Besides that the analogue signals and digital signals both are present on the single chip. Each block is surrounded by N+ and P+ guard rings and layout is floor-planned and blocks are placed keeping in mind interferences that come from RF signal path and digital logic [6].

Fig. 10 shows the layout of the RF and analogue blocks arranged in a rectangular block with the dimensions approx. 550 um x 700 um.

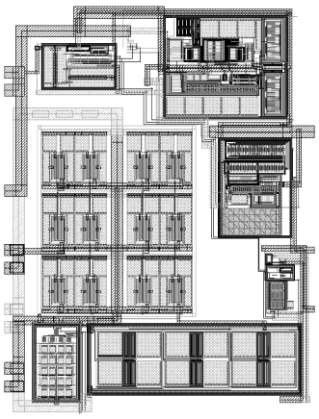

Figure 10. Layout of RF and Analogue Blocks.

E. Digital control

The digital control supports the EPC Gen2 protocol requirements for the communication with standard RFID readers. Protocol implements many features, but for the purpose of this application only a subset of commands is chosen to be included in the digital control. These commands and procedures from the IC side define a set of communication procedures with the reader that includes exchange of data regarding chip identification number and the data reading from the ADC. The minimal protocol subset is implemented to have low power consumption in the limited power budget.

Digital control is designed in VHDL, simulated and synthesized in Cadence tools. Digital control system is designed hierarchically, divided into seven major blocks, shown in the Fig. 11.

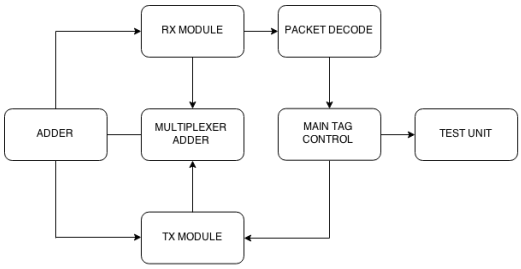

Figure 11. Digital Control Hierarchy.

The digital logic operates on the externally provided system clock of 2 MHz accompanied with the asynchronous reset signal for resetting the digital logic.

The input signal to the digital logic is the PWM signal coming from the envelope detector block.

Output signals are the digital signal for the modulation of the antenna load (backscattering) and some test signals for monitoring the state of the logic and for the debugging purpose.

The main Tag Control block is the block that synchronizes and controls the operation of the complete digital control. It places the tag in the receive mode or the transmit mode and controls the state of the tag (*Ready*, *Arbitrate*, *Reply* and *Acknowledged* states). Response to the protocol specific set of command and procedures (*"Inventory"*) allow sending of the required data over the communication channel.

The RX Module is in charge of receiving data coming in the form of the PWM signal and decoding it to the raw digital information.

The Packet Decode module decodes the information from the RX Module and forwards it to the Main Tag Control. CRC5 cyclic redundancy check and the generation of the pseudo-random digital word is a part of the block functionality.

The Pseudo-random number generation is implemented as 16-bit-LFSR (Linear Feedback Shift Register) [7]. The coefficients for the feedback are chosen to generate long sequences without repetition. Additional randomness is assured by feeding LSB bit in LFSR with the LSB bit of the counter in RX module. Since each chip has its own clock uncorrelated to the other chips and clocks, the LSB bit in each chip's counter is also random.

The TX module implements FM0 baseband modulation for the communication from the chip (tag) to the reader. It also includes FIFO buffer and CRC16 cyclic redundancy check as the part of the protocol requirements.

The Adder block implements 12-bit adder with the command sequences performing adding and subtracting using second complement arithmetic [8].

The Multiplexer Adder block is used for sharing resource of Adder block among other blocks. The architecture consisting of a multiplexer and one adder is chosen to minimize digital logic and have low power consumption. It is feasible because blocks and their corresponding operations are mainly done in sequence.

The Test Unit block is added for testing and debugging purposes. By setting two digital inputs it is possible to monitor 4-bit signals which corresponds to the states of internal blocks' state machines. Two additional test output signals monitor bit by bit information in the receive and the transmit mode.

F. Digital Logic Implementation Details

Logical and physical synthesis are performed on the VHDL code for the digital logic. The statistics on the final synthesized layout is summarized in Table I.

TABLE I. DIGITAL LOGIC STATISTICS

Gate count	Number	Area[a]	Overall Area[a] (with routing and power rails)
Sequential	493	0.032	0.112
Combinational	1520	0.022	

a. In mm^2

III. PROTOTYPE

The designed chip was sent for processing in UMC L180 Mixed-Mode/RF technology as Europractice mini@sic MPW run. The chip will be packaged in PLCC 84 pin package with test pins that will be used for the measurement purposes.

Beside analogue pins for testing, all input and output digital pins will be available for measurement and monitoring purposes. Beside the measurement on the synthesized logic, there is another option envisaged for the measurement and debugging. The external FPGA board can be connected to the input and output pins and used for synthesizing updated version of VHDL for the digital logic. In this way new version of the digital logic could be tested combined with the actual circuits and responses from the analogue blocks.

Measurements will be done with the standard RFID reader/development board with the low level communication data for the logging and the debugging.

IV. CONLUSION

This paper presents concept for intelligent wireless sensor networks based on the UHF EPC Gen2 RFID protocol. Widely used protocol, with many standard RFID readers available on the market gives a good ground for such a concept. The proposed compact chip solution, with a limited subset of communication protocol commands and the simple RF receiver and transmitter architecture, is an interesting solution for the low cost sensor networks without the battery supply. The simulation results of RF communication path showed that the concept is feasible. Measurements of the processed chip using standard RFID readers providing power and communication will show how the simulation results correspond to the chip functionality in the real environment. Built-in test features for both analogue blocks and digital control will allow detailed measurements, post analysis and debugging.

Abstract - We investigate the influence of temperature on multimode Fabry-Pérot laser output in a proposed colorless WDM system with self-seeding via modulation averaging reflector and with BLS-seeding. In particular, we investigate the connection between the information about the optical laser output from the laser integrated monitor photodetector and optical power output of the entire system with temperature change of the laser diode.

I. INTRODUCTION

Self-seeded colorless wavelength-division-multiplexed passive optical networks (WDM-PON) may give rise to access networks with the lowest cost bidirectional link per Gbps per user [1-4]. They have been investigated as a part of New Generation PON phase 2 development efforts on networks that are independent of present PON solutions. However, high transmitter cost still limits the widespread adoption of self-seeded WDM-PON and hence there is an opportunity and a market need for cost-effective colorless WDM transmitters. This work is directed towards creating an adaptable low-cost multi-wavelength transmitter for WDM-PON.

Self-seeding WDM-PON architecture comprises an extended resonator with an optical gain and modulation source at the client end and reflector and a wavelength-selecting filter in the remote node. This cavity can be many kilometers long. The filter in the remote node is a channel in an athermal array-waveguide grating (AAWG) with any number of channels tuned to the dense WDM ITU grid (AAWG with 16, 32, 40, 80, 96 channels are available today). Filtering the emission using many channels of the AAWG is also referred to as spectrum slicing. The number of channels and the corresponding channel separation (200, 100, 50, and 25 GHz available today) are adjusted to efficiently fill the communications window of the modern optical fiber. Presently, the target data rate per wavelength for spectrum-sliced systems is 10 Gbps at channel separations 100 GHz and smaller.

The filtered amplified spontaneous emission light emitted by self-seeded WDM-PON transmitters exhibits a fundamental noise and rate limits owing to the statistical properties of thermal light it emits [5], but up to date transmission rates over 10 Gbps have been reported in self-seeded systems [6], hence target is achievable.

Among the disadvantages of the self-seeded network architecture is intensity variation of the optical wave returning to the gain element (due to the presence of modulation in the seeding light) and fragile link stability. The first problem reduces the link margin but can be reduced by saturating the gain element (laser or reflective semiconductor optical amplifier) [7] or by using modulation averaging technique [8]. The gain elements are generally very polarization dependent, while the birefringence in the fiber and other optical elements degrade, add noise and can destabilize the link. Stabilization of self-seeded systems has been one of its difficult problems. Time reversal of the accrued polarization is one approach [9], while depolarizing the beam and stabilizing modulation using modulation-averaging reflectors (MAR) located in the remote node is another [8][10] (used in this work). The transmitting part of a self-seeded WDM-PON system is illustrated in Fig. 1 when a MAR is connected at the output of the AAWG (1). Light oscillates between the FP-LD and the MAR while it is being filtered with the AAWG and coupled out (as P4) of the cavity using a coupler.

Self-seeding is an alternative approach to the previous generation WDM-PON architectures which employ a broadband light source (BLS) to provide seeding light to identical transceivers connected to the WDM ports on the AAWG in the remote node. The BLS is typically located in the central office. Fig. 1, possibility (2), shows a simplified configuration of a transmitter using BLS to seed the gain elements. The light emitted from the BLS is filtered by the AAWG (also referred to as spectral slicing) and brought to the client end where it is used to injection lock the FP-LD or reflective semiconductor optical amplifier [11].

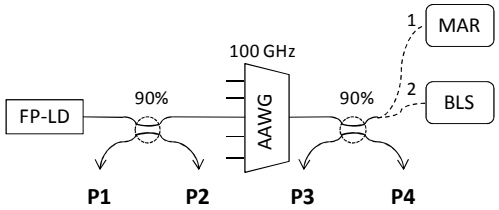

Figure 1. Measurement setup with a MAR or BLS seeding

The longitudinal modes of FP-LDs shift with temperature around 0.1 nm/°C or less. When using uncooled FP-LDs for injection locking, we strive to ensure that the seeding light matches the wavelength of one of the FP-LD resonant modes. If the wavelengths did not match, for example with temperature change of FP-LD, the output power of the FP-LD could not be sufficient for successful transmission. One way for eliminating this risk is to use AWG with channel frequency width wider than the frequency mode spacing of FP-LD, so that at least two mode wavelengths fit within the channel bandwidth. In this way, the seeding light always excites at least one mode regardless of the temperature of the FP-LD. A problem occurs when using AAWGs with channel spacing that is smaller than the longitudinal mode separation in the FP-LD. However, manufacturing of long FP-LDs is problematic because of higher cost. For 100 GHz wavelength separation, the FP-LD length has to approach 1 mm.

In this paper we present the temperature dependence of the light-emission characteristics of a short-cavity FP-LD as groundwork for temperature tuning of FP-LD performance in WDM-PON systems. We use a FP-LD extracted from a 16-channel 200-GHz BLS-seeded WDM-PON system and we are applying it to a denser 100 GHz athermal AWG by self-seeding and the original BLS.

II. Experimental Setup

The measurement setup, shown in Fig. 1, is an extended cavity comprising of an injection-locked Fabry-Perot laser diode (FP-LD), a 32-channel athermal array-waveguide grating (AAWG) with 100-GHz channel spacing, and either (1) a modulation-averaging reflector (MAR) or (2) broad-band light source (BLS) terminating the extended cavity on the other end. The elements are coupled with standard singlemode fiber and optical couplers were introduced between the FP and the AAWG, and between the AAWG and the cavity termination. By connecting the MAR (1) at the end of the cavity, the test setup forms a self-seeded multi-wavelength optical source, while connecting the BLS (2), the test setup forms a BLS-seeded multi-wavelength optical source. The test setup is designed with the intention to mimic a real-life WDM-PON system with the exception of the extended fiber lengths: distribution fiber between the client end and the remote node, and the feeder fiber between the remote node and the central-office. The fiber segments in our experiment have lengths equal to the patch cords of the optical couplers used. The couplers provide sampling of the optical power and spectra incident on the FP-LD (P1), emitted by the FP-LD (P2), reflected by the MAR or emitted by the BLS (P3), and emitted by the multi-wavelength optical source (P4).

A microcontroller was used to set the laser drive current I_{LD}, the power to the heater (10-Ω resistor), to monitor the integrated monitor photo diode (IMPD) current I_{PD}, and read the temperature T using the LM35 thermometer chip (Fig. 2). The optical powers (P1-P4) were measured using a table-top optical power meter with analog output which was also fed to the microcontroller. In this way, all the experiments, data acquisition and export were conducted using the microcontroller. The

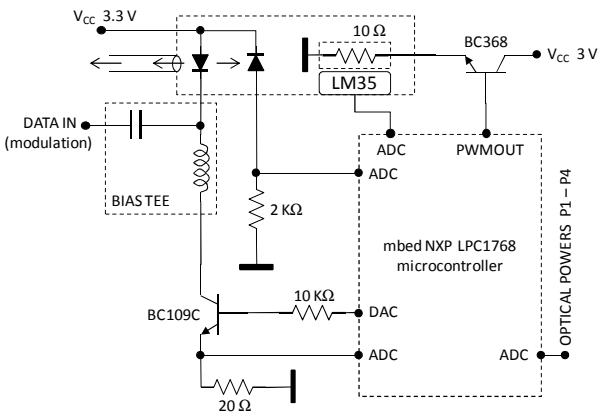

Figure 2. FP-LD driver scheme. Driver current (I_{LD}) was driven by the DAC port and monitored as voltage on a 20 kΩ resistor by the ADC port. The photodetector current (I_{PD}), temperature from LM35 temperature sensor and optical detectors (P1 - P4) were all sensed by the available ADC ports on the microcontroller. The heater (10Ω) was driven by pulse width modulated output. DATA IN port was not used.

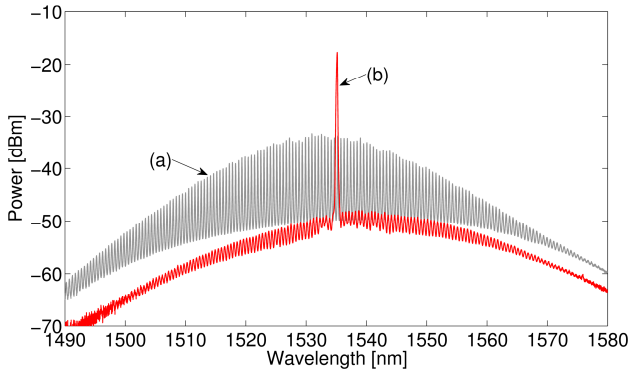

Figure 3. Emission spectrum measured at P2 when (a) neither MAR or BLS are connected on the other end of the cavity ("free-running emission") and (b) the emission spectrum measured when MAR is connected, namely, the FP-LD is injection-locked. The laser drive current in both cases was I_{LD}=35 mA.

advantage of this approach was its simplicity and it was a preliminary test for integrating the required functionality into a single fiber-optic module that would contain the FP-LD and a microcontroller.

The FP-LD was extracted from an optical network terminal (ONT) of a commercial BLS-seeded WDM-PON system (ADC PONy Express 16 DWDM PON). The laser is packaged in a Transmitter Optical Subassembly (TOSA) along with an integrated monitor photodiode (IMPD) and mounted on a temperature-controlled stage. The FP-LD laser came with a ~2% front-facet coating and about 60 GHz mode separation. Fig. 3(a) shows the free-running (no optical feedback) emission spectra of the FP-LD. When no optical feedback is provided, the laser does not reach threshold within the operating current range planned by the control circuit, hence the free-running spectra (Fig. 3(a)) never shows any dominant wavelengths. When the external cavity is terminated with a MAR, the AAWG provides optical feedback peaking at only one wavelength thus injection locking the FP-LD. This is manifested with a strong and narrow emission shown in Fig. 3(b) and reduced laser gain (shallower resonance fringes in the emission spectrum). Channel 3 of

AAWG with wavelength 1535.1 nm was used for all experiments.

For all experiments, FP-LD was operated in continuous-wave (CW) mode, without any modulation signal on data in port (Fig. 2). In all of the experiments a feedback control loop was implemented on the microprocessor to adjust the laser drive current (I_{LD}) in order to maintain either constant photodetector current (I_{PD}) or optical powers (P2 or P4) as we vary the FP-LD temperature. We refer to these measurement modes as *constant I_{PD} mode*, *constant P1, or P2 modes*. The effective coupling of optical energy from the cavity formed by the FP-LD and the AAWG (and possibly MAR) to the outside world (P4) is referred to as output coupling.

III. Results and Discussion

In the proposed injection locking schemes, a temperature change of the FP-LD should cause a change in output laser power (P2), photodetector current (I_{PD}), and the system output power (P4). Temperature increase causes a wavelength shift of longitudinal modes towards longer wavelengths. Since we are using an intra-cavity filter (channel 3 of the AAWG) it is clear that when any one of the FP-LD longitudinal modes coincide with the selected channel of the AAWG, the output power (P4) at given current should increase or conversely, if the output power (for example P4) was maintained constant, the laser current I_{LD} required to deliver the specified output power should reduce. Furthermore, inasmuch as the photodetector current I_{PD} is a measure of the optical power emitted from the laser, the I_{PD} can be used to determine when (as the temperature varies) the FP-LD mode coincides with the externally asserted filter center wavelength. For example, while in self-seeding mode, using the feedback loop to adjust the I_{LD} to maintain I_{PD} constant, should show a minimum in the I_{LD} when the extended cavity has lowest loss, namely, when the FP-LD mode coincides with the AAWG channel. The experiments reported in this paper show that this simple interpretation is generally true, but that the relationship between the photodetector current (I_{PD}), laser drive current (I_{LD}) and the outputs of the optical system (P1, P2, and P4) is a bit more complex and not entirely understood. For all measurements shown, we took data with heating and cooling temperature-scan directions. We observed a small (<1°) shift in temperature between the data for those two scans, while the relationships between currents (I_{LD}, I_{PD}) and optical outputs (P1, P2, and P4) remained unchanged. Hence we show only results for the cooling scans.

Our first group of experiments (sections A, B and C) uses a self-seeded configuration illustrated with Fig. 1 and connection 1 (MAR). In sections D and E, we characterize the same relationship by using a BLS (Fig. 1, connection 2 (BLS)).

A. *MAR self-seeding: Constant I_{PD}*

In this measurement, we varied the laser temperature from 43°C to 24°C while we kept I_{PD} constant and adjusted I_{LD} accordingly. We monitor the laser emission spectrum at P2 and note the output powers from P1, P2, and P4. The spectra shows that wavelengths of multiple modes of the FP-LD all drift towards longer wavelengths (Fig. 4), but that there is substantial mode-pulling when any of the FP-LD modes come close to the externally asserted low loss wavelength. This is visible by the peak wavelength jumping to or away from the constant value of 1535.1 nm.

Fig. 5 shows the I_{PD}, I_{LD}, P1, P2, and P4 normalized and plotted on the same graph. As the temperature increases and longitudinal modes of the laser go in and out of resonance with the externally asserted AAWG mode, the drive current oscillates and grows on the average. The I_{LD} average current increase is a result of laser gain reduction with temperature. When at some temperature the laser mode matches the AAWG channel, this means that the losses of the extended resonator (from FP-LD to MAR) are at minimum. Since lower resonator losses mean lower threshold gain, we expect the laser current to be at a minimum as well. The optical power P2 oscillates synchronously with the laser current I_{LD} and exhibits extrema that coincide with the extrema in the I_{LD} current. This is also expected as more current through the gain forces the laser to emit more spontaneous emission.

The temperature dependence of the emitted power P4 and the power returning to seed the FP-LD also exhibits an oscillation versus temperature. As temperature effectively controls the output coupler of this extended resonator, one would expect the minima in the laser-emitted power P2 to coincide with the maxima of the emitted and seeding powers P4 and P1, respectively. The variation in the seeding power P1 is proportional to P4 since P1 is effectively a filtered and reflected version of P4. However, surprisingly, the P4 extrema do not coincide with the extrema of P2: There is a small, but noticeable temperature offset between the P4 maximum and P2 minimum (shown in Fig. 5) where ideally there should be none. We observe a temperature offset between 1.2°C and 1.6°C. Optical power P3 was observed but not shown in the results, because it was the same as power P1 with small power difference due to the AWG channel attenuation.

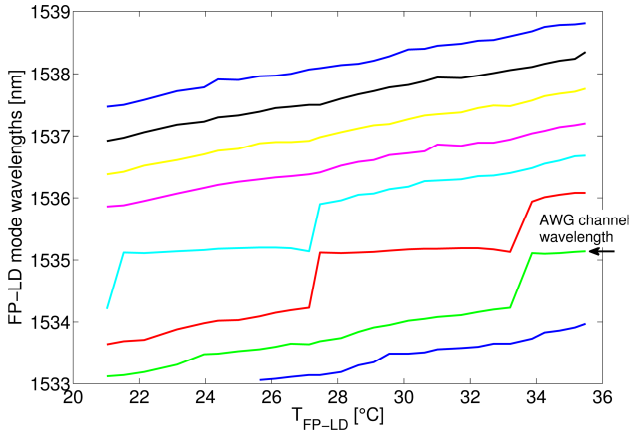

Figure 4. (MAR) Plot of the wavelengths of distinguishable local maxima in the emission spectrum P2 of the injection locked FP-LD as temperature varies.

B. *MAR self-seeding: Constant P2*

In this measurement, the I_{LD} current was driven to maintain constant power P2. The results, shown in Fig. 6 show behavior consistent with what was observed in Constant I_{PD} measurement previously: P2 is proportional to I_{LD}, except for the growth in average I_{LD} with temperature, and a small offset between the temperatures of maximum P4 and I_{PD}. Relative to temperature change, the change of I_{LD} current seems to be almost linear, with very small variations. Compared with results in Fig. 5, it can be confirmed that variations in laser power P2, with temperature change, depend mostly on variations of I_{LD} current.

C. *MAR self-seeding: Constant P1*

In this experiment, the I_{LD} current was driven to maintain constant power P1. The results show different behavior from what was observed in Constant P2 measurement previously: I_{PD}, I_{LD} and P4 all seem to be proportional with one another, except for the growth in average I_{LD} with temperature (Fig. 7). The temperature offset between maxima is very small. Relative to P4, the I_{LD} is in offset by ~ 0.2°C, and the I_{PD} is by ~ - 0.2°C. Compared with results in Fig. 6, the slope of the curves is to the right.

D. *BLS seeding: Constant I_{PD}*

In this method, the BLS was connected to the terminating end of the extended resonator as shown with connection (2) in Fig. 1. The seeding power was kept constant at P1= -21.6 dBm. The results of driving the laser current I_{LD} for constant I_{PD} current show similar variations in observed powers and currents, but without any temperature offset (Fig. 8). Note that the maximum in the optical power P4 coincides with the minimum in optical power P2 because when the laser mode matches the externally asserted mode (AAWG) the output coupling (from laser to P4) is lowest.

E. *BLS seeding: Constant P2*

In this experiment, the I_{LD} current was driven to maintain constant power P2. The results are shown in Fig. 9. It can be seen that the same almost linear variation of I_{LD} current was also observed as in for the self-seeded case shown in Fig. 6. The results are consistent with the constant I_{PD} measurements. Relative to the self-seeding

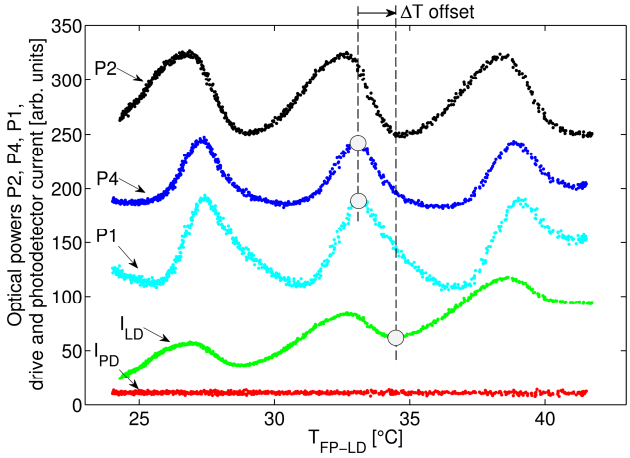

Figure 5. (MAR) Driving I_{LD} current for constant I_{PD} current. All values are plotted with linear units; P2≈[-12.94, -11.66] dBm; P4≈[-15.95, -14.67] dBm; P1≈[-21.73, -24.28] dBm; I_{LD}≈[20, 30] mA; I_{PD}≈250 μA.

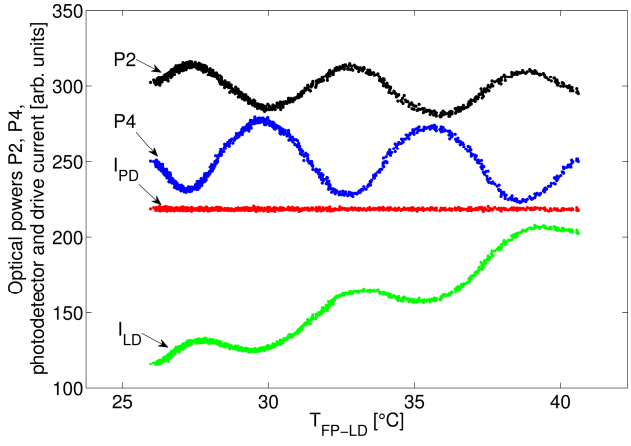

Figure 8. (BLS) Driving I_{LD} current for constant I_{PD} current. All values are plotted with linear units; P2≈[-9.28, -8.77] dBm; P4≈[-15.67, -14.65] dBm; I_{PD}≈250 μA; I_{LD}≈[27, 38] mA.

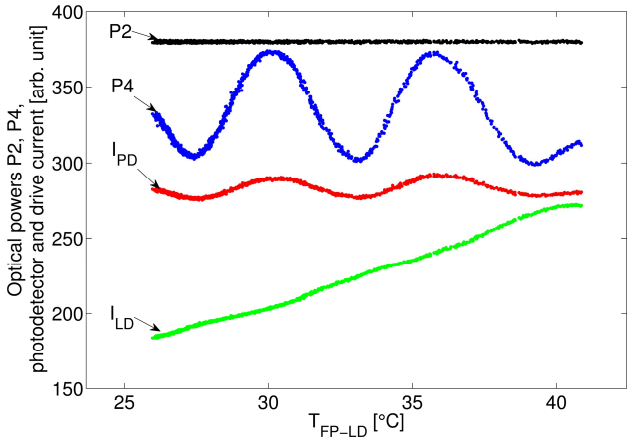

Figure 9. (BLS) Driving I_{LD} current for constant power P2. All values are plotted with linear units; P2≈ -8.99 dBm; P4≈[-15.71, -14.31] dBm; I_{PD}≈[240, 255] µA; I_{LD}≈[28, 37] mA.

results, the variations in I_{PD} current were significantly smaller.

IV. Conclusion

Injection locking of FP-LDs by either self-seeding or using a broadband-light-source, allows one to use the available optical and electrical variables at the client end (I_{PD}, I_{LD}, P1 and P2) to gain information about the interaction between the modes of the FP-LD and the AAWG at the remote node which is hundreds of thousands of meters away. The extended cavity formed by the FP-LD and the AAWG and MAR in the remote node is not coherent, but it exhibits a clear threshold behavior.

In this work, we presented a simple microprocessor-driven control system featuring feedback control loops for stabilizing the laser output depending on either monitor photodiode current, or any other optical power measured in the system. The developed algorithms will be implemented in a complete temperature and output optical power stabilizing system – the goal of this project.

The origin of the temperature offset between temperature-dependence of light emitted from the laser (P2) and the light emitted from the multi-wavelength optical source (P4) is not entirely understood. However, this effect occurs in a self-seeded system, but not in a BLS-seeded system which clearly indicates that the offset is related to the mode pulling and the mutual interaction of the laser with the AAWG mode.

Abstract – We demonstrate a fiber-optic sensor for monitoring mechanical vibrations in high-power electric machines built using 3D-printing. We describe the design, mechanical and optical modeling, and the results of its preliminary characterization. The measurements show linear sensor response in the frequency range 10 to 150 Hz.

I. Introduction

The overwhelming majority of the world's electric power is created by turbine-driven electric generators, while almost half of the energy in the world is consumed by electric motors. Many of these motors and almost all of power generators operate continuously, uninterrupted, and are brought off-line only for planned inspections and maintenance. A catastrophic failure of large generators or motors is generally a serious safety, structural, and financial problem. These machines therefore have to be protected from accidental over-stressing and damage. Presently this protection makes use of remote monitoring of the performance using a variety of sensors (temperature, vibrations, and mechanical stress) along with predictive data analytics to minimize the damage, time, and financial loss. Monitoring of vibration amplitude or acceleration is an essential element of this protection, performance optimization, and prolonging machine's life.

One approach to building vibration sensors is by employing electro-mechanical technology where inertial force is converted to an electric signal via piezoelectric sensing or time-varying capacitive or inductive coupling [1]. Electro-mechanical sensors regularly require electrical power to be delivered to the sensor. In high-power electric machines this is a problem, as sensors are most often needed in places where very strong alternating electric and magnetic fields are present. This, in turn, results in large induced electromagnetic forces in the circuit of the sensor and high danger of voltage breakdown. In such environments, one prefers vibration sensors that have no conductive parts.

Fiber-optic sensor, on the other hand, can be made non-conductive and can convert mechanical vibration into a modulation of an optical signal that is generated and sensed remotely. The common approach employed in fiber-optic vibration sensors is that the optical fibers themselves are allowed to bend and vibrate depending on their own weight and moment of inertia [2] - [6]. Optical fibers are made out of quartz or polymer and are encapsulated within insulating materials, while light propagation through them is not affected by electric or magnetic fields. This makes them suitable for installation in areas where very strong fields are present. Additionally, due to the very low light-attenuation in present-day optical fibers, the location where the light is generated and sensed can be meters or kilometers away from the sensor. Therefore, fiber-optic vibration sensors are an ideal match for this environment as the only connections between the sensors and the outside world are optical fibers that are electrically insulating, flexible, and lightweight.

The objective of this work to develop a highly sensitive, lightweight, and inexpensive fiber-optic vibration sensor for high-power electric machines and similar applications. The target specifications are bandwidth 10 Hz to 150 Hz and acceleration range from 0.1 to 10g. In this paper, we report on the design and demonstrate the operation of a prototype fiber-optic vibration sensor made using 3D printing. The prototype is simple to assemble, adjust, and repair. We discuss the design and show results of frequency response and linearity characterization.

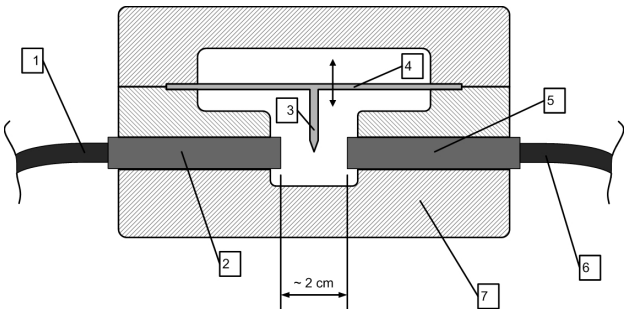

Figure 1 – Schematic of the fiber-optic vibration sensor developed and demonstrated in this work: (1) optical fiber, (2) graded-index collimating lens (source of light), (3) light-modulating blade, (4) bendable beam, (5) light-receiving graded-index collimating lens, (6) optical fiber, and (7) the housing.

II. Sensor Design

The working principle of our fiber-optic sensor is explained with the help of Figure 1. A multimode optical fiber (1) is terminated with a collimating graded-index (GRIN) lens (2) which emits a collimated beam of constant light intensity towards another identical GRIN lens (5) which focuses the beam back into another multimode fiber (6). The light beam is partially blocked using a blade (3) attached to a bendable beam (4) whose motion perpendicular to the optical axis of the beam modulates the intensity of the light reaching the GRIN

lens (5). The housing (7) is attached to a machine body and as the entire sensor vibrates in the *z*-direction, the blade moves relative to the optical beam and its motion is directly translated into intensity modulation of the light leaving with fiber (6).

The weight of the blade (3) and the beam (4) spring constant define the frequency response of the sensor and we desire flexibility in adjusting this response. In common fiber-optic vibration sensors the optical fibers themselves bend and vibrate depending on their own weight and moment of inertia and there one's primary design parameter is the length of the free-standing fiber (and a very limited range of fiber diameters and materials) [2]-[6]. In the structure shown in Figure 1, however, the dimensions and the material used in the bendable beam as well as the weight of the blade can all be adjusted without much restriction. In addition, the beam extending only halfway into the cavity and the blade attached at its end can be realized, while multiple sensors for different axes may be placed into the same housing enabling triaxial vibration measurements. In this work we demonstrate vibration measurement along only one axis.

The design of the sensor prototype was done iteratively considering available components, dimensions, and performance. We first selected GRIN lenses with beam diameter 1.8 mm. This defined the maximum blade excursion (i.e., beam deflection). We wanted the excursion of the blade at maximum acceleration (10g) not to exceed the width of the collimated beam. In this way we ensure that 100% light modulation will coincide with the maximum linear dynamic range of the sensor. In order to achieve the largest dynamic range, we desire that when there is no vibration, exactly one half the light passes through the sensor (the blade is at its central position). Under vibration, the largest excursion of the blade should be one half of the total (peak-to-peak) blade travel. If the blade was to travel outside the linear dynamic range, the light response would saturate introducing nonlinearity and higher harmonics into the response – an undesired feature which would obscure the fundamental intensity harmonic readout.

In order to accurately estimate the effect of the aperture excursion and its effect on the light transmission for our sensor, we modeled light transmission between the lenses for several practical lens-to-lens distances This analysis was performed analytically using ray tracing from an extended optical source (details are given in [7] and [8]). This excursion maximum was determined to be 1 mm. The next task was to design the mechanical part of the sensor that would operate in this range.

The analytic mechanical modeling of the sensor is based on a single beam suspended at two ends with a concentrated mass in its center. The ends of the beam are fixed and the central portion vibrates in direction perpendicular to the optical axis with amplitude $z_p(t)$, the blade attached to the center of the beam moves with amplitude $z(t)$. The solution for this problem is given by the following differential equation [9]-[11]:

$$\frac{d^2z}{dt^2} + 2\zeta\omega_0\frac{dz}{dt} + \omega_0^2 z = 2\zeta\omega_0\frac{dz_p}{dt} + \omega_0^2 z_p \qquad (1)$$

where z and z_p are the blade vertical position and housing vertical position, respectively. The two adjustable parameters in this linear model are the resonant frequency ω_0 and the damping factor ζ. The resonant frequency depends on the spring constant K:

$$\omega_0^2 = K/m \qquad K = 192EI/\ell^3 \qquad (2)$$

where E is the Young's modulus, I moment of the inertia along the beam, ℓ bendable length of the beam, and m the mass of the blade concentrated in the center of the beam. Here K [kg/s²] is the spring constant for vertical deflection of a bendable beam fixed at ends and force applied in the middle [12]. Modulation of light is proportional to the relative position between the blade and the housing, hence the relevant variable is $h = z - z_p$ and its Fourier transform, the transfer function $H(\omega) = h(\omega)/z''_p(\omega)$, which is defined as the optical modulation spectrum divided by the acceleration spectrum and is given by

$$H(\omega) = \frac{\omega_0^2}{\omega_0^2 + 2i\zeta\omega - \omega^2}. \qquad (3)$$

Inasmuch as the system has two poles, it is also clear that the step-response will be monotonic only when $\zeta \geq 1$. Our prototype design did not force this condition, but rather focused on demonstrating the technology.

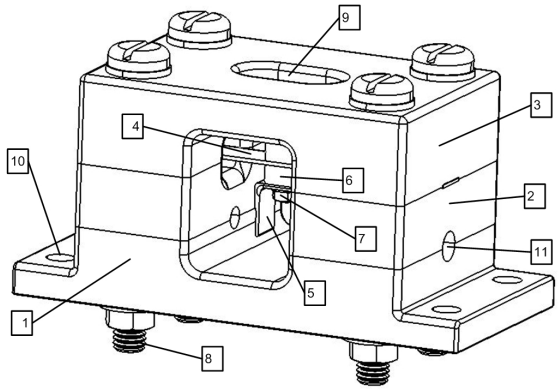

Figure 2 – Isometric view of the sensor

An isometric view of the designed sensor is shown in Figure 2. The housing comprised of three parts: the base plate (1), middle plate (2), and a cover plate (3). The GRIN lenses were clamped within a semi-cylindrical holes (11) and in between the base and the middle plates. The bendable beam (4) is clamped between the middle (2) and cover (3) plates. The plates were designed to allow the reception of beams (or membranes) of different lengths. The blade (5) was attached to a beam holder (6) using a nut/bolt (7). Provisions to adjust the weight (and tighten the nut) was made via hole (9) in the cover plate. In the construction of the housing we made an effort to reduce the number of sharp edges by making them round as much as possible. Four joints with metric thread M5 and related matrices were used to hold the plates together. In our prototype, the bolts were made out of steel, but nylon bolts were ultimately planned.

The dimensions of the beam and the weight of the blade (with the nut/bolt (7) combination) were adjusted to realize $\omega_0 > 150$ Hz. The damping ratio for the polymer to be used in the 3D printing was not known, so we used $\zeta = 0.025$, which is an average of the highest metal value ~0.01 and rubber ~0.05 [13]. The dimensions of the beam were thickness $b = 0.5$ mm, length of bendable section $\ell = 35$ mm, and width $a = 6$ mm. The weight of the beam and the blade were 106 mg and 334 mg, respectively, using the estimated specific weight of the polymer. We used finite-element method (commercial software package FEMAP/NASTRAN) to analyze the mechanical vibration of a weight suspended on a beam where the beam weight and the blade weight were treated as distributed. The computed resonance frequency was ~ 225 Hz.

We also estimated the boundaries of the resonance frequency analytically using equation (2). To this end we took into account that the center section of the beam was tightened with a bolt and two 5-mm wide flat shims, which resulted in an effective bendable length of the beam that was shorter than the physical length ($\ell' = 30$ mm) used in equation (2). Inasmuch as the beam mass is distributed along the beam, it is clear that its contribution to the resonance frequency (2) will be less than if it was concentrated in the center. Assuming that the spring constant was correct (888 kg/s²), using equation (2) we found that the resonance must be larger than 226 Hz, which is obtained with the mass of the blade and the beam assumed to be concentrated in the center. Also it should be smaller than 270 Hz, which is the value obtained if we set the beam mass to zero. These expected values satisfied the target bandwidth and we proceeded to manufacture the sensor.

The GRIN lenses were inserted firmly into the housing and tightened with the two plates. Due to varying tolerance of the housing we adjusted this by inserting a soft wrap around the lenses.

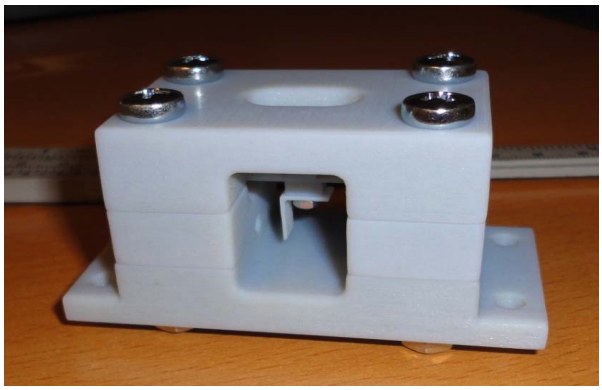

Figure 3 – Photograph of the complete sensor housing

An indentation in the middle and cover plates was made to hold the beam; it has to be held in place firmly with no ability to slip in any direction. The design allows membrane thicknesses between 0.2 and 0.6 mm. The membrane length can be varied ±6 mm. The blade was attached to the beam using an M2 bolt. Four ø5 thru holes were also added to the housing for mounting to the engine block.

The sensor prototype was manufactured using 3D printing using PolyJet Matrix technology on Stratasys CONNEX 350. We used DM 8515 Grey 35 Polymer. The housing and the beam (membrane) were built out of the same material. The density is ~ 1,180 kg/m³ and the Young's module of elasticity was estimated to be ~ 2 GPa, but no information was provided on the damping ratio ζ. The layer thickness was 16 μm.

III. Measurements and Results

The characterization of the sensor was performed by attaching the sensor to a commercially available vibrating table equipped with a powered oscillator and measuring the light transmission through the sensor. The optical fibers were multimode, the optical source a 1550 nm laser, and the receiver is a long-wavelength photodetector with built-in transimpedance amplifier. The acceleration of the vibration stage was monitored using a commercially available acceleration sensor (CAS) with bandwidth greater than 500 Hz [14]. A digital real-time oscilloscope was used to capture the waveforms and read out the data.

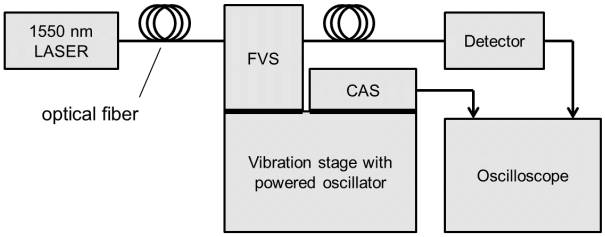

Figure 4 – Block diagram of the characterization setup: The fiber-optic vibration sensor (FVS) and the commercial acceleration sensor (CAS) are mounted on top of the vibration stage with powered oscillator whose amplitude and frequency is manually controlled.

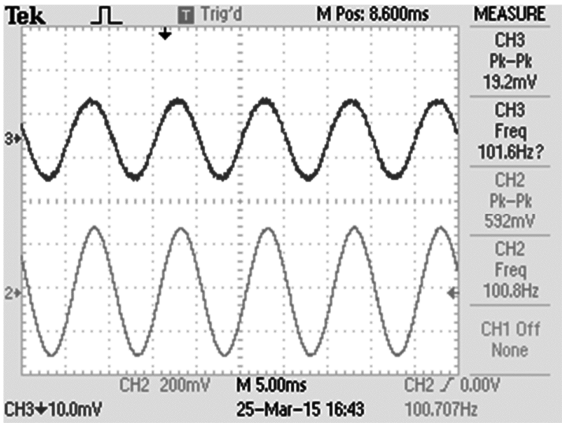

Figure 5 – Typical oscilloscope screen showing the vibrations measured on the fiber-optic vibration sensors (FVS, top curve) and the commercial acceleration sensor (CAS, bottom curve).

The measurement sequence for determining the sensor transfer function were performed as follows: A

frequency was set on the vibrating stage and the vibration magnitude was adjusted so that the commercial acceleration sensor showed 0.1 g for the stage. At this point a reading was made of the peak-to-peak amplitude from the oscilloscope screen (sample shown in Figure 5). The collected data were normalized so that the transfer function would show unity in the low frequency limit. Figure 6 shows the measurement of the transfer function $|H(\omega)|$ for several frequency points along with a fit to the transfer function shown in equation (3).

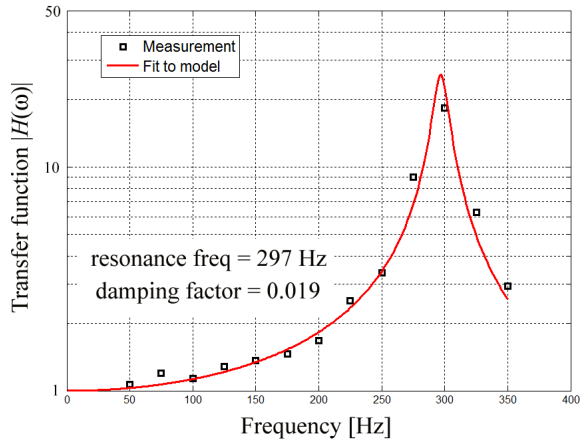

Figure 6 – Fitted transfer function using equation (3) with measured data for acceleration = 0.1 g. The best fitting parameters are listed.

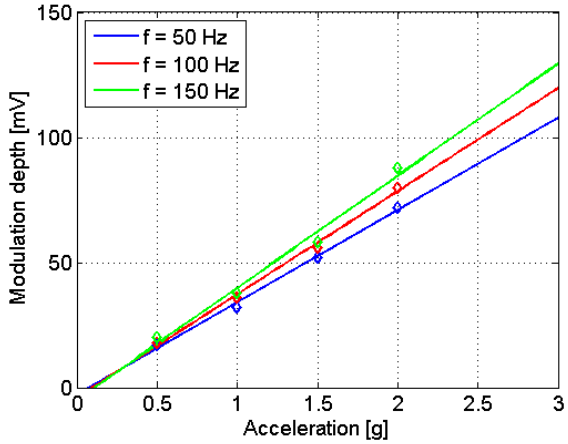

Figure 7 – Modulation depth measured as peak-to-peak voltage swing at the output of the detector versus acceleration for three different vibration frequencies. Maximum acceleration was limited to 3g due to the limit of our reference vibration sensor.

We used the data shown in Figure 6 to determine how close was our design to the sensor we built and to make corrections to the assumed values of the material and/or structure parameters. The fitting parameters for graph in Figure 6 were the resonance frequency (297 Hz) which is close to the values estimated by both numerical and analytical means. We also were able to estimate the damping factor for DM 8515 Grey 35 Polymer: $\zeta \approx 0.019$.

We checked sensor linearity by making measurements at 50, 100, and 150 Hz for different accelerations. The results, shown in Figure 7 show that the sensor is reasonably linear as one would expect.

IV. Conclusion

We demonstrated the design and the characterization of a novel fiber-optic vibration sensor and its straightforward conversion to a prototype by 3D printing.

The sensor shows expected bandwidth (> 150 Hz) and from our measurements, we estimated the damping ratio for DM 8515 Grey 35 Polymer to be $\zeta \approx 0.019$.

The sensor development is still on-going, with effort placed in adjusting the frequency response, acceleration sensitivity, and to minimize the size of the sensor to create a manufacturable prototype. The theoretical analysis shows that the frequency response will continue to exhibit a resonance, unless the damping factor of the system is increased to reach unity. This means some form of damping, such as, a viscous fluid or some other dissipative material, should be added to the structure.

***Abstract*— This paper compares the electromagnetic and electrical properties of a planar inductor used in a low-profile organic light-emitting diode (OLED) driver. A luminary consists of the OLED cell and its driver which uses a planar inductor. The proximity of the OLED cell and the constrained area makes the planar inductor lossy. The planar inductor represents a loop antenna and a main source of radiated emissions of the driver. The properties of the planar inductor are analysed w.r.t. the quality factor and the magnetic moment. The analysis uses a two-level experiment based on EM simulations to explore the geometrical parameters of the inductor. The experiment shows that the track width and the fill-ratio of the inductor have the largest effect on its properties. It is concluded that a planar inductor which introduces minimum power losses and radiated emissions to the OLED driver needs to be optimized w.r.t. the track width and the fill-ratio.**

***Keywords*—thick film inductor, electromagnetic modelling**

I. Introduction

Power converters utilize magnetic devices to store energy and low-profile applications use planar magnetic devices [1]. An example of a planar magnetic device which is commonly used in low-profile devices is the planar inductor [2]-[4].

Organic light-emitting diode (OLED) cells are planar, diffuse lighting devices and they form luminaries with a very low profile. The OLED luminary described in [5] drives the OLED cell using a buck converter. The buck converter utilizes a planar inductor which is considered lossy because of the proximity of the OLED cathode and the planar, distributed design. The planar inductor due to its inductive properties stabilizes the output current, while introducing power losses to the buck converter operation. Furthermore, the ripple of the output current of the buck converter causes the planar inductor to generate radiated emissions. The design of the planar inductor thus affects the operation of the buck converter and its radiated emissions.

The electrical properties of the planar inductor w.r.t. its geometrical design parameters is studied in [6]. A planar inductor on a printed circuit board (PCB) is used in a power converter and it is parametrized in [7]. The design of a planar inductor is optimized w.r.t. the power converter efficiency in [8] and a multiobjective optimization of the planar inductor is done in [9]. The electromagnetic compatibility (EMC) of the buck converters, i.e. its conducted emissions are studied in [10] and [11]. The radiated emissions of a power converter are considered w.r.t. the PCB layout in [12]. A buck converter which uses an air-core solenoid is characterized w.r.t. the magnetic field emissions in [13].

This work was supported by the European Commision under the Seventh Framework Programme (FP7) through project IMOLA „Intelligent light management for OLED on foil applications“ (Grant Agreement No. 288377).

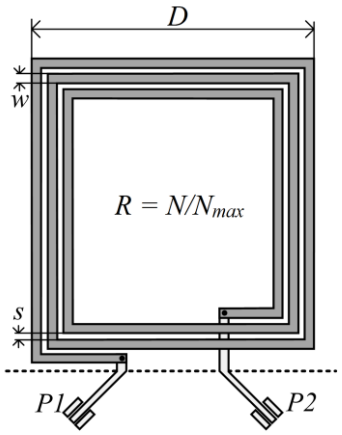

Figure 1. The design of the planar inductor and its parameters.

This paper compares the effects of the design parameters on the electrical properties of the planar inductor related to the buck converter and the radiated emissions of the planar inductor.

The analysis of the planar inductor is based on EM simulations described in Section II. The electrical properties of the planar inductor related to the buck converter are modelled in Section III, while Section IV presents the analysis of the radiated emissions of the planar inductor. The effects of the design parameters of the planar inductor on the electrical and electromagnetic properties are investigated using a screening experiment in Section V. The discussion of the experiment results is presented in Section VI, while Section VII contains the conclusions.

II. Electromagnetic Simulations

The planar inductor is a part of an OLED luminary which consists of the OLED cell and the backplane. The backplane contains the OLED driver, i.e. the buck converter that uses the planar inductor. The dimensions of the OLED cell limit the size of the backplane and thus the dimensions of the planar inductor.

This paper analyses a luminary which uses an OLED cell with dimensions 118x116 mm^2. The luminary is connected to a supply V_{IN} = 24 V and the buck converter supplies the OLED cell with the current I_{OUT} = 400 mA and the voltage V_{OUT} = 13.7 V. The buck converter operates at the switching frequency f_{SW} = 3.6 MHz.

Fig. 1 shows the layout of the planar inductor and its design parameters. The planar inductor has a square shape and its design is determined by the track width *w*, the track spacing *s*, the fill-ratio *R* and the outer dimension *D*. The fill-ratio *R* is the ratio of the number of turns *N* and the maximum number of turns which is determined by the pitch spacing *w+s* and the outer dimension *D*. The inductor structure has two ports *P1* and *P2*. The electrical properties of the planar inductor are simulated using COMSOL Multiphysics which result in two-port *S*-parameters [14].

The simulated substrate has two dielectric layers and three metal layers. The planar inductor is patterned on the 250 micron thick FR4 substrate and it uses two top metal layers which are made from 35 micron thick copper. The bottom metal layer represents the OLED cathode and the dielectric layer between the OLED cathode and the planar inductor represents the glass encapsulation.

The EM simulations analyse the frequency range 300 kHz to 300 MHz, which includes the switching frequency of the converter and the resonant behaviour of the inductor.

III. ELECTRICAL PROPERTIES

The electrical properties of the inductor are commonly represented by the quality factor *Q* which is defined at the frequency *f* as

$$Q(\mathrm{f}) = \frac{2\pi f L_S}{R_S} \tag{1}$$

where L_S is the series inductance and R_S is the series resistance of the inductor. The quality factor gives a ratio of the energy capacity of the inductor and its power losses.

The planar inductor stabilizes the output current of the buck converter, while introducing power losses in the conversion process. The stability of the output current is determined by the inductance, while the power losses are caused by the resistance of the planar inductor. The quality factor *Q* thus represents reasonable choice to represent the electrical characteristics of the planar inductor w.r.t. the buck converter.

The EM simulations of the planar inductor result in two-port *S*-parameters. The *S*-parameters are transformed to *y*-parameters which are used to define the interport, series admittance Y_3 by using

$$Y_3 = -\frac{y_{12} + y_{21}}{2}. \tag{2}$$

The series inductance L_S is extracted at the switching frequency by using

$$L_S = \mathrm{Im}\left[1/Y_3\right]/\left(2\pi f_{SW}\right) \tag{3}$$

and the series resistance R_S is extracted by using

$$R_S = \mathrm{Re}\left[1/Y_3\right]. \tag{4}$$

IV. ELECTROMAGNETIC PROPERTIES

The planar inductor consists of a number of turns and each turn acts as a loop antenna. The radiated emissions of the loop antenna are determined by its magnetic moment, i.e. the product of the loop area and current [15]. The magnetic moment *m* of the planar inductor is defined by the sum of the magnetic moments generated by the individual turns of the inductor which equals

$$m = \sum_{i=1}^{N} I_L A_{L,i} \tag{5}$$

where *N* is the number of turns of the planar inductor, I_L is the inductor current and $A_{L,i}$ is the area of the *i*-th inductor turn.

The current of the planar inductor I_L is determined by the ripple of the output current of the buck converter. The ripple current is related to the design parameters of the buck converter and the inductance of the planar inductor. The peak-to-peak value of the ripple current ΔI_{out} is defined as

$$\Delta I_{out} = \frac{V_{OUT}\left(V_{IN} - V_{OUT}\right)}{2\pi f_{SW} L_S V_{IN}}. \tag{6}$$

The magnetic moment of the planar inductor is derived by taking into account (6) and by determining the area of each inductor turn which leads to

$$m = \Delta I_{out} \sum_{i=1}^{N} \left[D - w - 2\left(i-1\right)\left(w+s\right)\right]^2. \tag{7}$$

V. GEOMETRICAL PARAMETER SCREENING

The geometrical design parameters of the planar inductor are screened by using a two-level full-factorial experiment [16]. Table 1 shows the levels of the design parameters used in the screening experiment. The planar inductor for each combination of the design parameters is simulated and the simulation results are used in determining the quality factor *Q* by using (1)-(4) and the magnetic moment *m* by using (6)-(7).

Fig. 2 shows the quality factor *Q* of the planar inductor w.r.t. the design parameters. Fig. 2 shows the relative value of the quality factor w.r.t. the two levels of the design

TABLE I
THE DESIGN PARAMETERS OF THE SCREENING EXPERIMENT.

Design parameter / Level	-1	+1
Track width *w* [mm]	0.2	0.5

Fill-ratio *R* []	0.05	0.3
Outer dimension *D* [mm]	75	100

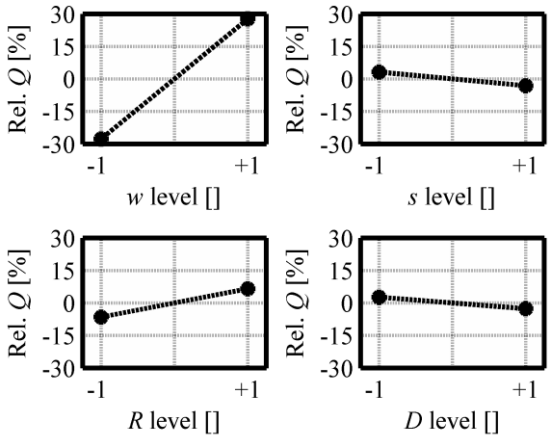

Figure 2. The quality factor Q w.r.t. the design parameters of the planar inductor.

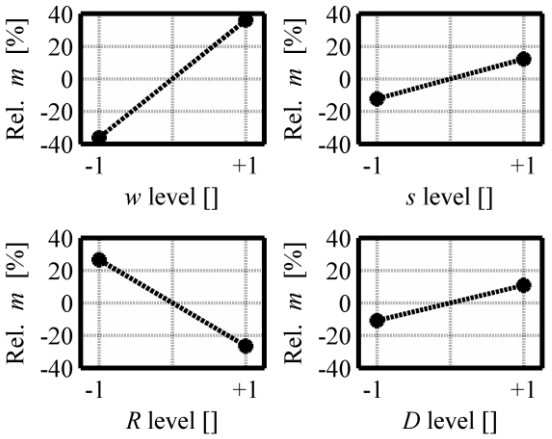

Figure 3. The magnetic moment m w.r.t. the design parameters of the planar inductor.

parameter. The results show that the track width w has the largest effect on the quality factor. It is observed that the effect of the fill-ratio R is relatively small, while the effects of the track spacing s and the outer dimension D on the quality factor are even smaller. The effects of the track width and the fill-ratio on the quality factor are positive, while the effects of the track spacing and the outer dimension are negative.

Fig. 3 shows the magnetic moment m of the planar inductor w.r.t. the design parameters. This figure shows the relative value of the magnetic moment w.r.t. the two levels of the design parameter. The results show that the track width w and the fill-ratio R have the largest effect on the magnetic moment. It is observed that the effects of the track spacing s and the outer dimension D on the magnetic moment are comparably smaller. The effects of the track width, the track spacing and the outer dimension on the magnetic moment are positive, while the effects of the fill-ratio are negative.

Table II shows the results of the analysis of variance (ANOVA) of the simulation results [17]. Table II shows the F-statistics and the p-value for the quality factor Q and the magnetic moment m w.r.t. the design parameters of the planar inductor. The results confirm the observations based on Figs. 2 and 3. The track width has the largest effect on the quality factor. The fill-ratio also has a notable effect, while the track spacing and the outer dimension have the comparably smallest effects on the quality factor. It is also confirmed that the track width and the fill-ratio have the largest effect on the magnetic moment.

VI. Discussion

Increasing the track width w reduces the resistance R_S of the inductor, while minimally influencing the inductance L_S of the inductor and thus the track width has a positive and a large effect on the quality factor Q.

The fill-ratio R determines the number of turns of the inductor. Increasing the fill ratio, i.e. the number of turns increases both the inductance L_S and the resistance R_S of the inductor. The results in Fig. 2 show that the inductance increase is larger than the resistance increase and thus the fill-ratio has a positive, notable effect on the quality factor Q.

The track spacing s influences the number of turns by modifying the track pitch. Increasing the track spacing while maintaining a fixed fill-ratio reduces the number of turns of the inductor. Due to the decrease in the number of turns, the inductance and the resistance of the inductor decrease as well. The inductance decrease is larger than the resistance decrease and thus the quality factor is reduced. The results on Fig. 2 show that this effect is indeed negative, but it is comparably smaller than the effects of the track width and the fill-ratio.

The outer dimension D influences the number of turns and the area of inductor. This influences the length of the inductor turns. These influences affect the inductance and the resistance of the inductor. The results show that these influences for the simulated parameter levels effectively cancel each other resulting in a very small, negative effect.

The magnetic moment m of the inductor is related to the ripple of the converter output current ΔI_{out}, i.e. the inductance L_S of the inductor. It is also related to the number of turns and the area of the inductor. Increasing the track width w while maintaining the fill-ratio R leads to a reduced number of turns. The reduced number of turns decreases the inductance of the inductor and consequently increases the ripple current of the buck converter. The results on Fig. 3 show that increasing the ripple current affects the magnetic moment much more than the decreased number of turns and results in a large, positive effect of the track width on the magnetic moment.

The fill-ratio R determines the number of turns and consequently influences the inductance of the inductor. Increasing the fill-ratio increases the inductance and thus reduces the current ripple. The results in Fig. 3 confirm that the inductance of the planar inductor has the largest effect on the magnetic moment and the fill-ratio has a large, negative effect on the magnetic moment.

Increasing the track spacing s reduces the number of turns and the inductance of the inductor. These changes

TABLE II
THE ANALYSIS OF VARIANCE OF THE SCREENING EXPERIMENT.

	Quality factor Q		Magnetic moment m	
	F	p-value [%]	F	p-value [%]
w	21.3	0.07	37.5	0.01
s	0.27	61.2	7.73	1.79
R	1.20	29.7	20.9	0.08
D	0.20	66.5	1.62	23.0

effectively cancel each other thus resulting in a comparably small, positive effect of the track spacing on the magnetic moment.

The outer dimension *D* directly influences the area of the inductor. Increasing the outer dimension increases the area and the inductance of the inductor. These changes effectively cancel each other thus resulting in a comparably small, positive effect of the outer dimension on the magnetic moment.

In summary, the results show that the track width *w* and the fill-ratio *R* have the largest influences on the quality factor *Q* and the magnetic moment *m* of the planar inductor. It is recommended to include these parameters in a co-optimization of the quality factor and the magnetic moment.

VII. CONCLUSIONS

A luminary consists of the OLED cell and its driver which uses a planar inductor. The planar inductor is the main source of radiated emissions of the driver. The properties of the planar inductor are analysed using EM simulations. The simulations are analysed w.r.t. the quality factor and the magnetic moment. The two-level screening experiment shows that the track width and the fill-ratio of the inductor have the largest effect on its properties. It is concluded that quality factor may be increased by increasing the track width of the inductor, while the magnetic moment is most sensitive to the changes in the inductance of the inductor.

***Abstract*—The electromagnetic compatibility (EMC) performance of the voltage regulators is the significant factor in the EMC performance of the complete electronic system. In this paper the characterization of the voltage regulator by direct power injection (DPI) method is presented. Although, the DPI method is defined by various standards, the repeatability of the measurement can be compromised by several factors. The DPI method measurement results are presented for the L4949 voltage regulator. The repeatability of the method is assessed by various factors related to the operating point of the voltage regulator and to the measurement set-up. The obtained results are compared to the results presented by other authors.**

***Index Terms*—DPI method; voltage regulator; measurement reapeatability**

I. Introduction

The electromagnetic compatibility (EMC) characterization of an integrated circuit (IC) is a mandatory step in the design of reliable electronic systems. The level of emission or immunity of an IC can compromise performance of the complete system. The immunity level for an IC is considered as the maximum radio frequency (RF) power level incident to IC through radiation or conduction which does not compromise the predefined normal operating conditions [1].

In this paper electromagnetic (EM) immunity of the low dropout (LDO) voltage regulator is characterized by measurements [2]. The measurements are performed according to direct power injection (DPI) method [3]. This standard defines the testing frequency range 150 kHz - 1 GHz. In this frequency range cable harnesses and/or printed circuit board (PCB) traces can act as efficient antennas. Thus an IC gets the unwanted RF energy through those pins connected to wires of such cables [3].

The same voltage regulator is characterized in [4], [5]. In [4] the DPI measurements are performed using PCB mounted bias tee in the frequency range 1 MHz to 1 GHz. The immunity fail criterion is defined as drift of the output voltage larger than $\pm$200 mV. In [5] the DPI measurements are performed using standalone bias tee in the frequency range 10 MHz to 3 GHz. The fail criterion is defined as drift of the output voltage larger than $\pm$100 mV. In this work the DPI measurements are performed on the same voltage regulator and results are compared to the previously published measurements. The effects influencing the measurement repeatability are discussed.

In Section II the measurement set-up and flowchart of the DPI method are explained. The DUT which is the low dropout voltage regulator L4949 mounted on a PCB are explained in Section III. Section IV brings the measurement results and discussion.

II. DPI Method

A. Measurement Set-up

The measurement set-up is presented in Fig. 1. It consists of the following instruments:

- R&S SMIQ 03B Signal Generator
- AR Amplifier 1W1000
- Tektronix CPS250 Power Supply
- RadiPower USB RF Power Sensors
- AR DC3001A Bi-Directional Coupler
- Bias Tees: Pasternack PE1601 and Mini-Circuits ZX86-12G-S+
- Agilent MSO7034B Oscilloscope
- BNC 6 dB Attenuator
- Desktop Computer (GPIB and USB ports)

The RF signal generated by the signal generator is connected to the 30 dB amplifier. The 6 dB attenuator is connected to the output of the amplifier in order to suppress reflections due to the variations of the output impedance of the amplifier. The bi-directional coupler gives possibility of measuring both forward and reflected power denoted as P_{fwd} and P_{refl}, respectively. Although, only the forward power with respect to the frequency is usually given as the figure of DUT immunity. This is due the fact that many ICs are most susceptible to the disturbances at frequencies where quite high reflections of the incident RF power occur [3].

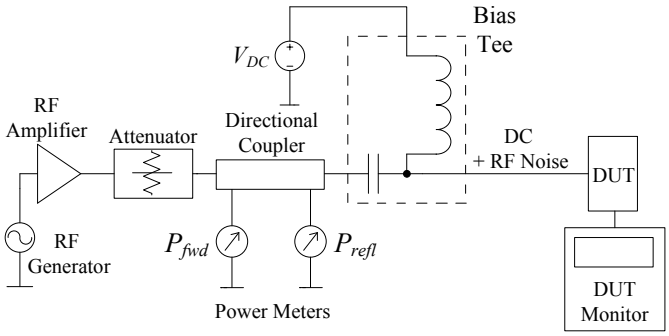

Fig. 1. Direct power injection measurement set-up. RF generator, power meters and DUT monitor are controlled by computer.

The oscilloscope is used to monitor the DUT output voltage level. Together with the RF power meters and the RF signal generator they are connected by desktop computer through GPIB and USB bus and controlled by Virtual Instrument Software Architecture (VISA) standard.

B. Flowchart

The DPI instrumentation is controlled by the graphical user interface designed using Matlab Guide [6]. The developed interface is presented in Fig. 2. It is used to connect to the instrumentation, setting up all relevant parameters related to the DPI method, starting the measurement and finally, saving data and disconnecting.

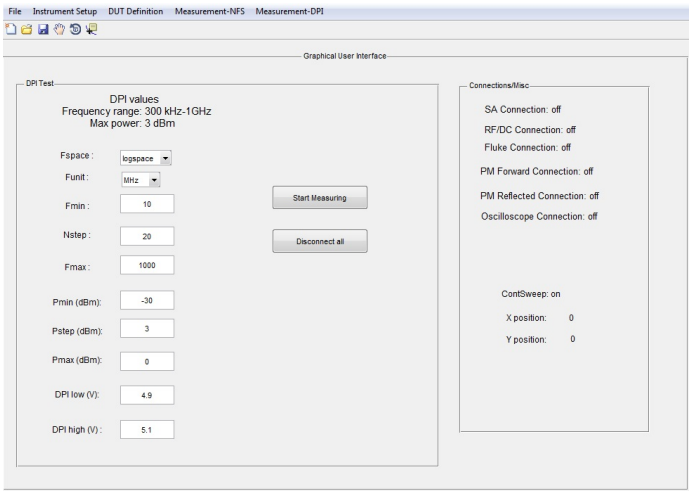

Fig. 2. Graphical user interface for controlling DPI instrumentation and for capturing the measurements.

The DPI method flowchart is shown in Fig. 3. The flowchart is defined according to [3]. The decision for DUT failure is based on the oscilloscope measurement. Every loop iteration the timebase of the oscilloscope is changed according to the frequency of RF disturbance signal. The timebase is set to enable measurement of five periods of the disturbance signal. Furthermore, the RF power meters are provided with the information regarding the frequency of RF disturbance signal in order to increase the measurement accuracy. Total dwell time is equal to 1.1 seconds which is in accordance with the value given by the standard.

III. Test Case: L4949

The DUT used in this paper is the 8-pin low dropout voltage regulator L4949 (ON Semiconductors) in small outline (SO) package. The input voltage can be in range from 5 to 28 V, while the nominal output voltage is 5 V$\pm$1%.

The complete schematic of the DUT is presented in Fig. 4a. The DC input voltage superimposed with RF noise is connected through end-launch SMA connector to the input pin of the voltage regulator. According to L4949 datasheet, two 10 µF capacitors connected to the input (C_S) and output (C_O) of the voltage regulator are recommended.

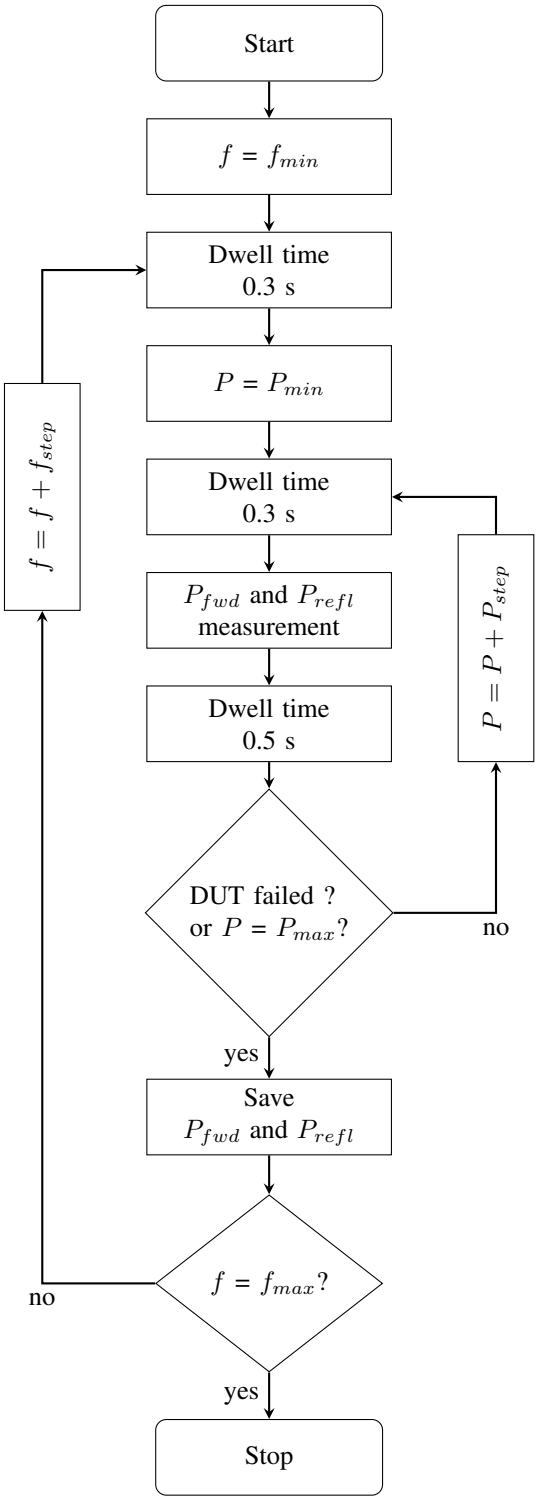

Fig. 3. Flowchart for implemented DPI method.

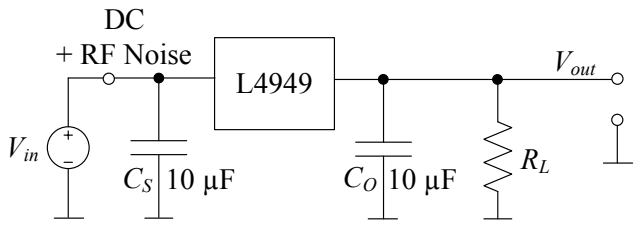
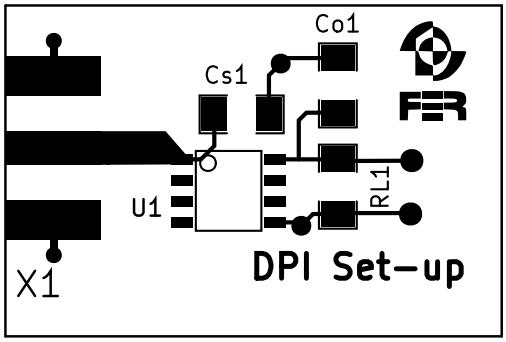
The top layer of the two-layer PCB is shown in Fig. 4b. All components are mounted on the top layer. The bottom layer of the PCB is a solid ground plane. The PCB is manufactured on the FR-4 substrate having the thickness of 1 mm. The loss tangent and dielectric constant are assumed to be 0.02 and 4.5,

respectively. In order to achieve the characteristic impedance equal to 50 Ω of the microstrip line between the DUT and SMA connector, the designed width of the line is 1.85 mm.



(a)



(b)

Fig. 4. DUT: a) schematic and b) PCB top-layer. Power is injected through end-launch SMA connector X1.

The PCB presented in Fig. 4b has the same dimensions (20 × 30 mm) as the PCB used in [5]. In [5] the stabilizing capacitor C_O with the resistor R_O is used for phase compensation, while in this work only C_O is used. In this work presented layout enables placement of C_S capacitor in order to assess its influence on IC immunity. The test bed presented in [4] is universal DPI fixture for SO packages with on-board bias tee. The transmission line that connects the Vin pin and SMA connector is ≈5 times longer than the line presented in Fig. 4b.

IV. Measurement Results and Discussion

In this section the measurement results are presented and compared to the results presented in [5] and [4]. The effects that influence repeatability of the presented results are discussed.

A. Comparison to [5]

The results presented in [5] are obtained for the fail criterion of the output voltage drift equal to ±2%. The output voltage is measured with the limited bandwidth of the oscilloscope input channel. Therefore, the bandwidth limitation function for the oscilloscope used in this work limits the bandwidth frequency to approximately 25 MHz and aquisition mode is set to 8-samples averaging. The input capacitor C_S is omitted from the measurements and the load resistor is set to 220 Ω. The measurements are performed in the frequency range from 10 MHz to 1 GHz for 20 logarithmically spaced points. The power of the RF generator is changed linearly from -30 dBm to 3 dBm in 1 dB steps.

The comparison to the results presented in [5] for the 6 dB attenuator connected to the output of the amplifier is shown in Fig. 5. The immunity level of the DUT is similar for the frequency range from 30 MHz to 200 MHz. At the frequency equal to 300 MHz the DUT measured in this work exhibits immunity lower approx. 8 dB. The difference of ≈4 dB can be seen up to 1 GHz.

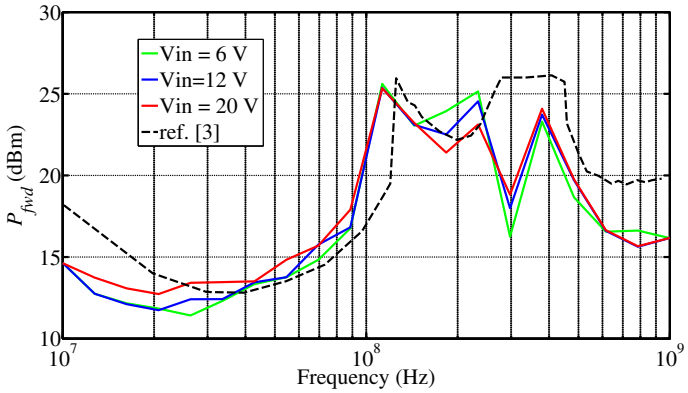


Fig. 5. Immunity levels for three different input voltages of voltage regulator. The results are compared to the results presented in [5]. The regulator input capacitor C_S=0 µF.

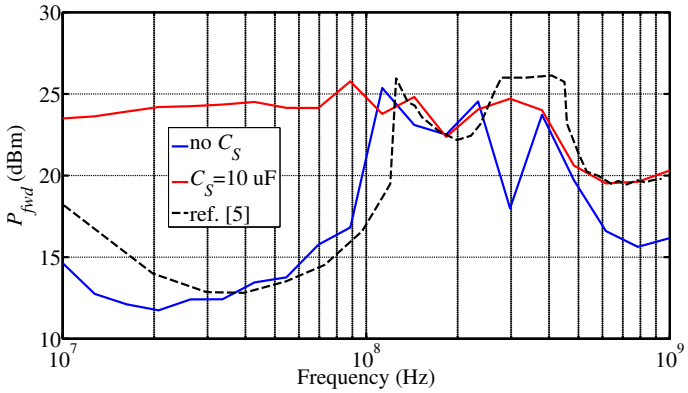

Fig. 6. Comparison of the immunity levels with respect to the input capacitor C_S=10 µF of the voltage regulator. The regulator input voltage V_{in}=12 V.

The measurement results are presented for three different values of the regulator input voltage. Although, the input voltage has an impact on immunity levels at lower frequencies, there is still difference of ≈4 dB at 10 MHz. This difference remains the same for various bias tees used in measurement.

In Fig. 6 the results are presented for the voltage regulator with the C_S capacitor connected at the input. The capacitor value is 10 µF and the input voltage of the regulator is 12 V. The result shows that the immunity level can be substantially improved by using the shunt capacitor at the input of the

regulator. Furthermore, the high frequency behaviour is similar to the results presented in [5].

B. Comparison to [4]

In [4] the results are presented for the fail criterion of the output voltage drift equal to ±4%. Since there is no information about the bandwidth limitation of the oscilloscope, the bandwidth limitation function is not used. In this work the measurements are performed with 350 MHz oscilloscope and therefore the comparison is provided up to the cut-off frequency. There is no load connected at the output of the voltage regulator, as well as no input capacitor C_S. The resistor of 10 kΩ is connected between the voltage regulator pins Vout and Reset. The input voltage of the regulator is equal to 12 V.

The measurements are performed in the frequency range from 1 MHz to 350 MHz for 20 logarithmically spaced points. The power of the RF generator is changed linearly from -30 dBm to -3 dBm in 1 dB steps. The 6 dB attenuator is connected to the output of the amplifier.

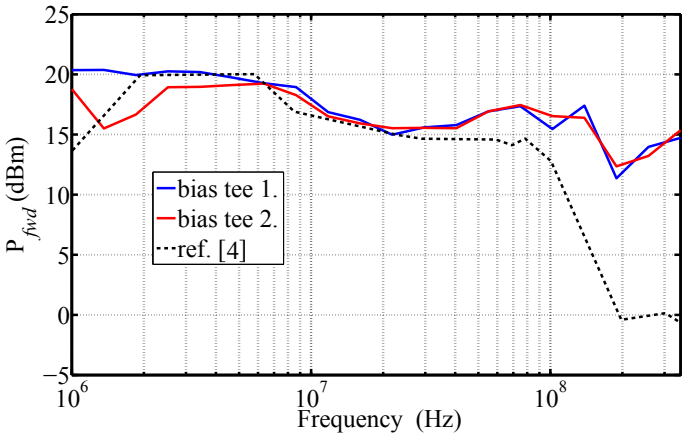

Fig. 7. Measurement results of the immunity levels compared to the results presented in [4]. The measurements are performed using two different types of bias tees.

The comparison of the measurement results to the results presented in [4] are shown in Fig. 7. Two bias tees are used in measurement set-up: Pasternack PE1601 (bias tee 1.) and Mini-Circuits ZX86-12G-S+ (bias tee 2.). In [4] the PCB bias tee is used, while in this paper the measurements are performed using the standalone bias tees. As can be seen on Fig. 7, the bias tee influence the immunity figure up to several MHz. At higher frequencies, the RF and DC path can be accurately approximated by a short circuit and open circuit, respectively, and the difference is negligible. In the frequency range above 100 MHz there is a difference of ≈15 dB. This difference can be partially attributed to the limited bandwidth of the oscilloscope (350 MHz).

V. Conclusion

This paper presents the direct power injection measurement results for the low dropout voltage regulator L4949. The measurements results are compared to the results already published by other authors. The repeatability of direct power injection measurements is strongly dependent on the measurement set-up and the set-up of the DUT. The same voltage regulator can exhibit qualitatively and quantitatively different immunity figures due to the single component change in the DUT schematic or in the measurement set-up of the DUT monitor.

***Abstract*—Operation of a 1.3-MHz, 12-to-1.2 V, 20-A synchronous buck converter is analyzed by SPICE simulations. Special attention is given to two resonances formed by the capacitance of FETs in the off-state and the total inductance of the input decoupling network. The resonances are the main source of the broadband electromagnetic (EM) interference. Two most common circuit level methods for reducing the EM interference, an RL snubber circuit and an RC snubber circuit, are analyzed and compared in terms of their impact on the radiation characteristics, efficiency and reliability of the analyzed synchronous buck converter.**

***Keywords*—conversion efficiency, electromagnetic (EM) interference, radiated emissions, reliability, switching-mode power supply (SMPS).**

I. Introduction

Switching DC-DC converters outperform linear converters in terms of efficiency and size, which makes them a preferred choice in various applications. However, because of their switching operation, they are sources of EM interference [1]. The resonance formed by the capacitance of the low-side FET in the off-state C_{oss} and the total inductance of the decoupling network is the main cause of ringing of the switching node and of an increased EM interference [2]. The resonant frequency is typically in the range of 50-300 MHz [3]. The resonant current is mostly confined in the input decoupling network because of the output inductor [3].

The methods for reducing the EM interference of switching DC-DC converters can be roughly divided into two categories - printed circuit board (PCB) methods and circuit level methods. The PCB methods minimize the radiated fields by carefully designing the input decoupling network (dimensions of metal plates and traces, stackup of the PCB, positioning of components and vias) [3], [4]. They present an efficient and cheap solution for reducing EM interference of switching DC-DC converters. However, the PCB methods are often limited by thermal considerations and geometrical parameters of the components.

The circuit level methods minimize the radiated fields by adding a resistance into the resonant loop which dampens the resonance. This can be achieved by adding an RL snubber circuit into the resonant loop [4], an RC snubber circuit to the switching node [5], [6], by using decoupling capacitors with high equivalent series resistance (ESR) [7], or by using FETs with high resistance in the off-state R_{oss} [8], [9]. The drawbacks of the circuit level modifications are an increased complexity of the circuit and an increased cost of the design. Additionally, increasing the resistance of the input decoupling network inevitably increases the losses and decreases the conversion efficiency of the DC-DC converter, while adding reactive components increases switching losses and affects the magnitudes of currents and voltages in the resonances which can compromise the reliability of the converter.

In this paper, the operation of a synchronous buck converter is analyzed by SPICE simulations with a special attention given to two resonances formed by the capacitance of FETs in the off-state and the inductance of the input decoupling network. Two most common circuit level methods, an RL snubber circuit and an RC snubber circuit, are analyzed and compared (ideal snubber circuits are considered, their parasitics not being taken into account). An extensive parametric SPICE analysis is performed for a wide range of values of the parameters of the snubber circuits. Impact of the snubber circuits on the radiation characteristics, efficiency and reliability of the synchronous buck converter is analyzed.

This paper is structured as follows. Section II presents the analysis of the operation of a synchronous buck converter. Section III and IV analyze the impact of RL and RC snubber circuits on the characteristics of the converter. Section V concludes the paper.

II. Operation of Synchronous Buck Converter

Synchronous buck converter analyzed in this paper is a 1.3-MHz, 12-to-1.2 V, 20-A output current converter. The PWM, FET drivers, high-side FET and low-side FET are co-packaged in a DrMOS module. More details on the chip can be found in [10]. The FETs are 30-V trench power FETs with a shielded gate [11].

The SPICE model consists of the PWM, FET drivers, high-side and low-side FETs (which include the model of a body diode [10]), package parasitics, output inductor and the equivalent model of the input decoupling network (which consists of the metal plates on the PCB and the decoupling capacitors). The parameters of the SPICE models of active components are extracted from the process simulations, while the parasitic elements of the system are estimated by experiments and finite element simulations. A simplified schematic of the analyzed converter is shown in Fig. 1. An RL snubber circuit and an RC snubber circuit indicated in the figure are analyzed in the following sections.

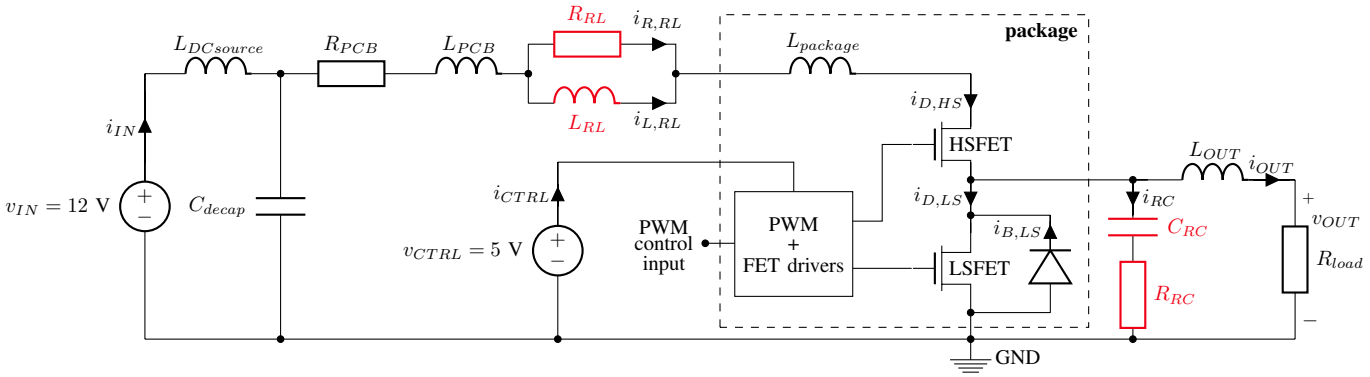

Fig. 1. Simplified schematic of the analyzed synchronous buck converter with some parasitic elements. RL snubber circuit is placed between the package and the decoupling network, while RC snubber circuit is added to the switching node.

The steady-state time-domain waveforms of the nominal simulation (without the snubber circuits) are shown in Fig. 2. The output voltage is set to 1.2 V by the duty cycle of the PWM. The output current of 20 A is set by the load resistance of 60 mΩ. Two resonances can be identified, the first one at the moment when the high-side FET turns on, and the second one, at the moment when the high-side FET turns off. The waveforms at each resonance are analyzed separately in the following subsections.

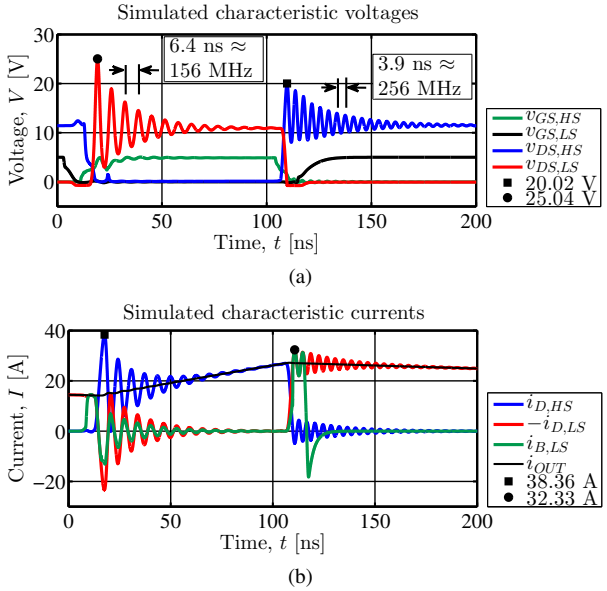

Fig. 2. Steady-state time-domain waveforms of the nominal simulation: (a) characteristic voltages and (b) characteristic currents. 200 ns of one period (774 ns) is plotted to show the waveforms in the resonances in more details.

A. Resonance at the leading edge

At the beginning of the simulation, the low-side FET is on, while the high-side FET is off. The low-side FET is turned off before the high-side FET is turned on in order to prevent a shoot-through (a low-resistive connection between the input voltage and the ground). The time during which both FETs are off is commonly referred to as the dead-time. During the dead-time, the current to the load is provided through the body diode of the low-side FET. The voltage of the switching node is tied to the negative value determined by the on-state voltage drop of the body diode (approximately $V_D = -0.7$ V).

Then, the high-side FET turns on. The current through the body diode $i_{B,LS}$ decreases while the current through the high-side FET increases by the rate determined by the input voltage and the inductance of the input network $di/dt = (V_{IN} - V_D)/L_{input}$ (or by the turn-on time of the high-side FET, depending on which of the two is slower). The diode does not switch off immediately, but undergoes a reverse recovery - the current through the diode falls to zero and continues to flow in the reverse direction, until the depletion region is sufficiently depleted so that the body diode is able to support the blocking voltage [12], [13], [14].

Then, the charge from the input decoupling capacitors charges the depletion layers of the transistor and the voltage of the switching node starts to increase. This charge, and the remaining charge in the depletion region of the body diode excite the resonant loop. The resonant loop is formed by the capacitances of the low-side FET in the off-state (which consists of a drain-to-source capacitance and the capacitance of the body diode, $C_{oss} = C_{ds} + C_j$) and the total inductance of the input decoupling network.

B. Resonance at the trailing edge

Similar process happens at the trailing edge. The high-side FET turns off and the current to the load is provided through the body diode of the low-side FET (the low-side FET is still off to prevent a shoot-through). The current through the high-side FET decreases, while the current through the body diode of the low-side FET increases by the rate determined by the inductance of the low-side FET (or by the turn-off time of the high-side FET, depending on which of the two is slower). This change triggers the resonance in the resonant loop formed by the capacitance of the high-side FET in the off-state and the total inductance of the input decoupling network.

Finally, the low-side FET turns on and the body diode of the low-side FET undergoes a reverse recovery. The charge accumulated in the depletion region of the body diode discharges through the on-resistance of the low-side FET and does not excite the resonant loop.

C. Comparison of two resonances

The two resonances have different resonant frequencies and different rate of decay, which is a consequence of different sizes of the high-side FET and the low-side FET. The high-side FET is smaller than the low-side FET, so the C_{oss} that corresponds to the high-side FET is smaller than that of the low-side FET. This results in a lower resonant frequency of the resonance related to the leading edge of $v_{DS,LS}$ compared to that related to the trailing edge. The on-resistance of the high-side FET $R_{dson,HS}$ is larger than the on-resistance of the low-side FET $R_{dson,LS}$ for the same reason (the high-side FET is smaller than the low-side FET). Therefore, the resonance related to the leading edge is more dampened and decays faster than the one related to the trailing edge.

The inductance forming the resonances is the same for both resonances and consists of the total inductance of the input decoupling network - the parasitic inductance of the package, the inductance of the PCB interconnects and the parasitic inductance of the decoupling capacitors.

D. Radiation characteristics

The energy trapped in the resonant loop at each resonance is either dissipated in its lossy elements or radiated into the space. The radiation characteristics of a DC-DC converter can be described by those of a small loop antenna [3], which is given by (assuming a constant spatial current distribution) [15]:

$$E = \eta \frac{\pi S I \exp(-\jmath k r)}{\lambda^2 r} \sin(\theta) \propto S I f^2, \qquad (1)$$

where η is the impedance of the free space ($\approx$ 377 Ω), λ is the wavelength ($\lambda = c_0/f$), c_0 is the speed of light in the free space, f is the frequency, k is the wavenumber, S is the effective area of the resonant loop, I is the spectrum of the resonant current (approximated by the current through the high-side FET), and r is the distance to the observation point.

The equation (1) suggests two ways of reducing the EM interference - reducing the effective area S is the basis for the PCB methods, while reducing the high-frequency spectrum of the resonant current I by increasing the resistance in the loop is the basis for the circuit level methods.

The maximum radiated fields as a function of frequency calculated by (1) for the nominal simulation (without the snubber circuits) and assuming $S = 1$ mm^2 are shown in Fig. 3. Two peaks can be identified. The first one corresponds to the resonance related to the leading edge, while the second one corresponds to the resonance related to the trailing edge.

The impact of the RL and RC snubber circuits on the radiation characteristics of the converter is analyzed by evaluating the frequencies of the two peaks and the radiated fields at those frequencies for each set of the parameters of the snubber circuits.

E. Conversion efficiency

Losses in switching DC-DC converters are a sum of conductive losses in the resistive elements and the switching losses in the reactive elements of the circuit. To assess the impact of RL and RC snubber circuits on the conversion efficiency of the analyzed converter, the conversion efficiency is calculated

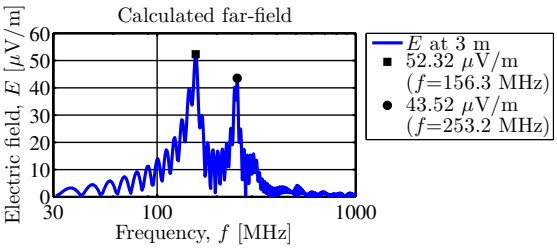

Fig. 3. Maximum radiated fields as a function of frequency calculated by (1) (at $r = 3$ m). The first peak corresponds to the resonance related to the leading edge, while the second one corresponds to that related to the trailing edge.

from the time-domain waveforms simulated for each set of the parameters of the snubber circuits as follows:

$$P_{OUT} = \text{average}(i_{OUT} \cdot v_{OUT}) \qquad (2)$$

$$P_{IN} = \text{average}(i_{IN} \cdot v_{IN}) + \text{average}(i_{CTRL} \cdot v_{CTRL}) \qquad (3)$$

$$\eta = P_{OUT}/P_{IN} \qquad (4)$$

Additionally, to get an insight into the dissipation of each element of the converter (low-side FET, body diode, high-side FET, input decoupling network, output inductor and snubber circuits), their dissipation is calculated as:

$$P_{ELEMENT} = \text{average}(i_{ELEMENT} \cdot v_{ELEMENT}) \qquad (5)$$

F. Reliability considerations

The peaks of the currents and voltages of the low-side FET and the high-side FET in the resonances can be several times larger than the nominal values of the converter. Adding reactive components into the resonant loop impacts those peaks which can compromise the reliability of the converter if the peaks exceed the maximum rated values of the devices.

The FET in the off-state has to sustain the input voltage and the voltage overshoot in the resonance, while the FET in the on-state has to sustain the output current and the resonant current. At the resonance related to the leading edge, $v_{DS,LS}$ and $i_{D,HS}$ can exceed their maximum rated values, while at the resonance related to the trailing edge, $v_{DS,HS}$ and $i_{D,LS}$ can exceed their maximum rated values.

Reliability of the analyzed converter is addressed by evaluating the maximum values of the time-domain waveforms of the currents and voltages simulated for each set of the parameters of the snubber circuits.

III. RL Snubber Circuit

An RL snubber circuit is added to the circuit model in order to analyze its impact on the radiation characteristics, conversion efficiency and reliability of the analyzed converter. The RL snubber circuit provides a high-resistance path for the resonant current, while providing a low-impedance path for the output current. The location of the snubber is shown in Fig. 1. The parametric simulations of the RL snubber circuit are performed for R in the range of 0.2 to 2 Ω with the 0.2-Ω step, and for L in the range of 0.2 to 2 nH with the 0.2-nH step. Altogether, 100 simulations are performed. The duty cycle is adjusted in each simulation to maintain the same output current

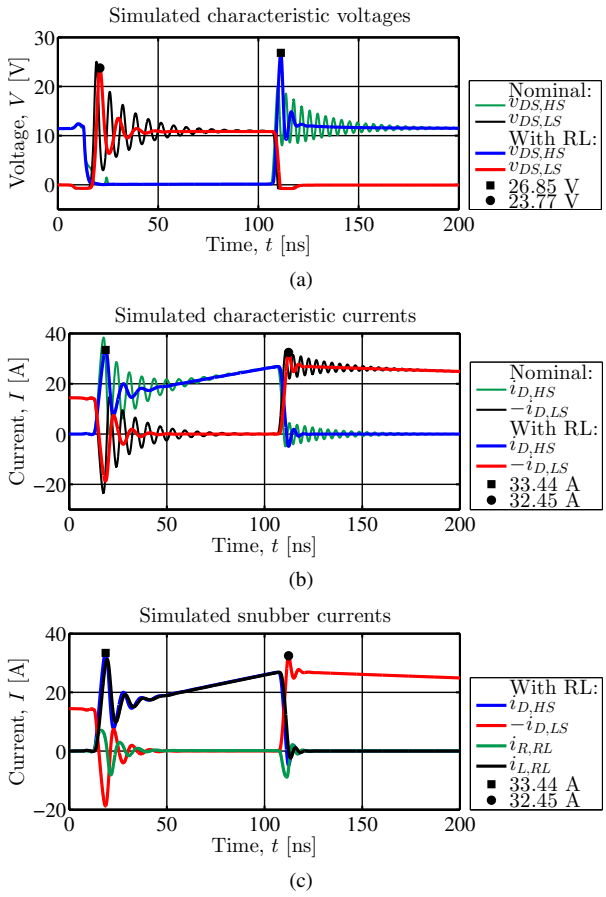

Fig. 4. Steady-state time-domain waveforms of the analyzed converter with RL snubber circuit ($R = 0.8\ \Omega$, $L = 0.8$ nH): (a) characteristic voltages, (b) characteristic currents, and (c) currents through the RL snubber circuit.

and voltage. The steady-state time-domain waveforms of the characteristic voltages and currents for $R = 0.8\ \Omega$ and $L = 0.8$ nH are shown in Fig. 4.

A. Radiation characteristics

The impact of an RL snubber circuit on the radiated fields is addressed as follows. The radiation characteristics of the converter are calculated by (1) under the assumption that adding the snubber circuit does not significantly alter the effective area of the radiating loop. The values of the two resonant frequencies and the corresponding maximum values of the radiated field are extracted for each combination of R and L. The results are given relative to the nominal simulation (without the snubber circuit) and are shown in Fig. 5. The reduction up to 18 dB is achieved. The results for $R = 0.8\ \Omega$ and $L = 0.8$ nH are compared to the nominal simulation (without the snubber circuit) in Table I.

B. Conversion efficiency

Adding an RL snubber circuit increases the losses of the circuit and decreases the conversion efficiency. The losses of the snubber circuit are calculated from the time-domain waveforms by (5). The efficiency is calculated by (4). The results are shown in Fig. 6. The results for $R = 0.8\ \Omega$ and

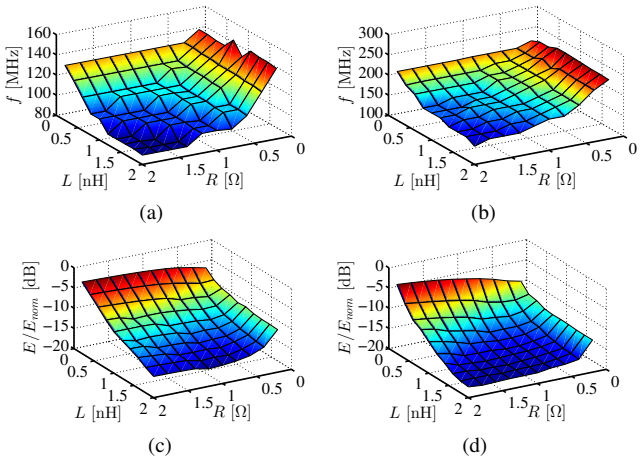

Fig. 5. Impact of RL snubber circuit on the radiated fields of the analyzed converter: resonant frequency of the resonance related to the (a) leading edge and (b) trailing edge, and maximum radiated fields in the resonance related to the (c) leading edge and (d) trailing edge.

TABLE I. RESONANT FREQUENCIES AND MAXIMUM VALUES OF RADIATED FIELDS OF THE ANALYZED CONVERTER WITH THE RL SNUBBER CIRCUIT ($R = 0.8\ \Omega$, $L = 0.8$ NH).

Parameter	Maximum value nominal simulation	Maximum value with the snubber circuit	Difference
$f_{res,1}$	156 MHz	112 MHz	-44 MHz
$f_{res,2}$	253 MHz	200 MHz	-53 MHz
E_1	52.32 µV/m	16.94 µV/m	-9.80 dB
E_2	43.52 µV/m	9.80 µV/m	-12.95 dB

$L = 0.8$ nH are compared to the nominal simulation (without the snubber circuit) in Table II.

The losses of the RL snubber circuit are dominantly a function of the inductance of the RL snubber circuit. When the high-side FET turns off, the current path between the input network and the load is disrupted. The energy accumulated in the inductance of the RL snubber is dissipated in the resistance of the RL snubber circuit. The energy accumulated in the inductance is a function of the output current. Therefore, the losses will be high for high-current converters.

Adding an RL snubber circuit adds additional source of losses. However, the reduction of the conversion efficiency is partially compensated by the reduction of the switching losses in the low-side FET, body diode, high-side FET, input decoupling network and output inductor as a consequence of the more dampened resonance compared to the nominal simulation (without the snubber circuit, see Table II).

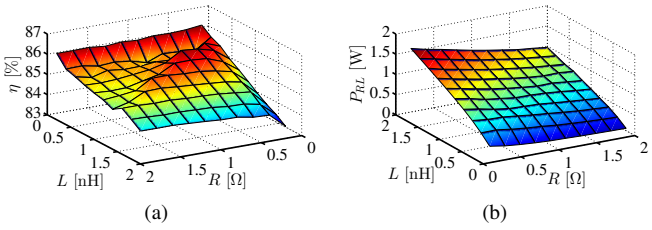

Fig. 6. Impact of RL snubber circuit on the efficiency of the analyzed converter: (a) conversion efficiency and (b) losses of the RL snubber circuit.

TABLE II. LOSSES IN THE ANALYZED CONVERTER WITH THE RL SNUBBER CIRCUIT ($R = 0.8\ \Omega$, $L = 0.8$ nH).

Element	Loss (P, W) nominal simulation	Loss (P, W) with the snubber circuit	Relative difference
Low-side FET	1.31	1.28	-2.29 %
(of which body diode)	(0.46)	(0.43)	-6.52 %
High-side FET	1.19	0.96	-19.33 %
Input network	0.98	0.90	-8.16 %
Output inductor	0.26	0.13	-50.00 %
Other	0.22	0.21	-4.55 %
RL snubber	-	0.61	-
η, %	86.69	86.32	-0.43 %

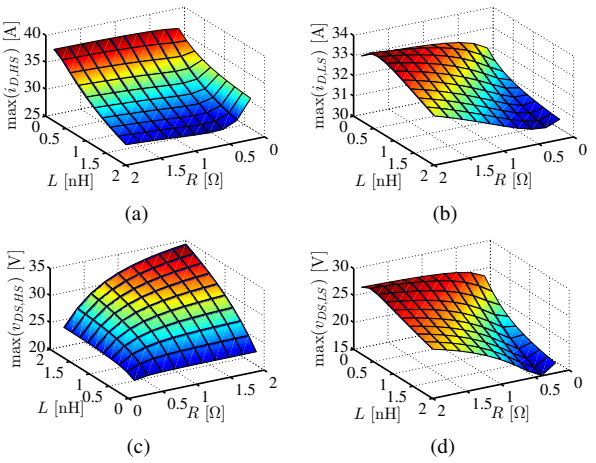

Fig. 7. Impact of RL snubber circuit on the reliability of the analyzed converter: maximum values of (a) $i_{D,HS}$, (b) $i_{D,LS}$, (c) $v_{DS,HS}$ and (d) $v_{DS,LS}$.

C. Reliability considerations

The maximum values of the currents and voltages of the high-side FET and the low-side FET are evaluated for each combination of R and L. The results are shown in Fig. 7. The results for $R = 0.8\ \Omega$ and $L = 0.8$ nH are compared to the nominal simulation (without the snubber circuit) in Table III.

The maximum value of $i_{D,HS}$ decreases when the RL snubber circuit is added to the circuit as a consequence of the more dampened resonance compared to the nominal simulation (without the snubber circuit).

The maximum values of $i_{D,LS}$ and $v_{DS,LS}$ can decrease as a consequence of the more dampened resonance compared to the nominal simulation (without the snubber circuit), or slightly increase as a consequence of the interaction between the body diode and the inductance of the input decoupling network, depending on which of the two effects is dominant.

The critical impact of adding an RL snubber circuit is an increased voltage overshoot of $v_{DS,HS}$ compared to the nominal simulation (without the snubber circuit). When the high-side FET turns off, the current path between the input network and the load is disrupted. The energy accumulated in the inductance of the RL snubber is dissipated in the resistance of the RL snubber circuit creating a voltage drop over the resistance and increasing the overshoot of $v_{DS,HS}$. The voltage drop is a function of the output current, so the overshoot will be high for high-current converters.

TABLE III. MAXIMUM VALUES OF CURRENTS AND VOLTAGES OF THE ANALYZED CONVERTER WITH THE RL SNUBBER CIRCUIT ($R = 0.8\ \Omega$, $L = 0.8$ nH).

Waveform	Maximum value nominal simulation	Maximum value with the snubber circuit	Relative difference
$i_{D,HS}$	38.36 A	33.44 A	-12.83 %
$i_{D,LS}$	32.33 A	32.45 A	+0.37 %
$v_{DS,HS}$	20.02 V	26.85 V	+34.12 %
$v_{DS,LS}$	25.04 V	23.77 V	-5.07 %

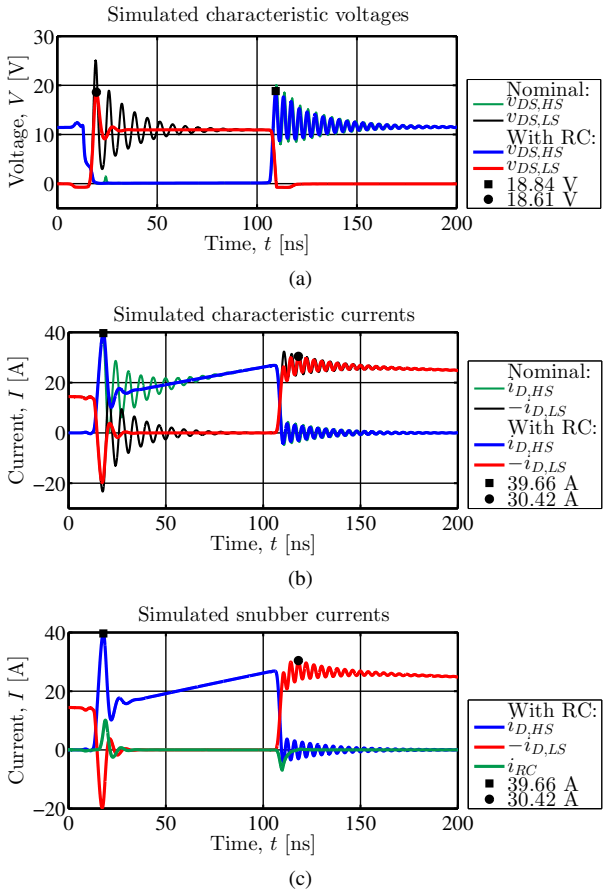

Fig. 8. Time-domain waveforms of the analyzed converter with RC snubber circuit ($R = 1\ \Omega$, $C = 2$ nF): (a) characteristic voltages, (b) characteristic currents, and (c) current through the RC snubber circuit.

IV. RC SNUBBER CIRCUIT

Equivalently to an RL snubber circuit presented in the previous section, an RC snubber circuit is added to the circuit model to analyze its impact on the radiation characteristics, conversion efficiency and reliability of the analyzed converter. The RC snubber circuit provides a high-resistance path for the resonant current, while providing a high-impedance path for the output current. The location of the snubber circuit is shown in Fig. 1. The parametric simulations of the RC snubber circuit are performed for R in the range of 0.2 to 2 Ω with the 0.2-Ω step, and for C in the range of 0.2 to 2 nF with the 0.2-nF step. Altogether, 100 simulations are performed. The duty cycle is adjusted in each simulation to maintain the same output current and voltage. The steady-state time-domain waveforms of the characteristic voltages and currents for $R = 1\ \Omega$ and $C = 2$ nF are shown in Fig. 8.

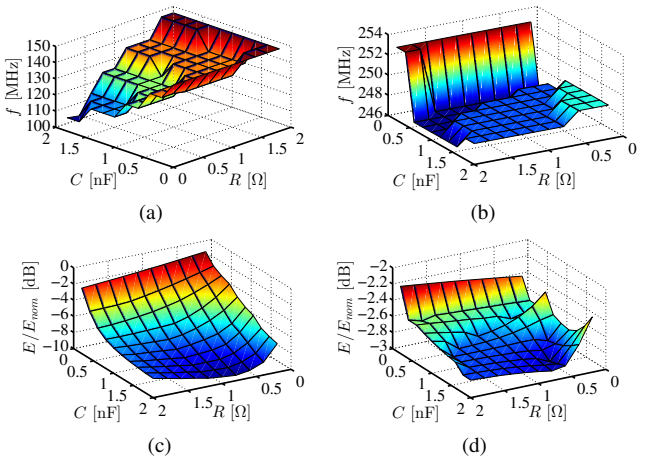

Fig. 9. Impact of RC snubber circuit on the radiated fields of the analyzed converter: resonant frequency of the resonance related to the (a) leading edge and (b) trailing edge, and maximum radiated fields in the resonance related to the (c) leading edge and (d) trailing edge.

TABLE IV. RESONANT FREQUENCIES AND MAXIMUM VALUES OF RADIATED FIELDS OF THE ANALYZED CONVERTER WITH THE RC SNUBBER CIRCUIT ($R = 1\ \Omega$, $C = 2$ nF).

Parameter	Maximum value nominal simulation	Maximum value with the snubber circuit	Difference
$f_{res,1}$	153 MHz	146 MHz	-7 MHz
$f_{res,2}$	253 MHz	248 MHz	-5 MHz
E_1	52.30 µV/m	16.71 µV/m	-9.91 dB
E_2	43.54 µV/m	37.67 µV/m	-1.26 dB

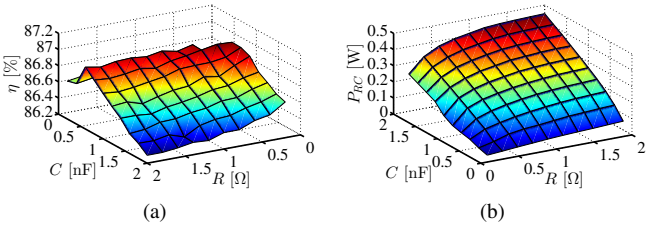

Fig. 10. Impact of RC snubber circuit on the efficiency of the analyzed converter: (a) conversion efficiency and (b) losses of the RC snubber circuit.

A. Radiation characteristics

The radiated fields of the converter are calculated by (1) under the assumption that adding the snubber does not significantly alter the effective area of the radiating loop. The results are given relative to the nominal simulation (without the snubber circuit) and are shown in Fig. 9. The reduction up to 10 dB is achieved. The results for $R = 1\ \Omega$ and $C = 2$ nF are compared to the nominal simulation (without the snubber circuit) in Table IV.

The RL snubber circuit shows better effectiveness in reducing the radiated fields than the RC snubber circuit. This is a consequence of the placement of snubber circuits: the RL snubber circuit is placed into the resonant loop, while the RC snubber circuit is placed parallel to the FET. Therefore, the resonant current has to flow through the RL snubber circuit, while it is divided between the RC snubber circuit and the capacitance of the FET in the off-state C_{oss} which limits its effectiveness.

Moreover, while the RL snubber circuit affects both resonances equally, the RC snubber circuit is more effective in reducing the resonance related to the leading edge. The RC snubber circuit is short-circuited by the low-side FET in the on-state, so it is not effective in dampening the resonance related to the trailing edge. However, the capacitance of the RC snubber circuit provides a charge tank for the load at the moment when the high-side FET turns off. Therefore, the peak of the current from the body diode of the low-side FET is reduced and the resonance related to the trailing edge is less excited. Another RC snubber circuit can be placed parallel to the high-side FET in order to dampen the resonance related to the trailing edge. Alternatively, it can be added to the input decoupling network to be effective in dampening both resonances.

B. Conversion efficiency

Adding an RC snubber circuit increases the losses of the circuit and decreases the conversion efficiency. The losses of the snubber circuit are calculated from the time-domain waveforms by (5). The efficiency is calculated by (4). The results are shown in Fig. 10. The results for $R = 1\ \Omega$ and $C = 2$ nF are compared to the nominal simulation (without the snubber circuit) in Table V.

The losses of the RC snubber circuit are dominantly a function of the capacitance of the RC snubber circuit. When the high-side FET turns off, the energy accumulated in the capacitance of the RC snubber is dissipated in the resistance of the snubber circuit. The losses are a function of the input voltage, so they will be high for high-voltage converters.

Adding an RC snubber circuit adds additional sources of losses. However, the reduction of the conversion efficiency is partially compensated by the reduction of the switching losses in the low-side FET, body diode, high-side FET, input decoupling network and output inductor as a consequence of the more dampened resonance compared to the nominal simulation (without the snubber circuit, see Table V).

C. Reliability considerations

The maximum values of currents and voltages of the high-side FET and the low-side FET are evaluated for each combination of R and C. The results are shown in Fig. 11. The results for $R = 1\ \Omega$ and $C = 2$ nF are compared to the nominal simulation (without the snubber circuit) in Table VI.

The maximum value of $i_{D,LS}$ decreases when the RC snubber circuit is added to the converter. The decrease is

TABLE V. LOSSES IN THE ANALYZED CONVERTER WITH THE RC SNUBBER CIRCUIT ($R = 1\ \Omega$, $C = 2$ NF).

Element	Loss (P, W) nominal simulation	Loss (P, W) with the snubber circuit	Relative difference
Low-side FET	1.31	1.27	-3.05 %
(of which body diode)	(0.46)	(0.42)	(-8.70 %)
High-side FET	1.19	1.13	-5.04 %
Input network	0.98	0.94	-4.08 %
Output inductor	0.26	0.11	-57.69 %
Other	0.22	0.21	-4.55 %
RC snubber	-	0.41	-
η, %	86.69	86.40	-0.33 %

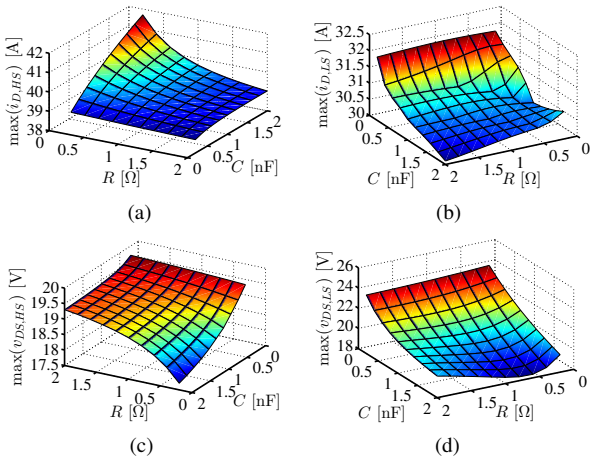

Fig. 11. Impact of RC snubber circuit on the reliability of the analyzed converter: maximum values of (a) $i_{D,HS}$, (b) $i_{D,LS}$, (c) $v_{DS,HS}$ and (d) $v_{DS,LS}$.

TABLE VI. MAXIMUM VALUES OF CURRENTS AND VOLTAGES OF THE ANALYZED CONVERTER WITH THE RC SNUBBER CIRCUIT ($R = 1\ \Omega$, $C = 2$ nF).

Waveform	Maximum value nominal simulation	Maximum value with the snubber circuit	Relative difference
$i_{D,HS}$	38.36 A	39.66 A	+3.39 %
$i_{D,LS}$	32.33 A	30.42 A	-5.91 %
$v_{DS,HS}$	20.02 V	18.84 V	-5.89 %
$v_{DS,LS}$	25.04 V	18.61 V	-25.68 %

dominantly a function of the capacitance of the RC snubber circuit. The capacitance provides a charge tank for the load at the moment when the high-side FET turns off. Therefore, the peak of the current from the body diode of the low-side FET decreases. The overshoot of $v_{DS,HS}$ decreases for the same reason.

The maximum value of $v_{DS,LS}$ decreases as a consequence of the more dampened resonance compared to the nominal simulation (without the snubber circuit).

The critical impact of adding an RC snubber circuit is an increased current overshoot of $i_{D,HS}$ compared to the nominal simulation (without the snubber circuit). When the high-side FET turns on, an additional current is needed to charge the capacitance of the RC snubber circuit. The additional current is a function of the input voltage, so the overshoot will be high for high-voltage converters.

V. CONCLUSION

The impact of RL and RC snubber circuits on the operation of synchronous buck converters is analyzed by SPICE simulations. The RL snubber circuit shows better effectiveness in dampening the resonances and reducing the radiated fields than the RC snubber circuit. The reductions of the calculated maximum radiated fields up to 18 dB are obtained for the RL snubber circuit, and up to 10 dB for the RC snubber circuit. The downside of the snubber circuits is the degradation of the conversion efficiency and the increase of the voltage and current stresses on the transistors. The losses of the RL snubber circuit are a function of the output current, while the losses of the RC snubber circuit are a function of the input voltage. The RL snubber circuit increases the overshoot of the voltage of the high-side FET as a function of the output current, while the RC snubber circuit increases the overshoot of the current through the high-side FET as a function of the input voltage. Therefore, the RL snubber circuit is more suitable for high-voltage, low-current converters, while the opposite is valid for the RC snubber circuit.

***Abstract*—A precise two-channel programmable time-delay pulse signal generator for synchronous DC-DC converter applications is presented. The developed system is required to generate high-side (HS) and low-side (LS) signal in frequency range from 1 MHz to 15 MHz and duty cycle values from 5% to 50%. While both generated signals have the same switching frequency, the pulse width and time-delay of each signal is adjusted independently of the other signal. The most notable characteristic of the developed generator is the ability to adjust dead-times between the generated signals as precise as possible in order to use the signal generator for testing the semiconductor devices for synchronous DC-DC converter applications. The developed signal generator has the ability to set the pulse width and time-delay with the precision of 250 ps. The system is designed to transmit generated signals using either the BNC or optical fiber cable. The functionality of the system is verified by measurements performed under various operating conditions.**

***Index Terms*—driving signals, pulse-width modulation, dead-time adjustment, fiber optic transmitter**

I. Introduction

The main advantage of synchronous over asynchronous rectifiers used in DC-DC converters is significant reduction in power losses which leads to the higher overall converter efficiency. If the MOSFET drain to source resistance in the on-state R_{DS-on} is sufficiently small, then its conduction power losses are lower than those obtained using a diode. The diode junction potential limits the lowest forward voltage drop of the diode and its conduction losses cannot be reduced further. This adverse effect in asynchronous rectifiers is even more expressed in common low-voltage (1.2 V, 3.3 V or 5 V) power supplies where diode conduction losses make the largest contribution in the overall losses of the DC-DC converter [1]. However, since the synchronous topology uses two MOSFETs, it has to be ensured that both of them are never turned on at the same time, so that shoot-through does not occur. The prevention of the shoot-through effect requires a more complex circuit for generation of the driving signals.

The typical model of a buck converter is shown in Fig. 1(a). The high-side (HS) and low-side (LS) MOSFET switches are driven using the two-channel pulse signal generator with adjustable signal properties. The example of the appropriate driving signals for the HS and LS MOSFET generated by a signal generator in 3.3V CMOS technology is shown in Fig. 1(b). Because of the non-zero values of rise and fall times of driving signals, the so-called dead-times t_{d1} and t_{d2} ensure

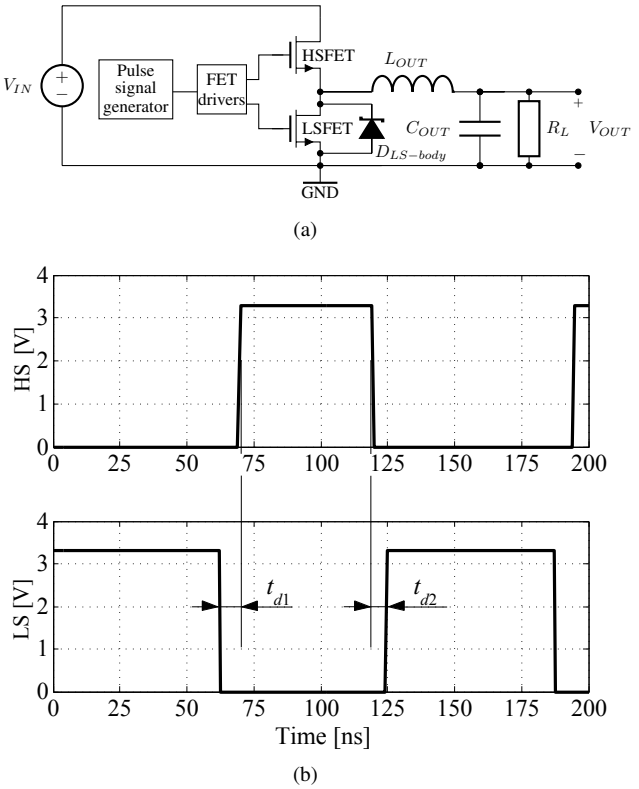

Fig. 1. Synchronous buck converter: (a) the model of a buck converter, and (b) ideal driving signals for proper work of the buck converter.

that one MOSFET is fully turned off before the other one enters the conduction mode. It can be seen that dead-times are not equal so, apart from the signal frequency, the driving signal for the HS MOSFET is controlled separately of the driving signal for the LS MOSFET and conversely.

If the influence of the dead-times t_{d1} and t_{d2} on the operation of the MOSFET switches is tested in realistic operating conditions, such as in a synchronous DC-DC converter, the pulse generator has to be able to adjust both dead times as precise as possible. Depending on the parameters of the DC-DC converter used for testing the operation of MOSFET switches, such as load resistance R_L, inductance and capacitance of the LC filter L_{OUT} and C_{OUT}, shown in Fig. 1(a), as well as the switching frequency; the dead-times

t_{d1} and t_{d2} have a different impact on the converter efficiency. Therefore, if the dead-times are adjusted separately, the impact of each dead-time on the DC-DC converter efficiency can be investigated. Furthermore, since the DC-DC converters aim at high switching frequencies in order to use smaller passive components and increase the density of the design, the pulse generator for testing purposes should be able to generate driving signals in the low megahertz range.

Since during the t_{d1} and t_{d2} neither one of MOSFET switches conducts, the current will flow through the body diode of the LS MOSFET and cause higher conduction losses than during the MOSFET conduction. Therefore, it is important for every model of the tested MOSFET switch under different operating conditions to identify the optimal dead-time values for the highest efficiency of the MOSFET switch, as well as the DC-DC converter itself.

Testing the influence of the dead-time values on the behaviour of the DC-DC converter implies the implementation of open-loop systems which are able to regulate the parameters of the driving signals regardless of any other system parameters. Therefore, the adaptive dead-time control techniques using the closed-loop systems presented in [2], [3], [4], [5] do not investigate the impact of different dead-time values on the operation of the DC-DC converters. The influence of the dead-time on the reverse-recovery effect in DC-DC converters has been tested in [6]. However, the achieved precision of setting the dead-time is only 10 ns and much more precise adjustment could be obtained.

Section II presents the developed precise pulse signal generator for synchronous DC-DC converter applications and describes its working principle. The functionality of the developed signal generator is verified by the measurement results given in Section III. The conclusion is given in Section IV.

II. The Developed Dual-Channel Driving Signal Generator

The developed system is required to generate two driving signals for HS and LS MOSFET that are controlled separately and have the same switching frequency of up to 15 MHz. Both generated signals should have duty cycle value of up to 50%, while one of them should be inverted relative to the other one in order to ensure the proper operation of the DC-DC converter test circuit. Therefore, if the HS signal would be used to drive the LS MOSFET and conversely, the generator would be able to achieve duty cycle values higher than 50% as it can be seen in Fig. 1. The important requirement of the generator is the ability to adjust the pulse width of each generated signal and relative time-delay between them with a sub-nanosecond precision for all switching frequencies and duty cycle values of interest. The dead-time adjustment is performed directly by adjusting the pulse width and time-delay of each signal.

The developed signal generator has the ability to adjust pulse width and time-delay of each generated signal, i.e. to adjust each dead-time, with the resolution of 0.25 ns for the complete range of switching frequencies and duty cycle values. This is the most important characteristic of the developed

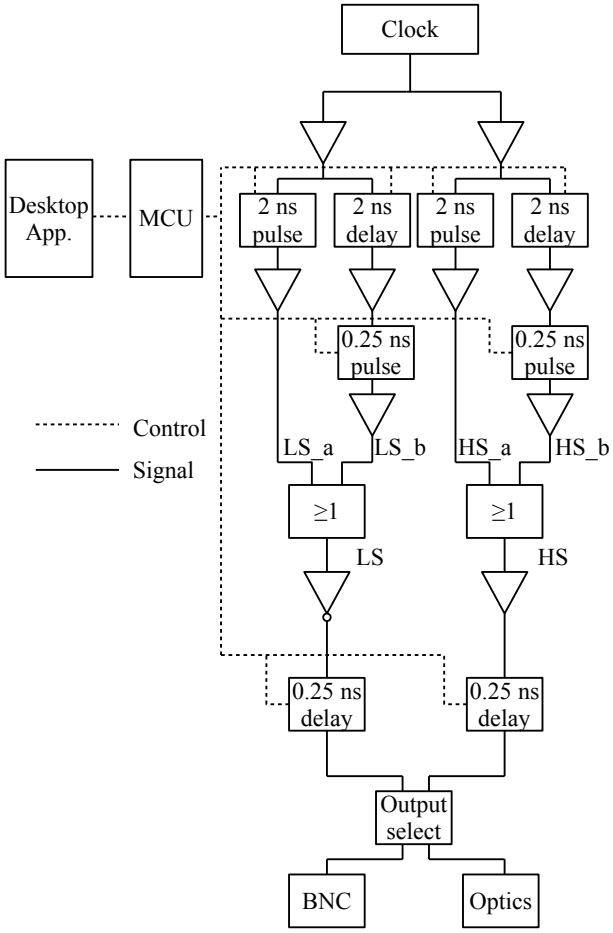

Fig. 2. Block diagram of the developed driving signal generator.

generator that overcomes the drawbacks of the similar driving signal generator developed earlier and presented in [7]. The block diagram of the developed driving signal generator is shown in Fig. 2.

All pulse width and time-delay elements are realised using the timing element DS1123L produced by Maxim Integrated that has both monostable and time-delay functions [8]. The used timing elements consist of an 8-bit step register (255 time-steps) and have a fixed time-step of either 2 ns or 0.25 ns. The 2-ns timing elements are used to obtain duty cycle values up to 50% while 0.25-ns blocks ensure the highest precision of the signal generator. In other words, the 2-ns blocks are used for coarse regulation of the generated signals while 0.25-ns blocks are used for fine adjustment of signal properties.

As it is shown in Fig. 2, each signal is constructed using one of these two methods: construction by 0.25-ns time-step division (signal path HS_b and/or LS_b) or construction by the pulse combination (HS_a+HS_b and/or LS_a+LS_b). Construction by the 0.25-ns time-step division is performed simply by setting the zero value into 2-ns-delay block and writing the wanted number of 0.25-ns time-steps into the 0.25-ns-pulse block. It can only occur if the wanted pulse width is less than 63.75 ns (0.25 ns $\times$ 255 time-steps). In

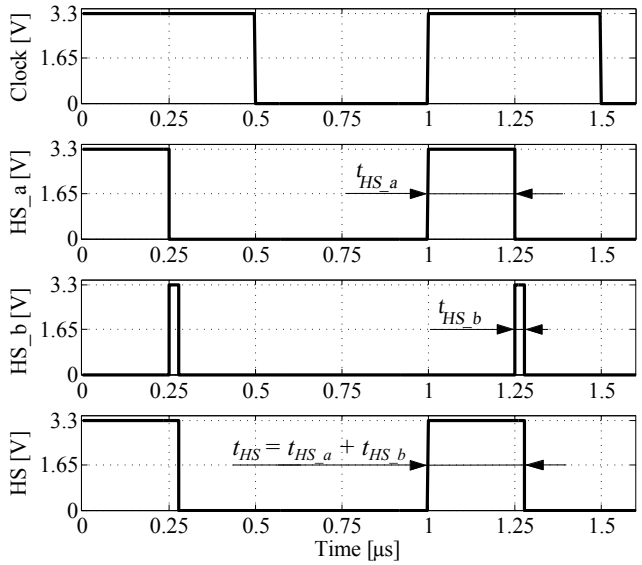

Fig. 3. Working principle of the signal construction by pulse combination (pulse width smaller than 63.75 ns) in the HS channel. (HS_a – wide pulse, HS_b – short pulse, HS – constructed PWM pulse).

this case, the signal is generated completely using the 0.25-ns block, i.e. using only the HS_b and/or LS_b signal path.

Otherwise, if the wanted pulse width is greater than 63.75 ns, the signals are constructed using the combination of both 2-ns and 0.25-ns timing elements (signal paths HS_a+HS_b and/or LS_a+LS_b). Construction by the pulse combination consists of two stages and the principle of the signal construction for one (HS) channel is shown in Fig. 3. First, a wide pulse HS_a is generated with a time-step of 2 ns (2-ns-pulse block). Second, a delayed short pulse HS_b is generated with a time-step of 0.25 ns (0.25-ns-pulse block). The short pulse HS_b is delayed (using the 2-ns-delay block) at the end of the wide pulse and, using an OR logic gate (noted with $\geq$1 in Fig. 2), those two pulses are added together resulting in a wide pulse with a precise time step adjustment as shown in Fig. 3. The same principle of the signal construction is applied for the LS driving signal.

The buffer stages, drawn as the blocks with point-down triangle in Fig. 2, are placed in between every stage of the pulse generator in order to prevent the input impedance of the following stage from affecting the preceeding stage. In order to generate appropriate driving signals for a synchronous buck converter test circuit, the output of the LS signal is inverted relative to the HS signal. Both buffer and inverter are from the same family of the integrated circuits so there is no difference in the inserted time-delay between the HS and LS signal path. The PCB traces carrying the HS and LS driving signals are routed to have the same physical dimensions so the insertion of any unwanted additional time-delay between generated signals is prevented. The 0.25-ns-delay block at both channels are used to insert a relative time-delay between generated signals. Therefore, by controlling the pulse widths and time-delay of both signals, the full control of dead-time adjustment is achieved and any time-delay mismatch can be calibrated.

As shown in Fig. 2, the developed generator has the ability to select either BNC (50 Ω) output or optical transmitter. The driving of the test circuit using the optical fiber is useful in the high-voltage DC-DC applications where, because of both functionality and safety reasons, the galvanic isolation between the pulse generator and high-voltage test circuit has to be implemented.

The operation of every timing element is controlled by the microcontroller unit (MCU in Fig. 2) that is controlled using the PC application shown in Fig. 4. Using the application, it is possible to set all relevant characteristics of generated signals. Additionaly, using the set values, the application calculates the duty cycle values of both HS and LS signal or number of time-steps written into the register of the corresponding timing-element.

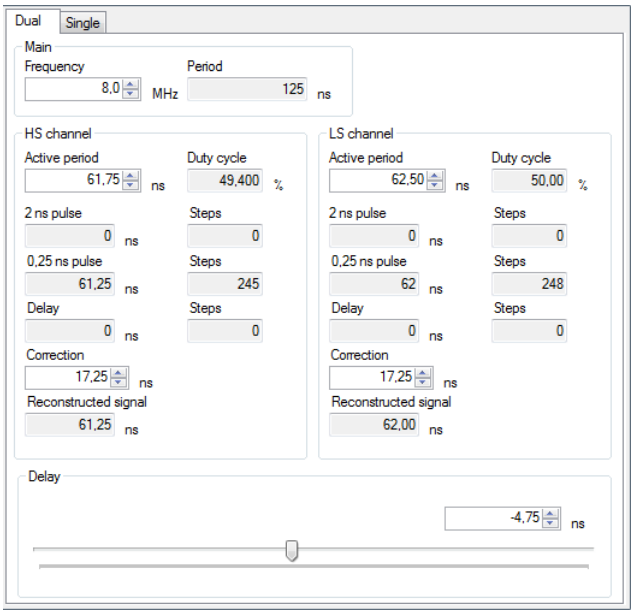

Fig. 4. The PC application used to control the operation of the developed signal generator.

III. Evaluation of the Developed Signal Generator

Before the developed signal generator is verified by measurements, the calibration of the system has to be performed. Besides the avoidance of the typical systematic errors (voltage offset, measurement errors, etc.), the calibration is also used to eliminate the mismatch of the time-delays due to the different number of elements between the signal paths LS_a (HS_a) and LS_b (HS_b).

The functionality of the developed signal generator is evaluated by measuring the HS and LS signal at both BNC and fiber-optic output. The focus of the evaluation of the system is set on testing the system precision (resolution) and system repeatability. Additionally, the functionality of the system at different ambient temperatures is also tested. All the tests are performed under different test cases as presented in Table I.

TABLE I
TEST TYPES AND TEST CASES FOR THE EVALUATION OF THE DEVELOPED SIGNAL GENERATOR.

Test type	Test case
Resolution	@f = 8 MHz (BNC and optics)
Repeatability (pulse width)	HS – 100 ns and LS – 150 ns @f = 1 MHz HS – 50.75 ns and LS – 55.75 ns @f = 5 MHz HS – 22.25 ns and LS – 26.75 ns @f = 10 MHz
Thermal stress	35 °C – 65 °C (5 °C step) @f = 8 MHz and Δt = 250 ps

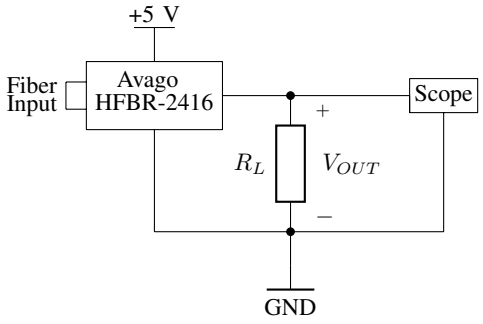

Fig. 5. The optical receiver circuit for testing the operation of the generated optical driving signals (R_L = 2.6 kΩ).

All waveforms are recorded using the Agilent MSO7034B oscilloscope and Agilent 10073D passive probe configuration as follows: 1:1 ratio, DC coupling, bandwidth limit: OFF, input impedance: 50 Ω, averaging: 256 samples. The functionality of the optical transmitter is verified using the circuit with Avago HFBR-2416 optical receiver as shown in Fig. 5.

The system resolution is verified by measuring the time-delay of one-step increment that gives the minimum difference between two pulse widths. The frequency of the generated driving signals was set to 8 MHz as noted in Table I. The recorded waveform of the rise edge for BNC and optical output are shown in Fig. 6. The voltage scales for recorded waveforms differ because the output of the optical receiver used only for testing purposes has to be buffered before it could be used as a driving stage for a MOSFET switch. The time-delay after a one-step increment for a BNC output has a value of exactly 250 ps, which was expected. Due to the slightly distorted signal observed at the output of the optical receiver, the 'bandwidth' function of the oscilloscope was turned on for this test so rise time of recorded signal is somewhat larger than for the BNC output. In order to get a clearer view of the resolution of the optical signal, four time-step increments were applied. The measured time-delay equals 1 ns which is also 250 ps for a single time-step increment.

The ability to achieve the wanted pulse width, i.e. the repeatability of the system, is tested at three different switching frequencies as shown in Table I. The repeatability test consisted of a constant reprogramming of the system for the given parameters in a repeating time period of 3 seconds for 50 test cases. Both HS and LS signals are monitored and the results of the repeatability test are shown in Fig. 7 and Fig. 8

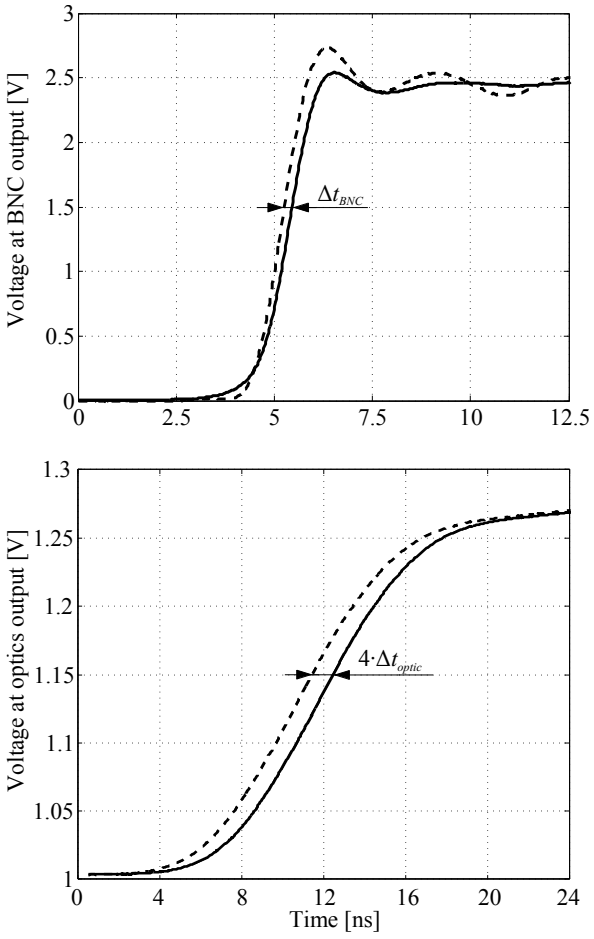

Fig. 6. Measured resolution of the generated signal before (dashed line) and after (solid line) a one time-step increment for BNC (top figure, Δt_{BNC} = 250 ps) and optical output (bottom figure, $4{\cdot}\Delta t_{optic}$ = 1 ns.

for BNC and optical output, respectively. For the HS and LS signal at BNC output, the difference of the measured pulse width and set value is less than a minimum time-step value of 250 ps. Somewhat larger deviation compared to higher switching frequencies is observed at 1 MHz. This could be mainly attributed to the less precise measurement due to the larger time-scale set on the oscilloscope in order to measure the wanted pulse width. However, as long as the deviation is lower than the minimum time-step value, it can be considered negligible. The obtained results for the optical output also show the ability of the system to achieve the deviation of the pulse width lower than 250 ps. However, the deviation is somewhat larger than 250 ps for signal frequency of 1 MHz. Besides the same cause as for the signals at the BNC output, the already mentioned distortion of the optical signal could also affect the measurement results.

In order to test the functionality of the system at higher ambient temperatures, thermal stress was applied to the system. The ability of the system to achieve its resolution of 250 ps at signal frequency of 8 MHz, as well as the stability of the set frequency value, is tested at different ambient temperatures as

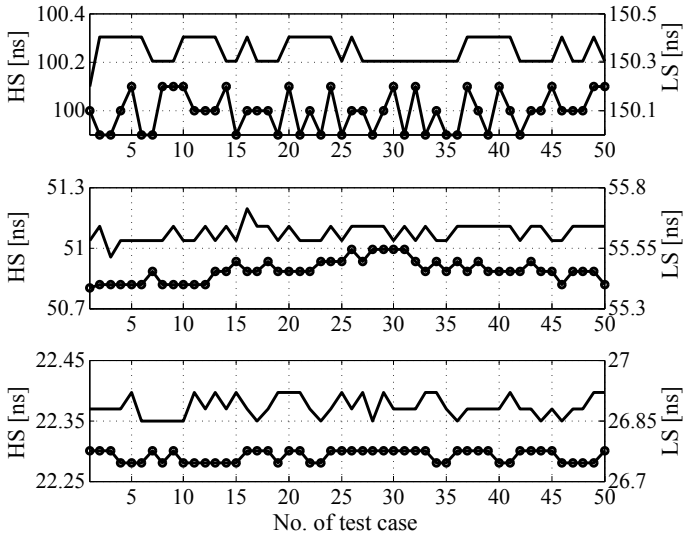

Fig. 7. Repeatability of set pulse width for HS (without marker) and LS (with marker) channel for BNC output.

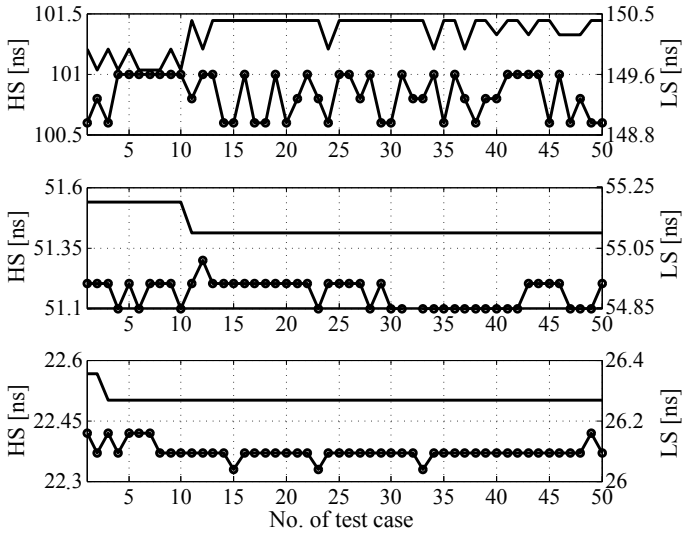

Fig. 8. Repeatability of set pulse width for HS (without marker) and LS (with marker) channel for optical output.

shown in Table I. The highest ambient temperature was chosen to be 65 °C so the temperature limit of 70 °C for the used timing element is not reached [8]. The results of the performed thermal stress are shown in Fig. 9. The displayed (normalised) quantities are the values of the signal frequency and pulse width divided by set values (8 MHz and 250 ps, respectively) written in Table I. It can be observed that signal frequency slightly increases as ambient temperature rises while the value of a single time-step increment is constant up to the highest ambient temperature. This frequency increase, that could be assigned to the impact of the temperature on the integrated oscillator circuit (clock generator), is still less than 0.3% for all ambient temperature values.

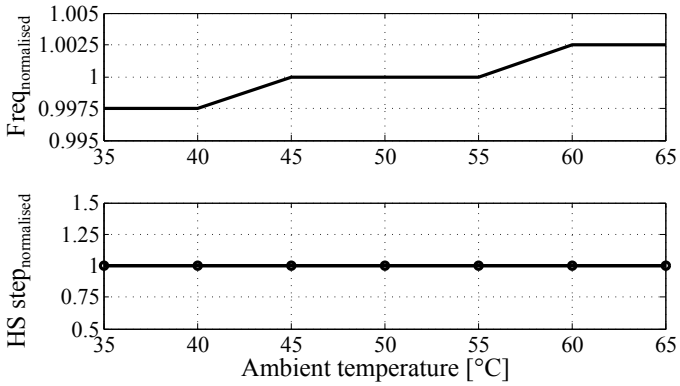

Fig. 9. Impact of ambient temperature on the signal frequency and pulse width for one (HS) channel for BNC (without marker) and optical output (with marker).

IV. Conclusion

In order to characterise the influence of switching frequency, duty cycle and dead-time values on the operation of different models of MOSFET switches used in synchronous DC-DC converters, it is necessary to implement a driving signal generator with precisely adjustable pulse width and relative time-delay between generated signals. Using the digital timing element with fixed time-step value as a basic block for pulse generation and time-delay achievement, it is possible to build a signal generator for synchronous rectifier with the sub-nanosecond precision. The measurement results showed that developed generator keeps its precision under various operating conditions. The optical output of the system, used for driving switches in high-voltage applications, also showed excellent stability during the performed tests.

***Abstract*— This paper presents the results of a study of the effect of dead time and finite semiconductor device voltage drops on the output voltage of three-level neutral point clamped power converters. Results showed that finite voltage drops and dead time caused a DC voltage shift, and lowered the base harmonic amplitude of output voltage. These effects were analysed and the results confirmed via simulation models. Voltage drops effect was confirmed using *Ansys Simplorer*, while the dead time effect was confirmed using *Matlab*. The results showed that the output voltage of the three-level neutral point clamped converters was dependant on the listed parameters. A method is proposed to suppress the negative effects these parameters have on converter voltage.**

I. Introduction

Multilevel topologies research has been intensifying over the past two decades. Due to their inherent advantages over classical two-level converters, primarily in lower switching losses, they are used in a growing number of applications, primarily in the mid-voltage range. In these uses, three topologies stand out among the many multilevel topologies: neutral point clamped, flying capacitor and cascaded. These topologies can be found with renewable energy sources, HVDC transmission, auxiliary power supplies in trains and trams, etc, [1].

Due to an increased number of input voltage levels and an increased number of switches, multilevel converter switches switch at a fraction of the input voltage, depending on the converter topology. This enables the use of semiconductor modules with lower voltage ratings. Despite the increased number of switches, multilevel converter switching losses are lower than those for two-level converters. An increase in the number of output voltage levels reduces the Total Harmonic Distortion (THD) factor. Lower THD factor enables the use of a smaller output filter. This, in return, decreases the converter's dimensions and mass. On the other hand, an increase in the number of switches means a more complex control algorithm. Multiple output voltage levels are achieved by dividing the input voltage into several smaller voltages using a voltage divider (often a series of capacitors), [2], [3], or using several galvanically isolated voltage sources (i.e. fuel cells), [4], [5], [6]. Furthermore, due to the series-connected input capacitors in some converter topologies, the switching states that connect an output phase leg to the neutral point cause voltage ripple.

A common issue with converter topologies of any number of voltage levels are converter nonlinearities, especially in open-loop modulation strategies. The most important nonlinearity is introduced by the necessary blanking time to avoid the shoot-through of either the DC link with two-level converters, or the input capacitors with multilevel converters, caused by the devices' finite turn-on and turn-off times. To ensure that two semiconductor switches operating in counterstroke never conduct at the same time, an initial delay in each switching period, called dead time, is introduced to the control signals.

Another common issue are the semiconductors' on-state voltage drops. If voltage drops vary within the semiconductors of one phase leg, a DC voltage component of both phase and line voltages can occur [7], [8]. These DC voltage components are fairly small, but if the load has a small impedance, the DC current components may be significant. One example of a low-impedance load is a transformer. Since transformers are designed to work near saturation, even a small DC current can lead to transformer saturation [9].

This paper investigates the effects of semiconductor voltage drop and dead time on converter output voltage. These effects are analyzed, and then simulated via *Matlab* and *Simplorer*. Finally, a simple compensation method is proposed.

II. Three-level neutral point clamped inverter

The term "multilevel" was first used by Nabae et al. in 1980, [10]. This paper also presented the neutral point clamped three-level inverter. The converter topology is shown in Fig. 1.

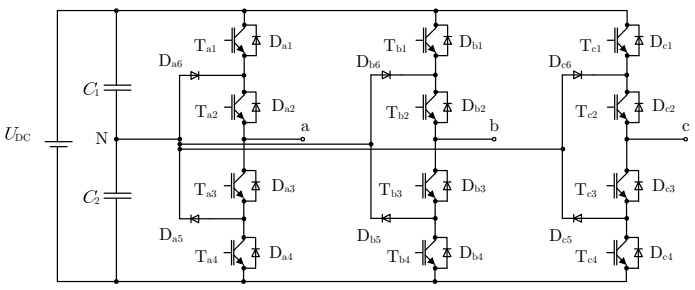

Fig. 1. A neutral point clamped three-level converter topology

The converter consists of 12 transistors and freewheeling diodes, along with six stand-alone diodes, called clamping diodes, all divided equally between three output legs.

The transistors T_{k1} and T_{k3}, as well as T_{k2} and T_{k4}, $k = \mathrm{a}, \mathrm{b}, \mathrm{c}$, work in counterstroke. There are three possible switch states, depending on the transistor on-state combination. The phase leg a switch states, along with their matching output voltages, are presented in Table I. The switch states and output voltages of the remaining two legs are generated in the same manner.

TABLE I

NEUTRAL POINT CLAMPED THREE-LEVEL INVERTER SWITCH STATES AND MATCHING PHASE LEG A OUTPUT VOLTAGE LEVELS

T_{a1}	T_{a2}	T_{a3}	T_{a4}	$U_{a\mathrm{N}}$
1	1	0	0	$+\frac{U_{DC}}{2}$
0	1	1	0	0
0	0	1	1	$-\frac{U_{DC}}{2}$

Control signals for the transistors of one output phase leg are generated by comparing one or more low-frequency modulation signals and one or more high-frequency carrier signals. The number and waveform of modulation signals and carrier signals depend on the control system. Figure 2 shows the assumption of one modulation signal per leg, and two carrier signals, along with the corresponding phase and line voltages.

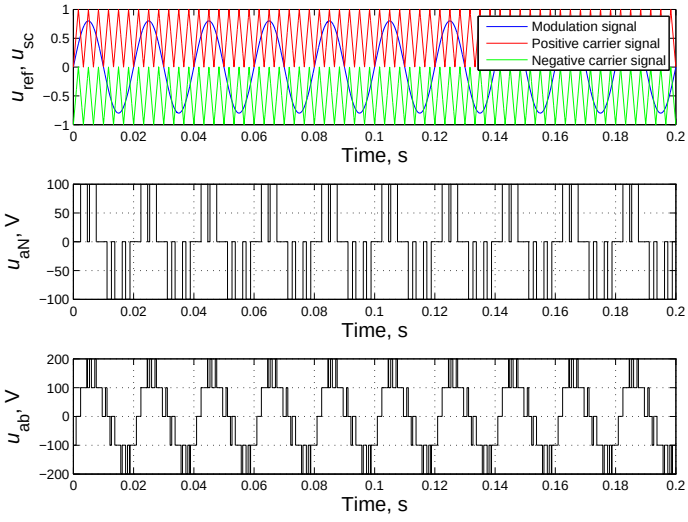

Fig. 2. Phase a modulation signal and carrier signals waveforms and phase and line voltage waveforms

Transistors T_{k1} and T_{k2} are in the on-state in those intervals in which the modulation signal is positive and greater than the positive carrier signal. Transistors T_{k2} and T_{k3} are in the on-state in those intervals in which the modulation signal is either positive and lesser than the positive carrier signal, or negative and greater than the negative carrier signal. Transistors T_{k3} and T_{k4} are in the on-state in those intervals in which the modulation signal is negative and lesser than the negative carrier signal.

Transistors conduct when in the on-state, and the output current direction of the matching phase leg matches the direction of the collector-emitter current. If the output current direction is the opposite of the transistor collector-emitter current, the according freewheeling diode conducts in that time interval.

Clamping diodes connect the phase voltages to the neutral point. In case a phase current is positive, diodes D_{k6} conduct, whilst if a phase current is negative, diodes D_{k5} conduct.

Fig. 3 depicts the phase a current paths. For instance, if phase a to neutral voltage is positive, and phase a current is negative, then the transistors T_{a1} and T_{a2} are in the on-state, as circled in Fig. 3, and diodes D_{a1} and D_{a2} are conducting. Other switching states and current paths are derived in the same manner.

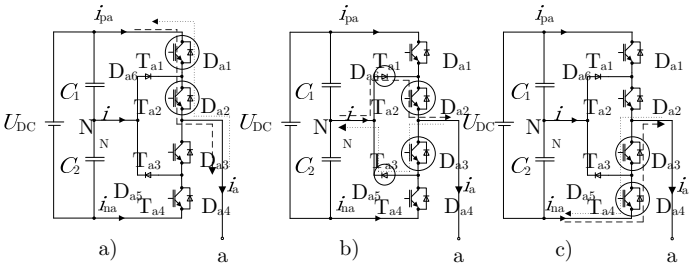

Fig. 3. Phase a current paths

III. VOLTAGE DROP EFFECT

It is generally assumed that all semiconductor voltage drops are either negligible, or equal. This need not necessarily be true. Semiconductor voltage drops in the on-state are listed in manufacturer datasheets, and vary with temperature and different production series. Datasheets usually list the minimum, typical and maximum voltage drop values for two working temperatures. Voltage drop values for the in-between temperatures are usually given graphically. For instance, the on-state voltage drops of IGBTs within one semiconductor module may vary as much as 1 V for 1200 V, 300 A semiconductor modules.

Figs. 4 a) and b) show the voltage drop effects on the phase-to-neutral voltage of an arbitrary phase leg, k, in the case of a positive modulation signal $u_{\mathrm{ref},\,k}\,(t)$ and positive and negative phase leg k load currents, respectively. u_{g}^{+} is the control signal for the phase leg switches that switch the load to the positive DC bus, u_{g}^{0} the control signal for the phase leg switches that switch the load to the neutral point, $u_{k,\,\mathrm{id}}$ the ideal output voltage waveform, and $u_{k,\,\mathrm{st}}$ the actual output voltage waveform.

Figs. 5 a) and b) show voltage drop effects on the phase-to-neutral point voltage of an arbitrary phase leg, k, in the case of a negative modulation signal $u_{\mathrm{ref}}\,(t)$ and positive and negative phase leg k load current, respectively. u_{g}^{+} is the control signal for phase leg switches that switch the load to the negative DC bus.

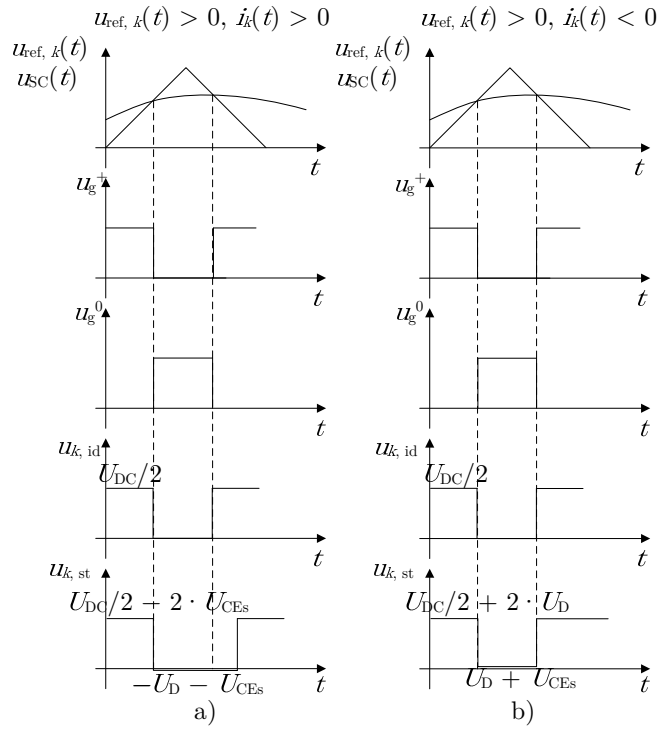

Fig. 4. Effect of semiconductor voltage drops on phase k phase-to-neutral-point voltage in case of a positive modulation signal and positive and negative load currents

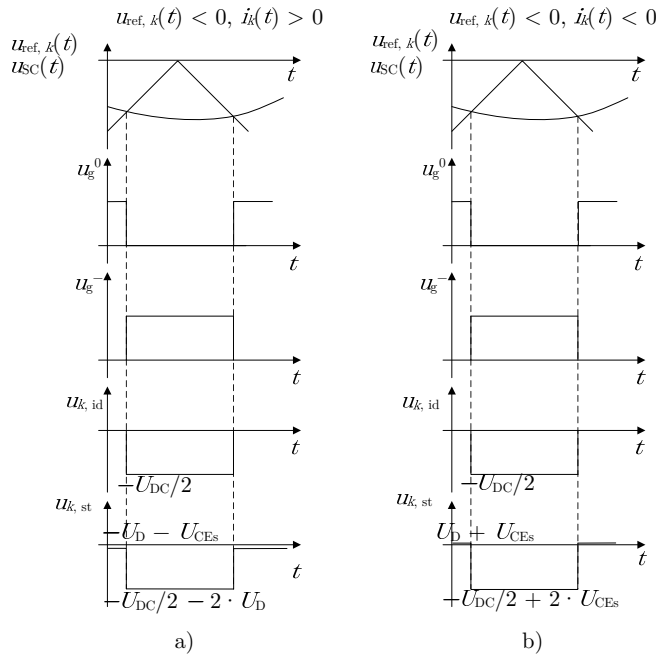

Fig. 5. Effect of semiconductor voltage drops on phase k phase-to-neutral-point voltage in case of a negative modulation signal and positive and negative load currents

During intervals where the modulation signal is greater than the carrier signal, and the phase current is positive, transistors T_{k1} and T_{k2} are in on-state and conducting, as depicted in Fig. 3.

During intervals where the modulation signal is greater than the carrier signal, and the phase current is positive, transistor T_{k2} and diode D_{k6} are conducting. In that case, transistor and diode voltage drops increase the one-cycle average. The same principle may be applied in the case of a negative modulation signal value. Therefore, if semiconductor voltage drops are equal for all transistors and diodes, no DC voltage component is present in the output voltage. In the case the semiconductor voltage drops vary from one semiconductor to another, the output voltage contains a DC component. The largest DC component can be predicted from the actual phase leg voltages shown in Figs. 4 and 5.

If transistor T_{k1} and T_{k2} voltage drops are maximum, and transistor T_{k3} and T_{k4} minimum, a maximum negative output voltage DC component can be expected. Let this be the negative worst-case scenario. Similarly, if transistor T_{k1} and T_{k2} voltage drops are minimum, and transistor T_{k3} and T_{k4} maximum, a maximum positive output voltage DC component can be expected. Let this be the positive worst-case scenario. DC components of the phase leg voltages U_{aN}, U_{bN} and U_{cN} were simulated for both worst-case scenarios.

The DC voltage components of phase leg a were simulated via *Simplorer*. The simulation parameters are listed in Table II.

TABLE II

THREE LEVEL NPC SIMULATION MODEL PARAMETERS

Parameter	Symbol	Value
Load resistance	R_{d}	$1.2\,\Omega$
Load inductance	L_{d}	$1920\,\mu\mathrm{H}$
Source voltage	U_{DC}	$750\,\mathrm{V}$
Modulation signal frequency	f_{ref}	$50\,\mathrm{Hz}$
Carrier and modulation signal frequency ratio	m_f	50
Modulation and carrier signal amplitude ratio	m_a	0.7

Semiconductor voltage drops were taken from the *Mitsubishi CM300DY-24A* power module datasheet. No minimum voltage drop was listed, instead, it was estimated at 2 V; the typical voltage drop is listed as 2.1 V, and the maximum voltage drop as 3 V for 25 °C. Since no listing was provided for the freewheeling diode voltage drops, a value of 2.17 V is assumed for the minimum, typical and maximum values. This value matches the value listed in the *IXYS MEE75-12DA-ND* datasheet, which is the clamping diode module.

The simulation results are presented in Table III. The middle column presents the results for the positive worst-case scenario, whilst the right column presents the results for the negative worst-case scenario.

TABLE III

PHASE LEG DC VOLTAGE COMPONENTS FOR WORST-CASE SCENARIOS FOR 25 °C

Voltage	Value	Value
U_{aN}	$969.81\,\mathrm{mV}$	$-835.42\,\mathrm{mV}$
U_{bN}	$843.42\,\mathrm{mV}$	$-811.72\,\mathrm{mV}$
U_{cN}	$747.75\,\mathrm{mV}$	$-801.74\,\mathrm{mV}$

The results show that phase leg voltages can contain a significant DC component, which can cause significant DC current components through a low-impedance load.

Line voltage u_{ab}, u_{ac} and u_{bc} DC components were simulated for various transistor T_{a1} and transistor T_{a2} voltage drops. This allowed for an investigation of the relationships between different voltage drops of one phase semiconductor components and line voltages. The results are shown in Fig. 6.

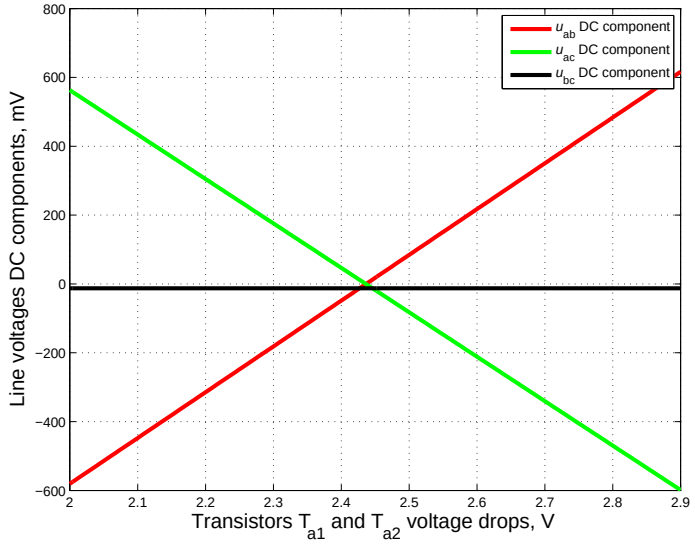

Fig. 6. Line voltages u_{ab}, u_{ac} and u_{bc} DC components

Fig. 6 shows that different voltage drops of one phase leg's semiconductor components can cause significant line voltages, which can cause significant DC current components through a low-impedance load.

A hypothetical situation was simulated, in which the converter temperature reached 125 °C. It was assumed that, before the converter temperature rose, all voltage drop values had been typical for 25 °C. After the temperature had risen, phase leg a semiconductor voltage drop values were assumed to cause the negative worst-case scenario DC component for 125 °C. Semiconductor voltage drop values for the remaining two phase legs were assumed typical for 125 °C. Voltage drop values were estimated the same way they had been estimated for 25 °C. Transistor $\mathrm{T_{a1}}$ and $\mathrm{T_{a2}}$ voltage drops are 3.3 V, transistor $\mathrm{T_{a3}}$ and $\mathrm{T_{a4}}$ voltage drops are 2.4 V, the remaining transistors voltage drops are 2.4 V, all freewheeling diodes voltage drops are 2.3 V, and all clamping diodes voltage drops are 1.85 V.

TABLE IV

PHASE LEG A AND LINE DC VOLTAGE COMPONENTS FOR 125 °C

Voltage	Value
U_{aN}	−511.65 mV
U_{ab}	−536.81 mV
U_{ac}	−521.5 mV
U_{bc}	20 mV

IV. DEAD TIME EFFECT

It is generally assumed that the output voltage is fully defined by the converter switching states. However, if the control signal contains dead time, this assumption becomes invalid and during dead time the output voltage is defined by the load phase current direction.

The influence of dead time on phase leg k voltage for the positive modulation signal is shown in Figs. 7 a) and b) for positive and negative load current, respectively. t_{d} denotes dead time duration, t_{on} turn-on time and t_{off} turn-off time.

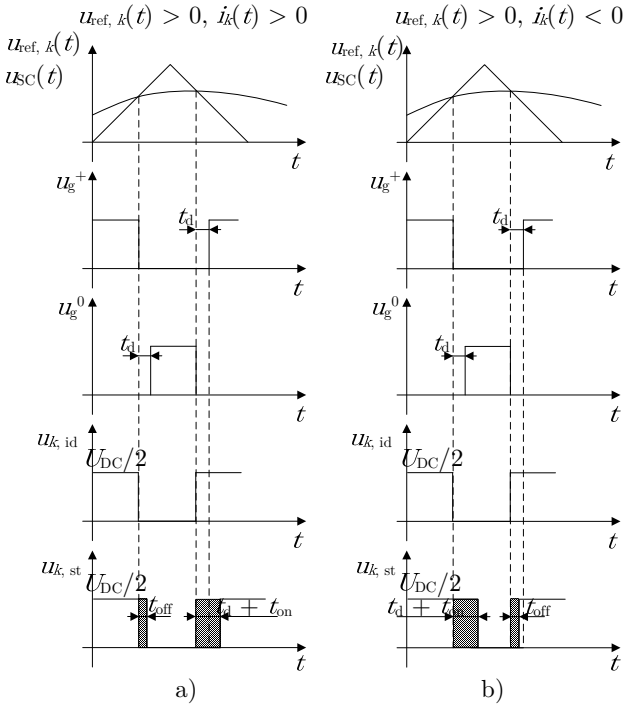

Fig. 7. Dead time influence on phase k to the neutral voltage - positive modulation signal

Dead time influence on phase leg k voltage for the negative modulation signal is shown in Figs. 8 a) and b) for positive and negative load current, respectively.

For instance, in the case that the modulation signal is positive and greater than the carrier signal, and the matching phase leg load current is positive, as shown in Fig. 7 a), transistors T_{k1} and T_{k2} are in the on-state and the phase leg output voltage is positive. When the modulation signal intersects the carrier signal, the transistor T_{k1} control signal shifts from one to zero (logical values). After t_{off}, the transistor current becomes zero and the transistor is now in the off-state. The output current commutes from transistor T_{k1} to diode D_{k6} and the phase leg voltage becomes zero. t_{d} after the modulation signal and the carrier signal intersect, transistor T_{k3} control signal shifts from zero to one, and after t_{on} transistor T_{k3} is in the on-state and the phase leg k output voltage remains zero. When the modulation signal and the carrier signal intersect for the second time, transistor T_{k3} is in the off-state after t_{off} and the phase current commutes back

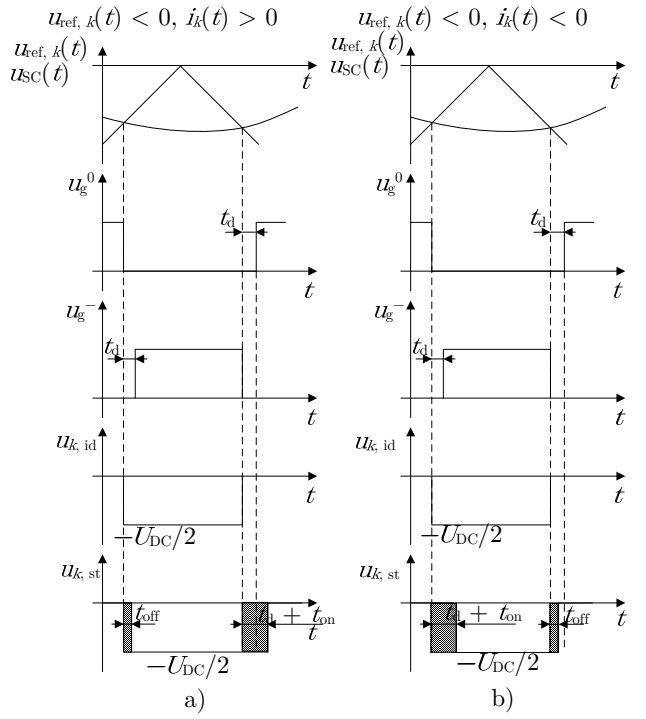

Fig. 8. Dead time influence on phase k to the neutral voltage - negative modulation signal

to diode D_{k6} and the output voltage remains zero. $t_{\mathrm{d}} + t_{\mathrm{on}}$ after the modulation signal and the carrier signal intersect for the second time transistor T_{k1} is in on-state and the output voltage is positive again.

Therefore, it is clear that during dead time, the converter's output voltage is not controlled by the modulation signal but, instead, is determined by the load current direction. This is equivalent to the discontinuation of the modulation signal. Hence, dead time has an effect on the converter's harmonic spectrum. This effect is prominent at lower frequencies. One-cycle average voltage deviation is constant for one current direction due to the dead time effect. This deviation is shown in Fig. 9, as Δu. Δu_1 is fundamental harmonic of Δu, u_{ref} is the ideal output voltage fundamental harmonic, u_1 is the actual output voltage fundamental harmonic, i_1 is the actual output current fundamental harmonic, and ϕ is the phase shift between the output voltage and output current fundamental harmonics.

Let M be the total number of switchings within one modulation signal period T_{r}. One-cycle average of the voltage deviation (over the course of one modulation signal period) is:

$$\Delta\overline{u} = \frac{M\left(t_{\mathrm{d}} + t_{\mathrm{on}} - t_{\mathrm{off}}\right)U_{\mathrm{DC}}}{2T_{\mathrm{r}}}. \tag{1}$$

It's fundamental harmonic amplitude is:

$$\Delta\hat{\overline{u}}_1 = \frac{4}{\pi}\Delta\overline{u}. \tag{2}$$

The effect dead time has on the output voltage can be calculated from the phasor diagram, Fig. 10. Using the law of

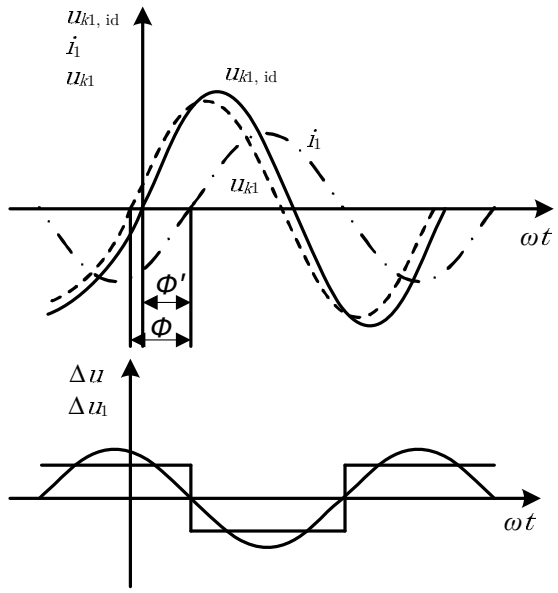

Fig. 9. Output voltage fundamental harmonic distortion due to dead time

cosines, the effect of dead time on the output voltage, normed to the output voltage fundamental harmonic, can be calculated as:

$$\frac{\hat{U}_1}{\hat{U}_{\mathrm{ref}}} = -\eta\cos\left(\phi\right) + \sqrt{1 - \eta\sin^2\left(\phi\right)}, \tag{3}$$

where η is the normed value of the voltage deviation fundamental harmonic:

$$\eta = \frac{8}{\pi}\frac{M\left(t_{\mathrm{d}} + t_{\mathrm{on}} - t_{\mathrm{off}}\right)}{T_{\mathrm{r}}m_{\mathrm{a}}}. \tag{4}$$

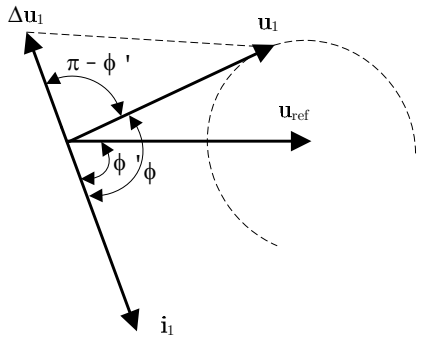

Fig. 10. Effect of the output voltage dead time

The effect dead time has on the converter output current's amplitude and phase shift was simulated via *Matlab* for various dead time and amplitude modulation ratio m_{a}. Model parameters are listed in Table V.

The simulation results are listed in Table VI and they show that the output current amplitude and phase deviations are larger for larger dead time values. This is contributed by the fact that the controllable voltage percentage drops when

dead time duration increases. They are also dependent on the amplitude modulation ratio. This fact was not predicted in the previous analysis, as the narrow impulse effect was neglected. Narrow impulses are present in areas where the modulation signal is near its greatest or lowest value, and around zero. When a narrow pulse is present, dead time lasts longer than the switch state, a situation present near the carrier signals' amplitudes. This influence is prominent for small or large amplitude modulation ratios, because of the higher narrow impulse content for such amplitude modulation ratios.

V. PROPOSED COMPENSATION METHOD

Since both semiconductor voltage drops and dead time influences are constant within one-half of the modulation signal and load current period, a simple modification to the basic modulation signal can be generated to compensate for these influences. This method is based on the so-called volt-second method, where the modulation signal is modified in such a way that the modified output voltage one-cycle average is equal to the ideal output voltage one-cycle average. This method is known from two-level converters, both for carrier-based modulation [11], [12], and for space-vector control [13]–[15].

Semiconductor voltage drops and dead time influences can be combined into one equation, depending on the modulation signal and current signs and on the modulation signal waveform. That equation can be simplified by neglecting the modulation signal waveform, due to its negligible contribution to the voltage deviation. These simplified influences are listed in Table VII.

TABLE VII

SIMPLIFIED OUTPUT VOLTAGE DEVIATIONS DUE TO SEMICONDUCTOR VOLTAGE DROPS AND DEAD TIME

u_{ref}	i_k	$\Delta\overline{u}_k$
+	+	$\frac{\mathrm{t_d}+\mathrm{t_{on}}-\mathrm{t_{off}}}{T_{\mathrm{s}}} \cdot \left(\frac{U_{\mathrm{DC}}}{2} - U_{\mathrm{CEs}} + U_{\mathrm{D}}\right) + \frac{U_{\mathrm{D}}+U_{\mathrm{CEs}}}{2}$
+	−	$-\frac{\mathrm{t_d}+\mathrm{t_{on}}-\mathrm{t_{off}}}{T_{\mathrm{s}}} \cdot \left(\frac{U_{\mathrm{DC}}}{2} - U_{\mathrm{CEs}} + U_{\mathrm{D}}\right) - \frac{U_{\mathrm{D}}+U_{\mathrm{CEs}}}{2}$
−	+	$\frac{\mathrm{t_d}+\mathrm{t_{on}}-\mathrm{t_{off}}}{T_{\mathrm{s}}} \cdot \left(\frac{U_{\mathrm{DC}}}{2} - U_{\mathrm{CEs}} + U_{\mathrm{D}}\right) + \frac{U_{\mathrm{D}}+U_{\mathrm{CEs}}}{2}$
−	−	$-\frac{\mathrm{t_d}+\mathrm{t_{on}}-\mathrm{t_{off}}}{T_{\mathrm{s}}} \cdot \left(\frac{U_{\mathrm{DC}}}{2} - U_{\mathrm{CEs}} + U_{\mathrm{D}}\right) - \frac{U_{\mathrm{D}}+U_{\mathrm{CEs}}}{2}$

If a compensation signal is superpositioned onto the original modulation signal, with regard to the modulation signal and output current signs, the influence listed in Table VII can be cancelled. This method requires very little computational power and a handful of measurements, and is therefore suitable for implementation in industrial systems.

VI. CONCLUSION

This paper presented the effects dead time and semiconductor voltage drops have on the three-level neutral point clamped converter output voltage. The influence on the one-cycle average output voltage value was analyzed analyticaly and the results were confirmed via simulations. Simulation results showed that different semiconductor voltage drops cause significant phase leg and line voltage DC components. Semiconductor voltage drop temperature dependence was analyzed and the results were also confirmed via simulation. Simulation results show that various semiconductor voltage drops cause a temperature-dependent output voltage DC component. The influence dead time has on the output current fundamental harmonic amplitude and phase shift was also simulated. Simulation results show that dead time lowers the amplitude of the output current fundamental harmonic, and that it introduces an additional phase shift. A compensation method was proposed to diminish the effects of dead time and semiconductor voltage drops, based on the conducted analysis.

Model of three level neutral point clamped converter (NPC) for grid connected photovoltaic systems

Mateja Novak, Viktor Šunde and Željko Jakopović
Faculty of Electrical Engineering and Computing/Department of Electrical Machines, Drives and Automation, Zagreb, Croatia

Abstract - Photovoltaic modules as direct converters of solar energy into electrical energy are typically connected to the power grid trough standard two level converters. A photovoltaics system can be connected to the power grid if it can satisfy the IEEE standardized conditions set by the power grid operator. The conditions include limitations of THD factor and current harmonics. Multilevel converters which have a lower THD factor than two level converters can satisfy these conditions and in the same time work at higher switching frequencies lowering the losses and the size of the output filter. The model implemented in Simulink® MATLAB consists of a photovoltaic array, boost dc-dc converter with MPPT control and three level neutral point clamped converter connected to the power grid. The simulation results are presented, analyzed and compared to the standard model with a two level converter to validate the benefits of the usage of multilevel converters for grid connected photovoltaic systems.

I. INTRODUCTION

The world energy consumption by the year 2050 is projected to reach 30 terawatts (TW). In order to stabilize the concentration of CO_2 in the atmosphere, about 20 TW would have to be generated by the non-CO_2 energy plants [1]. According to renewables 2014 global status report the capacity of installed solar power has already reached 139 GW [2]. As a distributed energy source it presents a challenge for the grid operator in terms of the availability as well as energy quality.

Typically the solar plants are connected to the grid by standard 2-level converters. The drawback of connecting the solar plants trough high frequency converters is injection of low level current harmonics to the grid and increasing the total harmonic distortion (THD) factor. To limit the grid pollution, standardized conditions defined by the IEEE and IEC which include THDV factor limitation to maximum of 5% and current harmonics limitations have to be met in order to obtain a permit from the grid operator to connect the solar power plant to the public grid. [3] Multilevel converters which have a lower THD factor then standard two level converters can satisfy these conditions and in the same time provide many benefits that can help in raising the efficiency of the energy conversion lowering the switching losses by working at higher switching frequencies and allowing the usage of smaller output filters [5][7][8]. Semiconductor manufacturers have recognized these values and are already offering complete phase-leg modules for various multilevel converter topologies [4][6].

Multilevel converter topology chosen for this simulation model is a standard three level neutral point clamped (NPC) topology, Fig. 1. NPC converter topology is currently mostly used for large variable speed drives and wind turbines in medium and high voltage range to improve the conversion efficiency.

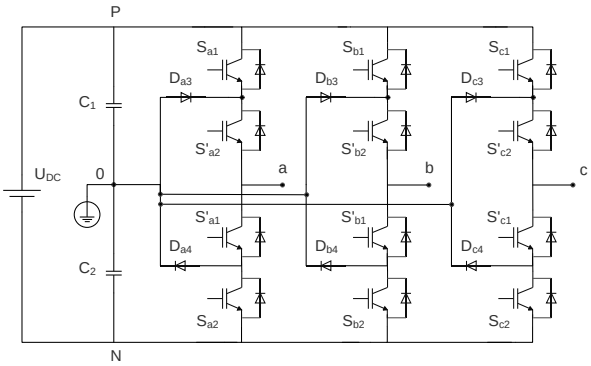

Figure 1. Three level NPC topology

As the losses in energy transport are proportional to square value of the current it is logical that the transport by higher voltage will provide the reduction of energy losses. For large scale photovoltaic power plants the dc link voltage reached the maximum voltage class of the semiconductor switches. In standard 2-level voltage source converters the voltage class of semiconductor switches has to be slightly higher than the dc-link voltage. Semiconductor switches in NPC topology bear half the voltage of 2-level, therefore the rated voltage of devices used is half of that in 2-level permitting the usage of NPC with higher dc-link voltage. A higher dc-link voltage also means that the output voltage of the converter will be higher.

To study the behavior of multilevel converters for grid connected PV systems in terms of energy quality and transmission efficiency a simulation model was implemented in Simulink ® MATLAB. The model consists of a photovoltaic array, boost dc-dc converter with MPPT control unit and grid connected 3-level NPC converter, Fig 2.

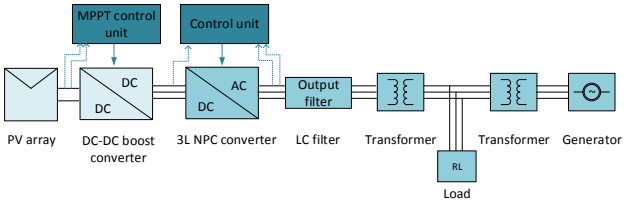

Figure 2. Model layout

II. SIMULATION MODEL

In subsections of this chapter a brief guidance is given for choosing the model parameters along with selected parameter values used in the simulation model presented in Fig.3.

A. *PV array*

Photovoltaic array consists out of 520 photovoltaic modules with rated nominal power of 305 W_p connected in 40 strings. Module characteristics are extracted from NREL System Advisor Model [9].To simplify the model temperature dependence of the PV array is not evaluated in the model. PV Module/Array parameters are given in Table I. Sampling times of current and voltage measurements of the PV array are T_S=1μs.

TABLE I. PV MODULE/ARRAY PARAMETERS

Parameter	Module	Array
V_{OC}	64.2 V	834.6 V
I_{SC}	5.96 A	238.4 A
V_{MPP}	54.7 V	711.1 V
I_{MPP}	5.58 A	223.2 A

B. *DC-DC boost converter with MPPT control*

In order to draw the maximum out of available solar power the duty cycle of the IGBT switch in the dc-dc boost converter is calculated by the MPPT (Maximum Power Point Tracker) control unit. Input parameters of the unit: PV array current, voltage and power measurements are calculated as average values over 1000 samples making the sample time of the MPPT unit T_S=1ms.

The implemented MPPT algorithm is based on the Incremental Conductance (IC) algorithm with a variable duty cycle increment as presented in Fig. 4. [10].
Variable increment (δ_V) is calculated as (1) if $\delta_V < \delta_{max}$:

$$\delta_v = N \cdot \left| \frac{dP}{dV} \right|_{\delta max} \quad (1)$$

Parameter N is chosen to satisfy (2) for a fixed step IC algorithm with maximum duty cycle increment.

$$N = \frac{\delta_{max}}{\left| \frac{dP}{dV} \right|_{\delta max}} \quad (2)$$

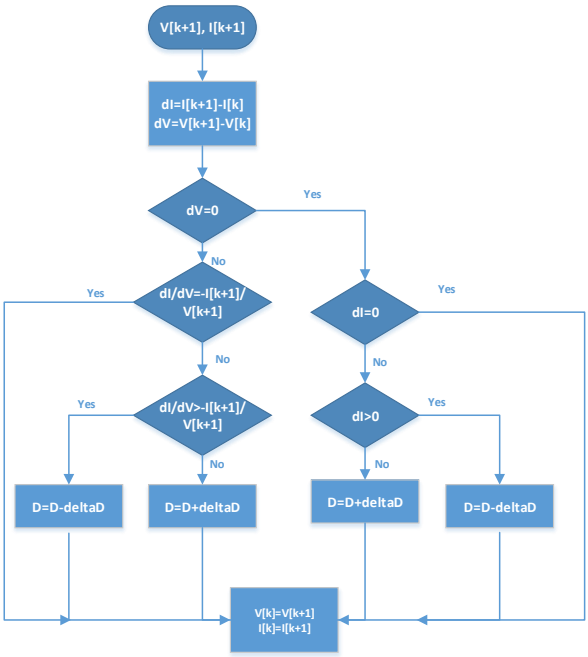

Figure 4. Incremental conductance algorithm

For maximum irradiation of 1kW/m^2 average value of duty cycle is 0.29. Switching frequency of the converter is set to 10 kHz. Parameters of the DC-DC boost converter are given in Table II.

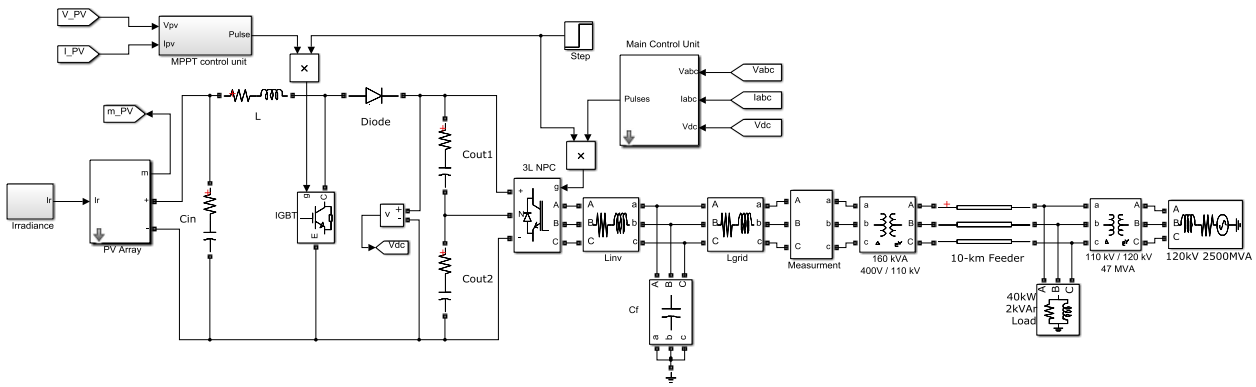

Figure 3. Simulation model in Simulink® MATLAB

TABLE II. DC-DC BOOST CONVERTER PARAMETERS

Parameter	Specification
C_{in}, R_c	100 uF, 1 mΩ
L, R_L	0.5 mH, 5 mΩ
δ_{max}	0.01
f_{PWM}	10 kHz
C_{out1}, C_{out2}	10 mF

C. NPC converter and control unit

Initial values of the dc-link capacitors were chosen as proposed in [11] and later adjusted to get the desired behavior of dc-link voltage during simulation. For the 160 kVA NPC converter nominal dc-link voltage V_{dc} is set to 1000 V, line rms output voltage is 400 V with nominal frequency of 50 Hz.

Control unit of the NPC converter includes a phase locked loop (PPL) block, current and DC voltage PI regulators, voltage reference generating block and PWM pulse generator. The d-axis current component reference is defined as output value of DC voltage regulator while the q-axis component reference is set to zero in order to maintain unity power factor. PWM pulse generator uses two triangular amplitude shifted 8 kHz (f_{sw}) carrier signals.

D. Grid connection

Output filter of the NPC converter is a wye connected LCL filter, Fig 5. designed as described in [12].

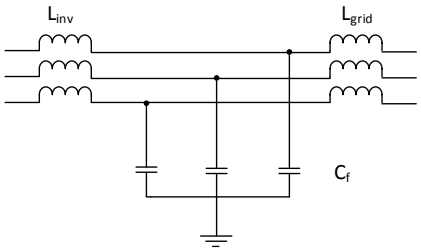

Figure 5. Wye connected LCL filter topology

To find the suitable values of filter parameters it is necessary to calculate the base impedance (Z_B) (3) and capacitance (C_B) (4). The voltage value used in equation is line rms value; frequency ω_N is nominal output frequency of the NPC converter and S nominal power of the converter in VA.

$$Z_B = \frac{3 \cdot U_{Lrms}}{S} \tag{3}$$

$$C_B = \frac{1}{\omega_N \cdot Z_B} \tag{4}$$

Maximum value of filter capacitance is 5% of the base capacitance because it is considered that the maximum power factor variation see by the grid is 5%.

$$C_f = 0.05 \cdot C_B \tag{5}$$

Inverter inductance is calculated for the worst case scenario when the duty cycle of the dc-dc boost converter is 0.5 (6). The inductor should be able to limit the ripple of output current to 10% of the rated amplitude value (7).

$$L_{inv} = \frac{V_{dc}}{16 \cdot f_{sw} \cdot \Delta I_{out,max}} \tag{6}$$

$$\Delta I_{out,max} = 0.1 \frac{P_n \sqrt{2}}{3 \cdot V_{PHrms}} \tag{7}$$

Relation factor *r* between the grid inductance and inverter (7) is defining the ripple attenuation and is usually set to 0.5.

$$L_{grid} = r \cdot L_{inv} \tag{8}$$

Calculated parameters for the LCL filter of the simulation model are presented in Table III.

TABLE III. LCL FILTER PARAMETERS

Parameter	Specification
L_{inv}, R_L	0.24 mH, 1 mΩ
L_{grid}, R_L	0.12 mH, 1 mΩ
C_f	50uF

The converter is connected through transformer to the 110 kV grid. A 10 km feeder represents the transmission grid connecting the generator.

III. SIMULATION RESULTS AND ANALYSIS

Simulation is performed for two irradiance curves representing different weather conditions. The half sine curve represents an ideal sunny day with maximum 1kW/m^2 irradiance peak, Fig. 6. To simplify and accelerate the simulation the average 12h of available daylight is scaled to fit the simulation time of 1s. Second curve represents rapidly changing irradiance as a result of cloud shading, Fig 7.

On both Figures can be seen that with the help of implemented MPPT algorithm the power output curve follows the irradiance change. The output voltage remains constant with peak phase to ground value of 320 V.

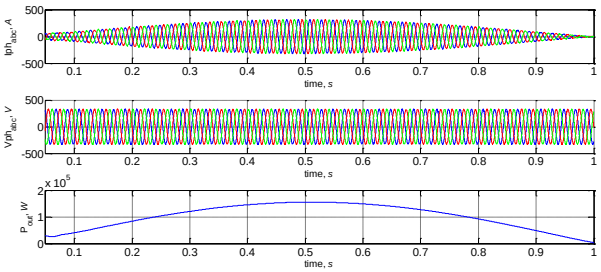

Figure 6. Output current, voltage and power for ideal irradiance curve

DC-link voltage for both irradiance curves is similar, Fig 8. During the first 1ms the capacitors are being charged without regulation of the main control unit.

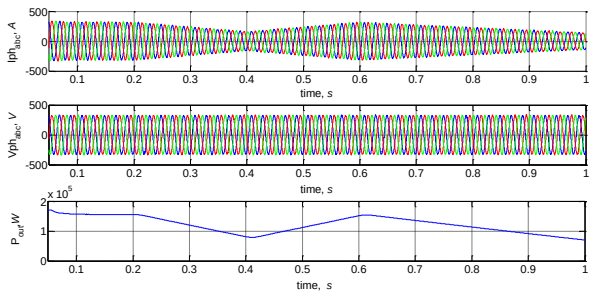

Figure 7. Output current, voltage and power for changing irradiance curve

After the main and MPPT control unit are enabled the dc-link voltage drops to the value of reference voltage. The voltage ripple remains within ±1% of the reference link voltage.

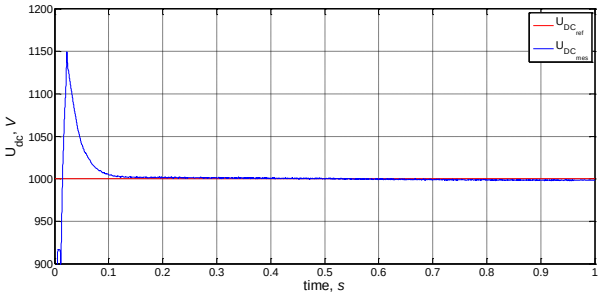

Figure 8. Simulated DC link voltage

Created model also copes very well with more extreme irradiance changes. Daily irradiance data uploaded on Sunny portal for a public available plant in Croatia was fitted on a 1 second scale and set as input irradiance variable for the simulation model [13].

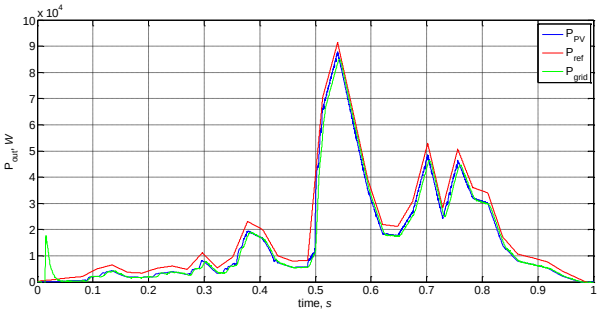

Figure 9. Simulated output power for extreme irradiance change

The results presented in Fig. 9 show the reference power obtained from the irradiance data (P_{ref}), PV power measured before the NPC converter (P_{pv}) and the power transmitted to the grid (P_{grid}). Even under difficult conditions the MPPT algorithm managed to draw out nearly the maximum of the available power.

IV. TWO LEVEL VSC AND THREE LEVEL NPC COMPARISON

In order to show the benefits of using 3-level NPC converter on higher switching frequencies for connecting the PV systems a comparison with an equally specified 2-level voltage source converter (VSC) model has been made. The primary focus of the comparison as stated in the introduction is the current distortion expressed through TDD (Total Demand Distortion) factor of the current waveform. TDD represents the ratio of the root-sum-square value of the harmonic current to the maximum demand load current hence at rated load, in this case maximum constant irradiation level, current TDD and THD are the same value. [3] For following switching frequencies 2, 4 and 8 kHz results of the simulation are presented in Table IV. During the simulation, irradiance level is set at constant value of 1kW/m^2. While performing FFT analysis over 10 cycle sample of the current signals, the sampling time of model was reduced to 0.1µs.

TABLE IV. CONVERTER OUTPUT CURRENT THD FACTOR

Carrier frequency	2-level VSC before filter	2-level VSC after filter	3-level NPC before filter	3-level NPC after filter
2 kHz	7.03%	4.97%	3.54%	2.6%
4 kHz	5.51%	2.34%	3.03%	1.79%
8 kHz	4.93%	1.35%	2.47%	0.72%

Filters for each frequency were designed as described in section II.D. It also has to be taken into account that a certain amount of current ripple has been produced through the boost dc-dc MPPT controlled converter.

When raising the switching frequency it can be seen that the usage of 3-level NPC converter produces less current distortion and can be used on higher switching frequencies and stay under 5% THD factor limit.

Additionally to prove that a reduction of filter size without a huge impact on the current distortion is possible for NPC converter, the simulation was also run for 4 kHz switching frequency but with a filter half the size as used for simulation in Table IV. Fig. 10 shows the result of FFT analysis of converter output current for 4 kHz switching frequency with smaller filter.

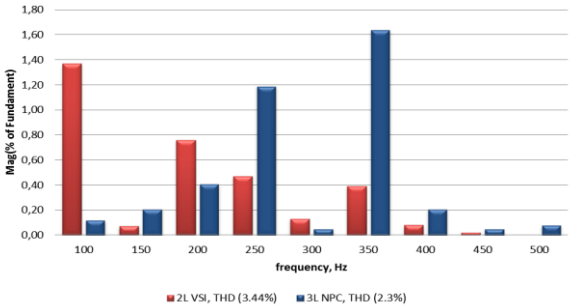

Figure 10. FFT analysis of I_{out}

The THD factor for the NPC converter output current was 2.3%, whereas for the 2-level VSC it was 3.44% making the difference between the two converters with smaller filters two times higher than when using larger filters in favor of the NPC converter.

V. CONLUSION

Developed model of NPC converter for grid connected PV systems showed that NPC converter performs well on high switching frequencies. The NPC converter output

current distortion was almost two times lower than when using standard 2-level VSC converter. It was shown that even with the reduced filter size the current distortion of the NPC is below the 5% THD factor limit.

In order to expand the analysis and comparison with 2-level converters the next step of this simulation model development will be to include switching losses and verify trough simulation results the thesis of reducing the switching losses and raising the conversion efficiency by usage of multilevel converters.

Fast development of a DSP-based control of three-phase four-leg inverter for auxiliary power supply converters using hardware-in-the-loop

Igor Musulin*, Josip Babić* and Željko Jakopović**
* Končar–Electrical Engineering Institute Inc., Zagreb, Croatia
** Faculty of Electrical Engineering and Computing, Zagreb, Croatia
igor.musulin@koncar-institut.hr

Abstract - This paper presents an easy and relatively fast way to design and implement control system of three-phase four-leg inverter in DSP (digital signal processor). The inverter model is emulated using hardware-in-the-loop simulator and control system is coded in TI DSP identical to the target system using graphically based block-diagram programming environment. A multi-loop cascade control is applied and two control strategies are implemented: i) the PI (proportional-integral) controllers with symmetrical sequence current and voltage decomposition and ii) the PIR (proportional-integral-resonant) controllers. Experimental results with symmetrical and single-phase loads are presented. The control algorithms are evaluated based on the execution time. Results show that PIR based control executes roughly three times faster that PI control.

I. INTRODUCTION

When designing new power electronics converter two different models are often used: time discrete model and average model. In time discrete model current and voltage waveforms are mathematically represented for each interval. This model is mainly used for detailed converter analysis. However, mathematical expressions can sometimes become complicated and, since the model is nonlinear, it is not suitable for the development of the control algorithm. For this reason, a linear frequency domain model is used and an averaging is done to get an average model. A control design engineer will usually spend a lot of time and work hours on the development, testing and optimization of a new design and/or algorithm while working with one of the previously mentioned off-line models. Furthermore, extensive experiments and tests on target converter, which can often be time and money consuming, can lead to new problems.

One promising alternative is using a digital real-time simulator that is capable of emulating power electronics hardware. Hardware-in-the-loop (HIL) simulation enables testing of control software and hardware for power electronics by replacing the real electrical system with a real-time emulator. Analog and digital signals are replaced and emulated using a virtual model. This accelerates the development of control algorithms. Some of the advantages of using hardware-in-the-loop simulators include safe testing environment, ability to test the full operating range, including failures test, repeatable testing, flexible reconfiguration and automated testing [1]. Hardware-in-the-loop simulators are already used in industries like automotive, aerospace, power systems, power quality (FACTS) and energy transfer (HVDC), but have not yet been extensively used for the development of the power electronic systems. This is mainly due to the inability to accurately simulate fast voltage-source converters with high-frequency PWM controls and large number of switches [2]. However, with the rapid development of fast field-programmable gate array (FPGA) chips, a wide range of commercially available HIL devices with low latency are available.

This paper is organized as follows. Chapter II introduces the problem of non-symmetrical loads in auxiliary power supply converters in railway vehicles. Three inverter topologies are presented, two of which are today considered as standard solutions in auxiliary power supply converters in railway vehicles. The last one, a three-phase four-leg inverter, with its modulation technique and control strategy is described in more details in Chapter III and Chapter IV. DSP and HIL implementation are described in Chapter IV. Simulation and experimental results, including the measurement of execution time, (Chapter V) and conclusion (Chapter VI) are given at the end.

II. NON-SYMMETRICAL LOADS IN POWER SYSTEM

A recent survey has shown that today non-linear loads, e.g. rectifiers, frequency converters, arc furnaces, controlled motor drives, etc. are approaching between 75 ÷ 90 % of the loading in electric utility distribution systems [3]. Non-symmetrical loads, e.g. single- or two-phase loads in a three-phase system lead to current and voltage unbalance. A large number of non-linear and non-symmetrical loads generate harmonics, cause increase of neutral currents, overheating of drives and equipment, reduction in the effective torque, etc.

While the problem is not so evident in low voltage electric grid due to somewhat evenly distributed single-phase loads, the influence of non-symmetrical loads is more apparent in isolated systems like uninterruptible power supply, distributed renewable energy sources operating in island mode and auxiliary power supply for ships, airplanes and railway coaches. For example, three-phase output inverter in an auxiliary power supply for trains

must generate three-phase and single-phase output with grounded neutral wire. The three-phase output is used for supplying air-conditioning units and auxiliary inverter, main inverter and transformer fans. Single-phase output supplies evaporators and condenser blower fans, lighting and 230 V general purpose power sockets for passenger use.

Single-phase output can be obtained from a three-phase inverter by:

- an additional single-phase 400/230 V or delta/wye three-phase transformer,
- a split dc-linked capacitors and tying the neutral grounded point to the midpoint of the dc-linked capacitors or
- a four-leg inverter topology and tying the neutral grounded point to the mid-point of the fourth leg.

Solution with a transformer is the most widespread, mainly due to its simplicity and minimal changes in design and control algorithm. Galvanic isolation and elimination of zero currents are considered advantages, while transformer price and weight are sometimes seen as disadvantages, mostly in applications like train or tram converters where the total mass of converter plays a significant role. Second solution, if rearranged actually consists of three single-phase half bridge inverters. This enables the independent control of the each leg, i.e. phase. In case of unbalanced loads, neutral current flows through the dc capacitors. Voltage oscillations across capacitors are directly influenced by neutral current [4]. Therefore, high value capacitors or additional balancing circuits must be used for voltage balancing.

III. THREE-PHASE FOUR-LEG INVERTER TOPOLOGY AND MODULATION

A three-phase four-leg inverter topology show in Fig. 1, although first mentioned in the literature in the early 90is, has not been extensively used in the commercial applications. The neutral wire is connected to the neutral point of the added fourth leg. Among main advantages are higher utilization of dc voltage (more than 15 % compared to conventional three-phase three-leg inverter) and neutral current flows through the fourth leg and not through the dc capacitors, thus minimizing dc input voltage oscillations. Complex modulation scheme and large number of semiconductor devices can be regarded as a disadvantage. Nevertheless, this type of inverter presents an ideal solution for four-wire systems for supplying non-symmetrical and single-phase loads since it offers independent control of currents of each phase.

Two modulation strategies for three-phase four-leg inverters operating at constant switching frequency are often used:

- carrier-based pulse-width modulation (PWM), and
- three dimensional (3D) space vector (SV) PWM

A 3D SVPWM is preferable for digital implementation, but requires faster processors since sector determination and switch ON time calculation can take up a lot of processor calculation time and lead to digital delay. On the other hand, carrier-based PWM algorithm [5–10] is easy to implement since it uses only the comparison of reference waveform with the triangular waveform. This modulation technique is similar to sinusoidal PWM where switching states are determined by comparing triangular carrier and three sinus reference waveforms. The only difference is in the reference waveform generation where additional, so-called, offset voltage is added to sinusoidal waveform. Best voltage synthesis, e.g. utilization of dc bus voltage and low harmonic generation can be achieved by operating in the linear modulation region and selecting offset voltage as shown in (1).

$$V_{n0}{}^{*} = \begin{cases} -\dfrac{V_{max}}{2}, & V_{min} > 0 \\ -\dfrac{V_{min}}{2}, & V_{max} < 0 \\ -\dfrac{V_{max} + V_{min}}{2}, & \text{otherwise} \end{cases} \quad (1)$$

where V_{min} = min (V_{an}, V_{bn}, V_{cn}) and V_{max} = max (V_{an}, V_{bn}, V_{cn}).

IV. DESIGN OF CONTROL SYSTEM

A multi-loop cascade control strategy is adopted in this paper. An outer voltage control loop is used for voltage reference tracking. Its output acts as a reference for the current control loop. Current control loop is used for protection of the inverter against overload and for the improvement of the control system response. Three-phase four-leg inverter control is based on dq0 coordinate transformation. However, with unbalanced load d and q channel voltage and current oscillate with frequency 2ω, while 0 channel voltage and current oscillates with ω. Therefore the control bandwidth should be high enough to attenuate disturbance caused by the unbalanced load. On the other

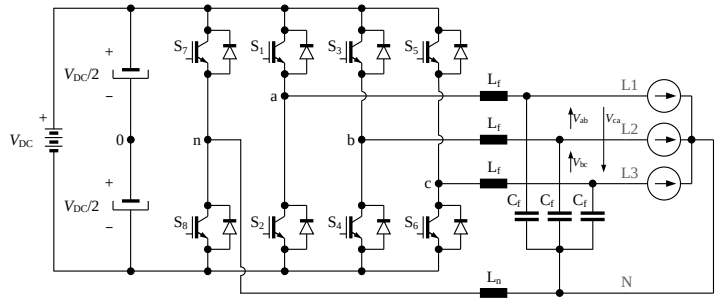

Figure 1. Three-phase four-leg inverter topology

hand, high bandwidth can affect system stability. Furthermore, since control values are oscillating classical PI controller cannot achieve zero steady-state error.

As a solution a transformation of current and voltage waveforms to the symmetrical components, i.e. sequence decomposition is proposed in [11–14]. From there, using abc/dq coordinate transformation and standard PI controllers, one can easily control positive, negative and zero component of a (now) symmetrical system. Instantaneous positive, negative and zero sequence are calculated using (2). Time domain implementation of an operator a ($= -1/2 + j\ \sqrt{3}/2$) is shown in Fig. 2. It can be seen that a 90 ° phase-shift associated with j is needed. This is done using simple second-order low-pass filter tuned at the input frequency ω_{in} with a damping factor $\xi = 1$ as shown in (3) and further explained in [15]. Time domain implementation of a second-order low-pass filter (*LPF*) is shown in Fig. 3. The operator a^2 can be implemented in a similar manner. Subsequently, sequence composition (4) and dq/abc transformation are used to get V_a, V_b and V_c for PWM modulation, Fig 4

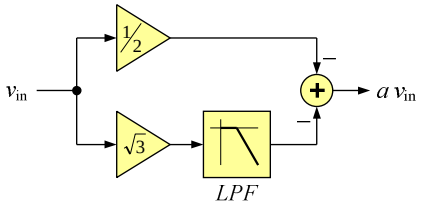

Figure 2. Implementation of operator a in time domain

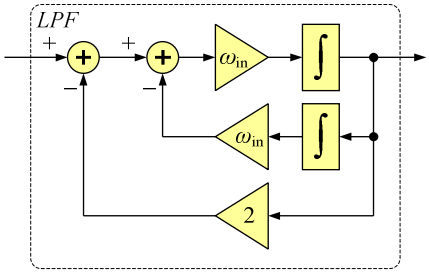

Figure 3. Implementation of *LPF* in time domain

$$v_{\text{abc positive}} = \begin{pmatrix} 1 & a & a^2 \\ a^2 & 1 & a \\ a & a^2 & 1 \end{pmatrix} \begin{pmatrix} v_a & v_b & v_c \end{pmatrix}^T$$

$$v_{\text{abc negative}} = \begin{pmatrix} 1 & a^2 & a \\ a & 1 & a^2 \\ a^2 & a & 1 \end{pmatrix} \begin{pmatrix} v_a & v_b & v_c \end{pmatrix}^T \quad (2)$$

$$v_{\text{abc zero}} = \begin{pmatrix} 1 & 1 & 1 \\ a & a & a \\ a^2 & a^2 & a^2 \end{pmatrix} \begin{pmatrix} v_a & v_b & v_c \end{pmatrix}^T$$

$$LPF = \frac{\omega_{in}^2}{(s+\omega_{in})^2} \quad (3)$$

$$v_{abc} = \begin{pmatrix} 1 & 1 & 1 \\ a & a & a \\ a^2 & a^2 & a^2 \end{pmatrix} \begin{pmatrix} v_{a\,positive} & v_{a\,negative} & v_{a\,zero} \end{pmatrix}^T \quad (4)$$

Another solution is using PR (Proportional-Resonant) or PIR (Proportional-Integral-Resonant) controllers for control [9], [13], [16–19]. PIR controller is represented by (5). Resonant based controllers have an infinitive gain at resonant frequency ω_0, the controller can successfully eliminate steady-state error when control values are oscil-

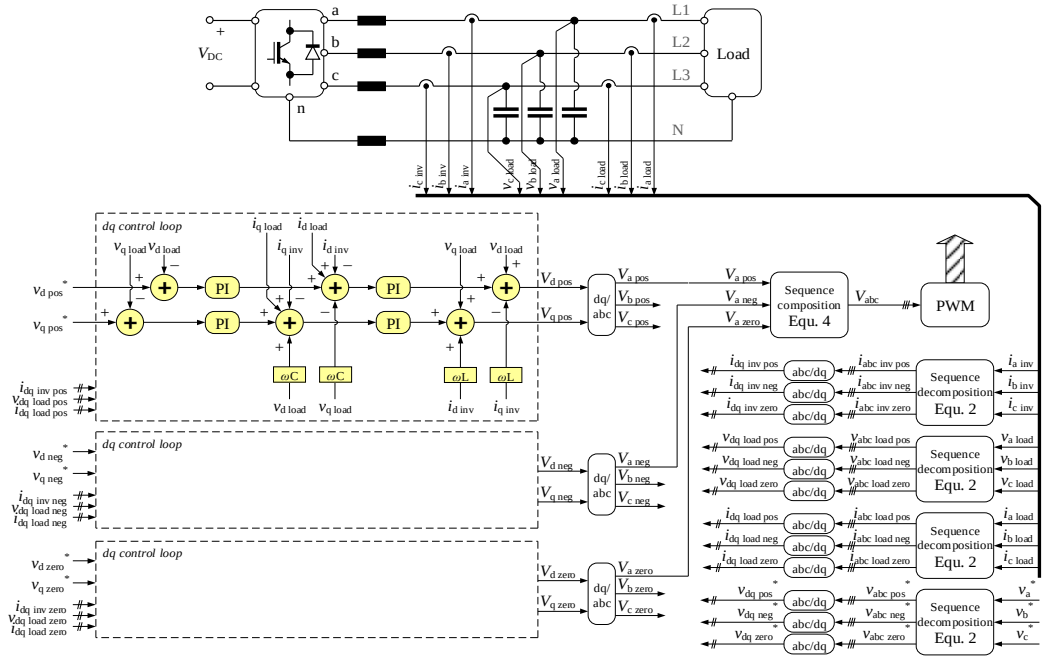

Figure 4. Three-phase four-leg inverter topology

lating with ω_0. Another advantage of using resonant based controllers is the simple control strategy, no additional coordinate transformations and fastest time of execution. The last point will be further explored in Chapter VI. It is important to note that abc/dq0 coordinate transformation must be used here.

$$G_c(s) = K_P + K_I \frac{1}{s} + K_R \frac{s}{s^2 + \omega_0^2} \quad (5)$$

where $\omega_0 = 2\omega$ for d and q frame and $\omega_0 = \omega$ for 0 frame.

V. DSP AND HARDWARE-IN-THE-LOOP IMPLEMENTATION

The control algorithm is coded using GRAP, graphical block-diagram based programming environment [20], so there is no need for textual coding and the programming is done relatively fast. Previously developed control algorithm in Matlab/Simulink environment is easily transferred using corresponding optimized block elements.

The code itself is implemented in Texas Instruments TMS320F28335 controlCARD with operating core frequency of 150 MHz. Three different control tasks are used, namely CT1, CT2 and CT3. The fastest control task is set to 20 kHz and it is used for acquisition, A/D conversion and PWM waveform generation. The second task (at 5 kHz) is used for sequence (de) composition, control sequence, and communication while the slowest task (at 500 Hz) is used for monitoring and diagnostics.

Using the HIL simulator one can easily implement any desired topology, as it was done with the three-phase four-leg inverter topology. A total of four voltage measurements (input dc voltage and three output ac phase voltages) and six current measurements (three inverter line currents and three load line currents) are used for control. Additional current and voltage measurements can also be used. HIL simulation time step is set to 1 μs. Experimental setup is shown in Fig. 5.

VI. HARDWARE-IN-THE-LOOP SIMULATION AND EXPERIMENTAL RESULTS

Two control strategies from Chapter IV are used: PI control with coordinate transformation and PIR control. An input dc voltage is set to 700 V while output reference ac phase voltage is set to 230 V. The inverter switching frequency is 3 kHz. Maximum three-phase output power P_{max} is set to 24 kW with cos φ = 1 while minimum power is set to P_{min} 500 W with cos φ = 1 and corresponds to the power of the main and auxiliary converter fans.

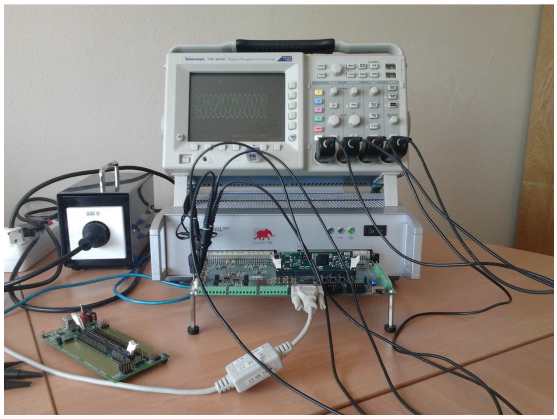

Figure 5. HIL experimental setup with controller and interface board

In Fig. 6 and 8 an output voltage and current response in the case of switching a 12 kW ideal resistive single-phase load into already symmetrically loaded three-phase output ($P_{three\text{-}phase} = P_{max}$) is shown. Dashed vertical line represents the start of transition. Both algorithms exhibit the similar performance regarding the settling time. For the first controls strategy, before switching a single-phase loads negative and zero sequence are equal to zero or approximately zero due to non-ideal acquisition and noise in measured channels. In the second algorithm, resonant part is equal to zero and PIR controller behaves as PI. Zero (0) part of abc/dq0 transformation is also equal or approximately zero.

Output voltage and current response for a switching of a 24 kW ideal resistive single-phase load from a minimum load ($P_{three\text{-}phase} = P_{min}$) is shown for two control strategies in Fig. 7 and Fig 9. It can be seen that both algorithms

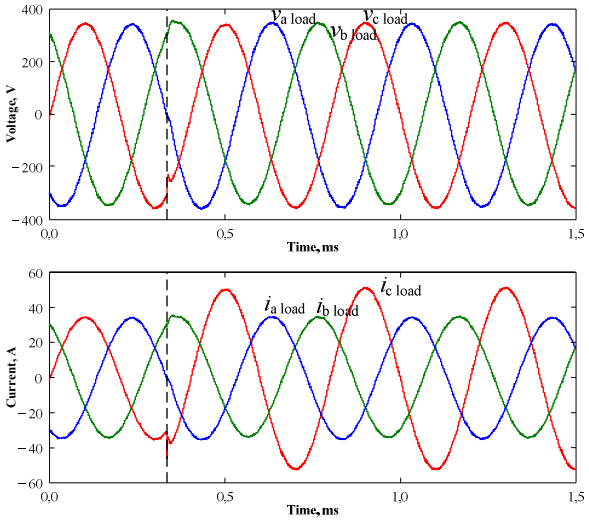

Figure 6. PI control; $P_{three\text{-}phase} = P_{max}$

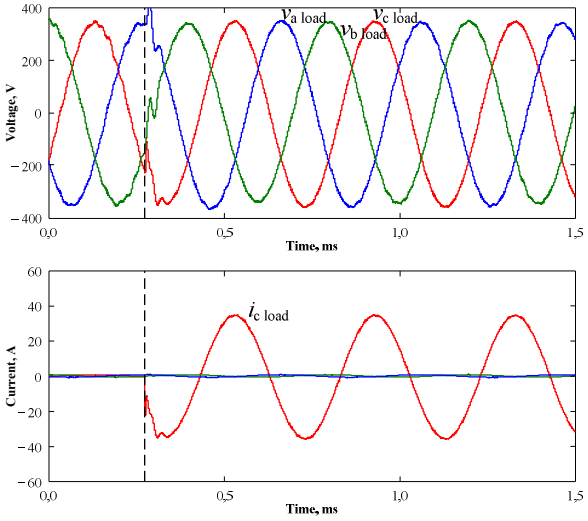

Figure 7. PI control; $P_{three\text{-}phase} = P_{min}$

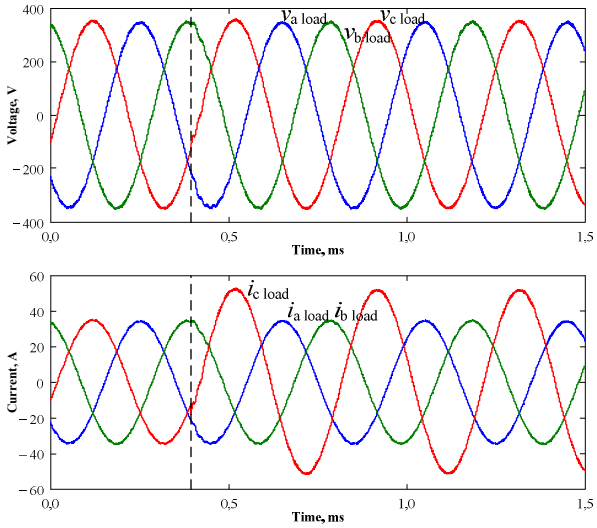

Figure 8. PIR control; $P_{three\text{-}phase} = P_{max}$

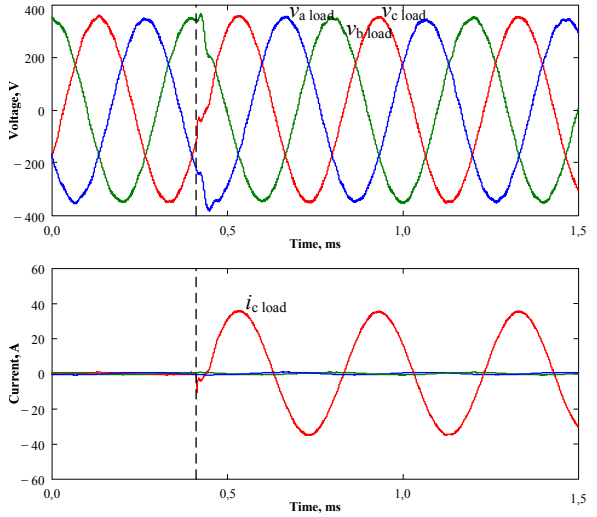

Figure 9. PIR control; $P_{three\text{-}phase} = P_{min}$

behave similar response and produce symmetrical output voltage in case of unsymmetrical loads. The response time depends on the controller parameters. While there is certainly a room for the further improvement, three-phase output response in an auxiliary power supply for trams and trains generally does not need to be a fast one. Loads are quite robust and the settling time of up to two periods is acceptable.

The identical waveforms can be seen on the HIL analog outputs, Fig. 10 and Fig 11. HIL input/output is ± 5 V so appropriate scaling must be done. In this case, voltage and current scaling factor is set to 100 V = = 1 V and 100 A = = 1 V, respectively.

Many papers dealing with the control of a three-phase four-leg inverter using coordinate transformation refer to complex control structure as an obvious disadvantage over PR or PIR based control. In this paper, apart from testing different control strategies, the execution time is measured for each one. Five distinctive parts of control algorithm are selected: sequence decomposition, sequence composition, coordinate transformation (abc/dq(0)and dq(0)/abc) and control. Other parts of the application program like system definition, A/D conversion, scaling, PWM and recorder are the same for each algorithm and are not measured. Execution times are given in Table I.

PI based control strategy (Fig. 5) has four sequence decomposition calculations (12,72 μs × 4 = 50,88 μs) and one sequence composition calculation. In Table I it can be seen that the sequence (de) composition takes roughly 65 % of total execution time. There are also twelve abc/dq and three dq/abc coordinate transformations per one task. Although single abc/dq transformation last only 0,78 μs compared to 1,21 μs for abc/dq0, a total coordinate transformation time is two times larger due to number of calculations. Also, control is executed three times per task, once for each system, i.e. positive, negative and zero. It is interesting to note that the control itself is executed faster (18,36 μs compared to 19,37 μs). This leads to conclusion that digital implementation of resonant part of PIR controller used in this example takes a lot of computing time. For PIR control strategy there is no sequence (de) composition and coordinate transformation is executed just five times (4 × abc/dq0 + 1 × dq0/abc) per task. The control is done only once per task, but there are three frames to control (d, q and 0), opposite to previous case where there are only two (d and q frame).

Comparing the total execution time for PI and PIR based control strategies, from Table I it can be seen that PIR executes roughly 60 % faster than PI. Since it exe-

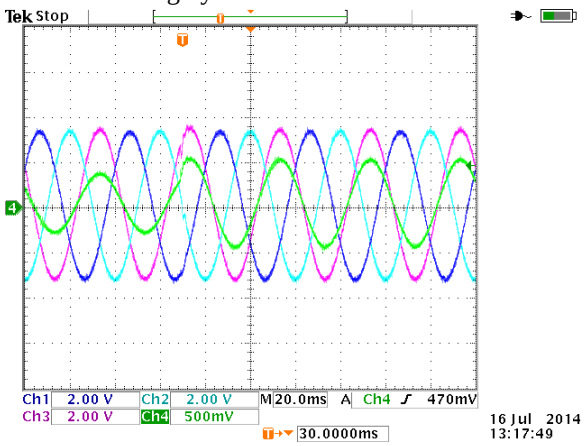

Figure 11. Voltage and current (Ch4: $i_{c\ load}$) waveforms corresponding to test case in Fig. 8; 1 V = = 100 V (A)

TABLE I. EXECUTION TIME

No.	Process	PI control	PIR control
1	Sequence decomposition	50,88 μs	–
2	Coordinate transformation	9,36 μs	4,84 μs
3	Control	18,36 μs	19,37 μs
4	Coordinate transformation	2,88 μs	1,35 μs
5	Sequence composition	7,41 μs	–
	Total (1+2+3+4+5)	88,89 μs	25,56 μs

cutes faster, meaning less code is needed for the same result, overall processor load is lower. This is desirable because usually single processor is used for other functions apart from inverter control including monitoring, communication, sequencing, error detection, etc. Further optimization regarding the stability of an inverter can be achieved be setting the control task CT2 in PIR control strategy to a higher sampling rate. But this depends on the processor load. On the other hand, optimization regarding the PI control strategy can be done by transferring sequence (de) composition calculations to dedicated chips, e.g. FPGA or implementing own digital integrators, e.g. First-Order IIR Digital Integrator based on backward rectangle method with lower computation time than the built-in elements.

VII. CONCLUSION

In this paper a new way of developing control algorithm using hardware-in-the-loop has been investigated. Two different control strategies have been implemented and tested. Special emphasis is given to measuring the execution time. PIR controller has the advantage compared to PI controller mainly due to lack of sequence (de) composition calculation and less coordinate transformation calculations.

Using this way of design, the process of prototyping and testing of complex control systems is simplified. Control is coded on the same TI controlCARD used in the target converter. This enables user to easy implement desired control strategy, test various control algorithms, compare overall exection time and load and, if necessary, further optimize algorithm, all before actually beginning to work on a target model.

Abstract – In this paper noise analysis of three different filter designs is performed. Voltage noise spectral density and RMS noise voltage in simply designed active RC, noise optimized active RC and switched capacitor (SC) filter design are calculated for fifth order Chebyshev low pass filter, with a cut-off frequency f_c=3.4kHz, and pass-band ripple α_{max}=-0.5dB. All three designs are realized as a cascade of two second order sections and one first order section. All filter analysis has been performed using MATLAB and SPICE program tools. Through the analysis it is shown that SC based filter has significantly lower noise when compared with active RC based filter.

I. INTRODUCTION

There are several quality assessment parameters of the electrical circuits and systems, and noise is one of them. Demand on noise as lower as possible is also a demand on higher dynamic range. Noise is very important factor for small signal processing in order to extract proper information from the signal. There are several noise origins which produce several types of noise, but in this paper only thermal noise has been considered [1]. One approach utilizes OTA-C filter structure in order to obtain a low noise design, however, main disadvantage of this realization is low dynamic range [2]. Another possible design uses active RC filter sections where noise optimization can be done to obtain low noise [3]. The third design uses switched capacitor (SC) filter structure, [4]. It is shown that this approach will reduce noise level more than other realizations. In this paper, noise properties are analyzed on simply designed active RC filter, noise optimized active RC filter and corresponding SC filter.

SC based circuits replace a resistor with a capacitor and two electric switches (usually MOS transistors) driven by the two phase non-overlapping clock [4, 5]. The time constant τ of such circuit is:

$$\tau = RC = \frac{C}{C_R}\frac{1}{f_{CL}}, \tag{1}$$

where f_{CL} is the clock frequency. Even though SC circuits have increased number of components, the overall size of the circuit is reduced since small valued capacitors can be used for acquiring desired C/C_R ratio, thus allowing the integration of the circuit into a single monolithic integrated circuit. Furthermore, the C/C_R ratio can be realized with great accuracy, even up to 0.1%, while RC error can range from 20% up to 50%. In addition, since τ is dependent of f_{CL} (1), the cut-off frequency of SC based filters can be regulated simply by varying the clock frequency.

In this paper, fifth order Chebyshev low pass filter with a cut-off frequency f_c=3.4kHz and a pass-band ripple α_{max}=-0.5dB is realized. All previously mentioned designs are realized as a cascade of two second order sections and one first order section. Sequence of the sections is such that their Q-factors are in descending order (first one being the greatest, and last one the smallest), and sections are based on the Sallen-Key topology. Through the paper significant improvement of the SC filter over the active RC filter in terms of noise reduction is shown.

II. CONTINUOUS ACTIVE RC FILTER

The continuous time transfer function of the active RC low pass Chebyshev fifth order filter with previously noted parameters is given by:

$$H(s) = H_1(s)\cdot H_2(s)\cdot H_3(s), \tag{2a}$$

$$H_1(s) = \frac{4.727\cdot 10^8}{s^2 + 4784s + 4.727\cdot 10^8}, \tag{2b}$$

$$H_2(s) = \frac{2.176\cdot 10^8}{s^2 + 1.252\cdot 10^4 s + 2.176\cdot 10^8}, \tag{2c}$$

$$H_3(s) = \frac{7740}{s + 7740}. \tag{2d}$$

The Sallen-Key topology of low pass filter is given in Fig. 1. The filter is realized as a cascade of two second order sections and one first order section. The transfer function of the given circuit is:

$$H(s) = \prod_{i=1,2} H_i(s)\cdot H_3(s), \tag{3a}$$

$$H_i(s) = \frac{\left(1+\frac{G_{3i}}{G_{4i}}\right)\frac{G_{1i}G_{2i}}{C_{1i}C_{2i}}}{s^2 + s\left(\frac{G_{1i}+G_{2i}}{C_{1i}} + \frac{G_{2i}G_{3i}}{C_{2i}G_{4i}}\right) + \frac{G_{1i}G_{2i}}{C_{1i}C_{2i}}}, \tag{3b}$$

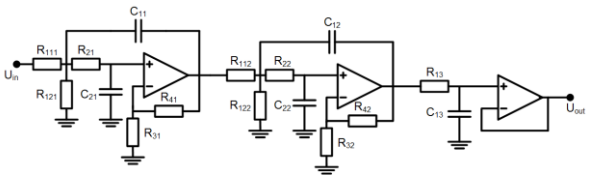

Figure 1. The Fifth order low pass active RC filter.

$$H_3(s) = \frac{\frac{1}{R_{13}C_{13}}}{s + \frac{1}{R_{13}C_{13}}}. \qquad (3c)$$

Element values have been calculated by comparing equations (2a) – (2d) with (3a) - (3d) with $C_{1i} = C_{2i}$ and $R_{1i}=R_{2i}$, and are given in Table 1.

Frequency responses of the filter are shown in Fig. 2. Calculated values are obtained from the filter transfer function (2a) - (2d), while simulated values are obtained by simulating the circuit shown in Fig. 1 with element values from Table 1. The difference between the characteristics is minimal, as can be seen in zoomed inset of Fig. 2.

The equivalent circuit of the active RC filter for the calculation of the voltage noise spectral density is shown in Fig. 3. Current noise sources: $I_{nji} = \sqrt{4kT}/R_{ji}$ were added parallel to the resistors, while voltage noise sources (E_n = 15 nV/√Hz for LT1055) were added at input of the operational amplifiers. The operational amplifier input noise currents were neglected since their values are significantly smaller (E_n = 1.8 fA/√Hz for LT1055). The total voltage noise spectral density is calculated as [5]:

$$V_n^2(\omega) = \sum^{m} |T_{I,k}(j\omega)|^2 \, (I_{n,k})^2 + \sum^{n} |T_{U,l}(j\omega)|^2 \, (E_{n,l})^2 \,, \qquad (4)$$

where $T_{I,k}$ and $T_{U,l}$ are the transfer functions of the current noise sources $I_{n,k}$ and the voltage noise sources $E_{n,l}$, respectively. Table 2 shows section specific transfer function of each noise source, and in order to get a complete transfer function, the section specific transfer function must be multiplied with transfer functions of all following sections. Figure 4(a) shows the total voltage noise spectral density. Voltage noise spectral density functions of all noise components based on their origin are also presented in Fig. 4(b, c, d). The small difference between calculated and simulated values can be explained with differences in noise source models. Real element noise models used in SPICE are slightly different than here used theoretical values made only from thermal noise sources. The noise RMS can be calculated as:

$$(E_n^2)_{ef} = \int_{\omega_1}^{\omega_2} V_n^2(\omega) d\omega \,. \qquad (5)$$

In order to decrease noise, optimization algorithm described in [3] has been applied, and operational amplifier LT1055 has been replaced with low noise

III. DISCRETE TIME SC FILTER

The discrete time transfer function is obtained by applying forward Euler transformation ($s \Rightarrow (z-1)/T_S$, where T_S is the sampling time) to the continuous time transfer function, defined by (2a) - (2d), with sampling frequency f_s = 900 f_c:

$$H(z) = H_1(z) \cdot H_2(z) \cdot H_3(z), \quad (6a)$$

$$H_1(z) = \frac{5.048 \cdot 10^{-5}}{z^2 - 1.998z + 0.999}, \quad (6b)$$

$$H_2(z) = \frac{2.324 \cdot 10^{-5}}{z^2 - 1.996z + 0.996}, \quad (6c)$$

$$H_3(z) = \frac{0.003}{z - 0.998}. \quad (6d)$$

Figure 6 shows the electric circuit of the discrete time SC filter based on Sallen-Key topology [5]. The transfer function of the given circuit is:

$$H(z) = \prod_{i=1,2} \frac{n_{1i}}{d_{1i}z^2 + d_{2i}z + d_{3i}} \cdot \frac{C_{R13}}{(C_{R13} + C_{13})z - C_{13}}, \quad (7a)$$

$$n_{1i} = C_{R1i}C_{R2i}(C_{1i} + C_{gi}), \quad (7b)$$

$$d_{1i} = (C_{1i} + C_{gi} + C_{R1i})(C_{1i} + C_{gi} + C_{R2i})(C_{2i} + C_{R2i}), \quad (7c)$$

$$d_{2i} = (C_{1i} + C_{gi})[C_{2i}(2C_{1i} + 2C_{gi} + C_{R1i}) + C_{R2i}(C_{gi} + 2C_{1i} + C_{R2i} + C_{2i})] + C_{R1i}C_{R2i}(C_{R2i} + C_{2i}), \quad (7d)$$

$$d_{3i} = n_{1i} - d_{1i} + d_{2i} = (C_{1i} + C_{gi})(C_{1i}C_{2i} + C_{1i}C_{R2i} + C_{2i}C_{gi}). \quad (7e)$$

By comparing (6a) - (6d) with (7a) - (7e) the element values of the circuit have been calculated and are shown in Table 4.

Transfer function of the filter is shown in Fig. 7. The values were calculated from a discrete time transfer function of the SC filter (6a) - (6d). The Z-transformation hasn't affected desired continues time designed filter specifications, as can be observed by comparing them with Fig. 2.

Noise RMS value is $(E_n)_{ef}$ = 0.123 µV (f_1 = 0.1 f_c, f_2 = 10 f_c).

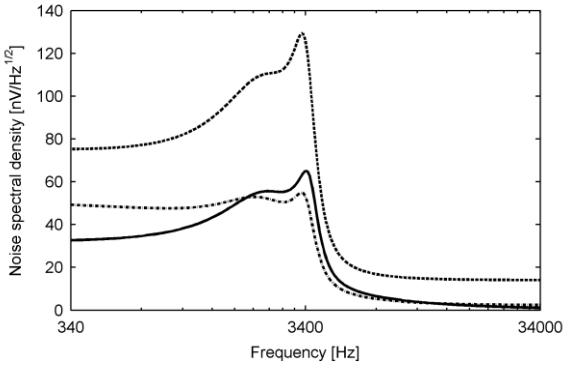

Figure 9. Simulated voltage noise spectral density of: active RC filter (dashed), optimized active RC filter (dot-dashed), and SC filter (full).

IV. CONCLUSION

In this paper noise analysis of three different filter designs are done. It is shown that discrete time SC based filter have better noise figure over the continuous time active RC based filter. Noise reduction measured with RMS noise voltage is more than twice in comparison with noise optimized active RC design and more than five times in comparison with simply designed active RC filter design.

Further improvement of the presented filter design can be implemented using more complex filter structure with feedbacks instead of used cascade filter structure.

Abstract - GMR (Giant MagnetoResistance) sensors, which are used in conjunction with magnetic encoders (magnetic pole wheels), have a huge number of applications in automotive and machine industry, where they are used to compute the rotational speed of rotating parts like wheels and shafts. In this paper, we present an analytical model of magnetic pole wheel signal as it is sensed by a GMR sensor. Experimental measurements are performed to check the validity of the mathematical model. Furthermore, we present a novel digital signal processing technique, which incorporates the Hilbert transformer to phase demodulate this GMR signals to compute high resolution instantaneous position and speed information. A frequency domain analysis is then deployed to analyze the signal for any low frequency vibrations present in the rotating part.

I. Introduction

MAGNETIC encoders used with magnetic speed sensors have wide applications in industry where rotational speed or position is needed to be known. The conventional method to compute the speed signal from any magnetic sensor, whether it is a GMR (Giant MagnetoResistance) or Hall sensor, involves an analog comparator which generates a square pulse, whose frequency is proportional to the speed of rotation. This method has an inherent discrepancy that very low resolution speed and position information is available. This limitation is a bottleneck in computing high resolution speed and position information precisely. The maximum samples per revolution is limited to $2N$, where N is the total number of pole pairs in the encoder. Fig. 1 illustrates the speed signal generated by a GMR sensor and the corresponding square pulse. The dotted line shows an ideal sinusoid which represents the ideal magnetic field signal while the solid line depicts the actual signal out of the GMR sensor. Conventional speed signal computation methods do not take into account the fact that the pole wheel suffers from manufacturing intolerances. All pole pairs are expected to be of equal length in $radians$. In reality, each pole pair has a different pole length and the pole periods vary from pole to pole in a single pole wheel, and are given by

$$\Delta\theta_i = 2\pi\left(\frac{\Delta t_i}{\sum_{i=0}^{N-1}\Delta t_i}\right) - \frac{2\pi}{N} \qquad (1)$$

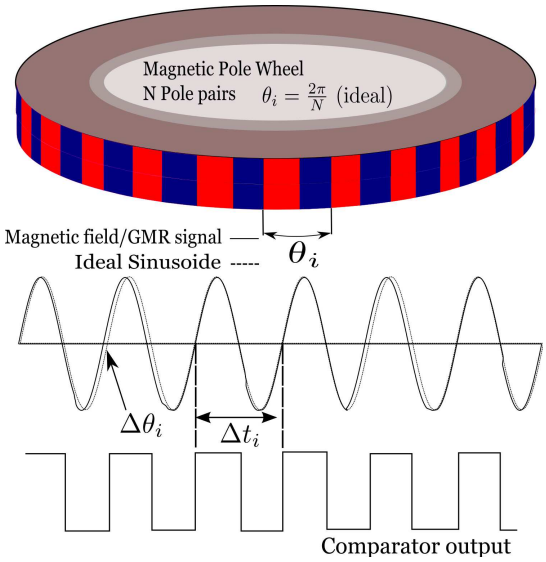

Fig. 1: Speed signal generated by GMR sensor and the resultant square pulse

where N is the total number of pole pairs.

The magnetic field signal of a magnetic encoder can be modeled as a phase modulated sinusoid, as illustrated in Fig. 1, where the phase signal is the pattern of the pole wheel. This is indicated after a discrete interval as $\Delta\theta_i$. Modern digital signal processing techniques can be applied to the analog magnetic field signal to extract the instantaneous values of the phase angle. The time derivative of the instantaneous phase then gives the instantaneous angular speed.

In the following, we present a mathematical treatment of the magnetic pole wheel signal as a phase modulated sinusoid, followed by a demodulation algorithm description using a Hilbert transformer in the frequency domain. Later, we present an experimental setup for measurements, we elaborate a frequency domain analysis of the results, which is followed by concluding remarks.

II. Magnetic pole wheel signal as phase modulated sinusoid

Due to the manufacturing intolerances, the magnetic field, strength from two poles differs and the width of two poles is not equal. This gives rise to sinusoid with slight offsets in phase from each other. The signal from the magnetic pole wheel can be modeled as a sinusoid, which is phase modulated by a pattern generated by the pole wheel intolerances. A general phase modulated signal can be written as [1],

$$x(t) = A_c \cos\left(\omega_c t + \theta_m(t)\right) \tag{2}$$

where $\theta_m(t)$ is a function of the pole wheel pattern, dependent on the geometry of the pole wheel. For all real scenarios $\theta_m(t)$, which is the variation in the phase angle from the absolute value, is very small. It has been observed for a pole wheel of 32 pole pairs to be in the order of 10^{-3} radians [2]. $\theta_m(t)$ is also inversely proportional to the number of pole pairs in a pole wheel. Expanding Eq. 2 and utilizing small signal approximation for $\theta_m(t)$ we get

$$x(t) = A_c \cos\left(\omega_c t\right) - A_c \theta_m(t) \sin\left(\omega_c t\right) \tag{3}$$

where we have assumed the approximations $\cos\left(\theta_m(t)\right) = 1$ and $\sin\left(\theta_m(t)\right) = \theta_m(t)$.

As mentioned earlier, $\theta_m(t)$ is dependent on the pole wheel geometry, which repeats itself each revolution. This can be modeled as a series of functions with periods ranging from T_o to $\frac{T_o}{N}$, where N is the total number of pole pairs and T_o is the period of one complete revolution of the pole wheel. Hence $\frac{T_o}{N}$ is the period of one pole pair, which corresponds to the highest frequency harmonic.

Let Ω_o be the rotational frequency of the pole wheel and ω_o be the rotational frequency of one pole pair then

$$\omega_o = \Omega_o N \tag{4}$$

which is the frequency of the basic pattern repeating itself in each pole pair. In this case, this is also the carrier frequency mentioned above as ω_c. Next is the pattern that is a combination of two pole pairs and it shall repeat at a frequency $\Omega_o(N-1)$. Similarly another pattern which is a combination of three pole pairs shall have frequency $\Omega_o(N-2)$and so on. We can generalize this as

$$\omega_p = \Omega_o(N-p) \qquad p = 0, 1, 2....N-1 \tag{5}$$

This indicates that the lowest frequency is of the pattern, which repeats once each revolution and is the pattern of the whole pole wheel.

To summarize above discussion, we can conclude that $\theta_m(t)$ consists of a linear combinations of functions of pole patterns with fundamental frequencies given by Eq. 5. So $\theta_m(t)$ can be generalized as

$$\theta_m(t) = \sum_{p=0}^{N-1} f_p(t, \psi) \tag{6}$$

where ψ is a space variable added for completeness. Plugging this value of $\theta_m(t)$ into Eq. 3, we get

$$x(t) = A_c \cos\left(\omega_c t\right) - A_c\left(\sum_{p=0}^{N-1} f_p(t, \psi)\right) \sin\left(\omega_c t\right) \tag{7}$$

Since $f_p(t, \psi)$ is periodic with fundamental frequency ω_p, multiplication by a $\sin(\omega_c t)$ will shift this frequency to the carrier frequency which is given by $\Omega_o N$. So the spectrum of the pole wheel signal will have harmonics at $\omega_c \pm \Omega_o(N-p)$ where $p = 0, 1, 2...N$. This pattern of harmonics will repeat itself in the Fourier transform of the signal where all frequencies will be centered around the carrier frequency.

III. Demodulation using Hilbert Transform

Since the magnetic pole wheel signal has been modeled as a phase modulated sinusoid, it can be demodulated by using the Hilbert transform. The Hilbert transform of a signal $x(t)$ is denoted by $x_h(t)$ and is given by [3]

$$x_h(t) = \frac{1}{\pi} \int_{-\infty}^{\infty} \frac{x(\alpha)}{t-\alpha} d\alpha \tag{8}$$

and in frequency domain

$$X_h(w) = -j\mathrm{X}(w)\mathrm{sgn}(w) \tag{9}$$

where $\mathrm{X}(w)$ is the frequency spectrum of $x(t)$. Hence a Hilbert transformer has a transfer function given by $-j\mathrm{sgn}(w)$. In essence, it shifts each spectral component of an input signal by $\frac{\pi}{2}$ while keeping the amplitude constant.

Once $x_h(t)$ is known, we can combine it with $x(t)$ to get an analytical signal $\hat{x}(t)$.

$$\hat{x}(t) = x(t) + j x_h(t) \tag{10}$$

The instantaneous phase of this analytical signal shall give us the value of $\phi_m(t)$, which is given by

$$\phi_m(t) = \arctan\left[\frac{x_h(t)}{x(t)}\right] \tag{11}$$

where $\phi_m(t) = \omega_c t + \theta_m(t)$ is the instantaneous phase of the analytical signal.

Hilbert transformer can be implemented either in time domain [4], [5] or in frequency domain [6], [7]. Time domain transformation is ideally a filter whose output is the Hilbert transform of the input signal. This method has inherent drawback that it suffers from bandwidth limitations. The Frequency domain approach is more elegant and utilizes the FFT (Fast Fourier Transform) to produce the analytical signal irrespective of the bandwidth. The Pole wheels' rotational frequency may vary from a couple of rotations per second to tens of rotations per second. The resultant signal bandwidth can be well over a KHz.

A. Implementation strategy

Fig. 2 shows the implementation algorithm for the demodulation of the magnetic pole wheel signal. The Hilbert transform of a sequence of length L is computed by the frequency domain technique where we take the Fourier transform of the input signal, set $-\pi < \omega < 0 = 0$ and take the inverse Fourier transform. For practical purpose, the DFT (Discrete Fourier Transform) of a long sequence is not implementable. This can be circumvented by a sliding window FFT. Each iteration of the loop computes the FFT, then sets $-\pi < \omega < 0 = 0$ and takes the inverse FFT. In the next iteration, the window is

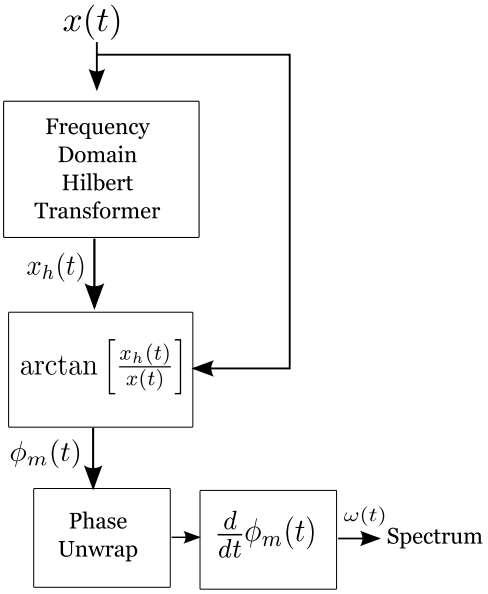

Fig. 2: Block diagram of demodulation algorithm

moved ahead half of its length and the same computation sequence is repeated. For optimal processing L must be power of 2 and must contain at least two periods of the input sinusoid. In essence, we compute the Hilbert transform of a certain length L of the input sequence, shift the window by $L/2$ and continue. After computing the phase angle in each iteration, the sequence from $L/4+1$ to $3L/4$ is retained and edges are discarded. Then this signal is concatenated with the output from the next iteration in the same way (after discarding its edges as well) to get continuous phase values. This prevents the effects of circular convolution from appearing in the phase signal. The technique is illustrated in Fig. 3.

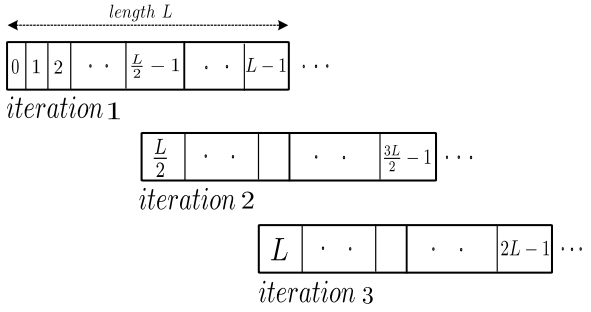

Fig. 3: Sliding window Hilbert transform computation

The Instantaneous phase of the analytical signal is computed using the arctan function. The CORIDC algorithm can be used to perform this task [8] . The computed phase is unwrapped and its time derivative gives the instantaneous rotational speed.

IV. Measurement setup and experimental results

Measurement data for analysis has been obtained from an experimental setup where a pole wheel was mounted on a shaft. A GMR (Giant MagnetoResistance) sensor has been placed at an optimal distance from the pole wheel so as to get a maximum undistorted magnetic field signal. The Magnetic field signal from the GMR has been amplified and then digitized at 100 kHz with a 16 bit ADC (Analog to Digital Converter). The pole wheel was rotated at 14 rev/sec.

Fig. 4 shows the instantaneous phase angle value computed with the above mentioned algorithm. Phase continuity has been ensured by use of the sliding window technique while computing Hilbert transform in frequency domain. Fig. 5

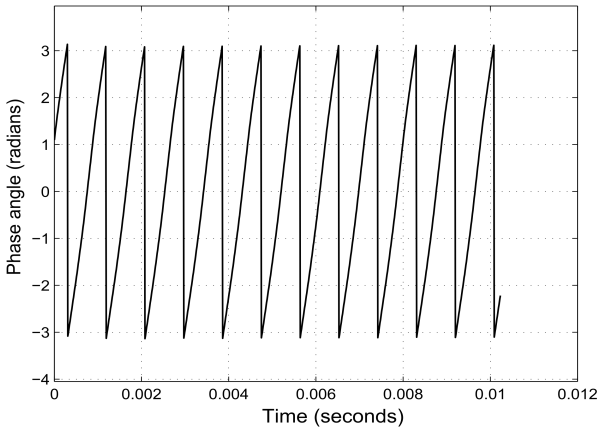

Fig. 4: Instaneous phase computed with Hilbert transform

shows the PSD (Power Spectral Density) of the modulated GMR signal. Fig. 6 shows the power spectral density estimate of the demodulated GMR signal $\frac{d}{dt}(\phi_m(t)$. It shows the lowest pattern frequency at about 14 Hz, which belongs to $p = N - 1$ in Eq. (5) . Below 10 Hz are the vibrations which have been modulated by the carrier frequency and now are visible in the low frequency band after demodulation.

A. Pattern calculation and removal

Pattern calculation and removal is a key aspect to clean the spectrum from regular harmonics and to isolate the vibrations

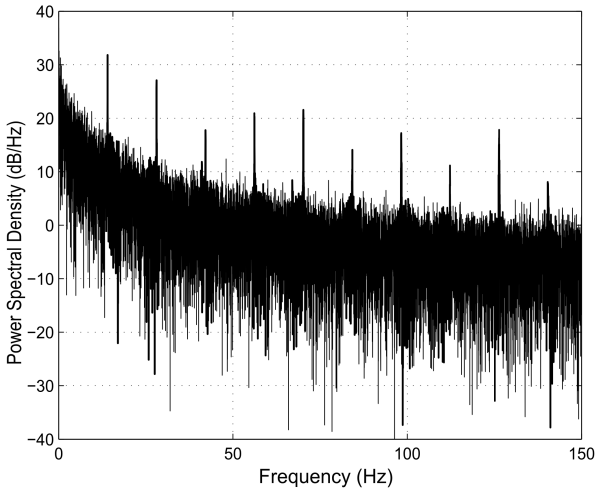

Fig. 5: Spectrum of modulated GMR signal

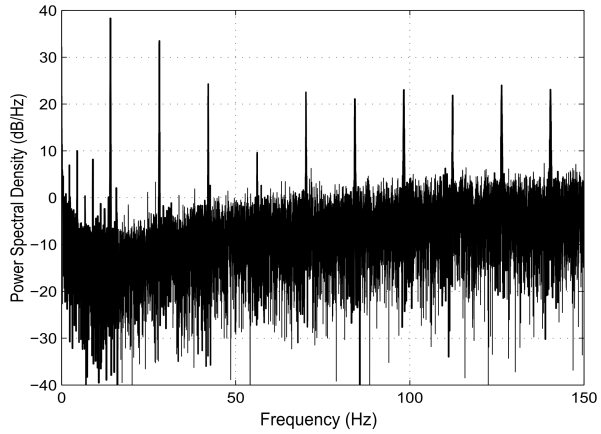

Fig. 6: Demodulated GMR speed signal spectrum

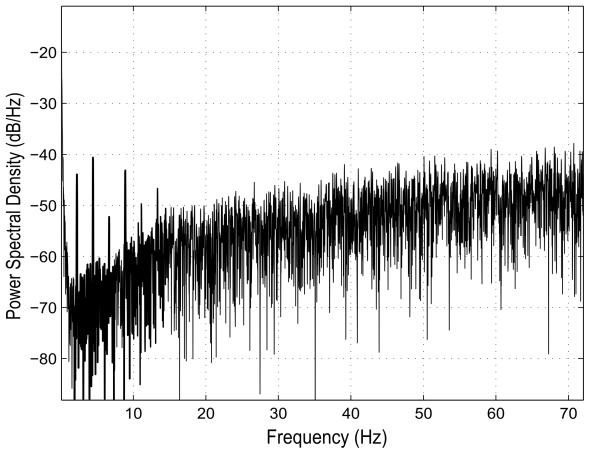

Fig. 7: Spectrum of demodulated GMR speed signal after pattern removal

frequency from the pattern frequency. Two algorithms for pattern calculations are explained in [2]. A Pattern algorithm can be used on the wrapped phase by computing the time difference between two phase shifts in the instantaneous phase. This shall give us an unambiguous pole pair width in time units. The resultant signal is a decimated version of the instantaneous phase with a frequency limited to $\Omega_o N$.

It is important to note that these results are only valid if $\Omega_o N$ satisfies the Nyquist criteria. For most practical purposes where the target is to identify low frequency vibrations which are below $\frac{\Omega_o N}{2}$, this method can be used. For high frequency vibration analysis, the computed phase signal can be re-sampled at regular intervals of angle and desired sampling frequency can be achieved.

Fig. 7 shows the final result after pattern removal, where low frequency vibrations induced from attached rotating parts are clearly distinguishable below 10 Hz. In the actual signal as shown in Fig. 5, these frequencies were modulated by the carrier frequency and are now demodulated which makes them distinguishable in the spectrum.

V. Conclusion

An analytical model of the magnetic pole wheel, as sensed by a magnetic GMR sensor,has been presented. A demodulation method based on Hilbert Transformer has been devised for the demodulation of the rotational speed signal. Frequency analysis has been presented to identify and isolate low frequency vibrations present in the rotating parts. A sliding window, frequency domain Hilbert Transform is used to compute the instantaneous phase of rotating magnetic encoder. This technique can be used in virtual sensing applications where direct measurement of vibrations is either costly or not possible by using existing sensor. In these scenarios, off-line signal processing can be used to identify vibrations present in the rotating parts of a machine or a vehicle.

Thin-film CIGS Solar Modules for Design Driven Applications in the Frame of the FP7 NMP Project SolarDesign

W. Brenner*, N. Adamovic*
* Vienna University of Technology/Institute of Sensor and Actuator Systems, Vienna, Austria
werner.brenner@tuwien.ac.at

Abstract - The FP7 NMP project SolarDesign addresses the demand for aesthetically integrated photovoltaic materials by the development of novel solar cell materials, manufacturing processes and supportive actions (design toolbox). One key technology is a laser based monolithic interconnection process for thin-film solar cells. The material in focus is CIGS (Copper, Indium, Gallium, Diselenide).

I. INTRODUCTION

Photovoltaics (PV) is widely recognized as one of the key technologies for the future energy supply. The cost reduction within the last 15 years is a result of the utilization of learning effects, expansion of production capacities, extensive automation and standardization efforts [1]. For design driven PV integrated product solutions customizable shapes, sizes, colours, transparencies or specific electrical properties are required, which have a decisive influence on the acceptance on the market. SolarDesign thus concentrates on aesthetically integrated photovoltaic materials.

Designers, architects and industrial manufacturers across the world share a common interest in using Photovoltaics (PV) as a decentralized and sustainable source of energy in their designs. Promising markets such as sustainable or temporary building structures, outdoor activities, and mobile computing make necessary decentralized, attractive energy solutions. Indeed photovoltaic modules are the only viable renewable energy solution that can be integrated directly into objects such as devices, textiles and surfaces of buildings [5].

CIGS based photovoltaic (PV) devices show the highest efficiency among the different thin film solar technologies. They obtained a value of 20.3% at cell level (0.5 cm^2) that is already comparable to the 25% record in single crystal Si solar cells, while record efficiencies of 12.8% and 17.6% have been reported for CIGS cells on flexible substrates. However the main problem is to bring the high efficiencies form laboratory scale into industrial production. It has been already achieved to some extent on glass substrates (up to 15% efficiency) [10], [11] but in the realm of flexible CIGS modules the efficiencies range between 8 and 13% depending on the chosen substrate and production process. Besides the high attainable efficiencies CIGS (Copper Indium, Gallium, Diselenide) is a compound semiconductor which allows modifying its band gap and spectral response. Since the intensity of solar radiation on earth is not homogeneous at different wavelengths it is possible to adjust the band gap/absorption edge of CIGS at theoretical maximum efficiency by its composition/mixture of copper-indium-gallium–selenium, which is unique in PV.

Current generations of CIGS thin film modules are optimized for Standard Test Conditions (25°C, irradiance 1000W/m^2, spectrum of Air mass 1.5). By adjusting the compositions and spectral responses of the functional layers of Thin Film Photovoltaics not only the overall efficiency can be improved but also energy yields under diffuse light conditions or at higher operating temperatures are changeable. This uniqueness of CIGS has potential for exploitation.

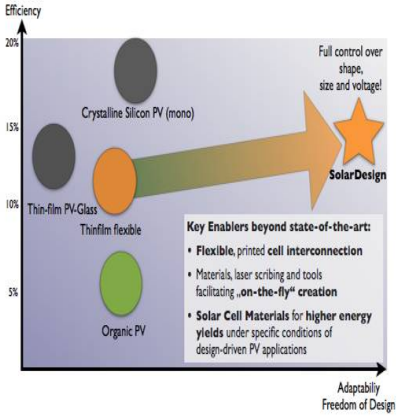

Figure 1. "Technical constraints" versus "design freedom"

Furthermore the designer who wants to integrate solar electricity into his/her work needs a service environment to be assisted in the creative process. Tools should offer support in conceiving, planning and producing the solar design products. The scientific and technical objectives (STOs) of the SolarDesign project are:

STO1: A flexible scribing and printing technology that allows producing a given photovoltaic module according to specific design requirements "on-the-fly". This flexible interconnection is applied on the solar foil (i.e. an endless solar cell) with a minimum width of 300 mm and allows curved solar cells and interconnection patterns with a minimum radius of 10 mm.

STO2: Novel materials for the underlying flexible solar cell technology to extend the design related degrees of freedom.

STO3: Novel materials for satisfying design related requirements on solar module level. Focus is laid on materials for the electrical conducting front grid to allow a high design freedom of patterns.

STO4: A methodological toolbox to provide design rules for the best solar cell super-structure and module design layout for a given application by using numerical modelling and simulation.

STO5: The developed technologies are demonstrated in the following applications: solar charging (cover for tablet PC and solar powered radio), solar powered light, solar powered sensor networks for detection of fire in forest, urban solar lighting (compact solar street lighting system) for Product Integrated Photovoltaics (PIPV), building skins with geodesic curvatures or other related forms for Building Integrated Photovoltaics (BIPV) and integration of PV in textile support.

II. SolarDesign Approach

The basic material is an endless thin-film solar cell based on the CIGS thin film technology as given below.

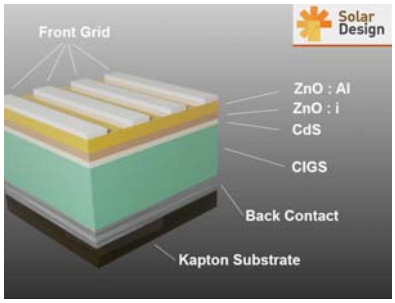

Figure 2. Cross section CIGS solar cell, SolarDesign aims at replacing CdS as buffer layer material

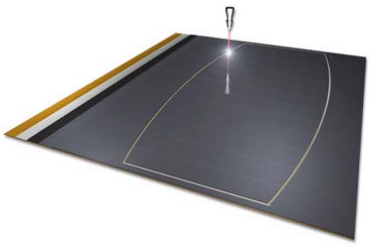

Figure 3. SolarDesign's endless thin-film solar cell

The basic fabric in SolarDesign is an endless produced solar cell. 140 µm to 180 µm wide micro-scale grooves are applied by an ultra short-pulse laser process into the solar foil. With the help of this laser process the edges of a given PV module are isolated and the thin-film layers can be ablated selectively so that the rear contact (which is initially covered by several thin functional layers) and the transparent front contact of the solar foil can be electrically interconnected. The electrical interconnection itself then can be printed in the same production step.

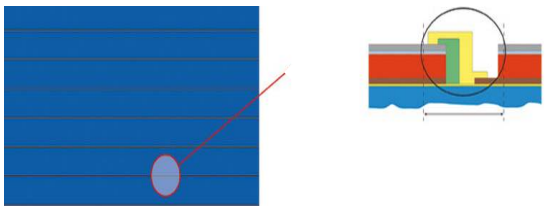

Figure 4. SolarDesign's approach: a flexible scribing and printing technology that allows producing a given photovoltaic module

Laser structuring processes for CIGS Thin-Film edge deletion: a laser structuring process is developed for the edge deletion of CIGS thin-film solar cells on glass and polyimide substrates by Munich University of Applied Sciences [13]. The transparent conducting oxides and the CIGS layers in the edge area of the solar cell are removed in this step. Then the solar cell is covered with a laminate layer which protects it against environmental influences. The edge deletion and the lamination avoid humidity diffusion through the CIGS layer into the cell and the corresponding derogation of the cell efficiency. For the edge deletion an electro-optically Q-switched 880 picosecond IR laser is used. In order to determine suitable process parameters, the pulses per position (PPP) and the fluence are varied. A process window between fluences of 0.8 and 1.5 J/cm² and a PPP of 1.6 to 6 is found. The occurring ablation mechanism is identified as lift-off process (see Fig. 5) allowing extremely efficient material removal. Removal rates down to 4 J/mm³ are determined for a fluence of 2 J/cm² and a PPP of 0.8.

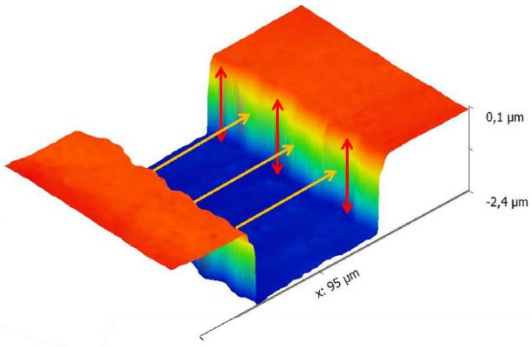

Figure 5. Confocal microscopy image showing the lift-off ablation of the TCO and CIGS layer for the edge deletion process of a CIGS thin film solar cell. Laser parameters: λ = 1064 nm, τ = 880 ps; PPP 4; F0 = 0.8 J/cm². (source: Munich University of Applied Sciences).

To understand the underlying physical mechanisms, a 3D axis symmetric finite element model was created and numerically solved. The model is verified by a direct comparison of experimental and numerical results. It includes volume absorption of the laser pulse, heat diffusion in the electron gas, and the lattice, thermal expansion of the solid phase and further volume expansion from phase transition to fluid and gas, and finally the mechanical motion of the layer caused by the resulting stress wave and the interaction with the substrate. The simulation revealed that irradiation of the Molybdenum layer with an ultra-short pulse causes a rapid acceleration in the direction of the surface normal within a time frame of a hundred picoseconds to a peak velocity about 100 m/s. The molybdenum layer continues to move as an oscillating membrane, and finally forms a dome after about 100 ns. The calculated strain at the edges of the dome exceeds the tensile stress limit at

fluencies that initiate the "lift-off" in experimental investigations. In addition, the simulation reveals that the driving mechanism of the "lift-off" is the ultrafast expansion of the interface layer and not the generated gas pressure [4], [7].

In the frame of SolarDesign M. Acciarri and S. Binetti [8] focus on the second generation thin film devices: the alloy Cu(In,Ga)Se2 (CIGS) which is the most promising material due to the high efficiencies. Nowadays there are two main approaches to produce CIGS solar cells: sputtering followed by selenization evaporation and coevaporation process. High efficiency solar cells are obtained by the sequential three stage co-evaporation process. On the other hand sputtering system is more suitable for an industrial application but the efficiencies are systematically lower. In SolarDesign a new hybrid sputtering and evaporation system was developed to obtain a scalable process combining the advantages of both techniques. This technique has been already applied to deposition on glass and stainless steel substrates. Good results were obtained reaching an efficiency of 15% on glass and 13% on stainless steel substrates respectively. A new research line on the alternative buffer layer is developed by UNIMIB. Thereby, one main thrust in the CIGS solar cells is to replace the cadmium sulfide CdS buffer layer with other material. Currently, a CdS thin film deposited by Chemical Solution Deposition (CSD) technique is utilized as a buffer layer in CIGS solar cells. The further process is not manufacturing-friendly due to the use of cadmium and the liquid waste. Thereby, the cell production is limited by the window materials, and there is need to develop wider band gap buffer layers alternative to CdS. The UNIMIB material candidates as alternative buffer layers in CIGS solar cells include zinc tin oxides (ZnxSnyOz), indium sulfide (InxSy) and zinc sulfide (ZnS) deposited by radio frequency sputtering technique which can be easily integrated into a roll to roll system.

Recently, a special attention is on the deposition of the CIGS absorber layer on flexible substrates [4], [8].

Sunplugged successfully installed a hybrid sputtering and evaporation prototype which is based on the CIGS formation process initially developed by University Milano-Bicocca [13].

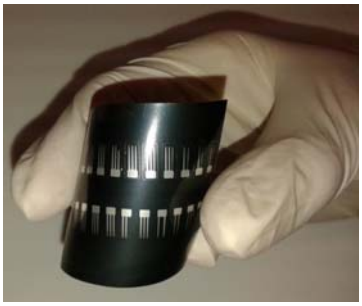

Figure 6. Flexible substrate (source: UNIMIB)

The full-scale prototype is able to produce the absorbtion layer endlessly on flexible substrates up to a maximum of 320 mm. Running in full production mode the prototype is able to produce about 10 running meters per hour.

Figure 7. Hybrid sputtering and evaporation prototype based on the CIGS formation process process initially developed by University Milano-Bicocca (source: Sunplugged)

A typical problem of PV systems is the power loss due to temperature increase, because modules often operate close to the building resp. product envelope with low ventilation. EURAC therefore evaluated and compared the PV temperature conditions of different PV module categories (in terms of PV technology and material type). A simple linear expression for the evaluation of the PV module temperature is $T_{mod}=T_{amb}+kG$ which links T_{mod} with the ambient temperature T_{amb} and the incident solar radiation flux G. Within this expression the value of the dimensional parameter k, known as the Ross coefficient, depends on several aspects (i.e. module type, wind velocity and integration characteristics). However, dispersed values for this parameter can be found in literature (in the range of 0.02-0.06 K m^2/W) according to different module types [12].

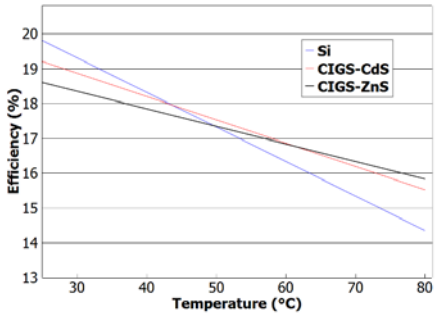

Figure 8. Overview of temperature coefficients of different thin film photovoltaic technologies [9]

As can be seen in Figure 8, the efficiency decrease of ZnS-buffered CIGS (Copper, Indium, Gallium, Diselenide) is smaller than for CdS-buffered CIGS. With further improvement of alternative buffers (like ZnS, ZnMgO, Zn(O,S)), the efficiency values of CdS-buffered CIGS at 25°C can be reached (demonstrated by Helmholtz Zentrum Berlin [3]. Due to lower temperature coefficient even higher efficiencies at operating temperatures (typically ~60°C for midsummer day) can be expected for alternative buffers – without using toxic Cd. For deposition of different buffer layer materials both sputtering and wet chemical process are available.

Vienna University of Technology (TUW) has finished development of the numerical model that describes solar modules based on CIGS technology. The model has two aspects. Firstly, it is used to optimize the fabrication technology by exploring the impact of physical

parameters of the solar cells. The simulation of the technology process is indispensable, as it saves both time and recourses by reducing the number of tests.

Figure 9. Application street lamp, an example for the need for reduced temperature coefficient to guarantee minimum values of luminescence which are standardized for street lighting, source: SIARQ)

Secondly, the developed model is used to meet the needs of the designers/architects. Specific user defined shapes of modules can be easily achieved, while respecting the electrical requirements. The design of metallization lines with varying thickness or shape, as well as arbitrary banding profiles is enabled. The simulations of the solar modules under different illumination levels has been taken into account, thus enabling the calculation of the daily or yearly energy performance of the considered modules [4].

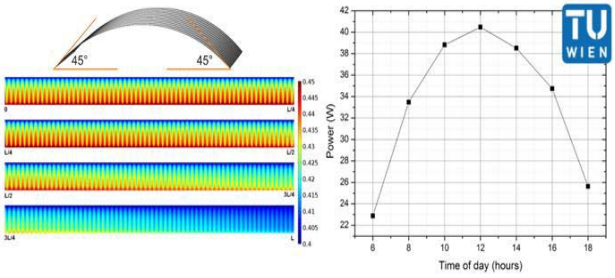

Figure 10. Example of the simulation of an arbitrary curved module: a) module geometry, b) voltage distribution along one cell, b) calculated power yield during a day [source: TU Wien]

The technologies for the printing step are screen printing and dispensing. For very small scale production (lot size below 200) this process is unsuitable because every pattern requires its own screen. Also after the printing of the isolation paste thermal curing needs to be applied. The main advantage of the dispensing technology is that it can be fully digitized and a "lot size one" is possible. It is an addition to the screen printing to fulfill customer demands regarding design for predefined cost limits.

Series interconnection of thin film solar cells is done by monolithic interconnection. It connects the transparent conductive oxide (TCO) of cell 1 with the rear contact of cell 2 and so on. While the rear contact which is normally a high conductive metal has at least a conductance of 35% compared to copper the commonly used TCOs like ITO (Indium Tin Oxide) or AZO (Aluminium-doped Zinc Oxide) have a conductance of less than 2%. This value depends of course of the thickness of the TCO and the layer beneath but a thicker TCO does also mean less transmittance thus reducing the efficiency. One improvement is the use of a metallic front grid, a standard solution for thick film solar cells but still in its infancy stage for thin film applications. There has to be found equilibrium between high conductivity and reduced shading of active areas. One objective in question is to find a solution to this problem coupled with an optimized pattern for front grids.

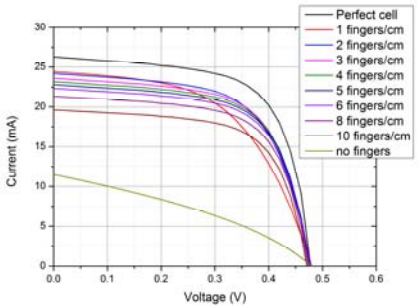

Figure 11. Metallization grid optimization, d_{Ag} = 20 µm, this provides good conductivity, therefore the width of the fingers can be a minimum: w_{finger} = 200 µm

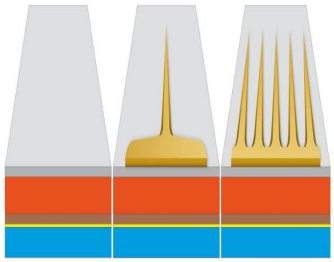

Figure 12. Different layouts of the metallic front contacts. The challenge for the design of the front contact lies in optimization of contradicting parameters like high conductivity and minimized losses by shading

In principle such a front contacted photovoltaic cell body is structured in three parts and two connecting interface regions in between with very different electrical and optical properties. The semiconductor layer (e. g. CIGS/n-layer), the transparent conductive oxide layer (TCO) and the metal grid (metal): the bottom semiconducting absorber layer has optimized high optical absorption and low reflectivity, the intermediated TCO-layer has a low optical reflectivity and absorption, and low electrical resistance, the top metallic grid layer has very high optical reflectivity and almost no optical transmission but very low electrical resistivity.

Encapsulants for CIGS solar modules require attention. The potential solution is a compromise between several technical and economical constraints: it has to be thin, flexible and transparent. It needs to protect the solar cell against external shocks and mainly against moisture. Suitable low-cost high performance encapsulation strategies are a key challenge to achieve sufficient lifetime. Indeed, most of these promising thin film technologies (CIS, CIGS, organic etc.) have to be protected with a gas barrier material to reach sufficient lifetime for the dedicated applications. In order to increase the barrier properties, Atomic layer deposition

techniques are mainly proposed in order to make deposition of several atomic layers of Al_2O_3. The encapsulation process needs the lamination of a barrier foil with gas barrier protection only reachable by depositing alternatively organic and inorganic layers on a polymeric substrate or by lamination of several single barrier films. In addition, photochemical stability of barrier films is an important aspect in the case of PV devices. Nowadays, commercial solutions appear at a pre-industrial level but some questions remain not completely resolved as the cost, stability, lamination process (adhesive), connection etc.

Figure 13. Color variations providing more freedom of PV design, using different novel encapsulants allows custom designed optical appearance (source: CEA)

SolarDesign is working on the development of a user oriented software tool taking into consideration all the parameters for the establishment of a numerical modelling and simulation tool that allows gathering the necessary information during the design process.

The actual innovation of this tool is that enables the user to calculate solar radiation received on any shape, allowing simulating any scenario on a complex shape. The user oriented software tool provides design rules for the best solar cell super-structure and module design layout, and addresses the efficiency in the incorporation of thin film to the different products or structures designed. The tool will help users to calculate a performance simulation to subsequently design the electronic and pattern for the production process. To develop and test the software tool, a building structure with a characteristic and complex shape called "domo" has been chosen on a first approach.

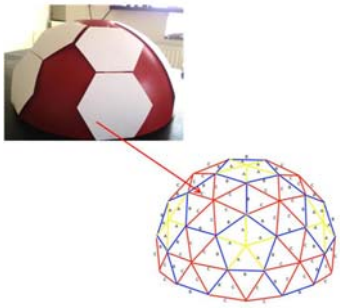

Figure 14. Domo Structure (Source: Julien Bollaro, GAIA, Application simulant la radiation solaire sur une installation afin d'assister le développement de la technologie Thin-Film dans le cadre du projet européen: SolarDesign. 2013)

III. Multi Tools Marketing Methodology

SolarDesign is an SME-targeted collaborative project within the work program topic "Novel materials and design-based solutions for the creative industry". Following this philosophy CEA has defined and applied a multi tools marketing methodology which can be used for projects with several potential key results. For SolarDesign the methodology aims at prioritizing 4 markets (outdoor lighting, BIPV, consumer products and textile) by considering their attractiveness vs. SolarDesign's technology assets. Four different actions were lead: a documentary research based on patents and economic data's analysis, a "field analysis" with qualitative interviews of well-chosen actors, a "quantitative analysis" inspired by Kano approach and a long-term news watch disseminated to the members through a share point dedicated to the project [4].

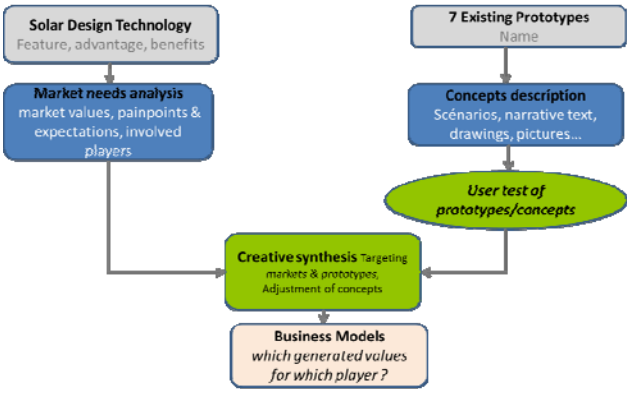

Figure 15. Market analysis (source: CEA)

IV. SolarDesign Consortium

The consortium formed by eleven partners belonging to six different countries, covers the needed expertise, namely, PV design, materials research, thin-film deposition and characterization, laser processing, interconnection manufacturing, and integration in products (PIPV) and buildings (BIPV). E.g.: company Sunplugged is developing own CIGS thin-film solar cells on flexible substrates production line. Vienna University of Technology (TUW) provides the numerical modeling and simulation tool that allows prediction of energy yields, performance, electrical-, optical-, thermal- and mechanical characteristics during the design process. Munich University of Applied Sciences (MUAS) has been involved in research of laser scribing processes of CIGS thin-film solar cell. Commissariat à l'Energie Atomique et aux Energies Alternatives (CEA) develops encapsulates for modules (new materials, new pigments, up scaling up to large surfaces). CEA has experience in BIPV (integration of modules into tile) and via CEA-INES has the module manufacturing capabilities. Consortium:

V. STANDARDS

The FP7 NMP SolarDesign Project is focused on new PV integrated product solutions. To achieve this, the project has the goal to develop new materials, flexible production - and business processes in PV powered product design and architecture. SolarDesign has decided to integrate standardization into the project's efforts [2]. Standards can enhance the economic value of research and innovation projects. Main questions according to [6] are:

- Are SolarDesign's R&D results expected to be compatible and interoperable with other technologies?
- Is there a need to ensure reliability, safety and comparability of R&D activity or result?
- Will results have a potential European or international market application?

Integrating photovoltaics in architecture and industrial design is in its infancy and taking into account different European perspectives is crucial for its success. This is especially true for Building Integrated PV where legal conditions like construction codes or feed-in regimes are differing from one European country to another. By seeing design from a stylish or sensory perspective regional characteristics exist. Taking product designers and PV experts from different European countries can ensure the incorporation of varying design manifestations. Dissemination, implementation and standardization cannot be seen as separate activities. They need coordination because they represent two sides of the same plan for market access. In the next step CEN/CENELEC was identified as relevant standardization partner. By this it is ensured that results are widely accepted and available.

VI. CONCLUSION

A growing number of designers, architects and industrial manufacturers across the world share a common interest in aesthetically integrated photovoltaic materials as a decentralized and sustainable source of energy in their product designs. For solar powered products customizable shapes, sizes, colours, transparencies or specific electrical properties are required. In SolarDesign a new hybrid sputtering and evaporation system was developed to obtain a scalable process combining the advantages of both techniques. This technique has been already applied to deposition on glass and stainless steel substrates. Good results were obtained reaching an efficiency of 15% on glass and 13% on stainless steel substrates respectively. Research on alternative buffer layers focuses on replacing CdS.

ACKNOWLEDGMENT

SolarDesign http://www.solar-design.eu has received funding from the EC 7th Framework Program FP7-NMP-2012-SME-6, Grant Agreement No 310220.

Measurement System for Object Detection Based on Multielectrode Capacitive Sensor

D. Ćika*, T. Martinović** and H. Džapo**
*Research and Engineering Center d.d., Zagreb, Croatia
**Faculty of Electrical Engineering and Computing, Zagreb, Croatia
drazen.cika@rec-global.com

Abstract - The problem of detecting objects, people and events is encountered in different forms in many application areas. In this paper we investigate the applicability of multielectrode capacitive sensors for monitoring the volume of interest by analyzing the disturbances in electrical field due to the influence of external objects. Capacitive sensors are particularly interesting as a low cost solution with minimum privacy issue concerns. The goal of this research was to characterize the performance of modern capacitance-to-digital converter (CDC) PicoCap PCap02 integrated circuit for detecting various types of objects in a multielectrode system configuration, with human detection as an example application. We present an analysis of an appropriate electrode geometry, propose a custom-designed data acquisition system which complies to the required capacitance measurement range and resolution, discuss sources of measurement errors and methods for minimization of their influence, and elaborate the applicability of the method beyond the simple object detection, by investigating the possibility of object class discrimination from acquired data.

Keywords: capacitive sensors, object detection, data acquisition, electronic instrumentation

I. INTRODUCTION

Object detection is the problem encountered in different forms in many application areas, such as industrial quality control, production process monitoring, security systems, traffic monitoring, inventory tracking etc. Intensive research led to the development of methods and techniques to solve particular practical problems for data acquisition and processing based on information acquired by different types of sensors, including cameras, motion detection sensors (ultrasound, infrared, radars), capacitive and inductive sensors, planar force detection sensors, acoustic sensors etc.[1]. Most advanced methods and achievements have been developed in the area of computer vision, using camera as data acquisition sensor, and employing image processing and machine learning algorithms to solve many practical problems in the field of detection and classification of objects and people. However, those methods are usually computationally demanding, and not suitable for low power embedded systems that are commonly encountered in practice. There are also privacy concerns which might exclude camera sensors in some applications.

Capacitive sensors are interesting due to possibilities for simple and low cost production (both electrode manufacturing process and data acquisition circuitry), and capability for detection of non-magnetic objects, without a need for direct galvanic contact. These characteristics make capacitive sensors an attractive choice also for non-metallic and non-magnetic object detection and discrimination, and also for applications including detection of people and animals. Capacitive sensors are used in many different applications [2], [3], such as precise displacement measurement (micrometers), proximity detection, pressure and force measurement, liquid level measurement, human-machine interfaces (touch screen displays, keyboards), inertial sensors (accelerometers), environmental conditions monitoring etc. [4]

The majority of advances in the area of multielectrode capacitive sensors applications has been achieved for human-machine interfaces, namely touch screen that must precisely determine a finger position in a real-time [5], [6]. Prior work in the area of person detection by means of capacitive sensors proposed using large electrodes in horizontal or vertical plane for detecting persons on the move [7], [8], detecting hand movement in the proximity of the metal processing machinery for increased operator safety [9], or detecting vehicle seat occupancy by electrodes embedded in seats [10], [11], [12]. Previous research also confirmed the applicability of multielectrode capacitive sensors systems for detection and classification of events, human activity, body position and movement [13], [14], [15], by using machine learning approach for sensor data processing.

In this article we investigate the possibility of object detection and discrimination by means of a custom-designed multielectrode capacitive sensor, with a signal conditioning part based on a single chip capacitance-to-digital converter (CDC). The integrated circuit PCap02 (manufactured by acam-messelectronic gmbh) was chosen due to its exceptional measurement characteristics, comparing with other available CDC solutions. The goal of the research was to assess whether the approach to people and object detection by using low-cost compact CDC-based integrated circuits is a viable solution for practical use cases.

II. PCAP02 CAPACITANCE-TO-DIGITAL-CONVERTER

A. PCap02 Integrated Circuit Characteristics

Typical PCap02 application schematic diagram when I^2C interface is used is shown in Fig. 1.

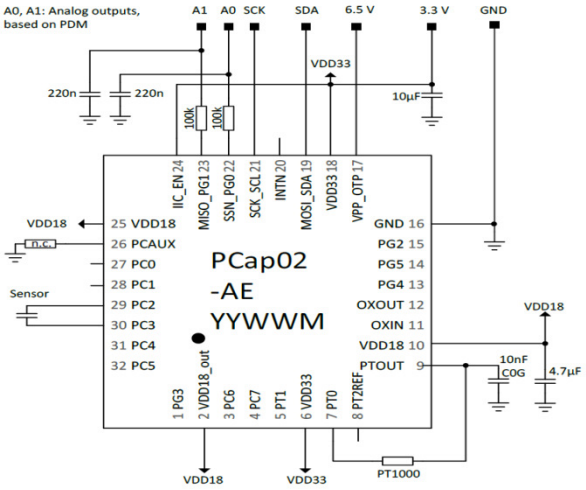

Fig. 1. PCap02A typical schematics, I2C interface

Detailed characteristics and explanation of principle of operation for this component can be found in [16], [17].

PCap02 has the digital signal processor (DSP) integrated in order to achieve on-chip data post-processing in addition to the basic converter functionality. The PCAp02 can handle larger offset capacitance on its inputs than some other comparable CDC chips, therefore it is inherently less susceptible to stray capacitance caused by connecting wires. Table 1 shows dependency between the output data rate and capacitive noise and resolution for 10 pF base and 1 pF span. Only part of the table for floating sensor configuration is shown here, more information can be found in [16].

The PCap02 is based on the discharge time measurement principle, which means that the capacitance is determined from the time needed to discharge the RC-network. The time is measured by high resolution time-to-digital converter (TDC), and the ratio of discharge times is directly proportional to the ratio of capacitor under test and the reference capacitor. The discharge time depends on the capacitor under test, and discharge resistor which can be selected under software control.

Output Data Rate [Hz]	FLOATING Fully compensated		
	RMS Noise [aF]	Eff. Resolution 10 pF base [Bits]	Eff. Resolution 1 pF span [Bits]
2.5	15	19.3	16.0
5	23	18.7	15.4
10	35	18.1	14.8
25	48	17.7	14.4
100	134	16.2	12.9
250	172	15.8	12.5
1,000	330	14.9	11.6
2,000	438	14.5	11.2
4,000	603	14.0	10.7
10,000	838	13.5	10.2

Table 1. PCap02 RMS noise and resolution

B. Connecting Sensors to CDC

Various configurations are possible when capacitance sensors are used, as shown in Fig. 2 and Fig. 3. Sensor plates can be connected in a single or differential configuration, and each can have external ground reference, or it can be floating. Depending on the chosen configuration, different number of electrodes can be used since the total number of measuring inputs on the PCap02 CDC unit is limited to eight, including the input for the reference capacitance measuring. If the single floating configuration is used, four capacitive sensors can be connected to the single CDC unit. Shielded cables are recommended to compensate the external parasitic capacitances against the ground for longer cables, as shown in Fig. 4. This measure alone may not be effective in some cases, so active shield driving might be necessary.

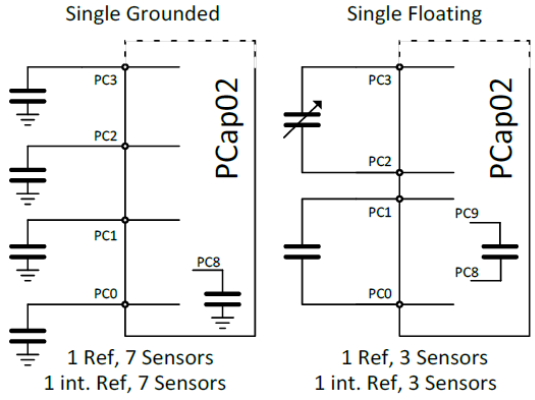

Fig. 2. Options for connecting sensors - single inputs

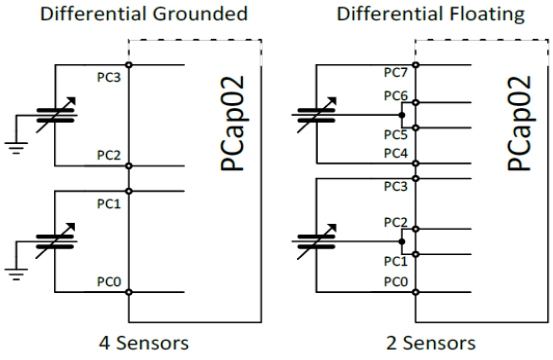

Fig. 3. Options for connecting sensors - differential inputs

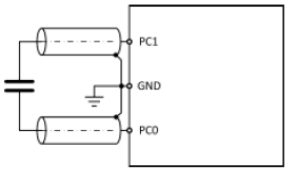

Fig. 4. Connection of shielded cables

III. DATA ACQUISITION SYSTEM PROTOTYPE

A. PCap02 Breakout Board

Although there is readily available PCap02 evaluation board (PCap02-EVA-Kit [18]), we decided to fabricate our own small breakout board, that is more suitable for cases where portability and small dimensions are needed. The breakout board contains only minimum set of components necessary for the PCap02 operation and communication with the host microcontroller. Breakout board dimensions are 20 x 20 mm.

The hand soldered PCap02 ready for test is shown in Fig. 5. The breakout board schematic is shown in Fig. 6. PCap02 pins necessary for functions not implemented on the breakout board are available at header pins distributed along the breakout board edges with the standard 100 mils pin spacing.

The power supply is not part of the breakout board, and user should provide the necessary 3.3 V DC voltage to the board. The 1.8 V DC is generated internally in the PCap02, and available at external pins for powering other components if necessary. The PCap02 breakout board power consumption measured on the prototype is 15 µA with I^2C interface used for communication with the host microcontroller. Additional power consumption should be added to the system power requirements, depending on the microcontroller type and clock speed selection, ratio of active versus sleep time operation, and other microcontroller operation specific parameters.

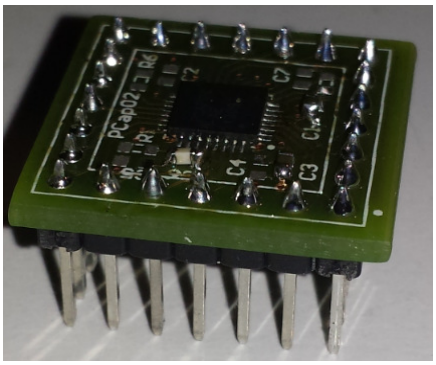

Fig. 5. PCap02 breakout board ready for test

The serial bus communication mode with the host microcontroller (MCU) is preselected by soldering the R3 solder bridge (0 Ω resistor) for the SPI, or the R4 solder bridge for the I^2C interface. The I^2C is more convenient when several boards needs to be connected with a minimum wiring, while the SPI offers higher data transfer rates, which was not a requirement for this project.

B. CDC Module and Firmware Support

The ARM Cortex M4 core family microcontroller was chosen for implementation of the experimental capacitive sensor data acquisition system, and the STM32F4 Discovery evaluation board is used [19]. Firmware was developed in the ARM Keil© uVision integrated development environment (IDE) [20] by defining and implementing hardware abstraction layer (HAL) C functions for the PCap02 sensor integration and support. In case of the MCU platform change, even to some other architecture, changes in the code would be minimized as there are no hardware dependencies.

The I^2C communication and other hardware dependent functions are implemented using the STM32F4 DSP and standard peripherals library [21], and some freely available open source wrapper functions on top of this library [22]. During the experiments, communication with the host PC was necessary in order to transfer data and display graphs, and the USB port was used for that purpose as shown in Fig. 7. The complete environment including the bench type laboratory power supply and a person standing between two electrodes while doing the measurement is shown in Fig. 8.

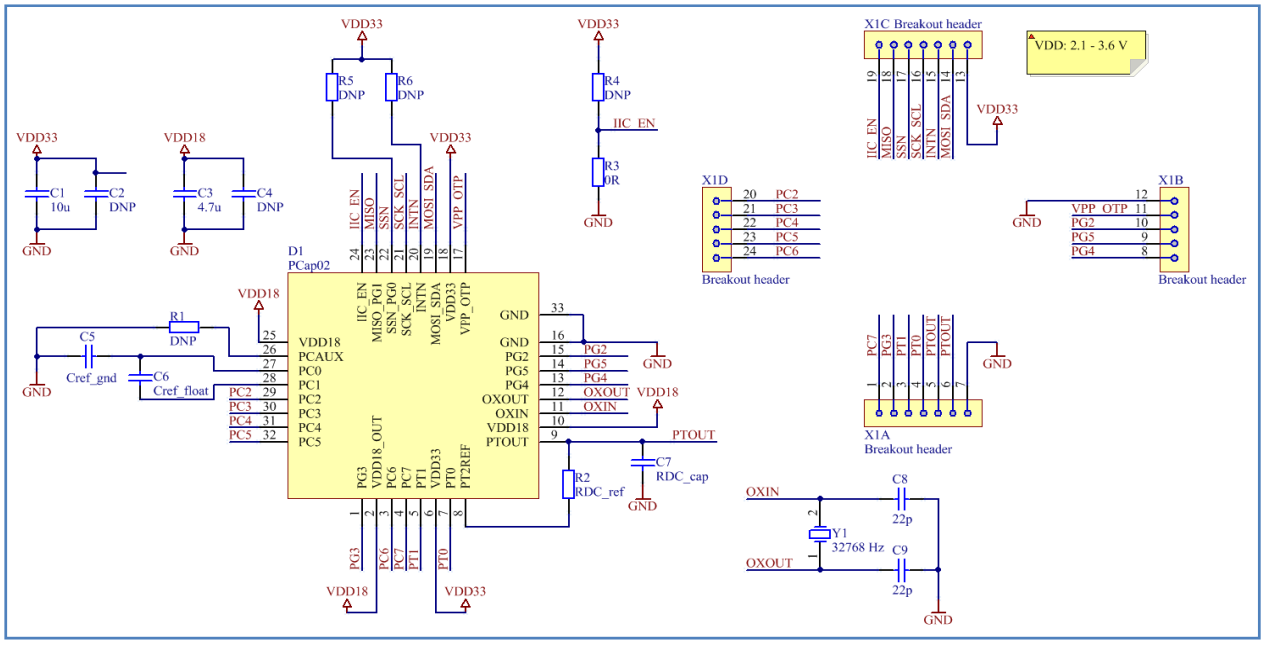

Fig. 6. Schematic diagram for the custom designed PCap02 breakout board

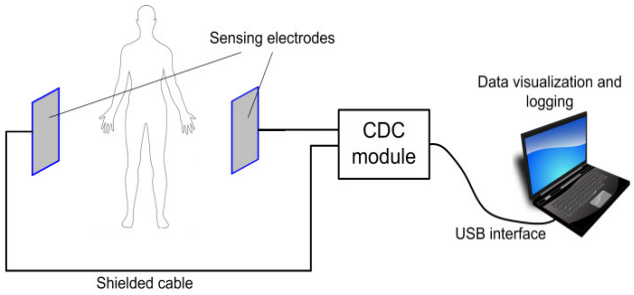

Fig. 7. Measurement setup block diagram

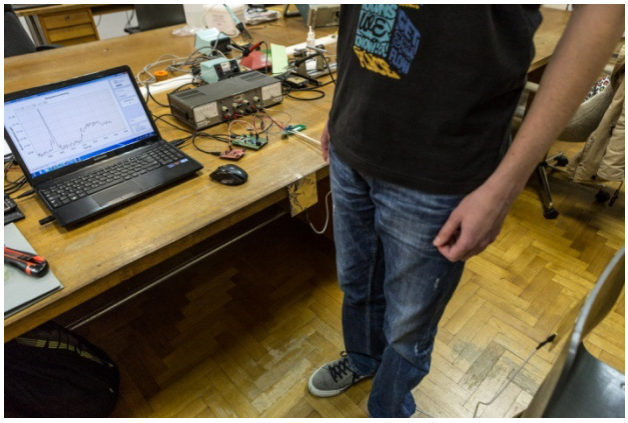

Fig. 8. The measurement setup including single pair of electrodes

IV. SIMULATION AND MEASUREMENT

A. Measurement Setup

The block diagram of the basic measurement setup already shown in Fig. 7 corresponds to the photograph shown in Fig. 8. For different electrode configurations the measuring setup would only be altered regarding the number of inputs. As long as up to three channels are needed, single PCap02 can be used, otherwise additional breakout board should be used.

The multielectrode measurement system can be arranged so that each pair of electrodes captures different area of interest. In the experimental setup described here only one pair of electrodes was used at the time, but the electrode placement and object orientation was varied to observe the resulting capacitance change.

B. Electrostatic Simulation

The expected experimental results can be estimated by means of electrostatic simulation, with different level of accuracy, depending on the tools available and quality of models that can be used with these simulation tools. In this research the simulations were performed by using The Robin Hood Solver [23] because it is fast, it has low memory requirements, scripting in the Lua programming language is supported, and it is easy to use with licensing policy suitable for academic use.

The simulation setup used two different electrode pairs (10 x 10 cm and 20 x 10 cm), and each electrode was divided into 1800 triangle elements. Electrodes were separated by 80 cm thus simulating the standard door.

The simulations were performed by using the metallic cylinder as very simplified model of the human body with satisfactory approximation results. The cylinder diameter was varied in the range of 30 cm, 35 cm, and 40 cm with 180 cm height, and it was divided into 5108 triangle elements for simulation purposes. By using the Robin Hood Solver scripting language, cylinder (i.e. person) is programmed to pass in the middle of the volume between the plates. Simulation results are shown in Fig. 9.

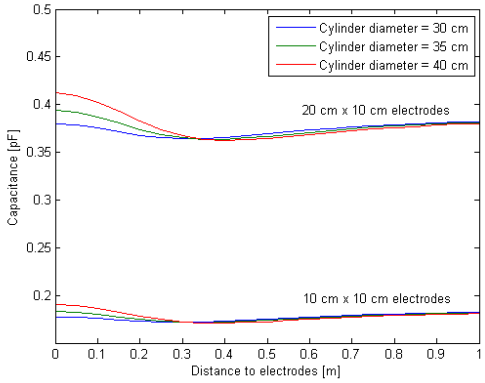

Fig. 9. The Robin Hood Solver simulation results

In a zero position, the cylinder is placed exactly between the sensing plates, and the distance is increased to 1 m in 5 cm steps. Two different sets of electrode dimensions were simulated, 20 x 10 cm, and 10 x 10 cm. The resulting capacitance change is between 15 fF and 50 fF, depending on a sensing plate size and cylinder diameter. While even smaller sensing plates could be used, resulting capacitance changes would be barely noticeable due to parasitic capacitance changes representing noise to the measuring system. These are very demanding and challenging requirements for the measurement system.

C. Measurement Results

The cable connection to the sensor plates is critical, and if the wiring is not done properly it can introduce noise, or result in much smaller measuring span. Measurements were performed by using:

1. unshielded cable,
2. shielded cables with grounded shield,
3. shielded cables with active shield driving.

First experimental setup was similar to those described in [10], [15]. The sensing plates are positioned on the chair backrest and seating area, person was standing, seating, and seating away from the backrest. Plate size is 20 x 30 cm. The results are shown in Fig. 10.

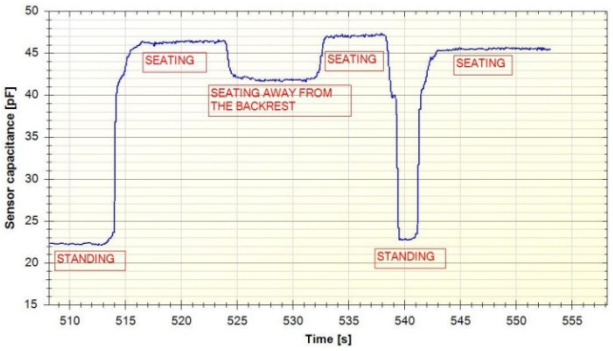

Fig. 10. Sensor electrodes positioned on the chair

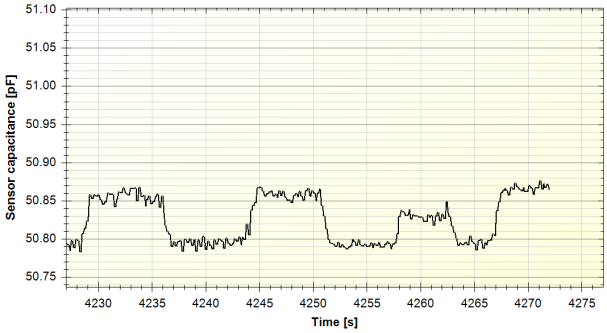

Fig. 11. Active shield, 20 x 15 cm electrodes, 80 cm distance

The distance of only few centimeters from seating person to the sensors could explain much higher capacitance values than simulated and found in following experiments. The unshielded cables also act as a part of electrode and contribute to the total measured capacitance. The noise visible in the results looks insignificant, but it is in the tenths of picofarad range, which is well above the capacity change predicted by the simulation and found in the following 'doorway' measurement setups where object was more distant from the sensor plates.

The second experimental setup was using the shielded cable grounded at the PCB side, but the longer cable still contributes to the input capacitance, and shielded cable of one meter length and more could saturate the inputs of the PCap02.

Best results were obtained in the third experimental setup, when the cable shield is driven with the same signal used for capacitive sensor excitation. Measurement results are shown in Fig. 11. The higher capacitance values correspond to the person passing through the doorway, and standing in the space between the sensor plates for about five seconds. First two peaks were obtained for 'normal' front facing orientation, and third peak which is a bit smaller in capacitance was measured for sideway walking and standing. This is result of a position where the body is a bit more away from the sensor.

The active shield measurement option was realized by using the same signal for the shield drive as the one driving the sensor plates. The TL082 operational amplifier in voltage follower configuration was used for each plate (two amplifiers per measuring channel), as shown in the schematic diagram in Fig. 12.

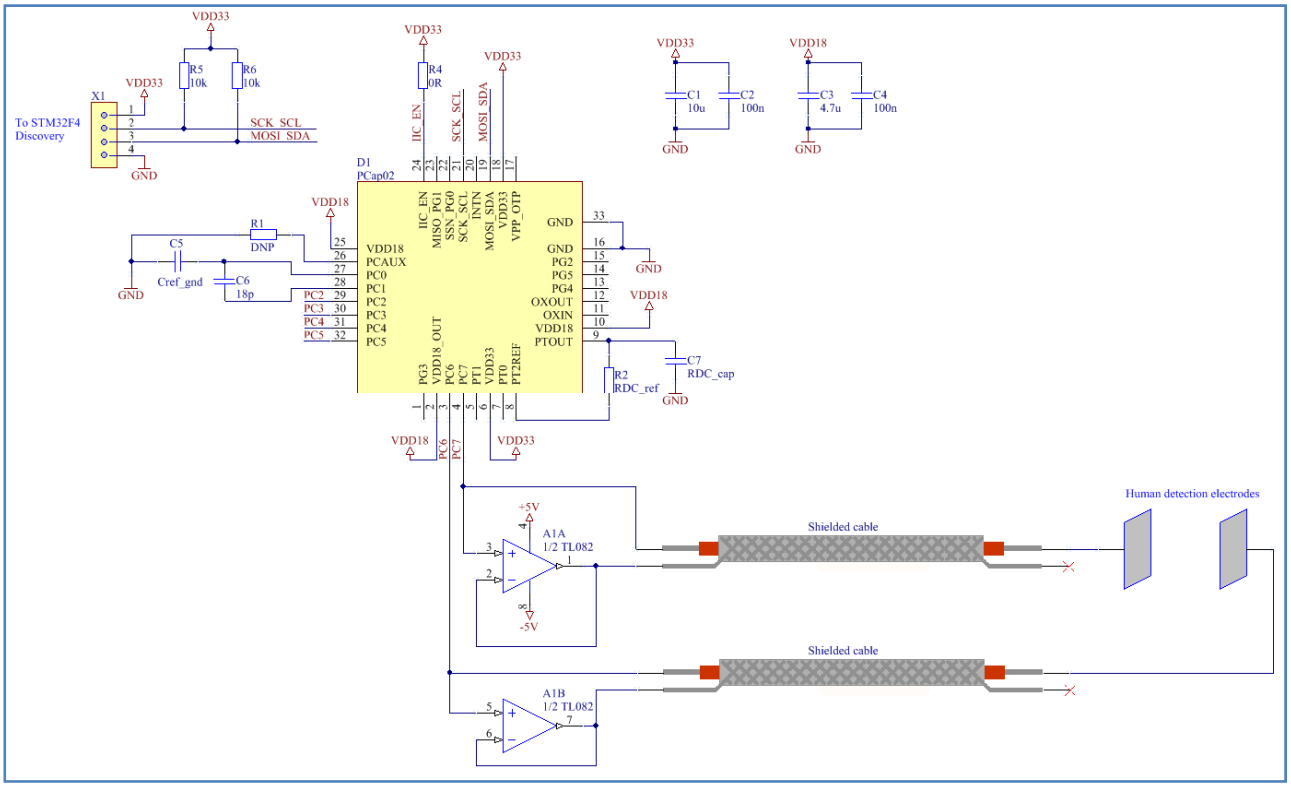

Fig. 12. Complete capacitive sensing circuit (without MCU board) with active shield driving

With the electrodes disconnected, the noise was around 1 fF peak to peak. With electrodes connected using the overall cable length of 3 meters, the noise was around 20 fF, less than half of approximately 50 fF capacitance change detected when person passed through the area observed. Measuring span is 144 pF for the 18 pF reference capacitance selected (span = 8 x C_{ref}).

V. CONCLUSION

The PCap02 CDC capacitive sensor can be used for object detection and discrimination applications based on the multielectrode capacitive sensors. Cabling is critical, and after active shield drive technique was used, the noise was reduced below the detection threshold using the reasonably sized electrodes, while in the same time cables longer than one meter are used. The firmware support developed can be easily applied to other low power MCU architectures, and portable battery operated device can be designed which would autonomously operate for extended period of time. The sensitivity and speed of the measurement setup is high enough to detect if the person was passing slowly or running, or is it standing facing front or sideways, if supported by appropriate detection and discrimination algorithms.

ACKNOWLEDGMENT

The research leading to these results has received funding from the project "Information and communication technology for generic and energy-efficient communication solutions with application in e-/-/m-health (ICTGEN)" co-financed by the European Union from the European Regional Development Fund.

IBMS - Intelligent Building Management System Framework

S. Tepić*, P. Pejić*, J. Domšić*, H. Mihaldinec*, H. Džapo*
* Faculty of Electrical Engineering and Computing, University of Zagreb, Zagreb, Croatia

***Abstract*—The ubiquitous availability of Internet connection in residential and industrial environments enabled limitless possibilities of connecting local sensor networks using various cloud technologies to provide value-added services for intelligent management of building facilities. One of the challenges in implementing a distributed smart building management systems is to enable interoperability of many different computational platforms by providing a common protocol across the wide range of devices, with different capabilities and resources. In this paper, we present an infrastructure architecture and software framework for building large interconnected sensor networks, with primary application for building management. We establish the terminology, system elements specification, functional description of different hardware and software building blocks, define a thin common interoperability layer with established message semantic and event-driven framework, providing a modular architecture that is easy to adapt and extend. Sensor nodes are connected through the data aggregators, which communicate with the remote scalable cloud service, designed for large sensor data collecting, syncing, storage, and event processing. For testing purposes, we implemented a demo system based on open source technologies that are integrated with our IBMS framework.**

***Keywords*—smart sensors and actuators, sensor networks, intelligent building management, Internet-of-Things**

I. INTRODUCTION

Internet of Things (IoT) is a paradigm that enables interconnection of sensors, actuators, and other types of small devices through the Internet infrastructure in order to enhance the possibilities of user interaction with physical environment [1], [2]. "Things" or devices can range from a simple sensor nodes to very complex embedded systems, depending on their purpose and role [3]. The IoT paradigm is believed to be a next big step in information technology development, after Internet and mobile communication network, which will provide more comprehensive interoperability and intelligence in management of Things.

The concept of Internet of Things was first proposed by MIT Auto-ID Labs, in a context of research of object localization and state recognition using wireless sensor networks [4], [5]. The report released six years later by the International Telecommunication Union (ITU) formally proposed the concept of the Internet of Things. This report shaped an idea in which all objects in the world can exchange information via the networks actively. It can be said that since then the era of the ubiquitous IoT communication has started [4], [6]. This domain has been identified by numerous companies as a source of new business opportunities, since it is expected that in a near future billions of small devices will be connected to the Internet [7].The possible areas of application include various fields, such as infrastructure management, security applications, environment protection, smart agriculture, industry, traffic, business services, urban management etc. [4], [8], [9].

The IoT paradigm demands a huge global distributed information system consisting of numerous devices that need to be identified, tracked, sensed, and processed. Therefore, there is a need to use standardized concepts and interoperable Machine-to-Machine (M2M) communication protocols, and to develop new ones to fit all IoT systems. With the support of new widely present technologies, such as broadband mobile communication and cloud computing, the IoT systems are able to process the objects' state and provide intelligent user interface for management to ease the necessary decisions based on the real-time notifications. Integration with machine learning and artificial intelligence approaches enables the development of cooperative IoT systems that do not require human intervention, thus making them completely autonomous. In implementation of such systems, it is crucial to provide an efficient way of collecting raw data for further processing and analysis. The IoT paradigm introduces heterogeneity, which inevitably induces the system complexity. Therefore, there is a great need for use of middleware that can overcome the complexity by providing the transparency for the end user. The main goal of this paper is to provide a middleware concept and layer implementation, which is simple, extensible, and based on readily available and widely used technologies and solutions.

The paper is structured as follows. The section II discusses the state-of-the-art solutions and the related work. The section III describes proposed system architecture. The section IV explains the inner system composition and implementation details more thoroughly. Paper is concluded with Section V.

II. RELATED WORK

One of important goals of the IoT paradigm is to automate the communication among devices, without a need for human intervention. Hence, the M2M concept takes a substantial segment of research and development in this field. There are several comprehensive IoT platforms in a process of active development, such as GSN [10] and OpenIoT [11]. These platforms strive to provide an overall and generic solution that would enable the interconnection of sensor and device networks with complex software data managements systems, by providing necessary functionality layers. These systems are designed to have a mediator role between sensors and sensor data consumers.

The main focus of our research is concerned with the system integration on a hardware side, and its implementation in small, low-power embedded systems. In general, the use of standard open technologies is preferred to proprietary closed solutions, since the latter are more difficult to maintain, manage and further develop, also with

a questionable long-term support. The common data exchange layer is typically built upon the Internet Protocol (IP), since the Internet infrastructure is omnipresent and readily available in residential, business, industrial and other types of environments. Traditionally, wireless sensor networks employ ZigBee or some other IEEE 802.15.4 based protocol for communication, since the main requirement is to provide a low cost and energy-efficient design, with ultra-low power capabilities of the underlying hardware solution [1]. In order to connect small devices with constrained hardware resources to the Internet, the 6LoWPAN protocol was developed. The main purpose of this protocol is to build TCP/IP stack compatibility for small networked devices, in order to encapsulate the IPv6 packets within ZigBee frames. TinyOS [12] is an instance of a real-time operating system for wireless sensor networks that has a lightweight implementation of 6LoWPAN called *BLIP*. Other alternative solution is *Sensor Networks for an All-IP World*(SNAIL), which integrates four technologies into its IP adaptation architecture, such as mobility, web enablement, time synchronization, and security [13].

Recent efforts in the field of power efficient and space constrained electronic system design lead to the development of low-cost Wi-Fi components and modules that are specifically designed for embedding in wireless sensor network nodes. They can achieve competitive technical characteristics and price when compared to IEEE 802.15.4 and similar technologies. Such solutions enable easier system field deployment and scaling with constantly changing demands. Modern sensor network hardware designs are continuously shifting towards the solutions implementing the native Wi-Fi support and such approach is becoming a dominant choice for the IoT domain. With a careful system design, in certain usage scenarios a battery life of several years can be expected, while providing an easy integration with the existing network infrastructure. Re-use of existing infrastructure is key point for cost savings, faster development, and scalable deployment. Moreover, Wi-Fi enabled devices offer native IP network compatibility out of the box.

The goal of our research was to develop a lightweight micro framework middleware for rapid IoT solution development that encompasses a minimum set of necessary components, both for embedded systems on a sensor network side, and for the cloud infrastructure. The solution is based on combination of various widely used web, networking, and embedded open source libraries and frameworks that are loosely coupled via thin common data exchange protocol layer. The proposed solution has been developed with modular approach in mind that would enable easy replacement of existing modules and development of future plug-ins. The system supports not only Wi-Fi wireless sensor nodes because it includes a bridge for transparent translation of any proprietary radio protocol into the common IP-based data exchange protocol. One of the important design goals was scalability in scenario when the size of the sensors network grows. Although the framework is suitable for a wide range of applications, the main practical design goal was to provide an easy implementation for remote building management; therefore we decided to name it IBMS - *Intelligent Building Management System Framework*.

III. IBMS System Architecture

The proposed IBMS system is logically divided into the following main system parts: *Sensors, Aggregators*, *Cores*, and *Generic Data Acquisition System* (GDAS). The Fig. 1 depicts the proposed system architecture and how the components are organized in the overall system.

Sensors are low-power embedded devices that collect sensory data from the physical environment, and they send readings to the other components of the system. Sensors are typically battery-powered devices that are connected to the local data *Aggregators* through wireless communication protocol in order to avoid the necessity for building the wired infrastructure. *Sensors* are equipped with low power microcontroller which is capable of implementing simple

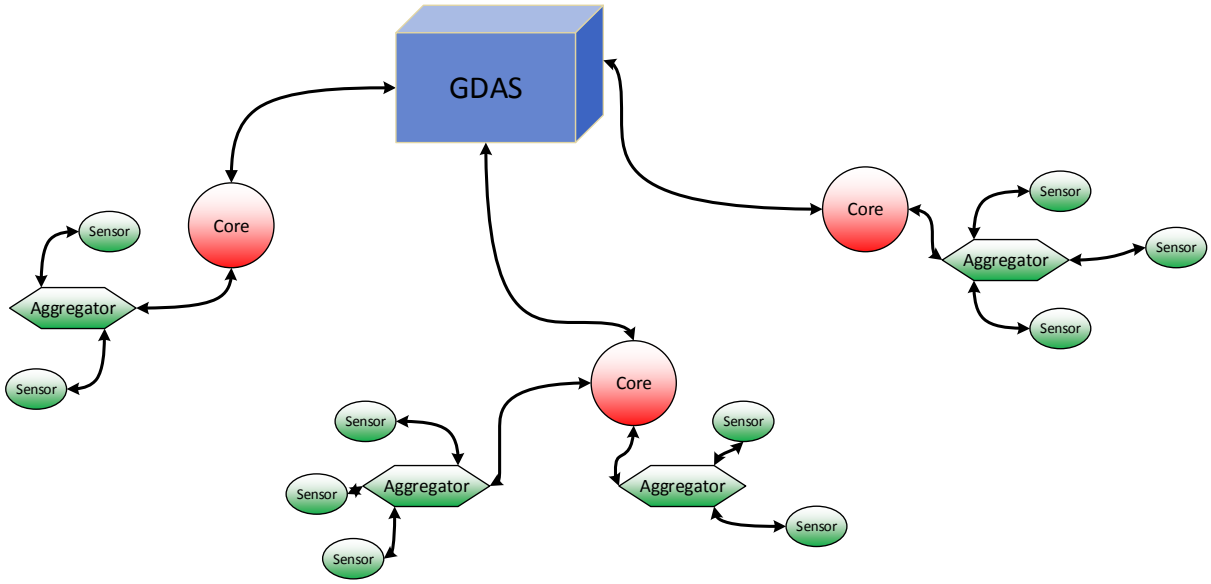

Fig. 1 The IBMS system architecture

protocol for data exchange with local *Aggregator*. The main design goal of *Sensor* is to provide ultra-low power operation, and possibly several years of autonomy from a single battery power source. Therefore, in some cases Wi-Fi might not be a viable solution, while 802.15.4 protocol may be also overkill in practice for very simple sensor nodes. System is designed to accept a *Sensor* equipped by any kind of wireless communication interface.

The role of the local *Aggregator* is to interact directly with wireless sensor nodes, collect raw data, monitor sensor status, update individual sensor configuration, etc. However, one of the most important roles of the *Aggregator* is serving as a *protocol bridge* between any type of wireless sensor radio communication protocol, and the rest of the system. Protocol translation in the *Aggregator* is transparent and all *Sensors* are seen in the exactly same fashion from the other higher level system components. Local *Aggregator* is typically based on microcontroller and equipped with the necessary communication interfaces (Wi-Fi, 802.15.4, proprietary RF, Ethernet etc.). Radio modules can be added in a modular fashion through standard microcontroller peripheral communication interfaces (USART, I2C, SPI, etc.). The *Aggregator* is typically connected to a continuous power supply and does not have to be designed for ultra low power operation. In the context of building management, an *Aggregator* will cover the wireless range of sensors that are assigned to it. In the large building, there would be typically a need for more than one *Aggregator* to cover the whole range of scattered sensors.

The role of the local *Core* is to monitor and control all local data *Aggregators* and to connect the local network consisting of several *Aggregators* to the remote cloud service for data collection and monitoring (*Generic Data Acquisition System*, GDAS). In a typical usage scenario, one *Core* would be assigned for each building, communicating with the *Aggregators* that are in range of wireless *Sensors*. In a special case of spatially limited sensor installations and small buildings, the *Core* can be designed to include also the described functionality of the *Aggregator* in a one single hardware module. The *Aggregator* can communicate with a local *Core* over any media supporting IP protocols (Ethernet, Wi-Fi etc.). *Core* is typically based on higher computational power embedded system that is capable of running general-purpose operating system (such as a Linux). Examples of such embedded systems are *Beagle Boneblack*, *RasperryPi* etc. The *Core* also needs to provide local data storage capabilities, for caching sensor data in case of limited or unavailable connectivity. Therefore, Linux-based embedded systems provide an excellent choice by enabling the use lightweight database managements system (DBMS).

The central part of the whole system is *Generic Data Acquisition System* (GDAS). The main purpose of GDAS is to provide means for scalable sensor data collection, processing, and storage. GDAS communicates with *Cores* as mediators for managing local sensor networks. Each sensor can be reached from GDAS via *Core*, who takes care of routing the messages between GDAS and *Sensor* through the right *Aggregator* to which sensor is connected. GDAS is implemented as a web service, and it is built upon widely used open source frameworks to provide minimum server side functionality needed for managing the whole system. An example of open source solution providing similar functionality is Zabbix[14].

Proposed system architecture is not limited only to applications for intelligent building management systems, and it can be used other similar usages scenarios (for example, environmental monitoring in forests, fields, smart agriculture applications etc.). The *Core* serves as a local central place where we can access information about each connected sensor, without a need to know how to directly communicate with it, and which end protocol to use. *Core* also takes a role of immediate local data storage and acts as a bidirectional message forwarding node. In order to provide a simple and consistent mean of communication and message exchange among all components in a system, a thin unified data exchange layer was proposed. We use the IP layer for low-level packet exchange between components to provide maximum independence of physical layer implementation. The communication between *Aggregators* and *Sensors* is the only place when other protocols for data exchange are used, but it is transparent to the rest of the system. Components have assigned IP addresses through which they can be reached, except for *Sensor* nodes, as they are not necessarily connected with *Aggregators* through the IP layer. *Sensor* nodes are assigned meaningful virtual addresses through which they can be reached, and *Aggregators* take care of routing the messages to access correct connected *Sensor*. Data is transferred by using TCP transport layer, and HTTP application layer is used to achieve protocol-independent execution with defined start, stop, transfer, and sync moments. HTTP layer is also a convenient choice because it enables direct communication with a web framework, as a part of GDAS. Messages sent between system components are in the *Java Script Object Notation* (JSON) format. Modularity, simplicity of parsing procedure, and widespread use in web technologies makes it

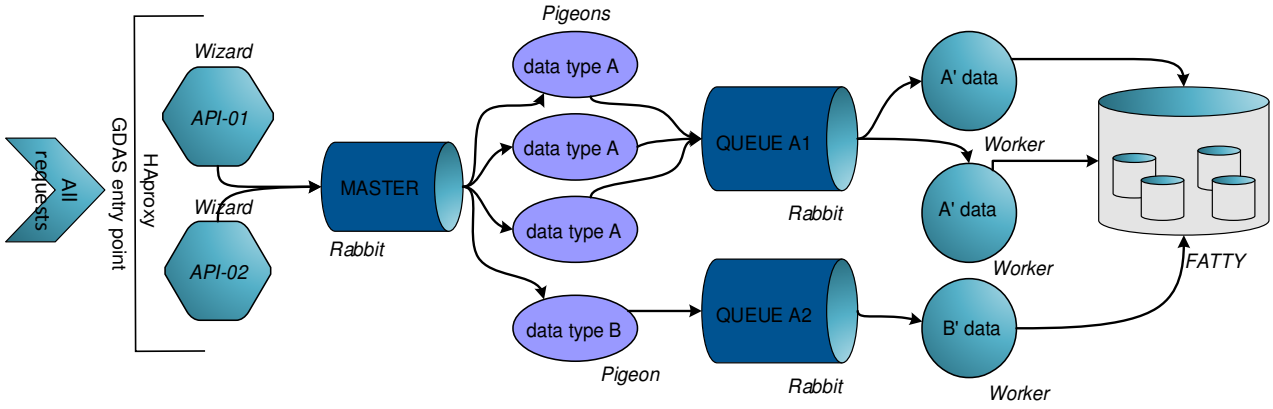

Fig. 2 Structure of the GDAS system

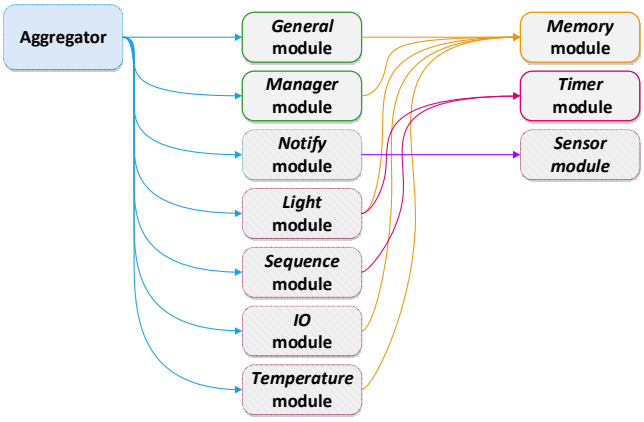

Fig. 3 Aggregator software architecture

an ideal choice, even from the embedded system standpoint. Lightweight, human readable format makes also system easier to debug and maintain.

A minimum required set of components consists of one *Core* and one *Aggregator*. For sake of simplicity for the rest of the system, *Sensors* assigned to some *Aggregator* are mapped into the *Aggregator Ports*. They are not seen as separate entities but as *Ports* of the *Aggregator,* with defined type and attributes. Local *Aggregator Ports* are mapped into sensor and actuator nodes.

The dataflow can be between *Core* and *Aggregator* is bidirectional, in a request-response manner. When the Aggregator sends data to the *Core*, there are two basic cases, synchronous and asynchronous. The synchronous case is when the *Core* requests a data from the *Aggregator* by issuing a HTTP GET request, and gets a response from the *Aggregator*. It is used when the state of the whole array of *Ports* is requested in one chunk. In the asynchronous case, the *Aggregator* sends HTTP POST packets to the *Core*, and it exchanges only a subset of *Ports*, including a case of information about a single *Port*. The *Core* sends data to the *Aggregator* in HTTP POST packets, only in case when some parameter on the *Aggregator* has to be changed. JSON formatted data is exchanged in the body of the message.

IV. Practical Implementation of Test Environment

Following the specification of the IBMS architecture from the previous section, an implementation of the proposed system and test environment for simulation of various use cases were designed. Three types of networks were included in a test environment setup to demonstrate the interoperability in merging IP protocol with an example of proprietary solution: IEEE 802.3(Ethernet), IEEE 802.11 (Wireless Ethernet) and NRF24L01+ Nordic Semiconductor proprietary physical RF layer for ultra-low power transceivers on wireless sensor nodes.

The *Core* module was implemented as an embedded system, which needs to satisfy the following requirements: embedded web server (with capability of serving dynamic content), Ethernet connectivity, database support for local sensor data caching, possibility of hardware extension via external plug-in modules, portability between different platforms, and simplicity of required software install. Requirements for small size and power consumption, above already mentioned requirements, lead to the conclusion that it is best to employ some Linux-based embedded system. Therefore, a *BeagleBoneBlack* platform was selected due to compliance with all previously stated requirements and low price.

The software for *Core* module was developed in JavaScript programming language, due to simplicity, and native support in most of modern Internet browsers. Additionally, JSON data format which is a base for thin common data layer is natively supported in JavaScript environment. As a development environment, the NodeJS was used due to the support over wide variety of platforms, and because it is a proven technology that it can deal with large number of concurrent requests. MongoDB was selected as a database backend because it supports JSON format natively, and it stores data into NoSQL database. Storing data into collections instead of tables like in classical SQL databases perfectly fits our proposed model for data collection and storage.

The functionality of the *Core* module itself can be divided into three main logical parts, that we call *Mainframe*, *Crawler* and *Notifier* module. The *Mainframe* module is in charge of serving the user request. User can be either a person that connects directly to the *Core* module via embedded web server running on the *Core*, or a GDAS subsystem running in the cloud. The *Mainframe* module is in charge for running web services and tracking the user sessions. It also has an ability to communicate with local NoSQL database in order to be able to present data to the user. The *Mainframe* module is implemented in *Express.js* environment, which has all necessary ingredients for agile development of web application. The *Crawler* module is in charge for collecting data from the *Aggregators*. It searches for changes in data for all *Aggregators* and copies data to the local database storage, aggregating them at the single point. *Crawler* is querying the *Aggregators* periodically, but in some cases (e.g. alarms) there is a need for instant event notification to user or GDAS subsystem. *Notifier* module is in charge of listening to asynchronous messages from the *Aggregators* and forwarding them to the users or GDAS subsystem. This is useful for processing high priority information, which needs to be forwarded further instantly.

GDAS subsystem is running at remote server or cloud infrastructure, and it uses the similar subset of technologies as a *Core*. Contrary to the requirements for a *Core*, GDAS is not intended to be implemented on embedded system. GDAS subsystem uses Python-based Flask web micro framework for handling incoming requests, RabbitMQ for storing data during processing, and MongoDB as a main

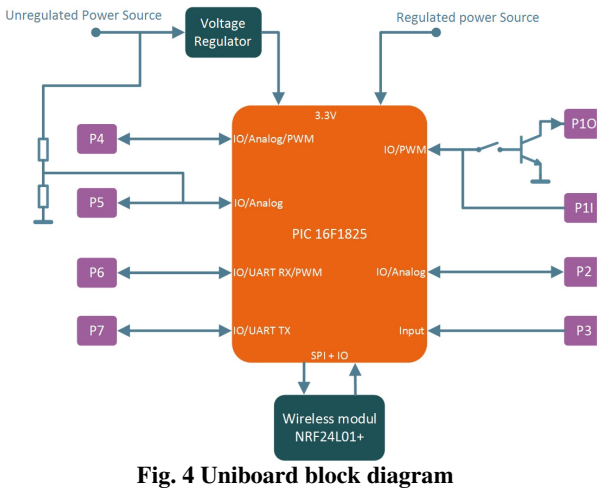

Fig. 4 Uniboard block diagram

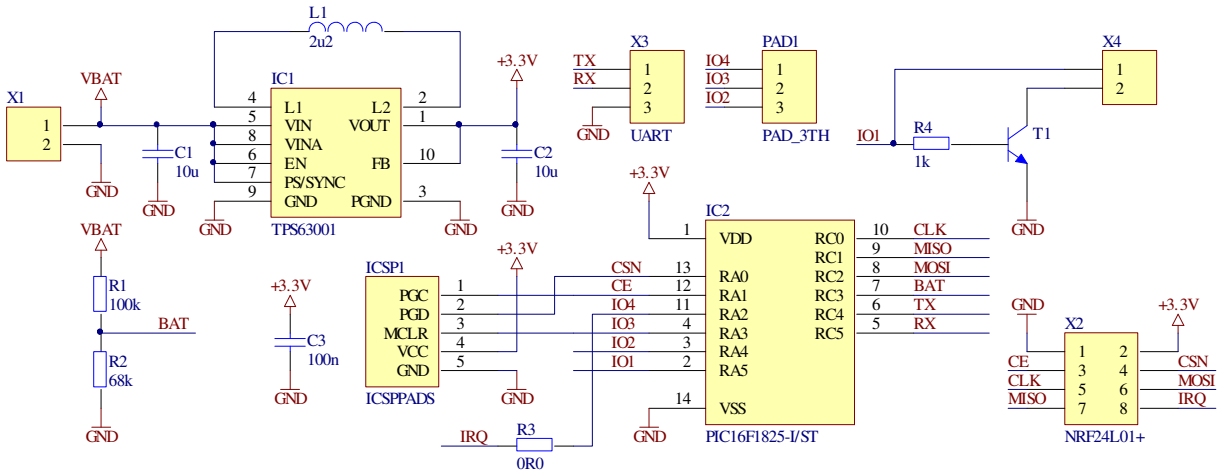

Fig. 5 Uniboard schematic

database storage facility. Flask micro framework was chosen because of excellent balance between low resource demand and high modularity and extensibility. RabbitMQ is a GDAS backbone, capable of storing messages up to the size of system random-access memory (RAM) and passing them from the publishers to consumers at large speed. GDAS has a simple structure that contains several separated modules, as depicted in the Fig. 2. *Wizard* is an entry point of the GDAS system, which is in charge of handling the incoming requests and distributing those requests to the *Workers* equally (load balancing). *Wizard* additionally validates HTTP requests format, and forward valid requests to the *Rabbit* module. *Rabbit* module is based on readily available RabbitMQ message queue implementation, which ensures that this critical part of the system sorts out incoming requests reliably by their keywords. Requests are transferred from the queue to the *Worker* module by means of *Pidgeon* microservice. The role of the *Worker* is to process and store incoming data. If the data passes necessary check, the *Worker* stores it in serialized format into scalable database called *Fatty*, based on MongoDB. All these GDAS segments are micro services, and they can be executed on the same or distributed machines, in a limitless number as independent instances. This ensures system scalability and modularity from the standpoint of resource management.

On the sensor side of the system, custom hardware solutions for both *Aggregators* and *Sensors* were developed. The *Aggregator* hardware must satisfy the following requirements: Ethernet connection with the embedded TCP/IP software stack, I/O connectivity with different buses (GPIO, USART, SPI, I2C etc.) for connection with sensors, actuators, and wireless modules, and microcontroller capable of serving all necessary workload with low latency in a real-time. For purposes of demo system implementation, the *Aggregator* hardware was realized by using Microchip PIC18F26K22 microcontroller and ENC28J60 Ethernet module. Software for the *Aggregator* was developed in a modular way, which enables easy inclusion of new functionality through *Modules*. Some examples of implemented modules are the temperature module (for managing temperature sensors), I/O module (for direct control of digital I/O pins), light module (controlling the lights, with fading capabilities), NRF24L01+ sensor module (communication with wireless sensor nodes with on-board NRF24L01+transceiver), timer module (timing services for other modules), sequence module (sequential actions control), memory module (permanent configurations management), manager module (synchronous communication with *Core*), notify module (asynchronous communication with *Core*), general module (basic information about the *Aggregator*, such as IP address, virtual ID etc.) etc. Fig. 3 shows all the modules in the *Aggregator* software architecture. In order to enable *Aggregator* to exchange messages in JSON format, we used a parser *Jsmn*, which is suitable for embedded systems with limited resources.

The wireless *Sensor* nodes were designed as ultra-low power hardware units, based on NRF24L01+ RF transceivers modules (operating at 2.4 GHz ISM band), and PIC16F1825 microcontrollers. Some of the important requirements for *Sensor* nodes were as follows: ultra low power operation, battery supply, possibility to apply external power supply from renewable sources (such as solar panel), capability of connecting different types of sensors, programmable output capable of driving higher levels of power (e.g. switch relays). To provide maximum flexibility of *Sensor* mode, we developed custom printed circuit board (*Uniboard*), which block diagram is shown in Fig 4. and implementation schematic in Fig. 5. The *Uniboard* is powered from Li-Ion battery (with 1000 mAh capacity and nominal voltage 3.7 V), it has embedded temperature and relative humidity sensor (DHT11), and LEDs for visual indication. The *Sensors* can be parameterized through the serial interface, what includes the local node address, frequency channel, *Aggregator* address, duty cycle (for controlling average power consumption) etc. *Sensor* nodes

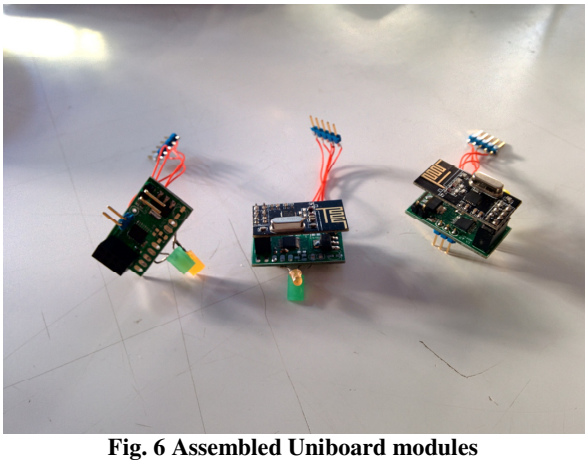

Fig. 6 Assembled Uniboard modules

based on *Uniboard* are shown in Fig. 6. Current consumption depends on application, and it can be reduced under 100 μA for typical periodical sensor polling applications.

V. Conclusion

In this paper we presented a novel framework for building and managing large interconnected sensor networks, with a primary focus on intelligent building management and monitoring. The system was designed as s lightweight middleware of loosely coupled components, distributed across very different set of computational platforms, ranging from a simple smart sensor low power devices, microcontroller-based local data aggregators, embedded Linux-based cores, and dedicated cloud-based service for remote management of the sensor network, and data collection and storage.

The proposed framework is based on widely used open source technologies that simplified and accelerated the system development and facilitated the interoperability among other open platforms. The proposed system architecture is modular, and it enables easy integration of new functionality or exchanging existing subsystems with the new ones. The efficient interoperability across the system components was achieved by use of the lightweight common message exchange protocol, based on HTTP application layer and JSON formatted packets, the use of the IP protocol to achieve the maximum independence of the physical layer, and bridging the proprietary wireless sensor network protocols at the point of the sensor connection to the rest of the system.

Experimental test environment was set up, and all system components' functionality was tested and verified in practical demo installation. The future research will encompass the further extension of the common data exchange protocol, functionality of the system components, adding support for wider set of embedded platforms, and testing the system behaviour under realistic loads expected for larger scale sensor networks.

Acknowledgment

***Abstract*—Obtaining dense disparity maps of stereo image pairs is a common problem in computer vision. We present a new hybrid method for dense stereo correspondence based on the well-known winner-take-all optimization and the three-dimensional recursive search (3DRS) algorithm. Originally devised for motion estimation and frame rate conversion in high definition televisions, the 3DRS algorithm employs predictive block matching to generate a coarse correspondence map between two images in a sequence. The algorithm is widely used in ASIC and FPGA implementations, achieving real-time performance in processing of 60Hz high definition video signals. In our proposed hybrid method, the 3DRS algorithm is applied to a stereo pair in order to generate a coarse disparity map, which is further optimized using a local, winner-take-all driven coarse-to-fine approach. The selected approach greatly reduces the local disparity space to be searched, yielding significantly better run-time performance while retaining or even improving the accuracy of the results. The method is evaluated using the Middlebury stereo datasets and compared with both the reference winner-take-all algorithm and coarse-to-fine hierarchical optimizations. The obtained results favor the proposed method in terms of accuracy and performance. The proposed method is suitable for implementation in custom parallel computing hardware, ASIC or FPGA.**

I. Introduction

Dense stereo matching, or estimation of disparity in a stereo image pair, has been a heavily investigated topic and an important problem within the field of computer vision [1]. The methods which are employed can generally be classified as either local or global, depending on the strategy used for the estimation. While in the global methods the disparity computation involves the minimization of a global energy function for the entire disparity map, the local methods choose the disparity associated with the optimum cost value at each pixel - a "winner-take-all" (WTA) optimization. While it has been shown that the global approaches deliver the highest quality results [2], they are also typically very slow and impractical [3]. The local methods, while faster and much more compatible to a practical implementation, are still behind the global methods quality-wise, nevertheless their computational complexity is still considerable. Research efforts have been therefore directed to both improving the quality [4] [5] of WTA algorithms, and reducing their computational requirements [6] [7].

This work has been supported in part by Croatian Science Foundation's funding of the project IP-11-201-3717.

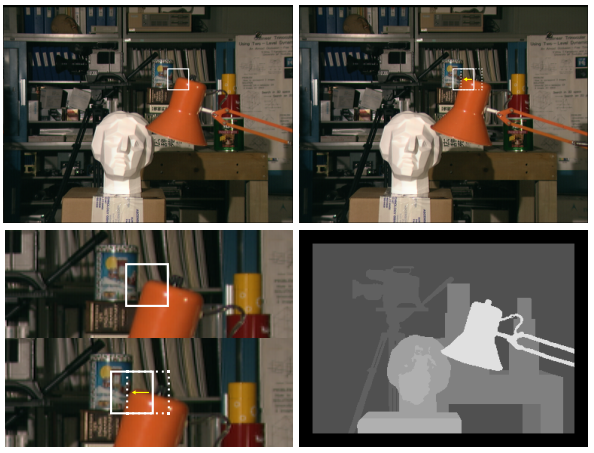

Fig. 1. Disparity estimation in stereo images using block matching.

II. Related Work and Motivation

A lot of research efforts have had a goal of improving the WTA optimization. Most of the approaches in improving the WTA optimization have focused on improving either the matching cost [8] or the cost aggregation [6], whether they are using traditional square windows, shiftable windows [9], variable or adaptive windows [10], or, more recently, non local aggregation through methods such as bilateral filtering [11]. Additionally, hierarchical and hybrid methods have been proposed with the goal of improving the performance and quality of local stereo methods.

The problem of computing correspondent features in two images has also been extensively studied in the field of motion estimation, where a motion map (also called the optical flow) of objects is generated for a sequence of images [12]. The goal is to establish a correspondence map of areas within a source image similar to areas within a reference image in a sequence. Two categories of motion estimators are present: the residue-minimizing, used in

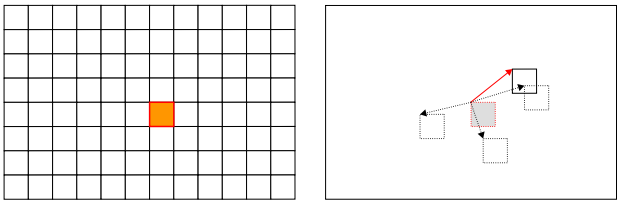

Fig. 2. An illustration of block matching. Left: Source image divided in blocks. Right: reference image with multiple matching candidates.

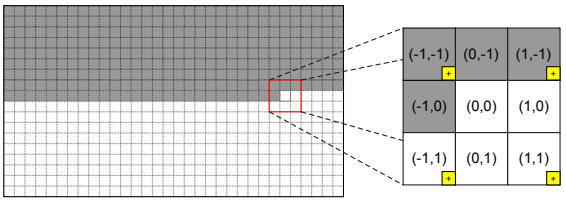

Fig. 3. The spatio-temporal neighborhood used in the 3DRS estimation. The vector for the block at (0,0) is currently being estimated. Vectors for the blocks at (-1,-1), (0,-1), (1,-1) and (-1,0) have already been estimated for this image. The remainder of the blocks used are from a previous estimation, making them temporal predictors. The predictors coming from the blocks marked with a '+' are additionally modified with update vectors.

video compression algorithms, and true motion estimators, used in video up-conversion and deinterlacing. One of the most successful true motion estimation methods is the Three-Dimensional Recursive Search (3DRS) [13], widely used due to its simplicity, low cost implementation, and the ability to provide good true motion estimates. The method has been successfully applied for real-time processing of 60 Hz high definition video and frame-rate conversion with frame rates up to 400 Hz, with specialized ASIC implementations.

It has been shown [14] that true motion estimation is necessary to produce good disparity estimation results, as well as that the 3DRS algorithm can be successfully applied in real-time stereo matching. The 3DRS, however, produces coarse results, while the goal of passive stereo matching is to produce dense disparity maps. A number of research efforts has successfully employed a coarse-to-fine hierarchical approach [15] [16]. In this paper, we will present a hybrid approach to dense disparity estimation combining the coarse disparities obtained from the 3DRS algorithm, with the subsequent refinement using the WTA optimization. By using 3DRS results to narrow the disparity space and applying the 3DRS principles on the WTA estimation to gain accuracy, the proposed method manages to vastly reduce the computational complexity and improve run-time, while also improving the quality of the final disparity map.

III. Algorithm Description

A. Three-dimensional Recursive Search (3DRS)

The 3DRS algorithm is a *block-matching algorithm*; the input source image is divided into blocks, for each of which the location of a best-matching block is searched in the reference image. A two-dimensional vector defining the distance between the original block position and the position of the matching block in the reference image is assigned, as shown in Figure 2. The map of vectors for all of the image blocks is the optical flow of the image and describes either the motion or disparity. For disparity estimations of epipolarly rectified stereo pairs, the vertical component can be ignored.

The blocks are matched through a *matching cost function*, such as the *sum of absolute differences* (SAD) or the *sum of squared differences* (SSD) or *normalized cross-correlation*(NCC). Finding the proper matching block involves finding the extreme value of the matching cost function. To find the extreme, an optimization method is usually applied, where the 3DRS algorithm reduces the number of required candidate blocks (or candidate vectors) by making the following two assumptions:

1) Objects are larger than blocks.
2) Objects have inertia.

The objects referred to are the features in the actual image, the movement (or disparity) of which is being estimated. Assumption 1) therefore implies that the vectors of the neighboring blocks provide a good predictor, or assumption, about the block being estimated. Assumption 2), on the other hand, implies that a temporal predecessor - a previously estimated motion vector, is also a good candidate for the new vector. The application of these assumptions to the estimation process significantly reduces the number of candidates which have to be evaluated. To introduce variation, *update vectors* which are either generated randomly, from a distribution, or a predefined set, are added to a subset of the predictors. The variation introduced by the update vectors ensures that the algorithm will progress towards a solution regardless of the initial conditions. The typical initial conditions are that the vector field contains only zero vectors. An example of the update vector set is:

$$U_v = \left\{ \begin{bmatrix} \pm 2^k \\ 0 \end{bmatrix}, \begin{bmatrix} 0 \\ \pm 2^k \end{bmatrix} \right\} \; k = 0, 1, 2, 3, ..., k_{max} \tag{1}$$

Sequentially for every block in the image, 3DRS selects the output motion (or disparity) vector from a set of prediction vectors chosen from a spatio-temporal neighborhood, with the addition of updates in order to evaluate alternate solutions, as seen in Figure 3. For an individual block, the matching cost function is evaluated for each predictor, and the predictor with the best matching cost is selected and assigned as the new vector for the current block, which then also becomes a part of the candidate set for the next location as the estimation progresses to the adjacent block.

The block evaluation order is defined by the *scanning direction*. The most common order is from top-left to bottom-right, with each line beginning on the left. This order defines which of the predictors are spatial, and which have also a temporal component, as seen in Figure 3. It

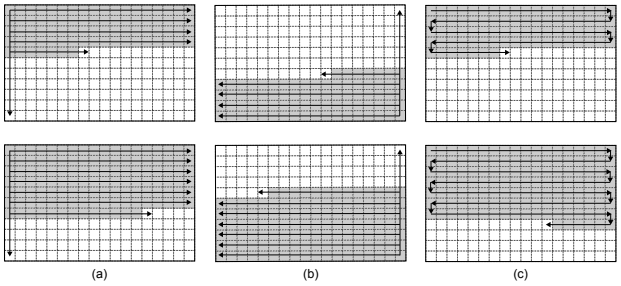

Fig. 4. Various scanning orders for 3DRS, shown in time progression from the upper to the lower image; (a): Top to bottom, left to right; (b): Bottom to top, Right to left; (c): Boustrophedonic/meandering. The darker areas illustrate the progression of current estimates throughout the image.

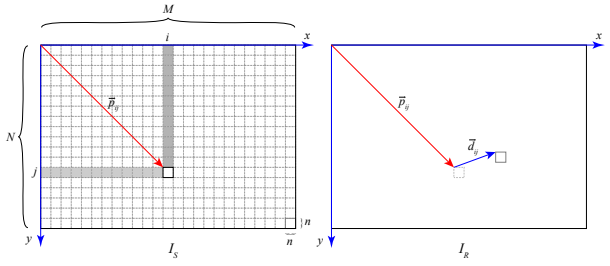

Fig. 5. 3DRS image space and coordinate system

also defines the direction in which the newly estimated, "good" values propagate within the image. Changing the scanning order from bottom-right to top-left on each new image, or alternating the scanning direction in a *boustrophedonic* or *meandering* way as shown in Figure 4, yields the propagation of good estimates in all four directions, helping the 3DRS to quickly converge on the final vector map. For the correct estimates to propagate even faster, multiple scans can be done for one image pair, alternating the direction and the meander of the scan on each pass. The *temporal* component of the 3DRS vectors refers to the results of the previous estimation, either for the current pair of images, or for a previous pair in a sequence of images. The initial state of the 3DRS vector field is that all components are set to zero, from where they converge to the proper value by aggregating update vectors during the estimation process.

The 3DRS algorithm works by analyzing the blocks in two images:the source image I_S and the reference image I_R, shown in Fig.5.

The source image I_S is divided into a rectangular grid of $M \times N$ blocks of $n \times n$ pixels as shown in the figure. For each block B_{ij}, i denotes the row index and j denotes the column index of the block. A motion vector $\vec{d}_{ij}$ is assigned to each block.

The pixel position vector $\vec{p}_{ij}$ for each block in I_S is defined as:

$$\vec{p}_{ij} = n \cdot \begin{bmatrix} i \\ j \end{bmatrix} \tag{2}$$

This vector points from the origin to the upper-left pixel of each block.

The 3DRS algorithm consists of the following steps:

1) For each block B_{ij} in I_S, form a set of predictors:

$$P = \begin{cases} \vec{d}_{ij} \\ \vec{d}_{i+k\,j} \\ \vec{d}_{i\,j+l} \\ \vec{d}_{i+k\,j+l} + \vec{u}_v \end{cases} \qquad k = -1, 1;\ l = -1, 1 \tag{3}$$

In the set above, $\vec{u}_v$ is the update vector, and a new one is selected either randomly of from a predefined set, for each of the predictors it is applied to.

2) Evaluate the matching cost for each of the predictors, and assign to $\vec{d}_{ij}$ the predictor with the minimum matching cost.

$$\vec{d}_{ij} = arg \min_{\vec{d}_P \in P} (MC(\vec{p}_{ij}, \vec{p}_{ij} + \vec{d}_P)) \tag{4}$$

where the matching cost $MC(\vec{s}, \vec{r})$ is the sum of absolute differences of pixels within the compared blocks

$$MC(\vec{s}, \vec{r}) = \sum_{y=0}^{n-1} \sum_{x=0}^{n-1} |I_S(\vec{s} + \begin{bmatrix} x \\ y \end{bmatrix}) - I_R(\vec{r} + \begin{bmatrix} x \\ y \end{bmatrix})| \tag{5}$$

3) Repeat the previous two steps for every block in the image based on the selected scanning direction.

B. Winner-Take-All optimization

In local approaches, correlation between intensity values inside a matching window $N(p)$ assigned to a reference pixel p is analyzed, based on the assumption that the pixels within the matching window have similar disparities. The generalized procedure of the WTA optimization [6] of a left disparity map in the case where *absolute difference* is used is as follows. For each of the disparity hypotheses, a per pixel cost $e(p, d)$ is calculated by using the image pair where the right image is shifted by the disparity d. An aggregated cost $E(p, d)$ is then computed via a summation of the per-pixel cost multiplied by a weighting function $w(p, q)$. The WTA optimization is finally performed for seeking the best disparity among all of the hypotheses:

$$e(p, d) = min(|I_l(x, y) - I_r(x - d, y)|, \sigma)$$

$$E(p, d) = \frac{\sum_{q \in N(p)} w(p, q) e(q, d)}{\sum_{q \in N(p)} w(p, q)} \tag{6}$$

$$d(p) = arg \min_{d \in [0, \ldots, D-1]} E(p, d)$$

where I_l and I_r are the left and the right images of the stereo pair. The per-pixel cost is additionaly truncated with a threshold σ to limit the influence of outliers on the dissimilarity measure.

Many research efforts have been directed at improving the WTA algorithm in terms of speed and accuracy. Diverse matching cost functions have been explored which bring accuracy improvements at varying computational

TABLE I
NUMBER OF EVALUATED HYPOTHESES PER CASE

r	Input Disparities D	Best Case	Worst Case
5	256	11 (-95,7%)	99 (-61,3%)

loads. However, the cost aggregation step remains the most important and the most time-consuming part of the calculation in the local approaches. Therefore, most of the efforts focus on defining the weighting function $w(p, q)$ which defines how the costs are aggregated within the window. For the classic square window, a noteworthy enhancement is the use of integral images [10], which greatly accelerates the algorithm's execution in comparison with the direct aggregation. A great part of the computational complexity, however, remains in the requirement to test all of the disparity hypotheses $d \in [0, ..., D-1]$ for each pixel p. The goal of the proposed hybrid method is to reduce the computational complexity by narrowing the disparity range to be tested per each pixel p.

C. The hybrid 3DRS-WTA method

In the proposed method, shown in Algorithm 1, a coarse analysis is performed first using the 3DRS algorithm, with the image divided into blocks. This yields a coarse map of estimated disparities d_{ij} assigned to each of the blocks. For each block, a disparity range to be tested using the WTA method is obtained by re-applying the 3DRS assumption that the correspondence vectors of a block's spatio-temporal neighborhood can be good estimates of the final result. Based on the user-defined parameter r, an initial disparity range is assigned to the estimated block and the blocks in its 8-neighborhood. Finally, a union of individual disparity ranges of blocks within the 8-neighborhood is performed to obtain a list of disparity hypotheses to be tested within the WTA optimization step.

The parameter r limits the range of disparity hypotheses evaluated per each block within the 8-neighborhood to $[d - r, ..., d + r]$, where d is the result of the 3DRS disparity estimation for each given block. In the optimum case where all of the 3DRS results in the 8-neighborhood are equal and the ranges perfectly match, the total number of hypotheses to test is $2 * r + 1$, the size of a single initial range. In the extremely unlikely worst case where the disparity ranges of within the 8-neighborhood do not intersect, the total number of disparity hypotheses to be evaluated is $9 * (2 * r + 1)$.

A comparison of the best and worst case for a typical range of input disparities is shown in Table I. While most local methods expect the user to specify a certain disparity search range to optimize the performance, the proposed hybrid method will address any range of disparities which occurs in the input stereo pair with constant performance.

end for
```

IV. EVALUATION

The proposed method was implemented in software within a simulation environment built specifically for testing stereo algorithms. The motivation of designing our own simulation environment was to reduce the dependency of the algorithm on external libraries as much as possible, in order to facilitate subsequent hardware implementations of the tested methods. Individual 3DRS and WTA implementations were developed and tested first. All methods operate on 8-bit grayscale images.

The 3DRS implementation does not include advanced optimizations such as hierarchical processing or penalties [17], but supports multiple iterations to improve algorithm convergence on static images. SAD and ZSAD [8] cost functions can be utilized for block matching. The WTA implementation implements the basic algorithm as denoted in Eq.6 with $w(p, q) = 1$. Traditional square windows, without shifting or specific filtering, are used to aggregate the cost values, for which both SAD and SSD cost functions can be used. Cost aggregation is accelerated with the use of integral images similar to the technique in [10]. The proposed method implementation follows Alg.1 directly. A WTA matching algorithm utilizing an image pyramid and a coarse-to-fine disparity optimization was additionally implemented to compare the proposed method with a different coarse-to-fine optimization method. The environment does not implement a sub-pixel disparity refinement step after the optimization, as the goal of the

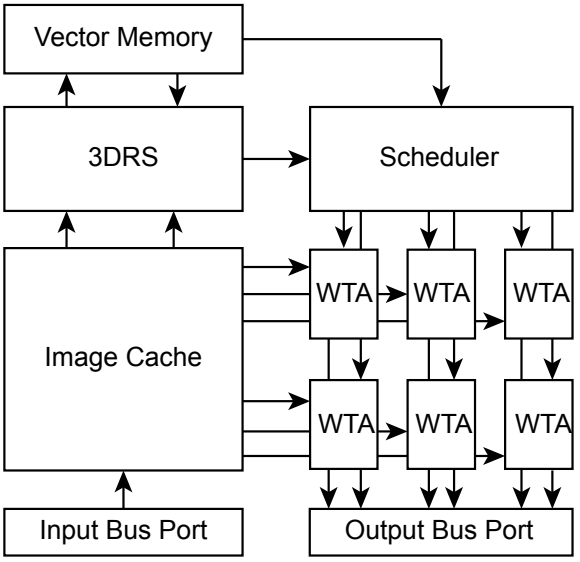

Fig. 7. Envisioned Hardware Architecture for the proposed method.

evaluation was to compare raw results of the optimization methods.

In our evaluation of the algorithm, we have measured two aspects of quality for the implemented methods. The first is the accuracy of the output results indicated by the percentage of incorrect pixels

$$B = \frac{1}{N} \sum_{(x,y)} (|d_C(x,y) - d_T(x,y)| > \delta_D) \qquad (7)$$

where d_C is the estimated disparity map, and d_T is the ground truth disparity map [1]. The threshold δ_D is 1. The second aspect is the algorithm run-time performance, indicated by the computation time. The method was tested on reference images from the Middlebury set [2]: "Tsukuba", "Venus", "Teddy" and "Cones". The resultant disparity maps are shown in Figure 6.

The measured accuracy results in Table II show that the 3DRS algorithm can provide coarse results with a level of accuracy comparable to the dense stereo optimizations such as the WTA, at a fraction of the computational complexity. The accuracy of the WTA method is typical for a fixed window implementation with the chosen window size of 15 ([1], Figure 11), although the results for the images "Teddy" and "Cones" exhibit an offset due to a large number of occluded pixels not excluded from evaluation. However, it is obvious that the proposed hybrid method either retains the accuracy of the WTA method or slightly improves it. The results of the WTA Pyramid method are similar to WTA while slightly lower in quality due to the lower resolution of reference images at the higher pyramid levels.

The computational time shown in Table III greatly favors the hybrid method in comparison to both the classic and the pyramid version of the WTA. The 3DRS execution time, although an order of magnitude faster, is provided for reference only, as it provides only coarse results.

V. FUTURE WORK AND HARDWARE IMPLEMENTATION

In our future research, we plan to explore the properties of the proposed method to increase accuracy of the results, as well as further improve the performance by evaluating different algorithm settings and cost functions in order to obtain the optimum configuration. The ultimate goal of the research is to develop a computing architecture leading to an efficient hardware implementation of the proposed method in an ASIC or an FPGA integrated circuit. As the WTA evaluations which yield the final dense disparity map are performed over discrete chunks of the image, the method is very suitable for a parallel computing implementation. The envisioned architecture is shown in Fig.7. Our idea is to combine an existing efficent 3DRS hardware implementation with a parallel computing array implementing multiple processing nodes, equipped with local memories required to store the local algorithm data. A shared cache memory should provide left and right image data to the processing units in order to exploit the locality imposed by the 3DRS scanning order. To enhance performance, a pipelined operation is envisioned, with the WTA operations dispatched as soon as the 3DRS results are available. We expect to achieve a real-time performance on high definition video at 60 frames per second.

VI. CONCLUSION

We have presented a new hybrid method for dense stereo matching which combines the 3DRS motion estimator and the classic WTA approach. The proposed method performs significantly better than the classic WTA implementation, while also being insensitive to the range of input disparities. The method is suitable for parallel hardware implementations. Our future work will focus on defining a hardware architecture for the proposed method.

Two Approaches to Derive Approximate Formulae of NILT Method with Generalization

L. Brančík* and N. Smith*
* Brno University of Technology/Department of Radio Electronics, Brno, Czech Republic
brancik@feec.vutbr.cz

Abstract - The paper deals with relationship between two approaches to derive approximate formulae of one specific numerical inverse Laplace transform (NILT) method, which is based on the approximation of the exp(st) function in the definition Bromwich integral, and the method based on the direct numerical integration of this ILT integral. It is shown that respective approximate formulae can also be derived by integrating the Bromwich integral numerically provided the integration path and the step are properly chosen as time-dependent. The generalization of the NILT formulae is also suggested leading to possibility to predict a limiting absolute error. The experimental error analysis is performed in the Matlab program for properly chosen Laplace transforms, and modified usage of Euler transformation to accelerate convergence of infinite series is tested successfully.

I. INTRODUCTION

The Laplace transform is used in many scientific and engineering areas to solve relevant differential equations. In field of the electrical engineering and electronics it is usually the solution of transient processes in linear time-invariant systems. After a given problem is resolved in the Laplace domain, $F(s)$, the inevitable step is to find the original in the time domain, $f(t)$. This is the most difficult part in general as finding original in its analytical form is either impractical, hard or even impossible in some cases. We can e.g. mention transcendental and irrational Laplace transforms which occur in systems with distributed parameters [1]. The numerical inverse Laplace transform (NILT) can thus be an effective tool to overcome these difficulties, when determining the original quite fast and accurately enough for practical purposes.

There is many various NILT methods that distinguish from one another in its accuracy, computation fastness, difficulty at the correct choice of the method's parameters, and its versatility to cover wide range of transforms which can be processed [2] - [6]. This paper is focused on the NILT method in which the inverse kernel of the Laplace transform, that is the exponential function $\exp(st)$, is approximated by relations containing hyperbolic functions sinh(.) and cosh(.), or their combinations [5], [6]. This method does not require the determination of poles of the image $F(s)$ to be inverted, and its accuracy can be improved by increasing the number of terms in the sum and by using the method for acceleration of convergence of the infinite series in the formula for computation of the original $f(t)$. It will be shown that the same NILT formulae can be derived by the other way, namely by direct numerical integration of the ILT Bromwich integral under condition both the integration path and step are chosen properly as time-dependent [7], [8]. Based on this fact the modification of the NILT [6] is suggested while keeping predictability of the absolute error. Experimental error analysis is performed on chosen Laplace transforms in the Matlab language environment, and modified version of the Euler transformation is tested to improve the accuracy. Finally, a practical example of the application to electrical systems with distributed parameters is presented.

Research described in this paper was financed by Czech Science Foundation under grant 15-18288S, by IGA BUT in Brno under grant FEKT-S-14-2281, and by Czech Ministry of Education in frame of National Sustainability Program under grant LO1401. For research, infrastructure of the SIX Center was used.

II. RESUMPTION OF ORIGINAL NILT METHOD

In [6] there is developed the NILT method based on the approximation of the Laplace transform's inverse kernel, $\exp(st)$, in the ILT definition Bromwich integral

$$f(t) = \frac{1}{2\pi \mathrm{j}} \int_{c-j\infty}^{c+j\infty} F(s) e^{st} ds \,, \tag{1}$$

considering assumptions

a) $F(s)$ is regular for $\mathrm{Re}\{s\} > 0$,

b) for $|s| \to \infty$ is $F(s) \to 0$,

c) $F^*(s) = F(s^*)$, by the relations,

by the relations

$$E_s(st, a) = \frac{e^a}{2\sinh(a - st)} \,, \tag{2}$$

$$E_c(st, a) = \frac{e^a}{2\cosh(a - st)} \,. \tag{3}$$

After replacing reciprocal hyperbolic functions by their infinite series expansions (below in a variable z)

$$\frac{1}{\sinh z} = \frac{1}{z} + 2z \sum_{n=1}^{\infty} \frac{(-1)^n}{n^2\pi^2 + z^2} \,, \tag{4}$$

$$\frac{1}{\cosh z} = 2\pi \sum_{n=0}^{\infty} \frac{(-1)^n \left(n + 1/2\right)}{\left(n + 1/2\right)^2 \pi^2 + z^2} \,, \tag{5}$$

and successive application of residual theorem, see [6] for details, it is possible to derive approximate formulae

$$f_s(t,a)=\frac{e^a}{t}\left(\frac{1}{2}F\left(\frac{a}{t}\right)+\sum_{n=1}^{\infty}(-1)^n\,\mathrm{Re}\left\{F\left(\frac{a}{t}+\mathrm{j}n\frac{\pi}{t}\right)\right\}\right), \quad (6)$$

$$f_c(t,a)=\frac{e^a}{t}\sum_{n=1}^{\infty}(-1)^n\,\mathrm{Im}\left\{F\left(\frac{a}{t}+\mathrm{j}\left(n-\frac{1}{2}\right)\frac{\pi}{t}\right)\right\}. \quad (7)$$

On the other hand, by expressing hyperbolic functions by their definition exponential functions, (2) and (3) can be arranged into the form of the sum of infinite geometric series, from which the absolute errors of the formulae (6) and (7) follow, respectively

$$\varepsilon_s(t,a)=\sum_{n=1}^{\infty}e^{-2na}\,f\left((2n+1)t\right), \quad (8)$$

$$\varepsilon_c(t,a)=\sum_{n=1}^{\infty}(-1)^n e^{-2na}\,f\left((2n+1)t\right). \quad (9)$$

The accuracy of the method can further be increased by considering the arithmetic mean of (6) and (7), which leads to an approximate formula

$$f_a(t,a)=\frac{e^a}{2t}\left(\frac{1}{2}F\left(\frac{a}{t}\right)+\sum_{n=1}^{\infty}(-1)^n\left(\mathrm{Re}\left\{F\left(\frac{a}{t}+\mathrm{j}n\frac{\pi}{t}\right)\right\}+\right.\right.$$
$$\left.\left.+\,\mathrm{Im}\left\{F\left(\frac{a}{t}+\mathrm{j}\left(n-\frac{1}{2}\right)\frac{\pi}{t}\right)\right\}\right)\right), \quad (10)$$

and gives an absolute error

$$\varepsilon_a(t,a)=\sum_{n=1}^{\infty}e^{-4na}\,f\left((4n+1)t\right). \quad (11)$$

Designating M as a maximal absolute value of an original $f(t)$, and using a formula for the sum of infinite geometric series, the limiting absolute errors of (6), (7) and (10) are

$$\varepsilon_{sM}(a)=\varepsilon_{cM}(a)=\frac{Me^{-2a}}{1-e^{-2a}}\approx Me^{-2a}, \quad (12)$$

$$\varepsilon_{aM}(a)=\frac{Me^{-4a}}{1-e^{-4a}}\approx Me^{-4a}. \quad (13)$$

It is evident that the absolute errors are adjustable by a proper choice of the parameter $a > 0$. Due to a finite number of terms which can be enumerated at the infinite series in practice, the real errors are higher. To suppress this effect an Euler transformation can be applied which is being used to accelerate alternating infinite series [5], [6]. A principle is that to the sum of N_S terms of the original series another N_E terms is added, but weighted by factors

$$2^{-N_E}V_{N_E-k+1}, \quad (14)$$

$k = 1, 2, ..., N_E$, and where V_r is given recursively as

$$V_{r+1}=V_r+\binom{N_E}{r}, \quad V_1=1. \quad (15)$$

III. Bromwich Integral Numerical Integration

Let's consider the ILT Bromwich integral (1), and the assumptions a) to c). Letting the contour be a vertical line, $s = c + \mathrm{j}\omega$, with c as its distance from the imaginary axis, such that $F(s)$ has no singularities on or to the right of this line, the original function can be evaluated by

$$f(t)=\frac{e^{ct}}{2\pi}\int_{-\infty}^{\infty}F\left(c+\mathrm{j}\omega\right)\left(\cos\omega t+\mathrm{j}\sin\omega t\right)d\omega. \quad (16)$$

Replacing the differential $d\omega$ for the difference Ω and the integration for the summation we get a formula

$$\hat{f}(t)=\frac{e^{ct}\Omega}{2\pi}\sum_{k=-\infty}^{\infty}F\left(c+\mathrm{j}k\Omega\right)\left(\cos k\Omega t+\mathrm{j}\sin k\Omega t\right). \quad (17)$$

In the case that a distance of the integration path from the imaginary axis, c, and the integration step, Ω, are chosen as time-dependent, namely inversely proportional to time in which the original is to be computed

$$c=\frac{a}{t}, \quad (18)$$

$$\Omega=\frac{\pi}{t}, \quad (19)$$

excluding beginning of the time axis, $t \neq 0$, (17) leads to

$$\tilde{f}(t)=\frac{e^a}{2t}\sum_{k=-\infty}^{\infty}F\left(\frac{a}{t}+\mathrm{j}k\frac{\pi}{t}\right)\left(\cos k\pi+\mathrm{j}\sin k\pi\right). \quad (20)$$

In the following two cases will be considered:

1) The summation index in (20) gathers integer values $k = \ldots -2, -1, 0, 1, 2, \ldots$, when this equation becomes

$$\tilde{f}_1(t)=\frac{e^a}{2t}\sum_{k=-\infty}^{\infty}(-1)^k F\left(\frac{a}{t}+\mathrm{j}k\frac{\pi}{t}\right). \quad (21)$$

Now, under assumption c), i.e. $F^*(s) = F(s^*)$, and validity $F(s)+F^*(s)=2\,\mathrm{Re}\{F(s)\}$, we get from (21)

$$\tilde{f}_1(t)=\frac{e^a}{t}\left(\frac{1}{2}F\left(\frac{a}{t}\right)+\sum_{k=1}^{\infty}(-1)^k\,\mathrm{Re}\left\{F\left(\frac{a}{t}+\mathrm{j}k\frac{\pi}{t}\right)\right\}\right), \quad (22)$$

which is, however, a formula corresponding to (6).

2) The summation index in (20) gathers fractional values $k = \ldots -3/2, -1/2, 1/2, 3/2, \ldots$, or substituting $k = l - ½$, it is possible to take integer index $l = \ldots -2, -1, 0, 1, 2, \ldots$. again, when this equation becomes

$$\tilde{f}_2(t)=\frac{e^a}{\mathrm{j}2t}\sum_{l=-\infty}^{\infty}(-1)^l F\left(\frac{a}{t}+\mathrm{j}\left(l-\frac{1}{2}\right)\frac{\pi}{t}\right). \quad (23)$$

Now, under assumption c), i.e. $F^*(s) = F(s^*)$, and validity $F(s)-F^*(s)=\mathrm{j}2\,\mathrm{Im}\{F(s)\}$, we get from (23)

$$\tilde{f}_2(t) = \frac{e^a}{t}\sum_{l=1}^{\infty}(-1)^l \operatorname{Im}\left\{F\left(\frac{a}{t} + \mathrm{j}\left(l-\frac{1}{2}\right)\frac{\pi}{t}\right)\right\}, \quad (24)$$

which is, however, a formula corresponding to (7).

From a geometric viewpoint, (22) and (24) correspond to a rectangular integration method, with the difference in a shift by half of the integration step (19).

Now, we will consider the integration step halfway in relation to (19), nameky

$$\Omega = \frac{\pi}{2t}, \quad (25)$$

while the Bromwich integration path is kept according to (18). Then (17) results in

$$\hat{f}(t) = \frac{e^a}{4t}\sum_{k=-\infty}^{\infty} F\left(\frac{a}{t} + \mathrm{j}k\frac{\pi}{2t}\right)\left(\cos k\frac{\pi}{2} + \mathrm{j}\sin k\frac{\pi}{2}\right). \quad (26)$$

Let the summation index be chosen again as integer, i.e. k = … –2, –1, 0, 1, 2, …. Then we get from (26)

$$\hat{f}(t) = \frac{e^a}{4t}\sum_{k=-\infty}^{\infty} \mathrm{j}^k F\left(\frac{a}{t} + \mathrm{j}k\frac{\pi}{2t}\right). \quad (27)$$

Considering again assumption c), $F^*(s) = F(s^*)$, identities $F(s) + F^*(s) = 2\operatorname{Re}\{F(s)\}$, $F(s) - F^*(s) = \mathrm{j}2\operatorname{Im}\{F(s)\}$, and collecting pairs of terms with neighbouring indexes, we get a result

$$\hat{f}(t) = \frac{e^a}{2t}\left(\frac{1}{2}F\left(\frac{a}{t}\right) + \sum_{k=1}^{\infty}(-1)^k\left(\operatorname{Re}\left\{F\left(\frac{a}{t} + \mathrm{j}k\frac{\pi}{t}\right)\right\} + \right.\right. \\ \left.\left. + \operatorname{Im}\left\{F\left(\frac{a}{t} + \mathrm{j}\left(k-\frac{1}{2}\right)\frac{\pi}{t}\right)\right\}\right)\right), \quad (28)$$

which is, however, a formula corresponding to (10).

If shifting the integration step by its half a resulting formula does not directly correspond to the original method [6].

IV. Proposed NILT Generalization

Some examples of the numerical inversion of typical Laplace transforms through approximate formulae (6), (7), and (10), incl. the experimental verification of limiting absolute errors (12) and (13), are presented in [6]. As was shown in previous chapter, however, these formulae are implicitly present in (17), while properly choosing parameters c, Ω, and a set of summation indexes. Let's adopt generalization when the integration step is further decreasing in compliance with

$$\Omega = \frac{\pi}{mt}, \quad (29)$$

m integer, while keeping c as in (18). Then (17) results in

$$\hat{f}(t) = \frac{e^a}{2mt}\sum_{k=-\infty}^{\infty} F\left(\frac{a}{t} + \mathrm{j}k\frac{\pi}{mt}\right)e^{\mathrm{j}k\frac{\pi}{m}}. \quad (30)$$

In the following we restrict the summation index to run integers k = … –2, –1, 0, 1, 2,…. The reason is that at the integration step (19) the limiting error is almost the same for fractional indexes, see (12), the difference is at a sign of absolute errors, cp. (8), (9). It is therefore expectable, when shifting the index k by ½, no significant change in errors occurs neither for the other Ω. Then (30) leads to

$$\hat{f}(t) = \frac{e^a}{2mt}\left(F\left(\frac{a}{t}\right) + \sum_{k=1}^{\infty}\left(F\left(\frac{a}{t} + \mathrm{j}k\frac{\pi}{mt}\right)e^{\mathrm{j}k\frac{\pi}{m}} + \right.\right. \\ \left.\left. + F\left(\frac{a}{t} - \mathrm{j}k\frac{\pi}{mt}\right)e^{-\mathrm{j}k\frac{\pi}{m}}\right)\right), \quad (31)$$

when, after considering assumption c), $F^*(s) = F(s^*)$, and identity $F(s) + F^*(s) = 2\operatorname{Re}\{F(s)\}$, a result is

$$\hat{f}(t) = \frac{e^a}{2mt}\left(F\left(\frac{a}{t}\right) + 2\sum_{k=1}^{\infty}\operatorname{Re}\left\{F\left(\frac{a}{t} + \mathrm{j}k\frac{\pi}{mt}\right)e^{\mathrm{j}k\frac{\pi}{m}}\right\}\right). \quad (32)$$

After considering $\operatorname{Re}\{F_1(z)\cdot F_2(z)\} = \operatorname{Re}\{F_1(z)\}\cdot\operatorname{Re}\{F_2(z)\} - \operatorname{Im}\{F_1(z)\}\cdot\operatorname{Im}\{F_2(z)\}$, (32) leads to

$$\hat{f}(t) = \frac{e^a}{mt}\left(\frac{1}{2}F\left(\frac{a}{t}\right) + \sum_{k=1}^{\infty}\left(\operatorname{Re}\left\{F\left(\frac{a}{t} + \mathrm{j}k\frac{\pi}{mt}\right)\right\}\cos k\frac{\pi}{m} - \right.\right. \\ \left.\left. - \operatorname{Im}\left\{F\left(\frac{a}{t} + \mathrm{j}k\frac{\pi}{mt}\right)\right\}\sin k\frac{\pi}{m}\right)\right). \quad (33)$$

When substituting $m = 1$ we can see the sine function is zero for all the k, while the cosine function alternates its sign, a result is (22). In case of $m = 2$, either the sine or cosine function is always zero, then after collecting pairs of terms with neighbouring indexes and taking into account alternation of the sign, we get (28).

Taking into account relations between the integration steps (19), (25), and the limiting absolute errors (12), (13), respectively, we suggest to generalize these error formulae to cover also the above NILT (33) as

$$\varepsilon_M(a,m) \approx Me^{-2ma}. \quad (34)$$

As this formula does not have direct support in the theory of the original NILT [6], it will be in the first instance verified numerically on chosen Laplace transforms with known originals in the time domain.

V. Experimental Error Analysis

For the experimental error analysis with the intention to confirm (34) we choose the Laplace transforms whose originals reach limiting absolute values $M = 1$ to be able to easily conclude about errors, see Tables I to III, and Fig.s 1 to 6. In Table IV and Fig. 7, examples for time delayed originals with discontinuities are shown.

TABLE I. TESTING LAPLACE TRANSFORMS AND THEIR ORIGINALS.

i	$F_i(s)$	$f_i(t)$
1	$\frac{1}{s}$	unit step, $1(t)$
2	$\frac{s}{s^2+\omega^2}$	$\cos \omega t$
3	$\frac{e^{-\sqrt{s}}}{s}$	$\operatorname{erfc}\left(\frac{1}{2\sqrt{t}}\right)$

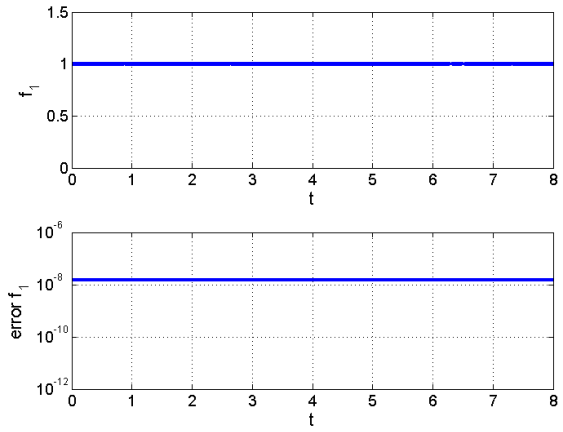

Figure 1. NILT results for $F_1(s)$ and $m = 3$

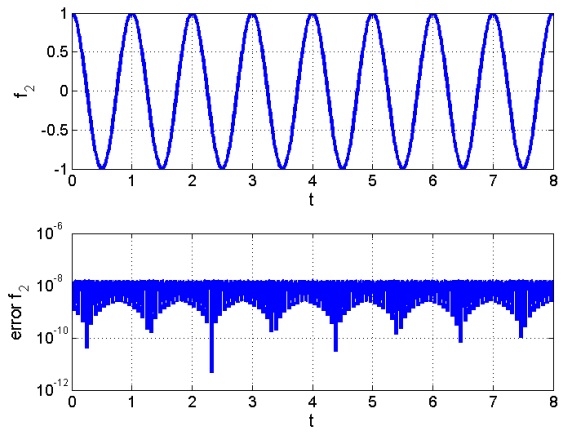

Figure 2. NILT results for $F_2(s)$ and $m = 3$

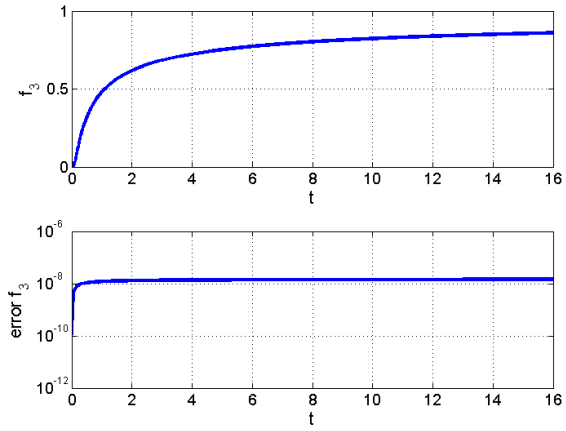

Figure 3. NILT results for $F_3(s)$ and $m = 3$

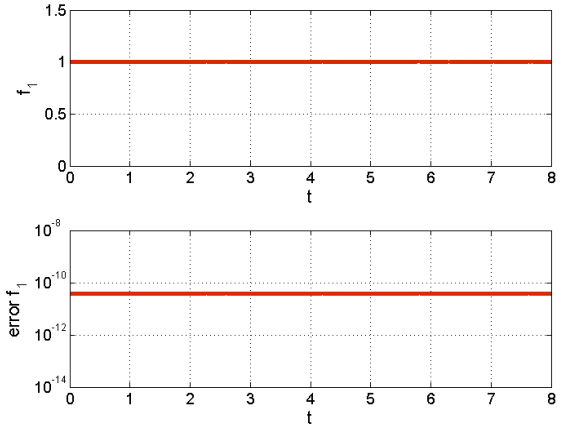

Figure 4. NILT results for $F_1(s)$ and $m = 4$

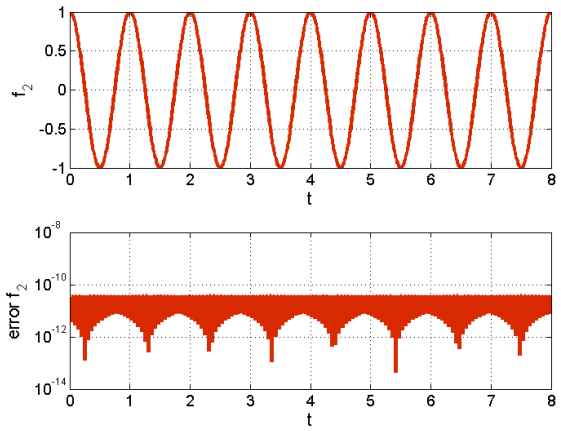

Figure 5. NILT results for $F_2(s)$ and $m = 4$

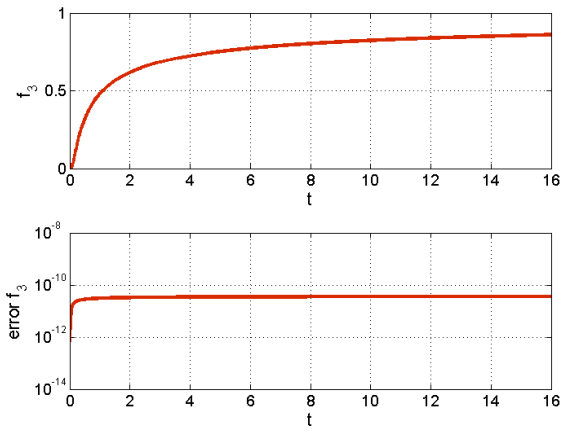

Figure 6. NILT results for $F_3(s)$ and $m = 4$

The other parameters of the NILT (33) are as follows: $a = 3$, $N_S = 100$ and $N_E = m \times 19$. The last item, a number of terms for the Euler transformation to accelerate the convergence of the infinite series, must be explained in more details. This transformation is efficient enough for alternating series only which is well fulfilled in case of $m = 1$ when its basic version (14), (15) can be used. In case of $m > 1$, however, the terms of series (33) do not alter with each change of the summation index k, therefore its modified version was applied when individual weights

are used repeatedly on neighbouring terms, namely m times. Based on a number of experiments, just such a choice seems to be well applicable. Even if the graphical results are shown only for $m = 3, 4$, to better quantify the errors, the computation was performed to get mean errors over 1000 time points, taking into account m from 1 to 4, see Table II.

TABLE II. MEAN VALUES OF ASOLUTE ERRORS ($a = 3$).

m	1	2	3	4
$\bar{\varepsilon}_{M1}$	$\mathbf{2.48\cdot10^{-3}}$	$\mathbf{6.14\cdot10^{-6}}$	$\mathbf{1.52\cdot10^{-8}}$	$\mathbf{3.78\cdot10^{-11}}$
$\bar{\varepsilon}_{M2}$	$1.58\cdot10^{-3}$	$3.91\cdot10^{-6}$	$9.69\cdot10^{-9}$	$2.40\cdot10^{-11}$
$\bar{\varepsilon}_{M3}$	$2.11\cdot10^{-3}$	$5.41\cdot10^{-6}$	$1.37\cdot10^{-8}$	$3.43\cdot10^{-11}$
theory	formulae (22), (24), see [6]		confirmation of (34)	
	$\mathbf{2.48\cdot10^{-3}}$	$\mathbf{6.14\cdot10^{-6}}$	$\mathbf{1.52\cdot10^{-8}}$	$\mathbf{3.78\cdot10^{-11}}$

We can see that for a unit step function these mean errors correspond almost exactly with the theory (highlighted by bold font styles), for the other functions the mean errors are even slightly less. If (34) is valid, the same or at least very close results should be obtained when keeping the product ma constant, see Tables II and III where is kept $ma = 3, 6, 9$, and 12.

TABLE III. MEAN VALUES OF ASOLUTE ERRORS ($m = 1$).

a	3	6	9	12
$\bar{\varepsilon}_{M1}$	$\mathbf{2.48\cdot10^{-3}}$	$\mathbf{6.14\cdot10^{-6}}$	$\mathbf{1.52\cdot10^{-8}}$	$\mathbf{1.88\cdot10^{-11}}$
$\bar{\varepsilon}_{M2}$	$1.58\cdot10^{-3}$	$3.91\cdot10^{-6}$	$9.69\cdot10^{-9}$	$3.02\cdot10^{-11}$
$\bar{\varepsilon}_{M3}$	$2.11\cdot10^{-3}$	$5.21\cdot10^{-6}$	$1.29\cdot10^{-8}$	$3.34\cdot10^{-11}$

From theoretical viewpoint is interesting that there are two possibilities how to improve the NILT accuracy, either by increasing the parameter a, which is in fact also a distance from the imaginary axis when applying a residue theorem in [6], and while keeping the integration step constant, or by decreasing the integration step while conversely fixing the parameter a on a constant value.

Hereafter, examples of the application of the NILT method to Laplace transforms leading to delayed original functions with discontinuities are presented, see Table IV.

TABLE IV. LAPLACE TRANSFORMS AND RELATED DELAYED ORIGINALS.

i	$F_i(s)$	$f_i(t)$
4	$\frac{e^{-s}}{s}$	delayed unit step $\underline{1}(t-1)$
5	$\frac{1}{s\left(1-e^{-s}\right)}$	staircase function

In this case, due to a Gibbs' effect, it is not possible to suppress effectively swings in a vicinity of discontinuities, as is obvious from Fig. 7. The acceleration of convergence of infinite series has lower effect here, and to improve the accuracy, the increasing number of terms in the sum to be evaluated has to be considered. As was already discussed in [6], slopes of delayed functions at their discontinuities depend just on a value of the delay. That is why, to keep the same precision when inverting such a kind of Laplace transforms a number of terms in the sum can be increasing according to the actual time.

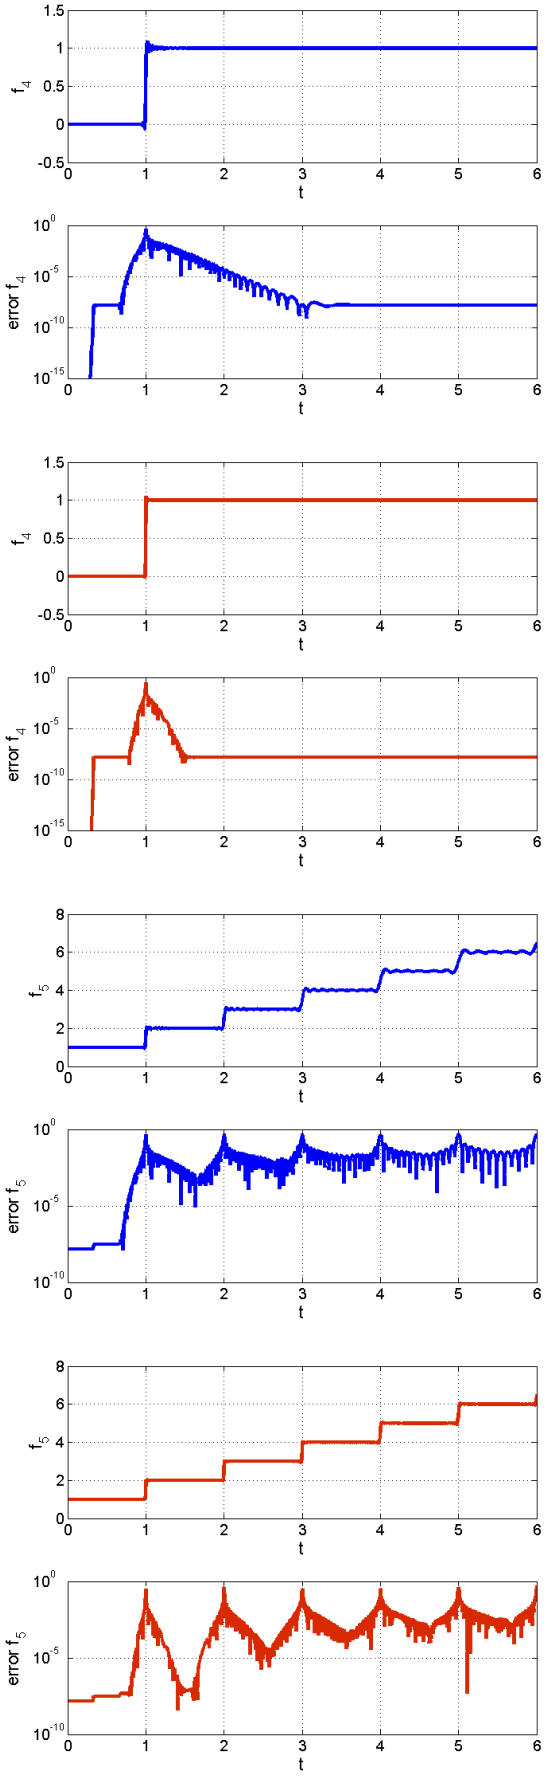

Figure 7. NILT results for $N_S = 50$, $N_E = 25$ (blue), $N_S = 200$, $N_E = 100$ (red), and $ma = 9$.

VI. Application in Electrical Engineering

Often applications of the NILT methods are to process Laplace transforms arising from the solution of systems with distributed parameters in which transcendental and irrational functions occur. As the example, let's consider a uniform lossy transmission line (TL) of the length l, being terminated in both ends by linear networks (or their Thévenin equivalents), see Fig. 8 [9].

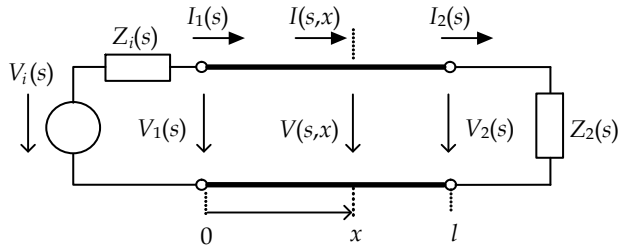

Figure 8. TL's Laplace-domain model with terminations

Our task is to determine a voltage waveform in the middle of the TL, i.e. $v(t,x)$, for $x = l/2$. The Laplace transform of the solution is [9]

$$V(s,x) = V_i(s)\frac{Z_c(s)}{Z_i(s)+Z_c(s)}\cdot\frac{e^{-\gamma(s)x}+\rho_2(s)e^{-\gamma(s)[2l-x]}}{1-\rho_1(s)\rho_2(s)e^{-2\gamma(s)l}}, \quad (35)$$

where $Z_c(s)$ and $\gamma(s)$ are the characteristic impedance and the propagation constant, respectively, equal

$$Z_c(s) = \sqrt{\frac{R_0+sL_0}{G_0+sC_0}}, \quad (36)$$

$$\gamma(s) = \sqrt{(R_0+sL_0)(G_0+sC_0)}, \quad (37)$$

with R_0, L_0, G_0, and C_0 as per-unit-length parameters, and $\rho_1(s)$, $\rho_2(s)$ as reflection coefficients in the TL's beginning and end, respectively, equal

$$\rho_1(s) = \frac{Z_i(s)-Z_c(s)}{Z_i(s)+Z_c(s)}, \quad (38)$$

$$\rho_2(s) = \frac{Z_2(s)-Z_c(s)}{Z_2(s)+Z_c(s)}. \quad (39)$$

Generally, in case of a lossy TL, an analytical form of the original cannot be found, thus just a proper NILT method should be utilized. Let's consider parameters as follows: $l = 1$ m, $R_0 = 1$ mΩ/m, $L_0 = 600$ nH/m, $G_0 = 2$ mS/m, $C_0 = 80$ pF/m, $Z_i = 10$ Ω, and $Z_2 = 1$ kΩ. The excitation voltage has a waveform $v_i(t) = \sin^2(\pi t/2\cdot10^{-9})$, if $0 \le t \le 2\cdot10^{-9}$, $v_i(t) = 0$, otherwise, with the Laplace transform

$$V_i(s) = \frac{2\pi^2\left(1-\exp(-2\cdot10^{-9}s)\right)}{s\left((2\cdot10^{-9}s)^2+4\pi^2\right)}. \quad (40)$$

The graphical result is presented in Fig. 9, when using the NILT parameters as in Fig. 7 (red).

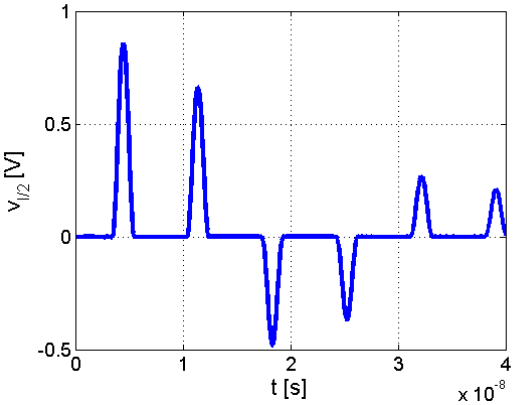

Figure 9. Voltage waveform in the middle of TL

VII. Conlusion

It is shown in the paper that the NILT formulae in [6] can also be derived by another way, through the direct numerical integration of the ILT Bromwich definition integral, namely if both a distance of the integration path from the imaginary axis and the integration step are suitable chosen as time-dependent. Further generalization was done towards the NILT formula which enables to increase the accuracy by decreasing the integration step, while allowing to predict a limiting absolute error. This approach can be regarded as an alternative way how to improve the accuracy, as in the NILT [6], this is already possible by increasing a, which is, on principle, a distance to the imaginary axis. In fact, both ways can be combined as is supposed by (34). In this case, however, the Euler transformation had to be applied with some modifications to ensure its efficiency. Thus other acceleration techniques will be investigated for this purpose, especially those also applicable on non-alternating series. Using the Matlab, CPU times were around tens of miliseconds for individual originals, and last example took about 400 ms.

zeljko.stojanovic@tvz.hr

Abstract - Laboratory exercise for amplifier class B/AB for sophomore is described. In the first part, the influence of quiescent current and input signal amplitude on output signal waveform distortion and amplifier efficiency is examined. Output signal waveform is observed in time domain qualitatively and in frequency domain quantitatively. In second part, amplifier's output resistance is measured. In each measurement students have to reason out measurement results, the difference between measurement results and analytical results and measurement uncertainty. Students learn concepts of quiescent point, harmonic distortion, power, output resistance and measurement uncertainty by encompassing different areas of electrical engineering – electronics, circuit and signal analysis, power analysis and measurements.

I. INTRODUCTION

Amplification of a signal is one of the main issues of analog electronics. Teaching amplifiers takes the most of the time in general analog electronics courses. It is not just that amplifiers play important, usually hidden role in many areas of human activities, but it is very interesting from educational point of view because it encompasses a variety of circuit analysis techniques related with different amplifier characteristics and levels of analysis. There are also different demands for amplifier characteristics. They depend on amplifiers purpose and they are often opposed one to each other. Essential characteristics for power amplifiers are output power, efficiency and linearity. Considering the quiescent point, power amplifiers are divided into classes like A, B, AB, C, D and others [1, 2, 3]. Amplifier classes are usually taught at sophomore level. On Polytechnics of Zagreb it is taught in courses Analog circuits and Electronic circuits. Freshmen are already introduced with concepts of quiescent point, power and efficiency, distortions and Thevenin theorem.

In this article laboratory exercise of class B/AB amplifier for sophomore [4] will be described and the main learning outcomes of the exercise will be pointed out.

Laboratory work generally helps students to become good engineers in many ways. It helps in proving and improving theory concepts, improves procedural knowledge, social skills and so on. The aim of the article is to remind teachers on varieties of circuit analysis techniques applicable for amplifier class B/AB analysis. Class B amplifiers are especially important from educational point of view, because they exhibit crossover distortion, and it is easy to approximately calculate powers and efficiency. Both classes are appropriate to learn adjustment of quiescent point. We think that power analysis in analog circuits is somewhat neglected. So, it is important to exercise power calculus, and these amplifiers are simple and concrete example for calculating powers. Importance of harmonic analysis is also one of our aims. This exercise is suitable as an introducing exercise for class D on higher level courses. One can compare class B, AB and class D efficiency and harmonic distortions. Further, impact of temperature on quiescent point and its consequences on power and harmonic analysis is also suitable way of investigation. At the end, adjusting, measuring and matching/bridging output impedance is important as an example of Thevenin theorem application or for power and efficiency consideration, small and large signal considerations and etc. One should be aware that there is a risk of overloading students with too many or too complex theory and measurement skills [5]. So, we will specify "basic measurements" which are obligatory to all students and "extensions of measurement" which is optional and suitable for earning higher grades as homework, project or as a thesis.

In exercise description all obligatory tasks during laboratory exercise will be presented and all parts that are considered as important will be commented. It is estimated 90 minutes to finish whole exercise. Some of optional tasks will be suggested as extensions of measurements. The extensions of measurement will not be analyzed in details. We think it is too broad for this article. We want to use those extensions to attract students and to increase their interest for electrical engineering.

II. DESCRIPTION OF THE EXERCISE

A. General considerations

Students have to test and compare three different amplifier configurations. One of them is class B amplifier, and the other two are low-bias and high-bias class AB amplifier [4].

There is always a compromise between benefits of assembling a circuit and loss of time for doing measurements and conclusions. We think that assembling a circuit is more important only for introductory courses and it is not so in this case. So, according to our and others [5] experience we decided to base the exercise on

conducting measurements and making conclusions, but we forced students to identify each component of physical realization of amplifier at the beginning of the laboratory exercise.

Before each measurement students have to assume the measurement results. After measurement they have to explain and comment measurement uncertainty and eventual differences between assumption and measurement results. If they are intrigued and interested they are encouraged to elaborate any part of exercise as a homework or research.

At the beginning of the exercise students are aware of its specificities and about differences between principal schematic and physical realization of the amplifier. The physical realization of amplifier is presented in Fig. 1 and its schematic is presented in Fig. 2.

B. Measurement setup

There are some differences between principle schematics and physical realization of the amplifier:

- Additional resistors R_D, R_{E1} and R_{E2} are used to fulfill thermal stability of quiescent point.
- Diodes D_1 and D_2 are also used to fulfill thermal stability of quiescent point. They are mounted together with transistors on the same heat sink [1, 5].
- Emitter resistors R_{E1} and R_{E2} are additionally useful for emitter current measurement by measurement of resistors voltage.
- Diode D_3 is used for protection of wrong polarity of supply voltage.

Change of amplifier class was realized by mechanical three-position switch. For the switch in position 1, 2 and 3 the amplifier works as a class B, low-bias class AB and high-bias class AB respectively. The single power supply was chosen because it was a smaller equipment requirement than dual power supply. The frequency of 500 Hz is chosen in order to put attention on frequency dependent and "partly accurate" measurement results obtained using ordinary multimeter. We think that each teacher should choose frequency according to his/her learning outcomes.

C. Quiescent point

Students are often unsecure in definition, and what is more important in meaning of quiescent point. The meaning of quiescent point becomes clearer in distortion considerations and in power considerations so main learning outcomes of this measurement are connected with distortion and power measurement.

Basic measurements: Depending on switch position there are three different amplifier configurations and three quiescent points. Students have to measure base-emitter voltage and emitter current for each configuration. Then, they have to determine which switch position is associated with particular amplifier configuration and to argue their conclusion. The teacher should immediately check their conclusion and comment it. The intention is to accentuate low-bias class AB amplifier and to keep it on mind and compare it with high-bias class AB and class B amplifier in later measurements. One another intention is to notice differences in base-emitter voltages between themselves and difference from the default value of 0,7 V.

Extensions of measurements: To embed potentiometer instead of resistor R_D in order to make measurements for any quiescent point. We think it is not suitable when group of students is doing exercise at the same time, because it is difficult to achieve equable quiescent point for each student in a group so it is not so easy to compare their measurement results.

D. Distortions of output signal

The amplifier is very suitable for study of various distortions of output signal. There are several sources of distortion [1, 2, 3]. Students are scenically introduced with crossover distortion, clipping distortion and distortion caused by nonlinearities of semiconductor components. It is important to underline to students that distortion of output signal is inevitable, because amplifier is consisted of transistors which *v-i* characteristics is nonlinear.

Basic measurements: There are two values of input

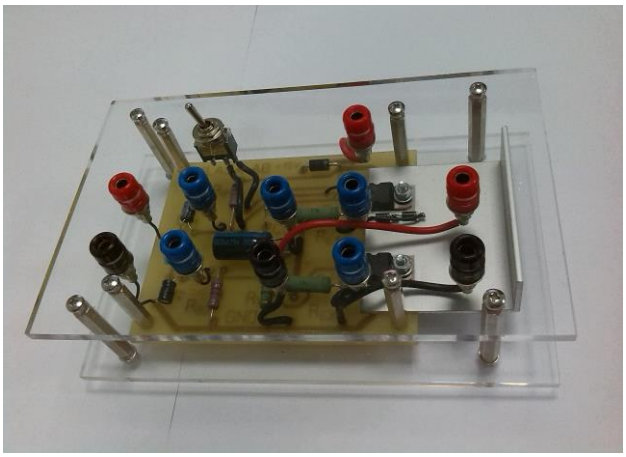

Figure 1. Physical realization of amplifier used in laboratory exercise.

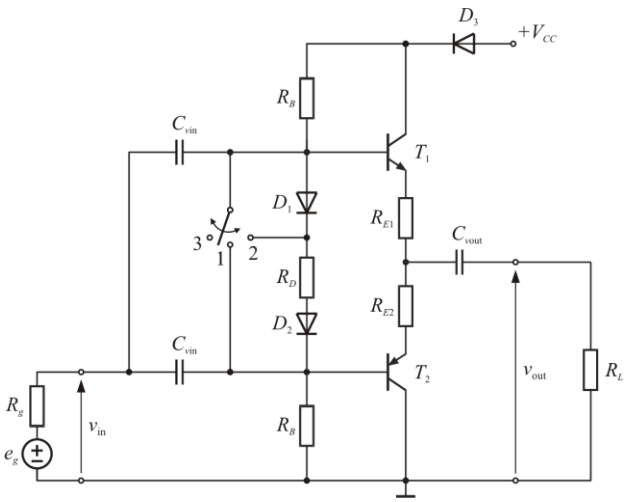

Figure 2. Schematic of amplifier used in laboratory exercise.

voltages. The smaller amplitude is 0,5 V in order to emphasize impact of threshold on signals having amplitude around base-emitter threshold voltage. The bigger amplitude was 5 V in order to reduce impact of crossover distortion on output voltage measurement. For each value of input voltage students have to measure output voltage for every switch position. Then, they have to reason differences between input and output voltage and between output voltages each other. The teacher should immediately check their conclusion and comment it. Typical measurement results are presented in Fig. 3. Students should associate these results with quiescent point determined in previous measurement.

The main learning outcomes are:

- To recognize various types of distortion and to associate them with their cause.
- To notice distortion dependence of quiescent point.
- To raise curiosity about signal distortion.

It is decided to use input voltage as a reference parameter instead of output voltage or output power because the goal was to direct the attention to crossover distortion.

Extensions of measurements: Although the distortion of output signal is very obvious it is useful in several ways to make harmonic analysis of output signal. Typical measurement results are presented in Fig. 4. The amount of higher harmonics is the biggest in "pure" class B amplifier and the smallest in high-bias class AB amplifier. It is obvious that decreasing of distortion is related with biasing. Students should associate these results with quiescent point determined in previous measurement. This measurement will also help students in understanding of Fourier analysis. It can be an introduction to Fast Fourier transform (FFT) and a way to properly choose type and width of FFT window. Students can also calculate total harmonic distortion (THD). Furthermore, it is very suitable to compare results obtained using FFT and using ordinary multimeter and True-RMS multimeter. Under certain conditions it is even better to use loudspeaker and hear the distortion. Obstacles in broader involving of FFT is that students learn FFT based signal analysis first time in later courses, but deficiency of measurement equipment also. So, this part of measurement is used only for earning higher grades through project or as graduation thesis.

E. Power and efficiency

High efficiency is one of essential amplifier characteristics especially nowadays, because energy consumption is becoming more and more important. Transistor power loss is easy to notice by touching the heat sink because the temperature of heat sink will be changed by varying the amplitude of input signal [2]. Students should be aware that efficiency in real use of

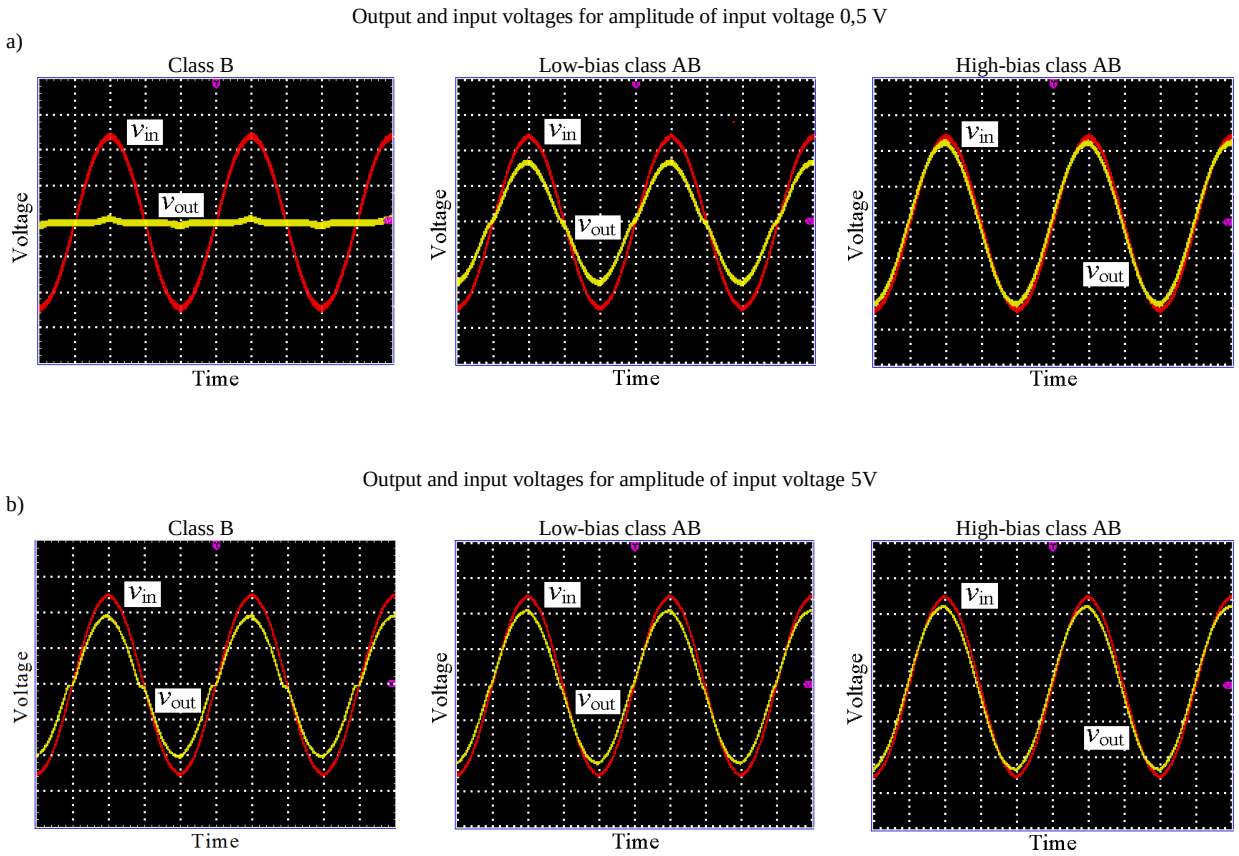

Figure 3. Input and output voltage waveforms:
a) Input voltage $\hat{V}_{in}$ = 0,5 V . Sensitivities 500 µs/div, 200 mV/div

b) Input voltage $\hat{V}_{\text{in}} = 5$ V . Sensitivities 1 kHz/div, 10 dB/div, Blackman window

amplifiers is much lower than maximum theoretical efficiency, not only because of inevitable power losses, but because input signal is most of the time much lower than the value which gives maximum output swing.

Basic measurements: There are three values of input voltages and two amplifier configurations – class B and high-bias class AB. The biggest value is the one give the maximum output swing in order to achieve the highest efficiency. The other two values are one half and one fourth of the maximum output swing. For each amplifier configuration and each input voltage students have to measure output voltage and calculate load power and supply voltage power. There are several ways to calculate/measure powers. It is possible to find load power using oscilloscope in time or frequency domain (FFT) or by using ordinary multimeter or True-RMS multimeter. Before making power calculations students have to comment the method they suggest to use. The teacher should immediately check their comments and recommend or approve method according to his/her learning outcomes and available instruments. Considering the time consumption, authors suggest use of waveforms obtained by oscilloscope or ordinary multimeter readings.

The main learning outcomes are:

- To exercise and learn converting from effective to average values of current/voltage in power calculus of supply voltage.
- To notice the difference between DC and AC components of power.
- To notice maximum efficiency and efficiency dependence on input voltage amplitude and to compare it with maximum theoretical efficiency.
- To notice the difference between maximum efficiency and efficiency feasible in real class AB amplifier excited with real signals which are usually signals of variable amplitude.

At the end of measurement, students have to compare and comment class B and class AB efficiency differences. The differences are too small for making reliable conclusion because they are affected by measurement uncertainty.

Extensions of measurements: Actual values of emitter resistors are $R_{E1} = R_{E2} = 10\ \Omega$, and load resistor is $R_L = 100\ \Omega$ in order to make lower costs and easier amplifier construction. Use of load $R_L = 4\ \Omega - 8\ \Omega$ and appropriate emitter resistors will make exercise more realistic. Under certain conditions it is even better to use loudspeaker. Another task is to check power balance of DC and AC power components separately and altogether.

F. Output resistance

The main learning outcomes are:

- To connect term of output resistance with concepts of Thevenin theorem and source resistance.
- To realize that these concepts are just a way how to descript real components or devices and to use that description (model) to do analysis.

- To notice the difference in small-signal and large-signal analysis or to do considerations about impedance matching/bridging.

These concepts are difficult to master even to the best students, but they do understanding of electrical engineering much easier.

Basic measurements: Output resistance is determined on the base of change of output voltage when the amplifier is loaded with two different loads. Measurement is conducted for default load $R_L = 100\ \Omega$ and another load $R'_L = 100\ \Omega \parallel 10\ \Omega$. Students have to comment the dependence of output voltage on load current and measurement uncertainty of the method.

Extensions of measurements: To use potentiometer as a load and to find the value which gives the half of the swing obtained for unloaded amplifier. Then, to compare results obtained with that method with results obtained by method used in exercise. Further, for the small/large signal considerations it is interesting to compare results obtained for different values of input signal. For general amplifier considerations it is convenient to examine how impedance matching/bridging will affect on whole structure of any amplifier.

III. ACTUAL STUDENT PERFORMANCE

There are many perceived obstacles for successful completion of the exercise. They are connected with general concepts and skills. We will mention and comment obstacles characterizing most of the students during basic measurements:

- Identification of components of physical realization of amplifier at the beginning of the laboratory exercise. This is not usual type of task in regular teaching in Polytechnics of Zagreb.
- Writing of explanations and conclusions. We think that writing skills are low for many students of technical area, not only in our Polytechnics but in whole country and we believe it is the same in whole world. So, if the teacher insists on proper writing students are not able to finish whole exercise.
- Correct notation of circuit variables and correct and clear notation of waveforms. We think that teachers should be more consciousness about that problem and they should increase their effort in correcting student's mistakes.
- Many of students do not make difference between effective and average value.
- Students believe that $P = UI$ works always regardless of the electrical component. It is hard to change first knowledge about electrical power acquired in their previous education or courses.
- Understanding of concept of output impedance. Understanding of Thevenin theorem is big obstacle for most of students. Dichotomous role of amplifier as load for input signal and as source for output signal also complicate understanding of amplifier parameters.

Successful parts of the exercise are connected with concepts specific to amplifiers and power amplifiers. We will mention and comment perceived one:

- Measuring of quiescent point. It is classic procedure in every laboratory exercise.
- Using of oscilloscope. It is classic procedure in every laboratory exercise, but still can be an obstacle for minority of class.
- Linking quiescent point with distortions.
- Recognition of various types of distortion and linking them with their cause.
- Linking efficiency with amplitude of signal.
- Noticing the difference between DC and AC power components.

Mentioned obstacles are more general concepts (except of identification of components) than successful parts of the exercise, so we believe they are more difficult to master. It is a task and duty for many courses and teachers to improve student's knowledge in these areas.

IV. CONCLUSION

Laboratory exercise of class B/AB amplifier was presented. There are four main topics – quiescent point, distortions of output signal, power and efficiency and output resistance.

Suggestion for basic measurements and extended measurements for each subject are given. The aim was to remind teachers on varieties of circuit analysis techniques applicable for amplifier class B/AB analysis and to create basis for (under)graduate thesis.

Comments of main obstacles in exercise and successful parts are given. We believe that obstacles are of very general nature, so it is a task for many teachers to improve student's knowledge in these areas.

Future work will include simulation of amplifier and implementation of suggested extended measurements in (under)graduate thesis and articles.

Abstract - Digital system design constitutes an essential part of engineering education. Many universities worldwide target the respective courses to field-programmable gate arrays and the relevant design flow. Recent programmable systems-on-chip integrating a processor-based computing system and a programmable logic rely on quite a different design philosophy constituting a new challenge for future engineers. These new trends have to be certainly reflected in the pedagogical activity so that the current students would, in a few years, satisfy the growing industry requirements. In this paper we analyze the new design flow and explore in detail one particular part of it: a possibility of directly generating hardware modules from software specifications through high-level synthesis. The reported teaching method is to be applied in two tightly collaborating Universities: University of Aveiro in Portugal and Tallinn University of Technology in Estonia.

I. INTRODUCTION

Any electrical engineering or computer science/engineering curriculum includes as least one course on digital design [1]. Many universities worldwide target the respective course(s) to Field-Programmable Gate Arrays (FPGA). There are many reasons that certainly justify such a choice. First of all, FPGA are easily reconfigurable by the user and can be employed to implement very different functionalities, from a simple logical gate to a complete microprocessor system. Secondly, different computer-aided design (CAD) tools are readily available that can be used by the students free of charge (frequently, in slightly limited versions, which are nevertheless well suited to educational purposes) [2, 3]. Very same CAD systems are employed in industry, so the students get adequately prepared for future work as engineers. And last but not least, there are many prototyping boards available on the market that include low-cost FPGA and simple peripheral devices, such as buttons, LEDs, switches, 7-segment displays, etc. [e.g. 4, 5]. Therefore the students can design circuits and interact with them through the existing simple peripherals. Moreover, frequently the boards have expansion connectors through which more complex peripheral devices can be connected such as temperature sensors, keypads, organic LED graphic displays, Wi-Fi interfaces and others [6], permitting interesting and varied projects to be proposed to the students. Many of such boards might be acquired for a special academic price and therefore can relatively easily be afforded by both educational institutions and students.

Recently, programmable system-on-chip (SoC) devices have appeared on the market that incorporate on a chip a processing system and a programmable logic. The processing system (PS) is based on general-purpose processing cores and is well suited to support operating systems and to execute software routines. The programmable logic (PL) is a traditional FPGA and is intended to be used for implementing high-speed co-processors/subsystems. Both the PS and the PL are linked through a variety of high-speed connections. This kind of chips brings a number of advantages over both traditional FPGAs and general-purpose processors because a single chip can potentially replace two devices resulting in cost saving. This is also true that the new kind of chips, to be appreciated at fullest, is more difficult to program comparing to a standalone FPGA or a processor. Actually, the traditional FPGA design flow is being largely revised and these new trends have to be certainly reflected in the pedagogical activity so that the current students would, in a few years, satisfy the growing industry requirements.

In this paper we analyze the new design flow and explore in detail one particular part of it: a possibility of directly generating hardware modules from software specifications through high-level synthesis. The rest of the paper is organized in five sections. Section II briefly introduces the targeted programmable SoC and analyzes the SoC design flow. Section III explores high-level synthesis design flow. Section IV presents an example of a typical student project that makes use of high-level synthesis. Section V discusses difficulties and challenges that arise with inclusion of the latest programmable SoCs to the educational process. Concluding remarks are given in section VI.

II. PROGRAMMABLE SOC DESIGN FLOW

One example of a programmable system-on-chip is Zynq-7000 [7] which combines on the same micro-chip an ARM dual-core Cortex™-A9 processor (PS) with a gate array (PL) from either Artix-7 or Kintex-7 FPGA families. Zynq product range comprises a number of devices, all with slightly different features and sizes. The PS is the same - dual core ARM Cortex-A9 with NEON and

This research was supported by EU through European Regional Development Funds, by the institutional research funding IUT 19-1 of the Estonian Ministry of Education and Research, ESF grant 9251, and by Portuguese National Funds through FCT, in the context of the project PEst-OE/EEI/UI0127/2014.

floating point extensions; only the maximum processor clock frequency ranges from 666 MHz to 1 GHz. The main difference lies in the type and density of programmable logic [7]. The smallest Zynq-7000 family member (Z7010) is based on FPGA of Artix-7 family and includes 17,600 look-up tables (LUTs), 35,200 flip-flops, 240 KB of embedded block memory and 80 digital signal processing (DSP) slices. The largest device (Z7100) is an FPGA of Kintex-7 family and has roughly 15 times more logical resources, 2,020 DSP slices, and high-speed communication interfaces.

The design process for Zynq-based devices is supported by Vivado design suite [8-10]. For Zynq, a wide variety of intellectual property (IP) cores is available and the whole design process is mainly targeted to the appropriate selection, integration and interconnection of the IPs. Such an approach permits the design abstraction level to be raised resulting in reduced design cost.

A simplified programmable SoC design flow is presented in Fig. 1. First of all functional requirements are decided upon, followed by the detailed specification and software/hardware partitioning. The realized partitioning is usually not final and can be subsequently adjusted if the designers discover that it is desirable to delegate certain software functions to hardware or vice-versa. Then development and testing of both hardware and software is executed. The designers have at their disposal libraries of pre-tested hardware and software IP modules to be reused. If an own hardware IP has to be developed, a variety of design methods might be used, such as register-transfer level (RTL) design with hardware description languages (HDL) and specification in high-level languages. Whatever is the design specification, it is further synthesized, tested and packaged to an IP to be integrated with other modules. Afterwards verification of both hardware and software is required which would frequently force the designers to go back to correct connections or functionality of certain modules. Finally, the whole system is integrated and tested.

It should be mentioned that the programmable SoC design flow differs significantly from the traditional FPGA design flow [11] and requires novel materials to be integrated in the respective advanced courses on reconfigurable systems.

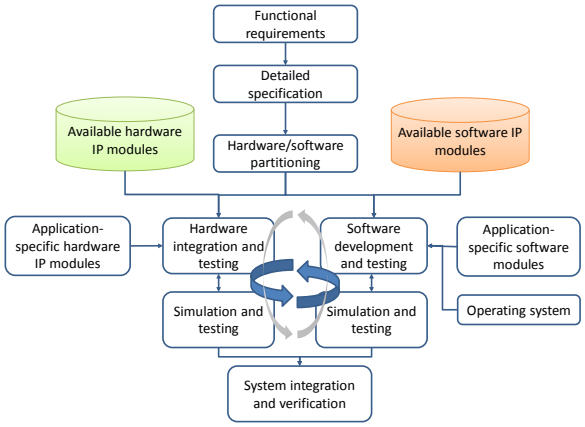

Figure 1. A typical programmable SoC design flow

III. HIGH-LEVEL SYNTHESIS

In this paper we pretend to explore one design possibility allowing hardware IP modules to be generated from high-level specifications. Commercial tools allowing digital circuits to be synthesized from high-level specification (HLS) languages, such as Handel-C and SystemC, appeared on the market in the mid-1990s - early-2000s. These languages are derived from the C language and introduce hardware-oriented extensions, libraries and compiler directives to specify features such as concurrency and timing. This fact allowed the designers to work at a higher level of abstraction. The recent high-level synthesis tools focus on using as many standard C/C++ constructs as possible to capture design intent. This makes the tools much more accessible to algorithm and system designers [12-14].

There are several reasons that force the designers to incorporate HLS languages in their practice [12, 15]:

- The growing design complexity pushes to raise the level of abstraction beyond RTL. HLS specifications allow code density to be reduced significantly compared to HDLs, resulting in increased design productivity.
- The latest HLS tools have made significant progress in providing wide coverage of language features and robust compilation technology that further lead to improved design productivity and reduction in FPGA resource usage compared to hand-coded RTL design.
- The design functionality may be specified for both embedded software and reconfigurable hardware within a programmable SoC. Therefore different software/hardware partitioning boundaries can be experimented and the respective area/performance trade-offs straightforwardly explored.
- HLS permits to leverage the experience of engineers comfortable with C/C++ languages for the purposes of digital design, greatly simplifying the process of converting a software function to a hardware module.
- The available system-level verification methods permit the RTL output to be simulated with the same test bench that was used to check the high-level code. Moreover, the verification and debug may be performed at earlier stages. This significantly reduces the verification effort because the simulation at higher levels runs much faster than at RTL level and the design errors are much easier to locate and fix.

As a result, a growing number of designs are produced using HLS tools in such application domains as video and image processing [16], wireless systems [17], aerospace applications [18], and others [19].

A. *High-level Synthesis Design Flow*

Fig. 2 illustrates a typical HLS design flow on the example of Vivado HLS tool [20, 21]. Basically, Vivado HLS transforms a C design specification into an RTL implementation that in turn can be synthesized [21].

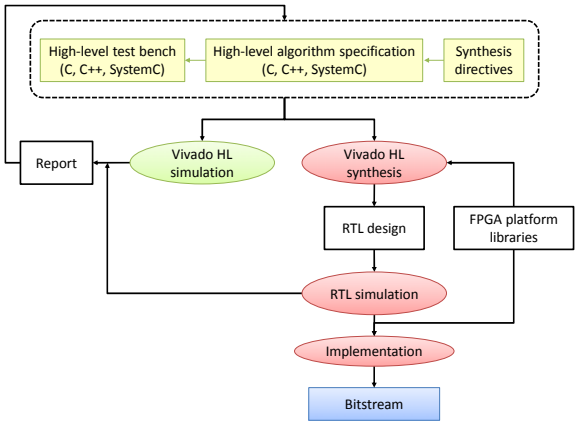

Figure 2. A typical HLS design flow on the example of Vivado

As input, specifications in synthesizable subsets of ANSI-C, C++ and SystemC are accepted [21]. Within further discussion we will limit to using C/C++ languages. The top-level of every C/C++program is the main() function and any function below the level of main() can be synthesized. The function to be synthesized is called the *top-level function* [21]. The main() function is used for verification and is therefore referred to as *test bench*. The test bench permits the behavior of the top-level function to be validated at both high and register-transfer levels.

HLS performs two types of synthesis on the design: algorithmic synthesis (which converts functional statements into RTL statements) and interface synthesis (which transforms function arguments and return values into RTL ports augmented with specific timing protocols) [21]. Synthesis directives permit the designer to improve the results of synthesis by driving the optimization engine towards the desired performance goals and RTL architecture [21]. For example, the designer might indicate which FPGA resources should be used, whether loops should be unrolled and pipelined and so on. The available profiling tool allows performance and resources to be analyzed for every level of design hierarchy and helps to apply the right synthesis directives.

The result of HLS is produced in one of the following languages: VHDL, Verilog, or SystemC [21]. The generated RTL might be verified using the original high-level test bench and is used by Vivado implementation tools to finally generate a bitstream to be uploaded to FPGA/programmable SoC or can be packaged as IP in a number of formats [21] and linked with other design modules developed using different specification methods.

IV. An Example of a Student Project

Fig. 3 illustrates a part of a software/hardware co-design project to be proposed to students which includes high-level synthesis of a single IP module. The designed system has to sort *N* *M*-bit data items with the aid of an iterative even-odd transition network [9, 22]. Sorting networks are very well suited for implementation in programmable logic because the data can be processed in parallel by a series of comparators/swappers as shown in Fig. 3 where an example of sorting *N*=8 integers is given. Every pair of connected black circles represents a comparator/swapper which compares items on its inputs and propagates the greater item to the top output and the smaller item to the bottom output. Two vertical lines of comparators/swappers (enclosed in a dashed rounded rectangle) form even and odd levels of the even-odd transition network. All the comparators/swappers that belong to the same even/odd level, function in parallel.

The data to sort are generated randomly in the PS and transferred to the PL through AXI-burst interface. Once the sorting accelerator implemented in the PL finishes, it forms an interrupt to the PS. Then, the PS either reads the sorted subsets from memory and displays the result or merges different subsets of sorted data enabling much bigger data sets to be sorted [9]. Note that a single even-odd level of the network can be reused iteratively (in different clock cycles) through a feedback register until the result of sorting is produced [22]. The maximum number of clock cycles for sorting *N* data items is equal to *N*/2. However, this can be less than *N*/2 [22, 23].

Let us describe in detail how the high-level design (in C++) of the sorting module can be accomplished in Vivado. The design entry is done with Vivado HLS tool [8] and includes two source files: ex_sort.h and ex_sort.cpp and a test bench file sort_test.cpp.

The sorter has to receive on its input the data to sort organized as a long vector of N×M bits. C/C++ built-in data types are supported by Vivado HLS, but these data types are on 8-bit boundaries (8, 16, 32, 64 bits). Since we need to process M-bit unsigned integers, we have to indicate this requirement explicitly so that only M-bit comparators will be synthesized. That is why the code will use ap_uint<M> data type instead of the unsigned int. In all other aspects standard C++ is used. C++ arbitrary precision types ap_uint<W> (for unsigned integers) and ap_int<W> (for signed integers) are defined in the file ap_int.h.

By default, the maximum width allowed for ap_uint<W> type is 1,024 bits (*i.e.* W=N×M cannot exceed 1,024). This default may be overridden by defining the macro AP_INT_MAX_W with a positive integer value less than or equal to 32,768 before inclusion of the ap_int.h header file [21]. Let us define the maximum allowed value as 16,384, which permits up to 512 32-bit data items to be received and sorted (16,384 / 32 = 512). The actual number of data to sort is defined with the constant N and the number of bits in each data item is specified with the constant M. The top-level function ex_sort will receive an N×M-bit vector of unsorted data and will return a N×M-bit vector of sorted data. As a result, the contents of the file ex_sort.h are the following (N is set to 16 in this example):

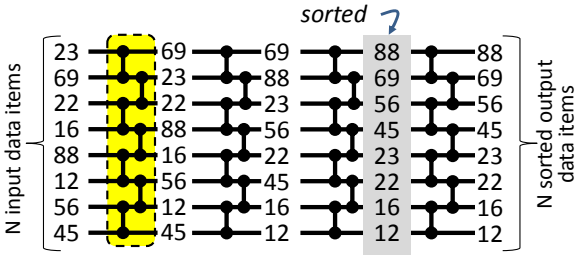

Figure 3. An example of even-odd transition sorting network for *N*=8

```
#define AP_UINT_MAX_W 16384 //must be defined before the next line
#include <ap_int.h>
const unsigned int M = 32; //number of bits in each data item
const unsigned int N = 16; //number of data items
ap_uint<N*M> ex_sort(ap_uint<N*M> input_data);
```

The parameterizable sorter functionality, based on the iterative even-odd transition network, can be specified as follows (file ex_sort.cpp):

```
#include "ex_sort.h"
ap_uint<N*M> ex_sort(ap_uint<N*M> input_data)
{  ap_uint<N*M> sorted_data;
   bool sorting_completed_odd, sorting_completed_even;
   ap_uint<M> work_array[N];

    //1. Fill in the work array
   ap_uint<M> mask = ~0;
   init_loop: for (unsigned i = 0; i < N; i++)
   {  work_array[i] = input_data&mask; //extract M Less Significant Bits (LSBs)
      input_data >>= M;                    // shift right M bits
   }

    //2. Sort the data
   sorting_completed_odd = sorting_completed_even = false;
   proc_loop:
   while (!sorting_completed_odd | !sorting_completed_even)
   {  ap_uint<M> swap;
      // processing even pairs of registers
      sorting_completed_even = true;
      sort_even: for (unsigned j = 0; j < (N / 2); j++)
            if (work_array[2 * j] < work_array[2 * j + 1])
            {        sorting_completed_even = false;
                     swap = work_array[2 * j];
                     work_array[2 * j] = work_array[2 * j + 1];
                     work_array[2 * j + 1] = swap;
            }
      // processing odd pairs of registers
      sorting_completed_odd = true;
      sort_odd: for (unsigned j = 0; j < (N / 2 - 1); j++)
            if (work_array[2 * j + 1] < work_array[2 * j + 2])
            {        sorting_completed_odd = false;
                     swap = work_array[2 * j + 1];
                     work_array[2 * j + 1] = work_array[2 * j + 2];
                     work_array[2 * j + 2] = swap;
            }
   }

    //3. Write the result
   write_res_loop: for (unsigned i = 0; i < N; i++)
   {        sorted_data <<= M;          // shift left M bits
            sorted_data |= work_array[i];    // write M LSBs
   }
   return sorted_data;
}
```

Data processing is organized in three steps:

1) First of all the work array work_array of N M-bit data items is filled in from the supplied data input input_data.

2) Then the data are iteratively sorted with the aid of two inner *for* loops: sort_even and sort_odd. The outer *while* loop proc_loop finishes processing when the data are sorted.

3) The result stored in work_array is written to the output N×M-bit vector.

Now the test bench has to be developed that would allow to verify the functionality of the sorter. The test bench has to be written respecting the following rules:

- The test bench has to call the function to be synthesized (ex_sort).
- The test bench has to save the output from the function under test and to compare the results with the known expected results.
- If the produced results do match the expected results, a message is issued confirming that the function has passed the test and the return value of the test bench main() function is set to 0. Otherwise, if the output is different from the expected results, a message indicates this, and the return value of main() is set to any value different from 0.
- The test bench must generate the same input stimuli every time it is executed to be used successfully for RTL verification (*i.e.* test values cannot be generated randomly).

Let us organize the verification procedure as shown in Fig. 4. The test bench will read data to sort from a text file input_data.dat, call the function ex_sort, store the result in the file sorted_data.dat and finally compare the results produced with the golden results kept in the file sorted_data.gold.dat and issue the verdict. Examples of files input_data.dat and sorted_data.gold.dat are given in Fig. 4. If the test fails, the students can debug the code [9].

When the behavior of the sorting function is verified we can proceed to synthesis. The synthesis report gives details on both the performance and resources of the RTL design. The results of the synthesis reveal that, besides of LUTs and flip-flops, one memory block is used. HLS tool may correctly estimate the design latency due to the involved resources but may not account net delays due to further RTL synthesis, place and route. The *latency* is the number of cycles required to produce the output. The *initiation interval* (II) is the throughput, *i.e.* the number of cycles between new input reads. The design has a latency of 51 cycles and II = 52. The latency is composed of the following values: 16 cycles to execute the loop init_loop, 8 cycles for the loop sort_even, 7 cycles for the loop sort_odd, 16 cycles for the loop write_res_loop and plus 4 cycles are required to enter each block. The initiation interval is 52 clock cycles, *i.e.* the next set of inputs is read after 52 cycles. This is one cycle after the result is written. This indicates that the design is not pipelined which is confirmed in the synthesis report.

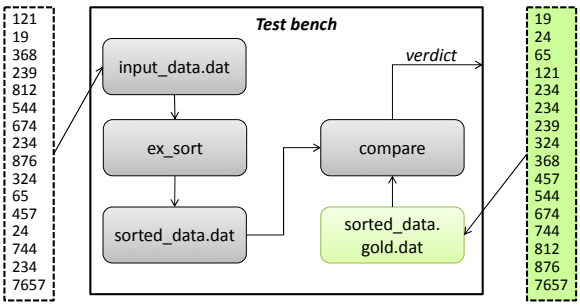

Figure 4. Verification procedure for the sorter project

Arrays in C/C++ are typically mapped to memories [21] and the array work_array was synthesized to a RAM. However, our idea is to process all even/odd data items in parallel and therefore all the array elements have to be accessed in parallel. This is obviously not possible when a RAM is used because the number of read/write ports is limited. Array optimization directives permit to map arrays efficiently to the available memory resources and to reshape or stream them [21]. The array work_array has to be implemented as registers and not RAM and this might be accomplished with the ARRAY_PARTITION directive.

ARRAY_PARTITION directive can be applied to the function ex_sort with *variable* set to work_array, *type* set to *complete* and *dim* set to 0. This directive permits arrays to be partitioned either in equally sized blocks containing consecutive elements of the original array (type *block*), in equally sized blocks containing interleaving elements (type *cyclic*), or in registers (type *complete*). The option *dim* specifies which array dimension to partition, if set to zero all dimensions are partitioned. If the design is synthesized, you can check that no memory is now used but the number of LUTs and registers has greatly increased. Moreover, latency was not improved. Therefore, additional optimization directives have to be applied to the design.

By default, all loops are kept *rolled* in HLS, *i.e.* all operations in the loop are implemented using the same hardware resources and each iteration is performed in a separate clock cycle. HLS provides the ability to unroll *for* loops, either partially or fully. When a loops is *fully unrolled* all the loop operations are performed in a single clock cycle by replicating the required for each iteration hardware resources. This leads to faster designs which however require more resources. We can fully unroll the loops init_loop and write_res_loop as well as the inner loops sort_even and sort_odd by applying the directive UNROLL to perform all comparison/swapping operations in parallel.

The final synthesis report indicates that the estimated number of LUTs and registers was reduced. The total circuit latency and the iteration latency and trip count of the loop proc_loop are not estimated correctly because the loop bounds are not constant, *i.e.* the number of times the loop is executed depends on the input data.

The results of *interface synthesis* are displayed at the end of the synthesis report. We have a sequential circuit therefore clock and reset signals have been added: ap_clk and ap_rst. Besides, signals ap_start, ap_done, ap_idle and ap_ready have also been included to support a block-level input/output (I/O) protocol ap_ctrl_hs. This is the default function-level handshaking I/O protocol. The input signal ap_start controls the block execution and must be asserted for the design to start. The output signal ap_done indicates that the function has finished and, if there is a return value, this value is valid and may be read. The output signal ap_idle, when asserted, indicates that the function is not operating (idle). The output signal ap_ready indicates when the design is ready to accept new inputs.

The remaining ports are implemented with ap_none protocol. This protocol indicates that no control signals will be included and therefore represents simple wires. By default, Vivado synthesizes input pass-by-value arguments and pointers as simple wire ports with no associated handshaking signal and output values/pointers with an associated output valid signal to indicate when the output is valid [21]. Besides of the mentioned protocols other types of interfaces can be synthesized such as two-way handshakes, RAM access ports and FIFO ports.

When the designer is satisfied with the results, RTL verification (cosimulation) can be initiated. By default, the cosimulation is performed using the generated SystemC RTL which uses the built-in C compiler. It is also possible to perform the verification in VHDL and Verilog using a third-party simulator. In cosimulation, first of all, the C test bench is executed to generate input stimuli for the RTL design. Second, an RTL test bench is created containing the input stimuli from the C test bench and the RTL simulation is performed with the selected simulation tool. And, finally, the output from the RTL simulation is fed back to the C test bench to check the results and a message is issued informing whether the design passed the test. Since the C test bench is executed twice (first to create the input stimuli and then to check the RTL simulation output), it is not possible to generate test values randomly. This is because, when the C test bench will be executed for the second time, it may create different (from the first run) test values, and a mismatch with RTL simulation output will be reported.

The final step in the HLS flow is to package the design as an IP block for use with other tools in the Vivado Design Suite [20]. As a result, an IP package will be created, which can be imported into the Vivado IP catalog and used in any Vivado design. When the final project is assembled in Vivado, which includes the communication modules using AXI-burst mode and the sorter, and implemented in the ZedBoard [24], we can see that the system occupies 4,950 LUTs (from 53,200 available) and 4,570 flip-flops (from 106,400 available).

High-level synthesis is only one of the topics covered within the course with either one or two dedicated labs. The remaining labs deal with the traditional FPGA-based design [11, 25, 26] and software/hardware co-design. In one of those labs the students implement the same sorting project from specification in HDL. After completing both projects (based on HDL and HLS) the students are asked to identify trade-offs of the used specification methods. For example, the sorter circuit synthesized from specification in VHDL (for N=16 and M=32) occupies 4,088 LUTs and 3,501 flip-flops. Such a teaching technique allows for students to try different design methods and broadens their experience.

V. DIFFICULTIES AND CHALLENGES

The new programmable SoC design methodology is being currently incorporated in courses on reconfigurable digital design in both University of Aveiro in Portugal and Tallinn University of Technology in Estonia [11, 25, 26]. Besides of the reported in the paper high-level synthesis, many other design and verification opportunities have to be covered within the courses, such as specifying design constraints, design of interfaces, analysis of synthesis results, simulation, power analysis, design integration, software development and real-time test. Many of these

topics are covered in [9, 10]. With the exception of these two books, there are no published materials in English on Zynq programmable SoCs which would be easily adaptable and suitable to the students. There are many technical reference manuals, but our experience shows that this kind of materials are not very easily adapted by the students because they need more guided references where the topics are explained in a step-by-step manner.

The second main difficulty that we currently envision is the relative complexity of the respective design and verification tools. Synthesis and test of even not-very complex systems takes too long time to be effectively used on not-the-latest generation computers connected in a network (which university labs are usually equipped with). Nevertheless we look optimistically into the future and are sure that the respective design tools will quickly advance and make the design and verification process of programmable SoC more straightforward and efficient. Because of this we are sure that the new trends have to be addressed right now by modernizing the respective course contents, design tools, and equipment.

VI. Conclusion

In this paper we reported the need to modernize courses on reconfigurable digital design due to the introduction of programmable systems-on-chip. The system-oriented design philosophy differs to the great extent from the traditional FPGA design flow and favors greatly the design reuse. One particular method of generating IPs from software specifications through high-level synthesis is analyzed in the paper in detail. Design reuse keeps aligned with the teaching methodology practiced within our universities during the last years which relies upon decomposition of the students' projects on *given to* the students and *developed by* the students components [11, 26]. This permits various components to be reused extensively leading to the increased project complexity without expanding timeslots allocated for the classes. Moreover, the students understand better the advantages and necessity of team working and are forced to document better their designs.

Abstract - The data-driven parallelization framework Hadoop MapReduce allows analysing large data sets in a scalable way. Since the development of MapReduce programs can be a time-intensive and challenging task, the application and usage of Hadoop in Biomedical Research is still limited. Here we present Cloudflow, a high-level framework to hide the implementation details of Hadoop and to provide a set of building blocks to create biomedical pipelines in a more intuitive way. We demonstrate the benefit of Cloudflow on three different genetic use cases. It will be shown how the framework can be combined with the Hadoop workflow system Cloudgene and the cloud orchestration platform CloudMan to provide Hadoop pipelines as a service to everyone.

The framework is open source and free available at https://github.com/genepi/cloudflow.

I. INTRODUCTION

Since the advent of high-throughput technologies in the field of molecular biology (i.e. Next Generation Sequencing (NGS)), even more data is produced and needs to be analysed. Thus, molecular biology has envolved into a big data science, where the bottleneck is no longer the production of raw data in the laboratory, but its analysis and interpretation [1]. To scale with the increasing data volume and the number of available resources, workflows need to be parallelized efficiently. MapReduce and Cloud Computing constitute an attractive alternative to deal with the large datasets [2]. However, writing a MapReduce job can be a challenging task that prevents domain experts from using such models in their daily work. Additionally, the reusability of the mapper and reducer functions is limited, resulting in a use-case specific implementation for every problem.

Existing high-level languages on top of Hadoop facilitate the development process and allow writing MapReduce jobs in form of queries. For example, Apache Pig (http://pig.apache.org/) provides a compiler to translate such queries into an execution plan, which is then automatically translated into a sequence of MapReduce jobs. Apache Pig provides interfaces for *filter*, *group* and *join* operations, extendible for application-specific logic using user defined functions (UDFs). However, Apache Pig has been developed to analyze datasets based on the relational model. The execution of complex calculations across several rows is limited. This implies the consequence that users have to write complex UDFs. Again, such functions need to be implemented by the end users and can be, similar to native MapReduce jobs, hard to implement, test and maintain. Several projects (e.g. SeqPig [3] or BioPig [4]) make use of UDFs and provide a collection of Pig scripts to researchers in Genetics. The goal is to provide ready-to-use workflows to end users, which can be then adapted to their use-case. Nevertheless, combining different scripts to a pipeline or reusing existing blocks does not build a key feature.

To overcome this issue, FlumeJava [5] proposed a new concept to compose pipelines based on immutable parallel collections where several operations can be used to process them in a parallel way. This concept was successfully implemented in Apache Crunch (https://crunch.apache.org/), which executes the pipelines as Hadoop MapReduce jobs. However, the utilization of such pipelines in Bioinformatics is still limited.

In this paper we present Cloudflow, a MapReduce pipeline framework, which is based on a similar concept as proposed by [5]. In contrast to existing approaches, Cloudflow was developed to simplify the pipeline creation in biomedical research, especially in the field of genetics. For that purpose Cloudflow supports a variety of NGS data formats and contains a rich collection of built-in operations for analyzing such kind of datasets (e.g. quality checks, mapping reads or variation calling). The main concept behind our approach is to break complex data analysis steps into three basic operations. All further use-case specific operations are built by implementing or extending one of the basic operations. Pipelines are then composed by creating a sequence of these operations. The framework itself translates the set of pipeline operations into one or more MapReduce jobs and decides which of the operations are executed in the *map* or in the *reduce* phase. Thus, Cloudflow hides the complexity and the implementation details of MapReduce jobs allowing scientists to build pipelines via an intuitive method. Moreover, Cloudflow can be utilised in combination with the workflow system Cloudgene [6]. To validate our approach, we developed three Genetics data-analysis pipelines with Cloudflow. The results demonstrate that our contribution (a) helps minimizing the development time, (b) increases the reusability of code, and (c) creates only a minimal overhead in terms of execution time compared to an identical MapReduce implementation.

II. MapReduce Background

MapReduce is a parallel programming model introduced by Google in 2004 with the aim to develop a simple and scalable method to process large datasets on several machines in parallel. The main idea behind this distributed programming model is that a long-time calculation is split into a map and a reduce phase which contains all the logic behind the calculation and is specified by the user. The underlying framework itself takes care of parallelization, task scheduling, load-balancing and fault-tolerance. Due to its simplicity, MapReduce is used to solve many scientific problems where large-scale computing is needed. Moreover, MapReduce is ideal for parallel batch processing of terabytes of input data. The data-flow of a MapReduce program consists of several steps, where only the map and reduce function are problem-specific and the other steps are loosely coupled with the problem and generalized. In the first step, the input data set is split into key/value pairs and a user defined map function is executed for each pair:

$$map(key, value) \rightarrow list((key_i, value_i)) \text{ , where } i = 0 \ldots n$$

The map function reads a pair, performs some problem-specific calculations and produces zero or n intermediate key/value pairs for each input pair. In the next step, the intermediate key/value pairs are grouped by similar keys and a merged list of all values for this key is created. Finally, the user-defined reduce function is applied to the intermediate key/list pairs:

$$reduce(key_i, list(value_i)) \rightarrow list(outvalue)$$

The values created by the reduce function are the final outputs of a MapReduce job.

A. Apache Hadoop

Apache Hadoop is an open source project including several sub-projects for distributed computing. It includes the most widely used open-source implementation of Google's MapReduce framework (simply called MapReduce), the distributed file system (HDFS), and several other sub-projects. In general, all previous discussed features of the original MapReduce approach are implemented in Apache Hadoop. Writing a MapReduce job with Hadoop can either be done directly in Java by implementing the relevant methods or by using Hadoop's streaming mode. This allows specifying a script or any executable as the mapper or reducer. Two different versions of MapReduce are available. MRv1 includes a namenode (centerpiece of HDFS), a secondary namenode (merging logs into a file system snapshot), a job-tracker (job assignment) and several task-trackers (workers). MRv2 or Hadoop YARN, splits the work of the job-tracker (resource management, job scheduling) into two different daemons, namely a resource manager and an application master. Additionally a node manager is introduced to manage the user processes per node. The application master describes a framework that works together with the node manager and the resource manager to monitor and to execute tasks. The idea behind this new model is that applications using frameworks different than MapReduce (e.g. Apache Spark) can be executed via YARN as well.

B. High-Level Languages based on MapReduce

To simplify the implementation of MapReduce jobs, Apache Pig has been introduced. It is based on HDFS and MapReduce and allows a fast implementation of data flows with already available data operations such as *join*, *filter* or *group by*. Data flows are specified in the Pig Latin language that describes a directed acyclic graph (DAG) and defines how data should be processed. A further advantage of Apache Pig is the ability to check the data flow on optimizations, e.g. if two grouping statements can be combined. The costs to write code in Apache Pig are lower than setting up a Java project and implementing the functions. But as stated earlier, Apache Pig includes only a limited number of operators and writing Apache MapReduce jobs directly in Java yields to advantages in speed compared to Apache Pig.

C. MapReduce Pipelining

The pipeline framework FlumeJava [5] is based on the concept of immutable parallel collections. This kind of data-structure can be used to process and analyze their items in parallel. The end user can either use one of the predefined functions or can combine them with its own. Each function is implemented as parallel for-each loop, which is than translated by the framework into a series of MapReduce jobs. During the translation, the framework itself decides if such a function should be executed locally (i.e. sequentially) or remotely (i.e. parallel). Apache Crunch is a freely available open source implementation of FlumeJava.

III. Cloudflow

The overall idea behind Cloudflow is to simplify the creation of analysis pipelines by encapsulating complex data analysis steps in simple operations. This approach helps hide the complexity and the implementation details of complex data-parallel pipelines. Moreover, the concept of using basic operations increases the reusability and enables the testing of the operation logic on a local workstation by using existing unit testing frameworks.

Since Cloudflow uses the Hadoop framework for pipeline execution, it offers parallel data processing, data reliability and fault tolerance out of the box. This fact is especially important in the field of Cloud Computing, where infrastructure often relies on commodity hardware and nodes can fail on a regular basis (e.g. due to miss-configuration or hardware failures). At the same time, the architecture of Cloudflow is independent from MapReduce; it provides parallelization constructs and abstraction interfaces that can be used to extend the system by implementing other parallel programming models in the future (e.g. translating the operations into Apache Spark jobs).

Instead of developing a new declarative language for the pipeline composition, we developd a clear Java API. The proposed framework implements different patterns to speed up the pipeline creation, to be extensible and to support test-driven pipeline development. The following

section gives an overview on the abstraction, explains the basic operations in detail, and shows how pipelines are created.

A. Data Types and Basic Operations

Cloudflow operates on records consisting of a key/value pair, whereby different record types are available (e.g. TextRecord, IntegerRecord, FastqRecord). A *loader* class is responsible to load the input data and to convert it into an appropriate record type. As mentioned earlier, Cloudflow supports three different basic operations. These are used to analyze and transform records; specifically, *transform*, *summarize*, and *group* operations exist.

The *transform*-operation is used to analyze one input record and to create between *0* and *n* output records. The user implements the computational logic for this operation by extending an abstract class. This class provides a simple function, which is executed by the Cloudflow framework for all input records in parallel:

```
Class MyTransformer extends Transformer {
    public void transform(Record) {
       doSomethingInParallel();
       emit(new Record());
    }
}
```

The *summarizer* operates on a list of records, whereby records with the similar key are grouped. Thus, the signature of the process method has the key and a list of records as an input:

```
Class MySummarizer extends Summarizer {
   public void summarize(Key, List<Record>) {
       doSomethingInParallel();
       emit(new Record());
    }
}
```

The *group*-operation is a special operation, which takes a list of records as an input and creates a *Record* group with the same key. Our framework inserts automatically a group-operation between a transform- and a summarize-operation. This ensures, that output records of the *transform* operation are compatible with the input records of the *summarize* operation. The *group*-operation is realized by using the shuffle phase of a MapReduce job.

Based on these three operations, the user defines pipelines by building sequences of operations. A pipeline has to start with a transform-operation, all further operations are optional and can be used in arbitrary order.

B. Extended Operations

Complex operations are built by combing one or more basic operations. We already implemented several standard operations that are helpful for the analysis of text or numerical data records:

- *Filter*: this operation is a special *transform*-operation, which emits the record to the subsequent operation iff a user-defined condition is fulfilled.
- *Split*: the *transform*-operation calculates for each input record a new split level (i.e. a new key). This key is used by the group-by operation to create chunks, which can then be analyzed by a user-defined summarize-operation.
- Aggregation (sum, mean)*:* This defines a *group-by*-operation followed by a *summarize*-operation to aggregate all values with the same key (e.g. calculates the mean of all values). One record with the aggregated value is then emitted to the subsequent operation.
- *Executor:* this *summarize*-operation writes all grouped values into a file on the local disk. It is then used as the input of an external UNIX command line program. Based on the lines of the output file, new records are created and emitted to the subsequent operation.

Since Cloudflow's operations are based on the Composite pattern, all these extended operations can also be used as a basis for new operations. In addition, this enables to split complex operations into several sub-operations, which improves testing and maintenance.

C. Pipeline Composition

The user builds pipelines by connecting several operations with compatible interfaces. For this purpose our framework implements the Builder pattern, which enables (a) building complex pipelines, (b) providing type safety and (c) the implementation of domains specific builders (see Section III.D). In addition, the Builder pattern ensures that only a valid sequence of operations can be created (i.e. after the group-by operation a summarize operation has to be added).

```
Class LineToWords extends Transformer {
   public void transform(TextRecord rec) {
    String[] words = rec.getValue().split()
    for (String word: words){
      emit(new IntegerRecord(word, 1));
    }
   }
}

pipeline.loadText(input)
        .transform(LineToWords.class)
        .sum()
        .save(output);
```

Listing 1. WordCount Example using Cloudflow

To help the user and accelerate the pipeline composition process, Cloudflow provides already a set of useful operations. This has the advantage that even a default WordCount example can be broken down into a few simple operations and is defined in a single line of code (see Listing 1). In a first step, the text file is loaded from HDFS (*loadText*). Then, for each record (i.e. line of input) the application-specific *LineToWords* operation is executed, which splits the line into words and creates a new record efor ach word. In the last step a predefined *sum* operation is executed. It extends the pipeline by a *group-by* operation and a *summarize*-operation in order to sum up all the values for a certain key.

For frequently used operations (e.g. sum, mean or count), we created special builder functions, which extend the pipeline and improve the code readability by keeping the code simple.

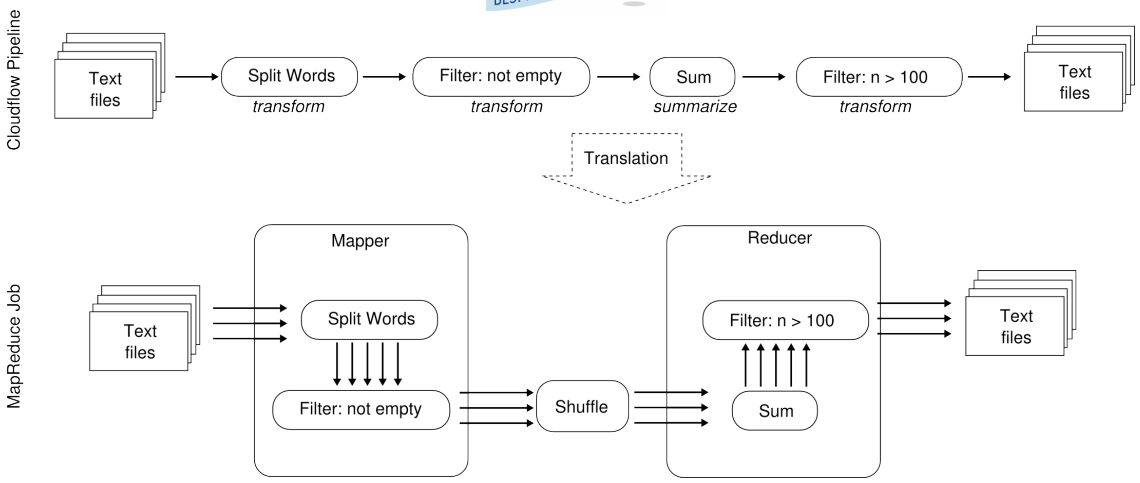

Figure 1. Cloudflow translates the operation sequence automatically into an executable MapReduce job

D. *Pipeline Execution*

Before the execution, Cloudflow checks the compatibility of input and output records of consecutive operations. This ensures that only valid and executable pipelines are submitted to a Hadoop cluster.

If the pipeline is executable and valid, then the operation sequence is translated into an execution plan, that decides if an operation is executed in the *map* or in the *reduce* phase. Based on this plan, Cloudflow creates one or more MapReduce jobs and configures them to execute the user-defined operations in the correct order. In this translation step, Cloudflow tries to minimize the number of MapReduce jobs by combining consecutive *transform*-operations and by executing all *transform*-operations after a *summarize*-operation in the same reducer instance (see Figure 1).

For additive *summarize*-operations (e.g. sum), Cloudflow takes advantage of Hadoop's combiner functionality. The idea of this improvement is to combine the key/value pairs that are generated by all map tasks on the same machine, into fewer pairs. Thus, the number of pairs that are transferred between mapper and reducer are minimized, which results in a positive effect on the network bandwidth since useless communication is avoided.

IV. CLOUDFLOW FOR BIOINFORMATICS

Cloudflow provides a variety of already implemented utilities, which facilitate the creation of pipelines in the field of Bioinformatics (especially for NGS data in Genetics). For that purpose, we implemented, based on HadoopBAM [7], several record types and loader classes in order to process FASTQ, BAM and VCF files. Moreover, we created several operations and filters for the analysis of biological datasets (see Table I for an overview of all currently implemented operations and filters).

For example, a typical quality control pipeline for VCF files can be implemented by simple combining of several built-in operations. First, we apply predefined filters to discard variations that are monomorphic, marked as duplicates, or are Insertions or Deletions (InDels). For all records passing the filters, Cloudflow applies a *summarize*-operation that calculates the call rate for each variation (see Listing 2).

```
Class CallRateCalc extends Transformer {
  public void transform(VcfRecord record) {
    VariantContext snp = record.getValue();
    float call = callRate(snp);
    emit(new FloatRecord(snp.getID(), call);
  }
}

pipeline.loadVCF(input)
        .filter(MonomorphicFilter.class)
        .filter(DuplicateFilter.class)
        .filter(InDelFilter.class)
        .transform(CallRateCalc.class)
        .save(output);
```

Listing 2. VCF Quality Control Pipeline using Cloudflow

V. DEPLOYING PIPELINES AS A SERVICE

Cloudgene [6] is a web-based platform to create and execute workflows consisting of Hadoop MapReduce, Apache Pig and command line-based programs. It can be seen as an additional layer between Hadoop MapReduce and the end user that hides the complexity of the MapReduce framework. Therefore, Cloudgene is the perfect candidate to provide Cloudflow pipelines as a service. Such pipeline can be integrated into the workflow platform by utilizing Cloudgene's plugin interface. No adaptation to the source code is needed, while only a simple plain text file including a header, input parameters, output parameters and the definition of the workflow itself need to be created. When launching Cloudgene, the manifest file is loaded and the client interface is automatically rendered using information from the file. As Cloudgene supports different technologies, it is possible to parallelize the calculations using Cloudflow and to visualize the results using R.

Cloudflow requires a compatible MapReduce cluster for executing pipelines. CloudMan [8] makes it possible to easily procure and configure a functional data analysis platform on a cloud infrastructure. The procured platform delivers a scalable cluster-in-the-cloud and a data analysis environment preconfigured with a number of applications. With its ability to be launched and managed via a web browser on a number of clouds, customized as necessary, and easily shared with collaborators, CloudMan makes it

TABLE I. CURRENTLY SUPPORTED DATA FORMATS AND OPERATIONS

Data Format		Pipeline Operation	Description
Fastq	Split	`split()`	Find pairs (for paired-end reads)
	Filter	`filter(LowQualityReads.class)`	Filters reads by quality
		`filter(SequenceLength.class)`	Filters reads by sequence length
	Other	`findPairedReads()`	Detects read pairs
		`align(referenceSequence)`	Aligns sequences against a reference (using jBWA for alignment)
BAM	Split	`split()`	Creates fixed size chunks (e.g. 64 MB)
		`split(5, BamChunk.MBASES)`	Creates logical chunks (e.g. 5MBases)
	Filter	`filter(UnmappedReads.class)`	Filters unmapped reads
		`filter(LowQualityReads.class)`	Filters reads by map.quality
	Other	`findVariations()`	Finds variations in aligned reads (using samtools)
VCF	Split	`split()`	Creates fixed size chunks (e.g. 64 MB)
		`split(5, VcfChunk.MBASES)`	Creates logical chunks (e.g. 5MBases)
	Filter	`filter(MonomorphicFilter.class)`	Filters monomorphic site
		`filter(DuplicateFilter.class)`	Filters duplicates
		`filter(InDelFilter.class)`	Filters inDels
		`filter(CallRateFilter.class)`	Filters by call rate
		`filter(MafFilter.class)`	Filters by MAF
	Other	`checkAlleleFreq(reference)`	Allele frequency check with external reference (e.g. 1000 genomes)

possible to readily utilize cloud resources in a research environment. The approach on how Cloudgene and CloudMan can be combined efficiently have already been demonstrated [9].

VI. EVALUATION

To evaluate our approach, we implemented three different Bioinformatics data-analysis pipelines using Cloudflow and integrated them into Cloudgene. The results of our experiments demonstrate that Cloudflow has only a minimal overhead in the execution time compared to an identical pure MapReduce implementation. However, the performance of Cloudflow is better than Apache Crunch's (see Figure 2).

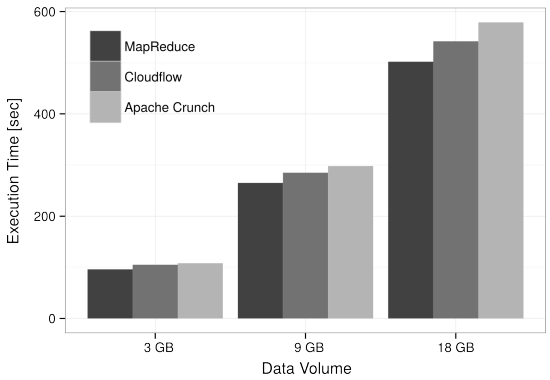

Figure 2. Execution Time of a Cloudflow pipeline, an Apache Crunch pipeline and a pure MapReduce implementation of WordCount

A. Preprocessing and Mapping

When working with NGS data, the quality of raw data needs to be checked before a successful subsequent downstream analysis (e.g. read mapping/alignment) can be achieved. The overall goal of alignment is to dock the vast amount of short reads, mostly in the FASTQ file format, to a reference genome. Factors such as read errors, insertions or deletions of bases must be considered that finally results in the most accurate genome position for each read.

The goal of the following pipeline is the alignment of paired-end data to a reference genome. Therefore, the FASTQ data is loaded using the FastqLoader, which creates records for each sequence. The records are then filtered by an average base quality of 30. Numerous other quality metrics (such as sequence length or C/G content) can be filtered as well. Since paired-end reads are used, read pairs are detected using a predefined *transform*-operation. The aligner step is implemented as a *summarize*-operation that calls a parallelized version of BWA-MEM [10]. This has been achieved by using JNIs (https://github.com/lindenb/jbwa). Similar to BWA-MEM 99,100 reads are aligned to the user-specified reference genome in one batch. Aligned reads are saved in HDFS in the BAM file format (see Listing 3.A).

B. Variation Calling

After data has been aligned and cleaned (e.g. removing duplicates, quality recalibration), the next step of NGS pipelines is the detection of reliable variants that can be used e.g. in association studies. A widely used pipeline for variant detection is GotCloud, developed at the Center of Statistical Genetics (University of Michigan) and utilized in the 1000 Genomes (1000G) project.

In this example pipeline, the aim is to find variations without a statistical model by implementing a simple counting approach of the four bases. This is only possible when using high coverage data. Therefore, in the first step the BAM file (created in the previous pipeline) is loaded and chunked in user-specified splits (e.g. 5 MBases). Variations are then detected for each chunk by counting

the occurrences of A, C, G, T on each position. Finally, the detected variations are stored in VCF files (see Listing 3.B).

C. Genome-Wide Association Studies

Many genome-wide association studies (GWAS) have identified associations between various phenotypes and common sequence polymorphisms, which might play a role for disease development. Technologies like microarrays have made it possible to measure millions of single nucleotide polymorphisms (SNPs) of one individual simultaneously and for low cost. Since the costs of microarrays is much lower than next-generation sequencing (NGS), it is today the cheapest method to genotype large-scale population studies. Such datasets are combined with collected phenotypes (e.g. diseases and measured data) in order to detect if one of these variations has a high impact on the value of a phenotype. Since the size of such datasets grows rapidly, a parallelization at the data-level is necessary to analyze the data in appropriate time.

```
//A. Preprocessing and Mapping
pipeline.loadFastq(input)
        .filter(LowQualityReads.class, 30)
        .findPairedReads()
        .align(refSeq)
        .save(output);

//B. Variation Calling
pipeline.loadBam(input)
        .split(5, ChunkSize.MBASES)
        .groupByKey()
        .findVariations(refSeq)
        .save(output);

//C. Genome-Wide Association Study
pipeline.loadText(input)
        .split(1000, ChunkSize.LINES)
        .execute(SnpTestExecutor.class).
        .filter(FilterHeader.class)
        .filter(FilterInvalidSnps.class)
        .save(output);
```

Listing 3. Complete NGS pipeline using Cloudflow

The parallelization of the association analysis was realized by splitting the list of markers into chunks. In detail, the mapper splits all input SNPs into chunks with a fixed number of SNPs (e.g. 1000). Then, the reducer executes the linear regression model for each chunk by using SNPTest. Finally, the reducer collects the results and merges them into a single file. The corresponding Cloudflow pipeline loads the text input file and automatically creates records for each line. On these records we apply the *split* operation, which creates chunks containing a fixed number of lines. For the execution of the SNPTest program, we can implement a special operation called *BinaryExecutor,* which enables us to write the chunks automatically to the POSIX file system. In the next step, we can use this file as the input file for SNPTest. After the execution the operation creates text records for each line of results (see Listing 3.C).

VII. Conclusion

Cloudflow's overall aim is to simplify the development of complex MapReduce pipelines by abstracting the map and the reduce function from end users. Therefore, operations need only be written once and can be re-used for future MapReduce usage. The major advantage of Cloudflow lies in the provision of validated operations, especially in the area of genetics, and its extensibility. Combining Cloudflow with CloudMan (cluster orchestration) and Cloudgene (Hadoop workflow system) allows users to use Hadoop without a deeper knowledge of the internal MapReduce concepts and could yield to a boost of Hadoop in genetics.

Acknowledgment

e-mail: gord@imp.kiev.ua

Abstract - The current tendency of human learning and teaching is targeted to development and integration of digital technologies (like cloud solutions, mobile technology, learning analytics, big data, augmented reality, natural interaction technologies, etc.). Our Science Gateway (http://scigate.imp.kiev.ua) in collaboration with High Performance Computing Center (http://hpcc.kpi.ua) is aimed on the close cooperation among the main actors in learning and researching world (teachers, students, scientists, supporting personnel, volunteers, etc.) with industry and academia to propose the new frameworks and interoperability requirements for the building blocks of a digital ecosystem for learning (including informal learning) that develops and integrates the current and new tools and systems. It is the portal for management of distributed courses (workflows), tools, resources, and users, which is constructed on the basis of the Liferay framework and gUSE/WS-PGRADE technology. It is based on development of multi-level approach (as to methods/algorithms) for effective study and research through flexible selection and combination of unified modules ("gaming" with modules as with LEGO-bricks). It allows us to provide the flexible and adjustable framework with direct involvement in real-world and scientific use cases motivated by the educational aims of students and real scientific aims in labs.

I. INTRODUCTION

The current tendency of human learning and teaching is targeted to development and integration of digital technologies like cloud solutions, mobile technology, learning analytics, big data, augmented reality, natural interaction technologies, etc. But the available e-Science and e-Learning frameworks (for example, in Massive Open Online Courses (MOOCs) [1] and OpenCourseWare [2] initiatives, like TIMMS [3], SlideWiki [4], Wikiversity [5], edX [6], Coursera [7], et al.) are: (a) very heterogeneous (the available learning content is quite different in various institutions), (b) often far away from the real-life learning situations, (c) in general, static like stationary web-pages with online access from desktop PCs only, (d) not flexible to the very volatile demands of end users (students, pupils, ordinary people) and real-world, (e) not-adjustable by complexity, duration, and range (e.g. for taking some modules, but not the whole course), especially in the life-long learning or vocational training, (f) the feedback is not available about the quality, value, and necessity of some parts of the course or combinations of some modules.

The work presented here was partially funded by EU FP7 SCI-BUS (SCIentific gateway Based User Support) project, No. RI-283481, EU TEMPUS LeAGUe (A Network for Developing Lifelong Learning in Armenia, Georgia and Ukraine) project No. 543839-TEMPUS-1-2013-1-SE-TEMPUS-SMHES, and partially supported in the framework of the State Targeted Scientific and Technical Programs in 2013-2015.

The paper is aimed on the description of the approach to close cooperation among the main actors in learning world (teachers and students) with industry and academia. Here, the new frameworks and interoperability requirements are considered for the building blocks of a digital ecosystem for learning (including informal learning) that develops and integrates the current and new tools and systems.

II. BACKGROUND

A vast amount of e-Science and e-Learning frameworks briefly enlisted in "Introduction" is published online to make their educational content accessible to a wide range of audiences. Many profound researches were dedicated to their estimation in the view of awareness of these courses among users and increase of popularity of these frameworks [7-9]. However, from a subjective experience of many users, online courses are mainly dull, outdated, and/or non-attractable. As it was observed in one of the researches [8]: ~28% of the courses are indeed open, ~12% are available in a language other than English, ~16% are available in a format facilitating reuse and repurposeability, ~30% were updated in the last 3 years, and <50% comprise self-assessment questions, only ~65% have at least one example and one illustration, ~60% have been objectively determined as low attractive, and only 10% have been categorized as highly attractive. In the context of this investigation (on 100 various online courses), the immediate conclusion is that the quality of these e-Learning courses and frameworks should be improved significantly, especially in the sense of better attractiveness, feedback (more interactive examples) and applicability (more practical use cases).

A possible solution for improving the quality can be found by leveraging the collaboration and sharing experience and e-Learning courses/frameworks. Several platforms (like SlideWiki [4] or Wikiversity [5]) were mentioned in "Introduction", which can be used to support the collaborative creation and usage of e-Learning courses by a wide range of authors (teachers, developers, providers) and users (students, ordinary people) communities.

In addition to this, the big potential of the recent "science gateway" (SG) ideology can be used [10]. In general, SG means a user-friendly interface between users (for example, scientists or scientific communities), various software tools and hardware resources, usually distributed computing infrastructures (DCIs). The aim SGs is to decrease the time and effort spent in setting up the environment and DCI for a specific scientific application. By means of SGs researchers can concentrate their efforts on their scientific goals and thus spending less time and effort on assembling and managing the required DCI components. The most important aspects of SG are: a simplified intuitive graphical user interface (GUI) that is highly tailored to the needs of the given scientific community; a smooth access to national and international computing and storage resources; collaborative tools for sharing scientific data. Nowadays various SG frameworks exist (for example, ASKALON [11], KNIME [12], MOTEUR [13], gUSE/WS-PGRADE [14]), which use different enabling components and technologies: web application containers (Tomcat, Glassfish, etc.), portal or web application frameworks (Liferay, Spring, Drupal, etc.), database management systems (MySQL, etc.), and workflow management systems. Here, our SG for distributed multiscale course management in e-Science and e-Learning, which is based on gUSE/WS-PGRADE framework, is described. The detailed description of SG ideology on the basis of gUSE/WS-PGRADE (https://guse.sztaki.hu) can be found elsewhere [14]. In short, WS-PGRADE portal is a web based front end of the gUSE infrastructure. gUSE (grid and cloud User Support Environment) is a framework that provides the user-friendly access to DCI resources. SG contains the workflow-oriented graphical user interface (GUI) to create and manage workflows for tasks executed on various DCI resources. The DCI resources can include PCs, clusters, service grids, desktop grids, clouds [15-17].

III. SCIENCE GATEWAY FOR COURSE MANAGEMENT

The aim of the approach is to increase attractiveness of e-Learning courses by direct involvement in design of learning process, feedback by more interactive examples and applicability by more practical use cases. It could be performed by development of multi-level approach (methods/algorithms) for effective learning through flexible selection and combination of unified modules ("gaming" with modules as with LEGO-bricks) under SG. This can provide the flexible and adjustable framework with the elements of direct involvement in real-world and scientific use cases. It should be motivated by the educational aims of students and real scientific aims in labs [16].

A. *Objectives*

The objectives of the approach are to design, create and implement:

- smart learning environments providing students with adaptive and personalized learning and assessment through multi-modal/multi-sensory interaction technologies and advanced interfaces;
- interactive learning systems with more efficient and natural ways of delivering content to users especially for the real scientific tasks;
- technologies to match and operate multiple applications in real environments, while research is expected to be based on freely available and re-usable tools and resources.

B. *General Structure and Main Components*

Due to SG technology several sets of modules can be linked together by the end users (teachers or students) along the desirable track, which can form the course customized by the end users, for example, for molecular dynamics (MD) simulations in computational physics (Fig. 1). To support such linking some basic requirements should be formulated and satisfied for wrapping and connecting the modules. They should be considered as meta-information (Table 1), which are obligatory for successful combination of various modules (mainly for their compatibility). In addition to this, the similar vocabulary should be used among designers and creators of the modules, which is the simple task for the developers from the same institution, but could be headache for combination of modules from various institutions.

The main components of the approach are: portal(s), portlets(s), content, tools, users, and their repositories. "Portal" is assumed to be collection of components like tools, users, and courses (workflows). The courses could be installed as the separate portlets. It is the technological backbone constructed on the basis of the Liferay framework with customizable scientific gateways (gUSE/WS-PGRADE) based on workflows. "Content" is a set of available "legacy" passive modules and new

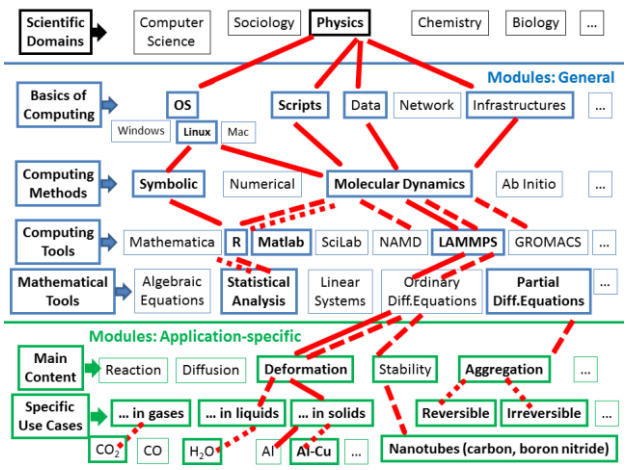

Figure 1. Example of the multiscale course hierarchy in materials science: beginner ("macro") tracks (solid lines), advanced ("mini") tracks (dash lines), expert ("micro" and "nano") tracks (dot lines)

active nano-, micro-, mini-, and macro- modules. The legacy modules should be "wrapped" by standardized meta-information about them to facilitate their combination and construction of workflows (customized tools). The legacy passive modules are assumed to be some sets of web-pages (with multimedia content), which can be enclosed in the portlets and attached to portals. The new active modules are based on the so-called "Virtual Labs" [16], i.e. software workflows (i.e. domain-specific applications connected to some research infrastructures) and enclosed in portlets, which can be attached to portals also. "Repositories" are considered as collections of content in the shape of multiscale modules (like macro-, mini-, micro-, and nano- courses) in the shape of workflows and portlets, which can be uploaded/downloaded and attached to portals.

C. *Meta-information*

The compatible meta-information for modules (Table 1) will be necessary for successful combination and compatibility of various modules. The information about "Previous module(s)" is considered as an input socket, i.e. a list of the available modules, which are pre-requisites (obligatory) to use (learn) this module. In similar way "Next module(s)" plays the role of an output socket, i.e. a list of the available modules, which can be used as continuation of this module. "Alternatives" is a list of the available modules, which can be selected as alternative versions of this module. "Categories" describes the place of the current module in the hierarchy of learning disciplines. "Complexity" is a subjective measure of the relative efforts that should be applied by students (it could be used to estimate grades, points, costs, and learning curve). "Scale" is a relative level of the module, i.e. macro-, mini-, micro-, or nano- level. "Duration" is a unit of the module length, which can be measured by time (hours, days, etc.) or lessons. "Workload" is a subjective estimation of time needed for studying the proposed content. "Exercises" are some questions and tasks with answers. "Keywords" are tags, which can be used for search of this module. "Languages" is a measure of universality of the content, i.e. multilingual content is desirable, but English should be obligatory for universal compatibility. Addition of any other languages will increase usability at a local geographical scale. "Rating" is a subjective estimation of the module attractiveness and usefulness, i.e. its quality. "Certificate" is a proof of any formal recognition marks. "Price" is a possible cost for this module (which is usually related with certificate costs, tuition fee, etc.)

TABLE I. EXAMPLE OF META-INFORMATION

Category	***Format***	***Example***
Title	String	MD Simulation of Metal Nanocrystals under Deformation
Previous module(s)	List of strings	MD Simulation of Metal Nanocrystals
Next module(s)	List of strings	MD Simulation of Defect Evolution in Al-Cu Alloys with Nanoinclusions
Alternatives	List of strings	MD Simulation of Non-metal Solids
Categories	List of strings	Physics:Computational Physics
Complexity	Number (1-5)	4
Scale	String from the set (macro, mini, micro, nano)	Mini
Duration	Number (in weeks)	2 (weeks)
Workload	Number (per week)	8-10 (hours/week)
Exercises	Number	5
Keywords	List of string	MD, metal, alloy, Al-Cu,
Languages	List of string	English, Ukrainian
Rating	1-5 stars	4
Certificate	String (Yes/No)	No
Price	Number (in $)	0

IV. USE CASES FOR STUDY AND INVESTIGATION OF FUNCTIONALIZED NANOMATERIALS

Here we demonstrate the capabilities of this approach applied for MD simulations and further data post-processing on the basis of LAMMPS package for MD simulation [18], and other packages like R for statistical analysis [19], Pizza.py Toolkit for manipulations with atomic coordinates files [20], AtomEye for visualization of atomic configurations [21], debyer for simulation of X-ray diffraction (XRD), and neutron diffraction (ND) analysis (https://code.google.com/p/debyer/), etc.

These use cases (Fig. 2) were targeted on MD simulation of nanocrystals under uniaxial tension (Fig. 3a) and functionalized nanomaterials like carbon nanotubes (Fig. 4a). Their user communities in the field of nanotechnologies include the user groups (teachers and students) from academy (G.V.Kurdyumov Institute for Metal Physics, National Academy of Sciences) and education (National Technical University of Ukraine "KPI"). MD simulation workflow (Fig. 2) was created and used for investigation of relaxation behavior of nanocrystals for different nanocrystals (Al and Al-Cu), physical conditions (tensile rate, size and orientation of the nanocrystals) and methodological parameters

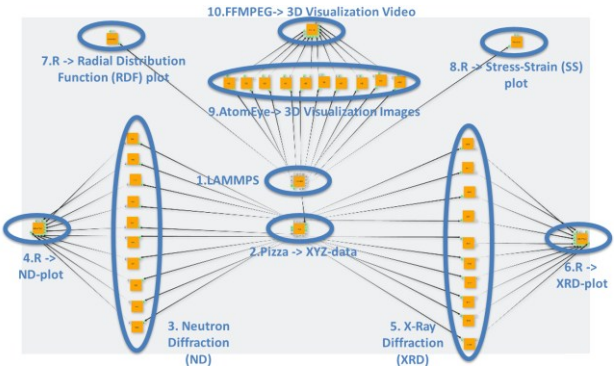

Figure 2. Example of workflow for MD simulations of functionalized nanomaterials. It is created by means of WS-PGRADE package: tools (yellow crates) inside the modules (thick ovals) with connecting links (thin lines)

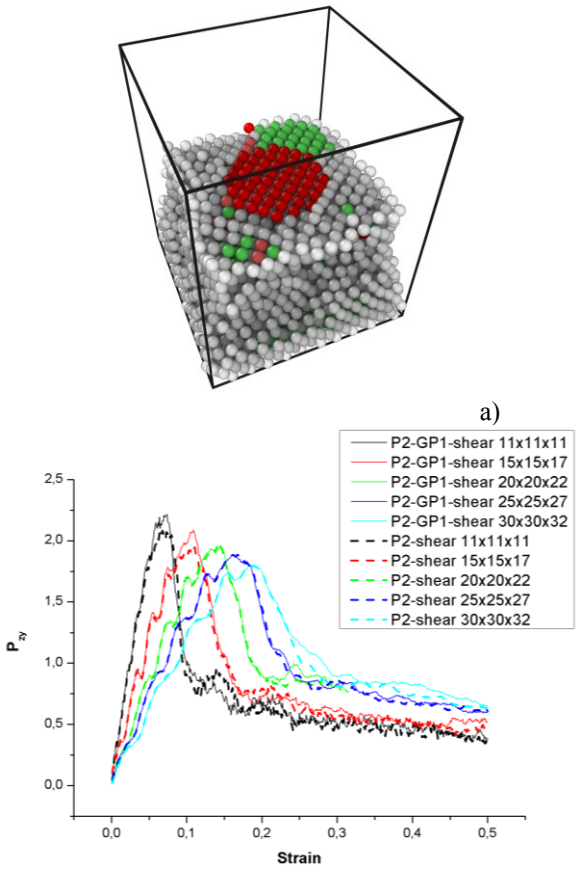

Figure 3. Examples of output data for MD simulations of functionalized nanomaterials: (a) 3D visualization by AtomEye: cross-section of nanocrystal with Cu-nanodisk (Guinier-Preston zone noted by red color), (b) post-processing by R environment: stress-strain plot

(potential type, boundary conditions, and others). The actually used workflow (Fig. 2) includes several subset workflows, which can be considered as separate tracks on the basis of separate modules (crates in SG terminology). The simulations included the following subset workflows: 1) LAMMPS + R-package — for MD simulations and plotting some post-processed values, like stress-strain dependencies; 2) LAMMPS + R-package + AtomEye + FFMPEG — for the same operations + visualization of intermediate states of atoms and final video visualization; 3) LAMMPS + R-package + AtomEye + FFMPEG + debyer — for the same operations + processing data for X-ray and neutron diffraction and their plotting, like XRD-plots. From the physical point of view it was shown that nanocrystal size and complex nanoscale defect substructure influence the strength properties of Al-Cu alloys (Fig. 3b). These results confirm and illustrate the known experimental data described in [22-24].

The potential for variability of this approach can be illustrated by possibility to change input/output scripts (for LAMMPS, AtomEye, and R crates-components) and parameters (for LAMMPS, AtomEye, FFMPEG, and debyer crates). By change of these scripts and parameters the workflow can be applied for the quite different use case, namely, for MD simulations of the nanosubstrates functionalized by carbon nanotubes (Fig. 4a).

As it schematically shown in Fig. 1 the general backbone structure (Fig. 2) can be used in the shape of some subsets for various scientific domains (Physics, Materials Science, Chemistry, Biology, etc.). These subsets can include various sets of modules (user can select the modules connected and emphasized by red color).

Among general modules, for example, “Basics of computing” set could include the crates with some executables dedicated to various computing aspects (basic operations in Linux, Windows, Shell Scripts, Data Operations, Network Basics, ...). “Computing Tools” set can comprise the correspondent binaries (Octave, R, SciLab, Matlab, Mathematica) and input/output scripts for them. “Mathematical Tools” can include static or dynamic content dedicated to some basic and more complex mathematical approaches (like Algebraic Equations, Linear Systems, Ordinary Differential Equations, Partial Differential Equations, etc.). The similar content can be in included “Computing Methods” set (like Symbolic Computation, Numerical Computation, Molecular Dynamics, Ab Initio).

Among application-specific modules, for example, “Main Content” can be related with the specific processes: physical (Diffusion, Aggregation, Reaction, Coalescence, etc.), mathematical (Random Walk, Fractals, etc.), biological, financial, geological, astronomic, and others.

Finally, “Specific Use Cases” can be concentrated on the more practical examples, which are illustrated in this section (Fig. 2 and 3).

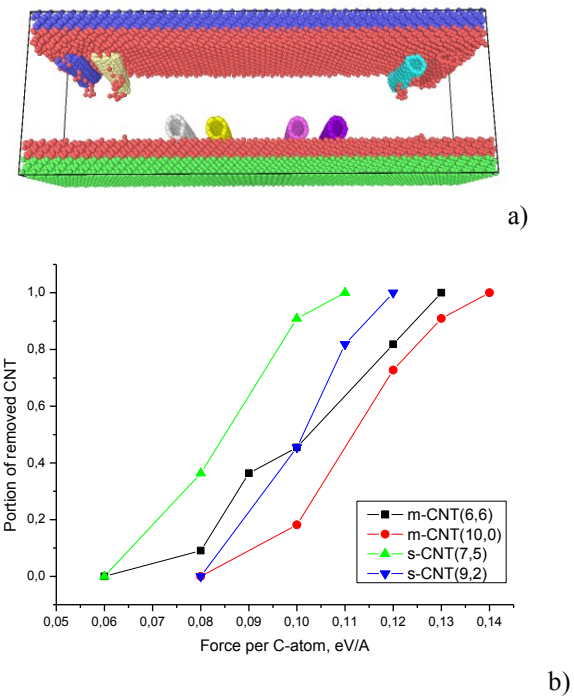

Figure 4. Examples of output data for MD simulations of the nanosubstrates functionalized by carbon nanotubes: (a) 3D visualization by AtomEye: nanotubes with various adhesion properties, (b) post-processing by R environment: the portion of removed nanotubes vs. the force applied to the nanotube

TABLE II. EXAMPLES OF SCALE LEVELS IN THE USE CASE OF MOLECULAR DYNAMICS SIMULATIONS OF NANOMATERIALS

Level	*Duration*	*Student Work*	*Topic*
Nano (skill)	10-30 min.	Input values	Basics of simulation (LAMMPS, NAMD, GROMACS, debyer), visualization (AtomEye, Ovito), simple plotting (R, ipython)
Micro (labwork)	1-8 hours	Input script	Scenarios of MD simulations (LAMMPS, NAMD, GROMACS), statistical processing (R), complex plotting (R, ipython)
Mini (module)	1-14 days	Set of scripts + parameters	Simple experiment (set of modules linked by scripts)
Macro (course)	1-6 months	Tree of scripts + parameters	Complex experiment, even up to diploma work

The additional way for variability of this approach can be illustrated by possibility to change the scale of the learning track. It is schematically depicted by connecting lines between modules in Fig. 1. The various scale levels are illustrated in Table 2 for the use case of molecular dynamics simulations of functionalized nanomaterials. All of these scale levels are actually constructed around various numbers of crates (SG components) and connecting links between them, which can be easily arranged and tuned in SG framework [16]. Our SG (http://scigate.imp.kiev.ua) in collaboration with High Performance Computing Center (http://hpcc.kpi.ua) was aimed on the close cooperation among the main actors in learning and researching world (teachers, students, scientists, supporting personnel, volunteers, etc.) with industry and academia to propose the new frameworks and interoperability requirements for the building blocks of a digital ecosystem for learning (including formal, non-formal, and informal learning) that develops and integrates the current and new tools and systems. This multi-level approach improves the effective study and research through flexible selection and combination of unified modules.

V. CONCLUSIONS

Usage of SG ideology for development and integration of real-world and user targeted digital technologies for learning will foster the academia to use them and stimulate the market for innovations in educational technologies. Industrial actors can create "supermarkets" of modules and courses, created by academia or in cooperation with academia, and provide "menus" to obtain the customized learning "meals" (learning courses) created by teachers or/and users. It could boost the formal learning (schools, universities, etc.), the life-long and vocational fields of learning, and, especially, in-formal learning.

The novelties and advantages of the proposed paradigm (in comparison to the numerous available online learning solutions) consist of:

- homogenization and smoother integration of the very heterogeneous available learning content from various institutions (by the standard requirements for the new modules and the wrappers of legacy modules),
- close approach to the real-life learning situations,
- dynamic content, i.e. some modules in the shape of Virtual Labs around the simulations or remote experimentations (if the latter will be found among the potential partners),
- flexible combinations of various modules on demands of end users,
- modules with various versions differed by complexity (beginner, advanced, professional, etc.), scale (duration) like "nano" (10-30 min), "micro" (1-8 hours), "mini" (1-14 days), "macro" (1-6 months), and range,
- "billing" system around modules to provide the feedback for teachers about the quality, value, and necessity of some parts of the course or combinations of some modules,
- open or commercial repositories of the "bricks": modules, Virtual Labs, remote experimentations,
- portal(s) for content, tools, and user management.

This flexible and multiscale approach can help to implement the paradigm of ubiquitous learning (which development is usually restricted in time and space), and it can be feasible and efficiently implemented in the modern education system.

ACKNOWLEDGMENT

The authors would like to thank Prof. P.Kacsuk, D.G.Iglesia and A.Pester for fruitful discussions of this approach and valuable critics.

Evaluation of POS Scheduling Algorithm for Distributed Computing Environment

Anastasia Shamakina and Leonid Sokolinsky
South Ural State University, Chelyabinsk, Russian Federation
shamakinaav@susu.ru, Leonid.Sokolinsky@susu.ru

Abstract - One of important classes of computational problems is the class of problem-oriented workflow applications executed in distributed computing environment. The problem-oriented workflow application can be represented by the oriented graph with the tasks as the nodes and the data flows as the edges. For the problem-oriented workflow application, we can predict the execution time of the task and the amount of data to be transferred between the tasks. Nowadays, the significant number of scheduling algorithms for the distributed computing environment are proposed. Some of them (like DSC algorithm) take into account the peculiarity of problem-oriented workflow applications. Others (like Min-min algorithm) take into account the many core structure of the node of computational network. However, no one of them take into account both these properties. We developed the new Problem-Oriented Scheduling (POS) algorithm for distributed cluster computing environment, which is able to plan the launch of a task on several processor cores, taking into account the limit of task scalability.

I. Introduction

Today a large number of scheduling algorithms for distributed computing environments are suggested [1, 2]. Only a small part of these algorithms takes into account the problem-oriented specificity of workflows in complex applications. This specificity is expressed in the form of setting an execution time of a task and an amount of transmitted data.

In this paper, we propose Problem-Oriented Scheduling (POS) algorithm for distributed cluster computing environment, which is able to plan the launch of a task on several processor cores, taking into account the limit of task scalability.

This paper presents the results of computational experiments to investigate the adequacy and efficiency of the POS algorithm for problem-oriented computing environments. The article contains the following sections. In section II, the basic idea of the POS algorithm is proposed. In section III, we present the evaluation of the POS algorithm. We describe a methodology of the experiments, methods of generating test job graphs and results of the comparison of algorithms POS, DSC and Min-Min. In section IV we summarize the results of our research.

The present work was supported by Russian Foundation for Basic Research (RFBR), Research Project No. 14-07-31159-mol-a "My first grant".

II. Problem-Oriented Scheduling Algorithm POS

We have developed a new scheduling algorithm for distributed computing environments, which enables to plan the launch of a task on several processor cores with a limitation of task scalability. A computing application, which represents a workflow, is presented as a weighted labeled directed acyclic graph. Each task (that is a graph node) is labeled by a pair of natural numbers: the executing time of the task on a single processor core and a maximum number of cores on which the task demonstrates a nearly-linear speedup. In future, we will consider tasks which have a nearly-linear speedup. The edge weights define the amount of transferred data. The proposed scheduling algorithm constructs a sequence of graph configurations in order to minimize a cost of the critical path in this graph. In the initial configuration, the graph is presented by a canonical tiered-and-parallel form (multilevel structure). Initial task clustering is defined. For each task a separate compute node is allocated. Respectively, each cluster includes only one task. All task are marked as non-fixed. Then a schedule of task execution is defined. All tasks belonging to the same tier have the same start time. The start time for all tasks of the first tier equals zero. Tasks of the second tier will able to execute when all tasks from the first tier were done and all necessary data for all tasks of the second tier were transmitted. Similarly, the start time of tasks from other tiers is calculated. The tasks of the first tier are marked as fixed on their compute node. The next step is a conversion to a new graph configuration. To reduce the total execution time of the graph, we can zero the communication cost of an edge between a fixed and a non-fixed tasks by joining these tasks to a particular cluster at the same compute node. To do it, we move the non-fixed task along its tier to the fixed task on another compute node. Also a new additional tier in the graph for the non-fixed task can be created. The task is marked as fixed. Thus, the clustering and the schedule are changed. The conversion to the new configuration is performed only in case when the cost of the critical path does not increase. The process of constructing a sequence of graph configurations is completed when all tasks are fixed. The detailed description of POS algorithm can be found in paper [3, 4].

III. Evaluation of the POS algorithm

A. Methodology of the experiments

We evaluate the POS algorithm using the following two classes of jobs:

1) multi-objective optimization (MOO);
2) random jobs (RJ).

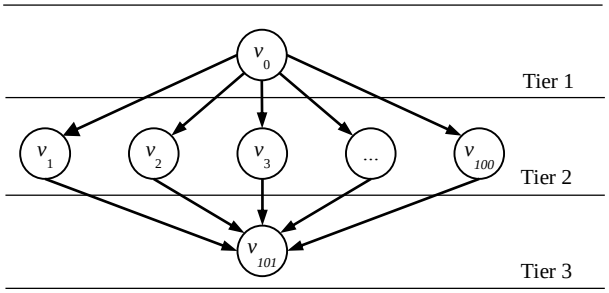

Figure 1. An example of a job graph of the MOO class

The MOO class is one of the most important classes of modern distributed computing system workload. Job graphs of the MOO class have the following structure: a tiered-and-parallel form consists of three tiers. The first and third tiers of the tiered-and-parallel form contain one vertex. The second tier contains *w* vertices. The number *w* is specified when the job graph is generated. The tasks in second and third tier are multiple copies of the same task in first tier. In practice, all tasks in different tiers are different. A vertex of the first tier is connected with all vertices of the second tier by edges. A vertex of the third tier is also connected with all the vertices of the second tier by edges. Each vertex is labeled by a pair of natural numbers (m_v, t_v). The first one is a maximum number of cores on which the task demonstrates a nearly-linear speedup. The second one is the time of task execution on a single processor core. For this experiment, numbers m_v and t_v are constants and they have the same value for all tasks. Practically numbers m_v and t_v may have different values. Similarly, each edge is labeled by a constant δ, which defines the amount of data transferred between the tasks. The constant δ has the same value for all edges. Fig. 1 shows an example of a job graph of the MOO class with a width of the tiered-and-parallel form *w* equals to 100.

The RJ class represents random jobs with different numbers of vertices and edges. A qualitative characteristic of a job graph in the RJ class is a ratio T/Δ, where T is the average executing time of all tasks on a single processor core, Δ is an average weight of all edges. According to this parameter in the RJ class Gerasoulis et al. [5] distinguish the following three important groups.

1) The group M1 is a set of balanced jobs graphs with the ratio $T/\Delta \in (0.8, 1.2)$. The average weights of computation and communication are close.
2) The group M2 is a set of coarse grain graphs with the ratio $T/\Delta \in (3, 10)$. In these job graphs, most of the time is spent on the computation.
3) The group M3 is a set of fine grain graphs with the ratio $T/\Delta \in (0.1, 0.3)$. In such jobs, significant time is expended on transmission data and the calculation requires a little time.

B. Results of the experiments

In the first series of experiments, we investigated a density of a schedule generated by the POS algorithm. Here, the density of a schedule is called the inverse of the number of compute nodes involved for a job.

TABLE I. PARAMETERS FOR CONSTRUCTING A JOB GRAPH OF MOO CLASS

Parameter	Semantics	Value
m_v	Maximum number of cores on which the task demonstrates a nearly-linear speedup	10
t_v	Executing time of the task on a single processor core	100
δ	Amount of data transferred between the tasks (conventional units)	50

TABLE II. PARAMETERS FOR CONSTRUCTING A JOB GRAPH OF RJ CLASS

Parameter	Semantics	Value
l	Height of a job graph	10
m_v	Maximum number of cores on which the task demonstrates a nearly-linear speedup	10
t_v	Executing time of the task on a single processor core	100
δ	Amount of data transferred between the tasks (conventional units)	50

TABLE III. PARAMETERS FOR CONSTRUCTING A JOB GRAPH FOR THE SECOND SERIES OF EXPERIMENTS

Parameter	Semantics	Value
m_v	Maximum number of cores on which the task demonstrates a nearly-linear speedup	20
t_v	Executing time of the task on a single processor core	40
δ_{M1}	Average weight of an edge for group $M1$ (conventional units)	40
δ_{M2}	Average weight of an edge for group $M2$ (conventional units)	10
δ_{M3}	Average weight of an edge for group $M3$ (conventional units)	400
d	Number of cores in a compute node	100

Firstly, the density of the schedule has been investigated for jobs from the MOO class. The experiments were carried out for three values of the parameter *w*, which determines a width of a job graph: 100, 200, 300. The same values of edge weights and vertex labeling were used for all edges and vertices of a graph. They are presented in Table I.

The experimental results are shown in Fig. 2 (A) as the dependence of the number of involved compute nodes on the number of processor cores on a single compute node. The plots show that if the number of cores in a compute node is increased, then the density of the schedule for the MOO class will increase and tend to the maximum value 1 in all considered cases. Herewith, the schedule density increases significantly with an increase in the width of the job graph.

Secondly, the density of the schedule has been investigated for jobs from the RJ class. The experiments were carried out for three values of the parameter *w*, which determines a width of a job graph: 30, 50, 70. The same values of edge weights and vertex labeling were used for all edges and vertices of a graph. They are presented in Table II. The experimental results are shown in Fig. 2 (B). The plots show that if the number of cores in a compute node is increased, then the density of the schedule will also

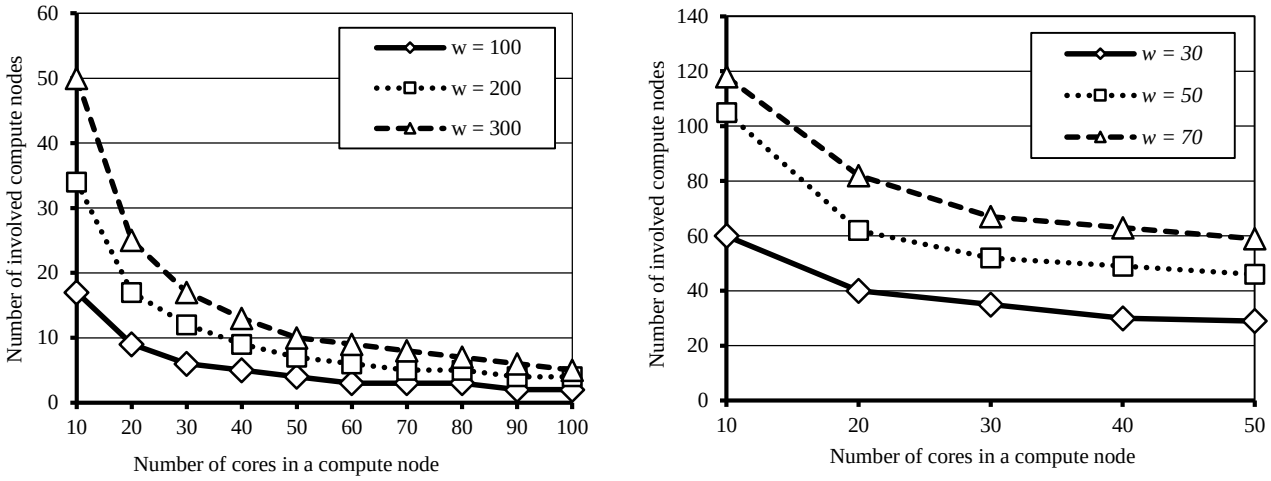

Figure 2. Dependence of the number of involved compute nodes on the number of processor cores on a single compute node: (A) for the MOO class; (B) for the RJ class

increase and tend to the maximum value 1 in all considered cases. Herewith, the schedule density increases significantly with an increase in the width of the job graph.

In the second series of experiments, we investigated the ratio of the execution time of a job graph by the POS algorithm in comparison with the other two scheduling algorithms: DSC [6] and Min-Min [7]. For this purpose three groups M1, M2 and M3 of job graphs have been prepared with the parameters given in Table III. The experimental results are shown in Tables IV-VI. The POS algorithm significantly exceeds algorithms DSC and Min-min by total time of a job in all cases. For example, an average acceleration of the POS algorithm in comparison with the Min-min algorithm exceeds 11, and with the DSC is more than 5 for balanced jobs graphs. The POS algorithm minimizes the number of involved compute nodes better, than the DSC algorithm.

IV. CONLUSION

The POS algorithm for distributed cluster computing environments allows to plan the launch of one task on multiple cores with the limitations on its scalability. This scheduling algorithm is designed to create a system of intelligent planning and scheduling a workflow in order to increase the efficiency of the supercomputer complexes with cluster architecture. This algorithm was implemented in Java as a service based on UNICORE platform. Computational experiments demonstrated that the POS algorithm significantly outperforms DSC and Min-min by the total time of job execution.

TABLE IV. COMPARISON OF ALGORITHMS POS, DSC И MIN-MIN FOR THE GROUP M1

No.	l	w	$\|V\|$	$\|E\|$	Number of involved compute nodes			The ratio of the execution time of a job graph	
					POS	DSC	MinMin	DSC/POS	MinMin/POS
1	5	10-20	51	126	7	21	4	3.78	8.86

***Abstract*— The technological advancements have resulted in substantial increase of commodity computing, mainly as the outcome of faster hardware and more sophisticated softwares. In spite the presence of super computers in present age, all the problems in the fields of science, engineering and business cannot be efficiently and effectively dealt with. This is mainly because of complexity factor and cost margin. For a complex program presented by any of the fields above, the data provided requires a number of heterogeneous resources that are scattered across the globe hence making the problem very cumbersome to handle. To address this; concept of grid computing evolved which combines and connects all the required heterogeneous resources to form a single entity which can resolve the problem at hand. With the implementation of grid at practical level lot of problems arise which need to be addressed before the system is put to use. One of the main aspects that must be kept under check while executing a problem set on grid is the security, which mainly includes the privacy and the integrity of the data that becomes vulnerable due to its distributed nature. This paper mainly focuses on the implementation of grid and gives the idea of the exponential difference between the performances of a stand-alone system in comparison to grid. In its broader view we intend to discuss analysis of a specific problem set on both the platforms, and provide the analysed data to support the high end performing nature of the grid in contrast to a stand-alone system.**

Index Terms*— Grid computing ,grid components, grid setup, performance evaluation.(keywords)*

I. INTRODUCTION

Grid Computing can be considered as an infrastructure service that makes computation available on demand like water, gas or electricity by joining resources spread over the globe at different locations. Grid is virtualization of resources which is a hardware software infrastructure that provides dependable, consistent, pervasive, and inexpensive access to computational capabilities, as described in Ian Foster and Carl Kesselman [1]. In grid computing sharing of computational resources (CPU cycles, disk space etc.) rather than data is be attained. Its key values are in the underlying distributed computing infrastructure technologies that evolve in support of cross-organizational application and resource sharing (virtualization) across platforms and organizations. This kind of virtualization is achievable through use of open standards, which ensure that applications can transparently take advantage of whatever appropriate resources made available to them. Grid computing could be defined as any of a variety of levels of virtualization along a continuum. Exactly where along that continuum one might say that a particular solution is an implementation of grid computing versus relatively simple implementation using virtual resources is a matter of opinion [2].

In most organizations there are lots of underutilized resources, such as computing and data resources. With the help of grid these unused resources can be properly utilized. Often, resources may have enormous unused disk capacity. Grid computing (more specifically, a data grid) can be used to aggregate the unused storage into a larger virtual data resource.

Grid also offers resource balancing by scheduling jobs on machine with low utilization.

On the basis of use, grid computing can be divided into different types:

- **Computational grids:** These type of grid are meant to provide secure access to computational resources, sufficient enough to perform processing of computational problems which otherwise would have required high computing power machines.
- **Collaboration grid:** With the advances in network hardware resources and Internet services, demand for better collaboration has increased. Such desired collaboration is best possible with these kinds of grids.
- **Utility Grid:** In this type of grid not only CPU cycles are shared, also other software's and special peripherals like sensors are also shared.
- **Network grid:** Even if we have computational machines with enough computational power as a part of grid but with poor network communication one can't utilize those machines optimally. Network grid provides high performance communication using data caching between nodes there by speed-up communication with each cache nodes acting as router.
- **Data grid:** There are two things, data and computation over that data. Data grid provides the support for data storage other data related services like data discovery, handling, publication, etc [3].

Globus: A software infrastructure that enables applications to handle distributed, heterogeneous computing resources as a single virtual machine. The Globus project is a U.S. multi-institutional research effort that seeks to enable the construction of computational grids. A computational grid, in this context, is a hardware and software infrastructure that provides dependable, consistent, and pervasive access to high-end computational capabilities, despite the geographical distribution of both resources and users. Globus is constructed as a layered architecture in which high-level global services are built upon essential low-level core local services. The Globus toolkit is modular, and an application can exploit Globus features, such as resource management or information infrastructure, without using the Globus communication libraries [4].

SETI@HOME: The seminal Internet distributed computing project, SETI@home, originated at the University of California at Berkeley. SETI stands for the "Search for Extra-terrestrial Intelligence," and the project's focus is to search for radio signal fluctuations that may indicate a sign of intelligent life from space. SETI@home is the largest, most successful Internet distributed computing project to date. Launched in May 1999 to search through signals collected by the Arecibo Radio Telescope in Puerto Rico (the world's largest radio telescope) [5].

II. IMPLEMENTATION

For realizing grid following steps should be taken into consideration:

- Integration and communication of various individual software and hardware components to act like a single system.
- Implementation of middle-ware so that the resource sharing and access becomes secure.
- Development of grid tools so that grid applications and resources can be easily monitored and managed.
- Developing applications that can be used to take the advantages of resources available in grid [6].

The components required to establish a grid are:

- **Grid Fabric:** It includes geographically distributed and accessible from anywhere on the Internet resources. It comprises computers (workstations or PC's running on different operating systems), databases, networks, resource management systems such as LSF, CONDOR or PBS and sensors or special scientific devices.
- **Grid Middle-ware:** It acts as intermediator between components of software with the applications, allowing them to communicate. It is made up of services sets such as remote process management, co-allocation of resources, information exchange, and security. Interoperability between two or more networked computers is enabled by grid middleware with the help of common protocols.
- **Grid Tools:** These tools helps in realizing grid, developing grid enabled applications and brokers that acts as user agents which can manage or schedule computational resources across grid.
- **Grid Applications and Portals:** Grid portals provide us user interface for accessing grid services. It can be used for submission of jobs and getting result back in grid environment [7].

While creating the grid environment, we walked through the following processes/tasks

1) Globus Toolkit Configuration: The Globus Toolkit is an open source software toolkit used for building computational grids and grid based applications. It allows sharing of computing power, databases, and other tools securely online across corporate, institutional and geographic boundaries without sacrificing local autonomy. It is being developed by the Globus Alliance. It is widely used as a basis for grid implementations all over the world, including Grid Ireland. The Globus toolkit has a modular design which contains at its core an implementation of the Open Grid Services Infrastructure (OGSI) specification. Globus provides resource management, data management and information services. Built upon this, there is a security infrastructure which provides security at a message level as well as authentication and authorization [8].
2) Network Setup: Configuring DNS: Domain Name System (DNS) converts the name of website (www.gridboss.mquad.com) to an IP address (192.168.0.6). This is important, because the IP address of a Web site's server, not the Web site's name, is used in routing traffic over the Internet. Everyone in the world has a first name and a last, or family, name. The same thing is true in the DNS world: A family of Web sites can be loosely described a domain. For example, the domain linuxhomenetworking.com has a number of children, such as www.linuxhomenetworking.com and mail.linuxhomenetworking.com for the Web and mail servers, respectively. The DNS queries from remote machines can be responded by BIND. It is an acronym for the Berkeley Internet Name Domain project, which is a group that maintains the DNS-related software suite that runs under Linux [9].
3) Security Implementation: For implementing security in grid environment one must consider the following security aspects.
    - Authentication: Is the process by which a resource or user's identity is verified. It is extremely important to correctly establish the correct identity of an entity.
    - Authorization: Once the identity of an entity is correctly established authorization is used to find what actions the entity is entitled to perform.

- Encryption: Any data passing over public networks is open to be intercepted. A sniffer has the ability to listen in on this data and extract sensitive information as well as usernames and passwords. To avoid this encryption is used to encrypt all transmissions. To a party sniffing the data it would appear as garbage.
- Data Integrity: This involves ensuring that the integrity of the data transferred across the Grid is maintained. This is extremely important in guaranteeing accurate results from jobs.
- Data Confidentiality: A lot of grid applications involve processing data. In many cases where this data is of a sensitive nature it is imperative to ensure that only those authorized to view this data be allowed.
- Single Sign On and Delegation: It is often the case that an entity A will act on behalf of entity B and will need to contact another entity C on B's behalf. Delegation of entities' credentials enables this to be possible [10, 11].

The attempt to fulfill these security requirements systems based on the Public Key Infrastructure (PKI) were used. The Globus Toolkit offers a Grid Security Infrastructure (GSI) that provides a PKI based security system that can be used to address most of the security problems encountered when dealing with grids [12].

For the Globus toolkit, X509 certificates were used for authenticating users, hosts and resources. This package uses OpenSSL commands to create public and private keys for the Certifying Authority (CA) [11].

III. RESULT

The implemented grid system is analyzed to see how it performs in contrast with stand-alone system. The performance of both the systems can be analyzed by the time taken for a job (operation) to get completed. Difference between the times taken by two systems to complete a job can be evaluated by:

$$t_d = t_s - t_g \quad (1)$$

where t_s is the time taken by stand-alone system to complete the job, t_g is the time taken by grid system to complete the job, and $t_{d\ is}$ the difference of time taken by the grid system and the stand-alone system to get job completed.

The jobs (operations) this paper is focused on are:

i) Copy operation: In this operation different set of data of varying size has been copied from one location to another on the same system both by the grid and stand-alone system. As shown in Fig1. the time taken by a stand-alone system for carrying out the copy operation is more than that taken by the grid system for the same job because in grid, computational power of different systems are utilized for carrying out the operation.

TABLE I. REPRESENTS THE TIME TAKEN BY GRID AND STAND ALONE SYSTEM TO COPY THE DATA OF DIFFERENT SIZES.

Time Taken By A Stand Alone System(In Sec)(Ts)	Time Taken In Grid(In Sec)(Tg)	Size(In GB)
0.86	0.79	0.1457
1.452	1.252	0.1958
13.236	7.134	0.3730
14.121	10.975	0.5689
27.049	25.59	0.746
31.023	28.263	0.7649
41.999	45.649	1
50.979	47.32	1.4

180.13	174.46	4
220.56	201.16	4.8
355.12	345.79	8
1661.68	1499.36	15.5
3265.68	2956.66	32

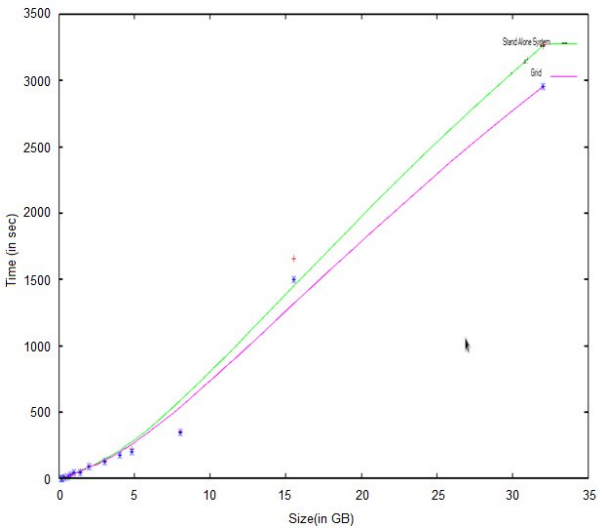

Fig1.Copy operation submitted to stand alone system and grid

From graph shown on Fig 1, it is evident that the copy operation processed on grid takes less time when compared with a standalone system.

ii) Tar operation: It is concerned with the archiving of different files into one compressed entity. On grid these

different files are compressed using resources of multiple components so as to enhance the overall performance for carrying out the mentioned operation.

TABLE II. REPRESENTS THE TIME TAKEN BY GRID AND STAND-ALONE SYSTEM FOR DOING TAR OPERATION ON DIFFERENT SIZES OF DATA.

Time Taken By A Stand-Alone System(In Sec)(Ts)	Time Taken In Grid(In Sec)(Tg)	Size(In GB)
0.032	0.028	0.0079
1.448	0.475	0.1457
1.754	1.542	0.1958
7.542	7.139	0.3730
12.045	11.477	0.5689
27.233	24.212	0.7649
38.145	35.968	1
57.19	50.15	1.4
100.011	95.79	2
147.56	140.67	3
192.16	182.76	4
236.06	217.56	4.8
370.72	352.16	8
1168.21	989.32	15.5
2502	1573	32

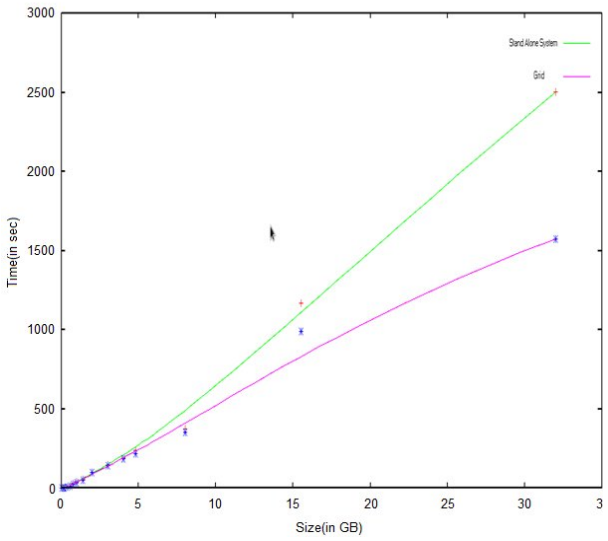

Fig 2 .Tar operation submitted to stand-alone system and grid.

Fig 2 clearly signifies that performance of operation on the stand-alone system is less than the same operation performed on the grid.

iii) Untar Operation: It deals with expansion of a compressed file back into its original form. The decompression is done over different machines by the distribution of the compressed data on the grid and then collected to form the original. The comparison of performing the operation on both the platforms reviewed that the Untar operation on the stand-alone system took more time than the same operation done on the same file on the grid.

TABLE III. REPRESENTS THE TIME TAKEN BY GRID AND STAND-ALONE SYSTEM FOR DOING UNTAR OPERATION ON DIFFERENT SIZES OF DATA.

Time Taken By A Stand-Alone System(In Sec)(Ts)	Time Taken In Grid(In Sec)(Tg)	Size(In GB)
0.046	0.027	0.0079
1.855	0.510	0.1457
2.301	1.627	0.1958
8.403	7.564	0.3730
29.56	27.52	0.5689
38.145	34.331	0.7649
47.230	42.778	1
65.45	58.65	1.4
107.517	99.70	2
158.77	150.76	3
199.79	187.66	4
249.24	238.56	4.8
395.96	360.23	8
1405.11	1107.56	15.5
2939	1893	32

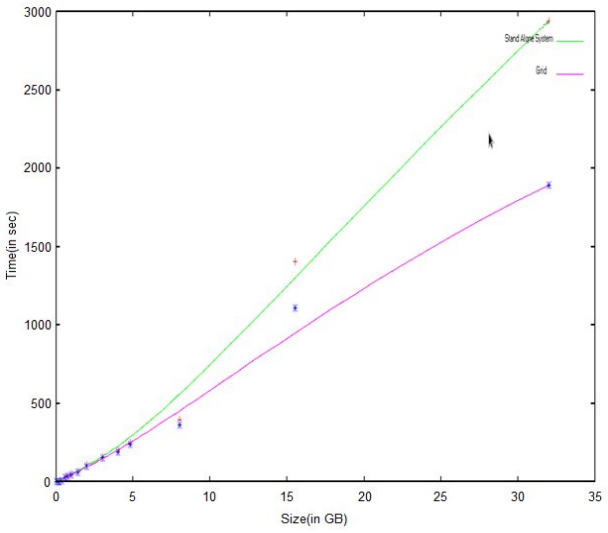

Fig 3 . Untar operation submitted to stand-alone system and grid

In consideration to Fig 3, it is consistent that grid performs faster than a standalone system.

When compared, the results of operations done on both the system, it is concluded that grid does no doubt perform a specific task much faster than the same operation performed on the stand alone system. These operations being COPY, TAR and UNTAR.

This can be verified by calculating the average time taken by the stand alone system and the grid system in TAR, UNTAR and COPY operations individually (The average time taken by grid (t_g) being 6091.905 sec, 4862.11 sec, 5648.377 sec for copy, tar and untar operations respectively and the time taken by stand alone system (t_s) being 5559.744 sec, 3682.251 sec, 4210.477 sec for copy, tar and untar operations respectively). Substituting the values of each in equation I:

COPY operation:

$t_d = 6091.905 – 5559.744 = 532.161$sec

TAR operation:

$t_d = 4862.11 – 3682.251 = 1179.859$sec

UNTAR operation:

$t_d = 5648.377 – 4210.477 = 1437.9$ sec

The positive values of 't_d' for each operation above show that grid actually performs better than the stand alone system.

Furthermore, performance of grid system is dependent on certain factors and this can be shown by:

$$t_p \propto \frac{S}{\sum_{i=1}^{n} Pi} \quad (2)$$

were t_p is time taken by grid system to complete an operation, S is size of the archiving operation and $P_1, P_2, P_3 \ldots\ldots P_n$ are the available processing power of n nodes participating in grid system.

It can also been seen that the variance in the time taken for the TAR and UNTAR operations in comparison with the stand-alone system is much larger than the variance observed in case of the COPY operation.

IV. CONCLUSION

With each passing nano second the complexity of problems provided to the stand alone computers is increasing exponentially so for now the preexisting super computers focused on a specific computational method may handle the problem but in the near future the one stand-alone super computer may not be sufficient to solve the high complexity problems. As we have presented in this paper, in support by the results that the factor by which the performance of computation on a problem set by utilizing the various resources around the globe is actually very high as compared to the same computation being performed on the stand alone computer. The fact that a technology can connect all the specific resources around a globe required for a problem and then single handedly solve the same by a high performance factor and in an affordable manner as that of a super computer of present or future gives us the glimpse of the importance of grid computing.

ACKNOWLEDGMENT

The work of course would not have been completed without support from family and guidance provided by the supervisor. It is worth mention that Mr. Naiman Altaf and Mr. Mohammad Nayeem Shah has provided support and vital role in completion of this research paper.

Abstract - The paper concerns the hype idea of "Citizen Science" and the related paradigm shift: to go from the passive "volunteer computing" to other volunteer actions like "volunteer measurements" under guidance of scientists. They can be carried out by ordinary people with standard computing gadgets (smartphone, tablet, etc.) and the various standard sensors in them. Here the special attention is paid to the system of volunteer scientific measurements to study air showers caused by cosmic rays. The technical implementation is based on integration of data about registered night flashes (by radiometric software) in shielded camera chip, synchronized time and GPS-data in ordinary gadgets: to identify night "air showers" of elementary particles; to analyze the frequency and to map the distribution of "air showers" in the densely populated cities. The project currently includes the students of the National Technical University of Ukraine "KPI", which are compactly located in Kyiv city and contribute their volunteer measurements. The technology would be very effective for other applications also, especially if it will be automated (e.g., on the basis of XtremWeb or/and BOINC technologies for distributed computing) and used in some small area with many volunteers, e.g. in local communities (Corporative/Community Crowd Computing).

I. INTRODUCTION

The proposed topic concerns the new hype idea of "Citizen Science" and volunteer involvement in science [1]. The main principle here is the paradigm shift: to go from the passive "volunteer computing" (widely used now in many fields of sciences [2-5]) to other volunteer actions under guidance of scientists as "volunteer measurements", "volunteer data processing and visualization", "volunteer data mining", etc. They can be carried out by ordinary people with modern standard computing units (wearable PC, smartphone, tablet, smart watch, etc.) with various operational systems (Android, iOS, Windows, Tizen, etc.) and the standard sensors in them or easily accessible external measuring units.

The work presented here was partially supported by EU FP7 SCI-BUS (SCIentific gateway Based User Support) project, No. RI-283481.

The main components of the idea or conditions for effective implementation of volunteer measurements are as follows: (a) they should be used by ordinary people – not scientists only, (b) they should be performed by easily accessible measuring units – like modern smartphones with numerous sensors, and (c) in unobtrusive way.

The most important expectations (and potential criteria of success) are possibilities to:

- leverage the available "crowdsource" resources: machine (personal CPUs + sensors) and human (brains, manual operations of sensors) ones,
- get huge number of volunteers (up to millions),
- obtain the new scientific "quality" from these huge "quantities",
- involve ordinary citizens in scientific process,
- report to society about the current scientific activities and priorities.

II. PREVIOUS WORK AND STATE OF THE ART

The feasibility of the proposed idea was already tested in several awarded volunteer projects with the several types of activities in different fields of science, which is illustrated by some use cases below in this section.

A. Monitoring Environmental Conditions

In 2012 "My Green City" project was initiated by the group of students for monitoring environmental conditions and their effects on everyday life [6]. It was motivated by the famous problem that vehicle exhausts are ones of the most dangerous sources of air pollution in cities, but global attempts to assess how emissions impact local city ecology have proven to be ineffective.

The aims of "My Green City" project were as follows:

- to estimate personal dosage of accumulated dangerous emissions by volunteers,

Figure 1. The typical volunteer gear: CO-gas-USB logger (top left), which can be attached to rucksack, and smartphone with GPS-navigator in the pocket (bottom left) of the volunteer (right)

- to determine real-time distribution of pollutants by vehicle exhausts in cities.

The technical implementation was based on integration of pollution data by vehicle emissions sensor (CO-gas-USB logger) and location data by GPS-navigator in ordinary smartphones (Fig. 1) for: estimation of personal dosage of accumulated dangerous emissions (so called "personal air health monitor"), and continuous air pollution data processing and construction of interactive air pollution map (Fig. 2).

To check feasibility of this proposal the student pilot project "My Green City" was implemented with construction of the air pollution map for the city of Kyiv (Ukraine) in 2012. The social incentive behind this pilot project can briefly be expressed by the slogan: "from volunteer scientific calculations to volunteer scientific measurements". It became one of the 15 global finalists in Google Science Fair 2012 [7].

Scientists can develop tools (personal air health monitor and online virtual air pollution map) by integration of location-based data from sensors of numerous volunteers. It can allow volunteers and communities to make real time estimations about the actual impact of vehicle emissions on a city environment.

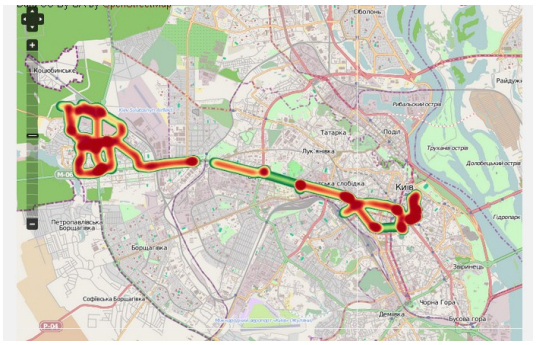

Figure 3. The interactive air pollution map for the city of Kyiv along the regular tracks of children acting as volunteers (http://dg.imp.kiev.ua/slinca/my-green-city/CO)

For municipal authorities, these tools could improve overall city traffic planning and city management accountability. For people, these tools could stimulate better personal planning and implement healthier behavior due to: (A) the greater public awareness of air pollution distribution by virtual air pollution map; and (B) the targeted estimation of personal dosage of accumulated dangerous emissions by personal air health monitor.

B. Monitoring Personal Health

The other volunteer measurement project «How to Make Old Age More Comfortable, Less Boring and Active for Your Nearest and Dearest» (2013) was dedicated to the following problem [8]. The human population become older and will continue to do so in the coming decades; elderly people suffer from various diseases. The project activities were based on the fact that elderly people suffer from various diseases, but their progress can be monitored by decrease of mobility. The aim of the project was to explore the use of sensors in the usual smartphone to monitor the health of older people by analysis of their locomotor activity. The similar method was used in this project, namely, embedded personal sensors (accelerometers) and smart phones were used for real time monitoring the motion pattern (mean, standard deviation, skewness, curtosis, etc.) for different types of motion (sleep, walk, run, etc.).

The technical implementation (Fig. 3) consisted in integration of personal measurement tools and attachment points on the basis of the following available gadgets:

- smartphone with accelerometer (G-sensor) on the arms (during writing, web-surfing, etc.) and legs during cycling (walking, running, etc.);
- "smart watch" (the arm wrist device ez430 by Texas Instruments) with accelerometer and wireless data broadcasting to a PC.

Multi-parametric moment analysis was applied for data analysis. And the previous results shown that

Figure 2. The typical location of measurement gear on volunteers: HTC smartphone with G-sensor on the arm during writing, web-surfing, etc. (top left) and on the leg during biking (top right), and "smart watch" (ez430, Texas Instruments) (bottom)

activities can be roughly classified, i.e. divided into groups (colored ellipses) with the similar values of the acceleration distribution parameters (Fig. 4, see legend in the color electronic version):

- passive (web surfing, read, sleep) (brown ellipse),
- moderate (writing, sitting) (green ellipse),
- active (sports, housework, walking) (blue ellipse).

To check feasibility of this idea the student project "How to Make Old Age More Comfortable, Less Boring and Active for Your Nearest and Dearest" (2013) was implemented in the local community. Again, the social incentive behind this pilot project can be expressed by the slightly different slogan: "from general to personal volunteer scientific measurements". It became one of the 90 Regional Finalists in Google Science Fair 2013 [9].

The tests have shown that some essential features of health and activity patterns can be distinguished and classified. By analysis of sensor (accelerometer) data scientists can develop tools (so called "personal activity monitor") that allow volunteers and communities to make real time estimations of the actual locomotor activity decrease and subsequent health decay. For health care authorities, these tools could improve overall elderly care and stimulate personal online elderly care services. For communities, these tools could stimulate closer attention to locomotor activity and its automated monitoring due to: (A) the greater public awareness of dangerous locomotor activity decrease and probable subsequent health decay; (B) the targeted estimation of personal dangerous decrease of locomotor activity by personal activity monitor; (C) increase of efficiency of elderly care in some communities by means of automatic detection of dangerous decrease of locomotor activities among neighbors, (D) decrease of burden on communities, which is related with a high costs of elderly care.

III. CURRENT PROJECT - AIRSHOWER@HOME

A. *Scientific Problem*

Cosmic rays originate mainly outside the Solar System. They may produce showers of secondary particles ("air showers") that penetrate and impact the Earth's atmosphere and sometimes even reach the surface. "Air showers" of secondary elementary particles affect electronics, health, environment. Their study is expensive (>$50 mln.) and limited in scale. The most energetic cosmic rays (>5×10^{19} eV) are most important, but very rare were observed, for example, 1 high-energy event is registered per month by Pierre Auger observatory. Pierre Auger Observatory — is an international cosmic ray observatory designed to detect ultra-high-energy cosmic rays [10,11]. It detects cosmic rays in the range of 10^{17}-10^{21} eV, costs >$50 mln., and has a detection area >12 km^2 and huge installation area >3000 km^2 (like Luxemburg). Cosmic rays affect electronics, because they have sufficient energy to alter the states of circuit components in electronic integrated circuits, causing transient errors like corrupted data in electronic memory devices, and incorrect performance of CPUs, often referred to as "soft errors" (not to be confused with software errors caused by programming mistakes/bugs!). They affect health, especially the health threat from cosmic rays is the danger posed by galactic cosmic rays and solar energetic particles to astronauts on interplanetary missions. They are one of the most important barriers standing in the way of plans for interplanetary travel by crewed spacecraft [12,13]. Cosmic rays affect environment directly or via solar-induced modulations in climate change, because solar variations modulate the cosmic ray flux on Earth, they would consequently affect the rate of cloud formation and hence the climate [14].

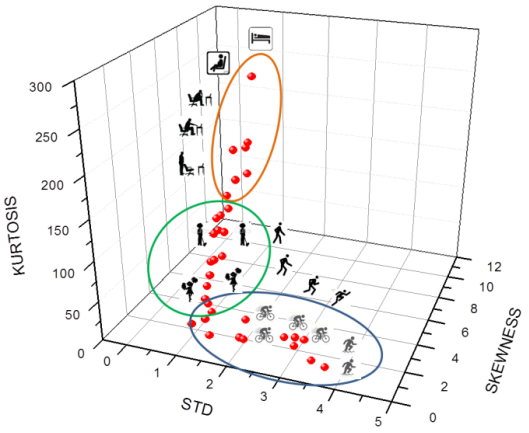

Figure 4. The moments (standard deviation, skewness, kurtosis) plot: activities (denoted by pictograms) can be classified by groups (colored ellipses in the color electronic version) with the similar values of the acceleration distribution parameters: passive (brown ellipse), moderate (green ellipse), active (blue ellipse)

B. *AirShower@Home Project Description*

As far as "air showers" of elementary particles created by cosmic rays affect electronics, they can be monitored by some available devices (like CMOS-camera chips).

The aims of AirShower@Home project were:

- to estimate possibility to identify "air showers" of secondary elementary particles,
- to determine frequency and distribution of "air showers" in the densely populated cities – by massive involvement of volunteers with creation of virtual online map of "air showers".

The volunteer measurements could be performed on the basis of the following tools:

- camera chips as embedded sensors in GPS-enabled smartphones;
- volunteer communities in densely populated locations for real time monitoring the "air showers" and analysis of their effects (on environment, electronics, health).

The technical implementation is based on integration of data about registered flashes (by radiometric software) in shielded camera chip, synchronized time and GPS-data in ordinary smartphones/tablets/other gadgets. The current workflow is shown in Fig. 5, where the size of the available academic solution, Pierre Auger observatory, is

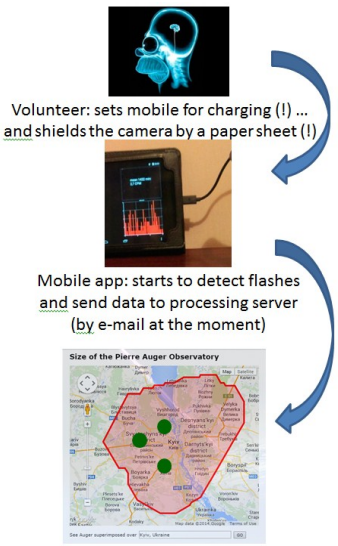

Figure 5. The diagram of the current workflow, where the sizes of Pierre Auger observatory are shown for comparison on the map of measurements in the city of Kyiv (bottom)

shown for comparison on the map of measurements in Kyiv. It includes the following components:

- hardware (various gadgets were tested: Samsung SIII (with 8 megapixels camera), HTC Amaze smartphone (8 Mpx), Nexus 7 tablet (1.2 Mpx), Nexus 7 tablet (5 Mpx), ASUS TF201 tablet (8 Mpx),
- "brainware", because some human actions are needed (volunteer should shield the camera, and perform manual post-processing, analyzing and mapping "air showers"),
- software (various mobile apps): radiation counters (used for tests only), apps for time synchronization, and e-mail clients for submissions of logs,
- volunteer community: >80 pupils and students were involved already (during the lab works in "Distributed Computing Course" at the National Technical University of Ukraine "KPI" in Kyiv).

IV. Results of the Current Project

One of the examples of the registered radiation results in counts per minute ("cpm") vs. time (within ~5 days) is shown in Fig. 6. The four smooth peaks corresponds to slow increases of background radiation (caused by the temperature increase during days), and numerous sharp peaks potentially correspond to cases of air showers caused by cosmic rays. The different colors indicate different values of filters used in the measurements. These results lead to conclusion that seasonal and other temperature changes could crucially influence the measured values of radiation and should be taken into account during such crowd measuring/computing projects.

The other example is related to tests performed on a board of the commercial air flight. The idea was to check feasibility of volunteer measurements of air showers on

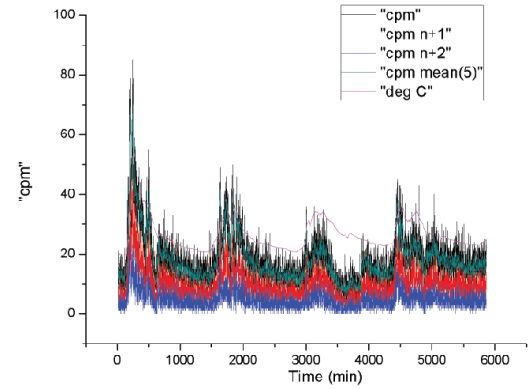

Figure 7. Registered radiation (counts per minute — cpm) vs. time

various heights using the standard commercial flights (with the usual safety precautions as to usage of electronics during commercial flights). Registration of air showers was performed simultaneously by two Nexus tablets (with different sensitivity) on a board of the Airbus 320 plane during flight Kyiv-Budapest on 10/03/2014. The radiation (in cpm) as a function of time was measured (Fig. 7), where smooth growth corresponds to increase of the registered radiation counts with altitude (9 km), and the same sharp peaks correspond to the events of simultaneous registration of the air showers caused by cosmic rays. As to possible pitfalls in such experiments, the problems related with gadget overheating can be also observed in the end of flight.

The initial stage of this crowd measuring/computing idea was performed among numerous volunteers from Lyceum 142 and the National Technical University of Ukraine "KPI" (Fig. 8). Mainly they were compactly located in the city of Kyiv (Fig. 8, inset), and this local concentration of volunteers is especially useful for the current scientific application. The measured data were send by mobile application to server, where they were collected, post-processed (in R environment for statistical analysis), mapped (by means of googleVis and Shiny packages for R environment), and published on the AirShower@Home project web-page at ShinyApps.io server (http://yocto.shinyapps.io/Height_test).

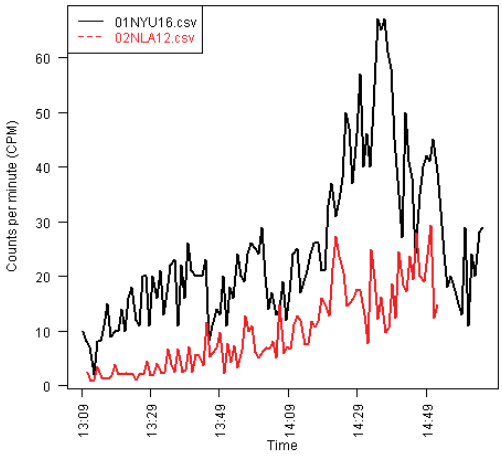

Figure 6. Registration of air showers during a commercial flight

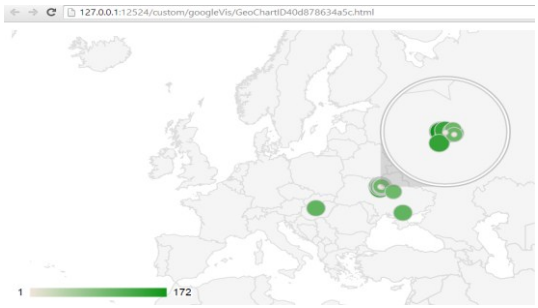

Figure 8. The map of heights at volunteers' locations among other maps with post-processed data of AirShower@Home project (http://yocto.shinyapps.io/Height_test)

Actually, these interactive maps contain information about volunteer locations, date and time of volunteer measurements, height of their locations (which are important for comparison), and the registered radiation counts.

In Table 1 the short comparative analysis is given for several solutions, namely, fdor academic solution (Pierre Auger observatory), do-it-yourself (DIY) solution with external sensor (customized solution on the basis of Raspberry PI single-board computer), and the current AirShower@Home solution with embedded sensor (widely available solution like smartphone). From this analysis it is clear that the AirShower@Home project provides an additional (not alternative!) way to study cosmic ray (by analysis of air showers) and their influence on civilization without huge installations, numerous high-qualified scientists, high basic and maintenance costs. Moreover, its crowd measuring/computing infrastructure can be effectively used for many other applications, for example, in two previous projects to upgrade and scale them up to worldwide scale.

TABLE I. COMPARISON WITH OTHER SOLUTIONS

	Academic solution (Pierre Auger observatory	*DIY solution with external sensor (Raspberry PI + sensor)*	*This "Citizen Science" solution (smartphone with sensors)*
Size	3000 km^2	1 cm^2	4 mm^2
Scalability	<30%	<10 times	> 10^6 (unlimited)
Maximal Area	~3000 km^2	~1 cm^2	>10^6 km^2
Staff (per installation)	500 scientists	1-3 scientists	1 ordinary human ("Citizen Scientist")
Cost	> $50 000 000	~$500	<$200 (smartphone)

V. CONCLUSIONS

Some lessons were learned during these three different volunteer measuring/computing projects. First of all, the positive aspects consist in feasibility:

- to leverage the available "crowdsource" resources (hardware and "brain-ware") even at this level – it is feasible, if sensors are embedded already (integration with external sensors is hardly can be attractive for potential volunteers),
- to get huge number of volunteers (millions) – it is feasible for project without sensitive data, but it could be hardly feasible for projects related with personal location and health data due to privacy issues,
- to obtain the new scientific "quality" from these huge "quantity" of data – it is feasible, and porting to the standard platforms for volunteer computing should help, because the limited automation is used at the moment,
- to involve ordinary citizens in scientific process – it is feasible, if task, results, and volunteer management will be fully automated, for example, by porting to BOINC [15] and XtremWeb environments [16],
- to report to society about the current scientific activities and priorities – it is feasible, again after porting to BOINC [15] and XtremWeb environments [16].

Taking into account these considerations and comparative analysis (Table 1) the immediate ways for improvement are seem to be based on porting this crowd measuring/computing infrastructure to the standard platforms for volunteer computing. Some of them (like BOINC and XtremWeb) are proved to be effective for distributed computing applications. For example, XtremWeb was successfully used for AIRES application used in relation to results obtained at Pierre Auger observatory [17]. Additional potential for improvement is related with optimization of the current workflow, for example, on the basis of the Science Gateway ideology. Now it is very promising way for integration and management of tasks, users, and resources [18,19], for example, on the basis of gUSE-WS-PGRADE package [20].

Such porting will allow better integration with embedded sensors and automatic cooperation with them (without manual operations), post-processing, analyzing and mapping results, and effective volunteer community management (job submission, data storage and analysis, forum, etc.) at server, especially, in open local and corporative communities (like schools, colleges, universities). As to potential contribution to science, many scientific phenomena can be investigated by ordinary people and in any place, not just in some secluded labs, which is essential for "Citizen Science" paradigm. This approach could be very useful, if it will be used in some areas with many volunteers, e.g. in local communities (which could be considered as Corporative/Community Crowd Computing)

ACKNOWLEDGMENT

The authors would like to thank numerous volunteers from Lyceum 142 and the National Technical University of Ukraine "KPI" who took part in the volunteer measurements during the initial stage of the project.

***Abstract*—Cloud computing paradigm offers instantiating and deactivating the virtual machine instances on demand according to the clients requirements. When some customer's application or a service needs more resources than a physical server can supply, the cloud provider offers a certain load balancing technique to distribute the load among several servers that will host the analyzed application or service. Additionally, the cloud provider should offer a resource broker to make the application scalable and elastic. In this paper we present a new solution for a low level load balancer, working on a network level. Our load balancer maps the memory addresses of the balancer and the target physical servers (or virtual machines on the cloud) and thus balances the load. The experiments showed that it adds small latency of several milliseconds and thus it slightly reduces the performance when the distributed system is underutilized. However, there is a region of client requests where the system achieves a superlinear speedup (speedup greater than the number of scaled resources). Our case study with doubled resources achieves up to 6.5 speedup (maximum expected linear speedup is 2).**

***Index Terms*—Distributed Computing; HPC; Performance; Services.**

I. Introduction

Information and communication technology offers a huge support for the business today by speeding up the internal business processes. However, a company must be prepared for the business processes that interact with its customers and handle the peaks in the load [1]. Adding more computing resources and balancing the load can solve this issue and various load balancers with different approaches for balancing techniques exist. The efficient and effective load balancer should have satisfy several functional requirements: balancing all incoming clients' packets to the available endpoint servers, having a configurable port where the requests should be sent their, having a pool of active endpoint servers with IP addresses that will handle the incoming packets, and the introduced load balancer between the clients and endpoint servers should improve the overall response time of the clients' requests.

Horizontal scaling is impossible without load balancing. Even more, todays most effective paradigm, the cloud computing, can not be imagined without load balancing. It is one of the four layers in the cloud application architecture [**?**], [**?**]. Rimal et al. [2] describe the load balancing techniques that are used by various cloud service providers and solutions, including Amazon, Google, SalesForce, Azure, Eucalyptus, OpenNebula, etc. Most of these techniques are implementations of a conventional Round Robin schema, weighted selection mechanisms, HAProxy, Sticky session, SSL Least Connect, Source address, cluster server load equalization, high performance protocols over EC2, hardware load balancing, cloud controllers, etc.

Load balancing is a widely used technique long time ago before the introduction the cloud computing paradigm and the virtualization technique. The performance of load balancing techniques in cloud is analyzed by several authors [3], [4].

Radojevic and Zagar [5] grouped them into three groups: Session switching at the application layer, Packet-switching mode at the network layer and Processor load balancing mode. On the other hand, Heinzl and Metz [6] classified the load balancers as hardware and software, and commercial and open source.

There are two main techniques in load balancing: centralized on a specific server or distributed on several servers. The former is controlled by a single central node with all the other endpoint servers communicate with it. Bhadani and For example, Chaudhary [7] proposed the Central Load Balancing Policy for Virtual Machines (CLBVM) solution, while the CLBDM solution [8] considers server load and application performance on top of the Round Robin Algorithm. However, the centralized load balancing approaches in cloud computing have desing limmitation and communication overhead, thus failing to offer full scalability features [9].

Simjanoska et al. [10] proposed an architecture for a Low Level Load Balancer (L3B). Their architecture can distribute server load among several machines that are integrated over the communication link [11]. The proposed architecture is realized on a network level. It dynamically balances the network packets of the clients among all end point servers and after the computation, it forwards the responses to the clients that send the requests. All these transformations are conducted on network layer, that is, by changing the information in the incoming and outgoing packet's header.

Ristov et al. [12] developed a naive implementation of the proposed L3B architecture, which unfortunately did not yield the expected results. In this paper, we present the redeveloped implementation according the same L3B architecture. The results of the conducted experiments not only that confirmed the successfulness of the implementation, but they show a superlinear speedup, that is, we achieved speedup of up to 6.5 by using two endpoint servers compared to the case when

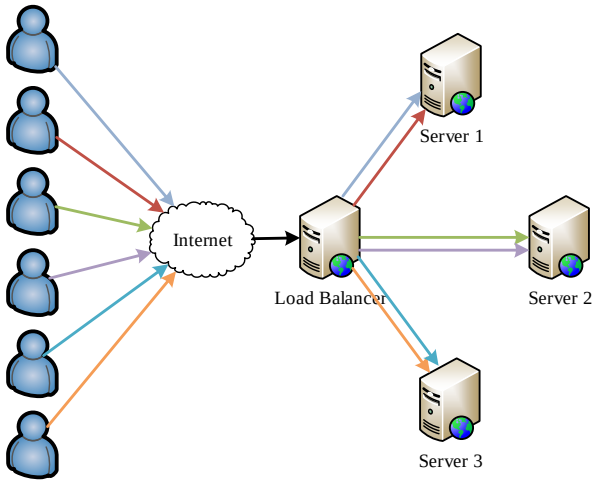

Fig. 1. L3B System architecture

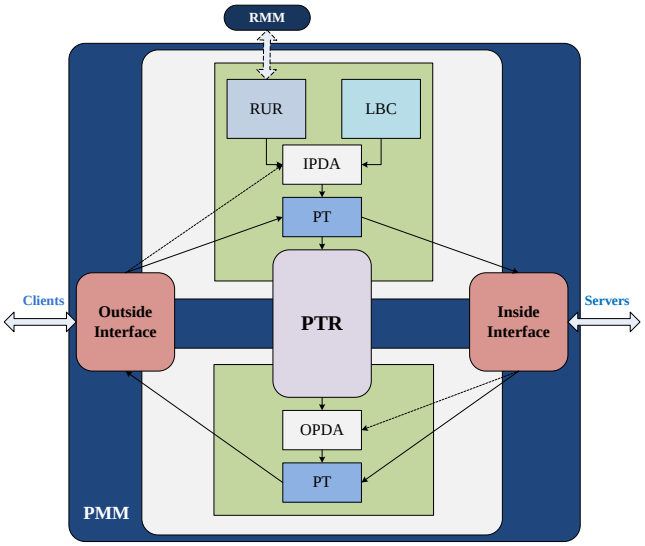

Fig. 2. Design of the PMM module

using only one endpoint server.

The rest of the paper is organized as follows. Section II briefly describes the background of L3B. The successful implementation of the L3B balancer is presented in Section III and experimentally confirmed in Section IV. Section V discusses the successful implementation of the architecture. Finally, Section VI concludes the work and presents future work.

II. L3B BACKGROUND

This section briefly describes the architectural concept and the naive implementation, which did not yield towards scalable balancer.

A. The architectural concept

The L3B's concept is presented in Fig. 1 [12]. The L3B balancer is hosted on a machine in front of a pool of endpoint servers and its main goal is to balance the clients' requests among the available servers. The latency due to balancer's additional layer should be compensated with faster response time of the endpoint servers.

The L3B balancer is designed with two main modules: *Resource Management Module (RMM)* and *Packet Management Module (PMM)* [10]. The main objective of the former is to provide new available endpoint resources according to the current clients' load and endpoint utilisation. PMM balances the incoming packets according to the received information of RMM about available and utilized resources. This paper focuses on the implementation of the PMM module. Its design is presented in Fig. 2.

PMM manages the client's requests, i.e., it forwards an incoming packet to a particular endpoint by using some balancing technique. After the target endpoint server responds back, PMM forwards again the response to the client that has initiated the request.

When a client request is received at the Outside Interface (OI), it sends information to the Input Packet Decision Agent (IPDA). which decides where to forward the request (which endpoint server), by using relevant information by the Resource Utilisation Repository (RUR) and Load Balancing Configuration (LBC) about current utilisation of the endpoint servers and load balancing configuration, correspondingly. The realized decision is sent to the Packet Translation (PT) agent, which proceed with the IP packet header translation using the NAT/PAT (Network Address Translation / Port Address Translation). These translations are stored in the Packet Translation Repository (PTR) as they can be used to forward the response back to the client. Finally, the transformed packet is forwarded to the Inside Interface (II) in order to be forwarded to the target endpoint server. The response packets are transformed similarly by the PT, by using the decision of the Output Packet Decision Agent (OPDA), according to the information stored in PTR. More details can be found in [10].

The L3B was developed as a Java implementation according to the proposed architecture, since modern Java virtual machines' performance is similar to C or C++ [13]. However, the results were not promising [12]. That is, introducing the L3B balancer reduced the performance even worse than the case without balancer. This motivated us to analyze various proposals how to make the L3B more efficient. The next section presents the improved L3B architecture that supports all functional requirements and provides better performance than its predecessor.

III. THE NEW IMPLEMENTATION

Since the naive implementation of L3B did not yield the expected results, we proceed to improve the L3B implementation. This section presents the development of the new improved implementation.

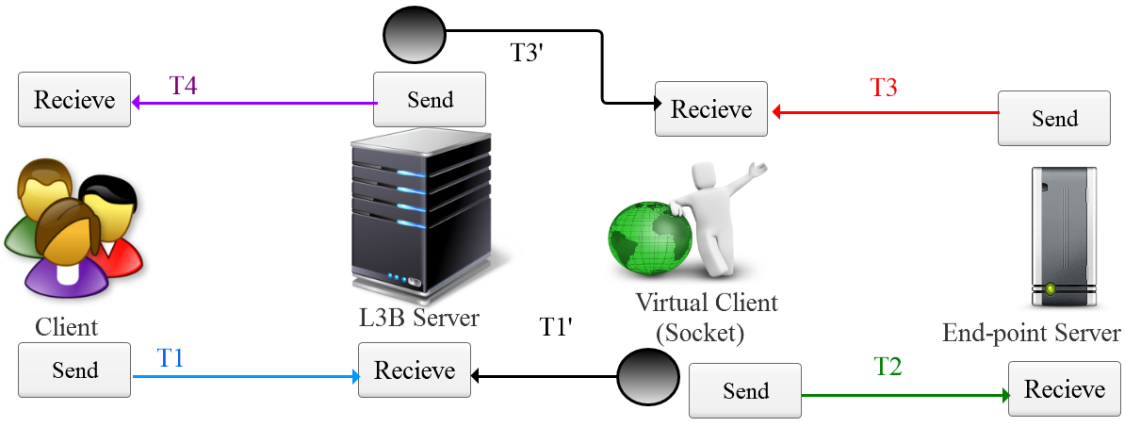

Fig. 3. Improved L3B implementation

A. The new implementation's concept

Fig. 3 presents the new improved implementation, based on creation of virtual client socket. When a packet arrives at the L3B server, L3B creates a "Virtual Client", which is a creation of a socket between new client on a certain port, and a port and IP address with the end-point server, presented as T_1 in the figure. Now, the L3B takes the memory (packet) from the received data in the state and prepares for transmission on the server (T_1'). The next step is to forward the packet to the end-point server, shown as T_2 in the figure. In the next step, denoted by T_3 in the figure, the server processes the request and returns the reply to the virtual client. Then the L3B prepares to send to the client everything that it has previously received and takes its memory (T_3 VirtualClient.Send = Balancer.Recieve). Further on, the final activity, denoted by T_4 is totally the same as previous case.

B. The implementation details

Robust, reliable and correct package transmitter from source to destination is used for complete conduction of our concept. Java Network Sockets features are extended in order to realize the load balancing concept.

The implementation is done in Java JDK 7.0, by using network sockets. The algorithm provides package forwarding using Sockets for TCP communication. It will be the same algorithm if a UDP communication is used, but in this case, the Datagram transfer should be used, instead of Sockets.

The details of the implementation are presented in Fig. 4. The L3B architecture is implemented with several classes:

- *Client* class, which sends the client's request to Balancer;
- *Balancer* class, which receives request from client;
- *ServerInput* class, which sends client's request to multiple servers;
- *ServerOutput* class, which receives the responses from the servers; and
- *PackageForwarder* class, which creates instances of ServerInput class and ServerOutput class as well as responds the outputed data to the client.

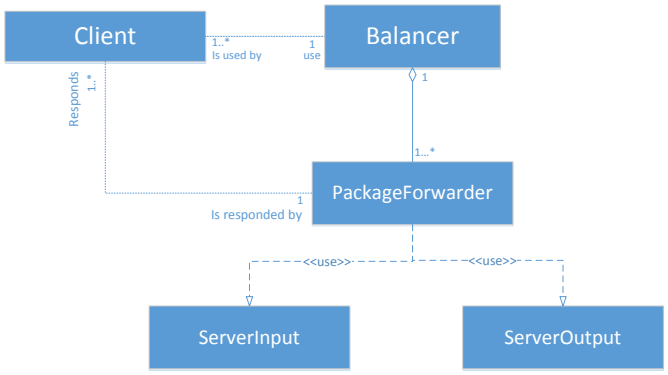

Fig. 4. The details of the implementation

IV. Experiments and Results

This section presents the results of the experiments to confirm the successfulness of the new implementation.

A. Testing methodology

Four workstations with the same hardware resources and platform are used as a testing environment. Each workstation has Intel(R) Xeon(R) CPU X5647 @ 2.93GHz with 8GB RAM memory, installed with Ubuntu 12.04. The client is on the same LAN as the L3B workstation and two end-point workstations to reduce the network latency.

A client requests a packet with constant web page content, which size is $56KB$. The different number of concurrent requests are then initiated to create various loads. We choose this page size in order to be smaller than the IP packet limit of 64KB. Usually the web requests and responses are smaller than $64KB$.

The concurrent requests are simulated with SOAPUI. Each test case consists of sending N concurrent requests per second, such that N varies in each test case starting from $N = 5$ until $N = 100$ requests, by increasing N with step 5. Each test case lasts 60 seconds.

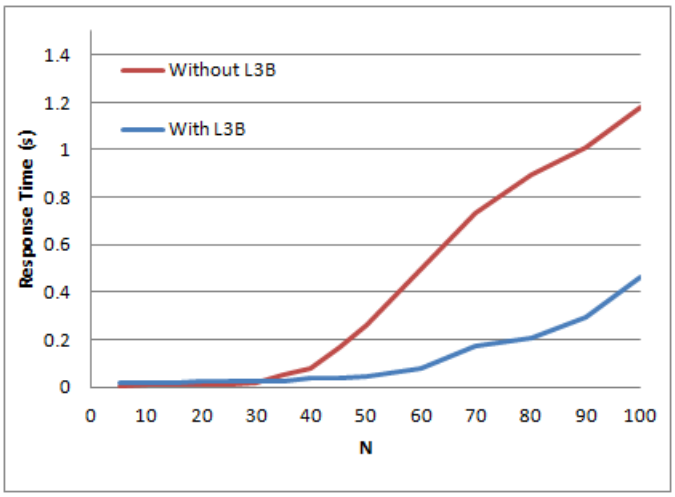

Fig. 5. Results of the experiments for the L3B implementation

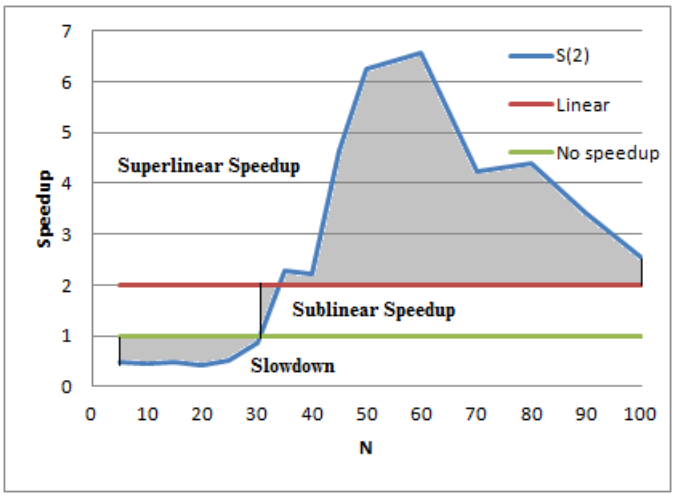

Fig. 6. The achieved speedup of the improved L3B when using two end-point servers

B. Performance analysis of the L3B implementation

Fig. 5 shows the results of the experiments that evaluated the performance of the new improved L3B implementation over the system which does not use L3B balancer. The results show that using the L3B is always better for each number of concurrent requests $N > 30$.

Let us explain why the scenario without the L3B balancer (4 CPU cores, 8GB RAM) is better comparing with the scenario with L3B (8 CPU cores and 16GB RAM) for $N \leq 30$, which uses double resources. Introducing L3B adds a constant delay per packet because a packet goes through the additional server (the L3B server) and virtual client (socket). For small server load N this delay is in the range of the server response time. But, when the total load is increased, the single server in the first scenario (without L3B) will be over-utilised, which will decrease its performance, while the second scenario (with L3B) will still work in the normal mode with better performance. The next section analyzes the scalability and achieved speedup by using the L3B balancer to balance the load among end-points in more detail.

V. Discussion about the L3B scalability

In this section we discuss the speedup of the improved L3B implementation. We conduct two experiments based on a configuration using two end-point servers.

A. Theoretical analysis

According to the Gustafson's law [14], adding more computing and processing resources (CPUs) to some parallel or distributed system will improve its performance limited with linear speedup (the speedup that is equal to the number of scaled resources). The *Speedup* $S(p)$ is defined in (1) as a ratio of the response time of the nominal system T_1 (without L3B with 1 end-point server) and the response time of the scaled system T_p (p end-point servers and the L3B in front of them).

$$S(p) = \frac{T_1}{T_p} \tag{1}$$

Our experiment is conducted using L3B with $p = 2$ end-point servers. That is, N client requests are sent to a single end-point server (as described in Section IV-A), while N client requests are sent to two end-point servers in the second scenario (with L3B), thus balancing the requests by $N/2$ per end-point server. According to the

B. Case study with scaling factor 2

Fig. 6 presents the speedup that the improved version of L3B achieves over the scenario without L3B. Three regions are observed:

- *Slowdown* region, where the speedup $S(p) = S(2) < 1$;
- *Sublinear* speedup region, where the speedup $S(p) = S(2) < p = 2$;
- *Superlinear* speedup region, where the speedup $S(p) = S(2) > p = 2$;

The slowdown region appears in the range $N < 30$ and the speedup in this region has a constant value. The servers in both scenarios are under-utilised, and the L3B reduces the system performance because it introduces a delay. When a load is increased, the first scenario is over-utilised, while the L3B balances the load and thus keeping both servers still in the normal working mode (going into Sublinear and Superlinear speedup regions). However, when the load reaches $N = 60$, that is, 30 requests per server, both servers become over-utilised and thus the speedup starts to decrease. Increasing the load $N > 100$ started to generate errors in the first scenario.

C. A superlinear speedup phenomenon

A superlinear speedup region is achieved in distributed environment. The superlinearity is a well known phenomenon in the cache intensive algorithms [15] because of using more CPU cache memory in parallel implementations compared

to the sequential, where the communication among CPUs is low. The superlinear speedup is achieved in the cloud virtual environment, despite the additional virtualisation layer [16], [17].

However, the reason why the superlinear speedup region appears in this distributed environment is totally different. The nature of web servers is such that increasing the incoming requests dive the server into CPU over-utilisation, while balancing the load among more servers keep the servers in the normal mode, and thus generating the superlinear speedup, despite the delay that the L3B introduces.

VI. Conclusion and Future Work

This paper continues the research in designing and implementing the new approach for a load balancer that works on a network layer of OSI model. Since the naive implementation of the L3B balancer did not yield the expected results, we have improved the implementation and redeveloped the improved L3B, which proved to be scalable with improved performance. Even more, a superlinear speedup region is achieved with the superlinear speedup up to 6.5 when scaling the resources by 2.

This paper presented the case study with introducing L3B in front of only two end-point web servers, loading them with a single static web page. Additional experiments and research will be conducted with larger number of end-point servers and different end-point services and algorithms, i.e., computation intensive, memory demanding or even cache intensive web services.

This implementation of L3B promises a lot and thus it will be upgraded even more. Additional plan is to upgrade the intelligent balancer to balance the load keeping the end-point web servers in the superlinear speedup region where the maximum speedup and the best performance are achieved.

Also, this version of L3B works well only for requests (messages) that do not exceed the size of IP packet. We will upgrade the L3B balancer to support an arbitrary message size, and measure its scalability. In this direction, the RMM module should be implemented to become an elastic load balancer, beside its proved scalability.

Abstract - Many scientific datasets (e.g. earth sciences, medical sciences, etc.) increase with respect to their volume or in terms of their dimensions due to the ever increasing quality of measurement devices. This contribution will specifically focus on how these datasets can take advantage of new 'big data' technologies and frameworks that often are based on parallelization methods. Lessons learned with medical and earth science data applications that require parallel clustering and classification techniques such as support vector machines (SVMs) and density-based spatial clustering of applications with noise (DBSCAN) are a substantial part of the contribution. In addition, selected experiences of related 'big data' approaches and concrete mining techniques (e.g. dimensionality reduction, feature selection, and extraction methods) will be addressed too. In order to overcome identified challenges, we outline an architecture framework design that we implement with open available tools in order to enable scalable and parallel machine learning applications in distributed systems.

I. INTRODUCTION

Statistical data mining methods can be roughly categorized in classification, clustering, or regression augmented with various techniques for data exploration, feature selection, or feature extraction. In many cases these methods are implemented with machine learning algorithms that have been mostly serially implemented in the past. Known tools that offer such algorithms are R, Matlab, Octave, Weka, or the Python-based scikit-learn.

As reported by Wood et al. in [18], a wide variety of scientific datasets we work with (e.g. earth sciences, medical sciences, etc.) increase with respect to their volume or in terms of their dimensions due to the ever increasing quality of measurement devices. One concrete example that motivates our work in this contribution is earth science data measurements being part of the PANGAEA collection [1]. This collection exceeds a total number of data sets of 349.871 with roughly 7.9 billions in terms of data items making manual quality control complicated today. Another example that motivates our work are hyperspectral remote sensing [24] images that are acquired with hundreds of channels over contigous wavelength bands by satellites (e.g. AVIRIS Indian Pine dataset [2]) . In this context, the application goal is to interpret the observed data and classify meaningful features or classes of land cover types.

In both cases, we observe limitations when analyzing the datasets with serial tools such as too long running times, or memory problems when loading samples of the dataset (even after feature extraction and dimensionality reduction techniques have been performed). More recently, we thus have been forced to analyze such aforementioned concrete examples of *'big data'* with parallel and scalable machine learning algorithms. Although we achieved a speed-up while at the same time maintaining accuracy of solutions, we observed a couple of challenges when working at the intersection of statistical data mining, data management/transfer, and High Performance Computing (HPC) infrastructures.

This contribution discussed these challenges by offerings lessons learned derived from two concrete data-driven science applications. We offer this with practice and experience obtained in the field of clustering time series data and classification of remote sensing images. In both cases, we observed a tremendous effort on working with a relatively high set of parameters, heterogenous job script, and complex HPC environments, that all in turn justify a demand for a data analytics framework that is less complex. This is important since the scientific domain scientists we typically work with as HPC experts are typically not experts in HPC. This paper therefore also outlines our approach of implementing such a framework that automates many processes and is implemented with open-source tools. By using open standard-based core building blocks in our outlined architectural design, we further demonstrate the advantages of using open standards in the concrete problem domain when using parallel and scalable machine learning algorithms.

This paper is structured as follows. After the introduction to the problem domain, Section II provides a a motivation in the light of recent activities around big data analytics and selected case studies. Section III offers the reader a survey of related work in the field of parallel and scalable machine learning frameworks, while Section IV describes lessons learned derived from a couple of scientific applications. Section V then outlines our architecture design and provides basic building blocks that we used for implementation. The paper ends with some concluding remarks of several findings and outlines future work elements.

II. MOTIVATION

Our motivation is driven by the needs of two concrete data-intensive science applications we introduced in earlier work [25] that require different parallel and scalable machine learning algorithms. Both raise a couple of joint requirements that we investigate in this paper and that motivate a more broader approach we refer to as a an *'open standards-based smart data analytics framework'* for parallel and scalable machine learning tasks.

The first data-intensive science application we refer to as PANGAEA time series analysis requires a parallel and scalable clustering algorithm. There are a wide variety of clustering algorithms available such as K-Means Clustering, K-Medoids Clustering, Sequential Agglomerative Hierarchic Nonoverlapping (SAHN), Clustering Using Representatives (CURE). We picked the Density-based Spatial Clustering of Applications with Noise (DBSCAN) algorithm [11], because the algorithm itself is able to handle outliers inherently that fits nicely with our goal of automatically detecting outliers in large quantities of marine measurement data as a subset of the PANGAEA data collection.

The second data-intensive science application we refer to as remote sensing image analysis requires a parallel and scalable classification algorithm. There are also a wide variety of classification algorithms available such as linear learning models (i.e. Perceptron), decision trees with ensemble methods, artificial neural networks, or naïve bayes classifier. We picked the Support Vector Machines (SVM) algorithm [22] with non-linear 'kernels', because they are considered to be one of the best out-of-the-box classifiers and used in a wide range of applications that classify image-based datasets. The datasets [15] are shared within the B2Share tool of the European Data Infrastructure EUDAT [3] after using domain-specific features enhancement and various extraction/selection methods (e.g. principle component analysis).

Orthogonal to our both motivational data-intensive science applications our work is motivated by the fact that parallel resources are often geographically dispersed and offer only seldom the full suite of all required machine learning tools and techniques. Our interest includes, for example, parallel HPC machines that are part of the Partnership for Advanced Computing of Europe (PRACE) infrastructure [4] or the US Extreme Science and Engineering Discovery Environment (XSEDE) [5].

Hence, domain-specific scientists are forced to obtain manual accounts at a wide variety of sites, tune each of the systems to satisfy the demands of the corresponding machine learning package, and consider manual techniques to transfer their datasets. In particular the latter one is getting a major problem with large quantities of data while the other challenges above seriously hinder a high productivity of domain scientists that are not experts in parallel HPC environments. Although we obtained a good results in those scientific applications when using parallel and scalable algorithms, we observed a wide variety of issues. Since we also start to engage in other *'big data'* analysis in the field of biomedical sciences, we are require a framework that overcomes the issues today.

III. RELATED WORK

The wide variety of single related work per topic can be significantly reduced by taking into account the intersection of two different study fields: parallel and scalable machine learning algorithms and distributed computing infrastructures. Also, in the light of open and reproducable data-intensive science, we focus in our survey on open source frameworks and leave out selected commercial frameworks that might cover some functionality (e.g. SAS business analytics software, IBM Watson Analytics, etc.).

Selected approaches can be found in the field of bioinformatics such as described by Holl et al. in [6] that influenced earlier work described by Memon et al. in [7] using an open standards-based approach with parameter sweeps. Some of these applications are close to machine learning algorithms in terms of requiring a high number of parameters to get insights into biological datasets. We pick up the approach of using open standards such as the reported Basic Execution Service (BES) standard specification [8] and the Job Submission Description Language (JSDL) standard specification [9], including its normative parameter sweep extension [10].

Other pieces of related work can be found in the context of worfklow engines that partly are able to take advantage of distributed computing infrastructures (e.g. Taverna [26], Kepler [27], etc.). For example, in Da Silva et al. describes in [12] the use of workflow tools in conjunction of DBSCAN. We have been not able to retrieve the parallel DBSCAN implementation and in contrast to our approach that is considered for production usage in a parallel center, the paper rather describes a research project than a production implementation.

Related work in the field of SVMs and workflows are described again by Holl et al. in [13] but using Taverna for a bioinformatics workflow in conjunction with the UNICORE middleware [14]. The work describes a serial SVM that is in parallel executed using the parallelization capabilities of the Taverna workflow engine, while we found no evidence for an inherent parallel SVM implementation. Although Taverna is interesting in terms of workflows, its execution model is not standard-based nor tuned for parameter sweeps and the access to HPC systems is based on UNICORE in that paper.

Another area of related work in the field of *'open standards-based data analytics framework'* for parallel and scalabel machine learning are solutions based on the map-reduce paradigm [16]. While the underlying framework implementations like Apache Hadoop Version 1.0 or 2.0 are scalable, we did not found an inherent parallel implementation of the DBSCAN or SVM implementation in on-top frameworks like Apache Mahout, or the more recent frameworks known as Apache Spark with its machine learning library MLlib. Finally, we surveyed several individual parallel implementations, like a parallel implementation of DBSCAN as described by Patwari et al. in [20]. Although it is open source, our analysis [17] revealed that it is not scalable for our given problem while the GPU-based LibSVM [21] is based on a proprietary framework from NVidea and not straightforward to implement yet.

IV. LESSONS LEARNED AND REQUIREMENTS

In this section we reveal selected *'practice and experience'* when working with scalable and parallel machine learning using two distinct methods: clustering and classification both using each a concrete algorithm.

'Clustering' is a data mining method that divides the data into various subgroups whereby each member within a found group is similar to all others (i.e. based on a defined similiarity measure, e.g. euclidean distance). It belongs to *'unsupervised learning'* methods since no response/output data is given that could supervise the data analysis. Our first part of the analysis of practice and experience is based on working with a concrete algorithm known as DBSCAN in scientific applications.

Figure 1. Parameter challenges when using the parallel DBSCAN algorithm implementation HPDBSCAN on HPC machine JUDGE.

DBSCAN is a density-based clustering algorithm and its principal idea is to find cluster cores in a data set and subsequently expand these recursively having two distinct parameters illustrated in Figure 1. Cluster cores are defined as a region that contains at least a number *minPoints (i.e. parameter -m)* of neighboring points within a given search radius *epsilon (i.e. parameter epsilon)*.

We implemented a parallel DBSCAN version known as highly parallelizable DBSCAN (HPDBSCAN) [17] that overcomes the inherent sequential processing step of the recursive expansion through three major techniques. It offers a 'spatial indexing structure', a 'quadratic split heuristic', and 'differential merging scheme' to combine sub-results into a common result. For more information about HPDBSCAN please refer to [17]. As this code is a hybrid MPI/OpenMP code, it requires also another parameter (i.e. parameter –t) in order to specify the number of threads used for OpenMP elements.

We work with marine scientists in order to perform clustering of time series earth observation measurement data using this tool and given already the couple of these parameters makes the use of this tool in a job script not straightforward. This is particularly a challenge since marine scientists are not experts using HPC machines.

Furthermore, the code has dependencies to many new libraries such as the Hiearchical Data Format (HDF) 5 (i.e. >= 1.8.13), C++ libraries (i.e. >=4.9 for compilation), and MPI (i.e. >= 3.0) that also need to be specified in the job script (cf. Figure 1) and that need to be supported by the HPC machine in question that is hard to find out for not HPC domain scientists.

'Classification' is a data mining method that creates a model that aims to separate data into different groups that are known as classes based on predefined examples. It belongs to *'supervised learning'* methods since predefined response/output is given that could supervise the data analysis. Our second part of the analysis of practice and experience is based on working with a concrete algorithm known as SVM in scientific applications.

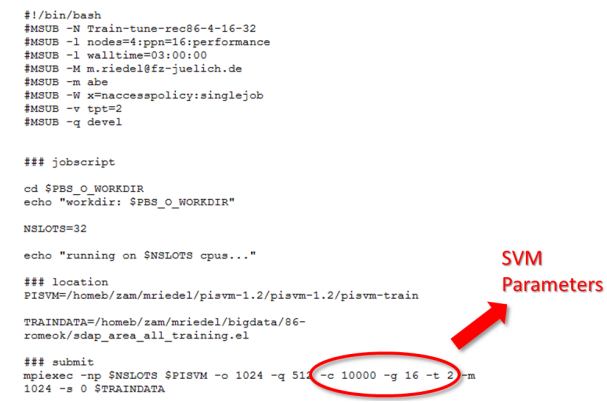

Figure 2. Parameter challenges when using the parallel SVM algorithm implementation piSVM 1.2.1 on HPC machine JUDGE.

SVMs are one of the commonly used out-of-the-box algorithms for classification and their fundamental idea lies on separating training samples which belong to different classes by tracing maximum margin hyperplanes in the space where the samples are mapped. A kernel-based SVM method maps input data instances into a high-dimensional feature space with a non-linear mapping function and then performs linear classification in the high-dimensional features space. The parameter set of the SVM and its used kernel such as the *Radial Basis Function (RBF) kernel (i.e. parameter –t 2)* require basically two parameters whereby the choice of the kernel itself is thus the third parameter shown in Figure 2. The first parameter enables violations of the maximum margin and can be considered as a *cost threshold of the violation (i.e. parameter –c)*. The second parameter is the Υ *parameter of the RBF kernel itself (i.e. parameter –g)*. Both latter parameters are typically obtained by performing cross-validation in order to perform model selection and are thus not known in advance and highly dependent on the dataset in use.

We tuned an existing parallel SVM version known as piSVM 1.2 (and recent 1.3) [19] that is in turn is based on the de-facto standard serial implementation libsvm and takes advantage of MPI. For more information about piSVM please refer to [19]. Tunings include the broader use of MPI collectives instead of individual MPI calls in loops and a better memory setup in order to scale much better in terms of *'big data'* (e.g. large number of samples, or large number of dimensions, etc.). The memory setup requires a couple of parameters (e.g. –o and –q) while some caching layout requires another (e.g. –m). The type of SVMs can be configured by parameter (e.g. –s).

We work with scientists that perform classification of hyperspectral remote sensing images using this tool and given all these parameters the use of the piSVM tool in a job script is not straightforward. This is particularly the

case since remote sensing scientists are not experts in HPC environments. Also, in many cases the scientists need to vary the above mentioned parameters in order to obtain good accuracies or have to apply feature selection/extraction mechanisms (e.g. principle component analysis, etc.) before the actual job run.

Based on these lesson learned we formulate the following four major requirements for a data analytics framework supporting machine learning tasks: *(a) abstraction from error-prone job scripts for specific HPC architectures; (b) standardized handling of job descriptions; (c) support for parameter studies; and (*d) *automation of data transfer into/out of a HPC system.*

V. Architectural Design & Implementation

In this section we outline the architectural design and describe the core building blocks of our implementation that is able to satisfy the requirements based on lessons learned raised in Section VI. Given the page restriction we concentrate on the overall design and only provide a brief description while referencing specific standard specifications and tools used for implementation.

As shown in Figure 3, HPC Resource A offers an MPI environment and deploys the parallel data analytics tool piSVM as part of its BES/JSDL implementation. Another center offers a HPC Resource B with an MPI environment and a preconfigured HPDBSCAN deployment as part of its BES/JSDL implementation. We can consider to use UNICORE as it offers a BES/JSDL implementation and this middleware is also deployed as part of the PRACE as well as XSEDE infrastructure. But any other BES/JSDL implementation (e.g. GENESISII [23]) can be part of the infrastructure deployment still being inline with the architecture.

By using BES/JSDL we satisfy requirement *(a) abstraction from error-prone job scripts for specific HPC architectures.* This is possible because implementations of these standard usually support different job scheduling systems underneath and thus job scripts will be automatically generated and forwarded to the corresponding scheduler of HPC resource A or B. The benefit is that low-level details such as specific dependencies of C++ libraries (e.g. HPDBSCAN with versions >=4.9) or HDF5 (e.g. HPDBSCAN with 1.8.13) can be easily abstractly used. This makes it more feasible to be used by domain-scientists since they do not need to manually edit job scripts. To work properly the JSDL implementation should support the JSDL HPC extension [X] illustrated in Figure 3 as part of the virtual workspaces using BES/JSDL functionality.

Another advantage of using these set of standards is to satisfy requirement *(b) standardized handling of job descriptions.* This enables that domain scientists can more easily choose a broader set of HPC resource of choice with the required data analytics tool for the given problem at hand. Domain scientists are able to use the same client for different machine learning packages and tools that even go beyond piSVM and HPDBSCAN both illustrated in Figure 3. One could also consider map-reduce-based implementations for example if needed (not illustrated).

We have to deeper explore another core building block illustrated as JSDL in Figure 3 in order to understand how our architectural design overcomes the requirement *(c) support for parameter studies.* The JSDL standard offers an extension that is very suitable to address the many complex parameter issues raised in Section IV. It is thus well suited to craft JSDL job descriptions that more easily are able to automatically sweep through different set of parameters. This is helpful for our given problem of HPDBSCAN and its parameters *epsilon* and *minPoints*, but also with respect of sweeping through different options of the piSVM parameters such as *C* and the *RBF kernel parameter* Υ.

Finding the right combination of these parameters is one of the most important elements of getting good results in the clustering application when analysing time series for outliers. It is also important for achieving good accuracy results in the classification application when analysing hyperspectral images. In both cases, the parameters are usually not known by hand and automation of this parameter search (also named gridsearch in machine learning or data mining) is very important. It this context it should be noted that cross-validation techniques benefit the most from running in parallel since it is usually a very time consuming process (e.g. Matlab runs over night for one 10 fold cross-validation run).

Finally, we would like to point out how we satisfy requirement *(*d) *automation of data transfer into/out of a HPC system.* In contrast to the automation meant by parameter sweeps, this requirement raise the demand for having a more automated process of *'staging'* [24] data into, or out of, an HPC environment. The JSDL specification supports this particular requirement very well thus avoiding the wide range of time consuming manual tools and approaches (e.g. using wget to obtain B2SHARE datasets). Of course, in this light, we need to mention the security challenge present in the architecture that we described with a focus on the needs of the scalable and parallel machine learning tools. Infrastructures such as EUDAT, PRACE, and others however have aligned to solve the security issue across infrastructures that is out of reach of this contribution to solve beyond Grid methods.

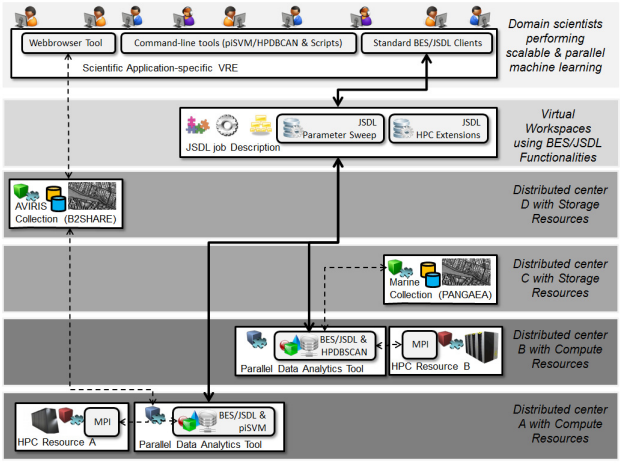

Figure 3. Architectural design with core building blocks of the tools we use to implement scalable and parallel machine learning tasks.

VI. CONCLUSIONS

The earth sciences have been always a major source of large quantities of data, because of the wide variety of measurement devices deployed to understand the world around us. We have performed parallel clustering and classification of concrete *'big data'* and obtained a wide variety of lessons learned in two distinct data-intensive earthy science applications. The practice and experience raised a couple of requirements that we have satisfied by our outlined *'big data analytics framework design'*, which implementation is based on open source tools.

We can conclude that the use of JSDL/BES, including its extensions for parameter sweeps and HPC, is a crucial design factor and enables to overcome many limitations of manually using different job scripts with parallel machine learning tools on heterogenous geographically distributed HPC machines. Most notably, because of the large number of parameters, but also with respect to data transfer/stagings and the overall automation provided by the corresponding JSDL/BES middleware.

In our case, we picked UNICORE as it is deployed on the PRACE and XSEDE infrastructure, but more generally, the architectural design building blocks can be implemented by other JSDL/BES implementations (e.g. GENESISII). We also focussed on only two particular machine learning tools (i.e. HPDBSCAN and piSVM), but we claim that also other parallel and scalable machine learning algorithm implementations for HPC systems can be equally well supported by the architecture.

Additionally, our design based on open standards bears a high potential when implementing new emerging regulations about open science, where scientific datasets and the means to get results (i.e. job configuration parameters, code, etc.) need to be publicly available in order to enable reproducable science. The JSDL specification and its normative extensions are perfectly suited to document this in a standard way being not influenced from underlying changes in HPC environments (i.e. different job scheduling scripts, file systems, etc.). Some of the publishers in science and engineering already have started to require such artefacts in order to publish a scientific article thus increasing trusted science output for decades to come.

By using the B2SHARE service of EUDAT we are inline with these requirements. All our datasets and processing results in the remote sensing classification application can be publicly viewed there and have been referenced in this paper. Hence, the findings can be reproduced when combining them with middleware tools like UNICORE and piSVM respectively. Also the HPDBSCAN tool is open source while the dataset is available in PANGAEA.

Future work includes an extension to the framework design in order to include work on GPUs since they become an important element in parallel and scalable machine learning. Another direction of future work is the support of in-situ analytics combining work from computational steering to augment a HPC simulation run with analytics during its runtime in order to offer on-the-fly statistical data mining (e.g. validation from data).

ACKNOWLEDGMENT

We thank Robert Huber and Andree Behnken (MARUM Bremen, Germany) for his close cooperation in the context of the PANGAEA automated outlier detection case study. We would like to express our thanks to Gabriele Cavallaro (University of Iceland) for his close cooperation in the context of the spectral image analysis.

Decomposition of Natural Join Based on Domain-Interval Fragmented Column Indices

Elena Ivanova and Leonid Sokolinsky
South Ural State University, Chelyabinsk, Russia
ivanovaev@susu.ac.ru, Leonid.Sokolinsky@susu.ru

Abstract - The paper describes decomposition of natural join relational operator based on the column indices and domain-interval fragmentation. This decomposition admits parallel executing the resource-intensive relational operators without data transfers. All column index fragments are stored in main memory in compressed form to conserve space. During the parallel execution of relational operators, compressed index fragments are loaded on different processor cores. These cores unpack fragments, perform relational operator and compress fragments of partial result, which is a set of keys. Partial results are merged in the resulting set of keys. DBMS use the resulting set of keys for building the resulting table. Described approach allows efficient parallel query processing for very large databases on modern computing cluster systems with many-core accelerators. A prototype of the DBMS coprocessor system was implemented using this technique. The results of computational experiments are presented. These results confirm the efficiency of proposed approach.

I. INTRODUCTION

Nowadays, human scientific and practical activities create the new challenges that demand big data processing. According to IDC study [1], the amount of digital data is doubling in size every two years, and by 2020 the digital universe – the amount of digital data created and replicated – will reach 44 zettabytes, or 44 trillion gigabytes. In 2013, only 22% of the information in the digital universe would be a candidate for analysis (useful if it were tagged) and less than 5% of that was actually analyzed. By 2020, the useful percentage could grow to more than 35%, mostly because of the growth of data from embedded systems.

One of the popular ways to process efficiently big data is using the parallel database system, which are able to process data in parallel on the high performance system with distributed memory [2] – [5]. The traditional approach for database storing is row-oriented representation. However, column-oriented database systems have been shown to perform more than an order of magnitude better than row-oriented database systems ("row-stores") on analytical workloads such as those found in data warehouses, decision support, and business intelligence applications. The elevator pitch behind this performance difference is straightforward: column-stores are more I/O efficient for read-only queries since they only have to read from disk (or from memory) those attributes accessed by a query [6]. Column-oriented databases are particularly well suited for compression because data of the same type is stored in consecutive sections. This makes it possible to use compression algorithms specifically tailored to patterns that are typical for the data type [7].

In recent years, more and more many-core processors are superseding sequential ones. Increasing parallelism, rather than increasing clock rate, has become the primary engine of processor performance growth, and this trend is likely to continue. Particularly, today's GPUs (Graphic Processing Units) and Intel's MIC (Many Integrated Cores), greatly outperforming traditional CPUs in arithmetic throughput and memory bandwidth, can use hundreds of parallel processor cores to execute tens of thousands of threads [8]. Recent trends in new hardware and architectures have gained considerable attention in the database community. Processing units such as GPU or MIC provide advanced capabilities for massively parallel computation. Database processing can take advantage of such units not only by exploiting this parallelism, e.g., in query operators (either as task or data parallelism), but also by offloading computation from the Central Processing Unit (CPU) to these coprocessors, saving CPU time for other tasks [9]. The many integrated cores of the Xeon Phi make this hardware accelerator a natural computing platform for an in-memory database engine or server. The database tables reside in the memory space of the MIC thus supporting fast in-memory database applications [10].

Main memory as the primary storage location is becoming increasingly attractive as a result of the decreasing cost/size ratio [7]. Main Memory Database (MMDB) eliminates disk access by storing and manipulating entire database in main memory. For performance-significant systems MMDB offer very low response time and very high throughput [11]. According to Gartner's 2013 Hype Cycle for Emerging Technologies report, in-memory database management system have 2 to 5 years until widespread adoption [12].

According to this, the problem of developing new efficient methods of parallel database processing in main

memory on modern compute clusters with many-core accelerators using column-oriented representation and data compression is important. To meet this goal, we offer a special type of index structures called distributed column indices. Distributed column indices allow to perform a decomposition of relational operators, which admits the efficient parallel execution of them on computing cluster system, equipped with many-core accelerators. In this paper, we consider the decomposition of the natural join operator. In this paper, we use the notation from [13]. The symbol $^\circ$ we use to denote the operation of concatenation of the tuples.

II. COLUMN INDEX

Let $R(A,B_1,\ldots,B_u)$ be the relation R with *virtual key* (virtual record identifier) A and the following attributes: $B_1,\ldots,B_u$. Tuples of R have length of $u+1$ and form of $(a,b_1,\ldots,b_u)$, where $a\in\mathbb{Z}_{\geq 0}$ and $\forall j\in\{1,\ldots,u\}\left(b_j\in\mathcal{D}_{B_j}\right)$. Here, $\mathcal{D}_{B_j}$ is the domain of attribute B_j. Let $r.B_j$ denote a value of attribute B_j. Let $r.A$ denote a value of the virtual key of tuple r: $r=(r.A,r.B_1,\ldots,r.B_u)$. The *virtual key* of relation R has the property: $\forall r',r''\in R\left(r'\neq r''\Leftrightarrow r'.A\neq r''.A\right)$. Define *tuple address* as a virtual key value of the tuple. To get the tuple by its address, we will use $\&_R$ *dereferencing function*: $\forall r\in R\left(\&_R(r.A)=r\right)$.

Let $R\left(A^*,B,\ldots\right), T(R)=n$ be given. Let a linear order be defined on set $\mathcal{D}_B$. The *column index* $I_{R.B}$ for attribute B of relation R is an ordered relation, which satisfies the following requirements:

$$T(I_{R.B})=n \text{ и } \pi_A\left(I_{R.B}\right)=\pi_A\left(R\right); \quad (1)$$

$$\forall x_1,x_2\in I_{R.B}\left(x_1\leq x_2\Leftrightarrow x_1.B\leq x_2.B\right); \quad (2)$$

$$\forall r\in R\left(\forall x\in I_{R.B}\left(r.A=x.A\Rightarrow r.B=x.B\right)\right). \quad (3)$$

Condition (1) means that the sets of virtual keys of column index and indexed relation are equal. Condition (2) means that index elements are sorted in ascending order of values of attribute B. Condition (3) means that attribute A of an index element contains the address of tuple of R, which has the same value of B attribute as the corresponding element of column index has.

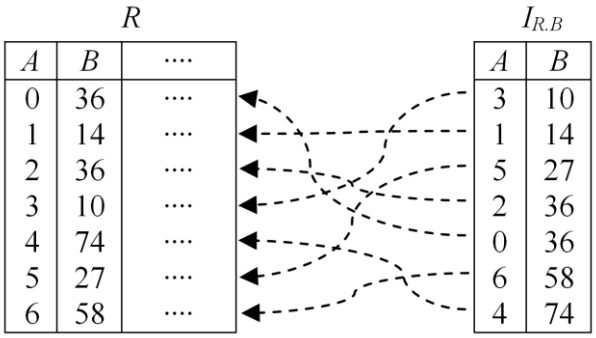

Figure 1. Column index

From the intensional point of view, the column index $I_{R.B}$ is a table with two columns A и B (see fig. 1). The number of rows in the column index is equal to the number of rows in the indexed table. Column B of index $I_{R.B}$ contains all the values of column B in table R (including duplicates). These values are sorted in ascending order inside column index.

III. DOMAIN-INTERVAL FRAGMENTATION

Let a total ordering relation be defined on domain $\mathcal{D}_B$. Divide $\mathcal{D}_B$ into $k>0$ nonintersecting intervals:

$$\left.\begin{array}{l} V_0=[v_0;v_1],V_1=(v_1;v_2],\ldots,V_{k-1}=(v_{k-1};v_k]; \\ v_0<v_1<\ldots<v_k; \\ \mathcal{D}_B=\bigcup_{i=0}^{k-1}V_i. \end{array}\right\}. \quad (4)$$

Define *interval fragmented function* on domain $\mathcal{D}_B$ as $\varphi_{\mathcal{D}_B}:\mathcal{D}_B\to\{0,\ldots,k-1\}$. This function satisfies the following requirement:

$$\forall i\in\{0,\ldots,k-1\}\left(\forall b\in\mathcal{D}_B\left(\varphi_{\mathcal{D}_B}(b)=i\Leftrightarrow b\in V_i\right)\right). \quad (5)$$

Let column index $I_{R.B}$ be given for relation $R\left(A^*,B,\ldots\right)$ with attribute B on domain $\mathcal{D}_B$. Let interval fragmented function $\varphi_{\mathcal{D}_B}$ be defined on domain $\mathcal{D}_B$. The function

$$\varphi_{I_{R.B}}:I_{R.B}\to\{0,\ldots,k-1\} \quad (6)$$

is *domain-interval fragmented function* for index $I_{R.B}$, if it satisfies the following requirement:

$$\forall x\in I_{R.B}\left(\varphi_{I_{R.B}}(x)=\varphi_{\mathcal{D}_B}(x.B)\right). \quad (7)$$

Define the ith fragment $\left(i=0,\ldots,k-1\right)$ of the index $I_{R.B}$ as

$$I^i_{R.B}=\left\{x\mid x\in I_{R.B};\ \varphi_{I_{R.B}}(x)=i\right\}. \quad (8)$$

It means that the ith fragment contains tuples, which have values of attribute B from the ith domain interval.
This fragmentation is called the *domain-interval fragmentation*. The number of fragments is the *degree of fragmentation*.

The domain-interval fragmentation has the following fundamental properties, which follow directly from its definition:

$$I_{R.B}=\bigcup_{i=0}^{k-1}I^i_{R.B}; \quad (9)$$

$$\forall i,j\in\{0,\ldots,k-1\}\left(i\neq j\Rightarrow I^i_{R.B}\cap I^j_{R.B}=\varnothing\right). \quad (10)$$

IV. Decomposition of the Natural Join Operator

Let two relations be given:

$$R\left(A^*, B_1, \ldots, B_u, C_1, \ldots, C_v\right)$$

and

$$S\left(A^*, B_1, \ldots, B_u, D_1, \ldots, D_w\right).$$

Let two sets of column indices be given for attributes $B_1, \ldots, B_u$:

$$I_{R.B_1}, \ldots, I_{R.B_u};$$

$$I_{S.B_1}, \ldots, I_{S.B_u}.$$

Let domain-interval fragmentation of degree k be defined for these indices:

$$I_{R.B_j} = \bigcup_{i=0}^{k-1} I^i_{R.B_j}; \quad (11)$$

$$I_{S.B_j} = \bigcup_{i=0}^{k-1} I^i_{S.B_j}. \quad (12)$$

Let

$$P^i_j = \pi_{I^i_{R.B_j}.A \to A_R,\, I^i_{S.B_j}.A \to A_S}\left(I^i_{R.B_j} \underset{I^i_{R.B_j}.B_j = I^i_{S.B_j}.B_j}{\bowtie} I^i_{S.B_j}\right) \quad (13)$$

for all $i = 0, \ldots, k-1$ and $j = 1, \ldots, u$. Define

$$P_j = \bigcup_{i=0}^{k-1} P^i_j. \quad (14)$$

Let

$$P = \bigcap_{j=1}^{u} P_j. \quad (15)$$

Define

$$Q = \{r.B_1, \ldots, r.B_u, r.C_1, \ldots, r.C_v, s.D_1, \ldots, s.D_w$$
$$r \in R \wedge s \in S \wedge (r.A, s.A) \in P\}.$$

Then

$$\pi_{*\setminus A}(R) \bowtie \pi_{*\setminus A}(S) = Q.$$

Note that calculation of P^i_j by (13) can be done in parallel on *k* different processors without data exchange. It ensures a near-linear speedup.

V. Performance Evaluation

The described approach was implemented as a prototype of DBMS coprocessor system. The source code of the program is openly available in the public GitHub repository [15]. Column indices and domain-interval fragmentation were evaluated using this prototype. We performed natural join operator over fragmented column indices $I_{R.B}$ and $I_{S.B}$. Attribute B of column index $I_{R.B}$ is a virtual key. Attribute B of column index $I_{S.B}$ is a foreign key. Join operator was implemented by merge join algorithm.

Number of column index tuples were following: $T(I_{R.B})$ = 600 000 and $T(I_{S.B})$ = 60 000 000. Column indices $I_{R.B}$ and $I_{S.B}$ were fragmented using domain-interval fragmentation. Every fragment of column indices was compressed by Zlib data compression library [14]. In described experiments, attribute B of column index $I_{S.B}$ had uniform and nonuniform (rule: 80/20, 65/20 and 45/20) data distribution.

The experiments were done on Intel Xeon Phi accelerator with 61 cores. Join operator was performed in 1, 2 and 4 threads per core (see fig. 2). The results of this experiment show that we have maximum speedup if we use 1 thread per core. The second experiment (see fig. 3) shows that load balancing can be effectively managed by increasing the number of fragments.

The experiments have shown that approach on base column indices allow to perform resource-intensive join operator for $T(I_{R.B})$ = 600 000 and $T(I_{S.B})$ = 60 000 000 during 1 second on one Intel Xeon Phi accelerator. The described approach eliminates data transfer, so we can expect a near-linear speedup on computing cluster systems with million nodes equipped with many-core accelerators.

VI. Related work

Binary table model was introduced in the paper [16]. On the basis of this model, several column-oriented DBMS were designed. As it was demonstrated by work [17] and [18], column-oriented systems offer an order-of-

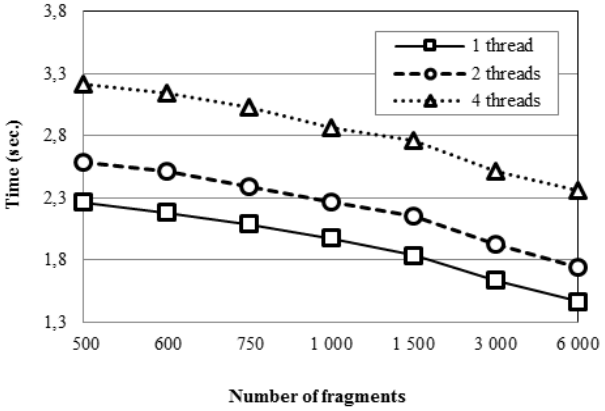

Figure 2. Dependence between time of calculation and number of fragments

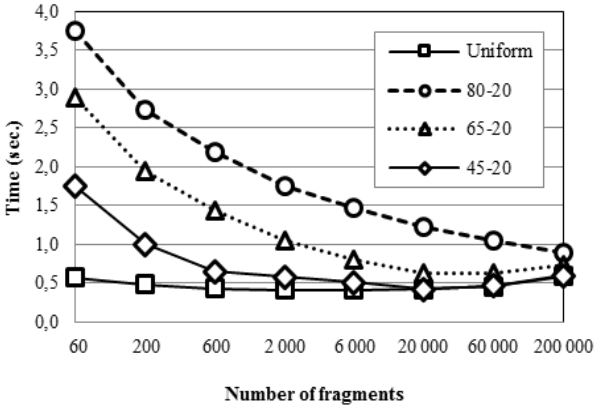

Figure 3. The influence of number of fragments on load balancing of Xeon Phi cores

magnitude performance improvement over traditional row-oriented systems for analytical processing workloads, such as those found in data warehouses or decision support systems. One of the main disadvantages of column-oriented DBMS is lacking the optimization technique, which is intrinsic to relational (row-oriented) DBMS. The work [19] investigated column-oriented simulation in a relational DBMS via the following techniques: vertical partitioning, index-only plans and materialized views. The investigation showed that such techniques do not improve the performance of row stores for analytical processing workloads. To overcome the problems faced with work [19], the work [20] introduced two new operators: Index Merge and Index Merge Join. The algorithms presented in this paper were designed specifically to take advantage of parallel processing whenever possible. Another approach was proposed in work [21]. This paper introduced a new index type, column store indexes, where data is stored column-wise in compressed form. Column store indexes are intended for data-warehousing workloads where queries typically process large numbers of rows but only a few columns. To further speed up such queries, the paper [21] also introduced a new query processing mode, batch processing, where operators process a batch of rows (in columnar format) at a time instead of a row at a time.

VII. CONCLUSIONS

In this article, we presented a decomposition of the natural join operator based on the column indices and the domain-interval fragmentation. Our approach was evaluated using the prototype DBMS coprocessor system. Experiments showed its efficiency for a resource-intensive natural join operator. Proposed approach can be used on computing cluster systems with many-core accelerators. Described technique is suitable for data warehouse workloads as well as for OLTP workloads.

As a direction of a future research, we are going to use described approach for the decomposition of another relational operators and compare speedup with existing DBMS.

Abstract - The solution of linear least squares system requires the solution of over-determined system of equations. For a large dense systems that requires prohibitive number of operations. We developed a novel numerical approach for finding an approximate solution of this problem if the system matrix is of a dense type. The method is based on Fourier or Hartley transform although any unitary, orthogonal transform which concentrates power in a small number of coefficients can be used. This is the strategy borrowed from digital signal processing where pruning off redundant information from spectra or filtering of selected information in frequency domain is the usual practice. For the least squares problem the procedure is to transform the linear system along the column to the frequency domain, generating a transformed system. The least significant portions in the transformed system are deleted as the whole rows, yielding a smaller, pruned system. The pruned system is solved in transform domain, yielding the approximate solution. The quality of approximate solution is compared against full system solution and differences are found to be on the level of numerical noise. Theoretical evaluation of the method relates the quality of approximation to the perturbation of eigenvalues of the system matrix.. Numerical experiments illustrating feasibility of the method and quality of the approximation at different noise levels, together with operations count are presented.

I. INTRODUCTION

The least squares method is one of the basic methods in data processing. In the case of linear models it comes down to solving over-determined systems of linear equations. For overdetermined system, usually none of the equations are satisfied exactly, but the sum of squared differences between observations and theoretical model is minimized.

Sparse systems are being solved by very efficient methods and problems with dimensions in millions are not uncommon. The dense problems are more problematic and rarely solved for dimension over 50000.

The paper extends the previous work [1] by extensive modeling and error analysis. Some equations developed previously [1] are briefly repeated here as final results without the details. The basic idea of constructing the approximate solutions for large, over-determined, dense systems using the Fourier space representation remains the same.

II. THEORY

The Fourier transform is formally done by multiplication with Fourier matrix but in actual computations FFT is used whenever possible.

$$b = Ac \tag{1}$$

Applying the Fourier transform on over-determined system of linear equations (1) is done along the columns. Premultiplying the (1) with Fourier matrix F, the transform along the column vector y and along the columns of matrix A is performed (2). It is a good idea that before the transformation, the elements of vector b and corresponding rows in matrix A are sorted in such a way that the transform has close to the most compact representation. That would concentrate the energy in the Fourier transform in as little number of frequencies as possible.

$$Fb = FAc \tag{2}$$

For the sake of simplicity Hartley transform [2] is used in the case of real systems to avoid computation with complex numbers. Noting that $Fb=d$ and $FA=D$ our original system (1) is now transformed with elements of vector d and columns in matrix D in frequency domain (3). This transformation does not affect the vector c which is still unknown solution for the systems.(1) & (3).

$$d = Dc \tag{3}$$

The over-determined system can be formally solved solved using normal equations and matrix inverse. Although that is not recommended for numerical reasons, it was formally used in [1] to develop feasibility of frequency selection and modeling of the linear algebra system [3-5].

III. METHOD

After the transformation the system (3) is of the same size as original system but is pruned down, possibly to a square matrix system. The selection of significant frequencies is accomplished by computing the magnitudes for frequencies in vector *d* and sorting them in decreasing order. Using that information, the vector *d* and matrix *D* can be shortened into significant parts to be retained and unsignificant parts to be discarded.

This would decrease the size (number of rows) of the system and represents the filtering out of non significant frequencies in order to build a smaller model system with less equations then the original system. In this respect our approach is different then Beylkin's [6] whose idea was to increase the sparsity of the matrix by using the wavelet transform. Using normal equations, residual matrix *R* and Taylor order expansion [1] it was shown that approximate inverse for system converges faster to exact normal equations inverse the smaller eigenvalues (λ) for (*I*-*R*) matrix are (*R* is residual matrix).

$$G = \left[D_0^T D_0 + D_1^T D_1 \right]$$

$$g_0 = D_0^T d_0 \quad G_0 = D_0^T D_0 \;\Rightarrow\; G_0 = G_0^T$$

$$G_0^{-1} \approx G^{-1}$$

$$R \equiv I - G_0^{-1} G \Rightarrow G_0^{-1} G = I - R$$

$$G = G_0 \left(I - R \right)$$

$$G^{-1} = \left(I - R \right)^{-1} G_0^{-1}$$

$$\delta c = \left(I - R \right)^{-1} G_0^{-1} \delta g$$

$$\left(I - R \right)^{-1} = \left(Q Q^{-1} - Q \Lambda Q^{-1} \right)^{-1}$$

$$= \left[Q \left(I - \Lambda \right) Q^{-1} \right]^{-1} = Q \left(I - \Lambda \right)^{-1} Q^{-1}$$

$$\lim_{\lambda \to 0} \left[Q \; diag \left(\frac{1}{1 - \lambda_i} \right)_{i=1,\ldots,n} Q^{-1} \right] \to I \qquad (4)$$

$$\left(I - R \right)^{-1} = I + R + R^2 + R^3 + \ldots$$

$$G_n^{-1} \equiv \left(I + R + \ldots + R^n \right) G_0^{-1}$$

$$G_\infty^{-1} \to G^{-1}$$

Where G_0 is approximation of $D^T D$ based on the most significant frequencies (computed using only the sub-matrix with index zero). Solving the model system will yield the approximate solution of original system (1). The approximate solution ($c+\delta c$) is different from true solution *c* for difference vector [7]. It is important to show how difference vector behaves depending on size of matrix G_0. The (4) shows that *R* should be a contraction mapping: its eigenvalues should all be non-negative, real and smaller then one. Smaller the eigenvalues are, closer $(I-R)^{-1}$ is to identity matrix as can be seen from the limit (4) and consequently closer G_0^{-1} is to G^{-1}.

The same system of linear equations as in [1] was again used here but with different levels of Gaussian noise. The least squares system [8] represents fitting of fourth degree polynomial. The numerical experiments are summarized in Tables I-V. Table I contains the results for data without noise, Tables II, III, IV and V contain the results for data with 1%, 5%, 10% and 20% noise respectively. Original system was of size 512 by 5.. The polynomial equation is:

$$P(x) = 24 - 14x - 13x^2 + 2x^3 + x^4 = 0$$

In the domain, 512 equidistant points in interval [-4, 3] were generated, and corresponding co-domain points were also generated and used as a vector of observations.

Normally distributed random noise mean equal zero and with variance of (1, 5, 10 and 20 percent) was added to vector y. For each noise level, the correct solution and series of approximative solutions using different number of frequencies (approximation levels) are presented.

The data in Tables I-V show remarkable robustness with respect to reduction in system size. There is no sudden degradation in solution quality for series of approximations and it seems possible to approach the square system size as shown in Figure 1.

IV. CONLUSION

The approximate method for a fast solution of linear least squares problems has been proposed. The quality of the approximation can be tested and controlled. We developed the equation which shows how the eigenvalues of residual matrix determine quality of solution and extent of corrections to be applied in order to approach the true solution. The conclusions are also supported by extensive numerical simulations using different noise levels.

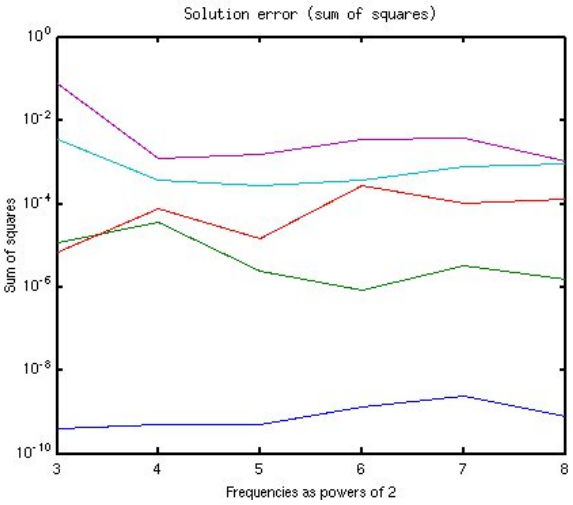

Figure 1. Plot showing the sum of squared errors in solution vector as function of the number of frequencies used to compute the approximate solution. The curves from bottom up are: no error, 1% , 5%, 10%, 20% error. Solution computed using all frequencies is used as correct solution

DARIAH Meta Hosting: Sharing Software in a Distributed Infrastructure

Jedrzej Rybicki and Benedikt von St. Vieth
Forschungszentrum Jülich GmbH, Jülich, Germany
{j.rybicki, b.von.st.vieth}@fz-juelich.de

Abstract - Research infrastructures have become an everyday tool for doing science. They constitute a cost-effective, quick, and increasingly easy-to-use collaboration tool. So far the focus was on sharing resources (especially data) and on offering a (rigid) set of services for processing and accessing the resources. It becomes clear, however, that there is a demand from the users to share not only the data they have gathered or created but also the software they implemented. Such a sharing has the potential to speed-up the scientific discovery. But only if the software runs i.e., if it can be applied by other researchers to new problems. Unfortunately, it happens often that the software implemented in a project is only understandable and deployable by the authors. In this paper we will address the problem of sharing services (e.g. new data analysis tools) between users and also touch on the problem of sharing services between infrastructures, for instance to facilitate cross-disciplinary exchange. Our goal was to increase the sustainability of the developed research software by enabling an easy extension of research infrastructures beyond the rigid set of services towards flexible Software-as-a-Service (SaaS) solutions. We share the initial experiences gained during the implementation of such a meta hosting service for DARIAH-DE research infrastructure.

I. INTRODUCTION

Digital methods have become commonplace in modern science. Their popularity is amplified by the recent establishment of the so-called data-driven science, which is expected to provide scientific insights by applying software solutions on digital data. The obvious prerequisite for such approaches is the availability and accessibility of the data. A problem which is acknowledge and addressed (if yet-not-completely-solved). The less obvious problem is how to share the scientific software used for analyzing the data. Such software is often a custom-made solution, developed in the course of a research project as an after-effect of answering concrete scientific questions. Other researchers might, nevertheless, benefit from using it to solve similar problems or for the validation of the results by applying the software to a different set of data [1]. Sharing software has the potential to accelerate scientific discovery. But even more important is the fact that software which is not sharable is, in the long run, not sustainable. Scientific discoveries done with such a software are, in worst case, not reproducable and thus useless. We believe that sharing data and software is a corner stone for doing science today. In this paper we will brush aside the social challenges of sharing software and data, and concentrate on technical solutions to facilitate such sharing.

It should be stressed that the open software repositories like *GitHub* or *sourceforge* do not solve the stated problem completely. The software is only usable when it runs. Installing, configuring, and satisfying the software dependencies often proves to be harder than expected. Especially when it is conducted on a different platform than it was developed on. Furthermore the knowledge on how to perform these steps is often only present in the heads of the software authors or within the project it was developed for (e.g. closed wiki). Hence the first requirement for the effective software sharing is the availability of the abstract, platform-independent, yet executable deployment descriptions. Such descriptions could be, for instance, system images, executable installation scripts, configuration management tools, or container-based solutions. We will discuss the applicability of these approaches in Section II.

The proliferation of the distributed research infrastructures like [2] and [3] adds a new dimension to the problem of sharing scientific software. Such infrastructures offer a quick and cost-effective way of sharing resources. They excel at enabling access to data and often provide some compute resources. The later is offered either in a Infrastructure-as-a-Service or Software-as-a-Service manner (for the definition of the terms see [4]). None of this approaches is optimal from the user perspective. IaaS solutions put quite a large burden on the users: they have to install, configure, and maintain not only the software they require but also the whole system (e.g. do system upgrades). Furthermore, the created instances cannot be easily shared: this remains in power of the user who created them and is usually technically challenging. The higher-level abstractions in form of Software-as-a-Service are much more attractive for researchers: The effort on their part is reduced and they can directly apply the software in their scientific endeavors. But the effort still exists: The installation work has to be done by the computer centers in the infrastructure. From software sharing perspective the problems are twofold. Firstly due to the rapid development of digital methods, researchers constantly require new versions or new types of software in the SaaS portfolio. Secondly, the distributed research infrastructures span across multiple resource providers, thus high level of heterogeneity has to be coped with, making the installation harder. To this end, the demanded software deployment descriptions must be platform-independent and portable. To account for the constantly changing requirements, the descriptions should be executable. Finally the system administrators should be able to audit them to verify if they are correct, trustworthy, and secure. In this paper we will show how

the deployment descriptions can be used to build a dynamic Software-as-a-Service solution, which allows for an easy extension of the offered software portfolio

The high development's pace of cooperative science together with the increasing importance of interdisciplinarity, bears one more use case for sharing research software: exchanging software between e-Infrastructures. This use case reinforces the previously mentioned requirement of making software deployment descriptions executable, auditable, portable, and sharable. The potential users of research software from different disciplines will have to invest some time to understand how to use the software. The time should not be increased by making the user to understand how to install, and deploy the software.

This paper is structured as follows. Related work is discussed in Section II. We provide a short introduction in the technology which we will use as a basis for the software sharing in Section III. Section IV presents how we used executable software deployment descriptions to implement a extensible Software-as-a-Service solution for DARIAH-DE. We conclude our paper with a summary in Section V.

II. Related Work

Let us now reflect on how software reusing is typically achieved nowadays. In the first step the scientific software has to be made discoverable. This step involves some social challenges, for instance willingness to share and use software, or efficient communication between the parties, involving software citation. In this paper, however, we focus on the technical challenges and claim that open-source repositories are sufficient for discovery. As stated above, the software is only useful if it can be applied to a new problem, and this is only possible when the software runs. Hence, the discovered software has to be installed. The process is conducted either locally on the researcher's machine or (in a more modern fashion) on a remote machine running somewhere in the cloud e-Infrastructure. The installation usually involves the configuration of the operating system (OS) and the provision of the run-time environment, additional libraries, and actual software. The knowledge on how to achieve this might be, to some extend, conveyed in the service documentation. The experience shows that the documentation is seldom up-to-date and does not cover all the corner cases encountered in the real-life deployments e.g., library dependencies or support for differing operating systems. When it comes to a migration of the service, the process must be started from scratch again, often by a different person. Even such a down-to-earth, recurring situation like the OS upgrade for the underlying machine might render a service unusable and result in the need for a re-installation. Since the process described above is quite laborious, let us now discuss ways in which it can be either simplified or done in such a way that other researchers can use the software without repeating the installation process.

A. Virtual machines

One way of sharing "already-installed" software is to prepare images from which virtual machines can be created. The most obvious case for such applications are clouds offering an IaaS interface [5][6], although local deployments of images are conceivable as well. VM image preparation involves repeating the above steps in a virtual machine while accounting for special properties of the given cloud. The later is often subsumed under the term: contextualization. When an image is created and uploaded to a cloud image repository it can be instantiated by other users to obtain running version of the application. VM images suffer, however, under some limitations. First of all, images are black boxes: one has to trust the creator and has very limited capabilities of auditing the actual content of the image. Thus it is hard to safe-guard that the images do not include some malicious software or are not misconfigured so that running instances can be easily hacked or destroyed by malicious third parties. Virtual images include a complete software stack comprised of the required software, dependencies, and operating system. This results in a high overhead in terms of both image size (what makes the sharing of images harder) and performance. The inclusion of the operating system results in the need for periodic updates of the image: for instance to apply new security patches. The further problem with images is, that they are infrastructure-specific: they strongly depend on the hypervisor used and contextualization solution provided in the particular cloud. Clouds include their own image repositories but moving images between the infrastructures i.e. between different clouds, remains an unsolved problem. A problem with obvious ramification for software sharing.

B. Configuration management tools

One way to create trustworthy and reproducible service deployments that are, to some extent, infrastructure, hypervisor, and OS agnostic, is to use configuration management tools like Puppet [7] or Chef [8]. With these tools it is possible to describe the service deployment in a declarative way. One defines which packages should be installed, which configuration changes should take place or which commands should be executed instead of applying all these steps manually. The tools can be used to provide a generic description of the service deployment that interested partners can apply to virtual machines or servers as the configuration management tools do not offer any isolation nor virtualization themselves. Here the same limitations with respect to overhead of running VMs apply. On the upside, the descriptions are human-readable and can be reviewed before the actual deployment, this contributes to their trustworthiness. Configuration management tools enable reproducible service deployment, but they fail to some extend at abstracting the underlaying platform, for this the developer has to spent additional effort.

One example for this is the deployment of a webserver like Apache HTTP server [9], a software often used to provide webservices. Listing 1 shows an excerpt from a deployment description that is used to deploy the software by installing (section *package* on Listing 1), configuring (*file*), and starting (*service*) it. Puppet brings an abstractions for package managers and it also provides wrappers for different *init* systems, but it has problems with the different package, path, and service naming. To keep it platform-independent and portable, one has to

prepare deployment descriptions for all the supported platforms. The first lines of the Listing 1 show how to coped with the fact that the same software is available under different names in RedHat and Debian repositories.

```
if $::osfamily == 'RedHat'{
   $user = 'apache'
   $name = 'httpd'
 } elsif $::osfamily == 'Debian' {
   $user = 'www-data'
   $name = 'apache2'
 } else {
   fail("Unsupported os: ${::osfamily}")
 }
 file { "/etc/$name/$name.conf":
   owner => $user
   ensure => 'present'
 }
 package { $name:
   ensure => 'latest'
 }
 service { $name:
   ensure   => 'running'
 }
```

Listing 1. Puppet example for deploying Apache httpd,

We establish that tools like Puppet solve a slightly different problem. They are perfectly suited for managing the configuration of software running in a distributed infrastructure. For this purpose, they allow for configuration changes of the running machines (such changes are then automatically loaded on all relevant machines). The scientific software sharing, on the other hand, will be rather used to create quickly disposable instances of given services. This instances will be used e.g. to verify the researcher's hypothesis or validate previous results and they will be discarded afterwards. We argue that there will be no need to manage the configuration changes in one instance, for the modified setup new instance will be spun off. Researcher will not be willing to spent much effort into the configuration management when it would be possible to simply, quickly, and cheaply create new instances.

III. CONTAINER-BASED VIRTUALIZATION

Container-based virtualizations like Linux VServer [10] or Docker [11] became very popular for building, shipping, and running applications across many machines. They constitute the perfect basis for an efficient sharing of scientific software. In this section we will first provide the reader with some basic information on how Docker works, and argue why it is better than the previously described system images and configuration management tools. The section will be concluded with a proposal on how the software sharing life cycle could be implemented in a distributed infrastructure.

A. Introduction to Docker

Docker is used as the basis for our software-sharing solution. This section will equip the reader with enough information about this technology to understand the rest of the paper. Readers interested in more details are referred to the extensive Docker documentation [11].

Docker is a lightweight, open-source, virtualization solution. In opposite to the full-stack virtualization solutions, Docker images do not include a guest operating system kernel. It lowers the overhead in terms of both performance and size of the images allowing near-native performance. Docker is based on mature Linux kernel technologies (*cgroups* and *namespaces*, among the others) to isolate independent application containers. Docker images use AuFS which is a layered file system, enabling sharing libraries between images on one hand, and inspecting the changes done in the images, on the other. The later feature permits rudimentary provenance tracking of images.

Let us now briefly discuss the Docker terminology and usage. Applications running with Docker are called containers, they are created from images. Images should be understood as hierarchical templates. It is possible to start with one image, add some software, and save the result as a new image. It is also easily possible to share images by using image repositories either private or public ones, like the *Docker Hub*. There are two main ways of shipping applications with Docker. In the first one (let us call it interactive), the developer starts a basis Docker image (e.g.: official Debian Linux image) and installs application, its dependencies, and everything else by issuing ordinary Linux commands. As soon as the application is installed, a snapshot of the running container can be created. Such a snapshot is, in fact, an image from which new containers can be created. Another way of creating images follows a declarative approach. The developer can describe the installation steps in a special *Dockerfile*. An image is created from such a description by issuing the *docker build* command. A generalization of the declarative approach are automatic builds. To setup an automatic build one has to publishing the *Dockerfile* in a public code repository (like *GitHub*). Afterwards a web hook has to be created, so that each time the *Dockerfile* is modified, a new image build is automatically triggered. Regardless of the way in which an image was created, it is possible to view all the changes done in the image during the installation of the software. The automatic builds go an extra mile to improve the trustworthiness of images: each user can review not only the content of the image but also the way they were created, since the description is publicly available.

Docker has a very important abstraction of data volumes which allows to separate software and data. The data are not included in the image, a problem often encountered in VM images. Data volumes, on the other hand, enable an easy injection of the data into the running containers. Hence the software in the container can easily be used for analyzing various sets of data. The separation of the software and the data diminishes one of the common barrier for sharing software. Researcher are afraid of leaking out the data in the software they made available.

Docker is available on almost all Linux-based platforms, there is a support for MacOS and recently announced support on Windows platforms. Since the images encapsulates the application and all the dependencies, starting new containers on a new system is like like starting statically linked, self-contained programs: no modification in the host system are required.

B. DARIAH-DE software sharing life cycle

DARIAH, the Digital Research Infrastructure for the Arts and Humanities, aims to enhance and support digitally-enabled research and teaching across the arts and humanities. It comprises a number of national initiatives, there is also a Germany-based effort, DARIAH-DE [2], where the described work was done. Efficient software sharing is essential for digitally-enabled research of its users. Also sharing software between infrastructures is becoming relevant in this context [12]. Software developed in one part of DARIAH might be passed over to other national efforts.

The technology for creating executable and deployable descriptions of software must be integrated into the scientific workflows and play well with existing e-Infrastructures. On Fig. 1 we present how such a integration could be conducted. We differentiate between three roles: developers, infrastructure operators, and researchers. We have also two central components: a code repository, where the deployment descriptions are stored, and Docker Hub repository where the images are stored and pulled from.

The process of making scientific software available kicks off with the developer wanting to advertise and make his software available. He can propose the deployment description by forking the official *GitHub* repository of DARIAH-DE Docker files, adding a new description (or updating an existing one), and creating a pull request[1]. The operators of the repository are notified about the the pull request. They can review the proposed solution, adjust it when required, or even reject it if it does not work. The *GitHub* repository is connected to the Docker Hub via web hooks. In short, this mechanism triggers an HTTP request to the Docker Hub each time the *GitHub* repository is modified. Upon such a request, a new build of the provided Dockerfile is started. The infrastructure operators can view the details of the build and act accordingly in case of a failure. Successfully built images are published into the official DARIAH-DE image repository in the Docker Hub. The researchers can explore the repository, select the software they are interested in, pull the images and start it on their machines. Pulling and starting requires just one command (*docker run*). The Docker Hub allows for storing additional information about the software. The developer can describe the typical applications or provide a link to a more extensive documentation.

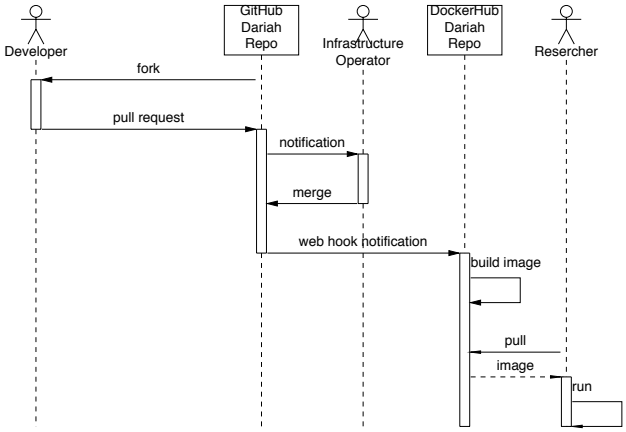

Figure 1. Proposed software sharing life cycle

The workflow described above can be repeated multiple times e.g., each time a new version of the software is made available. Moreover, the roles can be distributed or handed-over. Both repositories allow for registration of organizations. Such organizations can have multiple admins. Hence it is not required to have just one infrastructure operator but rather a group of people can be delegated for this task. Similarly, all the *GitHub* users can fork, and modify the Dockerfiles. The trustworthiness of the images is guaranteed by the reviews conducted by the operator who has to accept the pull requests. Of course each researcher can view the publicly available descriptions. The images (and Dockerfiles) are publicly available and they can be used by the researchers from outside of DARIAH-DE.

Fig. 1 depicts the simplest workflow, which ends with a local deployment of the software. It is sufficient to explain how the workflow works but clearly the local deployment is not always the optimal solution. In the next section we will show how a dynamic SaaS solution can be build, based on the proposed workflow.

IV. IMPLEMENTING META HOSTING

We have shown that Docker provides a means for a fast deployment of software. In the optimal case, the user has to issue just one command to obtain a running instance on her system. The optimal case requires some changes on the machine, at least the installation of Docker is required. Even if easily possible, the local deployments are not always the best option. One reason for remote deployments is efficiency: remote instances can run close to the resources they require. Many data-driven projects require long-lasting software runs. This is hard to perform on the local researcher's machine. Fortunately, e-Infrastructures like DARIAH-DE provide resources which can be used by the researchers for this purpose.

[1] Readers not familiar with the *GitHub* commands are referred to the documentation [13]

In this section we will show how the presence of deployable software description (as those provided by Docker) can facilitate a dynamic Software-as-a-Service solution. This service will offer all the benefits of the SaaS approach (i.e. very low effort is required to use scientific software shared by other researchers) whilst allowing for quick extensions of the software portfolio. We present our prototype solution which runs on low-level compute resources already available in the DARIAH-DE infrastructure. Our goal was a system which provides the researchers with an instance of the software she requires in just one request through a web page.

A. Actors

Fig. 2 depicts the architecture of the implemented dynamic Software-as-a-Service. It includes lots of components loosely coupled with each other by a messaging bus. Messaging is used for exchanging information between components in an asynchronous way. In production we use a *amqp*-based product (RabbitMQ [14]). Let us briefly discuss the roles and responsibilities of the single elements of our architecture.

The *Facade* is the entity facing the end-users. It is an entry point from which the commands (like create a new instance of a given software product) are issued. The Facade is stateless and it is possible to run multiple Facades. They can offer interfaces of different types, e.g.: a html-based for browser access or a json-based programmatic API.

The Facade has access to the messaging bus and a read-only access to the *Store*. Store is a system-wide cache with information about:

1. types of service registered in the system,
2. instances running in the system.

The content of the cache is updated by the *Store Updaters*. These entities subscribe for information about creation of new instances and registration of new types. Upon reception of such messages, Store Updaters write the information in the Store. It should be stressed that the content of the Store itself can be lost as it will be periodically republished. Store is solely used to speed-up the response times.

The *Workers* embody the main functionality of the system. Those are the entities which can manage instances of given service types (e.g. instances of eXist or neo4j databases). Each Worker upon its creation (and later periodically) informs other components about its capabilities (i.e. supported service type) and its current state (i.e. managed instances). Workers receive commands from users (via Facade) through the messaging system.

B. Communication with workers

The critical part of our system is the communication between the components. It is dynamic, asynchronous, and subject-based. We required the possibility to change the system capabilities during the run-time. In particular, to add new software to the portfolio of the offered Software-as-a-Service. This is done by adding (or removing) Workers. To become active in the system,

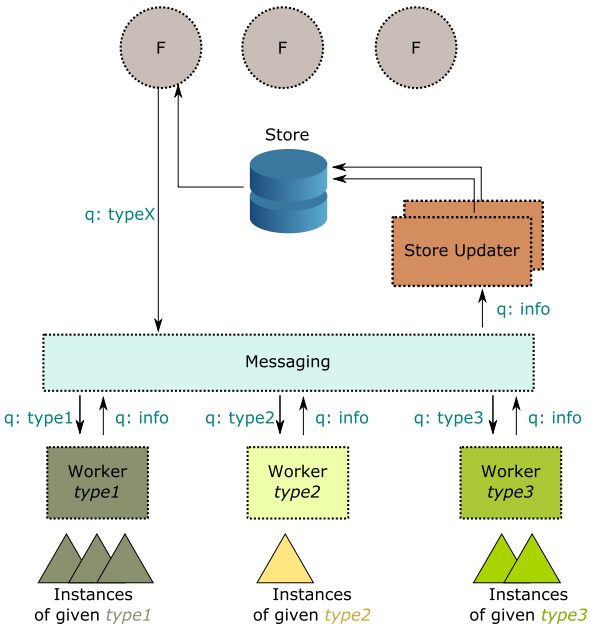

Figure 2. Architecture of the dynamic Software-as-a-Service

Worker needs access to the messaging bus. The incoming Worker publishes its "specialty" (i.e. instance type that it can provide) and subscribes for the messages in this instance-type-queue (like create new instance, delete instance). As can be seen on Fig. 2, for each instance type supported by the system, there is a separate queue. When a user requires a new instance of a given type it sends a message to the respective queue (via Facade). The message is routed to the proper Worker, it creates an instance and sends a response (via messaging) with details required for connecting to the just-created instance. Such details typically include IP address, protocol and port, username and password, etc. Workers republish their state periodically (i.e. instance types that they support and state of managed instances). Each worker has a dedicated queue for the incoming commands and all workers share a common response queue (the *info* queue on Fig. 2).

C. Implementation and operation

We have created a prototype of the dynamic Software-as-a-Service called DARIAH Meta Hosting. The implementation was done in Python and uses a set of frameworks and well-known products: Flask for the frontend, MongoDB as storage, and RabbitMQ for messaging. We offer two interfaces: one is a human-friendly web site, the other is a programmatic json-based API. We envision the later one to be used to script automatic deployments of software e.g. in data processing workflows.

One feature of our design was the division of the system into small, autonomous parts connected by messaging. The advantage of such a design was the ability to change the parts independently, for instance to scale up. We use Docker for deploying single parts and the Docker-based orchestration tool *fig* [15] to create test deployments including all the parts required. Fig is also able to scale out the system by spinning off additional

instances. In this self-test, the solution we use for the software sharing was successfully applied for the software we have implemented. Our prototype is deployed on OpenStack Infrastructure-as-a-Service cloud which we offer in DARIAH-DE. So far the complete system is placed in one data center but it should be possible to extend it beyond this one entity. This would only require to make the messaging accessible from the outside and deploy additional workers in different data centers.

For our prototype we have implemented a generic Docker worker. The deployment of Docker-based instances is usually conducted in the same fashion, regardless of what software is confined in the image. Hence the Worker is initialized with a name of the Docker image containing the software it will be responsible for. We create an instance of Worker for each software package offered in the dynamic Software-as-a-Service. To scale out the system it is also possible to have multiple workers offering the same type of the software. The requests will be then divided among the workers in a Round-robin fashion, allowing for fair load distribution.

At this stage it should be stressed, that the proposed architecture is extensible. The Workers abstract the technology used for creating the instances. It would be perfectly possible to write a worker which would use Puppet-based deployment descriptions or any other technology that might come around in the future.

V. CONLUSION

The motivation for this paper was the problem of scientific software sharing. A solution for that problem is crucial for the further development of reproducible data-driven science. We have argued that the problem is manyfold. It involves both technical and social challenges. In this paper we have focused on the former ones and firstly reviewed the technologies which could be used for the software sharing. Subsequently we have presented a workflow for sharing software in the context of e-Infrastructures like DARIAH-DE. In the second part of our paper we have shown how the presented software sharing solution can be used to leverage a dynamic Software-as-a-Service system. It enables a quick and easy deployment of the software on IaaS resources available in the e-Infrastructure. The proposed architecture is extensible and we have also shared some experiences gained during the implementation and operation of a working prototype.

ACKNOWLEDGMENT

The work has been supported by DARIAH-DE, which is partially funded by the German Federal Ministry of Education and Research (BMBF), fund number 01UG1110A-M.

Abstract - Unlike newly developed web applications that can be designed from the ground up to utilize cloud APIs and run natively within cloud infrastructure, most complex bioinformatics pipelines that are in advanced states of development can only be encapsulated within VMs along with all their software and data dependencies. To take advantage of the scalability offered by the cloud, additional frameworks are required to create virtualized compute clusters and emulate the most common infrastructure found on institutional resources where most of the existing bioinformatics pipelines are generally run. In this paper we describe one such framework, its compatibility with multiple Clouds and present an automated process for deploying the entire system so it can be made easily available on any Cloud.

I. INTRODUCTION

The adoption of cloud computing technologies has provided an opportunity to effectively democratize the field of computational biology, meaning that individual researchers and labs can now have access to the resources that were previously only available to the large sequencing and bioinformatics centers [1]. However, this presents challenges of its own, such as the need to configure and utilize bioinformatics software for next-generation sequencing, where significant expertise is required on UNIX based operating systems, programming languages, software compilation from source code, file systems, and large-scale data management [2]. For smaller laboratories this can become a significant obstacle, because in addition to coming up with the funds for building an informatics infrastructure with the capacity to handle large computations, they also need to hire trained bioinformaticians competent to install, configure and run sequence analysis software tools and manage the data. This can present a higher expense than that of acquiring the hardware.

The cloud computing model has showcased its ability to transform how access to compute resources is realized and has delivered on the notion of Infrastructure-as-Code [3]. However, this model presents the user with low-level resources that still need to be procured, configured, and managed. In the context of bioinformatics, this means installing required tools and reference data and setting up a virtualized cluster environment. As data volumes increase, this also requires utilizing compute and storage resources in a scalable manner. To address this, we have been developing CloudMan [4] as a versatile solution for enabling and managing compute clusters in cloud environments via a simple GUI web interface or a programmable API. As a full-fledged deployment, CloudMan integrates with the Galaxy framework [5], [6] and provides a comprehensive workbench for biomedical data analysis on the Cloud [7]; it enables one to seamlessly acquire cloud resources, assemble those into a compute cluster, upload data, perform data analysis by chaining output of one tool as the input of another, visualize the data, and finally share it. This is the end-user view. Internally, CloudMan manages cloud resources, operating system services, and application-level services.

As part of this article, we describe how we have extended CloudMan into an interoperable solution for multiple Clouds and built a framework for allowing anyone to deploy their own version. We describe the process for building the required cloud resources, how to launch an instance of the deployed components and how to configure CloudMan to manage a launched instance and correctly orchestrate any required runtime components. Once deployed, users will have a functional bioinformatics workbench and a dynamically scalable cluster for data analysis on a given cloud.

II. BACKGROUND

In recent years, cloud based bioinformatics data analysis systems such as Galaxy [7], CloVR [8], Cloud BioLinux [9] and bioKepler [10] were released, allowing smaller laboratories and institutions to perform large-scale data analysis with genomic datasets. All these platforms are available on the Amazon Elastic Compute (EC2) cloud, which provides data centers across the world, allowing any researcher worldwide to connect to the cloud end-point closest to their geographic boundaries.

Researchers or institutions with access to computing resources at their home institution have the option to implement their own private Cloud platform and run Virtual Machine (VM) servers, using the open-source Eucalyptus [11] or OpenStack cloud middleware. OpenStack is the official Cloud platform bundled with the Ubuntu Linux operating system [1] and can be readily installed on clusters running other Linux distributions[2],

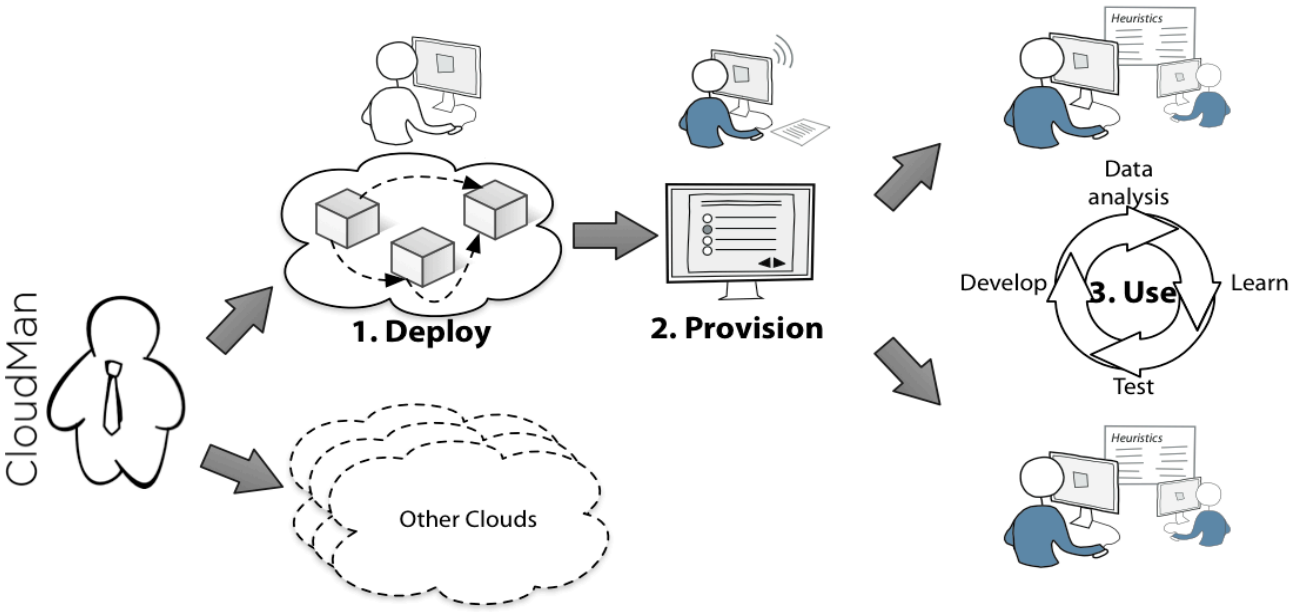

Figure 1. The effort described in this paper highlights the features of CloudMan as a platform for building and provisioning bioinformatics workbenches across multiple Clouds. With the multi-cloud compatibility of CloudMan (Section 3.A), **(1)** a deployer would use the provided automation methods to build and link the required cloud resources, tailored to the needs of the given research community (Section 3.B). Then, **(2)** a group leader, system administrator or even a domain researcher uses a launcher app to provision any number of instances of the workbench and possibly further customize those with custom data or tools (Section 3.C). Finally, **(3)** domain researchers use the workbench in their daily routine.

and Eucalyptus is similar. Both of these Cloud platforms offer Application Programming Interfaces (APIs) compatible with Amazon's EC2 service, and applications developed either on Eucalyptus or OpenStack work on the Amazon Cloud and vice-versa. Furthermore, users have the option to copy and execute VM server snapshots across installations of these Clouds as has been demonstrated with Cloud BioLinux.

For users who do not own local compute resources, nor have funds available to lease computing time from a public Cloud provider, there is the possibility of using government-funded Cloud infrastructures, such as the US-based Open Science Data Cloud[3], the Australian NeCTAR Research Cloud[4], or Helix-Nebula in the EU[5]. In addition, a number of academic computing centers in both the US and other countries have similar clusters with OpenStack installed[6], to which scientists can request access.

III. Deploying and Provisioning Virtual Environments

Despite the general availability of cloud computing resources around the world, due to the complexity of setting up a functional bioinformatics platform for data analysis, we have (1) expanded the capabilities of CloudMan to be interoperable with multiple cloud providers; (2) devised an automated method for deploying a complete system on compatible clouds; and (3) developed a launcher application allowing end-users to provision instances of the platform when and where needed. The overall concept is depicted in Figure 1 and each of these contributions is described in the following sections.

A. A Multi-cloud Cluster Manager

Architecturally, CloudMan is a standalone application written in Python that orchestrates cloud components (virtualized compute resources and software programs) to deliver persistent and functional user-level services (see [12] for the implementation details). To operate, CloudMan uses a number of cloud-level features and assembles those into a functional platform for performing data analysis [4]. Internally, CloudMan abstracts away the interaction with multiple cloud providers via a common cloud interface (`cloud_interface`). All the internal methods utilize the given interface providing uniformity throughout the code while supporting multiple cloud technologies. Compatibility with multiple clouds is achieved via a custom implementation of the cloud interface for each of the supported clouds (AWS, OpenStack and Eucalyptus). Adding support for future clouds is a matter of implementing the methods defined in the `cloud_interface`, with the option to inherit from the default AWS implementation and, again, identifying and implementing only the differences.

Because a running instance of the CloudMan platform represents a composition of multiple cloud services, in order to deploy the platform, it is necessary for the cloud middleware to provide the required features, as follows:

- *Customizable machine image*: this is the VM itself containing the operating system (Ubuntu) and required system level packages for applications such as Nginx, Slurm, RabbitMQ.
- *Instance user data*: this enables runtime contextualization [13], which is what makes it

[3] https://www.opensciencedatacloud.org/
[4] http://nectar.org.au/research-cloud
[5] http://www.helix-nebula.eu/
[6] https://www.tacc.utexas.edu/systems/rodeo

possible to have different and independent instantiations of the same platform. Sample data included as part of the instance data includes the API keys that CloudMan should use to connect to the cloud provider.

- *Security groups*: a virtual firewall offered by the cloud provider that permits selective traffic to one's compute instances based on user-defined access rules. CloudMan uses HTTP, SSH, FTP and several custom ports to enable access to the running services.
- *Persistent POSIX data storage*: this is where the user-uploaded and analyzed data is stored, as well as installed tools, databases, and tool configurations; it is leveraged to provide longevity beyond the uptime of an instance. Ideally, this storage is provided in the format of block storage devices of arbitrary size (i.e., data volumes) but other storage devices can be used instead, including mountable external file systems, such as NFS or Gluster, or the ephemeral storage on individual instances.
- *Block storage snapshots*: given that a significant amount of bioinformatics data is read-only reference genome data, the CloudMan platform maximizes data reuse by utilizing a single source of this type of data for multiple deployed instances of the platform. Technically, this is delivered via point-in-time block storage snapshots, which are converted into data volumes at runtime. To realize the reuse aspect of this data, the snapshots or archives need to be sharable. Alternatively, it is possible to use "tarballs" of file systems, which are archived in an object store and extracted at runtime onto an instance's ephemeral storage.
- *Object store*: persistent configuration data describing a given instance of the platform is stored in a globally accessible object store and it is used to recompose the CloudMan platform after it had been shut down. Information about running platform services (i.e., applications), utilized resources (e.g., volume, snapshot, machine image), and the CloudMan runtime code are stored here.
- *Per object ACL controls in the object store*: in order to enable instance sharing [14] with individual users, it should be possible to set Access Control List (ACL) permissions on each individual object inside the object store. Note that this is a requirement for the instance sharing functionality only.
- *Resource metadata*: popularly known as tags, assigning metadata to each of the utilized cloud resources helps identify all the components making up the complete platform. It also provides a fallback in case the platform needs to be recreated by hand following an unexpected corruption.

Given the feature-set of today's clouds, the above list is considered quite minimal and we strive towards minimizing it further. In the meantime, the required resources are available from a variety of cloud providers/middleware as bare-bones resources that behave consistently across those, making it possible to create the cross-cloud platform being described in this paper. This approach is in contrast to using custom (or high-level) services offered by a specific cloud provider and thus becoming locked-in to the given cloud or cloud features.

B. Automating Component Deployment

The previous section describes the multi-cloud support provided by CloudMan as a reusable framework and outlines the set of requirements a target Cloud must posses. In this section, we present a method for deploying the complete CloudMan platform. By deploying, we mean building the necessary components and making them available on the target cloud. These components will be joined at runtime (see next section) to deliver a functional, user-facing platform.

The process of deploying the required components has been automated using the Ansible automation framework. Ansible is a configuration management and provisioning tool; it uses files in YAML format to allow users to define tasks (e.g., `apt-get update`) and it then executes those tasks on target resources in an idempotent fashion. It uses SSH to communicate with target resources, hence imposing minimal requirements on setup. Conceptually, Ansible allows one to define reusable roles, which are composed of multiple tasks. It further allows multiple roles to be assembled into more comprehensive playbooks that can mix and match functionality offered by individual roles.

For the purposes of deploying a bioinformatics workbench backed by the CloudMan platform, we have developed a set of Ansible roles and assembled those into a playbook[7]. As stated above and described in detail in [12], the overall platform requires multiple components: the base machine image, an instance of the tools file system, and an instance of a file system containing indexed reference genomes. The playbook offers the capacity to build these components in an automated fashion. To start, it is necessary to build the machine image. This step leverages Packer[8], which is an additional layer of automation on top of Ansible. It handles provisioning of a VM on the target cloud, invoking the set of Ansible roles for building the machine image, creating the machine image, and cleaning up. Because Packer can run in parallel on multiple targets, it is possible to build the machine image with a single command (e.g., `packer build cloudman.json`) on multiple clouds at once. The built machine image will contain the required system packages and libraries, FTP server, Nginx proxy server, Slurm cluster manager and required configurations (e.g., users, environment settings).

Next, it is necessary to build the core file system, called `galaxyFS`. This file system holds all the tools, databases, the Galaxy application, and configuration

```

options that will be available via the workbench. Building *galaxyFS* is realized by launching an instance of the machine image built in the previous step, adding a file system of desired size (e.g., 10GB) via CloudMan's Admin page (note that CloudMan will be available because we are now using the image built in the previous step), and running the available Ansible roles. The roles will configure and initialize a PostgreSQL database as well as download and configure the Galaxy application with production settings. Installing the desired tools is realized via the ToolShed [15]. This step has been automated via a custom Python script that leverages the BioBlend API [16], [17] and installs more than a hundred tools at once. The list of installed tools is provided in a configuration file and can hence be easily modified. Once the process has been completed, it is necessary to create a snapshot of the resulting file system, which can be achieved via CloudMan's Admin page.

Similar to building the *galaxyFS*, it is necessary to build *indicesFS* - a file system containing desired reference genomes. The process is similar in that a new file system of adequate size needs to be added. Adding the reference genomes is performed via Galaxy Data Managers [18], which integrate with Galaxy and allow one to simply choose which genomes to include. Once the process has been completed, it is also necessary to create a snapshot of the resulting file system. Finally, it may be desirable to make the created snapshots public (or share them with select users) so others can launch instances of the deployed components (see next section). Also note that instead of creating volume snapshots, it is possible to create downloadable archives or shared file systems but, for brevity, we focus on volume snapshots alone.

C. Provisioning

Once the required components have been built, they need to be assembled into a provisioned instance of the platform. Instances can be provisioned by projects or labs to offer an 'always-on' ready-to-use workbench or by individual users on an as-needed basis (see Section IV). To make the process accessible, we have further automated the provisioning process via launcher web applications.

The build process described in the previous section produces a machine image and two file system snapshots. The provisioning process launches a VM instance based on the image, which starts CloudMan, and CloudMan then creates volumes based on the previously created snapshots to make functional file systems (along with setting up a virtual cluster and starting several service processes). Before an instance can be provisioned, it is necessary to compose the instance user data that contains access details for the given Cloud (e.g., region endpoints, ports) and information about the cluster (e.g., cluster name, access credentials). Once an instance of the image is launched, CloudMan will automatically start and continue the workbench contextualization process. To obtain the snapshot ID's, CloudMan refers to the *default_bucket* that is passed in with user data. This is an accessible object store container where a file (by default *snaps.yaml*) is stored and contains the details about the snapshots and corresponding file systems (see Table I). CloudMan will read the contents of the given file and proceed with setting up the system.

The above process can be somewhat detail-oriented and technical in nature. To simplify it, we have introduced a notion of a launcher web application that will handle the provisioning process automatically. The launcher app offers users a web form asking for cloud access credentials, a name for the instance, and a choice of VM type. The app then composes and formats the required information, instantiates an instance of the base machine image and informs the user when the launch process has completed. It also allows a previously created cluster to be readily recreated. There are two launcher applications available: one within the Galaxy application itself (CloudLaunch) and a standalone one (BioCloudCentral). CloudLaunch is automatically available on any Galaxy instance (at */cloudlaunch* URI) but requires a local instance of Galaxy (a public one is available at *https://usegalaxy.org/cloudlaunch*). Alternatively,

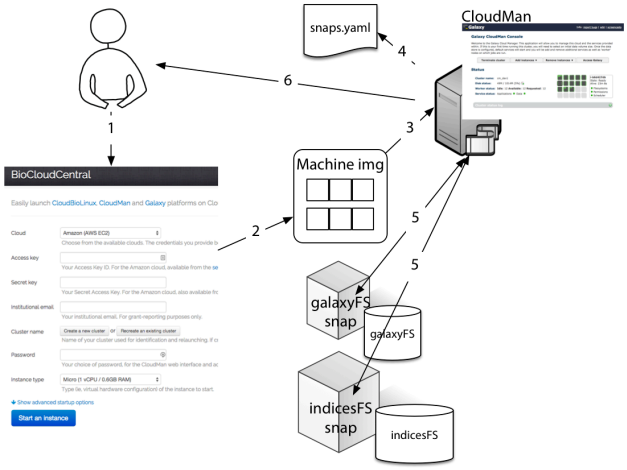

Figure 2. The process of deploying an instance of the platform, also showing all the required components.

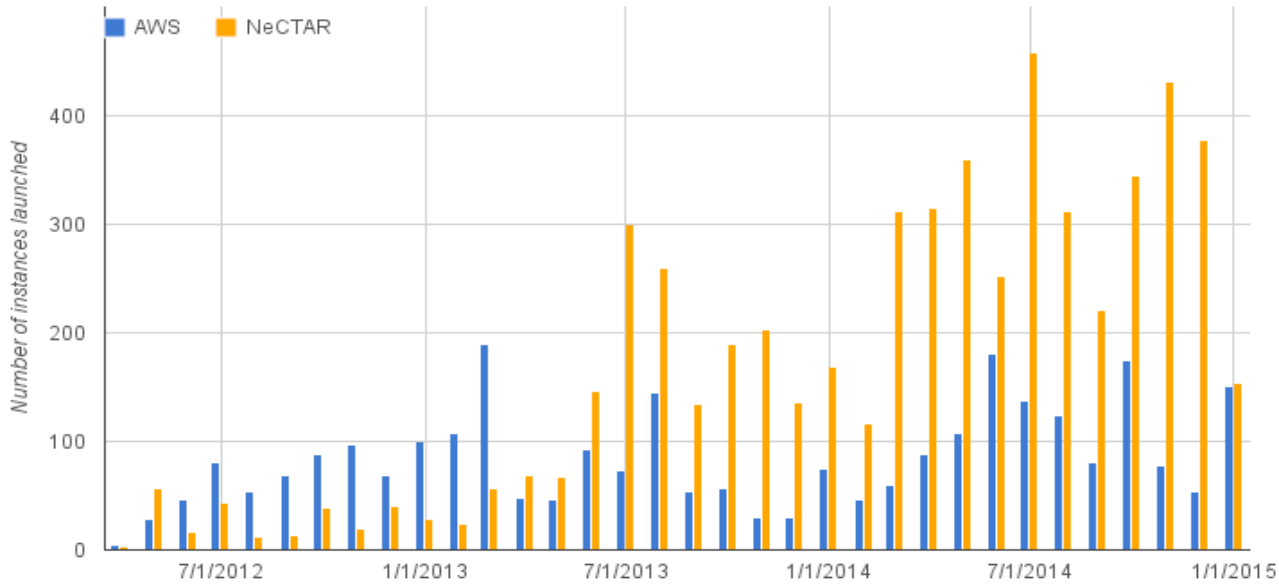

Figure 3. The process of launches per month of the CloudMan platform on two clouds, AWS and NeCTAR.

BioCloudCentral can be installed on a dedicated host and used independently of Galaxy (a public instance of this application is available at *https://biocloudcentral.org/*).

Figure 2 summarizes the described effort: after the required set of components has been built and registered in `snaps.yaml`, the launcher app is used to provision an instance of the platform. After the contextualization steps have completed, the user can start using the platform.

IV. DEMONSTRATION

The effort described in this paper allows anyone to build their own deployment of the CloudMan platform and the associated bioinformatics workbench. It further allows users to launch their own instances of the platform on the clouds on which it has been deployed. Currently, in addition to the long-standing deployment on AWS, the platform has been deployed on the Australian research cloud, NeCTAR; these represent two flagship deployments of the platform that are supported by the authors. Other deployments also exist but have been done by independent projects at their home institutions. Figure 3 captures the number of times the platform has been provisioned on the AWS and NeCTAR clouds over the past three years. The figure indicates that the NeCTAR cloud, despite the fact that it is available only to Australians, has been seeing approximately two to three times the number of instantiations as the world-wide deployment on AWS. We attribute this to the fact that the NeCTAR cloud is free of cost and that the Australian community has largely moved 'into' the cloud, especially for training and teaching purposes.

In addition to the count of provisioned platforms, the authors have been maintaining an always-on instance of the CloudMan platform on the NeCTAR cloud as part of the Genomics Virtual Laboratory (GVL) project[9]. This instance of the platform offers an instance of the Galaxy application that has been tailored for bioinformaticians training. During the course of the GVL project, a number of tutorials has been developed that demonstrate bioinformatics data analysis activities, such as variant calling or RNA-Seq analyses[10]. The instance, called *galaxy-tut* (available at *http://galaxy-tut.genome.edu.au/*), is where the tutorial data and tools are hosted, representing a fertile playground for training sessions. Besides being used during live training sessions, the instance is always available for anyone to follow the tutorials at his or her own pace. To accommodate these scenarios, the compute infrastructure behind the *galaxy-tut* user interface needs to scale with demand: as a lab full of students initiates a mapping job, the resource requirements rapidly grow. At the end of the compute-intensive portion of a tutorial, or during non-teaching periods, the resource requirements are much lower. The cloud model fits this scenario perfectly and the CloudMan platform is entrusted with keeping up with the cycle of requesting, configuring, managing, and releasing the necessary resources.

The *galaxy-tut* instance was launched as a default CloudMan instance on the NeCTAR research cloud and then manually customized to include all the data and Galaxy histories required for the tutorials. The master instance of the CloudMan cluster is running on an extra-large instance type (8 virtualized CPU cores, 16GB RAM). During training sessions, running of the jobs on the master instance is disabled via CloudMan's Admin UI and additional cluster nodes are explicitly launched. In addition, CloudMan's auto-scaling is left *on* to accommodate possible spikes in usage. The instance has nearly 500 registered users, stores 1TB of user data, and runs approximately 2000 jobs per month.

We have also deployed and run CloudMan and Galaxy on an experimental Eucalyptus cloud installation at the J. Craig Venter Institute[11]. The installation comprised of four

[9] https://genome.edu.au/

[10] https://genome.edu.au/wiki/Learn

[11] http://www.jcvi.org/

identical physical compute servers (16 core, 32GB memory, 1TB disk each). One of these servers was used as the cloud's head node to run Cloud Controller (CLC) service of Eucalyptus, and the remaining nodes running the passive Node Controllers (NCs) for worker VMs. The CloudMan framework has enabled us to bootstrap on-demand virtualized compute clusters with an easily accessible Galaxy interface on our private cloud. By simply starting with a pre-configured VM dropped on the CLC node, and configuring the Galaxy cluster endpoint to be handled by CloudMan, we were able to instantiate multiple transient VMs for parallel job execution across the Eucalyptus cloud nodes with CloudMan performing the initialization, management and termination of the VMs.

V. Conclusions

Dealing with the infrastructure and system level operations, such as acquiring cloud instances or managing operating system level services, requires a significant investment in time and expertise. Yet, for modern day bioinformatics it is an essential requirement. In our previous work, we have developed a system that provides a ready-to-use bioinformatics workbench with dozens of tools and gigabytes of reference genome data on the AWS cloud. This paper describes the effort of making the overall system underlying the workbench compatible with multiple Clouds and an automated process for deploying it. This makes it possible for anyone to deploy their own instance of the platform on a private cloud or under their own account on a public account. Each deployed instance can have a custom set of tools and reference genome data available, which are tailored to the specific needs of a group or an institution. Once deployed, others can launch the given instance of the workbench via provided launcher web applications.

Acknowledgments

The efforts of the Galaxy Team (Dan Blankenberg, Dave Bouvier, Martin Cech, Dave Clements, Carl Eberhard, Jeremy Goecks, Nitesh Turaga, Sam Guerler, Jennifer Jackson and Anton Nekrutenko) were instrumental in making this work happen. This project was supported through grant number HG005542 from the National Human Genome Research Institute, National Institutes of Health as well as grants HG005133, HG004909 and HG006620 and NSF grant DBI 0543285. Additional funding is provided by Huck Institutes for the Life Sciences at Penn State and, in part, under a grant with the Pennsylvania Department of Health using Tobacco Settlement Funds. The Department specifically disclaims responsibility for any analyses, interpretations or conclusions. Additional funding has been provided by the EU FP7-PEOPLE programme, under grant 277144. Further funding has been provided by the Australian NeCTAR project, under the Genomics Virtual Laboratory.

Abstract – Traditionally, collaborative coding has been practiced in open source communities where cooperation has mostly taken place on a coordination level. Nowadays, web technology is sufficiently advanced to enable collaborative coding in real-time as group work, which eases communication in software development. In this paper this phenomenon has been studied from a knowledge transfer and learning perspective. With the aid of two different example cases (code camps), we have examined the possibilities and challenges in learning during real-time group work. Additionally, we have evaluated the effect of the structure of log data created during software development. The research frame for this study is the utilization of log data visualization in evaluating group work and further improvement of the visualization in order to support software development.

I. INTRODUCTION

Software development today is a collaborative team effort where software engineers work together to produce new software to meet changing customer needs in what is often an evolving business domain. Global software engineering [1] and open source software [2] illustrate how software is created by a team of people with versatile expertise and backgrounds working in a globally distributed environment. On a similar note, the wide adoption of agile approaches such as Extreme Programming [3] illustrates the need for individuals working in collaboration.

The rise of the Internet and social media has made a further significant change in the ways people work together and collaborate. Through the Web 2.0 technologies people can share data and services to work together from a distance. Software development is also benefiting from this trend – collaboration tools like wikis are commonplace in software projects [4, 5] and even the use of social media is on the rise [6, 7]. Collaborative development tools on the lines of document editing services such as Google Docs [8] or Overleaf [9] have also been proposed in recent years. They include the online development environment Cloud9 [10] and the real-time collaborative environment to advance close collaboration called Collabode [11]. Saros [12] allows distributed pair programming through an Eclipse plugin. In this paper, use of a collaborative cloud based IDE (Integrated development environment) called MideaaS and its predecessor CoRED [13], both developed at TUT, is described. MideaaS is integrated with a hosting solution for fast deployment of the developed software as a service. MideaaS offers a simple yet powerful web-based tool for implementing and publishing web applications written in Java using Google Web Toolkit [14] and an open source web application framework for rich Internet applications called Vaadin [15]. The development of new software only requires a browser and concurrent editing is supported. Hence, several developers can work on the software simultaneously and see all of the edits in real time.

This shift towards the web is also reshaping education, as learning is inherently an activity where both the learner's own effort and the social context play a key role. The theory of Communities of Practice (CoP) [16, 17] illustrates learning as an outcome of social participation. A rising trend in modern education, massive open online courses (MOOC), is one example of leveraging the social and collaborative possibilities of the web. In a standard classroom environment, however teaching activities focus mostly on knowledge transfer from teacher to students; collaborative learning activities are left for problem-solving activities and even then can be optional. Computer- supported collaborative learning is a pedagogical approach that aims at learning through computer-mediated social interaction either in the classroom on online [18].

In order to study learning and knowledge transfer in collaborating teams, two different code camps were organized by the Department of Pervasive Computing at the Tampere University of Technology. These code camps utilized MIDeaaS for teaching students web development through team collaboration and coding. In this paper we present a study of the log data produced during the two camps. Large volumes of data of great variety can be recorded; however, the problem lies in recognizing, displaying, and utilizing the correct data. Different approaches to recording and visualizing data have been taken by others [19, 20, 21]. Here we focus on the quality and suitability of the data collected for analysis, the use of coding patterns to recognize learning through collaboration, and the detection of programming patterns in the log data.

The structure of this paper is as follows. Section 2 elaborates on the focus of research and the structure of the log data. Section 3 examines the visualizations made from the log data and explores work by others on visualizations and new possibilities. Section 4 contains discussion on

some issues on the topic of measuring collaboration and learning. Section 5 summarizes the paper.

II. EXISTING DATA

Documented here is the study made of real-time collaborative coding log data recorded during two different code camps organized by the Tampere University of Technology. During the first code camp [22] data were gathered from the use of the browser based CoRED software [23] which enables multiple users to collaborate simultaneously on a web software project. The distinctive features of CoRED are the ability to allow two or more users to edit the same source code file and display those changes in real-time; in addition, edits and other user actions such as creating a new file are logged and can be visualized to enable recognition of patterns in user behavior and ways of working. User actions are explained below in the section on studied data. The second code camp [24] featured a cloud-based IDE called MIDEaaS, which evolved from CoRED. Both of these development environments have been developed at the Tampere University of Technology. For the remainder of the paper, the IDE will be called MideaaS.

A. Research Focus

The code camps were run on the lines of an empirical experiment [25, 26]. During the two code camps, software engineering data on the development work were collected on the teams' work.

The purpose of the study was to perform analysis of the recorded log data. In this case we were interested in the following three areas:

- Validate the quality and suitability of the data.
- Expand one of the original research questions (Does collaboration help transfer knowledge between learners?) with user coding patterns.
- Examine visualizations derived from said data, visualizations made by other research groups on the same topic and explore the detection of programming patterns. Coding patterns were chosen because they provide the benefit from an educational viewpoint by possibly uncovering bad programming habits.

B. Studied data

The data gathered in the two code camp events focuses on user actions on files and source code. The data logged during the first code camp are more varied compared to the second, which concentrates almost solely on user edits. The changes in recorded data between code camps are discussed in section 4. Table 1 (below) contains a list of recorded events, event data, and which code camp logged the event. Each log entry is preceded by a 13-digit timestamp providing millisecond precision.

TABLE I. LOGGED EVENTS

Event	Recorded data	Code camp
New file	File name	1
Delete file	File name	1
Open file	File name, collab id, user id, user name	1
Close file	File name, collab id, user id, user name	1
Add marker	File name, collab id, marker id, marker type, start position, end position	1
Remove marker	File name, collab id, marker id	1
Edit	File name, collab id (code camp 1), user id (code camp 2), user name (code camp 2), insert/delete, position of edit, number of characters inserted/deleted, number of characters in file after edit	1&2
Chat message	User id, message	1&2
Created		2
Loaded from disk	File path for project	2

Of the first six events that are exclusive to the first code camp, four contain user information in the form of two id numbers. The collab id is assigned to a text editor window and one user can therefore have multiple collab ids should they have multiple text editors open. A user id is assigned upon login, so if the user logs in again they are assigned a new user id. Both of these types of ids are problematic since their persistence is not guaranteed.

The first four events are not elaborated on, as the information they contain should be self-explanatory. The add and remove marker events record visual pointers, either signifying a code error from the automatic error checker or the cursor or selection of another user. The marker events add a considerable amount of lines to the log files since typing in code manually will produce errors from the Java error checker. The other type of marker, the cursor location of another user, seems redundant considering that edit events log the activity of other users and contain more detailed information. The edit event utilized during the first code camp contains only the collab id as identifying information, which makes distinguishing between users difficult. This deficiency was fixed for the second code camp with the addition of the user name and a persistent id number for each user. The last two events are exclusive to the second code camp and replace the more verbose file events of the first code camp. The created event signifies the start of a project and is the first event in a log file.

Overall, the data recorded into log files is suitable for examining user actions both alone and in collaboration with others. The changes made in recording between code camps reduced the volume and verbosity of data although some of these changes, such as the removal of a new/delete file event from code camp 2 logs, might prove

detrimental. Section 4 contains further discussion on changes in recording log data.

C. Observations on Log Data

The quality of the log files was analyzed with Excel as the original research publications [22, 24] made no mention of errors. Analysis of the files found 4 different types of errors, which are listed in table 2 and discussed below.

TABLE II. TYPES OF ERRORS IN LOG FILES

Event/Recorded data	Description of error	Code camp
Entire row, edit events only	Logged data contains duplicate rows.	1 & 2
Timestamp	Within one millisecond a user is logged as having performed multiple edits (inserts and/or deletions).	1 & 2
Number of characters in file	The number of characters in file-property is static for multiple edit events. This occurs independently and also in connection with the above timestamp error.	1 & 2
User id and name	Some edit events do not contain a user id and name.	2

The existence of duplicate lines was known before analysis of the log files began but, since no hard numbers existed, a count was performed. Code camp 1 material contained 18 log files of which 5 had no duplicate lines. The remaining 13 files contained the vast majority (99.8%) of lines logged during code camp 1. The average for duplicate lines per total lines is 0.02 with the minimum value being 0.01 and the maximum 0.07. Code camp 2 produced 7 log files, all of which contained duplicates. The amount of files is smaller because each project's logged edits were combined into a single file per project. Unlike code camp 1, where there were no significant outliers in duplicate lines per total lines, code camp 2 contains two logs that deviate significantly from the rest. Logs 3-7 have an average of 0.01 duplicate lines per total lines although logs 1 and 2 contain 0.18 and 0.07 duplicate lines per total lines.

An issue with timestamps and edits exists wherein a single user is logged as having performed multiple edits within a millisecond.

The number of characters in file property reflects the total size of the file. It is updated after each edit but an error exists where the count is not properly updated. This causes visualizations that depict changes in file size to appear flat with sudden jumps in size. This could cause a false impression of programming skills, which is explored further in section 3 "Different types of visualizations".

The last issue found in code camp 2 logs is the lack of user id and name for some edit events. The average for missing user ids and names per total lines is 0.03 with a minimum of 0.01 and a maximum of 0.08. No strong correlation existed between project size and this error.

Overall, we conclude that while log recording has problems, the errors present in the existing data are not plentiful enough to threaten the results of the previous studies [22, 24]. We recommend the log recording process undergo a thorough review in order to dispel any uncertainty regarding results.

III. IDENTIFYING AND VISUALIZING USEFUL DATA

The aim of this paper is to investigate the quality of the data collected and their suitability for further analysis of the development process. The collected data are visualized in order to point out development patterns and possible social learning through shared knowledge. Next, we discuss the collected data, the data visualization and the possible anti-patterns the visualizations can help to shed light on.

A. Edits Done by Users

In terms of responding to one of the original research questions "Does collaboration help transfer knowledge between learners?" [24], user actions must first be examined in two dimensions: time and position, in order to detect possible collaboration. The edit event recorded in the log files provides detailed information on user actions with a millisecond precision timestamp, character position, and number of characters changed. The first problem to be solved is examining the proximity of logged edits to detect collaboration between users, i.e., how much is the maximum time that can elapse for users to be considered to be collaborating? The original research group chose 30 seconds as the limit of collaborative edits 24]. The second problem is measuring a change in programming skills. These two problems were approached by the original research group from multiple directions: "statistical analysis on the teams' work, log data and interview answers". The problem of measuring a change in programming skills from log data is discussed in more detail later in section 4.

B. Introduction to MIDeaaS Visualizations

This brief chapter contains an explanation of the visualizations produced from MIDeaaS log data. Fig. 1 (below) is made from code camp 1 log data but its form is the same as those used to visualize code camp 2 log data.

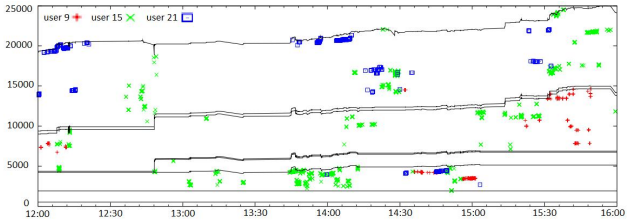

Figure 1 A four-hour long section of a log from one of the projects [22].

The above figure contains a four-hour segment of programming work done on a single project. The axes show the time and number of characters in the project. The gray lines separate different files and show changes in file size as the users perform edits. User edits are marked with a red plus sign, green x or blue square, as shown in the legend in the upper left-hand corner.

C. Scope of Data Visualizations

The visualizations produced from MIDeaaS log data focus on user actions on source code and interaction with other users. For the sake of readability, visualizations are limited to 2-hour segments as shown in fig. 2 and 4. This focus on user-level actions means that observing project-level patterns would require combining several 2-hour segments in order to form an overall picture of project-level progression. Additionally, neither IDE contains version control or issue tracking, thus limiting the options for detecting project level problems.

The currently available data focus on visible actions (edits) performed by users, however, it does not account for other kinds of user co-operation, such as advising done over communication software (Skype etc.) or live discussions. To determine whether this kind of 'invisible' co-operation has occurred, one possible solution could be to record which area of source code is being examined in the IDE. Should two or more users be examining and/or editing the same area of source code, knowledge transfer via problem solving or advising between users becomes possible. Fig. 2 [24] (below) has been edited to demonstrate this concept.

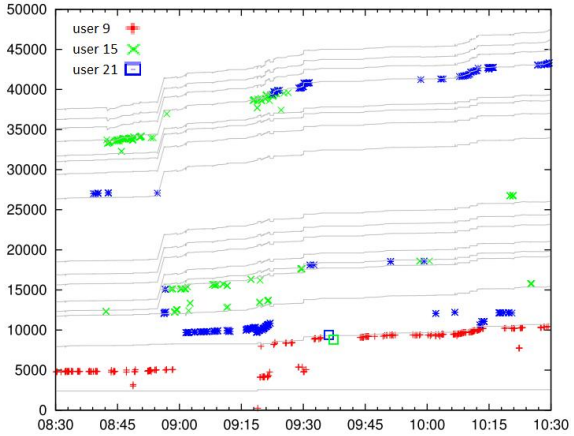

Figure 2 A typical two-hour-long editing session from one of the teams [24]. Edited to illustrate tracking of each user's focus.

Here the green and blue squares edited into the picture around the 09:35 mark illustrate the editor views of users 15 and 21 respectively, as they engage in problem solving with user 9. This method of observation is not without its weaknesses, however. Something as simple as a multi-monitor setup where two or more monitors have source code files open (or even one monitor with multiple source code files open) could provide another layer of complexity in determining exactly what file the user is actively following. Another problem with this approach to detecting 'invisible' collaborative activity is the fact that it is difficult to determine whether a user was actually co-operating with others or merely satisfying idle curiosity, unless they perform at least some edits in the observed area of source code. Nonetheless, this approach offers an additional method of detecting collaboration.

D. Different Types of Visualizations

Code size growth data have been examined by others as an indicator of programming skills by comparing the growth data curves between programmers of differing skill levels solving the same programming problems [19]. In the paper by Wang et al., the two best and worst performing programmers' code growth curves were compared, as shown in Fig. 3 (below).

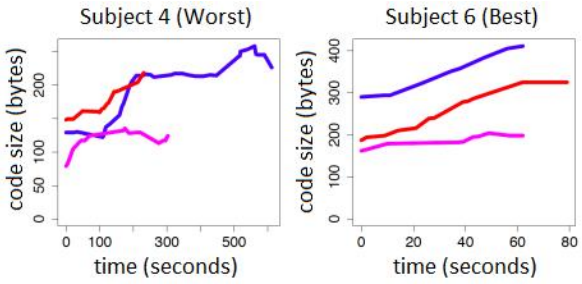

Figure 3 The traces of the worst and best performers [19]. Blue graph is problem A, red graph problem B, and orange graph is problem C.

The picture above contains code size growth curves for two different programmers whose programming skills were evaluated by making them individually solve the same problems. The colors in the figure correspond to different problems. The axes show code size in bytes and time in seconds, although the scales of the plots are different. However the main issue here is the behavior of the code growth rather than the scales of the plots.

The worst performing programmer's curve behaved in an "erratic" way compared to the best programmer, whose code growth curves were "very smooth and generally monotonically increasing". Wang et al. suggest that "Drastic drops imply code deletion indicating that corrections or refactoring occurred. Plateaus suggest "think time" possibly because users were experiencing challenges preventing them from making steady progress".

A direct comparison of code size growth curves between code camp participants cannot be performed since the participants worked on different projects and engaged in collaborative work. However, the approach by Wang et al. could be utilized together with the 'invisible' activity detailed above to observe knowledge transfer and its effectiveness. As an example, let us assume that a user in a collaborative project has been working on a file alone but at some point determines that they are unable to solve a problem on their own. Another team member is asked to provide assistance, which they supply either in the form of advice ('invisible' activity) or coding (edits). The outcome of this interaction could be observed from the code size growth curve of the user who requested help. If the curve behaves in a "smooth and generally monotonically increasing" way after interaction, we can say that collaboration has transferred knowledge successfully. Other possible areas of interest around this kind of scenario would be to examine how successful (does the advisee's code size growth curve indicate hesitation or confidence in their work?) different users are in this kind of situation in different roles (adviser or advisee). To summarize the benefits of the approach described above would help detect collaboration that would be missed by examining only edits and help determine the successfulness of collaboration.

As an addition to the suggestion of Wang et al. about drastic drops in code size, we propose that a drastic code insertion is either refactoring (if the insertion follows a deletion) or copy and paste programming (if the insertion occurs without a corresponding deletion). Examining edit events by a single user to determine the occurrence of either refactoring or copy and paste programming would not be prudent in this case due to the collaborative nature of the code camp projects. For example, two users working together but examined separately could lead to false conclusions regarding refactoring. Fig. 4 (below) contains collaborative work around a drastic change in code size [24].

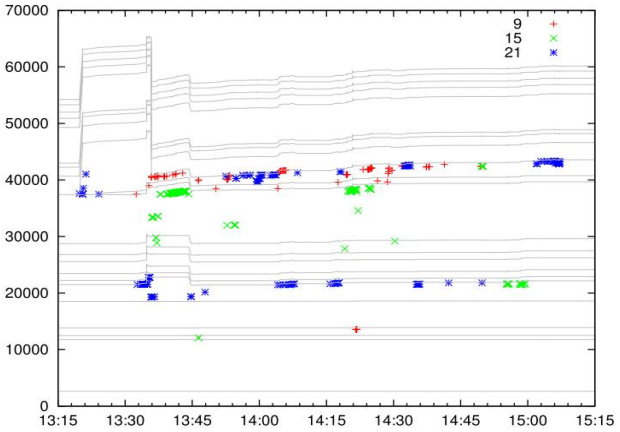

Figure 4 A typical two-hour-long editing session from one of the teams [24].

Here user 21 has inserted a large amount of code around 13:19. However, further work on the file is continued by user 9, whereas user 21 has moved on to work on another file. A task handover has been performed between users 9 and 21, and it is reasonable to assume that some knowledge must have been exchanged via advice regarding the code added by user 21 and possible further work needed on it.

E. Detecting a Potential Anti-pattern

Andrew Koenig first introduced the idea of an anti-pattern [27] in software engineering in 1995. He defines it as follows: "Anti-pattern is just like pattern, except that instead of a solution it gives something that looks superficially like a solution, but isn't one." Whereas a (design) pattern provides a solution to a design problem, an anti-pattern is a solution that appears to be beneficial but contains disadvantages that may negate any potential benefits. Since all existing visualizations produced from MIDeaaS log data focus on measuring and displaying user edits and code size growth, observable anti-patterns are coding, code, or work habit related. The anti-patterns presented below are rudimentary and not collaboration-specific but nonetheless offer an opportunity to detect problematic coding behavior.

Visualization of MIDeaaS log data can be used to detect at least one problematic coding-related anti-pattern: copy and paste programming [28], which is the reuse of code, possibly without fully understanding its purpose. The use of this technique is in some cases justified with increased productivity via code reuse. However, should one of the copied parts of code contain an error that is not immediately evident through inspection and/or testing, tracking down and fixing all instances of the copied code can become costly. Copying and pasting can be detected in the visualization graphs as vertical increases in code size that clearly differ in the scale of increase when compared to manually typed code. Fig. 4 above contains an example of a possible copy and paste occurrence, although the earlier edits should also be examined to determine whether refactoring was the case there.

A code-related anti-pattern that is observable from visualizations is the god object [29]. In programming, a god object breaks good object-oriented design by containing most of the information or methods of the entire program in a single class. In the MIDeaaS visualizations, a god object can be found by comparing file sizes; no exact definition for the size of a god object exists but should one file clearly exceed the size of the others in one project and the class in question be tightly coupled with the rest of the project's classes, the class should be inspected for the existence of this anti-pattern.

The visualizations produced by MIDeaaS allow not only a view of collaboration within a team but a window to individual coding habits and behavior. This presents a chance to help users by detecting possible bad coding habits.

IV. Discussion and Future Work

What cannot be derived from data or visualizations? The effects of real-time co-operation on learning and knowledge transfer in general are difficult to measure. In order to determine an increase in programming skills in an individual, one would first have to examine behavior over a long time in order to establish a baseline. Even determining a metric or a set of metrics to evaluate someone's skill is not a trivial task. Assuming that a suite of metrics could be chosen to represent a person's coding performance and a change in behavior (for better or worse) could be detected, the next step would be to determine exactly what caused this change. Pinpointing the exact event or group of events could be impossible; a human being engaging in creative work such as coding is not a glass box state machine with clearly labeled inputs and outputs. Changes in behavior could be a result of a host of factors all taken together. An additional problem is the fact that neither visualizations nor log data reveal the specific type of programming problem that is being solved. Collaboration might transfer knowledge that helps in solving a specific problem but another type of problem could again hinder a programmer. It is for the above reasons that we suggest that a combination of user edit information and 'invisible' activity should be used to study the effectiveness of collaboration. In collaboration situations, attention should be paid to the following facts: the time spent collaborating, its effectiveness (was work continued by the original programmer?) and any recurring pattern in collaborators (do some people mesh together better than others?). We believe that this could expand on one of the original research questions by the MIDeaaS team: Does collaboration help transfer knowledge between learners?

Changes in recorded data between code camps. The original research group chose to discard six logged events: new, delete, open and close file, in addition to add and remove marker. These events were possibly deemed not informative enough to provide insight into knowledge transfer among users. It is also possible that the file-related events were merely added to help in visualizing log files. Of the six discarded events, new and delete file could help provide information on a project level about library additions or refactoring. This could help clearly differentiate between adding a library file and pasting a large amount of code.

Collaboration thresholds. A possibly interesting avenue of further study would be to examine user actions after launching the application and especially situations where the application terminated with an error. A per user threshold for collaboration could be explored by examining possible patterns in a user seeking collaboration to help solve a problem with an application experiencing errors. This approach should be combined with that described in the first chapter of this section to maximize the amount of data available. MIDeaaS does not currently support deploying the application if another user is in the middle of editing code. This problem would have to be solved first as currently deploying and running the project is on the whole a group effort.

V. SUMMARY

In this paper we first studied and made observations on the validity of existing log data. Based on our findings, we made recommendations on future data logging. We also studied the visualizations produced from existing log data and made recommendations on how the visualizations could be improved to detect collaboration more effectively. User performance was explored via a comparison to a visualization used by another research team. Ways to utilize currently existing visualizations to detect bad coding habits were also explored. Finally, we examined some problems in measuring learning and knowledge transfer. Additionally, we also pondered on how to detect collaboration that occurred, not during coding but while running the project. We hope that by combining the existing visualization and the suggested improvements, the motives and causes of collaboration could be observed more fully than now, which could be a relevant research theme in the future.

Abstract – Microservice architecture is a cloud application design pattern that implies that the application is divided into a number of small independent services, each of which is responsible for implementing of a certain feature. The need for continuous integration of developed and/or modified microservices in the existing system requires a comprehensive validation of individual microservices and their co-operation as an ensemble with other microservices. In this paper, we would provide an analysis of existing methods of cloud applications testing and identify features that are specific to the microservice architecture. Based on this analysis, we will try to propose a validation methodology of the microservice systems.

Keywords - Microservices, Services Oriented Architecture, Cloud computing, PaaS, testing, validation

I. INTRODUCTION

The microservice architecture is a cloud application design pattern that implies that the application is divided into a number of small independent services, each of which is responsible for implementing of a certain feature. Microservices can be considered as meta-processes in a Meta operating system (OS): they are independent, they can communicate with each other using messages and they can be duplicated, suspended or moved to any computational resource and so on.

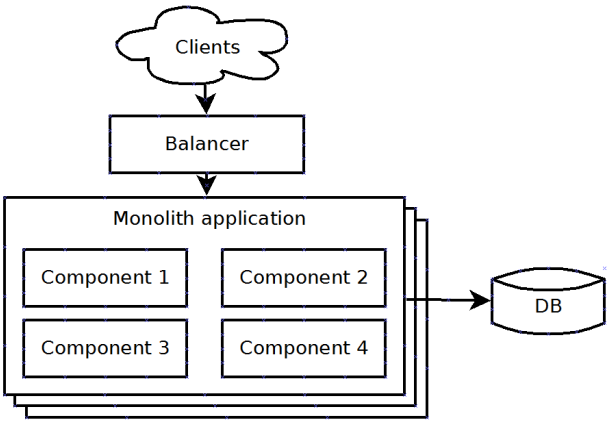

Figure 1. Monolithic system architecture

There are several examples of software systems, which were designed and implemented in accordance with microservice concept. Such companies as Netflix [19] and SoundCloud [3] use the microservice concept in their architectures, while Amazon [20] offers services like S3, which can be considered as microservices.

We can describe microservice architecture by comparing it with the monolithic architecture style, when an application built as a one big single unit (figure 1). The server-side monolithic application will handle HTTP requests, execute domain logic, retrieve and update data from the database, and select and populate HTML views to be sent to the browser. Such a design approach may result in that a change made to a small part of the application, requires the entire monolith to be rebuilt and deployed. Over time, it is often hard to keep a good modular structure, making it harder to keep changes that ought to only affect one module within that system [13].

In a case of microservice architectural style (figure 2), we can divide the application into a several independent components (microservices) and scale them independently. It is useful in a case of high-loaded systems and systems with lots of reusable modules.

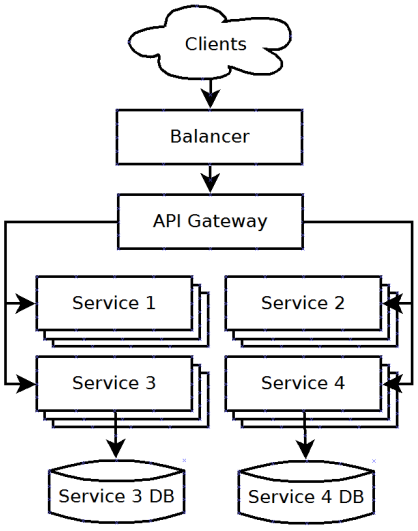

Figure 2. Microservice system architecture

Some developers and researchers believe that the concept of microservices is a specific pattern of implementation of Service Oriented Architecture [11]. In particular, the developers of the Netflix platform, which is considered the embodiment of the microservice architecture, named their approach of a design of software

The reported study was partially supported by RFBR, research project No. 14-07-00420-a and by Grant of the President of the Russian Federation No. MK-7524.2015.9

architecture as "a fine grained Service Oriented Architecture" [12]. However, the microservice pattern defines following specifics of software services development process [13]:

- microservices should use lightweight mechanisms for the communication (often an HTTP resource API);
- microservices should be built around business capabilities;
- microservices should be independently deployable by fully automated deployment machinery;
- there should be a bare minimum of centralized management of these services, architecture should provide decentralized service governance and decentralized data management.

However, the microservice approach is not an ultimate solution to deal with the system complexity. Using microservice approach, we are shifting the accidental complexity [2] from inside of the application out into infrastructure. That is why we should use special approaches to manage that complexity. Programmable infrastructure allows automating the microservices lifecycle management [18]; including automation of service deployment and termination, load balancing, service naming, continuous integration and delivery etc. Such support can be provided by a PaaS cloud platform, in order to scale the system automatically, manage it and provide middleware for the message communication. In addition, there should be implemented monitoring mechanisms to control the flow of the microservice application. It can be implemented as a specialized PaaS [16] solution or integrated in the existing PaaS.

Since the continuous integration is the only option of the implementation of the microservices architecture pattern, the question arises about the support this process on the methodological and software level. One of the most important stages of the process of continuous integration and deployment is validation of the developed software.

Our research goal is to develop the microservice validation methodology and a software support for microservice testing. To reach this goal, during our research we should solve the following tasks:

- to provide a review of existing software validation methods to identify testing features that are specific to microservice architecture;
- to develop a methodology for microservice systems validation, including approaches for component and integration testing;
- to develop a software solution that provides support for microservice systems testing on the basis of the proposed methodology.

In the framework of the current article, we would concentrate on the analysis of the current software validation standards and approaches and their relevance to the microservice architecture pattern. This paper is organized as follows. In Section II we will provide a review of the research and standards, related to the microservices testing and validation. In Section III we would try to identify special aspects of microservice validation, related to the component, integration and system testing. In Section IV we would propose microservice validation techniques for the Mjolnirr cloud platform prototype. In section V we summarize the results of our research and further research directions

II. Related research

Microservices concept is relatively new, so there are few materials in the field of microservice validation and testing right now. Basic information about the microservice approach is provided in the article [13] by James Lewis and Martin Fowler. In this article, they define the concept of microservice as well as the specific features of microservice architecture. Toby Clemson in his article [5] provides strong emphasis on the analysis of possible strategies of microservice systems testing, including certain types of microservice systems architecture; unit, integration, component and contract testing. Neal Ford provides a review of the proposed approaches on this subject is his work [6]. He describes basic ideas about microservice systems development, monitoring and testing. In addition, several commercial companies successfully moved to microservice architectures and published their result. For example in the paper [14] Netflix provide an overview of their PaaS system and mechanisms that they use to provide features of their platform to the components that initially was not designed to be used inside of the Netflix PaaS platform.

In our previous works, we described a prototype of distributed computing system called Mjolnirr [17]. This system works with isolated components, connected using message passing pattern. This system also can be considered as a microservice platform, because each component is isolated, fine-grained and has open standardized interface. In addition, automated scheduling and planning mechanisms have been implemented within the Mjolnirr platform in order to optimize the system load [15].

The ISO/IEC standards, ISO/IEC 25010 – Software Product Quality [7] and ISO/IEC 29119 – Software Testing [8], serve as the starting point of the study of microservice system testing and validation. Generally, we define testing as a combination of verification and validation [8]. In this research, we define microservice testing as microservice validation, because in general it is impossible to apply static testing methods to the compiled microservice.

As we mentioned before, we can consider microservices as a subset of Service Oriented Architecture (SOA). Thus, we can use SOA validation techniques in application to microservices systems. Some of existing approaches to SOA validation use SOA's BPEL business model for constraints-based SOA functional testing [10], other use white-box testing [1] to determine, is service covered with tests enough.

When we are talking about service testing and validation, we should decide, which quality characteristics are important for the product we are going to validate. Quality in use is defined in the ISO/IEC 25011 standard: “Quality in use of a service is the degree to which a

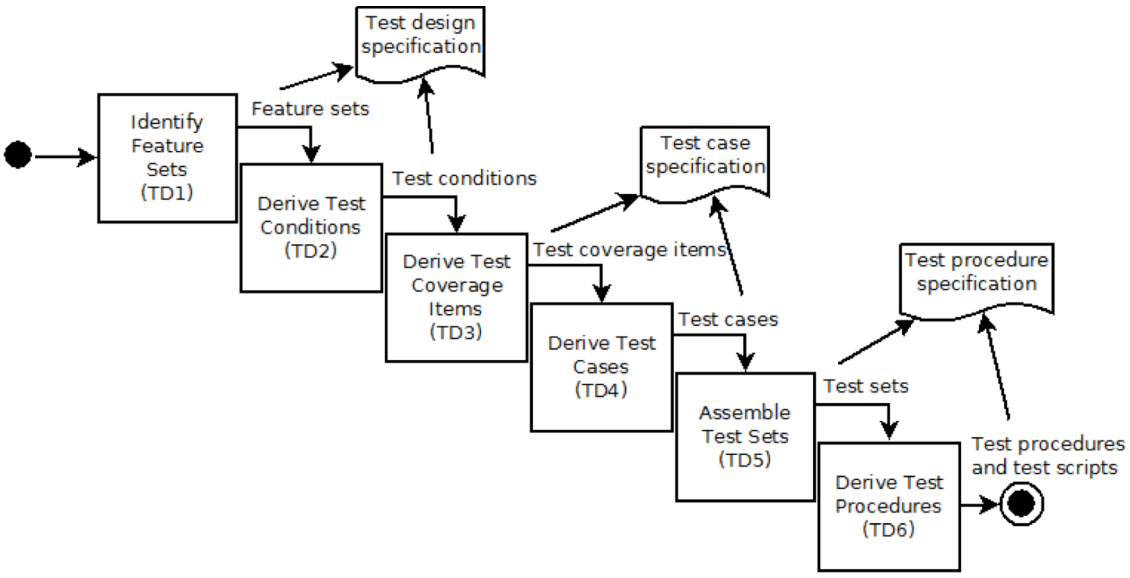

Figure 3. ISO/IEC/IEEE29119-2 Test Design and Implementation Process (modified)

service can be used by specific users to meet their needs to achieve specific goals with effectiveness, efficiency, satisfaction, freedom from risk and SLA coverage" [8]. ISO/IEC 25011 standard defines eight quality characteristics of services: Service Suitability, Service Usability, Service Security, Service Reliability, Service Tangibility, Service Responsiveness, Service Adaptability, and Service Maintainability. All of them, except Service Tangibility, can be applied to microservices. In addition, in a case of microservice system, we do not care about effectiveness and efficiency – these characteristic should be provided and measured by application programmer. However, satisfaction (stability of the whole system, quick response, etc.), freedom from risk and SLA coverage are important when we want to validate microservice system.

According to ISO/IEC 29119-4 standard, test design and implementation process consists of 6 steps – identifying feature sets (TD1), deriving test conditions (TD2), deriving test coverage items (TD3), deriving test cases (TD4), assembling test sets (TD5) and deriving test procedures (TD6) (see Fig. 3) [8]. To describe the microservice validation methodology, we should focus on the TD2, TD3, TD4 and TD6 steps.

III. Special Aspects of Microservice Validation

In this study, we define microservice as a software-oriented entity, which has following features:

- *Isolation* from other microservices as well as from the execution environment based on a virtualized container;
- *Autonomy* – microservices can be deployed, destroyed, moved or duplicated independently. Thus, microservice cannot be bound to any local resource because microservice environment can create more than one instance of the same microservice;
- *Open and standardized interface* that describes all available communication methods (either API or GUI);
- *Microservice is fine-grained* – each microservice should handle its own task.

Let us consider the most significant stages of the validation process, in relation both to the software as a whole and in particular microservice systems and define the features of the validation to be considered for microservice systems. By *unit validation* we understand individual validation of the microservice, by *integration validation* – validation of the interaction between individual microservices and by *system validation* – validation of the whole system (see Table 4).

System validation does not seem to offer features to microservices testing, since validation of the system level does not consider the internal structure of the application. The internal structure of the system can be considered as a black box, so there would be no difference in the system validation process for any application for which network resources access is needed.

A. Microservice unit validation

Functional Unit validation of microservice systems involves independent validation of individual microservices to meet the functional requirements. This

TABLE I. Featured Types and Levels of Testing

	Component	Integration	System
Functional	+	+	–
Load	+	+	–
Security	+	+	–
– - no features for microservice validation + - has features for microservice validation			

type of validation is based on a formal description of the functional requirements (including requirements as input and output data) imposed on each microservice. To provide the functional unit validation, microservice does not require to be deployed in a cloud environment, as this type of validation considers microservice as an isolated component.

Development of a software system in accordance with microservice approach is a process of development of individual independent microservices interacting exclusively based on open protocols. Thus, each microservice represents independent software product that should be developed and tested independently of the other microservices. Functional unit validation of the microservices can be divided into two stages (see Fig. 7):

1. unit, integration and system validation of the microservice source code or/and internal components (basic level);
2. self-validation of the microservice interface.

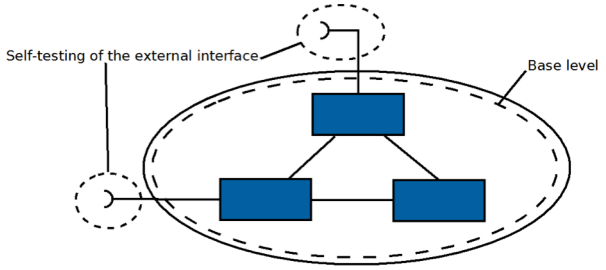

Figure 4. Functional unit validation of the microservice

Each microservice can be a relatively complex software system, which consists of several software components (local storage, web server, etc.) encapsulated in a container. Even in a case of ready-made software solutions, integration of such a component ensemble inside a container must be accompanied by validation the correctness of these components work together.

After that, it is necessary to test the interface provided by the individual microservice on its compliance with the specifications defined in the design. In this case, the entire microservice should be tested in general using its external interface.

Functional unit tests of a microservice should be conducted automatically on each microservice configuration change.

Load unit validation is aimed at the individual microservice validation at a certain load. Such validation may also be performed automatically for each microservice. Microservice load validation allows to identify resources that should be provided to the microservice container to ensure its correct work.

Security unit validation is aimed at the security and isolation validation of the individual microservice. As in the case of functional validation, microservice security does not end with the security of its individual classes. In component security validation we test the security of the whole microservice in the complex (for example, for typical vulnerabilities of web servers, injections, etc.). This stage of validation is performed without the presence of application programmer.

B. *Integration microservice validation*

Integration validation of microservice systems involves validation of all types of communications between the microservices. It includes validation of communication protocols and formats, resolution of deadlocks, shared resource usage and messaging sequence. To provide all of this validation techniques, we need to track all the messages, transmitted between microservices, and build the messaging graph. For this purpose, we need to know the messaging direction, message origin and destination. This information must be provided by microservice standard contract.

Functional integration validation ensures interoperability of the validation individual microservices. In this type of validation, we check for correctness of sending requests from one microservice to another, the sequence of interactions, microservice orchestration and choreography. In this type of validation, we can generate test cases in semi-automated mode – we need to know the communication sequence, and this data should be provided by the developer. Using this data, we can produce communication graph and test the system according to this graph.

Load integration validation is aimed at checking the microservice correctness under automatic deployment, backup and transfer, as well as microservice orchestration and choreography. This type of validation can be done automatically. Unlike functional integration validation, this type of validation includes loading of communication channels to discover the maximum load the microservice can handle before failure.

Integration security validation is aimed at validation of the security of communications between microservices, as well as checking for the interception of messages from outside or inside by anyone, besides the message recipient. Microservice specific validation should also take into account the particular environment in which the microservices are applied.

IV. VALIDATION OF MJOLNIRR-BASED MICROSERVICES

We have developed a prototype of the Mjolnirr microservice platform [17]. This platform supports microservices, implemented using JVM-compatible languages and Java-based containerization. Integration with Mjolnirr will be the first step of our validation framework implementation. This step includes Java-specific methods of software validation, such as jUnit for component validation. Let's describe, how validation implementation steps that we have highlighted in Chapter 2 could be implemented on the basis of Mjolinrr platform.

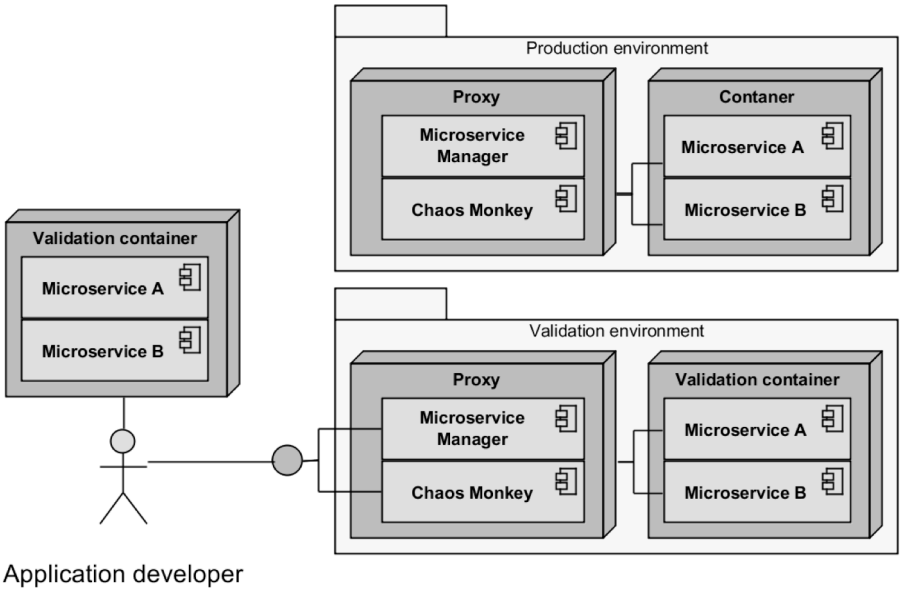

Figure 6. Validation of Mjolnirr-based microservices

TD2 (Derive test conditions) describes the testable aspects of components, in our case - microservices. In Mjolnirr, we can consider microservices and their calls as test conditions. As mentioned in Chapter 3, each microservice is isolated and autonomous and can be tested in a fully isolated JVM. Microservices are communicating using messages. Therefore, conditions, which determine quality of microservice system, are following: full isolation for component level, message communication for integration level and encapsulation for system level.

TD3 (Derive test coverage items) describes the attributes, derived from test conditions. Test conditions are microservices and their communications, therefore, test coverage items would be microservice methods and messages. Each microservice method and communication channel should be covered. Coverage items can be covered automatically or by application developer.

TD4 (Derive test cases) describes the test cases generation process. According to quality characteristics and ISO/IEC 29119-4 standard, we can decide, what test design techniques we should use and find exact technologies to implement those techniques. To perform a component-level testing, we can use only specification-based techniques, such as Boundary Value Analysis, Equivalence partitioning, Use case testing, Random testing and Scenario testing. In a case of component security testing, we can also scan microservice for typical vulnerabilities of the specific middleware, used in its infrastructure.

TD6 (Derive test procedures) describes the testing process. In Mjolnirr we use both automated and user-provided test cases, so we should cover all the coverage items, provided by microservice interface, and call all the test cases, provided by application developer. Test case can modify the microservice environment and state, therefore, microservice validation should be executed in an isolated environment, which should be purged after each set execution. As shown on figure 6, Mjolnirr has three sets of environments – special validation container for isolated component-level validation, validation environment for integration-level validation and production environment for end users. Validation environment and production environment has built-in Chaos Monkey service to ensure system stability. These three steps should be passed by each microservice to go to production.

To use those techniques, we need to have detailed microservice interface description, including input and output variables types, boundaries and syntax. Using this information, we can perform black box testing to each microservice in addition to the simple unit tests. Microservice interface definition described on figure 7.

```
{
  "name": "test_microservice",
  "inputs": [
    {
      "type": "integer",
      "min": 0,
      "max": 10
    },
    {
      "type": "string",
      "syntax": "he.?lo"
    }
  ],
  "outputs": [
    {
      "type": "integer",
      "min": 0,
      "max": 10
    }
  ],
  "input_connections": ["test_microservice2"],
  "output_connections": ["test_microservice3"]
}
```

Figure 7. Microservice interface description

In a case of integration testing we have knowledge about internal structure of the tested system. Therefore, we can use the testing techniques, mentioned before, and structure-based test design techniques, such as data flow testing, branch condition testing, etc. As shown on figure

5, microservice interface also describes input and output connections for each microservice, and we can use this knowledge to produce call graph and validate this structure.

Integration-level validation cannot be implemented on a container level, so this type of validation will be handled by Proxy node. Proxy will store the call graph, compare it with the desired structure, based on component interface. Also, Proxy will use different integration validation techniques, like Chaos Monkey [4] and random messaging, which are useful in a case of high load system.

V. CONLUSION

In this article, we described microservice testing features and validation techniques. In addition, specific test design techniques were mentioned. We have described the basics of microservice approach, provided and overview of methods and standards of software testing and validation. We described microservice validation features and proposed an approach to microservice validation. At last we proposed a brief overview of possible methods of implementation of microservice validation framework based on a Mjolnirr platform.

As a further development of this study, we will implement microservice validation framework, which will be able to perform automated and semi-automated validation to the microservices.

Abstract - In the scientist's community one of the most vital challenges is the issue of reproducibility of workflow execution. In order to reproduce the results of an experiment, on one hand provenance information must be collected and on the other hand the dependencies of the execution need to be eliminated. Concerning the workflow execution environment we have differentiated four levels of provenance: infrastructural, environmental, workflow and data provenance. During the re-execution at all levels the components can change and capturing the data of each levels targets different problems to solve. For example storing the environmental and infrastructural parameters enables the portability of workflows between the different parallel and distributed systems (grid, HPC, cloud). The describers of the workflow model enable tracking the different versions of the workflow and their impacts on the execution. Our goal is to capture the most optimal parameters in number and type as well and reconstruct the way of data production independently from the environment. In this paper we investigate the necessary and satisfactory parameters of workflow reproducibility and give a mathematical formula to determine the rate of reproducibility. These measurements allow the scientist to make a decision about the next steps toward the creation of reproducible workflows.

I. INTRODUCTION

Nowadays in many scientific research fields the experiments are especially compute and data intensive processes. The execution of these experiments in most cases requires parallel and distributed infrastructures.

The successive steps of an experiment are chained to a so called workflow, which can be represented by a directed acyclic graph (DAG). The nodes are so called *job*s, which includes the experimental computations based on the input data accessed through their input ports. In addition these jobs can product output data, which can be forwarded through their output ports to the input port of the next job. The edges of a DAG represent the dataflow between the jobs (Figure 1.).

Different users for different purposes may be interested in reproducing the workflow, for example scientists (author of workflow) in order to prove their results, readers or other scientists in order to reuse results or reviewers in order to verify the correctness of the results [1]. The scientist community has to face two important challenges related on the reproducibility of results: on one hand more and more metadata and provenance data are necessary about the infrastructure, the environment, the changes and the partial results of an execution in order to reconstruct the execution at a later time. The collected data called provenance help to store the actual environments, the partial and final data products and system variables [2], [3]. The saved information can be used in many fields concerning workflows (failure tolerance, optimization, user steering and dynamism [4], [5]). During the processing of scientific workflows four components can change: infrastructure, environment, abstract workflow model and input data. The provenance information collected at the different levels can support different features, services and goals. On the other hand the preparing reproducible workflows require careful and precise design which eliminates the dependencies and includes detailed description about the model and input/output data. Examples of dependencies can be a special hardware requirements, demand of third party or special local services or the usage of random based computing.

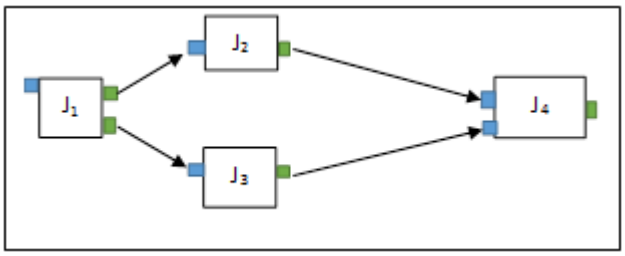

Figure 1. Workflow example with four jobs (J_1, J_2, J_3, J_4)

In this paper we investigate the necessary and satisfactory parameters of reproducibility, we examine the possibility and advantages of a four level provenance. We also give a mathematical model to measure the rate of reproducibility (RoR) to support the scientist in designing and creating reproducible workflow.

The rest of the paper is organized as follows: In the next section we provide a short background and overview about works related to our research. Section 3 presents the necessary and satisfactory requirements of scientific workflow reproducibility including our four level provenance structure. In section 5 we give a mathematical model and define the dependency functions to determine

the rate of reproducibility of a given workflow. Finally we summarize our conclusions and reveal the potential future research directions.

II. RELATED WORKS

Currently the reproducibility of scientific workflows is a burning question which the scientist community has to face with and has to solve. Accordingly in the latter one-two years many researchers investigate this issue. One part of the literature analyzes the requirements of reproducibility and the other part deals with the implementation of such tools or frameworks.

The first group agree on the importance of the careful design [6], [7], [8], [9], [10] which on one hand means the increased robustness of the scientific code, for example with a modular design and detailed description of the workflow, and of the input and output data examples, and consequent annotations [11]. On the other the careful design includes the careful usage of volatile third party or special local services. In these cases two solutions exist, but reproducibility is uninsurable: 1. taking a digital copy of the entire environment using a system virtual machine/hardware virtualization approach 2. capturing and storing metadata about the code and environment that allows it to be recreated later [11].

Zhao et al. [12] in their paper investigate the cause of the so called *workflow decay*, which means that year by year the ability and success of the re-execution of any workflow significantly reduces. They examined 92 Taverna workflows submitted in the period from 2007 to 2012 and found four major causes: 1. Missing volatile third party resources 2. Missing example data 3. Missing execution environment (requirement of special local services) and 4. Insufficient descriptions about workflows. Hettne et al. [13] in their paper list ten best practice to prevent the workflow decay. Grothe et al. [14] analyze the characteristic of applications used by workflows and list the requirements in order to enable the reproducibility of results and determination of provenance. Compared to the former mentioned requirements they assumed the deterministic feature of applications in order to perform appropriate provenance collection.

There exist available tools, VisTrail, ReproZip or PROB [15], [16], [17], which allow the researcher and scientist to create reproducible workflow. With help of VisTrail [15], [18] reproducible paper can be created, which includes not only the description of scientific experiment, but all the links for input data, applications and visualized output which always harmonizes with the actually applied input data, filter or other parameters. ReproZip [16] is another tool, which stitches together the detailed provenance information and the environmental parameters into a self-contained reproducible package.

III. NECESSARY AND SATISFACTORY REQUIREMENTS

The two main difficulties of reproducing a workflow are dependencies of workflow execution and collection of provenance data. The former can be determined as necessary requirements and the latter one gives the satisfactory requirements.

A. *Necessity – Dependencies*

The execution of a workflow may require many resources, such as third party or local services, database services or even special hardware infrastructure. These resources are not constantly available, they can change their location, their access condition or the provided services from time to time. These conditions, which we refer to as dependencies, significantly complicate the chances of reproducibility and repeatability. We have classified the dependencies into three categories: infrastructural dependency, data dependency and job execution dependency as shown in table 1.

TABLE I. CATEGORIES OF DEPENDENCIES OF WORKFLOW EXECUTION

infrastructural	data	job execution
• spec. hardware demand	• changing • TP demand • local spec demand	• deterministic • dependency between jobs • Third Party demand • Local spec demand

By infrastructural dependency we mean special hardware requirements, which are available solely on the local system or not evidently provided by other systems, such a special processing unit (GPU, GPGPU).

In the group of data dependency we listed the cases which does not guarantee the accessibility of the input dataset in another time interval. The causes can be that the data is provided by a third party or special local services. Occasionally the problem origins from the continuously changing and updated database that stores the input data. These changes are impossible to restore from provenance data.

The job execution can also depend on a third party or local services, but the main problem arise when the job execution is not deterministic. The operation of GPU or GPGPU are based on random processes consequently the results of re-executions may differ. More over if the dependency factor is too high between the jobs the reproducibility is harder to guarantee.

These conditions are all necessary to perform reproducibility of workflow execution. In the next section (IV) we give a mathematical formula to determine the rate of reproducibility of a given workflow. With help of this measurement the scientist can see how much part of the workflow can be reproducible with 100 percent at a later period of time. Knowing this information the scientist can decide to apply for example an extra provenance policy with extra resource requirement, which stores the whole third party data or apply virtual machine towards the reproducibility.

B. *Satisfying – Provenance*

We defined four levels of provenance data because during the execution of workflow four components can change that would affect the reproducibility: the infrastructure, the environment, the data and the workflow model.

The first is a system level provenance, which stores the type of infrastructure, the variables of the system and the timing parameters. At this level happens the storing the details of the mapping process as a results we can answer the question of what, where, when and how long has been executed. This information supports the portability of the workflow which is a crucial requirement of reproducibility.

The environmental provenance stores the actual execution details which includes the operating system properties (identity, version, updates, etc), the system calls the used libraries and the code interpreter properties. The execution of a workflow may rely on a particular local execution environment, for example, a local R server or a specific version of workflow execution software, which also has to be captured as provenance data or virtual machine snapshot.

The third category is data provenance. In the literature the provenance often refers to data provenance, which deals with the lineage of a data product or with origin of a result. With this data provenance we can track the way of the results and dependency between the partial results. This information can support the visualization, the deep and complete troubleshooting of the experimental model, the proving of the experiment but first of all the reproducibility. In addition in one of our previous paper [Krakko] we investigated the possibility and the need of user steering. We found that some parameters, filter criteria and input data set need to be modified during execution, which rely on data provenance.

The last provenance level tracks the modifications of the workflow model. The scientist during the workflow lifecycle often performs minor changes, which can be undocumented and later it is difficult to identify or restore. This phenomenon is usually referred as workflow evolution. Provenance data collected at this level can support the workflow versioning.

These structured provenance information of a workflow can support reproducibility at different levels if it meets the requirements of independency discussed before. In addition extra provenance information can be stored in that cases, in which however the workflow contains some dependencies but these dependencies can be eliminated with usage of extra resources.

IV. MEASUREMENT OF REPRODUCIBILITY

A. The model

The *workflow* (Wf) is represented by the set of job, the *job* (*J*) is defined by the series of input and output ports and the *dataflow* is considered between the given output port of a job and input port of another job:

- $WF=\{J_1, J_2, \ldots, J_N\}$,
- $J_i(p_1, p_2, \ldots, p_{Ki}, P_1, P_2, \ldots, P_{Li})$
- $dataflow(J_i, P_l;J_j;p_k)$

where N, K_i, L_i are natural numbers and denote the number of jobs in a given workflow, the number of input ports (p_i) and output ports (P_i) in a given J_i job.

B. Dependency functions

In order to determine the measure of reproducibility of a given workflow we need to define six binary dependency functions. These functions can indicate whether a given job or port depends on any services, input data, random value or each other, in which cases the reproduction of workflow is not possible or especially difficult. We call these criteria together *non-repro* criteria.

$$Dep_{service}(J_i) = \begin{cases} 1, \text{ if the } J_i \text{ job calls a Third party or special local service} \\ 0, \text{ else} \end{cases} \quad (1)$$

$$Dep_{infra}(J_i) = \begin{cases} 1, & \text{if the } J_i \text{ job depends on a special hardware} \\ 0, & \text{else} \end{cases} \quad (2)$$

$$Dep_{input}(J_i, p_j) = \begin{cases} 1, \text{ if the } p_j \text{ input port of the } J_i \text{ job depends on third party, local or changing data} \\ 0, \text{ else} \end{cases} \quad (3)$$

$$Dep_{random}(J_i) = \begin{cases} 1, & \text{if the } J_i \text{ job depends on true random generator} \\ 0, \text{ else} \end{cases} \quad (4)$$

$$Dep_{all}(J_i) = \sum_{i=1}^{N} \left(Dep_{service}(J_i) + Dep_{infra}(J_i) + Dep_{random}(J_i) \right) + \\ + \sum_{i=1}^{N} \sum_{j=1}^{K_i} Dep_{input}(J_i, p_j) \quad (5)$$

$$Dep_{job}(J_i, J_j) = \begin{cases} 1, & \text{if the } J_i \text{ job depends on } J_j \text{ and } Dep_{all}(J_j) \geq 1 \\ 0, & \text{else} \end{cases} \quad (6)$$

The functions (1), (2), (3), decide whether a given job or input port use third party services, local services, or the execution of the job requires special hardware. The function (4) examines the determinism of the results of a given job. A result of a job is deterministic, if during repeated executions the same input data give the same results. For example a computation is non deterministic, if it based on random process and random values or the job requires human intervention. The function (5) returns 1, if at least one of the above mentioned criteria is true. The last function examines the relation between a given job and all other jobs, and it returns 1, if the given job is based on a job which depends on a non-repro criteria (one or more of the functions (1), (2), (3), (4), (5) return 1).

C. Rate of Reproducibility

After determining the dependency functions we can define the *Decay*(J_i) function, which returns 1 if the job is not reproducible.

$$Decay(J_i) = \begin{cases} 1 \ \textit{if} \ Dep_{all}(J_i) + \sum_{j=1}^{N} Dep_{job}(J_i, J_j) \geq 1 \\ 0 \ \textit{else} \end{cases} \quad (7)$$

With help of function (7) we can define the rate of reproducibility, RoR:

$$RoR(Wf) = \frac{\sum_{i=1}^{N} Decay(J_i)}{N} \quad (8)$$

The RoR function says how big part of a given workflow is surely reproducible. At this point, the user – before finally submits his workflow – can think over the model, after viewing the results he can modify the model and eliminates certain dependencies or he can decide to apply extra provenance or virtualization tools to preserve the workflow.

V. CONLUSION

In this paper we investigated the necessary and satisfactory requirements of scientific workflow reproducibility. We approached the problem from two perspectives. On one hand we deal with the design and preparation of a workflow. Many best practices for appropriate designing exist in the literature, but one of the most important issue investigates the dependencies of execution (infrastructural dependency, services dependency or random based compute dependency), which add more difficulties to the reproducibility of a workflow at a later time. To eliminate these dependencies there are the necessary requirements of reproducibility. We gave a mathematical model to describe the execution dependencies and we defined the rate of reproducibility. Our goal is to support the scientists to make their experiment reproducible or to support in using some other tools (extra provenance data collection or virtual machine) to achieve reproducibility.

The second perspective is the possible structures of provenance. We determined a four level provenance, which gives the satisfactory requirements of the reproducibility. The information captured at the different levels can support the different levels of reproducibility, such portability or repeatability.

***Abstract*—The Topology and Orchestration Specification for Cloud Applications (TOSCA) standard is used to describe a cloud application and cloud architecture in order to allow a portable deployment to other compatible cloud and multi-cloud applications. P-TOSCA is recently proposed model and proved concept, which is an extension of the TOSCA standard to improve the TOSCAs ambiguities and weaknesses. In this paper we use the P-TOSCA model for other issues that are also very important in virtualized datacenters and cloud computing, that is, to enlarge/extend the energy efficient management system. A prototype application that dynamically creates a target virtual machine on utilized physical compute node, ports the application(s) from a virtual machine hosted on an underutilized physical server to the target virtual machine in Eucalyptus cloud is presented, which is specified with P-TOSCA. After migration, the prototype application will shut down the underutilized empty physical node.**

***Keywords*-Cloud computing, green computing, portability.**

I. Introduction

The employment of cloud computing offers new processing models that allows penetrations of applications from scientific, user and business domain. For this purpose virtualization is used, which as first phase is deeply implemented in data centers. The next phase should be directed towards interoperability, portability and energy efficiency.

The amount of energy that servers in cloud/data center environment use altogether with the amount of energy consumed by cooling systems represents a large portion of the overall cost of spent energy. Below are some examples given of how much energy is consumed in order to realize the importance of energy saving and reducing costs.

The US Agency for Protection reported of 100 billion KWh energy spent in 2011, whereas the infrastructure and energy cost was estimated to be 75% from the overall costs in 2014. Worldwide, the amount of energy spent in data centers has increased for 56% for the period from 2005 to 2010 and the proper cost was 1.5% of the total electricity use [1]. In addition, authors in [2] investigated that the average amount of energy spent on one Google site is 180kWatts, if we take into account that at each site there are 40 racks, each with 80 PCs connected. Therefore, reducing the amount of energy is of great importance not only in lowering costs, but also for the reliability, availability and productivity of the cloud environment/data centers. Besides it will contribute to a cleaner environment.

Another challenge is enabling automated portability and interoperability. In this area there are several research directions in creation of standards and complementary solutions like TOSCA, CDMI, OCCI, OCF, jClouds or mOSAIC. An addition of these solutions is P-TOSCA, an extension of the current TOSCA standard.

In [3] we proposed a solution for energy efficient data center, where the administrator manages the physical servers by startting or shutting down, them thus reducing the amount of wasted energy, and cost. On the other hand, in [4], [5] a model of an automated portability of applications is designed that is applied to migrate applications between different cloud providers. In this paper we merge these two models. Moreover, we propose an innovative solution for constant consolidation, integration, migration of VMs based on available resources, network topology and server status, and providing reliable QoS. We are extending the domain of P-TOSCA with energy efficiency module.

The remainder of this paper is organized as follows.

II. Related work

The larger the cloud data center is, the more energy it consumes. Many authors have proposed energy management models and mechanisms, such as the mechanism described in the paper [6]. The goal of this mechanism is to adjust the voltage of the system based on the utilization of the CPU, by transferring tasks from the heavy-server to the server that has more resources available. Another task scheduling model is presented in [7]. Authors have proposed approach for minimizing energy consumption by scheduling tasks to a minimum numbers of servers. The problem is formulated as an integer programming problem which minimizes energy consumption by scheduling tasks to a minimum numbers of servers while keeping the task response time constraints.

A Reinforcement Learning-based Dynamic Consolidation method (RL-DC) is proposed in [8] that aims to minimize active hosts based on current resource management. The servers power mode is determined by an agent that uses reinforcement learning method to learn from past knowledge in order to decide when a host should be switched to proper mode.

In order to minimize the energy consumption and VM migration at same time, authors in [9] focused on dynamic

on-demand resource model. This model is based on network-flow algorithm that switches part of idle servers off. For many researches, the main technique to develop an energy efficient data center is to migrate VMs and power off the unnecessary compute nodes.

Authors in [2] proposed an algorithm that will monitor the servers resources, and then by demand to switch the node off. Although this technique gives good direction for saving energy, it is not dynamic enough touching user specifications and needs. On the contrary, the domain of implementation is not the cloud, indeed in the papers we analyzed that consolidation of VMs between heterogeneous clusters it is not considered.

Similar approach is presented for energy efficient scheduling of Virtual Machines in cloud data centers [10]. A combination of an optimal allocation with a consolidation algorithm of VMs has been proposed, so when resources are leased, a VM migration is performed to adapt placement of those resources. However, as the previous example, this paper as well does not address the cloud environment i.e. is this migration performed within the same cloud data center? Furthermore, is migration between two different cloud platforms considered?

We concluded that in order to spent less energy the focus of the most proposed approaches are shifting tasks between servers or dynamic algorithms are implemented, that on base on available resources VMs are migrated, and therefore the server node is turned off. But, what if specific VM is needed to be created or deleted?

Furthermore, there is not addressed or even designed an energy efficiency and portability model for cloud data center. This gave us an additional motivation to explore and also develop such model that features consolidation, migration and incorporation of VMs on the basis of available resources of the physicals servers, and providing reliable QoS.

III. Background

In this section we will give a brief overview of the P-TOSCA model as well as on the Application for Modern Energy Efficient Data Center.

A. P-TOSCA

Authors in [4], [5] had designed and implemented a model of an automated portability of Platform as a Service hosted applications from one cloud environment to another. This model is called P-TOSCA, it extends TOSCA 1.0 standard [11], thus representing an application specification.

The main idea is to enable a possibility to switch between different cloud providers and vendors. P-TOSCA model [4] is used as an application specification and automated portability of Platform-as-a-Service (PaaS) hosted applications from one cloud environment to another. P-TOSCA is an extension of TOSCA 1.0 standard [12] and defines details on PaaS implementation.

A deployment and migration using TOSCA and P-TOSCA is performed by using Cloud Service Archive (CSAR), artifact that includes a XML description of the application topology

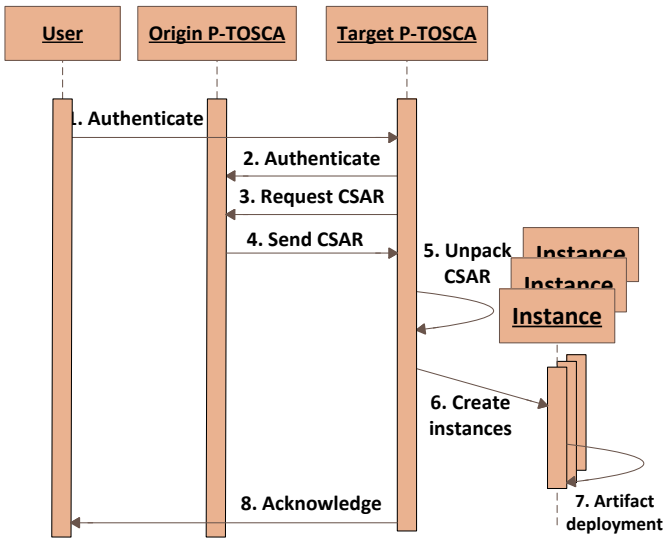

Fig. 1. Activities in P-TOSCA engine application portability

and deployment required artifacts like scripts, war files, zip files, libraries etc. Fig. 1 presents a set of steps performed by the P-TOSCA engine during application migration. In step 1 the user authenticates to the target cloud and specifies the origin cloud and the application. In step 2 authenticates on the origin cloud by using the target P-TOSCA. In steps 3 and the user requests the CSAR for the chosen application which is sent to the target cloud. In steps 5, 6 and 7 the P-TOSCA engine unpacks the CSAR, processes the model, creates the instances and deploys the artifacts. Finally, in step 8, the user is informed of the action result.

B. App for Energy Efficient Data Center

A new approach, named Application for Modern Energy Efficient Data Center was presented in [3]. The purpose is to reduce the amount of wasted energy by remotely managing, i.e. powering on/off the servers in the data center. The data center consists of a pool of servers connected on a switch, thus forming an Ethernet network of one or several VLANs. One server is used as a management station, and the other servers, called clients, must have previously enabled the WOL property on their NICs in the BIOS, so that they can listen to the network for incoming packets. When the administrator selects the proper server to power on/off, the IP and MAC addresses of that server are used to form a magic packet. Then, this packet is send through the Wake-On-LAN protocol as UDP packet to the destination.

IV. The new model

In this section we describe the model we propose. We present the challenge and we propose an extension to the P-TOSCA model which will include energy efficient resource management.

```
<NodeTemplate id="LinuxVm"
              name="LinuxVm for Tomcat"
              type="Server">
       <Properties>
         <ServerProperties>
              <NumCpus>1</NumCpus>
              <Memory>1024</Memory>
              <Disk>10</Disk>
              <EnergyEfficient>
                    true
              </EnergyEfficient>
         </ServerProperties>
       </Properties>
...
</NodeTemplate>
```

Listing 1. Example of extended *Node Template* with *EnergyEfficient* property

A. Challenge

The main challenge is to create energy efficient management system that will operate along with the P-TOSCA engine. The main goal is to create a prototype application that dynamically creates a target virtual machine on utilized physical compute node, ports the application(s) from a virtual machine hosted on an underutilized physical server to the target virtual machine in Eucalyptus cloud. For this goal we use and extent the P-TOSCA. Thus not only that energy efficiency will be achieved, but also a better performance can be obtained.

B. P-TOSCA Extension

In P-TOSCA each virtual node is specified using Node Template, defined and included in the XML description of the application topology. Our main goal is to extend the node description by adding another property to the template which will indicate that the decision for node location will be performed by the application for energy efficient management. For that purpose we extend the ServerProperties element of the Node Template by adding new property: *EnergyEfficient*. This property can have Boolean values (i.e. true or false). Listing 1 illustrates the extended Node Template definition.

C. Architecture

By using this model we can migrate instance from one server to destination, target physical server, and turning off the source server in order to save energy consumption. In Fig. 2 the architecture of the energy efficient portability mode is given followed by an explanation.

When VMs has to be migrated or instantiated, the proper server has to be determined. For this purpose, the Energy Efficient Application utilizes Intelligent Agent, discussed in [13]. If in the cloud data center exists a server that has enough resources needed, then this agent returns the particular server as target server.

In the next step, this target server is used by the P-TOSCA engine to instantiate or migrate the VM on that particular server. (Step 2 from the sequence diagram).

Then, the Intelligent Agent again checks for allocated and/or available resources among the servers in the cloud data center, in order the administrator to be aware of their status. Based on these statuses, the administrator has the privilege to turn off the server that has no resources allocated. (step 5).

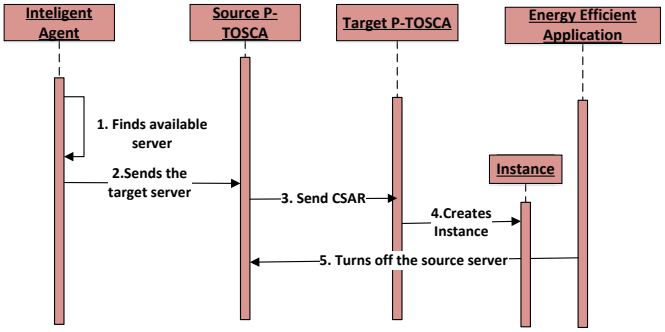

Fig. 2. P-TOSCA energy efficient portability mode

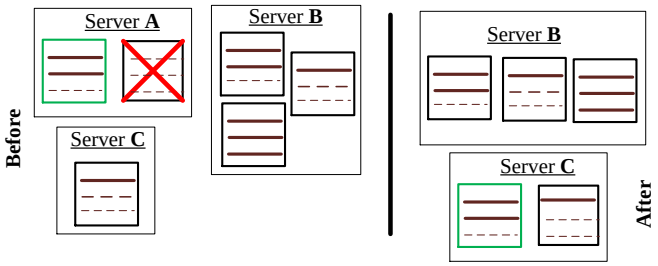

Fig. 3. Case study 1: before and after scenarios

V. Pilot Application

In this section we will describe the energy efficient model with P-TOSCA specification through the following two cases that are usually challenge for cloud:

- Which physical server to migrate particular virtual machine on?
- What physical server to instantiate new virtual machine on?

In both cases energy efficient and QoS is considered.

1) Case 1: Migration using P-TOSCA / Shutdown: This case we tested on four computer nodes, of which three are active. As shown on Fig. 3 servers A and B have two virtual machines instantiated, with corresponding resources, and server C has one. From server B we shut down one virtual machine, leaving one VM active. In order to save energy, we first migrate the virtual machine on some of the active server nodes left, and then power the compute node off. In order to do this, we start by listing all the available and used resources from the controller machine. The question is, on which server to migrate the virtual machine? A resource strategy described in [13] determines/finds the server with enough resources for the new VM. If proper server exists, we set that server as target server in the extended P-TOSCA specification, in order to migrate the virtual machine on that particular server.

2) Case 2: Instantiating new Virtual Machine: The next case that we will consider is when a new virtual machine (with particular resources such as number of cores, memory.)

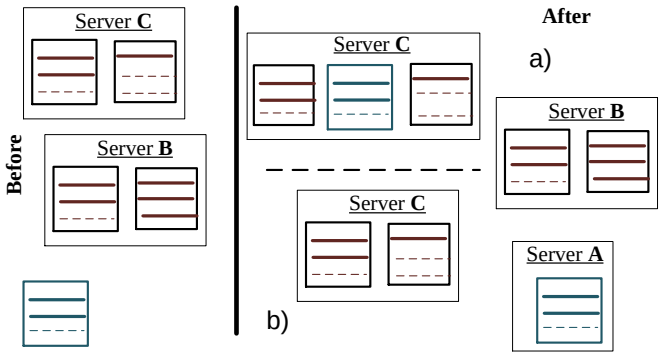

Fig. 4. Case study 2: before and after scenarios

has to be instantiated. The whole scenario is presented on Fig. 4. The testing environment for this case is as same as in case 1, i.e. it differs in number of active servers. Before the new virtual machine is instantiated, the proper server has to be determined/settled, whether it will be an existing or a new one. A brief discussion (of these sub scenarios) follows.

For this scenario we have 2 active server nodes, with 2 and 3 active VMs respectively, and two non-active. In order to determine where to instantiate the new VM, a resource provision strategy is used, based on the greedy algorithm [13]. If the number of required resources of the new VM matches with the number of available resources left from any of the active server nodes, the algorithm returns the particular server as target server. Then, using the P-TOSCA model we instantiate the new VM on that target/particular server.

On the contrary, if none of the active serves matches the required resources, using the application first we click on the server icon to power it on and then mark that server as target server in the P-TOSCA specification. At last, the new VM is instantiated on that server.

VI. Discussion

A. Performance impact

Physical server underutilization will enable better performances. In this paper a diiferent approach with same purpose is presented.

Each physical server consumes $P_0 + L * P_L$ electricity, where:

- P_0 is the energy consumed without utilization,
- L is the overload
- P_L is the energy consumed during overload

As the number of active servers decreases, the total amount of electricity will also decrease.

B. Cooling problems

Our previous paper [3] discussed energy efficient laboratory, that is, usually laboratory with 20 PC-s, without concerning the temperature conditions. Usually, the cloud data system does not consists of a small number of servers, but it consists of several racks and each rack has approximately 20 physicals

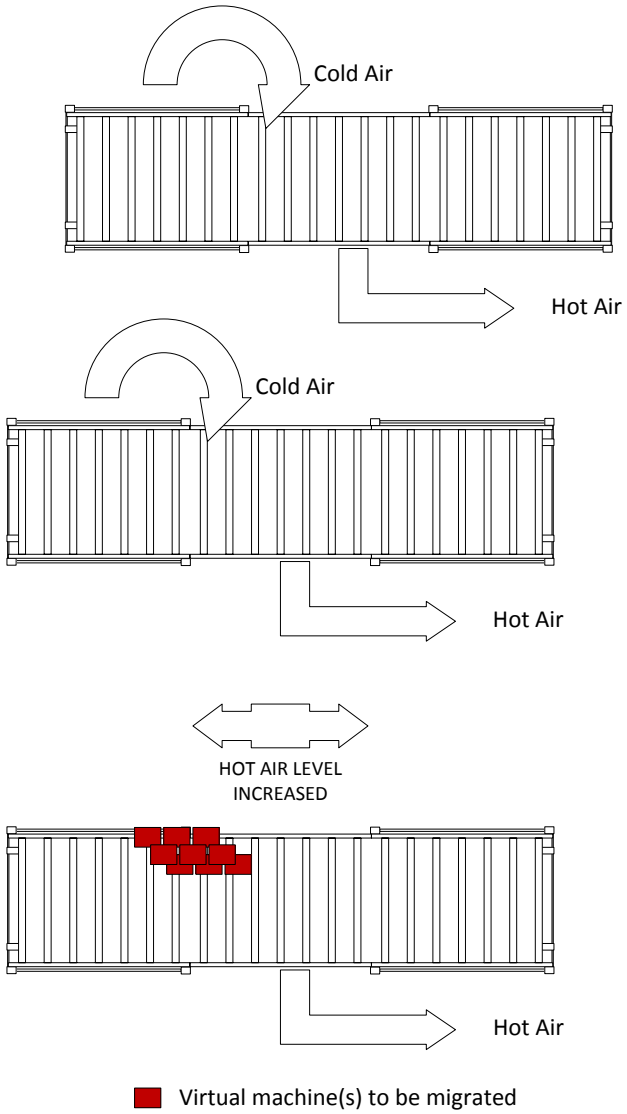

Fig. 5. Cooling consumption in cloud data center

servers, from where multiple virtual machines are instantiated. As analyzed in [14], for every watt of power, server needs 1 to 2 watts of cooling. Therefore cooling takes more than half of the total electricity usage in cloud data centers.

Besides Energy Efficient model, a low-power cooling system in a data center is needed so that costs can be reduced. Therefore, our next challenge is to develop a new solution that will determine which virtual machine from which physical server of a particular rack has to be migrated, so that the physical server is powered off in order to accomplish cooling balancing and spent less electricity.

C. Live migration

As described in [15], the Live migration is performed within seconds whereas, migration with P-TOSCA can take up few minutes. Compared to our solution, live migration is much faster.

On the other hand, the domain of Live migration is limited, while the domain of our proposed solution is much broader. The P-TOSCA model can migrate application between different cloud frameworks (e.g. Eucalyptus and OpenStack) using the native cloud APIs as well as it can be used with different types of applications (e.g. N-Tier [5] and SOA [16]). Besides this, the P-TOSCA model can be applied on application that are on premise hosted and using this model to migrate the application to the cloud, unlike Live migration.

D. Open Virtualization Format (OVF)

Open Virtualization Format (OVF) represents a standard for packaging and distributing virtual appliances [17]. The general goal of the standard is to provide hypervisor agnostic migration of virtual machine software. Every virtual appliance is described using OVF meta-data, which is later used for deployment with pre-built configuration described by the data.

In comparison to other solution, the OVF standard requires a substantial network throughput in order to migrate the data, given the fact that this standard packs and distributes a whole virtual machine. Another drawback is the amount of time required for data migration. Given the fact that most images of virtual machines can be already pre-contextualized with general used software or to use local repository for software installation, the task to move a whole virtual machine can take more time than the other approaches.

VII. Conclusion and future work

This paper proposes a model for energy efficient management of a cloud center. It presents two cases for consideration and offers servers consolidation by migration of virtual nodes from one physical server to other and powering off servers. It also considers the case of shortage of physical resources in the data center and proposes instantiation of new preconfigured physical server in the given cloud as Compute Node.

For this goal we propose an extension of the P-TOSCA model by extending the description of the properties of the Node Template including energy efficiency property. By this we are planning to achieve two goals:

- During the process of new instance creation we can state the physical server to which the application node(s) will be created and the selection of the physical server will be based on intelligent algorithm
- We can migrate applications (with their nodes) from one physical server to other based on intelligent algorithm decision for energy efficiency

In our future work we plan to include metrics related to the cooling process in the intelligent algorithm for energy efficiency management. The algorithm will choose which server from which rack to be powered on given the current temperature conditions. The algorithm will also suggest which server should be powered down based on the temperature conditions in the data center (i.e. which part requires more cooling at the moment).

Scientific workflows are data and compute intensive thus may run for days or even for weeks on parallel and distributed infrastructures such as HPC systems and cloud. In HPC environment the number of failures that can arise during scientific workflow enactment can be high so the use of fault tolerance techniques is unavoidable. The most frequently used fault tolerance techniques are job replication and checkpointing. While job replication is based on the assumption that the probability of single failures is much higher than of simultaneous failures, the checkpointing saves certain states and the execution can be restarted from that point later on. The effectiveness of the checkpointing method depends on the checkpointing interval. Common technique is to dynamically adapt the checkpointing interval. In this work we give a brief overview of the different checkpointing techniques and propose a new provenance based dynamic checkpointing method.

I. INTRODUCTION

Scientific workflows being data and compute intensive may require long execution time, which can even last for weeks. During such long intervals it is inevitable to adapt to the dynamically changing environment which can be caused by unwanted input data, crash faults or network problems. In of our earlier works [4] we defined the main requirements of dynamic workflow execution systems as: the ability to react to or to handle unforeseen scenarios raised during the workflow enactment phase, to adapt to new situations, to change the abstract or concrete workflow model or to give faster execution and higher level performance according to the actual environmental conditions and intermediary results. In our other work [2] we have defined the three main areas of dynamism which are optimization of the workflow execution according some criteria, user-steering (user or administrator interaction during execution) [3] and fault tolerance behavior. In this work we investigated fault tolerance behavior.

Fault tolerance is the ability of a system to perform its functions even in the presence of a failure. There are two main groups of failures that could arise during enactment. The first group includes the crash faults or fail-stop faults which may come with faulty system components that result in complete data loss. The other group consists of byzantine faults which result the system components to behave unpredictably and maliciously. Byzantine failures can occur, e.g., due to software bugs, (transitional or permanent) hardware malfunction, or malicious attack. In our work we consider only crash faults where the complete state of the actual task and environment must be restored.

Fault tolerance policy can be reactive and proactive. While the aim of proactive techniques is to avoid situations caused by failures by predicting them and taking the necessary actions, reactive fault tolerance policies reduce the effect of failures on application execution when the failure effectively occurs. There are several solutions in the literature for fault tolerant behavior and other complementary methods in its connected fields [1].

To achieve fault tolerant behavior the most widely adopted methods are:

- Checking and monitoring which is a key factor in failure detection.
- Checkpointing and resubmission where the system state is captured and saved based on predefined parameters (i.e.: time interval, number of instructions) and when the system undergoes some kind of failure the last consistent state is restored and computation is restarted from that point on.
- Replication where critical system components are duplicated using additional hardware or with scientific workflows critical tasks are replicated and executed on more than one processor. We can differentiate active and passive replication. Passive replication means that only one primary processor is invoked in the execution of a task and in the case of a failure the backup ones take over the task processing. In the active form all the replicas are executed at the same time and in the case of a failure the replica can continue the execution without intervention. The idea behind task replication is that replication size r can tolerate r-1 faults while keeping the impact on the execution time minimal. We call r the replication size. While this technique is useful for time-

critical tasks its downsides lies in the large resource consumption, so our attention is focused on mainly checkpointing methods in this work.

We propose a new checkpointing algorithm, that monitors the resources and dynamically adjust the checkpointing interval based on the task's dependency Factor and the already occurred failures.

In the proposed algorithm there is no need to take global checkpoints of the workflow, and therefore there is no need of synchronization of any kind (based on time or based on communication channels between the processors). The parallel threads of the workflow may run on different type of computing infrastructures (for example on virtual machines of different cloud providers) therefore it would be a complex challenge to solve the synchronization between them. The new proposal is based on provenance support. Provenance carries information about the source, origin and processes that are involved in producing data. The main target of collecting provenance support is to provide reusability and reproducibility among a scientist's community but provenance support can provide users, scientists, workflow developers and administrators with wide range of services. For example provenance can also support fault tolerant behavior by providing statistics about historical executions, such as failure rates or distribution and by storing the intermediary results generated by each tasks of the workflow.

Our paper is organized as follows. After the introduction we give a brief overview about existing checkpointing methods, and in chapter III we introduce our checkpointing method. After a brief conclusion the bibliography closes our work.

II. RELATED WORK

Concerning dynamic workflow execution fault tolerance is a very important issue and checkpointing is the most widely used methods to achieve fault tolerant behavior. We investigated the different algorithms in order to give a brief overview of them.

According to the level where the checkpointing occurs we differentiate application level checkpointing, library level checkpointing and system level checkpointing methods. Application level checkpointing means that the application itself contains the checkpointing code. The main advantage of this solution lies in the fact, that it does not depend on auxiliary components however it requires a significant programming effort to be implemented while library level checkpointing is transparent for the programmer. Library level solution requires a special library linked to the application that can perform the checkpoint and restart procedure. System level solution can be implemented by a dedicated service layer that hides the implementation details from the application developers but still give the opportunity to specify and apply the desired level of fault tolerance [5].

From another perspective we can differentiate coordinated and uncoordinated methods. With Coordinated checkpointing (synchronous) the processes will synchronize to take checkpoints in a manner to ensure that the resulting global state is consistent. This solution is considered to be domino-effect free. With uncoordinated checkpointing (independent) the checkpoints at each process are taken independently without any synchronization among the processes. Because of the absence of synchronization there is no guarantee that a set of local checkpoints result in having a consistent set of checkpoints. It may lead to the initial state due to domino-effect.

The frequency of the checkpointing interval also imposes many opportunities in checkpointing algorithms. Young in [6] has already in 1974 defined his formula for the optimum periodic checkpoint interval which is based on the checkpointing cost and the mean time between failures (MTBF) with the assumption that failure intervals follow an exponential distribution.
Sheng et al in [7] has also derived a formula to compute the optimal number of checkpoints for jobs executed in the cloud. His formula is generic in a sense that it does not use any assumption on the failure probability distribution.

The drawback of these solutions lies in the fact that the checkpointing cost can change during the execution if the memory footprint of the job changes, or depending on network reachability issues or when the failure distribution changes. Thus static intervals may not lead to the optimal solution. By dynamically assigning checkpoint frequency we can eliminate unnecessary checkpoints or where the danger of a failure is considered to be severe it can introduce extra state savings.

Meroufel and Belalem [8] proposed an adaptive time-based coordinated checkpointing technique without clock synchronization on cloud infrastructure. Between the different VMs jobs can communicate with each other through a message passing interface. One VM is selected as initiator and based on timing it estimates the possible time interval where orphan and transit messages can be created. There are several solutions to deal with orphan and transit messages, but most of them solve the problem by blocking the communication between the jobs during this time interval. However blocking the communication increases the response time and thus the total execution time of the workflow which can lead to SLA violation. In Meroufel's work they avoid blocking the communication by piggybacking the messages with some extra data so during the estimated time intervals it can be decided when to take checkpoint or logging the messages can resolve the transit messages problem.

The initiator selection is also investigated in Meroufel and Belalem's another work [9] and they found that the impact of initiator choice is significant in term of performance. They also propose a simple and efficient strategy to select the best initiator.

Sheng at al also propose a new adaptive algorithm to optimize the impact of checkpointing regarding the checkpointing or restarting costs in [7].
Theresa et al in their work [10] propose two dynamic checkpoint strategies: Last Failure time based Checkpoint Adaptation (LFCA) and Mean Failure time based Checkpoint Adaptation (MFCA) which takes into account the stability of the system and the probability of failure concerning the individual resources.

To the best of our knowledge there does not exist an adaptive algorithm that takes into account the effect of the failure occurring on a task on the execution time of the whole workflow.

III. PROPOSED MODEL

A. Environmental Conditions

- the system resources are monitored and failures can be detected as soon as possible, therefore the fault detection time (t_f) does not add high latency to the overall makespan of the workflow execution. (t_f=0)
- Task A_j cannot be started before it has received the output from all its predecessors and the results of Task A_i can only be sent to its successor tasks after the task has been finished.
- There is an ideal case so that tasks can be executed as soon as the results from the predecessor tasks are ready and available. The system resources are inexhaustible in number, so the system can allocate the required number of resources to execute all the tasks parallel that are independent from each other.
- The system supports the collection of provenance data, therefore the intermediary results generated by the individual tasks are saved and in case of failure they can be easily retrieved. Thus there is no need to take checkpoints at the end of the tasks, and there is no need to take global checkpoints, since in the case of failure only the effected task should be rolled back.
- The system also support provenance data about failure statistics, so the probability of failures for a certain period of time is available for each resource component taking into account the aging factor as well.

B. General notation

Workflows in general and also scientific workflows are represented as directed acyclic graphs (DAG) $W = (N, E)$, where the nodes (N) represent the computational tasks or jobs and the directed edges (E) represent the dependency between them. The dependency can be data dependency, and control dependency. In the former case the output of a Task A_i gives the input of a Task A_j if there exists an $A_iA_j \in E$ directed edge in the workflow. The control dependency describes the precedence of the tasks: If an A_iA_j directed edge exists in the workflow, then the execution of task A_i must precede the execution of task A_j in time. Here follows a list of the most frequently used symbols in this paper:

T_c the optimal checkpointing interval,
C is the checkpointing cost
X is optimal number of checkpoints during the execution of a task
$T(A_i)$ is the execution time of task A_i
T_f is the mean time between failures (MTBF)
$E(Y)$ is the expected number of failures during the execution of a task
t_l is the loading time, to restore the last saved checkpoint state,
t_f is the fault detection time, the time to detect the failure
A_0 is the first or entry task of the workflow.

C. Algorithm

The primary goal of this algorithm is to minimize the effect of the checkpointing overhead (time, resource) while still keeping to the soft-deadline of the workflow and the performance level at a satisfactory level.

Young [6] and Sheng [7] have already proved that the optimal checkpointing interval can be computed by (1) and (2). In both cases the fault detection time is considered t_f=0. Equation (2) is a more general form of Young's formula, because it does not depend on any probability distribution, unlike Young's (1) formula which needs to assume that failure intervals follow an exponential distribution.

$$T_c = \sqrt{2CT_f} \tag{1}$$

$$X = \sqrt{\frac{T(A_i) \cdot E(Y)}{2 \cdot C}} \tag{2}$$

In our proposed algorithm we use (2) as a starting point to compute the checkpointing intervals. The main idea is that there is a dependency factor between the tasks. Namely if a failure occurs during the execution of a task A_i then it not only has a local effect on the task itself, but has a global effect also on the whole workflow concerning the execution time. Since if a failure occurs during the execution of task A_i then it has to be re-executed from the last checkpoint. It means the execution of the task ends later, so it may cause all of the successor tasks of task A_i to wait for the results. This can result the whole workflow execution to last longer.

We define local cost (3) of a failure on task A_i which is the execution time overhead of a task when during execution one failure occurs.

$$C_{local} = \frac{\overline{ET(A_i)} + \frac{T_c}{2} + t_l}{ET(A_i)} \quad (3)$$

We define global failure cost (4) of a task A_i: which is the execution time overhead of the whole workflow, when one failure occurs during Task A_i

$$C_{global} = \frac{\frac{T_c}{2} + t_l + rank(A_i) + brank(A_i)}{rank(A_0)} \quad (4)$$

where (5) and (6) are classic formulas that are used in tasks scheduling [12] [11]. Basically the rank() function is the critical path from task A_i to the last task, and can be computed recursively backward from the last task. The brank() value is the backward rank value from task A_i backward to the entry task A_0. It is the longest distance from the entry task to task A_i excluding the computation cost of the task itself.

$$rank(A_i) = ET(A_i) + \max_{A_j \in succ(A_j)} rank(A_j) \quad (5)$$

$$brank(A_i) = \max_{A_j \in pred(A_i)} \{brank(A_j) + ET(A_j)\} \quad (6)$$

It can also be calculated recursively downward from task A_0.

Before executing a task A_i, C_{global} can be evaluated. If $C_{global} < 1$ then one failure occurring during execution of task A_i does not add extra latency to the total execution time of the workflow so in that case T_c can be increased until $C_{global} = 1$. From that we get:

$$T_c = 2 \cdot (rank(A_0) - t_l - rank(A_i) - brank(A_i)) \quad (7)$$

Based on the global failure cost and using the assumption that when faults occur during a checkpoint interval (between two consecutive checkpoints) the expected average time loss is half of the checkpointing interval. This is the average time to re-execute the task from the latest checkpoint.

If there occurred already failures during the actual task, or during the predecessors of the actual task, then it may be possible, that default checkpointing intervals cannot be increased, because the cumulative overhead of the occurred faults can negatively affect the whole workflow execution time.

To take earlier faults into account we need information about the realistic execution time of the tasks. With provenance support the real execution time can be obtained and it can be substituted in (7) in place of the brank value. The $C_{global} < 1$ inequality gives the answer whether the checkpointing interval can be increased without lengthening the whole workflow execution time.

IV. CONLUSION

In this paper we investigated the different checkpointing techniques, which are the most widely used proactive fault tolerant methods. We gave a brief overview of the different checkpointing perspectives with special attention on those solutions where the checkpointing intervals are periodic or it changes adaptively during execution. We proposed a provenance based dynamic algorithm that takes into account the global cost of a failure occurring during the execution of a task, and depending on this value can adjust the checkpointing interval in order to eliminate blind checkpoints while still maintaining soft deadlines. In our future work we would like to deeper investigate the various fault tolerant methods for crash faults or even for byzantine faults.

Operating System Impact on CPU and RAM Utilisation when Introducing XML Security

Sasko Ristov and Marjan Gusev
University Ss. Cyril and Methodius, Faculty of Computer Science and Engineering,
1000 Skopje, Macedonia
{sashko.ristov, marjan.gushev}@finki.ukim.mk

***Abstract*—Introducing XML security to a web service increases the message size, which impacts the XML parsing of the greater message and complicates its processing due to complex cryptographic operations. Both tasks impact the web server's CPU and RAM utilisation.**

The performance impact is even more expressed when the number of concurrent messages is rapidly increased. In this paper we analyze the impact of securing a web service message with XML Signature and XML Encryption over the hardware performance, varying the message size and the number of concurrent messages.

The results show that web server that is installed on Linux utilizes the CPU less than the same web server that is installed on Windows. The situation for RAM memory is opposite, that is, the web server installed on Windows operating system occupies less RAM memory.

***Index Terms*—*CPU*; *Operating systems*; *Performance*; *RAM*; *Web service*.**

I. Introduction

Web services are the third generation of the web, after the static web sites and dynamic web applications [1]. They are widely used in today's web applications because they are platform independent and can be deployed on various web servers and operating systems.

The performance of web services is an important factor, both for customers and providers, by different aspects. The former would like to receive the response in a tolerable time, regardless of the period of a day. The latter expect smaller hardware utilisation to predict the capacity of web servers and reduce the power consumption for the equipment and cooling [2]. The important issue for administrators is to predict the web service performance when it is targeted with a particular load (number of messages, their size, type, etc) and hosted on a web server with some amount of hardware resources (CPU, RAM, HDD, I/O).

Web services should be secured if they use sensitive data. Secure Socket Layer / Transport Layer Security (SSL / TLS) can provide a point-to-point security only, but it cannot provide an end-to-end web service's security [3], which can be achieved by WS-Security, but considerably slower [4]. Creating SOAP message and implementing XML Signature increases the message with a constant size, regardless of the message size [5], while introducing XML Encryption additionally linearly increases the message size [6].

Although web services are platform independent, their performance varies on the platform. For example, Ristov and Gusev [7] reported that web services deployed on Linux provide better response time rather than those hosted on Windows, if they are loaded with small number of small concurrent signed or unsigned messages. For all other cases, Windows platform is better.

In this paper we extend this research in order to examine the impact of introducing XML security on web server's hardware resources, hosted with various platforms, i.e. Linux and Windows. Series of experiments are conducted by varying the parameters: message size M and number of concurrent messages N.

The paper is organised in several sections that are described below. Related work in the area of web service performance is presented in Section II. Section III describes the testing methodology for all test cases of series of experiments. The results of the experiments for particular hardware parameter are presented and analysed in Section IV. In Section V we discuss the results, and provide additional analysis of the results for the particular operating system. Finally, the conclusion and plan for future work are given in Section VI.

II. Related work

Many authors propose various techniques to improve the web service performance after detailed analysis. For example, Wichaiwong and Jaruskulchai [8] proposed to use the FTP instead of HTTP protocol to transfer the SOAP messages, thus reducing the data transfer time. Eckert et al. [9] conduct a more comprehensive analysis. They maximized the throughput and minimized the delay by using several worst-case workflow performance optimizations. The SMP (SOAP multicast protocol) reduces the network traffic by grouping the similar SOAP messages into a compact SMP message [10]. Yue-min [11] predicts and maintains the fading performance of the web servers by using a technique based on chaotic theory. Filtering XML data and forwarding to the endpoint web servers such that each web server handles a specific type of XMLs improve the overall performance [12]. Web services composition is optimized by combination of services by Yu et al. [13].

Performance in virtual environment is also analysed. Ristov et al. [14] reported that virtualised environment decreases the web service performance of 30% compared to the same bare-metal compatriot (using the same CPU and memory hardware resources).

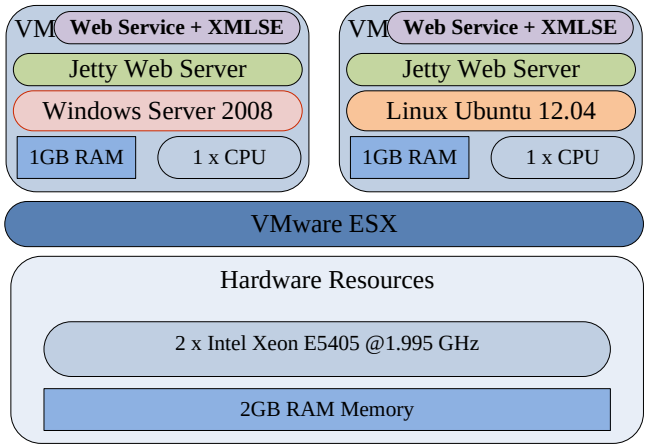

Fig. 1. Virtualised testing environment

Implementing cryptography seriously affect the web service performance. The processor increases its activity and the memory leaks [15]. Chen et al. [16] reported that web service security policies and message sizes impacts a lot on web service performances. Rodrigues et al. [17] achieve a trade-off between security and performance. AES 192 suffers less performance degradation when the number of concurrent messages increases [18]. Tang et al. [19] used the fact that there is a small difference between latencies using Username and X.509, even when the message size grows, and thus they used X.509 keys for XML Signature and XML Encryption. Several optimisations of various WS-Security stages were proposed by Engelen and Zhang [20], [21].

Less analyses were realised on the operating system and hardware impact, which is the goal of this paper. Tan et al. [22] proposed several improvements of hardware bottleneck of different cryptographic algorithms on network processors.

III. Methodology

A series of experiments are conducted to determine the operating systems impact on web server's hardware resources in virtualised environment. This section describes the testing methodology for conducting the experiments.

A. Testing environment

Two experiments with several test cases are realised on a client-server architecture deployed on the same hardware infrastructure and runtime environment, but different operating systems. The environment is virtualised, that is, two virtual machines are instantiated with VMware ESX 4.0, one with Windows Server 2008 and the other with Ubuntu 12.04, as presented in Fig. 1. Both virtual machines are allocated with the same amount of hardware resources, 1GB RAM and 1 CPU Intel Xeon E5405 @1.995 GHz.

Eclipse Jetty [23] is deployed on both virtual machines and test loads are created with SOAPUI [24]. A web service, which receives two strings and returns its concatenation is hosted in web servers in both virtual machines, is used as a demo application. XML Signature and XML Encryption are introduced in web service. That is, the accepted message is encrypted and signed, which the web server decrypts and verifies. Afterwards, the web service generates the concatenation of the input strings into SOAP message, then signs and encrypts it.

Only one virtual machine is active at a time in order to avoid impact on the other [25]. Also, the client and server are in the same LAN to avoid network impact [26].

B. Test cases and experiments

Each test case consists of sending N concurrent messages with M bytes each in a period of 60 seconds. An experiment consists of series of test cases in order to examine the impacts of increasing the parameter M for constant N, and increasing the parameter N for constant M. The parameter M is defined in kilobytes of the original (regular) SOAP messages and has values $M \in \{0.2, 2, 10, 20, 60, 70, 100, 1000\}$, while $N \in \{1, 10, 50, 100, 150, 200\}$. In this range the web server works in normal mode and does not reply any error message.

C. Test data

Average *CPU Utilisations* CPU_L and CPU_W are measured in each test case for both operating systems Linux and Windows in percents (0-100%), where indexes L and W are used for corresponding operating systems - Linux and Windows. Similarly, average *RAM Utilisations* RAM_L and RAM_W are measured in Megabytes.

In order to compare both operating systems for both parameters CPU and RAM, *Relative CPU Utilisation* R_{CPU} and *Relative RAM Utilisation* R_{RAM} are calculated and analysed, which are defined in (1) and (2), correspondingly.

$$R_{CPU} = \frac{CPU_L}{CPU_W} \tag{1}$$

$$R_{RAM} = \frac{RAM_L}{RAM_W} \tag{2}$$

IV. The Results

This section presents a comparative analysis of how the introduction of both XML Signature and XML Encryption (XMLSE) impacts the hardware resources (RAM and CPU) as a function of parameters M and N, on both operating systems.

A. CPU Utilisation Impact

This section elaborates the impact of XMLSE on CPU utilisations CPU_L and CPU_W on a particular operating system for different loads. It also analyses the correlation of different operating system for a constant load.

1) CPU Utilisation on Linux CPU_L: Fig. 2 presents the CPU utilisation on Linux for various values of parameters M and N. CPU_L is almost horizontal for constant N, regardless of the values of parameter M, which means that it does not depend on the message size.

On the other side, two regions are observed for parameter N. Increasing the number of concurrent messages up to $N = 50$ also increases the CPU utilisation linearly up to $CPU_L = 75\%$. After this, the CPU utilisation saturates up to $CPU_L = 80\%$, for both parameters M and N.

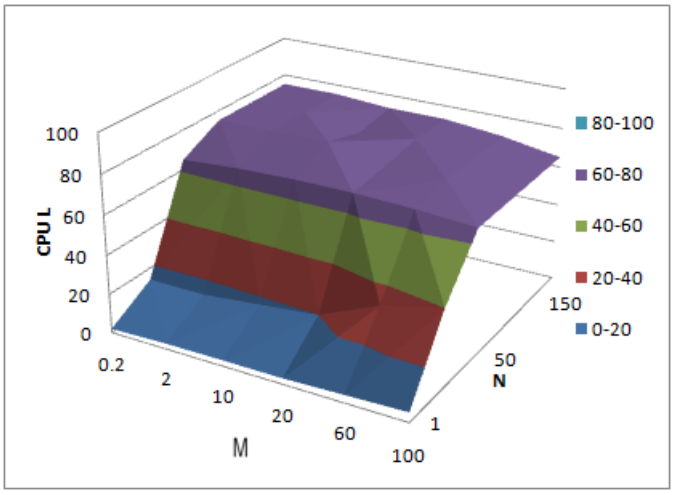

Fig. 2. CPU Utilisation on Linux as a function of both parameters M and N

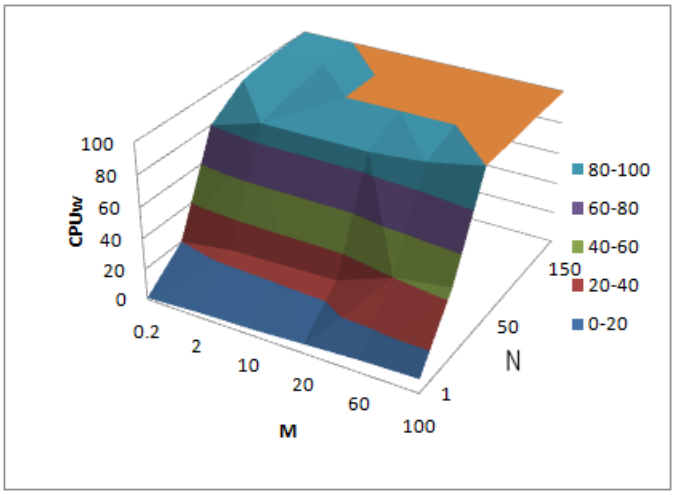

Fig. 3. CPU Utilisation on Windows as a function of both parameters M and N

2) CPU Utilisation on Windows CPU_W: The results of the experiments for CPU utilisation on Windows operating system for various values of parameters M and N are presented in Fig. 3. The CPU_W is also almost horizontal for constant N as CPU_L, regardless of the values of parameter M, i.e. it does not depend on the message size.

The similar linearly increasing region of CPU Utilisation saturation is observed for constant value of M, and changing the parameter N up to $N = 50$. Afterwards, the CPU saturates also, but in this experiment on value $CPU_W = 100\%$ for both parameters M and N.

3) Relative CPU Utilisation R_{CPU}: Comparing figures 2 and 3, one can conclude that the CPU utilisation behaves similarly on both platforms. Also, the impact of both parameters M and N is similar on both operating systems. However, CPU_W's curve is steeper than Linux's for smaller N, and it is higher than Linux's in saturation region.

Better analysis offers the relative CPU utilisation R_{CPU}, which is presented in Fig. 4. The curve is almost horizontal for each value of the parameters M and N.

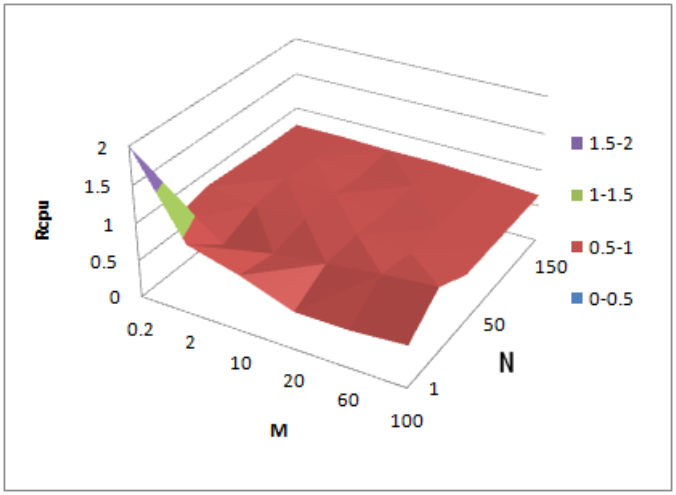

Fig. 4. Relative CPU Utilisation as a function of both parameters M and N

We observe that $0.5 < R_{CPU} < 1$ for almost all test cases, which means that Linux provides smaller CPU utilisation than Windows. Only for small values of parameters M and N, $1 < R_{CPU} < 2$, i.e. Windows provides up to two times smaller CPU utilisation than Linux. But the CPU utilisation in this region is minor and does not impact on the overall web server's performance.

B. RAM Utilisation Impact

Similar to previous subsection, this section elaborates the impact of XMLSE on RAM utilisation for both operating systems RAM_L and RAM_W, and relative utilisation R_{RAM}, for various load.

1) RAM Utilisation on Linux CPU_L: Fig. 5 presents the utilisation of the web server's RAM memory installed with Linux operating system for various values of parameters M and N. The behavior of the RAM_L curve is totally different than the CPU_L's.

RAM_L is almost horizontal (constant) only when the constant parameter (either M or N) is small, but it increases exponentially when the constant parameter (either M or N) is increased. For example, RAM_L increases from 781 up to 1010 for maximum value of constant $N = 150$ and M increases. Also, RAM_L increases from 738 up to 1010 for maximum value of constant $M = 100$ and N increases.

2) RAM Utilisation on Windows CPU_W: The results of the experiments for RAM utilisation on Windows operating system for various values of parameters M and N are presented in Fig. 6. The impact of RAM utilisation is also totally different than the CPU utilisation on the same operating system, but is similar as the RAM utilisation on Linux operating system.

RAM_W is almost horizontal (constant) only when the constant parameter N is small. It increases also as the RAM_L, but starting from lower value and slower. For example, RAM_W increases from 740 up to 930 for maximum value of constant

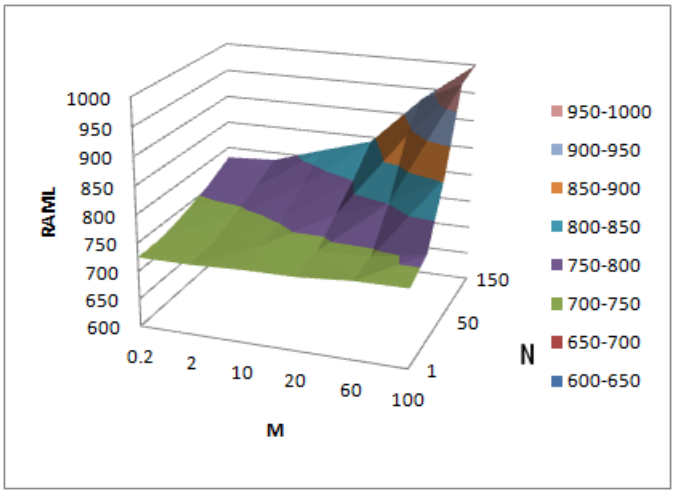

Fig. 5. RAM Utilisation on Linux as a function of both parameters M and N

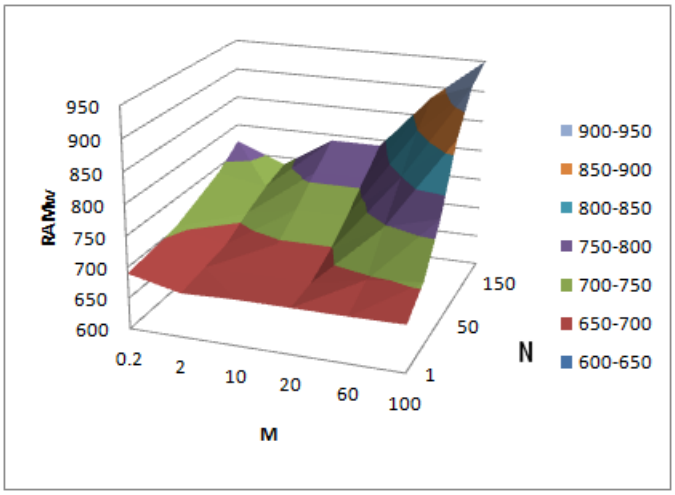

Fig. 6. RAM Utilisation on Windows as a function of both parameters M and N

$N = 150$ and M increases. Also, RAM_W increases from 675 up to 930 for maximum value of constant $M = 100$ and N increases.

3) Relative RAM Utilisation R_{RAM}: By comparing figures 5 and 6, one can conclude that both RAM utilisations RAM_L and RAM_W behave similarly. However, RAM_W's curve starts with lower values for smaller parameters M and N than Linux's and it also finishes with lower values for the greatest M and N. That is, Windows operating system utilises smaller amount of RAM memory than Linux.

More detailed analysis offers the relative RAM utilisation R_{RAM}, which is presented in Fig. 7. We observe that $R_{RAM} > 1$ for all test cases, which leads to the conclusion that Linux operating system utilises more RAM memory than Windows. Even more, this is more emphasized more in the region for the greatest values of parameters M and N (the greates load), where the relative RAM utilisation R_{RAM} has the values in the range of $1.1 < R_{RAM} < 1.2$.

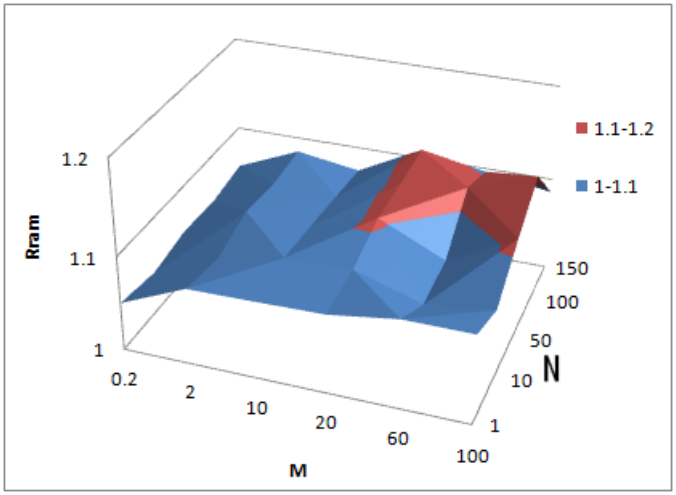

Fig. 7. Relative RAM Utilisation as a function of both parameters M and N

V. Discussion

Previous section presented the results and analysis of the impact of various operating systems (Windows and Linux) on the specific hardware resource: CPU and RAM. The results show that Linux operating system utilises CPU less than Windows, while the Windows operating system utilises less RAM memory than Linux. This is more emphasized for greater load (greater message size and number of concurrent messages).

In this section, we extend the analysis in other direction, that is, to analyse how a specific operating system impacts on both hardware resources CPU and RAM memory, as a function of both parameters M and N. By observing figures 2 and 5, one can conclude that parameters M and N impact different to CPU and RAM on Linux operating system. If a CPU utilisation depends mostly on the number of concurrent messages N, where it saturates after a certain value of N, the RAM utilisation depends on both parameters M and N. This means that CPU suffers more by the number of concurrent messages. This could open other research direction towards grouping several messages into one greater message, that should improve the overall performance.

Very similar conclusion is for Windows operating system, with the opposite behavior of the Linux operating system on RAM and CPU.

VI. Conclusion and Future Work

Several parameters impact the web service performance reported as a response time: the computation that the web service is performing [27]; the CPU power and cores; the number of concurrent messages, the message size and the introduced security [6], even of the resource orchestration in the cloud virtual environment [28] and the platform (operating systems) [7]. This paper analysed the impact of the platform over the other web service performance parameters, i.e. CPU

and RAM utilisation, for two most common web servers' operating systems: Windows and Linux.

The experiments lead to conclusion that web server with Windows operating system should use more powerful CPU than the one installed with Linux, if XMLSE is implemented on a web service, in order to reduce the CPU utilisation, and thus the power consumption. However, this conclusion does not implicitly mean that the web service response time is better if the same web service is hosted on Windows operating system [7].

The conclusion for RAM memory utilisation is opposite. That is, a web server with Linux operating system should have more RAM memory than the one installed with Windwos and the XMLSE is implemented on a web service, in order to improve the overall performance. The gap in the utilised RAM memory is even more emphasized for greater load, regardless of the load type: either the number of concurrent messages or the message size.

The CPU utilisation directly impacts the server's power consumption, which directly impacts to the cost for cooling in the data centers. The results of this paper can be used in consolidating of virtual machines on a specific physical servers to reduce the total costs and improve the performance in the modern data center.

We will continue by analysing the impact on the performance of other types of web services and servers (CPUs, RAM) will be measured in order to generalise the conclusion.

Abstract - The speed of the computers work depends directly on the number of processor cores used in the parallel execution of the programs. But, there are some other parameters that have impact on the computer speed, like maximum allowed number of threads, size of cache memory inside the processors and its organization. To determine the impact of each of these parameters, we have experimented with different types of computers, measuring the speed of their work during solving a certain problem. To compare impacts of particular parameters on the computers speed, the results we have presented graphically, through joint diagrams for each parameter.

I. INTRODUCTION

Currently, on the market there are different types of computers with multi-core processors. Use of computers with these features has an important impact on their parallel work. Users have difficulties to distinguish which is the best solution for them, knowing clock speed of processor, or the information for the type of processor, like Core i3, Core i5 or Core i7 (in this case often it is assumed that we have to do with the processor that have 3, 5 or 7 cores) [5].

Programs that are written to be executed on a single processor or in a processor core without having the possibility to execute more instructions immediately, are known as serial programs, or sequential programs [1]. On the other side, programs that are written for simultaneous execution in more cores, or more logical processor, are known as parallel programs [2][13]. Parallel execution of programs in a computer is based on the parallel work of processor cores. But, using the Intel's technology that is known as Hyper-Threading it is possible for each core to work as two logical processor [5], respectively it is possible for the processor with 4 cores to work parallel with 8 logical processors.

The parallel work of microprocessors has a great influence on the calculation speed of computers which is important for the massive use of computers in communication through the Internet, also searching on the Web, in the processing of various biometric information, monitoring the climate changes in real time, scientific researches, in complicated three-dimensional games on the computer etc.

Measuring the performance of computers during parallel execution of programs is not an easy task, because in the speed of their work, except clock speed, indicates cores number, model, the support of Hyper-Threading technology, organization of cache memory in separated levels [7] etc.

II. EXPERIMENTAL RESULTS

In order to get relevant conclusions, initially we have experimented with numerous computers that have different processor types of Intel producer. In order to measure the speed of the computer work during experimentation we have used an ordinary algorithm for multiplication of two square matrices with different dimensions, from 100 x 100 to 1000 x 1000 (10 cases). For parallelism of loops are used methods of programming language C# [3][10][12], which are included in Microsoft Visual Studio 2010 package.

We have started the experimentation with computers that are built using previous processor 2 Duo, which have cache memory only on the level L2, then with Core i3, Core i5 and Core i7 processors (short i3, i5, i7) [16], whose memory are on the levels L2 and L3 and processor used for servers, such as Xeon type [15]. Finally from all the computers that are used for experimentation, we have singled out only the results of 15 computers with Intel processor, whose characteristics are given in TABLE I, without differentiating as desktop or notebook computer.

TABLE I. LIST OF USED COMPUTERS

Computer	Model	Clockspeed (GHz)	L2 (KB)	L3 (KB)	Cores	Logical processors
C1	i5	2.90	1024	6144	4	4
C2	i5	3.10	1024	6144	4	4
C3	E3	3.10	1024	8192	4	4
C4	i5	1.70	256	3072	2	4
C5	i3	2.40	256	3072	2	4
C6	i5	3.33	512	4096	2	4
C7	i7	2.20	256	6144	4	8
C8	i3	3.30	512	3072	2	4
C9	2 Duo	2.93	3072	0	2	2
C10	i5	1.60	256	3072	2	4
C11	i7	3.60	1024	8192	4	8
C12	2 Duo	2.66	3072	0	2	2
C13	i5	2.50	256	3072	2	4
C14	i7	2.00	256	4096	2	4
C15	i3	2.40	256	3072	2	4

From the given table we can see that the model of the processor does not automatically determines the number of cores, neither the number of logical processors. Thus,

for example, computer C7 belongs to model i7 and and contains 4 cores and 8 logical processors [8]. But, his memories L2 and L3 are smaller, e.g. than at the model i5 processor of computer C2. On the other side, the computer C14 has model i7 processor, but with two cores and four logical processor [9]. At the same time, processors of earlier generation 2 Duo, which are included in the computers C9 and C12 have relatively large cache memory on the level L2, but don't have the level L3 memory and in parallel work they have shown lower speed than computers with processors of next generation.

A. *Influence of number of cores*

To have a clearer overview in how much does the parallel execution of programs indicates, initially we have experimented with serial execution testing program for matrices multiplication, by activating only one core of the processor. Then, we have measured the execution time of a parallel program when all cores are active, respectively all logical processors. Finally, using the results of measurements, we found the execution speedup and the level of parallelism of the program. Having no chance to present all the results obtained, in the following section we have given only the graphically results for four computers from the list given in TABLE I, who have clock speed approximately the same level (above 3 GHz).

1. *Serial execution time*

Results of serial execution time (Ts) for four specific computers are shown in the diagram given in Fig.1.

The diagram shows that computer C11 is faster, which uses a processor that is ranked in the group of processors that are actually fastest [8], the i7 model, with maximum clock speed of 3.60 GHz, and with 4 cores (short 4-c) and 8 logical processors (short 8-lp). Computer C2, whether it is the i5 model, has competitive speed with computer C11. This is seen in the daily ranking of Intel processors [9], where he has high position in the list. Simultaneously, the computer C6 with i5 processor is slower than computer C8 who have i3 processor. From the given diagram is clear that the curves are ranked based on the clock speed of processors.

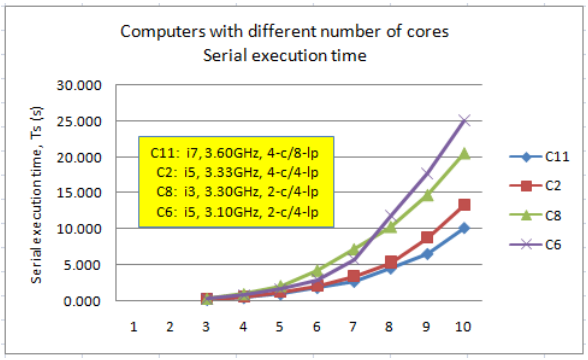

Figure 1. Serial execution time of the program

2. *Parallel execution time*

During the parallel execution of the testing program in separate computers, parallel execution time (Tp) have big difference from serial execution time (Ts), which can be seen from the diagram given in Fig.2.

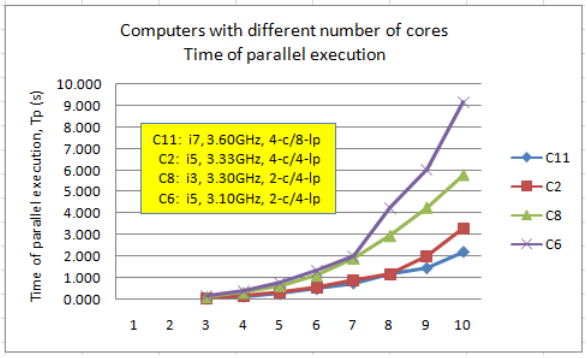

Figure 2. Parallel execution time of testing program

Here it is seen that computer C11 has higher speed, and computer C6 is slower, which is consistent with their speed in serial work. But, in this case execution times are significantly shorter. Thus, for example, computer C11 multiplication of matrices with dimensions 1000 x 1000 performs for more than 2 seconds, and during serial execution is needed more than 10 seconds.

Parallel execution time in computers C11 and C2 do not differ much between them, despite being different models of processors (i7 and i5). During the parallel work of computer C11 are 8 logical processor active, and in computer C2 - 4 logical processors. On the other side, as it is shown in the diagram, with increased dimensions of matrices, the speed of the computer C6 drops dramatically, despite having the i5 processor and its clock speed of 3.10 GHz. From what was said and by experimentation that we had with other computers, we can conclude that the speed of parallel execution of the program can't be determined based on the model of the processor (i3, i5 or i7), or number of cores, because it is also influenced by the clock speed of processor.

3. *Execution speedup*

If it's known the serial execution time (Ts) and parallel execution time (Tp) of the testing program, can be calculated execution speedup (S) through the expression [6]

$$S = \frac{Ts}{Tp} \qquad (1)$$

Using the experimental results mentioned above, execution speedup of 4 computers taken into consideration, it will look like is given in Fig. 3.

Even the execution speedup maintain the sequence of curves for specific computers as well as in diagrams for execution time. But curves have variations, with increases and decreases. At the end of their, obvious that only the computer C11 continues accelerating growth (finally reaches the value of 4.5 times), while the three other computers values stay the same, or decrease. As it is seen from the diagram given, and even from experimentation that we had with other computers too, the execution speedup is greater if the number of operations that are executed (e.g. multiplication of matrices with large dimensions) increases up to a certain thresholds. During

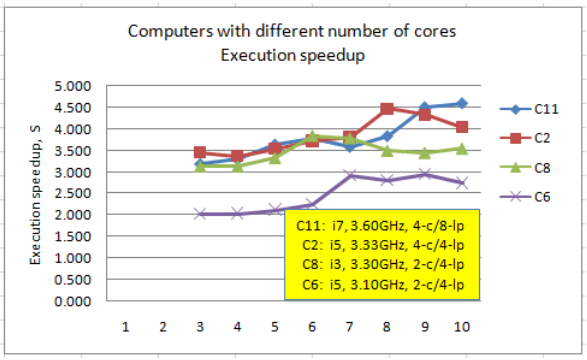

Figure 3. Execution speedup of the execution process

this there is no continual growth execution speedup, which shows that parallelism is not perfect.

B. *The impact of cache*

In the speed of the computer work it is important even the size of the cache memory. Models of the last generations of processors contain cache memory on the three levels. Initially we have experimented with computers of prior generations, like 2 Duo processor cores. In TABLE I we've included computers C9 and C12, whose processors have only memory L2 level and we have noticed that compared with other computers in parallel work are extremely slow, despite having relatively higher clock speeds. Then we experimented with other 6 computers also included in the TABLE I and the results obtained for them are presented in the diagram given in Fig. 4.

From the given diagram it is shown that computer C7 with i7 processor is faster and has large cache memory on the third level whether that it has the lowest clock speed. Computers C2 and C1 have approximately the same speed, with processor of model i5, clock speed much greater than computer C7 and have a maximum cache memory at two levels. In the overall ranking of

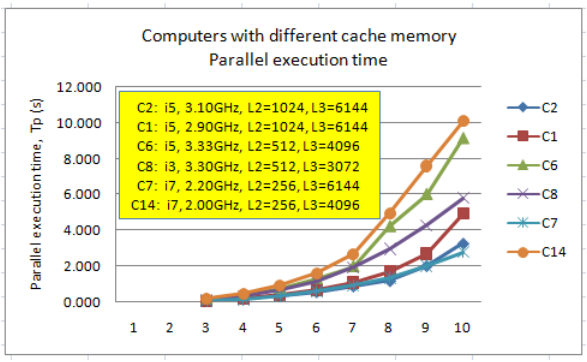

Figure 4. Parallel execution time of computers with processors that have different cache memory

processors, processor of computer C1 have higher rank than the computer C2 [9].

Speed of computers C8 and C6, despite that they have processors i3 and i5, in their speed ranking have higher speed clock and cache memory size. The Computer C14, with i7 processor, have the highest execution time.

C. *The level of parallelism*

The maximum execution speedup of program can be determined by Amdahl's Law [4][6]

$$S = \frac{1}{(1-P)+\frac{P}{N}}. \qquad (2)$$

Here, N is the number of processors, and P represents the relative percentage of the program parallelism. Starting from the given Law, through mathematical operations can be derived expression for the calculation of the level of parallelism of a program:

$$P = \frac{N(S-1)}{S(N-1)}. \qquad (3)$$

Since in the measurement of execution speedup values are calculated using (1), and knowing the number of cores, i.e. the number of logical processors (N), the level of parallelism can be calculated through (3). Thus, for computers with i7 processor, the level of parallelism will appear as is given in Fig. 5.

From the diagram provided and experimentation that we have done with other computers, it is shown that the relative level of parallelism of the program execution is over 0.65 and just a bit under 1.00, which is directly linked with the speed of parallel execution of the program.

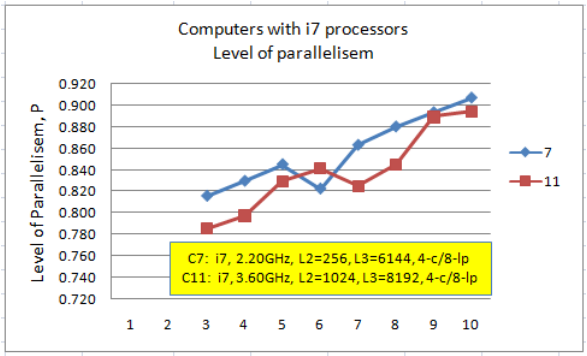

Figure 5. Parallel execution time of computers with processors that have different cache memory

D. *The maximum rate of parallelism*

During the parallel work of computer, the operating system determines the number of threads that are activated [10], or being allocated as needed certain number of threads to programs that run in parallel [11]. However, this can be done by the user too, by limiting the number of threads. If parallel execution relates only to a program, computer work can be optimized if the number of threads deal as far as the number of cores, i.e. the number of logical processors. To show this we experimented with several computers. But in Fig. 6 have just given diagram of parallel execution time of testing computer C4, limiting the number of threads between the values 4 and 20.

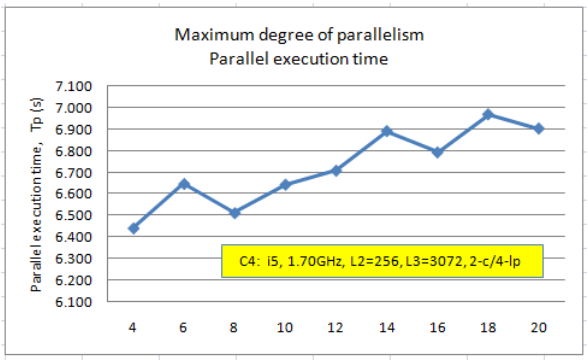

Figure 6. The rate of parallelism

The given diagram clearly shows the execution time is minimal if the maximum degree of parallelism obtained 4, which corresponds to the number of processor cores of the computer where the program is executed. Execution time increases if it's allowed a higher degree of parallelism, which is observed in most of the computers with which we experimented. From this we can conclude that the higher speed of parallel program execution is usually achieved when the maximum degree of parallelism is taken as far as the number of processor cores.

III. CONLUSION

The speed of the serial execution of the program for different computers mainly is indicated directly from the processor clock speed. But the speed of parallel execution of the program can't be determined based on the model of the processor, or the number of cores, because the cache memory size and clock speed have an important impact. Execution speedup of the computer, depends on the number of processor cores, as well as the level of parallelism of the program being executed. But the level of a parallelism of a program execution depends directly on the speed of the parallel work of the computer. In computers with which we experimented, level of parallelism is over 0.65 and just under 1. In order to optimize the parallel speed of computer we can manipulate with the allowed number of threads. Experimental results show that if a single program is executed, the speed of computer work is usually better if the number of threads deal as far as the number of processor cores.

***Abstract*—In this paper we explore if the applications with scaled user demands, such as the number of HTTP transactions achieve proportionally scaled performance. In addition, we explore which configuration is most convenient and achieves the best performance as a final conclusion about performances when applying the scaling of resources or demands. The experiments are performed for an e-Business solution hosted as a SaaS application on Windows Azure. Finding an optimal cloud infrastructure is not a trivial problem, since there are a lot of possibilities to organize multiple virtual machines in a cloud. The results obtained from the experiments show that the optimal configuration is based on use of a lower number of bigger VMs. In addition to this, the number of operations has an impact on the performance proportionally.**

***Keywords-e-Business solutions, SaaS, cloud computing, scaling, performance, Windows Azure, load testing, jMeter*.**

I. Introduction

Lately the cloud becomes one of the most popular platforms for hosting a solution. The power that the cloud represents in terms of the scalability and the pay-as-you-drink paying model attracts more and more companies to use it for hosting their software solutions.

The cloud is considered as industry platform when a solution becomes open to more than one company. The Software as a Service model (SaaS) went that far beyond the expectations of the clients development platforms. The offered web services or APIs of the SaaS applications make a system 'open, but not open' or 'closed, but not closed'. The SaaS model on the cloud represents an efficient way to use the hardware resources by multiple customers [1].

There are a few cloud computing platforms on the market, such as Amazon AWS, Google Cloud and Windows Azure. The latter provides neutral platform regarding the technologies, and at the same time allows the developers to extend the range of programming languages they use. On the other hand, Microsoft managed to implement their services and products in the Azure platform (Windows Live, Office Live, SQL Server, .NET and Sharepoint services, Visual studio) [1].

The cloud use has large impact on saving the budget that a company can afford for hosting a software solution. In this paper we aim to find out what is the right resource configuration from which a company can benefit? Does it depend on the software solution architecture and also the cloud infrastructure used?

To obtain relevant conclusions one has to provide measurement of a real-world user traffic and demo of a real application deployed on the cloud. We use an approach of performing load testing or stress testing. The test execution takes place in the cloud environment. The main reason why the cloud testing is important is to leverage the cloud resources for the price paid. It also helps in the domain of scalability of the solution in the cloud [2].

The model of the e-business system, which will be used in this research represents the processes by the means of a ticket management system. The benefit includes familiarity with monitoring an issue state (for example, an order was put through the system as new, than it was accepted and processed by the salesman, after which the invoicing and payment are being processed by the commercialist)[3].

We suppose that the system may behave differently under different conditions: when heavier operations are executed, the demand for more powerful server resources is requested, and other way around, when lighter operations are executed, the system will require lower server power. On top of this is the user load, considered to be in a range between small to medium (0-1000 users).

The cloud solutions are hosted on a set of virtual machines (VMs) and the main goal in this research is to find the optimal organization of VMs to host a real e-Business application, by analyzing the performance of various configurations for providing sufficient processing speed and quality of service. For this purpose we set the following hypotheses:

Hypothesis 1: An application that requires more processing activities is executed proportionally in more processing time.

Hypothesis 2: A system with a configuration that consists of multiple smaller VMs, such as A1 type VMs achieves better performance than a system with a configuration that uses the same total number of cores but uses large VMs, such as A3 type VMs.

II. Related work

The research conducted by Gushev et al. [4] shows the optimal cloud configuration in which a ticket management system reaches the best performance with small or medium user load. The configuration that enables the best performance in Microsoft Azure clouds is the one that uses several virtual machines with low number of cores. How Amazon EC2

environment behaved with an application that is data-intensive was examined by Schad et al. [5]. Similar parameters were considered as in the previous research: CPUs, memory speed, disk I/O, network bandwidth and they were examined on instances of different size (small, large etc). From this paper it is concluded that there is a large difference in the performance of different sized instances.

Another research conducted by Gusev et al. [6] suggests that the optimal configuration of compute intensive algorithms is better in configurations that use lower number of more powerful VMs, each with more cores (for example, at least 4 cores). This case is recommended when the company wants to scale the current cloud resources.

Xiong et al. [7] carried out a research that examines the percentile of the response time of a cloud solution. A solution that uses a queueing network model is used for the research purposes. Using the calculation of the probability distribution function of the response time (cumulative distribution functions), they developed a method to predict the service performance of the cloud computing software.

Iosup et al. [8] studied the behavior of a scientific software of the many-tasks nature. Their results showed that the cloud environments are still not as powerful as grids or parallel production infrastructures, but on the other hand, it gives great value for the money when the scientists need resources immediately and for short time.

Khanghahi et al. [9] summarized the way the cloud computing performance evaluation can be categorized. The evaluation can be based on the criteria and the characteristics of the solution or it can be based on simulation (that uses data centers locations, number of users etc. In our research, we will use simulation that is based on different cloud configuration and the number of users at specific moment.

III. Methodology

The demo application with an e-Business solution is hosted on the Microsoft Windows Azure cloud platform. There are two ways of consuming the platform resources: Windows Azure sites or virtual machines. The first approach is used for smaller web applications, with small user load and transactions, while the second is used for business applications or resources demanding applications. In this particular case, we consider the load of topmost thousand users, and our e-Business solution will be hosted on VMs.

For the research purposes, we will use three types of the standard set of VMs available on the Windows Azure, with capacities presented in Table I, which shows that the prices increase proportionally depending on the number of used CPU cores. It suggests that the price per core will be the same regardless of the VM. For example, renting one big (A3) VM will cost the same as four small (4 x A1) [10].

The architecture of the testing environment is presented in Fig. 1. The database of the system is hosted on a dedicated single VM. Since the database needs more server power, it is recommend to use the A3 type VM. The application used for the load testing is jMeter in its desktop version. It is installed on the same VM as the database, presented in Fig. 1.

TABLE I
Azure VM resources configuration and prices

Type	Cores	RAM	Price
A1	1	1.75GB	$ 0.09/hr (approx. $ 67/mo)
A2	2	3.5GB	$ 0.18/hr (approx. $ 134/mo)
A3	4	7GB	$ 0.36/hr (approx. $ 268/mo)

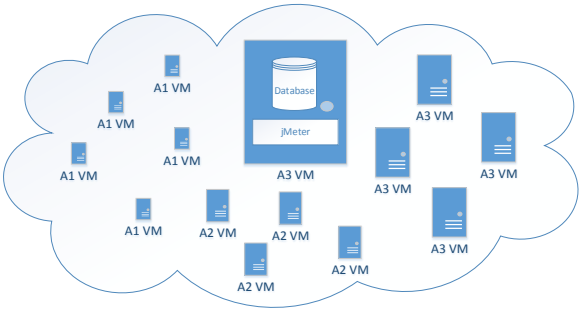

Fig. 1. Architecture of the testing environment and demo application

TABLE II
Testing configurations

cores	organization	id
1 core	1 A1 type VM	1xA1
2 cores	2 A1 type VMs	2xA1
2 cores	1 A2 type VM	1xA2
3 cores	3 A1 type VMs	3xA1
4 cores	4 A1 type VMs	4xA1
4 cores	2 A2 type VMs	2xA2
4 cores	1 A3 type VM	1xA3
5 cores	5 A1 type VMs	5xA1
6 cores	6 A1 type VMs	6xA1
6 cores	3 A2 type VMs	3xA2
8 cores	8 A1 type VMs	8xA1
8 cores	4 A2 type VMs	4xA2
8 cores	2 A3 type VMs	2xA3
10 cores	10 A1 type VMs	10xA1
10 cores	5 A2 type VMs	5xA2
12 cores	6 A2 type VMs	6xA2
12 cores	3 A3 type VMs	3xA3
16 cores	8 A2 type VMs	8xA2
16 cores	4 A3 type VMs	4xA3

The application itself will be hosted on several VMs of the same type and configuration. For example, a set of 1,2, 3 or 4 A1 VMs to be used along with the database VM. For our testing purposes, the number of VMs is limited to 20 and the test cases are defined with less than 20 cores (since the target is SME). Table II presents the VM resource organizations with various number of cores.

In our experiments, all VMs run in the same Azure datacentre placed in South Central US.

Demo used in this paper is the SaaS solution [11], as a hybrid between the ordinary e-Business system and the ticket management system. The idea is to use states for the processes in the e-Business, so each document can be tracked by the users. It is a realization of a transactional web application that processes documents related to the e-Business ordering,

invoicing and financial clearing processes.

The target users of this system are the SMEs (Small and medium enterprises). It allows the SMEs to be aware of every process that happens in their company, and at the same time it saves the budget of the company reserved for software solutions.

System features include management of: products, product catalogs and pricelists, offers for the customers, customers orders, invoices and payments according to the bank statements. Each of these documents and corresponding processes is described by several states of its lifecycle [11].

The system is developed in ASP.NET framework as a multi-tier web application. The database tier is realized by the Microsoft SQL Server database management system.

Two test cases are defined for the load test experiment.

TC1: Selection of all the orders from the system - This test case consists of a few test steps. In the first step, a user from the manager role logs in to the system. In the second step, the user navigates through the system to find the page where all the orders are listed. The final step is to open the page with the listed orders. Overall, the test case makes 3 HTTP requests.

TC2: Insertion of a new offer in the system - This test case is more complex than the previous one. It is made of 6 HTTP requests. First of all, a user from the manager role logs in to the system, and navigates to get to the page where all a history of the offers is presented. By clicking a button for adding a new offer on this page, a new page is presented with several information input fields. The required fields of this form are to be populated and the form submitted to save the offer. After this, the user is redirected to the list of all offers.

Both test cases are loaded with various users considered as small or medium users loads: starting from 1, 5, 10, 50, 100, and increasing by 50 up to 1000 users.

The basic test data for each test case and configuration is the response time T_R for executing the HTTP requests of the test case under a certain user load.

Performance P is equivalent to the processing speed (number of executed requests), derived from the response time for each configuration, calculated by (1).

$$P = N/T_R \tag{1}$$

where N is the number of HTTP requests of the test case and T_R is the response time in seconds. The unit which expresses the speed is *requests per second*.

The other performance indicators are based on evaluation of the performance (processing speed). The Relative speedup R is calculated for two differently structured configurations with the same number of cores, for instance 4xA1 and 1xA3 both having 4 cores. The relative speedup is always calculated within one test case (TC1 or TC2). The relative speedup between two configurations marked with x and y is calculated by (2) where P_x is the speed of the configuration x and P_y is the speed of the configuration y.

$$R_{xy} = P_x/P_y \tag{2}$$

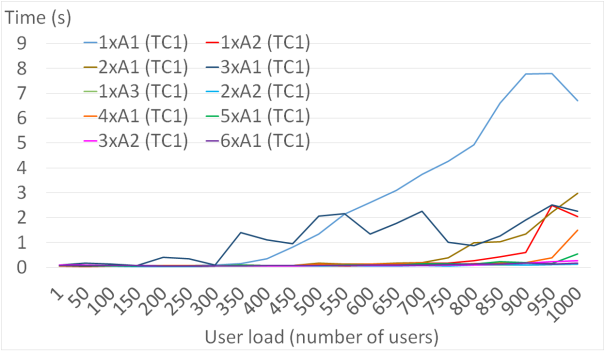

Fig. 2. Response time for TC1 on configurations with <8 cores

Let's analyze how the evaluation will be performed. To prove Hypothesis 2 we have to compare two configurations x and y that have the same number of cores. Let the configuration x use configurations with smaller number of more powerful VMs, such as A3, and y those with greater number of less powerful VMs, such as A1 or A2. If the relative speedup satisfies the relation $R_{xy} \leq 1$ it means that the x configuration achieves less performance and the Hypothesis 2 is valid, meaning that the configurations with smaller VMs achieve better performance and are optimal.

The experiment to prove the Hypothesis 1 compares two test cases realized as systems x and y, where the system y denotes the test case TC2 and x the test case TC1 for the same resource configuration. It means that system y needs more processing in comparison to x and one expects that $R_{xy} \geq 1$ to prove the Hypothesis 1. It shows that the processing activities take proportionally more time to be finished.

IV. Analysis of Results

In the first test case (TC1) we experiment how the system behaves when a list of the orders have to be selected under a certain user load. The test case contains 3 HTTP requests which is the total number of request per each user.

The second test case (TC2) shows how the system behaves when a user inserts a new offer under a certain user load. The test case contains 6 HTTP requests which doubles the amount of requests per user of the previous test case.

The parameters that are taken to compare the configurations are the response time of each configuration for user load and processing speed for each configuration.

The results for obtained response times are presented by charts, where the X-axis corresponds to the user load and Y-axis to the response time measured in seconds.

The results of the load tests for TC1 on cloud configurations using VMs with less than 8 cores (1, 2, 3, 4, 5 or 6 cores) are presented in Fig. 2. If we compare the configurations with 2 cores, we can see from the chart that both configurations have nearly the same time up to 750 users, and afterwards the configuration with A2 machine has better response time. When 4 cores are used, the chart represents that there is no such a difference in the response time of the configurations

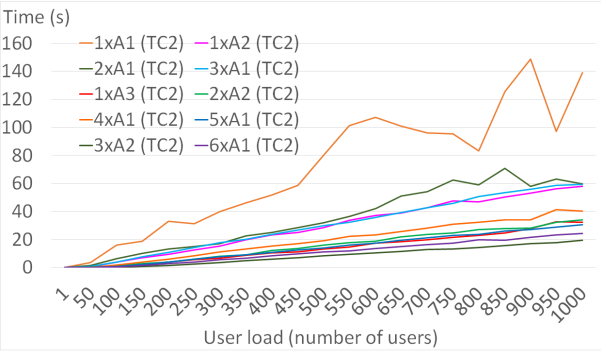

Fig. 3. Response time for TC2 on configurations with <8 cores

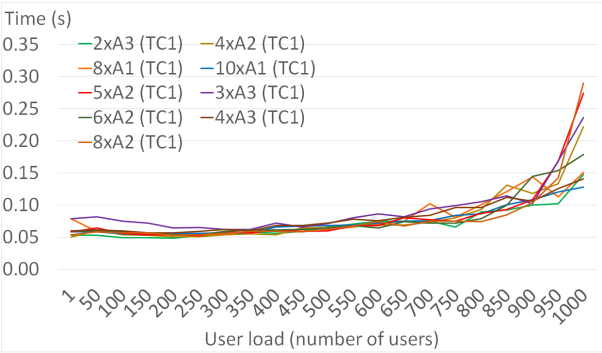

Fig. 4. Response time for TC1 on configurations with ≥8 cores

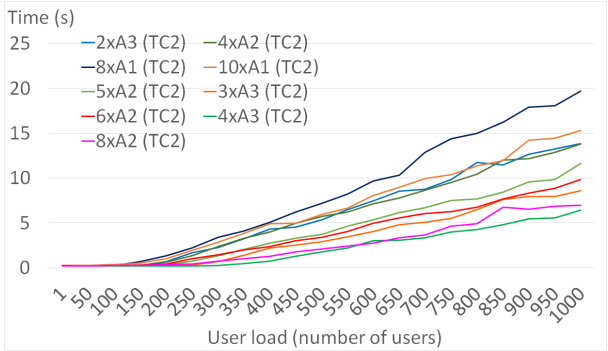

Fig. 5. Response time for TC2 on configurations with ≥8 cores

with lower number of VMs and higher number of cores (A2, A3) while the usage of A1 type of VMs has close response time to the previous configurations up to 900 users. When configuration of 6 cores is used for TC1, we obtained slightly better response time when the type A1 is used. Overall, one might easily conclude that the configurations with higher number of resources result with smaller response times.

The results of the load tests for TC2 on cloud resources using VMs with less than 8 cores are presented in Fig. 3. This test case contains more requests which results in a higher response time than TC1 at all times. When 2 cores configurations are used for TC2, it is clearly the configuration with VM of A2 type has better response time. For the set of 4 cores, the best response time in TC2 has the configuration of VM of A3 type regardless of the user load. In the case of 6 cores configuration in the TC2, we have the opposite result than TC1. For this configuration, at all the times, the configuration of A2 type VMs has better response time at all the times. The best case is when there are 6 cores and 3 VMs of A2 types, meaning VMs with multiple cores.

Figures 4 and 5 show the results of tests on configurations with a total of 8 or more cores (8, 10, 12 and 16 cores) respectively for the load test of TC1 and TC2. All the cores in one configuration are part of the same VM type (A1, A2 and A3).

In the case of using 8 cores in TC1, the configuration of less VMs shows better response time. The other two with bigger number of VMs get closer in the response time up to the load of 700 users. In the 10 cores configuration in TC1, better response time is obtained when higher number of VMs of A1 type is used. The other configuration of A2 type VMs provides response time closer to the previous configuration up to load of 900 users. Similarly to the previous configuration, when we have configuration of 12 cores in TC1, a better response time is given by the configuration with higher number of VMs of A2 type this time. The results for the configuration of 16 cores used in TC1 show that the set of higher number of VMs of type A2 has better response time up to the load of 900 users. Above this load, the configuration of lower number of VMs of A3 type has better response time. From this, we can sublime that we have the optimal results in the case when there are 8 cores in a configuration 2 VMs of type A3. For TC2 of this core number range, that is one of the configurations with the lowest number of cores.

The configurations that have A2 and A3 type of VMs in 8 cores set give almost the same response time in the terms of TC2. Both of the response times are better than the configuration that has A1 type of VMs. For 10 cores configuration set, the configuration with better response time is the one that uses A2 type of VMs in every user load. When 12 cores are used for TC2, the configuration with lower number of VMs of A3 type provides a better response time for each user load. Using 16 cores, the configuration that has better response time in almost all user loads is the configuration of A3 type of VMs and that is the optimal response time obtained for all the configurations in this case.

Based on the measurements of the response time for each test case and each configuration, we are able to calculate the processing speed dependent on the number of requests by (1). The results about the performance (processing speed) are presented in Figures 6 and 7 respectively for for TC1 and TC2. X-axis represents the user load and Y-axis the speed measured in requests per second.

We observe that at certain load, the cloud configuration gets saturated. After these points the speed gets even lower, due to queues and incapability to process all the requests. This is more evident for more processing demands, such as TC2.

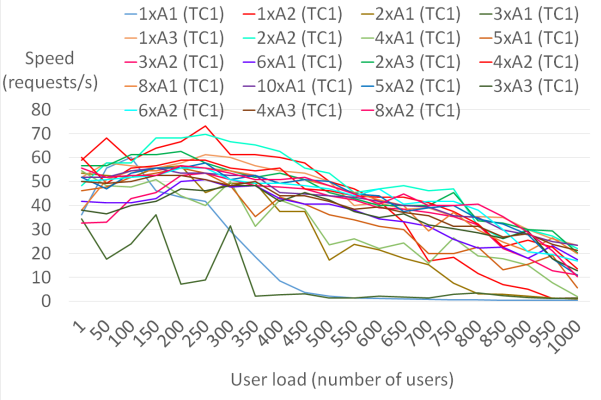

Fig. 6. Processing speed for TC1

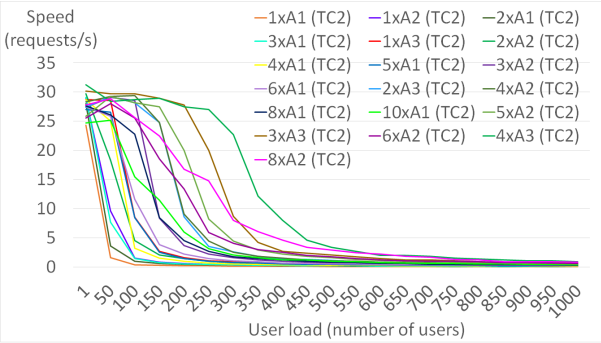

Fig. 7. Processing speed for TC2

When analyzing TC1, saturation appears mainly for the configurations that use A1 type of VMs (1xA1, 2xA1, 3xA1) and there is one case when A2 type VM is used, as presented in Fig. 6. At the worst case, the saturation starts from the user load of 500 users for 1xA1 configuration, while the best case when saturation appears is 2xA2 on 950 users at the user load. The chart also shows that the configuration 10xA1 has the optimal speed for the maximum user load of 1000 users, which is 23.4 requests/second.

Every configuration enters the saturation state at some point of the user load scale, as shown in Fig. 7. The worst case happens again for the 1xA1 configuration, which enters saturation when the load is only 100 users. The best case is the 4xA4 configuration which is saturated at 600 users of user load. At the user load of 1000 users, the configuration 4xA3 has the best speed, 0.4 requests/second.

In this section we compare the speeds of all the configurations for TC1 and TC2, where the processing demands are doubled. According to (2) we expect that TC2 will achieve at most half processing speed of TC1.

Fig. 8 presents the relative performance between TC1 and TC2 for each configuration. TC2 demands more processing and consumes more resources, at least double than TC1. The measurements show that the speedup value for some user loads and configurations goes up to 264 times. This approves the

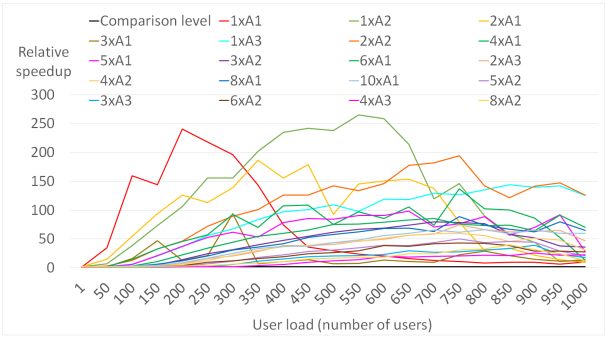

Fig. 8. Relative comparison for each configuration in TC1 and TC2

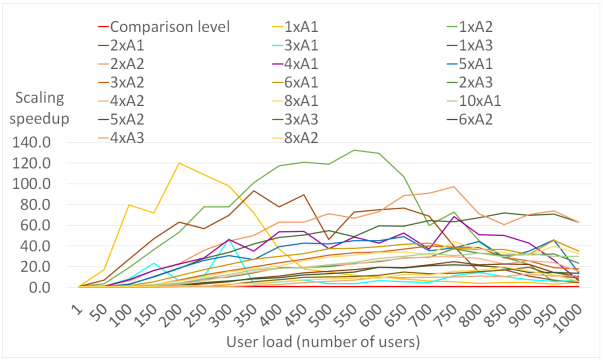

Fig. 9. TC1 and TC2 scaling speedup

Hypothesis 1.

More precise indicator is the scaling speedup. Since TC2 uses at least twice as much HTTP requests than TC1, the scaling factor is 2. Fig. 9 shows the speedup values of the same configurations for TC1 and TC2. We can see that all the configurations get scaling speedup greater than the linear, which means, the scaling factor is at least 2.

The optimal configuration is analyzed by the relative speedup of the configurations with the same number of cores. We perform experiments with 2, 4, 6, 8, 10, 12, and 16 cores, for both TC1 and TC2.

Fig. 10 shows the relative speedup of the configurations for TC1. There are only four cases that achieved results below the linear speedup, which means the better configuration is the one with more VMs of smaller type (it is A2 type in all the cases). The rest of the cases show different values for the relative speedup above the linear, which means the configuration with less larger VMs is better, and the optimal configuration can be chosen depending on the user load.

The relative speedup for the selected configurations for TC2 is shown in Fig. 11. In most of the configurations, the configurations using larger VMs perform better and can be chosen as optimal. Yet the optimal configuration for this test case is 3xA3 that contains 12 cores.

Table III shows the optimal configurations for number of cores for TC1 and TC2. From here, we can sublime that in most of the cases the optimal configuration is using less large

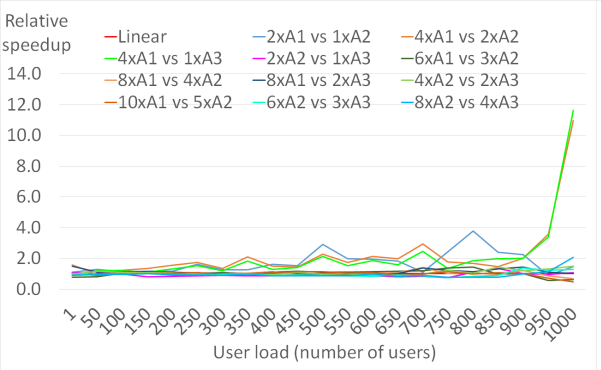

Fig. 10. Relative performance for TC1

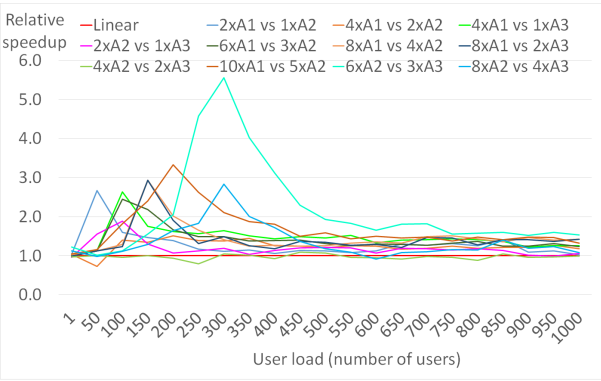

Fig. 11. Relative performance for TC2

TABLE III
OPTIMAL CONFIGURATIONS FOR TC1 AND TC2

Configurations	Cores	TC1	TC2
2xA1 vs 1xA2	2	1xA2	1xA2
4xA1 vs 2xA2	4	2xA2	2xA2
4xA1 vs 1xA3	4	1xA3	1xA3
2xA2 vs 1xA3	4	2xA2	1xA3
6xA1 vs 3xA2	6	3xA2	3xA2
8xA1 vs 4xA2	8	4xA2	4xA2
8xA1 vs 2xA3	8	2xA3	2xA3
4xA2 vs 2xA3	8	4xA2	4xA2
10xA1 vs 5xA2	10	5xA2	5xA2
6xA2 vs 3xA3	12	6xA2	3xA3
8xA2 vs 4xA3	16	8xA2	4xA3

VMs with higher number of cores (or type A2 or A3).

It means that the Hypothesis 2 fails, and the system performs better when using a configuration with small number of large VMs.

V. CONCLUSION

The results showed the optimal solutions for the e-Business system depends on the operations that it might have, 'heavy' and 'light' requests that also include the database transactions.

Our first test case in the realized e-Business solution is a 'light' operation, since it contains operations, such as changing the document status or listing the documents. These operations are quite common and massively used in the e-Business system since they do not involve a lot of database transactions. However, the e-Business system can be considered as a system with a lot of 'light' operations, but there are even more 'heavy' operations that include numerous insertions of new data, such as offers, orders, invoices or bank statements which requires a lot of input fields, various calculations of the account balance, and also processing the data for the purposes of reporting.

Moreover, the frequency of the heavy operations depends on the company business. If it is a business that has a huge number of orders everyday, the operations will be very often. Once the order is created and processed, it triggers the creating of an invoice, which then partially guarantee that there will be a bank statement which matches the invoice. Each process will trigger an operation which is considered to be heavy, and will eventually make the system work better on more powerful server resources under a heavy user load.

Our experiments on the performance of the e-Business SaaS solution has showed that:

- Hypothesis 1 holds when comparing the results of the relative performance of two test cases, one of which has double the amount of HTTP requests.
- Hypothesis 2 fails, which means that the optimal configuration is the one with lower number of large VMs.

We conclude that for a real transactional based e-Business application, it is better to choose configurations that use lower number of larger VMs (A3 type). When scaling, the software provider must have in mind that the speedup will be equal or higher than the number of cores. An application, such this, that requires more processing (for HTTP requests, database transactions etc.) demands proportional processing time to the requests.

***Abstract*—Computing middlewares play a vital role for abstracting complexities of backend resources by providing a seamless access to heterogeneous execution management services. Scientific communities are taking advantage of such technologies to focus on science rather than dealing with technical intricacies of accessing resources. Multi-disciplinary communities often bring dynamic requirements which are not trivial to realize. Specifically, to attain massivley parallel data processing on supercomputing resources which require an access to large data sets from widely distributed and dynamic sources located across organizational boundaries. In order to support this abstract scenario, we bring a combination that integrates UNICORE middleware and the Global Federated File System. Furthermore, the paper gives architectural and implementation perspective of UNICORE extension and its interaction with Global Federated File System space through computing, data and security standards.**

I. Introduction

Distributed computing middleware platforms are expected to provide an abstract and convenient interface through which scientific communities can manage complex simulations and workflows. As we have seen a recent wave of big data which covers data intensive applications requiring unified data access and bringing large data sets to execution services representing high performance computing resources. The execution service which is a part of compute middleware, aid and orchestrate these large workflows and aggregates data from multiple sources for pre-processing and analysis tasks. These sources might be managed by different kinds of remote data management services. The data management interfaces for reading and writing data are significantly different from each other. Thus, it is imperative to let execution service know the interface of each data management service instance. In order to enable an execution service for multiple data services may require adaptors, which in the worst case proportional to the number of intended data management interfaces, therefore it is not practically feasible to develop and maintain all of them. With this, we deduce two following requirements from the execution service's perspective. Firstly, a federated data management system should be in place that supports interoperable data sharing through a unified interface. Secondly, the execution service which exposes high performance computing resource, is capable of interacting with data management systems in a secure and reliable manner.

For the sake of gaining more insight on requirements and architectural implementation we consider XSEDE infrastructure as a case study. XSEDE has a diversified set of user communities which are running jobs on high performance computing (HPC) and high throughput computing (HTC) resources. In XSEDE the UNICORE [1] middleware provides execution service capabilities and abstraction over multiple batch systems deployed on high performance computing clusters. For some applications the use of resources can span both HPC and HTC type of resources, for example in case of a complex workflow. In our scenario the federated data access across multiple sites is realized through the Global Federated File System (GFFS) [2]. It is an open standards based data management service for accessing a myriad of file systems in a consistent heirarchical representation. The GFFS is an integral part of GenesisII middleware [3], which is a services suite for realizing high throughput computing scenarios. The scope of our work is to extend UNICORE for the scientific communities who are using the GFFS and the GenesisII middleware. This will be useful to the scientific communities who are already using the UNICORE services over XSEDE infrastructure and may want to access data from GFFS space. Another impact will be on a group of users who are intending to run complex workflows spanning the simultaneous use of both high performance (through UNICORE) and throughput (GenesisII) jobs that use and share data through the common GFFS space. To enable UNICORE managed jobs to interact with the GFFS, the execution service of UNICORE should understand the interfaces through which the GFFS data can be managed and transported. In this paper we describe which part of the UNICORE's execution tier is extended for the GFFS, and how the GFFS server and client is modified to recognize UNICORE services.

The rest of the paper is conformed to the following structure. Section II gives a background on technologies and standards involved. Section III elaborates the security model, while the technical aspects of middleware extensions are described in Section IV. Section V describes the related work.

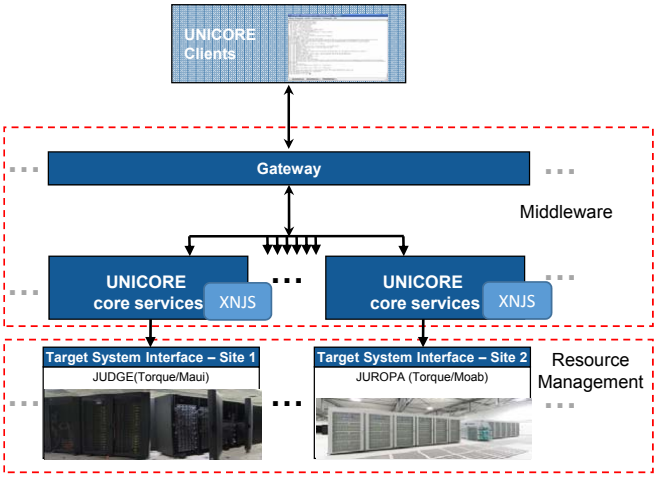

Fig. 1: An overview of UNICORE Architecture.

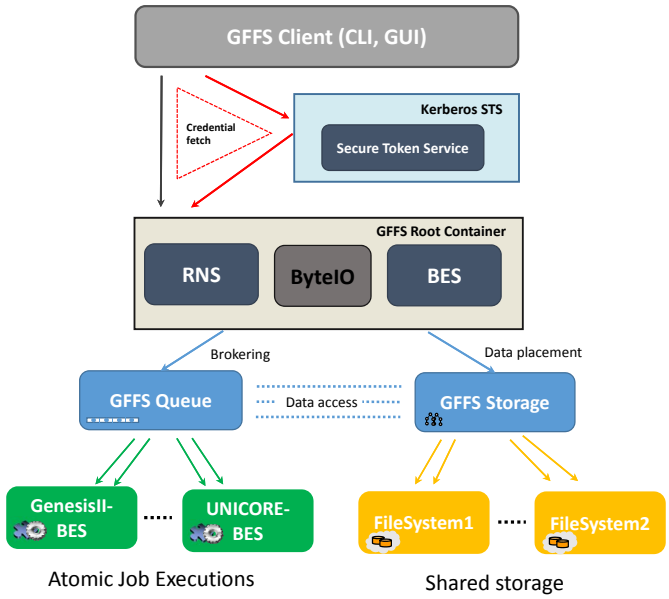

Fig. 2: A holisitic view of the Global Federated Filesystem architecture.

We conclude the paper in Section VI.

II. Background

This section provides an overview of the technologies which are involved in the implementation.

A. UNICORE

UNICORE is a service oriented middleware which provides a set of compute and data services to access high performance computing resources. The UNICORE architecture is composed of three layers as shown in Figure 1.

The client layer is responsible for providing user interface, which includes preparing and sending client requests to the remote deployed UNICORE web services. The server side is founded upon the principles of service oriented architecture. It encapsulates a SOAP based web services environment capable of hosting WS-I (Web Services - interoperability) and WSRF (Web Services Resource Framework) compliant service endpoints. The job execution and data management capabilities are exposed through web service endpoints. Once the client submits a job, it is forwarded to XNJS (Extended Network Supervisor), which processes a job request by first validating the submission request and then after a successful validation it is communicated to the Target System tier. At this layer the Target System Interface (TSI) component is deployed on a login node of a batch system. It directly interacts with the low level batch system, and has a main responsibility of translating job requests into batch system specific command scripts. It also monitor job statuses, and manage underlying running file transfers during the job's execution life cycle.

B. The Global Federated File System

The Genesis II Global Federated File System (GFFS) is at its root a networked file system that provides researchers with tools for securely managing and sharing their computational data. The GFFS also provides a means of managing jobs that use that data via the GFFS-Queue. The GFFS implements a web services architecture that uses standards-based protocols for storing and accessing data over a network. To support federation across different organizational entities, the GFFS provides a rooted file system structure with standard namespace locations for storing users (via Secure Token Services), groups, home directories, and computational resources such as queues and Basic Execution Service endpoints (BES) for processing jobs. Figure 2 shows a simplistic view of the integrated architecture encompassing GenesisII and UNICORE Basic Execution Service (BES) endpoints interaction with the GFFS's root container. The UNICORE's BES implementation is explained in the next section.

Several mechanisms are implemented for storing and retrieving data in the GFFS. The GFFS implements many of the standard Unix commands (such as "cp" and "mv") in a console-mode grid shell. There is also a graphical user interface view of the GFFS, which supports drag and drop file management. The GFFS also provides a "FUSE" file system that allows users to mount the GFFS on a Unix directory and operate on files in the GFFS as if they were simply part of the local file system. Lastly, the GFFS also provide an exports feature that allows users to make part of their own file system visible within the GFFS. The GFFS Queue supports submission of multiple jobs for subsequent distribution to the execution service endpoints connected to the queue. The GFFS Queue provides researchers with a mechanism for managing and controlling their computations via a graphical user interface as well as with familiar command line tools such as "qstat" and "qkill". Jobs will be distributed to BES resources automatically by the GFFS Queue, but can also be rescheduled as needed. The XSEDE project benefits from the GFFS by giving researchers a way to securely share data with their colleagues and by providing a high level view of the computational resources available at XSEDE in the GFFS Queue.

```

Fig. 3: JSDL XML instance showing GFFS data staging.

C. Related Standards

In order to carry out file system operations such as mkdir or cp, the RNS (Resource Namespace Service) [4] protocol is used. The RNS specification provides client applications to have human readable mappings with WS-Addressing based endpoints. Considering the WSRF based endpoints wherein web service resources can have a nested heirarchical structure, the RNS can be very helpful in this case by providing a fault and location transparent access to resources in a simple and human readable representation. The GFFS implements the RNS and also its Web Services Resource Framework (WSRF) [5] rendering to access web service resource endpoints. As far as the data transfer is concerned the GFFS primarily uses the ByteIO [6] standard. ByteIO provides a set of interfaces to interact with bulk data sources and sinks.

Job Submission Description Language (JSDL) [7] is XML based data model that describe computational job's requirements in terms of application, resources, that will run in distributed computing environments. UNICORE and GenesisII clients specify job requirements in the JSDL format. UNICORE server side implements most of the JSDL, and its related profiles and extensions.

OGSA-Basic Execution Service (BES) [8] provides a web services based interface for managing and monitoring computational jobs in high performance and high throughput computing environments. For a job submission use case BES interface accepts a JSDL instance as a parameter and then runs it on backend resource. In our scenario UNICORE server exposes its computing capabilities via BES, and GenesisII client use this interface to invoke remote calls on the UNICORE endpoint.

III. Security Model

The GFFS' security model is based on the SAML [9] standard, and specifically adopts the UNICORE's SAML profile [10] and implementation. The GFFS implementation of SAML extends the UNICORE model to understand the "delegation chains" of the Genesis II security model. A delegation chain encodes that a User has delegated some amount of trust to a resource in the GFFS in order to achieve a task, such as processing a job. Most delegation operations can be considered to start with three "entities" involved. These entities are (1) a grid user (for our example, called U, (2) a TLS connection identified by an X509 certificate (called C), and (3) a grid resource (called R). Longer delegation chains usually contain all three of these types of entities as the first links in the chain.

In the GFFS, the first entity U is always a user defined as a grid STS (Secure Token Service) object. This entity is the prime mover for any operations that are performed in the GFFS. The user's rights within the grid's access control list permission system dictates what that user can and cannot do with regards to every grid resource.

The client software must authenticate as the grid user U to obtain services from a GFFS container. This is where the second security entity C comes in; it is the connection made by the client software at the behest of the user. Initially, the client credentials only contain C, as one makes the connection before STS (Secure Token Service) authentication occurs. In the XSEDE Login process, this connection is always based on X509 credentials obtained from the XSEDE MyProxy server, and thus can be a well-known identity within both Genesis (via a Kerberos-based STS) and UNICORE (via the grid-mapfile). In the example, the client software first authenticates to MyProxy by using user's name and password to obtain the certificate C. Then, the client authenticates to the Kerberos STS in the GFFS to obtain grid user U.

After the user authenticates, the client software's "credential wallet" will contain the first delegation of trust, U -> C. This states that the grid user U trusts the TLS connection C to act on its behalf. Afterward, all of the actions taken by the TLS connection C are understood to be U's actions. Any access that provide U with permissions will also be granted to C. That may include submitting a job to a BES (Basic Execution Service) named R. This is the second point where trust is delegated; the certificate for TLS connection C signs a new trust delegation that says "C trusts R" to perform a job execution. This extends the length of the delegation chain by one, so that it now has all three entities involved in two trust delegation objects. This can be represented with delegation arrows such as:

First delegation: U -> C (The grid user trusts the TLS connection) Second delegation: C -> R (The TLS connection trusts the resource) Full Chain: U -> C -> R (The user U trusts the connection C which trusts R to run a job)

This new delegation chain can be presented by the resource R when it needs to do further actions on the grid user's behalf. Actions might include storing file staging results back to RNS space (U -> C -> R -> D, where D is a Data folder) or possibly submitting the job to another BES for final processing. The important point is that entity D is just another resource to which trust can be delegated, and the chain can be continued in that manner for as long as its delegation depth limit allows.

The prior implementation of Genesis II security, was not based on SAML, used nested, serialized Java objects to define a tightly coupled chain, with each nesting level signed by the issuer at that level. This implementation was considered to be a problem for interoperability because it is tightly-coupled with the GFFS Java classes and cannot in any sense be considered a standard (or standardizable). The new SAML implementation relies instead on UNICORE's SAML assertions, which represent the delegation chain as isolated X.509 based assertions that are tied together with unique identifiers. Each SAML assertion is also signed by the issuer, but there is no nesting and no reliance on serialized GFFS Java objects.

One challenge to interoperating between the GFFS and UNICORE implementations arose due to a difference in interpretation of the SAML assertions. The delegation chains in the GFFS are tightly-coupled, and do not allow mixing and

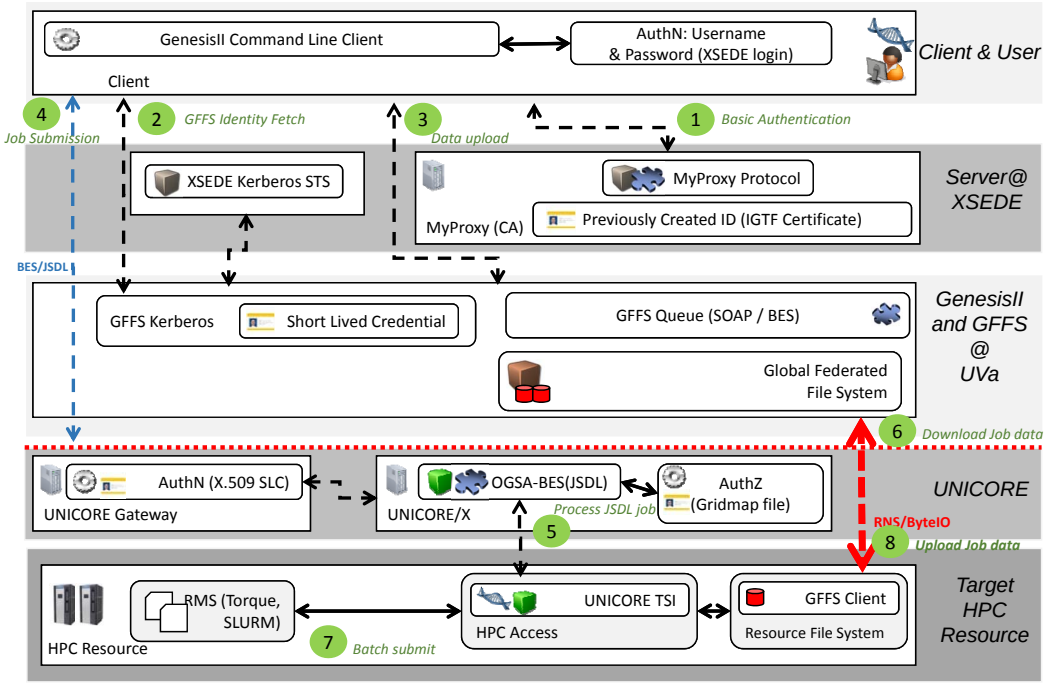

Fig. 4: Integrated architecture showing GenesisII client interacting with UNICORE and the GFFS

matching of individual entities. This is not directly provided by the UNICORE's SAML implementation, which permits the receiver to mix and match any delegations provided in a message (U -> C -> R is considered to be two separable delegations U -> C and C -> R). In the GFFS model, a delegation chain must be used in its entirety or not at all.

To address this difference, the GFFS implementation of SAML adds a unique identifier to each SAML assertion. A chain such as U -> C -> R is built by embedding the identifier of the U -> C assertion in the C -> R assertion. To make this cryptographically secure, the signature of the U -> C assertion is also embedded in the C -> R assertion before C -> R itself is signed. This enforces the connections between the GFFS delegation chains while still leveraging the UNICORE's Security Assertion Markup Language (SAML) implementation. Upon reception, the chains are reassembled and any assertions that are referenced by a longer delegation chain are removed from the pool of available assertions.

IV. Middleware Enhancements

UNICORE's server tier is extended to accept the incoming requests from GenesisII remote clients. The remote clients here implies the GFFS's GFFS-Queue component which is an entry point for a user to submit job. The GFFS-Queue acts as a meta scheduler that brokers a job based on its resource requirements on available set of living Basic Execution Service (BES) based computing endpoints. While considering UNICORE as one of the BES endpoints we need to understand how to interpret, authenticate, and authorize the incoming GFFS-Queue requests. A separate UNICORE server extension is implemented that is invoked when server finds a security token containing GFFS related information in the incoming client request. The extension validates the SAML chain by looking into every element of the chain. These elements are entities which contain every stake holder including end user or service through which the request was passed. The details of the entities are described in the previous section.

Before a GenesisII client is able to send jobs to a UNICORE's Basic Execution Service (BES) endpoint, a Genesis II container should recognize and link the UNICORE's Basic Execution Service (UNICORE-BES) instance into the RNS space. The linking is achieved through Endpoint Reference Minting process. An EPR (Endpoint Reference) is the basic component of the Resource Namespace Service (RNS). Every location in the GFFS namespace has an EPR that identifies (1) where the resource lives and (2) the X.509 certificate that represents the resource. Minting an EPR is the process of creating a new EPR as an XML document that represents an external resource, such as a UNICORE-BES. The process of minting an EPR combines the URI where the resource is located with the X.509 certificate expected as the resource's identity (which it would report over a TLS connection). Once an EPR is minted, the EPR's XML document can be stored locally as a file or added as a new link to the grid namespace. When linked into the grid, a user with appropriate credentials can see the entry in the GFFS files ystem and can use it to obtain whatever services the resource provides.

The user's XSEDE identity is extracted from the delegation chain, and the retrieved identity is validated against the authorization store of the UNICORE server deployment. If the user is found under the authorization store then the required user context is created for carrying out GFFS data staging call outs. After the context creation phase, the server extension releases its control and job moves to the next phase of execution. In the beginning of the execution phase the request is processed further to carry out the GFFS based data stagings of jobs. Figure 3 shows the job request encoded in JSDL containing application requirements and data staging elements pointing

to the GFFS space. Note that the job will be executed on the UNICORE site, therefore GenesisII-BESes are not involved in this sequence.

The GFFS based data transfer is realized through an XNJS extension. The GFFS download component prepares a command to pull data from the GFFS. The command which looks like "grid cp remote-source job-working-directory", will be forwarded to the Target System Interface (TSI) that invokes the GenesisII's "grid" command gracefully and downloads the data to the job's working directory. In a likewise manner the GFFS upload takes care of uploading output files to the remote GFFS location. Any failure will make UNICORE fail the job and abandon any further processing related to it. For every job which is sent by GenesisII client UNICORE server extension maintains an additional folder in each of the job's working directory that contain user's contextual information.

The pictorial representation of a simple job submission sequence is shown in Figure 4. In the first step GenesisII GUI client asks a user to login through an XSEDE provided credentials. After the authentication phase, she uploads a data to the GFFS folder. The user then creates a job request with application details, and location of the data that is mentioned just before. In a similar manner, output data paths are also specified. The user then selects a UNICORE endpoint and run the job. The cient continuously monitors the job until it reaches to a terminal state. Once the job is finished successfully the outputs are fetched back from the remote job working directory which is located on cluster's file system to the GFFS space. For the sake of brevity a sequence of major steps are being highlighted.

V. Related Work

In this section we present computing middlewares integrated with wide area file systems. GridFTP [11] is one of the major data transfer protocols used in today's scientific and commercial data infrastructures. Specifically, GlobusOnline data transfer service is mainly using this protocol to move data across widely distributed endpoints. UNICORE's GridFTP extension [12] help scientists to submit job executions on UNICORE and using GridFTP based data endpoints for data stagings. From the implementation perspective, both the GridFTP and GFFS extensions are hooked in at the same architectural level, that is in XNJS. In the case of GridFTP integration, the clients requiring UNICORE server to perform data staging on user's behalf need to send at least X.509 proxy certificate chain along with the job submission request. For the GFFS the entities communicating the job request to the server must send the complex chain of SAML assertions.

ARC [13] is a middleware suite used by communities which mostly use high throughput computing capabilities. ARC's integration with [14] and DDM (Distributed Data Management) [15] solutions are mostly used by particle physics community, ATLAS [15] at the Large Hadron Collider. dCache and DDM are distributed data management platforms providing storage and retrieval of huge amounts of data. dCache and the GFFS share mostly the same set of scenarios, but the major difference is, the GFFS expose its interface via RNS and ByteIO, whereas dCache is accessed through the SRM [16] interface.

WS-PGRADE / gUSE (grid and cloud user support environment) [17] is an open source scientific gateway framework that allows access to hetrogeneous grid and cloud resources. gUSE provides a client extension in the form of DCI bridge [18] to the GFFS by invoking GenesisII clients. It is much similar to the way UNICORE integrates the GFFS. The framework provides access to UNICORE and ARC job submission services through the OGSA-BES interface.

VI. Conclusion

UNICORE's OGSA-Basic Execution Service (BES) based execution and the RNS- and ByteIO-enabled Global Federated File System allow standards based combination for sharing and accessing resources across infrastructural boundaries. The representation and accessibility of resources such as files, directories, jobs, compute endpoints, and other web services can be accessed through usable hierarchical structure which is common to physical file systems. Presently, the proposed work has passed rigorous testing by the XSEDE's Software Development & Integration, and XSEDE operations team according to functional, security, and performance use cases. Now the implementation is accepted for production deployment, for which some sites are in transition of updating UNICORE endpoints for the GFFS access. In the current version, UNICORE explicitly invokes the GenesisII command line client to access the GFFS space. This usage of the GFFS client requires that client be installed on each resource management system where UNICORE resides. In the next iteration of UNICORE, the dependency of the client will be removed and instead the GFFS' programmatic interface will be adopted.

Enabling UNICORE to access the wide-area distributed GFFS can help scientific communities perform effective processing of large data sets on high performance computing platforms. This work has generated an interest from the science gateway communities across XSEDE who are intending to run data and compute intensive jobs that leverage the GenesisII based high throughput features and UNICORE supported high performance computing resources.

Abstract – Frequency table computation is a common procedure used in variety of machine learning algorithms. In this paper we present a parallelized kernel for computing frequency tables. The kernel is targeted for dataflow architecture implemented on field programmable gate array (FPGA). Its performance was evaluated against a parallelized software implementation running on a 6-core CPU. The kernel with six concurrent input data streams running on 300 MHz achieved speedup of up to 6.26×, compared to 6 threaded software implementation running on 3.2 GHz CPU.

Keywords – frequency table, dataflow, field programmable gate arrays, decision tree learning

I. INTRODUCTION

The 2D frequency table is a two-dimensional extension of histogram. In machine learning context, the frequency table is often used to provide information on how frequent specific combinations of attribute and class values are in a given dataset. This specific use is a key part of the attribute selection process in decision tree learning algorithms [1]. Applications of decision tree learning, as well as the field of data mining in general, are faced with continuing increase in dataset sizes. This drives efforts to develop new faster and more efficient algorithms, as well as developing new hardware platforms that provide high computational power [2].

One hardware platforms that is gaining more ground in computing is the field programmable gate array (FPGA). FPGA. FPGAs are digital integrated circuits designed to be user-configured after manufacturing [3], [4]. They enable fast development and deployment of custom digital hardware, and thus allow implementation of custom computational architectures that can be reconfigured on demand.

The most suitable computational mode for FPGA is the dataflow model. Most computer systems implement a control-flow model, in which the computation is described by a sequence of operations that are executed in specified order. In dataflow model, computation is described by chain of transformations applied to a stream of data [5]. The dataflow is described in form of a graph. Nodes of the graph represent operations, and edges represent data links between the nodes. The dataflow graph maps naturally to the hardware implementation. Nodes/operations are translated to functional hardware blocks, while edges are translated to data buses and signals. By dividing the graph into stages separated by registers, it's transformed into a pipelined structure suitable for implementation on FPGA.

In this paper we present a novel implementation of 2D frequency table computation targeted for dataflow architecture realized on FPGA. The kernel is developed for integration with C4.5 decision tree learning program [6], [7]. Its result is used to calculate dataset split quality, using an entropy based measure, which is then used for attribute test selection.

II. RELATED WORK

2D frequency table computation implemented on FPGA has been previously published as a part of efforts in implementing decision tree learning algorithms. FPGAs have been proven to be suitable of implementing data mining algorithms, though so far little attention has been directed to decision tree learning algorithms. Only a few attempts of using FPGAs to accelerate execution of decision tree learning have been reported [8], [9].

Chrysos et al. [9] implement frequency table computation on FPGA as part of HC-CART system for learning decision trees. Frequency table computation is implemented in Frequency Counting module, which receives attribute-class label pairs. The pairs are used to generate addresses for frequency table locations which contents are then incremented by one. In their implementation, all attribute-class label pairs received by the kernel have to be prepared by program running on CPU, and then preloaded to memory attached to FPGA. Input data is transferred from CPU to FPGA memory many times in the course of program execution.

In our previous work [10], we implemented a 2D frequency table computation using FPGAs. The *ComputeFreq* kernel receives two input streams – one for address and one for class labels – and counts occurrences of pairs in FPGA's internal memory. The dataset is held in FPGA attached SDRAM. The dataset is transferred to the FPGA's SDRAM only once, and only data transfer between the kernel and the host system is the transfer of computed frequency tables. We build upon this work by expanding it to multiple attribute streams which allow computation of several tables simultaneously, and by implementing efficient data transfer for the computed tables.

LMem ↔ FPGA bandwidth	38.4 GB/s max.

III. DATAFLOW ENGINE ARCHITECTURE

The accelerator is implemented in form of a dataflow engine (DFE) which consists of at least one kernel and a manager. The computation is implemented by kernels, while the role of manager is to organize data movement within the DFE. Kernels are instantiated within the manager, and data links between the kernels, external RAM, and CPU are defined.

The frequency table computation was implemented using the Maxeler platform [11]. The platform includes an FPGA board, drivers, and API. The DFE is coded in Java, using the API which provides objects and methods that are translated to hardware units by the compiler. The compiler translates the Java code into VHDL, and generates software interface for CPU code [12]. The DFE was implemented on Maxeler Vectis-Lite board, which contains a single FPGA, and on-board SDRAM. The board is connected to the host PC workstation via PCIe bus. Basic information on the board is shown in Table I.

A. Kernel architecture

Architecture of the *ComputeFreq-MS* kernel is shown in Fig. 1. The kernel has two scalar inputs for parameters: one for number of items to process (*items*), and one for stream length in items (*strmLen*). Stream length sets the number of items to read from the on-board SDRAM, which requires all accesses to be made in 96 byte blocks, i.e. 24 item blocks (4 bytes per item). The kernel processes the first *items* elements from the stream, while the rest are read from memory and ignored.

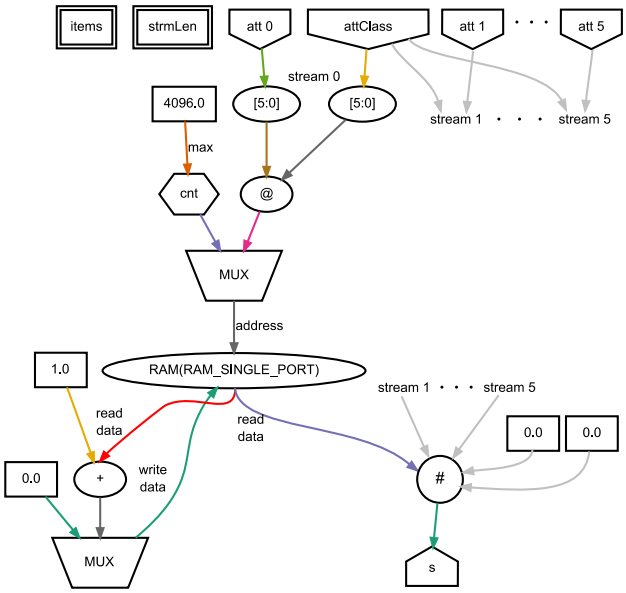

Figure 1. ComputeFreq kernel architecture for up to 64 unique attribute and class values (N_A = 6, N_C = 6).

The kernel consists of six identical frequency counter structures. Each frequency counter receives two input streams – one for attribute and one for class values. Both streams carry 32 bit unsigned integers. The input streams are sliced so the low N_A bits retained from the attribute, and N_C bits are retained from the class values. The retained bits are concatenated to form the frequency table address. In the table address, the attribute value is the high, and the class value is the low part of the address word.

The kernel has a total of seven stream inputs, six for attribute (att_0 – att_5), and one for class (*class*) value streams. Each attribute value stream is connected to a single frequency counter. The class value stream fans out to all frequency counters, so that they all receive identical class value streams.

The frequency tables are stored in on-chip memory – block RAM (BRAM). Each frequency counter has one BRAM which is addressed by the address formed from the low bits of attribute and class streams. The addressed location is read, its value incremented by one, and written back to the same location. The BRAM is configured as single port RAM with read-first synchronization. Due to access latencies of the BRAM itself, and the registers inserted by the compiler, there are latencies inside the loop. To ensure correct counting, the kernel's input streams are throttled to allow input of one element each *m* clock cycles, where *m* is the internal latency of the loop.

After all elements of interest are streamed in, the contents of the BRAMs are streamed out to the host main memory through stream output *s*. The output stream *s* is made by joining output streams from all frequency counters (s_0 – s_5) into a one vector stream. The output vector is padded to 8 elements, i.e. two additional dummy elements are added to it. The padding enables efficient conversion of the output stream to word width of 128 bits which is used in communication over PCIe bus.

As BRAMs are read, they are at the same time reset to zero. During the read phase, the BRAMs are addressed by a counter, and their write ports are switched from increment-by-one values to constant zero. In this case there are no loop dependencies, and the output stream is not throttled – it outputs one element every clock cycle. At the same time, any remaining elements in the input stream are read un-throttled (one per clock) and ignored.

B. Manager

A single *ComputeFreq-MS* kernel is instantiated in manager. Input streams *attClass* and att_0 – att_5, are linked to on-board SDRAM. All input streams use linear memory access pattern. Output stream *s* is linked to

TABLE II. FPGA RESOURCE USAGE BY THE DFE

Resource	Used	Total available	Utilization
LUTs	34,724	297,600	11.67 %
Flip-flops	50,064	297,600	16.82 %
DSP blocks	0	2,016	0.00 %
Block RAM	226	2,128	10.62 %

computer main memory. Source addresses for input streams att_0 – att_5, *attClass*, values for scalar inputs *items* and *strmLen*, and destination address for output stream *s* are defined through the generated DFE interface.

The kernel parameters were set for up to 64 unique attribute and class values (N_A = 64, N_C = 64). Each frequency table holds 4096 32-bit words. Due to the frequency counter's loop latency, it can process one item (attribute - class pair) every five clock cycles. Kernel clock frequency is set to 300 MHz. With six attribute streams, the DFE can process up to 360×10^6 elements per second. FPGA resource usage for the DFE is given in Table II.

IV. Experimental Results

A. Test environment

The kernel was benchmarked using code form C4.5 Release 8 decision tree learning program [13]. Parts needed to load the datasets, and computing the frequency tables were extracted from the program and used for benchmarking. The frequency table computation was parallelized using OpenMP [14] by distributing attributes of the dataset over the threads. This included replicating the frequency table data structure to accommodate multi-threaded execution. The original *ComputeFrequencies* function was modified to use the replicated data structure. Since the attributes were distributed over threads, multiple invocations of *ComputeFrequencies* function were necessary if number of attributes exceeded the number of threads.

Functions for transforming the dataset to the appropriate format, and loading it to the DFE were added to the benchmark program. For execution on DFE, a new function was created by modifying the original *ComputeFrequencies* function. Modifications involve removing the computation loop and replacing it with function calls to the DFE. Received results are transformed into the frequency table data structure used by the parallelized software implementation. Since the DFE processes six attributes in parallel, the *ComputeFrequencies* function is invoked once for every group of six attributes.

Time measurement was added to the *ComputeFrequencies* function. Entire run time of the function is measured. The function's throughput is calculated from the measured times using the formula:

$$T_{a,i} = \frac{a\,i}{t_{a,i}} \tag{1}$$

where a is number of attributes, i is number of items, $t_{a,i}$ is function execution time, and $T_{a,i}$ is the calculated function throughput for the dataset with a attributes, and i items.

A set of 102 synthetic datasets were used in the benchmark. Number of attributes ranged from 6 to 1,536, in a geometric sequence 6×2^i, with i = 0, 2... 7. Number of items ranged from 2048 to 4×2^{20}, in a geometric sequence 2^i, with i = 11, 12... 22. The dataset size was limited to 3 GiB, i.e. to 768×2^{20} elements. Datasets were generated randomly, with uniformly distributed values in range of 1-63 for attribute values, and 0-64 for class values.

Benchmark program was compiled using gcc compiler, version 4.4.7. Benchmarks were run on Intel Xeon E5-1600 workstation, with 16 GiB DDR3-1600 RAM, under Centos 6.5 Linux OS.

B. CPU benchmark results

For the baseline CPU performance, the measurements were conducted on a six-threaded parallelized implementation of *ComputeFrequencies* function. Measured execution times are given in Table III, and are shown in Fig. 2. For datasets with over 128×2^{10} items, execution time scales approximately linearly with number of items. There is a larger increase in execution in area of 16×2^{10} – 32×2^{10} items, for datasets with 96 or more attributes, and 32×2^{10} – 256×2^{10} for datasets with less than 96 attributes.

This increase in execution is more obviously visible in function throughput, shown in Fig. 3, as a sharp drop of the throughput. From the figure it's visible that for datasets with fewer items, the throughput increases with increasing number of items. Once the dataset exceeds a certain number of items (dependent on number of attributes), throughput drops, and quickly stabilizes to an approximately constant value. As number of attributes increases, function throughput decreases, assuming equal

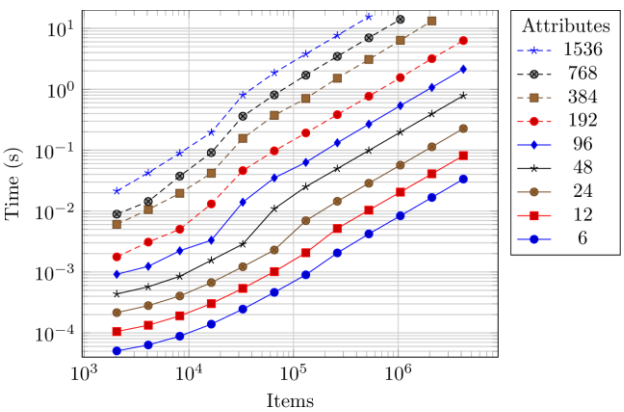

Figure 2. Execution time on CPU as function of number of items, measured for datasets with 6 to 1,536 attributes

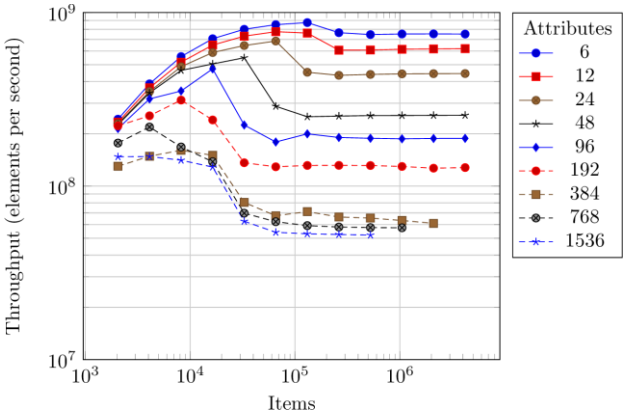

Figure 3. Throughput on CPU as function of number of items, measured for datasets with 6 to 1,536 attributes

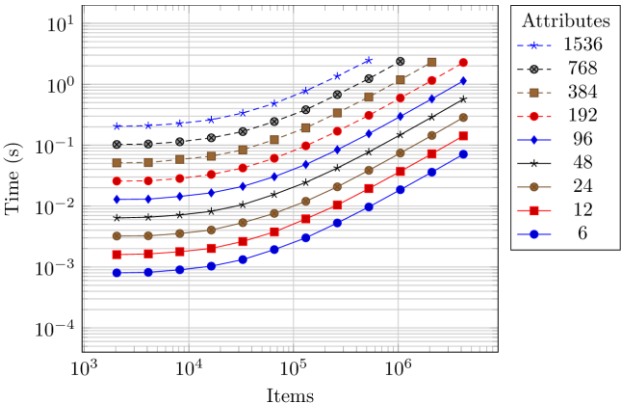

Figure 5. Execution time on DFE as function of number of items, measured for datasets with 6 to 1,536 attributes

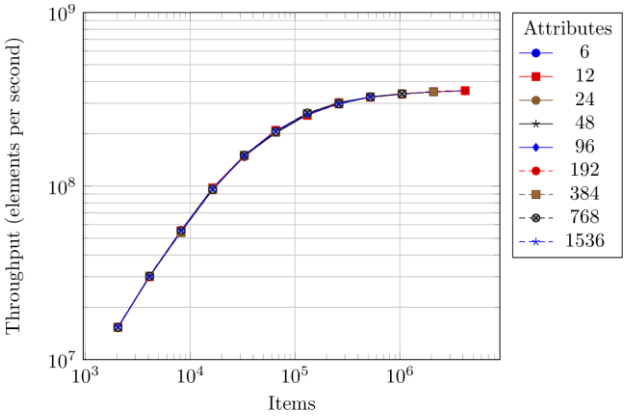

Figure 4. Throughput on DFE as function of number of items, measured for datasets with 6 to 1,536 attributes

number of items. The number of items at which peak throughput is recorded, also decreases with increasing number of attributes, as well as the peak throughput value itself. For datasets with 384 or more attributes, there is no increase of throughput. Throughput just drops from one approximately constant value to another.

Maximum measured constant (invariant to number of items) throughput is 617×10^6 elements/s, achieved on dataset with 12 attributes. Minimal measured constant throughput is 52.2×10^6 elements/s, measured on dataset with 1,536 attributes.

The drop in function throughput is most likely a consequence of interaction of CPUs cache system and main SDRAM. Smaller datasets have a smaller likelihood of cache miss, which translates into higher throughput for smaller datasets. Another important factor is the data structure for storing ht dataset. The dataset is stored in attribute major order, which leads to memory accesses with stride. With more attributes, the stride is larger, and consequentially, so is the likelihood of cache miss.

C. *DFE benchmark results*

DFE was benchmarked under the same condition as the six-threaded software implementation. Execution times measured on DFE are given in Table IV, and shown in Fig 4. Execution time on DFE scales approximately linearly with number of items in the dataset, on datasets with 512×2^{10} or more items. On datasets with fewer items,

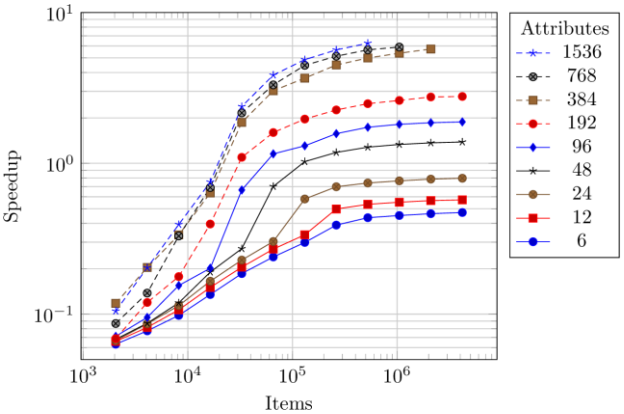

Figure 6. Speedup, measured for datasets with 6 to 1,536 attributes

the execution times asymptotically approach a certain minimal value, dependent on number of attributes. For a fixed number of items, the execution times scale linearly with number of attributes.

The kernel throughput graph, shown in Fig 5, shows that curves for all number of attributes form a tight group. The curves for different number of attributed cannot be distinguished one from another. On datasets with 512×2^{10} items, the throughput is approximately constant at 340×10^6 elements/s. The measured throughput is close to the theoretical maximum of 360×10^6 elements/s.

The DFE performs better with datasets with larger number of items, close to theoretical maximum when number of items is 512×2^{10} or more. This is a consequence of communication and control overheads between the DFE and the host computer. The overhead is independent from number of items, and its influence diminishes as the number of items increases. As can be seen from Table IV, execution times are approximately constant for datasets with 8,192 or less items. The minimum DFE execution time was calculated from these measurements, amounting to 801.1 µs.

D. *Comparison of the results*

DFE and CPU results were compared by computing speedup, i.e. ratio of execution times on CPU and on DFE. The speedup is shown in Fig 6. For most of the test dataset sizes, execution on DFE is slower than on CPU. For datasets with fewer than 48 attributes, the DFE is slower no matter what the dataset size is. For 48 attributes the speedup exceeds unity value for numbers of items 128×2^{10} or more. The maximum speedup is achieved on datasets with 384 and more attributes. Speedups on these datasets are close in value, suggesting that by further increasing number of attributes will result in negligible increase in speedup. These values can then be used as approximation of the upper bound on speedup. The maximum speedup measured is 6.26×, achieved on dataset with 1,546 attributes and 512×2^{10} items.

The total performance of the DFE was estimated by calculating the weighted average of speedups, weighted by number of elements in the dataset:

TABLE III. MEASURED EXECUTION TIMES ON CPU

Number of items	Number of attributes / Execution time								
	6	**12**	**24**	**48**	**96**	**192**	**384**	**768**	**1,536**

524,288	4.215 ms	10.35 ms	28.61 ms	98.80 ms	267.1 ms	766.7 ms	3.079 s	6.987 s	15.44 s
1,048,576	8.365 ms	20.48 ms	56.80 ms	197.3 ms	537.8 ms	1.553 s	6.359 s	14.01 s	–
2,097,152	16.70 ms	40.80 ms	113.3 ms	394.1 ms	1.071 s	3.176 s	13.21 s	–	–
4,194,304	33.49 ms	81.27 ms	226.3 ms	787.0 ms	2.139 s	6.303 s	–	–	–

$$S = \frac{\sum_a \sum_n a\, n\, s_{a,n}}{\sum_a \sum_n a\, n} \quad (1)$$

where S is the average speedup, and $s_{a,n}$ is the speedup on dataset with a attributes and n items. The average speedup is 4.1.

For further comparison, execution efficiency was computed for CPU and DFE. The efficiency is defined as:

$$E_{a,n} = \frac{m\, f}{F_{a,n}} \quad (1)$$

where $E_{a,n}$ is efficiency and $F_{a,n}$ is throughput for dataset with a attributes and n items, f is clock frequency, and m is number of threads or number of streams on CPU and DFE respectively. Peak throughput values were used to calculate efficiency.

The software implementation (CPU baseline) was executed on six threads, on CPU clocked at 3.2 GHz. Peak throughput was 875×10^6 elements/s. The DFE uses six streams, and was clocked at 300 MHz. Peak throughput on DFE was 355×10^6 elements/s. Execution efficiency on CPU is 21.9 clock cycles per element, and on DFE it's 5.08 clock cycles per element. Of the 5.08 clocks, 4 are consequence of the frequency counter's internal loop latency.

V. CONLUSION

In this paper we presented a multi-streamed compute architecture for 2D frequency matrix computation, implemented on FPGA platform. This multi-streamed architecture is an advancement on our previous work [10].

Benchmark results reveal that CPU outperforms DFE for smaller datasets. This is a consequence of control and communication latencies between the FPGA board and the host computer. Minimal time required to execute any action on DFE is approximately 800 µs, regardless of dataset size. Small datasets are easily processed by the CPU in less time. The DFE outperforms CPU for larger datasets, that have at least 48 attributes, 32×2^{10} items, and 6×2^{20} elements. Best speedup achieved by DFE is 6.26×. The DFE is more efficient in processing data, requiring only 5.08 clock cycles per dataset element, while CPU requires 21.9, when performing at peak efficiency. Of the DFE's 5.08 clock cycles, 4 cycles are consequence of frequency counter's internal loop latencies.

The kernel can be further improved by vectorizing inputs stream in the same manner its output was vectorized. This will allow efficient processing of more

elements in parallel, and better utilization of available memory bandwidth. Another improvement would be reducing or eliminating the internal loop latencies. This can potentially quadruple its performance assuming that operating frequency of the kernel does not drop due to higher design complexity.

In future work, in addition to the stated improvements, this kernel will be integrated in the C4.5 program as accelerator unit. However, to achieve significant performance gains the communication latency between host computer and FPGA will have to be compensated for. This will most likely involve adding support for batch processing of a series of small dataset, and require some modifications of the original algorithm. Overall, with additional improvements the kernel is expected to outperform the CPU for a wider range of dataset sizes.

ACKNOWLEDGMENT

The research leading to these results has received funding from the European Union's Seventh Framework Programme (FP7), under grant agreement no. 317882 – E2LP Embedded Computer Engineering Learning Platform.

***Abstract*—Although many companies and universities migrated their services, applications and data on the cloud, still significant part did not move yet, due to variety of reasons. Migration to other platform can cause the client many problems, and several directions have emerged to automate it as much as possible.**

P-TOSCA is a recently proposed Platform as a Service (PaaS) extension for TOSCA for automated application portability. In this paper, we demonstrate the migration of an application with most common N-tier architecture from on-premise to cloud, as well as from one cloud to another, by using P-TOSCA portability model, the development of application topology and execution plan. Although the presented demo was tested to migrate and transfer an N-tier application to Eucalyptus and OpenStack open source clouds, this model and procedure can be used for automated migration and transfer among any open standard that supports PaaS and P-TOSCA application specification.

***Index Terms*—*Automated management*; *Cloud*; *Portability*.**

I. Introduction

Several years after Amazon promoted the first cloud, IT managers had a dilemma whether to migrate their IT systems to a cloud. It was a new emerging concept with many challenges, such as security, trustworthiness, how to choose an appropriate cloud service provider, vendor lock-in or migration cost [1] and problems. Some challenges are mitigated. For example, almost all most common cloud service providers implemented information security management system [2], defined strict SLAs with several "nines" for their availability, free trial accounts, thus improving the trustworthiness with their customers.

Raising new cloud service providers with new and improved cloud services, transformed the dilemma *whether to migrate* into *when to migrate* to a cloud. Unfortunately, some challenges remained, such as automated portability. This means to migrate an application to a cloud neither with changing the application, nor server configuration, nor the new operating and cloud environment [3]. The automated portability will mitigate the risk of vendor lock-in [4] for the applications that are built on open standards. This will allow a customer to easily migrate to the cloud, transfer from one cloud to another, or even migrate back to its premise, without concerning the cloud platforms, infrastructures, APIs etc.

Recently, Kostoska et al. [5] identified several weaknesses and ambiguities of TOSCA, and promoted the P-TOSCA model as an extension of the TOSCA 1.0 standard [6], which can be used for portable cloud services [7]. P-TOSCA is used to describe a PaaS application specification and for automatic porting it to cloud environment. In this paper, we demonstrate how an N-tier application analyze the PaaS applications hosting portability regardless of their deployment model, whether they are public or private, as long as they integrate the open standards or use standardized (Application Programming Interfaces) APIs.

The rest of the paper is organized as follows. Related work in the area of cloud application portability is elaborated in Section II. Section III describes the P-TOSCA and definition and procedures of porting the N-tier application. Evaluation of results and discussion are given in Section IV, while the contribution of our work and plan for our future work in Section V.

II. Related Work

In the area of cloud portability standards there are few active working areas. Two standard oriented researches represent Open Virtualization Format (OVF) and Topology and Orchestration Services for Applications (TOSCA). The Distributed Management Task Force (DMTF) suggests the OVF [8], which specifies transport mechanism for moving virtual machines from one hosted platform to another and between different hypervisors. TOSCA defines a portable and manageable specification of services and applications that can be deployed on any cloud provider.

The TOSCA standard is research interest in many directions. OpenTOSCA, approach defined by Binz et al. [9], represents execution environment that offers imperative processing of the TOSCA. Other directions include modeling tools for TOSCA like Vino4TOSCA and Winery [10], [11], as well as TOSCA topology specification [12], [13].

Other efforts in the area of standardization are delivered by IEEE Cloud Computing Initiative (CCI), where two new standards are in progress: Cloud Portability and Interoperability Profiles (CPIP) [14] and Standard for Intercloud Interoperability & Federation (SIIF) [15].

Other researches propose introduction of abstraction-driven approach. In this area Ranabahu et al. [16] use an abstraction-driven approach to specify solutions. This approach is used in two research projects using Domain Specific Language (DSL). Hill and Humphrey [17] develop a storage abstraction layer

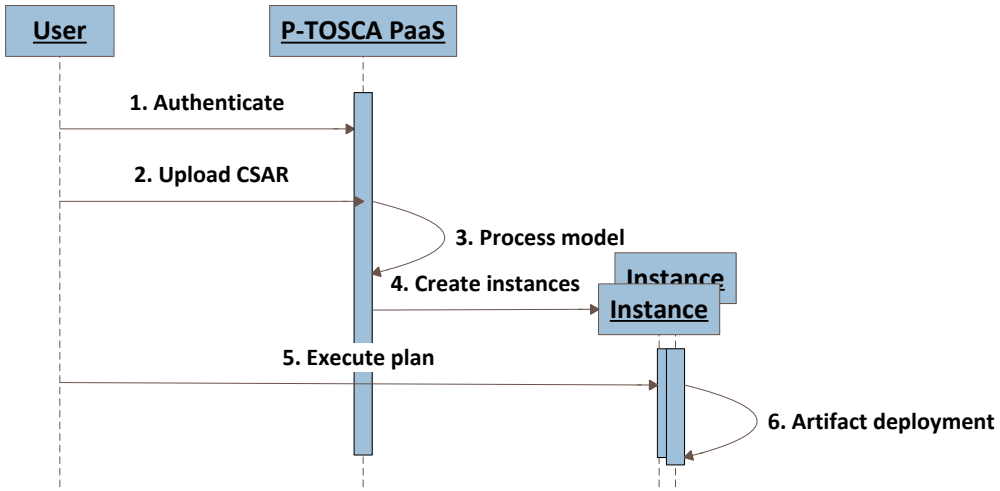

Fig. 1. Migration procedure using P-TOSCA PaaS deployment

(CSAL) that provides Blob, Table, and Queue abstractions. This approach is centered on the cloud storage and can be used in addition to another approach that solves application portability.

Usage of semantic technology is also popular approach. Loutas et al. [18] focus on this technology to enable deployment, migration and interoperability of PaaS hosted applications. Cretella and Di Martino [19] propose an approach that aims at automatic analysis of cloud vendor APIs. Petcu et al. [20] exploits the this technology to create a new set of APIs and to enable functional portability through the vendor-agnostic API and data portability through the use of drivers for the same type of data

In our previous research we demonstrated porting of a simple SOA application by using the P-TOSCA model and P-TOSCA engine [21]. In this paper, we present how to describe an N-tier application and migrate from on-premise to two different cloud environments, as well as to transfer the application from one cloud to another.

III. Cloud application portability based on P-TOSCA

This section describes the N-tier application and the P-TOSCA specification for its porting.

A. About P-TOSCA

The P-TOSCA model [5] enables:

- better description of application topology and
- definition of specific cloud properties,

in addition to the original TOSCA specification.

The application topology, which contains the types, templates and artifacts, are described by XML file. Additional files (artifacts) represent files needed for The information about the application deployment and configurations (scripts, libraries, wars or zips) are stored in other files called artifacts. The specification and the required artifacts are packed in a Cloud Service Archive (CSAR).

1) Application migration: The detailed procedure of migration is presented in Fig. 1. The first step is the client authentication, and then upload the CSAR archive in the step 2. The P-TOSCA PaaS platform processes the model and contacts the cloud controller to create instances (it is an N-tier application and need at least two instances). After creation of the instances, the user selects the plan for execution, followed by artifact deployment.

2) Application transfer from one cloud to another: This procedure differs of the migration at the first steps. After the authentication to the target P-TOSCA cloud, the user does not upload the CSAR, but he/she selects the hosted application and specifies the source and destination clouds. The CSAR is requested by the source and sent by the destination automatically between P-TOSCA. After unpacking the CSAR, the destination P-TOSCA creates instances, deploys the artifacts and acknowledges the user for finished transfer of the application.

B. N-Tier application

The application is a Java MVC student records management application. The selected application is a 2-Tier application (database and application server), but the model can be generalized for 3- or 4-Tier application. The first tier is a database tier and it is installed with MySQL DBMS to host a databases. The second tier consists of the presentation and logic tiers. It is installed with Tomcat web application server, to host the application.

C. P-TOSCA topology description for the N-Tier application

We have generated the topology description for the N-Tier application.

The generated *Node Types* (base, specific and custom) for this application are shown in Fig. 2. It is specified by three main categories:

- *Base type* - requires basic components (operating system, web server, web application, database and DBMS);

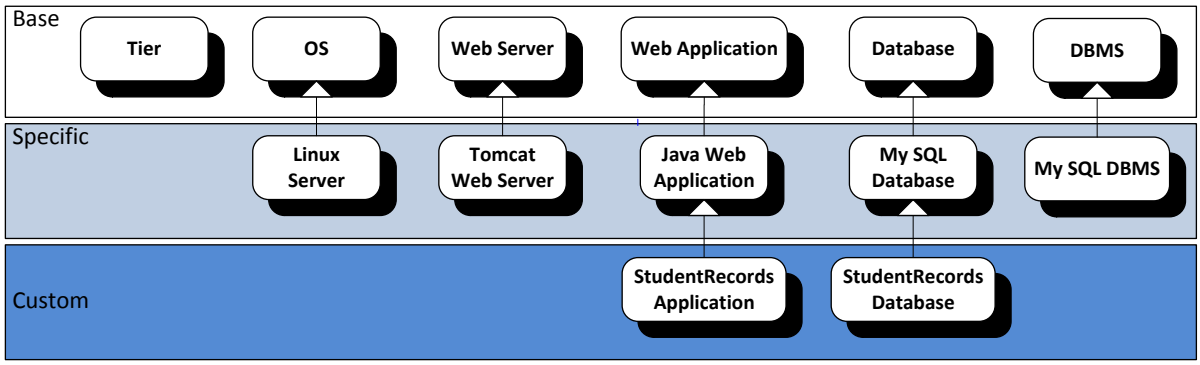

Fig. 2. *Node Types* and their hierarchy for Student Records (N-tier) application

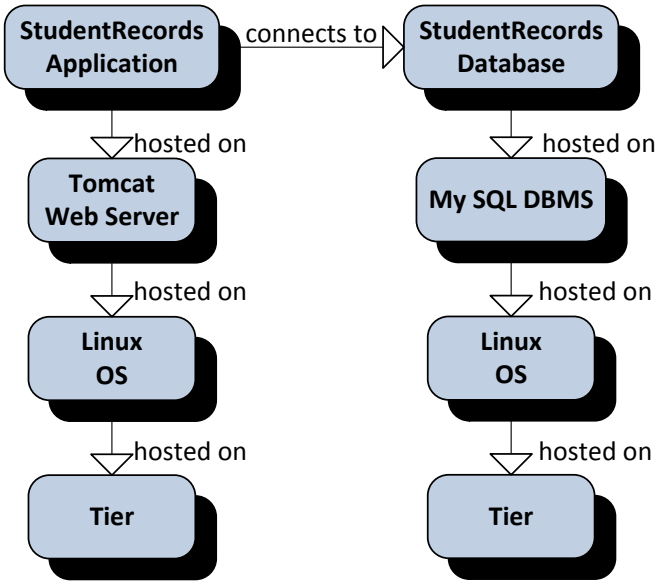

Fig. 3. Topology template for Student Records (N-tier) application

- *Specific type(s)* - requires application topology (Linux operating system), Tomcat web server, Java Web Application, MySQL database and MySQL DBMS); and
- *Custom node types* - defines specifically developed application components.

The *Topology Template* defines the topology elements (nodes) that the application is consisted of. Each node is specified by node template and is defined (i.e. type of) given node type. The *Topology Template* presented in Fig. 3, which shows the topology of the application.

Each node of the topology is specified by a node template, and the relationships between the nodes are specified using relationship templates. Same as nodes, the relationship types are initially set in the specification and each relationship template specifies the type of relationship.

The information about the infrastructure (required instance for application and security protocols and port settings) is defined in Table I. Listing 1 presents the XML Tomcat Tier node template definition.

TABLE I
TIER NODE TEMPLATE DEFINITION

Server property	value
Number of CPUs	2
Memory size	2 GB
Disk size	10 GB
Initial instances	1
Security rule protocol	TCP
Security rule ports	80, 443

TABLE II
LISTENING PORTS OF THE TOMCAT SERVER

Server property	value
HTTP port	80
HTTPS port	443

Table II defines http and https ports where the Tomcat server listens for request, while Listing 2 defines the TomcatWebServer Node template definition.

Values for artifact template for configuration of Student Records (N-tier) application are given in Listing 3. The configuration script requires input parameters for location (IP address) of the database server, as well as username and password required for the connection string to the database.

The CSAR is a zip archive that packs:

- all node and template definitions,
- Tomcat installation and deployment artifacts,
- MySQL installation and deployment artifacts,
- application deployment artifact, and
- database deployment artifacts.

IV. EVALUATION OF THE RESULTS AND DISCUSSION

This section presents the testing environment and testing data and evaluates and discusses the results of the migration from on-premise to both cloud environments and transfer from one to the other cloud environment.

A. Testing environment

The testing environment consists of two open source cloud frameworks:

```
<NodeTemplate id="VmTomcat" name="VM for Tomcat"
    type="Server">
      <Properties>
       <ServerProperties>
            <NumCpus>2</NumCpus>
            <Memory>2048</Memory>
            <Disk>10</Disk>
            <InitialNumInstances>
                  1
            </InitialNumInstances>
            <ServerSecurityProperties>
           <ServerSecurityProperty>
            <protocol>
                        TCP
                  </protocol>
            <port>
                        80
            </port>
           </ServerSecurityProperty>
           <ServerSecurityProperty>
            <protocol>
                        TCP
            </protocol>
            <port>
                        443
                  </port>
           </ServerSecurityProperty>
          </ServerSecurityProperties>
       </ServerProperties>
      </Properties>
      <Requirements>
        ...
      </Requirements>
      <Capabilities>
        ...
      </Capabilities>
</NodeTemplate>
```

Listing 1. Tomcat Tier node template definition

```
<NodeTemplate id="TomcatWebServer" name="Tomcat Web
    Server" type="TomcatWebServer">
      <Properties>
            <httpport>80</httpport>
            <httpsport>443</httpsport>
            <username>x</username>
            <password>x</password>
      </Properties>
      <Requirements>
        ...
      </Requirements>
      <Capabilities>
        ...
      </Capabilities>
</NodeTemplate>
```

Listing 2. TomcatWebServer Node template definition

- OpenStack cloud, which is installed with Ubuntu 12.04.3 LTS on one server with both cloud and node controller), and
- Eucalyptus cloud, which is installed on three servers, each with CentOS 6.5: one for the node tier - node controller, and two for cloud tiers - cloud and cluster controllers).

Fig. 4 depicts the cloud environments. More servers are used for Eucalyptus since it is more scalable than other open source clouds [22]. All physical servers of both clouds are the same, each containing 4 cores CPU and 4GB RAM. Internal networks are isolated from external. Public (float) networks of both clouds are isolated in separate VLANs [23], and since they are private IP addresses, they are NAT-ed to Internet through router.

Each experiment is conducted five times and average values are presented.

```

                      <InputParameter
                          nodeTemplateId="VmMySql"
                          property="ServerIPAddress"/>
                      <InputParameter
                          nodeTemplateId="VmMySql"
                          property="DBuser"/>
                      <InputParameter
                          nodeTemplateId="VmMySql"
                          property="DBpass"/>
                </InputParameters>
          </Include>
    </ArtifactReference>
   </ArtifactReferences>
</ArtifactTemplate>
```

Listing 3. Artifact template definition for Student Records application configuration

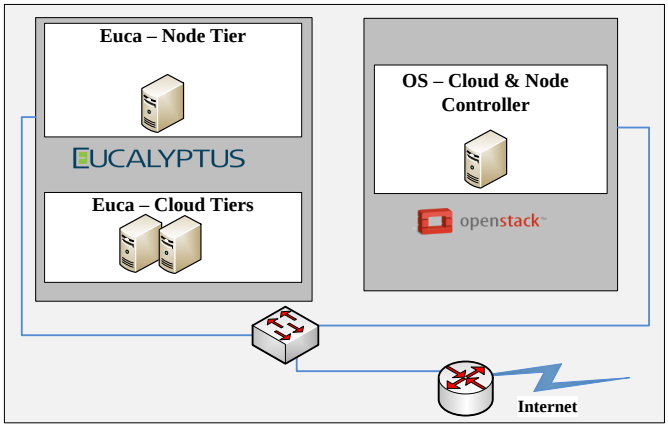

Fig. 4. Cloud environments for OpenStack and Eucalyptus

B. Evaluation and discussion

The evaluation of the migration and transfer using P-TOSCA model is presented in Table III.

First of all, all four experiments were successful, that is, migration from on-premise to OpenStack and Eucalyptus

TABLE III
TIME EVALUATION OF PORTING THE N-TIER APPLICATION

Source	Destination	Value (sec)
Eucalyptus cloud	OpenStack cloud	269
OpenStack cloud	Eucalyptus cloud	237
On-Premise	Eucalyptus cloud	1136
On-Premise	OpenStack cloud	1202

clouds, as well as transfer of the N-Tier application from OpenStack to Eucalyptus and vise-versa were successful on each cloud environment.

Migration to OpenStack takes almost 6% more time than to Eucalyptus, due to better Eucalyptus' architecture. Similar to migration, transfer of the application is also faster for 13.5% from OpenStack to Eucalyptus, rather than from Eucalyptus on OpenStack.

Finally, we observe that migration is much slower than the transfer between the clouds, which is normally since the former requires upload of CSAR from outside network.

V. CONCLUSION AND FUTURE WORK

This paper demonstrates the proof-of-concept and a procedure for porting a typical N-tier application neither with changing the application nor source nor target environment. A P-TOSCA model of a typical N-tier application is defined.

Two demo scenarios are presented: migration from on-premise to two different clouds Eucalyptus and OpenStack, and transfer the application from one cloud to another. Not only that the porting is proved, but it is conducted in a reasonable time, even with definition of the P-TOSCA specification. That is, after preparing the P-TOSCA specification of an application, it can be used for efficient porting to a cloud. This portability demonstration can be generalized if an application is portable and uses open standards.

This is only a starting point for automated porting of an application of any type. Our further research will be to define and conduct the porting of other type of applications, such as software oriented architecture, and on other open source clouds. Special focus will be on improving the performance and definition of security rules.

ACKNOWLEDGMENT

This work was partially financed by the Faculty of Computer Science and Engineering at the "Ss. Cyril and Methodius University", Skopje, Macedonia through the project XaaSinCloud.

The iKnow project has been developed as a part of the Tempus JPGR 511342 Project.

***Abstract*—With the development of various cloud technologies and their increased usage, the newly arisen challenge is the migration of a cloud-based application and data among various cloud environments and vendors. In the absence of a standardised mean by which full portability can be achieved, various tools exist in the form of APIs, standards, and protocols. In this paper we conduct an overview of the state of the art regarding the topic of migration and portability of cloud-based applications, in order to determine the possible challenges that today's technologies might have, as well as to find the most appropriate automated way to port an application from one to another cloud, or to migrate an on-premise application to the cloud.**

***Keywords*-Cloud Computing, services, standards.**

I. Introduction

The increase of usage of cloud computing technologies also introduces the existence of various clouds framework softwares that operate separately. Portability implies the ability to use software components across multiple different hardware and software platforms and environments. In this paper, portability between clouds, is defined as the ability to smoothly and fluently transfer a software component, application, service or data into another cloud environment, ensuring undisturbed continuity and elasticity.

As the current trend implies the usage of cloud services, the cloud consumers should be offered the possibility to use services across different clouds, whether it is to simply migrate to another cloud or seek an on-demand scaling of resources by expanding their system onto external resources, outside the native cloud where their application or service resides [1].

Various different approaches have been taken to explore the possibilities of theoretically and practically achieving some level of portability of an application between clouds. These efforts range from scientific papers which offer ideas and overviews, to proof-of-concept implementations or models, to even commercial products. Most groups stress the importance of such a study, given the fact that portability is still one of the greatest and most important obstacles that hinder the increase of adoption of cloud technologies [2].

The aim of this paper is to produce an analysis of the state-of-the-art efforts and their approaches in cloud portability, including their structure and a study of their respective APIs. Furthermore, the paper presents a study of the structure of web and cloud based applications. Lastly, conclusions are drawn regarding the current efforts which identify the weak points in the approaches attempted today.

This paper is separated into several sections which explain the following. Section II elaborates the need for cloud portability and clearly outlines the difference between portability and interoperability. In addition, it outlines the architecture of web applications, as the most common type of application in the cloud computing service market, and compares it to the architecture of the cloud applications with the intention to understand the transition process during the migration process. Section III introduces an overview of the state-of-the-art efforts that attempt to achieve cloud portability, elaborating upon TOSCA, mOSAIC, AWS CloudFormation as well as Heat. Lastly, Section IV draws the conclusions, along with our plans for future work.

II. Motivation and Background

The cloud is a rapidly developing technology that bases its greatest advantages upon the ubiquitous network access to a shared and virtualised set of hardware and software resources. These resources can be numerous and of various nature, most of which including processing, network, storage, message transport and queuing, all of which can be provisioned. The existence of various resources that make up the cloud computing model leads to a different cloud structure depending on the implementation of each of the aforementioned resources. The current software stacks of most cloud services are very heterogeneous and therefore the features each of them provide offer varying levels of incompatibility between each other. This kind of a heterogeneity is a great obstacle in the face of the demands of the cloud consumer as well as the vendor, and can be both seen as an issue with portability and interoperability [3].

A. Difference between cloud portability and interoperability

Cloud portability and cloud interoperability are very frequently seen as synonyms that share the same concept, mainly because numerous solutions solve both, even though originally have been intended for one of them. Still, these two concepts have their differences which will be elaborated below.

Cloud interoperability ensures the simultaneous and mutual work of diverse cloud services, data and application. Primarily it is a concern among cloud service providers, who must offer fluent functionality of the services they offer with the external world, be it public clouds or other cloud providers. This kind of a concept implies a previously specified knowledge of both systems, including agreements upon which the systems will interoperate. While the cloud service providers work to maintain

the interoperability between the systems, the cloud customers are usually entirely unaware of these added functionalities.

On the other hand, cloud portability is a concept that also concerns both the cloud customer and provider. By definition, it deals with the minimization of the human efforts when migrating an application, data or service from one cloud to another, which in turn lessens the need for re-designing and re-writing parts of the application. This way, cloud consumers are able to not only run instances of their application on multiple clouds, but also use external resources [4].

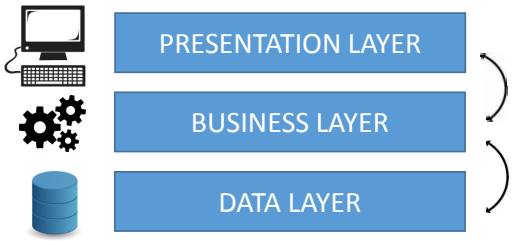

Fig. 1. Three layer architecture.

B. Motivation

1) Economic reasons: Portability within the cloud is necessary from an economic aspect for several reasons. On one hand, the customers of the cloud would gain protection over their investments in their application developments. Due to the heterogeneity of the cloud, the migration of a software application, along with its data, from one cloud to another often requires the rewriting of large parts of both the services and the application, all in order to comply with the new environment to which the application is migrating. On the other hand, the cloud service providers would be interested in enhancing the opportunity for application portability in order to promote their own attractiveness within a highly dynamic and demanding market. In addition, the need for portability also allows the development of third party organisations which would be able to mediate between the cloud customer as well as multiple cloud providers. This kind of arrangement would enable deployments depending on the customer's requirements, and all kinds of necessary adaptations would be provided by the third party.

2) Technical reasons: From a technical point of view, cloud portability is of immense importance in order to exploit cloud elasticity to a maximum extent, as well as to ensure the continuity in a given application along with its functionality of a service. Throughout a lifetime of an application, a point might come at which external resources are required from a public cloud, and so it needs to be redeployed from a private cloud. This kind of a porting process is triggered by the cloud customer. Furthermore, in order to achieve continuity, precaution measures such as regular back-ups must be made, not only of data, but of application instances as well. This implies that an application must be able to use various cloud services which in turn will aid the replication of the application as well as its data. This kind of a porting process is most commonly in accordance to the provider's agreements, and is usually considered in the design phase.

3) Legal reasons: The laws within a country may change rather abruptly, triggering the need for software to be deployed from one cloud system to another. A cloud service provider may also provide faulty service which in turn would call for immediate redeloyment of applications on another cloud platform. In this sense, efficient portability mechanisms are essential for fast recovery. Situations like the aforementioned one are also attempted to be avoided by creating contracts which guarantee a sufficient contingency plans if the cloud provider fails. These can only be provided if portability between various cloud services exists. In addition, contracts between parties may also demand the usage of certain metrics which measure the quality of the cloud's performance, including its portability, which in turn reveals the demand for a metric system that can assess the level of portability within a cloud [5].

C. Components of cloud applications

While the applications in the cloud computing service market range in nature, the most successful ones are the web applications. Understanding the differences between web applications and Cloud applications is essential for the development of a solid transition process from web applications to cloud applications.

The structure of a traditional web 2.0 application heavily relies upon a three layer architecture which allows numerous benefits, as well as drawbacks in some instances. For example, the separation of the layers into presentation, logic and data outlines the application into parts which interact with each other, but are essentially disjunct Fig. 1 [6]. If a certain application is made up of several components, then this kind of a separation in layers greatly aids the connectivity between the components, allowing layers to interact with their respective layer. On the other hand, this architecture runs into a problem when the need for scalability and elasticity escalates. The design patterns that are used in its development are most commonly adapted for a limited number of users. The data in these applications is also often used in databases which have difficulties scaling or replacing in the events of failure, and any change in their schema requires the disruption of the continuity of the application life.

A cloud application is expected to have an unpredictable load and a much larger user base that would exploit the elasticity of a system. The transformation of a web application into a cloud application requires a general architecture of a cloud application. Petcu et al. [7] propose an architecture form presented in Fig. 2. There are numerous commercially available APIs that aid the developers with the building of applications. Some of which attempt to hold to the outline of the aforementioned multi-layer cloud application architecture. TOSCA and mOSAIC specifically offer APIs which facilitate the development of portable and interoperable cloud applications.

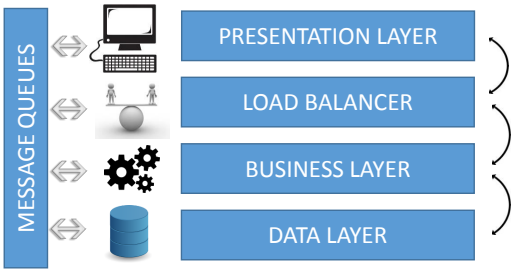

Fig. 2. Cloud application architecture.

III. Overview of current standards

There have been numerous efforts at researching as well as implementing some of the standards that are already out on the market, most of which free to use and require no royalty compensation if applied. Most of these are independent projects developed by either organisations or companies and have not yet been widely adopted [8] [9] [10].

In this section several of these solutions are elaborated, describing their structure and methodology, as well as the basic outline of their APIs and how they can be used. Some of them are presented in greater detail with the aim to portray the contact points with the developer, explaining in detail how their architecture aids the portability and interoperability of cloud applications.

A. CAMP

One of the very few steps that need to be taken towards an enhanced interoperability is the unification of management interfaces across several cloud infrastructures. OASIS proposes the Cloud Application Management for Platforms (CAMP) standard, which is a specification designed to ease the management of applications across PaaS. CAMP specifies a RESTful self-service application and a platform management API, which is neutral in several aspects, including the language, framework as well as platform. Its expectations primarily lie in the creation of an ecosystem filled with common tools, plugins, libraries and framework, which then offer vendors increased performance when it comes to interoperability between clouds [11].

The aforementioned CAMP API is made up of a resource model and a protocol that is used to manipulate the resources remotely. The resources contained in the resource model are generally separated into a Platform, Assemblies, Platform Components and Application Components. Excluding the Platform, all of these resources can exist in an instantiated and in a deployed form. The platform type of resource describes a PaaS as a whole and references all applications on the platform, allowing the discovery of the other existing Platform Components. These platform components can be database services, web services etc. An Application Component is an artefact, such as source code or metadata which can use other Application Components, depending on its respective Platform Component. Finally, an Assembly is a resource that represents an application by referencing the components it is composed of, allowing management at runtime [12].

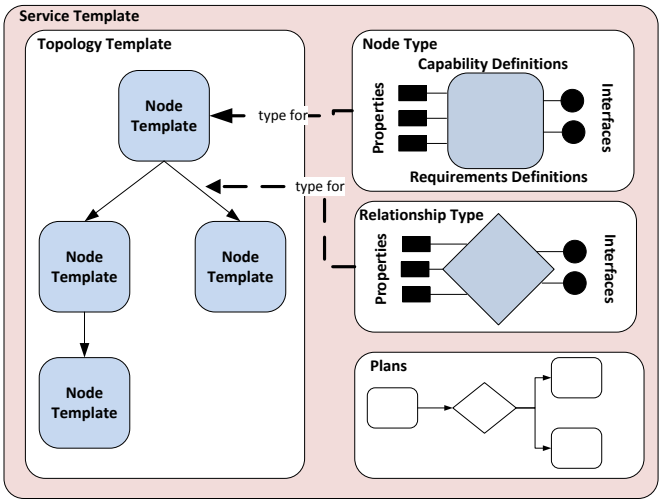

Fig. 3. Tosca service template.

B. TOSCA

TOSCA, Topology and Orchestration Specification for Cloud Applications, is created with the aim to enhance the portability specifically for cloud applications and services. TOSCA enables the interoperable description of applications and the infrastructure cloud services, the relationship between various components of the service, as well as the operational behaviour of these services. All of the aforementioned are independent of the suppler that creates the service, including any particular cloud provider or hosting technology. OASIS ensures that increasing the service and application portability within a vendor-neutral ecosystem, TOSCA enables a portable deployment to any compliant cloud, easier and more intuitive migration of existing applications to the cloud as well as offering dynamic, multi-cloud provider applications.

As opposed to CAMP's limited functionalities that deal with portability and orchestration, TOSCA is superior as it proposes a more comprehensive approach. This industrially-endorsed specification allows the software components of an application along with their respective relationship and management procedures to orchestrate basic operational behavior (deployment, patching, shut down), using descriptions based on the specified XML-based language which ensures a high level of universality and interoperability [13].

TOSCA introduces Service templates which are a concept used to specify the topology and orchestration of IT services. This mainly refers to the structure and invocation of management behavior within the service. The general structure of a Service template can be seen in Fig. 3, encapsulating a Topology Template which describes the structure of an application. In addition, this Topology template is a directed graph consisted of a set of Node Templates and Relationship Templates.

A node in this graph is represented by a Node Template which specifies the occurrence of a Node Type as a component of a service. A Node Type defines the properties of these components and the operations available that have the opportunity to manipulate the component.

A Relationship Template, on the other hand, specifies the occurrence of a relationship between the nodes in the Topology template. Each Relationship Template contains a Relationship Type which defines the nature of the relationship as well as any properties that belong to it. These are most commonly defined separately so they may later be reused [14].

The first available open source tool was first published in 2013 through the OpenTOSCA initiative. A modelling tool called Winery [15] was published, which allows the definition of a cloud application topology using a web GUI. An initial version of the TOSCA container infrastructure was also released. Kostoska et al. [16] pointed the benefits and drawbacks of TOSCA specification. The P-TOSCA was introduced as an extension of TOSCA to overcome several TOSCA's drawbacks. Using P-TOSCA, porting of a small SOA [17], [18] and N-tier application [19] was conducted.

Though a relatively new standard, TOSCA has been offered for implementation on a free basis, and various companies, non-profit organisation, academic institutions, individuals including governments have already attempted to implement their applications using this specification. Numerous companies which are world leaders in the IT industry, such as ASG, Fujitsu, HP, IBM, SAP and others, congratulate this specification as an advancing of higher levels of interoperable and portable cloud solutions [20].

C. mOSAIC

mOSAIC is an open source API and platform that ensures the portability and interoperability between multiple clouds. While the API is the key element that ensure smooth portability, the platform offers numerous features, which aid the portability of an application.

In short, mOSAIC's intention is to aid the cloud application developer build an application that is easily portable between different clouds, as well as offer guidance as to which are the proper resources required to run an application. Moreover, mOSAIC also offers a software platform including a set of application tools, a semantic engine, a cloud agency as well as a service discoverer. The main issue that mOSAIC attempts to resolve is the one of the developer of the cloud application. Instead of worrying about implementing the application for a specification of a particular cloud, the developer can only focus on the development of the application using mOSAIC's API, and later on deploy the application on any cloud the developer wishes. Therefore, the application's portability and elasticity are ensured and the developer has a choice of a programming language of implementation.

mOSAIC offers several layers of abstraction which in turn ease the development of cloud applications. Separating the abstraction into various layers, the developers are able to assemble an application based on several components with

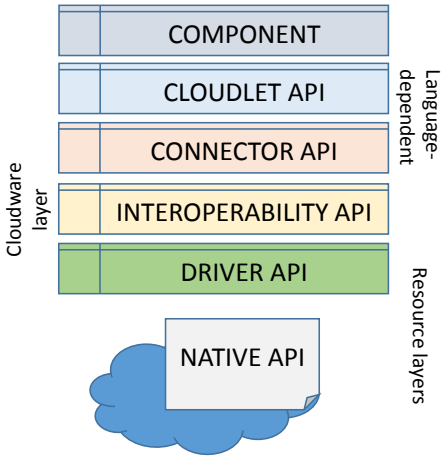

Fig. 4. mOSAIC's API layers.

defined properties and relationships, previously described by an application descriptor which is used in the lower ends of the deployment process. An Eclipse plug-in, if the developer uses Java, for instance, will define the graphical interface of the application, generating its own code which is then passed onto higher levels of development. In addition, a layer of abstraction is also designed for the owners of existing applications who intend to deploy the application onto other clouds. First parts of the application must be rewritten to comply with mOSAIC's requirements, which in turn allows for the smooth deployment onto multiple clouds. Lastly, two separate layers of abstraction deal with debugging, testing and manual control of the resources, as well as billing purposes [10].

Fig. 4 presents the layers of the mOSAIC APIs intended to support the cloud components' development and communication. Applications that use mOSAIC are made up of configurable Cloud Building Blocks which have the abilty to communicate between each other. These building blocks can be either a Cloud Resource or a Cloud Component. Cloud components are controlled by the application developer and follow the implemented behaviour which defines its functionalities.

As shown in Fig. 4, Cloudlet APIs are language dependent and provide standard programming components to the developer. The Connector API provides an abstraction for the cloud resources. Depending on the chosen programming language the developer of the application may interact with this API, or not at all. This API ensures the uniformity of the programming paradigms, assuming that the implementation of the connector API in an object oriented programming language generally have similar hierarchies and patterns. The Interoperability API as a member of the Cloudware layer aims to provide interoperability on programming language level, enforcing protocol syntax as well as semantics. Most often it enables Connectors to invoke operations that are enabled in the Driver API, without any knowledge of the technology

it supports. The Driver API, also known as a wrapper, has the role to wrap the native API and provide the initial level of uniformity. All cloud resources of the same type are processed and exported with the same interface. The Native resource API is most often a library provided by the cloud vendor and is usually language-dependent. This layer provides a very low level of uniformity.

In order to develop a fully mOSAIC compliant application, the developer is required to use the Cloudlet API which would ensure the scalability of the application, offer improved fault tolerance, and provide autonomy, in the sense that the components will be able to run in a cloud environment independent of other components. A Cloudlet Container is the host of a single Cloudlet, however it is possible to host several running instances of the same Cloudlet within the same Container. Each of these containers has a unique identifier which enables its identification during runtime. Therefore, it is not possible to distinguish between the different instances running in the same Container. Still, as a general rule, mOSAIC ensures that the functional behaviour of the Cloudlet must be independent from the number of instances or Containers [21].

D. AWS CloudFormation

AWS CloudFormation is an orchestration approach developed by Amazon, and as such it acts as a proprietary to the Amazon infrastructure. Using JSON templates, it describes a set of AWS resources, forming a stack. This stack, once created, can be managed as an entity. The AWS CloudFormation is able to automatically resolve dependencies. In addition, its primary aim is to orchestrate the creation of AWS resources which have previously been declared by the JSON templates, with the ability to connect these resources afterwards. This way, there is no need to specify management or deployment processes [22].

The AWS CloudFormation implies the work with templates and stacks. Templates are used to describe the user's AWS resources as well as their properties. This is most commonly done by saving the template with any extension compliant with the JSON standard (.json, .template, .txt), which can then be read by the CloudFormation and considered a guideline for building the specified AWS resource.

A stack, on the other hand, unifies and therefore manages related resources. The user can create, update and delete a set of resources by creating stacks and organising their resources within them. By modifying the stack or applying any changes to it, the resources that belong to the collection assigned to the respective stack are also changed [14].

E. HEAT

As one of the most popular cloud middleware software, OpenStack suggests its program, Heat, aimed to deal with orchestration. Heat is portable between OpenStack clouds, and it enables declarative infrastructure provisioning. It implements a cross-compatible AWS CloudFormation for OpenStack clouds, using multiple languages for describing templates. It provides a template based orchestration that describes cloud applications by executing appropriate OpenStack API calls which in turn generate cloud applications [23].

Like the AWS CloudFormation, Heat also introduces the usage of stacks and templates. These templates allow the creation of most OpenStack resource types, as well as some more advanced functionality such as instance autoscaling or nested stacks.

Heat generally uses two templates: HOT (Heat Orchestration Template) and CFN (short for AWS CloudFormatioN). The HOT template can only be used with OpenStack and is not backwards compatible with AWS CloudFormation templates. HOT templates are typically required to be expressed in YAML. CFN, on the other hand, are templates normally expressed using JSON [24].

F. IEEE P2301

The IEEE P2301 - Guide for Cloud Portability and Interoperabilty Profiles (CPIP) standard is a guideline written by the IEEE Computer Society. Its purpose is to assist cloud computing vendors as well as users in the processes of producing cloud systems with increased portability and interoperability based on standardized means and services. The guideline identifies various elements that Cloud Computing Systems possess and provides an enumerated group of portability, management, interoperability interfaces, file formats and conventions used for each of these elements. The guideline groups the suggested enumerations into logical entities which in turn increases the level of portability and commonality [25].

G. Unified Cloud Interface

Recognizing the high level of diversity among the numerous approached towards a standardized mean that increases Cloud portability, the Unified Cloud Interface Project (UCIP) has the goal of producing an API that uses all other API's that the Cloud systems provide as external interfaces. Since independent cloud systems provide both similarities as well as difference in the way fundamental and additional functionalities are implemented, the UCIP attempts to arive at a certain level of abstraction that's beyond the API of the Cloud API. The resolution of the heterogeneities between the cloud APIs and the existing protocols and standards is achieved through the usage of various ontologies as well as the Web Ontology Language (OWL) [26].

H. Open Cloud Computing Interface

With the establishment of the several cloud offerings, spanning the stack, ranging within the Information as a Service (IaaS), Platform as a Service (PaaS) and Software as a Service (SaaS). The Open Cloud Computing Interface (OCCI) comprises a large set of open specifications, offering a Protocol and an API for different types of management tasks. Initially the scope of the project were simply IaaS model based Serices, however it has developed into a rather flexible API with a focus on interoperability, innovation, integration and portability, while still holding scalability in a high regard.

Currently, all service models are covered by the API. Due to its high level of flexibility, many academic and industry giants currently support the OCCI.

IV. Conclusion and future work

Cloud portability is a well-recognised problem ever since the beginning of the cloud computing technologies. Different approaches for portability across multiple cloud platforms already exist, some of which in the form of standards, while others as platforms or APIs, proof-of-concept attempts etc.

Web applications are the most common and successful type of applications. Their structure heavily relies upon a three layer architecture that consists of a Presentation layer, a Business layer and a Data layer. The cloud application architecture assumes the existence of a Presentation Layer, a Load Balancer, a Business Layer, a Data Layer as well as Message Queues. The Load balancing layer acts as a distributor of requests through instances of the application in order to avoid overload, while the Message queues serve as communication pathways between each of the layers.

None of the existing approaches are widely adopted for several reasons. Firstly, most of them focus on a specific topic and attempt to excel achieving completeness in certain aspects of interoperability and portability. Secondly, the majority of cloud providers are reluctant to share their work as it provides a crucial advantage in their companies on the market. Lastly, despite the numerous attempts and approaches, there is no solution yet that envelops all aspects of portability and migration due to the great versatility of applications, platforms, services and languages.

Several additional approaches can be relevant for the future advancement in the field of cloud portability and interoperability. For instance, the introduction of global standards will enhance the number of implementations compliant with these standards, therefore increasing the likelihood of a unified portability solution. In addition, these standards can be made up to establish metrics, monitoring and security. TOSCA and CAMP are newly emerged standards which still have an increase of users, while ISO/IEC 27017 is a standard for the information security management for cloud systems and is currently in preparation [27]. Furthermore, the introduction of a limitation in the sphere of an architectural design for these portability solutions would help immensely with reducing the heterogeneity between each other. Limiting the architecture to several fixed levels of abstraction will provide greater room for automated and flawless portability, while reducing the room to implement exotic features which would hinder the smoothness of the solution.

In-Situ Anonymization of Big Data

Tomislav Križan, Marko Brakus, Davorin Vukelić
Poslovna Inteligencija d.o.o., Zagreb, Croatia
{tomislav.krizan, marko.brakus, davorin.vukelic}@inteligencija.com

Abstract - With organizations storing and even openly publishing their data for further processing, privacy becomes an issue. Such open data should retain its original structure while protecting sensitive personal data. Our aim was to develop fast and secure software for offline anonymization of (distributed) big data. Herein, we describe speed and security requirements for anonymization systems, popular techniques of anonymization and de-anonymization attacks. We give a detailed description of our software for in-situ anonymization of big data distributed in a cluster tested on a real Telco customer data record (CDR) dataset (dataset size is around 500 GB).

I. INTRODUCTION

Vast amount of data is being generated from versatile sources and organizations are primarily interested in analyzing it for further information and improved decision making. Data analysis surely leverages data value for the organization and opening data publicly benefits wider community and fosters further scientific research. However, analysis means disclosing data to other employees, third party organizations or even publishing it on the internet for everybody to use. Stored data is often secret, proprietary or protected by data protection and privacy laws and organization can suffer significant financial loss if that data is misused. Huge cost of data theft and misuse urged organizations to improve security measures and protect data.

Ideally, data would be void of any sensitive information which is protected by law while retaining all other information and structure valuable for further analysis. These sensitive parts of dataset need to be changed in a way to make it impossible or at least infeasible to trace the changed values back to the original ones. Such a transformation would ensure that confidential data, even when outsourced, published or stolen, could not be misused. *Anonymization* (de-identification, depersonalization, masking, obfuscation, etc.) is a process that changes or removes sensitive data while preserving its structure. It is considered successful if it is impossible or computationally infeasible to track original sensitive data from the anonymized dataset.

Anonymization is traditionally done on organizations' files, databases or centralized warehouses. Data is usually extracted from different sources, validated, transformed and loaded into databases. Due to nonstandard data demands, organizations employ newer *Big Data* technologies characterized by increased data volume (great data size), velocity (real-time and near real-time systems to meet high-speed data streams) and variety (lack of data structure). Such high volume of data should be processed preferably at velocity close to the one at which it was generated so that it can possibly be included in a data pipeline. Distributed environments and traditional centralized processing assume costly data movements (CPU time, network bandwidth and energy consumption) and additional vertical scaling on the place of processing. Therefore, data should preferably be processed at the same place where it was generated to avoid costly data movement. *In-situ* methods are inspired by such demands, where inter-node communication should be reduced. Thus, data movement should be minimized by doing computing locally where data was created. One of the most common applications of the in-situ processing is in visualization by doing rendering on the nodes where data was generated [1]. Also, in-situ method is appropriate for monitoring distributed environment [2] generating real time streams of data (network equipment, sensors, etc.).

In this work, we give a description of anonymization process which encompasses defining organizations' sensitive data, setting requirements for anonymization system, choosing appropriate anonymization techniques and considering their vulnerabilities. We then present our implemented solution for anonymization of Big Data inspired by in-situ data processing. It is exhibited how various aspects of Big Data are met with in-memory object store for high data volumes and fast messaging for inter-node communication. It is shown how the system is designed for anonymization of data at the nodes where data is

created by minimum client-server communication. Lastly, we present system performance measurements for anonymizing an example telco mobile customer data record (CDR) dataset in a distributed environment.

A. Types of Sensitive Information

Personal data [3] is defined as "any information relating to an identified or identifiable natural person ("data subject"); an identifiable person is one who can be identified, directly or indirectly, in particular by reference to an identification number or to one or more factors specific to his physical, physiological, mental, economic, cultural or social identity." Some examples of such data are: address, credit card number, bank statements, criminal record.

Sensitive data attributes/fields/columns/identifiers can be classified into several types regarding their sensitivity. *Direct (explicit) identifiers* contain values that can uniquely identify persons or organizations (i.e. sensitive entities). Examples are name, telephone number, email address, credit card number, various IDs, etc. *Indirect (implicit, quasi) identifiers* can identify the entity but only indirectly. Examples include geographical location, gender, marital status, profession, date of birth, etc.

B. Data Anonymization System Requirements

Data anonymization is meant to make restricted and confidential data harder to misuse and available to unauthorized people, both inside and outside of the organization.

Even (database column-level) encryption using SQL scripts is a valid approach for data anonymization. If the databases are different, inconsistency may pose a problem, i.e. the same customer would appear differently in each database. There could also be inconsistency between departments using different versions of the same technology and "referential integrity" thus cannot be maintained. Also, such scripts are not flexible and hard to maintain. Therefore, a specialized data masking tool would be more appropriate for any enterprise-wide data anonymization initiative.

A system for anonymization should adhere to several requirements, primarily security and speed.

Security should be strong enough to make any tracing of masked (anonymized) values back to original sensitive information hard enough or impossible. This can not only be achieved by strong encryption, where used keys also need to be protected properly, but also by other masking methods. Letting only authenticated users run the masking would also improve system's security.

Speed is measured in number of records masked in unit of time. This capability determine whether the system is capable of working online (real-time mode, data in motion) or only offline (batch mode, data at rest). The process should in any case be finished inside reasonable time.

Techniques. Supported algorithms should be able to anonymize/generate/format all the different value types of the dataset (credit card numbers, zip codes, telephone numbers, etc.). Also, different ways of masking should be supported, e.g. partial masking (masking only part of the value).

Connectivity. With data commonly being stored in databases, the system could offer connecting to various databases, creating queries and preserving physical structure, indices, primary keys, triggers and referential integrity across tables. For input from file, various file formats (fixed width records, delimiters and encodings) should be supported. Output can also be of different types. Integration into a larger data process such as ETL (Extract-Transform-Load) is also desirable.

Resilience. The system should skip/report invalid data such as improper or missing values in a record/row. Checkpointing (marking the last successful record) would enable restarting the masking from before the record of last failure. Also, examining system's logs should reveal the source of possible failure (improper data or system error).

C. Data Anonymization Techniques

The term anonymity has a different meaning in different countries. In some countries it corresponds to *computational anonymity* (difficulty to computationally trace original values from the masked ones) and in other countries to *perfect anonymity* (theoretically impossible to trace original values from masked ones) [4].

There are two main approaches to anonymization: one based on *randomization* and other on *generalization* [4]. Randomization comprises any modification of the original values either by removing them (nullifying), replacing them with randomly generated or chosen values, adding noise or swapping. Generalization techniques convert values into more general ones and is therefore not suitable when we want to retain data structure and information.

Techniques can be further described with several characteristics. *Deterministic* (*repeatable*) - same original value always maps into the same masked value. *Uniqueness* – two different original values cannot map into the same masked value. *Conditional sensitive* - different masking for different given conditions/parameters. *Partial* – masking only part of the value (e.g. only several last digits of the telephone number). *Realistic* – masked output looks meaningful. *Length preservation* - masked value is of the same length as the original. *Reversibility* – it is possible to get original value from the masked one (e.g. provided the encryption key). *Information loss* – how much information is lost during the masking.

Substitution technique replaces the original value with some other fake masked value. This fake value can be either randomly chosen from the given list (*pseudonymization*) of fake values or generated randomly. The original value can also be changed by *noise addition* where random noise is added to the original value. The variant when the masked value is chosen from the given

list (usually external file) is called *lookup substitution.* While it replaces original values with meaningful masked fake values its list can easily be exhausted for a large number of different original values.

Shuffling or data swapping randomly rearranges values inside one dataset column while preserving the order in other columns. To make masked data more realistic, *group shuffling* can be used to rearrange several columns together. It is safer to do shuffling on larger dataset where tracing the original values is harder.

Blurify technique changes the original value by a given variance. Usually financial data such as salaries are randomly increased or decreased for the specified variance percentage, e.g. -/+ 5% (*Numeric variance*). Minimum and maximum limits can be specified along with the variance to keep the masked value within meaningful boundaries. The technique can also be applied to temporal data such as birth dates (*Date variance*).

Nulling out simply deletes the original value. Normally, the technique cannot be used on non-nullable columns of the database.

Character masking technique is similar to nulling out and replaces the original value with a specified character constant. E.g. first several digits of a credit card number are masked with a character constant.

Encryption technique encrypts the original value into anonymized one by using the provided key. Although the confidentiality is provided, the output value is not realistic. Also, the key needs to be managed and if disclosed, data can be compromised. It is suitable when the anonymized data later needs to be de-anonymized back into original form.

Hashing is a form of encryption technique where no key is used and data of arbitrary length is irreversibly masked into fixed length message digest output. Same as with encryption, hashing is wrongly equated with anonymization, and although it may put itself as a first intuitive choice for obfuscating data, it is not advised [4].

Aggregation aggregates several clustered records and replaces their values with generalizations. Numerals can be averaged, dates can be generalized into months or years, exact salaries into ranges, etc.

K-anonymity is a requirement that pseudo-identifiers of each record must match at least *k* other records in the anonymized dataset. Optimal k-anonymization is an NP-hard problem and there are various approaches to meet this requirement. *L-diversity* and *t-closeness* models are refinements of *k-anonymity.*

D. Data De-Anonymization Risks

Anonymization techniques are as secure as difficult it is to trace the original value from the masked or infer any details about the sensitive information. There is no generally accepted mature method to evaluate this difficulty of de-anonymization [4]. Therefore, choosing the most resistant anonymization technique is nontrivial and dependent on the use case.

According to [4], there are three main approaches to de-anonymization. *Singling out* corresponds to the possibility to isolate record(s) which identify an individual. *Linking attack* tries to link records from different datasets containing common indirect identifiers.

The widespread misbelief about pseudonymization, substitution, encryption or hashing is that if the original sensitive data is replaced by random values or encrypted with state of the art encryption with long enough a key or even completely removed, it is perfectly anonymized [4]. Hashed data can be reversed back to original by brute force attacks or reversing the algorithm. While state of the art encryption does offer high degree of protection, weak custody of the key could make it possible to identify the data. Furthermore, abundant data on the internet can be used to form auxiliary datasets which are then combined with the anonymized ones to help re-identify sensitive information. De-anonymization of Netflix prize is a popular case where data, ostensibly anonymized by randomization, was revealed with the help of auxiliary dataset obtained from the internet [5]. Generally, a dataset with not only perfectly obfuscated but even removed direct identifiers remains vulnerable to singling out and linking to other datasets.

Generalization techniques, while resistant to singling out, require sophisticated tuning against linkability and inference attacks. The main flaw of the k-anonymity is the inference attack, which is improved in l-diversity and t-closeness techniques. Although these refinements are imperfect, they make inference attacks much less successful.

II. RELATED WORK

Growing volume of data and privacy concerns spawned work both in newer anonymization techniques and their merging with popular large scale distributed computing systems. These better anonymization techniques strive to be more resilient to background knowledge and linking attacks done by using increasingly available online datasets. Incorporating the anonymization and privacy preservation into distributed frameworks adds special requirements for secured network protocols, prevention of data disclosure to other nodes in the environment and restricting types of data queries.

In [6] a solution for k-anonymizing vertically distributed data is presented. Vertically distributed datasets are first anonymized locally and then joined. A special secured protocol is constructed that achieves global k-anonymization between two separate nodes. [7] describes anonymization of data horizontally distributed among several cluster nodes. It argues that anonymizing data separately on each node fails to meet referential integrity and that centralizing in on a third party secured server is infeasible. Therefore, a special distributed anonymization protocol is implemented that queries distributed data sources and guaranties that such virtual union of datasets is k-anonymous. Similarly, in [8] an

encrypted global view of the horizontally or vertically distributed dataset is constructed by means of a special secured protocol.

Cloud computing and Big Data offer organizations cost effective computing resources. Yet, organizations are hesitant or legally forbid to use them because of the possible security risks. There are several proposed solutions for privacy protection of Big Data in the cloud. [9] presents data anonymization framework which upgrades MapReduce computing with privacy protection. MapReduce query jobs are constrained by enforced value ranges, preventing unwanted disclosure of original data. The framework enables large-scale computation on data that originates from different sources and belong to different owners. It concentrates on preserving differential privacy by adding noise to the output of the computation. However, data stored in the cloud is not actually anonymized, not all query types are possible and the query results contain added noise. Other two systems described in [10] and [11] provide a privacy-aware cloud computing based on partitioning MapReduce jobs to process sensitive data on private clouds and insensitive data on public clouds. The systems transparently upgrade MapReduce framework and not much adjustments to the existing jobs are needed. It is argued that traditional techniques fail to anonymize large scale data and that it is more efficient to modify or restrict the running MapReduce jobs that access data. Thus, stored data itself remains unanoymized.

III. ANONYMIZATION SYSTEM OVERVIEW

The anonymization system described herein was developed for the purposes of European FP7 FERARI (Flexible Event pRocessing for big dAta aRchItectures) project [12]. The project's goal is to develop novel in-situ methods for detection of events in distributed environments producing Big Data. The system is originally used to anonymize real world telco Customer Data Records (CDR) dataset, which is then used in the project primarily for the research purposes of developing methods of Deep Packet Investigation (DPI) for Mobile Fraud Detection.

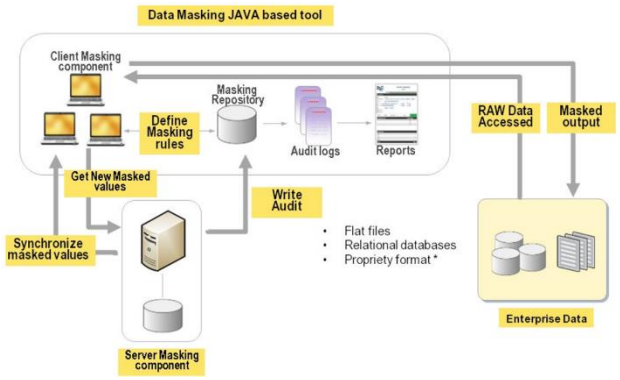

Figure 1 : Architecture of in-situ data anonymization system

The intention was to develop a generalized Java solution that would work both for data residing on a single node and for dana scattered across a distributed environment as exhibited in Figure 1. In addition to anonymization of stationary data, the system attempts to meet demands of high velocity dynamic data. Therefore, multiple inputs are supported, client server communication is minimized and data structures are adjusted for high volume data.

A. Data Connectivity

Connection to standard stationary data repositories such as databases and flat files is supported. Connection to database table is done by JDBC connection and executing the table retrieval query given in the client's configuration. Currently, two main flat file types are supported: delimited text files and fixed width text files. Description of file type and columns is given in the client's configuration. Files are read and written by buffering with *java.io.BufferedReader* and *java.io.BufferedWriter*, which showed to be the simplest and fastest way of reading and writing text files. Both flat files and table rows retrieved by the query should match the columns description specified in the client's configuration. Input of data in motion for real time (dynamic) masking is implemented by supporting JMS messaging queue through *javax.jms.QueueReceiver*. Specifically, ActiveMQ [13] high-performance asynchronous messaging queue library was used for testing. Similarly as for input, data output is provided into database table, delimited or fixed width text file or JMS message queue.

B. Anonymization Techniques

The system currently implements several anonymization techniques of randomizing type. Namely, substitution by pseudonymization, partial substitution, key generator, nullify, blurify and random.

The implemented substitution masking method replaces each value with a fake masked one. The list of possible masked values is given in a file in masker client configuration. Also, the technique can be made deterministic and unique. Similarly, partial substitution masking method replaces only part of the value with a randomly generated characters. The part to be masked is specified by starting position on the left and maximum masked length starting from the right.

The implemented key generator method generates random alphanumeric or only numeric strings of specific length. It can also be made deterministic and unique. Similarly, the random method works on the client side by replacing the value with a random string of specific length and can not be deterministic or unique.

The nullify method simply erases the value by returning an empty string.

To preserve referential integrity among different data sources possibly on different nodes, some mapping data used for anonymization has to be centralized on a server node accessible from all other client nodes. In case of substitution methods, mappings of keys into masked values are kept in a map data structure, which is accessible on the server node.

C. Mapping Data Structure

Pseudonymization masking techniques to be deterministic and preserve referential integrity store mappings of keys into masked values. We implemented hash table of key to masked value mappings for retrieving past mappings. Also, a Bloom filter was implemented for checking if some masked value already exists in the hash table. When processing higher volumes of data, the heap available to Java program can easily become a constraint. The increase of allocated heap also increases the time that the garbage collector needs to collect unused memory objects. Contrary to the popular belief, it is the number of used (live) objects that slows down garbage collection. Garbage collection can therefore greatly and unpredictably increase response time by creating long pauses. Thus, offloading data structures to off-heap native direct memory successfully scales vertically improving performance [14] and adjusting the system for higher volume and higher velocity of Big Data. Access to off-heap direct memory is provided by *java.nio.ByteBuffer* and *java.nio.MappedByteBuffer*. Although the former is faster, we employed the later to map the off-heap hash table data structure to a disk file and thus ensure persistence. Such memory mapped file is guaranteed by the OS to be stored to the actual file on disk in the case the program brakes. However, one single *java.nio.MappedByteBuffer* instance can refer to no more than approximately 2 GB of memory as it is accessed by 32-bit integer index. To overcome this limitation, several overlapping buffers are used to refer to larger memory area. Thus, the complete mapping data structure is located in an array structure inside multiple *java.nio.MappedByteBuffer* objects pointing to one large memory area.

The map data structure located on the server node is accessed from multiple client nodes (Client Masking Component and Server Masking Component in Figure 1) and is therefore made concurrent. Concurrency is implemented with multiple locks similar as in *java.util.concurrent.ConcurrentHashMap*, where each lock *guards* one part of the table. The maps used on clients do not need concurrency and are not run with locks to avoid unnecessary overhead.

D. Internode Communication

The system is divided into multiple clients and one server to support anonymization of datasets scattered or generated on different nodes across the network or cluster. The server node contains shared data needed to perform unique masking across multiple nodes. To comply with the in-situ idea, when masking a value, only if the specific masking technique does not find necessary data locally, it requests it from the server node. For example, when pseudonymizing string value by using the substitution technique, if the client node does not find the mapping in its local map, the server node is queried for that mapping. The server node looks up the key in its map and returns it if it is found, otherwise the mapping is generated. The client node stores the received mapping in its local map to avoid the future query to the server. In case no maps specified by the configuration are found locally when the node is run, the client requests the maps from the server. Map files are quickly transferred as data streams.

Finagle [15] asynchronous Remote Procedure Call (RPC) system is used for client server communication. Finagle server exposes callable RPC services *com.twitter.finagle.Service* for each masker. The client handles asynchronous requests to the server by *com.twitter.util.Future* objects, which invoke registered callbacks when the result from the server arrives. Thus, the masking blocks for rows of data, not for each field.

E. Integration into Apache Storm

We integrated anonymization system into Storm [16] - a distributed, fault-tolerant system for processing streams of data. Its topology comprises two main types of nodes – *spouts* and *bolts*, which are scattered across the network cluster and perform data reading/writing and data processing, respectively.

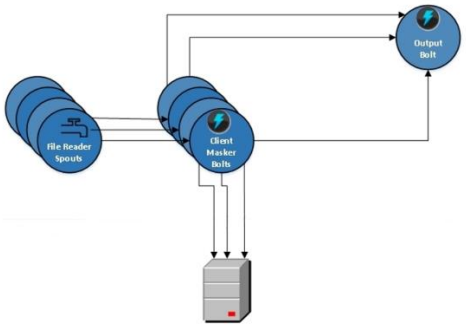

Figure 2 Masking clients inside multiple Storm bolts

As depicted in Figure 2, input into the topology is done by *spout* node type, which is subscribed to Kafka [17] Topic to get lines of text to anonymize. Kafka is a messaging queue distributed on a cluster, accompanying Storm with a messaging system. The input is then parsed in *LineSplitterBolt* node and sent down the topology into multiple *ClientDataMaskingBolt* nodes in form of tuples. Tuples contain sets of values to anonymize. Each such node functions as a client in the masking process and contacts the *ServerDataMaskingBolt* if the masking technique requires so. *ServerDataMaskingBolt node*

provides access to one or more maps, same as in the non-Storm masking cluster. Each *ClientDataMaskingBolt* is provided with the details of masking server location before the topology is submitted. The Storm topology is defined in a java program and automatically submitted to the cluster from any cluster node. Anonymized data is passed from each running *ClientDataMaskingBolt* bolt to *KafkaSinkBolt*, which writes the output.

F. Configuration

Configuration for client part of the process comprises description of input (file format, database table connection, messaging queue parameters) and specification of dataset columns to anonymize (column index, type of anonymization, masker id and masker seed). For the server part of the process it contains description of the server-side maskers (masker id, masker seed and masker specific parameters). When running the system on a single node, configurations are passed as XML files from the command line. In case of both in-situ processing or processing on Storm, client and server anonymization nodes obtain configuration from Zookeeper [18] - a centralized service for maintaining configuration information and distributed synchronization. The configuration from the XML file is stored into Zookeeper by passing path to XML configuration files to Zookeeper's store similar to file system by '*zkcli.sh –cmd upconfig –zkhost 127.0.0.1:2181 –d /path/to/config/files –n anonymization'* script. Uploaded configuration files are retrievable from the running Zookeeper service like '/configs/anonymization/client_config.xml'.

G. Dataset and Measurements

We used real telco *Call Data Record* (CDR) dataset for testing the performance of the anonymization system. CDR data is the fundamental subject of analysis such as churn prevention and user segmentation in telecoms. It is generated by telecoms' equipment to record the details of the phone call that is made through that specific device. As it is generated in different places of a distributed environment, it is suitable for in-situ data processing. Also, analysis of customer data raises concerns about privacy and demands anonymization.

The sample CDR dataset used for testing comprises approximately 465 GB of post-paid and 73 GB of pre-paid customer data records for a period of 6 months. The dataset is stored in multiple CSV text files and comprises attributes like id, call start and end time, geographic location, duration, cost, event type, tariff, etc. For post-paid data, we chose to mask fields BILLED_MSISDN, CALLING_NUMBER, CALLED_NUMBER and OTHER_PARTY_TEL_NUMBER with partial substitution masking technique using the same server-side masker. Similarly, we masked fields MSISDN_NUMBER and B_NUMBER of the pre-paid dataset with partial substitution technique. Thus, the same partial substitution masker was used to mask the chosen fields and provide consistency across two independent dataset.

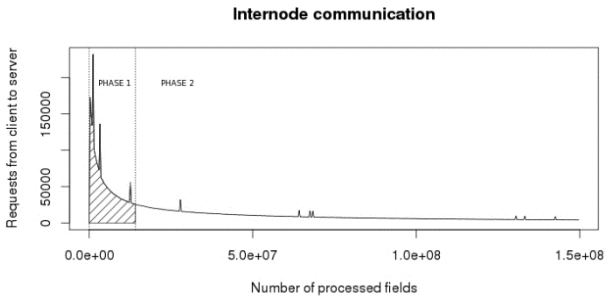

Figure 3 Frequency of masking requests *from client to server*

The effect of in-situ processing is depicted in Figure 3, where it is shown that clients' requests to server exponentialy decrease as data fields are anonymized. In *Phase 1*, phone numbers (in reality generated at different telecom base stations) are unknown and requests to the server are frequent. Later in *Phase 2*, no new phone numbers appear and there is no need for requests to the server because the client masking nodes (in reallity located on base stations) contain all the mapping data.

The spikes visible in the Figure 3 are due to the fact that the provided CDR dataset is in combined form with calls not strictly ordered by date but clustered based on their arival from appropriate base station. Also, spikes within *Phase 2* correspond with seasonality of summer holidays and additional new numbers entering into system (by roaming users).

In everyday use of distributed anonymization system, impact of *Phase 1* communication can be minimized by using pre built memory maps, or utilizing historical dataset on server side with only gathering distinct values to speed-up memory map buildup. After that, in-situ processing on all distributed nodes can be started and behaviour of whole system from that point will be only aligned to *Phase 2* of internode communication.

After anonymizing more than 3 billion CDR records, the map contained 21,308,495 distinct phone number mappings. Original dataset didn't have standardized phone numbers, thus same number could appear multiple times within masked value set depending on formatting of that specific number (e.g. with country prefix, with city prefix, shortcode, etc.). Standardization of phone numbers was out of scope for this paper.

Actual test results compared towards existing (and non-distributed) commercial Enterprise Data Masking solutions were omitted from this paper because we didn't get necessary approvals in due time.

IV. CONCLUSION

Anonymization is becoming more important with growing volume of generated data and privacy protection concerns. Newer anonymization techniques are required to resist the background knowledge and linking attacks that are possible by versatile datasets available online. Also, the techniques need to be built into processing systems capable of handling high volume and high velocity of Big Data. Our work presents a system suitable for in-situ anonymization of data in places where it was generated. It is appropriate for high volume of data with masking techniques' appropriate mapping data structures. Moreover, latencies and unexpected pauses are minimized to adhere to the requirements of high velocity real time data. Also, internode communication in a distributed environment is minimized. Beside from the in-situ processing architecture, the system is also used in Storm distributed realtime computation system. In further work, datasets from other domains will be anonymized and distributed environments of different sizes and data generation speeds will be tested.

VISUALIZATION SYSTEMS

A GPU-based Simultaneous Real-Time EEG Processing and Visualization System for Brain Imaging Applications

Z. Juhasz and Gy. Kozmann
University of Pannonia/Department of Electrical Engineering and Information Systems, Veszprem, Hungary
{juhasz,kozmann}@virt.uni-pannon.hu

Abstract – A data-driven prototype software is presented for EEG processing and visualization. The system relies on the GPU architecture for providing simultaneous processing and visualization of the EEG data. Two example brain imaging algorithms, the surface Laplacian and the spherical forward solution are used for illustrating the effective use of the massively parallel GPU hardware in speeding up computations. The paper describes the architecture of our system, the key design decisions, and the performance optimization of the parallel implementation. Using the CUDA-OpenGL interoperability, the computing subsystem can directly modify potential data in the OpenGL vertex memory, avoiding unnecessary GPU-Host data transfers. The system and our parallel implementations demonstrate that real-time processing and visualization is possible for a range of algorithms during EEG processing. We are confident that these results can pave the way for supercomputing-class implementations and open up new opportunities in the clinical practice and neuroscience research.

I. INTRODUCTION

High-resolution EEG imaging is an increasingly important tool in neuroscience [1]. Unlike CT or MRI that only provide structural information, EEG can measure functional brain activity. Its time resolution typically is in the millisecond range which is vastly superior to other functional imaging methods, such as PET or fMRI. Consequently, EEG is indispensable in areas where high temporal resolution brain activity mapping is required, e.g. in epilepsy diagnosis in the clinical setting [2], [3] or in cognitive experiments based on evoked or event-related potentials [4].

The neuroscience community relies on commercial as well as open source software products for EEG processing. The commercial systems are more common in the clinical area, whereas open source packages, such as the EEGLab [5], Fieldtrip [6] or CSD [7] Matlab toolboxes, dominate in the research labs. While the open source approach reduces development time, facilitates sharing of methods and data as well as serves as a verification infrastructure, by being a de-facto standard, halts innovation in the area of EEG processing software. We argue that innovation is required as the processing speed achieved during routine evaluations is intolerably low.

Since the state-of-the-art EEG systems can employ up to 256 electrodes and operate at as high as 16 kHz sampling frequency, even a few second measurement in such a system can generate hundreds of MBytes of data. The evaluation of these experiments results in long execution times (varying from minutes to hours depending on methods, data size and control parameters). This can be somewhat tolerated in single-shot experiments but it clearly presents a serious obstacle in large multi-patient studies or if EEG is ever to be considered as a diagnostic tool in the daily clinical routine.

This paper presents a novel parallel computing approach to EEG data processing and describes an experimental software environment developed at the University of Pannonia. We have developed a GPU-based massively parallel system that demonstrates that near real-time processing speed is achievable in key brain imaging algorithms, such as the spherical surface Laplacian [8] or the forward solution for source localization [9]. Although the program is created for EEG brain imaging, it can be used after little modifications for ECG-based multi-channel body-surface mapping applications [10], [11], [12].

At the center of our implementation is the GPU architecture that acts as a computing and visualization engine. The most advanced cards today can achieve up to 5 teraflops (10^{12} floating point operations per second) computational performance on a single chip using approximately 100 W power consumption. This performance-per-watt value cannot be matched in any other CPU-based parallel system. We use OpenGL [13] for visualization and the NVIDIA CUDA [14] technology for the parallel implementation on the GPU.

The structure of our paper is the following. Section II describes two illustrative imaging method, the surface Laplacian mapping as well as the forward algorithm indispensable in solving the inverse problem. Both approaches aim at detecting the spatial and temporal patterns for cortical brain activity. Section III describes the rationale behind using graphical processors for increasing processing speed as well as providing data visualization capabilities in our program. We highlight peculiarities of these systems from the algorithm design and optimization point of view. Section IV explains the core architecture of our software and the key design concepts, while Section V discusses our results to date.

II. EEG IMAGING METHODS

The electric potential measured on the scalp is the combined result of different activity sources in the brain. The potential is rarely usable as recorded due to the low signal-to-noise ratio and the presence of unwanted artifacts, such as the effect of eye movements, hence require filtering and other pre-processing steps. Nonetheless, the filtered potential data is seldom used on its own for activity mapping. A fundamental problem in the interpretation of scalp potential maps and in the solution of the forward/inverse problem is the so-called smearing effect of the skull. As the electric field propagates within the head, regions with the different conductivity spread the effect of the original sources, making their size grow on the scalp.

A. The Surface Laplacian

Laplace imaging can be used to 'sharpen' the scalp potential images, i.e. to reduce the smearing effect. The surface Laplacian [15], [16], [17] – the second derivative of the surface potential – computes the current source density (CSD) of the brain that is strictly related to the activity level of cortical areas. Several methods are known that apply the Laplace operator to focus the potential image before solving the inverse problem [18], [19], [20], [17].

The advantage of the Laplacian is that it is independent of the reference electrode choice, relatively insensitive to eye-movement artifacts and generates a relative topographic image that is well suited to activity pattern recognition. The Laplacian of the potential filed in the three-dimensional Cartesian coordinate system is expressed as

$$\nabla^2 f = \frac{\partial^2 f}{\partial x^2} + \frac{\partial^2 f}{\partial y^2} + \frac{\partial^2 f}{\partial z^2}$$

Where f is the potential function represented by the discrete potential values measured at the electrodes. One of the most widely used algorithm for computing the surface Laplacian on a sphere was proposed by Perrin [8], [21], which uses spherical splines

For a point *E* on the sphere, the Laplacian (a.k.a. the current source density), *C*, is given as

$$C(E) = \sum_{i=1}^{n} c_i h\big(cos(E, E_i)\big),$$

where E_i is the i^{th} electrode on the surface of the sphere, and the c_i s are the solution of

$$GC + Tc_0 = Z$$
$$T'C = 0$$

with

$$T' = (1,1,\dots,1),\ C' = (c_1, c_2, \dots, c_n),$$

$$Z' = (z_1, z_2, \dots, z_n),\ G = (g_{ij}) = \Big(g\left(cos(E_i, E_j)\right)\Big),$$

where z_i is the potential measured at electrode E_i. The function $h(x)$ is defined as the sum of the following series

$$h(x) = \frac{1}{4\pi} \sum_{n=1}^{\infty} \frac{(2n+1)}{n^{m-1}(n+1)^{m-1}} P_n(x)$$

where $P_n(x)$ is the n^{th} degree Legendre polynomial and m is the stiffness parameter of the spline.

A typical application of the surface Laplacian is in event-related experiments, in which normally multi-trial average of a 5-10 second time window of brain activity is analysed. In the widely used Matlab-based CSD Toolbox [7] program, the calculation is carried out in two steps; first, an H matrix is created by solving $h(x)$, than the Laplacian is calculated for the entire data window. The Matlab execution times are given in Tables I and II measured on an Intel Core i7-3820 2.70 GHz processor. Table I shows the calculation time of the *H* matrix for a different number of electrodes and summation limits for $h(x)$. Table II shows the overall execution time including the H matrix and the window calculations for $N = 15$. Even at this summation limit, it is evident that one window can take 10s of seconds to calculate. For $N = 50$, the execution time moves to the order of minutes.

TABLE I. CALCULATION TIME [SEC] OF THE H MATRIX (CSD)

N	Number of electrodes		
	64	128	256
15	5.74	22.84	92.50
50	34.00	137.51	552.12

TABLE II. TOTAL SURFACE LAPLACIAN CALCULATION TIME [SEC], N=15

Number of samples	Number of electrodes		
	64	128	256
1	5.74	22.84	92.51
512	5.81	23.03	92.89
1024	5.89	23.15	93.28
2048	6.04	23.47	94.07
5120	6.50	24.40	96.33
7160	6.80	25.03	97.94

B. The forward solution

While the surface Laplacian can help in focusing the potential image obtained on the scalp, it does not contain information about the cortical placement of the activity sources. Source localization methods can help in extracting this information, whose aim is to identify the location and magnitude of activity sources (dipoles) based on the measured potentials. The difficulty lies in the problem that any number of dipole combinations can generate identical scalp potential maps. This is the bioelectrical inverse problem which has no unique solution except when a priori constraints can be applied.

The basis of the inverse solution is that one or more hypothetical dipoles are placed in the brain within the head model and the generated potentials are computed – this is called the *forward problem* – then compared to the measured values. During the process, the position, orientation and magnitude of the dipoles are varied until an acceptable solution is found. Since there is no theoretically unique solution (except in the case of a single equivalent dipole), several solution methods have been proposed. Reviews and comparisons of these and other

frequently used inverse solution methods can be found in [22], [23], [24], [25].

The inverse solution requires the computation of hypothetical dipole generated potentials, known as the bioelectrical forward problem. This is based on the electrical field computation in the head model. The simplest head model is the spherical models that can contain up to five layers. Spherical models have closed form solutions, therefore they are computationally less demanding. Various solutions are developed for the multi-layer spherical head model forward calculation [26], [9]. The main advantage of the spherical head models is computational efficiency. Due to the closed form solution, the computational cost is relatively modest. This is crucial in localization where a large number of dipoles need to be tested for.

The widely used Fieldtrip Matlab toolbox [6] contains the implementation of the 4-layer spherical forward solution algorithm proposed by Cuffin and Cohen [9]. The computation of the generated potential is based on the following equation that calculates the effect of the x component of a source dipole vector. Similar equations are used for the y and z components.

$$V = \frac{P_x \cos\varphi}{4\pi\sigma_4 R^2} \sum_{n=1}^{\infty} \frac{(2n+1)^4 f^{n-1} (c*d)^{2n+1} P_n^1(\cos\theta)}{n\Gamma}$$

where

P_n^1 is the associated Legendre polynomial,

$$\Gamma = d^{2n+1}\{b^{2n+1} n(k_1-1)(k_2-1)(n+1) + c^{2n+1}(k_1 n + n + 1)(k_2 n + n + 1)\}\{(k_3 n + n + 1) + (n+1)(k_3-1)d^{2n+1}\} + (n+1)c^{2n+1}\{b^{2n+1}(k_1-1)(k_2 n + k_2 + n) + c^{2n+1}(k_1 n + n + 1)(k_2 - 1)\}\{\mathrm{n}(k_3-1)(k_3 n + k_3 + n)d^{2n+1}\},$$

R is the radius of the scalp sphere, f is the coefficient for the dipole position and

$k_1 = \frac{\sigma_1}{\sigma_2}, k_2 = \frac{\sigma_2}{\sigma_3}, k_3 = \frac{\sigma_3}{\sigma_4}$, and b, c, d are radius coefficients for each layer given as

$$b = \frac{r_1}{r_4}, c = \frac{r_2}{r_4}, d = \frac{r_3}{r_4}, R = r_4.$$

C. Computational cost

The forward solution is a critical operation since it has to be calculated many times during the solution of the inverse problem. In the most general case, the location, orientation and magnitude parameters of each dipole are adjusted until the best fit is found. Table III contains illustrative execution time figures obtained using the Fieldtrip Toolbox using 64 and 128 electrodes and varying number of dipoles. Execution time is measured on an Intel Core i7-3820 2.70 GHz processor.

III. EMBRACING GPU TECHNOLOGY

The traditional approach to speeding up the illustrated algorithms is to implement the algorithms in C/C++ and ideally write it in a parallel manner so it could scale over a range of CPU cores. Unfortunately, the achievable parallelism is limited in traditional computers as the number of cores is limited to 8 on Core i7 systems and 16 on state-of-the-art Xeon processors. We ignore the distributed-memory systems using multiple CPUs as they are not typical in the medical field.

TABLE III. SEQUENTIAL EXECUTION TIMES [SECONDS] OF THE SPHERICAL FORWARD ALGORITHM IN THE FIELDTRIP MATLAB TOOLBOX

Number of dipoles	Number of electrodes	
	64	128
1	0.25	0.32
10	0.52	0.95
100	3.34	7.22
500	15.93	35.13
1000	31.90	70.03
10000	314.86	700.02

A. GPU overview

Graphical processors, due their origin in 3D graphics, are designed for massively parallel execution of pixel graphics instructions. Today's GPUs are generally programmable and can be used the general computational tasks. State-of-the-art chips can contain over 2000 cores and their computational performance can exceed 4 teraflops. The key to this performance is the very efficient and coordinated execution of thread groups. GPU programs are ideally data-parallel, executing the same instruction sequence for a large amount of data. Threads can be arranged into 1D, 2D or 3D grids and efficiently mapped onto physical cores.

GPUs run the program from their own global memory that resides on the GPU card. They also use faster memories, such as the shared memory that can be used by a group of threads or registers for the exclusive use of a single thread. Global memory access is very expensive, thousands of instructions can be executed with a single read/write cycle. Even more expensive is the data transfer between the host and the GPU, shown in Fig. 1. While the GPU is treated by many as a co-processor, the efficient use requires that the GPU can execute at its own speed without the tight control of the CPU program.

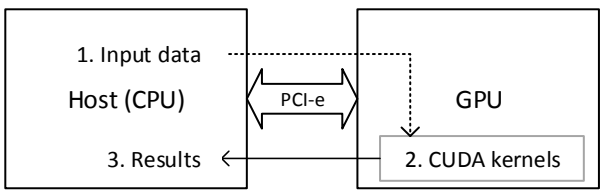

Figure 1. Data transfer between the Host and the GPU during operation.

B. Parallel execution strategy

Our primary aim was to explore various GPU parallelization strategies and to compare different implementations in order to *a)* speed up computation as

much as possible as well as to *b)* investigate the effect of design decisions on performance.

Both algorithms fall into the data-parallel class of problems. The first design decision is how to partition the problem in a scalable way, the second is how to use the memory the most efficient way and the third is how to minimize the number of cycles not spent with computation.

1) The GPU surface Laplacian

In contrast to the original surface Laplacian algorithm, in which the Laplacian is only computed for the electrode coordinates, in our system we are interested in the values at every position of the head. Our implementation computes interpolated values for a larger set or points. The exact number of points is determined by the resolution of the 3D sphere mesh used to build the head model.

The problem is partitioned by the surface points. The Laplacian at each point is computed independently from the other points. Since the spline interpolation is a global operation, all the electrodes are shared by the parallel threads (kernels).

2) The GPU forward solver

Our parallel forward solver implementation is based on the work reported in [27]. The underlying structure of the algorithm is a dipoles × channels thread grid, in which each thread calculates the effect of one dipole on one scalp electrode. We have added several performance optimizations to this algorithm. Using an optimized grid allocation strategy, restructuring code to optmize memory access and exploit on-chip instruction level parallelism better, we were able to almost double the performance of the original algorithm.

Another approach for improving the overall execution time was to use a more efficient base algorithm. The algorithm proposed by Sun [28] uses an interpolated function to avoid the lengthy computation of the Legendre sums in the original Cuffin algorithm. This version brings another ten-fold increase in performance.

IV. Software Architecture

Traditional EEG processing systems follow the traditional batch processing style of computation; data is input from a file, a set of algorithms are executed on the data and the results are saved in output files. They are also CPU-centric, i.e. the CPU controls the entire execution flow as well as performs the heavy mathematical computations. This type of software architecture is the result of the type of traditional computer architecture used in the past few decades that are often commonly referred to as "Denial Architecture" [29]. They pretend that computers operate sequentially and that the memory architecture is flat. GPU architecture explicitly exposes the underlying parallel hardware components and encourage the user to take advantage of locality in the hierarchical memory organization offering new opportunities for increasing performance and optimizing execution.

Our software architecture follows the explicit parallelism design principle and is based on the stream computing paradigm. The basic underlying model is of the data pipeline. Data is pumped from the measurement instrument or fetched from the data file, as required, and passed on through FIFO channels to processing nodes. The nodes output data to further processing or visualization nodes. The execution of the algorithms are triggered by the arrival of data and is carried out with maximum level of hardware parallelism. Other key design decisions were to remove any unnecessary data movement (keep as much data as possible on the GPU) and overlap CPU-GPU data transfer with computation to hide data latency.

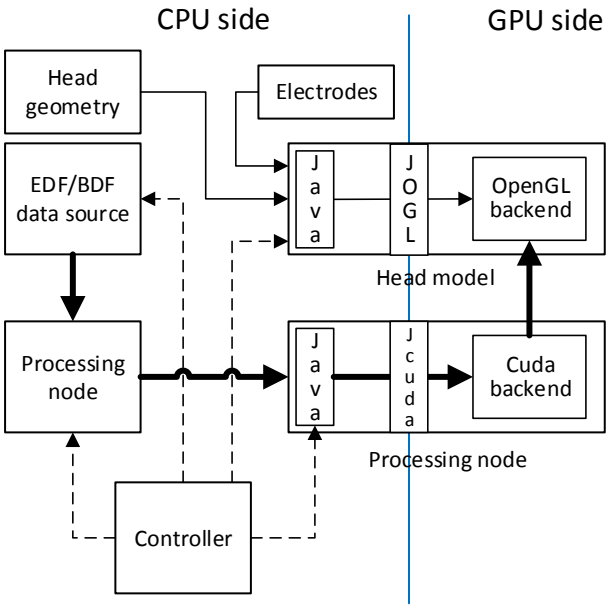

Figure 2. The high-level view of the GPU stream architecture. Solid arrows indicate data movement, thick arrow depicts live data update path (stream), whereas dashed arrows indicate control port connections. Data copied to the GPU memory are available to both the OpenGL and the CUDA backend. Processing node may or may not have GPU implementation parts. Their number and order are not limited.

A. Visualization

The visualization subsystem is implemented in OpenGL. We have avoided the use of any open-source visualization toolkit to retain maximum design freedom. Since the primary visualization aim is the display of time-varying potential (or potential-derivative) data on a static 2D or 3D geometry, head and electrode cap geometry data is cached into the GPU memory on initialization. Only potential data is updated continuously. A thin Java object wrapper layer is created to structure the view into higher-level objects (head model, electrodes, etc.) and to control the underlying OpenGL implementation.

B. Computation

Potential data is processed and transformed by the GPU using CUDA kernels. The largest potential performance penalty in a GPU-based computational and visualization system is if the GPU-computed results are copied back to the host in order to be displayed by the visualization system. The CUDA-OpenGL interoperability architecture allows us to avoid this by directly modifying OpenGL data structures from CUDA kernels.

Our algorithms are designed for scalability. As new GPU processors appear with more compute cores, the implementation automatically scales. If needed, the system can run with several GPU cards installed, in which case computation and visualization can be partitioned to separated GPU devices.

The CUDA threads are called via the JCuda wrapper library. To better manage the GPU code sections, the kernels are embedded in Java processor objects that manifest high-level EEG operations, e.g. `MovingAverageFilter`, `SphericalLaplace`, etc. These objects provide a clean programming interface to the rest of the system.

V. Results

Our prototype EEG processing and visualization system is operational. The current system consists of an Intel Core-i5 hosted NVIDIA Quadro K4200 card (1344 cores, 2.1 teraflops) and four 46" Samsung edge-lit display panels arranged as a 2×2 grid. The surface area and the 4K resolution of the display wall is sufficient to simultaneously display the EEG measurement plots, the 2D and 3D potential and Laplacian maps as well as RMI images and (if available) video recordings of epileptic patients.

The EEG plot (Fig. 3) allows for amplitude and time axis zoom, selection of measurement sample with marker. The marker can be moved or the measurement can be replayed at selectable speed. Fig. 4 illustrates the result of the surface Laplacian computation and its visualization on a 3D realistic head model. The focusing effect the of the Laplacian is clearly visible.

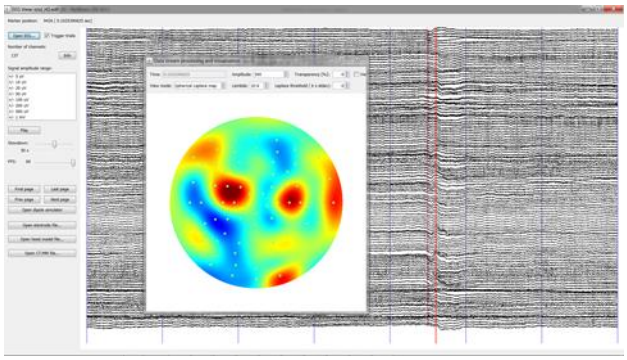

Figure 3. Screenshot of the prototype showing the multi-channel EEG plot and the 2D Laplacian map computed from the potentials.

A. Achieved computational performance

Our system has achieved considerable increase in computational performance. As shown in Table IV, using 128 electrodes and up to 2K (N=50) or 8K (N=15) surface points, the system can compute and visualize the Laplacian map real-time up to 2 kHz sampling frequency. The execution times shown in Tables IV and V are measured on an NVIDIA GTX 980 GPU card (2048 cores).

The performance results for the forward problem are similarly impressive. Using several code optimization steps we were able to improve the performance of the GPU-version of the Cuffin-Cohen algorithm [27]. Using Sun's algorithm could further increase the performance and reach msec range execution time for 128 channels and 5000 dipoles. The results are displayed in Table V.

TABLE IV. GPU-based Surface Laplacian Performance (128 electrodes)

Number of surface points	Execution time [msec]	
	N=15	***N=50***
1024	0.144	0.497
2048	0.152	0.578
4096	0.293	1.086

VI. Conclusion

This paper presented a novel, GPU-based stream-oriented EEG processing software system. We demonstrated that the GPU architecture is well suited to simultaneous EEG visualization and processing. The computational performance offered by current GPUs make it possible to carry out simultaneous computation and visualization in real-time, or online if live measurement is performed. We were also interested in exploring new architectural and performance optimization methods that could lead towards the development of EEG software systems higher flexibility and with several orders of magnitude larger performance than that available today.

We have demonstrated with two important imaging algorithms how a GPU-based stream-oriented system can be created, and showed that computational performance up to 3 orders of magnitude higher than Matlab can be achieved while providing simultaneous interactive 2D/3D visualization. Our forward solver implementation is faster than any other GPU-based methods known to us in the literature. Our fast implementation of the surface Laplacian can serve as a basis for high-resolution cognitive studies and BCI applications. The system is integrated into a 4K resolution 2×2 display wall system creating a very high-performance, yet cost-effective brain imaging system. Future development plans include the integration and coupling of other imaging modalities such as MRI and fMRI, implementing fast realistic head-model based imaging algorithms as well as adapting the system for use in body-surface potential mapping applications.

Acknowledgment

The authors wish to thank their students A.G. Nagy (MSc) and D. Kenyeres (BSc) for their invaluable help in the development of the prototype system described in this paper.

Web Portals for Visualizing and Searching Spatial Data

Lejla Bećirspahić*, Almir Karabegović *
* University of Sarajevo, Faculty of Electrical Engineering, Sarajevo, Bosnia and Herzegovina

Abstract - Spatial data have proven to be extremely useful in many areas. Accordingly, there are more and more web GIS solutions. These solutions allow the visualization of spatial data to all Internet users. A large number of available online resource introduced the problem of efficient retrieval of relevant information. The aim of this paper is to describe the way in which web portals can be used to search and presentation of spatial data.

The paper first analyzes the area of the web portal. It provides an overview of the web GIS technology, with particular emphasis in its advantages and disadvantages and how the client/server architecture can be applied to web GIS solutions. Then, it describes how the service oriented architecture can be used to resolve interoperability problems, and gives an overview of OGC standards: WMS, WFS, and WCS. In the end, it explains the need for introducing a geoportal, as a special type of a web portal.

In the practical part of this paper is implemented interactive map of Bosnia and Herzegovina. An overview of the technologies was given: PostGIS, Boundless SDK, GeoServer and OpenLayers, which are an integral part of the OpenGeo Suite. The paper also describes how to integrate local data sources with public web services: MapQuest, Bing Maps and OpenStreetMap.

I. INTRODUCTION

A geographic information system (GIS) is a computer system that allows capturing, modeling, manipulation, retrieving, analysis and presentation of spatial data. A majority of the early GIS users were professional users. Expansion of the Internet has made GIS available to casual users. The most important web GIS functionality is web mapping or visualization, which is the process of creating and using online maps. Modern web GIS solutions let users interact with maps.

A single source is almost never sufficient for satisfying information needs of today's users. A real potential of web GIS can be achieved through the integration of spatial data from multiple sources. WMS, WFS and WCS are three web services that are suggested in order to support the interoperability.

Web portal centralizes access to information from different sources and enables searching large amounts of data in a fast and efficient way. A geoportal is a type of web portal used to find and access spatial data and services via the Internet.

II. WEB PORTALS

There is no unique definition of a web portal. Depending on their own standpoints, different authors have proposed different definitions. One group of authors suggests that a web portal is a specific web page, which allows access to other web pages. When interpreting previous definition, one has to keep in mind that a web portal is more than a simple web page containing hyperlinks to other related pages. By its design, web portal should facilitate finding of relevant information in today's informational chaos. Information originating from different sources are consolidated and represented in a web portal, in a way that enables more efficient and fast search. In a broad sense, the use of web portal is not limited to accessing web pages, but also to accessing various network resources [1]. Other group of authors emphasizes the possibility of a portal's customization, so that user needs can be satisfied [2]. User customization in business environment implies adaptation to user role in an organization, so that user does not need to worry about inessential data. This enables user to fulfill tasks in a quality manner. Web portal also supports decision making process, because it provides a single point of access to useful information [3].

There are several ways to classify web portals. Mainly, web portals are classified as horizontal or vertical. Horizontal web portal is designed as a starting point for browsing the web [4]. Vertical web portals or vortals can be divided into three subclasses: corporate portals, used by employees to get access to organizational data and services, industry portals, used for information sharing and business transactions between business partners, and customer portals, used for customer support. Another common type of web portals are informational web portals. Informational portals are designed to satisfy information needs of specific groups in community. These groups are formed based on different criteria: age, gender, ethnic, national or racial affiliation [2].

Web portal can be compared to the front page of a newspaper [1]. No one is going to buy a newspaper with poorly designed front page and irrelevant news. The same rule applies to web portal – its success depends on how

fast required information is delivered to user, but also on capability to represent this information in accessible manner.

III. WEB GIS

Desktop GIS solutions are intended for professional users, who have specific knowledge and skills. In addition, desktop GIS application requires an installation of some necessary software. This approach cannot expand the full potential of GIS. The web has introduced a new era in GIS development, that is characterized by web GIS. The main idea of web GIS is online publishing, searching, processing, analysis and presentation of spatial data.

In simple terms, web GIS is any GIS that uses web technologies. This means that a web browser is all that is needed for accessing a web GIS application and it is simpler and more accessible than desktop GIS solutions. The combination of the Web and GIS has expanded the range of users, who can access the GIS functionality regardless of their current location. Wider availability has led to new GIS application, such as decision-making support, planning and problem solving. Areas of application are diverse: government, economy, health, research and scientific programs. Spatial data have proven useful in various fields, wherefore the number of users is further expected to increase [5].

Web GIS provides following features [5] [6]:

- Visualization or web mapping – the most used functionality. This includes a presentation of spatial data in a form of map.
- Collection of geospatial information – professionals and amateurs voluntary collect spatial data within collaborative projects like Wikimapia and OpenStreetMap. Data collected in this way is termed as VGI (volunteered geographic information).
- Dissemination of geospatial information – although VGI is useful, reliability of data can be doubtful. When making an important decisions, data sources must be accurate and reliable. Web GIS can integrate spatial data from multiple sources and present them on a single map.
- Personalization – web GIS can support personalization option. This allows user to create custom maps, add locations, descriptions, images, videos or links, and share that with other users.
- Geospatial analysis – web GIS can support analytical functionalities.
- Printing maps – user can select an area and layers for printing.

Web GIS has following advantages [6]:

- A global reach – after publishing to the Internet, Web GIS application is accessible to the whole world.
- A large number of users – unlike desktop GIS applications, which can be accessed only from a computer with appropriate software installed, web GIS can be used concurrently by hundreds of users.
- Cross-platform compatibility – web browsers support different operating systems. This means that web GIS is platform independent.
- Lower cost – instead of buying a software, individual users can access web GIS functionalities from a web browser.
- Ease of use – web GIS is intended for a wide range of users, who might not have knowledge about GIS.
- Automatic update – most web GIS clients are automatically updated.
- Diverse applications – desktop GIS applications are intended for professionals, and have limited use. On the other hand, web GIS is available to casual users.

Web GIS has following disadvantages [7]:

- Internet can be unreliable – availability and accuracy of external sources cannot be guaranteed.
- A high bandwidth is required – users with slow connection may have difficulty loading the map, which can be frustrating.
- Spatial data are expensive – spatial data are publicly available and free of charge in the USA. However, spatial data can be very expensive in other parts of the world.
- Copyright infringement – use of spatial data without owner's permission can cause copyright violations and legal consequences.
- Limited screen space – devices with small screens are less suitable for viewing web maps.

A. Web Mapping

Web mapping or visualization is the process of designing, implementing, generating and delivering maps on the Web [7]. Web mapping is extremely important functionality, since it allows visualization of complex spatial data on a map. When shown on the map, spatial data are suitable for different analysis. In this way, it is easier to detect relationships among them. Web mapping has introduced maps to a wide range of users. It is sufficient that a user opens a web browser and utilize numerous opportunities offered by web GIS.

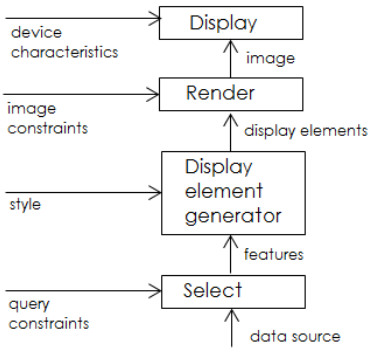

Figure 1. OpenGIS model for interactive web mapping [8]

Interactive web mapping involves creation of dynamic web maps on user demand. OpenGIS Consortium has developed a model of interactive web mapping, shown in figure 1.
The model of interactive mapping has four tiers [8]:

- Selection retrieves spatial data from a data source according to the constraints set in the query. Connection between the map server and the spatial database is achieved at this stage.
- The display element generator turns the selected spatial data into a sequence of display elements. It also applies appropriate styles.
- Render generates a map from input display elements.
- The rendered map is displayed on the output device.

In interactive web mapping, map server generates a new map on each user request. Generating maps from raw data is time-consuming operation. Response time of the server is determined by the bandwidth between a client computer and a remote computer. If a response time is slow, users will wait longer for the server's response. Large load of a map server can lead to worse performance. This means that user will wait longer to load the map, which is unacceptable for web applications.

Tile-based maps represent a significant improvement. This technique divides the map into discrete set of zoom levels, where each zoom level is divided into tiles of the same size. Described zoom levels form a hierarchy that can be visualized as a pyramid. The biggest advantage is in accessing certain tiles, instead of the entire map. Therefore, only the requested tiles are rendered. Tile-based maps enhance the performance and achieve savings of computing power and memory space. For this reason, they are used frequently in today's GIS solutions [9].

B. Web GIS Architecture

Web GIS architecture is similar to the client/server three-tier architecture [8]. A client is usually a web browser, which can be accessed on the local computer. Web browser interacts with a remote computer – server. A client sends a request to the server, while the server processes this request and sends a response to the client.

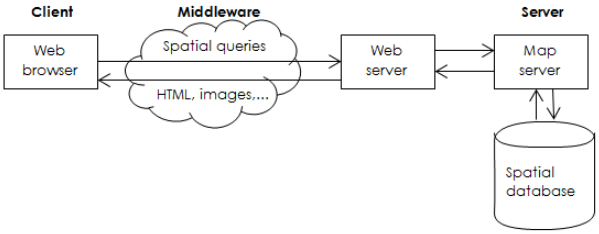

Figure 2. Client/server architecture of web GIS application [8]

Figure 2 show main components in client/server architecture of web GIS application: web browser, web server, map server and spatial database.

GIS components on the server side [7]:

- Web server – handles http requests. In the simplest case, web server returns static documents (HTML pages, raster images). Also, if there is a need for an interaction, web server sends requests to CGI applications or server-side scripting languages. The most popular web servers are Apache and Microsoft Internet Information Server.
- Map server – handles spatial data and generates maps (usually in PNG, JPG or SVG format). The most popular open-source map servers are UMN MapServer, GeoServer and Mapnik. Commercial alternatives are ESRI ArcIMS, Intergraph GeoMedia WebMap and Autodesk MapGuide.
- CGI applications – implement Common Gateway Interface standard and enable communication between the web server and map server. A CGI application is usually executed on the web server. It processes the request sent by client and forwards this request to the map server, then receives server's response and forwards this response to the client.
- Scripting languages (PHP, Perl, ASP, Python, Ruby) – are built into the web server and can be used to achieve communication between the web server and map server.
- Spatial databases – are relational databases with spatial data types and methods. Examples of spatial databases are PostGIS, Oracle Spatial, Microsoft SQL Server, IBM DB2 and MySQL.

GIS components on the client side [7]:

Web browser is sufficient for viewing static pages. Most of today's GIS solutions require additional plugins:

- ECMAScript – is standardized version of JavaScript. It is necessary for the implementation of the interaction on the client side.

- Event support – events can trigger script execution. Examples of events are mouse moves, mouse clicks, keyboard presses, etc.
- Network requests – are necessary to load additional data on the website.
- The Document Object Model (DOM) – is a standard for access and manipulate HTML and XML documents.
- Scalable Vector Graphics (SVG) – is a format that integrates vector graphics, raster graphics and text.
- Java applet – is a small application that can be included in a web page.
- Web browser plugins – Adobe Acrobat, Adobe Flash, Apple QuickTime, Adobe SVG viewer, Sun Java plugin.

C. *GIS Web Services*

A real potential of web GIS can be achieved through the integration of spatial data from multiple sources, so that a picture of the overall situation is created. On this way, information is exchanged within and outside the organization. Data integration raises the question of interoperability between spatial data and services [10]. Interoperability is defined as the ability to communicate, program execution and data exchange between different functional units. The user knows little or nothing about characteristics of these units. To make this possible, data is exchanged over common procedures, with use of agreed formats and protocols. As a result, interoperability contributes to overcoming problems in communication between components of different manufacturers, reduces redundancy and encourages knowledge exchange [11].

A single map cannot satisfy information needs of today's users. In these situations, it is inevitable to access different data sources. The most acceptable solution is to combine data from multiple sources into one composite map. However, standard client/server architecture offers little interoperability. Figure 3 shows situation where user, in order to access data from three different sources, needs to run three different web applications. The server will generate a map for each request.

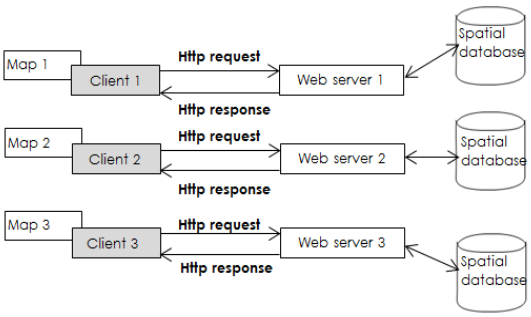

Figure 3. Lack of interoperability in the case of a client/server architecture [10]

In these solutions is lacking transparency, because each source is accessed through a specific server [10].

Interoperability can be achieved by introducing web services [11]:

- The Web Map Service (WMS) is a standard for visualizing spatial data on the Internet. It provides uniform access to maps rendered by map server. Maps can be generated from the raw data, as well as vector and raster data. Client, which implements WMS, can access any server that implements WMS. In this way is achieved the integration of data from different sources.
- The Web Feature Service (WFS) is a standard specified by OGC that is used for requesting/sending spatial objects on the Web. Spatial objects can be viewed as the source code behind a map. The WMS returns a map in the form of an image, on which are not supported any modifications or analysis. The WFS provides operations for manipulation of spatial objects.
- The Web Coverage Service (WCS) is a standard specified by OGC that is used for requesting/sending spatial data as coverages. A coverage is the digital spatial information that represents an object in some geographic area. While the WMS returns static images, the WCS gives more information, including valuable metadata. The WCS is WFS for raster data.

Service oriented architecture (SOA) is an approach to building software applications based on the use of web services. In this architecture, web services are the only way to access network resources. Figure 4 shows that the user can access data from three different databases from a single client. All the required information is displayed on a single map [10].

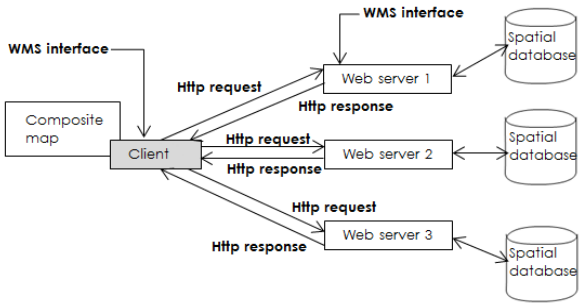

Figure 4. Interoperability of a SOA [10]

IV. GEOPORTAL

Organizations from different domains collect and publish spatial data. It is common that each organization focuses on their issues. This means that one organization will have data about roads, the other will have data about

woods, etc. A user needs a complete picture of some area. For him, this organization of spatial data does not have usability. The same problem can arise inside an organization, if each department collects processes and analyses data in distinct way. An efficient solution for the described problem is the development of geoportal. A geoportal is a type of web portal used to find and access spatial data and services via the Internet [12]. A geoportal can also be defined as a central point of access to spatial information, regardless of their location, format and structure [13].

V. INTERACTIVE MAP OF BOSNIA AND HERZEGOVINA

A. *Used Technology*

OpenGeo Suite is used for implementation of the interactive map of Bosnia and Herzegovina. OpenGeo Suite is a complete platform for managing spatial data and building maps for web browsers, desktop and mobile devices. OpenGeo Suite includes following open-source components [14]:

- PostGIS – a spatial extension to PostgreSQL.
- GeoServer – an open-source server written in Java, which allows retrieving, sharing and editing spatial data.
- GeoWebCache – a tile caching server, which accelerate the display of the maps.
- Boundless SDK – provides tools for building web GIS applications. It uses OpenLayers - a JavaScript library for viewing and interacting with spatial data in the web browser

B. *The Application Architecture*

Figure 5 shows the architecture, used for the realization of interactive map of Bosnia and Herzegovina. The bottom layer is a spatial database – PostGIS, in the middle is application server – GeoServer and GeoWebCache, while at the top is a user interface with OpenLayers library. This is client/server architecture.

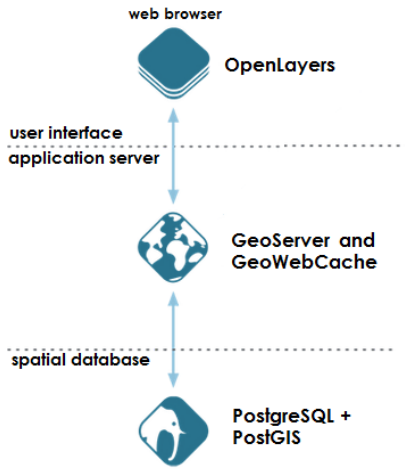

Figure 5. The Application Architecture [14]

C. *Web Services Integration*

OpenLayers 3 (OL3) allows easy integration with public web services. Restriction is that these maps have to be background (base) layer. For this reason, every layer that was created in this way will be grouped in background group.

MapQuest is a free web mapping service. A creation of a layer, that will use a MapQuest server as a source, is very simple and not much different from creating a layer form a local source. OL3 includes a class ol.source.MapQuest that allows the integration of a MapQuest map in the project. Figure 6 shows a MapQuest map.

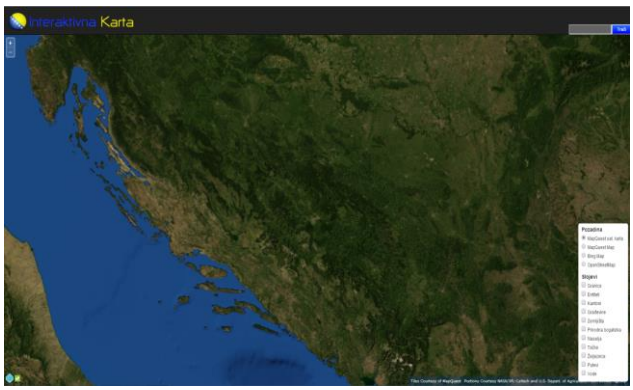

Figure 6. MapQuest satellite map

Bing Maps, originally known as Virtual Earth, is web mapping service developed by Microsoft. OL3 includes a class ol.source.BingMaps that allows the integration of a Bing map in the project. To gain an access to the Bing Map service, it is necessary to obtain appropriate API key. Figure 7 shows a Bing map.

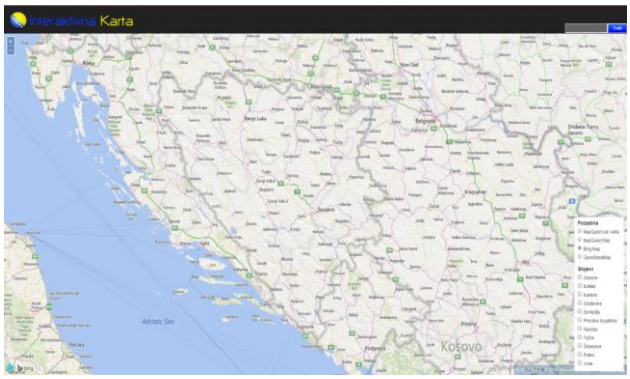

Figure 7. Bing map

OpenStreetMap is a collaborative project that aims to create a free map of the world. OL3 includes a class ol.source.OSM that allows the integration of an OpenStreetMap map in the project. Figure 8 shows an OpenStreetMap map.

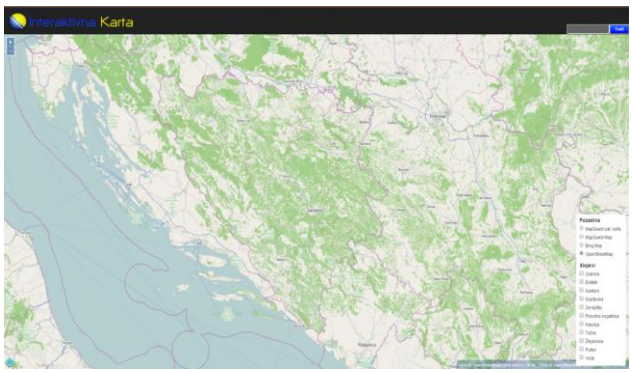

Figure 8. OpenStreetMap map

D. Viewing Layers with information about Bosnia and Herzegovina

Available layers are shown in the lower right corner of the screen. Layers are grouped into two groups: background and layers. This control enables user to select the layers, which will be shown on the map located in the central part of the screen. Only one background can be active at a time. On the other hand, multiple layers can be displayed on a single background. Figure 9 shows how to combine data about the borders of Bosnia and Herzegovina with an external source – a MapQuest satellite map.

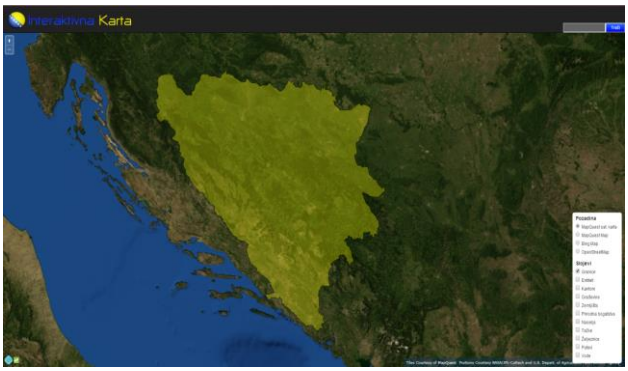

Figure 9. Layer with borders of Bosnia and Herzegovina

Zoom in/out controls are included by default. They are shown in the upper left corner of the screen. Figure 10 shows how to zoom in the layer in order to see the building located in the streets of Sarajevo.

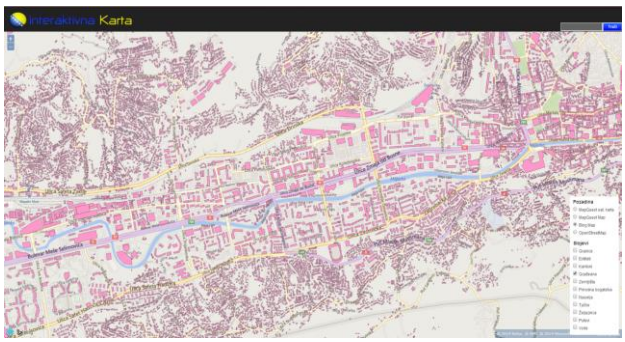

Figure 10. Layer with building in Bosnia and Herzegovina – zoomed view

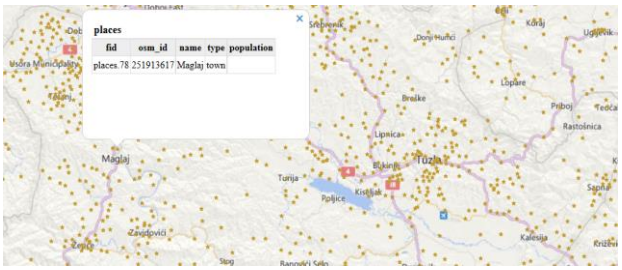

Figure 11. Layer with places in Bosnia and Herzegovina – a pop-up window with details about the place

When a user clicks on some point on the map, a pop-up window will appear, containing information about the place positioned at this location.

E. The Place Search on the Map

Interactive map has a place search functionality that allows locating nearly any place in Bosnia and Herzegovina. The user enters the name of the required place in the search box, which is located in the top right corner of the screen, and then click search. If that place exists, a red marker will appear on map.

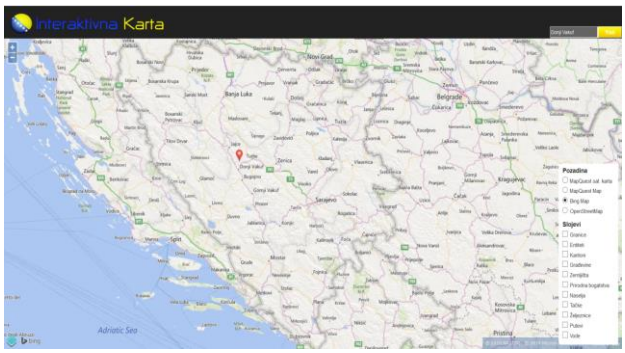

Figure 12. Layer with places in Bosnia and Herzegovina – a pop-up window with details about the place

VI. IMPLEMENTATION STEPS

1) Creating a database
   a. Finding adequate sources of vector data is the first step in the making of a map. List of used .shp files is shown in table 1.
   b. Next step is to design a logical data model.
   c. PostgreSQL is selected for a DBMS. PostGIS, that is a PostgreSQL extension, is installed for a spatial support.
   d. Separate table is created for each .shp file in the table. These files are loaded into the database using pgShapeLoader. A physical data model is created.

1) SPATIAL DATA ABOUT BOSNIA AND HERZEGOVINA

Name	*Description*
Borders	Data about the borders
Entities	Data about the entities
Cantons	Data about the cantons
Buildings	Data about museums, universities, bus stations, hotels, hospitals, etc.
Terrains	Data about the terrains
Natural resources	Data about the natural resources (woods, parks, etc.)
Places	Data about the populated places
Points	Data on a variety of objects
Railways	Data about the railways
Roads	Data about the roads
Water	Data about the water

2) Creating an infrastructure for an web application
   a. GeoServer 2.5 is chosen for a server that will generate maps and manipulate with spatial data.
   b. Eclipse Jetty is a web server that will contain web application.
   c. OpenLayers 3 is chosen for the front end development.
3) Creating layers in GeoServer
   a. To create layers of the map, the user interface of the GeoServer is used for adding a new source of vector data.
   b. These data are published as a new layer by GeoServer.
4) Integrating with external sources
   a. Local layers will be integrated with the following external maps: MapQuest, Bing Maps and OpenStreetMap.
5) WebGIS application development
   a. A user interface is designed.
   b. The code for creating map is written. A map of Bosnia and Herzegovina will be rendered in the central part of the user interface.
   c. Then, a control for layer selection is added.
   d. To implement the popup window, a listener for a single click event must be defined.
   e. Final step is the implementation of search functionality.

VII. CONCLUSION

The primary goal of building a geoportal is to provide a single source of spatial data. Namely, organizations from different domains are collecting and publishing spatial data. Such data sources introduce the problem of inconsistency and redundancy. In such environment, finding the relevant information is time-consuming. Geoportals integrate data from different sources, and provide an efficient mechanism for their search. Because of this, it is considered that a geoportal can satisfy information needs of today's users.

Besides searches, geoportals are useful for spatial data visualization on the web map. Spatial data are complex. They need to be presented on a map to have some value for a typical user. Visualization facilitates the identification of the relationship between spatial data and performing an analysis.

OpenGeo Suite is used for implementation of the interactive map of Bosnia and Herzegovina. An experience of working with this tool has confirmed that the emergence of web GIS has made spatial data available to ordinary users: interactive map was implemented without a wider knowledge of geography.

Prototyping of visualization styles of 3D scalar fields using POV-Ray rendering engine

J. Opiła*
*AGH University of Science and Technology
Department of Applied Computer Science, Faculty of Management, Cracow, Poland
jmo@agh.edu.pl

Abstract – There is a persistent quest for novel methods of visualization in order to get insight into complex phenomena in scientific domains as various as physics, biomedicine or economics. Research teams involved achieved excellent results, however some problems with elaboration of novel visualization styles connected with flexibility of the software used and quality of the final images still persist.

In the paper results of inspection of four visualization styles of 3D static scalar field employing POVRay ray-tracing engine are discussed, i.e. equipotential surface method using direct implementation of isosurface{} object, cellular trilinear interpolation approach, application of texture and eventually pseudo-particles design. All styles presented have been tested for hybrid visualizations and compared concerning computing time, informativeness and general appearance. It is shown in the work that Scene Description Language (SDL), domain specific language implemented in POV-Ray is flexible enough to use it as a tool for fast prototyping of novel visualization techniques. Visualizations discussed in the paper were computed using selected components of API of ScPovPlot3D, i.e. templates written in the SDL language.

Keywords - POVRay, pseudo-particles, scalar field visualization, ScPovPlot3D, visual data analysis

I. INTRODUCTION

In the recent years technologic development enabled elaboration of numerous outstanding data gathering methods, which produces a large amounts of data including numeric and raster image formats. Amongst most productive disciplines one can mention astronomy, engineering, economics, econometrics, medical sciences including medical imaging and this short list is hardly complete. Often collected or computed data are in the form of 3D scalar field, static or dynamic, for example spatial temperature distribution in the sleeve and block of piston engine or pressure distribution in the rocket engine combustion chamber. Scalar fields can be described by differential equations which sometimes can be reduced to a simple formula e.g. for gravitational, electrostatic or (approximate) molecular Lenard-Jones potential. However in numerous cases they can be obtained by measurements only for example distribution of greenhouse gases in Earth's atmosphere [1] or distribution of mineral resources, principally ore deposits, such as coal or oil. Reliable analysis of such a data more often than not requires intensive usage of computer data processing and subsequent visualization.

Though there is an agreement on visualization styles of many data arrangements, visualization of 3D scalar fields still may be refined according to characteristic of a specific case, e.g. implementation of hybrid designs. Thus visualization software or library should allow not only for minor adjustments like color or shape of data points but for experimenting with new styles as well. In order to meet this requirement visualization software has to be sufficiently flexible. Unfortunately, ready-made, even state of the art software, no matter if proprietary (i.e. closed source), or Free and Open Source (FLOSS), always offers only closed list of variants of charts and graph layouts [11], as all of them have to be explicitly compiled into the machine code of the final application or library. As a result, efficient and fast prototyping of novel designs is usually difficult, even if using low level visual toolkits, and sometimes impossible without writing many lines of a new code. This weakness can be overcome by choice of efficient renderer (in order to obtain high quality images) equipped with scripting high level language (to avoid compilation overhead) and published as FLOSS software (to be free from license restrictions).

II. VIRTUAL LABORATORY

In order to inspect problems set above, one needs to conduct some experimental research. However, all "experiments" to be done requires computer only, thus name "numerical experiments" fits well. Because numerical experiments were performed in "virtual laboratory", below is explained how such "laboratory" has been designed.

A. The choice of rendering engine.

In search for the suitable software platform several packages have been examined: BioBlender [23], Blender [14], Diderot [18], gnuplot [10], ParaView [25] RasMol [24], Shadie [20],[21], [22], VTK [17] but only POV-Ray [2] met the all, drafted above, requirements. Some of them just cannot produce visualization of 3D scalar field but molecules only [24], [23] or have disappointing output [11], the over requires tedious low level coding in Python [14] or C++ [17] Below is a short resume of this analysis, software is listed in alphabetic order, except for the POV-Ray which is discussed as the last item.

The work was supported by AGH University of Science and Technology under grant nr. 11.11.200 (job .7)

BioBlender [23] – It is a very interesting add-on to Blender, however is limited to plain visualization of molecules; may use native Blender, Cycles or POV-Ray engine for rendering output images.

Blender [14] – Blender is a 3D animation program, equipped with a choice of efficient raytracing modules (Blender native or Cycles) but capable of employing POV-Ray for raytracing as well. Blender offers user space API written in Python, which can be used for preparing custom charts. While this is really flexible solution for experts, for end user it would be too complex. Thus one of the main objectives of this work, which is possibility of easy building new types of 3D charts, could not be reached because every new kind of plot ought to be separately programmed using complex triangular meshes.

Diderot [18] – excellent, but limited to medical imaging and because of usage of rarely used computer language SML/NJ [19], has very sloppy learning curve,

gnuplot [10] – is a simple but powerful as well as multiplatform chart plotting program, licensed as Free Open Source. However it offers only simple line-art level graphics and limited number of charts and styles. Moreover, plotting algorithms cannot be extended by user written shaders.

RasMol [24] – This toolkit has been designed to model molecules. However it seems to be discontinued, latest release available is from 2009,

Shadie [20] – Python based toolkit and domain specific language, able to use GPU CUDA engine in order to do volume visualization using CT or X-Ray data. Originally designed for medical purposes may be used for other fields of science as well, however this application is restricted, because Shadie requires as input data grayscale bitmaps. Another problem is that the project seems to be discontinued; the latest source files are dated on 2011 year.

VTK [17] – excellent and extended toolkit, but requires laborious coding phase, in order to built case specific final program. While adding novel designs is possible by extending base classes it requires excellent programming skills.

POV-Ray [2] is the well known, raytracing program producing stunning photorealistic images. Unfortunately it is controlled by text files containing sequence of statements written in specific to POV-Ray domain specific language dubbed by developers "Scene Description Language" – SDL. SDL as domain specific language is built into POV-Ray, and its full documentation is available on POV-Ray's home page and dedicated Forum. SDL implements a couple of predefined graphics primitives (i.e. readymade "shapes"), simple [1] and complex [2] ones, all of them defined as mathematical entities. Objects inserted into scene description file are thus parameterized by a set of attributes and can also be scaled, rotated, translated and skewed. Because POV-Ray is founded on mathematical modeling it offers to the end user a number of valuable numerical methods like root solvers (including Sturmian solver), spline functions, fractals and vector analysis functions (ex. gradient finding). While SDL is good enough for programming of even very complex scenes, it lacks some features characteristic for modern languages like constants, structures or classes. Another problem is connected with coordinate system employed by the program, which not only is left-handed but rotated too. Because of these weaknesses only those skilled in programming and 3D aware users are able utilize its full potential and power. Luckily, SDL implements many constructs sufficient for coding of efficient Application Programming Interface (API), like macros, inline functions, function and macro pointers, conditionals, loops and arrays. Furthermore, POV-Ray is equipped with comfortable Integrated Development Interface [3] (IDE), featuring a.o. syntax coloring, word completion and simple debugger.

B. What ScPovPlot3D is and why has been used.

In the recent years set of templates for POV-Ray, named ScPovPlot3D (**S**cientific **POV**-Ray **Plot**s in **3D**) has been developed [3]. Beginning with simple histogram chart some years ago it can now help prepare a range of 3D charts including raw or smoothed 3D surfaces, wireframe "surfaces" and surfaces based on irregularly dispersed data [7],[8],[9] (employing simple kriging method) available in the stable branch. Experimental modules include procedures for a.o. fuzzy numbers [5], hybrid charts [6], vector field and potential visualization. Moreover helper modules delivers easy to use items like smart cameras ("Cameras.inc" library), coordinate systems as well as text with enhanced formatting.

Main achievement of the toolkit is a reasonable balance between ease of use, flexibility and quality of produced images. As a result, less experienced users can prepare custom charts in minutes, just by modifying included examples, while expert users may tune code of the scene to obtain novel designs. In the following chapters prototyping of visualization styles of 3D static scalar fields using the POV-Ray, complemented with ScPovPlot3D templates is discussed.

C. Choice of exemplary scalar field

To compare different visualization styles the same scalar field produced by selected molecular structure should be used for all tested styles. The structure chosen should obey at least two, contradictory, constraints. Firstly, it should be complex enough to reveal unknown properties, for example at boundary or in case of structural defects (e.g. lack of one of atoms). Secondly, it has to be as simple as possible to be computable in reasonable time on regular workstation. Based on these assumptions Lennard-Jones potential (often referred as L-J potential) around single layer hexagonal structure (thus referred in the paper as "graphene like") composed from 40 neutral molecules, has been chosen. It should be mentioned, that electrostatic potential around real graphene flake is generated by electric charge distributed continuously due to the principles of the quantum mechanics and should be

[1] ex.: plane, cylinder, torus.
[2] 3D Bezier patch, isosurface, fractals,

[3] Windows™ version only

computed by integration over space using Coulomb's Law.

Although in the paper electrostatic potential is taken into account conclusions remain the same for any static scalar field, e.g. tissue density restored from NMR or X-Ray DICOM images.

D. Lennard-Jones potential

Visualization of molecules is a real challenge. First of all, world in nanoscale is governed by quantum mechanics so phenomena like hybridization of orbitals [15] or elusive Casimir effect [16] are often observed. In particular nanoscale objects, due to presence of continuous electric charge distribution, does not sport a well defined (i.e. rigid) surface like a billiard or golf ball so a special convention should be adopted, e.g. specific value of potential or ionic radius resulting from measurements, to be enable drawing "surface" of the molecule. It should be noted, that ionic radius depends on the electronic structure of an element in a molecule. Another problem is connected with numerical calculations, namely, in equations very small values (ε, r_0, r_m, r) are placed one in denominator and the other in nominator what is a serious source of round-off errors. This requires special attention at designing and writing source code.

For a single neutral atom or spherical molecule a relatively simple formula for electrostatic potential was developed by Lennard-Jones (1) [12]:

$$V_{LJ}(\vec{r}) = \varepsilon\left[\left(\frac{r_m}{|\vec{r}-\vec{r}_0|}\right)^{12} - 2\left(\frac{r_m}{|\vec{r}-\vec{r}_0|}\right)^{6}\right], \qquad (1)$$

where $\vec{r}_0$ is position of the source molecule, $\vec{r}$ points at observation point, $\boldsymbol{\varepsilon}$ is a depth of the potential well and r_m is distance at which value of the potential is minimum. As results from (1) L-J potential is spherically symmetric.

For a set of molecules summation over all $\boldsymbol{N}$ sources have to be done (2). For the case presented in this paper $\boldsymbol{N}$=40:

$$V_{LJ}(\vec{r}) = \sum_{i=1}^{N} \varepsilon\left[\left(\frac{r_m}{|\vec{r}-\vec{r}_{0,i}|}\right)^{12} - 2\left(\frac{r_m}{|\vec{r}-\vec{r}_{0,i}|}\right)^{6}\right]. \qquad (2)$$

While alternative formulations of the L-J potential are possible but this one has been implemented in ScPovPlot3D API. Prototypes presented in the next part of the paper require passing value of the scalar field in the form of POV-Ray "function". However, functions in POV-Ray have many limitations and resembles inline functions of C++ rather than fully featured subroutines. Although formula (2) seems to be simple, coding it in the form of POV-Ray function is not. Because loops and temporary variables are not allowed inside POV-Ray "functions" whole definition of the function, including header and statements, has to be explicitly injected into the code of the scene at runtime. The solution is to design dedicated function factory using #macro{} syntax completing this task. The code of function factory for L-J potential is presented in the Fig. (1). Although code of the function factory is short, after expansion may inflate to hundreds of lines for larger structures.

Code snippets discussed in next sections are reduced to the most important lines. Full source code, required to re-compute included graphics is available on-line [4]. POV-Ray documentation is available from within IDE.

E. Computer

Most calculations were done on ASUS 1215N, which is rather slow, if compared to high-end workstations. Computation time on multicore computer, in comparison to obtained times, may be over a dozen times shorter.

In the next chapters, prototyping and search for optimal 3D visualization style of Lennard-Jones potential produced by "graphene like" flake is presented.

III. ISOSURFACE

Spatial distribution of the scalar field **V**, given by a function **V**=V(x,y,z) (not necessarily continuous) is being customarily visualized using "same value" surfaces, called "isosurface" or "equipotential" if the potential field (for example gravitational or electrostatic) is under

```
#macro CreateVLJ(_PTs)  // creates Lenard-Jones potential function from network  of neutral molecules given by structure table _PTs[][]:
    // using variant of L-J formula employing radius of minimum of the potential well r_m
    #if (_PTs[0][0]>0)      // need one charge at least!
       function(x,y,z){
          _PTs[1][6]*( pow( _PTs[1][5] *_PTs[1][5]/(pow(x-_PTs[1][1],2) + pow(y-_PTs[1][2],2) + pow(z-_PTs[1][3],2)), 6)
                    -2*pow( _PTs[1][5] *_PTs[1][5]/(pow(x-_PTs[1][1],2) + pow(y-_PTs[1][2],2) + pow(z-_PTs[1][3],2)), 3))
          #for(i, 2, _PTs[0][0]) // loop  #for...#end  is part of macro not function
             +
             _PTs[i][6]*(pow( _PTs[i][5] *_PTs[i][5]/(pow(x-_PTs[i][1],2) + pow(y-_PTs[i][2],2) + pow(z-_PTs[i][3],2)), 6)-
                       2*pow( _PTs[i][5] *_PTs[i][5]/(pow(x-_PTs[i][1],2) + pow(y-_PTs[i][2],2) + pow(z-_PTs[i][3],2)), 3))
          #end
          }
    #else
         function(x,y,z){0} // just for safety
    #end
#end // CreateVLJ() end definition
```

Figure 1. Function factory for L-J potential defined as macro injecting raw code into scene file at runtime. Relevant data are defined in the global table _PTs[][]. First index, i=1…N (first row for i=0 has special meaning), enumerates all molecules in the structure, and the second has following interpretation (i-index of the molecule): [i][0] charge, [i][1,2,3] x, y and z of observation point, [i] [4] L-J ionic radius R [i][4], L-J radius of minimum of potential well [i][5], potential well ε [i][6].

consideration. POV-Ray sports dedicated object for this purpose called *isosurface*, definition is presented below. Notation adheres to common convention: key identifiers are in bold, optional parts are in square brackets, options are separated by '|' character [2]:

```
isosurface {
  function { FUNCTION_ITEMS }
  [contained_by { SPHERE | BOX }]
  [threshold FLOAT_VALUE]
  [accuracy FLOAT_VALUE]
  [max_gradient FLOAT_VALUE]
  [evaluate P0, P1, P2]
  [open]
  [max_trace INTEGER] | [all_intersections]
  [OBJECT_MODIFIERS...]
}
```

Only one item is obligatory, namely 3D scalar function. The most important optional item is a float *threshold*, which determines value constant over the isosurface object. Object modifiers describe look and finish of the surface. However, if omitted, default values are used. Detailed description of other attributes is given in documentation of POV-Ray.

Isosurface visualization style may be simple or hybrid. In the first case only shape of equipotential surface is revealed and colorful texture may be used to differentiate between surfaces with different threshold values. Thus a few surfaces may be shown in a single picture.

In the second case texture may be calculated using, for example, value of the gradient of the field over the surface. That way two different functions may be visualized at the same time as shown in Fig. 2.

However two hard to solve problems arise, both related to POV-Ray limitations. The first one is connected with computation time, the other with syntax.

Computation of the perfect looking isosurface requires use of very precise root finding algorithm, which in turn makes a lot of calls to potential function. Moreover, the potential function, due to limitations of POV-Ray syntax, has to be defined in rather inefficient way as a very long formula. Furthermore, algorithm is forced to search for the roots everywhere around the particle. Reducing searched space using **contained_by** modifier may solve this problem to some extent.

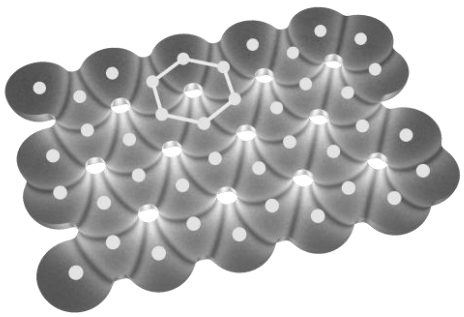

Figure 2. Hybrid representation of electrostatic L-J field around "graphene like" flake. Light gray circles marks "carbon" atoms, bonds of one hexagon are shown. The shape of the surface represents surface of constant potential and tint represents gradient of the potential: dark – low gradient, white-high gradient.
Computation time was 1h 07m. Source: own.

Limitations of syntax of function makes programming of user-function governed textures very difficult. In general, user defined potential function has to be passed as an argument to the gradient function building macro. Then the gradient aware texture may be defined:

```
#local gMin =    75; // assumed gradient minimum
#local gMax = 150; // assumed gradient maximum
SetGradientAccuracy(.0001) // const. for fn_Gradient()
// fn_Gradient(VLJ) makes from passed VLJ function
// gradient length of VLJ as a function.
#local grV0 = fn_Gradient(VLJ);
// definition of clipped function grV, useful for
// color_map{} texture
#local grV = function{
   clip(grV0(x,y,z)-gMin, 0, gMax-gMin)/(gMax-gMin)
};
SetIsoTexture(  // setting gradient governed texture..
  texture{
    pigment{
      function{ grV(x,y,z) } // gradient aware texture
      color_map{ _ColorMap }
    }
    finish{ Dull }
  }
)
// preparing of the isosurface,
#declare ISO3 = MakeEquiPlane( VVV, 5, Min, Max )
// and displaying it:
object{ISO3}
```

The aim of cellular trilinear interpolation method, presented in the next chapter is to overcome inefficiency of function coding and to improve efficiency of root searching algorithm.

IV. CELLULAR TRILINEAR INTERPOLATION

In case of very large structures counting hundreds of atoms potential function produced by function factory becomes extremely inefficient. Additionally finding isosurfaces over extended areas abruptly increases computation time. The first problem may be solved by simplification of function code through some kind of multi-linear interpolation the other by splitting whole search space into cells, then rejecting from analysis those cells where no piece of isosurface can be found.

Trilinear interpolation function $f:\Re^8 \rightarrow \Re$ implemented in ScPovPlot3D is defined in recursive manner (3) [26], [27], relevant geometry and symbols are displayed in the Fig.3. First, by linear interpolation of "Q" along edges of the cell, $Q_{ij} = \lambda Q_j + (1-\lambda) Q_i$ (where Q is scalar defined in vertices of the given cell - Q may be interpreted as charge, potential value, etc.) edge intermediate values denoted as e.g. Q_{12} are computed (3a). Then edge intermediate values are combined across common face (3b) producing two face intermediate values, in Fig. 3 denoted as Q_D and Q_U. Finally face intermediate values produce approximated value of Q denoted as Q_A (3c). It can be easily shown, that

interpolated value Q_A does not depend on specific sequence of calculation of edge and face intermediate values. Sequence presented in the Fig.3 may be described by [yxz] notation and the same values for Q_A will be obtained if sequence [xyz] or [zxy] would be used.

$$\lambda_x = \frac{x}{L_x}; \quad \lambda_y = \frac{y}{L_y}; \quad \lambda_z = \frac{z}{L_z};$$

$$\begin{cases} Q_{12} = \lambda_y Q_2 + (1-\lambda_y) Q_1 \\ Q_{34} = \lambda_y Q_4 + (1-\lambda_y) Q_3 \\ Q_{56} = \lambda_y Q_6 + (1-\lambda_y) Q_5 \\ Q_{78} = \lambda_y Q_8 + (1-\lambda_y) Q_7 \end{cases} \quad a) \qquad (3)$$

$$\begin{cases} Q_D = \lambda_x Q_{12} + (1-\lambda_x) Q_{34} \\ Q_U = \lambda_x Q_{56} + (1-\lambda_x) Q_{78} \end{cases} \quad b)$$

$$Q_A = \lambda_z Q_U + (1-\lambda_z) Q_D \quad c)$$

Because (3) uses only simple arithmetics, i.e. additions and multiplications, it can be computed relatively fast, however this does not mean, that whole computation time is short. Test hybrid image (isosurface plus gradient) presented in the Fig. 4, has been rendered using 300×150×60 cell grid, hence potential value in 2'772'511 nodes had to be calculated. After that every cell was tested, if isosurface threshold may be found inside, if yes, isosurface object was injected into scene file, if no, processing was passed to the next cell. Computing of nodal values and preparing isosurface pieces for rendering took approximately 90% of scene computing time. Because algorithm is approximated, some circular artifacts for gradient may be observed on the calculated surface. As isosurface algorithm avoids crawling through empty space, computation of surface itself is fast.

The overall efficiency may be improved using external command line driven program written in C language as numerical calculations using machine level instructions

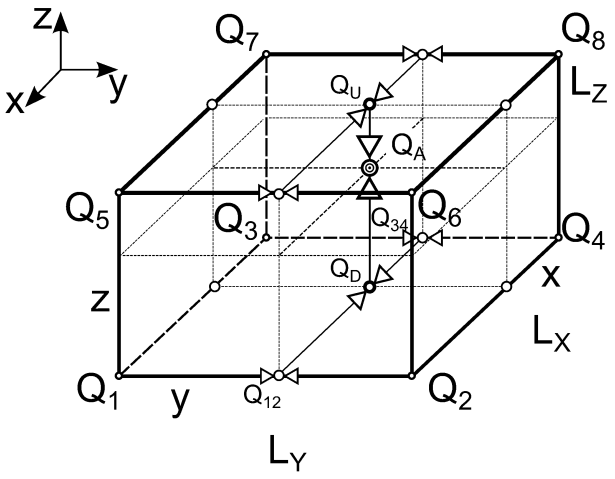

Figure 3. Illustration of multilinear interpolation algorithm. Approximated value of potential $V(Q_A)$ in point $Q_A(x,y,z)$ marked with a triple circle is given by (3). White arrows shows sequence of calculations. In the upper left corner symbolic reference to coordinate system is shown. Source: own.

(as is common in "compiled" languages) are very fast. Furthermore, as cells are mutually independent, this algorithm may be easily implemented as parallel employing GPU CUDA technology. Another improvement toward reducing number of cells and enabling smooth surface transitions between them, requires implementation of more sophisticated interpolation algorithm, based for example on spline paradigm.

V. PSEUDOPARTICLES APPROACH

Another possible visualization style is based on pseudoparticle idea. "Particles" in 3D computer graphics, implemented as "media" in POV-Ray, simulate presence of 0-sized objects scattering, absorbing or emitting light. These objects may get specific color due to programmer's demand. Similar paradigm has been implemented in very old program HPOV [15], designed for visualization of hybridized electron orbitals.

Because media calculations in POV-Ray are very slow a plenty of very small spheres may be used instead. Hence visualization is reduced to point calculations now, limitations of syntax are lifted. As a result this style is very flexible, up to possibility of including representation of third scalar function as e.g. shape variation.

In presented implementation all pseudo-particles were obtained by the drawing of x,y,z coordinates from three independent pseudo-random number generators (PRNG), then comparing potential for the point drawn with desired threshold value. If difference is smaller than assumed accuracy, position of this point is refined using gradient of the potential. Eventually a little sphere is injected into the scene, with texture related to gradient of the potential. Exemplary image obtained using this technique is presented in the Fig. 5.

Although this style has some advantages it has shortcomings as well. First of all, PRNG implemented in POV-Ray is very slow and most of "shots" are missed. However positions of pseudoparticles may be computed by external program and then read in from text file.

VI. COLOR MAPS

"Color map" is feature of POV-Ray allowing for assignment of color (texture or pigment as well) to the float value given by space dependant "pattern function". Thus any scalar function including potential function and

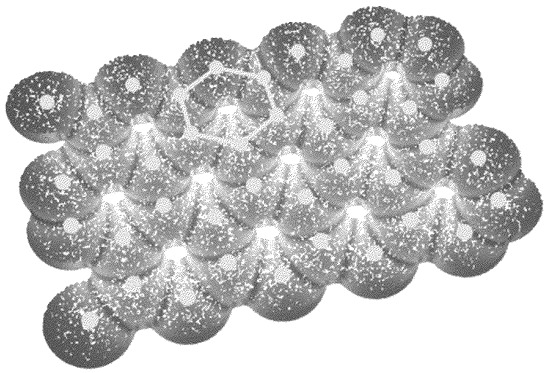

Figure 5. Hybrid representation of LJ potential and gradient using pseudoparticles approach employing 10^5 spheres. Due to small efficiency of drawing algorithm computation time was 4h 8m. Despite large number of spheres drawn,still same artifacts are visible. Source: own.

its variants (gradient length, divergence …) may be passed to texture definition as pattern function. As a probe object a plane or another suitable for research aim object may be used. Amongst advantages of this approach one can mention very short computation time and high flexibility.

The "Potential.inc" module from ScPovPlot3D library [3] offers relevant API functions. Exemplary image rendered that way is presented in Fig. 6. As input, decimal logarithm of LJ potential was used. Black and white stripes are painted every tenfold increase of potential on three perpendicularly oriented planes, revealing potential holes as possible two-state molecular switches (single particle may be trapped up or below the plane).

VII. Conlusion

High quality 3D render program equipped with

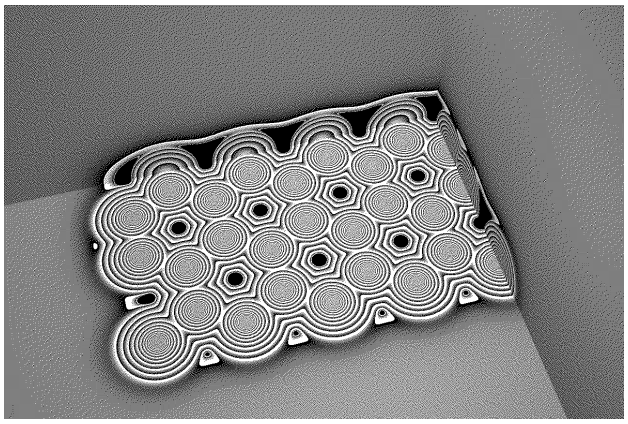

Figure 6. Color map representation of decimal logarithm of LJ potential painted on three perpendicular probe planes. BW stripes marks 10 times increase of potential value. Computation time, 0h 2m. Source: own

efficient scripting language and supplementary API, like POV-Ray, may be used for fast prototyping of complex visualization styles.

Because of numerical efficiency problems in some cases external program should be used.

Due to relatively short computation time color map style is very well suited for fast introductory analysis of new structures.

Acknowledgment

I thank to Mr. Prof. J.T. Duda for encouragement and personal support.

Abstract - This paper proposes a novel 3D direct interaction modelling system for manipulating voxel based objects using currently available 3D motion sensing input devices such as Microsoft Kinect. The guiding principle while developing the system was to imitate natural human modelling behaviour and provide a real life experience of 3D object manipulation, inspired by the techniques used in modelling clay. Properties of a functional prototype application are presented and software architecture of the created tool is analysed. Descriptions of newly developed algorithms are included, grouped into several categories. Visualization algorithms are used for defining properties and creating usable modelling mass from volumetric models. On the other hand, algorithms related to object recognition and human computer interaction include various techniques for depth segmentation, contour detection, finger recognition and virtual control with gestures.

I. INTRODUCTION

Computers of various sizes and forms surround us in everyday life and it is hard to imagine life without them, but in some cases interaction is still somewhat unintuitive because methods of indirect control are used. Usually, we first have to learn how to use the controller and only then can we perform the desired task. Notable examples include using a mouse to control a pointer and activate onscreen actions or using gamepads or joysticks to control the environment with different buttons and sticks. Rapid development of new and interesting technologies related to human-computer interactions encouraged us to research and develop a novel interaction model which could improve our experience when interacting with 3D objects in a computer generated world. The key motivation behind technologies which use direct manipulation is not only to naturally represent human actions, but also to promote the notion of people performing tasks themselves, and not through some intermediary, like a computer. Problem with unnatural controls is especially apparent when doing 3D modelling since usually 2D controllers are used for manipulating objects in 3D world. One of the possible solutions for performing these tasks in a more natural way will be presented in this paper. Final goal is to have a functional prototype which would be more like a real life experience, for instance, as you would do clay modelling. Therefore, suitable hardware for direct 3D control has to be found and accompanying software support has to be developed.

In the last couple of years situation with direct control in consumer devices is getting better because smartphones and tablets became widely available and the main method of interaction is via touchscreen surfaces. Touch interfaces allowed users to use movements from real life (like translations) to be directly mapped to corresponding actions for onscreen elements. There are some programs like Autodesk 123D Sculpt on iOS which use this kind of interaction but unfortunately, with current technology, there is no depth information so operations like extruding or making holes in the model feel unnatural and don't provide good feedback. Reconstruction of depth information can be somewhat alleviated by adding gyroscopes and accelerometers which provide limited 3D movement recognition. One of the best examples of such controller is Nintendo Wiimote because of its high precision, wide availability, user friendliness and popularity. Drawback is that the controller has to be held in a user's hand which means that fingers can't be used for modelling with a fine level of detail [1, 2]. Also, our goal is to provide a truly natural user interface without any additional devices that would be a burden to a user.

An alternative approach is offered by Microsoft with Kinect where a user's own body acts as a controller. The advantage in this case is the ability to use the full 3D range of movement "without" constraints[1] and have free hands to interact with the virtual world in a natural way, and that was one of the initial prerequisites. Another device with similar characteristics, which could be also suited for the 3D modelling methods described here, is Leap Motion Controller. Since the mode of operation and detection is similar compared to Kinect, it should be relatively easy to adapt the developed prototype for use with Leap.

This paper is divided into six sections. Section 2 investigates related work where relationship with our prototype is based on similar ideas or a similar controller was used. Section 3 consists of several subsections where technical implementation details of used algorithms are described. In section 4, both performance and functional results are presented and discussed. Section 5 provides insight into possible future development of the prototype and finally, section 6 concludes the paper.

II. RELATED WORK

During the development of our prototype, we focused our research on a combination of computer modelling and

[1] There are still some constraints like usable sensor range or speed with which the user moves the hands.

motion gesture interfaces. Our proposed 3D direct interaction modelling system was significantly inspired by the work of Cho et al. [3] presented in the paper under the title "Turn: A Virtual Pottery by Real Spinning Wheel" and later expanded journal article [4]. Cho proposes a digital pottery system that successfully reflects real-world gestures to their virtual counterparts. The study focuses on the specific aspect of clay modelling where the freedom of movement and possible creations are limited by a spinning-wheel modelling technique. On the other hand, the interaction model proposed in our paper tries to implement virtual freeform modelling and object manipulation without spatial restrictions or any predefined movements.

In the paper "Gesture Interface for 3D CAD Modelling using Kinect", Dave et al. [5] successfully bring the intuitiveness of motion gestures to a CAD environment using Kinect in combination with constructive solid geometry and deformations, which produces results similar to traditional clay modelling. However, the restriction of the proposed creative solution is that Kinect could be only used to control tools which are already present in standard CAD programs. Using their prototype as an inspiration, we tried to remove any kind of restriction that could be a potential obstacle in providing a real life experience of freeform modelling in its true sense. Oliver Kreylos [1,2] also created modelling prototypes with motion input devices, but these prototypes were using motion controllers like Razer Hydra and Wiimote. Oliver's presented work did not try to achieve direct interaction via natural user interfaces, but instead, it utilized benefits of motion controllers to develop highly accurate and usable modelling system. The evaluated results are very impressive, and therefore present great challenges to be overcome, compared to our modelling system with less accurate, object recognition based, methods, i.e. without motion controllers.

Finger recognition techniques used in this paper were partially based on the algorithms described by Daniel James Ryan [6] in his thesis. Although it was possible to directly use the algorithms as they were described in his thesis, we decided to adapt and optimize recognition algorithms to better accommodate our requirements where main reasons for modifications were strict performance requirements.

III. PROPOSED SOLUTION

Our solution can be divided into several distinct components which, when combined, achieve the final goal of having a real-time system which allows completely freeform 3D modelling that also imitates real life clay modelling behaviour. Basic components of the proposed solution are representation of the virtual clay, the finger recognition system and the visualization and interaction framework.

A. Virtual clay

The first component of the proposed solution defines the properties of the virtual modelling clay compound. An approach based on voxels was chosen because while analysing different alternatives for mesh representation this seemed like the most natural solution when dealing with multiple simultaneous extrusions and intrusions. The marching cubes algorithm [7] was used to render the volumetric model, but in a GPU accelerated variant, to make the prototype sufficiently fast to be executed in real-time. GPU acceleration could have been achieved using some GPGPU APIs, like OpenCL or CUDA, but since our goal was also to provide support for older computers, a more compatible approach using shaders was chosen. The method used for GPU acceleration of marching cubes was based on the guidelines from the NVidia's GPU Gems article [8]. The main idea is to load the model in a 3D texture and then use GPU shaders to process all cubes simultaneously. A version with multiple shader passes was used, which enabled moving as much computations as possible from the geometry shader to the vertex shader. Reducing the workload in the geometry shader was required because that shader is extremely slow compared to other shaders.

Two passes were used, where coordinates of the corners of the voxel were the initial input and rendered polygons were the final output. The first pass in the vertex shader calculates positions of the voxels and their polygon configurations. Voxel positions and polygon configurations are then sent to the geometry shader where empty voxel configurations are rejected and simple markers for relative positions of triangle vertices are generated. Up to five markers are generated since five is the maximum number of polygons per voxel. Markers are then used in the vertex shader of the second pass where real 3D world space polygons coordinates are calculated, as well as normals. All of these previous steps led to an optimization which improved performance because it reduced the workload on geometry shader. The shader just had to stream out newly generated vertices and did not have to calculate anything. Finally, pixel shader is used to calculate lightning and render the model with proper colours.

B. Finger recognition

The second component in the developed system is related to finger recognition and it is based on Microsoft Kinect combined with algorithms for detecting and tracking body and various joints. The official Kinect API provides support for obtaining 3D coordinates of major joints so hand positions could be easily found, but for coordinates of individual fingers custom segmentation and recognition algorithms had to be developed and this process can be divided into several stages. In the first stage Kinect API is used to roughly detect the centre of the hand, and then, we propose algorithm based on the coordinates of the detected centre hand points. The image around the detected points is segmented by depth and hand contours are extracted. Segmentation was based on the assumption that hands are always in front of the body so it could be performed more easily.

Since the obtained contour is saved in a 2D field, it has to be converted to a 1D aligned array so it could be used with a k-curvature algorithm that is used to detect fingertips. Conversion was done with a custom algorithm which collects neighbouring contour points using circular search pattern where starting search position for the next

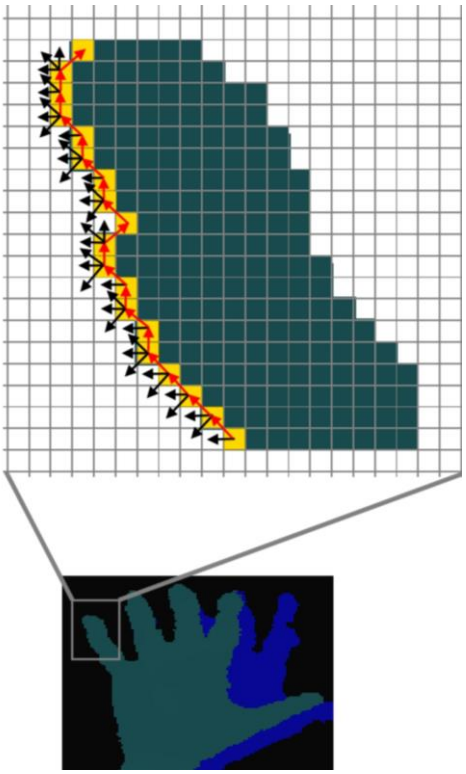

Figure 1. Execution of the contour detecting algorithm. Arrows show how the algorithm advanced while searching for the contour. Black arrows point to rejected background pixels and red arrows show the direction of contour pixels.

point depends on the positions of the current and previously found points. Figure 1 shows a simplified example of the contour-finding algorithm. In the extracted contour, k-curvature calculates the fingertip positions by taking three points from the array separated by factor k. Curvature and centroid calculations performed on the selected three points are used as features for detection of fingertips, as seen on Figure 2. The proposed algorithm works with the assumption that hands are mostly curved smoothly compared to the fingers, and centroid calculation is used to distinguish fingertips from valleys between fingers because these are the only places with sharp angles.

After finger positions are calculated, they have to be converted to Kinect's projection space coordinates so they are comparable with real world dimensions. Coordinate conversion was done using methods from Kinect API. After the final feature positions have been obtained, they were transferred to the interaction system where they were processed and converted into gestures.

C. Interaction system

Finally, there is a visualization step and interaction system that connects the other two, previously described, components and provides an input/output interface for the user. It is implemented using SharpDX Toolkit API, which is based on DirectX 11 and can be considered as an unofficial successor to Microsoft XNA Framework. SharpDX is currently the fastest managed DirectX APIs and is just 1.5x times slower than native code. It also forms a basis for many graphics engines, of which MonoGame is the most famous one.

Primary output is visual and is represented by a window where volumetric model with its bounding box is displayed. In the main window, there is also an abstract model which uses simple spheres to represent hands and fingers. Also, to ease the positioning in front of Kinect, because of the limited range and viewport, an additional sub-window is displayed, which shows depth and finger recognition data.

Hand gestures are used as primary input and were designed to be as intuitive as possible, but it still takes some time to get used to controls since there is no force feedback. Gestures are defined in the following way: if hands are not touching the model, it is possible to adjust the view by closing them (like grabbing an object) and then move, rotate and zoom it, and if they are inside the model or touching it, virtual clay is either added or removed on coordinates calculated based on the position of the fingertips. Some possible manipulations while using the program can be seen in the images in Figure 3. Additionally, keyboard controls can also be used for view manipulation, as a backup for cases when Kinect isn't connected or stops functioning properly due to bad lighting.

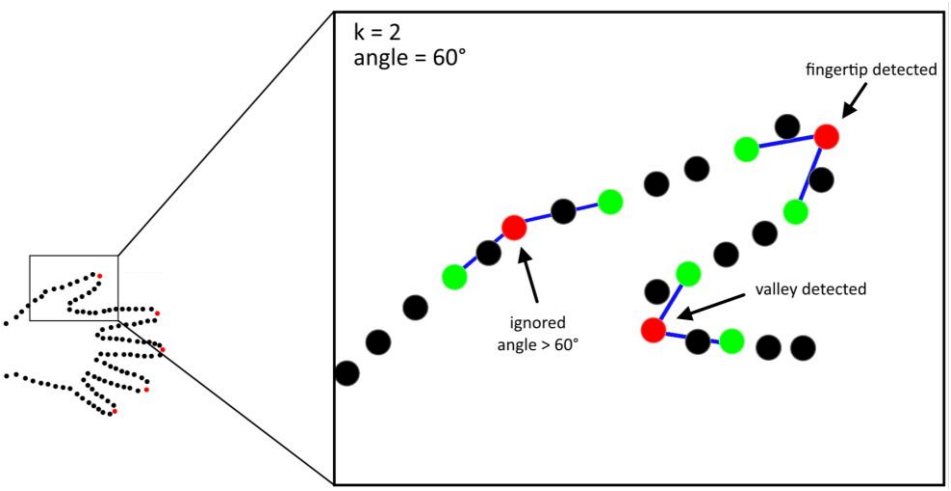

Figure 2. Simplified representation of the k-curvature algorithm. Fingertips are detected based on the angle between three points separated by factor k. Valleys as false positives are ignored because their centroid isn't located inside a finger

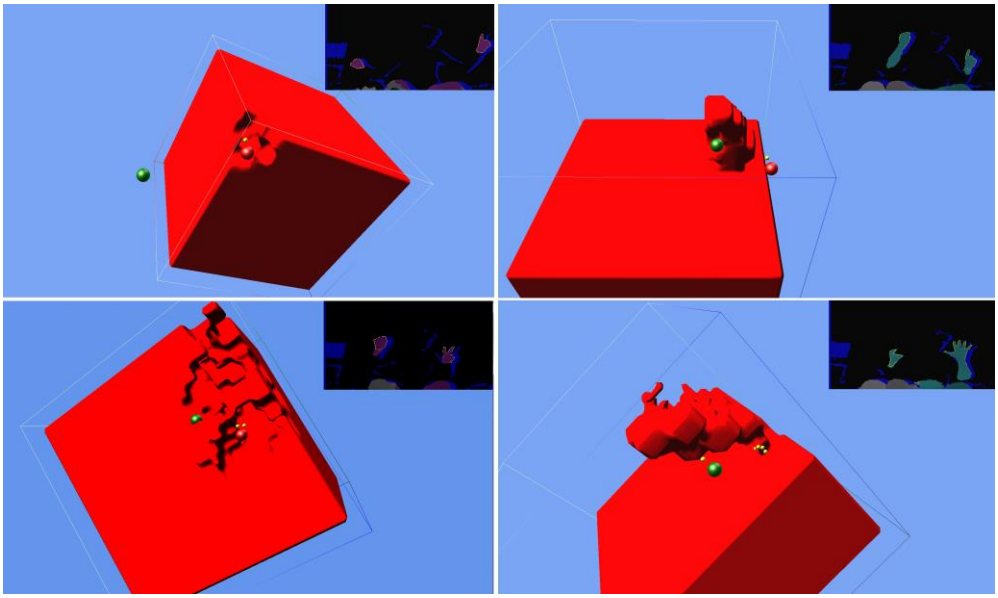

Figure 3. Several images of a working program where various intrusions, extrusions and view manipulations on a model can be observed

IV. RESULTS

The developed prototype application showed that results are promising, both considering performance and functionality. Even on relatively underpowered hardware, represented by Configuration 1, compared to other listed configurations, it is possible to track the fingers and render the model with reasonable quality in real-time with all, initially planned, features enabled. There were several hardware configurations on which this program was tested to show its scalability and also good compatibility, considering the variety of the used components. Table 1 lists relevant parts of the specifications for each of the configurations. Since the host part of the program is single-threaded and the main computation, which is multi-threaded, is executed on the graphics card, turbo frequencies will be listed for the CPUs, and the number of cores with their frequencies for the GPUs, so scaling can be more easily evaluated.

Performance results were measured on a cubic model with Kinect connected and finger recognition turned on. An example of the model and the pose used for evaluation are shown in Figure 4. Samples were taken for several resolutions to show which cases are usable in practice for different configurations and how the algorithm scales depending on the complexity. A numerical representation of the results and used resolutions can be seen in Table 2. In Figure 5, which shows graphical representation of the results, it can be seen that drawing speed, measured in frames per second, scales as expected depending on the GPU architecture and considering the small differences between CPU performances it can be concluded that this prototype is GPU bound.

While measuring performance results where Kinect was active were not much different than results with Kinect inactive. There was a slight performance hit, but it was observable only on smaller resolutions, which means that image processing for Kinect took at most 5-10 ms of GPU time. Memory usage was also observed in both cases and results showed that when Kinect is not connected, each time when model resolution is changed, it steadily increases from 50 MB to 320 MB, but when garbage collection activates, after all assets have been loaded, transferred to GPU and not needed on CPU side anymore, it drops to around 60 MB. With Kinect connected, memory usage is constant and floats around 200 MB, even after garbage collection has activated.

Functionality-wise, gestures and model manipulations are working well while Kinect detects user joints correctly, but quite often it does not. One of the cases when Kinect does not detect joints at all is when users leave the Kinect detection range. The detection range is limited to distances between 0.8–3.5 m. This usually happens when moving hands closer to Kinect to change farther parts of the model and it could be avoided if users would not stand too close to Kinect, but in that case another problem arises because Kinect's resolution is not high enough and the algorithm which detects fingers does not work well anymore. In our case, experiments showed

TABLE I. HARDWARE CONFIGURATIONS USED FOR TESTING

	Configuration 1	Configuration 2	Configuration 3
CPU	Core2Duo T7500, 2.4 GHz	Core i5-430M, 2.53 GHz	Core i7-3630QM, 3.4 GHz
GPU	Radeon HD 3650m, 120x600 MHz	Radeon HD 5650m, 400x550 MHz	Quadro K2000M, 384x750 MHz
RAM	4 GB DDR2, 800 MHz	4 GB DDR3, 1066 MHz	8 GB DDR3, 1600 MHz
OS	Win8.1 x64	Win8.1 x64	Win7 x64

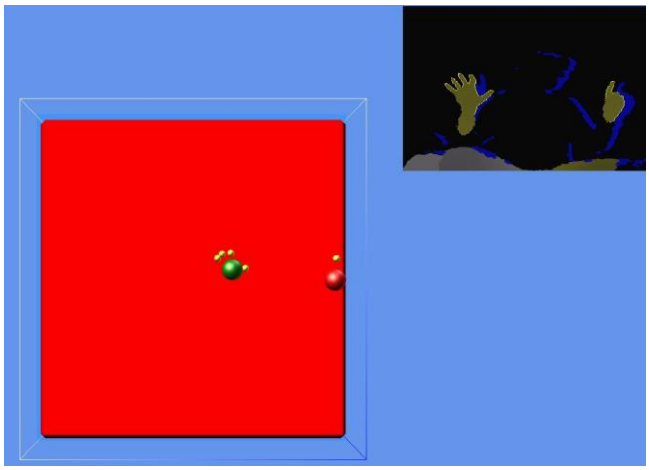

Figure 4. Example of the used benchmark scenario where simple cube was loaded while finger recognition was active

that the best distance is if the user is positioned at around 1.2m. Another case is when Kinect confuses other parts of environment or other joints as hands (usually when a user moves too fast) in which case wrong image fragment is used when trying to detect fingers. In general, most problems happen because Kinect does not have high enough temporal and spatial resolution and all of these problems should disappear in future implementations since use of other controllers is already planned.

Since there are no directly comparable products on the market which offer gesture based modelling, we subjectively evaluated the usability and satisfaction of users after using our prototype application. Although our proposed solution, in its current state, lacks the precision of the professional 3D modelling tools, feedback collected from the users proves that the concept of intuitive, computer based, 3D modelling is feasible. Simplicity and ease of use of the developed prototype application became apparent when users without any modelling experience managed to quickly figure out the gestures and started modifying the preloaded model.

TABLE II. PERFORMANCE DEPENDING ON THE MODEL SIZE

Cube length	Configuration 1	Configuration 2	Configuration 3
(N vertices)		*(FPS)*	
50	127	358	670
100	24	57	124
150	7	20	42
200	4	8	18
250	2	4	10

V. FUTURE WORK

As an interesting future research topic and potential improvement, we consider changing the controller. Since Kinect was designed to recognize larger body parts, competitive devices with finer recognition capabilities would be a better choice for this application, such as Leap Motion Controller or the new Kinect v2. Another interesting feature, which would improve immersion and usability, would be an interactive perspective projection transformation based on the user's head position which is easily obtainable through Kinect API. The idea is that the virtual view responds to the user's head movement, and we believe this feature would positively affect the experience of the virtual 3D world. There is also high probability that the mentioned feature would be also implemented with a virtual headset, such as Oculus Rift, since it has higher availability compared to other similar devices.

There is also some room for improvement regarding the application's performance. One of the optimizations is related to eliminating the redundant vertices created by the marching cubes algorithm since the edges on the neighbouring cubes share the same vertices. The idea would be to create only a single instance of each vertex and then use indexing to describe where each vertex is located. Another useful optimization would be partial dynamic model loading, especially when dealing with high resolution volume models. Since the complexity of the algorithm is high, this feature could considerably

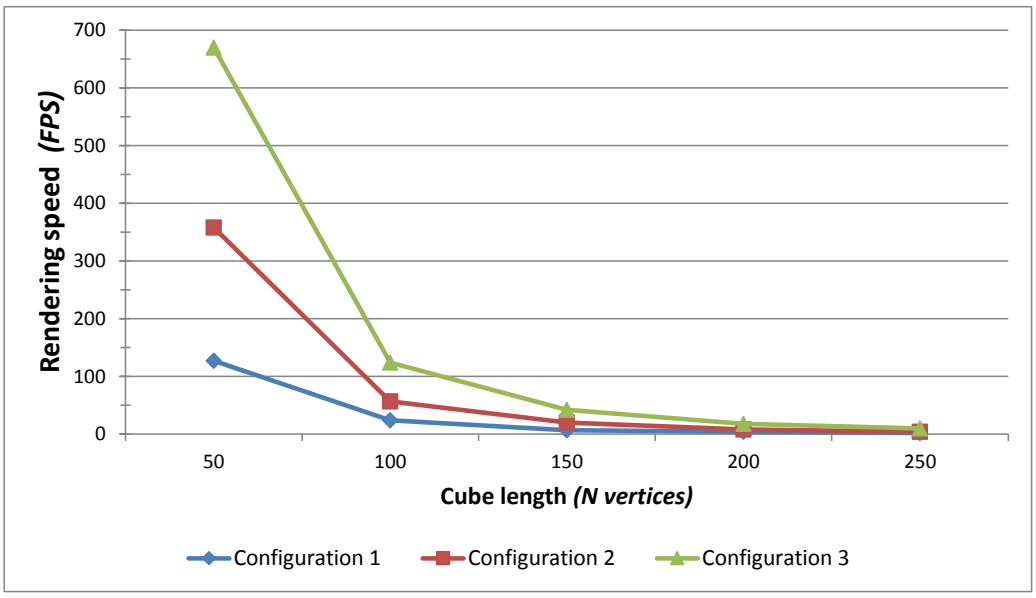

Figure 5. Graphical representation of the benchmark results

affect the performance of the program when used on large models. An implementation would probably be similar to the culling technique where a model could be divided into smaller regions and when comparing depths those that are further from the camera would not be processed.

VI. CONCLUSION

Natural user interface technologies can be more than just a platform for gaming and entertainment because they possess a great potential in revolutionizing human-machine interactions. In these types of interface designs 3D motion sensing input devices like Microsoft Kinect have proven to be a suitable and valuable hardware choice. However, the effectiveness of the hardware heavily depends on the accompanying software which still does not follow any generally accepted interaction model. This article proposes a solution to this problem in the form of a functional prototype that tries to imitate a real life experience of traditional human skills such as clay modelling.

A functional prototype presented here forms the basis for the future versions with an improved interaction system, which could provide tremendous opportunities for addressing various problems, and also opens new frontiers and new challenges in user interaction with virtual objects.

Abstract - The focal mechanism of an earthquake and fault plane solutions provide insight into the geology of an area. The objective of this paper is to give a means of better understanding fault movement when an earthquake occurs. In this paper we present an interactive 3D visualisation of possible fault plane solutions, which are usually represented as 2D "beach-ball" plots, with their respective block models. Additionally a 3D alleviation display of an area, with respective beach ball earthquake representations, provides a more in depth picture of seismological maps under the earth's surface. The program solution allows a better grasp of space, which is useful to students of seismology and anyone who wants to visualize fault movement of an earthquake.

Key words: interactive visualisation, fault plane, focal mechanism,

I. INTRODUCTION

Seismology is the scientific study of earthquakes. An earthquake is the result of a sudden release of energy in the Earth's crust in the form of seismic waves. The most common earthquakes are tectonic earthquakes, caused by rupture of geological faults. Faulting is relative movement of two geological blocks (walls), by creating a new fault or shifting along an existing fault plane [1].

The full process of an earthquakes hypocentre is very complicated and difficult to describe exactly. However, some of the properties observed on seismograms can be described by mathematical models of a point source with the conditions to observe phenomena far from the source and in the short time after the earthquake begins [2].

When the earth suddenly moves during an earthquake, energy is released and seismic waves radiate from the Earthquakes hypocentre in all directions [1]. The waves travel through the Earth's interior towards the surface. There are two types of waves: the faster longitudinal waves (P-waves) and slower transverse waves (S-waves). The waves are recorded by seismographs, and correspond to up and down movements on the seismogram [3].

II. FAULT MECHANISM

In the early 20th century, by observing the pattern of first motions (first arriving P waves), seismologists noticed that the first movement of a seismographs pen (recorded direction of the first shift of a geological block)

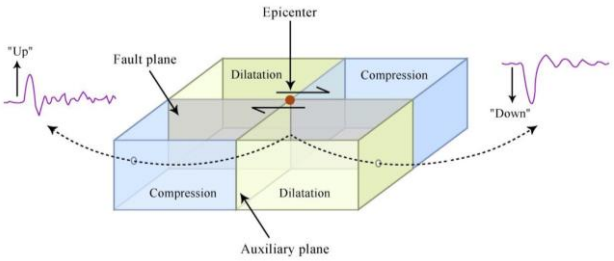

Figure 1. First motions observed from different directions[2].

depends on where the station is located relative to the epicentre [2].

The fault walls move in different directions which creates a different P wave polarity (seen in Fig. 1). If a block moves towards a seismological station, the seismograph will record the first shift as a compression with an up movement, but if a block moves away from the station, it is called dilatation and it will be recorded with a down movement. On a map, these areas can be divided by lines into four quadrants, each of which has a different polarity, but without further information there is no way to decide what type of a fault it is [3].

Seismologists examine the first motion of the P waves from local and remote stations to reconstruct the initial forces that triggered the event [1].

A. *Fault types*

There are three main fault types [2]:

- strike-slip, where the offset is predominately horizontal, parallel to the fault trace.
- dip-slip, offset is predominately vertical and/or perpendicular to the fault trace.
- oblique-slip, combining significant strike and dip slip.

An earthquake is described by the faults orientation and shift direction (seen in Fig. 2) [1]:

- Strike (φ) is the azimuth of a line created by the intersection of a fault plane and a horizontal surface, 0º to 360º, relative to North

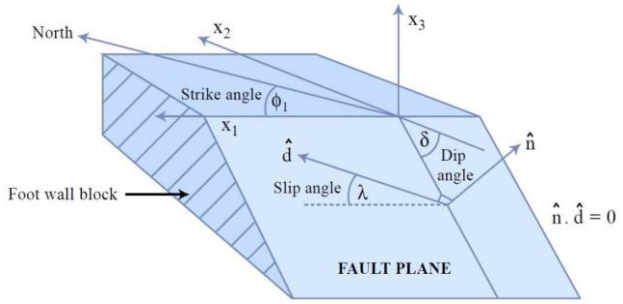

Figure 2. Fault geometry: fault orientation determined by the direction of the fault, dip angle and rake angle [3].

- Dip (δ) is the angle between the fault and a horizontal plane, 0º to 90º
- Rake (or slip, λ) is the direction a hanging wall block moves during rupture, as measured on the plane of the fault relative to fault strike, -180º to 180º (CCW)

The orientation is defined such that a fault dips to the right side. The hanging wall block is therefore always on the right, and the foot wall block on the left [1].

If the fault breaks the surface, the angles can be determined by geological methods, but in most cases, earthquakes do not break the surface and seismological data must be used to determine fault plane solutions [3].

B. Fault mechanism in practice

After an earthquake occurs, seismologists create graphics of focal mechanisms by mapping the P wave information on a focal sphere, informally referred to as a *beach ball*, to show the faulting motions that produced the earthquake. Focal mechanisms, also known as fault-plane solutions, are based on the direction of the first arriving P wave [1-4].

The orientations of the first P waves are gathered from a number of stations and plotted onto the focal sphere. If there are sufficient observations, two planes are drawn to divide the compressive from the tensional observations and these are the nodal planes (seen in Fig. 3). By convention the compressional quadrants are color-filled and the tensional (dilatation) left white [3,5].

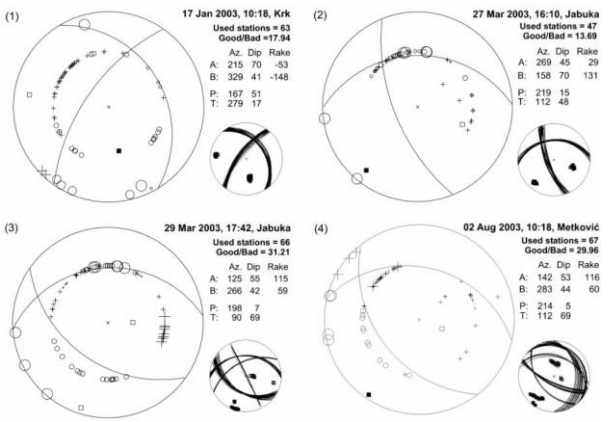

Figure 3. Focal mechanism examples for Croatian earthquakes that took place in Middle Dalmatia, the island of Krk and Jabuka [6]. The crosses represent compression and circles dilatation.

Figure 4. Example of ambiguity

The fault plane responsible for the earthquake will be parallel to one of the nodal planes, the other being called the auxiliary plane. Unfortunately it is not possible to determine solely from a focal mechanism which of the nodal planes is in fact the fault plane [3, 5].

A typical example can be seen in Fig. 4. A strike-slip fault with shift direction towards north (rake $\lambda = 0º$, strike $\varphi = 0º$) is indistinguishable from the strike-slip fault with shift direction towards west (rake $\lambda = 180º$, strike $\varphi = 90º$) [7].

To remove the ambiguity other geological or geophysical evidence is needed. There are a number of methods such as the terrain method (knowing the geology of the area will help identify the most likely fault geometry) or by comparing the two fault-plane orientations to the alignment of small earthquakes and aftershocks [7].

III. IMPLEMENTATION

Interpreting fault plane solutions can be difficult, especially because they are generally given as two-dimensional stereographic projections of the lower hemisphere of a focal mechanism sphere. In order to make it easier to understand and visualize, we present an interactive three-dimensional visualisation of faults and their matching beach balls.

The program solution offers the possibility of entering fault parameters (strike, dip and rake) with the option of seeing a matching beach ball as a three-dimensional sphere and the stereographic projection that is usually used on seismic maps. Furthermore a 3D relief display of Croatia, with respective beach ball earthquake representations of selected earthquakes provides a more in depth picture of seismological maps under the earth's surface.

To make our solution easily available for learning purposes, the technologies used were WebGL with the Three.js JavaScript library.

A. Fault visualisation

To simplify an earthquake process, geological blocks are displayed as cuboid bodies (seen in Fig. 5). A transparent plane represents the fault plane and a helper

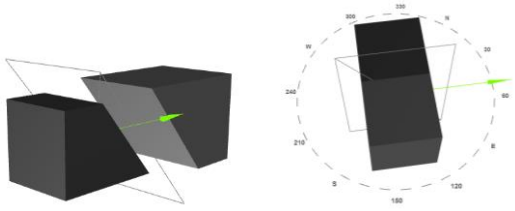

Figure 5. Fault visualisation

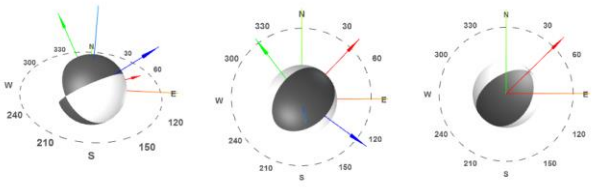

Figure 6. Beach balls with local and global axis

vector shows the direction of the hanging wall. Additionally, a compass points around the fault blocks helps to show the azimuth relative to north. The hanging wall shift is emphasized for the sake of demonstration.

B. *Focal sphere visualisation*

The focal sphere, informally referred to as a beach ball, is a sphere divided into four parts. The color fields describe a shift from the focus (compression), while white fields describe towards the focus (dilatation).

For better understanding, the beach ball is shown both as a 3D interactive sphere and as a generally used two-dimensional stereographic projection of the lower hemisphere.

C. *Fault visualisation with the focal sphere*

To better illustrate the focal mechanism solutions, we take as an example the earthquake that took place near the island Jabuka on 27th March 2003 (which focal mechanism solution can be seen in Fig.3) and show both of the possible solutions as a block model with the respective beach balls. The ambiguity between the two possible physical solutions obtained from seismic data and seen in Fig. 6 can now easily be seen from the presented block model and the corresponding focal spheres.

D. *Relief map*

One of the methods to remove the ambiguity is the terrain method, where knowing the geology of the area will help identify the most likely fault geometry. For this

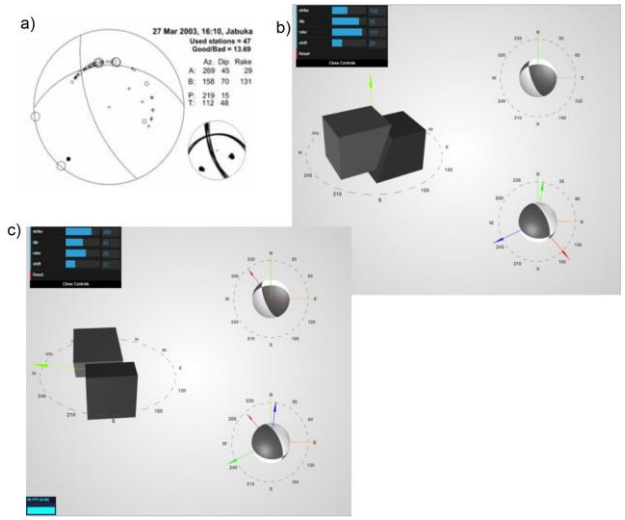

Figure 7. Visualized data from the earthquake that occurred near the island of Jabuka on 27th March 2003

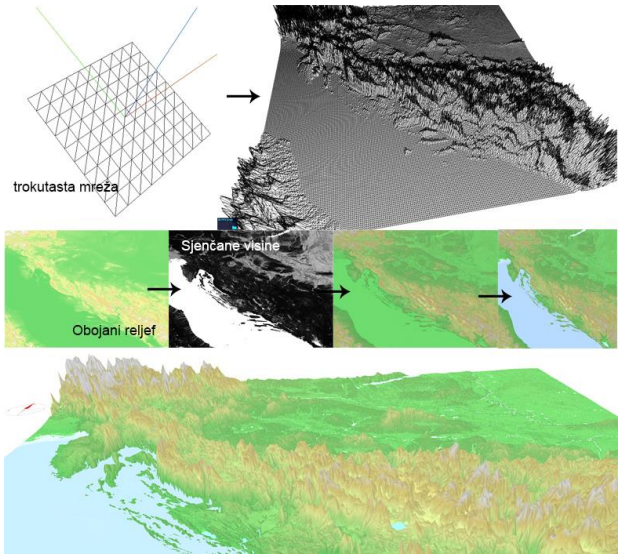

Figure 8. The process of creating the terrain map

purpose we made a map of Croatia on which we placed focal mechanism solutions of representative earthquakes from the Archives of the Department of Geophysics [8].

The height map and terrain texture were made based on data from OpenTopography [9-13] and Corine Land Cover dataset from European Environment Agency (EEA) [14]. The area covered is from 42 ° to 47 ° N and from 13 ° to 20 ° E. The process and final map can be seen in Fig. 8 [15-18]. The relief was accentuated for demonstration purposes. Selecting a beach ball shows information about the earthquake (date, magnitude, coordinates and depth), the block model and corresponding beach ball (seen in Fig. 9).

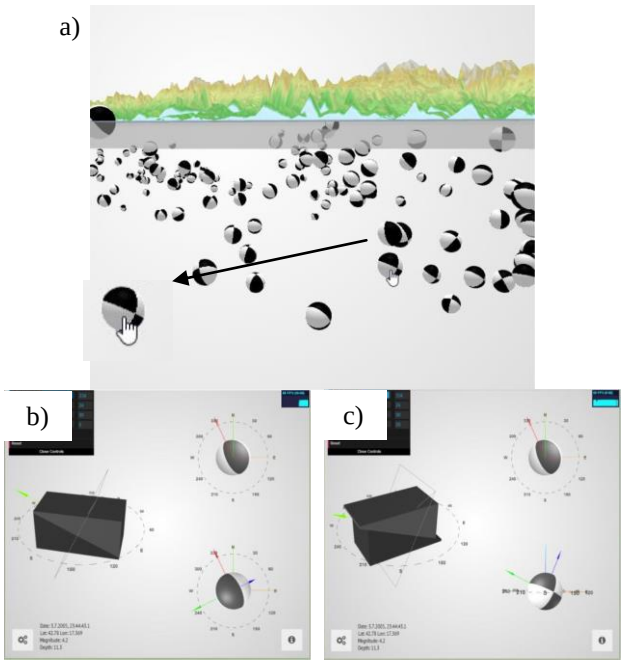

Figure 9. a) Selecting a particular earthquake shows b) the focal mechanism of the earthquke, where one can change the view angle and visualise the shift of the fault plane in space. This example shows an eathquake that took place on 23rd March 2005 at 23h 44m, magnitude 4.2 ($\varphi = 334°$, $\sigma = 24°$ and $\lambda = 90°$).

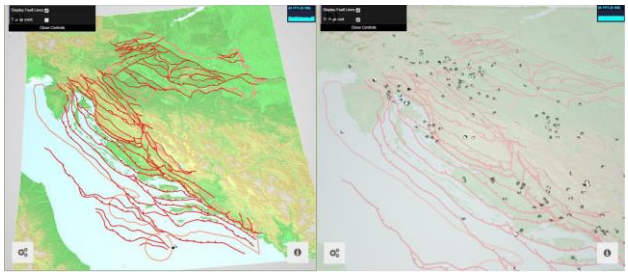

Figure 10. The map with the Geological map of Croatian faults (shown with full opacity and partly transparent so the beach balls can be seen from all angles)

Furthermore, we add a second texture showing the Geological map of Croatian faults (seen in Fig. 10) [19].

Fig. 11 shows how this allows for a better visualisation of fault plane solution spatial distribution.

E. User interface

The program was implemented using WebGL and Three.js JavaScript library as a website [20]. The menu is in the left bottom corner, where the user can change between the focal mechanism visualisation and catalogue of Croatian earthquakes in map view. It takes a little time for beach balls representing the earthquakes to load and apply needed transformations, as there are quite a number of them.

IV. CONLUSION

Focal mechanisms are determined based on earthquake analysis from a number of seismic stations. Its importance lies in the geological and seismological information that is gained about an earthquake's physical process. Fault plane solutions allow insight into the geological structure of an area.

The main objective of this paper was to give a means of better understanding fault movement by giving an interactive 3D visualisation of possible fault plane solutions (usually represented as 2D plots) with their respective block models. The program solution allows a better grasp of space, which is useful to students of seismology and anyone who wants to visualize fault movement of an earthquake.

Additionally a 3D relief display of Croatia with respective beach ball representations provides a more in depth picture of seismological maps under the earth's surface.

Abstract - Enhanced environment awareness is a key element of life protection in dangerous situations. Thus the Personal Protection Equipment (PPE) clothing industry is forced in the direction to develop highly innovative "intelligent" products, and equip their products with sensors and actuators combined with smart technologies. Besides basic functions of protection, thermal and ergonomic comfort, these new generation protective garments have additional functions such as monitoring and/or alarming for prevention in case of emergency situation. Such systems are costly because even if the clothing and engineering parts of the development are feasible, their combination is far from trivial. The different system parts have different requirements, and these requirements are sometimes not compatible with each other. Parameters such as cost, bulkiness, accuracy, independency, scalability, robustness are key parameters, which can cause high acceptance or usage prevention rapidly by the end-users. Our research is focusing on the seamless integration of the various subsystems to develop effective and user friendly, intelligent situation aware personal protection systems. Our solution helps to receive accurate information about user performance and activity conditions. The main goal of our work is to adapt the already existing monitoring solution and provide it to people working in harsh environment. The paper describes the results of our development with the description of the main functionalities.

Keywords

Sensor data acquisition, location and situation awareness, health monitoring

I. INTRODUCTION

The surrounding micro end macro environment changes all the time. Measurements convert the environment parameters into information, what we can process and evaluate to better understand the environment, and predict its parameter changes. Enhanced environment awareness (situation, location, etc.) is a key element of life protection in dangerous situations. Thus the Personal Protection Equipment (PPE) clothing industry is forced in the direction to develop highly innovative "intelligent" products, and equip their products with sensors and actuators combined with smart technologies. Design requirements such as cost, bulkiness, accuracy, independency, scalability, robustness are key parameters, which can cause high acceptance or usage prevention of location sensor devices rapidly [1]. We are designing and developing an intelligent Personal Protective System (PPS) integrated with a data acquisition (DAQ) system and we are using enabling technologies to collect location information and a wide range of environment information. In this paper we show how our first prototype of environment and location monitoring is designed and developed. In this paper we provide a detailed overview how information acquisition is realized within the PPS to monitor and provide situation and location awareness to the PPS user. Besides basic PPE functions of protection, thermal and ergonomic comfort, the new generation protective garments have additional functions such as monitoring and/or alarming for prevention in case of emergency situation. This paper shows how we have built up our biosignal, micro and macro environment monitoring solution to support human operations in harsh environments using intelligent PPS. In the second section we provide an overview how our system fits into the generic data acquisition concept. In the third section an overview is given about sensor data integration and sensor data fusion and some related problems described. In section four we give sensor fusion.

II. STATE-OF-THE-ART

A. DAQ

1) Single sensor DAQ

A single sensor measurement is the simplest method to receive information about the environment. In such case

the accuracy of the sensor determines the maximum accuracy of the measurement.

2) Multi-sensor DAQ

In case of multi-sensor measurements the inclusion of additional sensor provides different effect on the measurement and on the accuracy as well.

Multi-sensor data acquisition requires by definition complex solutions. Sensors can be operated inside as a homogenous set, or they can vary in types (multi-modal), resolutions, they can differ in monitoring target, temporal

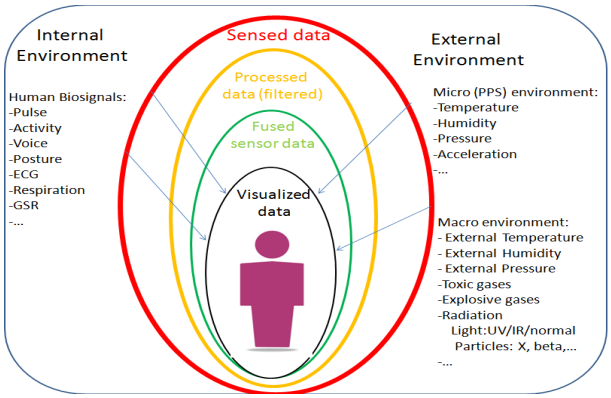

Figure 1. Multi modal DAQ of the PPS

or spatial parameters. Formal frameworks are available for multi-sensor data fusion. [2]

a) Multi-modal DAQ

Biosignal, micro and macro environment DAQ

Biosignal, micro and macro environment data acquisition is achieved using different type of sensors. The possible sensor configurations can be differentiated according to the Durrant-Whyte [3] classification, sensors can be: complementary, competitive or cooperative. Internal environment parameters of the PPS user are acquired by biosignal sensors, such as pulse sensors, activity sensors, ECG, GSR sensors, respiration sensors and posture sensors. The external environment is divided to two main areas. The PPS environment information is acquired by sensors attached to the internal layer of the PPS such as: temperature, humidity, pressure, acceleration sensors. The environment which is located outside the PPS is monitored by external sensors, such as: toxic/explosive gas sensors, radiation sensors (IR, gamma, beta, etc.) (in Figure 1.) Audio and video streams are also captured about the environment in real-time.

Location DAQ

Location information acquisition is a challenging task [4]. The location sensors are ranging from low accuracy sensors (with almost global coverage) to high accuracy (short range) solutions. The proposed localization solution based on a combination of different technologies. Most of the technologies are using radio wave communication. We are tracking the position of the PPSs, combining absolute and relative positioning techniques. Relative positioning is measuring signal strength difference; thus works with relative distance and direction of arrival measurements. Absolute measurements are done when signal from known position fixed elements can be detected. Fixed elements are the satellites emitting GPS signals and fire-engines at known locations providing ranging functions in the UHF band. We acquire periodically from the different sensor devices location information. For outdoor environment (if available) the system relies on GPS satellite signals and GSM signals, both techniques have large coverage, but their accuracy is poor. In indoor environments the distance measurements are more suitable, and positions are estimated from triangulations among the different signal senders. The distance measurements are done parallel with UHF and UWB radio technology. UHF distance measurements provides below 5 m accuracy in a long range (200 m-1500 m depending on environment) while UWB distance measurements give an excellent 1 m accuracy in a shorter range (20 m-100 m depending on environmental conditions). For offline movement tracking and for the support of position estimation in extreme conditions we acquire also Inertial Measurement Unit (IMU) information, which provides multi-axis acceleration information.

3) Remote DAQ in harsh environment

Remote data acquisition systems can effectively collect sensor data and transfer to remote locations. Autonomous data acquisition requires significant power supply and data storage, its transparency (location independency) and user friendliness is crucial from usability point of view.

There are already existing solutions to acquire sensor data in harsh environment such as simple sensing capability from RECCO, or pilot solutions for Firefighters and Civil Emergency Workers by ProeTEX (IP Firefighter), or product level solutions from Viking Life-Saving Equipment A/S and Globe Manufacturing Co. [11, 12, 13, 14].

III. DATA EVALUATION AND IDENTIFIED PROBLEMS

A. Definitions

Multi-sensor integration: The data integration is a usage of sensor data set to realize a particular task.

Multi-sensor data fusion: The data fusion is a process of combining input data into a common representation format. Basically multi/sensor data fusion can improve sensing in the following four different ways: Representation, Certainty, Accuracy, Completeness [5] Multi-sensor data fusion system classification can be done in various ways, one good example is Dasarathy's [6] I/O Data fusion model.

B. Performance, accuracy and scalability issues

The large number of data sources, with high sampling rates can produce huge data quantities, what could be difficult to transmit, to process, to visualize or even to store. Additionally multi-sensor data processing requires complex solutions for data representation, sensor value normalization and sensor data fusion. More sensors can provide more sensing information however one should be careful here, because this is not directly lead to any gain.

Due to the multiplicative effect caused by measurement errors/problems a single sensor can outperform a multi-sensor data fusion system (e.g.: catastrophic fusion).

C. Environment awareness

To gain environment awareness we not only just need to collect information about the surrounding environment, but we need to process it (fuse, filter, etc.) and merge it with our already existing knowledge. During sensor data processing we need to provide a common representation format of the sensor data.
Symbolically we are representing a sensor observation by adding more parameters to the generic five-tuple [5] equation. Our modified equation is the following:

$$O =< E, S, x, Tm, Tp\{\}, Y, Yu, \Delta Y > \quad (1)$$

Where E is the entity name (Sensor ID), S is the sensor type, x is the spatial location (position in space),T_m is the time instant when the measurement was occurred, T_a is the list of time instances when the measurement was processed, Y is the measurement (the physical property as measured by the sensor element),Y_u is the measurement unit, Δy is the error set which influences y caused by the measurement setup (including measurement errors, calibration errors, etc.).
The used biosignal, micro and macro environment sensors are complementary and cooperative type sensors.
The primary fusion algorithm converts the received sensor information and construct a common view in the time domain. Beside the accuracy parameter, all sensor data has a decay parameter as well.

D. Location awareness

Location awareness is a crucial to effectively work or even to survive in harsh environment.
Main requirements here are the specification of the followings:

- absolution location of the individual sensor owner
- location of other objects and entities
- relative directions and distances of other objects and entities

We are using a primary fusion algorithm to convert the received location information. We are using competitive and cooperative sensors and constructing a common coordinate system. The different technologies provides different operational parameters (such as availability, accuracy, etc.), which are related directly to the surrounding PPS environment. We are also evaluating the correctness of the received location data, because extreme ever-changing conditions can bring weird sensing situations.

IV. SYSTEM OVERVIEW

As the large scale data acquisition systems are producing vast amount of data, we need a multilayered approach for data processing. Due to the different - in most cases proprietary and incompatible- sensor technologies and solutions, it is challenging to realize generic, multi-modal data acquisition system [9-11]. The first level of data evaluation has multiple layers: the basic layer handles single source, primitive data types (integers, float, double, etc.) and provides range focused evaluation; the second layer of data evaluation is targeting the complex data types (e.g.: ECG, EEG curves), where complex pattern searching is required. The second level of data evaluation is used by trend analysis using calculation of derivatives in higher dimensions.
Our proposed solution combines existing; self developed hardware units, with client and server side applications and frameworks. Security is a pivotal point of the system. Sensor data is transported end-to-end in an encrypted way.

A. PPS side hardware

PPS side DAQ hardware is modular, and based on the embedded sensor infrastructure. The PPS internal communication system is capable to use a vast amount of technologies:

- wired: USB, I^2C, 1w, CAN
- wireless: WiFi, GSM/3G, XBee, Bluetooth 2/4

B. PPS side software

On the PPS (client) side we are using our own DAQit modular, multi-platform, generic data acquisition software framework, with in-built data processing, visualization and management capabilities. The framework:

- collects “personalized” biosignal (digital fingerprint of the patient’s/person’s psychophysical status and performance), and micro/macro environment information
- archive the data locally and at remote locations
- process, analyze and visualize the acquired data
- sends the acquired data towards to the datacenter for further processing.
- uses the following communication technologies at software level: ssh, https

Other basic software functionalities and features:

- Multi-language support (English, German, Italian, and Hungarian).
- Silent sensor DAQ mode (automatic data collection).
- Fused sensor data visualization.

- Data compression and encryption during data transmission.
- Automatic sensor data pre-evaluation.
- Store and forward mode to enable offline data collection

C. *Server side*

On the server side we have designed a modular, generic data processing, visualization and management system. The GUI is a Liferay [7] based open source, online, service-rich front-end with the following features:

- Data management and data sharing

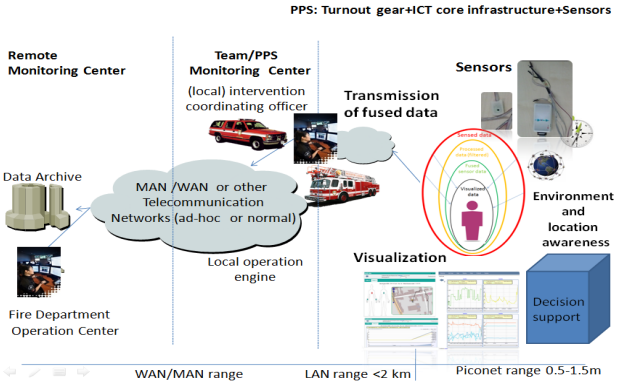

Figure 2. System overview of the PPS and remote monitoring centers

- Data visualization (multi-sensor)
- Real-time monitoring (environment and location)
- Strong authentication

Beside near real-time monitoring, the portal users can access the acquired, processed, fused and archived sensor data. The system has the capability to share information among other similar server instances. A hierarchical server cascade can built up from such servers in a scalable way. The sensor data processing and data fusion services are located separately. High-throughput real-time sensor data processing requires large computational resources [8]. Appropriate HPC infrastructure can be added to the system in a loosely coupled way to cope with the high processing demand.

V. SUMMARY AND FUTURE WORK

We have designed and realized an intelligent PPS solution using combined multi-modal sensor infrastructure for emergency service personnel. Intelligent PPS systems which are capable to support environment and location awareness are costly because even if the clothing and engineering parts of the development are feasible, their combination is far from trivial. Our research is focusing on the seamless integration of the various textile materials, DAQ/ICT subsystems, and sensors to develop effective and user friendly PPS. Our solution helps to receive accurate information about user performance, activity conditions, environment and location parameters autonomously.

During sensor fusion we are converting the data to a common representation format. The acquired data is processed on different levels, and we evaluate/filter sensor data in near real-time. The combination of the sensors provides better environment and location awareness even in special locations/ extreme environments for the PPS users. The acquired location data can be visualized by the PPS user and/or can be transmitted towards a remote location to let visualize the emergency service team activities. Sensor data acquisition and fusion enables both PPS end-users and emergency team officials to receive near real-time, highly accurate monitoring data. The server side system enables seamless data archiving to do comparative performance analysis between the PPS users or retrospective situation analysis if needed.

VI. ACKNOWLEDGMENTS

The projects have been supported by the European Union. The authors would like to thank GOP-1.1.1-11-2012-0055- Dialogic „DIALOGIC – Mathematical model based decision support system for diabetes monitoring” for its financial support. This work makes use some of the results produced by the AALAMSRK project (Research & development of assisted living patterns and their integration into decision support system to promote the quality of life at home), Hungarian National Technology Programme, A1, Life sciences project.

***Abstract*—Steganography and Digital Watermarking are concerned with embedding information in digital media such as images, audio signals and video. Both scientific disciplines develop methods for conceal message (a sequence of bits) by modifying the host (cover) digital object but their goals are slightly different.**

In this work we discuss two methods of information embedding in spatial domain: a matrix embedding by q-ary codes and a method based on pseudo-noise patterns and which explodes the erasure capability of error correcting codes.

We have made numerous experiments with picture from several galleries (with grey-scale and color images) and many error control codes for both type of algorithms. Our observations show that q-ary codes are good choice in the case of syndrome embedding.

I. Introduction

Data hiding technique provide a way to embed extra information within the original contents, without serious degradation of the quality. With the development of proper and robust data hiding systems, more technologies have found new and promising applications.

Steganography and Digital Watermarking are concerned with embedding information in digital media such as images, audio signals and video. Both scientific disciplines develop methods for conceal message (a sequence of bits) by modifying the host (cover) digital object but their goals are slightly different. Digital watermarking is a data hiding technique with a trade-off between the embedding capacity, robustness and quality. Its goal is to prevent piracy or to prove the ownerships by imperceptibly altering the digital media object. The purpose of steganographic techniques is to alter the cover object in undetectable manner, that is, no one but the intended recipient to be able to detect the altering of the cover work. Both digital watermarking and steganography are subject of a strong interest and research activity especially in the last decade. A lot of techniques as well as commercial realization of some of them have been proposed. A comprehensive overview of the mathematical methods and the core techniques can be found, e.g., in [3], [7].

The application of error correcting codes to steganography and watermarking started with so called matrix embedding introduced by Grandall [5]. Since that time it has been popularized, developed, and carefully analyzed by many authors. We shall mention just few of them here [9], [10], [11].

In this paper we discuss two methods of information embedding in spatial domain: the aforesaid matrix embedding by q-ary codes and a method based on pseudo-noise patterns and which explodes the erasure capability of error correcting codes.

II. Preliminaries

The process of hiding information can be described in general as a mapping (***embedding process***)

$$\mathcal{E}: \left| \begin{array}{lcl} (\mathfrak{P},\mathfrak{T},\mathfrak{K}) & \rightarrow & \mathfrak{P} \\ (\mathbf{c}_0,\mathbf{m},\mathbf{k}) & \rightarrow & \mathbf{c}_m=\mathcal{E}(\mathbf{c}_0,\mathbf{m},\mathbf{k}) \end{array} \right. ,$$

where $\mathbf{c}_0$, the cover object, is an element of the set $\mathfrak{P}$ of possible digital objects (images), $\mathbf{m} \in \mathfrak{T}$ is the message intended for embedding, and $\mathbf{k}$ is a key randomly taken from the space of keys $\mathfrak{K}$.

Respectively, the process of revealing the hidden text consists of applying a ***decision function*** (which is based on the chosen ***detection metric***) to the received, eventually distorted copy $\mathbf{c}_{mn}$ of the sent work $\mathbf{c}_m$:

$\mathbf{m}'=\mathcal{D}(\mathbf{c}_{mn})$, or $\mathbf{m}'=\mathcal{D}(\mathbf{c}_{mn},\mathbf{c}_0)$, if $\mathcal{D}$ needs the original. In many cases the distortion can be considered as an additive noise $\mathbf{n}$, i.e, $\mathbf{c}_{mn}=\mathbf{c}_m+\mathbf{n}$. In our study $\mathbf{c}_{mn}=\mathbf{c}_m$.

In the described considerations and experiments the embedding process is a composition of two mappings. The first one, $\mathcal{M}$, transforms the cover image into a matrix over Z_q, the ring of integers modulo q, or into the finite field $GF(q)$ of q elements. We shall denote the set of such matrices by $\mathfrak{M}$, that is,

$$\mathcal{M}: \ (\mathfrak{P},\mathfrak{T},\mathfrak{K}) \ \rightarrow \ \mathfrak{M}.$$

The transformation $\mathcal{M}$ depends on the cover object and the chosen key. After careful analysis of the image some pixels are market as "wet" pixels which are not used. The order of the embedding into the rest ("dry") pixels is also determined according to the chosen key. The second transformation realizes the embedding algorithm based on the use of error control codes. Usually it is referred to as ***embedding function*** and we shall keep the notation $\mathcal{E}()$ for it.

Herein we discuss two methods of concealing data into images and both are realized by embedding into the spatial

domain: A) the aforesaid syndrome (matrix) embedding using q-ary codes, and B) a method based on pseudo-noise patterns.

A. Syndrome Embedding

Syndrome embedding (also known as matrix embedding) is a method in which the parties agree on a parity-check matrix $\mathbf{H}$ of a linear code and the secrete message is extracted as a sequence of syndromes (with respect to $\mathbf{H}$) from the cover digital object. With a few exceptions ([10], [8]) the codes used in the proposed algorithms are mainly binary codes, e.g., BCH, Reed-Solomon, random codes, etc.. In these case $\mathcal{M}$ transform the digital object that is in fact a matrix of 8, 16 (images), or 12 (CD audio) bits long unsigned integers (i.e., elements of $\mathbb{Z}_{2^b}, b = 8, 12, 16$) into a binary matrix $\mathbf{D}$. All these algorithms are based on looking among the elements of a given coset for a vector that minimize distortion in the image. The covering radius of the code is also very important characteristic.

More detailed description of this method in the form used by us is given in Section 3.

B. Noise patterns embedding

In most general form this embedding algorithm can be described as

$$\mathbf{c}_m = \mathcal{E}(\mathbf{c}_0, \mathbf{m}) = \mathbf{c}_0 + \alpha \mathbf{w}_m, \tag{1}$$

where $\mathbf{w}_m$ called ***message pattern*** is a function of the message and the set of predefined reference patterns (and eventually of $\mathbf{c}_0$). The scale constant α controls the tradeoff between visibility and robustness of the embedded data. The set of predefined reference patterns $\mathbf{W} = \{\mathbf{w}_{r1}, \mathbf{w}_{r2}, \ldots, \mathbf{w}_{rk}\}$ consists of matrices whose entries have a given probability distribution, most often normal or uniform distribution. These patterns are pair-wise orthonormal according to the chosen detection metric $\delta(\ ,\ ) : \mathfrak{M} \times \mathfrak{M} \to \mathbb{R}$. In fact it is enough $\delta(\mathbf{w}_{ri}, \mathbf{w}_{rj})$ to be relatively small, not necessarily exact zero.

Assume that the message is a binary vector $\mathbf{m} = (m_1, m_2, \ldots, m_k)$. Then

$$\mathbf{w}_m = \gamma\left(\epsilon_1 \mathbf{w}_{r1} + \epsilon_2 \mathbf{w}_{r2} + \cdots + \epsilon_k \mathbf{w}_{rk}\right),$$

where

$$\epsilon_i = \begin{cases} 1, & m_i = 1 \\ -1, & m_i = 0 \end{cases}.$$

The coefficient γ, when it differs from 1 is used for a kind of normalization of $\mathbf{w}_m$, for example, $\gamma = \frac{1}{\sqrt{k}}$ normalizes the variance to 1.

The process of revealing message is also based on the detection metric. For $i = 1, 2, \ldots, k$ the receiver calculates $\delta(\mathbf{c}_{mn}, \mathbf{w}_{ri})$ and according to the sign of its value decides what is the i-th bit m_i. Here is the most used detection metrics:

- ***Linear correlation***:

$$lc(\mathbf{x}, \mathbf{y}) = \frac{1}{N}\mathbf{x} \cdot \mathbf{y} = \frac{1}{N}\sum_{i=1}^{N} x_i y_i,$$

where N is the length of the vector;

- ***Normalized correlation***:

$$nc(\mathbf{x}, \mathbf{y}) = \frac{\mathbf{x} \cdot \mathbf{y}}{|\mathbf{x}| \cdot |\mathbf{y}|} = \frac{\sum_{i=1}^{N} x_i y_i}{\sqrt{\sum_{i=1}^{N} x_i^2}\sqrt{\sum_{i=1}^{N} y_i^2}}.$$

- ***correlation coefficient***:

$$cc(\mathbf{x}, \mathbf{y}) = \frac{\hat{\mathbf{x}} \cdot \hat{\mathbf{y}}}{|\hat{\mathbf{x}}| \cdot |\hat{\mathbf{y}}|},\ \hat{\mathbf{x}} = \mathbf{x} - \mathrm{E}[\mathbf{x}],\ \hat{\mathbf{y}} = \mathbf{y} - \mathrm{E}[\mathbf{y}]$$

III. Syndrome embedding and q-ary codes

In this section we describe in short our approach to syndrome embedding underling the differences with the usual one. Assume $\mathbf{c}_0$ is a matrix of elements of $\mathbb{Z}_{256}$. We will skip descriptions of $\mathcal{M}$ in concern of the use of the key and determination of the "dry" pixels, and will consider only the part that concerns embedding function. The aforesaid feature of $\mathcal{M}$ are implemented in the developed software, but in most of experiments they are skip and realize only what follows.

Let $q' \geq q$ be an integer less than 255. Consider $\mathbf{D}' = \mathbf{c}_0 \pmod{q'}$. This is the target matrix of the embedding. If q' is a power of 2 the action is equivalent to embedding in the several less significant bits. In this case binary codes can also be used. In order to prevent the embedding to be visually detected we must have $q' < 2^5$.

Algorithm:

Let $\mathbf{H}$ be a $r \times n$ parity-check matrix of a linear code over $\mathbb{Z}_q$, or a finite field $\mathbb{F}_q$ of q elements. Let $\mathbf{D}$ be a $n \times N$ matrix over $\mathbb{F}_q$ or $\mathbb{Z}_q$ obtained from the target image by the transformation $\mathcal{M}$. Let the message (randomized and eventually encrypted) be also transformed into a $r \times N$ matrix $\mathbf{m}$ over $\mathbb{F}_q$.

1) Compute $\mathbf{S} = \mathbf{m} - \mathbf{HD}$, i.e., $\mathbf{m} = \mathbf{S} + \mathbf{HD}$
2) Find $n \times N$ matrix $\mathbf{E}$ such that $\mathbf{S} = \mathbf{HE}$
3) Compute $\mathbf{V} = \mathbf{D} + \mathbf{E}$
4) Construct an image $\mathbf{c}_m$ such that $\mathcal{M}(\mathbf{c}_m, \mathbf{k}) = \mathbf{V}$ and send $\mathbf{c}_m$.

The receiver

1) Determines $\mathbf{V} = \mathcal{M}(\mathbf{c}_w, \mathbf{k})$
2) computes $\mathbf{HV} = \mathbf{HD} + \mathbf{HE} = \mathbf{HD} + \mathbf{S} = \mathbf{m}$

Embedding efficiency in the case of syndrome encoding using a code with $r \times n$ parity check matrix is

$$E_f = \frac{r \log_2 q'}{n} \quad \text{bits/pixel}$$

Note that the embedding efficiency does not depend on which field (ring) the code is defined over. The number of its elements is usually $q = q'$, but it can be in partial $q = 2$ when q' is a power of 2.

Our approach simplifies the process of determining the matrix $\mathbf{E}$. The representative of the coset that corresponds

to a given syndrome is chosen to be with the minimum Lee weight and its entries to be with minimum absolute value. For example, between the $\mathbb{Z}_4$-vectors $(0,3,3)$ and $(2,0,0)$ the first vector is preferable ($3=-1$ in $\mathbb{Z}_4$).
Here is a simple example

Example 1. Let $q=4$ and $\mathbf{H}=(1\,2)$ be the parity check matrix of $[2,1]$ code over $\mathbb{Z}_4$. The set of syndromes $Synd=\mathbb{Z}_4=\{0,1,2,3\}$. The matrix of error patterns corresponding to the syndromes is

$$\mathbf{Eh}=\begin{pmatrix}0&1&0&3\\0&0&1&0\end{pmatrix},\quad \text{i.e,}\quad \mathbf{H}.\mathbf{Eh}=(0\ 1\ 2\ 3)$$

The target image $\mathbf{I}$ ($a\times b$ matrix over $\mathbb{Z}_{256}$) is transform to $\mathbf{Der}\equiv\mathbf{I}\pmod 4$ and then by rearranging to $2\times ab/2$ matrix over $\mathbb{Z}_4$. The message is transform to $1\times ab/2$ matrix $\mathbf{m}$ over $\mathbb{Z}_4$ and then we follow the described above algorithm. The j column of the matrix $\mathbf{E}$ is the $\mathbf{S}(j)+1$ column of $\mathbf{Eh}$, where $\mathbf{S}=\mathbf{m}-\mathbf{HD}$.

IV. Pseudo-noise patterns and erasure codes

A. *Algorithm*

Embedding

A-1. Let C be a binary $[n,n-r]$ linear code. Encode the source message into a binary sequence $\mathbf{m}$.

A-2. Starting with a given state (used as password) of the random number generator generate t reference patterns of size $a\times b$: $\mathbf{W}=\{\mathbf{w}_1,\mathbf{w}_2,\dots,\mathbf{w}_t\}$.

A-3. Divide (in some way) the cover work into N blocks, $\mathbf{c}_1,\dots,\mathbf{c}_N$, each of size $a\times b$.

A-4. (optional) Replace the set $\mathbf{W}$ by the set of patterns $\{\mathbf{h}_i\}$ which are orthogonal to all blocks $\mathbf{c}_1,\dots,\mathbf{c}_N$.

A-5. In each block $\mathbf{c}_j,\ j=1,2,\dots,N$, embed t bits of the message sequence $\mathbf{m}$ by

$$\mathbf{c}_{jw}=\mathbf{c}_j+\frac{\alpha_j}{\sqrt{t}}\left(\epsilon_1\mathbf{w}_1+\epsilon_2\mathbf{w}_2+\cdots+\epsilon_t\mathbf{w}_t\right),$$

where $\epsilon_i=\begin{cases}1, & m_{ji}=1\\ -1, & m_{ji}=0\end{cases}$.

The scale constant α_j controls the tradeoff between visibility and robustness of the hiding data.
Embedding efficiency in this case is

$$E_f=\frac{(n-r)tN}{nab}\ \text{bits/pixel.}$$

Detection and Decoding

A-6. The recipient divides the received image into N blocks $\{\tilde{\mathbf{c}}_j\}$ and knowing the reference patterns (or the key to generate them) calculates

$$\delta(\tilde{\mathbf{c}}_j,\mathbf{w}_i)=\delta(\mathbf{c}_j,\mathbf{w}_i)+\frac{\alpha_j}{\sqrt{t}}\delta(\mathbf{w}_i,\mathbf{w}_i)\,\epsilon_i,$$

where $j=1,2,\dots,N,\ i=1,\dots,t$, and $\delta(,)$ is the chosen detection measure. (Indeed $\tilde{\mathbf{c}}_j$ are noise versions of $\mathbf{c}_{jw}$) Then recover the message:

$$\tilde{\mathbf{m}}_{ji}=\begin{cases}1, & \text{if}\quad \delta(\tilde{\mathbf{c}}_j,\mathbf{w}_i)>\tau\\ 0, & \text{if}\quad \delta(\tilde{\mathbf{c}}_j,\mathbf{w}_i)<-\tau\\ \text{an erasure} & \text{if}\quad -\tau\le\delta(\tilde{\mathbf{c}}_j,\mathbf{w}_i)\le\tau\end{cases},$$

A-7. The error control code decoder corrects errors and erasures. Its output can be

- "there is no watermarking or hidden message", when the number of erasures is $>N/2$;
- a decoded message (a sequence of bits);
- a decoded message with warning "errors are possible".

B. *Error analysis*

The expected value of $\delta(,)$ is $\mu_1=\mu=\frac{\alpha}{\sqrt{t}}$, when $m_i=1$, and $\mu_0=-\mu=-\frac{\alpha}{\sqrt{t}}$, when $m_i=0$ is embedded, respectively (see A-5 and A-6). Let us assume that $\delta(,)$ is normal distributed. Then the variance is $\sigma^2=\sigma^2_{\boldsymbol{w}_i}(\sigma^2_{\boldsymbol{c}}+\sigma^2_{\boldsymbol{n}})$, where $\sigma^2_{\boldsymbol{w}_i}=1$, and $\sigma^2_{\boldsymbol{c}}$ and $\sigma^2_{\boldsymbol{n}}$ are the variance of the cover work and the channel noise, respectively. Usually $\sigma^2_{\boldsymbol{c}}\approx(60/255)^2$. Let $p_c,\ p_{er}$ and p_{es} be the probability of correct detection, of error, and of an erasure, respectively. Then in both cases, when $m_i=1$ and $m_i=0$ is embedded:

$$p_c=\frac{1}{2}\operatorname{erfc}\left(\frac{\tau-\mu}{\sigma\sqrt{2}}\right);\qquad p_{er}=\frac{1}{2}\operatorname{erfc}\left(\frac{\tau+\mu}{\sigma\sqrt{2}}\right);$$

$$p_{es}=1-p_c-p_{er}=\frac{1}{2}\left[\operatorname{erf}\left(\frac{\tau-\mu}{\sigma\sqrt{2}}\right)+\operatorname{erf}\left(\frac{\tau+\mu}{\sigma\sqrt{2}}\right)\right].$$

The probability of **a false positive decision** ($\mu=0$) is given by

$$P_{fp}=\sum_{i=0}^{\lfloor\frac{N}{2}\rfloor}\binom{N}{i}p^{N-i}(1-p)^i, \tag{2}$$

where $p=\operatorname{erfc}\left(\frac{\tau}{\sigma\sqrt{2}}\right)$

The embedded n bits can be correctly decoded with a probability

$$P_{corr}=P_1+P_2+P_3,$$

where

$$P_1=\sum_{s=0}^{\lfloor\frac{d-1}{2}\rfloor}\binom{n}{s}p_{es}^s\left(\sum_{t=0}^{\lfloor\frac{d-1-s}{2}\rfloor}\binom{n-s}{t}p_{er}^t p_c^{n-t-s}\right),$$

$$P_2=\sum_{s=\lfloor\frac{d-1-s}{2}\rfloor+1}^{d-1}\binom{n}{s}p_c^{n-s}p_{es}^s,$$

$$P_3=\sum_{s=d}^{n}\binom{n}{s}p_c^{n-s}(q-p_c)^s,$$

d is the minimum distance of the code, and

$$q = \frac{1}{2}\operatorname{erfc}\left(\frac{-\mu}{\sigma\sqrt{2}}\right)$$

(this is p_c with $\tau = 0$) is the probability of positive (resp. negative) value of $\delta(\tilde{\mathbf{c}}_{wn}, \mathbf{w}_i)$.

(**b**) The probability of correct decoding in the case when the codes are used only in error correcting mode is given by

$$Q_{corr} = \sum_{t=0}^{\lfloor \frac{d-1}{2} \rfloor} \binom{n}{t} q^{n-t}(1-q)^t.$$

(**c**) If more than $N/2$ erasures are marked for a given watermark pattern $\mathbf{w}_i$ then the detector outputs "there is no watermark", that is, it makes **false negative decision**. The probability, P_{fn}, for such an output is given by

$$P_{fn} = \sum_{i=0}^{\lfloor \frac{N}{2} \rfloor} \binom{N}{i} p_{es}^{N-i}(1-p_{es})^i. \qquad (3)$$

Since pixels can be interpreted (are presented) as elements of $\mathbb{Z}_q$ (usually $q = 256$) a function (called *distortion function*) ρ

$$\rho : \left| \begin{array}{ccc} \mathbb{Z}_q & \rightarrow & \mathbb{R} \\ x & \rightarrow & \rho(x) \end{array} \right.$$

can be used as a measure of the embedding impact

One natural choice of ρ for algorithms that change the pixel value by up to $\pm x$ is

$$\rho(x) = [1 - \Pr(-x \le t \le x)]^{-1} = \left[\operatorname{erfc}\left(\frac{x}{\sqrt{2}}\right)\right]^{-1}$$

which is the reciprocal value of the probability of the random variable's deviation (dispersion) in the standard normal distribution to be greater than x.

V. Experiments and Conclusions

We have made numerous experiments with picture from several galleries (with grey-scale and color images) and many error control codes for both type of algorithms. Also, we have tested the cover images with the available in the internet software for stego-analysis. Nevertheless, the channel is assumed noiseless and detection blind, that is, the receiver and the opponent don't have the original, we have compered the results of stego-analysis on both original and cover objects.

Our observations show that q-ary codes are good choice in the case of syndrome embedding. For both algorithms it is better to use

Abstract - The goal of the paper is to find model of using GIS in monitoring and evaluation of postal service management. The methodology which is used is two visualize some data about work efficiency by creating separate layers and analyzing them. The analysis of results shows big potential of GIS as a tool for economic analysis. In the case of postal system of Serbia it proves that cross cutting analysis of various factors and their visualization gives better model for economical improvements of system management. The scientific contribution of this paper is to introduce GIS as valuable tool for economical research.

I. INTRODUCTION

The geographic information systems are family of software for visualization of geo referenced data. They could be used for different analysis which offers visualized solutions. Geographic referenced data are more acceptable for human use.

Geographic location is the element that distinguishes geographic information from all other types of information. Without location, data are termed to be non-spatial and would have little value within a GIS. Location is, thus, the basis for many benefits of GIS: the ability to map, to lap layers, to measure distances and to tie different kinds of information together because they refer to the same place as in [1].

II. LITERATURE OVERVIEW

Some authors discuss the use of GIS in econometrics. At the begining, GIS was widely used in business, government and in a range of academic disciplines and its application in economics has been more limited. The most frequent application in economics is the use of GIS for vizualisation or mapping of economic data which have spatial components. GIS use in econometrics begins with "plot the data" at an early stage of analysis to help identify trends, outliers etc. GIS provides a simple and efficient way to identify some economic trends. Less common, but more interesting, is the use of GIS to generate additional data as inputs in to further statistical analysis by using storage and management functions. This enables use of the GIS to cross cut spatial data from many sources. Some of them, like sampling and census data, are familiar to economists [2]. Rosenthal and Strange [3] provide an example of the use of GIS to implement such an instrumental variables strategy. They are interested in whether density of employment helps determine wages. The problem is that higher wages should attract more workers and lead to higher employment densities. That is, density may be caused by wages and not vice-versa.

GIS is used to construct area zones or to define neighbourhoods ("buffers") around objects. For example in [4] authors use such overlapping zones in their study of urban spreading

There is ability of GIS to combine spatial data from various sources that allows the creation of new data sets. It is combining socio-economic data from different spatial units like, population data from US census with employment data. Many economists use mappings between sets of spatial units and merging of such data. GIS offers flexibility in allowing users to create their own cross maps of different geographical units with data from different sources [5] .

For telecomm industry GIS is very important tool. Even the smallest companies use GIS for automatisation of localized tasks such as network design and planning and gain strategic advantage by standardising information throughout their organisations. Marketing staff is using the same data for mapping of customer distribution and engineers are designing fibre networks in GIS. All data are stored in structured database with many interfaces [6].

Postal operators use GIS for many services like address code, routing, marketing. For example, in the USA for the fiftieth anniversary of the ZIP Code, the Office of the Inspector General at the USPS has released a paper exploring ways to improve the ZIP code, "both to save postal costs and to enhance the opportunity for third party innovators to discover new uses and applications." In the report, entitled "*The Untold Story of the ZIP Code*", the executive summary recommends linking the USPS address database with GIS to create a more efficient ZIP Code system:

One such enhancement would be to combine the ZIP Code with the precision of geocodes (latitude and

longitude coordinates). This could have a direct impact on the U.S. Postal Service's bottom line by facilitating delivery route reconfiguration. Historically, the Postal Service has delivered mail via set delivery routes where each carrier visits the same homes every day. With the anticipated growth of parcel delivery, including the possibility of same-day delivery, the Postal Service will find it necessary to develop dynamic carrier routing. Combining the ZIP Code with the geocoding of addresses could ease the processing necessary to improve the efficiency of parcel delivery [7] .

Some papers deal with complex postal routing problems and with servicing of limited number of known location from one or more depots, in presence of certain limitations regard to demands of service and available recources by using GIS [8] .

Post of Serbia has developed the following services based on the Geographic Information System (GIS):

- Sale of coordinate position of a house number on the map
- Sale of coordinate position of streets on the map
- Sale of coordinate position of PAK on the map
- Generation of alphanumerical data based on coordinate position of house number
- Generation of alphanumerical data based on coordinate position of PAK
- Sale of data on number of households on the level of house number*
- Delivery of data on number of households on the level of PAK.

The Post of Serbia has been developing the Geographic Information System since 2002 with goal to analyse the territorial availability of postal service to the citizens and to rationalise transport and delivery of postal items.

The Post has geo-positioned the complete street network in Serbia, that means 103,000 kilometres of streets and roads. The company delivered coordinates for about 900,000 houses.

As regards the rural areas, where the houses are not marked with numbers, the Post created system wich coordinates positions of PAKs. In this way, the Post of Serbia geo-referenced over 113,000 PAKs on the Serbian territory.

Post of Serbia has developed a GIS portal to enable citizens and post service users to have spetial information of the area in which the services are performed.

The Post of Serbia offers to its users the address standardisation service which provides that any detail of our user which includes address detail shall be geo-positioned.

Based on the data of Geographic Information System, various analyses are possible like this presented in Figure 1:

- analyses of territorial accessibility to facilities and users,
- planning of advertising material distribution,
- planning of routes,
- generation of address lists by zones,
- analysis of population density aiming to plan infrastructure capacities, or selection of the most favourable sites for opening of new facilities, etc. [9].

.

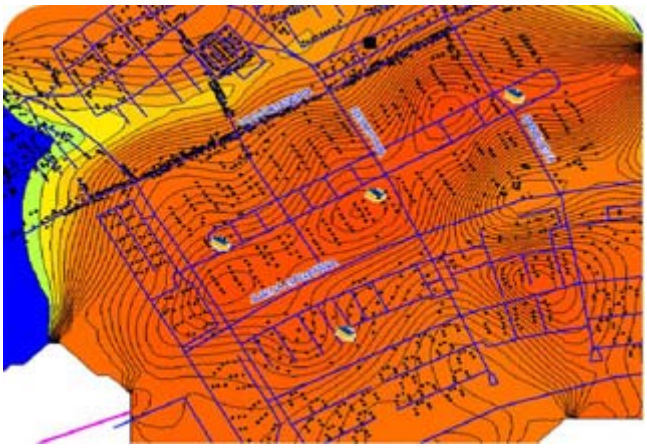

Figure 1. Analysis of population density and position of post offices

Reference [10] gave a contextualized professional development approach for geographic information technologies as a project-based science.

Innovative approach for analysis by using GIS is described in articles of reference [11].

Geographic information systems (GIS) are presented and explained as decision support in the paper referred in [12, 13].

III. GEOGRAPHIC INFORMATION SYSTEM

Due to the increasing development of science and technology and development of human society, the importance of information about the area becomes larger and extends from the idea to implementation of a project to change the space that surrounds us. Therefore, there are developed different survey methods to collect data on the area, and the different ways of storing and sorting data, collected them and a better analysis according to various criteria.

The spatial data describe the location, shape and orientation of objects in space. They are known as geospatial data. Geospatial data can describe the characteristics of many different types of objects on the surface. These objects can be tangible, physical things such as an office building, landscape or abstract forms such as the imaginary line that marks the political boundary between the states.

From the moment when first started collecting spatial data and display them on maps, there is a tendency for

them to be systematized and made available. Over a long historical period, the most effective way to display spatial information was analogous to the map. Map was the forerunner of the original spatial database, the original spatial information systems, and in some ways a forerunner of spatial data infrastructure. Map is important to display the spatial distribution, connectivity and interaction of objects and phenomena, as well as view qualitative and quantitative alteration of the condition over time.

Technologies of GIS are the "main culprit" for the change. Geographic information integrated into other products and software applications have become mass-market product. Forerunner of spatial data infrastructure in today's terms it is probably the concept of integrated mapping of different thematic layers of data from the sixties. Thanks to information and communication technologies, conventional way of presenting information about the area is the past. Today, spatial data is usually collected, stored, processed, analyzed and presented in digital form through a number of applications. Spatial data types provide fundamental abstraction mechanisms for modeling the geometric structures of spatial data, its attributes, operations on them, and the relations between them.

"A GIS is a collection of software that allows you to create, query and analyze geospatial data. Geospatial data refers to information about the geographic location of an entity. This often involves the use of a geographic coordinate, like a latitude or longitude value. Spatial data is another commonly used term, as are: geographic data, GIS data, map data, location data, coordinate data and spatial geometry data." [9] .

GIS is a system for managing spatial data and their associated properties. In the strictest sense, it is a computer system capable of integrating, storing, editing, analyzing and displaying geographic information. In a broader sense, GIS is a "smart card" that gives users the ability to set interactive queries (user created surveys), analyze spatial information, and edit data. The technology of geographic information systems can be used for scientific investigations, resource management, property management, development planning, regional planning, mapping and infrastructure planning. GIS is often used for the purposes of market research, then in geology, civil engineering, but also in all areas that use data related to the map.

A. Work in GIS

Information is data on artificial and natural objects in an area. These are, for example, infrastructure facilities, housing, sports and other buildings, construction of reservoirs, rivers, land use, elevation terrain data, geology, terrain, etc.. They are called features in GIS. Each feature has its attributes. If feature is mobile telecomm operator in Serbia, than the features could be: number of users per towns, number of different services...

Information on the geometry of the object can be in the form of:

- Grid and
- Vector.

Grid consisting of rows and columns of cells, called pixels, where each of these cells has a single, particular, digital value. In the case of images, the numerical value represents the number of colors (colors are coded with numbers). In the case of display other information, the pixel value is not only the color but also represents the spatial data. Examples, in some areas there have been excesses in the form of emission of toxic gases. Raster that shows the amount of pollution, consisting of pixels whose numerical values carry spatial information on the concentration of toxic substances in the air in each fraction of the space.

Displaying information in vector form refers to the geometry of the shape (length, height, and shape), either in terms of line or polygon entities and their spatial position (the position of the coordinate system).

In addition to this information in GIS is no additional information, so-called. spatial data, which can bind to a particular raster or vector data. Example: noise can be spatially displayed in the form of irregular polygons (polygons entity) and non-spatial data can be information about the types of trees, their numbers, percentages, different types (Figure 2), etc.

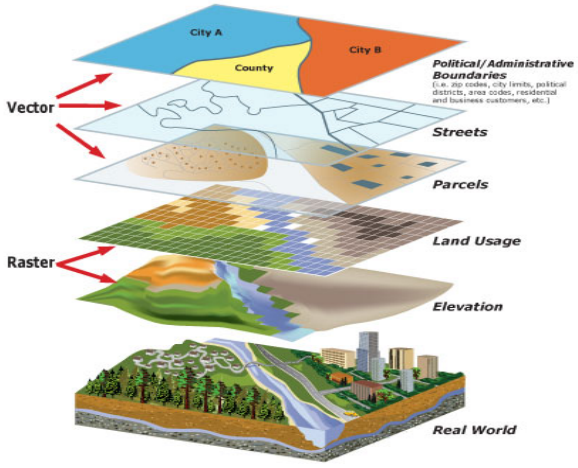

Figure 2: Example of vector and raster layers in GIS

B. Application of geographic information systems

GIS is an essential tool in all areas of design, planning, management and analysis. Around the world, used by electrical, mechanical and civil engineers, architects, bankers and economists, journalists, teachers, geodetic engineers, environmentalists, politicians, criminologists, planners, health professionals and others.

Business people see the world as a collection of information about sales, customers, warehouses, demographic profiles and much more. The basis for all of this information is the address, sales region, or transport routes of delivery which can all be displayed and interactively operated on the map.

The planning and engineering tasks that can be easily solved with the help of GIS are:

- location analysis,
- supervision and monitoring
- automatic mapping,
- analysis of water quality,
- modeling field
- geo-bibliography,
- soil analyzes (soil analysis)
- inventory and stock control.

Competitive pressure and new legislation causes management to an efficient and responsible manner. This requires access to information based on a geographically distributed elements and operations. In today's world, concurrent, successful management requires the maximum of all the resources, people, equipment and information. Using GIS to integrate geography with other relevant data, gives the system fully equipped for this task.

IV. ANALYSIS OF POSTAL SERVICES EFFICIENCY: CASE OF THE POST OF SERBIA

This paper refers to the use of GIS for analysis of the postal services in the Public enterprise PTT Srbija. The intention of the authors was to find different possibilities and to focus on the application of the GIS in monitoring and evaluation of postal service management. The essential problem of managing postal system is distribution of employees as function of distribution of residents. Hereof visualization is recognized as a good tool which is used to present some data of work efficiency by creating separate layers and analyzing them. The analysis of results shows big potential of GIS as a tool for economic analysis. Although, the postal system of Serbia like many others, uses GIS only to locate post offices, customers, fleet management systems, this paper indicates big potential for economical research. It proves that cross cutting analysis of various factors and their visualization gives better model for economical improvements of postal system management. The scientific contribution of this paper is to introduce GIS as a valuable tool for economical research and decision makings.

A. GIS maps

Some data which are available are analyzed. The map in Figure 3 shows density of inhabitants of Serbia. The most density is in Belgrade region and then in Južna Bačka region in Vojvodina area. The graduated presentation is used.

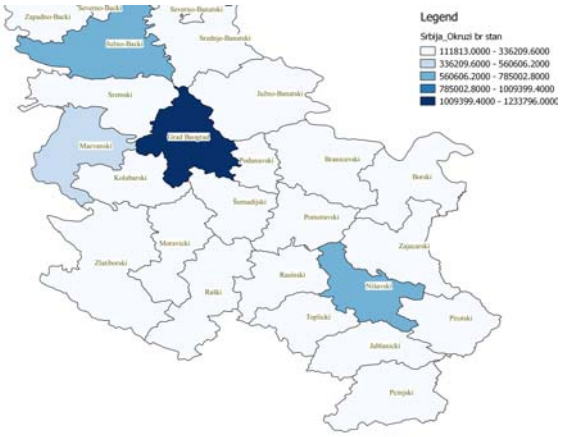

Figure 3. Inhabitants density according to counties

Next Figure is showing number of post offices in Serbia. From the graduated map can be seen that the most offices are in:

1. Belgrade county
2. Južna Bačka county
3. Srem and Južni Banat counties.

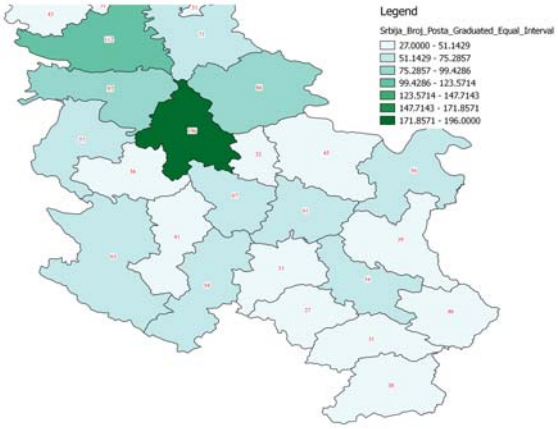

Figure 4. Post offices density according to counties

Figure 5 presents number of employees in post offices in Serbian counties:

1. Belgrade region and Južna Bačka ounty
2. Južni Banat i Srem counties.

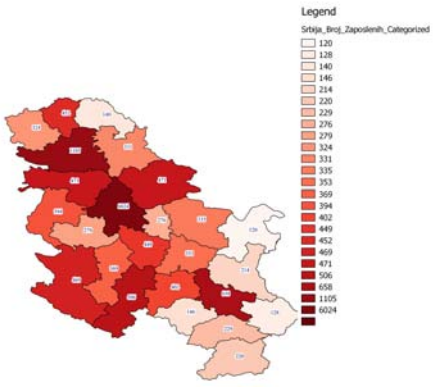

Figure 5. Number of employees in post offices in counties

The next map in Figure 6 presents average number of inhabitants per employed in postal system at certain county.

Results are:

1. Bor and Severni Banat
2. Jablanički and Pčinjski
3. Podunavski and Pirotski counties.

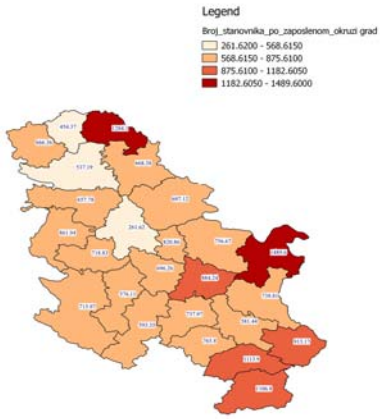

Figure 6. Average number of inhabitants per employed in counties

Figure 7 is giving the picture about average number of employees in a post office.

Belgrade is with the most workers and than a group of regions is with similar average number (the same group in a graduated presentation).

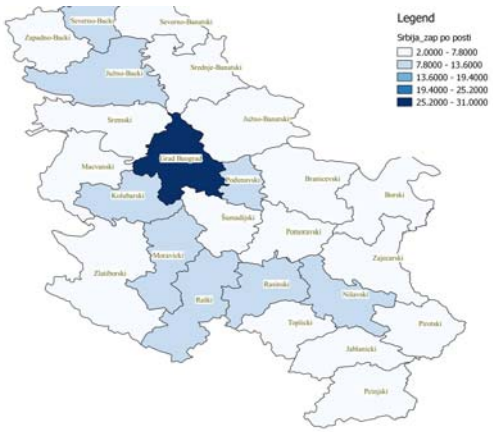

Figure 7. Average number of employees in a post office according to counties

V. CONCLUSION

The presented figures offer set of different analysis which are possible only with geo refernced spatial data. Layers created as vector layers in GIS enable comparisson of data. The most significant conclusions can be drown when verlapping differnt layers and making cross cutting analysis.

Conclusions made from presented analysis of efficiency of postal system in Serbia are:

The most density of inhabitants per employees are in Bor and Severni Banat. Bor is a county which belongs to the most developed counties, above the Republic average. The Severni Banat county is among the less developed. This needs further analysing. Severni Banat is probably with less economic turn over and this could be reson that it has less employed.

Reason that Bor has not many employed could be efficiency of workers, good management of working chain, well educated employers. Post office reflects the general picture of the county.

The biggest number of employees are in post offices on the territory of Belgrade and Južna Bačka counties. Explanation is that these counties have the biggest population and big settlements which require big post offices with more workers.

The most post offices are in the north part of the country. Niš county, where is the third large town in Serbia, has not enough number of post offices.

These are some conclusions:

Financial data are not available for external use and thez would be additional support for the concusions. Adding them wouldmake picture more clear. The proposal is to create some additional financial maps with data like:

- Postal income per county, per office, per employee, client
- Profit per county, per office, per employee

and some similar. These would offer cross cutting analysis which could give more interesting results. Such results could signal some changes in work management and improve work results. Corrections will bring new picture which must be presente in GIS, again and this will lead to continous monitoring of effects that changes caused. Precondition are databases with real data and carefully selected data. Investment into GIS and educated people who could use it in the right way brings improvement of organisation functioning

Generalization of hypersphere function

D. Letic* and I. Berkovic **
University of Novi Sad, Technical Faculty "Mihajlo Pupin", Zrenjanin, Serbia
* dletic@open.telekom.rs, ** berki@sbb.rs

Abstract - In this paper are presented the results of theoretical researches of hypersphere function on the basic of generalization of two known functions referring to hypersurface $S(k,r)$ and hypervolume $V(k,r)$ of sphere and supposed recurrent relation between them. On the basis of the two introduced freedom degrees is performed the generalization of these functions. So, we have got a special continual function, i.e. generalized hypersphere function. Symbolic evaluation and numerical experiment are realized by the program packages MathCAD Professional and Mathematica.

I. INTRODUCTION

Hypersphere function is a hypothetical function can necked with multidimensional space. It belongs to the group of special functions, so its testing is being performed on the basic of the known functions as the types *gama, psi, beta* and the like. The most significant value is in its generalization from desertion to continuum. In addition to it we can from the scope (fields?) of natural integer of values, pass to the set of real and noninteger values. So, there gather conditions as well for its graphic interpretation and more concise analysis. For the development of the hypersphere functions theory are especially responsible: *Neville* [12], *Manning* [9], *Rucker* [13], *Conway* [2], *Sommerville* [14], *Wells* [15], *Maunder* [10], *Hinton* [5], *Freden* [3], *Hocking* and *Young* [6].

A. Hypersphere Surface and Volume

As analyses present, the surface of the hypersphere of the diameter r can be defined as a form function [19]:

$$S(k,r)=\frac{k\sqrt{\pi^k}\,r^{k-1}}{\Gamma\left(\frac{k}{2}+1\right)}=\frac{2\sqrt{\pi^k}\,r^{k-1}}{\Gamma\left(\frac{k}{2}\right)}, \qquad (1)$$

where $\Gamma(x)$ ($x\neq 0$) is *gama* function, while k is specially defined dimension degree ($k\in N$). In the intergration result, we get the term for hypersphere volume (V), of r radius [16]:

$$V(k,r)=\int_0^r S(k,r)dr=\frac{\sqrt{\pi^k}\,r^k}{\Gamma\left(\frac{k}{2}+1\right)}. \qquad (2)$$

The obtained terms are key ones for defining more general function that would enclose both previous ones, and so would be performed a unique interpolation between these vectors by which are being described surfaces, i.e. volumes of hypersphere.

B. Hypersphere function with two degrees freedom

Previous results (1) and (2), as it is known, present, respectively two-dimensional (surface-surf), that is three-dimensional (volume-solid) entities. In addition to certain generalizations, these terms may create a notion of a hypersphere functions family, whose development would now flow along "horizontal" dimensions or freedom degrees n , where is $n\in N$. Within every "horizontal" freedom degrees n , exists as well "vertical" one of freedom, k (that is orthogonal in relation to n) (Figure 1 and 2).

C. General Form of Hypersphere Function

The function (2) will be in continuation marked with $HS(k,3,r)$ (*Hypersphere*), where k is the dimension within the third degree of freedom ($n=3$), and r hypersphere radius. General mark would be now presented by the functions of three arguments, in the form of $HS(k,n,r)$. With the hypersphere of the third degree of freedom, the point is, as it is emphasized, about volumes or solids, while with the hypersphere of the second, to which is adequate the function $HS(k,n,r)$. Consequently, on the basic of previous, there are:

$$HS(k,2,r)=S(k,r) \quad \text{and}$$

$$HS(k,3,r)=V(k,r). \qquad (3)$$

The transition anto the higher function than the appropriate one (e.g. from surf to solid), is reached by integrating, so that the previous functional equation $HS(k,3,r)$ can be expressed by the next form:

$$HS(k,3,r)=\int_0^r HS(k,2,r)dr=\frac{\sqrt{\pi^k}\,r^k}{\Gamma\left(\frac{k}{2}+1\right)}=\frac{2\sqrt{\pi^k}\,r^k}{k\Gamma\left(\frac{k}{2}\right)}. \qquad (4)$$

The *freedom degree* is here conditionally defined and presents dimensions level of hypersphere entity. So, in the zero ($n=0$) and the first degree of freedom ($n=1$) is included the entity out of man's experience perception. It is related as well to higher freedom degrees that are included from the fourth, the fifth to the n -th degree. These concepts (notions) are precisely defined in topology and geometry, and in this paper are specially approached

(treated). For the fourth horizontal freedom degree, follows the hypersphere form function:

$$HS(k,4,r)=\int_0^r HS(k,3,r)dr=\int_0^r\int_0^r HS(k,2,r)drdr$$

$$=\frac{2\sqrt{\pi^{\,k}}\,r^{\,k+1}}{\Gamma\left(\frac{k}{2}\right)k\,(k\,+\,1)}\,, \qquad (5)$$

where: $HS(k,2,r)$ is hypersphere function of the second freedom degree. The integration procedure to higher freedom degrees would lead to the n -th hypersphere function, and general value of the placed integral. This is also a way how, and the basic of recurrent relation based a differentiation, respectively integrating (integralling), to perform hypersphere function generalization. So, there are:

$$HS(k,n,r)=\int_0^r HS(k,n-1,r)\,dr\,. \qquad (6)$$

This result can be achieved in many equivalent ways.

On the basis of general integral value follows final or *generalized form of hypersphere function*, as:

$$HS(k,n,r)=\frac{2\sqrt{\pi^{k}}\,r^{k+n-3}\Gamma(k)}{\Gamma(k+n-2)\Gamma\left(\frac{k}{2}\right)}\quad (k,n\in N\,). \qquad (7)$$

Concluding about general value of this integral, is supported by the fact that:

$$\frac{1}{\prod_{i=0}^{n-3}(k\,+\,i)}=\frac{1}{k\,(k\,+\,1)(k\,+\,2)\,\cdots\,(k\,+\,n\,-\,3)}=$$

$$\frac{1}{\prod_{i=0}^{n-3}(k+i)}=\frac{1}{k(k+1)(k+2)\cdots(k+n-3)}=\frac{\Gamma(k)}{\Gamma(k+n-2)}=\frac{1}{(k)_{n-2}}\,. \qquad (8)$$

The previous functional equation can be presented as well by so-called *Pochhammer's* symbols [20]. At the same time, with the deductions according to the radius r, we can, as well, perform "motions" to lower *freedom degrees*, starting from the n -th one, on the basic of recurrent relations of the type

$$\frac{\partial}{\partial r}HS(k,n,r)=HS(k,n-1,r)\qquad \text{and}$$

$$\frac{\partial^n}{\partial r^n}HS(k,n,r)=HS(k,0,r)\,. \qquad (9)$$

The example of derivation of known sphere functions shows that the second ($n=2$) freedom degree is achieved, and it is level lower than level of volumes (columns).

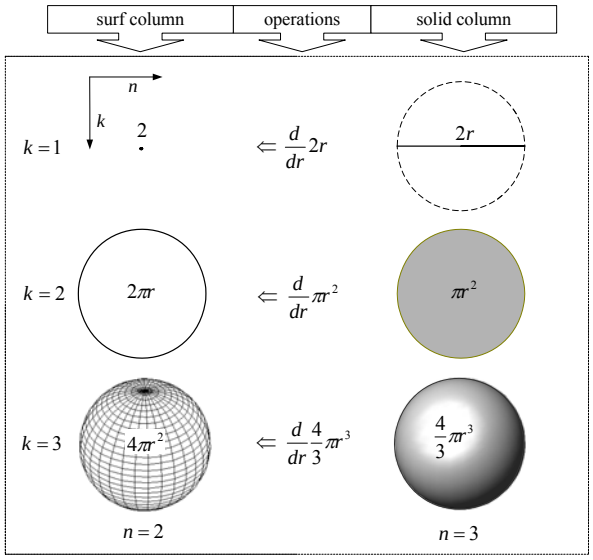

Figure 1. Moving through the vector of real surfaces: Deducting one freedom degree k of surface sphere we get circumference, and for two (degrees) we get the point 2 (left). Moving through the vector of real solids, i.e. by deduction of one freedom degree k from the sphere, we get a circle (disk), and for two (freedom degrees), we get a line segment or diameter (right column)

The right column in Figure 1 relates to sphere solids. For example *HS* - solid with the freedom degree $k=n=3$ is a sphere solid or a sphere. Within this column, for $k<3$ every primitive is called a hypersphere solid. For $k>3$ ($k\in Z$) these objects are hypersphere primitives. Consequently, the first hyporsphere solid is a circle (or a disc), while the second is diameter. Formally, they are solids with deducted one, respectively two freedom degrees k. When k is $\in R$, then, also, are stake hypersphere objects. Similar division is related as well to the freedom degree $n=2$, that relates to the surface sphere objects, or surf (the left column).

II. THE MATRIX FORM OF HYPERSPHERE FUNCTION

A. *The Summary of Hypersphere functions*

Taking into consideration that the hypersphere function is two-dimensional (leaving reserve toward radius r, as the third dimension), and that its values change depending on number of freedom degrees n and k ($i=0,1,2,3,\ldots n$ and $j=0,1,2,3,\ldots k$), cache of them can be presented, in discrete form, by the next matrix

$$\left[M_{ij}\right]=M_{kxn}\,. \qquad (10)$$

For example for two adjacent columns of this matrix $[M]^{<i-1>}$ and $[M]^{<i>}$ follows:

$$[M]^{<i-1>} = \frac{\partial}{\partial r}\begin{bmatrix} \frac{r^{i-3}}{\Gamma(i-2)} \\ \frac{2r^{i-2}}{\Gamma(i-1)} \\ \frac{2\pi r^{i-1}}{\Gamma(i)} \\ \frac{8\pi r^{i}}{\Gamma(i+1)} \\ \vdots \\ \frac{2\sqrt{\pi^k}\, r^{k+i-3}\Gamma(k)}{\Gamma(k+i-2)\Gamma(k/2)} \end{bmatrix} =$$

$$= \begin{bmatrix} \frac{r^{i-4}}{\Gamma(i-3)} \\ \frac{2r^{i-3}}{\Gamma(i-2)} \\ \frac{2\pi r^{i-2}}{\Gamma(i-1)} \\ \frac{8\pi r^{i-1}}{\Gamma(i)} \\ \vdots \\ \frac{2\sqrt{\pi^k}\, r^{k+i-4}\Gamma(k)}{\Gamma(k+i-1)\Gamma(k/2} \end{bmatrix}, \text{ for } \quad i = \overline{0,n}\,. \quad (11)$$

Interesting results can be obtained on the basic of *horizontal* (n) or *vertical* (k) *freedom degrees*. Thus, for example, it follows that

$$\left.\frac{2\sqrt{\pi^k} r^k}{k\Gamma(k/2)}\right|_{k=3} \vee \left.\frac{8\pi r^n}{\Gamma(n+1)}\right|_{n=3} \vee \left.\frac{2\sqrt{\pi^k} r^{k+n-3}\Gamma(k)}{\Gamma(k+n-2)\Gamma(k/2)}\right|_{k=3\wedge n=3}$$

$$\Rightarrow \qquad \frac{4}{3}\pi\, r^{\,3}\,. \qquad (12)$$

Consequently, this property is very essential, because it can bring the same result on the basic of two special formulas, or using only one general (formula).

On the basic of general form (10) of the matrix M_{kxn} $(k, n \in N)$ follow concrete values (Figure 2) for the selected submatrix 11x12 ($j = -3, -2, \ldots 7;\ \ i = -5, -4, \ldots 6$).

B. Hypersphere Function Gradients

Gradient can be applied to hypersphere function, taking into consideration its multi-dimensionality. As this function contains three independently changeables: k, n and r, follows the solution of the gradient functions $\nabla_{k,n,r}$ in vector form:

$$\nabla_{k,n,r}\{HS(k,n,r)\}$$

$$= HS(k,n,r)\begin{bmatrix} \ln 2r\sqrt{\pi} + \frac{1}{2}\psi_0\left(\frac{k+1}{2}\right) - \psi_0(k+n-2) \\ \ln r - \psi_0(k+n-2) \\ \frac{1}{r}(k+n-3) \end{bmatrix}. \quad (13)$$

This function has special meaning with the establishment of the extreme of contour HS -functions.

C. The graphics of hypersphere functions

The graphics of the function $HS(k,n,r)$ can be presented for the field of real numbers, including both freedom degrees, and accepting radius as parameter.

Graphic generating (Figure 3) has been performed by the program package *Mathematica*. In $k, n \in N$ domain and with the unit radius, the function is convergent. In the other three quadrants of the coordinate system, the oscilations are characteristical, the appearance of zeros and the singularities of the function $HS(k,n,1)$, so it is demanding for analytical testings.

The same characteristics are noted on the presented matrix, too (Figure 2).

$$
M_{k,n}=\begin{array}{c|ccccccccccc|c}
 & -3 & -2 & -1 & 0 & 1 & 2 & 3 & 4 & 5 & 6 & 7 & n/k \\
\hline
 & \frac{113400}{\pi^3 r^{11}} & -\frac{11340}{\pi^3 r^{10}} & \frac{1260}{\pi^3 r^9} & -\frac{315}{12\pi^3 r^8} & \frac{45}{2\pi^3 r^7} & -\frac{15}{4\pi^3 r^6} & \frac{3}{4\pi^3 r^5} & -\frac{3}{16\pi^3 r^4} & \frac{1}{16\pi^3 r^3} & -\frac{1}{32\pi^3 r^3} & \frac{1}{32\pi^3 r} & -5 \\

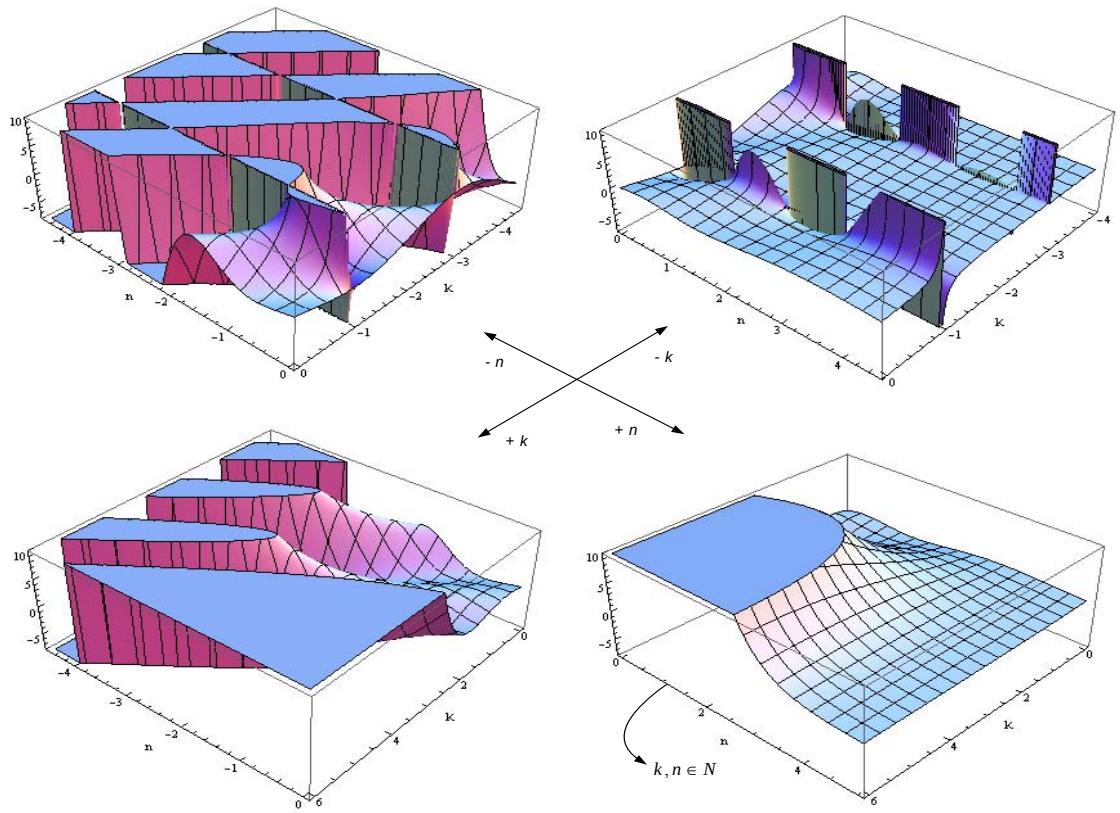

Figure 3. Visualization of the hypersphere function in the field of real numbers, for all four quadrants

III. CONCLUSION

In researching the hypersphere function there are left at stake the next expanding: dimensions k and n higher than three. Continual dimensions that include noninteger values, zero dimension, the domain of lower than zero dimensions, consequently, the area of complex freedom degrees and the like theoretically they exist, and the generalization achieved by this paper, directs to generality in phenomene that are met in multi-dimensional geometry and topology. In any case, the matrix of negative dimensions demands special structuring and deeper mathematical analysis. Hyperspheres present one part of multi-geometrical objects. In the introduction is stated that sphere is the most symmetrical geometric body. Some other bodies have such property, but not completely. Namely, cube is symmetrical along orthogonal coordinates, if its center is in the concurrence of big diagonals, and the axes of coordinate system are parallel to cube edges. This property have some other polyhedrons. Cube, because of its orthogonallity, has retained the property, that its functions derivations of solid entity (create) generate surf-entity functions. With the objects that have not the property that recurrency is being made on the basic of derivation function, have to be introduced new freedom degrees depending on object complexity. The next object that has some properties similar to sphere, is cilynder (this similarity is caused by the equality of cilynder height and diameter). Its symmetry is twofold and is not any more unambigous along all coordinate axes as with sphere. These properties are essential suppositions for defining recurrent relations that would give the connestion among functions of some entities and along the columns and along progressions (lines) of cube, respectively cylinder. The examined analysis of multi-dimensional space and formula of this geometry, leads to the conclusion about its complexity and connections with spacial functions and the other areas of mathematics.

ACKNOWLEDGEMENT

Paper presents results of project TR32044 "The development of software tools for business process analysis and improvement" financed by Ministry of science and technology development, Republic of Serbia.

Abstract - Understanding the past is one of the key factors of human culture. Cultural heritage contributes to the preservation of collective memory. It is difficult to imagine the original appearance of monuments while observing their archeological remains. Digital technologies are an efficient tool for visualization and multimedia presentation of cultural heritage. This paper describes the use of these technologies through the workflow of the White bastion 4D visualization project, from collecting information, through 3D modeling and texturing to interactive web implementation using the most advanced web 3D technologies. We discuss the advantages and drawbacks of each technology for this particular purpose.

I. INTRODUCTION

Cultural heritage (CH) is a silent witness of our past. We are surrounded by remains that the previous generations left behind, as remainders of the glorious times, events and cultures. Most of those remains do not reflect the magnificence of the objects in their time. Computer graphics and digital technologies provide tools to recreate the original appearance of cultural heritage objects and take the visitors to the journey through the past.

There are many techniques and methods used for visualization of cultural heritage. This field is still a very hot research topic. However, most of the CH visualization professionals use similar workflows to obtain the desired goal. Visualization can be performed for various purposes, such as archaeological scientific research, archiving and presentation. In this paper we will focus on cultural heritage visualization for presentation purposes, particularly the interactive visualization.

The goal of interactive CH visualization is to enable the user to interact with the digital model of CH object. In case of small objects, for example museum artifacts, the user can turn them around and click on their various parts, change the illumination and open the additional digital content for learning about their history and purpose. In case of buildings and architectural complexes, interactive visualization enables the user to virtually walk through the objects and explores their various sections, learning about them through the additional digital content such as stories, avatars and 3D models of their smaller elements.

We will present the workflow of a 3D interactive visualization using the case study of the White Bastion 4D digitization project. We will identify the common problems and issues arising in the process of conversion of the 3D geometry from non-interactive into interactive format. We will analyze different web 3D technologies for presenting 3D models online and discuss their advantages and drawbacks. At the end we will offer our conclusions as a contribution to the future CH visualization projects.

II. RELATED WORK

Interactive visualization of cultural heritage has been implemented in the last decade through many projects and case studies. They range from 3D scanning and virtual restoration of damaged artworks and artifacts to interactive virtual reconstruction of whole buildings and monuments.

The Digital Michelangelo project [1] presents a hardware and software system for digitizing the shape and color of large fragile objects under non-laboratory conditions using laser triangulation rangefinders, laser time-of-flight rangefinders, digital still cameras, and a suite of software for acquiring, aligning, merging, and viewing scanned data. As a demonstration of this system, they digitized 10 statues made by Michelangelo, including the well-known figure of David, two building interiors, and all 1163 extant fragments of the Forma Urbis Romae, a giant marble map of ancient Rome. It was one of the first achievements in cultural heritage digitization, introducing the issues of large data sets and their management in the research. Some of those issues were addressed and solved through MeshLab, a system for the processing and editing of unstructured 3D triangular meshes [2].

Ancient history comes to life through virtual walks around Ancient Olympia [3] and valley of pyramids in Giza [4]. At the Virtual Reality programme in the Hellenic Cosmos Theater in Athens, there is a tour at the peninsula and the city of Miletus, as it was 2000 years ago. Visitors can explore the virtual city and learn about the most important public buildings. Starting from the gate at the Port of the Lions, they enter the sanctuary of Apollo Delphinios. Then, they visit the Ionian Stoa, which housed the stores of the city, the Hellenistic Gymnasium, the North Agora and the Bouleuterion, being able to see even the details of the buildings' architecture. They can “fly” over the city for one last panoramic view of the perfect city planning design, or even “dive” into its port.

For the famous Giza Pyramids, the Sphinx, and surrounding tombs and temples, just west of modern Cairo (3rd millennium BCE), the Giza Project at Harvard University is putting together older traditional archives

(digital photos, archaeological drawings, object metadata) with realistic 3D visualization of the site. This project provides revolutionary access to Giza, its statues, hieroglyphic inscriptions, architecture, and wall decoration. Real-time immersive models allow the visitors to pose new research questions, provide interactive classroom instructions, and investigate diachronic approaches to Giza's evolution over several millennia.

The potential of 3D technologies is proven also in protection of cultural heritage sites from destruction caused by many visitors. The Pure Land project presents "a full-scale augmented digital facsimile of Cave 220 from the UNESCO World Heritage site, the Mogao Grottoes, Gansu Province, northwestern China. The peerless treasuries of paintings and sculptures at Dunhuang are extremely vulnerable. Comprehensive digitization has become a primary method of preservation at the site." [5]

Virtual Museum Transnational Network V-MusT.net has integrated a number of interactive visualizations of cultural heritage into the international multimedia exhibition Keys To Rome [6], held at the same time in Rome, Amsterdam, Alexandria and Sarajevo. The exhibition presents these 4 locations within the Roman Empire through an interactive storytelling application enabling the visitors to walk through Roman villas and thermal baths, basilicas and temples, collecting objects and learning about their history.

The mentioned projects represent just a small part of a rich collection of virtual cultural heritage applications. Through this work some open issues aroused and have been identified by Scopigno in [7]. The problems of obtaining interactivity without sacrifice on quality (simplification and multi-resolution), web and mobile presentations of the interactive virtual environments, finding the best interaction and navigation methods and integration with other media are still subjects of intensive scientific research. We hope to offer some solutions through the case study presented in this paper.

III. CH VISUALISATION WORKFLOW

The fortification known as „White Bastion" is one of the most impressive and important historical sites in Sarajevo. It is located on the southeast outskirts of the City, with an overview on the city valley (Fig. 1). The remains found on the site date from 14th till 18th century. The goal of the White Bastion 4D digitization project is to present the development of this valuable cultural heritage object through history using interactive 3D visualization combined with digital storytelling.

Although the cultural heritage visualization applications differ in technologies they use and purpose for which they have been created, we can define a common workflow they all follow during their development. This workflow consists of steps presented in Fig. 2.

Collection of materials for the White Bastion project included the drawings and blueprints of the archaeological remains, consultations with historians and archaeologists working on excavations and review of available literature from historical sources. This step resulted with identification of 6 different building shapes to be modeled and presented in time within the interactive application.

Figure 1. White bastion fortress, Sarajevo, Bosnia and Herzegovina

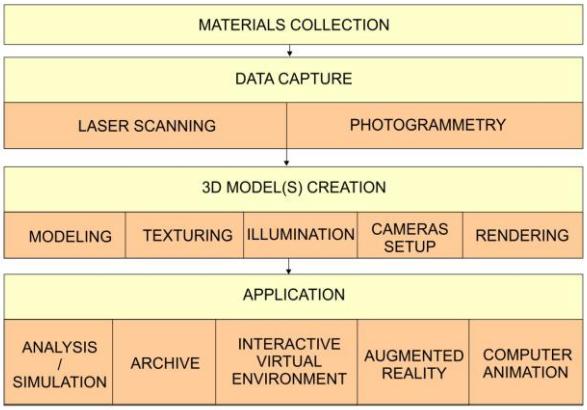

Figure 2. Cultural heritage visualization workflow

For the fortress geometry we skipped the data capture step, as we had no equipment available for laser scanning the remains, while capturing the geometry using photogrammetry was not possible due to the large dimensions of the object and difficulties of approach from some sides.

However, the selected archaeological findings, such as remains of weapons, helmets and similar objects will be digitized using photogrammetry and added to the 3D models' geometry.

IV. 3D MODELLING

In order to present the development of the White bastion through history, we consulted the archaeologist who was leading the excavations on the site. He identified six 3D models of the object to be created, some of them different from each other by the addition of interior objects, and exterior extensions.

The modeling process was started by building the terrain. In order to create precise terrain model the Digital Elevation Model over Balkans area from the GMES RDA project [8] was used. This geotiff map was then imported in Global Mapper - GIS application for reading and

conversion of different kinds of spatial datasets. Sarajevo area terrain was extracted from the map and exported as 3D VRML file which was then used in Cinema 4D as the precise Sarajevo terrain model.

3D models of White bastion are created in Cinema 4D, while Adobe Photoshop is used for creating and adjusting the textures. Six final 3D models correspond to six different construction phases, the first one, from the medieval period, looking completely different from the last one from Austro-Hungarian period.

In order to achieve photo-realism in renders of Bastion, the atmosphere with vegetation and Miljacka river flow was added and rendered at high quality (Figures 3 and 4).

Figure 3. Exterior and interior 3D models of fortress from the medieval period

Figure 4. 3D model of fortress from the first phase of the Ottoman period

V. CONVERTING TO HYPERMEDIA

For the purpose of web presentation of 3D models a few different web technologies we have used. Firstly, we have used MeshLab for conversion the 3D models of White bastion to PLY format which was then used in 3D Heritage Online Presenter (3DHOP) [9]. 3DHOP constructs the model web presentation through the WebGL API technology and SpiderGL JavaScript library. Although we have used 3DHOP for the model web presentation in the other projects before, this time it was unusable. We have previously used the much simpler 3D models, but this time the 3D models (of White bastion) were quite complex and 3DHOP was unable to load and present them.

After an unsuccessful attempt with 3DHOP, we have decided to use XML based X3D files which are well supported in HTML5. MashLab is again used for conversion the 3D models of White bastion to X3D format. When we export X3D file, we can convert X3D format to HTML5 webpage, for example using InstantReality X3D converter [10]. However, similar to the previous case, and this time, due to the complexity of the models and size of the XML file, conversion to HTML webpage was not successful.

After all, we have decided to use Unity Web Player [11] with whom we have had the most success in the other projects. 3D models of White bastion, created in Cinema 4D, were exported as FBX file which was then used in Unity Web Player. From Unity Web Player we have build web presentation of the models without any problems.

VI. INTERACTIVE DIGITAL STORYTELLING APPLICATION

The final output planned in this project is an interactive digital storytelling application which will combine the geometry of the 6 models with stories about the object, its history and related events and characters. This part of the project is still in progress.

Our idea is that the user of the application will watch interactive digital stories interlinked in a common structure with interactive 3D models. The stories consist of the main story presenting the insight in the chronology of White bastion's development and sub-stories presenting details about different time periods in object's history,

legends related to the object and characters who left their mark in development of the fortress. Each digitized archaeological artifact will be adjoined with the story about its purpose and history. From each sub-story the user will be able to open the link to the corresponding 3D model of the fortress and explore it virtually.

VII. CONCLUSION

In this paper are discussed digital technologies that are an efficient tool for visualization and multimedia presentation of cultural heritage. The paper described the use of these technologies through the workflow of the White bastion 4D visualization project, from collecting information, through 3D modeling and texturing to interactive web implementation using the most advanced web 3D technologies. Benefits and limitations of using these technologies for visualization and multimedia presentation of cultural heritage are indicated.

ACKNOWLEDGMENT

The project "Visualization of White Bastion fortress based on 3D Spatial Documentation of Material Cultural Heritage And Interactive Digital Storytelling" is a case study of the MPNS COST Action TD1201 "Colour and Space in Cultural Heritage" (COSCH).

Abstract - Shannon information entropy measures were used as filters of different kernel sizes to detect edges in digital images. The concept is based on communication theory with splitting of edge detection kernel into source and destination parts. The arbitrary shape of the kernel parts and the fact that information filter output is a real number with reduced problem of edge's continuity represents the major advantage of this approach. The results are compared with traditional edge detection algorithms like Sobel to illustrate performance and sensitivity of the information entropy filters. Besides the well known test image Lena, the real life examples are taken from medical X-Ray imaging of knee joints in order to illustrate the algorithm performance on real data.

I. INTRODUCTION

Shannon developed his information theory [1] for the analysis of communication channels. Central to his theory is the concept of information entropy (1) which is a measure of unpredictabilty of information. However, the concept of information entropy and entropy measures are used in other fields besides communications. Some examples are statistical inference, natural language processing, cryptography, evolutionary biology and various forms of data analysis [2],[3].

The edge detection is one of the most important procedures in image processing. It is usually a first step in image processing sequence to acieve segementation of images, extraction of details, search for a pattern, data reduction and many other complex tasks.

The idea to use information entropy has been proposed more twenty five 25 years ago in digital microscopy [4], and in various forms has been in sporadic use since then [5],[6]. It is still active area of research [7],[8] wiith open possibility for improvement and wider application.

The main goal in our work presented here was to achieve continuity of the edge in low contrast and noisy X-ray images, which is a first necessary step for shape analysis of femur (thigh bone) in a knee joint. The success opens the possibility for automatic shape analysis of femur.

II. THEORY

The information entropy H, is defined in (1) for a system containing n discrete states, each state i with its own probability p_i.

$$H = -\sum_{i=1}^{n} p_i \log_2 p_i \tag{1}$$

Some information theory measures which are used for simultaneously analyzing two distributions are presented bellow. Traditionally, those two distributions (X & Y) are source and destination in communication theory. The measures used in this paper are joint entropy (2), conditional entropy (3) and mutual information (4).

Joint entropy

$$H(X,Y) = -\sum_{i=1}^{n}\sum_{j=1}^{m} p\left(x_i, y_j\right) \log_2 p\left(x_i, y_j\right) \tag{2}$$

Joint entropy $H(X,Y)$ is the measure of how much information is contained in a system of two random variables. It ranges from $H(X)$ for the same variables to $H(X)+H(Y)$ for independent variables.

Conditional entropy

$$H(X \mid Y) = -\sum_{i=1}^{n}\sum_{j=1}^{m} p\left(x_i, y_j\right) \log_2 p\left(y_j \mid x_i\right) \tag{3}$$

Conditional entropy $H(X|Y)$ is a measure of information still contained in X after Y is known. It ranges from zero for the same variables to $H(X)$ for independent variables.

Mutual information

$$I\left(X,Y\right) = \sum_{i=1}^{n}\sum_{j=1}^{m} p\left(x_i, y_j\right) \log_2 \frac{p\left(x_i, y_j\right)}{p\left(x_i\right) p\left(y_j\right)} \tag{4}$$

Mutual information $I(X,Y)$ is a measure of mutual dependence of variables X and Y. It ranges from zero (for independent variables) to $H(X)$ for the same variables.

Sobel operators

$$S_x = \begin{bmatrix} -1 & 0 & 1 \\ -2 & 0 & 2 \\ -1 & 0 & 1 \end{bmatrix} \quad S_y = \begin{bmatrix} -1 & -2 & -1 \\ 0 & 0 & 0 \\ 1 & 2 & 1 \end{bmatrix} \qquad (5)$$

Sobel operator is a simple filter for finding edges in digital images. It has 3 by 3 kernels (5) which are convolved with a testing image [9].

III. METHOD

One of the reasons for using information entropy kernel is that their size and/or shape can be very arbitrary. The only restriction is that two variable kernels *H(X,Y)* (2), *H(X|Y)* (3) and *I(X,Y)* (4) have to be split into two equal parts with pixels in one to one correspondence (source and destination parts). Information entropy kernel *H(X)* has no such restriction (1).

To illustrate improvements of our entropy based methodology over Sobel filtering the series of pictures is presented here. Main test image is the well known test picture Lena found in most digital image processing books [9].

The Fig. 1 shows application of Sobel operator on Lena picture. The main problem is discontinuity and noisy appearance of the edges.

Fig. 2 shows the result for application of information entropy operator *H(X)* in the direction of columns, while Fig. 3 shows the result for application of information entropy operator *H(X)* in the direction of rows.

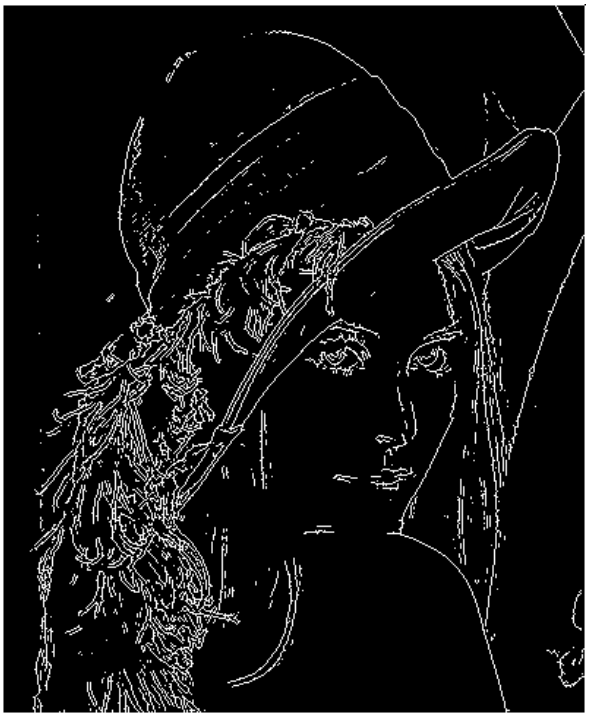

Figure 1. Sobel operator (5) applied to Lena picture

Figure 2. Entropy operator (1), columns direction

Figure 3. Entropy operator (1), rows direction

Figure 4. Conditional entropy operator *H(X|Y)* (3), columns direction

The application of information entropy operator *H(X)* (1) in both directions Fig. 2 and Fig. 3. shows better continuity of the edges and lower level of high frequency noise.

Fig. 4 shows the result for conditional entropy operator H(X|Y) while Fig. 5 shows the result for joint entropy operator H(X,Y)

Figure 5. Joint entropy operator *H(X,Y)* (2), columns direction

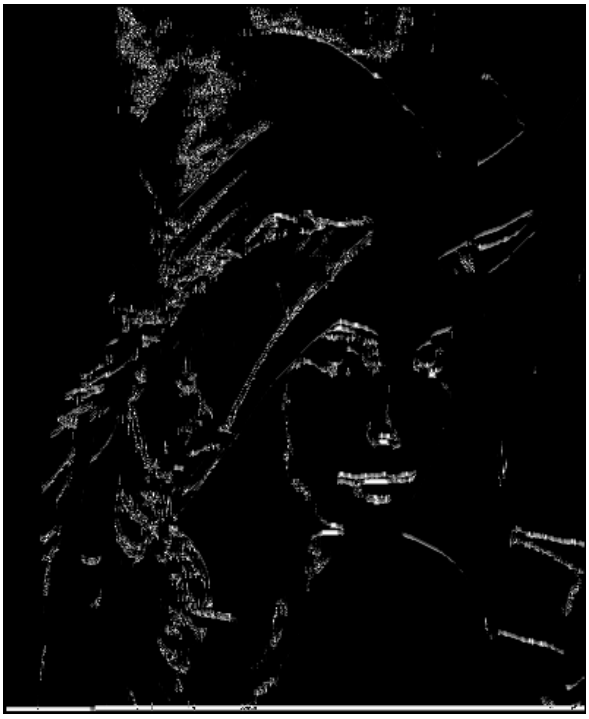

Figure 6. Mutual information *I(X,Y)* (4), columns direction

Fig. 6 shows the result for mutual information operator *I(X,Y)*. All information entropy kernels are of size 5 by 5.

The results on test images illustrate that the main purpose of designing entropy based edge detection has been achieved. With the exception of mutual information operator (4) whose results are shown in Fig. 6, all entropy operators have a better continuity of edges then Sobel operator.

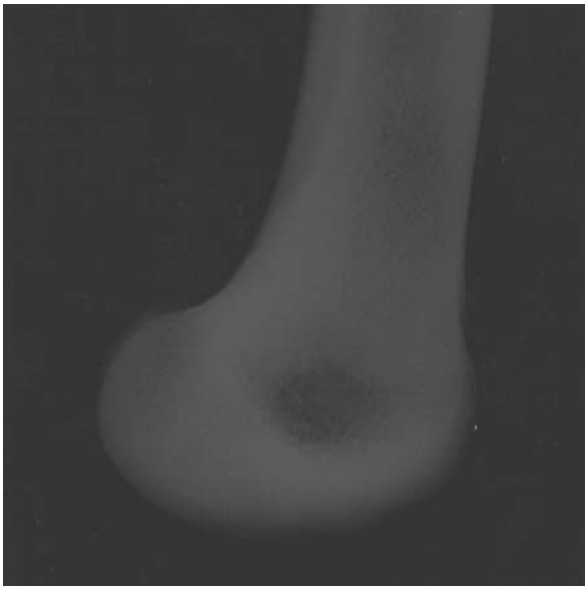

Figure 7. X-Ray image of knee bone

The entropy operators are also applied to the X-ray pictures of bone from knee joint. This type of images are often low contrast and noisy, but entropy algorithms can be adjusted to work on them. The example of such an

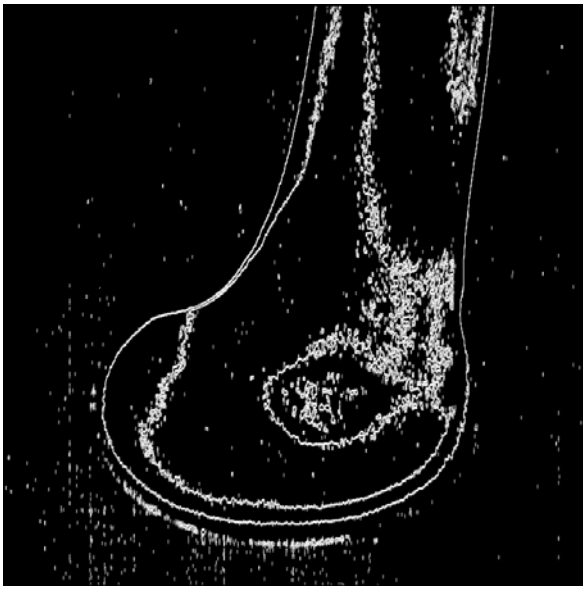

Figure 8. Entropy *H(X)* (1), applied on image in Fig 7, column direction

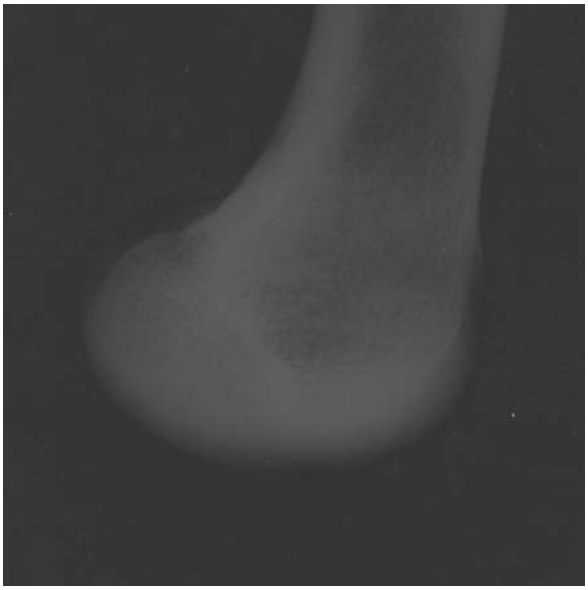

Figure 9. X-Ray image of knee bone

image is shown in Fig. 7 and application of entropy operator in Fig. 8.

Another example of femur image is shown in Fig. 9 and application of entropy operator in Fig. 10.

IV. CONLUSION

The information entropy based approach using four entropy based measures for detecting edges in X-ray digital images has been outlined and tested. First testing was done on a well known image Lena, then on the X-ray images of femur bones. Our results strongly indicate that the better edge continuity is achievable with entropy operators then with Sobel operator. The only exception was mutual information operator (4). The better performance is due to considerable flexibility which

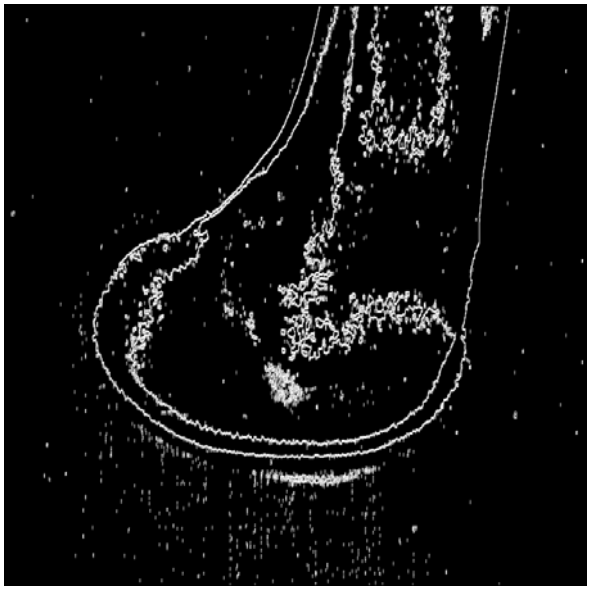

Figure 10. Entropy *H(X)* (1), applied on image in Fig 9, column direction

entropy based operators have in sense of size, shape and orientation, as well as the fact that their result is a real number from predefined range. The edge continuity opens a possibility for automatic edge detection and bone shape extraction and analysis which is the main goal of our future work. From the medical standpoint, the shape analysis of multiple knee joints will provide orthopedic surgeon with detailed statistics about variability in the shape of a knee joints.

Future work would also include construction of user friendly software (on the basis of our present research version), targeted for the use by medical personnel.

Abstract - **A comfortable option for long term monitoring of heart activity will hopefully soon be available in veterinary medicine also. This is the first report of the ECG data obtained in animals with a wireless body electrode attached to the skin and able to convey measured data to a smart device via low power Bluetooth technology. The ECG data were obtained from two dogs, one with sinus rhythm and the other with atrial fibrillation and ventricular extrasystoles. Beside determination of average heart and respiratory rates, identification of sinus rhythm, atrial fibrillation and ventricular premature complexes, the device was able to identify ventricular pre-excitation and asynchronous depolarization of ventricles. With appropriate software this device offers an immense potential for the veterinary cardiology. Due to its simplicity, long autonomy and high reliability it can substitute the conventional Holter monitoring in veterinary medicine.**

I. INTRODUCTION

In a patient with clinical signs caused by a cardiac arrhythmia that occurs only intermittently, a few minutes ECG performed in the veterinary hospital may be normal if the arrhythmia is not occurring at the time of measurement. A long-term monitoring is therefore required in many cases. In veterinary medicine conventional 24-hour Holter monitoring is often not easily available. The measured ECG interpretation can be obtained with human cardiology software only, which is not suitable. As a result, long-term monitoring of cardiac rhythm is expensive, time-consuming and not supported by reliable interpretation rules. Additionally, it is uncomfortable for the patient. All this set aside, the diagnostic yield can still be low due to the monitoring of a relatively short period of time. Therefore, cost-effective wireless body electrodes that enable long-term monitoring of cardiac rhythm in real-world environment are being developed. They are suitably small and attached directly to the skin with a patch carrier, therefore dubbed ECG patch monitors. They are waterproof and include wireless communication technology. Beside the wearing comfort, which is achieved by reducing the number and length of the wires, these devices have very high reliability [1, 2, 3, 4, 5, 6, 7].

In human medicine supporting clinical validation data on wireless body electrodes grow [1, 5, 6, 7, 8, 9, 10, 11, 12], but in veterinary medicine this is to our knowledge the first report of the ECG data obtained in animals with a wireless body electrode attached to the skin and connected to a smart phone (tablet) via low power Bluetooth technology. The aim of these pilot measurements was to find out whether the limitations of the conventional Holter monitoring could be surmounted.

The authors acknowledge the financial support from the state budget by the Slovenian Research Agency under Grant P2-0095.

II. PRESENTATION

A. Materials and Methods

The wireless body ECG sensor incorporating an electronic module with battery and a pair of self-adhesive skin electrodes, on a distance of 9 cm, was attached to the skin of the dog. The wireless connection of ECG sensor with the smart device (tablet, Nexus 7) was established via low power Bluetooth technology. The electrodes recorded one bipolar lead (Fig.1). Alternatively, a wire extension was used to record the standard lead I (Fig. 2). The wireless communication with a smart device allowed an immediate display and evaluation of the ECG. This device records real-time data from the ECG sensor and is described with more details in [12, 13, 14, 15]. Detailed analysis of ECG recordings was made off-line using NevroEKG custom research software for ECG interpretation [16].

Fig. 1: Wireless body ECG sensor is placed on the left side of the thorax and real-time ECG data is transmitted to the tablet on the floor in front of the patient.

Fig. 2: Wireless body ECG sensor with a wire extension is used to record the standard ECG lead I.

The ECG data were obtained from two dogs, one with sinus rhythm and the other with atrial fibrillation (AF), ventricular premature complexes (VPCs) and dilated cardiomyopathy (DCM). Different positions of electrodes have been tested and the recordings have been made while dogs were lying, sitting and walking. From recorded measurements, average heart rate and respiratory frequency have been determined. In addition, a comparison of the recordings with standard 6-lead ECG has been made.

B. Results

In the dog with sinus rhythm respiratory sinus arrhythmia (RSA) is prominent, which is evident from Fig. 3. Beat to beat frequency varies for more than two times (Fig. 4). The RSA is a vagally mediated modulation of heart rate that is only partially understood. It is synchronous with respiration. However, it remains unclear whether this is due to a central or baroreflex mechanism [17].

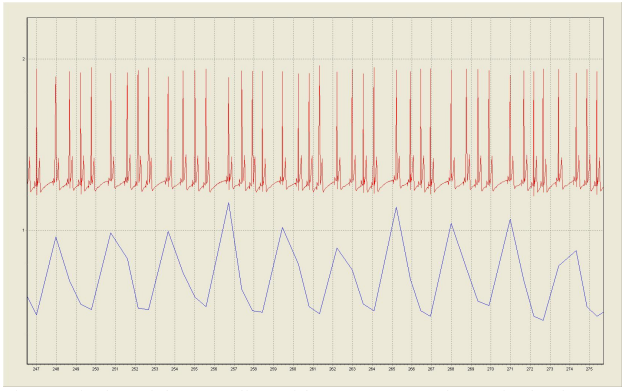

Fig. 3: Display of the recording with NevroEKG software in the dog with sinus rhythm. Upper trace is ECG signal (red line), lower trace shows the time between successive RR intervals (blue line).

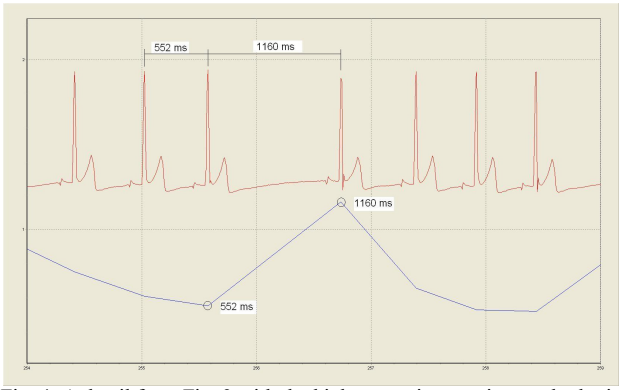

Fig. 4: A detail from Fig. 3 with the highest respiratory sinus arrhythmia (RSA). Durations of two consecutive intervals between beats are indicated. Beat to beat frequency varies for more than two times.

The sinus arrhythmia could be interpreted as a physiological irregular rhythm. To such an extent as in dogs (Fig. 3), RSA is never present in human ECG recordings.

In the measurement of the dog with AF and VPCs the AF can be recognized due to the absence of P waves, supraventricular QRST morphology and the non physiological heart rate variability, which is visible in Fig. 5. Atrial fibrillation is caused by multiple reentry circles. Ventricular rate is dependent on the refractoriness of the atrioventricular node. The VPCs can be differentiated from atrial premature complexes (APCs) due to a wide and bizarre appearance of QRST waves and the compensatory pause (Fig. 6). The frequency, configuration, consecutiveness and the rate of the VPCs can be evaluated, and as such, graded. In this case there were 3.6 VPCs/min (18 VPCs in 5 min recording), there were no couplets or triplets, no ventricular tachycardia and no fast rate.

Beside the correct identification of atrial fibrillation and ventricular premature complexes, as shown in Fig. 5, the device was able to identify also an asynchronous depolarization of ventricles (R notch), in the dog with VPCs, which is evident from Fig. 6. In standard 6-lead ECG R notch was seen only in lead III. A moderate slope at the start of R wave (before the encircled notch in Fig. 6) has as well been observed, which might indicate pre-excitation of the ventricles.

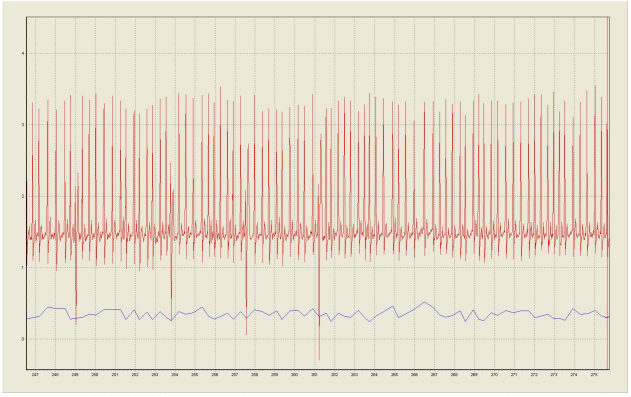

Fig. 5: Atrial fibrillation and 4 ventricular premature complexes in a dog with DCM. The electrodes were placed on the left side of the thorax, negative on atrium and positive on ventricle. ECG (red line), beat to beat heart rate (blue line).

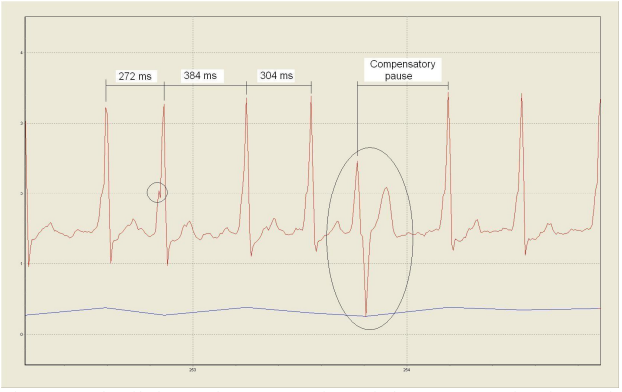

Fig. 6: A detail from Fig. 5. Duration of three consecutive intervals among heart beats. A notch in R wave and a VPC are circled.

This slurred upstroke of the R wave has not been seen in standard 6-lead ECG measurement. Since there are no P waves due to AF, a further analysis is needed to determine if this could be a delta wave as in the Wolff-Parkinson-White syndrome, where an accessory path is present between atrium and ventricle. In such a case the refractoriness of the atrioventricular node is decreased and a higher heart rate can thus be explained.

C. Discussion and Further Work

In human medicine the wireless ECG monitoring has proven to be highly reliable. It can be used during various activities and for prolonged cardiac monitoring having therefore a high diagnostic yield and a high patient compliance. It can exceed and could thereby replace conventional Holter monitoring in human patients [5, 7, 12]. A more definite comparison of the new ECG monitor with a reference device in a larger population of animals is pending. However, it is reasonable to assume that wireless ECG monitoring could replace conventional Holter in veterinary medicine, as well.

In animals, hand-held wireless monitors are already used for reliable differentiation of various arrhythmias as a few minute screening of the patients [18]. There is also a report of a non-invasive wearable sensor used to monitor vital signs, including ECG, remotely and continuously, but even in this telemetric method wires were used on the body of the dogs [19].

The prototype of the described wireless ECG sensor has been successfully applied in the synthesis of a 12-lead ECG with an insignificant loss of diagnostic information. Smaller number of measurement sites (electrodes) and fewer wires is a big advantage of these systems that can also synthesize the multi-lead ECG [20, 21, 22, 23]. Further development and validation are expected in this interesting field.

For the time being, in veterinary medicine only human cardiology software is available for Holter monitoring, which is mostly unsuitable. Due to big differences in normal heart rates and prominence of respiratory sinus arrhythmia, overinterpretations or underinterpretations are common. Therefore, it remains veterinarian's obligation to assess the ECG segments [3]. For this reason, the diagnostic method is very time-consuming and expensive. The development of appropriate software, tailored to veterinary medicine, could significantly lower the cost of the long-term cardiac monitoring in veterinary medicine and would make such diagnostic methods much more available and popular.

Besides the differences in heart rate and rhythm discussed above, other significant variations are also present in dogs when compared to humans. The myocardial infarctions are extremely rare. The continuous ECG monitoring is indicated in animals with intermittent weakness, collapse, and syncope. It is used in animals with arrhythmia before and during the treatment with antiarrhythmic drugs. In some breeds (Boxers, Dobermans) long-term ECG monitoring is utilized as screening for arrhythmogenic forms of cardiomyopathies and for detection of arrhythmia that could be the cause of sudden death in dogs with increased risk due to a previously diagnosed or occult disease [2, 3].

III. CONLUSIONS

The improvement in information and communication technology offers immense opportunities for the development of more accurate, cheaper and wearable devices that are urgently needed in veterinary medicine also. The wireless electrocardiographic monitoring presented in this work has a huge potential. It enables a long-term monitoring of cardiac rhythm in real-world environment with appropriate accuracy and reliability. Since there are crucial differences in human and veterinary electrocardiography, the future development of appropriate software for reading and interpretation of the veterinary measurements would even further increase the potential of the presented device.

Abstract - Normal acid-base status represents the value of hydrogen ions in extracellular fluid is within pH range of 7.36 (44 nmol/L) and 7.44 (36 nmol/L). Acid-base balance disorders may be a result of enhancement or reduction in amount of hydrogen ions, and include four basic disorders: metabolic and respiratory acidosis, metabolic and respiratory alkalosis. First step implies diagnosing the type of acid-base status disorder. The application input consists of blood analysis data and body weight info. Next step is determining the significance of the disorder and finally recommending future treatment. Software offers the optional functionality of entering mineral level values to improve treatment recommendations. Following the latest trends, along with the aim of increasing availability and mobility of the system, the software is developed for the Android platform using the Java programming language.

Keywords - acid-base balance, disorder, treatment, mobile application

I. Introduction

Normal organism acid-base implies fluctuation in hydrogen ions in extracellular fluid within narrow limits of pH, from 7,36 (44nmol/L) to 7,44 (36nmol/L) [1].

Acid-base status of trans-cellular spaces is regulated utilizing active transfer of acids and bases outside of cellular space. Pathological conditions with an increased concentration of hydrogen ions are called acidosis. Conversely, states with reduced concentrations of hydrogen ions are called alkalosis. Acidosis and alkalosis are terms that are associated with systemic disorders in concentration of hydrogen ions. Disturbances in the concentration of hydrogen ions, occurred in blood, are called acidemia and alkalemia.

In order to keep acid-base status within physiological limits, organism engages powerful regulatory mechanisms: buffer systems, lungs, kidneys and skeletal system. Buffer systems act immediately, but have relatively small capacity. Respiratory system is activated after several hours. Most powerful buffer capacity lies in the kidneys and skeletal system, but they also require most time to activate. Buffer systems act within extracellular and intracellular fluid. Most important extracellular system is the bicarbonate buffer system. On the other hand, the most important intracellular system is the protein and phosphate buffer system [2]. Considering their ability to remove carbon dioxide from the organism, lungs can have a significant impact on acid-base status. If lung ventilation doubles, pH blood value will increase (alkalosis). Conversely, the reduction in lung ventilation will decrease pH value (acidosis). The total buffering power of respiratory system is almost twice the power of all chemical buffer systems combined.

Renal system buffering effect is in conserving filtered bicarbonates, regulating titratable acidity and forming ammoniac ion.

Skeletal system has a role in correcting chronic disorders of acid-base status. In conditions of chronic acidosis, demineralization of bone tissue occurs (release of calcium and bicarbonate), which can compensate the disturbance of acid-base status.

II. Acid-base status disorders

Causes of acid-base disorders may be metabolic disorders or dysfunction of the respiratory system. Thus disturbances of acid-base status include four basic disorders: metabolic and respiratory acidosis, and metabolic and respiratory alkalosis. According to the change of pH levels (if compensatory mechanisms are present), the mere compensation can be: full - full normalization of pH with the preservation of compensatory mechanisms, sub compensation - insufficient correction of pH value with preservation of compensatory mechanisms and decompensation- altered pH and lack of compensatory mechanisms.

Metabolic acidosis (pH <7,35, reduced level of bicarbonate <24 mmol/L, compensatory hyperventilation-reduced pCO_2) occurs as a result of increase in the amount of hydrogen ions and due to loss of bicarbonate ions (increased intake of acid, increased synthesis of volatile acids, the accumulation of metabolic acids, chronic renal failure, distal renal tubular acidosis, diarrhea, malignant processes, proximal renal tubular acidosis, Fanconi syndrome, Wilson's disease).

Base deficit is the basis of metabolic acidosis, and is due to the above mentioned etiological factors. At the expense of reduction of plasma bicarbonate concentration (used to buffer the hydrogen ions), there is an increase in the concentration of other anions (in order to achieve and maintain electro neutrality). The anion may be chloride (Cl^-) or other anion of a metabolic product acid. Based on this, we distinguish: hyperchloremic metabolic acidosis (kidney disarrangements-interstitial nephritis with uremia, hydronephrosis, proximal and distal renal tubular acidosis, gastrointestinal causes-diarrhea, uretero-enterostomy) metabolic acidosis with anion deficit (renal failure, diabetic ketoacidosis, L-lactacidemia, ingestion of salicylates) and their combination (L-lactacidemia) [3]. Anion gap higher than 15 mmol ⁄ L indicates metabolic acidosis, and greater then 25 mmol ⁄ L confirmes metabolic acidosis. Furthermore, based on the value of the anion gap it can be determined whether acidosis is with elevated or normal anion gap.

$$\text{Anion gap} = Na\ (\text{mmol} \diagup L) - Cl^-(\text{mmol} \diagup L) + HCO_3(\text{mmol} \diagup L) \quad (1)$$

The primary cause of respiratory acidosis (pH <7,35, elevated pCO_2, compensatory decrease levels of bicarbonate <mmol/L 24) is an acute or chronic respiratory system insufficiency (acute airways obstruction, acute restriction lung disease, acute circulatory insufficiency, depression of the respiratory center , neurological diseases-poliomyelitis, polyneuropathy, myasthenia gravis, chronic obstructive pulmonary disease, chronic inhibition of respiratory center of the chest wall diseases, diseases of the lung parenchyma). Metabolic alkalosis (pH> 7,45, serum bicarbonate levels> 24 mmol/L, compensatory hypoventilation - increased pCO_2) occurs due to loss of acid outside of cellular liquids (loss of HCl by vomiting, hypokalemia, hypercalcemia, use of diuretics who do not save potassium - furosemide, ethacrynic acid), and because of the influence of factors that increase the concentration of bicarbonate in the extracellular fluid (milky-alkali syndrome, Conn's disease, Liddle's syndrome, the therapeutic use of the mineralocorticoid, the application of organic acids, post hypercapnic condition). Metabolic alkalosis can be divided into those that are salt dependent - Cl responsible (contraction alkalosis, vomiting, use of diuretics, antacids entry - chlorides correct them) and to those not dependant of salt - Cl resistant (sodium chloride is not used in treatment, potassium chloride is used - presence of chloride in the urine). Respiratory alkalosis (pH> 7,45, hyperventilation - decreased pCO2, compensatory reduction in the level of bicarbonate <24 mmol/L) is such a disturbance of acid-base balance in which increased alveolar ventilation causes a decrease in pCO2, and consequently reduce the level of bicarbonate, and increasing pH blood values. It is divided into acute (hyperventilation due to anxiety, high temperatures, salicylate poisoning, sepsis) and chronic (brain tumors, encephalitis, liver cirrhosis, coma, pregnancy).

TABLE I. DISORDERS IN ION CONCENTRACION AND IN PARTIAL PRESSURE OF CO_2 DUE TO ACID-BASE DISORDERS (R - REDUCED, I - INCREASED, * - SIGN FOR PRIMARY DISORDER)

	pH	**H^+**	**pCO_2**	**HCO_3^-**
Norman	7,4	40 nmol⁄L	5,3 kPa	24 nmol⁄L
Respiratory acidosis	R	I	I*	I
Respiratory alkalosis	I	R	R*	R
Metabolic acidosis	R	I	R	R*
Metabolic alkalosis	I	R	I	I*

In everyday practice, complex forms of acid-base status disorders are not rare (a combination of these conditions). Complex forms may be additive, as a combination of respiratory and metabolic acidosis (in diabetes that lasts for a long time - a combination of diabetic ketoacidosis and in uremic acidosis due to diabetic nephropathy - severe academia). Respiratory and metabolic alkalosis are usually seen in patients who are on mechanical ventilation and nasogastric suction - heavy alkalemia. Combinations of respiratory alkalosis and metabolic acidosis occurs in septic shock and is characterized by a reduced concentration of bicarbonate in plasma and reduced pCO_2 . Respiratory acidosis and metabolic alkalosis occurs in chronic obstructive pulmonary disease, and during the use of diuretics - elevated bicarbonate concentration in plasma and increased pCO_2 .

Condition for proper treatment of acid-base disorders is an accurate diagnosis. Based on patient history, disease symptoms and laboratory tests, we can determine if there is a disorder of body fluids and acid-base status. Arterial blood is taken for laboratory tests, and the analysis of pH, bicarbonate concentration and pCO_2 is necessary [4]. Treatment of all disorders is reflected in the etiological treatment as well as in the treatment of associated disorders that can lead to their aggravation, with a special overview of trace elements' concentration in human body. Treatment of metabolic acidosis is based on eliminating the metabolic disorder that led to this condition. Acute metabolic acidosis is frequently encountered in critically ill patients [5]. Therapy with $NaHCO_3$ is indicated when the pH is lower than 7,20. Compensation is determined according to the following formula:

$$NaHCO_3\ (\text{mmol}) = BE\ (\text{mmol}) \times 0.3 \times BW\ (\text{kg}) \quad (2)$$

BE – base excess
BW- body weight

The treatment implies giving 8,4 % $NaHCO_3$, where 1 ml of the solution corresponds to 1 mmol in the formula. Half of the solution is given immediately, and the rest is given according to the disorders' improvement. Hyperkalemia is an accompanying symptom of metabolic acidosis , and for its treatment calcium gluconate in combination with insulin is used. Glucose administration helps the entry of potassium into the cells and reduces the

concentration of potassium in plasma. If the acidosis is of lactate origin and if it is associated with cardiogenic shock , treatment with bicarbonates can only aggravate the existing condition.

Treatment of metabolis alkalosis is suggested depending on its type. Chloride responsible ones are treated with NaCl (serum Cl is reduced), and alkalosis with Cl^- the resistant ones are treated with KCl with obligatory monitoring of electrolytes levels, and continuous ECG monitoring. Amount of Cl ions necessary is calculated using the following formula [6]:

$$\text{Corrected Chloride} = \text{Cl} \times (\text{Na normal} / \text{Na observed}) \quad (3)$$

Severe metabolic alkalosis (pH > 7,7) is treated by the administration of isotonic HCl. (iv . 150mmol - l). A pH greater than 7,65 may carry a high risk of mortality (up to 80%) [6]. Bicarbonate excess is calculated using the following formula:

$$\text{HCO3 (excess)} = 0.5 \times \text{BW (kg)} \times (\text{HCO3 found} - \text{HCO3 desired}) \quad (4)$$

The goal in treatment of respiratory acidosis is primarily removing the cause. By improving the ventilation, the increased CO_2 is removed. In case of a very low pH (< 7,2), the patient must be connected to mechanical ventilation. In case of pH lower than 7.1 and HCO_3 below 15 mmol/ L , treatment with $NaHCO_3$ is indicated. Excessive correction of chronic hypercapnia leads to alkalosis. Although the symptoms, signs, and physiologic consequences of respiratory acidosis are numerous, the principal effects are on the central nervous and cardiovascular systems [7].

Respiratory alkalosis is an extremely common and complicated problem affecting virtually every organ system in the body. This article reviews the various facets of this interesting problem. Respiratory alkalosis produces multiple metabolic abnormalities, from changes in potassium, phosphate, and calcium, to the development of a mild lactic acidosis [8]. Respiratory alkalosis is treated by removing the cause. Heavy alkalemia pH > 7,6 requires therapy with arginine or ammonium chloride. In psychogenic disorders, use of sedatives is giving good results.

III. Software Diagnostics of Acid-Base Status Disorders

With the aim of maximizing the availability, the application was developed for the Android platform using the Java programming language. In 2012, the market share of Android devices accounted 75% of the world market, with 136 million devices shipped worldwide [9]. The application requires entry of key parameters necessary for diagnosis of acid-base disorders:

- blood pH (normal value 7,35 to 7,45),
- partial pressure of carbon dioxide in the blood (expressed in kilopascals) (normal 4,3-6,4 kPa),
- partial pressure of oxygen in the blood (expressed in kilopascals) (normal 7,3-10,6 kPa),
- bicarbonate value (expressed in mmol/L) (normal 24 mmol/L),
- base excess and
- body weight of the patient.

Diagnosis of acid-base disorders is made based on parameters obtained from the arterial blood sample (Figure 1.).

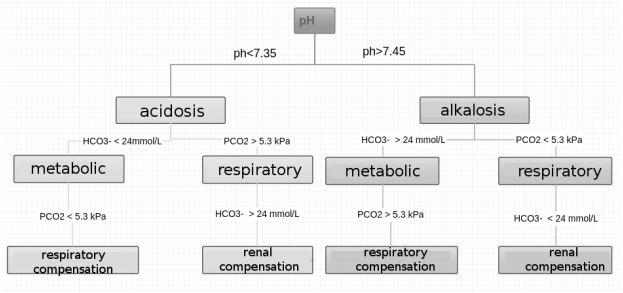

Figure 1. Diagnosis of acid-base disorders

Home screen of application (Figure 2. and Figure 3.) contains fields for entering the above mentioned data.

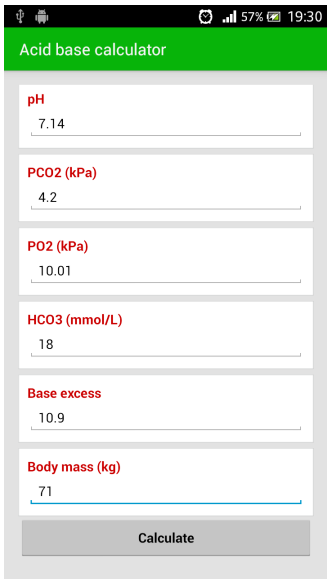

Figure 2. Application home screen, metabolic acidosis input

The data are typical for particular disorder or combination of disorders, and based on them the type of disorder can be determined, and also compensatory responses, with defense mechanisms of the organism. (Figures 2, 3, 4, 5)

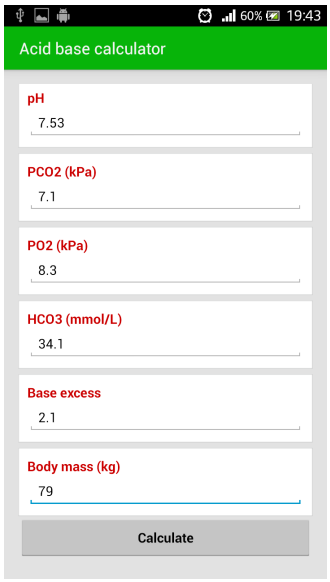

Figure 3. Application home screen, metabolic alkalosis input

In the next step application determines the type, significance and compensation of disorders. Figure 2. and Figure 4. represent one patient, and Figure 3. and 5. second patient. The next step is to enter pathological values of certain elements in the body (Figure 4. elevated level of potassium - reference value is from 3,5 to 5,2 mmol/L).

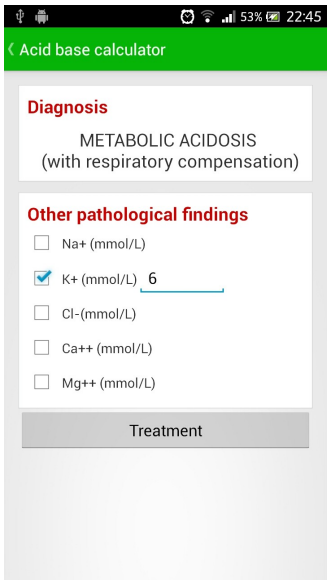

Figure 4. Metabolic acidosis diagnosis

The user can select and enter disturbed values of one element or combination of disturbed values of more elements. Reference values for sodium are 137-146 mmol/L, for chloride 101-111 mmol/L, for calcium 2,14-2,53 mmol / L, for magnesium 0,65-1,05 mmol/L.

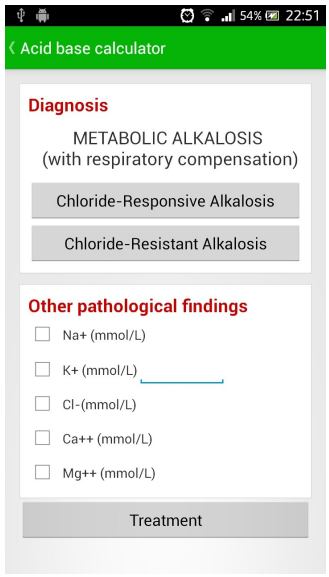

Figure 5. Metabolic alkalosis diagnosis

The user can optionally enter diagnosis of the patient, if it is already known, and the application will take that into account when determining the disorder and displaying the appropriate therapy (Figure 6.) .

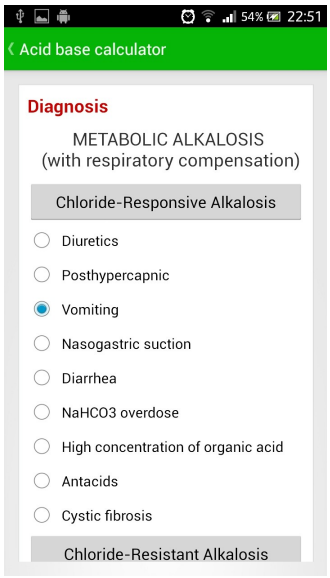

Figure 6. Additional input

Based on the data entered in Figure 2. and Figure 3. application will recommend the treatment for the patient, with the exact values, based on the set of mathematical formulas and recent guidelines for the treatment of acide-base disorders (Figure 7.).

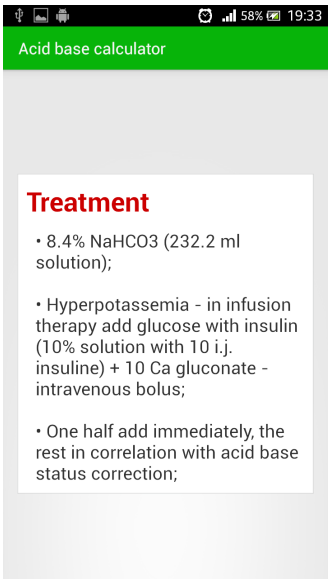

Figure 7. Treatment recommendations

Based on the characteristic values, the application recognizes and takes into account combination of acid-base disorders.

By browsing online solutions and literature in the field of telemedicine, it was realized that there are many Android and web applications which in the form of a calculator give the option of differentiation of disorders, and some of them, determining its compensates. This application should be a pioneer in advising therapy, taking into account the current state of the patient, their medical history and any pre-existing co-morbidities. With the aim of automating the process, future versions of the application will have the functionality of photographing findings of arterial blood. Within the application optical character recognition would be performed, with the aim of recognizing the necessary parameters. Library for optical character recognition would enable autofill fields, necessary to diagnose a disorder. The functionality would be provided through an open-source Tessaract library, originally developed by Hewlett-Packard, and since 2006. maintained by Google.

IV. Conclusion

The application would provide assistance to doctors in clinical practice and is focused on treatment in the intensive care unit. It is easy accessible, practical, and is extremely useful in the treatment of metabolic acidosis (reducing the time required to calculate the necessary therapy-when calculating the required values of sodium bicarbonate) and in the treatment of metabolic alkalosis (calculating the excess bicarbonate). The solution contains guidelines for the therapeutic effect of each disorders, with reference to fluctuations in trace elements, and therapeutic effect in the event of their disorders, which in modern medicine is a challenge in therapy. Combinations of acid-base disorders can greatly complicate the work of the doctor, and such combinations represent a challenge when making software solutions of this type.

Abstract – The sensitivity to electrode misplacement of the 12-lead ECG, synthesized from differential leads, was analyzed by simulating the electrode misplacement, with a help from interpolated body surface potential maps. The electrodes forming optimal differential leads were independently moved only on the lines defined by gradient vectors, calculated on the integral body surface potential map, obtained from juxtaposed average beats for each of the 47 multichannel ECGs used in the study. The 12-lead ECGs were synthesizes from the simulated moved differential leads and compared to the ECGs synthesized from the nominal electrodes' positions, by using correlation coefficients and RMSD. The results show that synthesized 12-lead ECGs are less accurate if electrodes with bigger associated gradients are misplaced, but also suggest that small displacements of up to 1 cm do not have a big influence on the synthesis quality. From the perspective of ECG synthesis, the presented methodology can be used to define an additional criterion for optimal triplets of differential leads selection, which will ensure that the differential lead triplet are optimal not only in terms of the quality of the synthesized leads, but also in terms of being minimally sensitive to electrode misplacement.

I. INTRODUCTION

A number of previous studies have shown that electrode misplacement of standard electrode positions, for the acquisition of the 12-lead ECG, can cause differences in ECG signals and their interpretation [1]. It has also been shown that misplacement of electrodes employed by a reduced-lead set {I, II, V2, V5}, has effects on synthesized 12-lead ECGs, in terms of increased root-mean-square deviation (RMSD), as the electrode distances from their nominal positions increase [2].

Body surface potential maps (BSPM) [3] have been used before for the purpose of simulating the electrode misplacement in standard 12-lead electrode set [4] or in a reduced-lead set [2]. They enable the measurements obtained from simulated misplaced electrodes to be synchronous in time with signals from other electrodes, but also enable position changes over distances smaller than the once possible to realize physically.

In this study, BSPM are used to investigate how the electrode misplacement effects 12-lead ECGs synthesized from differential leads (DLs). Differential leads [5] are bipolar leads that measure the potential between two closely placed body-surface electrodes. The DL measurements can be obtained by so called wireless body electrodes (WBEs) – novel devices that enable minimal obtrusion and wireless transmission of recorded signals [6]. Since there are an infinite number of possible directions of electrode misplacement, normally authors choose to restrict the simulation of electrode misplacement to only vertical and/or horizontal directions. In this study however, we consider the most significant direction for the electrode misplacement to be in the direction of the BSPM gradients on each electrode.

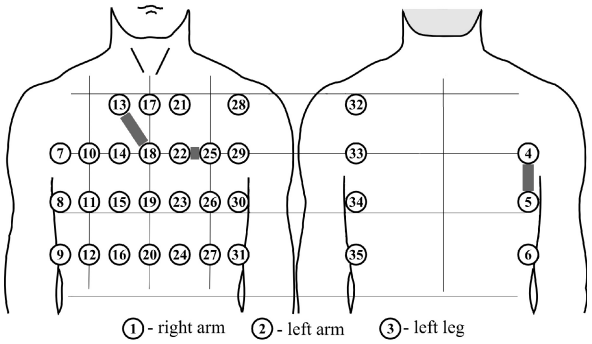

Figure 1. Schematic locations of multichannel ECG (MECG) electrodes on the chest (left) and the back (right). The gray lines represent the calculated optimal universal leads for the 12-lead ECG synthesis: {(13, 18), (22, 25), (4, 5)}.

In our previous studies, we have shown that it is possible to synthesize quality 12-lead ECG from three DLs [5]. By using our algorithm for selection of optimal DLs, we have also identified optimal universal positions of three DLs (see Fig. 1) from which 12-lead ECG can be synthesized by employing universal or personalized transformations [7]. In this study, we investigate the impact DLs' electrodes misplacement has on the 12-lead universal and personalized transformation. There is also the third approach to the synthesis in which both DLs positions and transformations are personalized. We have not investigated this fully-personalized approach for the electrode misplacement effect since for that approach a multichannel ECG (MECG) needs to be obtained from each person, which makes it possible to mark on the skin the positions of electrodes of the optimal personalized

DLs and thereby minimize the possibility of misplacement.

II. METHODS

A. Studied data

Twenty healthy volunteers (13 male, 7 female, mean age ± SD = 50.6±9) with no previous medical record related to heart disease and with a normal 12-lead ECG, and twenty-seven patients (22 male, 5 female, mean age ± SD = 58±10), scheduled for a coronary artery bypass surgery, were included in our study. Informed consent was obtained from all the subjects before the study. A single MECG measurement was obtained from each person. For the data recording device and procedure please refer to [8]. The measurements were obtained during our previous studies [9]. The positions of the MECG electrodes are specified in Fig. 1.

The length of each measurement was 360 seconds. They were processed using MatLab (MathWorks, Inc.) where the average beats were obtained for each lead of the baseline corrected MECGs, by the procedure described in [7]. Note that the high-frequency noise is satisfactorily damped by the averaging.

B. Generic differential leads

A method of juxtaposing measurements was used: the average beats from each MECG were concatenated for each lead thus forming generic MECG leads. The generic DLs are formed by taking differences of juxtaposed MECG leads.

C. Body surface potential maps

For the interpolation of potentials between MECG electrodes, the cubic spline interpolation has been used to provide smooth transition of approximated data between measurement positions. The interpolated potential maps [10] were used for the simulation of electrode misplacements in each time instant. Additionally, an integral BSPM [11] was calculated for the generic differential leads. We will refer to this map as generic integral BSPM (GIBSPM). Since the GIBSPM is calculated from juxtaposed average beats from each person, it can be thought of as estimation of average integral map (for the whole beat) across all the persons covered by the study. The estimation is of course more precise as the variance of average beats lengths across different persons is smaller.

D. Experimental procedure

Gradient vectors were calculated from GIBSPM for each MECG electrode position. We have considered the worst-case scenario of electrode misplacement to be if the electrodes are moved on the line defined by associated gradients, since the gradients define the directions of fastest changes in potential. We have defined the movement of each electrode {13, 18, 4, 5, 22, 25} that makes the three optimal differential leads (see Fig. 1) in both directions of the gradient defined lines, up to 3 cm, in 0.5 cm steps. The electrodes were moved one at the time, i.e. while one electrode was moved the positions of all other electrodes were kept nominal.

For each person, five second intervals were identified in the MECGs and associated 12-lead ECG, that were not used for the calculation of universal positions and transformations used for the synthesis. For each person and for each independent movement of the six electrodes, the 12-lead ECG was calculated using the universal transformation, and by using personalized transformation. Here the simulated moved electrode measurement is taken from integral map for each time instant. The correlation coefficients (CCs) and RMSDs were calculated between the obtained synthesized 12-lead ECGs and 12-lead ECGs synthesized from the nominal electrode positions.

III. RESULTS

Fig. 2 shows the calculated GIBSPM. The gradient vectors are oriented in the direction of increasing potential

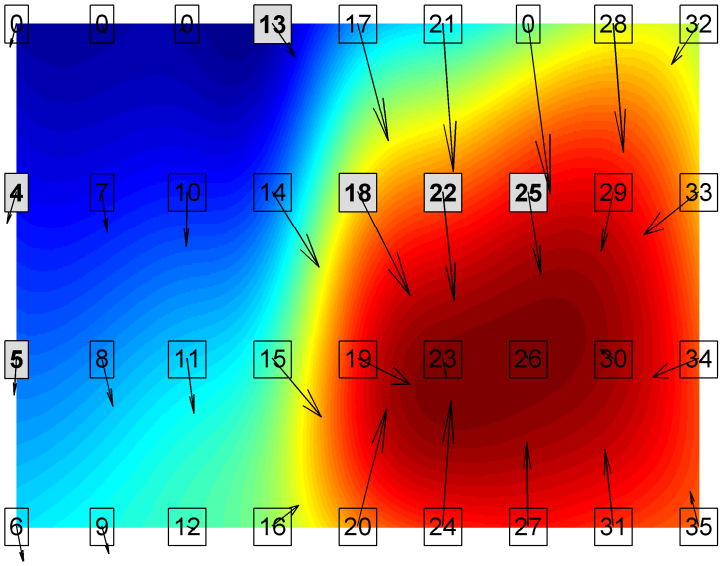

Figure 2. Generic integral BSPM (GIBSPM) for the juxtaposed whole average beats. Electrodes are organized in a matrix as defined by Fig.1. Positions without electrode are denoted with 0. Electrodes forming the optimal lead tripelt, the moved electrodes, are denoted with gray boxes.

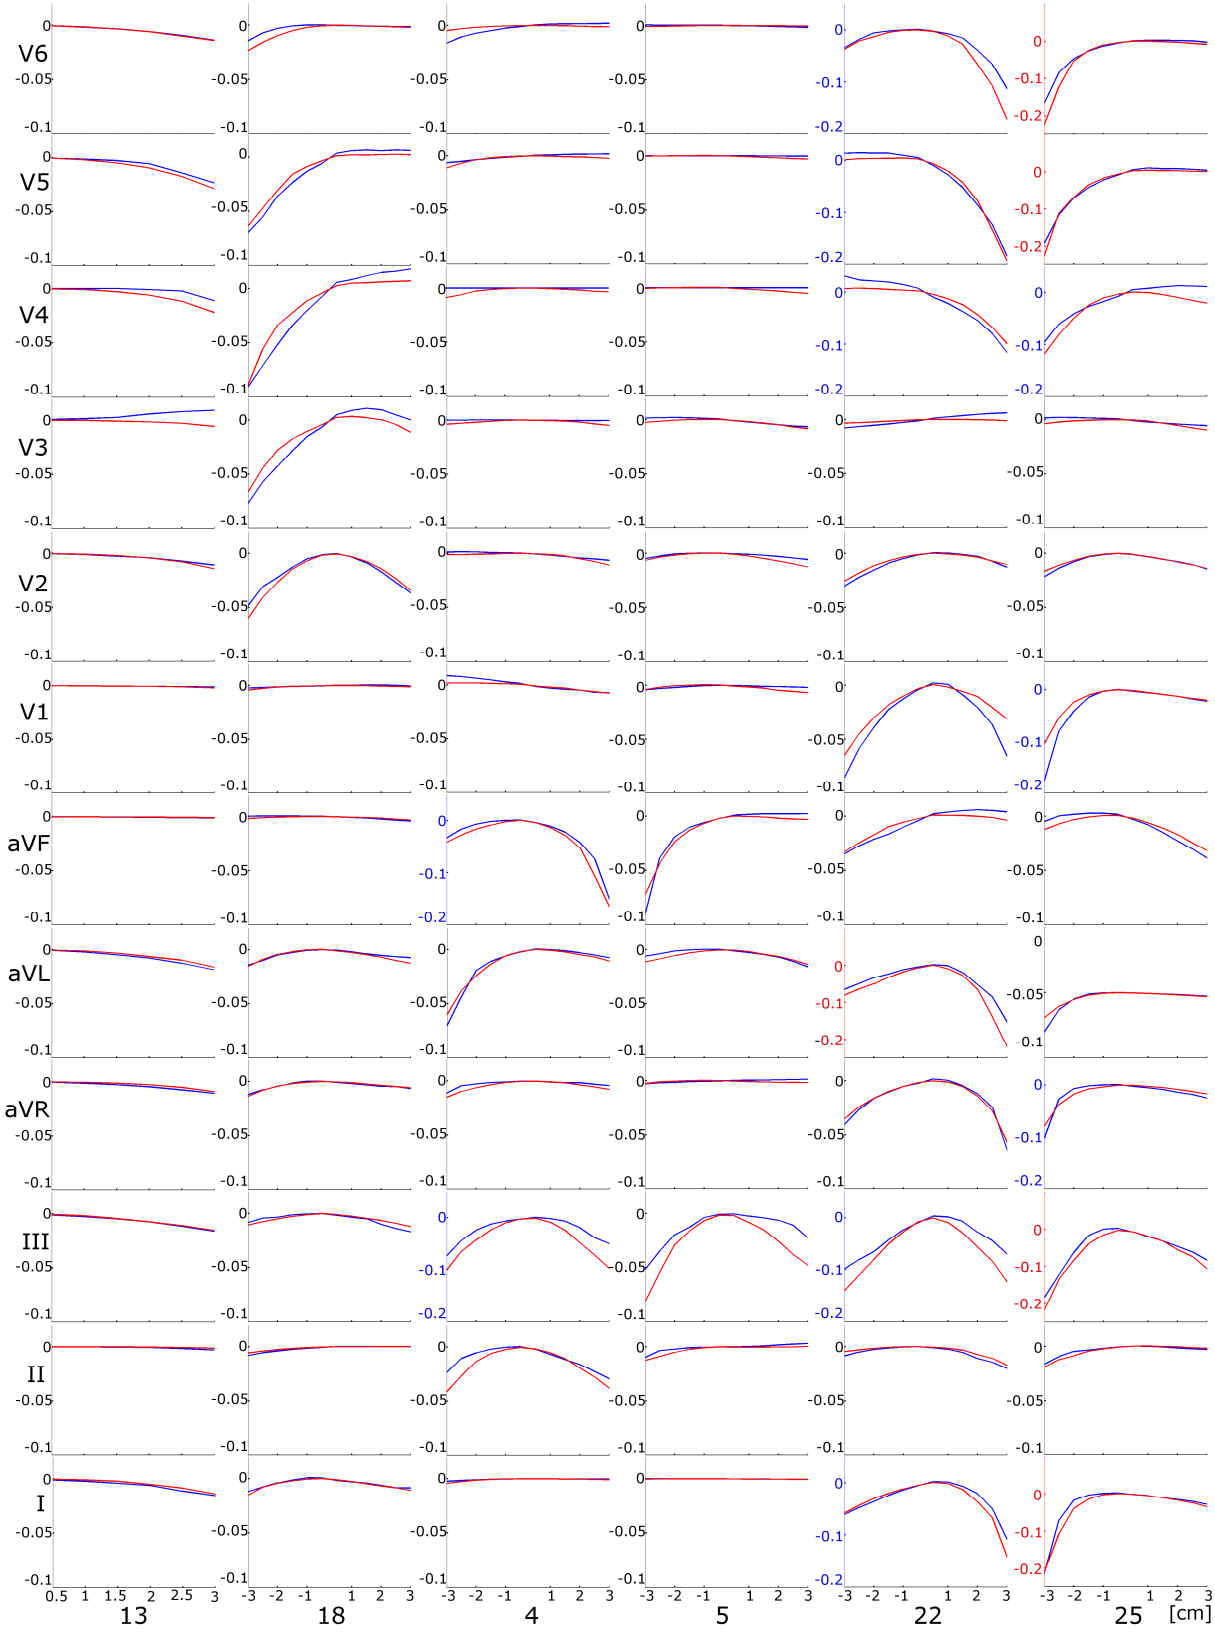

Figure 3. Median differences (dCCs) between CCs for misplaced position and the CCs obtained for nominal electrode positions (lower values imply lover synthesis quality). The CCs are calculated between target and synthesized leads. The columns represent the six electrodes. Each electrode was moved from -3 to 3 cm in steps of 0.5 cm (x axes), except for the electrode 13 which was moved from 0.5 to3 with the same step (0.5). Three scales used in the graphs: black for the dCCs above -0.1, blue for dCCs above -0.2, and red for dCCs below -0.2. Blue curves correspond to dCCs for universal transformation whereas the red line is for the personalized transformation.

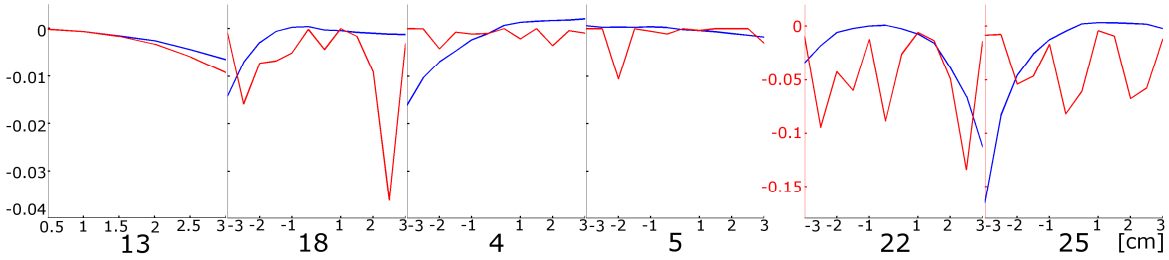

Figure 4. Median differences (dCCs) between CCs for misplaced position and the CCs obtained for nominal electrode positions across all leads of the 12-lead ECG (lower values imply lower synthesis quality). The CCs are calculated between target and synthesized leads. The columns represent the six electrodes. Each electrode was moved from -3 to 3 cm in steps of 0.5 cm (x axes), except the electrode 13 which was moved from 0.5 to 3 with the same step (0.5). Three scales used in the graphs: black for the dCCs above -0.04, red for dCCs below -0.15. Blue line corresponds to universal transformation whereas the red line is for the personalized transformation.

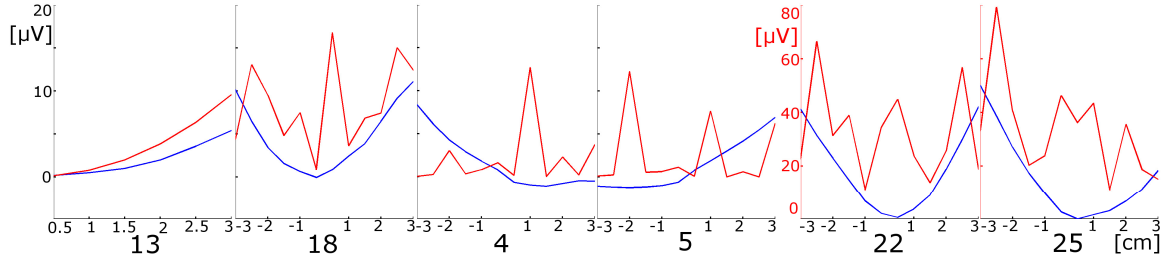

Figure 5. Median differences between RMSDs for misplaced position and the RMSDs obtained for nominal electrode positions across all leads of the 12-lead ECG (higher values imply lower synthesis quality). The RMSDs are calculated between target and synthesized leads. The columns represent the six electrodes. Each electrode was moved from -3 to 3 cm in steps of 0.5 cm (x axes) , except the electrode 13 which was moved from 0.5 to 3 with the same step (0.5). Two scales used in the graphs: black for the RMSDs below 20μV, red for RMSDs abow 60μV. Blue line corresponds to universal transformation whereas the red line is for the personalized transformation.

(positive direction). Gradient vectors for electrodes 4 and 5 point only slightly outside of the interpolated map. Therefore for these two electrodes, instead of using extrapolation, the gradients were just postulated to be pointing straight downward to keep them inside the map. For electrode 13 (also a boundary electrode) the misplacements were calculated only in the direction of its gradient (positive direction), and not in the negative direction since it falls out of the map.

Medians of calculated CCs between synthesized and target 12-lead ECGs are presented on Fig. 3 for each of the six electrodes and for each misplacement distance. The CCs were subtracted by the CCs obtained for the corresponding nominal electrodes positions and therefore negative values represent decrease in synthesis quality as each electrode is moved.

We have also calculated the median CC differences across all synthesized leads (Fig. 4). The analogous RMSD differences are presented on Fig.5.

IV. Discussion

It can be suspected by analyzing Fig. 3 that in most cases the synthesis using personalized transformation loses more in quality when electrodes are misplaced. This becomes obvious form Fig. 4 and Fig 5. Fig 4. shows that CCs distances from the CCs obtained for nominal positions are in general larger when personalized syntheses parameters are used (red lines). Similarly, Fig. 5 shows that RMSDs deviations from the RMSDs obtained for nominal electrode positions, are in general larger for the personalized transformation parameters (red lines).

These results are a bit unexpected since one would expect a more personalized synthesis algorithm to perform better in any aspect, compared to the universal one. Even though this shows that the approach with personalized transformation is more susceptible to electrode misplacement, it does not say that the approach with personalized transformation is inferior by any means. The results certainly show that the personalized approach loses more on the synthesized leads quality, but then again it has more to lose since it provides better synthesized 12-lead ECGs, from the nominal electrode positions [7].

All three figures show that as the misplacement increases, the synthesis quality decreases. Still, Fig. 3 points out that in general small misplacements in range [-1, 1] cm do not influence the synthesis significantly. It is also possible that a small misplacement even increases the synthesis quality (for example, lead V3 for electrode 18). There is however quite a big variation between the electrodes and between the synthesized leads. For example, lead V2 is much less vulnerable for any of the six electrode misplacements compared to lead III (Fig. 3).

Even more obvious is that electrodes 22 and 25 have the biggest influence on the synthesis quality (Fig, 3, 4, and 5). This can be explained by the fact that they together form one DL and are located in the GIBSPM area with fast potential changes – they both have big gradients (Fig. 2). Electrode 18 also has a much bigger gradient than electrodes 4, 5, and 13, and hence a higher impact on the synthesis quality (Fig. 4 and Fig. 5).

We have considered only displacements in the direction of gradient vectors obtained from GIBSPM. This

makes a good sense since the gradient is the direction of fastest potential change. Still the gradients were obtained for the whole beats but are in general different for different ECG segments or intervals. To apply the same approach, but concentrating only on a part of the beat, one would need to construct integral map only for the segment/interval of interest and calculate their gradients.

V. CONLUSION

The results suggest that synthesized 12-lead ECGs are more distorted if electrodes with bigger associated gradients are misplaced. Additionally the results confirm what could be expected: as the electrodes are moved more from the nominal positions, the quality of the synthesized leads decreases in terms of CC and RMSD. Small displacements however, show only small decrease in CC and RMSD.

In this study, only one electrode is moved at a time. A possible extension of this work is to simulate simultaneous movements. Furthermore, this study employs only the CC and RMSD for comparing waveforms, but they can be rather crude in expressing similarities or finding differences between detailed waveform patterns. A small RMSD or a large CC can lead to differences in the diagnostic content of the synthesized and the target 12-lead ECG. Further work is therefore needed to assess the diagnostic accuracy of the ECGs synthesized from displaced electrodes.

Finally, the approach presented here can be employed as an additional criteria for selection of optimal DLs, for 12-lead ECG synthesis. As there are a number of combinations of three DLs that can be used for the synthesis of 12-lead ECG [7] (in this work only one combination was used), by applying sensitivity to misplacement as the additional criteria, another triplet can be obtained that is not only suitable in terms of the quality of the synthesized leads, but also in terms of being minimally sensitive to electrode misplacement.

Extranodal Pacemaker Activity During Sleep - a Case Study of Wireless ECG Sensor Data

V. Avbelj
Department of Communication Systems, Jožef Stefan Institute, Ljubljana, Slovenia
viktor.avbelj@ijs.si

Abstract - **Sleep apnea is a breathing disorder during sleep which is characterized by breathing cessation lasting at least 10 seconds. Sleep apnea is associated with sudden cardiac death. Every apnea event is accompanied by cardiovascular changes. In polysomnography, to perform cardiorespiratory sleep study in today's sleep laboratories, many parameters such as ECG (electrocardiogram), EEG (electroencephalogram), respiration effort, oronasal airflow, snoring (by microphone) and oxygen saturation in blood are recorded. We present a case where only single channel ECG obtained from wireless electrodes was used to study heart-rate dynamics during sleep apnea events. A sudden change of morphology of atrial P wave in ECG recording was observed during sleep. This observation supports the hypothesis that sinus node is not the only physiological pacemaking structure in the atrium.**

I. Introduction

Sleep apnea is characterized by breathing cessation during sleep, lasting at least 10 seconds. These events are accompanied by cardiovascular changes and are associated with sudden cardiac death. Many parameters are measured in polysomnography in modern sleep laboratories (ECG, EEG, respiration, airflow, snoring, oxygen saturation in blood) to identify the possible sleep apnea [1]. Whether these complex measurements could, at least partially be replaced by simpler methods, is the question of this text.

We present a case study where only one ECG channel is used during sleep. A detailed analysis of the recording shows that a variety of information can be obtained from the bare ECG signal. Low sampling rate prevented direct application of the ECG signal for obtaining surrogate respiration signals. Appropriate interpolation solved the problem partially. Amplitude and morphology of the ECG waves probably changed according to changes of the positioning of the body. If another sensor for 3D acceleration (gravity) was available, the movements and position changes could reliably be measured also. In the ECG signal, the skeletal muscle signals are also visible (normally as unwanted noise), but in this case study we use them as signs of the effort to change the position of the body during sleep. Detailed examination of the recording revealed unexpected extranodal pacemaker activity. This extranodal pacemaking is not recognized as a normal physiological activity of human atrium, but here we present an example that extranodal pacemaking could be present widely, although broadly unrecognized [2].

II. Presentation

A. Materials and Methods

In this case study an ECG measurement of a woman (58 years) is presented. The measurement was made during night by small body ECG sensor (mass 15 g) with a wireless connection to a smart device (tablet, Nexus 7) via low power Bluetooth technology [3]. The two self-adhesive Ag/AgCl electrodes (Skintact T-401, distance 9 cm) were placed horizontally approximately 10 cm below the left clavicle. The ECG data were collected overnight in the tablet for off line analysis. The ECG signal was sampled at 125 Hz with a 10 bit A/D converter on the ECG sensor. For derivation of the respiration from the ECG signal, a few preprocessing steps have been done.

The amplitude of the ECG waves is modulated by breathing due to the changes in the lung and thorax volume. The ionic current sources in the heart produce electric potential difference between the locations of the two electrodes. This potential difference is modulated due to the varying volume impedance. At 125 Hz sampling rate, the R wave is represented by only a few values (Fig. 1). The amplitudes of the R waves, taken from measured values are coarse.

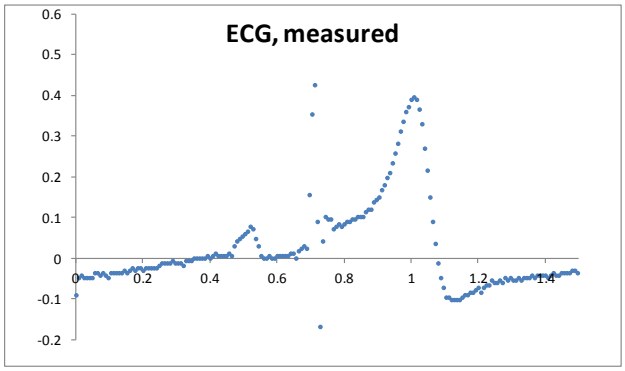

Fig. 1: The ECG data points at sampling rate of 125 Hz. The R wave is represented by only 4 data points. The peak of the R wave is at time 0.712 s where the value is 0.426 mV. The minimum value (peak of the S wave) is at time 0.728 s, where the amplitude is -0.168 mV.

By interpolation techniques better amplitude fidelity could be obtained from the sampled data. We used cubic spline interpolation with 8-fold increase in sampling frequency. The result is present in Fig. 2.

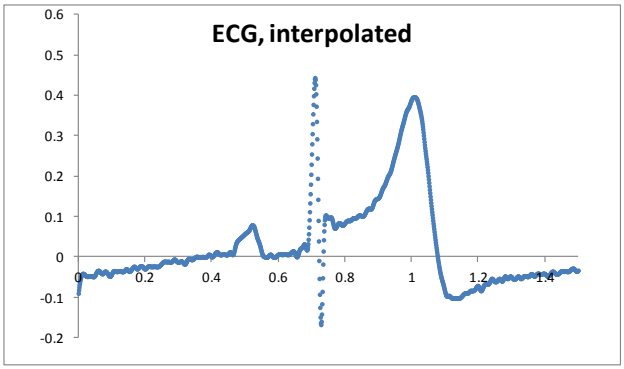

Fig. 2: The same signal as in Fig. 1 where interpolated samples are inserted between the measured ones. Synthetic sampling frequency is 1000 Hz and the peak of the R wave is at time 0.710 s where the amplitude is 0.4437 mV (4% more than in Fig. 1). The minimum value (the peak of the S wave) is the same as in Fig. 1.

If the PQ interval is clamped to zero potential (correction of baseline wandering) the peak value of the R wave could be determined precisely. The successive peaks of the R waves represent an ECG derived respiration signal. The process of interpolation is shown in Fig. 3, where original and interpolated samples are shown separately.

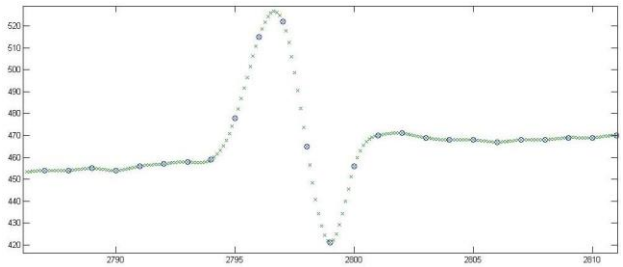

Fig. 3: The R and the S waves of the ECG where the measured values are marked with circles and interpolated with crosses. The time and amplitude resolution is enhanced. Horizontal axis counts the measured samples of the recording while the vertical axis represents direct A/D converter values.

Using NevroEKG software, we performed the following steps in the processing of the ECG recording: determination of successive RR intervals, baseline correction adjustment and the determination of the peak of the R waves that represented an ECG derived respiration signal [3]. The result is a graph with three channels: ECG, RR intervals and R peaks (respiration surrogate). The graph of this ECG recording was examined in detail regarding long-term ECG amplitude variations, respiration, and details of ECG waves around abrupt changes in the signals.

B. Results

In Fig. 4 overnight ECG is presented beginning at 1:57 AM. Initially (first 1300 s) the ECG had fast varying amplitude that was probably associated with frequent changes of the body position before falling asleep. Subsequently we observed blocks of fairly constant amplitude of the ECG signal that was changing abruptly. Large spikes were present where the ECG signal was lost due to the unfavorable position of the transmitting sensor relative to the receiving tablet. There was also a large interval with no signal in the 7/8 of the recording.

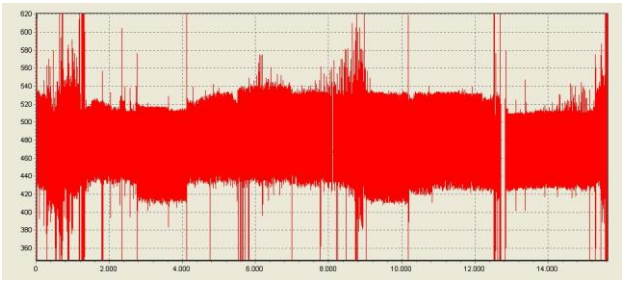

Fig. 4: Amplitude of the ECG signal of the whole overnight recording. There is an interval of around 2 minutes, where the signal from the electrode was completely lost (see the interval in 7/8 of the recording).

The next step was to find out what is the reason of abrupt changes in the amplitude of the ECG recording. An expressive event of this type is noticed some time after 4000 s of the recording and is shown in Fig. 5. Before the event the R wave is smaller than the S wave and the T wave is much higher than the R wave. After the event the opposite is true. The R wave is larger than the S wave while the T wave stays approximately the same. During the change the large noise signals (not shown) are present, connected probably with moving of the electrodes during the change of the body position in the bed.

Fig. 5: Abrupt changes of the ECG waves, especially the R and the S wave before and after the change of the position of the body.

There were similarities in other discontinuities of the ECG amplitudes in the cases shown in Fig. 4.

There were many fast changes of the heart rate during the night. The most striking event could be observed around 10800 s (at 5 AM). Before the change, the heart rate was 48 beats/min and increased to 86 beats/min in less than 15 s. Then the heart rate quickly dropped to 55-58 beats/min, and finally dropped abruptly to a value from before the episode which lasted 76 s. The relative amplitudes of the QRST waves before and after the episode remained unchanged (Fig. 6). It is not known what the reason of the heart rate speed-up was. When the heart rate started to rise, the muscle noise was visible for 5 s, the QRS waves became smaller and then returned to previous values while the heart rate still continued to rise (not shown in Fig. 6). An abrupt change of the morphology of the atrial P wave occurred in the speed-up of the heart rate.

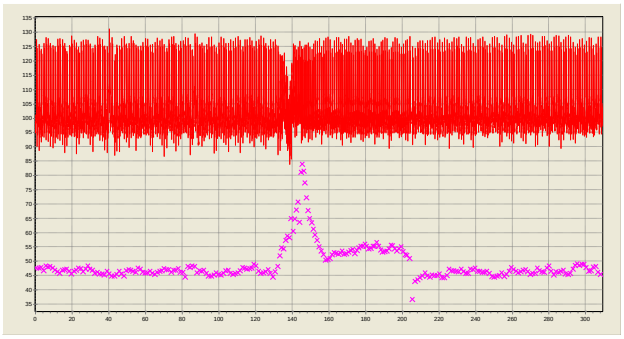

Fig. 6: The ECG (upper trace) and the heart rate (lower trace) during a fast change in the heart rate around 5:00 AM. In the beginning of the episode the heart rate changed from 48 to 86 beats/min.

The changed P wave's morphology remained the same until the end of the episode when the heart rate returned to the previous value. The change in the morphology of the P wave means that the leading pacemaker region changed the position. It is believed that the sinus node is the origin of each heart beat in normal cases, although there is growing evidence for the physiological operation of extranodal pacemaker sites of a widely distributed atrial pacemaker complex in the human heart [2]. In a previous study, we documented such a pattern in the process of deceleration of the heart rate during spontaneous cardioinhibitory syncope [4].

In establishing the reason for the episode shown in Fig. 6, we examined the surrogate respiratory signal (amplitude of the R waves). Although the signal amplitude diminished in the seconds before the acceleration of the heart rate, it cannot be reliably detected as a sleep apnea episode. Again, this signal diminished immediately after the end of the episode as it can be seen in Fig. 7.

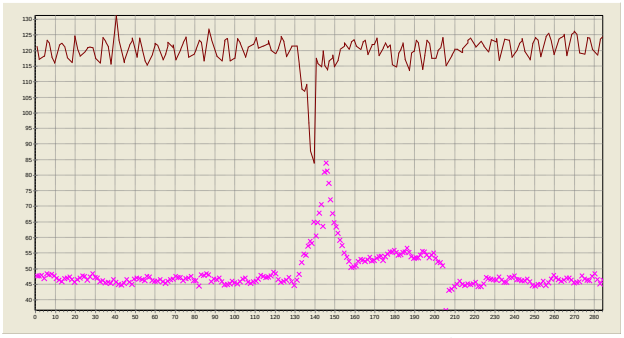

Fig. 7: The surrogate breathing signal (amplitude of the R waves in the upper channel) and the heart rate (lower channel) around 5:00 AM.

III. CONLUSIONS

The case of long-term one channel ECG recording was presented, where only the slow sampling rate (125 Hz) ECG signal was available. With interpolation the signal was enhanced to serve also for the extraction of breathing information - ECG derived breathing. Even more precise data could be obtained should the amplitude of the R waves be determined in the ECG sensor at a higher sampling frequency. It has been shown that with thorough examination of the ECG signals, the morphology of the P waves could be studied in detail. In our case, an unexpected pattern of pacemaking structures in the atrium was observed during sleep. Many ECG recordings should be thoroughly examined for minute changes in the morphology of the P waves to find out whether this was a common phenomenon during sleep. It would be a substantial improvement if the ECG sensor had an accelerometer to find out the position of the body and the movements during sleep.

Abstract - Melanoma is considered the most dangerous form of skin cancer, however if detected in early stages there are high success rates of recovery, making prevention essential. The risk assessment of skin lesions usually follows the ABCD rule (asymmetry, border, color and dermoscopic structures). This paper presents a methodology to assess the number of ABCD rule colors of skin lesion images. It starts by extracting 660 color features and several feature selection and machine learning classification methods are tested in order to minimize classification errors. The developed methodology has the advantage of being adaptable to the dataset used. Two publicly available dermoscopic image datasets and one mobile acquired dataset were used to test the methodology, achieving accuracy rates of 77.75%, 81.38% and 93.55%, respectively, for ABCD rule color feature assessment.

Keywords – Image analysis, Color Features, Melanoma, Teledermatology.

I. INTRODUCTION

Skin cancer is currently one of the most common types of cancer in Caucasian population and its increasing incidence has been leading to multiple public campaigns with the goal of raising awareness of the general population. Although Malignant Melanoma (MM) accounts for only a small percentage of skin cancer, it is far more dangerous than other skin cancers, while being responsible for most skin cancer related deaths [1]. Therefore, considering the high success rates of recovery when the malignancy is detected during the early stages of its development, the early diagnosis of MM is extremely important.

The majority of the computer-aided diagnosis (CAD) systems to analyze skin images automatically proposed hitherto in the literature are based on dermoscopic images. In [2] it is presented a systematic review of dermoscopy and CAD systems. Dermoscopy is a non-invasive method [3] that allows the in vivo evaluation of colors and microstructures of the epidermis, the dermo-epidermal junction and the papillary dermis not visible to the naked eye, opening a new dimension in the examination of pigmented skin lesions and, especially, in the identification of the early phase of MM.

The risk assessment of skin lesions in primary care centers is often conducted by looking at changes in the ABCD rule of dermatoscopy [4]. This algorithm addresses quantitatively the issue of whether a lesion is benign, suspicious or highly suspicious of Malignant Melanoma based on the analysis of four visual features: Asymmetry, Border, Color and Dermoscopic structures. The Total Dermoscopy Score (TDS) is given by the multiplication of each feature score by a weight factor (1.3, 0.1, 0.5 and 0.5, respectively), and depending on the obtained values, a grading of the lesions is possible with respect to their malignant potential.

The ABCD rule proposes the identification of six different colors in skin lesions considered highly relevant for melanoma diagnosis: white, black, blue-gray, red, light brown and dark brown. Different approaches have been suggested to assess the colors' presence in skin lesions [5]: by using a color palette; performing color histogram analysis; or using statistical parameters from different color spaces. In [6], the authors created a color palette constituted by six group colors which involved different color patches for each color group and assigned all the pixels of the skin lesion to the most relevant color patch in order to infer about the melanoma colors presence. Alternatively, a pattern recognition software toolkit was used to classify clinical skin lesions using relative color features obtained by histogram analysis [7]. Finally, in [8], the authors extracted features like mean and standard deviation of three lesion regions (lesion, inner periphery and outer periphery) over the three channels of six different color spaces to infer on the malignancy of the lesion.

In this work, a methodology to assess the number of ABCD rule colors present on a skin lesion image is presented, based on cluster characteristics analysis, having the advantages of being adaptable to different datasets. The paper is organized as follows: section II describes the datasets used; section III presents and explains the proposed methodology; section IV presents the obtained results; at last, conclusions are drawn in section V.

II. DATASET

The methodology suggested in this study was applied in two dermoscopic image sets and one mobile acquired dataset, described next. Examples of skin lesions from both datasets are depicted in Fig. 1.

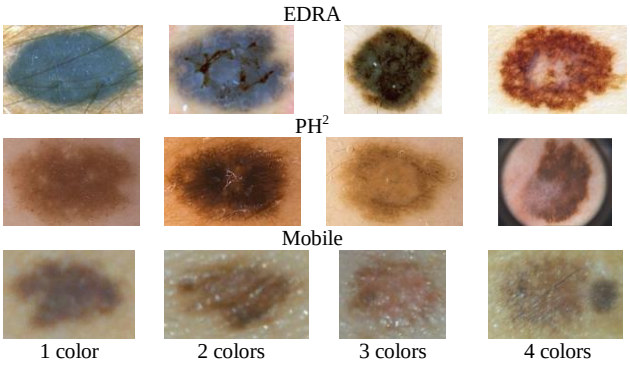

Figure 1. Examples of skin lesions from EDRA, PH^2 and Mobile datasets classified by medical experts according the number of colors

A. EDRA

The dermoscopic image set used consists on images obtained from two databases. The first is the CD-ROM Interactive Atlas of Dermoscopy [9], which is an image collection acquired in three institutions: University Federico II of Naples, Italy, University of Graz, Austria, and University of Florence, Italy.

A total of 296 images were used in this study. Moreover, all images were annotated by medical experts regarding the lesion color with the following distribution: 11 images with 1 color; 130 images were classified with 2 colors; 127 with 3 colors; and 28 images with 4 colors.

B. PH^2

The second dataset considered is the PH2 database with images collected in the Dermatology Service of Hospital Pedro Hispano (Matosinhos, Portugal) under the scope of the ADDI project [10].

A total of 160 images were used in this study. Analogously, all images were annotated by medical experts regarding the number of colors of the skin lesion: 52 images with 1 color; 88 images were classified with 2 colors; 15 with 3 colors; and 5 images with 4 colors.

C. Mobile

This dataset was collected at the Portuguese Institute of Oncology of Porto, under the scope of the project Melanoma Detection [11]. The dataset contains 80 24-bit color images with 652x652 pixels of resolution, acquired with a HTC One S mobile phone.

The dataset is composed by 15 images of 1 color, 51 images with 2 colors, 13 images with 3 colors and 1 image with 4 colors.

III. METHODOLOGY

The main goal of this methodology is to determine the number of ABCD colors present in a skin lesion image, ranging from 1 to 6 colors.

The first step of this methodology consists in performing the skin lesion segmentation. In the case of dermoscopic images, an adaptive threshold segmentation algorithm based on Otsu's threshold method was applied [12]. The threshold parameters used in this segmentation algorithm are dynamically estimated according to the image pixel resolution. In the case of lesion images acquired via mobile devices, a mobile application for the Android OS was used to help the image acquisition process, which performs real-time detection of the region of interest of the target skin lesion and segments the skin lesion [13].

Afterwards, the proposed methodology extracts 660 color features pooled in two different groups: global and relative features. Several feature selection techniques are later combined with different machine learning classifiers, in order to obtain the optimal subset of color descriptors, as well as the respective best classifier for a specific dataset (see Fig. 2).

A. Feature Extraction

The first step for the extraction color features consists in transforming the original image of the skin lesion, given in the RGB color space, to the Lab color space and also to the device independent $LC_{ab}H_{ab}$ color space [14]. In order to facilitate the clustering process, a mean shift filtering algorithm is applied to the three color spaces of the original image. Mean shift filtering removes noise by smoothing the image but preserves discontinuity, i.e. smoothing near edges is reduced [15].

The k-means clustering is then performed, with k varying from 1 to 6 clusters. Afterwards, a total of 660 features are extracted from two distinct groups: one that gathers the global characteristics of the skin lesion; and another uses relative features obtained from the Euclidean distances between the clusters centers, as summarized in Table 1.

For the relative color features, the mean, $\mu_{cluster}$, and standard deviation, $\sigma_{cluster}$, of each cluster previously found by k-means are calculated and also $measure_1$ and $measure_2$, that are defined as:

$$measure_1 = \frac{\mu_{cluster} - \mu_{skin}}{0.5(\mu_{cluster} + \mu_{skin})}, \quad (1)$$

$$measure_2 = \frac{\mu_{cluster}}{\sigma_{cluster}} - \frac{\mu_{skin}}{\sigma_{skin}}, \quad (2)$$

where μ_{skin} and σ_{skin} represent the mean color and standard deviation of the skin surrounding the lesion, respectively. The design of these cluster-based features was motivated by the need of using features with the potential of being adaptable to different skin lesion images datasets.

To better comprehend these cluster-based features, consider the case that k=4 where 4 clusters are obtained from the skin lesion. For each of the 4 clusters obtained, four metrics are calculated (mean, standard deviation, $measure_1$ and $measure_2$), the Euclidean distances of each pair of clusters (meaning 6 combinations) are obtained and the distances rearranged in descending order. In addition to the former features, the least square regression line from the resulting distances is calculated, and two extra features are extracted, namely the slope and coefficient of determination. The former procedure is repeated for the three color spaces with k varying from 1 to 6.

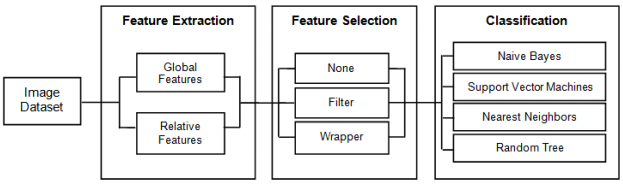

Figure 2. Block diagram of the color assessment methodology

TABLE I. Summary of the extracted color features

Group	Color Space / Channels	k	Descriptors
Global	R, G, B L,C_{ab}, H_{ab}	k=1	mean, standard deviation, energy, entropy, skewness, kurtosis, L1 norm, L2 norm
Relative	RGB Lab L$C_{ab}H_{ab}$	1≤k≤6	Euclidean distances: mean, standard deviation, measure$_1$ and measure$_2$
		3≤k≤6	slope and coefficient of determination: mean, standard deviation, measure$_1$ and measure$_2$

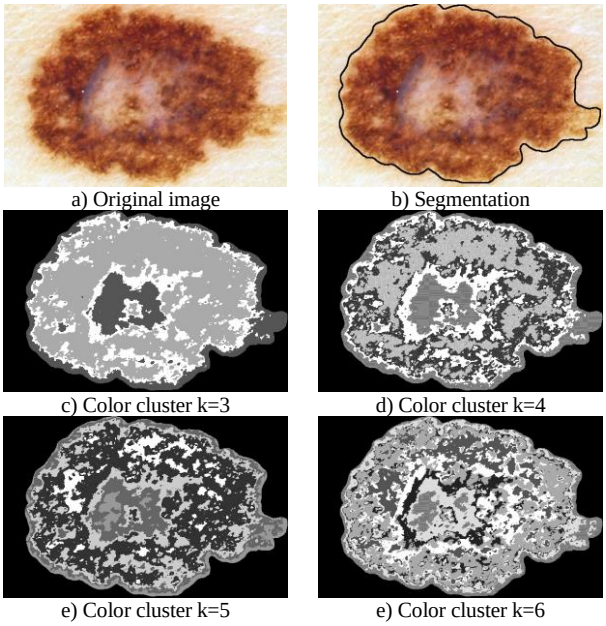

Figure 3. a) Example of skin lesion from the dataset, b) the segmentation obtained, c-e) color cluster masks obtained for 3≤ k≤6.

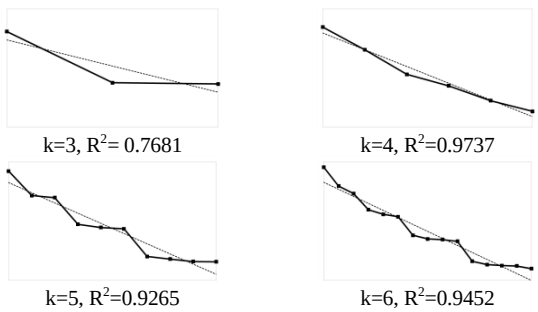

Figure 4. Example of Euclidean mean distance values obtained for 3≤ k≤6, rearranged in descending order, and respective regression lines and coefficient of determination ,R^2, of a skin lesion with 4 colors

The formulation of these cluster-based features was based on the fact that, for the ideal k value of a particular image, i.e. its actual number of ABCD colors, the clusters will be significantly distant from each other. This means that the regression line extracted from the referred cluster distances can present particular characteristics when traced for the ideal k value. As an illustrative example, in Fig. 3 and Fig. 4 the mask clusters obtained as well as the regression line are shown, for different k values, of a skin lesion image with 4 ABCD rule colors. For instance, the coefficient of determination with a value closest to one is obtained for the ideal k value.

B. Feature Selection

Feature selection algorithms can be classified into two main categories according to their evaluation criteria: filters and wrappers [16, 17]. In order to choose the best method of feature selection for each classifier, after a thorough research about the most effective and common approaches [17], three different feature selection methods were chosen: one filter-based method and two wrappers. The filter-based method used was the Correlation based Feature Selection (CFS). Regarding wrapper methods, the search methods used were Linear Forward Selection (LFS) and Greedy (G). In addition, the feature selection step using wrapper methods was performed independently for the four selected classifiers.

C. Classification

The last step of our approach consists in training a classification process with the feature attributes selected. Several techniques have been adopted to diagnose skin lesions [18] and so far no consensus has been reached on the best one to choose for. Due to the former reasons, four different classifiers were adopted: Bayes, Support Vector Machines (SVM), K-Nearest Neighbors and Random Tree. The first classifier was the Naïve Bayes that has the advantage of requiring a small amount of training data to estimate the parameters necessary for classification. In the second classifier, the Sequential Minimal Optimization (SMO) algorithm was applied for training a SVM, through a polynomial kernel. For the nearest neighbors, K=3 was used, meaning that the algorithm locates the 3 nearest instances to the query instance and determines its class by identifying the single most frequent class label. The last classifier considered was the Random Tree, also widely used in this field.

During the experiments, 10-fold cross-validation was used, meaning that 90% of the samples were used for training and the lasting 10% were used for testing purposes.

IV. RESULTS

The methodology presented was applied in two dermoscopic image sets, EDRA and PH^2, and one mobile acquired dataset. In order to deal with class imbalance, a widely used synthetic over-sampling technique, SMOTE [19], was applied. Other studies like [8, 20] also use this technique, which over-samples the minority classes introducing synthetic samples using the k minority class

nearest neighbors, in this study k=3 was used. Table 2 presents the dataset distribution before and after applying SMOTE.

The classification results are presented in terms of three metrics ordinarily used for this purpose: 1) accuracy (AC), i.e. the percentage of lesions corrected classified overall; 2) kappa statistic is a measure of agreement, where a value close to 1 mean better reliability; and 3) ROC area, that quantifies the overall ability of the test to discriminate the number of colors, being a good classifier when the value is near 1.

Tables 3 and 4 summarize the results obtained with the various feature selection methods and classifiers adopted using each dermoscopic dataset and Table 5 presents the results obtained using the mobile acquired dataset. Regarding the overall results one can confirm that feature selection besides reducing the number of features to be analyzed (from 660 features to less than 100), improves the performance of the classifier, except for the SVM classifier. Another common result is the performance of the Random Tree classifier that is significantly lower than the others.

Moreover, the best performances for both dermoscopic datasets are given by the SVM classifier using all 660 features (accuracy of 77.75% and 81.38%). For the EDRA dataset, the second best classification is given by the Naïve Bayes classifier using the wrapper evaluator with greedy search method, that selects 12 features and achieves 74.22% of accuracy, while for the PH^2 dataset the second best classifier is the Ib-3 using the wrapper evaluator with greedy search method, that selects 9 features and achieves 77.78% of accuracy. The selected features are different in the datasets, include features from both global and relative groups, choosing features from the 3 color spaces and mainly focusing on metrics like slope and coefficient of determination.

Regarding the classification results obtained with the Mobile dataset, the Naïve Bayes classifier using the wrapper search method with LFS attains the best results, with 93.55% of accuracy, using 23 features. The second best classifier was the SVM using all 660 features achieving 89.03% of accuracy. For the Mobile dataset the selected features also include features from the 3 color spaces and focus on metrics like slope and coefficient of determination, likewise as the case of dermoscopic images.

Thus, the former results confirm that the proposed methodology is adaptable not only to dermoscopic image datasets acquired with different dermoscopes, which might present considerable differences in terms of image quality and illumination conditions, but also to a mobile acquired image dataset.

TABLE II. Dataset distributions before and after SMOTE data sampling application

Number of colors	EDRA		PH^2		Mobile	
	before	after	before	after	before	after
1	11	110	52	83	15	52
2	130	130	88	88	51	51
3	127	128	15	82	13	52
4	28	113	5	80	1	-

V. CONCLUSIONS AND FUTURE WORK

In this work, a methodology to assess the number of ABCD rule colors of skin lesions from images is presented. Most of the methodologies presented to date for color skin lesions analysis are highly dependent of the image quality and illumination conditions of the images

used, like the popular color palette approach, which has the disadvantage of not being adaptable to datasets acquired with different dermoscopes.

The novelty of methodology proposed in this work consists on the granular color skin lesion analysis approach, by assessing the ABCD rule color score of the skin lesions. In order to be adaptable to different datasets and different image types, another differential factor of this methodology is the usage of cluster-based features, whose design was motivated by the need of using features with the potential of being independent of the characteristics of the used image dataset. Following this new cluster-based approach, two new descriptors were proposed ($measure_1$ and $measure_2$) as well as existing descriptors were also calculated for each cluster. Moreover, and since no consensus exists on the best classifier to apply in this type of studies, four different classifiers were tested.

The results confirm that the methodology accurately classifies the number of ABCD rule colors, and is adaptable for different dermoscopic image datasets and the mobile dataset used. For the EDRA dataset, the SVM classifier obtains the best performance with 77.75% of accuracy extracting all features, while Bayes classifier using wrapper feature selection with greedy method obtains 74.22% of accuracy using 12 features. For the PH^2 dataset, the SVM classifier obtains the best performance with 81.38% of accuracy extracting all features, followed by the Ib-3 classifier using wrapper feature selection with greedy method obtains 77.78% of accuracy using 9 features. In comparison with a similar study [21] that presents 62.5% of accuracy in the evaluation of the number of colors in a skin lesion, the proposed approach achieves better results. However, most of the studies in the literature focus on classifying the skin lesions in terms of melanoma or non-melanoma, whether than concentrating on each criteria of the ABCD rule of Dermatoscopy.

For the Mobile dataset, the Bayes classifier using wrapper feature selection with LFS method obtains 93.55% of accuracy using 23 features, followed by the SVM classifier with 89.03% of accuracy extracting all features. For dermoscopic images the possible range of colors varies from 1 to 6. According to a dermatology expert, the number of colors possible to distinguish in mobile acquired images is at most 4 colors. One hand, the dermoscopic images uses epiluminescence microscopy that allows the observation of morphologic key structures, with more detail and thus more colors, located in the epidermis down to the upper dermis. One the other hand, mobile acquired images capture information only from the epidermis, less structures can be observed with fewer colors. Thus, the clusters color variability is lower in mobile acquired images, which can explain the higher accuracy rates obtained using this type of images.

As future work, the authors plan to develop a similar methodology to assess the differential structures score, with the main goal of assembling a risk triage framework for skin lesion analysis based on ABCD rule that scores each feature independently.

***Abstract*—Manual cell counting in microscopic images is usually tedious, time consuming and prone to human error. Several programs for automatic cell counting have been developed so far, but most of them demand some specific knowledge of image analysis and/or manual fine tuning of various parameters. Even if a set of filters is found and fine tuned to the specific application, small changes to the image attributes might make the automatic counter very unreliable. The goal of this article is to present a new application that overcomes this problem by learning the set of parameters for each application, thus making it more robust to changes in the input images. The users must provide only a small representative subset of images and their manual count, and the program offers a set of automatic counters learned from the given input. The user can check the counters and choose the most suitable one. The resulting application (which we call Learn123) is specifically tailored to the practitioners, i.e. even though the typical workflow is more complex, the application is easy to use for non-technical experts.**

I. Introduction

Cell counting on microscopic images of various types is one of the fundamental tasks for many researchers and practitioners in all life-sciences. Being such a fundamental task, many automated solutions exist. Despite this abundance of tools for automated counting, the majority of counting tasks are still done manually by the practitioners. The main reasons for this can be boiled down to two problems. The first problem is the inaccuracy of the automated counters and the second one the difficulty to use for non-technical experts. Our work is focused on overcoming both of these problems, i.e. to develop an accurate tool, and a tool that is simple to use out-of-the-box.

Currently several programs for cell counting are already available. From many commercial solutions, such as MetaMorph, BioQuant, Image-Pro and SymenTec to free software, such as ITCN ImageJ Plugin [5], CellProfiler [4], UTHSCSA ImageTool [1], and CellC [10]. However, all of the existing solutions require some additional input or even some image preprocessing of the raw images, which is not only time-consuming but can also be too complex to some biology field experts. [3].

We already developed a cell counting tool called CellCounter [7], with which we demonstrated that for a particular application (i.e. cell viability estimation), a fixed set of filters with specifically tailored parameters can give great results, making the human counting almost obsolete and thus speeding up the analysis of the experiment results in life-sciences by an order of magnitude. This result is very important in practice, however it is still not the silver bullet for all the problems one might encounter in every such application.

The program was developed in collaboration with a research group, who used cell counting as a way to determine cell viability [2] and transfection efficiency [8] for certain experimental settings. By fluorescently staining cell nuclei they obtained fluorescent images with higher contrast compared to BF or PC images, but it still left them with large number of microscopic images to count, requiring a more efficient way to process the images than manual counting.

To get an intuitive picture of all the problematic features of the counting of cells, let us mention some of the problems, that typically arise in practice: different types of assays resulting in a large variety of images which are hard to generalize, inability to detect individual nuclei in multinucleated cells, overlapping cells, uneven illumination and other equipment related factors, such as electronic and/or optical noise [6], that lead to images having variable contrast and quality, low contrast of the image, different cell shapes, internal cell structures, extracellular debris, and varying density of cell culture.

Due to all these possibilities, there is a large set of variations that prevent a general solution for any circumstance to be developed. The optimal tool would detect all these variations without any user intervention. However, the many failed attempts to find such a tool demonstrate that a different approach is needed. The main goal of this article is to present such an application, which is able to adapt to the specific use-case, with (as little as possible) guidance from the user. The user only provides a set of examples, from which the application learns the general counting as accurately as possible.

Since one of the major objectives is also a widespread usability of this application, the following goals are sought:

- the learning should be done as intuitively as possible,
- the result of the learning should be easily verifiable, to ensure that the obtained results are sound,
- the workflow must not be too complex, avoiding any technology related terms,
- the learning has to be a repeatable and incremental process,
- the results of the learning and counting must be usable also in other de-facto standard applications of the user-base.

Automatic learning is a widespread area of research, so there are plenty of possible approaches to developing such an application. We define the learning as an optimization problem,

where the goal is to optimize the difference between the counting results defined by the user, and the counting obtained by the automatic counter. As mentioned above, the CellCounter application used a predefined sequence of filters, where the parameters were fine-tuned for a particular application. We used this sequence as a general framework, and the parameters of the image filters represent the vector which needs to be optimized.

As the optimization method we chose an evolutionary approach, because of the many positive features. Namely, the evolutionary approach is very flexible, we can easily change the goal function, stop the process at any point and get feasible solutions, start from existing solutions and improve the solution by interacting with the user.

The remainder of the article is structured as follows. Section II. presents the learning application, section III. describes all the implementation details, the framework, and the technologies used, section IV. describes the experimental evaluation of the application, and finally, section V. concludes the paper and gives directions for our future work.

II. Description of the Application

In this section we will first describe the application from a purely user perspective. Since one of our basic goals is to make the application as simple as possible for the end-user, we managed to strip down all the unnecessary concepts. The user does not have to be aware of any underlying algorithm and technology and in the workflow it can only focus on the images and the task at hand. This is an extremely important aspect for the practical usability of such application. Many similar applications overflow the user with technical terms and make them specify various parameters of algorithms, of which the end user should not be aware of.

The application is subdivided into two sub-application. The first one being the learning part (Learn123) and the second the counting part (Count123) of the application. In what follows we describe in more detail the tasks that constitute a typical workflow, starting with the learning part of the application.

A. Choosing a subset of images

The first task of the user is to select a representative subset of images. The subset needs to be relatively small (typically around 10 images) and the images spawn as many different aspects of the entire set (i.e. different sizes of object, different lighting conditions, different shapes, etc.).

B. Manual count

The second step for the user is to manually count the objects in the images. The information that it provides are only the approximate centers of the object. This is another very useful simplification, since some counting tools require the user to provide the contours, or at least the center and the radius of the object. Providing only the centers speeds up this step significantly.

C. The learning process

Once all the objects in the images have been manually annotated, the learning process can be initiated. The length of the learning process depends mostly on the size of the image subset, the typical span of the learning is from 5 minutes to about an hour. But the user can also participate in this ongoing process, since a set of candidate counters is immediately offered. This set is the set of currently best known counters and the user can assess the given counters. If the user is satisfied with the results he/she can interrupt the learning and use the counter.

D. Assessing the quality of the counters

When the program finishes its learning process, the set of 10 best counters is presented to the user. The user can see the count of the automatic counter visually and compare it to the counts made manually. If none of the counters is satisfactory, the user can add new images to the testset, remove some old images, and restart the learning process. Fig. 1 shows an example of a counter assessment. Notice that the learning does not start from scratch, it uses most of the information learned from the previous learn run.

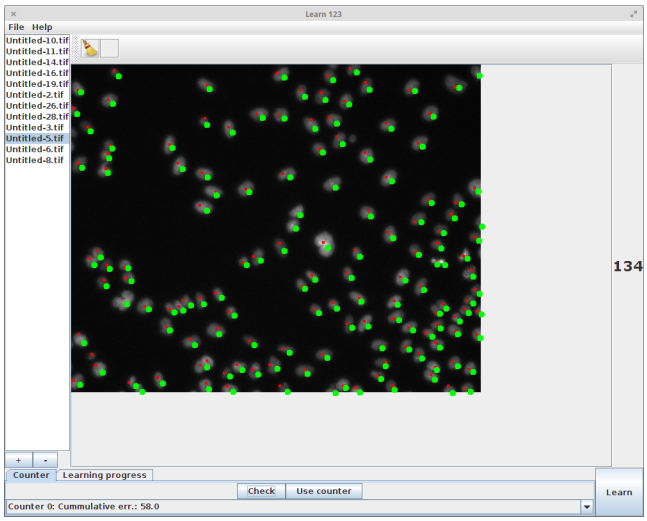

Fig. 1. The comparison of the manual and automatic count in a test image. The small red dots represent the manual count, the larger green dots represent the automatic counter.

E. Counting application

When a suitable counter is found by the above process, it can be used in the second sub-application, the Count123. The user can choose all the images in the set and the application will visually present the results. All the results can thus be checked and any point can be added or removed to correct any errors.

The assessment can also find some images on which the automatic counter behaves badly. These images (or one typical representative) can be added to the testset and the new learning process will adapt also to this type of images.

If the obtained results are satisfactory, they can be easily exported and used in other applications for further data analysis.

Fig.2 show an overview of the workflow. Every part of the workflow is technically neutral, agnostic about any algorithms used behind the scenes.

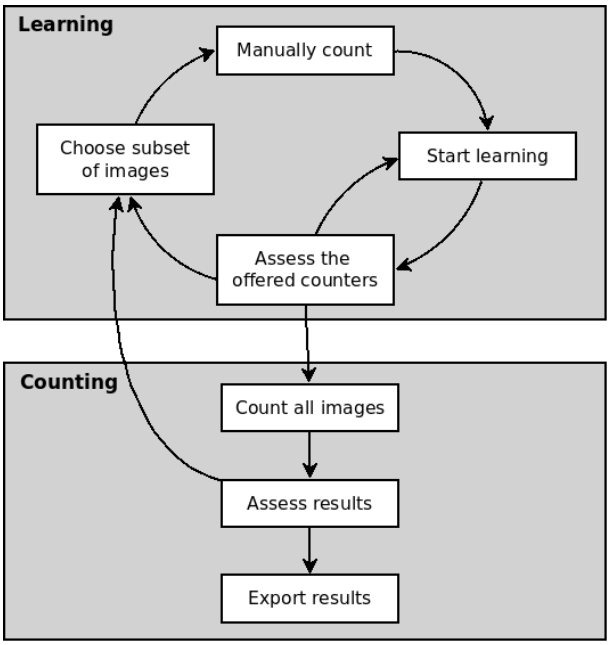

Fig. 2. The user workflow in the Learn123 application.

III. Implementation details

The implementation details can be boiled down to three aspects: (1) the modeling of the learning as an optimization problem, (2) the algorithm used for the optimization, and (3) the technologies used for the implementation.

A. The optimization problem

Intuitively, the objective of the learning process is to find a counter (specified by a (numeric) vector) with minimal counting error on the learning set. There are many possibilities how to encompass this problem into a mathematical model, the presented optimization model empirically demonstrated very good results, showing its good applicability to real problems.

As the input, a set of k images is given:

$$Img = \{img_1, img_2, \ldots, img_k\}.$$

For every image img, the manual count is given by a sequence of points in the plane, indicating the (approximate) centers of the identified objects:

$$C_{man}(img) = \{p_1, p_2, \ldots, p_n\}$$

The subject of the optimization is a vector of parameters

$$P = \{param_1, param_2, \ldots, param_l\},$$

which uniquely define the automatic counter. These parameters can be integer values, boolean values, real numbers, or certain objects from specific sets, but without any loss in generality we can assume only integer valued vectors.

The result of applying the counter defined by the vector P to the image img will be denoted by the set of points:

$$C_P(img) = \{p_1, p_2, \ldots, p_m\}.$$

Now for the most important part of the model, we have to define the goal function (criteria), which will model what we consider to be an accurate counter. Intuitively, there are two criteria that a good counter should fulfill:

- the difference of the obtained counts (the numbers) should be as small as possible, and
- the positions of the found objects should be as close as possible.

These two intuitive criteria have to be modeled appropriately and combined into a suitable goal function. We will first define this function for one image img. The first criterion is simple to model as a simple absolute difference between the number of points found with the manual counts and number of points with automatic counts on the same image:

$$\Delta(C_{man}(img), C_P(img)) = ||C_{man}(img)| - |C_P(img)||.$$

The second criterion compares all the points found with the manual count and see how far are they from the points found with the automatic counter.

The goal function for the second criterion was chosen as

$$D(C_{man}(img), C_P(img)) = \sum_{p \in C_{man}(img)} d(p, closest(p, C_P(img)))$$

,

where d is the Euclidean distance between the two points, and $closest$ is a function that finds the closest point from a given point to the given set.

This goal function is simple and fast to compute, but it can run into problems on some corner cases where it prefers degenerate counters. An example of the problem with this function is given in Fig. 3. This problem will be amended by combining the two goal functions. How these two goal functions are combined is described together with the algorithm, since it is more specific to the way the algorithm works.

The functions Δ and D model the differences in counts for a single image. Now we need to choose a suitable function that combines the results of these two function on all images. We experimented with a few variations, such as the maximum value, the median value, and the average value over all images. Empirically the simple average gives the best results, so the goal functions which combine Δ on all images is

$$G_\Delta(P, Img) = \sum_{im \in Img} \Delta(C_{man}(img), C_P(img)),$$

and an equivalent definition is used for G_D.

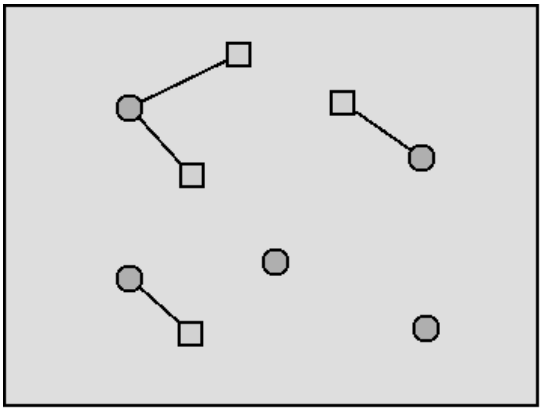

Fig. 3. An example of the D criterion matching between manual counts and automatic counts. The circles represent automatic counts, the square represent manual counts. This example also demonstrates the shortsightedness of this goal function, which has to be amended with the function Δ.

1) Evolutionary algorithm: An evolutionary algorithm is used for the minimization of the above defined optimization problem. The main reason for this choice is the general applicability of this algorithm, robustness, and the fact that at any point there are feasible solutions available, which can be immediately presented to the user for assessment. The framework of each counter is a sequence of filters for which we demonstrated in [7] to be a very adequate sequence for counting cells in electronic microscope images. This sequence of filters was manually fine-tuned for the specific application. Namely, each filter has a set of parameters, and the final count is very sensitive to the specific values of these parameters. The sequence of filters (i.e. image-processing algorithms) used for counting is as follows:

1) Enhance contrast - the images have typically a very low intensity and a very low contrast. By enhancing the contrast, many more features of the image are visible, and the results of the counting improve dramatically.
2) Threshold - in the second step, the image is converted to binary format. For this a threshold is set, by using either a specific value of the threshold or one of the 13 possible algorithms.
3) Watershed - by thresholding we typically loose the boundary between different cells, and by watershedding [9] this merged objects are divided again.
4) Holefill - after the application of the above filters, the objects are not uniformly filled. With this filter, the holes in the objects are filled, making it more suitable for the next detection step.
5) Particle analysis - the last step of the algorithm detects the remaining blobs of active pixels in the image and decides whether to add an object to the count or not. There are a few parameters upon which this decision is made - the most important being the minimum radius, the maximum radius, and the eccentricity of the object. With this parameters the counter can adapt to count only specifically shaped objects or objects with specific sizes.

The parameters for these filters represent the chromosome, as it is shown in Fig. 4, and a typical evolutionary algorithm

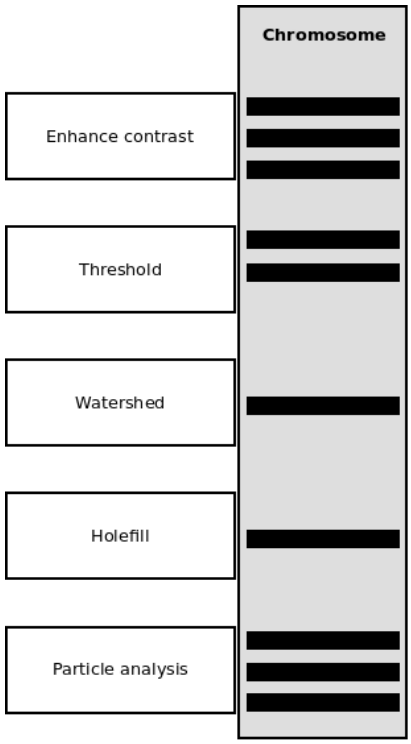

Fig. 4. An overview of the basic chromosome.

is used to evolve from completely random counters to very successful ones. The pseudocode for the algorithm is shown in Algorithm 1

Algorithm 1 The outline of the learning algorithm

```
1:  population = randomPopulation(populationSize);
2:  for gen ∈ [1, 2, ..., numGen] do
3:      if gen ≤ numGen/10 or gen%2 = 0 then
4:          goal = G_Δ
5:      else
6:          goal = G_D
7:      end if
8:      rankedPop = sortByFitness(population, goal)
9:      pop1 = select(rankedPop,populationSize)
10:     pop2 = select(rankedPop, populationSize)
11:     population = crossover(pop1, pop2)
12:     population = mutate(population)
13:     population = take(population, populationSize)
14: end for
```

Lines 3-6 of the pseudocode demonstrate the aforementioned combination of functions Δ and D. The first 10% of the generations, the fitness function is only Δ. After this starting generations, the D function is used in every other generation, eliminating possibly corrupt counters that accidentally count a similar number of cells, but on completely different positions that those obtained by the manual count.

The selection (lines 8-10) of the counters which are used for creating a new generation is done with rank selection, i.e. the probability that a counter is chosen is proportional to its rank in the current population.

The crossover (line 11) used is a one-point crossover, i.e. a random position in the chromosome is chosen and the two chromosomes exchange the parameters to the left of that position. The mutation (line 12) is not a bit-level mutation (as it is usually the case with genetic algorithms), but we used a mutation on the parameter level, where a uniformly random value is chosen from the parameter domain.

Ultimately, to obtain the next generation, only the best counters are chosen in line 13.

B. The technologies used

The program was developed in the programming language Scala. Scala compiles to the JVM, making the Learn123 application completely platform independent. Furthermore, a wide range of de-facto standard Java tools can be used as a part of the application. We integrated the entire ImageJ application into Learn123; for the users to help them further manipulate the images as well as for the algorithm itself, since most of the filters in the counting algorithm are directly used in ImageJ. Since a lot of researchers use this tool for their everyday work, they can use Learn123 just to find the appropriate counter and then use it entirely in ImageJ.

IV. Experiments

The algorithm was developed and optimized based on microscopic images obtained from several experiments the collaborating research group provided, but one experiment was selected for the evaluation of the program efficiency.

The experiments were done on Chinese hamster ovary cells (CHO) grown in Ham's tissue culture medium for mammalian cells (HAM) supplemented with 10% fetal bovine serum (FBS) at 37 °C in 5% CO_2-enriched air at saturation humidity. All experiments were performed on 24h old cell cultures in exponential growth phase.

The cell viability experiment was performed as described previously [2]. Briefly, cells were incubated with increasing concentration of polycationic polymer coated magnetic nanoparticles for 24 h and stained with two fluorescent dyes; Hoechst 33342, which stained cell nuclei, and propidium iodide (PI), which differentially stained dead cells. At least 15 visual fields at 200 × magnification were taken of each sample for each used fluorescent dye using a fluorescent microscope (Zeiss 200, Axiovert, Germany). The images were recorded by MetaMorph imaging system software (Visitron, Germany) and saved in lossless TIFF format.

For the Hoechst dye 173 images were obtained and for the PI dye 159 images were obtained. All these images were manually counted. Then (for each dye separately) a small training set was chosen (15 images for PI and 13 images for Hoechst). The manual counting was done again using Learn123 and the learning process offered a set of the best counters (according to the function G_Δ). The best offered counters were used to perform the automatic count on the entire set of images. Figures 5 and 6 show a scatterplot of the comparison between automatic count (x-axis) and manual count (y-axis).

The results show a very good correlation between the manual and automatic counts. Only a couple of images in the entire set exhibit a somewhat larger error. But even these errors can be easily detected by quickly skimming through the results in Learn123, and manually add or remove the few erroneous points.

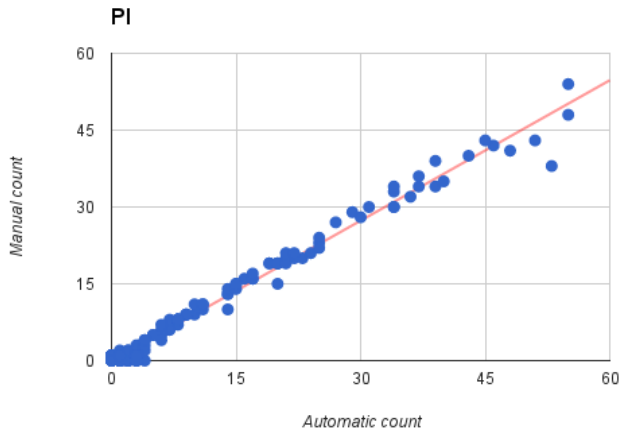

Fig. 5. Scatterplot showing a very good correlation between manual counting and automatic counting.

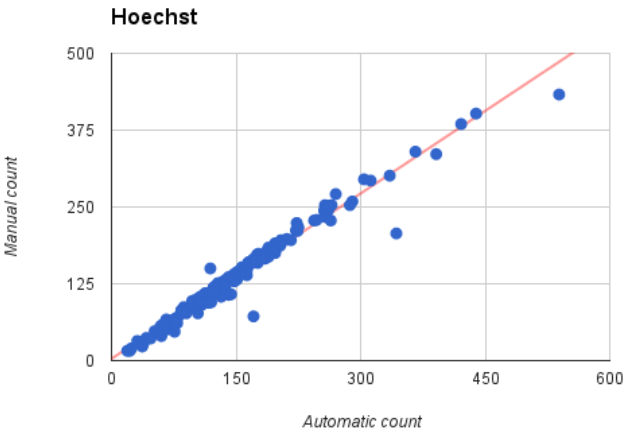

Fig. 6. Scatterplot showing a very good correlation between manual counting and automatic counting.

V. Conclusion

We presented a novel application for cell counting. The application enables regular, non-technical users to find better suited automatic counters, tailored specifically for their set of images. This is one step towards overcoming the problem of huge variations of the problems set, which can only be solved by a great adaptability of the application. Learn123 offers a simple workflow in which the user can teach the program how to count, by only giving example counts on a small subset of all the images.

The presented method was used on a fixed sequence of filters, however it can easily be extended to any sequence. Our future goal is to extend this application for any sequence

of filters that can be defined as an ImageJ macro. With this extension Learn123 will become a truly flexible tool, usable not only for cell counting, but for many other counting applications.

Assessing Blood Pressure Unobtrusively by Smart Chair

D. Zazula, J. Kranjec, P. Kranjec and B. Cigale
University of Maribor, Faculty of Electrical Engineering and Computer Science, Maribor, Slovenia
damjan.zazula@um.si

Abstract – We developed a smart chair with unobtrusive sensors that measure functional-health parameters of a person sitting on the chair. Capacitive sensors are placed in the chair's backrest and seat, while the armrests support a combination of U-shaped electrodes and incorporated photoplethysmographic (PPG) sensors for synchronous electrocardiographic (ECG) and PPG measurements. In a set of experiments with 11 young males, the two types of signals were acquired. Time distances were estimated between the ECG R-wave peaks and the PPG foots as detected by our heartbeat search, yielding the so called pulse transit times (PTTs). The experiments were conducted in two phases: the first one at rest and the second one after a minute of intensive squats. Referential systolic and diastolic blood pressures were taken just before every trial by a Critikon Dinamap Pro 300 sphygmomanometric device. Our goal was to model the relationship between blood pressure and estimated PTTs in both experimental phases. The obtained linear models revealed an interesting observation. Subjects reacted in two different physiological ways; 6 out of 11 participants conformed to a different model as the other 5 did. The main difference is the rate of decrease of either systolic or diastolic pressure per 1-ms change of the PTT.

Key-words: Smart chair, Unobtrusive sensing, Pulse transit times, Electrocardiogram, Photoplethysmogram, Blood pressure

I. INTRODUCTION

Today's common practice in home care and home health monitoring still depends largely either on the skills of the observed persons or help of caregivers. As for the elderly or impaired persons, even simplest tasks, such as pressing a button, may not be feasible. Also persons without physiological or mental problems often feel discomfort if they are expected to take care about a measuring device, measuring procedure, and data forwarding or interpretation. For example, most telemetric projects currently underway include interventions of people being monitored. A person is expected that he or she regularly measures his/her blood pressure, which means taking and switching on a device, mounting a pressure cuff, activating and monitoring the measurement, reading out the results and forwarding it over the phone or in an e-mail. This is very hard for elderly, if not impossible, and very error-prone. And due to severe worldwide healthcare budget cuts, it became unreal to count on constant help of caregivers.

It is then obvious that any home measurement must be completed automatically, without a need of any personal awareness or interaction. This, of course, implies unobtrusiveness. Sensors, or sensing devices, must reside in dwelling environments in such a way that daily activity of people living there, and also all abnormal situations, activate measurements in parallel. If, for example, sensors (and algorithms) can detect heartbeat and breathing unobtrusively, a measuring device can be built into the bed and transmit signals whenever a person in bed. Similar solutions are available for chairs, shoes, etc. Not only long-term and unobtrusive monitoring of functional-health parameters is feasible, but also all deviations from normal can be detected and automatically reported.

By the end of 2013, we developed a system of unobtrusive sensors and devices for observing functional health, which was funded within the framework of the Biomedical Engineering Competence Centre. The system includes measuring of biopotentials from human body parts, in particular palms and fingers, mechanical and acoustic vibrations due to the activity of internal organs, such as the heart and lungs, mechanical movements of the body and body parts, changes of pulsative pressure in blood vessels, blood oxygenation, the temperature of body parts, and face colour and emotions. Sensors were placed into household appliances, beds, mirrors, and shoes [1].

A logical step forward was to build a smart chair (Fig. 1), which is a perfect example of unobtrusive solution with sensors the persons are not even aware of when performing their daily activities at home. When seated, the invented device and methods detect the subject's heartbeat, compute heart rate, estimate the level of oxygen in the blood and blood pressure, acquire several nonstandard electrocardiographic (ECG) leads and the temperature of fingers, follow respiration by the breathing curve, detect movement and the subject's posture and position of their body and body parts.

In this paper, we are going to concentrate on measurements made by a combined sensory device in the chair armrests. It captures photoplethysmographic (PPG) [2] and ECG signals in parallel, which enables assessment of various cardiovascular parameters. In Section II, the construction of the device and signal-processing methods are revealed. Section III describes experiments and results, while Section IV discusses the results and concludes the paper.

II. DEVICES AND METHODS

A common posture when sitting in a chair is with hands leaned on the armrests. If the armrests have rounded and rather thin endings, sitting persons usually grasp it and bend their fingers under it. We took advantage of this fact and developed a supporting U-shaped dry electrode that is fixed under the chair armrest. A PPG sensor is built in the bottom of the electrode carrier. Its shape guarantees a stable and good contact between the subject's skin and the electrode conductive surface, which improves the quality of ECG measurements, while at the same time minimizes the influence of ambient illumination on PPG sensing (Fig. 2). Both the left and right dry electrodes incorporate LEDs with two different wavelengths, three optical sensors (photodiodes) to acquire light reflected from person's fingers, and two thermistors to measure finger temperature.

Figure 1. Modified gaming chair: smart, unobtrusive sensors are built in the backrest, seat, and armrests.

Figure 2. A detail: dry U-shaped ECG electrode having incorporated components for photoplethysmographic and temperature measurements.

Experiments described in this paper analyze parallel recordings of the PPG and ECG signals only. All acquired measurements are synchronized by a microcontroller build in the chair and wirelessly transmitted to a host computer. Analysis algorithms extract relevant features and estimate parameters of functional health. These are rendered by user interface that is adapted to run on different mobile devices.

A. *Detection of heartbeats*

We have developed a robust approach to the heartbeat detection from the PPG signals and published it in [3]. The same idea was used with the chair PPG sensors.

In every trial, 6 PPG signals were acquired in each hand with 3 photodiodes at two different light wavelengths. The latter was not important in our experiments, except that the heartbeat detections were more robust due to the observation of the same phenomenon by 3 sensors in parallel and at two different light sources. To avoid high-frequency disturbances, we applied low-pass filtering to every signal and averaged the six acquired in each hand to a single recording. Denote the obtained PPG signal by $\mathbf{s} = [s(0), \ldots, s(N\text{-}1)]$. The PPG values decrease fast to the PPG foot at every systole and increase slower to the PPG peak during diastolic intervals. Fast systolic changes can be detected by differentiating the signals:

$$d(n-1) = s(n) - s(n-1);\ n = 1,\ldots,N-1 \qquad (1)$$

Differences in $d(n)$ from Eq. (1) introduce high-frequency components due to the differentiation. There is also a higher contribution of the frequencies caused by regular heartbeats. These depend on heart rate, which is physiologically limited to a range between 40 and 210 beats per minute, i.e. 0.67 and 3.5 Hz. Heartbeat detection is then looking for these frequencies, and to do it most efficiently all other frequencies should be suppressed. We completed the job by constructing an adequate band-pass filter based on wavelets. A suitable range of scales α was applied, so that a set of wavelets, $\psi_\alpha(n)$, was built. A sum of the wavelets over the selected scales produced desired filtering band-pass characteristic:

$$\psi(n) = \sum_{\alpha \in S} \psi_\alpha(n);\ n = 0,\ldots,N_\alpha \qquad (2)$$

where ψ_α designates the chosen mother wavelet at scale α, ψ the constructed band-pass filter, S a set of preselected scales, and N_α the length of the wavelet at highest scale chosen.

The filter from Eq. (2), when applied to the PPG gradient **d,** maximizes the response at different frequencies dependent on heart rates. Optimum heartbeat detections, therefore, reside on the following signal:

$$p(n) = \sum_{k=0}^{N-1} d(k)\psi(n-k);\ n = 0,\ldots,N-1 \qquad (3)$$

Local minima in $p(n)$ represent heartbeats as detected in the PPG signal.

B. *Blood pressure and pulse transit times*

Following the example from [7], we computed pulse transit times (PTT) as a time interval between an ECG R-wave peak and the nearest subsequent heartbeat location in the analyzed PPG. PTTs are inversely proportional to the instantaneous blood pressure [4, 5, 6]. However, there are several properties of the individual physiology that influence the relationship between blood pressure and PTT. Referring to [8], PTTs change with transmural blood pressure, i.e. the pressure that appears as a difference of inner distending blood pressure and outer contact pressure across the vessel walls. If the transmural pressure becomes negative, which happens when the contact forces from outside overwhelm the pressure inside blood vessels, PTT doesn't change with it anymore and is constant for all negative transmural pressure values. On the contrary, when transmural pressure is positive, PTT decreases with the increasing pressure.

The functional relationship of PTT versus transmural pressure depends mainly on three individual physiology properties. It depends on maximum blood vessels compliance, maximum arterial volume, and the arterial volume at zero transmural pressure. These characteristics are not easily determined with independent measurements. Most common estimation uses PPG measurements at known transmural pressures.

Due to the fact that we didn't calibrate individual vascular parameters prior to our smart-chair experiments, we were not in the position to estimate blood pressure from the measured PTTs. Therefore, we used obtained PTTs in comparisons with referential blood pressure measurements and observed differences in the individual characteristics of tested subjects.

III. Experiments and Results

Our experiments were organized in two-phase measurement sessions where subjects relaxed on our smart chair by grasping properly the U-shaped sensors under the both armrests by fingers. In the first phase, referential blood pressure was verified before a 3-minute smart-chair signal acquisition at rest. In the second phase, subjects were asked to keep squatting for one minute and, immediately after that, referential blood pressure was verified again. A second 3-minute interval of measurements followed with subjects relaxing on the chair.

Their ECGs were recorded between the two hands and, in parallel, also the PPG signals (Fig. 3).

All the PPG and ECG signals were synchronized by the microcontroller firmware and resampled to a common sampling frequency of 200 Hz.

The R-wave peaks were detected in the ECGs by well-known Pan-Tompkins algorithm [9]. All R-wave detections were checked and, if necessary, corrected manually. Heartbeats were also detected from the PPG signals by our own algorithm based on continuous wavelet transform [3] as described in Subsection II.A. Low-pass filtering was applied to the signals with a cut-off frequency at 10 Hz prior to the differentiation. After it, a band-pass filtering was based on a combination of Morlet wavelets at scales 60, 72, 84, 96, 108, 120, 132, 144, 156, and 168.

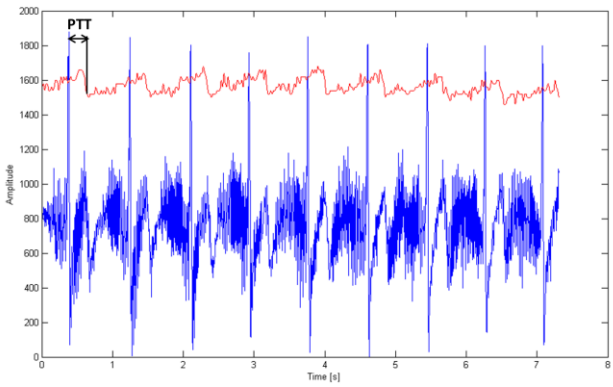

Figure 3. A combination of ECG (blue) and PPG measurements (red) that enable an estimation of blood pressure based on PTTs. The principle of PTT estimation is marked as a distance between the ECG R peak and a subsequent PPG foot

Eleven healthy male subjects participated in experiments. Their mean age is 28.9±6.6 years, their height 180.6±5.1 cm, and their weight 90.2±16.9 kg. All gave their informed consent before the experimental trials. Referential data were also taken for blood pressure before every trial. A Critikon Dinamap Pro 300 was applied for a sphygmomanometric measurement of systolic and diastolic blood pressure in every participant.

After detecting ECG R waves and PPG-based heartbeats, we were ready to compare referential blood pressure in tested subjects with computed PTTs. We measured time distances from the referential R peaks to the PPG foots as detected by our heartbeat search. PTT values were estimated from 10 consecutive heartbeats at the beginning of every trial. PPG signals from the left hand were taken into account. Inverse values of PTTs are expected to be proportional to mean blood pressure [6, 12].

We modeled the relationship between PTTs and subject's blood pressure by linear model in four situations: for systolic and diastolic referential pressures at rest and after the exercise. Obtained formulas transform PTTs to blood pressure estimates in the least-square-error sense. Table I summarizes estimated PTTs for all 11 participants at rest and after exercise.

TABLE I. Systolic and Diastolic Blood Pressures Measured Before Every Trial and Mean PTTs Estimated at the Beginning of Every Trial

Subject	At rest		After exercise	
	***Systolic/diastolic BP* [mmHg]**	***Mean PTTs* [*ms*]**	***Systolic/diastolic BP* [mmHg]**	***Mean PTTs* [*ms*]**
1	129/70	236.4	137/85	195.9
2	153/87	197.3	143/67	160.9
3	121/73	233.7	119/67	269,1
4	110/69	250.2	120/74	233.2
5	129/79	285.0	163/79	168.2
6	126/78	244.1	134/84	213.4

Sub-ject	At rest		After exercise	
	Systolic/dias-tolic BP [mmHg]	*Mean PTTs* [*ms*]	*Systolic/dias-tolic BP* [mmHg]	*Mean PTTs* [*ms*]
7	135/72	268.6	212/78	201.4
8	161/94	190.0	240/108	135.6
9	134/65	259.8	153/72	172.3
10	140/84	191.6	140/77	174.8
11	121/65	270.0	150/72	225.2

Best-fit analytical models, i.e. formulas that transform PTTs into corresponding blood pressure, are depicted in Table II along with mean-square errors. These were computed between the referential blood pressures and their estimates according to obtained analytical models. Agreement between the references and modeled estimates is not accurate enough for systolic, but is acceptable for diastolic pressures.

TABLE II. ANALYTICAL RELATIONSHIPS BETWEEN REFERENTIAL BLOOD PRESSURE MEASUREMENTS AND ESTIMATES OF PTTS QUANTIFIED BY MEAN SQUARE ERRORS (MSE)

BP type	At rest		After exercise	
	BP [*mmHg*] *vs. PTT* [*ms*] *relationship*	*MSE* [*mmHg*]	*BP* [*mmHg*] *vs. PTT* [*ms*] *relationship*	*MSE* [*mmHg*]
Sys-tolic	$BP = -0.1352 \cdot PTT + 167.87$	4.75	$BP = -0.6103 \cdot PTT + 275.63$	8.43
Dia-stolic	$BP = -0.2041 \cdot PTT + 124.54$	1.84	$BP = -0.1589 \cdot PTT + 109.50$	2.80

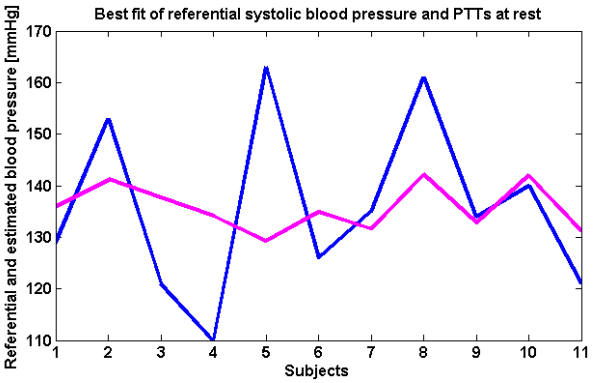

Figure 4. Referential systolic blood pressure (in blue) and its estimate according to PTTs (in magenta) measured at rest.

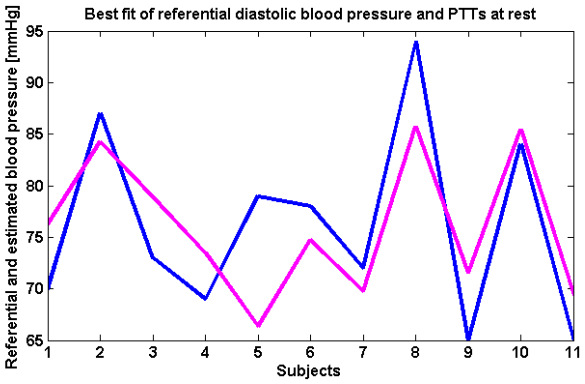

Figure 5. Referential diastolic blood pressure (in blue) and its estimate according to PTTs (in magenta) measured at rest.

Figs. 4, 5, 6, and 7 show the referential blood pressures as measured before the experimental trials by the Critikon Dinamap device in blue and, in parallel, their analytical estimates computed with the corresponding formulas from Table II.

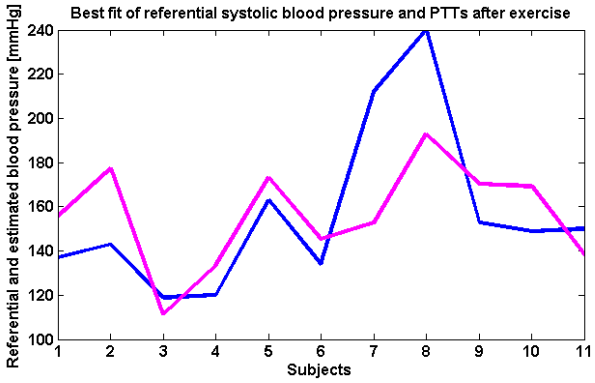

Figure 6. Referential systolic blood pressure (in blue) and its estimate according to PTTs (in magenta) measured after exercise.

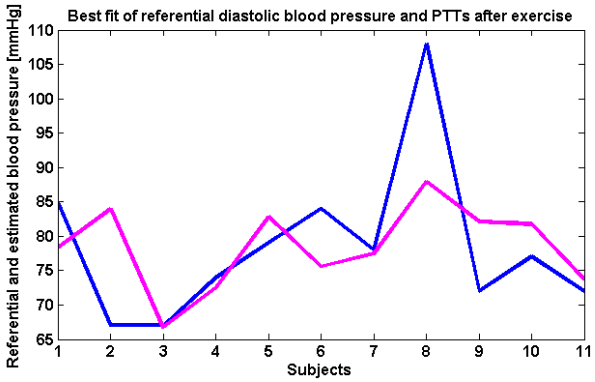

Figure 7. Referential diastolic blood pressure (in blue) and its estimate according to PTTs (in magenta) measured after exercise.

IV. DISCUSSION AND CONCLUSIONS

Contact forces on fingers change transmural pressure and also PTTs [10]. At the same time, PPGs from oppressed fingers show weaker dynamics and lower changes between the systolic and diastolic levels. This aggravates correct heartbeat detections. In spite of being instructed not to do so, participants in our tests may have pressed by their fingers against the armrest sensors on our smart chair. We couldn't collect any information on that, so we expect that transmural pressures in our experiments equal distending blood pressures in arteries. Anyway, errors neglected this way in the PTT estimation do not exceed 18 ms at 0.5 N of external contact force, which equals about 80 mmHg when 2 cm^2 of finger's surface are oppressed [8]. We are quite positive that much lower forces were unconsciously exerted in our experiments, which alludes that errors of this type remained in PTTs blow 5%.

Relationship between referential blood pressures and estimated PTTs unveiled inferior fitting of systolic blood pressures, both at rest and after exercise. We suspect the reason might be individual differences in vascular parameters that, as we explained in Subsection II.B,

influence this relationship. Therefore we tried to exclude these differences by modelling changes of blood pressures from the rest to post-exercise condition with changes of PTTs for each subject. We expected this might circumvent interpersonal variations. Figs. 8 and 9 depict differences between post-exercise and rest blood pressures and PTT-based estimates for systolic and diastolic measurements, respectively.

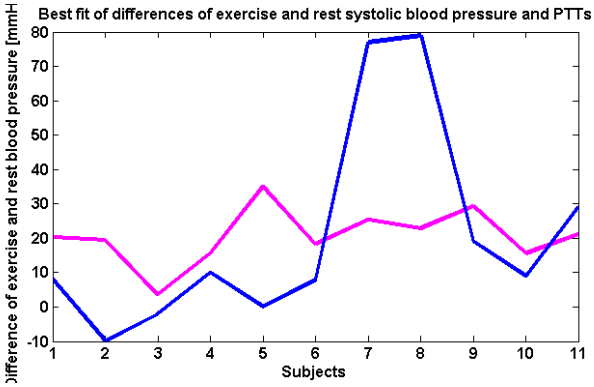

Figure 8. Changes of systolic blood pressures (in blue) from resting to post-exercise period are aligned with changes of estimated blood pressures as modelled by PTTs (in magenta.)

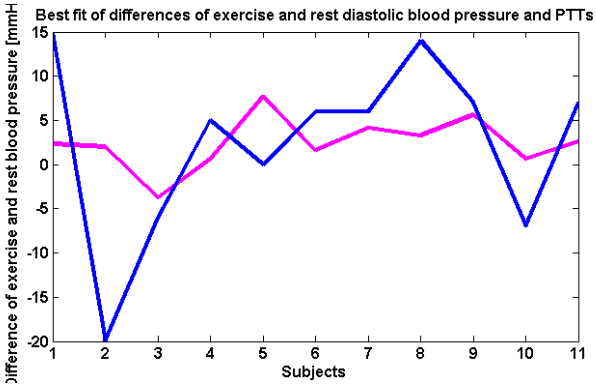

Figure 9. Changes of diastolic blood pressures (in blue) from resting to post-exercise period are aligned with changes of estimated blood pressures as modelled by PTTs (in magenta.)

Figs. 8 and 9 indicate different physiological reactions of individuals. While the predictions of blood pressures based on the PTTs in subjects 1, 3, 4, 9, 10, and 11 follow the direction of changes in referential blood pressures, the same doesn't hold for subjects 2, 5, 6, 7, and 8. Two groups with different response in their blood pressure and estimated PTTs are formed.

Therefore, we repeated modelling systolic condition for the first group of subjects 1, 3, 4, 9, 10, and 11, due to inferior results obtained by analytical estimates of blood pressures based on the PTTs both at rest and after exercise. New models decreased MSE to 3.45 mmHg at rest, and to 3.47 mmHg after exercise.

We are not able to explain different observations in the two groups of participants. They do not differ significantly either by their body indexes or referential blood pressure changes or heart rate changes when comparing the outcomes at rest and after exercise. Additional research is planned with more participants for better statistical assessment. Deeper insights will be induced into the vascular parameters and also more attention paid to possible stress and muscle tonus of participant during experimental measurements.

Abstract - Miniature and noninvasive sensors play a major role in healthcare, by monitoring vital health parameters in real time. Furthermore, energy efficiency is an important issue in human-centric embedded systems. In this paper we describe a new approach for a contact-less bioimpedance measurement. The basic idea stems from the permittivity measurement of electronic circuit substrate. A common procedure in this case is to design and fabricate a substrate with a given resonator structure where the dielectric constant can be calculated from the measured resonant frequency and known resonator geometry and substrate thickness. Similar principle can be employed for bioimpedance measurement. The resonator can be designed such that the resonant frequency lies within the responsive range of the target tissue where the resonant frequency changes are highest following physiological processes. The changed value of the frequency reflects the dielectric properties of the target object. The measured frequency thus implicitly reflects biological and physiological processes within the target object. Some preliminary experiments are described in this paper.

I. INTRODUCTION

Human body or part of the body can be represented as distributed volume conductor. Spatial impedance variability can be measured to detect different physiological phenomena. Measuring chest impedance is one of the most popular techniques to detect respiration activity. The respiration and ECG are usually measured simultaneously. Impedance measurements can be implemented with several non-invasive measurement principles. Bioimpedance sensors can be integrated within other sensors (e.g. ECG electrodes can be used to measure impedance of the thorax) or as separate sensors for more specific measurements.

Impedance pneumography is commonly-used technique to measure respiration rate. The operation principle is based on changing impedance of the thorax. The thorax impedance analysis can be described using proper impedance model. The thorax represents volume conductor with constant and varying component of volume impedance [1].

Therapeutic decisions in intensive care unit are based on measurement results from different sensors indicating the status of a patient's vital signs. One of the important parameters is cardiac output. The cardiac output is calculated from stroke volume measurements. The stroke volume is difference between end diastolic volume and end systolic volume. Stroke volume can be measured with invasive and non-invasive methods. One of the non-invasive methods to determine cardiac output is thoracic electrical bioimpedance measurement [2].

Proper impedance model is required to investigate the impedance variations within thorax due to different physiological processes. There are many different models for whole human body or just thoracic volume with accurate tissue properties [3-6].

Standalone ultra-low power wireless bioimpedance sensors are rare or non-existent. However, the combination of biopotential+bioimpedance sensors is more common. They can be seen as wireless ECG with integrated respiratory functions. Integrated circuits supporting such combination were developed and are commercially available from different vendors.

Another option for investigation in this area can be oriented on sensor, which is more intrinsic and can operate with lower power. Microwaves are used to measure dielectric properties of the materials. The permeability perturbations are known in biological tissue caused by (patho-) physiological processes [7]. Ring resonators are simple and efficient components for measuring permeability. They can be realized in micro-strip technology. A tuned micro-strip ring-resonator oscillator was reported to have a wide tuning bandwidth of 30%[8]. Both building blocks can be used for low power wireless bioimpedance sensor. A GHz range oscillator can reach power consumption in sub-0,100mA range [9]. What is even more motivating, the concept of microwave impedance measurement of biological cells have been reported reaching very high sensitivity capabilities [10].

Another system can detect and display the detected heartbeat and respiration in real time was implemented as Doppler radar system measuring periodic movement [11]. The authors reported using short wavelengths to improve sensitivity and reduce the power consumption.

More than one vital sign can be measured with micorwave non-invasive sensor. A multi-purpose, low-cost and non-invasive vital signs sensor that was capable of measuring heart-rate, respiration rate, changes in the lung water content, and the heartbeat waveform was presented based on the measurement of reflection coefficient [12].

II. BIOIMPEDANCE MEASURING CIRCUIT

Low power contact-less bioimpedance circuit for measuring changes in dielectric properties of a observed tissue was constructed. The circuit measures resonant frequency deviations in microwave resonator. Similar method was introduced by several authors for the measurement of dielectric constant of some materials [13]. The resonant frequency depends on permeability of material above microstrip planar resonator. The block diagram of the circuit is shown in Fig. 1.

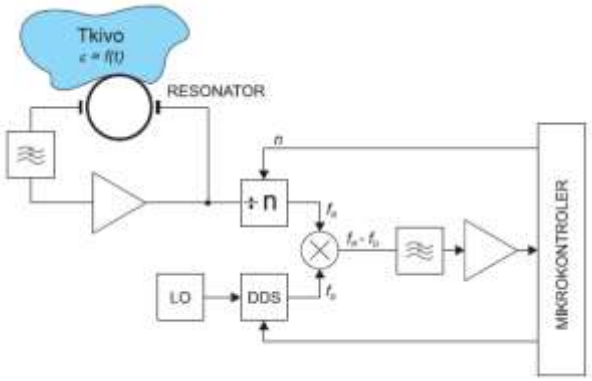

Fig. 1 - Large tuning range resonant sensor

As an example, electrical impedance measurements of the lungs at lower frequencies were reported. Significant dependence of impedance on air content was measured in the frequency range 9.6 kHz–1.2 MHz [7]. This phenomenon indicates the relationship between impedance and air content of lung tissue. The tissue impedance in microwave region depends mostly on salt content. The conductivity is proportional to molar concentration of NaCl [15].

The above idea has been developed and preliminary evaluated by numerical simulations in a commercial finite-element code (Comsol Multiphysics). The model of the resonator structure was studied under different boundary conditions and loads (i.e., different human body tissues) according to the expected application in practice. Obtained results were within the range of the human bio-impedance frequency response. Simulation results were compared with measurements on physical prototype of the resonator. Resonator measurements were performed with a vector analyzer. The key parameter for oscillator design (scatter parameter S21) was measured between 2MHz and 6GHz. The simulation and measurements results showed good match at resonant frequencies. This confirmed the feasibility of the proposed approach.

A. Resonator

The ring resonators are excellent components for many sensing applications [16]. Some typical measurement applications are optimisation of microstrip substrate thickness [17], discontinuity and equivalent circuit parameters [18], dielectric and dispersion characterization [19, 20], or broadband materials characterisation [21]. The ring resonators are also standard structures to measure dielectric properties of printed wiring board materials [22]. Resonator operation in free air was simulated with agilent ADS.

The basic ring resonator circuit is shown in Fig. 2. It consists of two feed lines with coupling gaps and the resonator ring. The ring is powered via feed lines. Separation between lines and ring is provided by coupling gaps. The gaps represent loose coupling and should be optimal to provide proper oscillation within the ring structure. The structure supports waves that are integral multiple of the guided wavelength of the circumference

$$n\lambda_g = \pi D, \quad n = 1,2,3, \ldots$$

where n is mode number and D is ring mean diameter. When the total length of the resonator, resonant frequency f and the resonance order n are known, the effective permitivity (i.e., the permittivity of the tissue, which changes with physiological state) can be calculated.

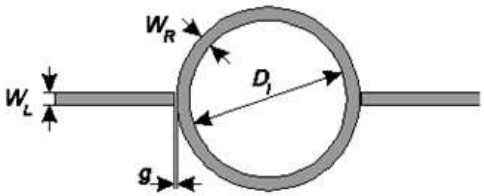

Fig. 2 - Microstrip ring resonator geometry

B. Oscillator

The ring circuit is a resonator and it can be utilized to stabilize an oscillator. In our case, the active part of the oscillator is NPN Silicon RF Transistor BFP520. Amplifier input is connected to the ring resonator via low pass filter. This filter rejects all higher harmonics above maximum operating frequency of the resonator.

The output of the amplifier feeds the resonator and provides output signal. The output of the oscillator will be connected to the next stage, the frequency divider in the first prototype.

The designed sensor will be tested first component-by-component and finally as whole module. Long term stability of the measured frequency should be tested without testing subject.

C. Test results

Preliminary measurements show detectable deviation in resonator frequency during changes in permittivity of loading media around resonator.

III. CONCLUSION

The presented sensor is based on proven microwave measuring principle. The operating frequency is based on the tissue dielectric properties, which are stable within the frequency range and mainly dependent only on the tissue composition and current physiological state. Since the tissue composition is not changing significantly, the principal sensitivity of the sensor is on the tissue physiological changes. The sensor operation was tested measuring the breathing, which was easy detectable and

phenomenon. However, the sensor utilization is not limited to simple breathing detection. Many sources describe correlation between dielectric properties and different health related states [1-7]. The presented measurement methods elsewhere were mostly with direct electrical contact between skin and sensor electrodes. Our contactless, non-invasive method can be used in many different bio-impedance measurement applications.

Exploring bacterial biofilms with NAMD, a highly scalable parallel code for complex molecular simulations

Drasko Tomic

Hewlett-Packard, Zagreb, Croatia, drasko.tomic@hp.com

Abstract –Bacterial biofilms are highly complex structures. We are more and more recognizing that bacterial biofilms are predominant forms of the bacterial existence against the planktonic one. Under certain circumstances, bacteria starts to build biofilm and forms 3D structure, so called extracellular matrix. Hulled within this matrix, bacteria becomes more prone to host defense mechanisms and most antibiotics, thus expressing considerably higher virulence and antibiotic resistance than its planktonic form. Because of their importance, numerous researchers investigated bacterial biofilms in the last decades, using numerous methods, like electron microscopy, mass spectroscopy and nuclear magnetic resonance. However, neither of these methods is able to reveal an exact structure of extracellular matrix. Exploring dynamics of extracellular matrix is even more complex, and out of the reach for known analysis methods. For these reasons, there is a need for more effective method, and this could be computer driven simulation. In order to check if it could be a method of choice, we estimated the computational resources needed to simulate the bacterial biofilm. We found that possibility of performing this simulation in the reasonable time on fastest supercomputers today does not exists, and will not be available until at least 2028. For this reason, we explored possibilities of running NAMD based bacterial biofilms simulations on Cloud, and landed with the same conclusion. Besides, we found that for both approaches NAMD has to extend its scalability from about current 500.000 cores to many millions of cores in the future.

Key words: bacterial biofilm, extracellular matrix, NAMD, high performance computing, cloud computing

I. INTRODUCTION

In the last decades, our belief regarding the organization of the bacterial swarms in aqueous environments change dramatically. In opposite to the former view of bacteria as predominantly planktonic, we now believe that biofilms are predominant forms in aqueous environments, and that quantity of bacteria in biofilms is for several orders of magnitude higher than planktonic. Because of its very high complexity, we still do not know the exact structure of biofilm. Besides, bacterial biofilms are highly diverse in nature, which means that the biofilm for two different bacterial species differs in its architecture and ingredients. The complexity of bacterial biofilm is even higher, as its structure is dependent of environmental parameters, like the concentration of oxygen, temperature and ph [1]. In addition, bacterial biofilms are not static, but dynamical organization of many bacteria, embedded in the so-called extracellular matrix. Dynamical means that it changes over the time, started from the initial attachment of the bacteria to the surface, their growth and production of adhesins, which enable bacteria for the initial attach to the surface and interaction with other bacteria in its proximity [2]. After the initial phase of attachment and growth, this structure is going to mature, from time to time opening its surface to dissipate bacteria in its proximity. Under certain circumstances, biofilm may disperse as well [3]. What we well understand today is that it is 3D matrix like structure, and its main ingredients are polysaccharides, proteins, DNA and RNA [4]. Usually, we call this structure extracellular matrix. In Fig. 1, there is a typical seeing of the biofilm surface, under electronic microscope:

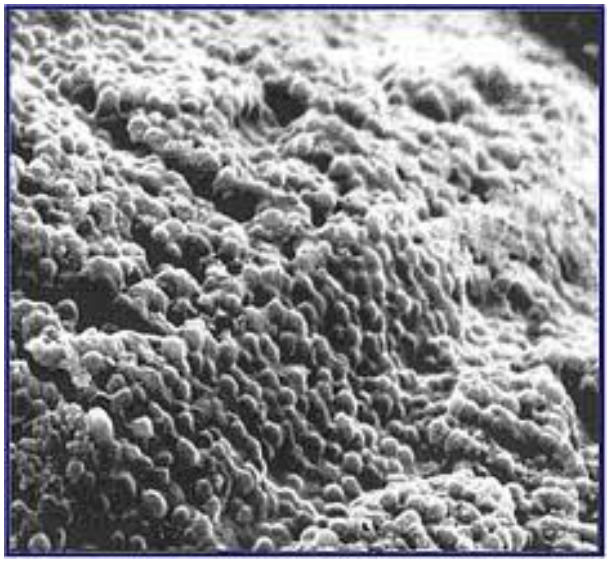

Fig.1: Bacterial biofilm image under electronic microscope

However, many bacterial species developed additional surviving strategies, like ability to penetrate deep in the tissues, autonomous movement, and production of toxins able to damage not only host, but also other competitive bacteria. Today, we know several dozens of elements that contribute to the initial bacterial adhesion to the surface, biofilm growth and its maturation [5]. To make things even more complex, different bacterial species can form common biofilm. Fig.2: schematically describes life cycle of bacterial biofilm:

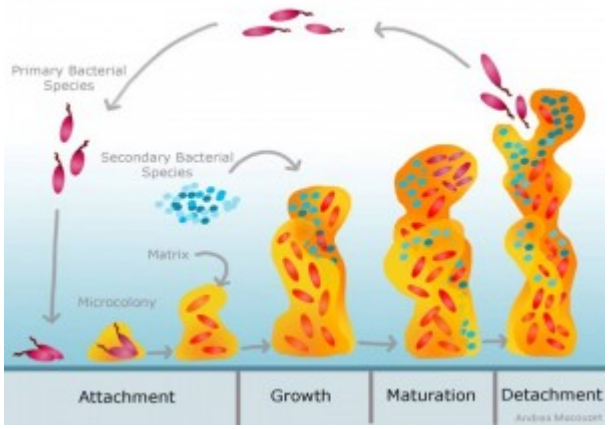

Fig.2: The life cycle of the bacterial biofilm

After initial attachment of bacteria to the surface, growth phase follows. In this phase, other species eventually join the primary one and contribute to the biofilm growth and formation. Maturation phase is probably the most complex phase, as it involves synchronization and message exchange between bacteria and involves many protein types and other molecules. Biofilm detachment is the last stage, where some of bacteria are spreading out of biofilm, and seeking other patches for the attachment, and eventually biofilm growth. Nevertheless, it is important to stress out that biofilm growth needs not to start even if the attachment was successful. It is not so clear what triggers biofilm growth, but it is supposed that the main factors are environmental, like temperature, ph and osmotic properties of the surface. Besides, nowadays is more than ever clear that bacterial biofilm enables bacteria to survive in very harsh environments, hide it from the host defense system, and even enable it to escape from antibiotics. For all mentioned before, it is evident that bacterial biofilm analysis is a very hard problem, and can be even harder in case of the multi-species bacterial infection. Number of methods for analyzing bacterial biofilms were proposed and developed in the past, like solid-state NMR spectroscopy, electron microscopy, biochemistry and their combination [6]. However, neither of these methods is capable to approach bacterial biofilm in all aspects; some of them can give us some insight in the architecture and content of extracellular matrix, but are not capable to clarify or visualize biofilm development stages. As it also became more and more evident that bacterial biofilm contribute to bacterial virulence, it is crucial to develop agents that are able to destroy bacterial biofilms, or at least help antimicrobial agents through the biofilm surface and kill bacteria hidden in it [7]. Experimental methods for finding such agents have led to the development of several drugs that can do this, however these experiments are expensive and last for days. Besides, there is rarely, if ever, a possibility to observe in-vivo effect of agents to the surfaces colonized with bacterial biofilm, thus danger of side effects is extremely high. In addition, as already pointed out by Max Planck, each experiment induced some uncertainty into the observed system. For smaller system is the greater probability that observer will induce uncertainty in it. Indeed, bacterial biofilms are not so great structures; they can envelop whole organs, e.g. bladder and lungs, but they are at most several hundred micrometers high.

Therefore, the only method known today which would be able to reveal such complex structure like bacterial biofilm and its interaction with antimicrobial agents and surfaces is the computer-based simulation. Popping up as a first choice is the computer simulation of large biomolecules. Among many microbiological simulation programs, NAMD is probably one the best known [8]. Its popularity is due to several factors: excellent scaling which enable to use NAM over thousands of processor cores, plus large database of proteins, polysaccharides and genomes, which is open for anyone to use it. That all together makes NAMD as one of the most preferred choice for the potential use of the bacterial biofilm analysis. However, the complexity of the biofilms and number of atoms to be simulated can eventually prevent using NAMD for this even on the available supercomputer resources. For this reason, we will try in the next section to estimate computational resources NAMD needs to perform bacterial biofilm analysis. In addition, we will try to estimate how long it could take to perform the simulation. Lastly, we will propose some ways to improve it.

II. CALCULATING MICROBES

The mass of an average sized virus is about 1.5 femtogram (1.5*10^-15 gram) and viruses are made up primarily of proteins. Some coat themselves in sugars or other substances but these tend to be the bigger ones. Protein is roughly 70% carbon, 12% nitrogen, 10% oxygen, and 7% hydrogen by mass. We can then break down the mass of the virus into parts and get as following for carbon, nitrogen, oxygen and hydrogen parts of it::

C:1.05*10^-14g
N:1.95*10^-16g
O:1.50*10^-16g
H:1.05*10^-16g

Consulting a periodic table we find that carbon consists of 12g/mol=12g/6*10^23 atoms. It follows:

1.05*10^-14g / (12 g / 6*10^23 atoms) = 1.05*10^-14g * 6*10^23 atoms / 12 g.

Units cancel and we can multiply the terms in the numerator:

6.3*10^9 atoms / 12 = 5.25*10^8 atoms = 525,000,000 atoms of carbon.

We can now perform the same calculation for other elements:

N: 8,360,000 atoms
O: 5,630,000 atoms
H: 63,000,000 atoms

gives us approximately 600,000,000 (six hundred million) atoms. For the simulation of smaller problems, e.g. the simulation of the capsid of HIV virus, we need supercomputer at Illinois University that delivers about 1PLOFS computational power. Next figure shows simulated capsid as the brawn nucleus in the middle of HIV virus:

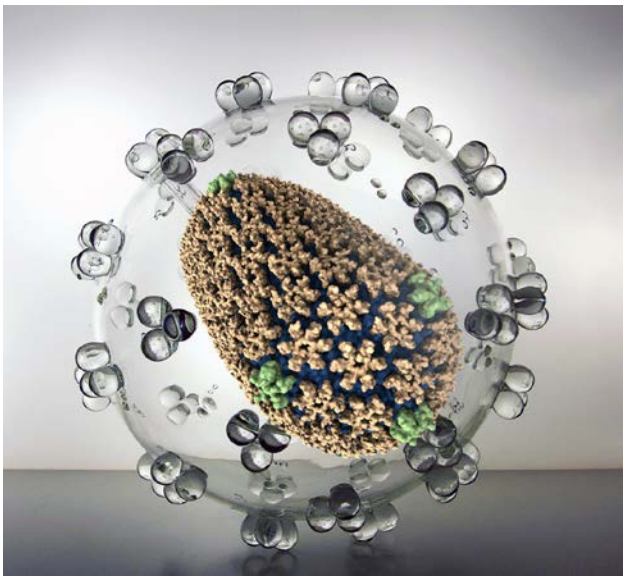

Fig.1: HIV and its capsid simulated at University of Illinois with NAMD

Now we will try to estimate number of atoms in bacteria. Our first assumption is that atoms in a bacterium are packed as closely as physically possible, which is idealization since a bacterium is mostly liquid. Besides, there are many different types of atoms in a bacterium, but the main components are hydrogen and carbon. Hydrogen has a radius of .025nm and carbon has .07nm. We know the volume of the bacterium, so one has to find out the volume of the atoms. We will estimate them as spheres with V = 4/3pi*r^3. We get an atomic volume of 4.18 x 10^-30 cubic meters. Dividing the volume of the bacterium by this we get a value of about 2.4x10^11 atoms. We know that a bacterium weights about 1

picogram (1 x 10^-12 grams). We further know its chemical composition is mostly water, and we'll estimate that the average atom has an atomic weight of 6 (which means 6 times the atomic mass unit, which is 1.6 x 10^-27). We arrive at the result that there are about 10^14 atoms in a bacterium. This means about 10^6 more atoms then in virus.

III. SIMULATING BIOFILM ON ZETTAFLOP COMPUTER

In order to find out how the need for computational resources increases with the number of atoms, we performed several standard NAMD benchmarks on Openstack based Cloud infrastructure with 4 VCPUs and 16GB RAM. Standard benchmarks were ApoA1, ATPase and STMV, with 92.224, 327.506 and 1.066.628 atoms, respectively. Elapsed times for these benchmarks on 4 VCPUs and 16GB RAM were 246, 719 and 2483 seconds, respectively. This experiment showed us that computational resources needed scale approximately linearly with number of atoms. Under this assumption, we estimated about 10 PFLOPS computational power would be needed to simulate the whole virus, and about 10^6 Pflop/s needed to perform bacterial simulation. If we take the look at top500.org, the list of most powerful computers, the fastest supercomputer today is able to deliver about 34 Pflop/s [9], enough to perform virus simulation, but far behind resources we would need to perform bacterial and biofilm simulations. Besides, by taking view at the performance development of the fastest supercomputers over time, we can see that performance increases exponentially, and we can expect that Exaflop supercomputer delivering 10^3 Pflop/s supercomputer will be available in 2018, while Zettaflop supercomputer delivering 10^6 Pflop/s will be available somewhere in 2028 year. Fig.4 shown how the performance of 500 fastest supercomputers developed in the last two decades:

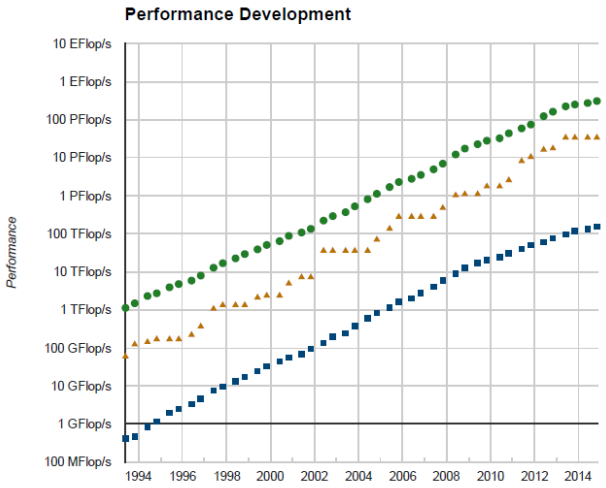

Fig.4: Performance development over the time

From other experiments, it is apparent that NAMD is not able to scale on more than several dozens of vCPUs on Cloud [10]. On the other side, NAMD proved to scale linearly over hundred thousands of CPU cores on standard supercomputers. For this reason, Cloud needs to undergone important changes if we want NAMD and other HPC applications to scale on it as on monolithic supercomputers. Besides providing support for ultra-fast optical interconnect, some other technologies like containers, SR-IOV and cluster instance placement groups must become a standard for HPC in the Cloud. We already have seen movements in these directions from Amazon, Google and other Cloud providers. Regarding installed computational power, none of these companies provides the number. Nevertheless, according to some estimations it could be up to 40 Pflop/s for some of them, and this back in 2012. It is evident that there is at least the same computing power available on Cloud as on top500.org, where the total computing power in 2012 was 100 Pflop/s. Besides, today's trend in HPC is that HPC Cloud is growing with about the same factor as the standard HPC. For this reason, we do not believe HPC Cloud growth will overtake standard HPC in the near future. Anyway, the cost of running HPC applications on Cloud is considerably lower than on Supercomputers, so it could be an additional boost to further investigate and develop Cloud based bacterial biofilm simulations. The next important factor to consider is NAMD scalability. Envisioned Zettaflop computer, either monolithic or Cloud based, will have many millions of cores. Currently, NAMD is scaling up to 500000 cores.

For it, we need improved load-balancing strategy, able to increase NAMD scalability by far beyond the current limit.

III. CONCLUSION AND THE FUTURE WORK

Until today and as of our knowledge, there is a little or no work at all in the area of computational simulation of bacterial biofilms. Microbiologists explore bacterial biofilms experimentally, and there are several reasons for this. Firstly, bacterial biofilms are highly complex structures. Moreover, although in last several decades our knowledge and understanding of bacterial biofilm grew enormously, we still do not have a clear picture of its architecture, their interaction with various environmental habits, and influence of the environmental parameters to its formation, maturation, and eventually dispersion. Thus, setting up the computational model of a certain bacterial biofilm is very challenging and complex task. Another important reason for not performing computer simulations of bacterial biofilms is the lack of computational resource available, even for the relatively simple virus simulations. Simulation of bacterial biofilm would impose the usage of costly computational resources, thus limited to the very small number of scientist. However, with the advent of cloud computing, the availability of high-performance computing resources with affordable cost has enormously increased, providing us a chance to simulate bacterial biofilms on the Cloud. Besides, before being able to simulate biofilms on Cloud, we need to extend the current scalability of NAMD from several dozens to several thousand Cloud instances by implementing new Cloud technologies like ultra-fast optical interconnect, SR-IOV, containers and cluster instance placement groups. In addition, for running bacterial biofilm simulations on either Zettaflop monolithic or Zettaflop Cloud based supercomputer, NAMD load-balancing scheme needs improvement: to enable scaling from todays 500.000 to many millions of cores in the future. Anyway, for both Zettaflop monolithic and Cloud supercomputer based bacterial biofilm simulations, we have to wait at least until the end of the next decade.

Information System of the Institute for Blood Transfusion of Montenegro

Doc.dr Adis Balota

Faculty of Information Technology, Podgorica, Montenegro; adis.balota@unimediteran.net

Abstract - **This paper presents a developed Information System of the Institute for Blood Transfusion of Montenegro, which functions within the Integrated Information System of Healthcare System of Montenegro. Introduction of IT support of transfusion activity provides better availability and accuracy of data on blood donors in the healthcare system, as well as tracking the blood supply in a centralized manner on the level of the state of Montenegro.**

By introducing the bar-codes on drawn blood units, Information System of the Institute for Blood Transfusion has ensured compliance with the basic transfusion principle of tracking blood from 'the donor's vein' 'to' 'the recipient's vein'. Information system will increase the possibility for control and analysis of work, rational use of resources, and it will also modernize the health statistical database from the field of blood transfusion. Administrative work of healthcare workers, which refers to multiple input of data, will be reduced, as well as the possibility of errors.

Interoperability of business processes has been fully achieved by using shared IT infrastructure of the healthcare system, and the final goal of this approach is to improve the quality, safety, efficiency, financial accountability and clinical use of blood components in Montenegro.

I. INTRODUCTION

For the purposes of the Institute for Blood Transfusion of Montenegro, information system (ISIBT) has been developed, which presents a part of Integral Health Information System in Montenegro (IHISM) [1].

ISIBT contains **business information system** (staff operations, financial operations, payroll, etc.), as well as service records and **medical information system**. Medical Information System of the Institute for Blood Transfusion includes IT support for the processes of collecting, testing, processing, storage and issuing of blood and blood components, while complying with the principle of traceability as the basic one in blood transfusion system. This allows tracking and recording blood units and blood components from donor to recipient, as well as records of side effects. By development of medical part of information system, Information System of the Institute for Blood Transfusion has been completed, which is fully integrated with the Integral Health Information System (IHIS) as a whole.

Integration involves two directions: integration on the level of Institute for Blood Transfusion and integration of ISIBT with ISs of hospitals which use blood in the treatment and with the Institute of Public Health in the part of legally defined reporting.

A. Business goals expected from ISIBT are:

1. Ensure monitoring and control of costs and quality of work as well as rationalization of activities of healthcare providers,
2. Provide a platform for exchanging information electronically,
3. Increase the possibility of systemic quality control of services provided,
4. Increase the number of available useful information required to make timely decisions,
5. Rationalization of the system of collecting health information at all levels and creation of the strategy of adaptation and integration of all health information systems,
6. Revising and modernizing the methodology and scope of collecting health statistical data.

B. Special goals of ISIBT are:

1. Greater availability and accuracy of medical information about the patient,
2. Ensure traceability - tracking of blood units from blood donor to blood recipient,
3. Better management of blood transfusion system at the national level,
4. Increase the quality of transfusion service work,
5. Automation of the reporting system to the relevant institutions of the system and international organizations,
6. Eliminate the need of multiple input of data (name, surname, ID number, ...)
7. Reduce errors in work through introduction of automation during the input,
8. Integrated collection of information necessary for efficient management,
9. Reduction of administrative work,
10. Reduce the consumption of resources and time by reducing unnecessary printing of paper.

II. SYSTEM DESIGN

Integrated Health Information System of Montenegro integrates in its composition nine different subjects which use the same shared IT resources [1]. The shared resources involve great number of codebooks, databases, server and network communication equipment. Table 1. presents current number of locations, number of computers and number of application users per individual developed information system.

TABLE 1. DEVELOPED INFORMATION SYSTEMS

Information system	Number of connected locations	Number of computers in the system	Number of application users
Health Insurance Fund	21	212	194
Pharmaceutical institution Montefarm	45	125	314
Health centres	60	1092	2145
Institute for Emergency Medical Service	19	30	291
General hospitals	7	572	1386
Dentistry	170	190	341
Institute of Public Health	1	150	154
Agency for Medicines and Medical Devices of Montenegro	1	30	36
Institute for Blood Transfusion of Montenegro	9	50	62
	333	2451	4923

Table 1. shows that the Institute for Blood Transfusion is organized through 9 dislocated units.
The implemented information system of the Institute for Blood Transfusion, among other things, provides:

1. Unbreakable chain of business processes, activities and information from the moment of drawing blood from donor to blood recipient,
2. Full integration with the existing IS in the Institute (Business Information System),
3. Full integration with institutions in the healthcare system of Montenegro,
4. Integration with institutions outside the public healthcare system (private hospitals and clinics),
5. Integration with the Health Insurance Fund,
6. Integration with the Institute of Public Health,
7. Integration with the Ministry of Health,
8. All the records will be based on valid and structured medical documents or a version thereof, where necessary,
9. Management of blood supplies and blood components on the basis of information on supplies in all organizational units of the Institute, as well as of the current needs (requisitions) by all parameters.

Figure 1. shows a schematic representation of the concept of 'unbreakable chain' of business processes, activities and information from the moment of drawing blood from donor through the stages of processing, storage, and distribution to the final stage, i.e. the blood recipient. This chain, i.e. all the stages that are listed represent the so-called 'Traceability'.

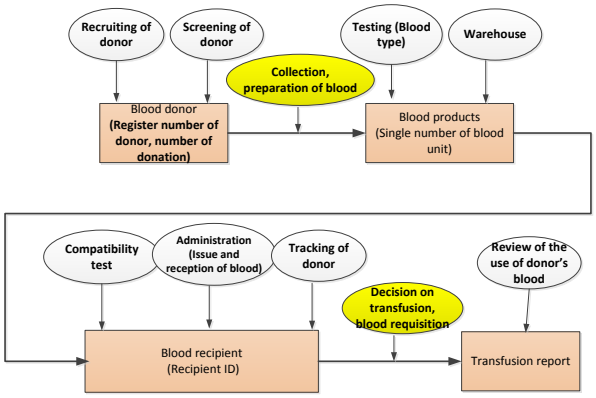

Figure 1. Unbreakable chain - traceability

Figure 2. shows a schematic representation of unbreakable chain in terms of the tracking process.

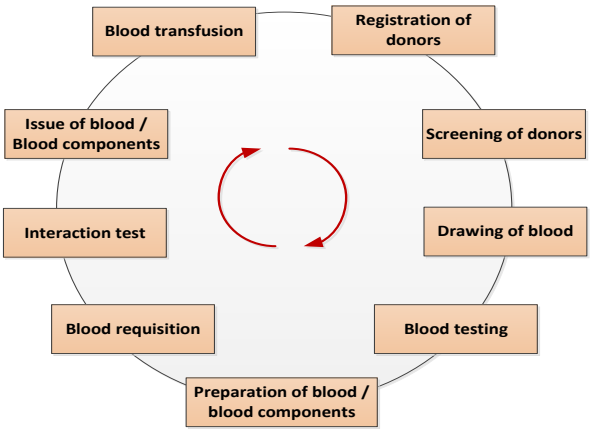

Figure 2. Unbreakable chain – process of tracking blood units from donor to recipient

Figure 3. presents logical connectivity scheme of IHISM

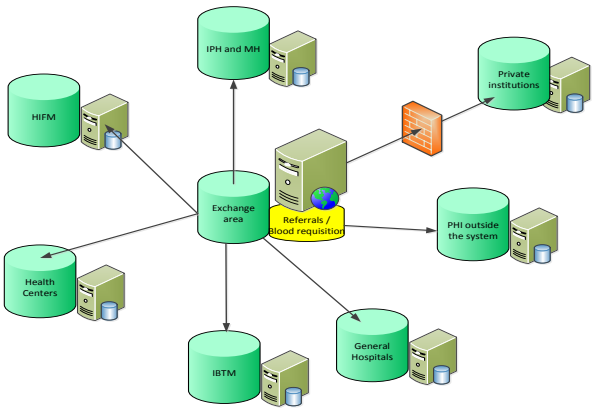

Figure 3. Logical connectivity scheme of IHISM

IT support of business processes in the Institute provides the establishment of basic registries and continuous functioning of main business functions:

1. Forming of Registries of blood,
2. Preparation of blood, processing and testing,
3. Storage and distribution of blood and blood products,
4. Preparation of blood for testing, interaction and issuing of blood,
5. Record of laboratory services,
6. Registry of blood donors.

Information System in the Institute has a function to track all the processes related to blood transfusion through all its stages, i.e. tracking of blood by the principle from the donor's vein to the recipient's vein. Special advantage of this concept represents a considerable increased level of achieved safety of blood, as well as the best way of achieving the principle of traceability of blood. Critical events may occur in the process, for example, side effects on blood transfusion, incompatibility of donor and recipient, disease transmission, etc. That is why it is necessary to provide accurate and reliable information on tracking of blood and blood products.

Implementation of information system of the Institute has allowed creation of a unique database of blood donors, i.e. Registry of blood donors.

Electronic record of blood donors (Registry of blood donors), represents a basic view of the organization of database and complete CORE application of IBT IS.

Figure 4. presents the design solution where the donor is traced from the moment of their occurrence in the system, all their activities related to blood donation, testing, processing, to final transfusion, or disposal due to date expiration [4].

According to the design solution, the data of donor are accessed with use of ID (identification number) or a unique registration number, and the administrative part of data and any other specific data become available if the user is authorized to receive such information.

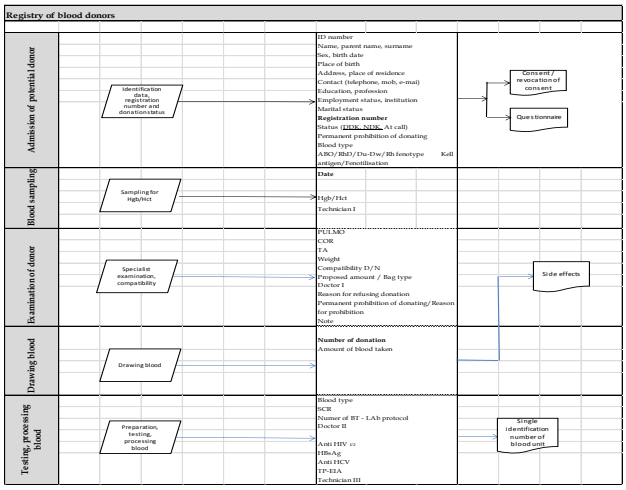

Figure 4. Registry of blood donors

Thus organized unique and centralized blood donors registry provides multiple functionalities, as follows:

- management by recruiting new donors, either from mobile collection points, in hospitals or centrally in the Institute for Blood Transfusion,
- research of the suitability of existing blood donors, whether it be the voluntary blood donors or blood donors at call.

Figure 5. is a block diagram of Registry of blood donors.

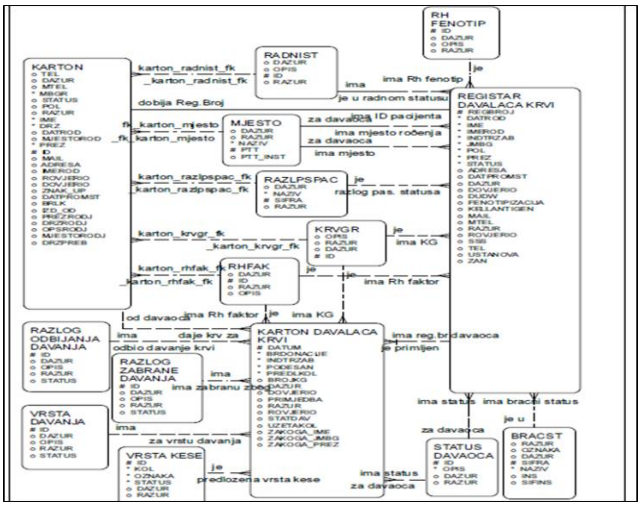

Figure 5.ERD – Registry of blood donors

I. NECESSARY PRECONDITIONS FOR THE FUNCTIONING OF ISIBT

For the implementation of software solution it was necessary to provide a direct exchange of data with the registries and codebook systems that are already formed within the Integrated Health Information System of Montenegro, and which are maintained by the Health Insurance Fund of Montenegro. Integration is achieved with the following registries: Registry of the insured, Registry of healthcare workers, Registry of healthcare institutions, Registry of drugs by ATC classification, Registry of diagnoses [2]. All locations of the Institute for Blood Transfusion are connected to server infrastructure Central office through MPLS transport links. Technical solution has also been developed for the mobile teams work, which collect blood units on the field in the form of organized actions, and which exchange information using 3G signal. Also, all departments of Hospital and Clinical Centre of Montenegro are associated with the system of the Institute, and the user application is provided, through which the data are exchanged for hospital patients with the Institute for Blood Transfusion.

This operating mode, i.e. online mode, guarantees high flexibility and availability of IS, as well as security of data and information. Also, information are taken at the place of their origin and they can be seen only by the participants in the system that have been granted the right. Hence, once entered data is no more re-entered, which significantly shortens the time of administration, as well as the possibility of errors in the administration.

II. FUNCTIONAL REQUIREMENTS

It is essential that ISIBT covers all the fields that the Institute involves, according to legal and other acts. On the basis of that, functional units of the Institute for Blood Transfusion IS are clearly identified. In order that the information system achieves its projected function, possibility of the following basic records is provided:

1. Record of blood collection,
2. Record of preparation of blood components,
3. Record of blood processing and testing (immunohaematological blood tests and tests for infection diseases) – for hospitalized patients and outpatients,
4. Record of blood storage and blood components,
5. Record of blood requisition and blood components by health institutions,
6. Record of blood requisition for the patient, tests, interactions and issues of blood by organizational units,
7. Record of issue of blood and blood components per patient (recipient).

Functions under the numbers 1-4 are in the organization of the Institute and responsibility of the Service for collecting blood, blood component preparation, testing, processing of blood units and distribution, except from number 3 for outpatients, which is the responsibility of the Service for laboratory and other diagnostics.
Functions under the numbers 5-7 are the responsibility of the Service for clinical transfusion and therapeutic services per units of the Institute which are at 9 locations.

The main function in the future functioning of the Institute is to unify blood banks in Podgorica, as the central warehouse, with the existence of auxiliary warehouses by locations (in Podgorica and within seven General hospitals and specialized hospitals in Risan).
Figure 6. shows the procedure of blood distribution and blood components in the Institute.

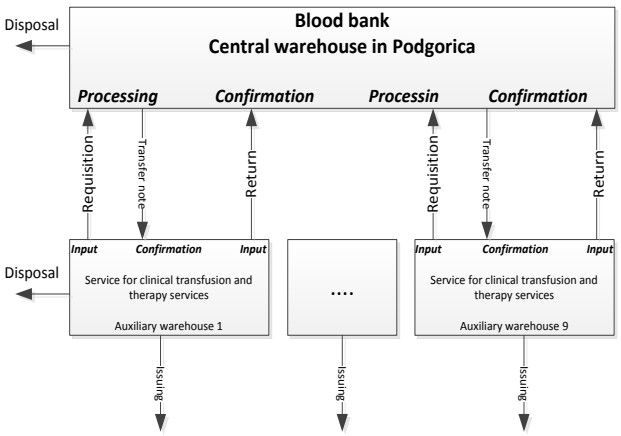

Figure 6. Procedure of blood distribution and supporting documents

In order to achieve the proposed model of establishing a centralized blood bank, it was necessary to provide a single identification of each blood unit (or component) to the level of the whole Institute, which was done.
All the necessary procedures of requisition and distribution of blood have been defined and adopted, as well as the internal documents that will accompany the requisition and distribution of blood, as well as their record within the Institute IS.

Figure 7 shows a schematic representation of the procedure for collecting blood from a potential donor.

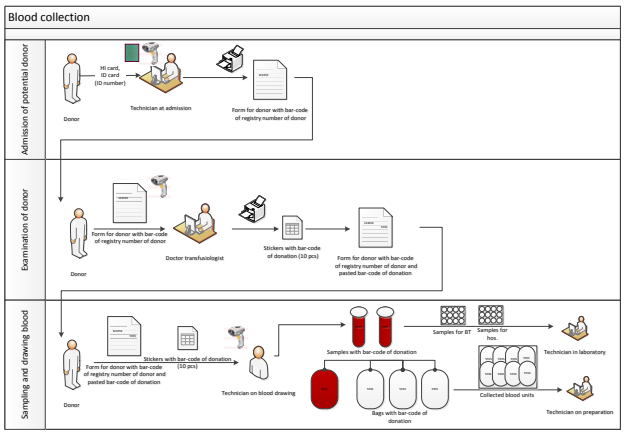

Figure 7. Procedure for collecting blood

III. CONCLUSION

By introducing bar-codes on drawn blood units, the implemented Information System of the Institute for Blood Transfusion provides compliance with the basic transfusion principle of tracking blood from donor's vein to recipient's vein. The information system covers all business functions of the Institute, and it also provides full integration with other parts of the health system. The system provides higher availability and accuracy of medical data about the patient. Also, registry of blood donors is developed, and a single electronic record for blood donors is implemented. There is also provided easy management of the storage of blood supplies and blood components, which is now centralized. Integrated collection of information for the management is achieved, which is necessary for efficient management.
The administrative work of healthcare workers, which refers to multiple input of data, will be reduced, and the possibility of errors. Modern transfusion system requires efficient and adequate information system in order to further improve the quality and efficiency of transfusion service in Montenegro. Developed information system of the Institute is one of the main parts of the Integrated Health Information System of Montenegro. The main task of the system is to improve the quality, security, efficiency, financial accountability and clinical use of blood components in Montenegro.

TELECOM MARKET AND REGULATIONS

Effective Strategies for Implementation of Customer Experience Management in MSPs in Bosnia and Herzegovina

N. B. Ćurguz* and D. Ilišević *
* Telekomunikacije RS A.D., Banja Luka, Bosnia and Herzegovina
natasa.banovic-curguz@mtel.ba, dijana.ilisevic@mtel.ba

Abstract – One of global trends and key areas of interest for mobile service providers (MSPs) today is introduction of Customer Experience Management (CEM). MSPs that build high-performing networks, recognize and predict user's needs, provide real-time information and offer more innovative services will secure their market position.

In this paper, we have presented short overview of three different approaches for CEM implementation in telecom area. We have analyzed current state in performance/customer management segment for mobile service providers in Bosnia and Herzegovina in terms of giving the most important CEM recommendations.

I. INTRODUCTION

Many different network and system modernization and transformation programs have been implemented by the region's mobile service providers (MSPs) in order to migrate towards full service operation whilst attempting to balance improvement of service levels and at the same time increase revenues and customer loyalty. While the traditional mobile and broadband services still account for most of MSP's revenue, there is a significant growth in new services such as IPTV, online gaming, Internet search, social networking and digital music. Services are consumed through increasingly various devices and they are also more interactive, in real-time, with online gaming, chat, VoIP, social networks. As quickly as customers can consume data, more data is produced. For the last few years, mobile operators have been talking about developing new sources of revenue since the costs of voice and data services are being constantly pressed through competition. This driver, combined with technological advances, has led to new products, services and markets, as well as innovative approaches for operational efficiency. These can be summarized as machine-to-machine and cloud based services, analytics for marketing and monetization of consumer data, shared networks, operational efficiency, and growth into broadband services to complement existing services and generate new revenue.

Service assurance investments are currently focused on improving customer experience. Mobile suppliers are putting greater importance on solutions supporting customer experience than ever before. The transition to service operations centers is creating a demand for unified service assurance solutions that combine performance, fault and service management functions. Heavy investments into network maintenance and upgrade are not the only way to improve network performance and services. Another option is forcing more effective internal processes and their management in terms of monitoring, controlling and predicting service levels along all touch points in the customers' lifecycle.

The new approach requires a greater focus on the customer point of view. The performance of a service is not only measured based on a set of underlying systems and network elements working correctly, but also based on customers' perception. Customer Experience is defined as the sum of all experiences a customer has with a company, over the duration of their relationship [1]. From customer's point of view the main reasons for telecom services churn are pricing, poor coverage, voice quality, data connection speed and reliability, billing accuracy, ease of recharging/reloading of prepaid credit and service bundling offer. In order to reduce the churn rate, MSPs have to scale down their efforts to the individual customer level. New processes have to monitor Quality of Experience (QoE) based on individual customers. With customer oriented Operation and Maintenance (OAM), greater importance is attached to customer QoE. All OAM resources are centered on improving customer experience. The difference between traditional network oriented and customer oriented OAM is given in Table I, [2].

TABLE I. THE DIFFERENCE BETWEEN CUSTOMER ORIENTED AND TRADITIONAL NETWORK ORIENTED OAM.

	Network Oriented OAM	**Customer Oriented OAM**
Orientation	Equipment or network oriented	End-to-end service or customer oriented
Focus	Network performance and fault	Quality of Experience (QoE)
Assessment	Key Performance Indicator (KPI) dominated	Customer Experience Index (CEI)→Key Quality Indicator (KQI)→ Key Performance Indicator (KPI)
Analysis	Bottom-up approach	Top-down approach

II. CURRENT STATE IN B&H

The global changes in telecom sector are reflected on the market in B&H. The environment is changed around the telecom operator, including the customer needs, the competitors and the regulators. Even in conditions of complex political structure of B&H with weak economic growth and very specific market, official data of Communication Regulator Agency shows that there is a potential for growth. The level of penetration of mobile telephony in B&H at the end of 2013 is 90.79%, [3]. That is much less than in neighbouring countries and EU. The ratio Contract/Prepaid shows that there is a low level of confidence between customers and operators. That is a huge potential for growth of contract users.

But, mobile operators in B&H cannot compete only on the basis of price and network quality. They try to adapt their services to the customers in order to increase loyalty and profit. If mobile operator wants to be the customer relationship leader in the field, also must take into consideration many of the specific contexts and cultural changes on B&H market to achieve this ambitious objective, [4]. Customers increasingly adopt smart phones, tablets and a variety of new mobile broadband services. Also, customer expectations can change according to their position in the relationship cycle.

In MSPs in B&H conventional vertical management structure is used for network operation and maintenance. The focus of service performance has been on the measurement of network operations performance. Mobile operators use traditional network oriented operation and maintenance (OAM) concept. Key performance indicators (KPIs) are based on alarm, performance, and network configuration data; analysis data from active/passive probing and packet capturing, and billing data. A dedicated network, such as a radio access network (RAN), core network (CN) or bearer network, has its own proprietary element management system to ensure network availability and QoS. KPIs for CN, RAN, and IP bearer networks can be very high. This means the network quality is excellent. However, it may be that calls are dropping in an abnormal cell. Customers in this cell may be experiencing very bad service, but this low-quality cell is covered by other cells with high KPIs. Therefore, network KPIs do not necessarily reflect end-to-end QoS and should not be the sole basis for enhancing QoS. High network KPIs do not necessarily mean good QoE.

Mobile operators in B&H mostly implement Customer Relationship Management (CRM) that is in charge of managing the company's interactions with customers. The methodology employed by CRM mainly focuses on sales activities, marketing, and business procedures, not taking into account the customer needs on the service quality. As a result, there is a large gap between the approach of the company and customer's expectations. CEM has the potential to overcome the limitations of CRM to deal with common customers' technical problems and performance issues of services. The differences between CRM and CEM are given in Table II, [5].

TABLE II. THE DIFFERENCES BETWEEN CRM AND CEM.

	CRM	**CEM**
Who	Target user –Sales	Target user -Marketing
What	Manage and automate the sales pipeline, store interactions with customers and prospects.	Understands the customer life cycle and provides personalized experience in all touch points.
Why	Increases satisfaction by providing better services and manages sales pipelines.	Increases loyalty, ROI and reduces churn.
How	Mostly a singular viewpoint.	Gives a general overview of the customer life time-value

CEM approach is designed to focus on procedures and a methodology to satisfy the service quality needs of each end-user. Every time a company and a customer interact, the customer learns something about the company. In CRM approach it is vice versa. In large organizations, CRM and CEM should work side-by-side and exchange customer data while each focuses on a different area of the business, [6].

III. THE TRANSITION FROM NETWORK PERFORMANCE MEASUREMENT TO CEM

A. Proactive approach

Real-time monitoring and preventive assurance on service quality and customer experience helps MSPs to have an improved experience in a short time. As it is given in [7] MSPs should shift the focus from traditional KPIs to end-user experience and from reactive response to proactive and predictable maintenance. This CEM solution focuses on proactive customer care for high-value customers, experience improvement for unsatisfied users and market intelligence analysis for the operator.

High-ARPU individuals, roamers, and enterprise groups can all be classified as high-value customers. The proactive approach in identification of problems prior to the receipt of a customer complaint, helps to time user-operator interactions so that satisfaction and loyalty are maintained. This CEM solution provides various means of identifying potentially unsatisfied users. The methodology is to identify a KQI threshold (from subjective customer survey) and an objective KQI association, and then identify the root causes/factors. Market analysis must integrate subjective inputs, such as customer behaviour and user satisfaction surveys which are the most commonly accepted method for assessing customer loyalty. To avoid extreme answers, [7] suggests operators using customer experience index (CEI) that

involves the tracking of customer behaviour, and can be used for tracing and checking individual survey results.

This CEM solution delivers the following key benefits: transformation from network-centric to service/customer-centric operations, proactive and efficient care for high-value users to maintain or improve their satisfaction and loyalty, creating a lifetime value and revenue, reduced churn through proactive identification and problem resolution for potential unsatisfied users, precise and measurable marketing campaign, reduced revenue loss through proactive fraud management.

B. Holistic approach

Customer Experience Management is defined as a holistic approach taken to monitor, measure and improve all aspects of customer interactions between the operator and the customer, [8]. Five distinct stages in the customer lifecycle are identified: initial experience (relating to product selection and signup), billing and payment process (including the related terms and conditions), account management (the ease of which information can be accessed), service and support (the ability to rapidly resolve any performance or technical issues), loyalty building (ensuring regular personalized rewards for ongoing loyalty). Identifying what is important in customer relationship requires careful consideration of each step of the lifecycle in order to be able to address any planned improvements.

The approach, recommended in [8], includes three fundamental steps to realize customer experience management concept. As it is shown in Table III, it includes identifying what is important in the relationship with the customer, monitoring those interactions and defines a clear transformation lifecycle to improve customer experience.

TABLE III. KEY QUESTIONS OPERATORS NEED TO ANSWER, IN ORDER TO FOCUS ON CE.

	Key question
Identify	What are the most important elements affecting my company's customer experience?
Monitor	How can I measure those interactions through the customer lifecycle?
Transform	How can I implement improvement programs that deliver financial benefits?

MSPs need to identify and determine the relevance of each interaction with customer and correlate satisfaction with importance. Also they need to develop quality indicators that can bridge from customer interactions to specific network and indicators, allowing operators to drill down from the customer plain to the infrastructure level for troubleshooting. The largest barrier is the gap between network element performance indicators (KPI) and actual subscribers' experience. As subscribers rapidly adopt smart phones and new applications, they become more demanding of their network experience. Network operation centers must be enhanced with customer experience assurance centers, enabling the accurate correlation of customer experience with network performance.

C. Extended CEM-oriented approach

Extended CEM-oriented approach that includes the technical and customer care operations departments is proposed in [9]. By involving the entire organization in the CEM strategy and processes, it is possible to manage all interactions along the customer lifecycle. In order to enhance customers' QoE, the technical and customer care departments have to redesign their internal processes according to this new model. In CEM approach all the company's units operate as a single entity in terms of the customer's perception instead that the various departments interact with the customer according to its own needs. Management should concentrate on better performance of communication between the technical department and customer care. Sharing information between departments about the status of the network and the performance of services in real-time is the only way for the MSP to guarantee a coherent and consistent QoE. The flow of information between customer care and the technical department should be bidirectional. Customer care, being directly in touch with customers, can provide the technical department with vital information about the customers' perception of service performance.

In order to effectively introduce CEM in their operations technical department should shift the focus to monitoring end to end service performance and customer experience and put effort into predicting customer experience. Also, it is necessary to introduce new processes and tools to monitor a new set of values that are known as Key Quality Indicators (KQIs). This approach provides a more reliable view of faults and service issues and their impact on service. Put effort into predicting customer experience to move from a traditional reactive model to a predictive one using advanced proactive model. Technical department listen not only to complaints, but to the whole customer base, correlating customer satisfaction and expectations, monitored by the KQI and/or periodical surveys (including structured surveys and unstructured social media sources), to the KPI values of the operating performances.

Accessibility and ease of use, response effectiveness and operations efficiency are fundamental drivers in designing a customer care strategy that maximizes the QoE offered to the customers [9]. Enhancing the accessibility of MSP's services in terms of the CEM means: offering multiple channel access to customer care services (social networks, live web, chat), providing a uniform view of their customer care and simplifying the process to receive support and information. Communicating information about scheduled interventions automatically may improve the performance of service, reducing customer complaints. Effectiveness in customer care services means enhancing of the quality of the information MSPs provide throughout the customer care services. Customer care operators should be able to

access a complete view of the customer during the support process and provide real time information. This requires all the internal information systems to be deeply integrated and interconnected, in order to establish an efficient internal communication flow between customer care and other departments. Monitoring and predicting QoE enables the anticipation of future customer needs.

All three above-mentioned solutions suggest proactive customer-centric model that includes analyzing of customer behaviour and user satisfaction surveys. Traditional indicators should be integrated with additional information. Make an effort into predicting customer experience to move from a traditional reactive model, in which technical operations only track customers' complaints and the company's subsequent response, to a predictive one is essential. In the predictive model, technical operations merge data from business, technical and even social media, in order to predict customer expectations and habits and effectively focus investments in CEM. Customer Care becomes more relevant with advanced devices and services. CEM makes easier than ever for operators to hear "the voice" of their customers and manage the customer experience. Defining and executing a business transformation program across the organization to address key areas of improvement is a critical step. Customer experience improvement program must be driven across the whole organization and involves multiple different processes, systems and domains. In according to [9] this can be achieved by making the technical department a key enabler in the process.

D. CEM Metrics

Customer experience metrics are aggregate calculations derived from survey results. They allow consistently performance monitoring over short and long term periods as well as performance comparing across all channels, [11]. There are different strategies for selecting proper types of CEM metrics to use for a customer experience program. They are evaluated in [12]. With numerous metrics to choose, MSPs can tailor what they would like to measure about their customers' interactions and develop solutions for improvement. It is essential to choose metrics that make the most sense for the company. Very effective metrics are:

- Customer Satisfaction (CSAT) directly measures how satisfied customers are. This classic metric makes it possible to measure and improve how happy customers are.
- Customer Effort Score (CES) is used to measure how much work is required of a customer to solve a problem. CES has its main strength in measuring the smoothness of experience customers have specifically in an interaction touch point. It is easy to link with internal metrics, such as number of calls, number of transfers on a call.
- Net Promoter Score (NPS) identify promoters, those who speak positively about the company, the detractors, those who speak negatively about it, and those who are passive. NPS is able to measure the percentage of customers who would put their own reputation on the line and recommend the company to others, which is the highest form of loyalty.
- General Question Index & Customer Experience Index (GQI&CEI) are used to measure the strength of a customer's experience with a company. GQI&CEI contain multiple questions and can be customized through weighting, allowing some questions to carry greater influence depending on the decisions of the company.
- Voice of Customer (VoC) programs are about continuous consideration of customer expectations, needs and wishes in company's business. In addition to market research surveys, VoC programs include customer data such as feedback, reclaims and also employee input.

In most cases, the best solution is to use a combination of metrics. In a multichannel environment, the challenge is determining customer expectations for each channel and understanding how they may evolve. It is important to listen the voice of every customer, everywhere and all the time. Real-time feedback from a variety of touch-points, including structured surveys and unstructured social media sources, is scaled and integrated with network's data, pushing relevant insights to all levels of business.

IV. B&H PROPOSED CONCEPT

Over the years, MSPs in B&H invested in CRM systems, but in too many cases the expected returns were not clearly visible. CRM alone can not improve loyalty and ARPU, because there is no single CRM application that can deliver all requested functionalities. CRM should be a part of an overall CEM strategy, because CRM and CEM complement one another. Based on analysis of three presented CEM concepts we recommend that mobile operators in B&H apply the combined model of previously mentioned approaches. CEM needs to be established in practice across all functions of the company with the engagement of all staff.

Introduction of CEM is a complex organizational transformation for all MSPs in B&H. The complexity of MSP's organizations is in fragmented systems, multi-vendor environments, multiple service/network layers and regulatory obligations. All of them present numerous challenges to CEM introduction. These challenges can be broadly grouped under the categories of defining, measuring and improving customer experience.

Customer experience management means handling not only the technology and the people involved, but the processes as well. CEM process consists of reactive and proactive part, as it is shown in Figure 1, [10]. MSPs need to identify which customers, products and channels

are the most profitable and determine what changes would increase that success. When compared to the traditional approach of collecting vast amounts of system logs and data points, and then attempting to correlate this vast amount of data, carefully defined measurement and monitoring enables operators to be proactive and take corrective action before customers even notice. This approach makes it possible to identify potential revenue threatening situations as well as network abnormality. MSPs need to control all interaction channels along the customer lifecycle, from service delivery to post-selling and complaint management. The priority must be improving the communication flow between the technical department and the various business functions.

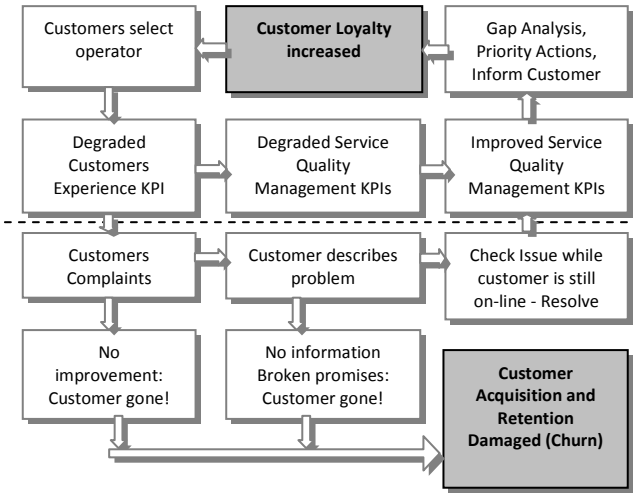

Figure 1. The Customer Experience Management Process, [10].

MSPs in B&H need to start looking at the network from the viewpoint of the quality of services delivered to the end customer. The traditional network/resource perspective, typical for fault and performance management systems, needs to be transformed. This transformation aims to translate network faults and metrics into customer service issues and metrics KQIs. Unlike KPIs, that "speak a technical language", KQIs are designed to "speak the customers' language". This means that MSPs need to measure service quality from the same perspective as the customer. The augmentation of the performance management systems with service quality management should translate technical network metrics KPIs into customer service metrics KQIs. Using the existing performance management systems entails two main benefits. Firstly, it is avoiding unnecessary investments, and secondly, service quality management is built over performance management systems, enabling customer experience issues to be tracked down to the cause of network performance problems, which is essential for end-to-end customer experience management.

A. Challenges and recommendations

In order to ensure high level of service performances MSPs in B&H need to follow this new approach: compose a complete register of services prioritized by economic relevance, compose a register of platforms and network elements underlying any service, define a register of Service Level Agreements (SLA)/KQIs for each service/customer segment, describe the end-to-end process of every service, define a technical fault prioritization matrix according to service impact. The objective of this kind of monitoring is to have real and continuous knowledge of service performance, enabling the immediate resolution of any technical problems that may have a negative impact in real time.

Improving the customer experience is a complex project that requires cooperation among different departments within an organization. MSPs in B&H have to redesign their organization according to these new trends:

- Operating an open, transparent and reputable business.
- Investing in more staff training (continues training of customer-facing employees, aligning each employee with the organization's customer-centric culture).
- Integrating all the workflows in one solution.
- Using innovative knowledge management tools with real-time update.
- Applying customer-centric behaviours and coaching across multiple touch points of interaction (incl. internet, mobile applications, interactive voice response IVR).
- Providing customers with a personalized experience. The customers should always receive the most updated coherent and consistent information from customer care across all touch points.
- Providing prompt responses to customers (inform him/her about taken actions to resolve problem).
- It is important to simplify the process of receiving support and information. Reduce the number of steps that customers have to perform to get the information they need.
- Measurement and evaluation of customer's emotions using most suitable metrics to gain feedback (comments, reactions). Predicting future customers' needs. It is essential to choose metrics that make the most sense for the concrete company.
- Automatization of processes. Reducing the number of escalations to back office through redesigning the front office role. Front office should be able to handle problem troubleshooting, provisioning verification and handling tickets.

In the case of customer experience, a transformation program takes an even more important role. A significant aspect of the transformation is enabling integration with BSS systems. It is important to automatically find, what network problem is causing the issue and start the process of problem resolution. This way, when a customer issues a complaint, he can at least be provided with information that the problem resolution is already in progress. Ideally the process should be proactive. Also KQIs can be used

to define SLAs with customers. When any extra fees for service quality apply, the customer is aware of what he is being offered for the extra money.

V. CONCLUSION

As mobile operators migrate towards full service operation, market competition is becoming fiercer. Today, operations need to be more focused on the business and customer perspective, shifting from network performance measurement to measurement and control the whole end-to-end experience that a customer has when using a service. Implementing CEM in MSPs in B&H is imperative in order to provide superior telecom services and to manage churn. This can be achieved by integrating CEM efforts throughout the organization. It requires making a larger investment in people and processes as well as technology.

Regulatory Aspects of Child Online Protection

Suada Hadžović, Dragana Šerval and Saša Kovačević
Communications Regulatory Agency of BiH, Sarajevo, Bosnia and Herzegovina
shadzovic@rak.ba

Abstract - Every day, children around the world are exposed to many online dangers. In this paper we try to give an overview and comparison of current EU and BiH regulatory measures and self-regulatory activities regarding the protection of children against child pornography and other forms of sexual abuse and exploitation through information and communication technologies.

Communications Regulatory Agency of BiH like regulators in EU does not have jurisdiction to regulate Internet content, but it has responsibility for protecting the interests of end users of telecommunications i.e. children as the most vulnerable groups of end users too. Additionally, Communications Regulatory Agency of BiH has been involved in drafting state level action plans in order to improve the system for combating child pornography and other forms of sexual exploitation and abuse through Information and Communication Technologies in BiH.

In the view of recently adopted regulations and the latest action plan, it is expected significantly improving the level of protection of children on the Internet in BiH in the future.

I. INTRODUCTION

According to the Communications Regulatory Agency of BiH (CRA) Annual Report – Survey, licenses for providing Internet services in BiH in 2013, there were 2,188,429 Internet users in Bosnia and Herzegovina in 2013. There was a certain increase in the number of Internet users in 2013 compared to the year 2012 with an index equal to 100.65. In addition, the Communications Regulatory Agency estimated that the rate of utilization numbers of Internet in Bosnia and Herzegovina for 2013 is 56.96% [1]. Having in mind that research has shown that children in front of computer are in three times more danger than those on the street [2], adding the constant increase in the number of Internet users, the number of children who are exposed to risks on the Internet is dramaticaly increasing.

Riscs children face when accessing the Internet are numerous. One of the classification is the following [3]:

1. Content (Child as recipient of information):
   - Advertising, spam, gaming;
   - Violent/hateful content;
   - Pornographic/harmful sexual content.
2. Contact (Child as participant in communications):
   - Child being bullied, harassed or stalked;
   - Tracking/ harvesting personal information of children and misuse of this data, blackmailing;
   - Self-harm, unwelcome persuasion;
   - Child groomed online for sexual abuse offline;
   - Child sold online for sexual abuse both online and offline;
   - Child made the subjects of child abuse images;
   - Child abused through prostitution using the Internet and mobile phones;
   - Adults or young people who engage in 'cyber-sex' with children.
3. Conduct (Child as actor initiating abusive or risky behavior):
   - Creating/ uploading pornographic material;
   - Bullying or harassing another person;
   - Young people sharing personal information online;
   - Young people who place (indecent) images of themselves or other young people (unwanted) online;
   - Children who download sexually abusive images of children;
   - Children meeting 'friends' online.

This article is structured as follows. Following this introduction, Section II provides a brief overview of the recently adopted CRA rules as well as action plans concerning the protection of children on the Internet in which drafting and implementation CRA was involved. Part III performs linking EU Kids Online classification of countries in regard to the protection of children on the Internet and its mapping to BiH. Part IV is devoted to aspects of self-regulation mentioning some of the major initiatives in the EU and gives an overview of the situation in BiH. Part V represents a conclusion.

II. REGULATORY AGENCY INVOLVEMENT IN CHILD ONLINE PROTECTION IN BIH

Communications Regulatory Agency of BiH does not have jurisdiction to regulate the content that is available on the Internet. However, under the protection of end users, the CRA rules are dedicated to protect the most vulnerable groups of users, i.e. children, such as the following [1]:

- Rule 60/2012 on providing service of Internet access („BiH Official Gazette", No 36/12). According to the article 8.2 of this Rule, Internet service provider (ISP) is obliged to disable access to the Internet addresses for which is, by such special regulations or decisions of the competent institutions in BiH, determined to be harmful and unlawful. This specially refers to dissemination of child pornography and similar harmful contents, illegal

online gambling, dissemination of computer viruses or harmful programs, unlawful obtaining of personal data, dangers to public safety, unlawful use of computer programs and applications, as well as other dangers to safe use of the Internet. Therefore, if online content is declared to be harmful by the court or other competent authority, CRA is obliged to order ISPs to withdraw such content from webpages that are stored on its servers.

- Regulation 69/2013 on conditions of providing public communication services and end-users relations („BiH Official Gazette“, No 28/13). According to the article 9.2 of this rule, CRA obliges ISP to include minor protection provisions in their subscriber's contracts and also terms and conditions. Additionally, through Article 36 of this rule, CRA requires ISPs to take all necessary measures to protect minors. In order to protect end users, compliances with the Rule 69/2013 have been made, so, CRA has in past carried out an inspection of general business conditions, subscription contracts and tariffs for more than seventy operators. ISPs suggested that in the forthcoming period, their websites make and put guidelines in order to protect users on the Internet.

Additionaly, Communications Regulatory Agency of BiH has taken an active part in drafting action plans in order to improve the system for combating child pornography and other forms of sexual exploitation and abuse through IT technology in BiH. These action plans are:

- Action Plan for the Improvement of Protection System in the area of Child Pornography and other forms of Sexual Exploitation and Abuse of Children through Information and Communication Technologies in Bosnia and Herzegovina 2010 – 2012. This action plan was adopted by Council of Ministers in December 2009, and covered initiatives on prevention, harmonization of domestic laws, strengthening of institutional capacities, cooperation with ISPs, and providing support to the victims.
- Action Plan for Protection of Children and Prevention of Abuse through Information and Communication Technologies in BIH for the period of 2014-2015, which is an extension of the first 2010-2012 Action Plan, has been adopted by the BIH Council of Ministers on 4 April 2014. This Action Plan includes many activities that relevant authorities in BiH will implement by the end of 2015 in order to ensure efficient mechanisms of protection of children against pornography and sexual exploitation through technology.

The strategic objectives of new Action Plan that include Communications Regulatory Agency are following [4]:

- The strategic objective A2. Amendment to the Criminal law and alignment of subordinate legislation in Bosnia and Herzegovina. Activity A-2.3. Creation of feasibility study and the possibility of implementation of the program called "black list" which would contain information on domains where are facilities of violence against children through information and communication technologies located.
- The strategic Objective B2. Capacity building of ISPs and cooperation with law enforcement agencies and justice institutions. Activity B-4.1. Establishing cooperation between ministries of interior, the juridicial authorities, ISPs and CRA in order to treat the phenomenon of violence against children in ICT. Activity B-4.3. Creating uniform guidelines on the treatment of ISPs in cases of detection pages that show violence against children.

Communications Regulatory Agency of BiH actively participates as a member of the Safer Internet Day (SID) Committee in the preparations for the celebration on a Safer Internet Day in BiH. This body is formed in 2011 with the aim of implementing preventative and promotional activities for the protection of children and youth in their use of information and communication technologies. The committee is headed by the Coordinator for Combating Trafficking in Human Beings and Illegal Migration, and its members include representatives of the CRA, IFS-EMMAUS, Save the Children, OneWorldSEE, and Microsoft BiH. Safer Internet Day celebration is just one in a series of activities that these organizations, individually and jointly, have implemented with the aim of educating children and parents about the risks that the Internet brings, and how to adequately protect themselves from them.

Safer Internet Day 2015 in BiH was celebrated on 10 February, under the slogan „Let's create a better Internet together" through collaboration with partner CSO „Center for Missing and Exploited Children" (CNZD) from Osijek, Croatia, and through the development of special web site (www.boljiinternet2015.com) including applications for online competition for children of primary schools on Internet safety. The competition consisted of an online quiz with questions related to safe use of the internet, which was active on the February 10th. Winners were chosen randomly from participating children who had answered at least 80% of questions correctly, and these winners of prizes were announced on the aforementioned website. During the competition, through interactive maps, data was available regarding the number of children who participated in the quiz and from which cities of Croatia and BiH they came. From BiH, more then 3300 children entered the competition [5].

III. COUNTRY CLASSIFICATION

Four cluster classifications of 25 European countries that were included in the survey based on the activities undertaken, the exposure to risk and harm, and type of internet safety mediation experienced by young people across Europe, was developed by EU Kids Online [6]. A

grouping of countries in 4 distinct clusters was developed as follows:

1. Supported risky explorers (Denmark, Finland, Norway, Sweden and the Netherlands).
2. Semi-supported risky gamers (Bulgaria, Cyprus, Czech Republic, Estonia, Poland and Romania).
3. Protected by restrictions (Belgium, France, Germany, Greece, Ireland, Italy, Portugal, Spain, Turkey and the UK).
4. Unprotected networkers (Austria, Hungary, Lithuania and Slovenia).

There are cross-national differences between countries and it is concluded that some parts of Europe have better support and others receive somewhat less public support for Internet safety. Figure 1 presents ten indicators of policy implementation mentioned in EU Kids Online report [6].

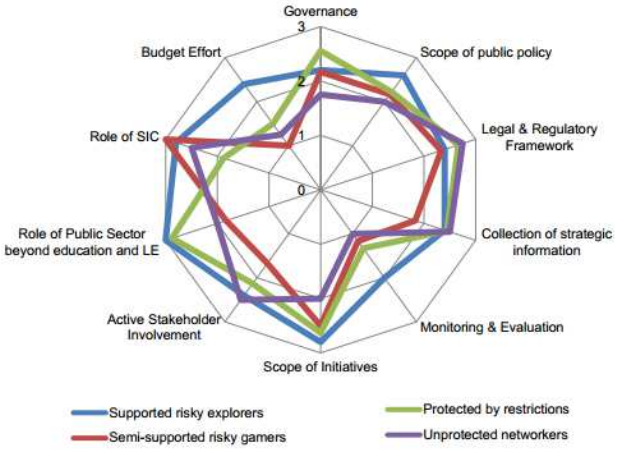

Fig. 1. Clusters comparison

In the 'Supported Risky Explorers' and 'Protected by Restrictions', countries clusters engage more initiatives in promoting safer internet practices than those in 'Semi-supported Risky Gamers' or 'Unprotected networkers'. Countries in the 'Semi-supported risky networkers' and 'Unprotected networkers' clusters shows rather uneven sort of commitments. They invest fewer than other countries, have a lower level of public sector involvement, and with less proof of coordination. By contrast, the countries in the 'Protected by restrictions' cluster have done more to create structures, and to endorse legal and regulatory frameworks around online safety even to the loss of promoting online opportunities. Countries in the 'Supported risky explorers' cluster have higher levels of public sector involvement, opposite to the Safer Internet Centers. There is more evidence of budget investment and evaluation of policy results. There are higher levels of Internet flow and digital skills among both parents and children, and a more proactive approach to arbitration.

It is also the case that countries have different starting points when it comes to internet safety: in some cases, in those countries in 'Protected by Restrictions' there is quite long history of policy involvement on the part of both the public and private sector. In other regions in Europe, developing policies and implementing strategies for Internet safety is more recent. For that reason, those parts of Europe that have had the longest experience of engaging with Internet safety policy and harmonizing the competing demands of promoting young people's opportunities while protecting against the most pressing risks provide a crucial guide for future solutions.

In terms of EU Kids Online classification, BiH belong to Unprotected networkers group of countries. But in the view of recently adopted previously mentioned rules of the Agency and the latest action plan, it is expected to significantly improve the level of protection of children on the Internet in BiH in the future.

IV. SELF – REGULATION

In line with Article 15 of EU Electronic Commerce Directive 2000/31/EC of the European Parliament and of the Council of 8 June 2000 E-Commerce Directive, ISPs are not under general obligation of monitoring information they transmit or store, nor any requirement to seek proof indicating illegal activity [7].

Despite their limited responsibility under the E-Commerce Directive, Protecting Children in the DigitalWorld report of 13 September 2011 presented a survey of EU member states, which showed that ISPs are increasingly involved in the protection of minors [8].
Then, several self-regulation initiatives have been taken by the industry at European level, for example:

Self-regulatory initiative of the European mobile industry titled The European Framework for Safer Mobile Use by Younger Teenagers and Children puts forward recommendations to ensure that younger teenagers and children can safely access content on their mobile phones. Party European mobile providers, with support from signatory content providers, have proposed an EU-wide common framework to reflect developments and to inspire all relevant stakeholders to support safer mobile use. This framework will be a subject to national implementation by party providers. As of March 2014, there are 91 party companies implementing the Safer Mobile Framework through the roll-out of national voluntary agreements, known as national codes of conduct. These codes of conduct are now in place in 27 EU Member States [9]. These recommendations relate to classification of commercial content; access control mechanisms; education and awareness-raising and fighting illegal content on mobile community products or the Internet.

A number of GSMA Europe members joined the ICT Coalition for the Safer Use of Connected Devices and Online Services by Children and Young People (''the ICT Coalition''). The ICT Coalition for Children Online is made up of 22 companies from across the (ICT) sector [10].

In 2009, leading web firms signed a European agreement i.e. The Safer Social Networking Principles to improve the safety of minors who use social networking sites [11]. But, survey of 25,000 young people in 25 European countries, published by the EUKidsOnline network, shows that some of the social networking sites

that are popular among children in Europe are not signatories to the Safer Social Networking Principles [12]

European Internet Services Providers' Association is the pan-European association of ISPs for the EU and is the largest association of ISPs in the world [13].

If we consider self-regulatory role in BIH, ISPs in BIH like ISPs in EU generally have no specific mandate regarding the protection of minors.

The situation in BiH on this is diversified, i.e. on a case by case basis. Some operators have access to this problem with extreme care and offer a pretty good solution; others are only superficially touched upon the problem and offered some solutions.

According to information collected from BiH Mobile operators and ISPs web sites, ISPs do not organize themselves and do not belong to EU or international associations focused on online children protection. Consequently, they do not have such kind of codes of conduct, but they have satisfactory terms and conditions for subscribers and subscriber's contracts that include minor protection provisions according to Article 36 of CRA Rule 69/2013 [14].

V. CONCLUSION

Online child safety is listed as one of the main priorities in Digital Agenda for Europe. Recommendations state that combinations of policies are required to deliver a better Internet for children. Legal regulation remains an option if necessary, but it should be avoided in favour of more adaptable self-regulatory tools and proper education of children, parents, teachers and others on how to to use the Internet and new technologies safely and responsibly.

Communications Regulatory Agency of BiH, like EU national regulators have no authority over content regulation of the Internet. However, regulations brought aiming to protect consumers apply also to the protection on children online. Beside, Communications Regulatory Agency of BiH was involved in many activities from which most important are those relating to the creation and implementation of action plans which aim to protect childrean online.

In EU, ISPs are increasingly involved in the protection of minors, despite their limited liability and responsibility under the E-Commerce-Directive. Relating to that, better protection of minors on the Internet requires the active involvement of ISPs in BiH too.

Abstract - Over the last few years OneM2M global initiative has been working on creation of global specification and standards for M2M. In order to facilitate the development of future M2M applications, which will be consolidated with this M2M standard, this paper compares OneM2M standard with ETSI M2M standard, which was defined by European Telecommunications Standards Institute, and presents ETSI M2M and OneM2M latest specification versions in the scope of architecture model and the functionality of the M2M platforms.

I. INTRODUCTION

The term Machine-to-Machine (M2M) denotes technologies that enable communication and networking of different devices and is a part of the Internet-of-Things (IoT) vision, whose main idea is networking of devices via the Internet.

The continuous growth of M2M technologies forced many standardization bodies, including European Telecommunications Standards Institute (ETSI), to define M2M standards and that lead to appearance of different standards. Because of the resulting situation, OneM2M initiative was formed with a goal to create a global M2M specification and standard. In the process of their creation, existing standards are also being considered including all of the existing specifications and they are being partially included in the global specification. A decision has been brought that big part of ETSI M2M specification will be included in the global OneM2M specification [1].

Since it is expected that future M2M applications will convey the global standard, it is necessary to compare architecture models proposed in ETSI M2M and OneM2M standards. This will simplify their creation and will also provide information necessary for the possible transition of ETSI standard compliant applications to OneM2M compliant applications.

Second chapter introduces overview of M2M standards. Third chapter presents architecture models of ETSI and OneM2M standards, while the fourth chapter explains in more details the functional requirements on M2M platforms. Fifth chapter brings overview of the recent most popular M2M platforms and the sixth chapter concludes this paper.

II. M2M STANDARDS

According to the Gartner's Hype Cycle the term Machine-to-Machine (M2M) has passed the peak and it is near hitting the lowest expectations trough disillusionment [2]. On the other hand the term Internet-of-Things (IoT) is at the peak inflated expectations. Lots of people do not find differences in those two terms. There is open debate on the Internet regarding that. We believe that the IoT and M2M have lots of parts that intersect but there are parts of M2M that is not IoT and there are parts of IoT that are not part of M2M [3].

The goal of IoT is to connect things to Internet by using standard IP protocols. The major focus of IoT is exchanging data, organizing data semantically and processing it. The underlying network is not in focus of IoT. In some cases things do not have to be connected to the network (e.g. thing tagged with NFC or QR code).

On the other hand, M2M is mostly focused on the system that is connected over public telecommunication network, usually mobile network. M2M focuses on how to connect machines (devices) and how it will impact mobile network because currently the mobile network is designed for exchanging large data over high speed. The machine that senses (e.g. temperature periodically) and sends measurement to the network occasionally connects to the network and sends few bytes of data. The mobile network and current protocols are not efficient in such environment because there is lots of data overhead. M2M also focuses on security of connection, identification and management of devices. Because of that all major standardization bodies such as ITU, ETSI, BBF, OMA, etc. started standardization processes.

ETSI started M2M standardization in 2008 by analyzing requirements and missing standards. The ETSI started defining M2M platform that will serve different verticals (smart metering, e-health, transportation, manufacturing, facility management, etc.). The ETSI did not try to standardize parts that other standardization bodies already standardized. The ETSI members involved in other standardization bodies were actually representing needs of ETSI M2M and were proposing solutions in BBF, OMA, 3GPP, etc. ETSI published first release of standard in 2011, and second release in 2013. The ETSI is European standardization body and the need for standards in the whole world was growing. In 2012 ETSI organized consortium of 7 standardization bodies from different continents and started project OneM2M in the similar organization as 3GPP. The goal of OneM2M was the same as for ETSI M2M but on the global scale. The ESTI M2M releases were the most important inputs for defining global standard. OneM2M released first global standard in the February 2015.

III. M2M STANDARDS' ACHITECTURES MODELS

This chapter describes the architecture models proposed by ETSI M2M and OneM2M standards.

A. *ETSI M2M Functional Architecture*

The high-level model of ETSI functional architecture proposed in specification "TS 102 690" [4] consists of a *Network Domain* and *Device and Gateway Domain* (Figure 1.).

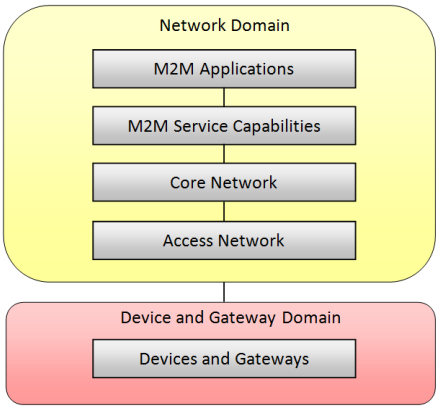

Figure 1. ETSI M2M high-level architecture

Device and Gateway Domain includes an *M2M Device*, *M2M Gateway* and *M2M Area Network*.

M2M Device runs one or more M2M Applications using M2M Service Capabilities. It can connect to Network Domain in three ways. First method of connection is "Direct Connectivity": M2M Device connects to the Network Domain via the Access network. It performs the procedures such as registration, authentication, authorization, management and provisioning with the Network Domain. It may also provide service to other devices (e.g. legacy) connected to it, but they are hidden from the Network Domain. Second method of connection is "Gateway as a Network Proxy": M2M Device connects to the Network Domain via an M2M Gateway, and connection to the M2M Gateway is accomplished using the M2M Area Network. The M2M Gateway acts as a Proxy for the Network Domain towards the M2M Devices connected to it. In that case the proxy performs the procedures of authentication, authorization, management and provisioning. The third method of connection is an extension of the second and includes multiple Gateways: M2M Devices may be connected to the Network Domain via multiple M2M Gateways.

M2M Area Network provides connectivity between M2M Devices and M2M Gateways. Examples of such network are Personal Area Network technologies such as IEEE 802.15.1, ZigBee, Bluetooth, IETF ROLL, etc.

M2M Gateway runs one or more M2M Applications using M2M Service Capabilities. It acts as a proxy between M2M Devices and the Network Domain. It may also provide service to other devices connected to it, but they remain hidden from the Network Domain. For instance, an M2M Gateway may run an application that collects and processes various information (e.g. from sensors).

The Network Domain consists of the *Access Network*, *Core Network*, *M2M Service Capabilities*, *M2M applications*, *Network Management Functions* and *M2M Management Functions*.

Access Network allows the M2M Device and Gateway Domain to communicate with the Core Network. It includes (but is not limited to): xDSL, HFC, satellite, GERAN, UTRAN, eUTRAN, W-LAN and WiMAX.

Core Network provides IP connectivity at a minimum and connectivity means or others, service and network control functions, interconnection with other networks and roaming. Each Core Network offers different features sets. Core Networks include (but are not limited to) 3GPP Core Networks, ETSI TISPAN Core Networks and 3GPP2 Core Networks.

M2M Service Capabilities provide M2M functions that will be shared by different applications and exposed through a set of open interfaces. They use Core Network functionalities and simplify and optimize application development and deployment by hiding network specificities.

M2M Applications are applications that run the service logic and use M2M Service Capabilities accessible via an open interface.

Network Management Functions consist of all the functions required to manage the Access and Core Networks. These include Provisioning, Supervision, Fault Management, etc.

M2M Management Functions consist of all the functions required to manage M2M Service Capabilities in the Network Domain. The management of the M2M Devices and Gateways uses a specific M2M Service Capability. They also include a function for M2M Service Bootstrap called MSBF (M2M Service Bootstrap Function) which is realized within a server. Its role is to facilitate the bootstrapping of permanent M2M service layer security credentials in the M2M Device or Gateway and M2M Service Capabilities in the Network Domain.

B. *OneM2M Functional Architecture*

OneM2M functional architecture proposed in published specification "TS-0001-V1.6.1" [5] comprises of several functions: *Application Entity*, *Common Services Entity* and *Network Services Entity* (Figure 2.).

Application Entity (AE) represents an instantiation of application logic for end-to-end M2M solutions. Each AE is identified with a unique AE-ID. For example, an AE can be an instance of application for fleet tracking, remote blood sugar monitoring, power metering, etc.

Common Services Entity (CSE) represents an instantiation of a set of *Common Services Functions* of the M2M environments, where each CSE is identified with a unique CSE-ID. Such service functions are exposed to other entities through reference points, where one of them is used for accessing Underlying Network

Service Entities. Service functions offered by CSE include Data Management, Device Management, M2M Subscription Management and Location Services. Such "sub-functions" may be logically and informatively conceptualized as *Common Services Functions* (CSFs). The normative Resources which implement the service functions in a CSE can be mandatory or optional.

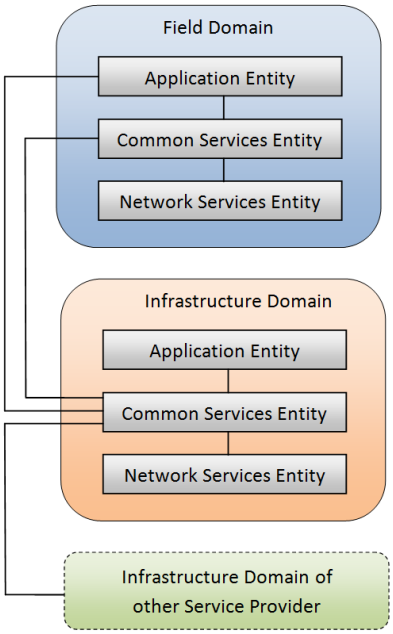

Figure 2. OneM2M functional architecture

Network Services Entity (NSE) is an underlying entity which provides services from the underlying network to CSEs. However, even though underlying networks provide data transport services between entities in the OneM2M System, such data transport services are not included in the NSE. NSE provides services of device management, location services and device triggering.

Two general kinds of OneM2M Nodes are supported, a *Common Services Entity-Capable Node* and a *Non-Common Services Entity-Capable Node*. A Common Services Entity-Capable Node is a functional entity that contains one CSE and zero or more AEs. The Application Service Node and Middle Node are examples of a Common Services Entity-Capable Nodes. CSEs resident in different Nodes could not be identical and are dependent on the services supported by the CSE in that Node. A Non-Common Services Entity-Capable Node is a functional entity that contains one or more AEs and no CSE. The Application Dedicated Node is an example of a Non-Common Services Entity-Capable Node.

OneM2M supports four basic types of Nodes: *Application Service Node*, *Application Dedicated Node*, *Middle Node* and *Infrastructure Node*. As functional objects, such Nodes may or may not be mapped to physical objects.

Application Service Node (ASN) contains one CSE and contains at least one AE. There may be zero or more ASNs in the Field Domain of an M2M System. An ASN may communicate with either exactly one Middle Node or exactly one Infrastructure Node. An ASN also communicates with NSE. Physically, an ASN could reside in an M2M Device.

Application Dedicated Node (ADN) contains at least one AE and does not contain a CSE. There may be zero or more ADNs in the Field Domain of an M2M System. An ADN communicates with a Middle Node or an Infrastructure Node. Physically, an ADN could reside in a constrained M2M Device.

Middle Node (MN) contains one CSE and zero or more AEs. There may be zero or more MNs in the Field Domain of an M2M System. A MN communicates with ASNs, ADNs, NSEs, other MNs and Infrastructure Nodes. Physically, a MN could reside in an M2M Gateway.

Infrastructure Node (IN) contains one CSE and contains zero or more AEs. There is exactly one logical IN in the Infrastructure Domain per OneM2M Service Provider of an M2M System. It may contain CSE functions not applicable to other node types. An IN communicates with one or more MNs, one or more ASNs, one or more ADNs, NSEs and INs of other M2M Systems. Physically, an Infrastructure Node could reside in an M2M Service Infrastructure.

Another type of Nodes is possible, a Non-oneM2M Node (NoDN). It does not contain any of the OneM2M Entities. Physically, NoDNs are devices attached to the OneM2M system for interworking purposes, including management. These nodes reside in Field Domain.

C. *Comparison of functional architectures*

OneM2M and ETSI have similar architectures and certain parallels can be drawn; between ETSI's M2M Applications and OneM2M's Application Entity, ETSI's M2M Service Capabilities and OneM2M's Common Services Entity, while ETSI's Core Network and Access Network could be considered correspondent to OneM2M's Network Services Entity. However, OneM2M architecture is not an extension of ETSI M2M. Both architectures consider two domains, but their internal organization differs. ETSI considers devices and gateways in the *Device and Gateway domain*. OneM2M has brought in the term of various types of "Nodes", which can reside in both of OneM2M domains, but the devices (considered as Application Service Nodes or Application Dedicated Nodes) and gateways (considered as Middle Nodes) reside in Field domain.

IV. FUNCTIONAL REQUIREMENTS ON M2M SOFTWARE PLATFORMS

M2M ecosystem consists of several components performing different functional roles. As defined by OneM2M [6], those functional roles are: *The User* (individual or company), *The Application Service Provider*, *The M2M Service Provider* and *The Network Operator*. The User uses the M2M Solution; The Application Service Provider provides an M2M Application Service and operates M2M Application; The M2M Service Provider provides M2M Services to Application Service Providers operates M2M Common Services; and the Network Operator provides Connectivity

and related services for M2M Service Providers and operates an Underlying Network (Figure 3.). Any of the above functional roles may coincide with any of the other roles.

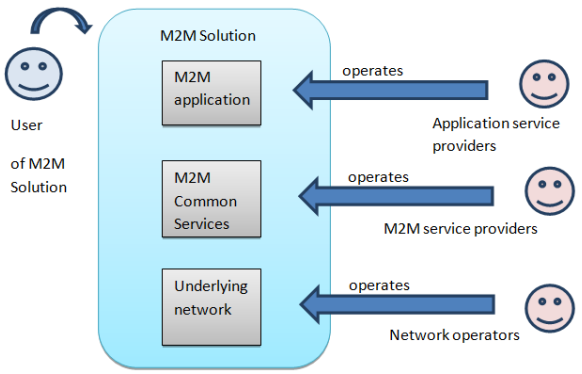

Figure 3. Functional Roles in the M2M Ecosystem

The functionalities required to achieve one M2M service span across three layers, connectivity layer, common service layer as well as the application layer. One M2M solution provider may be responsible for only one part of the solution (for example giving only the connectivity), some parts of the solution (for example giving connectivity and common service) or for the whole end-to-end solution. Depending on that one solution provider may have one or several software platforms that are handling different parts on the M2M solution.

M2M software platforms are key tools in the delivery of M2M services. Over the past several years M2M software platforms have developed rapidly and by the functional requirements can be divided as follows [7],[8]:

Connectivity Support Platforms are designed to ensure the most fundamental tasks to configure and support a machine-to-machine connection in a (typically) cellular environment. Examples of those would be connection provisioning, usage monitoring and some level of support for fault resolution. Platforms of his type are typically owned by telecom operators and are characterized by low costs and Telco grade operational excellence. The emphasis is on robustness and reliability, rather than functionality. Example of this kind of platform would be Ericsson Device Connection Platform or Jasper.

Service Enablement Platforms are flexible and have extensive horizontal capabilities in terms of solution support, reporting and the provision of a software environment and APIs to facilitate solution development for different vertical applications (industries). A key difference between the Service Enablement platform level and the Connectivity Support platform level is that the Service Enablement level will offer abstraction services: effectively a single CSP's Service Enablement Platform can potentially support access to, and offer a window onto, the Connectivity Support Platforms of multiple CSPs. This arrangement allows a single CSP to offer a multi-country solution to a client, including devices that are connected to third party networks. Together, Connectivity Support and Service Enablement functions represent the "horizontal" elements of the M2M platforms industry. Example of this kind of platform would be Ericsson Service Enablement Platform or Jasper.

Device Management Platforms are designed to support devices connected through multiple networks. They are typically designed for specific devices type and usually for a single vendor or group of devices compliant to some specific protocol suit (for example for smart meters), where those devices typically require some form of non-standard systems support (reporting, management, etc.). Device Management platforms are at this moment a niche proposition since in the future it is predicted that Service Enablement platforms will make a point of developing the capabilities required to support more and more devices. Until such time, Device Management platforms often bypass Service Enablement platforms and directly "plug in" at the Connectivity Support level. Example of this kind of platform would be Ericsson Remote Device Management Platform or Sierra.

Application Support Platforms are typically targeted at niche customer sectors. They are characterized by the provision of tailored and often specialized solutions, encompassing connected devices potentially of multiple types, potentially connected with multiple technologies, and potentially connected to the networks of multiple CSPs. Application Support platforms provide a higher level of value-added service than Device Management platforms, but still to some extent are subject to the same effect of "standardized" solution components migrating to the Service Enablement platform level. The key difference between Device Management and Application Support platforms in this regard is that this standardization and migration effect will allow an Application Support platform to focus more on their core value add proposition, whereas standardization and migration of capabilities can render corresponding Device Management platform capabilities effectively redundant. Example of this kind of platform would be Axeda or Sensor Logic.

Solution Provider Platforms used by systems integrators to support turnkey and client-specific solutions. In most cases, a solution provider M2M platform should be regarded as an enabler for a wider systems development initiative, rather than as a standalone offering. The role of Solution provider platforms is unlikely to be significantly impacted by increasing standardization within the M2M market.

Market demands software platforms that power M2M ecosystem by eliminating silos and support the creation and delivery of innovative M2M solutions, platforms that are industry-agnostic, horizontal and scalable for a wide range of industries as well as ones based on proven technologies that are deployed globally.

As already stated one M2M solution provider can operate one part of the solution or whole end-to-end solution. Based on that, one M2M solution provider will operate one or more M2M platforms. When trying to compare platforms regarding functionalities we can make a parallel with comparing different players on the M2M market. Today, most telecom operators offering M2M

services are acting as connectivity providers and operating Connectivity support platforms (TABLE I.). This includes cost efficient connectivity & more intelligent smart pipe services e.g. self-care, portals, mass provisioning, M2M charging, statistics etc. Service Enablement platforms are usually also operated by telecom operators as they are equally well suited to supporting applications that run over public or private networks and are not industry specific. Their focus on relatively complex applications and are complex to develop, however once they are developed and all the common services functionalities implemented, they can be used for different industries and use cases which makes them cost efficient and horizontal. Device Management platforms are typically operated by a M2M service company since they greatly depend on type of end user device. It can be seen that in the future Device Management platforms will support more type of devices and will move from vertical to more horizontal solutions. Application support platforms today are usually owned by M2M service companies and seldom exist as stand-alone offering since network and commons functionalities are required for end-to-end M2M service.

TABLE I. PLATFOM COMPARIOSON BY FUNCTIONAL REQUIREMENTS

	Functional layer	Typically operated by	Industry specific
Connectivity support	Underlying network	Telecom operators	No
Service Enablement	Common services	Telecom operators	No
Device Management	Underlying network	Telecom operators or Service providers	Yes
Application support	Application	Service providers	Yes

V. M2M PLATFORMS

With the development and spread of M2M technologies, many M2M platforms were developed. Regarding the support of standards, many of them support some standard partially or they do not support any of the standards at all. Since this report focuses on the standards ETSI M2M and OneM2M, this chapter will bring more details about standardized M2M platforms, most of which are open-source.

A. InterDigital

InterDigital's Standardized M2M Software Development Platform (M2MSDP) provides a standard M2M middleware solution with common APIs for scalable and horizontal M2M services. It is a scalable service platform, which features SOA and RESTful architecture, configurable charging, internetworking via Interworking Proxy Unit, lightweight device management, cognitive semantic services, automated service discovery, etc. This platform conforms to ETSI TC M2M Release 1 and Release 2 standards. It basically supports peer M2M Service Capabilities at M2M Devices, M2M Gateways and M2M Servers. It also supports four M2M reference points [9], while constrained M2M devices are supported as M2M Device Applications.

B. Eclipse OpenM2M

OpenM2M (OM2M) project is an open-source implementation of the ETSI M2M standard. It provides a horizontal M2M service platform for developing services independently of the underlying network. Its aim is to facilitate the deployment of vertical applications and heterogeneous devices. Key features of this platform are a RESTful API, modularity and extensibility [10][11]. RESTful API provides primitive procedures for machine authentication, resource discovery, application registration, etc. OM2M is built in Java as an Eclipse product using Maven and Tycho. It runs on top of OSGi Equinox runtime, thanks to which it is highly extensible via plugins. It is remotely configurable without requiring a reboot. This platform implements the ETSI M2M standard. It provides a horizontal Service Capability Layer (SCL) that can be deployed in an M2M network, device or a gateway.

C. OpenMTC

The Open Machine Type Communications (OpenMTC) Platform provides solution for conducting applied research activities and developing innovative M2M and IoT applications. It is a prototype implementation of an M2M middleware, which enables interconnection of various sensors and actuators from different vertical domains with a platform that can aggregate the collected data, forward it to the application and mediate instructions for the control of devices. OpenM2M platform aims to be aligned with multiple international standards such as ETSI M2M, OneM2M and 3GPP [12]. However, only ETSI is implemented completely. OpenMTC can be integrated with 3GPP core elements. Platform's front-end Field Domain layer and back-end cloud-based platform layer follow the OneM2M standards, proposed in oneM2M-TS-0001 (in drafting stage), and ETSI M2M standards, proposed in TS 102.921 and TS 102.690.

D. LG U+'s and SK Telecom's platform

At the end of December 2014, LG U+ and Korean SK Telecom have announced that they will create the industry's first open-source IoT platform based on OneM2M specifications [13]. Until 2012, SK Telecom was developing an ETSI TC M2M based platform, which was then commercialized and is now known as OpenM2M [14]. From 2012 until 2014, they were adding OneM2M standard to their existing IoT service infrastructure, and so did LG U+ with their platform. They united on this project of creating a first OneM2M IoT platform, which is planned to be finalized during the first quarter of 2015.

E. Comparisson of platforms

In TABLE II. is given a simple comparison of ETSI-complying platforms. Comparison of OneM2M-complying platforms is not given because LG U+ and SK Telecom platform was not announced yet, and rest of platforms are not supporting all specifications required by standards.

TABLE II. PLATFORM COMPARISON

	InterDigital	OpenM2M	OpenMTC
REST API	+	+	+
Scalability	+		+
Connectivity	HTTP CoAP	HTTP CoAP	HTTP CoAP Web sockets Diameter MQTT

Open MTC announced that compatibility with OneM2M standard will be enabled, so comparison of OneM2M platforms can be done in future work.

VI. CONCLUSION

This paper investigates current standards in M2M. The architecture of ETSI M2M and OneM2M are compared. Nodes and other parts of architecture have different name but denotes similar entities. The reason can be found in the fact that OneM2M is based on ETSI M2M. The functional comparison shows similar results.

In the last section the paper analyzed M2M platform implementations. Although OneM2M have just published their first standard, currently there are no implementations and the comparison will be in future work. That is the reason that the paper is focused on implementations of ETSI M2M. The Open MTC platform is compliant with ETSI standard and the OneM2M compliance is announced. Beside that only the Open MTC has supported connectivity by Web socket, Diameter and MQTT. In the future work we will concentrate on analysis of OneM2M platforms.
