U prostornoj bazi podataka LRS-ovi predstavljaju zasebnu tematsku cjelinu. U analizi su *sredstvo* za komparaciju i temelj logičkog modela podataka. Sa stanovišta teorije prometnih tokova pridruživanjem atributa LRS-ovima određena su *očekivana svojstva* prometnog toka na lokaciji. Procesom *transformacije prikupljanih podataka* prema LRS-u ostvareno je prepoznavanje *karakterističnih promjena* u podatcima u odnosu na očekivanje na toj lokaciji (LRS-u). Prepoznavanje *karakterističnih događaja* koji se vezuju za lokaciju ostvareno je kroz *grupiranje podatkovnih točki prema svojstvima* u odnosu na LRS, njegovu geometriju i atribute koji su karakteristični za lokaciju. Time se u analizi smanjila računalna složenost obrade i kompariranja podataka za dvije dimenzije. Stoga da bi proces *grupiranja* mogao ostvariti svoju funkciju nužno je osigurati i dobro organiziranu infrastrukturu prostornih podataka (IPP; eng. *Spatial Data Infrastructure* - SDI) kao širi pojam prostorne baze podataka.

TABLICA I. PREGLED ČESTO PRIMJENJIVANIH METODA PREDVIĐANJA PROMETNOG TOKA [9]

Tip metode	Metoda	***Prostorna karakteristika***			***Vrsta prometne mreže***		***Formativno vrjednovanje rezultata od 1 do 5***

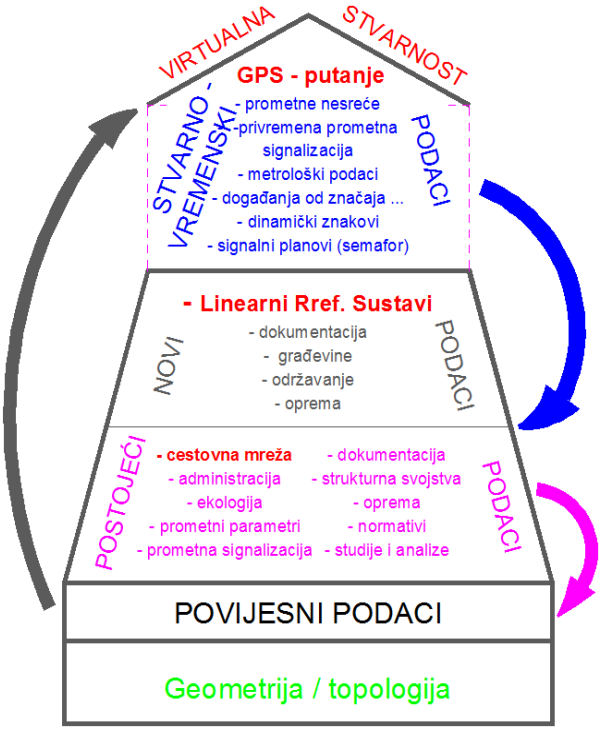
Ovakvim pristupom višestruko se olakšalo grupiranje podataka i povećala iskoristivost prikupljanih prostorno-vremenskih podataka. Olakšalo se kompariranje s drugim infrastrukturama u smislu jednostavnije uporabe, što stvara temelj za ostale aktivnosti i usluge. Na *slici 1.* prikazan je širi opseg i načelna organizacija podataka u modelu IPP-a koja zadovoljava potrebe analize operativnih karakteristika JGP-a. Uspješna implementacija pojedinih logičkih dijelova IPP-a podrazumijeva standardizaciju procedura koje omogućuju integraciju svih podataka u *tematski sloj* (eng. *layer*) koji sadrži LRS-ove.

Istraživanja koja su provedena pokazala su značajan napredak u kvaliteti i iskoristivosti prikupljanih podataka (GPS-putanja) uvođenjem *logičkog modela podataka* i prikladnih procedura za linearno referenciranje. Dobar primjer takve prakse je integracija prostornih podataka u europske infrastrukture prostornih podataka kao što je INSPIRE (eng. *Intermodal referencing system for traffic-related data*) [16]. Istraživanja u okviru projekta OKSTRA (Njem. *Objektkatalog für das Straßen- und Verkehrswesen*) ukazuju na važnost linearnog referenciranja za opisivanje objekata u blizini prometne infrastrukture kao i u procesu spajanja stvarno-vremenskih podataka o prometnim tokovima s ciljem da se postignu što točnije percepcije uvjeta u mreži [17].

U eksperimentalnom dijelu procjena pokazatelja odnosno operativnih karakteristika javnog gradskog prijevoza ostvarena je temeljem prikupljanja podataka GPS-zapisivačem (eng. *Logger*). Za potrebe istraživanja prostorna baza podataka u GIS-u [2] nadopunjena je tematskim slojem *linearnih referentnih sustava* i isprogramirane su odgovarajuće funkcije. To je omogućilo realizaciju sustava primanja i obrade podataka od pokretnih osjetila na način koji je omogućio analizu pokazatelja JGP-a. Na *slici 2.* prikazan je segment tramvajske prometne mreže s postavljenim LRS-ovima.



Slika 1. Opseg i organizacija prometnih podataka u modelu IPP.

[2] Geografski informacijski sustav koji je razvijen pod nazivom „OptaGis“ na Fakultetu prometnih znanosti za potrebe istraživanja

II. OBRADA PODATAKA POKETNIH OSJETILA

A. Formaliziranje procesa mjerenja svojstava prikupljanih podataka

Postupak izračuna kvantitativnih pokazatelja JGP-a korištenjem podataka globalnog pozicioniranja direktno je vezan za infrastrukturu prostornih podataka. Polazi se od teze da su karakteristične vrijednosti o položaju i vremenu sa *svojstvima površina* na kojima se odvija promet dovoljne za pouzdanu prostorno-vremensku procjenu stanja prometnog toka vozila JGP-a.

Svojstva površina opisana su *atributima* u *logičkom modelu podataka* koji je ostvaren LRS-ima. Nakon definiranja LRS-a ostvarene su procedure grupiranja prema istima. Samo grupiranje promatrano je kroz izračun udaljenosti te geometrijske usporedbe vektoriziranih ulaznih podataka koje su u radu označene kao *mjere težine svojstva*, a dobijaju se mjerenjem kao primjerice na s*lici 3.* Na slici je prikazano mjerenje udaljenosti u odnosu na prometni tok na osnovu kojeg se može sa sigurnošću utvrditi da se radi o stajanju unatoč greški u pozicioniranju.

Mjerama težine svojstva (MTS) definirani su entiteti tj. prikupljani podaci ili podatkovne točke kroz niz vrijednosti. Formalni zapis podatkovnih točki je najčešće vektor u kojem svaka dimenzija, odnosno vrijednost prikazuje neko svojstvo. Obzirom na kompleksnost vektor sadrži diskretne i kontinuirane vrijednosti, a odabir svojstava je u direktnoj vezi s površinom na kojoj se odvija prometni tok.

Pored jednostavnog prikaza entiteta kroz geometrijske značajke važno je svojstvo vremena koje karakterizira svaku podatkovnu točku. U tom prikazu vrijeme je *različnica* iz cijelog skupa entiteta i čini tj. definira novo svojstvo koje je ključno za logički model podataka. Stoga, prikazom grupiranja prema svojstvima *različnica*

Slika 2. Grafički prikaz dijela tramvajske mreže s LRS-ovima (*projekt: „Razvoj planova održive urbane mobilnosti“*

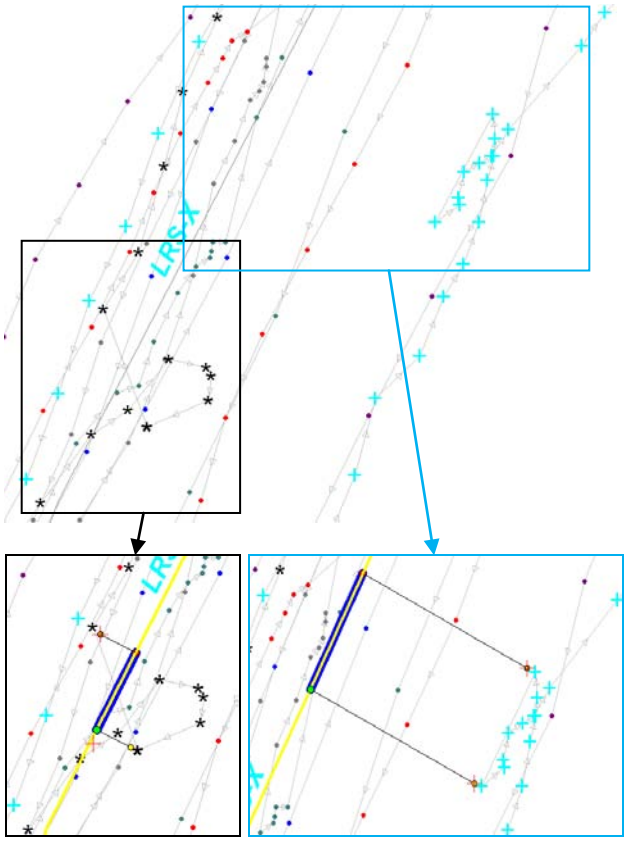
možemo dodatno upotpuniti zaključivanje na temelju prostornih značajki.

Postupak formaliziranja procesa mjerenja svojstava prikupljanih podataka na lokaciji, u daljnjem tekstu *pojavnica*, može se sažeti u dva zadatka:

- promatranje grupe točaka prikupljenih pokretnim osjetilima na mikro razini i određivanje njihovih MTS-a u odnosu na LRS,
- grupiranje na osnovu izračunatih svojstava i izračun novog svojstva koje se vezuje za lokaciju.

Analiza je pokazala da čistoća pojavljivanja neke *pojavnice* predstavlja *„događaj"* koji je važan za analizu operativnih karakteristika kroz *različnice*. Pokazalo se da je *bilježenje učestalosti pojavnice* kao dodatne mjere težine svojstva podatkovnih točaka dobar način za određenje relevantnosti *pojavnice*.

Evidentno je da su najčešće *pojavnice* upravo funkcijski vezane za događaje na prometnoj mreži ali kao izoliran događaj koji se ne može direktno i sadržajno uvijek uzeti u razmatranje. Bez uporabe funkcije cilja u puno slučajeva one nisu relevantne za pojedine pokazatelje upravo zato što im je *razlikovna vrijednost* u direktnoj sprezi s drugim utjecajnim čimbenicima, primjerice regulacijom prometa. Iz tog razloga potrebno je kao MTS koristiti one mjere koje uspijevaju prikazati koliko je neko svojstvo posebno za neki *„događaj"*, odnosno koliko ono uspijeva razlikovati taj *„događaj"* od drugih *„događaja"* ili očekivanih vrijednosti.



Slika 3. Primjer određivanja geometrijskih mjera težine

B. *Primjena linearnih referentnih sustava*

Glavni zadatak LRS-a je ostvarenje logičkog modela podataka koji omogućuje jednostavniju interpretaciju prikupljanih podataka i time olakšava mjerenja, analizu i izračun prometnih značajki. Na *slici 4.* grafički su prikazani LRS-ovi definirani na nekim od križanja koji se često pojavljuju u gradskim sredinama.

Uloga i značaj LRS-ova može se sagledati kroz učinke procedura mjerenja svojstava, a može se opisati kroz aktivnosti:

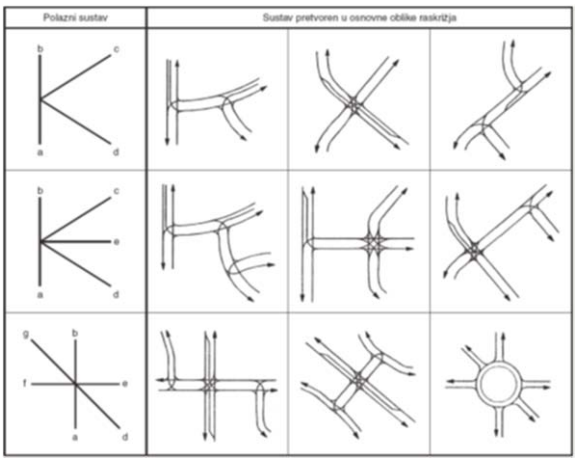
- segmentacije podataka (eng. *data segmentation*)
- pronalaženje prvog „karakterističnog" podatka u segmentu (eng. *first data detection*)
- pronalaženje veza između tih segmenata (eng. *story link detection*)
- grupiranje podataka prema svojstvima (eng. *cluster detection*)
- komparacija s referentnim vrijednostima uvažavajući geometriju prometnih tokova
- definiranje *„događaja"* u kontekstu prikupljanja podataka

Temeljne odrednice razvoja procedura za prihvat prikupljanih podataka su direktno vezane za strukturu i atribute definiranih LRS-a.

C. *Funkcije udaljenosti i sličnosti u procesu integracije podataka*

Funkcije sličnosti obzirom na prikupljane podatke mogu se podijeliti u funkcije iz područja *teorije skupova*, područja *geometrije* kao i područja *teorije informacija*. Kako se radi o prepoznavanju sličnosti među podacima koji su sadržani u *podatkovnim točkama*, koje su povezane i promatraju se kroz vrijeme, razvijen je veliki broj različitih funkcija. Zadatak tih funkcija je omogućavanje izračuna sličnosti/različitosti među prikupljanim podacima i očekivanim vrijednostima na temelju MTS-a s tim da je domena za grupiranje definirana LRS-ovima.

U procesu grupiranja podataka i zadacima



Slika 4. Tipični primjeri definiranja LRS-a na križanjima

prepoznavanja *pojavnica* (*„događaja“*) potrebno je primijeniti funkcije tj. mjerenja koje omogućuju izračun vjerojatnosti da podaci koji se obrađuju pripadaju točno određenoj grupi. *Pojavnice* ukazuju na karakteristične osobine prikupljanih podataka i u direktnoj su vezi sa *očekivanim svojstvom* prometnog toka na lokaciji. Takve mjere koje se rade na osnovu određenih kriterija zvat će se *mjerama sličnosti*. Jedna od mjera sličnosti koja je primijenjena je geometrijska mjera izračuna udaljenosti podataka od LRS-a.

Za izračun geometrijske udaljenosti u svrhu komparacije podataka korištene su *Manhattan* i *Euklidova* udaljenost. Njihovom primjenom moguće je izvršiti mjerenje geometrijskih udaljenosti između podatkovnih točaka kao i objekata u vektorskom prostoru. Ako su podatkovne točke $\boldsymbol{i}$ i $\boldsymbol{j}$ prikazane kao p-dimenzionalni vektori (1):

$$\boldsymbol{i} = (x_{i1}, x_{i2}, \ldots, x_{ip}) \quad \text{i} \quad \boldsymbol{j} = (x_{j1}, x_{j2}, \ldots, x_{jp}). \tag{1}$$

Manhattan udaljenost se računa (2)*:*

$$Udaljenost_{manhatten}(i,j) = \sum_{m=1}^{p} w_m |x_{im} - y_{im}| \quad . \tag{2}$$

Dok se *Euklidova* udaljenost računa (3):

$$Udaljenost_{euklid}(i,j) = \sqrt{\sum_{m=1}^{p} w_m (x_{im} - y_{im})^2} \quad , \tag{3}$$

gdje je $\boldsymbol{w_m}$ težina $\boldsymbol{m}$-te varijable (veća težina dodjeljuje se važnijim varijablama).

Pored izračuna udaljenosti podataka u odnosu na LRS kao mjera sličnosti korištena je *„kosinus“* mjera koja je popularizirana u pretraživanju informacija. Glavna joj je prednost prema *Manhattan* i *Euklidovoj* udaljenosti činjenica da olakšava grupiranje povezanih podataka (putanja-trajektorija) u odnosu na postavljene LRS-ove i otpornija je na stršeće podatke. Analitički je identična skalarnom produktu dvaju normaliziranih vektora. U primjeni s GPS podacima veoma je korisna jer svaka podatkovna točka ima i smjer kretanja. Opći obrazac za računanje *„kosinusne“* mjere dviju točaka je (4):

$$Slicnost_{kosinus}(i,j) = \frac{\boldsymbol{i} \times \boldsymbol{j}}{|i||j|} = \frac{\sum_{m=1}^{N} i_m \cdot j_m}{\sqrt{\sum_{m=1}^{N} i_m^{\,2}} \cdot \sqrt{\sum_{m=1}^{N} j_m^{\,2}}} \quad . \tag{4}$$

Nakon geometrijskih mjera i grupiranja podataka primjenom LRS-a često su isti podaci pridruženi u više grupa, pa je potrebno usporediti skupove grupiranih podataka kako bi se donijela konačna odluka o pripadnosti podatka. U tom smislu koristi se *Jaccard* koeficijent koji korijen ima u teoriji skupova te predstavlja mjeru sličnosti dvaju skupova. Formalna definicija te mjere može se napisati kako slijedi (5):

$$Slicnost_{jaccard}(s_1, s_2) = \frac{|s_1 \cap s_2|}{|s_1 \cup s_2|} \quad . \tag{5}$$

U ovom izrazu presjek skupova podrazumijeva sumu vrijednosti manjih dimenzija, dok se unija smatra sumom većih vrijednosti u pojedinim grupama.

D. Postupak grupiranja prikupljanih podataka

Grupiranje prikupljanih podataka je postupak razdjeljivanja podataka u grupe (*klastere*) koje sadrže podatke prema nekoj pripadnosti, tako da su slični podaci (*slični po nekom svojstvu*) svrstani u istu grupu, a različiti podaci u različite grupe. Svrha grupiranja je nalaženje “*prirodnih*” grupa u skupu prikupljanih podataka. Grupiranje podataka kao metoda primjenjuje se u različitim stručnim i znanstvenim područjima. Pod pojmom grupiranje podataka (eng. Clustering) u metodi koja se u ovom radu istražuje podrazumijeva se proces klasifikacije podataka pokretnih osjetila (eng. *data points*) temeljem mjera težine svojstva (eng. *feature vectors*) u grupe (eng. *Clusters*) koje su definirane LRS-ovima.

Sljedeća uočena prednost ovakvog tretiranja podataka od pokretnih osjetila je u segmentu *spremanja prikupljanih podataka* čime oni postaju *povijesni podaci* koji su važni za analizu operativnih karakteristika JGP-a. Cilj je da su primjenjivi i korisni bez potrebe za ponovnim složenim računalnim zahtjevima obrade, a smanjuje se količina prikupljanih podataka. U narednim istraživanjima taj dio će se detaljnije istražiti.

E. Višekriterijska analiza prikupljanih podataka

Višekriterijska analiza ostvarena je grupiranjem svojstava na lokaciji prema težinskim vrijednostima *pojavnica* i *različnica* tj. prema udaljenosti i vremenu gdje je rezultat dobiven temeljem uvjetne vjerojatnosti. Uvjetna vjerojatnost definirana je na osnovu teoretskih postavki koje se temelje na poznavanju ponašanja prometnih tokova u realnim uvjetima (*koji vladaju na lokaciji*). Definiranje kriterija se temelji na predviđenim i prepoznatim karakterističnim pravilima ponašanja prikupljanih podataka koja asociraju na događaje iz stvarnog svijeta.

Pored važnosti pojedinog kriterija neophodno je ustanoviti i njegovu pouzdanost. Stoga je za neke kriterije dodatno definirano svojstvo *podrška pravila* (eng. *Support rules*) ($A \Rightarrow B$) = $P(A \cup B)$. Ako je podrška pravila $\boldsymbol{p\%}$, to znači da je tom vjerojatnošću ($\boldsymbol{p\%}$) ono ostvareno. Ukazuje na pouzdanost prepoznavanja događaja iz prometnog toka na temelju analize.

Na ovaj način analizom i primjenom kriterija koji su specifični za lokaciju, uvažavajući teoriju dinamike prometni tokova, ostvarena je analiza operativnih karakteristika JGP-a.

III. ZAKLJUČAK

Po svojoj naravi *infrastruktura prostornih podataka* predstavlja fenomen koji još uvijek nije u potpunosti istražen, posebice kada se radi o prometnim tokovima. Njena implementacija, poboljšanje i razvoj predstavljaju izrazito kompleksan i dinamičan proces koji se konstantno mijenja u skladu s promjenama u njenom okruženju. Teza od koje kreće ovaj rad je postojanje infrastrukture prostornih podataka u određenom obliku i na određenoj razini.

Uz pojam infrastruktura prostornih podataka u literaturi se koristi i pojam geoinformacijska infrastruktura (GII; eng. *Geoinformation infrastructure*) koja nastoji udovoljiti sve prisutnijem zahtjevu za stalnu interakciju vozila i/ili pješaka s infrastrukturom i centralnim mjestom za upravljanje u svrhu podizanja kvalitete usluge, optimizacije prometa, te podizanja razine pouzdanosti („*putovanje – vrijeme – pouzdanost*“; eng. „*Journey Time Reliability*“). Kako se u pravilu radi o analizi prometnih tokova i njima svojstvenim *događajima* istraživanje je potvrdilo nužnost primjene LRS-a. Njome je ostvaren znatan napredak u iskoristivosti podataka dobivenih pokretnim osjetilima, a ujedno je smanjena složenost analize prometnih tokova za dvije dimenzije.

Proces određivanja *svojstava* i *grupiranja* podatkovnih *točaka* korelira s pitanjem kako prepoznati „*događaj*“? Ostvaruje se prema nekom od *kvantitativnih svojstava* dobivenih na temelju LRS-a koje nazivamo *mjera težine svojstva*, a ukazuju na važnost tog svojstva za prometni tok i lokaciju kojoj pripadaju podatkovne točke. Stoga je nužno definirati i odrediti kriterije za određivanje MTS-a kao mjere relevantnosti nekog „*događaja*“ ili grupe točaka. Dvije su mogućnosti za to: izračunom (*teorija prometnih tokova*) i *analizom povijesnih podataka*, vodeći računa o zakonitostima kretanja vozila u urbanim sredinama ne *zanemarujući* opće uvjete odvijanja prometa (primjerice, *prometna regulacija*), složenost prometnog toka (primjerice, *broj kolničkih traka*) i vremensku neravnomjernost prometne potražnje.

Radnje i procesi koji su potrebni za realizaciju metode prepoznavanja *karakterističnih stanja prometnog toka* na temelju prikupljanih podataka pokretnim osjetilima su:

- definiranje logičkog modela prostornih podataka (*atributi i oblik LRS-a*),
- proces transformiranja i grupiranja podataka prema LRS-ima (metodama mjerenja: *Manhattan, Euklidova udaljenost i kosinusna metoda*),
- utvrđivanje svojstava i referentnih vrijednosti (*varijabli*) na osnovu općih uvjeta odvijanja prometa i/ili „*povijesnih*“ podataka neovisno za svaku lokaciju,
- definiranje kriterija za *prepoznavanje karakterističnih stanja* prometnog toka temeljem svojstava prikupljanih podataka.

U procesu obrade prikupljanih podataka, transformacijom prikupljanih podataka u LRS, omogućeno je mjerenje *svojstava* i grupiranje na osnovu tih *svojstava* što je omogućilo prepoznavanje *„specifičnih događaja“* na unaprijed određenim lokacijama (LRS-ovima), a rezultiralo je *pokazateljima* operativnih karakteristika JGP-a.

Njihova primjena je višestruka, pa mogu poslužiti i za evaluaciju mjera unaprjeđenja gradskog javnog prijevoza kao i za druge ITS aplikacije koje ovise o dinamičkim podacima prometnih tokova. Imajući na umu sam proces prikupljanja podataka može se konstatirati da je prikupljanje podataka pokretnim osjetilima jednostavno i jeftino, rezultati obrade prikupljanih podataka su prihvatljivi, a mogućnosti primjene velike.

Optimizacija procesa naplate cestarine na Autocesti Rijeka-Zagreb

Josip Ostojić, Dr.Sc.* i Elmin Kalajdžić**
*HAC-ONC d.o.o., Zagreb, Hrvatska
josip.ostojic@hac-onc.hr
**Enel-Split d.o.o., Zagreb, Hrvatska
nino@enel.hr

Sažetak - Autocesta Rijeka-Zagreb je tijekom 2013. pokrenula nekoliko projekata iz domene unapređenja poslovanja i uvođenja novih poslovnih i organizacijskih rješenja. Obzirom na nužnu potrebu unaprjeđenja poslovnih procesa, prepoznata je poslovna potreba optimizacije poslovnih procesa naplate cestarine.

Poslovni proces naplate cestarine na Autocesti Rijeka-Zagreb, kao jedan od ključnih poslovnih procesa uključuje sve relevantne aktivnosti od trenutka evidencije ulaska vozila na autocestu pa sve do evidentiranja ove transakcije u financijskom modulu SAP ERP sustava.

Cilj projekta „Optimizacija poslovnog procesa naplate cestarine na Autocesti Rijeka-Zagreb“, je bio osigurati transparentnost poslovnih procesa uzevši u obzir cjelokupnu postojeću infrastrukturu tvrtke i sve postojeće uvjete plaćanja cestarine. Jedan od prioriteta projekta je bio i izrada novog, pouzdanog sučelja koji vrši prijenos podataka iz Sustava naplate cestarine u SAP ERP sustav.

Kao potpora unapređenju poslovnih procesa odabrana je platforma ARIS, njemačke firme Software AG. Tijekom analize poslovnih procesa ciljano su se uočavale slabe točke koje su se tretirale kao prigode za poboljšanja, te su na kraju projekta dokumentirano predstavljene zajedno sa prijedlozima na koji način poboljšati i unaprijediti poslovne procese.

I. UVOD

Temeljem odluke Vlade Republike Hrvatske, osnovano je dioničko društvo Autocesta Rijeka-Zagreb d.d. (ARZ) za građenje i gospodarenje autocestom, koje je započelo s radom u ožujku 1998. godine.

Društvu je dodijeljena koncesija na vremenski rok od 28 godina. Prihodi Društva su od naplate cestarine i naplate korištenja pratećih i uslužnih objekata na trasi autoceste.

Gospodarska svrha Društva je zatvaranje financijske konstrukcije, građenje, gospodarenje i održavanje autoceste Rijeka - Zagreb, te njenih cestovnih i pratećih objekata na cestovnom zemljištu u sklopu ostvarivanja prava iz koncesije koje se Društvu dodjeljuje na temelju odluke Vlade.

U cilju unapređenja poslovanja, tijekom 2013-te godine Društvo je iniciralo više projekata. Cilj ovih projekata je podizanje učinkovitosti i kvalitete poslovanja i poslovnih procesa, uvođenje novih tehnologija, usklađivanje sa obvezujućim propisima, normama i standardima, te uvođenje organizacijskih promjena kao kontinuirane poslovne aktivnosti.

Proces naplate cestarine kao temeljni proces za realizaciju prihoda Društva je imao određenih problema. Ovaj poslovni proces uključuje sve povezane aktivnosti od trenutka ulaska vozila na autocestu do trenutka okončanja transakcije u financijskom modulu SAP ERP (Enterprise Resource Planning) sustava.[3][4]

Rezultati projekta „Optimizacija poslovnih procesa naplate cestarine na Autocesti Rijeka-Zagreb“ morali su omogućiti učinkovitu transformaciju poslovnih procesa i zadovoljiti slijedeće zahtjeve:

- Dokumentiranje mape procesa ARZ i dokumentiranje detaljnog tijeka svih poslovnih procesa ključnih za naplatu cestarine uključujući sve resurse nužne za izvršavanje poslovnog procesa
- Dokumentiranje svih podataka nužnih za učinkovitu naplatu cestarine
- Dokumentiranje svih IT (Informatička tehnologija) sustava uključenih u proces naplate cestarine i njihove integracije
- Analiza dokumentiranih procesa, podataka i IT sustava, definiranje slabih točaka i izrada prijedloga optimizacije procesa
- Razvoj aplikacije za integraciju koja vrši prijenos podataka iz Sustava naplate cestarine u SAP ERP sustav po načelima definiranim prijedlogom optimizacije procesa.

U radu će se izložiti analiza postojećih procesa sustava naplate cestarine, softverske infrastrukture koja podržava taj proces, naglasiti slabe točke uočene tijekom analize i dati prijedlozi za njihovo otklanjanje.

II. ARIS – PLATFORMA ZA ANALIZU POSLOVNIH PROCESA

Poslovanje u suvremenim uvjetima se nalazi pod stalnim pritiskom velike konkurencije i striktne regulative. Kako bi postala i ostala konkurentna, poduzeća sve više obraćaju pozornost na svoj poslovni model i svoje poslovne procese. Uspjeh poduzeća ovisi o sposobnosti efikasnog upravljanja vlastitim poslovnim procesima.

Kako bi shvaćanje kompleksnih poslovnih procesa bilo učinkovito, razvijeni su posebni softverski alati za

modeliranje poslovnih procesa. Za razliku od običnih alata za grafičko prikazivanje, aplikacije za analizu poslovnih procesa kreiraju repozitorij modela i njihovih sastavnih elemenata kao bazu podataka u kojoj se za svaki element vežu odgovarajući atributi korisni za provođenje različitih analiza i simulacija.

Repozitorij modela poslovnih procesa tako postaje baza znanja koja, osim grafičkog prikaza poslovnih procesa, sadržava i sve međusobne veze i odnose elemenata u modelima. Time su omogućeni pogledi na procese iz drugih perspektiva: organizacijske (npr. koje poslove obavlja ovo radno mjesto ili odjel), informatičke (npr. koje poslovne procese pokriva ova aplikacija), podatkovne (npr. za koje poslovne procese je bitan ovaj dokument ili podatak), i slično…

Na tržištu postoji veliki broj aplikacija koje podržavaju analizu i izradu modela poslovnih procesa. Gartner u svojim izvješćima iz kategorije „BPA tools“ navodi ključne karakteristike koje treba imati kvalitetan alat za analizu poslovnih procesa i po tim kriterijima donosi preporuke za odabir0.

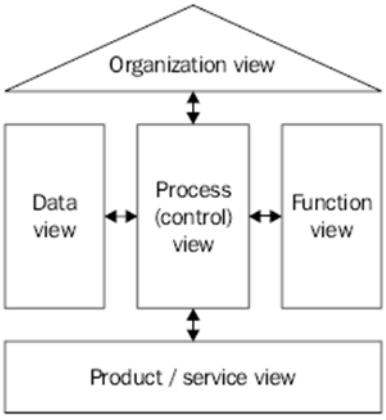
Lideri na polju alata za analizu poslovnih procesa (Slika 2) su IBM (WebSphere Business Modeler i BlueWorks), Metastorm (ProVision BPA), Mega (Mega Modeling Suite) i Software AG (ARIS).

Prije nekoliko godina (2007) Autocesta Rijeka-Zagreb je odabrala ARIS za dizajn i analizu poslovnih procesa, pa je ova platforma korištena i tijekom ovog projekta.

Na odabir ARIS-a kao standarda u ARZu utjecala je činjenica da ARIS u sebi sadrži metodološki okvir za modeliranje poduzeća (enterprise modelling). Taj okvir podrazumijeva skup metoda za analizu poslovnih procesa, podataka, IT sustava i drugih elemenata ključnih za razumijevanje i upravljanje poduzećem.

ARIS je nastao na osnovama akademskog istraživanja Prof. Dr. August-Wilhelma Scheera tijekom devedesetih. Ima vrlo raširenu industrijsku primjenu, osobito u Europi. Praktički ne postoji niti jedna velika europska firma koja ga ne koristi u svom poslovanju.[2]

Osnova ARIS metodologije je „ARIS kuća“ (Slika 1)



Slika 1: ARIS kuća

Source: Gartner (December 2011)

Slika 2: ARIS u Gartnerovom izvješću za BPA Tools0

koja predstavlja različite perspektive/poglede na poduzeće:

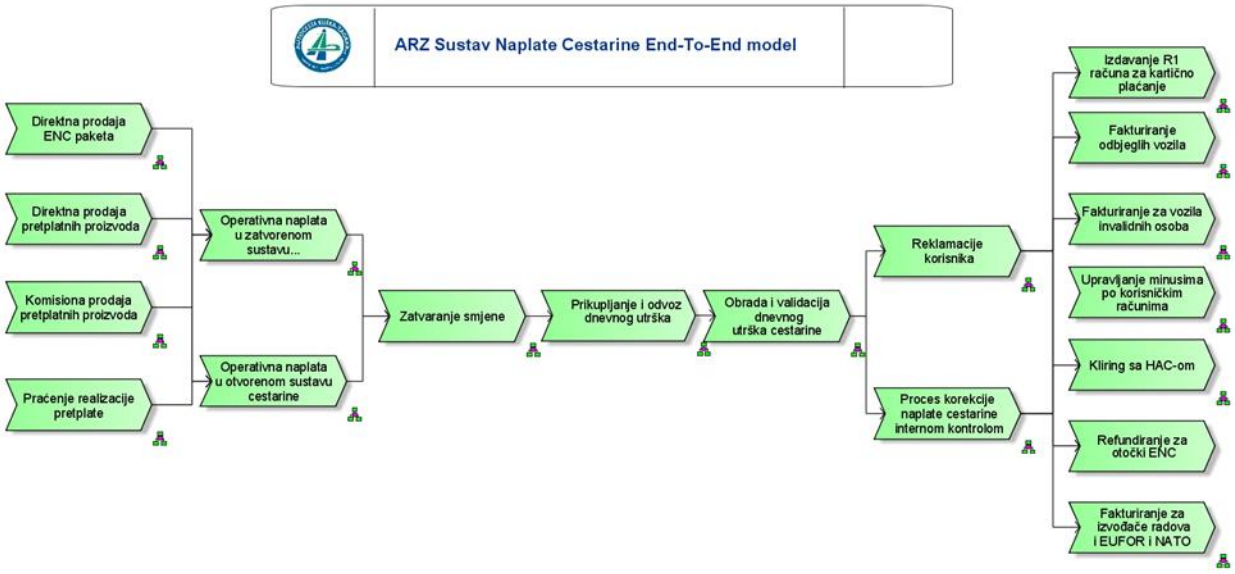
- Organizacijski pogled
- Podatkovni pogled
- Procesni/kontrolni pogled
- Funkcijski pogled
- Proizvodno-servisni pogled

Vrlo intuitivan, grafički jasan i metodološki u potpunosti zaokružen koncept ističe ARIS kao jedan od omiljenih i rado korištenih alata.

III. AS-IS ANALIZA POSLOVNIH PROCESA NAPLATE CESTARINE

Pod pojmom „Procesi naplate cestarine“ objedinili smo sve procese od prodaje pretplatnih proizvoda, preko operativne naplate do završnih knjiženja u jedinstven end-to-end proces.

Analitičkim pristupom, dekompozicijom procesa na elementarne funkcije [5][6], napravljeni su modeli koji grafički prikazuju stvarne (AS-IS) odnose izvršitelja, radnji/postupaka, te dokumenata, odnosno IT aplikacija. Tijekom radionica sa neposrednim izvršiteljima i rukovoditeljima, te uvidom u ISO (International Organization for Standardization) standard dokumentaciju, osim samog modeliranja, raspravljalo se i o problemima u radu, te mogućim načinim rješavanja tih problema. Na taj način se prikupljalo i dokumentiralo „procesno znanje“ poduzeća. Prezentirani ARIS modeli su odraz tog znanja i njihovim objavljivanjem na intranetu poduzeća pruža se prilika svim djelatnicima poduzeća da to znanje usvoje, ali i da interveniraju (kroz definiranu proceduru) kao procesni inovatori i tako malim, ali svakodnevnim koracima potiču procesnu kulturu, kao i kulturu inovacije.



Slika 3: ARZ Sustav naplate cestarine End-To-End VAC (Value-Added Chain) model

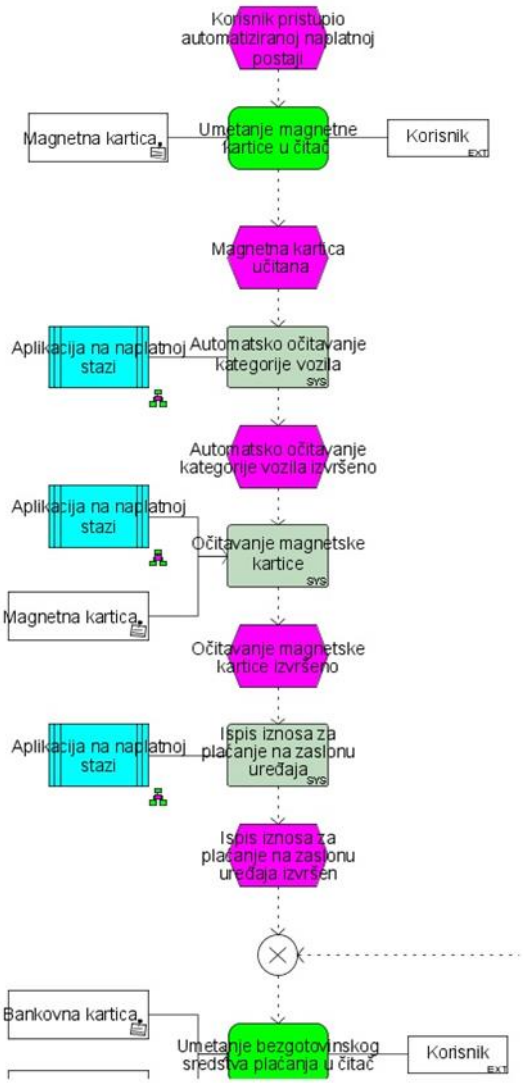
Tijekom analize prvo su prepoznate osnovne grupe procesa u procesu naplate cestarine i izrađeni su procesni modeli niske razine detalja. Zatim se analiza nastavila modeliranjem procesa sve veće i veće razine detalja uvođenjem i drugih ovisnih elemenata koji prate procesne korake. Na kraju se, sintetičkim pristupom integrirajući modele, kreirao tzv. „End-To-End“ model (Slika 3), kojim je cijeli proces naplate cestarine zaokružen u preglednu cjelinu. Uz svaki element modela u ARIS-u vidimo simbol u donjem desnom kutu koji nam „otvara“ modele veće razine detalja.

Početni modeli osnovnih procesa niske razine detalja, kao i „End-To-End“ model se prikazuju VAC (Value-Added Chain) metodom, čiji je prvenstveni cilj prikazati slijed dodavanja vrijednosti u procesu.

Modeli veće razine detalja se uobičajeno prikazuju EPC (Event-driven Process Chain) metodom, koja prikazuje slijed procesa na način da postoji uzrok (event) za neki proces, a kao rezultat tog procesa nastaje novi uzrok za slijedeći proces. Na taj način se uzroci i procesi vežu u lančani slijed (Slika 4).

Osim uzroka i procesa, na tim modelima se prikazuje i cijeli niz povezanih grafičkih simbola kao što su izvršitelj, dokument, IT sustav, rizik, KPI (Key Performance Indicator), strateški cilj, itd. Odabir koji će se elementi uključiti se definira dokumentom „Konvencije modeliranja“ koji se usvoji na početku projekta. Naravno da količina odabranih elemenata i razina detalja modela ovisi o predviđenom trajanju projekta, potrebama korisnika i budžetom projekta, pa je na početku potrebno imati konsenzus oko očekivanih rezultata projekta.

VAC i EPC modeli se, u cilju povećavanja prikaza razine detalja slažu u slojeve na način da svaki slijedeći sloj prikazuje više detalja. Uobičajeno je da se prve dvije ili tri razine prikazuju VAC modelima, a najveća razina detalja EPC modelima. Nije nužno da svi procesi imaju isti broj slojeva.



Slika 4: Prikaz dijela EPC modela

IV. ANALIZA SOFTVERSKE INFRASTRUKTURE KOJA PODRŽAVA PROCESE NAPLATE CESTARINE

Analiza procesa nužno otvara pitanje „Koji informacijski sustavu podržavaju pojedine procese?“. Odgovor na to pitanje nam pokazuje adekvatnost i pokrivenost procesa softverskim aplikacijama i informatičkom infrastrukturom, te ukazuje na potencijalne praznine (engl. gap) gdje informacijski sustav nedovoljno podržava poslovne procese.

Tijekom analitičkih radionica otvaraju se i pitanja upotrebljivosti informacijskih sustava, lakoće rada, pouzdanosti i ostalih svakodnevnih problema u radu. Prikupljena znanja se koriste kao podloga za poboljšanje poslovnih procesa, aplikacija, informatičke infrastrukture, organizacije i ostalih elemenata o kojima ovisi uspješno poslovanje.

Aplikacije koje podržavaju Sustav naplate cestarine u ARZ-u su:

- Aplikacija na naplatnoj stazi NJN-TST
- Aplikacija na naplatnoj stazi QFREE
- Aplikacija na naplatnoj stazi GEA
- Aplikacija na naplatnoj postaji NJN
- Aplikacija u centrali ARZ-a WARZ
- ERP sustav SAP

Podaci kroz ove sustave putuju u oba smjera. U smjeru od naplatne kućice do ERP SAP-a i obrnuto (Slika 5). To je ključno za naplatu, jer su u SAP-u tekuća salda svih pretplatničkih sredstava plaćanja. Brzo i pouzdano propagiranje ovih informacija kroz sustav sprječava malverzacije i osigurava točnu naplatu.

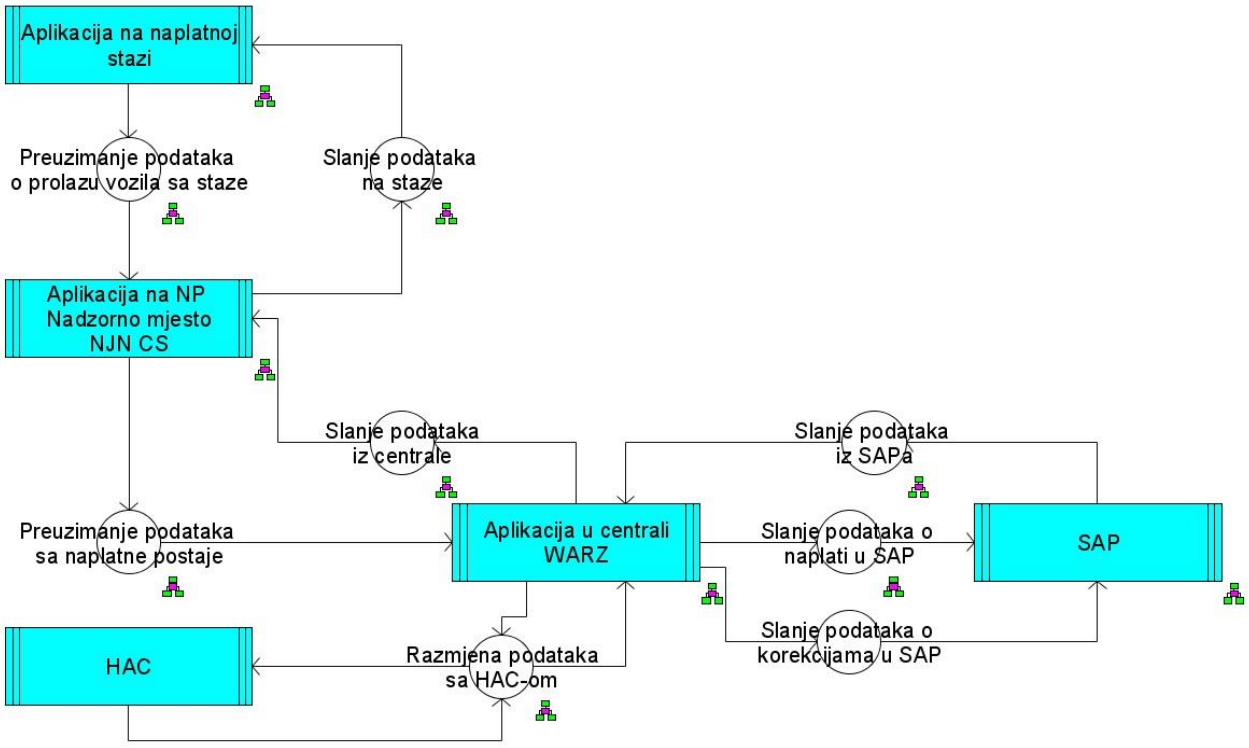
Obzirom na postojanje više različitih sustava raznih proizvođača, integracija tih sustava predstavljala je stručni izazov izvođačima. Izvedeno rješenje sa raznim sučeljima koja djeluju u oba smjera, izvedena point-to-point načinom integracije (klasični način integracije aplikacija prema kojoj se svaka aplikacija pojedinačno povezuje sa svim aplikacijama s kojima treba komunicirati) usložnjavaju razumijevanje, nadzor i održavanje, pogotovu iz razloga što je svako sučelje izvedeno različitim načinom i programirano različitim alatima. Neka sučelja su izvedena koristeći razmjenu datoteka, neka direktnim prebacivanjima SQL (Structured Qurey Language) upitima iz baze u bazu.

Naravno da bi se upotrebom nekog servera specijaliziranog za integracije (Microsoft BizTalk Servera, SAP NetWeaver Process Integration Servera, Software AG Integration Servera ili IBM Message Broker Servera,…[7]) povećala stabilnost, olakšao nadzor i održavanje, ali bi se time višestruko povećala inicijalna cijena investicije, pa bi nužno bilo tu činjenicu razmotriti uzimajući u obzir širi kontekst investicija u ARZ-u.

V. SLABE TOČKE I PRILIKE ZA UNAPRJEĐENJE

Tijekom analize poslovnih procesa i pripadajućih organizacijskih i infrastrukturnih elemenata posebna pažnja se pridaje pronalaženju tzv. „slabih točaka“ (engl. weak points) koje u ovom kontekstu treba promatrati kao prilike za unaprjeđenje.

Te se prilike klasificiraju kao „Quick Win“, odnosno prilike koje se mogu relativno brzo implementirati bez većih troškova, te kao „To be“, odnosno prilike za koje je



Slika 5: Model tijeka podataka između aplikacija

potreban veći organizacijski i/ili troškovni angažman.

Neke od slabih točaka su strateške prirode, a neke su vrlo detaljne i razumljive samo direktnim operativcima koji se s njima svakodnevno susreću. Upravo takav široki spektar pokazuje kako se prilike za poboljšanja mogu pronaći u svim segmentima poduzeća i kako je potreban sustavan pristup na svim razinama kako bi se iskoristio taj inovacijski potencijal.

Na završnim radionicama sa odgovornim osobama u ARZ-u ti problemi su analizirani. Rezultat analize su prijedlozi rješenja koji su klasificirani i prikazani u tablicama. Ovako formirane tablice predstavljaju smjernice za daljnja djelovanja.

Od ukupno 26 uočenih prilika za poboljšanja ovdje možemo navesti par primjera (TABLICA I,TABLICA II).

TABLICA I. PRIMJERI STRATEŠKE RAZINE

Opis problema	Prijedlog unaprjeđenja
Neadekvatna međusektorska komunikacija. Iako je rješavanje operativnih problema na razini jedne organizacijske cjeline dosta efikasno, operativni problemi za čije rješavanje je potrebna suradnja između dvije ili više organizacijskih cjelina dugo se rješavaju.	Poboljšati komunikaciju među organizacijskim cjelinama prilikom rješavanja otvorenih pitanja. Komunikaciju je potrebno i formalizirati i proceduralno opisati, te za svako otvoreno pitanje definirati nositelje i rokove za rješenje. Uspostaviti listu otvorenih pitanja i po njoj pratiti uspješnost rješavanja.
Veliki značaj, složenost i distribuiranost informacijskog sustava nalaže bolje svakodnevno praćenje operativnog funkcioniranja informacijskog sustava.	Potrebno je poboljšati svakodnevni nadzor nad funkcioniranjem informacijskog sustava u cilju bržeg uočavanja hardverskih kvarova, softverskih pogreški, ispravnosti prijenosa podataka i slično. U tom cilju predlaže se izrada nadzornih konzola, posebnih automatskih softverskih procedura koje prate i kontroliraju tijek podataka i alarmiraju neslaganja,…

TABLICA II. PRIMJERI TAKTIČKE RAZINE

Opis problema	Prijedlog unaprjeđenja
Iste informacije se mogu dobiti iz različitih aplikacija i sa različitim ulaznim parametrima, pa često dolazi do nesuglasica u tumačenju podataka. Česta je upotreba ad-hoc formiranih Excel tablica u kojima su često podaci stavljeni u pogrešan kontekst.	Potrebno je definirati „jednu verziju istine“ na način da se odrede mjesta u sustavu (izvještaji) koja su mjerodavna za tumačenje. Preporuka je formirati listu izvješća iz sustava sa točnom definicijom za koje poslovne potrebe se koristi i po mogućnošću sa uputom kako se ispravno koristi. Ostala izvješća time se proglašavaju kao operativna i nemjerodavna za tumačenje konkretnih poslovnih rezultata.
Način rada sa kunskim i deviznim polozima otežava kontrolu izvoda banke u računovodstvu. Računovodstvo prilikom knjiženja pologa dnevnog utrška ne može provjeriti da li su podaci ispravni ili je došlo do pogreške, jer ne mogu jednostavno zbrojiti kunski polog i devizni (u kunama) i dobiti zaduženje za naplatnu postaju.	Za ovaj problem postoji više prijedloga rješenja od drugačijeg pakiranja deviznih pologa, pa do izmjene načina knjiženja u SAP-u ili izrade kontrolnih izvještaja. Izmjena pakiranja donosi dodatne troškove, dok izmjene knjiženja usložnjavaju rad knjigovodstva. Najbolja varijanta bi bila izrada kontrolnih izvještaja, za što je informatika već predložila rješenje opisano u posebnom dokumentu.
Neprepoznate bankovne kartice od strane softvera na naplatnoj stazi ne dolaze ispravno u SAP, što stvara razlike u knjiženjima u odnosu na doznaku banke koja je karticu prepoznala i po njoj doznačila sredstva.	Dogovorom između informatike i financija problem je riješen otvaranjem posebnog konta za sve neprepoznate kartice na koje će se knjižiti promet.

Jedna od bitnih slabih točaka, uočenih i prije nego je projekt počeo, je problematičan rad sučelja koje prebacuje podatke iz aplikacije WARZ u SAP.

Uočena nestabilnost u radu, s vremena na vrijeme dosta usporen rad i sporadično pojavljivanje netočnosti u podacima, potakle su odgovorna osobe iz Sektora za informatiku ARZ-a da se u okviru ovog projekta razmotri redizajn tog sučelja.

Višestrukim pokušajima prije ovog projekta da se u postojećem sučelju pronađu pogreške nisu urodila plodom, pa je izvedba novog sučelja u ovom slučaju bila optimalno rješenje.

Obzirom na raspoloživi budžet projekta, odlučeno je da se novo sučelje izvede sličnom metodologijom point-to-point integracije. Korišteni su SQL upiti kojima su se iz Oracle baze WARZ aplikacije podaci prebacivali direktno u Oracle bazu SAP ERP sustava u transportne tzv. Z-tablice, a onda su se vremenski upravljanim procedurama pokretali posebno razvijeni BAPI-ji (Business Application Programming Interface) koji su iz tih tablica knjižili stavke u financijskim tablicama SAP ERP sustava.

Na taj način se dobilo zadovoljavajuće ubrzanje prijenosa podataka, podaci su bili točni (bez pogreški u zaokruživanju kod izračuna rabata), a cijelo sučelje je donekle i pojednostavljeno.

VI. ZAKLJUČAK

Ovim projektom izgrađena je važna baza podataka poslovnih procesa u Sustavu naplate cestarine. Uz grafički dokumentirane poslovne procese, povezani su svi izvršitelji i aplikacije koji prate te procesne korake.

Sve dokumentirane informacije o poslovnim procesima, podacima i IT sustavima su pohranjene u ARIS repozitoriju poslovnih procesa, ali i u HTML formatu kako bi im se moglo pristupiti koristeći Internet preglednik.

Time je postignuta transparentnost kao preduvjet za upravljanje i permanentno usavršavanje poslovnih procesa na svim razinama odgovornosti, kao i usavršavanje informatičke infrastrukture koja podržava poslovanje.

Analizom su uočene određene slabe točke, te se njihovim identificiranjem stvorila podloga za unapređenja.

Izmjenom SAP sučelja prema centralnoj WARZ aplikaciji otklonjene su smetnje koje su predstavljale problem u svakodnevnom funkcioniranju informacijskog sustava.

Projektom su postavljene osnove za uvođenje procesne kulture u poslovanju poduzeća. Takva korporativna kultura u svakom, pa i najmanjem procesnom koraku traži način kako bolje poslovati i svakodnevno razmatra bolje varijante rada.

Vođenje elektroenergetskih mikromreža na osnovi sinkroniziranih mjerenja

S. Skok *, M. Filipović ** i V. Kirinčić *
* Tehnički fakultet Sveučilišta u Rijeci, Zavod za elektroenergetiku, Rijeka, Hrvatska
** HEP-Operator distribucijskog sustava d.o.o., Gospić, Hrvatska
srdjan.skok@riteh.hr, milan.filipovic@hep.hr, vedran.kirincic@riteh.hr

Sažetak - Područje elektroenergetike nezaustavljivo se sve više usmjerava prema tematici naprednih elektroenergetskih mreža (engl. Smart Grid) i mikromreža (engl. Microgrids). Naime, operatori sustava suočeni su sa sve većim izazovima koje nameću ekonomski pokazatelji, odnosno kako sa što manjim ulaganjima u elektroenergetsku mrežu postići što veću "zaradu". Ovaj je rad pokušaj pomoći u vođenju elektroenergetskoga sustava, odnosno rješenja vezanog uz podjelu distribucijskoga elektroenergetskog sustava na mikromreže s integriranim obnovljivim izvorima energije. Rad se posebno odnosi na mogućnost odvajanja mikromreže u otočni pogon te vođenje i nadzor mikromreže u stvarnom vremenu na osnovi već primijenjene tehnologije sinkroniziranih mjerenja fazora napona i struja. Cilj je rada otvoriti pitanja vezana uz primjenu mikromreža, kao i uz moguće izmjene postojećih Mrežnih pravila, te u konačnici odrediti prioritete razvoja u elektroenergetici.

I. UVOD

Teme istraživanja u elektroenergetici mijenjaju se tijekom godina u skladu s primjenom novih tehnoloških rješenja, primjenom novih matematičkih modela, adaptivnih tehničkih rješenja ili drastičnijih primjera kao što su promjene topologije i koncepcije mreže uzrokovane integriranjem distribuiranih izvora (obično tzv. obnovljivi izvori energije) ili pak energetskim paketima i "novim" energetskim strategijama razvoja elektroenergetskoga sustava (EES). Gledajući vremenski, tematika istraživanja mijenja se gotovo s jednakom vremenskom konstantom (5-7 godina). Naime, u svjetskim okvirima, određeno područje postaje zanimljivo prilikom dolaska kapitala i potencijalnih ulaganja u istraživanje te implementacijom tehničkih rješenja koja su rezultat spomenutih istraživanja.

Pregledom stanja na području mikromreža (elektroenergetskih, naravno) u RH može se uočiti da trenutačno ima nekoliko projekata koje sufinancira država te postoje udruge i klasteri koji se bave tim područjem, ali do sada nema konkretne primjene [1, 2, 3, 4]. Posebice je indikativno da trenutačne projekte ne sufinanciraju subjekti iz privrede, osim pojedinih vezanih uz mikromreže s integriranim vjetroelektranama. No sadašnja, konzervativna, Mrežna pravila EES-a [5] definiraju da vjetroelektrane ne mogu raditi u otočnom pogonu, što uvelike smanjuje njihovo korištenje kao pomoć operatoru u vođenju sustava te uspostavu mikromreže s vjetroelektranom.

Svjetska istraživanja u području mikromreža mogu se okarakterizirati kao eksponencijalno rastuća i prema broju objavljenih članaka i prema broju projekata te održanih i predstojećih konferencija. Slika 1 i tablica 1 prikazuju broj članaka vezanih uz područje mikromreža prema tri relevantne baze – Scopus, Science Direct i IEEE Xplore.

U nastavku će se dati pregled mikromreža i stanje razvoja u svijetu i RH.

II. NAPREDNE ELEKTROENERGETSKE MREŽE – MIKROMREŽE

A. Napredne elektroenergetske mreže – Smart Grid

Današnja elektroenergetska mreža obuhvaća više od 50 vrsta dalekovoda u uporabi, a još više u razvojnoj fazi. Nadzor, zaštita i vođenje prijenosne mreže zasnovane na sinkroniziranim mjerenjima (engl. Wide Area Monitoring, Protection and Control – WAMPAC) više nije apstrakcija, nego se primjenjuje u mnogim elektroprivredama [9]. Razvijeni su sustavi koji služe zaštiti cjelovitosti prijenosnoga EES-a, uključujući stabilnost, sprečavanje poremećaja i minimiziranje njihovih posljedica, jedinstvenoga naziva SIPS (engl. System Integrity Protection Scheme) ili SPS (engl. Special Protection Systems) [10].

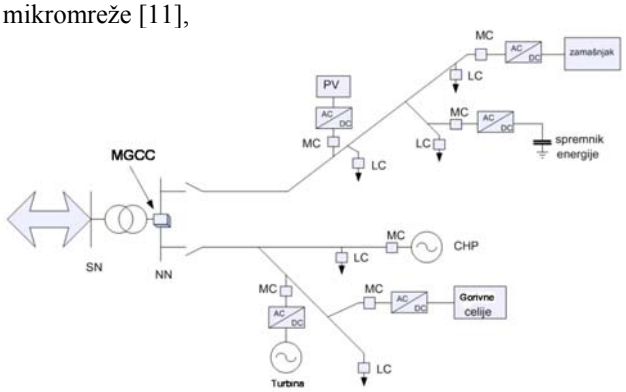
Napredne elektroenergetske mreže odnosno Smart Grid nova su generacija elektroenergetskih mreža, koje koriste nove dostupne tehnologije radi poboljšanja pouzdanosti i ekonomičnosti.

Napredne prijenosne mreže razvijaju se usporedno s tehnološkim inovacijama, u prijenosu i distribuciji i u IT i telekomunikacijskim inovacijama. Napredne mreže pružaju dvosmjerni tok energije u stvarnom vremenu, povezivanje svih sudionika u lancu proizvođača i korisnika električne energije – omogućuju bolju komunikaciju između proizvođača i operatora prijenosnoga sustava, bolju koordinaciju između distributera električne energije i krajnjih potrošača.

B. Mikromreže

Napredne mikromreže (engl. Smart Microgrids ili µGrid) moderni su, mali centralizirani elektroenergetski sustavi koji sadrže sve sastavnice kao i veliki elektroenergetski sustavi (proizvodnja – uobičajeno obnovljivi izvori električne energije; sustavi za skladištenje energije; prijenos – od izvora do potrošača; potrošači). Osnovno je svojstvo da se mikromreža može voditi kao i veliki EES te da može raditi otočno ili vezano za veliki EES. Također je bitno naglasiti da mikromreže imaju vlastite izvore proizvodnje električne energije – distribuirane izvore električne energije (uobičajeno obnovljivi izvori energije). Kao i veliki EES, napredne mikromreže proizvode, prenose, skladište i distribuiraju električnu energiju i reguliraju tok električne energije prema potrošačima, ali na lokalnoj razini. Napredne mikromreže imaju točno određene granice, jedinstveno su upravljiv entitet i mogu raditi vezano na EES kao i u otočnom pogonu. Napredne mikromreže čine sastavnice – blokove napredne elektroenergetske mreže. Naime, s razine cjelokupnoga EES-a upravlja se lokalno ograničenim naprednim mikromrežama.

Određivanje optimalne veličine, vrste i lokacije mikromreža u razdjelnim mrežama važno je za korisnika mikromreže (upravljanje proizvodnjom i dobavom energije poslovni je oportunizam) i operatora razdjelne mreže (predviđanje opterećenja i planiranje investicijskih ulaganja, pomoć pri održavanju konstantnoga napona i frekvencije). Metode korisne i upotrebljive u tržišnim uvjetima moraju se temeljiti na višekriterijskim metodama optimiranja i teoriji odlučivanja te moraju uključivati neizvjesnosti i odgovarajuće vrednovati moguće rizike. Slika 2 prikazuje tipičnu topologiju mikromreže [11],



Slika 2. Tipična topologija mikromreže

gdje je:

MGCC – centralni kontroler i nadzor mikromreže (u ovom se radu predlaže da to bude Local Area Network, odnosno nadzor i vođenje zasnovano na sinkroniziranim mjerenjima fazora napona i struje, što će biti opisano poslije) (engl. MicroGrid Central Controller). MGCC trebao bi imati tehničke i ekonomske funkcije da bi potpuno optimirao proizvodnju iz mikromreže.

MC – kontroler izvora u mikromreži (engl. Microsource Controller)

LC – kontroler potrošnje u mikromreži (engl. Load Controller).

III. NADZOR, ZAŠTITA I VOĐENJE MIKROMREŽE U STVARNOM VREMENU

A. Motivacija

Mrežna pravila EES-a [5] za sve pogonske probleme koje donosi utjecaj distribuiranih izvora u EES-u imaju rješenje u bezuvjetnom odvajanju od mreže. Danas su sve glasnija razmišljanja o potrebi promjene Mrežnih pravila [12] na strani opstojnosti paralelnoga pogona s mrežom te omogućivanju otočnoga pogona određenih vrsta elektrana s dijelom mreže.

Glavni izazovi identificirani u sklopu razmišljanja o promjeni Mrežnih pravila vezanih uz predmetnu problematiku su:

- zahtjevi prema elektrani s gledišta statičke i dinamičke potpore stabilnosti napona u točki priključenja
- mogućnosti prolaska pojedinih vrsta elektrana kroz stanje kvara u mreži i održanje elektrane u paralelnom pogonu (N-1 kriterij za distribuirane izvore energije)
- utvrđivanje primjerenih uvjeta paralelnoga pogona elektrane i mreže te uvjeta za odvajanje iz paralelnoga pogona i prelazak u otočni pogon
- otočni pogon elektrane s dijelom distribucijske mreže.

Sve to dovodi do zaključka o potrebi promjene Mrežnih pravila i donošenja novih Tehničkih uvjeta za priključenje distribuiranih izvora na distribucijsku mrežu.

Kao posljedica spomenutih glavnih razloga za stvaranje novih uvjeta koji vode k paralelnom pogonu distribuiranih izvora s distribucijskom mrežom te otočnoga pogona potrebno je definirati i sljedeće:

- izrada odgovarajućih matematičkih modela, algoritama i simulatora kao alata za pomoć u vođenju distribucijskoga EES-a
- korištenje distribuiranih izvora radi smanjenja gubitaka u distribucijskom sustavu
- održavanje kvalitete napona
- uređenje postupaka resinkronizacije distribuiranih izvora na mrežu nakon odvajanja
- procedure i uvjeti automatskoga uključenja izvora na mrežu.

B. Moguće rješenje

Problem koji se javlja ako se Mrežna pravila budu mijenjala kako je opisano jest kako ostvariti nadzor, zaštitu i vođenje distribucijske mreže. Rješenje u prijenosnom sustavu je poznato i zasniva se na uređajima za sinkronizirano mjerenje fazora (PMU uređaji – engl. Phasor Measurement Unit). Tako razvijen sustav naziva se WAMPAC odnosno Nadzor, zaštita i vođenje prijenosne mreže na osnovi sinkroniziranih mjerenja [9-10], [13-16].

Brojne su studije pokazale da tradicionalna zaštita može otkriti i izolirati kvarove u mikromreži u različitim režimima rada, pogotovo kada su u otočnom pogonu. Razlog je u značajnim razlikama struje kvara i struje opterećenja kao i u smjeru struje. Pokazalo se da se mikromreža može odgovarajuće zaštititi korištenjem naprednih digitalnih releja razmještenih na svako čvorište unutar mikromreže [17]. To se postiže uzorkovanjem napona i struje valnih oblika po stopi uzorkovanja od 1 kHz ili više te prijenosom izmjerenih vrijednosti drugim relejima u sustavu. Time se zapravo gradi shema diferencijalne zaštite koja će otkriti kvar bez obzira na način rada mikromreže. Taj je postupak veoma učinkovit u pogledu zaštite, ali je preskup.

Rješenje se može naći u preslikanoj shemi s prijenosnoga sustava, primjerice nazvanoj LAMPAC (engl. Local Area Monitoring, Protection and Control) ili Nadzor, zaštita i vođenje mikromreže. Predloženom bi se shemom u mikromreži koristili PMU uređaji i centralni kontroler. PMU uređaji mjerene vrijednosti fazora napona i struja u 20 ms razlučivosti prenose centralnom kontroleru, koji provođenjem određenih algoritama može primjerice odvojiti, mikromrežu u otočni rad. U nastavku će biti opisano predloženo moguće rješenje.

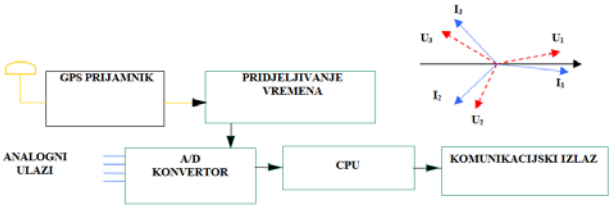
C. Local Area Monitoring, Protection and Control – LAMPAC

PMU uređaji

Uređaji za sinkronizirano mjerenje fazora tehnološki su napredak u korištenju sistemskoga nadzora i čine njegovu osnovu. Ti su uređaji objedinili klasične uređaje sekundarnih sustava i potrebno novo funkcijsko svojstvo za prikupljanje podataka u stvarnom vremenu. Tek tako oblikovani omogućili su kvalitetnu realizaciju sistemskoga nadzora.

Razvoj tih ili sličnih uređaja započeo je ranih 1980-ih, uglavnom u Sjedinjenim Američkim Državama (SAD). Početkom devedesetih objavljena je i prva norma američkoga strukovnog udruženja IEEE (eng. Institute of Electrical and Electronics Engineers). Norma IEEE 1344 o sinkrofazorima doživjela je više promjena, a najnovija verzija nosi naziv IEEE 1344-1995.

Razvojem uređaja za sinkronizirano mjerenje fazora izrađena je nova norma, koja je globalno prihvaćena (norma nosi oznaku C.37-118-2005).



Slika 3. Osnovna blok-shema uređaja za sinkronizirano mjerenje fazora

Kao i svaki drugi uređaj sekundarnih sustava, uređaji za sinkronizirano mjerenje fazora pretvaraju analogni signal u digitalni, uz određeno filtriranje i brzinu uzorkovanja. Ključna prednost uređaja za sinkronizirano mjerenje fazora pridjeljivanje je vremenske oznake za svaki uzorak. Tek se nakon toga informacija o struji, naponu i frekvenciji šalje prema daljinskim centrima vođenja. Glavne karakteristike uređaja za sinkronizirano mjerenje fazora su:

- brzina uzorkovanja od 10 do 50 uzoraka u sekundi
- uzorkovanje napona i struja
- pridjeljivanje točnog vremena uzorku, s točnošću od 10-6 (1 μs)
- vrijeme obrade unutar sinkronizirane mjerne jedinice do nekoliko milisekundi
- prijenos direktne komponente, napona, struje i frekvencije
- lokalna mjerenja i lokalne funkcije
  - funkcija podnaponske zaštite
  - funkcija nadnaponske zaštite
  - funkcija podfrekventne zaštite
  - funkcija nadfrekventne zaštite
  - funkcija nadstrujne zaštite
  - funkcije lokalnoga upravljanja i signalizacije
- brzine komunikacijskih ulaza/izlaza 10, 100 ili 200 MB
- lokalni prikaz mjerenja na uređaju.

Centralni sustav prikupljanja podataka – centralni kontroler

Centralni kontroler sastoji se od strojnoga dijela (hardware - HW) i programske podrške (software - SW), koja je najčešće smještena u sklopu opreme i podrške za nadzor, zaštitu i vođenje mikromreža u regionalnim, nacionalnim i područnim centrima upravljanja.

Hardver se u principu uvijek sastoji od konfiguracije server + klijenti. Moguće su dvije osnovne konfiguracije:

I. jedan server + klijenti

II. jedan glavni server + više podservera + klijenti.

Server može objedinjavati više funkcija:

- prihvat podataka iz mreže PMU uređaja
- obrada podataka

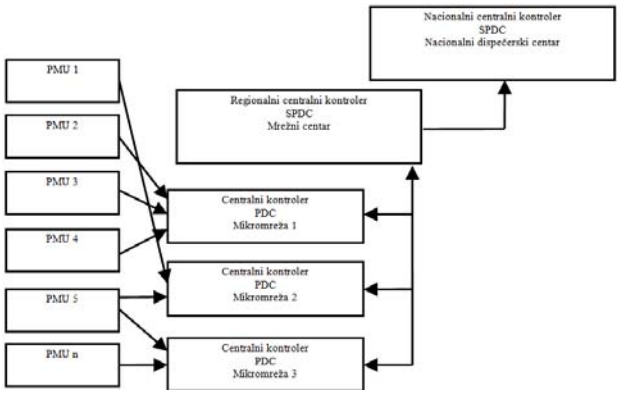
- ostvarenje funkcija nadzora, zaštite i vođenja
- arhiviranje podataka
- sučelje prema operatorima.

Osnovna razlika između konfiguracija I i II u načinu je prikupljanja podataka. Konfiguracija I ima samo jednu razinu na kojoj se prikupljaju podaci (centralni kontroler, engl. Phasor Data Concentrator – PDC), a konfiguracija II ima dvije ili više razina. Server koji prikuplja podatke na višoj razini naziva se i Super Phasor Data Concentrator (SPDC).

LAMPAC

Objedinjena ugradnja opisanih PMU uređaja na točno određena čvorišta u mikromrežama (proračuni tokova snaga i struja kratkoga spoja za različita pogonska stanja, kao i dinamički odziv distribuiranih izvora) povezana s opisanim centralnim kontrolerom, na kojem se instalira programska podrška koja pomaže operatoru sustava u nadzoru, zaštiti i vođenju, predstavlja LAMPAC sustav.

Na slici 4 prikazana je blok-shema LAMPAC sustava.



Slika 4. Blok-shema LAMPAC-a

Ako u mikromreži postoji relativno mali broj PMU uređaja, moguće ih je kvalitetno i sigurno povezati samo jednim centralnim kontrolerom. Kada se taj broj poveća, odnosno povezuje se više područja, potrebno je migrirati u pravcu više centralnih kontrolera, koji su na kraju objedinjeni s jednim regionalnim centralnim kontrolerom. Obrada podataka unutar centralnoga kontrolera ne usporava bitno protok i brzinu slanja – kašnjenje je u tom slučaju nekoliko stotina milisekundi.

Centralni kontroleri prikupljaju i obrađuju podatke iz PMU uređaja, iz cijele mikromreže u stvarnom vremenu, čime se dobivaju trenutačne snimke stanja mikromreže. Tako se ostvaruje stvarna slika stanja unutar mikromreže. Vrijeme za ostvarenje uvida u stanje mikromreže i osvježavanje podataka manje je od 200 ms. Ekstrakcijom, obradom i uporabom ekspertnih algoritama (programska podrška) omogućuje se i pravodobno informiranje i upozoravanje operatera u dispečerskim centrima. Bitna razlika u odnosu na klasične SCADA sustave je u brzini prikupljanja podataka. Klasični SCADA sustavi kasnili su s prikazom stanja unutar EES-a do nekoliko minuta i uz takvu brzinu nisu mogli pružiti sliku stanja mikromreže u stvarnom vremenu.

D. Primjeri nadzora, zaštite i vođenja mikromreža u svijetu

U svijetu se nadzor, zaštita i vođenje mikromreža zasnovano na sinkroniziranim mjerenjima fazora sve više naglašava kao rješenje te se ispituje simulacijama i pilot-projektima.

Kao primjer se može istaknuti dokument Office of Electricity Delivery and Energy Reliability – Smart Grid R&D Program, Department of Energy, USA [18], koji ističe sljedeće: "Potrebno je razviti normirani sustav koji obuhvaća hardver i softver te podržava komunikacijske protokole i Cybersecurity norme da bi omogućili tzv. plug and play distribuiranih izvora; razviti sustav na osnovi sinkroniziranih mjerenja (PMU uređaja) za proračun estimacije stanja, vođenje sustava, odnosno sustav koji bi omogućio sinkronizaciju i rekonekciju mikromreže."

IV. HRVATSKO RJEŠENJE

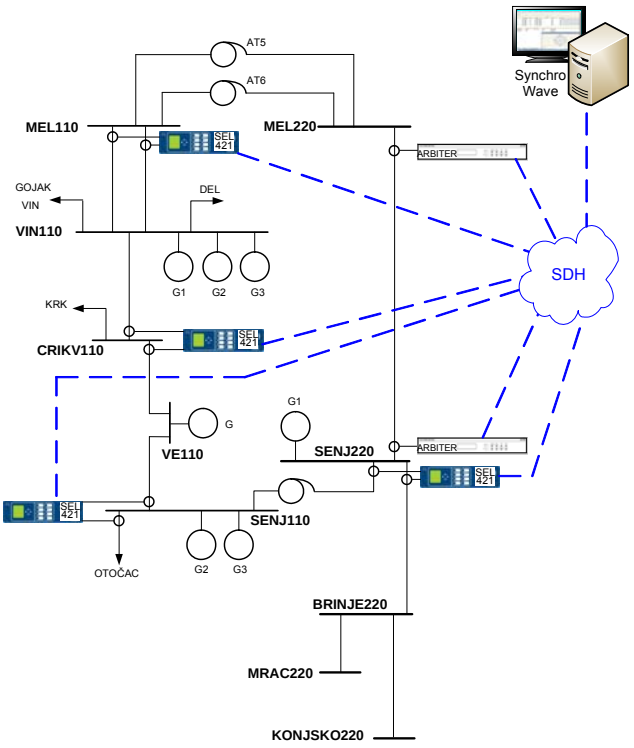
Tijekom rada na dva znanstvena projekta [19, 20] razvijen je sustav nadzora, zaštite i vođenja prijenosnoga sustava s integriranim obnovljivim izvorima energije.

Razvijeni sustav imao je smjernice da u svakom trenutku treba održavati ravnotežu između proizvodnje i potrošnje električne energije te osiguravati sigurnost i stabilnost EES-a (i to uz minimalne troškove).

Ciljano, odnosno ostvareno stanje nadzora, zaštite i vođenja prijenosnoga EES-a rješenje je koje se odnosi na tri temeljna cilja: očuvanje stabilnosti i integriteta EES-a u cjelini (odnosno SIPS), omogućivanje regulacije proizvodnje odnosno evakuacije viška snage iz dijelova EES-a u svakom trenutku te mogućnost napajanja potrošača, odnosno dobavu manjka energije. Potrebno je naglasiti da ni u kojem slučaju sustav nije zamjena za dispečera nego pomoć pri odlučivanju.

Razvijeni sustav podrazumijeva zajedničko automatsko djelovanje, zasnovano na funkcijama upravljanja, zaštite i mjerenja, radi očuvanja zadanog stanja dijela prijenosne mreže. Zahtjevi na brzinu djelovanja su ekstremni te je potrebno djelovati u stvarnom vremenu, uz veoma sigurne i pouzdane telekomunikacijske putove. Razvijeni sustav, kompletna oprema s PMU jedinicama implementirana je u Prijenosnom području (PrP) Rijeka, gdje se nalazi vjetroelektrana Vrataruša te više konvencionalnih izvora električne energije. Na slici 5 prikazana je shema nadzora, zaštite i vođenja PrP Rijeka s naznačenim PMU uređajima.

Na principima razvijenoga sustava za prijenosnu mrežu pristupilo se modificiranju za potrebe nadzora, zaštite i vođenja mikromreže, uvažavajući postojeća Mrežna pravila te zahtjeve operatora sustava i vlasnika distribuiranih izvora električne energije.

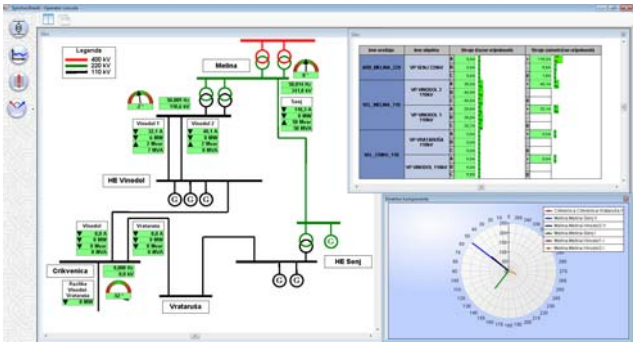


Slika 5. Shema nadzora, zaštite i vođenja PrP Rijeka s naznačenim PMU uređajima

Osnovne naznake arhitekture sustava su sljedeće:

- sustav je zasnovan na PMU uređajima opisanima u poglavlju 3.3., slika 4
- sustav je razvijen na Microsoft .NET 4.0 platformi te podržava Microsoft Windows Server 2008/2012 operacijski sustav za poslužiteljske komponente i Microsoft Windows 7/8 za korisničke aplikacije
- grafičko sučelje za operatore sustava omogućuje prikaz izmjerenih, uvezenih, izračunatih i arhiviranih vrijednosti te alarma i događaja kroz sljedeće vizualne module: prikaz vektorskih dijagrama, topološki prikaz promatrane elektroenergetske mreže (transformatorske stanice i vodovi) s pridijeljenim izmjerenim i izračunatim vrijednostima na elektroenergetskom objektu (napon, struja, frekvencija, radna snaga, jalova snaga i prividna snaga), prikaz podataka iz arhive
- alarmiranje i lista događaja – sustav upozorenja prati i signalizira promjene u radu EES-a. Pragovi za upozorenja i alarme mogu se podešavati po svim parametrima za sve granice za stanje EES-a i za sve proračune
- implementirani su proračuni: izračun radne snage (P), jalove snage (Q) i prividne snage (S), izračun razlike kutova napona sabirnica u EES-u, izračun temperature voda, izračun oscilacija frekvencije, radne snage i napona
- sustav podržava protokol IEEE C37.118 za prikupljanje i izvoz podataka
- sustav koristi Microsoft SQL Server 2008 ili višu verziju RDBMS-a za spremanje konfiguracije svih komponenti sustava i modela mreže
- u bazu podataka sprema se model mreže koji se koristi za proračune koji zahtijevaju poznavanje topologije mreže
- konfiguracijska baza i baza modela mreže podržava verzioniranje, tj. mogućnost spremanja više verzija konfiguracija i modela da bi se održala konzistentnost arhive podataka uslijed promjena konfiguracije i promjene topologije mreže
- arhiva izmjerenih i izračunatih veličina sprema se u raspodijeljenu bazu (bazu koja može biti raspodijeljena na više fizičkih servera), koju korisnik vidi kao jednu bazu, čime se postiže redundancija i segmentiranje podataka po serverima. Baza nema ograničenja vezana uz količinu i vremenski period čuvanja podataka.
- korisniku je omogućeno da bilo koji set podataka izveze u CSV format
- omogućeno je parcijalno arhiviranje na događaj u EES-u.

Na slici 6 prikazano je grafičko sučelje razvijenoga programskog paketa (prikaz je za prijenosni sustav i trenutačno se prilagođava za potrebe mikromreža).

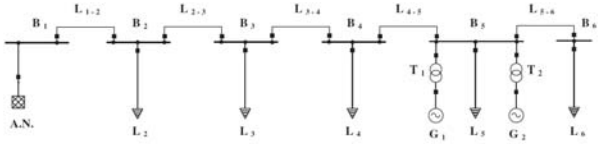


Slika 6. Prikaz razvijenoga programskog sučelja za nadzor, zaštitu i vođenje

Analiza primjenjivosti LAMPAC sustava provedena je na primjeru mikromreže Sveučilišnoga kampusa u Rijeci, za koji je predviđena kogeneracija (Combined Heat and Power – CHP) kao distribuirani izvor [21]. CHP je dizajniran da bi osigurao toplinsku energiju za Sveučilišni kampus, bolnicu na Sušaku i okolne privatne potrošače te omogućio proizvodnju električne energije.

CHP projekt obuhvaća potrebne prilagodbe u distribucijskom sustavu, ali daje LAMPAC rješenje koje omogućuje otočni pogon toga dijela distribucijske mreže, odnosno mikromreže s neprekinutom opskrbom kritičnih potrošača (npr. bolnica) električnom i toplinskom energijom. Takav je slučaj razmatran u slučaju ozbiljnog poremećaja u distribucijskom sustavu.

Na slici 7 prikazana je mikromreža Sveučilišnoga kampusa u Rijeci,



Slika 7. Mikromreža Sveučilišnoga kampusa u Rijeci

gdje je:

Bx – sabirnica

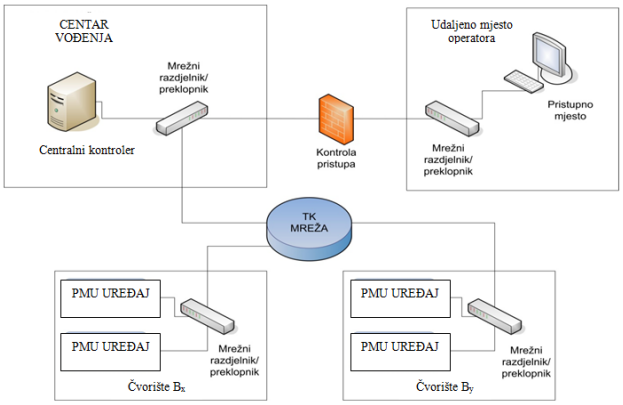
A.N. – mjesto priključka na distribucijsku mrežu

Lx-x – kabeli

Lx – tereti

Gx – generator za proizvodnju električne energije snage 1063 kW.

Na slici 8 prikazano je idejno rješenje LAMPAC sustava.



Slika 8. Idejno rješenje LAMPAC sustava za potrebe mikromreže Sveučilišnoga kampusa

V. ZAKLJUČAK

Značajan i rastući trend integriranja distribuiranih izvora u elektroenergetsku mrežu nameće operatorima sustava izazove u smislu nadzora, zaštite i vođenja distribucijske mreže. Također je potrebno preispitati postojeća Mrežna pravila te pravilnike o priključku distribuiranih izvora radi korištenja pozitivnog djelovanja distribuiranih izvora i pomoći u vođenju sustava. Da bi se to ostvarilo, potrebno je promijeniti pristup nadzoru, zaštiti i vođenju sustava prema stvarnom vremenu i voditi se smjernicama vođenja dijelova distribucijskih sustava – mikromreža paralelno s distribucijskom mrežom i u otočnom pogonu. U radu je prikazano jedno od mogućih rješenja nadzora, zaštite i vođenja mikromreža, zasnovano na sinkroniziranim mjerenjima, nazvano LAMPAC (engl. Local Area Monitoring Protection and Control). Predstavljeno rješenje podrazumijeva raspodjelu distribucijskoga sustava na više mikromreža te postavljanje PMU uređaja u određena čvorišta svake mikromreže, što se određuje provedbom proračuna tokova snaga i struja kratkoga spoja za karakteristična pogonska stanja. Mikromreže se nadziru i vode pomoću centralnoga kontrolera, koji se nalazi u centru vođenja. To rješenje obuhvaća već razvijenu programsku podršku koja ima svoju pozadinu u prijenosnom sustavu. Programska podrška vezana uz vođenje prijenosnoga sustava s integriranim obnovljivim izvorima osnova je za izradu LAMPAC sustava. Za potpuno gotov LAMPAC sustav potrebno je izraditi algoritme koji su specifični za svaki pojedini distribucijski sustav, a izraditi ih treba u suradnji s uputama operatora sustava.

Prikazano rješenje nalazi svoju financijsku i tehničku opravdanost na primjeru primjene LAMPAC sustava u mikromreži Sveučilišnoga kampusa u Rijeci. Daljnji razvoj treba svakako usmjeriti prema sličnim sustavima u stvarnom vremenu, primijenjenim na mikromreže kao temelj budućega vođenja distribucijskoga sustava. Važno bi bilo i ostvariti suradnju s operatorima sustava te izraditi pilot-projekt predloženoga LAMPAC sustava.

***Abstract*—This paper conducts a survey of modern binary pattern flavored feature extractors applied to the *Facial Expression Recognition* (FER) problem. In total, 26 different feature extractors are included, of which six are selected for in depth description. In addition, the paper unifies important FER terminology, describes open challenges, and provides recommendations to scientific evaluation of FER systems. Lastly, it studies the facial expression recognition accuracy and blur invariance of the Local Frequency Descriptor. The paper seeks to bring together disjointed studies, and the main contribution is to provide a solid overview for future research.**

I. INTRODUCTION

When a scientific field sees a burst of published articles it often results in a clutter where an overview of state-of-the-art is lost. Today, this is what has happend to the field of *Facial Expression Recognition* (FER). Many of the recent articles focus on feature extraction and description. Especially extractors that are somewhat related to *Local Binary Patterns* (LBP) are popular. We term this kind of extractors: *Binary Pattern Flavored* feature extractors. The main contribution of this paper is to provide an overview of how this feature extractor type has been applied to FER. From our literature survey it is evident, that a substantial amount of researchers still base their FER systems on the relatively outdated LBP feature. Often it is not explicitly stated why LBP was chosen, but better performance and general robustness could have been achieved if a different and newer feature had been used. Thus, a clear overview of the current state-of-the-art will allow for the construction of better systems as well as extending them.

In order to provide a thorough overview, we make the following contributions:

- Unification of the FER terminology
- Elucidation of unresolved challenges in feature extraction for FER
- Considerations for choosing a feature extractor
- Overview of binary pattern flavored features currently used for FER
- Recommendations for good evaluation practice of feature extractors for FER

The remainder of the paper is divided according to the list above. Section II defines the FER terminology, Section III elucidates unresolved challenges, Section IV defines feature extractor considerations, Section V provides an overview of current binary pattern flavored features, Section VI provides evaluation recommendations, Section VII performs an example study of how the *Local Frequency Descriptor* (LFD) feature extractor performs for FER, and Section VIII concludes the paper.

II. TERMINOLOGY

By looking through the literature, one can see that different researchers use a slightly different FER terminology. To encourage consistency in the future, we seek to define a set of pivot terms based on the general FER surveys [1], [2], [3], and [4].

Spontaneous expressions are based on a true, underlying felt emotion. They are typically what FER systems aim at recognizing as they are the ones carrying true emotion information.

Posed expressions are acted expressions. According to [5], posed and spontaneous expressions look differently. Spontaneous expressions are hard to obtain, which is why most facial expression databases contain posed expressions.

Micro expressions are expressions which never reach full apex because the executing person suppresses the expressions before they are fully formed. Micro expressions can be very informative in some applications, such as clinical psychology.

Basic facial expressions were defined by [6]. They are six expressions which has been proved universal and are as follows: Happiness, Sadness, Anger, Surprise, Disgust and Fear. Sometimes Neutral is included as well. The basic expressions have been extensively used in FER research, but [7] and [8] argue that they are inadequate.

Entity based FER recognizes expressions by considering the entire face as one entity. This is by far the most popular

and most researched form of FER [9].

Action Unit based FER recognizes muscle contractions and relaxations in the face and use them to recognize the expression. These activations of face muscles are known as *Action Units* (AU) as described by the *Facial Action Coding System* (FACS) [10].

Permanent facial features are features being permanent in the face, such as the eyes and mouth [11].

Transient facial features are volatile face features, meaning that they occur and disappear as the face moves, such as wrinkles and furrows [11].

Geometric features are image features which describe some form of physical parameters of the face, such as positions, shapes, sizes, or similar. Usually, a set of easily recognizable salient points are defined on the face and their positions and mutual distances are used to describe the face.

Appearance features describe image properties based directly on pixel intensities. Often, they are formed by filtering images by a bank of image filters and use their outputs as features. Binary pattern flavored features fall in this category.

Global feature descriptors describe the features over the entire face. Thus, a very small amount of feature location information is kept.

Local features descriptors contain information about the spatial position of features. Many ways of retaining locality information exist, but it is often done by dividing faces into smaller regions, each with its own descriptor.

Engineered features arefeatures which have been explicitly designed and therefore convey some form of meaningful information about the objects in the image.

Learned features are features which are learned from a dataset of observations by a learning algorithm. As a result, the features do usually not convey any meaningful information.

Binary pattern flavored features describe objects in an image by binary patterns extracted from small local image patches. The standard example is LBP. Some authors use the term ”local features” but obviously this term is too easily confused with the term *local feature descriptors*, as defined above.

III. RESEARCH CHALLENGES

In 2011, the first *Facial Expression Recognition and Analysis Challenge* (FERA2011) [12] was held as a way to uncover the then current status of the FER field. A meta analysis of the submitted papers was published in 2012 [9]. Based on this meta analysis, and our thorough literature survey, there seems to be a recent overweight of papers that focus on entity based FER from high-resolution faces viewed front on. The meta analysis concluded that this problem can be considered largely solved for the person-specific case.

We believe that the continued substantial amount of research going into this problem is due to missing awareness of the state-of-the-art. Clarifying the current general challenges of the FER field also results in clarification of the feature specific challenges, as they must be correlated.

Be aware that research has already been done on some of the challenges in the following list, but that more is needed. Also note that most papers only tackle few challenges at a time. Thus, there is unexplored territory to conquer for researchers who are interested in creating multi-invariant systems.

Blurred faces can result from disturbances in the atmosphere or out-of-focus images. *Local Phase Quantization*, developed by [13] for face recognition in blurred images and applied to FER by [14] and [15], is particularly interesting. Note that neither [14] nor [15] investigates FER in blurred images. They use LPQ solely for its high descriptiveness.

Illumination variations results from changes in direction or intensity of light used to illuminate faces. This is often seen in face images obtained in a real-world setting. A substantial amount of research has been done on intensity invariance, and it is a natural property of most binary pattern flavored features. In our survey, we only encountered research on direction invariance as a subparts of larger studies, such as [16].

Transformation of face position and orientation happens if a person is allowed to move freely, as would be the case in a real-world setting. Quite a lot of research has gone into rotation and scaling invariance, such as rotation and scale invariant LBP [17]. Translations aligned with the image plane are often handled by the segmentation algorithm. Changes to face orientation have been studied, such as [18], but it remains an open problem.

Face occlusion happens if there is not a direct line of sight between the camera and the face. Occlusion is often due to mustaches, glasses or hair. It has seen a relatively large amount of research, such as the comparative study done by [4]. However, the topic still remains active and unsolved.

Variations in faces between different people make facial expressions person dependent. [19] proposed to use the difference between the expressive face and the neutral face to eliminate the person specific contributions. However, this requires the setting to be person specific, thus with known identities.

Multiple faces in one image could be a problem. We are aware that this challenge has been studied for face recognition, but so far we have not encountered any such research related to FER.

Variations in facial expression intensity happen because humans can form both subtle and explicit versions of facial expressions. A smile might be small and subtle, it can be large and explicit, or somewhere in between. So far, we have not encountered any research which addresses this challenge.

Recognition of AUs has been done, but as noted in the meta analysis of FERA2011 there is room for a lot more. Reliable recognition of AUs is still a challenge.

Processing time is an important factor in instant feedback systems, which is usually the case for social robots [56] and the like. Some researchers provide notes about the processing time of their systems, but often just as a minor detail. A comparative study would be worthwhile.

TABLE I. FEATURE ABBREVIATIONS

Abbr.	Phrase
LBP	Local Binary Patterns [26]
$LBP^{riu2}_{R,P}$	Rotation Invariant LBP [27]
FLBP	Fuzzy LBP [28]
PLBP	Pyramid of LBP [29]
MBP	Median Binary Patterns [30]
LTP	Local Transitional Patterns [31]
MTP	Median Ternary Patterns [32]
VLBP	Volume LBP [33]
LBP-TOP	LBP from Three Orthogonal Planes [33]
SLMBP	Spatiotemporal Local Monogenic Binary Patterns [34]
LGBP	Local Gabor Binary Patterns [35]
LGBP-TOP	LGBP from Three Orthogonal Planes [36]
LGDP	Local Gabor Directional Patterns [21]
RGJ	Radial encoded Gabor Jets [37]
LGTP	Local Gabor Transitional Patterns [38]
LDP	Local Directional Patterns [39]
LDPv	LDP variance [40]
GDP	Gradient Directional Patterns [41]
WLD	Weber Local Descriptor [42]
LPQ	Local Phase Quantization [14]
RI-LPQ	Rotation Invariant LPQ [43]
VLPQ	Volume LPQ [44]
LPQ-TOP	LPQ from Three Orthogonal Planes [15]
LCVBP	Local Color Vector Binary Patterns [45]
TPCF	Tensor Perceptual Color Framework [16]
CLBP	Curvature Local Binary Patterns [46]
PRICoLBP	Pairwise Rotation Invariant Co-occurrence Local Binary Pattern [47]
Ferns	[48], [49]
LEP	Local Energy Patterns [50]
LFD	Local Frequency Descriptor [51]

IV. FEATURE EXTRACTOR CONSIDERATIONS

A set of considerations for selecting a feature extractor for FER has to be made. A flowchart of the choices can be seen in Fig. 1. Five binary primary choices, all based on ones research focus, has to be made, some with sub-choices. Note that two opposite choices can be combined for potential higher recognition rates as reported by [20].

Most researchers tend to make these choices implicit without arguments. We believe that making choices explicit with solid argumentation will lead to better understanding and therefore better science. Therefore, we encourage future researchers to provide argumentation for the choices they make.

V. BINARY FLAVORED FEATURES

This section provides an overview of modern binary pattern flavored features which have previously been applied to the FER problem. Fig. 2 shows the relationships between these features, including four new, promising features. These four features were selected because they have provided promising results for other applications. We strived to make the list of previously used features as comprehensive as possible, but please note that some could be missing by accident.

From the figure it is evident, that there is a large overweight of feature extractors which use still images containing 2D intensity data as input. In fact, only a single extractor relies on 3D depth data. Only a handful of extractors relies on image sequences. The rest use still images. Based on our survey, this tendency seems to be a good indicator for the status of the FER field in general. We hope that this survey will help to change that. The used abbreviations are explained in Table I.

We encourage readers to use this overview to select a proper feature extractor for their own research, and to minimize the development of redundant features. In 2011, [18] proposed to use *Local Gabor Binary Patterns* (LGBP) for makeing a face-orientation invariant FER system. Later the same year, a system using LGBP for AU based FER won the AU recognition sub-challenge of FERA2011 [35]. As recent as 2014, a new paper on entity based FER using LGBP was published by [52]. The authors seems to be unaware of the previous use of LGBP, as they make no notes or citations to the two articles listed above. Thus, redundant work could have been avoided by a clear overview of the state-of-the-art.

Below we have selected six of the most interesting recently used feature extractors for a more detailed description. We hope that the descriptions will help readers choose a good, modern feature extractor, and thereby enable them to develop highly accurate and robust FER systems for practical use. Note that the novel *Local Frequency Descriptor* (LFD) will be studied in Section VII. As proposed by [53], all of the described features use local descriptors formed by dividing the input images into a set of non-overlapping blocks, each with its own descriptor. The descriptors are then concatenated into one, large descriptor, thus keeping some locality information. This is informally known as the *grid division approach*. Also note that all the referenced methods use entity based FER.

A. Features from static image data

Pyramid of Local Binary Patterns (PLBP) was proposed in 2013 by [29]. PLBP is interesting due to their high level of descriptiveness and low complexity compared to other pyramid methods. The key idea is to extract $LBP^{u2}_{R,P}$ features from a given rectangular region of the image. That region is then sub-divided into four smaller regions, each of which can be further sub-divided and so on. LBP features are extracted from all regions, and their resulting descriptors are concatenated into one. The authors show that two subdivisions are enough, thus creating a total of five histograms for each region. They use the region covering the mouth and the region covering the eyes. PLBP requires less memory and provides faster computation than previous pyramid features. Further, PLBP provides a stronger discriminative ability than previous non-pyramid methods. However, it has not been compared against LPQ or similar modern features.

Median Ternary Patterns (MTP) was proposed in 2013 by [32]. MTP is interesting due to their robustness and high level of descriptiveness. MTP combines the strengths of MBP and LTP to form a highly illumination and random noise invariant feature. The idea is to quantize each pixel into a ternary pattern. For a given pixel, the median of the intensities of its eight directly neighboring pixels is calculated. The neighbors are quantized into three states depending on their relation to the median. The ternary pattern is split into two binary patterns and their two corresponding descriptors are concatenated together. MTP has a higher recognition rate and better illumination and noise robustness than pixel intensity *Principal Component Analysis* (PCA), LBP, MBP, and LTP. No comparison against LPQ or similar has been done.

Local Color Vector Binary Patterns (LCVBP) was proposed in 2013 by [45]. LCVBP is interesting because they

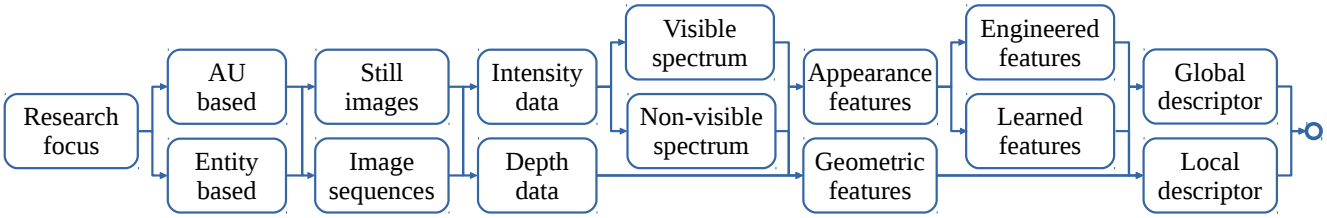

Fig. 1. Flowchart of considerations for selecting a feature extractor. Making these choices should always be based on what is best in relation to the research focus. Opposite choices can be combined, e.g. a system could use both intensity data and depth data to achieve a higher descriptiveness.

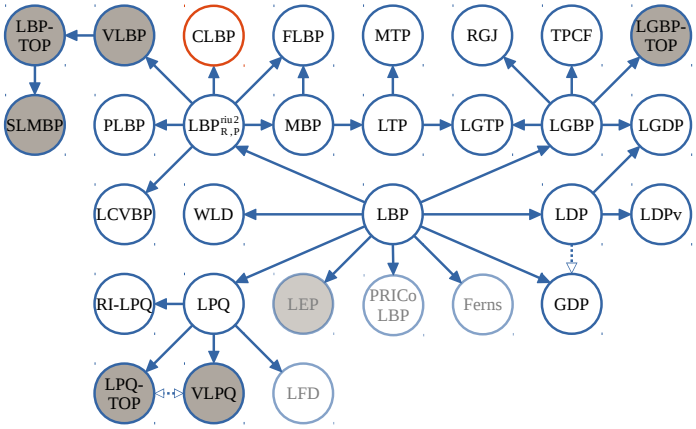

Fig. 2. Overview of 26 binary flavored feature extractors which has been applied to FER, along with four new features. Each node is a feature. Coloring codes: White node = still image data, Gray node = image sequence data, Blue rim = 2D intensity image data, Orange rim: 3D depth data. Solid arrows indicate a direct extension of a previous method. Dotted arrows indicate an inspirational link to a previous method. Transparent nodes indicate new features. The abbreviations are defined in Table I.

are among the few binary flavored features which incorporates color information. The key idea is to treat the color of each pixel as a three dimensional vector of which the magnitude can be calculated by $r = \sqrt{R^2 + G^2 + B^2}$. Binary patterns are created from the magnitude response similarly to the process used by $\text{LBP}_{R,P}$. In addition to these patterns, also magnitude difference patterns, color directional patterns, and color directional arc patterns are extracted. The descriptors from the four pattern types are concatenated to form the final descriptor. LCVBP provides a higher recognition accuracy than a large set of previous features, including $\text{LBP}^{u2}_{8,2}$, LGBP, and TPCF, but excluding LPQ. Further, it is shown that LCVBP allows for sparse representation, is person-independent, and robust against illumination changes.

Local Gabor Directional Patterns (LGDP) was proposed in 2012 by [21]. LGDP is interesting because it revives the use of Gabor wavelet filters in modern binary pattern features, and attain a high recognition rate in doing so. LGDP combines Gabor wavelet filtering and *Local Directional Patterns* (LDP). This is done by exchanging the eight Kirsch compass kernel filters normally used in LDP by eight Gabor wavelet filters corresponding to eight different angles. The eight filter responses are encoded using the same approach as LDP. This is done at five different scales, creating five descriptors which are concatenated. LGDP is showed to provide higher recognition accuracy than LDP and LBP (among others), but it is not compared to LPQ. It is further showed that it is invariant to illumination changes and random noise.

B. Features from image sequence data

Local Phase Quantization from Three Orthogonal Planes (LPQ-TOP) was proposed in 2011 by [15]. LPQ and its derivatives are interesting due to its well established theoretical background, invariance to image blurring and illumination changes, and high level of descriptiveness. It has been showed, that the spatial phase angles of a centrally symmetric *Point Spread Function* (PSF), such as atmosphere and out-of-focus blur, is 0 at frequencies with positive real valued frequency responses. LPQ encodes the phase angles, which makes it blur invariant. The Three Orthogonal Planes framework was developed as an LBP extension by [33]. A given spatial 2D image sequence is considered as a 3D space by letting the movement in time represent the third dimension. From the 3D space, three orthogonal 2D planes are extracted. LPQ descriptors are extracted from each plane and concatenated together to form the sequence descriptor. LPQ-TOP provides higher recognition rates than LBP-TOP and is invariant to image blurring as well as intensity changes. The TOP framework has also been applied to LGBP, forming the LGBP-TOP descriptor by [36]. Unfortunately, LGBP-TOP and LPQ-TOP was not compared.

C. Features from 3D depth data

Curvature Local Binary Patterns (CLBP) was proposed in 2013 by [46]. CLBP is interesting because it is the only binary pattern flavored feature we have encountered which uses 3D depth data. CLBP is invariant to changes in face rotation, face orientation (pose), and changes in illumination. Four types of curvature measures are calculated, namely the two principal curvatures k_1 and k_2, the mean curvature, and the shape index. The four curvature measures are encoded by LBP, and the four resulting feature descriptors are concatenated. It is showed that the recognition accuracy of CLBP is higher than that of two state-of-the-art 3D FER methods, which does not use binary pattern flavored features. It would be interesting to compare this 3D feature to state-of-the-art 2D features with respect to invariance and recognition accuracy. Such a study would provide arguments for choosing one type of input data over another.

VI. RECOMMENDATIONS FOR EVALUATION

To extend the state-of-the-art, one has to benchmark results against those previously reported. Benchmarking can easily be done if all researchers use the same well defined benchmarking datasets along with the same well defined benchmarking procedures. As things are now, quite a few different facial

expression databases and evaluation procedures are used. This includes different databases containing static and sequential images, static and sequential 3D depth data, labeled with basic facial expressions for entity based FER, and/or AUs for AU based FER.

Some 3D depth databases of facial expressions exist, but as was shown in Section V, research on 3D methods is relatively sparse. Therefore, we have not been able to identify a standard benchmarking database and procedure for 3D methods.

For 2D methods in intensity images, the *Cohn-Kanade* (CK) and the *Extended Cohn-Kanade* (CK+) [22] databases are popular. Both databases were primarily created for research in AUs and AU based FER. Therefore, they contain AU labels for all images, but only CK+ contains facial expression labels. As a consequence, researchers who use the original CK database have to manually apply labels to the images, thus potentially creating different labels. To fairly compare results, procedures such as the number of cross-validation groups and the specific identity of samples in each cross-validation groups have to be precisely the same. This process also tends to vary from researcher to researcher.

A good candidate for a unified benchmarking dataset is the well defined dataset and procedure which was used for FERA2011 called GEMEP-FERA2011 [12]. It is composed of two subsets of the original GEMEP dataset, one annotated by FACS for AU based FER and one annotated by emotions for entity based FER. The used emotions are: Anger, Fear, Joy, Relief, and Sadness. Though it has been little used since the competition, it is still maintained and available.

Naturally one usually wants to know how well their FER system recognizes real facial expressions. As mentioned in Section II, true spontaneous expressions are difficult to obtain. Some databases containing spontaneous expressions have been compiled, such as the Rochester/UCSD FacialActionCodingSystem Database 1 (RUFACS1) [23] for 2D intensity data and the BP4D-Spontaneous [24] database for 3D depth data. However, when using only a single database there is the risk of training ones system to recognize some underlying property of the images, other than the actual facial expressions. If so, artificially high recognition rates will generally be obtained when testing on images from the same dataset. To avoid this, [25] showed that cross-database evaluation on multiple facial expression databases will provide a closer-to-real-world recognition accuracy.

VII. AN EXAMPLE STUDY

This section performs an experiment which studies how well LFD recognizes blurred facial expressions. We chose to compare LFD against $\mathrm{LBP}^{u2}_{8,1}$ due to its continued popularity within the field and against LPQ due to its link to LFD as well as its high blur invariance and level of descriptiveness. LFD was developed by [51] as an extension of LPQ which includes magnitude information. They showed that LFD provides higher recognition rates than LPQ for face recognition in blurred images. Thus, our hypothesis was that LFD would also provide higher recognition for FER in blurred images.

We chose to use the CK and the *Karolinska Directed Emotional Faces* (KDEF) [54] databases because of the larger number of images contained in both databases compared to the GEMEP-FERA2011 dataset. Previous research on LPQ have focused on entity based FER. As we wished to benchmark LFD against the state-of-the-art, we also focused on entity based FER. For the same reason we chose still images as our input data.

We chose to base our system on the baseline system defined for FERA2011 because of its simplicity. Our system started by extracting LBP, LPQ, and LFD features using the grid division approach. Then, the dimensionality of each of the feature descriptors was reduced to 140 dimensions by PCA. Lastly, One-Versus-One Support Vector Machines (SVM) [55] were used for classification. Five fold cross-validation was used, and the experiment was executed a total of 10 times with 10 different partitions for the five cross-validation groups. This was done to lower the risk of obtaining bad results due to a bad selection of cross-validation groups.

Every time the experiment was run, the clear images in the four training cross-validation groups were used. The images in the remaining cross-validation group were blurred and used for testing. Gaussian blur was used, and a total of 17 different kernel variances were tried, ranging from 0 to 4 in steps of 0.25. The results of the experiment can be seen in Fig. 3.

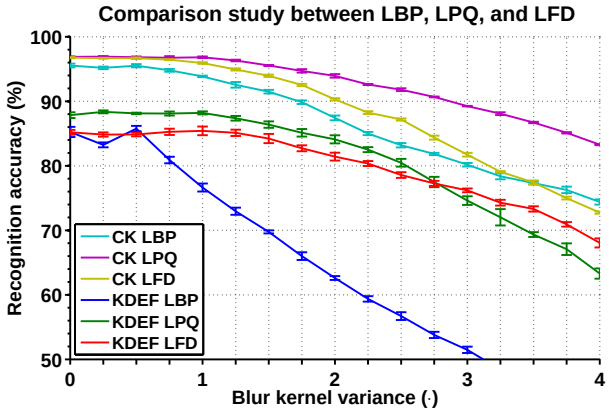

Fig. 3. FER accuracy of LBP, LPQ, and LFD features extracted from blurred images from the CK and KDEF databases. Note that LPQ performs generally better than LFD which again performs generally better than LBP for both databases. Error bars are used to indicate the variance of the recognition accuracy calculated based on 10 runs of five fold cross-validation.

We observe that LPQ generally performs better than LFD, which generally performs better than LBP. A steeper decline in the recognition accuracy of LPQ than LFD is observed for KDEF, which makes LFD better than LPQ at blur-variances of 3 or higher. However, the this effect is not seen for CK. A reason might be, that the CK dataset contains more explicit expressions compared to the KDEF set (which is why the accuracy for CK is generally 10%-points higher than for KDEF). Thus, LFD might have an advantage over LPQ for recognizing subtle expressions in very blurred images. Note that this correlation is highly speculative, and more studies on other datasets containing subtle expressions would have to be done to state anything conclusive.

VIII. CONCLUSION

This paper compiled the most comprehensive overview of the use of binary pattern flavored features for FER to date. We chose to focus on this type of features due to their high popularity and thus large number of recent publications. In addition to the overview, we unified the fundamental FER terminology, elucidated unresolved FER challenges, provided considerations for selecting an FER feature extractor as well as recommendations for scientific evaluation of FER systems, and studied the descriptiveness of the novel LFD feature by comparing it against LBP and LPQ.

Our study of LFD showed that it provides a recognition rate and blur invariance which is higher than LBP, but lower than LPQ.

Despite the large quantity of research in the field, we showed that there are still challenges to overcome. In particular, we showed that multi-robust systems, the use of 3D depth data, the use of image sequences, and FER based on AUs are all more or less open topics. In particular, we see AU based FER as an interesting topic. Recognizing AUs would open up for the possibility of recognizing micro expressions as well as indicating the intensity of recognized expressions. Those properties would be of value to clinical psychology as well as advanced human-machine interfaces. Further, de-identification would be a natural part of an AU system if only the recognized AUs are stored. This could make the system easier applicable to public spaces as no personal identity information would be stored.

***Abstract*—Human detection is an actively researched problem in computer vision, and it has driven the development of a number of detectors, both problem-specific and general purpose. We investigate the performance of human detection in video sequences when three commonly used detectors are combined: background subtraction, boosted cascades of Haar-like features and histograms of oriented gradients. We qualitatively analyze the performance of each of the detectors and quantitatively estimate the performance gain obtained by combining all three. We employ sequences from the publicly available TUD dataset. HOG and background subtraction perform reasonably well when used individually, while boosted cascades of Haar-like features performs inadequately in terms of localization accuracy and false positive rate. Our results indicate that overall detection precision and recall can be improved when combining HOG with background subtraction. Adding the boosted cascades of Haar-like features does not contribute to the overall performance. We conclude that combining HOG and background subtraction is an elegant solution for utilizing the advantages of video data to improve detection performance while maintaining a low processing cost.**

I. Introduction

Reliable human detection in image and video data is essential for the advancement of many actively researched problems in artificial intelligence. For example, a good person detector is at the core of pedestrian detection and collision prevention in smart cars, visual modules of robots for help in the home, intelligent surveillance systems that take into account privacy and similar systems. Detecting humans helps in building better, more advanced human-computer interfaces, one recent and well known example being the Kinect sensor.

In this work, we consider building a system for human detection by combining three heterogeneous detectors: (i) boosted cascades of Haar-like features [1], (ii) histograms of oriented gradients (HOG) [2] combined with a support vector machine classifier, and (iii) background subtraction [3]. Our goal is to benchmark how well a combination of these detectors performs on video data, and whether the performance of image-based detectors, namely histograms of oriented gradients and boosted cascades of Haar-like features, can be improved by introducing video-specific cues obtained using background subtraction. Recent research [4], [5] identifies false positive detections as the main problem of state-of-the-art human detectors. Experiments suggest that low miss rates can be obtained at the cost of several false positive detections per image. We show that false positives can be reduced by assuming motion of people in video, and using the motion information obtained by background subtraction as a support for detections reported by the HOG detector and boosted cascades of Haar-like features. We take special care to support detection in cases when there is no motion, due to a human stopping in the scene. To that end we use a history of background subtraction outputs to infer the probability that such a situation had occurred. An outline of our system is shown in Figure 1.

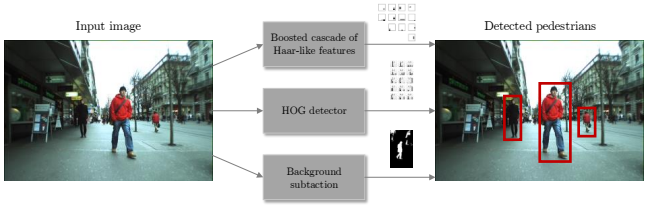

Fig. 1: An outline of the proposed system.

II. Related work

The past decade has been marked by a high interest in pedestrian detection and object detectors in general. In their seminal work [1] Viola and Jones proposed a detector based on a boosted cascade of Haar-like features and applied it to the problem of face detection, obtaining very high performance rates. The work was later extended to the problem of pedestrian detection [6].

Dalal and Triggs [2] proposed a descriptor based on histograms of oriented gradients (the HOG descriptor), that has ever since been used as a standard solution for detecting humans, and has inspired a number of derived and extended approaches.

One of the most promising extensions of HOG is the Deformable Part Model (DPM), proposed by Felzenszwalb et al. [7]. The basic idea of DPM is to model the object of interest with a number of parts. Each part is modeled with histograms of oriented gradients, and can be deformed to a degree. Recent research results [8], [9] suggest that the strength of DPM lies in allowing object deformations rather than in object division into parts, as similar performance can be achieved by using deformations of a single template.

Dollar et al. [10] proposed integral channel features that build upon the ideas of HOG and boosted Haar cascades. The idea is to compute a function of the input image that preserves image layout; the output of such a function is called a channel.

Possible channels include specific gradient orientations, gradient magnitudes, components in RGB, HSV, or LUV color spaces etc. The detector is trained using boosting, similar to the framework of Viola and Jones [1]. The used features are simple sums within rectangles, easily computed using integral images of the considered channels. An extended version of the integral channel features, called the Katamari-v1 [5], has been shown to be the best-performing detector on the Caltech-USA dataset among more than 40 state-of-the-art detectors.

Recently, deep learning has gained considerable popularity in the computer vision community. Several authors [11], [12], [13] propose methods for detecting humans based on deep learning. Although acceptable performance can be obtained by using a convolutional neural network trained on raw pixel values [11], there is a measurable performance improvement when deep architectures are trained using manually crafted features (e.g. edge or color features) [12], [13].

Background subtraction is a method for finding moving objects in videos that can be used as a secondary cue for human detection. For example, Harville [14] proposed combining background subtraction with dedicated higher-level modules for person detection and tracking in order to achieve better overall performance. There are many different background subtraction algorithms that mainly differ in the manner in which the background model is constructed [15], [16], [17]. A comparative overview of several background subtraction algorithms for detecting pedestrians and vehicles in urban scenes can be found in the work of Cheung et al. [15]. Considered algorithms include simple frame differencing, median filtering, linear predictive filtering, non-parametric estimate of the pixel density function, approximated median filter, Kalman filter and mixtures of Gaussians. Experimental evidence suggests that mixtures of Gaussians [18], [19], [20] produce the best results. Similar results can be found in the work of Herrero and Bescós [16], where it is shown that top-performing methods are chi-square modelling, mixtures of Gaussians and simple median filtering.

More details on the current human detection methods can be found in several comprehensive review papers [21], [4], [5]. Dollar et al. [21] introduced the Caltech Pedestrian dataset, benchmarked seven different detectors and proposed to measure false positives per image rather than false positives per detection window in order to obtain a fair estimate of method performance. They followed up this work in [4], by evaluating sixteen state-of-the-art human detectors on six public datasets. Benenson et al. [5] performed an in-depth evaluation of the state of the art in pedestrian detection in the past ten years.

III. The considered detectors

A. Boosted cascade of Haar-like features

The boosted cascade of Haar-like features, proposed by Viola and Jones [1], is a very fast generic object detector. There are several key concepts used in the detector:

1) Haar-like features: A Haar-like feature is a simple rectangular feature commonly drawn as a rectangle consisting of black and white parts, as illustrated in Figure 2. The value of the feature is calculated by summing the pixel intensities under white parts and subtracting them from the sum of pixel intensities under black parts. The computation of the value of a simple 2×2 feature on a 4×4 image is illustrated in Figure 3.

Fig. 2: Examples of Haar-like features.

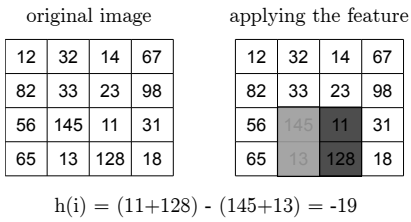

Fig. 3: Computing the value of a Haar-like feature.

Haar-like features are designed to be sensitive to particular image structures, such as edges or angles. In itself, a single Haar-like feature paired with a threshold comprises a very simple classifier. For instance, one might design a classifier by pairing the feature in Figure 3 with a threshold of -5, and designating each image for which the feature takes on a value less than or equal to -5 as belonging to one class, and otherwise belonging to another class.

2) Integral image: An integral image is calculated from the original image in the following way: the value of the pixel (x, y) of the integral image is equal to the sum of the values of all the pixels in the rectangle spanned between points $(0, 0)$ and (x, y) of the original image. Using an integral image, one can compute the value of a Haar-like feature very efficiently, using only four array references.

3) AdaBoost: AdaBoost is a machine learning algorithm that enables combining weak classifiers (i.e. classifiers that are only slightly better than random guessing) into a strong classifier.

In order to build the detector, one needs a training set consisting of object and background images. Based on the training set, the learning process selects a number of very simple classifiers based on Haar-like features that best discriminate object images from background images. The selection is made from a pool of possible Haar-like features, constructed by considering all possible locations and sizes of each feature type. The selected classifiers based on Haar-like features are arranged into a cascade. The cascade is divided into several stages, and each stage comprises of a number of features paired with thresholds. The main idea behind using a cascade structure is the fast rejection of non-objects. Easy non-objects are discarded early on, and harder examples go through to deeper stages in the cascade that are trained on harder examples.

After the training process is complete, the detector is usually applied to a query image in a sliding window fashion, so that sub-windows of the image are scanned for the presence of the object of interest. The detector is very fast and can be used in real time on modern computers.

B. The HOG detector

The HOG detector is a generic object detector comprising of two components: the HOG descriptors and a support vector machine (SVM) classifier. The main idea behind the detector is to represent the image using a grid of histograms of oriented gradients, concatenate the histograms into a feature vector, and then classify the feature vector into object or non-object using a support vector machine classifier.

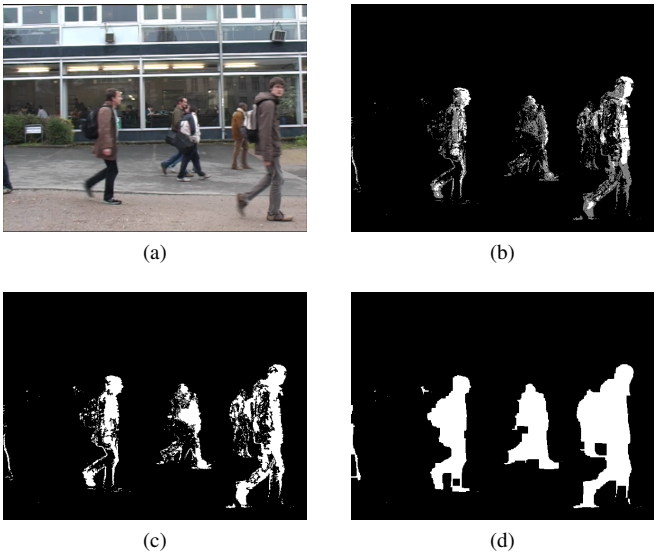
In order to build a feature vector of an image, the image is first divided into a regular grid of cells. The cells are usually rectangular (R-HOG), although Dalal and Triggs [2] also proposed using a circular grid geometry (C-HOG). For each cell, a histogram of gradients is built by calculating the gradient orientation and magnitude in each pixel. The histogram bins represent ranges of gradient orientations, and the weight of the vote of a pixel for a particular orientation is determined by the magnitude of the gradient in that pixel. To reduce the influence of illumination changes, neighboring cells are grouped into blocks, and the contrast in each block is normalized using the total histogram energy computed over the block. The resulting cell histogram probabilities in a block, concatenated into a single vector, are referred to as the HOG descriptor. The final HOG feature vector is obtained by concatenating HOG descriptors of all the blocks.

The detector is trained in a supervised manner, having a dataset of object and background images. Each instance from the training set is represented by its HOG feature vector. Dalal and Triggs [2] suggest using a linear SVM as a classifier. To detect objects in an image, a window is moved across the image and the region of interest spanned by the window is classified as either object or background using the trained SVM classifier.

C. Background subtraction

Background subtraction is a method for finding moving objects in video data. The basic idea of background subtraction is that by observing a sufficient number of frames one can learn a background model. Foreground objects, i.e. objects that are moving in the scene, can then be found by subtracting the learned background model from the query frame.

In this paper we consider the background subtraction algorithm based on mixtures of Gaussians proposed by Zivkovic [20]. The distributions of values of each pixel over time are represented with a mixture of weighted Gaussian distributions. The weights of the Gaussians are updated based on each new frame, and older frames lose influence over time. It is assumed that the distributions of all pixel values will have the highest weights assigned to the Gaussian mixture components corresponding to background, given a sufficiently wide time window. If the time window is wide enough, it can be expected that the number of frames in the window in which the background is being occluded is smaller than the number of frames in which the background is being visible. The Gaussian mixture components of each pixel are ordered according to their weights and thresholded to obtain background and foreground models. The number of Gaussian mixture components is not fixed, but computed dynamically for each pixel based on the available data.



(a) (b) (c) (d)

Fig. 4: Background subtraction in the proposed system: (a) the original frame, (b) the output of the background subtraction algorithm, (c) the extracted and filled contours, (d) the output after morphological closing

Example output of the described background subtraction algorithm is shown in Figure 4 (a) and (b).

IV. Combining the detectors

Our goal is to combine the outputs of the HOG detector, background subtraction and boosted cascades of Haar-like features in order to reduce false positives. We start by post-processing the output of background subtraction. As illustrated in Figure 4(b), the output foreground pixels of the used background subtraction algorithm often do not cover all pedestrian pixels, i.e. some pedestrian pixels are marked as background. As we would like to detect all pedestrian pixels as foreground, we first extract and fill contours of foreground pixels (Figure 4(c)). As some small and unconnected regions still remain after this step, we then apply the morphological operation of closing (dilation followed by erosion), as illustrated in Figure 4(d).

For each HOG detection, we calculate the ratio of foreground and background pixels obtained by background subtraction within the HOG detection rectangle. If the calculated ratio is greater than the predefined threshold called overlap threshold, the detection rectangle is retained, otherwise it is discarded.

The output of boosted cascades of Haar-like features is used as additional evidence for the correctness of detections. We apply several boosted cascades that detect frontal faces, profile faces, lower and upper body and full body. However, in the video sequences that we used the boosted cascades of Haar-like features did not produce satisfactory results and therefore the importance of their output was downweighted. Further details are given in the experimental section.

In combining the output of HOG detector with the output of background subtraction, we need to take into account that some pedestrians in the video can be motionless for some time. Therefore we extend the algorithm logic to take into

Fig. 5: Example frames from the TUD-campus (left) and TUD-crossing (right) sequences

account detections from previous frames. The idea is to retain the detections with weak support from background subtraction if there is evidence of pedestrian presence in recent frames. In our experiments, we retained the HOG detections that do not contain enough foreground pixels if they overlap at least 75% with the detection in the previous frame.

V. Experimental evaluation

We evaluate the performance of the proposed system both qualitatively and quantitatively, in terms of visual inspection of detector output and the achieved precision and recall. For the evaluation, we use two video sequences from the TUD dataset [22]: TUD-Campus and TUD-Crossing. This dataset is chosen over more commonly used ones (e.g. Caltech [21]) due to the fact that it is filmed with a static camera, which is a requirement for applying background subtraction. We use the standard Pascal overlap criterion (intersection over union) [23], counting the detection as correct if its overlap with the annotation is at least 0.5.

The TUD-Campus sequence consists of 71 frames, while the TUD-Crossing sequence consists of 200 frames. Both sequences contain multiple pedestrians. Figure 5 shows example frames from the TUD-Campus and TUD-Crossing sequences.

Qualitative performance of our system is illustrated in Figure 6. It can be seen that the individual outputs of the HOG detector and background subtraction are significantly better than the output of boosted cascades of Haar-like features. We employ the pre-trained HOG detector from the OpenCV library [24], as well as pre-trained boosted cascades. As mentioned previously, we apply several cascades simultaneously, specialized for detecting different pedestrian parts (frontal faces, profile faces, lower and upper body and full body). Although the boosted cascades produce some responses around pedestrians, localization is poor, not all pedestrians are detected and there are a number of false positive detections. The HOG detector detects all pedestrians with some localization errors and two false positives. Background subtraction produces strong responses on the pedestrians and some minor noise, visible at the windows of the building in the scene. Combining the responses of the HOG detector and background subtraction (as explained in the previous section) results in reliable pedestrian detection with no false positives.

Quantitative results of our experiments for combining HOG with background subtraction can be seen in Figures 7 and 8. In each figure, individual curves represent the results of a series of experiments. To obtain each curve we vary the SVM classifier

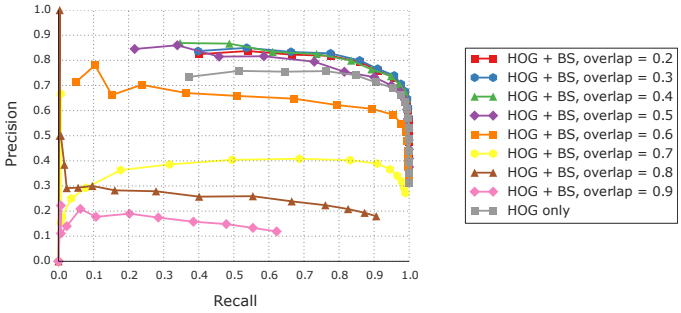


Fig. 7: Precision-recall curves for the TUD-Campus sequence, histograms of oriented gradients (HOG) combined with background subtraction (BS)

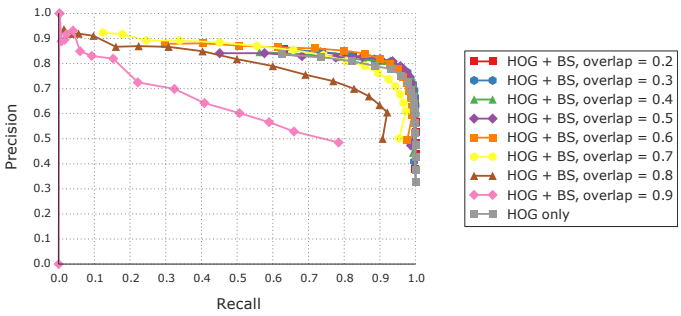

Fig. 8: Precision-recall curves for the TUD-Crossing sequence, histograms of oriented gradients (HOG) combined with background subtraction (BS)

threshold of the HOG detector while fixing the overlap threshold between HOG detections and foreground pixels identified by background subtraction. The SVM classifier threshold takes values from the interval $[-1.6, 1.6]$ with a step of 0.2, while the overlap threshold takes values from the interval $[0.2, 0.9]$ with a step of 0.1.

As can be seen from Figures 7 and 8, applying our method with an adequate overlap threshold and SVM threshold improves performance over HOG only. For a fixed recall we achieve improvements in precision of 5% to 10% in TUD-Campus sequence for overlap thresholds ranging from 0.2 to 0.4, and around 2% to 5% in TUD-Crossing sequence for overlap thresholds ranging from 0.2 to 0.6. Greater values of overlap threshold significantly decrease performance of the detector. This decrease is expected because HOG returns a rectangle around each pedestrian that contains not only foreground but also a considerable amount of background pixels. By increasing the overlap threshold we effectively require more and more foreground pixels in the detection rectangle, which is not a realistic expectation given the average pedestrian shape and motion.

Figures 9 and 10 show detection results obtained by combining all three individual detectors (HOG, background subtraction and boosted cascades of Haar-like features). As already mentioned, this combined detector retains HOG detections that have either enough overlap with the foreground area, or at least some overlap with the detections obtained by the boosted cascades of Haar-like features. Detections that do

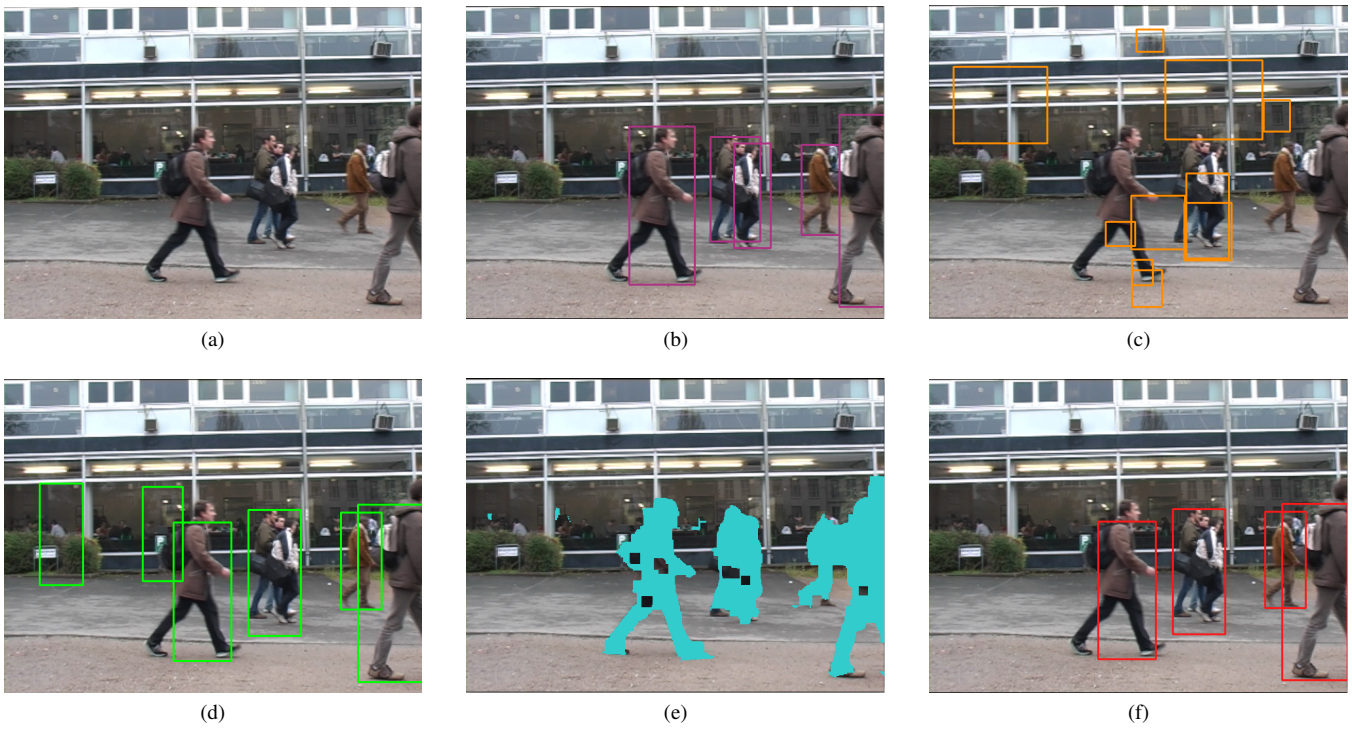

Fig. 6: Performance of our system on an example frame from the TUD-Campus sequence: (a) the original frame, (b) pedestrian annotations, (c) the output of the boosted cascades of Haar-like features, (d) the output of the HOG detector, (e) the output of background subtraction, (f) the output of the combined detector (HOG + background subtraction)

not satisfy neither of the two requirements are rejected as false positives.

The individual precision-recall curves in Figures 9 and 10 were obtained by varying the SVM classifier threshold of the HOG detector while keeping the following two thresholds fixed: (i) the overlap threshold between the HOG detections and foreground area found by background subtraction, and (ii) the overlap threshold between the HOG detections and boosted Haar-like cascade classifier detections. Different curves were obtained by repeating the procedure for different values of the overlap threshold between HOG detection and foreground. However, in this set of experiments we consider only overlap thresholds in the range between 0.2 and 0.6 (with the step of 0.1), since the previous set of experiments showed that larger values of this threshold only degrade the results. The overlap threshold between the HOG detections and boosted Haar-like cascade classifier detections was fixed to a constant small value (0.1) during all of the experiments, as preliminary qualitative evaluation revealed that majority of the detections of boosted cascades of Haar-like features were poorly localized and quite small compared to full HOG detections. The small size of the detections is to be expected, given that we used cascades that detect pedestrian parts rather than full pedestrians. For example, face detections are significantly smaller than full body HOG detections. Hence, we estimated that requiring a greater overlap would effectively trigger no confirmed responses from the boosted cascades.

As can be seen from Figures 9 and 10, adding boosted cascades of Haar-like features to the combined classifier does not result in significant improvement in the classification

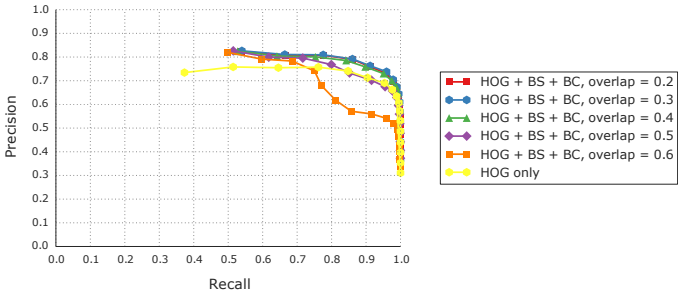

Fig. 9: Precision-recall curves for the TUD-Campus sequence, histograms of oriented gradients (HOG) combined with background subtraction (BS) and boosted cascades (BC)

performance compared to combining HOG and background subtraction only. We attribute this lack of improvement to disappointingly poor detection and localization rate of the used boosted cascades of Haar-like features (see Figure 6(c)).

VI. Conclusion

We proposed a method for detecting humans in videos by combining outputs of three heterogeneous detectors: boosted cascades of Haar-like features, histograms of oriented gradients (HOG) combined with a support vector machine classifier, and background subtraction. The proposed method was succesfully employed to improve performance of the baseline (HOG) detector by reducing false positive rate.

There are several possible improvements of the described

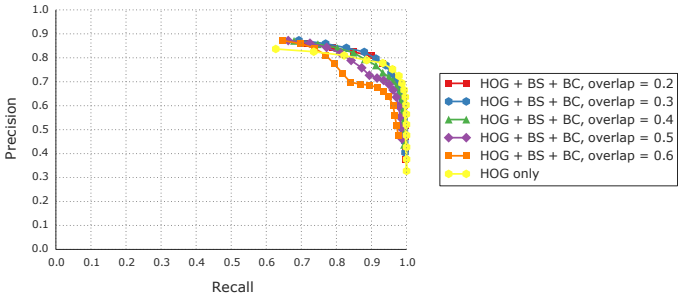

Fig. 10: Precision-recall curves for the TUD-Crossing sequence, histograms of oriented gradients (HOG) combined with background subtraction (BS) and boosted cascades (BC)

idea that will be the basis of our future work. First, better pedestrian detectors can be used instead of HOG + SVM, for example recently proposed pedestrian detectors such as Deformable Part Models combined with latent SVM, or the detector based on Integral Channel Features and boosted ensemble of depth-2 trees. Second, better and more recent methods of background subtraction can be used, less sensitive to stationary foreground objects. Finally, more sophisticated methods of fusion of detector outputs can be considered, such as combining the corresponding feature vectors before classification instead of voting after classification.

ACKNOWLEDGEMENTS

This work has been supported by the Croatian Science Foundation, within the project "De-identification Methods for Soft and Non-Biometric Identifiers" (DeMSI, UIP-11-2013-1544), and by the COST Action IC1206 "De-Identification for Privacy Protection in Multimedia Content". This support is gratefully acknowledged.

The authors would like to thank UNIZG-FER students Martin Blažević and Mateo Srebot who developed parts of the framework used for experiments in this paper.

tonco.marusic@gmail.com

Abstract - Handwritten signature is used in various applications on daily basis. Whether one signs a contract, work documents, petition, or wants to approve a check payment, one will use personal signature to do all those things. In this paper we use this daily based biometric characteristic for identification and classification of students' papers and various exam documents used at University of Mostar. In this paper we used OpenCV library as an image processing tool for feature extraction. As regards to classification method, we used Support Vector Machine.

I. INTRODUCTION

In the teaching process, teaching staff (professors, assistants) must organize and manage a lot of documentation. Exam lists, quizzes, written assignments, tests, attendance lists are just some of them. When we bear in mind that these materials must be archived and stored for some time, it is clear that it is necessary to digitize. This heap of documentation can then be used for various analyses, as well as for formation of a knowledge base. In the process of digitizing, we can use different types of scanners or even cameras from smartphones. Once the documents are scanned, they should be grouped, sorted and stored in individual folders and directories. This entire process can be automated.

Generally, signatures and student ID numbers are used for identification of these documents. Handwritten signatures or handwritten ID numbers represent non-invasive and inexpensive identification methods.

Recognition of individual digits of a number is a problem that is relatively well resolved. A much difficult problem is to recognize digits when some of the handwritten digits are connected. A simple solution is keeping digits separated during enrollment, and to write them to bounding boxes. This is illustrated in Figure 1 that represents proposed header of documents used in various student exams.

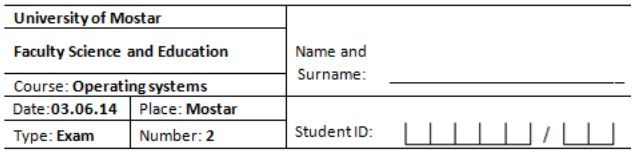

Figure 1. Proposed header of test documents with place for signature and student ID.

During this enrollment, students often type the wrong digit by mistake or they simply cross the bounding box reserved for the individual digits, which will inevitably result in the wrong classification of digits, and thus the misidentification of the author of the document. It would be desirable that the system is resistant to these situations, and potential candidate is to use signatures as a way of verification and/or identification of the author. In this paper, we will check what are the possibilities for identification of various scanned exam documents based on students' signatures. After recognition of the authors, the documents can be automatically classified in the individual directories and linked to document management system (DMS).

As regards to literature, there is much more to deal with the offline verification of signatures in relation to the offline identification of signatures. Terms are similar in that they rely on the database which contains records about user's biometric characteristic features. Then we compare given biometric characteristic features with those stored in the database. The main difference is that verification answers the question: "Is the user really who he or she says to be?'' On other hand, biometric identification answers the question: "Who is the person?"As regards to classification point of view, verification is often referred to as „one-to-one" comparison. Biometric identification is known as „one-to-many" comparison [1]. Since they are similar, papers that deal with verification can be used in our analysis.

Various off-line techniques have been proposed in literature for the signature verification problem. These techniques include: Hidden Markov Models (HMM), Neural classifiers, Wavelets, Dynamic Time Warping [2], Graph matching, Support Vector Machines and so on. Generally, we can say that SVM outperform HMM [5] and Neural networks [3], therefore, we chose SVM as a classifier.

Offline signature verification and identification is a pattern recognition problem and a typical pattern recognition system has the following steps [4]:

- Data Acquisition
- Preprocessing
- Feature Extraction
- Classification
- Performance Evaluation

II. ACQUISITION OF SIGNATURES

There are inevitable variations in the signature patterns produced by the same person (intrapersonal variability) [6]. Some factors that affect our signatures are: a person's physical and psychological state, body position, writing material, purpose of signing (formal vs. informal). In order to build a reliable system, we must obtain a database of signatures extensive enough to capture possible individual variations. We can address this issue by modeling acquisition system that will include different size rectangle areas, pens with different stroke width, different color of imprint, different angle and so on [7].

There are two types of acquisitions in our approach. First, we collected the signatures from 30 students. Each student wrote 22 signatures on a printed sheet A4 paper with the same size rectangles. They used different pens with different color (blue, black, red) and with different stroke width. During the acquisition, we emphasized to students that during the signing the boundary lines should not be touched. With the development of technology for the purpose of acquisition, we can use cameras and mobile phones with additional image processing. After that, the whole A4 document was photographed with a camera from mobile phone Sony Xperia T with a resolution of 4128 * 3096 (13Mpx). For purpose of photography we built improvised tripod with led lamps that illuminate the document. The signatures were manually extracted using an external tool for image processing Gimp. These signatures were then used for our database.

Another type of acquisition included collecting various tests, exam papers of students to whom we performed our classification. In total, we collected 145 documents. We photographed them in an analogous manner with the same resolution as above. However, in this case we did not extract the signatures by manual cropping, but we used computer vision algorithms for doing this automatically. We used mobile phone camera just to capture the documents and all processing was done on PC.

III. PREPROCESSING

Preprocessing is a set of subsequent operations applied for the improvement of quality of signature image and locating ROI (Region of Interest) of signature.

The various sub-processes which can be considered as image preprocessing are: Cropping, Binarization, Noise removal, Morphological Operations, Image normalization, Skeletonization, etc.

A. Binarization

Binarization represents an initial step in most systems for the analysis of document images. It refers to conversion of the gray-scale image into a binary image. It is crucial, because it is the basis for successful segmentation and recognition of characters, words or zones. Generally, we distinguish global and local methods. Global methods use one threshold value to classify the pixels in the image object or to classify the background. On other hand, local schemes can use multiple values based on the information in the local area. Global techniques are not suitable for binarization of documents that are delivered via camera, because such documents suffer from non-unformed lighting, low contrast, shadows [8]. We used local adaptive technique instead.

B. Image denoising

After image acquisition and adaptive threshold, noises like salt and pepper, Gaussian noise were generated during painting. In the documents it is possible to use a series of filters as the median, Gaussian and Wiener filter. We used the median filter which reduces noise with a very small degree of image degradation an also preserves sharp edges unlike the mean filter and considerably less blurs the image in relation to the Gaussian filter.

C. Data Area Cropping and rotation

At the top of each test sheet there is a header containing basic information about the exam. This information consists of the name of the exam, the exam type, number of exam period, the date of the exam, the student's signature, index number, etc. If we are dealing with documents, we must first segment the header, and then in the header we locate the region of interest of signature. For this purpose, the algorithm used is based on the topological structural analysis of the image that has been implemented in OpenCV [9]. This is illustrated in Figure 2 and Figure 3.

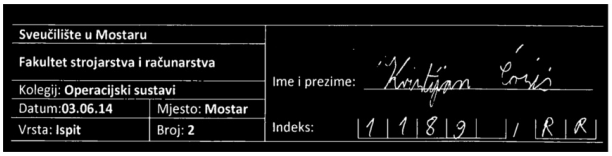

Figure 2.Header document after median filter in negative

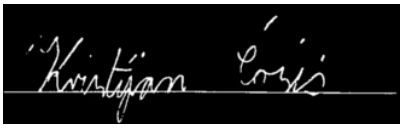

Figure 3. Signature with baseline

In Figure 3 wecan see that base line is extracted with a signature. This line is of great importance to us,we can very easily determine and correct the angle of image acquisition to zero with rotation and using contour segmentation. In this way we improve accuracy of feature extraction.

D. Morphological operations

After binarization, cropping and rotation, we continue processing resulting images in order to improve the quality of text regions and preserve connectivity within certain characters, and meet some possible gaps, holes within the character. For this purpose, we used mathematical morphology operations such as: dilation and image erosion. These operations are usually applied to binary images. Furthermore, in this process we removed the base line with dilation and bitwise operation. After cropping, we found bounding box of signature like in Figure 4

Figure.4. Bounding box of a signature

E. Normalization width

Width of the photographed document is 3096 pxs. Region which the signature occupies is approximately one-third of the header. Once we determine the signature region, each signature will be scaled using bicubic interpolation to constant width of 384 pixels keeping fixed aspect ratio.

F. Skeletonization

When signing the test sheet, a student does not always use the same pen. Thick imprint of pens can greatly affect the value of extracted features. Precise determination of values for certain features in this paper can only be obtained on the skeleton image. Furthermore, this speeds up the execution of algorithms in gathering values for some features. This is illustrated in Figure 5.

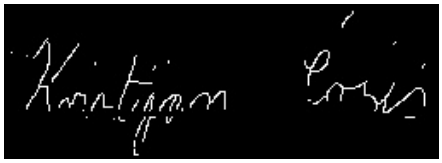

Figure 5. Skeleton signature image

After preprocessing, we can move to determine values of global, grid and SIFT features.

IV. EXTRACTING FEATURES

Features are a key process in achieving high accuracy in identifying signatures. The ideal separation techniques use minimal sets of features that are used to maximize the difference among different people's signatures while minimizing the difference of the same person's signature [10].

Global structural and statistic features of signatures are extracted from the entire image signatures. Grid features are extracted from the grid formed by the parts of the signature [7]. Also we used SIFT feature descriptor in our work.

A. Global features

In literature, there are numerous possible global features [7][10][11][12][13][14][15][16]. After the analysis and testing, we chose 16 global features that proved their efficiency.

1. Aspect ratio - represents the proportionality rate of the skeleton signature image. This is calculated by dividing the height with the width of the signature;

2. Signature occupancy represents the number of pixels that belong to the signature;

3. Baseline shift is a difference between the vertical center of gravity of the left and right side skeleton signature image. At first, counting divided the image signature vertically in two halves and calculated the center of gravity for each half of the CL and CR. Then baseline shift (baseline shift) was defined as BSL = CL – CR;

4. Global Slant Angle - It is the overall direction of line strokes in the skeleton signature. The original signature was rotated from -45degrees to +45 degrees in steps of 5 degrees. For each rotation, the original signature was first pre-processed followed by counting the number of vertical 3-pixels connections from the rotated skeleton image. The global slant angle is the angle which has the maximal number of vertical 3-pixels connections. This is illustrated in Figure 6.

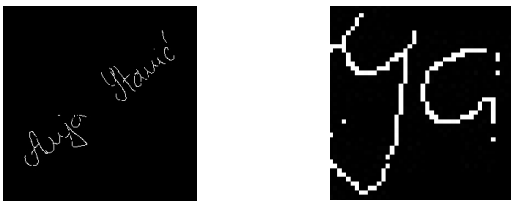

Figure 6. Rotated and skeletonized images for procedure of finding Global slant

5. Number of Edge Points - According to [15] an edge point is a black pixel which has only one 8-neighbour. This is illustrated in Figure 7.

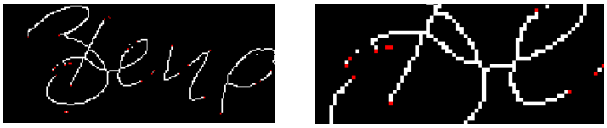

Figure 7. Number of edge points

6. Number of Cross-Points and Spatial Symbols [14]

Every person uses some spatial symbols in his signature, such as: some 'x' marks (cross marks), star

marks or other symbols. The total number of spatial symbols of a person's signature is unique. If we find that one pixel has more than two neighbors, then those pixels will form a spatial symbol. Such types of pixels are shown in Figure 8.

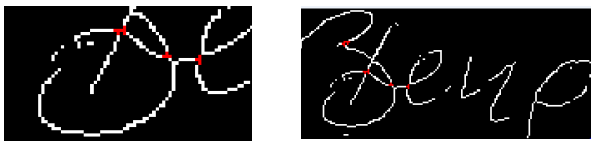

Figure 8. Number of Cross-Points and Spatial Symbols

7. and 8.Horizontal and vertical center of gravity

Center of gravity is pair (X,Y) represented with formula (1)

$$X = \frac{1}{N}(\sum_{i=1}^{n} x_i) \qquad Y = \frac{1}{N}(\sum_{i=1}^{n} y_i) \qquad (1)$$

where x_i and y_i represent numbers of white pixels in columns and rows respectively on binarized image. Part X represents horizontal centre of gravity, and part Y represents vertical centre of gravity.

9. and 10. Length name, Length surname

After analysis of students' papers, we can say that students identify themselves with full first and last name. Generally, there is a considerably larger gap between first and last name in relation to the distance between the individual characters that are often completely connected. This property can be utilized to segment first name and last name, and then retrieve the width for each part. For this purpose, we iterated morphological dilation operation until we got only two segmented parts. During the acquisition we found no instance where all pixels of a signature were completely connected. However in case that there is only one connected contour left during this process, both features would be set to value 0. In case that person has multiple names the largest gap between names is used for division.

11. and 12. Maximal horizontal and vertical histogram

The horizontal histogram is calculated for each row. Row with the highest value is taken as the maximum. Similarly, we calculate the vertical histogram for each column. Column with highest value is taken as maximal vertical histogram.

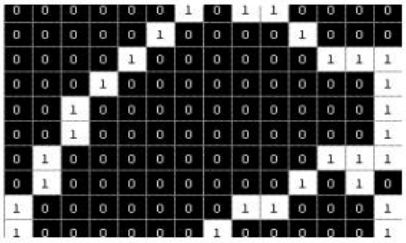
13. The length and ratio of Adjacency Columns [14]

In this stage, we firstly computed the length of the adjacency columns from top and from bottom of the Sample signature image and stored it in a 1D array L_T and L_B. Then we computed the sum of all elements of L_T and all elements of L_B. Overall procedure for this feature extraction is shown in the following Figure6. Upper half of Figure 6 shows a portion of a signature image. Lower half of Figure 6 shows the length of the corresponding adjacency columns from the top and from the bottom.

Now Adjacency Ratio can be calculated (2) as follows:

$$Adjacency\ Ratio = \frac{Sum\ (L_T)}{Sum\ (L_B)} * Si\ gnatureOccup. \qquad (2)$$

Adjacency ratio will be more or less the same for every signature of a person. This is shown in Figure 9.



Length From Top (L_T):													
8	6	4	3	2	1	0	9	0	0	1	2	2	2
Length from Bottom (L_B):													
0	2	4	6	7	8	9	0	1	1	2	3	2	0

Figure 9. Illustration of finding the length and ratio of Adjacency Columns [14]

14. "Heaviness of signature"

Calculation of this feature is based on previous feature. We calculated the absolute difference between the top and the bottom adjacency columns (Figure 10).

Figure10. Illustration of "heaviness" procedure

Then we summed up the difference. After that, we calculated the ratio of difference between sum and background area (black pixels). We used formula (3) based on previous figure.

$$ALR = \frac{sum(height - (L_T + L_U))}{number\ of\ black\ px} \qquad (3)$$

15. Ratio of first vertical pixel to height of image.

In the bounding box image we calculated distance between top left pixel and the y coordinate of the signature first pixel. Then, this distance is divided with height of bounding box. In this way we can find out where the first vertical pixel in our picture is located in relation to height.

16. Number of Closed Loops

It represents the number of closed regions in a signature. We first find the closed region using [9] and then we subtracted with original image and counted contours that left out. In figure we can see 2 closed loops (Figure 11).

Figure 11. On the leftthere is a filled signature, on the right there is a subtracted imagewith two contours

There are a significant number of other global features in literature that we can use, such as: height, pure width, pure height, local slant angle. Since we normalized the width of signature area, some features like width and height were redundant. Instead of a pure width, we used width of two main parts of a signature (name and surname).

B. Grid Features

Each signature image is divided into 18 equal grid regions. From these grid regions, grid characteristics as local features are estimated, such as: width, height, area of signature pixels of each grid region, center of gravity, horizontal and vertical projections, etc. [13]. The global features can also be considered as local features for each grid region. In this implementation we only used number of pixels that belong to a signature for every particular region as a grid feature. We divided signature bounding box to 18 regions so in total we collected 18 features per signature.

C. SIFT Features

SIFT operator is an image local feature descriptor introduced by David G. Lowe in 2004[17]. It is one of the most popular local features. SIFT algorithm detects features in the scale space and confirms the location and scale of key points. Then, it sets the direction of gradient as the direction of the point. Thus the scale and direction invariance of the operator are realized. SIFT is a local feature, which is invariant to rotation, scaling and change of light and stable in a certain extent of changes in visual angle, affine transformation and noise. It ensures specificity and abundance, so it is applicable to fast and accurate matching among mass feature data. Its large quantity ensures that even a few objects can generate a number of SIFT features, high-speed satisfies the requirement of real-time, and extensibility makes it easy to combine with other feature vectors.

We used SIFT features using Bag of Words Model. This model method is extensively used in image classification and retrieval [18].
The main steps are as following:
(1) Detect key points though image division or random sampling etc.
(2) Extract the local features (SIFT) of the image and generate the descriptor.
(3) Cluster these feature related descriptor (usually via K-means) and generate visual vocabulary, in which each clustering center is a visual word.
(4) Summarize the frequency of each visual word in a histogram.
This method was applied to grayscale images. After extracting the features, descriptor was clustered using k - means algorithm where k = 48. In this way we obtained 48 features.

When we obtained a set of global, grid and SIFT features, we combined these feature sets into a feature vector of 82 elements.

V. DATA TRAINING

In this paper, offline identification of signatures was made with the support of vector machine (SVM). The SVM, a learning method introduced by Vapnik et al. [19][20], tries to find an optimal hyper plane for separating two classes. Therefore, the misclassification error of data both in the training set and the test set is minimized. Basically, SVM was used for linear separation of the two classes. When data are non linearly separable, a kernel function is used as polynomial function, radial basis function (RBF) or multi layer perception. The classification based on SVM involves training and testing stages. The training stage was used to find the optimal parameters. Hence, the two parameters should be determined: the kernel parameter and the regularization parameter. These two parameters were found experimentally depending on the dataset. The testing stage allowed evaluating the robustness of the classifier parameters [21]. For finding parameters and for evaluation of robustness of classifier we used signatures from acquisition. That is, we used 15 collected signatures per student for training (15*30=450) and 5 signatures for testing (5*30=150). Various kernels were tried, and the best results were achieved using a RBF kernel. Parameters C and γ for RBF kernel were determined through a grid search in Weka, machine learning software. Overall prediction accuracy for learning model was 98%.

VI. PERFORMANCE EVALUATION

In order to test proposed system with real exam documents, we collected 145 various exam documents of 30 students (from 5 students, we collected 4 documents and for rest it was 5 per student). After feature extraction and learning model on signatures from database, we started identification/ prediction of the authors using SVM as classifier. For measuring performance concerning of the identification of signatures and its affiliation in a particular set of students we used accuracy measurement. The testing was carried out individually for each set of features as well as combination of three selected feature sets.

Results of evaluation are shown in Table 1.

TABLE 1. RESULTS OF IDENTIFICATION OF AUTHORS ON EXAM DOCUMENTS BASED ON SIGNATURE

Method	Correct Prediction	Error Prediction	Average Accuracy (%)
Global Features	104	41	71.72%
Grid Features	90	55	62.07%
SIFT Features	84	61	57.93%
Global + Grid + SIFT features	129	16	88.97%

From the table 1, it can be concluded that global structural and statistic characteristics of signature were the best discriminators with 71.72% accuracy. Set of SIFT and Grid features had a significantly worse accuracy. However, when these individual feature set are joined into a single vector of features we gained significantly in performance and get the best accuracy of the proposed model with 88.97% correctly identified signatures and consequently authors of exam documents.

VII. CONCLUSION AND FUTURE WORK

In this paper we examined the problem of classification of exam documents based on the vector of global, local and SIFT features of students' signatures. The best performance was achieved by using global, local and SIFT features combination, where average accuracy was 88.97 %. Although the learning model showed excellent performance, when we tested the model on real documents it showed significantly lower results. We believe that problem was during acquisition where we emphasized to students that during the signing on rectangular areas, the boundary lines should not be touched. But on real documents they generally crossed the baseline with lower parts of signature.

However the results are promising, considering that our approach is relatively simple. Certainly, the results can be facilitated by using some other feature set (Histogram of oriented gradients, Dynamic Time Warping, Sparse Coding, Features using graph theory) and with some other classifier or with ensemble of classifiers.

In general, we can say that the proposed system will be of great help when used with the system for the recognition digits of the students' ID numbers.

Abstract - Multimedia documents such as text, images, sounds or videos elicit emotional responses of different polarity and intensity in exposed human subjects. These stimuli are stored in affective multimedia databases. The problem of emotion processing is an important issue in Human-Computer Interaction and different interdisciplinary studies particularly those related to psychology and neuroscience. Accurate prediction of users' attention and emotion has many practical applications such as the development of affective computer interfaces, multifaceted search engines, video-on-demand, Internet communication and video games. To this regard we present results of a study with *N*=10 participants to investigate the capability of standardized affective multimedia databases in stimulation of emotion. Each participant was exposed to picture and video stimuli with previously determined semantics and emotion. During exposure participants' physiological signals were recorded and estimated for emotion in an off-line analysis. Participants reported their emotion states after each exposure session. The *a posteriori* and *a priori* emotion values were compared. The experiment showed, among other reported results, that carefully designed video sequences induce a stronger and more accurate emotional reaction than pictures. Individual participants' differences greatly influence the intensity and polarity of experienced emotion.

I. INTRODUCTION

Any multimedia file can generate positive, negative or neutral emotions of varying intensity and duration [1]. By observing still images, films, printed text or listening to sounds, music and voices emotional states of affected subjects may be modulated [2] [3]. This spontaneous cognitive process is an important research topic in psychology, neuroscience and cognitive sciences but also in many interdisciplinary domains like Affective Computing and Human-Computer Interaction (HCI).

Multimedia documents with *a priori* annotated semantic and emotion content are stored in affective multimedia databases and are intended for inducing or stimulating emotions in exposed subjects. Because of their purpose such multimedia documents are also referred to as stimuli. Affective multimedia databases are standardized which allows them to be used in a controllable and predictable manner: the emotion elicitation results can be measured, replicated and validated by different research teams [4] [5]. Combined with immersive and unobtrusive visualization hardware in low-interference ambient affective multimedia databases provide a simple, low-cost and efficient means to investigate a wide range of emotional reactions [6] [7].

Compared to static pictures and sound, video is more powerful format for elicitation of emotional states because it can seamlessly and concurrently stimulates visual and auditory senses thereby multiplying their individual impacts through psychophysiological and neurological underlying mechanisms [8] [9]. It has been repetitively experimentally demonstrated that if careful attention is paid to video editing, i.e. the temporal and contextual alignment of multimedia stream relative to personal cognitions of targeted subjects, it is possible to achieve more intense and accurate stimulation of emotional states and related phenomena such as attention, anxiety and stress [7]. In practical terms affective video databases are much more useful tools than picture of sound databases. However, today very few affective video databases exist while the most prevalent are picture databases. Therefore, it is important to explore the possibility and scope of using documents from existing picture and sound databases to construct successful video sequences for fast, accurate and strong stimulation of emotional states. This goal was behind the motivation for the described study.

The remainder of this paper is organized as follows; Section 2 provides background information about the experimental study and its setup. Section 3 brings forward the results of the study which are discussed in Section 4. Finally, Section 5 concludes the paper and outlines future work into this subject.

II. METHOD

The study was performed at University of Zagreb, Faculty of Electrical Engineering and Computing in cooperation with experts from Department of Psychology, Faculty of Humanities and Social Sciences. A homogeneous group of *N*=10 college students (4 males, 6 women) with an average age 23.8 years (*std* = 4.35) participated in the experiment.

Each participant was stimulated with videos and still images taken from the International Affective Picture System (IAPS) [4] and the International Affective Digital Sounds System (IADS) [5]. IAPS and IADS are two of the most cited databases in the area of affective stimulation. These databases were created with three goals in mind: *i*) better experimental control of emotional stimuli, *ii*) increasing the ability of cross-study comparisons of results, and *iii*) facilitating direct replication of undertaken studies [10]. In this experiment a picture from IAPS and a sound from IADS were combined to make one video-clip. Same IAPS pictures were also used as still image stimuli without

sounds. Some of the pictures used to construct the emotion elicitation sequences are shown in Fig. 1.

Fig. 1. A sample of IAPS pictures used as emotion eliciting video clips and images. Neutral (left column), fear (middle) and happiness dominant emotion stimuli (right).

The dominant emotions purposely elicitated in the experiment were happiness and fear. The stimuli were selected using published research on emotion norms in IAPS and IADS [11] [12] as the most powerful images and sounds for simulation of the two targeted emotions. Firstly, using 200 images and 100 sounds were selected and ranked based on their intensity of happiness and fear emotion norms [11] [12]. Secondly, the sorted list was thoroughly examined by psychology experts and 20 optimal pictures and 20 sounds were manually selected for inclusion in the elicitation sequences. These stimuli were considered the most likely to induce happiness and fear in the participants' population.

Each participant was exposed to four emotion elicitation sequences in two separate sessions or series. Each session consisted of one happiness sequence and one fear inducing sequence, and also of one video sequence and one still image sequence. A single sequence was made up from 10 images or 10 video-clips (Fig. 2). Therefore, in total each participant was exposed to 20 images and 20 video-clips. The length of each stimulus was exactly 15 seconds after which the participant was shown a blank neutral screen and had to write down his affective judgments in a self-assessment questionnaire (SAQ). The expression of subjects' ratings was not time restricted after which the participant could resume the sequence by himself (i.e. with a mouse click). Immediately before the start of the experiment each participant was separately introduced to the stimulation protocol with a neutral sequence. The neutral sequence consisted of one low arousal and valence picture (N Pic) and one video-clip without dominant emotions (N Video). All stimulation sequences are available by contacting the first author.

Half of the participants were first exposed to happiness sequences, and then fear sequences, and also a half of the participants first watched still images and then videos. To prevent the unwanted drift of physiological signals (cardiac and respiratory) before nonneutral sequences participants were exposed to a neutral stimulus until their baseline response was established [13]. The neutral blank screen only showed teal color which − according to [14] − has an optimal ratio of stimulating positive and negative emotions.

The participants' emotional responses were recorded by two methods: 1) self-assessment responses i 2) real-time monitoring of physiological signals. After each exposure to a stimulus participants filled out a self-assessment questionnaire. Each report was unique to a specific stimulus and participants could not see its contents before the stimulus has finished. The test contained following instructions: 1) "Evaluate the type and intensity of emotions" for each of the emotional norms ("happiness", 'sadness", "disgust", "fear" and "some other emotion" if none of previous) on a scale with values 0 − 9, where 0 represented "None", 9 "Extremely" while 5 was a neutral value; and 2) "Evaluate pleasure and arousal" with values -4 – 4 where value -4 was labeled "Extremely unpleasant" and "Extremely calming", and 4 "Extremely pleasant" and "Extremely arousing". Value 0 indicated a neutral sensation of valence or arousal. The report was validated during the preparations for the experiment.

The monitored physiological signals were skin conductance, electrocardiogram (ECG), respiration and skin temperature with a sampling frequency of 1250 Hz. For the acquisition of signals we used BIOPAC MP150 with AcqKnowledge software. The system was synchronized with SuperLab tool for presentation of stimuli to the participants. Emotional states were estimated off-line, with varying levels of certainty, from the recorded signals using previously developed MATLAB software [15] [16]. Before starting the experiment, each participant read the instructions, filled introductory questionnaire and signed informed consent agreement. Additional help, if necessary, was provided by the trained lab assistant who also placed physiological sensors on the participant's body. Participants were seated in a separate part of the lab, 60 – 90 cm before a 19" 4:3 high-definition LCD computer monitor and wore ergonomic headphones. The supervisor station was equipped with a separate computer monitor where the experiment was controlled and participants' psychological signals were monitored in real-time [16].

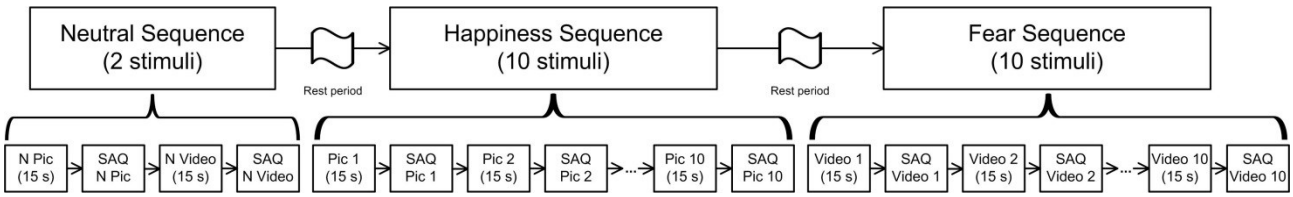

Fig. 2. The timeline of emotion stimulation paradigm. The order of dominant emotion (happiness/fear) and multimedia format (picture/video) were randomized.

†This research has been partially supported by the Croatian Ministry of Science, Education and Sports.

The experimenter and participants were physically separated by a solid artificial wall and had no mutual visual or auditory contact. Additionally, participants did not experience sensory distractions during the experiment. The implemented procedures and the experimental layout were compatible with a setup of a common psychophysiological laboratory [17].

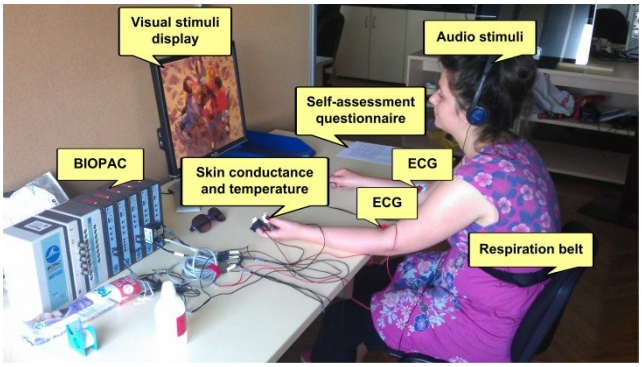

Fig. 3. The layout of participants' station. A person is observing LCD screen with audio headphones and wearing skin conductance, electrocardiogram, respiration and skin temperature contact sensors connected to BIOPAC MP150 system. Self-assessment questionnaire is on the desk. Supervisor is seated on the other side of the wall barrier.

A rest period followed each exposure session during which participants relaxed. This was verified by examining the physiological signal parameters that were visualized in real time. The exposure could resume only after the baseline signal levels were reestablished.

III. RESULTS

The potential of evoking emotional reactions using video clips − constructed from IAPS pictures and IADS sounds − and IAPS pictures was evaluated under equal conditions. Emotional dimensions pleasure and arousal were rated on a scale 1 − 9, and emotion norms (i.e. discrete emotions) on a scale 1 − 10. A lower value (1 − 3) in both scales implies a lesser experience and a higher value (7 − 10) a more intense experience of the particular emotional dimension or norm, respectively. Also, higher frequency of ratings in the upper part of the scale (response > 5) or the highest attainable values (9 and 10) signifies a more intense and powerful stimulation. The frequencies of responses are displayed as frequency distribution diagrams. The aggregated results are shown in Fig. 4.

IV. DISCUSION

Results based on the analysis of participants' self-assessments indicate that the most pronounced reported difference is in arousal emotion dimension. Indeed, videos relative to pictures can more frequently stimulate higher arousal in sequences with dominant happiness and fear. Additionally, video sequences often stimulated higher levels of pleasure in happiness sequences, and lower levels of pleasure in fear sequences, but this distinction is less pronounced than with arousal.

From Fig. 4 it is evident that video sequences were more powerful in stimulation of both emotional dimensions than picture sequences. Happiness-dominant video sequences more often elicited higher levels of happiness basic emotion than happiness-dominant picture sequences. Similarly, fear-dominant video sequences provoked more above average fear ratings than fear-dominant picture sequences. Although frequency distribution differences in basic emotions are present, they are less obvious than the spread in emotional dimensions, especially arousal. In general, the emotion provoking potential of video is more apparent in emotional valence and arousal than in specific emotions happiness, sadness, disgust and fear. Due to reported low stimulation of other emotions except fear and happiness it may be concluded that the sequences were emotionally accurate. This is particularly evident in very low levels of disgust and sadness in happiness sequences and even in fear sequences. In overall video sequences provoked a "cleaner" and more powerful affective response, i.e. with lower reported intensities of emotions different from those targeted, than picture sequences which corresponds well with findings from previous studies [13] [18].

However, because of relatively small number of participants the results analysis is strongly influenced with noticable differences between individual reports. There is a significant variability in the intensity of provoked emotion, polarity (i.e. positive or negative) and discrete category among some participants. Such discrepancies are present in video and picture sequences.

Unfortunately, due to objective reasons it was not possible to include more participants in the study. Subsequently, an independent stimulation protocol could not be implemented and the same visual stimuli had to be used in video and image sessions. If the number of participants was significantly larger different stimuli could be used in videos and images.

Based on the collected results it can be expected that multimedia sequences, carefully prepared for a particular group of participants, will be able to provoke targeted emotional states with the desired intensity. However, construction of optimal sequences proved to be difficult because IAPS, and particularly, IADS databases do not have a wide selection of stimuli with accentuated specific basic emotions. A better choice of provoking visual stimuli is clearly needed which encourages construction of more affective multimedia databases, annotated both with emotional dimensions and discrete emotions, and having a large semantic space. This in turn necessitates development of powerful tools for multimedia stimuli retrieval which can efficiently perform multifaceted search in such databases, along several emotional, semantic and contextual data dimensions, thus assisting researchers in finding optimal stimuli for personalized emotion elicitation sequences [19].

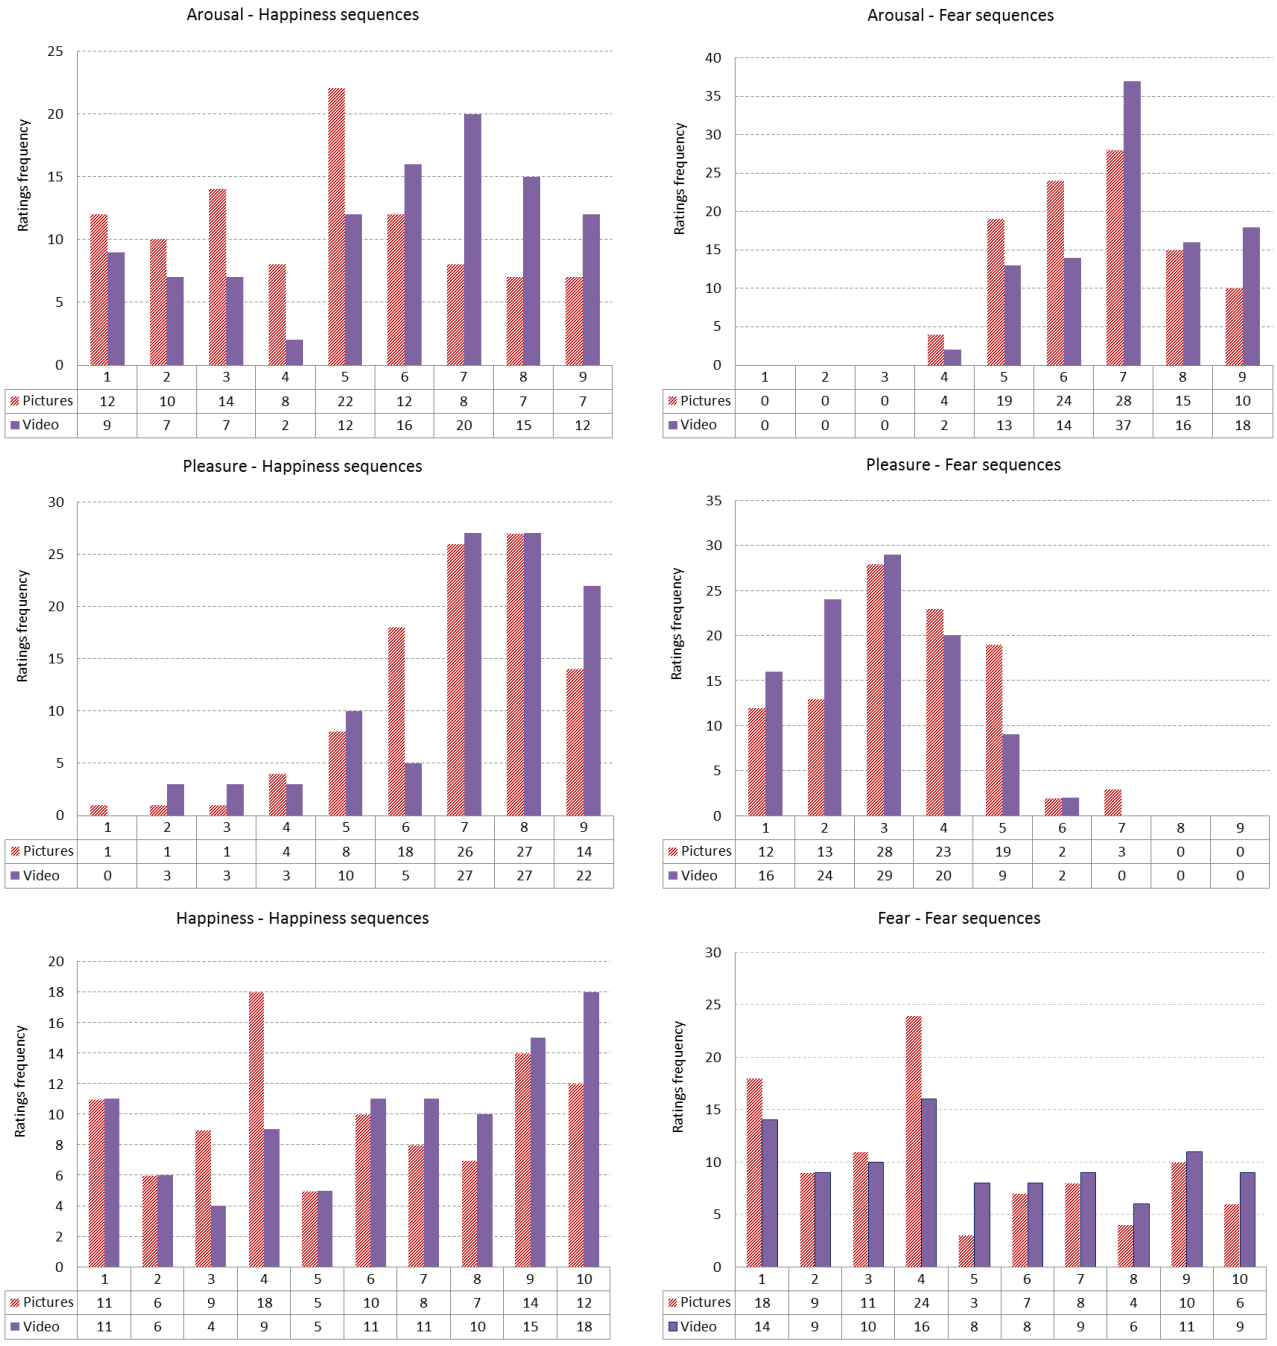

Fig. 4. Frequency distribution of *N*=10 participants' ratings after elicitation with IAPS and IADS video clips ("Video") and IAPS pictures ("Pictures"). Reported emotional dimensions arousal and pleasure (upper and middle rows), discrete emotions happiness and fear (bottom row).

V. CONCLUSION AND FUTURE WORK

Emotional reactions can be induced by virtually any multimedia format: films, pictures, sounds, voice and even text. Participants' responses depend not only on stimuli content, properties and type, but also on a number of intrinsic and extrinsic factors which may be difficult to control in a practical experiment [13] [17]. For example, participants' motivation, attitude, character traits, beliefs, past experiences and the experimental environment (i.e. the setup of the laboratory and the experimental protocol) play an extremely important role in formation of emotion. Therefore, a comparison of emotional reactions induced by pictures and videos may be regarded as a hands-on tutorial for researchers as to which multimedia stimuli properties can lead to more accurate, precise and faster elicitation.

The study showed that standardized picture and sound databases can be joined together and used as videos for elicitation of high-arousal emotional states. Deliberate and practical stimulation of discrete emotions happiness and fear is attainable but it is more difficult and prone to error, especially happiness. The least successful was stimulation of very positive, i.e. high valence, emotional states.

We hope that the presented study could be used in design of emotion elicitation protocols as well as future affective multimedia databases. Additionally, the study's

results may help researchers to find the optimal multimedia format for elicitation of emotion even if appropriate video stimuli are not available.

Abstract - The ability to efficiently search pictures with annotated semantics and emotion is an important problem for Human-Computer Interaction with considerable interdisciplinary significance. Accuracy and speed of the multimedia retrieval process depends on the chosen metadata annotation model. The quality of such multifaceted retrieval is opposed to the potential complexity of data setup procedures and development of multimedia annotations. Additionally, a recent study has shown that databases of emotionally annotated multimedia are still being predominately searched manually which highlights the need to study this retrieval modality. To this regard we present a study with $N = 75$ participants aimed to evaluate the influence of keywords and dimensional emotions in manual retrieval of pictures. The study showed that if the multimedia database is comparatively small emotional annotations are sufficient to achieve a fast retrieval despite comparatively lesser overall accuracy. In a larger dataset semantic annotations became necessary for efficient retrieval although they contributed to a slower beginning of the search process. The experiment was performed in a controlled environment with a team of psychology experts. The results were statistically consistent with validates measures of the participants' perceptual speed.

I. INTRODUCTION

Manual searching of multimedia datasets such as picture repositories and video databases is still predominately based on keyword-based information retrieval. However, range and expressivity of manual data description process are limited. When adding a picture to an Internet repository or social network users are asked to describe the picture, who or what is portrayed, when and where the photo was taken, which emotion does the picture stimulate etc. Frequently users provide contextual information which is insufficient for searching. The retrieved datasets are large and inaccurate [1]. Various semantic categories, available multimedia content and metadata are used to boost retrieval accuracy and improve ranking of results important to the posed query [2] [3] [4] [5]. These procedures are the subject of ongoing research but each of them has restrictions and in practice cannot completely substitute missing expert information.

The missing data problem is especially exacerbated in affective multimedia databases because they implement only sparse annotation with unrestricted keywords [6]. These databases are especially important tool for study of emotion and attention in the areas of psychology, neurology and cognitive sciences [7]. Retrieval of loosely annotated data, with only one expert-defined tag per picture, is even more open to errors than with, for example, social media with community generated tags, hashtags or folksonomies. Although tags are noisy they can still provide useful information if combined with intelligent algorithms for statistical reasoning [8]. As has been shown in a recent survey on usage modalities of emotionally-annotated picture databases [9], the ultimate consequence of such poor semantic annotation scheme is that it is more productive to browse affective multimedia databases visually, although they may contain hundreds or thousands of images, than to search them with keywords. Additionally, this survey showed that 70% of experts need more than 1h to retrieve optimal pictures for a single emotion elicitation sequence and 20% require more than 12h which is extremely impractical. Therefore, it is necessary to establish how much context information is enough to enable efficient keyword and emotion search paradigms in affective multimedia databases. How formal and expressive must the data representation be? Is it necessary to better describe multimedia semantics or emotion, or both? These and other similar questions may be theoretically examined but ultimately only a controlled experiment can provide a definite answer to them. Annotation quality and retrieval efficiency are in a mutual tradeoff. More thorough annotation comes at a cost of better data preparation, but will result in a more accurate search. The experiment described in this paper was motivated to explore optimal methods for annotation of semantics and emotion in affective multimedia databases.

The presented research had two goals; considering the results of the survey it was necessary to determine how fast and accurately experts can find a specific picture stimulus in ideal circumstances. The second goal was to establish minimal emotion and semantic annotation requirements which still enable an efficient searching of affective multimedia databases.

The remainder of this paper is organized as follows; Section 2 provides detailed background information and describes the experimental setup. Section 3 specifies and visualizes all obtained results, and the following Section 4 discusses the results from the perspective of the experiment's goal. Finally, Section 5 concludes the paper and outlines future work into this subject.

II. METHOD

The controlled experiment was performed at the Department of Psychology of University of Zagreb, Faculty of Humanities and Social Sciences. A total of N=75 college students (10 males, 65 women) with an

†This research has been partially supported by the Croatian Ministry of Science, Education and Sports.

average age 19.49 years (*std* = 0.87) participated in the experiment.

All participants performed two tasks; Task 1: find five pictures with particular emotion, and; Task 2: find five pictures with specific emotion and semantics. The search criteria can be considered similar to emotion elicitation sequences typically used in real settings. All participants first performed Task 1 and then Task 2. The results help to estimate the average time to retrieve a stimulus on the basis of the set of semantic and affective criteria, and the number of errors that can occur at the same time.

In both tasks, participants had to, as quick as possible perform visual search tasks in the valence-arousal emotion plane to find the desired stimuli [10] [11]. However, to achieve an optimal search strategy in the second task it was necessary to first input search keywords to reduce the stimuli subset and leave only those pictures that match the Task 2.

A preselected subset of 250 picture stimuli from the International Affective Picture System (IAPS) [12] database was used for both tasks. In total 50 pictures (20% of the subset) matched the search criteria. In Task 1 the participants had to find IAPS pictures with values of emotion dimensions within a given region of valence-arousal plane (*valence* > 5.0 and *arousal* > 5.0), while in Task 2 the pictures had *arousal* > 5.0 and preset semantics (i.e. children, families, specific animals etc.). For Task 2 the participants were given a list of keywords they had to match with the presented stimuli. All tasks were designed with positive, i.e. non-null, results. The tasks' texts and the list of picture stimuli used in the experiment are available by contacting the first author.

The participants used a previously developed software tool "Intelligent stimuli generator" to search for stimuli with emotion and semantic parameters [7]. The tool was specially adapted for the experiment: user interface was greatly simplified for implementation of the experimental protocol. All search paradigms except the manual search and other unnecessary features were removed. However, a comprehensive logging module was added which can enumerate, record and timestamp different user actions, search attempts and categorize them as successful or not. The logs are generated automatically and can be later analyzed with dedicated statistical tools like SPSS or Matlab.

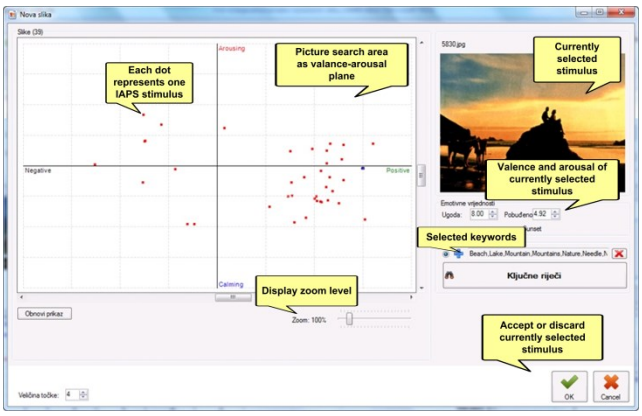

Fig. 1. The main screen of the "Intelligent stimuli generator" tool displaying IAPS stimuli subset in Task 2 defined with selected keywords.

A week before the experiment the college students were given comprehensive written instructions about the "Intelligent stimuli generator" tool so they could familiarize themselves with the user interface and the types of tasks they will have to carry out. The experiment itself took place in the laboratory of the Department of Psychology of University of Zagreb, Faculty of Humanities and Social Sciences. The laboratory contains a number of separate sound-proof cabins with a bench, two seats, PC computer, 17" 4:3 LCD monitor and sound speakers. At a time each cabin seated one lab assistant with psychology training and one experiment participant.

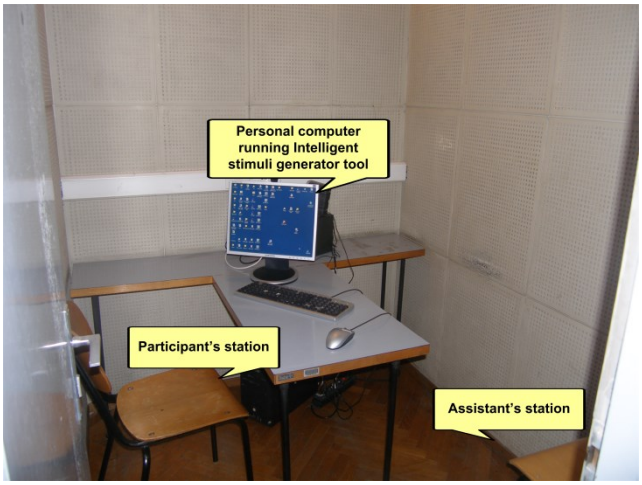

Fig. 2. A soundproof cabin used in the study with two stations for the participant and assistant, and a personal computer for picture retrieval with semantic and emotional cues.

Before the picture search experiment all participants took two standard psychological tests of their perceptual speed [13]. Each test lasted 5 minutes and they were also conducted in controlled conditions with minimum outside sensory interference. The aim of these additional tests was to investigate the relationship of participants' visual search performance and achievement on perceptual speed tests, as a measure of stable individual traits connected to the perceptual ability [14].

III. RESULTS

Complete results of N_{RTOT}=750 pictures retrievals are shown in Fig. 3. Each point in diagrams represents an aggregated mean of N_R=75 records for each of the five searched pictures (numbered 1−5 on x-axis) in Task 1 and Task 2, respectively, with indicated standard deviation. Picture retrieval duration in seconds is provided on y-axis.

The results show that in Task 1 on average 10.74 s (*std* = 8.66) was necessary to find a picture using only valence and arousal emotion constraints. More time was needed to locate files by searching semantics. In Task 2 average 47.48 s (*std* = 15.18) was needed to retrieve a picture with specific keywords and emotion which is more than 4 times longer than the retrieval without semantics.

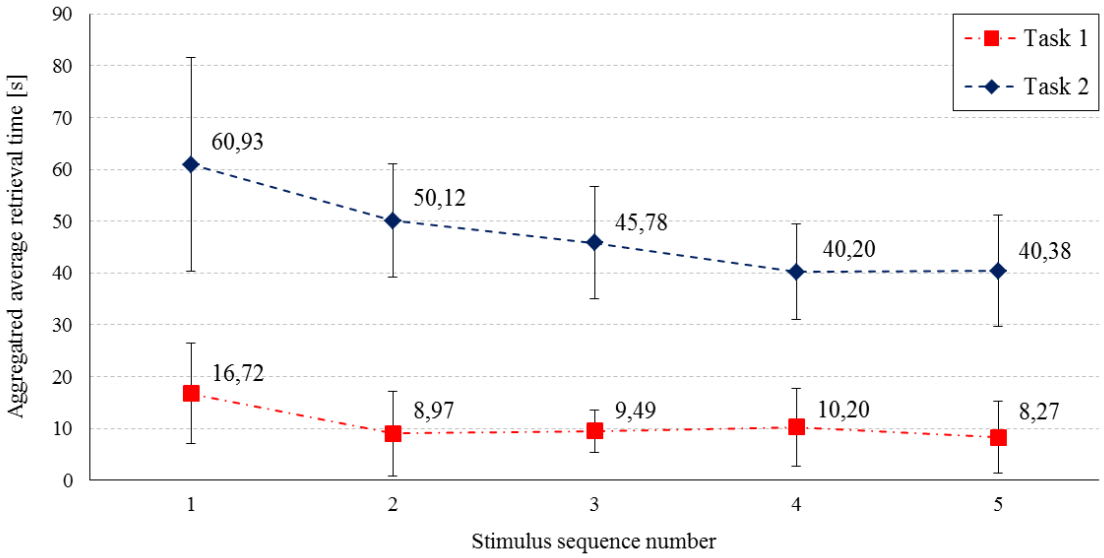

Fig. 3. Aggregated average performance of N=75 participants in Task 1 and Task 2. Individual searched pictures (labeled 1−5) are represented on x-axis, and the recorded search time is y-axis.

In Task 2 the search time monotonically decreases with each found picture and the difference between the first and the last search is over 20 s − from 60.93 s (*std* = 20.67) down to 40.38 s (*std* = 10.73). In Task 1 the average time spent to found one picture was marginally better with 16.72 s (*std* = 9.66) for the first and 8.27 s (*std* = 6.91) for the fifth and last picture.

In Table 1 are the correlations between the two perceptual speed, and Task 1 and Task 2. Both tests are significantly statistically related only with Task 2 but not with Task 1.

TABLE I

Correlation measures (r) among achievements on perceptual speed tests (Test 1, Test 2) and efficiency in picture search tasks (Task 1, Task 2). Each measure was calculated on N_R=75 sample (*p<0.05; **p<0.01).

	Test 1	**Test 2**	**Task 1**	**Task 2**
Test 1	1	0.57**	0.08	-0.27*
Test 2		1	0.11	-0.33**
Task 1			1	-0.07
Task 2				1

The aggregated average number of incorrectly found images (false positives) in Task 1 was 2.75 (*std* = 2.75), while only 1.26 (*std* = 0.53) in Task 2 is an indication of greater search accuracy which was made possible by introduction of semantic constraints. Also, statically very large dispersal of false positives was present in Task 1 suggesting that some participants' search strategy was based on volume, i.e. fast processing of many pictures, rather than on accuracy and precision.

IV. DISCUSSION

The study showed that in ideal conditions, i.e. if the stimuli database is sufficiently small, it is possible to relatively quickly find a specific image just based on affective tagging. But at the same time this approach results in relatively large error rate and participants participant retrieved more false pictures before finding the correct one.

Stimuli retrieval with keywords was initially slower, which is especially apparent by comparing search times for first pictures in both tasks, but once the required keywords were found the displayed set of images contained enough true positives so the required picture could be retrieved relatively quickly and at the same time the participants consistently made less mistakes. In both tasks the average retrieval time asymptotically falls with the increasing sequence number of the image, indicating that respondents needed a period of getting used to work with the "Intelligent stimuli generator" tool, but they could quickly achieve their relative maximum search efficiency.

However, it should be pointed out that in this study the original IAPS database was substantially reduced and the participants searched a subset with only 250 of the original 1182 IAPS stimuli (21.15 %), and in this subset 96 pictures (38.4 %) matched the overall search criteria. It reasonable to assume that the search times and the number of errors being made would be grater if realistic (i.e. larger and more complex) emotionally annotated multimedia databases were used or if the participants could not have the benefit of having a pre-defined set of semantic tags at their disposal.

Perceptual speed is defined as the speed of accurate perception of details in observed structures. It is measured with the speed of accurate recognition of similarities and differences between the observed structures [14].

Correlation among scores on perceptual speed tests and Task 2 (stimuli retrieval with keywords) were obtained (Table 1). Correlations (i.e. Pearson coefficients) have negative values which can indicate that those participants who were better in perceptual tests required less time to find keywords given to them in Task 2. It also demonstrates that stable interindividual traits may, at least to some extent, explain efficiency of keyword-based database retrieval method. Additionally, it could also mean that an intelligence measure could explain part of retrieval efficiency, because the perceptual speed has low to moderate correlation with intelligence which points out to their common probable cause [15]. The obtained correlations are not strong, but stable − both tests have similar correlation to time of retrieval. Indirectly, correlation values indicate that when task was more complex some cognitive individual differences played a role in general retrieval efficiency. This was expected and means that participants were motivated in both tasks.

V. CONCLUSION

Multimedia databases may be searched and retrieved by any combination of available text and visual features. With current knowledge models it is possible to describe emotion and high-level semantics in XML-derived formats thus enabling reasoning about emotional states, anxieties, phobias, stress or mental fatigue that a multimedia file may provoke or be related to [16]. During construction of affective multimedia retrieval information systems the optimal solution is to have the simplest possible requirements on the complexity of data model but at the same time to achieve high search efficiency and retrieval accuracy.

We showed that if emotionally annotated multimedia databases have a few hundred images it is not necessary to annotate their semantics. If databases are relatively small they can be efficiently searched just by using information about multimedia affective content. However, semantic-based search is practical in large multimedia sets. In a two-step retrieval process the search space must be first reduced with semantic constraints to a manageable size which enables multimedia to be searched efficiently with emotion or other metadata tags.

We hope that the presented study could be used in design of future affective multimedia retrieval systems as well as affective multimedia databases. The study's results may help researchers to find the optimal choice between the data model complexity and the required affective multimedia search efficiency.

Abstract - The Geneva Affective Picture Database WordNet Annotation Tool (GWAT) is a user-friendly web application for manual annotation of pictures in Geneva Affective Picture Database (GAPED) with WordNet. The annotation tool has an intuitive interface which can be efficiently used with very little technical training. A single picture may be labeled with many synsets allowing experts to describe semantics with different levels of detail. Noun, verb, adjective and adverb synsets can be keyword-searched and attached to a specific GAPED picture with their unique identification numbers. Changes are saved automatically in the tool's relational database. The attached synsets can be reviewed, changed or deleted later. Additionally, GAPED pictures may be browsed in the tool's user interface using simple commands where previously attached WordNet synsets are displayed alongside the pictures. Stored annotations can be exported from the tool's database to different data formats and used in 3rd party applications if needed. Since GAPED does not define keywords of individual pictures but only a general category of picture groups, GWAT represents a significant improvement towards development of comprehensive picture semantics. The tool was developed with open technologies WordNet API, Apache, PHP5 and MySQL. It is freely available for scientific and non-commercial use.

I. INTRODUCTION

Affective multimedia databases are repositories of multimedia documents with annotated semantics and emotion. They are primarily used as standardized tools for stimulating specific emotional responses in exposed subjects. Affective multimedia databases are frequently employed in psychology and neuroscience for research of subjective, psycho-physiological, behavioral and neurophysiological reactions induced by viewing affective stimuli (per example [1] [2] [3]).

The landscape of affective multimedia databases is very diverse with many different and structurally unrelated databases [4] [5]. Currently, affective multimedia databases are created by manual annotation of semantics and emotion in which volunteers record their personal impressions using standardized questionnaires [6] after being induced by stimuli. Obtaining affective annotations always includes a psychological experiment conducted with a statistically relevant group of participants. Software tools for querying affective multimedia databases and extraction of stimuli are virtually nonexistent [7]. The databases are still being mostly searched manually by experts in a lengthy, repetitive and labor intensive process [7].

Typically, affective multimedia databases have very simple structures constituting of a multimedia repository and a description file [4] [5]. The repository is a container with uniquely indexed multimedia which is referenced in the description file. The repository has a very simple implementation as a file system folder – databases must be acquired from their owners and installed on a user's computer. All multimedia metadata, emotion and semantic annotations are stored in the description file which is also located in the repository as a formatted text or comma separated values (CSV) file. The format of the description file differs between databases; no two databases share exactly the same format.

GAPED is a relatively new and large affective multimedia database with 730 pictures [8]. It has an even simpler architecture than most other databases. Pictures are stored in six separate folders each compromising one semantic category: "snakes", "spiders", "human concerns", "animal mistreatments", "neutral" and "positive". The first four categories are emotionally negative. All pictures have unique names by which they are referenced and emotionally described. However, there are absolutely no semantic annotations and objects or events in pictures are not specified. The semantic content of pictures can only be vaguely implied by their semantic category membership, and a more detailed context can only be obtained by accessing and observing each individual picture.

GWAT was developed with a motivation to improve the GAPED semantically sparse dataset and to provide an opportunity to reuse GAPED content in other domains which require a more expressive multimedia description. The tool is free for academic and nonprofit use and can be obtained by contacting the first author.

The remainder of this paper is organized as follows; Section 2 gives an overview of the tool and its system architecture. Sections 3 and 4 illustrate how the multimedia content is displayed in the user interface and how to browse through pictures, together with already existing GAPED-WordNet annotations. Section 5 provides information on how to retrieve WordNet synsets in GWAT and use them to annotate GAPED pictures. Finally, Section 6 concludes the paper and provides insight into future work.

II. GWAT ARCHITECTURE

The NAPS Search Tool is a thin-client web application written in PHP 5.4 programming language. The application requires a web server (e.g. Apache HTTP Server) configured to run PHP 5.x, or newer versions, and MySQL 5.0 database to be preinstalled on the target computer. The tool is distributed as a single package with PHP pages, presentation files and a SQL script for MySQL database import. The distribution package also contains a help file with instructions on how to install the tool, configure the web server and create a new instance of GWAT relational database.

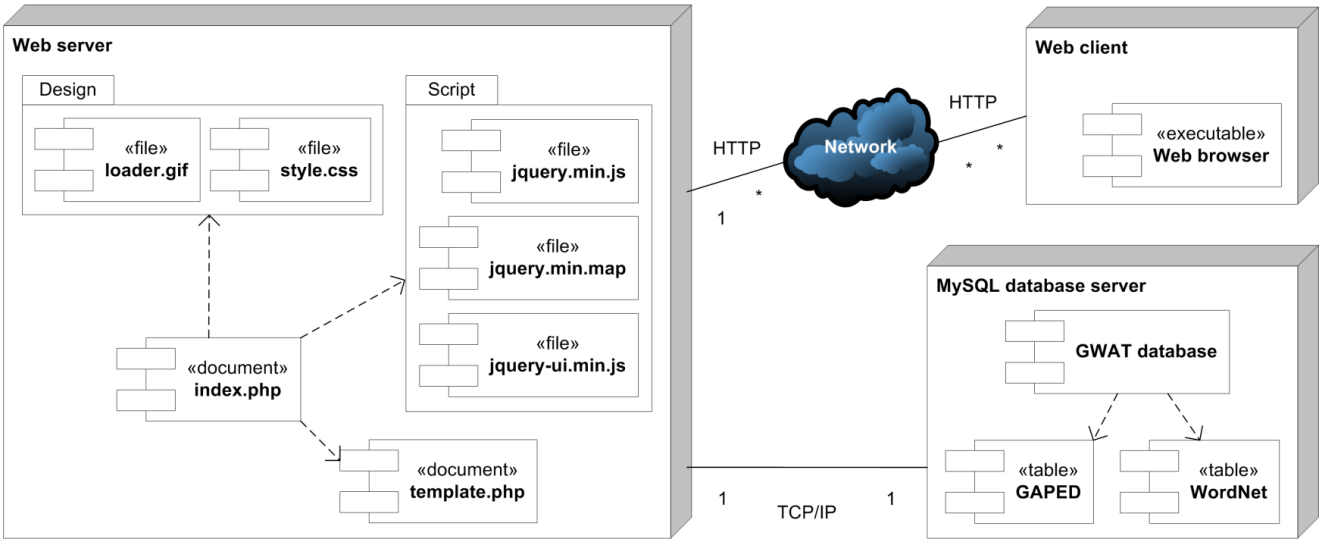

Fig. 1. GWAT's UML component and deployment diagrams.

The architecture is simple and consists of the presentation layer, the logic layer and the data layer. Cascading Style Sheet (CSS), graphics and JQuery scripts form the presentation layer, while PHP5 code files implement application logic and connect the data layer with the presentation. GAPED picture identifiers, WordNet synsets and pictures annotations created with GWAT are stored together in a single MySQL database. Pictures and affective ratings are not provided with the tool and have to be obtained from the Swiss Center for Affective Sciences[1].

WordNet semantic network is employed as a dictionary to describe semantics of GAPED pictures [9]. WordNet represents a very important component of the tool's architecture. WordNet is a large knowledge taxonomy with >100,000 individual concepts or synsets (i.e. synonym sets) connected by different semantic relationships such as IS-A and PART-OF. It is freely available and comes with an extensive software development interface. The glossary, originally in English but subsequently translated to a number of other languages, contains uniquely referenceable nouns, verbs, adjectives and adverbs. WordNet offers many benefits to description of multimedia compared to plain keywords and user defined tags. Firstly, it has very large and sufficiently expressive vocabulary. Since the glossary is controlled and standardized, picture annotations can be transferred to any other application compatible with WordNet. Finally, WordNet glossary enables users to search queries in a linguistically more natural and expressive manner as already demonstrated by existing WordNet stimuli annotating tools (per example [10] [11]).

The GWAT's UML component and deployment diagrams are shown together in Fig. 1. The main PHP page is "index.php". It uses "template.php" as a modular component for presentation of different GAPED pictures, three JQuery files for client-side functionality and CSS definition file with an animated GIF picture for design.

The program user interface has six major components:

1) the selected stimulus component for displaying a single stimulus,
2) GAPED search box,
3) GAPED navigation buttons,
4) WordNet annotations component for displaying the list of synsets describing picture semantics,
5) WordNet component for searching and attaching synsets to pictures,
6) help box with useful information for GWAT users.

The components' functionalities are described in next sections.

III. DISPLAYING GAPED CONTENT

After starting the web tool, i.e. opening the main page "index.php", first GAPED picture A001.bmp is always automatically loaded and displayed in the selected stimulus component for displaying a single stimulus. The component is placed in the central region of the main page. If GAPED database is not installed on the server a busy JavaScript animated icon will be visible instead of the picture. All pictures can be accessed and displayed in the tool's main page together with their existing WordNet annotations. The layout of the main page is explained in the Fig. 2.

The name of the picture file with its extension is shown above and to the left of the displayed picture, and GAPED search box is on the right. User can enter name of a picture, from any of GAPED folders containing different semantic categories ("A", "H", "N", "P" "Sn" and "Sp"), to be loaded and displayed in the main page. It is not necessary to specify a specific folder because the tool will search all folders until the desired picture is found. Picture format extension is obligatory. It is necessary to specify picture names exactly – special search characters such as "*", "?" etc. are not supported in the current version of GWAT.

[1] http://www.affective-sciences.org/

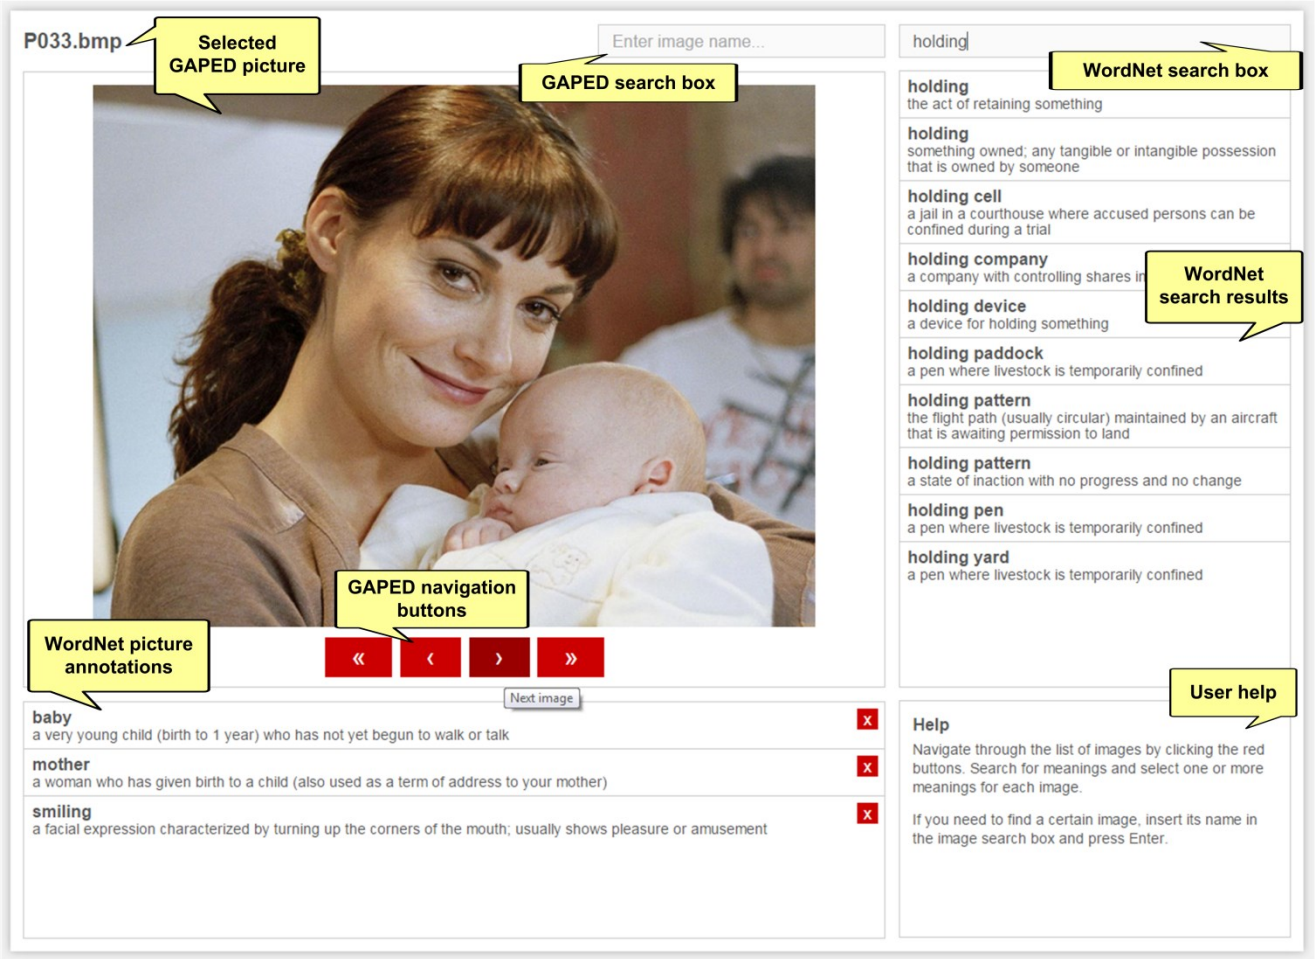

Fig. 2. The GWAT's main page.

The picture search starts only after pressing enter key and not after each letter keystroke in order to minimize resource requirements from quickly repetitive database queries. If a picture cannot be found, i.e. search query returns NULL value, a JavaScript generated (i.e. client-side) error message is shown informing the user that the particular picture cannot be found.

Below the central area are four navigation buttons (Fig. 2). The left most button ("<<") shifts the focus to the first picture in alphabetical order ("A001.bmp"). The right most button (">>") moves the focus to the last picture in the set ("Sp160.bmp"). Buttons ("<") and (">") change current display by one position towards lower position or higher position in the alphabetically sorted sequence, respectively. For example, if picture "P033.bmp" is shown (as in Fig. 2) then by pressing two times button ("<") "P032.bmp" will be displayed first followed by "P031.bmp". After pressing (">") the selection returns to "P032.bmp". The navigation buttons can also be used to circulate the view between both ends of the set: if the last picture "Sp160.bmp" is selected then with (">") the first picture "A001.bmp" will be displayed, and vice versa with ("<"). Tooltips are provided for all buttons so users can get accustomed to the tool's interface more easily.

IV. GAPED-WORDNET ANNOTATIONS

Below the navigation buttons is the WordNet annotations component with a list of WordNet synsets assigned to the currently displayed GAPED picture. The content of the component is refreshed dynamically whenever a new picture is shown in the main page. Synsets are displayed in rows with their name, full description and a large "X" button to the right (Fig. 2). By pressing the red "X" button the particular annotation is immediately removed from semantic description of the currently shown picture. This feature is implemented with JQuery JavaScript framework. There is no undo action so the synset has to be attached again if it was removed in error.

Initially the component is always empty because the GWAT database does not contain any annotations, but as − in the course of working with the tool − new semantic descriptions are generated they will be made visible in the component.

The annotations are displayed together in the component interface, sorted alphabetically and grouped based on their lexical type (noun, verb, adjective and adverb). The database is designed so that, at least in theory, there is no limit to the number of synsets that can be assigned to a single picture.

All attached synsets can be exported from the tool's database as a SQL script containing CREATE TABLE and

ADD ROW statements with identifications (IDs) of GAPED pictures and WordNet synsets associated with SQL foreign key relationship. Using the script it is possible to transfer the generated annotations to other applications or 3rd party systems compatible with SQL standard and WordNet semantic network.

V. USING WORDNET TO ANNOTATE GAPED PICTURES

WordNet search component is located on the right side of the main page. Search box is on the top of the component and a frame with search results below. The component is implemented by almost exclusively relying on JQuery JavaScript framework functionalities. The search starts on each keystroke, i.e. when browser registers keyboard press event, and depending on the user's computer performance several seconds are needed for results to be retrieved from the database. The waiting time is inversely proportional to the length of WordNet query − if only a few letters are used in search the retrieval process takes longer − and becomes progressively shorter as the query gets longer. The busy JavaScript animated icon is visible during retrieval execution indicating that the query has been accepted by the system and is being processed. With regards to the implementation the search is executed by JQuery JavaScript framework dynamically querying MySQL database, i.e. directly from the client to the server without any additional server-side PHP code.

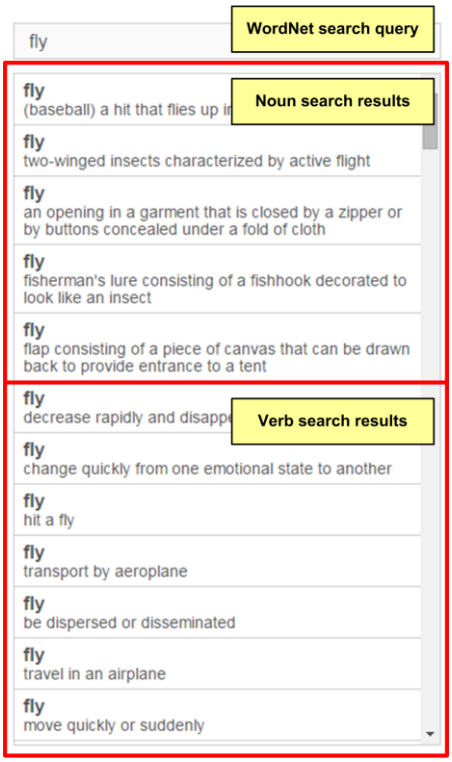

Fig. 3. WordNet search results for query "fly" in GWAT. Lexically identical synsets are grouped together.

The WordNet search results are presented as a vertical list with each row in a separate frame containing the name and description of one found synset. To improve the search component's usability synsets are sorted alphabetically and, additionally, those with the same lexical type are grouped together. If a search returns synsets of different lexical types they will be sorted in the following order: nouns first, adjectives second, verbs third and finally adverbs as the fourth group (Fig. 3). If many synsets are retrieved a vertical scroll bar will appear on the right side of the component allowing users to slide between different parts of the list.

When a synset is found with the desired semantic meaning user must click the row containing the synset with left mouse button to attach it to the currently displayed GAPED picture. This process is almost instantaneous, even on a computer with a modest performance, because the client code is short and on the server side only a single row has to be inserted in the table connecting the synset in WordNet table and the row in the table with GAPED pictures' names.

Once the synset attaching process is completed server-side, and the confirmation is received on the client, a new item is automatically generated in the WordNet annotations component for displaying the list of synsets describing picture semantics. The new item can be removed at any time by clicking on "X" button, if added in error, and a different synset can be attached instead.

VI. CONCLUSION

GWAT is web-based image annotation tool for manual identification of objects and events in GAPED images and annotation with WordNet knowledge taxonomy. Generated semantic annotations are stored in a relational database where they can be modified as needed and later exported to 3rd party tools. The purpose of GWAT is to enable a more detailed semantic description of GAPED pictures with a large and standardized linguistic ontology. There are many potential applications which benefit from rich multimedia semantics. Primarily, these can be used to build multimedia search tools that take advantage of WordNet semantic similarity measures to improve quality of the retrieved dataset. The similarity measures may also be used to rank the results relative to their significance. It has been already demonstrated with other affective multimedia databases that WordNet annotations significantly improve ranking accuracy and precision in picture retrieval [4]. Secondly, GWAT generated data provides an opportunity to study the relationship between semantics and emotion in multimedia. This line of research could establish statistically relevant relationships which can then be used to automatically infer emotion of a picture or video from their semantic description. If successful, such applications could eventually lead to machine-based emotion indexing of multimedia and emotional search engines [5].
However, both of these applications are impossible with the current state of GAPED semantics and can be investigated only with tools such as GWAT.

Web image repositories and tools for semantic annotation of pictures are fairly common, but there are not many tools for construction of affective multimedia databases. Therefore, the development of GWAT is interesting as a relatively new research area in the fields of applied computing and construction of information systems.

The future work will focus on development of new GAPED search tools which use WordNet descriptions generated with GWAT. In this regard we plan to develop a web-based search tool compatible with WordNet described GAPED. Furthermore, we would like to extend GWAT so it is possible to annotate image regions and associate WordNet description to individual blobs, features or objects in pictures. GAPED pictures are high-quality and contain a wide range of semantic content so detailed annotations could be used in computer vision research for automated object recognition. Additionally, it could be expected that such more detailed annotations would also further increase the quality of picture search.

Abstract – The paper considers the use of qualimetric expertise and ontological approach for evaluation of the quality of voice transmission over IP telephony in order to choose which of operators provides telecommunication services of the best quality. On the base of the suggested approach, an application the of the developed decision support system "Qualimetric Expertise" for automation of the process of voice transmission quality evaluation and identification of the possible causes of the quality loss is shown.

I. INTRODUCTION

Due to telephony, people from different cities and countries can always find out the latest news, the information about health of their relatives and just communicate. Telephony allows connecting people in spite of the distance. IP telephony today is one of the most promising and cheap means of communication in the world.

IP telephony is a telephonic communication over Internet Protocol. It means a number of communication protocols, technologies, and methods that provide the following typical for telephony things: dialing operation, call completion, two-way voice communication, and also video communication over the Internet or over any other IP networks. The signal is transmitted over the link channel in a digital form. As a rule, it is converted (compressed) before the transfer in order to remove the excess of information and to reduce the load on the data transmission network.

IP telephony is an application of a more general VoIP (Voice over IP) technology for two-way communication. The VoIP technology in general means all variants of voice transmission over IP including those not related to telephony and communication of people. For example, the VoIP technology is used for sound transmission in IP video monitoring systems, alarm systems, by broadcasting of webinars, by online film watching and so on [1].

The date of birth of IP telephony (or Internet telephony) is considered to be August 1996. Just then the company Vocal Nec (Israel) has completed a gateway testing. The gateway allows the connecting of the traditional phone network with the data transfer system in the Global Network. In fact, IP telephony is a technology that makes it possible to use the Internet as a means of organization of telephone conversations quite effectively [2].

A large number of operators provide customers with IP telephony services. The main selection criterion is for the end-user a price and quality correlation of provided telecommunication services in a certain direction.

Currently the challenge is how to make a quantitative evaluation of the quality of voice transmission over IP telephony for traffic grooming and selecting of the best operator providing telecommunication services, as well as for finding out of possible causes of quality loss with the aim of early detection and solving of telecommunication problems.

II. TRADITIONAL QUALITY EVALUATION OF IP TELEPHONY

The quality of IP telephony is evaluated today in a number of ways.

- An ACD (Average Call Duration) is a statistical parameter of telephony. It indicates an average call duration in one or other direction. A call detail record (CDR) is usually the basic data for calculation of the ACD value. Operator companies often use the ACD for an evaluation of the demand for directions, and indirectly for a telecommunication quality determination of a certain direction. For example, if in the given direction the average ACD value decreases, this may mean that subscribers do not like the telecommunication quality. The ACD is calculated by the formula: ACD = (the total duration of all calls in the given direction) / the number of completed calls.
- ASR (Answer Seizure ratio) and ABR (Answer Bid Ratio) are statistical parameters. They determine the quality of a telecommunication through a particular communications node (or IP telephony communications node) in a given direction. ASR and ABR are defined by the International Telecommunication Union (ITU) in "SG2 Recommendations: E.411: International Network Management – Operational Guidance". The ASR is calculated as a percentage ratio of the number of answered calls to the total number of

call attempts in the given direction. An engaged condition of the subscriber is considered as a failed call, as well as other situations with a call rejection. The calculated value of the ASR parameter may vary depending on the behavior of the called subscriber [3, 6].

- A MOS (Mean Opinion Score) is evaluation of the service quality by user on the 5-point scale and calculation of the arithmetical average. In practice, MOS – P.800 series can rarely be above 4.5 [4, 5, 6].
- An E-model is a multi-criteria evaluation of the quality (R-factor) in the range from 1 to 100 points [4].
- All these results (except for MOS) are obtained only through CDR (Call Detail Record) analysis [3, 6], after a number of calls in the given direction have been completed to provide objective data analysis and to obtain corresponding results. MOS calculation does not provide information on what criteria the quality does not conform. The authors believe that the mentioned methods of call quality evaluation by IP telephony are not objective as they do not take into account such parameters as disconnection during a call, false billing, use of various electronic secretaries by terminating party, voice disappearance during a call, noises, direction of a call to another subscriber. To eliminate these problems, the authors suggest to apply a quite new science, qualimetry. Qualimetry is applied for the quality evaluation of objects described by number of features.

III. USE OF ONTOLOGICAL APPROACH TO SOLVE THE TASKS OF QUALIMETRIC EXPERTISE

Qualimetry is a science dealing with a quantitative evaluation of an objects quality described by number of features. These features form a hierarchy. It means that one of them in the underlying level includes a number of features of the overlying level. The hierarchy forms a calculation model of an object.

A qualimetric expertise is one of the tools of integrated management system in companies. The difference between qualimetry and qualimetric expertise is that qualimetric expertise needs experts not only in the field of quality evaluation, but in the fields of development and application of the investigated (evaluated) object (variant).

In order to carry out the qualimetric expertise, a team of experts should make a calculation model of an object quality evaluation, that is a description of object properties at different hierarchy levels. The properties of the object have definite priorities for the object quality evaluation. There are morphological, functional, combined, integrated and mixed calculation models of evaluations.

It is usually selected a combined calculation model of an evaluation. It is presented in a form of combination of morphological and functional calculation models. The result of the expertise is a calculated integral performance index (in the range from 0 to 1). The qualimetric expertise is carried out at all stages of the life cycle of any product.

The concept of ontology is widely used in information science and artificial intelligence. The ontology in knowledge engineering is understood to be a precise specification of a certain subject area, which includes a glossary of this area and many logical connections between components of the glossary.

In the centre of ontologies are usually classes that describe concepts of a subject area. Slots (parameters) describe the properties of classes. An ontological analysis is based on a description of a system in terms of essentialities. The ontological analysis begins with a compilation of a glossary used in discussion and study of objects characteristics composing the considered system and also with a creation of a system of terms definitions [7, 8, 9].

As qualimetric expertise is based on the hierarchy of features, and ontology development is a construction of a features system, the authors suggest applying the ontology system as basic data for qualimetric expertise. As evaluated parameters for the qualimetric expertise of IP telephony, the authors take the following most significant criteria, which were found out after conducting a customer survey among customers using IP telephony in everyday life:

- disappearance of words of subscriber B
- sound disappearance during a conversation
- noises
- audibility of subscriber B
- calls control signals
- echo.

In accordance with the notation of IP telephony, the origination subscriber is a subscriber A, and the called subscriber is a subscriber B. As an editor of the ontology was selected the package OntoStudio. Fig. 1 shows the ontology developed for IP telephony quality evaluation. The ontology developed in OntoStudio and presented in markup Object Logic Language (OBL) contains a description of ontology classes, instances, their attributes and relations. The ontology in OBL allows us to make any adjustments, to change names, to add and delete information adhering to the overall structure of the ontology.

Let's explain every feature of the ontology. Call direction means a direction in which a subscriber A calls, for example, a call in the direction of Azerbaijan using the code 994 or in the direction of Kazakhstan using the code 77. Disappearance of words of a subscriber B means a disappearance of speech fragments (words, words ending) during a voice transmission. Sound disappearance during a conversation is an absolute absence of a voice traffic transmission. It means that one or both subscribers cannot hear each other after a time. Noises mean a side tone during a conversation. Audibility of a subscriber B is a level of a transmitting sound during a conversation. Calls control signals mean signals of a telephone exchange,

designed to assure an origination subscriber that a called subscriber's line is ringing, but a subscriber B does not pick up his phone yet. Echo is a repetition of words with a short delay. It makes an echo effect during a conversation. The developed ontology graphically demonstrates list of features and model of the evaluated object.

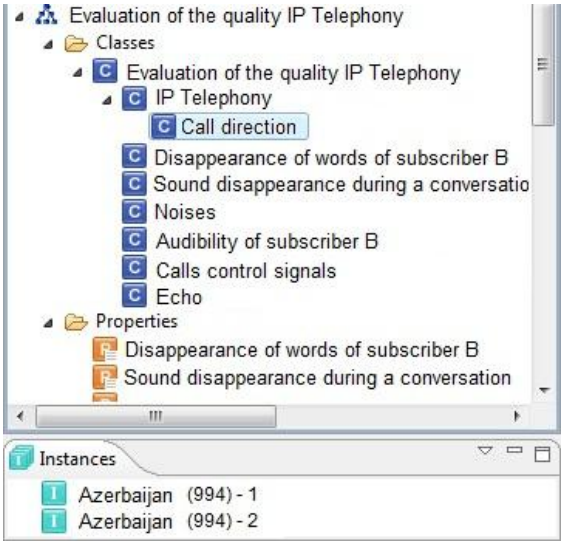

Figure 1. The ontological features system for IP telephony

Subscribers A will score these parameters on the scale from 1 to 5, where 1 means "dissatisfied", 5 – "completely satisfied". The polling will follow the termination of a conversation. It is implemented by means of the IVR menu. IVR is an interactive voice response, a computer system. It gives the possibility to the user, usually subscriber, to select options from a voice menu and interact with the computer system [3]. The authors have developed the decision support system (DSS) "Qualimetric Expertise" for calculation of the total quality evaluation and diagnosis of causes of the quality loss in the automated mode. The ontological system of features is the basic data for the expertise. In order to transform the ontology in OBL, the authors have developed the application ONT-Converter. Further, the result is imported in the DSS "Qualimetric Expertise". Fig. 2 shows the result of the import of characteristics for quality evaluation.

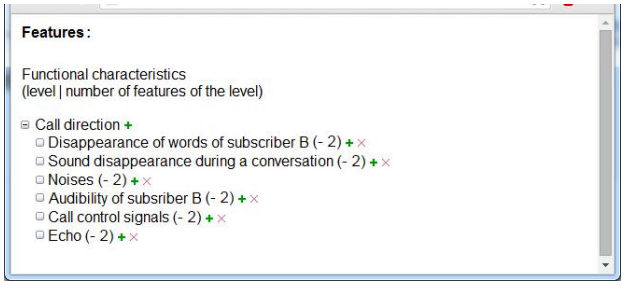

Figure 2. The features ontology in DSS "Qualimetric Expertise".

The results received from subscribers A in every direction are stored as the average values of the features indexes scaled to the qualimetric scale by (1) and (2) and used in the quality evaluation.

$$k_s = (val_s - ng)/vg, \tag{1}$$

$$ks_s = (k_s - ng)/(vg - ng), \tag{2}$$

where *val* = index value entered by the user by means of IVR, *vg* = upper bound (in our case is 5), *ng* = lower bound (in our case is 1).

Subscribers A will make calls to Azerbaijan through two different line operators using the code 994. To provide customers with better telecommunication, it is necessary to identify which line operator provides the best telecommunication quality in this direction.

After calculation of the integral characteristics in hierarchy levels by (3) – (9) and calculation of the resulting integral evaluations by (10) – (13) the following characteristics shown on the Fig. 3 are obtained.

$$znkv_j = \sum_{i=1}^{m} val_i, \tag{3}$$

where *znkv* = sum of index values for all subscribers A, *m* = quantity of subscribers A participated in the survey, *val* = index value on a hierarchy level.

$$sum = \sum_{j=1}^{k} znkv_j, \tag{4}$$

where *sum* = sum over all indexes, *k* = quantity of indexes.

$$znkv'_j = \frac{znkv_j}{sum}, \tag{5}$$

$$QS = \sum_{j=1}^{k} (znkv'_j * ves_j), \tag{6}$$

$$DQS = 1 - QS, \tag{7}$$

where *QS* = quantitative value of the object quality conformance to the requirements calculated as a sum on the one hierarchy level, *DQS* = quantitative value of the object nonconformance to the requirements, *ves* = importance factor of a feature by evaluation; in our case all importance factors have the same value, which is equal to 1/6 = 0.1666.

$$QP = \prod_{j=1}^{k} znkv'^{ves_j}_j, \tag{8}$$

$$DQP = 1 - QP, \tag{9}$$

where *QP* and *DQP* = quantitative value calculated as a product.

$$SQS = \frac{\sum_{g=1}^{f} QS}{f - 1}, \tag{10}$$

$$SDQS = \frac{\sum_{g=1}^{f} DQS}{f-1}, \quad (11)$$

$$SQP = \frac{\sum_{g=1}^{f} QP}{f-1}, \quad (12)$$

$$SDQP = \frac{\sum_{g=1}^{f} DQP}{f-1}, \quad (13)$$

where f = maximal quantity of hierarchy levels $f \neq 1$, *SQS* (*Q*) = total quantitative value of the object quality conformance to the requirements calculated as a sum, *SDQS* (*DeltaQ*) = quantitative value of the object nonconformance to the requirements calculated as a sum, *SQP* (*Q*) = total quantitative value of the object quality conformance to the requirements calculated as a product, *SDQP* (*DeltaQ*) = quantitative value of the object nonconformance to the requirements calculated as a product.

Figure 3. The result of combined characteristics calculation for both operators

Q in this instance is the quantitative value of the object quality conformance to the requirements. *DeltaQ* is the quantitative value of the object nonconformance to the requirements. The calculation of integral characteristics is possible by the sum or by the product.

IV. Analysis of Results

After we have obtained the results, it is possible to carry out an analysis of them to discover deviations in the features values from the features of the object with the best parameters. For this purpose, the function "Analysis of Results" implemented in the application is used. Fig. 4 shows the result of the function.

Analysis of Results

Name of parameters	Level	Azerbaijan (994) -1	Azerbaijan (994) -2	Comment
Disappearance of words of subscriber B	2	0.75	0.84	Azerbaijan (994)-2 provides the better telecommunication quality. Recommended.

Figure 4. The result of analysis of obtained data

As it is seen from the results, the second operator provides the better telecommunication quality in the direction of Azerbaijan. It is reasonable to send a voice traffic using the equipment of this operator. After the comparison of the results, the DSS makes the analogical decision from the knowledgebase by correlation of date from several operators concerning the quality of voice transmission over IP telephony.

In this way, the developed decision support system with use of ontology and qualimetric expertise allows us to make the quantitative evaluation of the voice transmission quality over IP telephony for traffic grooming, as well as to identify the possible causes of the quality loss through the visual analysis of comparative results.

Abstract - In this paper, an automatic Computer Aided Diagnosis (CAD) system is completely designed for breast cancer diagnosis and it is verified on a publicly available mammogram dataset constructed during Image Retrieval in Medical Applications (IRMA) project. This database comprises three different patch types indicating the health status of a person. These types are normal, benign cancer, and malignant cancer and they are labeled by the radiologists for the IRMA project. In the realization of CAD system, all mammogram patches are firstly pre-processed performing a histogram equalization followed by Non-Local Means (NLM) filtering. Then, the Local Configuration Pattern (LCP) algorithm is performed for feature extraction. Besides, some statistical and frequency-domain features are concatenated to LCP-based feature vectors. The obtained new feature ensemble is used with four well-known classifiers which are Fisher's Linear Discriminant Analysis (FLDA), Support Vector Machines (SVM), Decision Tree, and *k*-Nearest Neighbors (k-NN). A maximum of 94.67% recognition accuracy is attained utilizing the new feature ensemble whereas 90.60% was found if only LCP-based feature vectors are used. This consequence obviously reveals that the new feature ensemble is more representative than an LCP-based feature vector by itself.

I. INTRODUCTION

Breast cancer is one of the major causes of female deaths all over the world, but mortality can be reduced with early diagnosis [1]. Although mammography is known as the most effective radiological imaging technique both for breast examination and diagnosis, mammogram images contain little information since X-ray permeabilities of normal and cancerous regions are not very different [2]. Besides, important issues on mammograms may be overlooked during interpretation of mammography depending on breast tissue type or human factors. Hence, usage of a Computer Aided Diagnosis (CAD) system, which detects and diagnoses cancer, gives smoother view to radiologists and allows reconsideration of mammography resulting in increased sensitivity of cancer detection.

A CAD system consists of four stages. The first of these stages is a pre-processing stage where some filtering operations for noise reduction, contrast enhancement operations, and structural improvement operations like label and pectoral muscle removal from mammogram images are realized. Papadopoulos et al. compared five different image enhancement algorithms for microcalcification detection: Contrast Limited Adaptive Histogram Equalization (CLAHE), Local Range Modification (LRM), Redundant Discrete Wavelet (RDW), Wavelet Linear Stretching (WLST), and Wavelet Shrinkage (WSRK), then the best performance is obtained by applying LRM technique with $A_z = 0.932$ where A_z is defined as the area under the Receiver Operating Characteristic (ROC) curve [3]. Wavelet transform [4], polygon modeling [5], Wiener filtering [6], morphological operations [6-8], Hough transform [7], and histogram processing operations [7, 9-10] are widely used image enhancement and noise reduction methods.

In the second stage, suspicious regions for breast cancer, Region of Interest (ROI), are detected from the whole breast mammograms. Wavelet transform [11], segmentation algorithms [12-13], edge operators [14] are the samples of commonly used methods for lesion detection in the past studies. Moayedi et al. detected ROIs by thresholding intensity variances. In this method, regions with lesions have low intensity variance, and the high frequency components of these regions are close to zero beside the energy of lesion boundaries are higher than non-cancerous regions [10].

Efficiency of a CAD system highly depends on feature extraction stage, the third stage, in which mammogram data is represented by the most discriminative features in a low-dimensional feature space. Feature extraction for mammogram images can be performed using statistical methods [4, 15-17], model-based methods [18-19], signal processing methods that compute tissue features due to pixel characteristics [3, 17] or frequency spectrum [9-10, 15, 20] of an image, and mammographic features [5, 7, 21-23] like shape, spicule index, contour, size, density and brightness.

Finally, a classification stage is realized using the features obtained in the third stage. Artificial neural networks [3-4, 18, 20, 22], support vector machines [4, 7-10, 16, 24], subspace learning algorithms [8, 16-17, 24], Bayes, decision tree, and *k*-nearest neighbor classifiers [4, 16] are the most common classifiers used for mammogram classification.

In this paper, it is aimed to prepare a CAD system for breast cancer diagnosis. For this purpose, the mammogram images in the database are firstly pre-processed performing a histogram equalization followed by Non-Local Means (NLM) filtering as described in Section 2. Secondly, feature extraction is realized as explicitly explained in Section 3. The classification methods and the experimental study performed in this paper are given in Sections 4 and 5, respectively. Finally, conclusions are presented in Section 6.

II. PRE-PROCESSING

Radiologists basically face two important problems during analyzing mammogram images. These problems are originated from low-contrast and noise issues. Therefore, contrast enhancement and noise reduction operations are needed in order to investigate mammogram images. In this study, a histogram equalization performed for contrast enhancement is followed by NLM filtering for noise reduction.

A. Histogram Equalization

Histogram equalization maximizes image contrast by applying a gray-level transform that tries to flatten the histogram of an image [25]. Therefore, histogram equalization is an essential step for mammogram classification problem since brightness is one of the most critical concerns for mammograms.

B. Mammogram Image Enhancement

Non-Local Means (NLM) filter is an adaptive smoothing filter that changes the window size according to the similarity between neighborhoods of any two pixels as well as preserves the fine details by computing a weighting function according to the derivatives in the corresponding search window [26]. Given a discrete noisy image $v = \{v(i) \mid i \in I\}$, the filtered value $NL[v(i)]$ of any pixel i is computed as:

$$NL[v(i)] = \sum_{j \in I} w(i,j) \cdot v(j) \tag{1}$$

where $w(i,j)$ refers to the weight coefficient computed utilizing the similarity between the pixels i and j, and satisfies the conditions $0 \le w(i,j) \le 1$ and $\sum_j w(i,j) = 1$.

The above mentioned similarity between pixels i and j is measured as the Gaussian weighted Euclidean distance $\|v(N_i) - v(N_j)\|_{2,\pm}^2$, where $\pm$ ($\pm > 0$) is the standard deviation of the Gaussian kernel; $v(N_i)$ and $v(N_j)$ are the neighborhoods of pixels i and j in the similarity window. The pixels with a similar neighborhood have larger weights computed as in Eq. (2). $Z(i)$ and h in the Eq. (2) refer to the normalizing constant and the degree of filtering, respectively.

$$w(i,j) = \frac{1}{Z_i} \cdot e^{-\frac{\|v(N_i) - v(N_j)\|_{2,\pm}^2}{h^2}} \tag{2}$$

$$Z_i = \sum_j e^{-\frac{\|v(N_i) - v(N_j)\|_{2,\pm}^2}{h^2}} \tag{3}$$

III. FEATURE EXTRACTION

Feature extraction is the most crucial stage in CAD systems because the little differences between any normal and abnormal tissues on mammogram images play very important roles. In this study, Local Configuration Pattern (LCP) algorithm is used for feature extraction with additional statistical and frequency-domain features.

A. Local Configuration Pattern

Local Configuration Pattern (LCP) is a method that describes the local structural information and pattern occurrences together, and it forms rotation-invariant feature vectors [27].

Local structural information is found by Local Binary Pattern (LBP) algorithm that labels every pixels of image I comparing its P neighbors in the circular neighborhood with radius R as:

$$LBP(P,R) = \sum_{i=0}^{P-1} u(g_i - g_c) \cdot 2^i \tag{4}$$

$$u(x) = \begin{cases} 1, x \ge 0 \\ 0, x < 0 \end{cases} \tag{5}$$

where g_i and g_c refer to the intensities of neighboring pixel i and the central pixel (c), respectively. Rotation-invariant LBP vectors are obtained by rotating each bit pattern circularly to a minimum value so that the maximum value will be the last element of the vector. Eq. (6) defines the rotation-invariant LBP vector in where U is the uniformity measure identified by the bit-wise transitions.

$$LBP^{riu2}(P,R) = \begin{cases} \sum_{i=0}^{P-1} u(g_i - g_c) \text{ , } U(LBP(P,R)) \le 2 \\ P+1 \qquad\qquad \text{, otherwise} \end{cases} \tag{6}$$

In some cases, LBP representations may be the same although the neighborhoods are quite different due to the quantization of gray-level differences to binary levels. In order to handle this problem, local variance (VAR) of each pattern is computed, and the joint histogram (O) is obtained.

$$VAR = \frac{1}{P} \cdot \sum_{i=0}^{P-1} (g_i - \mu)^2 \tag{7}$$

$$O = \frac{LBP^{riu2}}{VAR}, \tag{8}$$

where « is the average intensity of the neighboring pixels.

In case of LBP^{riu2} vectors with equal variances, same feature vectors are obtained although patterns have different configurations. In order to resolve this problem, the microscopic configurations of the patterns are modeled. In this model, the optimal weights (A_L) of neighboring pixels are calculated using the least square estimation to form the central pixel. Then, 1D Fourier transform is applied on A_L and H_L values are obtained to make the optimal weight vectors rotation-invariant. The magnitude of H_L is the microscopic feature of the pattern. LCP vector of any pattern is obtained by associating local structures with microscopic configuration as:

$$LCP = \left[\left[H_0\right];O_0\right],\left[\left[H_1\right];O_1\right],\cdots;\left[\left[H_{q-1}\right];O_{q-1}\right], \quad (9)$$

where q is the number of patterns.

B. Statistical Features

In addition to the LCP vectors, some statistical and frequency-domain features are also computed to increase the data representability of the feature vectors. Statistical features utilized in this study are the energy, mean, variance, maximum, minimum, standard deviation, skewness, kurtosis, area-descriptor, mean energy, energy variance and entropy value of any LCP vector. Among all statistical features, area-descriptor is computed as :

$$Area-descriptor = \frac{\pm}{\ll} \quad (10)$$

where ± and « refer to the standard deviation and the mean of an LCP vector, respectively.

C. Frequency – Domain Features

Frequency-domain features are obtained from the 2-level Two-Dimensional Discrete Wavelet Transform (2D-DWT) of the pre-processed mammogram images using Daubechies1 (db1) wavelet and therefore 16 sub-bands are obtained. The energy values of each sub-band are calculated on account of the fact that brightness is one of the most vital issues for breast cancer diagnosis.

IV. CLASSIFICATION METHODS

Four different classifiers which are Fisher's Linear Discriminant Analysis (FLDA), Support Vector Machines (SVM), Decision Tree, and *k*-Nearest Neighbors (k-NN) are performed in this study.

A. Fisher's Linear Discriminant Analysis

FLDA tries to find the projection matrix that projects the training data onto a low-dimensional space which maximizes between-class variance as well as minimizing within-class variance [28]. This is known as the Fisher maximization criterion and defined as:

$$J(\vec{w}) = \frac{\vec{w}^T \cdot S_B \cdot \vec{w}}{\vec{w}^T \cdot S_w \cdot \vec{w}} \quad (11)$$

where $\vec{w}$, S_B and S_w refer to the projection vectors, between-class and within-class scatter matrices, respectively.

On the test stage of FLDA, any test vector is projected via $\vec{w}$ projection vectors and the distances to the training vectors on the low-dimensional space are calculated. Decision criterion for FLDA is given as:

$$K = \arg\min_{1\le c\le S}\left\{\left\|\vec{\Omega}^c - \vec{\Omega}_{test}\right\|\right\} \quad (12)$$

where c is the class index, S is the total number of classes, $\vec{\Omega}^c$ and $\vec{\Omega}_{test}$ are the projected training vector of the c^{th} class and the projected test vector, respectively.

B. Support Vector Machines

SVM, also known as maximum margin classifier, aims to find the optimal hyperplane which maximizes the distance between the hyperplane and the support vectors [29]. Support vectors are the training vectors nearest from each class to the hyperplane [30]. As it can classify linearly separable data, SVM can classify non-linear data by transforming the data to a higher-dimensional space by using an appropriate kernel function [30]. If the training set is $TS = \{(\vec{x}_1, L_1), (\vec{x}_2, L_2), \cdots, (\vec{x}_M, L_M)\}$ for a two-class problem, where $\vec{x}_i$ ($i = 1, 2, \cdots, M$) is the training data and L_i ($L_i \in \{-1, 1\}$) is the class label, test vector is classified according to the sign of the function given as:

$$f(\vec{x}_{test}) = \sum\left\{\sim_i \cdot L_i \cdot \left(\vec{x}_i^T \cdot \vec{x}_{test}\right) + b\right\} \quad (13)$$

where $\sim_i$ ($i = 1, 2, \cdots, M$) are the non-zero quadratic coefficients, and $\left(|b| / \|\vec{w}\|\right)$ is the perpendicular distance between the hyperplane and the origin while $\vec{w}$ is the normal vector of the separating hyperplane.

C. Decision Tree

The principle of the Decision Tree classifier is to cluster any data into sub-groups until all elements of any sub-group have the same class label [31]. The branches and the leaves of a tree in this classifier refer to the classification rules and the class labels, respectively. In the training stage, classification rules are defined by clustering data into the leaves. In the test stage, those rules are applied to any test sample and the leaf which the test sample reaches, gives the class label of test sample.

D. k – Nearest Neighbors

k-NN classifier categorizes any test vector considering the distances between test and training vectors in the feature space [32]. This classifier assigns a test vector to the respective class that its k-nearest neighbors belong at most. Although it is obvious that classification performance is directly related to parameter k, there is no obvious information on the selection of k except that it should be positive and not be a multiple of the total number of classes.

V. EXPERIMENTAL STUDY

In this paper, a CAD system that classifies mammogram images into normal, benign, and malignant classes is proposed. At first, histogram equalization is applied to the mammogram images, then this process is followed by NLM filtering. Secondly, the LCP feature vectors, statistical and frequency-domain features are obtained to construct the feature vectors. Finally, these feature vectors are classified with four different classifiers; SVM (using linear and quadratic kernels), FLDA, Decision Tree, and k-NN.

A. Database

It has great importance to work on the images with their ground truths for medical imaging applications. In this study, a publicly available mammogram dataset constructed during IRMA project is used [33]. This dataset consists of 12 classes defined by Breast Imaging Reporting and Data System (BI-RADS). These classes are four breast tissue classes (fatty, fibro-glandular, heterogeneously dense, and extremely dense) and three health status classes (normal, benign cancer, and malignant cancer) for each breast tissue type. It has 233 mammogram patches at a resolution of 42-50 μm/pixel for each class and therefore totally 2796 patch images are collected in the dataset [33].

In this paper, a database of 600 patches from fatty tissues is used. Each of normal, benign cancer, and malignant cancer cases has 200 patches. Sample patches of size 128x128 of each class on the used part of the IRMA database are shown in Fig.1. The rows of the Fig.1 illustrate five different samples of the normal, benign cancer, and malignant cancer cases, respectively.

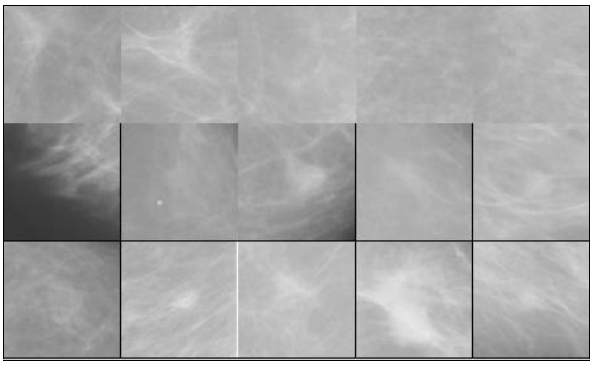

Figure 1. Sample mammographic patches

These patches are classified using 10-fold cross-validation technique. It implicitly means that 180 patches in each class are used for training while the remaining 20 patches are treated as the test patches. This scheme is repeated ten times in the cross-validation technique.

B. Feature Vector Construction

The key idea is to extract rotation-invariant features for obtaining representative feature vectors for breast cancer diagnosis. In this study, the LCP technique is used for rotation-invariant feature extraction. In order to extract these LCP-based feature vectors, firstly, pre-processed mammogram patches are decomposed into four sub-bands that are LL (low-low), LH (low-high), HL (high-low) and HH (high-high) by 1-level 2D-DWT utilizing db1 wavelet. Therefore, 81x1 dimensional LCP vectors of each sub-band are constructed. The endmost values in those LCP vectors are appreciably high, so they are removed to get rid of their domination over other features. The rest 80-dimensional feature vectors of each sub-band are then weighted with the coefficients shown in Table I; and they are summed up to form an 80-dimensional feature vector for each mammogram patch.

TABLE I. COEFFICIENTS OF EACH SUB-BANDS AND CORRESPONDING LCP CODES

LCP Code	LL-LH-HL-HH Coefficients
LCP 1-1-1-0	1-1-1-0
LCP 1,4-1-1-0	1,4-1-1-0
LCP 1,8-1-1-0	1,8-1-1-0

In the weighting process, HH sub-bands are completely ignored by using 0-coefficient since they introduce the noise component of the mammogram patches. Similarly, LL sub-bands, namely approximations in Wavelet theory, are the most meaningful components of the patches. Hence, effect of LL sub-bands is examined by three different coefficients used in [2].

In order to increase the representative power of feature vectors, 12 statistical features computed from the LCP feature vectors, and 16 frequency-domain features are concatenated to the LCP feature vectors. Consequently 108-dimensional feature vectors are obtained for each mammogram patch. Table II summarizes the feature vector construction process.

TABLE II. FEATURE VECTOR CONSTRUCTION PROCESS

108-dimensional Feature Vector Content		
LCP-based Feature Vector	**Statistical Features**	**Frequency Domain Features**
80 x 1	***12 x 1***	***16 x 1***
The 80-dimensional LCP-based Feature Vector	LCP: Energy LCP: Mean LCP: Variance LCP: Maximum LCP: Minimum LCP: Standard Deviation LCP: Skewness LCP: Kurtosis LCP: Area-Descriptor LCP: Mean Energy LCP: Energy Variance LCP: Entropy	LLLL: Energy LLLH: Energy LLHL: Energy LLHH: Energy LHLL: Energy LHLH: Energy LHHL: Energy LHHH: Energy HLLL: Energy HLLH: Energy HLHL: Energy HLHH: Energy HHLL: Energy HHLH: Energy HHHL: Energy HHHH: Energy

In the Table II, the phrase “LCP: Energy” means the energy value of an LCP vector whereas the “LLLL: Energy” is the energy of the LLLL (low-low-low-low) sub-band.

C. Performance Evaluation

Four different classification methods are performed on three different feature vector set for the CAD system in this study. Average classification accuracies of classifiers obtained by 10-fold cross-validation using "LCP 1-1-1-0", "LCP 1,4-1-1-0", and "LCP 1,8-1-1-0" coded feature vectors are shown in Table III.

The phrases "SVM ('p', 1)" and "SVM ('d', 2)" in the Table III are the SVM classifiers using linear and quadratic kernels, respectively.

TABLE III. AVERAGE CLASSIFICATION ACCURACIES OF CLASSIFIERS OBTAINED BY 10-FOLD CROSS-VALIDATION USING "LCP 1-1-1-0", "LCP 1,4-1-1-0", AND "LCP 1,8-1-1-0" CODED FEATURE VECTORS

CLASSIFIERS	FEATURE VECTOR CODES		
	LCP 1-1-1-0	***LCP 1,4-1-1-0***	***LCP 1,8-1-1-0***
SVM ('p', 1)	94.00	94.17	94.67
SVM ('d', 2)	94.33	94.00	84.33
FLDA	94.00	94.17	94.17
Decision Tree	86.33	86.17	84.50
k-NN (k=5)	45.67	49.50	48.83

VI. CONCLUSION

In this paper, a Computer Aided Diagnosis (CAD) system is entirely designed and verified on the mammogram images with their foreknown ground truths for breast cancer diagnosis. The benchmark mammogram database includes three different patch cases indicating the health status of a person. These cases are labeled as normal, benign cancer, and malignant cancer. The LCP algorithm is performed by itself for several image processing applications. Moreover, it is recently used in a biomedical image processing study [2], but LCP is not adequate to more correctly classify mammogram patches since it can be affected from various issues. Therefore the usage of LCP by itself does not result in representative features for a mammogram image. Not only discriminative but also descriptive features are to be computed in the feature extraction stage. Twelve statistical features calculated from the LCP feature vectors, and 16 frequency-domain features are concatenated to the LCP-based feature vectors. A maximum of 94.67% recognition accuracy is attained for LCP 1,8-1-1-0 coded feature vectors whereas 90.60% was obtained [2] if only LCP-based feature vectors are used. This outcome explicitly shows that the new feature ensemble is more representative than an LCP-based feature vector by itself. Furthermore, the linear SVM classifier (94.67%) is more successful than the other ones when the attained recognition accuracies are extensively examined. This consequence is another outcome for this study in order to be taken into consideration. Other feature types and combinations are planned to be exhaustively investigated as future works.

marko.meza@fe.uni-lj.si

Abstract - The paper presents a prototype method for detection of cardiac arrhythmia from pneumatic cuff pressure course, obtained during oscillometric blood pressure measurement. Oscillometric blood pressure measurement is an indirect method for blood pressure measure where pneumatic cuff is placed on patient's extremity, usually upper arm, inflated and then gradually deflated. During deflation phase the pressure oscillations in the cuff caused by squeezed blood vessels are analyzed to determine patient's blood pressure. Since presence of arrhythmia can be detected through observation of heart rhythm, it is possible to detect arrhythmia during blood pressure measurement. We have captured cuff pressure courses – samples from 34 patients of which 6 had arrhythmia present. From captured pressure courses we determined a set of features which we used to train a classifier for discrimination of samples with present arrhythmia from samples where arrhythmia is not present.

I. INTRODUCTION

Atrial fibrillation is one of the most common abnormal heart rhythms. It is relatively common in older patients. It affects about 1 percent of patients younger than 60 years and about 8 percent of patients older than 80 years [1]. It may occur in episodes lasting from minutes to days. It can result in reduced cardiac output or formation of blood clots in the heart [2] [3], which can lead to various serious complications [4]. Patients suffering from atrial fibrillation have symptoms including palpitations, chest pain, dyspnea, and fatigue [3, 5].

However, atrial fibrillation may be asymptomatic, and thus subclinical, causing no alarm to doctor or patient [5].

A standard test used to evaluate atrial fibrillation is usage of 12-lead electrocardiography, which is used to diagnose atrial fibrillation and identify other arrhythmia (e.g., atrial flutter, atrial tachycardia) [1]. Nevertheless, examination using 12-leads electrocardiograph is relatively complicated and therefore not suitable for widespread screening purposes.

It is crucial to have simple to perform and therefore widely available detection method for screening of the patients with atrial fibrillation. Besides 12-lead electrocardiogram several other methods for detection of atrial fibrillation exists. One of simplest and cheapest methods is pulse palpation [6]. Other cost effective and therefore accessible to wide population method for detection is usage of modified blood pressure monitor [6]. Several successful implementations of blood pressure monitors, capable of detecting atrial fibrillation during blood pressure measurement already exist.

A. Motivation

Since we have already developed a blood pressure monitor for monitoring blood pressure using oscillometric method [7], we wanted to adapt the monitor with an algorithm for atrial fibrillation detection. We conducted a pilot study, where we collected pressure course samples from 34 patients and used them to develop a proof of concept version of an algorithm for detection of atrial fibrillation. Since it is possible to detect atrial fibrillation solely by palpation, it is therefore also possible to detect it during using oscillometric blood pressure measurement [6].

II. BACKGROUND

A. Oscillometric blood pressure measurement

The blood-pressure in vessels is not constant. It oscillates from its maximal - *systolic* to the minimal - *diastolic* value. It is caused by the heart muscle beating. To explain the blood-pressure course, the heart-muscle beating cycle is divided into two phases, namely systole and diastole. During the systole phase, the heart muscle contracts and forces the blood into the arteries. During the systole phase, the blood pressure reaches its highest value - the systolic blood pressure. During the diastole, the heart muscle expands and draws blood from the blood-vascular system. During this phase, just before the systolic phase begins again, the blood pressure in vessels is at its lowest value - the diastolic pressure. The blood pressure is reported in unit [*mmHg*].

The arterial blood pressure can be measured in several ways. The most accurate method is a direct measurement, requiring the pressure sensor to be connected over tubing filled with liquid to a cannula needle, placed within the arteries. The method is used in clinical practice. The method is invasive and difficult to perform and therefore unsuitable for our approach. Besides this invasive direct method, there are noninvasive indirect blood-pressure measurement methods [6].

The oscillometric method is an indirect blood-pressure measurement method. It is used in most of commercial and home usage-intended blood-pressure measurement devices [8, 7]. It measures the blood-pressure through air pressure oscillations in the cuff, caused by the compressed arteries pulsations. Using this method, the cuff pressure is gradually released and measured. At a certain air pressure, when the blood pressure in vessels overcomes the air pressure in the cuff and blood starts to flow through the vessels, the air pressure in the cuff starts to oscillate. After the air pressure is further reduced, the oscillation amplitude increases to a certain maximum value and then decreases until oscillations vanish. By measuring the air oscillations amplitude the systolic, diastolic and mean blood pressure can be determined. Analyzing the oscillations, heart pulsation course can also be observed.

III. MATERIALS AND METHODS

A. Data collection

Data for algorithm development was collected in two phases. During the first phase, dataset of three persons was acquired. This step was taken in order to agree on all data items to be captured and to test if selected format of data capture is adequate. In second phase, data from actual patients in hospital was acquired.

Each data sample consisted of several data items for a specific patient. The first data item was raw cuff pressure course from temperature compensated and calibrated pressure sensor SLP33A, sampled with 200Hz, using 16bit A/D converter. Along pressure course, several metadata items were collected and recorded. Metadata consisted of patient's age, height, weight, diagnosed condition and smoking habits.

We acquired data of 34 patients of which 6 had atrial fibrillation present and 28 didn't. 17 patients were males, 17 were females. Patient's average age was 63.03 years with standard deviation 20.2 years. Minimum age was 25 years and maximum age was 89 years. Patient's average weight was 76 kilograms with standard deviation 13.8 kilograms. Minimum weight was 42 kilograms and maximum weight was 112 kilograms. Two patients were smokers.

For each patient we have also recorded 12-lead ECG signal.

All measurements were performed by skilled clinical practitioners who are performing these measurements during their daily clinical practice.

B. Tools used

Data was preprocessed using Matlab version 7.12.0.635 (R2011a). The algorithm required two low-pass filters which were designed using a Matlab filter design tool: *filter design*.

Machine learning was performed using Rapid Miner, version 5.3.015. Using the Rapid Miner Neural Network, SVM, Decision tree, Logistic regression, Random forest, and Naïve Bayes classifiers were tested. Classifier performance was evaluated using leave-one-out cross-validation scheme.

C. Classifier performance measure

For each classifier accuracy and classification error were calculated from classifier's confusion matrix. Actual classifier was selected observing classifier's confusion matrices through googles of domain knowledge. Classifier was selected based on harmonized performance classifying positive and negative samples with regard that available dataset was highly biased.

IV. ALGORITHM DEVELOPMENT

The algorithm consists of several phases. In first phase, the signal is processed to extract features, which are in our opinion relevant to discrimination of pressure course samples where atrial fibrillation is present from samples where atrial fibrillation is not present.

In the second phase, extracted features are used to build a classification model, which classifies samples into two classes: class where atrial fibrillation is present (class 1) and class where atrial fibrillation is not present (class 0). Then classifier results are evaluated and compared and best performing classifier is selected.

A. Data preprocessing

1) Conversion of voltage samples into actual pressure values

In the first stage, raw values of A/D convertor sampling voltage from pressure sensor are converted to pressure values. The relation between the cuff pressure, given in units *[mmHg]*, and the voltage, sampled by the A/D converter from the pressure sensor is given with a set of equations eq. 1, where ADC_{ref}, ADC_0 and ADC_{200} values are calibration values for used pressure sensor and A/D converter [7].

$$\begin{aligned} ADC_{ref} &= 2521 \\ ADC_0 &= 325 \\ n &= \frac{ADC_0 * 65536}{ADC_{ref}} \\ k &= \frac{(ADC_{200} - ADC_0) * 65536}{200 * ADC_{ref}} \\ p &= \frac{adc - n}{k} \end{aligned} \tag{1}$$

2) Elimination of the pressure course caused by the cuff air deflation and noise removal

The raw pressure course contains whole measurement pressure course, sampled by 200Hz. Measurement starts by cuff inflation using a pneumatic pump until the desired air pressure in the cuff is reached. Then the pump is switched off and air is gradually released from the cuff through a pneumatic valve. The deflation part of the pressure course is interesting for further analysis. It is therefore isolated and processed in further process. The goal of processing is extraction of pressure oscillations caused only by pulsating blood vessel.

At first, the course of air pressure in the cuff, caused by air deflation is determined. The course contains cuff

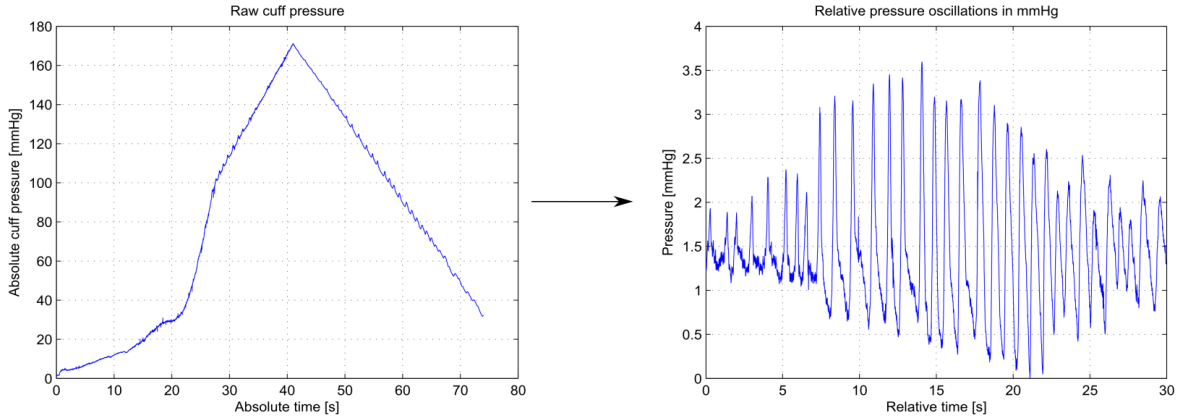

Figure 1. Transformation of raw cuff pressure course signal (left) to filtered signal where only by vessel pulsating caused pressure oscillations in cuff are present (right). Only the deflation part of raw pressure course used in further processing is shown on the left graph.

deflation pressure course without superimposed pressure oscillations caused by pulsating blood-vessels. By subtracting obtained course from the pressure course, only pressure oscillations, caused by the pulsating vessels are obtained. To obtain the deflation pressure course, the pressure data is filtered using a low-pass filter. We used Hamming low-pass FIR filter of order 100 with low-pass frequency F_{cut}=*0.1Hz*. The frequency was chosen empirically and lies well below the expected lowest frequency of the signal, representing pressure pulsations. Obtained cuff deflation pressure course is then subtracted from non-filtered pressure course. The signal is then filtered again to remove high-frequency noise. Used noise removal filter is Hamming low-pass filter of order 100 with low-pass frequency F_{cut}=*20Hz*. Frequency 20 Hz was chosen empirically and is well above the expected frequency of the pressure-oscillation signal [7].

Since filter responses are known, signal obtained after filtering is trimmed in order to remove filter ringing on beginning of the signal. Figure 1 illustrates effect of processing on raw signal, resulting in signal where only by blood-vessel pulsation caused oscillations are present in the signal.

3) Detection of heart beats from pressure course

In order to detect heart beats from pressure course, local pressure oscillations signal extreme search is performed, using the method *peakdet*, proposed by author cited in [9] on in previous step filtered, but still partially noise occluded signal.

To determine maxima and minima of the signal in partially by the noise occluded signal an assumption that local maxima and minima follow each other in an alternating manner is made. The algorithm scans through the data alternating search of local maximums and minimums. To declare the next local maximum, its value must differ from the previous local minimum for at least δ. The value of δ is determined empirically with regard to the analyzed data. When the algorithm finds the next extreme, it records its value and index and moves to the next extreme search. Figure 2 shows local extreme search algorithm result.

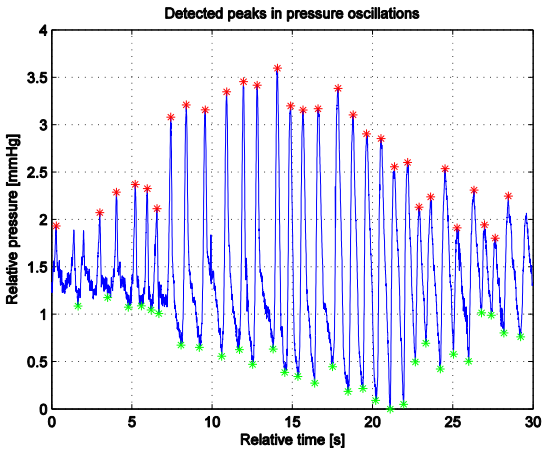

Figure 2. Local extreme search using peakdet [9] algorithm. Detected local maxima and minima of the signal are marked with stars.

B. Feature extraction

1) Detection of irregular heart beats

First step of feature extraction is determination of times of heart beats and beat intervals. In order to determine times of heart beats, previously detected local maxima of pressure course are used. From vector containing maxima, beat intervals are calculated by differentiating the vector containing beat times. In order to determine irregular heartbeats, beats that differ from average beat time by more than through optimization determined threshold are marked. Using our dataset, optimal value of threshold was beat time difference of 45% from average beat time.

To detect irregular heartbeats, first an average beat frequency is determined from beat intervals. In our case, best results for overall heart beat frequency are obtained calculating median of vector, containing beat intervals. Next, beats differing from overall average beat frequency more than threshold are marked. Figure 3 illustrates result of irregular heart beat detection.

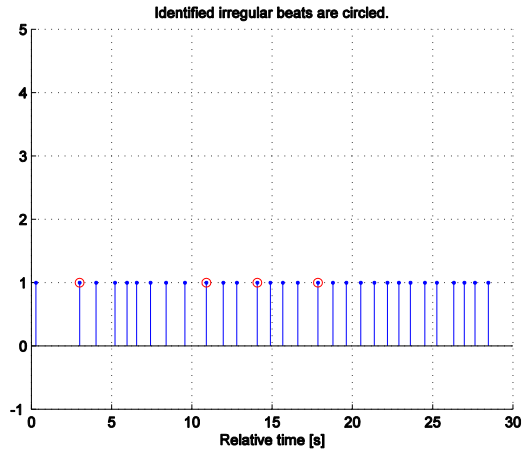

Figure 3. Timeseries of detected heartbeats. Detected irregular heartbeats differing from average frequency are marked by circles.

2) Features determined

From vector containing heartbeat intervals and irregular beats several features relevant for atrial fibrillation determination are computed. Computed features are:

- **Beat frequency (BF)**, which is computed by computing median of beat intervals. Obtained value is then used to calculate beat frequency in beats per minute;
- **Ratio of irregular beats (RIB)**, which is computed by counting irregular beats and dividing the value with number of all detected beats;
- **Average irregular only beat interval (aIRBI)**, which is calculated by computing mean value of all irregular beat intervals;
- **Standard deviation of irregular only beat interval (stdIRBI)**, which is calculated by computing standard deviation of all irregular beat intervals;
- **Number of consecutive irregular beats (NCIB)**, which is calculated by finding maximum value of consecutive irregular beats.

TABLE I. EXAMPLE OF DATASET CONTAINING SET OF FEATURES, USED TO TRAIN CLASSIFIER.

Sample	BF	RIB	aIRBI	stdIRBI	NCIB	AF
1	69.7	0.13	329	143.5	0	1
2	70.6	0.08	316.7	100.8	0	1
...						
7	67.9	0.03	357	0	0	0
8	69.4	0.05	212.5	171.8	0	0
9	63.2	0	0	0	0	0
…						

Determined features for each patient (processed pressure course) are recorded in a single vector, and label about presence of atrial fibrillation (**AF**) is added from metadata. The vector, containing all features, is then exported into a CSV file. Table I illustrates dataset excerpt, containing features of 5 samples.

C. Modelling

Dataset containing features was processed in Rapid Miner. At first, data was imported, using "Read CSV" operator. AF attribute role was set to label.

1) Selection of best classifier

Several classifiers were tested and evaluated. Since available dataset was small, leave one out cross-validation scheme was used for each classifier. For each classifier confusion matrix was computed. Since available dataset was highly biased (6 positive vs 28 negative) overall accuracy of classifier is not representative measure of classifier's performance. Best classifier was selected based on performance of classifying positive samples correctly.

Tested classifiers were: Naïve Bayes, Logistic regression, Decision tree, Random forest, SVM and Neural network. All classifiers were used using their default settings.

V. RESULTS

Several classifiers were trained and evaluated using "leave one out" validation process. Table II illustrates classifier performance. Overall classifiers accuracy ranges from 50% for Naïve Bayes to 85.92% for Neural network. However, observing class recall and class precision, it is evident that classifier accuracy is not effective performance indicator. For example, SVM classifier predicted all sample classifications as negative and therefore scored 82.35% on accuracy regardless it failed to predict any positive class. Observing the confusion matrices, we believe, best classifier for our problem is Neural network classifier, since it was able to find nearly all positive samples (5 of 6) and produced 4 false positives. It also correctly predicted nearly all negative samples (24 of 28) and produced 1 false negative.

TABLE II. EVALUATED CLASSIFIERS PERFORMANCE.

Naïve Bayes (accuracy 50%)			
	true 1	**true 0**	**class precision**
pred. 1	6	17	26.09%
pred. 0	0	11	100.00%
class recall	100.00%	39.29%	
Logistic regression (accuracy: 61.76%)			
	true 1	**true 0**	**class precision**
pred. 1	3	10	23.08%
pred. 0	3	18	85.71%
class recall	50.00%	64.29%	
Decision tree (accuracy: 76.47%)			
	true 1	**true 0**	**class precision**
pred. 1	2	4	33.33%
pred. 0	4	24	85.71%
class recall	33.33%	85.71%	
Random forest (accuracy: 79.41%)			
	true 1	**true 0**	**class precision**
pred. 1	0	1	0.00%

SVM (accuracy: 82.35%)			
	true 1	**true 0**	**class precision**
pred. 1	0	0	0.00%
pred. 0	6	28	82.35%
class recall	0.00%	100.00%	
Neural network (accuracy 85.29%)			
	true 1	**true 0**	**class precision**
pred. 1	5	4	55.56%
pred. 0	1	24	96.00%
class recall	83.33%	85.71%	

VI. CONLUSION

Developed algorithm performed above expectations. This can partially be caused by the fact, that the best performing classifier is able to fit relatively complex functions. Therefore it is possible, that the classifier is over-fitting the data and will not perform so great when confronted with more real data samples. But nevertheless, the algorithm looks promising. We will therefore continue with its development. Our first task will be focused on collection of a larger dataset, on which the algorithm will be furtherly tested and optimized. Main reserves for algorithm improvement lie in more precisely determined feature values, determined from raw data. Since feature extraction process was partially iterative, during which certain feature extraction thresholds were back set based on classifier performance, we believe, that features will be more precise when a larger dataset is available. Further work will be also focused on determination of features, based on which atrial fibrillation can be distinguished from other arrhythmias.

Sometimes atrial fibrillation cannot be distinguished from ectopic beats by only observing heart beats detected from oscillometric method. However the described method is intended as a screening method, based on which, patients with detected rhythm anomaly are referred to further, more invasive examinations.

Abstract – There is an increasing number of diabetic diseases in the population. Early diagnosis increases possibility of healing and decreases healing expenses. This paper is focused on modeling of an expert system for assessing diabetes risk using artificial intelligence methods. The model is hierarchical with neuro-fuzzy blocks and voting on the output. Model optimization (learning) is done using the data of real patients acquired in a one public health institution. The expert system is implemented in the Matlab/Simulink environment. Validation of the system shows high sensitivity of 100% which is important for early diagnoses. Specificity is lower – only 90% which means that some patients are sent to further diagnoses although they are healthy. Results indicate that this modeling approach is applicable on assessing diabetes risk. The medical domain knowledge and experience contained in the real data is successfully transferred in the solution model – the proposed expert system. Validation of the proposed expert system indicates that such a system can be used as an auxiliary expert for early diagnoses of diabetes and improve the quality of health systems with lower diagnostic expenses.

I. INTRODUCTION

Human life quality is related to health. Improving health is related to reducing risks of diseases. Best way to reduce risks of diseases is to increase the quality of diagnoses and provide early diagnosis which gives better healing possibilities. Disease early diagnostic and risk estimation reduces treatment costs which is very important for healthcare institutions.

Nowadays, public each healthcare institution has information system which enables monitoring of the health status of patients and keeping records of their treatments. However, these data are not sufficiently used to support and help doctors in primary health care decision making. On the other side, possibilities to exploit these data are increasing, especially in the area of artificial intelligence [1].

There are a number of papers related to the diagnostics of diabetes mellitus and its association with risk factors, through the use of artificial intelligence and data mining. T. Jayalskshmi and A. Santhakumaran in their work [2] discuss various data processing techniques. Artificial neural networks (ANN) [1] represent a significant area of interest for solving health problems because of their capability to learn from data with the high accuracy (near 99% accuracy in many applications). Marcos. A. González-Olvera et al in their work [3] presented data-driven modeling of the insulin dynamics in different patients using a recurrent ANN with the output feedback. GG Gardner et al in their work [4] investigated usage of neural networks in detection of diabetes through images of the retina of the eye and showed the comparison in the pictures of the patients (the sample of 147 diabetics and 32 normal). By comparing the results of ophthalmologists and the network, the network has achieved 88.4% sensitivity and specificity of 83.5% for the detection of diabetic retina. Compared to the ophthalmologist, the network has reached good accuracy, and the system can be used to support the screening of diabetic patients.

II. METHODS AND DATA SOURCES

One of the most frequently used combinations of soft computing methods is the one that combines fuzzy logic and neural computing, usually in the form named neuro-fuzzy system. The most popular neuro-fuzzy system is the adaptive-network-based fuzzy inference system (ANFIS) [5] that is capable to learn from data, i.e. to optimize fuzzy rules using a neural network as an optimization mechanism.

The overall model (see Fig.1) of the expert system for assessing diabetes risk is divided in two parts. The first part is based on ANFIS and the second part uses simple neural network. Results from these two parts are combined (ensemble) in voting block to produce final diabetes risk assessment. Using two different models and combining results is for safety reasons, i.e. decreasing possibility of the wrong assessment. In medical terminology this is like second opinion of another doctor.

In the first part, input data are divided into three groups and fed into three ANFIS. This way ANFIS execution is simplified because of the lower dimensionality. It would be better to use all nine input variables in one ANFIS but that makes the problem much complex for execution and output fuzzy model is much harder to understand. In this way fuzzy models of all three blocks are simple, but price is necessity to ensemble results by using one voting block.

In the second part all input data are fed into one neural network. Training, testing and validation are performed for complete model, including both parts, simultaneously. That means that training data are fed in the first part (three ANFIS) and in parallel to the second part (neural

network). Output from the system represents a percentage risk for diabetes disease development.

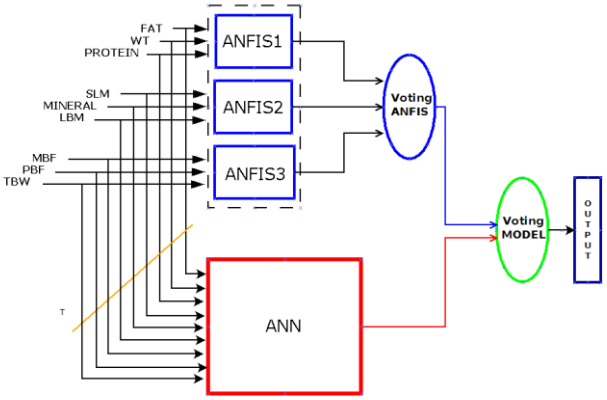

Figure 1. Hierarchical structure of the neuro-fuzzy system for assessing the risk of diabetes

TABLE II. DESCRIPTION AND ABBREVIATIONS OF THE MEASURED VALUES

Abbreviation	Description
FAT Fatness (%)	Fatness measure in percentages compared to the standard body weight FATNESS = ((*real weight – standard weight*) / *standard weight*) * 100
WT Weight	Measured body weight
PROTEIN Protein (kg)	Weight that remains when water is eliminated from muscle mass
SLM S.L.M.	Mass of lean tissue (*weight – fat mass – mass of bones*)
MINERAL Mineral (kg)	Weight of bones and electrolites
LBM L.B.M. (kg)	Weight body weight less fat. Shows the mass: water, muscle, minerals and other lean tissue
MBF M.B.F. (kg)	Weight of body fat in kilograms
PBF P.B.F. (%)	Percent of Body Fat - weight ratio of body fat compared to body weight
TBW T.B.W. (kg)	Weight of water in the body (intracellular and extracellular)

Data used in this research are real measurements of parameters collected by Croatian Institute of Public Health of the Medimurje County, using body composition analyzer Avis 333. The dataset contains samples for 165 adults of different ages and sexes.

Nine collected measurements are described in table I. Classification of samples, those at risk for diabetes (class 1) and those, in which there is no risk (class 0), was conducted by the domain expert. This way is prepared the dataset for supervised [1] training of the model.

A. *ANIFS modeling*

After the dataset preparation, it is split into subsets for training, testing and validation. Structures of Sugeno fuzzy systems are created from data using ANFIS tool, which also enables training and testing of the created fuzzy system.

In order to break the complex multidimensional data structure into a smaller dimensional structure, data segmentation was performed in the way that nine input attributes – variables are split in three sets, so that three FIS structures are created.

B. *Neural network*

In this research is experimented with 12 different architectures of the neural network. The 12 architectures differ in the number of hidden neurons, transfer functions in the hidden and output layer, and error function. It was also experimented with different dataset divisions on subsets for training, testing and validation to obtain valid statistics of model creation.

III. RESULTS

Obtained results were assessed, and finally one neural network, that gives the best result, was selected (see table II). Final model is presented on Fig.2. It is a Simulink block model. Voting bloc VOTER_ANFIS is created as perceptron type network, while voting bloc VOTER_MODEL is created as single-layer network with a linear transfer function (see Fig.3). Decision about network type used in voting blocs is made experimentally.

TABLE I. RESULTS OF TRAINING, VALIDATION AND TESTING. THE MOST EFFECTIVE BACKPROPAGATION NEURAL NETWORK IS THE ONE WITH 5 NEURONS IN THE HIDDEN LAYER (NET10)

Neural Network	Net10
Sample division Training% Validation% Testing%	70% 15% 15%
Number of neurons in the hidden layer	5
Transmission function in the hidden layer	tansig
Transmission function in the output layer	purelin
Number of epochs	18
Lowest error (MSE)	$1{,}8405*10^{-11}$

IV. DISCUSSION, CONCLUSION AND FUTURE WORK

Validation of the system is done by using 20 samples not used in system creation and learning (optimization). Half of them are of class 1 (positive) and half of them are of class 0 (negative). System showed high sensitivity (100%) which means that all patients with the risk (class 1) are recognized by the system properly, but specificity of the system is lower (90%) which means that some of patients that have not diabetes risk are recognized as patients with the diabetes risk. In reality that means that they would be send to further medical examinations. Additional check for each patient does not present a burden, and it can eliminate the doubts. That produces less damage than in the opposite case (when the specificity is higher than the sensitivity).

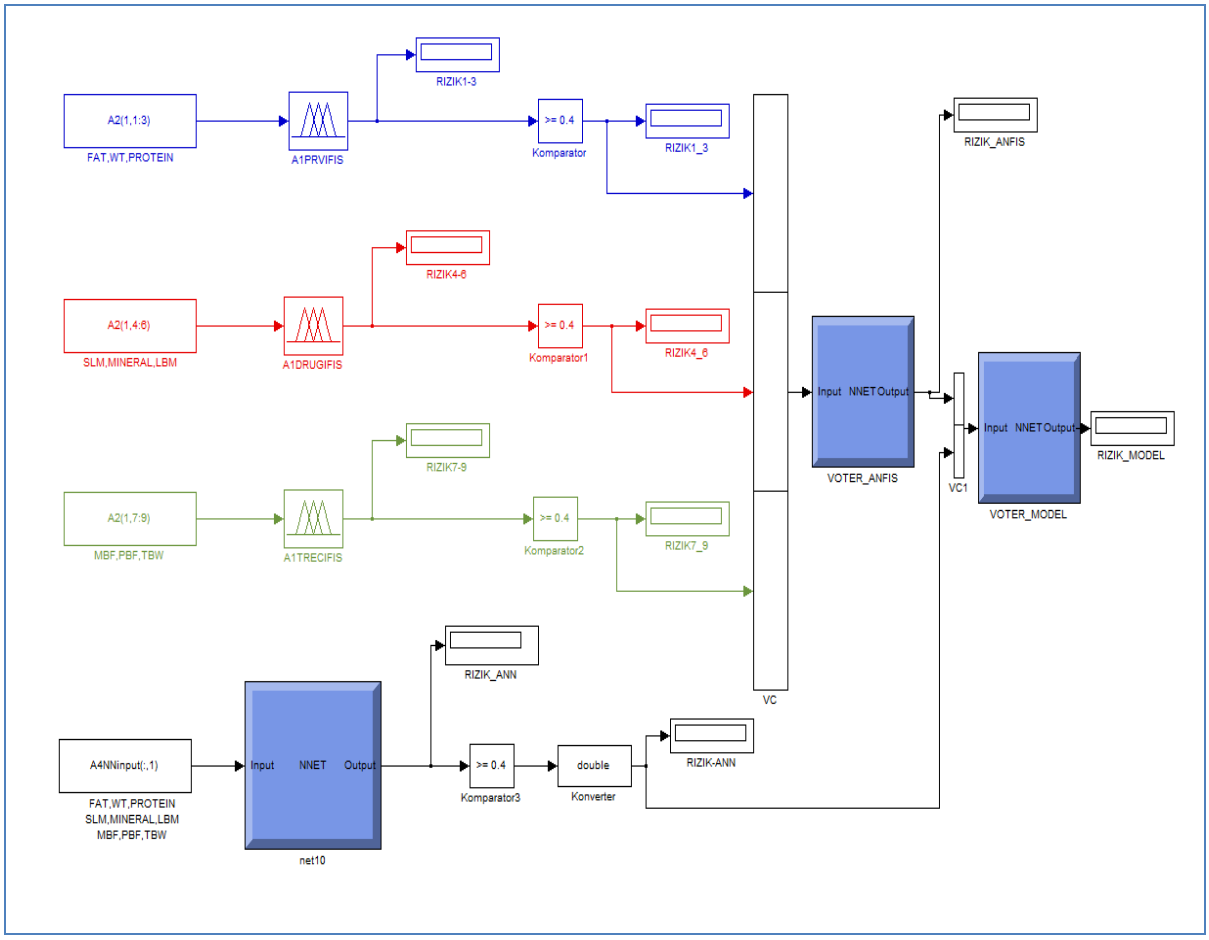

Figure 2. Simulink application

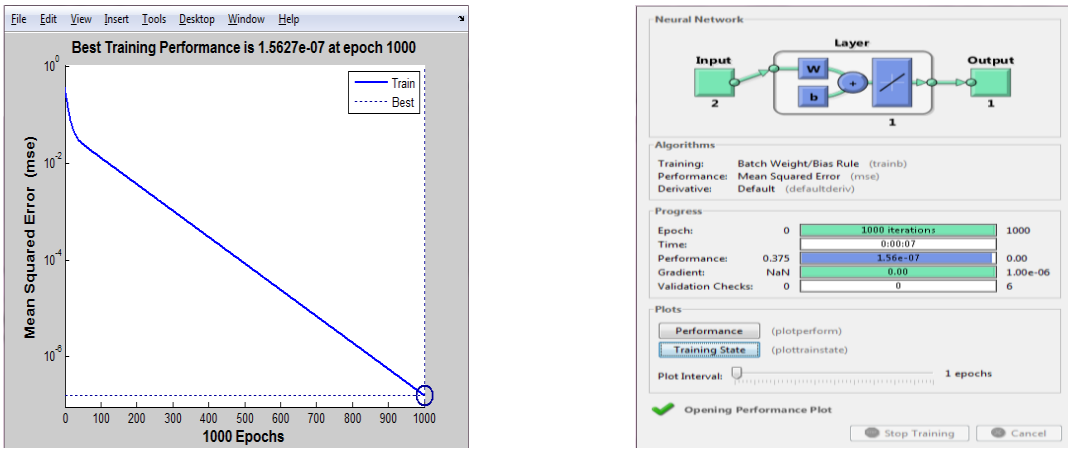

Figure 3. VOTER_MODEL performances and neural network

The aim of this study was to develop a model of intelligent system which takes a number of attributes, input parameters, and based on them provide risk assessment of a disease. It is implemented as two models that complement each other. Both models use same input data. The first model (FIS structures) is developed and implemented using ANFIS tool, and for easier construction it is divided into three parts with three input parameter attributes within each FIS structure. Neural network, as the second model, showed slightly lower results than the first model, considering the fact that it is a relatively small data set for training, testing and validation.

After system creation, validation of the system showed good results However, for a more complete and better assessment of the risk of disease, it is necessary to have a larger number of samples available, and the greater number of attributes for the model to be more representative for decisions making.

It should be taken into consideration that only nine attributes where used, and that for complete and comprehensive diagnostics the glucose levels for all cases

should be included. This can be one of directions for a future work.

{daniel.domovic, tomislav.rolich}@ttf.hr

Abstract - Strip-packing problem is a combinatorial optimization problem with a goal of finding optimal positions of cutting patterns that meet the following conditions: each pair of cutting patterns must not overlap and they must be placed within the boundary of rectangular material area. An optimal placement that utilizes material usage needs to be created. Strip-packing problem is a common textile industry problem where it is also known as automated marker making problem. In this paper a sequence pair abstract representation is used to obtain a non-overlapping placement. For that reason cutting patterns are approximated with a rectangular bounding box and placement of rectangles is obtained first. Non-approximated cutting patterns' positions and material dimensions are then decoded using longest common subsequence method. These methods are combined with simulated annealing algorithm to find an optimal placement of cutting patterns. Experiments were conducted on 4 benchmark datasets: MARQUES and ALBANO (24 cutting parts), DAGLI (30 cutting parts), and MAO (20 cutting parts) with material utilization of 83.54%, 82.02%, 69.86%, and 71.26% respectively.

Keywords - sequence pair, longest common subsequence, simulated annealing, irregular items, strip packing problem.

I. INTRODUCTION

In order to remain competitive on modern market a part of the budget needs to be invested in the improvement of production. Referring to textile and garment industry specifically it has been recognized that the industrial advance lies in the investment in new technologies, developing new products, specialization and export [1].

Considering the fact a large part of production process in garment industry is still done manually, by applying new technological achievements into the production process it is possible to improve productivity and production speed.

Collaboration between computer science and textile industry can contribute to this process. In that context a strip-packing problem is introduced, also known as the automated marker making problem in garment industry.

This research is conducted to create an algorithm that will automatically create markers consisted of cutting patterns optimally allocated on a material. Since the material greatly influences final garment price, it is important to rationally nest cutting patterns, and to speed up the production process to reduce its cost.

In computer science a problem of automatic marker making is referred to as 2D-irregular strip-packing problem and is described as follows. In a container i.e. rectangular shaped material of fixed width and infinite length, cutting patterns i.e. polygons of convex and non-convex shape need to be placed on material to create a placement that utilizes the material length. Two conditions have to be met: any of the two items should not overlap and polygons must not exceed the boundary of a container. When items are irregularly shaped the strip-packing problem is commonly referred to as nesting problem [2].

Formally, a set of items $I = \{i_1, i_2, \ldots, i_n\}$, where n is the number of items in I ($|I| = n$) needs to be placed in the container C so the following conditions are satisfied: (1) $i_i \cap i_j = 0$, and (2) $i_i \cap C = i_i$ [3].

Strip-packing problem belongs to a larger field of packing problems. An attempt to categorise the subproblems has been made by Dyckfoff [4] and more recently Wäscher [5]. Wäscher differs packing problems by the criteria of dimensionality, problem goal, large objects, small objects and shape of small objects.

Packing problems can be examined from three perspectives: container count minimization, optimal subset selection, and container size minimization (area minimization). In this research the width of a container as well as the length have arbitrary size. Therefore we deal with finding a minimal circumscribed rectangle in which all items can be placed.

The paper is organized as follows: in Section II a literature overview is given. In Section III methods used in this paper are described. In Section 0 the results are presented alongside a short discussion. The paper is concluded in Section V.

II. LITERATURE OVERVIEW

Strip-packing problem is known to be NP-complete which means that globally optimal solution is unlikely to be found using polynomial algorithms [6]. As a result solution methodologies predominantly utilize heuristics [2]. Since obtaining a feasible rectangle packing is a core of our approach we present some rectangle packing methods used in the literature.

The authors in [7] cope with a layout in physical design of VLSI which is in its core a rectangle packing problem. All circuit elements in a chip have to be packed

without violating design rules. A packing representation called sequence-pair has been proposed where each sequence pair corresponds to a packing. A method to transform a sequence pair into a horizontal and vertical constraint graph is also described. A solution space is searched using simulated annealing.

Since block placement algorithms usually use simulated annealing, a fast algorithm is needed to transform a sequence pair into a corresponding placement. In [8] an approach that uses longest common subsequence (LCS) to evaluate a sequence pair in $O(n^2)$ and an improved algorithm in $O(n\log n)$ running time is presented. LCS algorithm is able to record and reconstruct the position of each block and dimensions of a placement.

In [9] the author interprets the sequence pair as a packing order. Generated placements are semi-normalized, i.e. each item is moved as far left and down as possible according to the current packing contour. A transformation of sequence pair to placement in $O(n\log\log n)$ time has been presented. For large packing problems it is able to find solutions quickly that waste no more than 3%–5% of the space.

As seen from the literature overview, to our best knowledge, sequence pair has only been applied to obtain rectangle packing. For that reason and because of the complexity irregular items introduce to the implementation authors have tried to approximate items using convex hull (as in [10] and [11]) or circumscribed rectangle (often referred to as bounding box). The rectangular approximation is used in this paper so the sequence pair method can be applied.

III. METHODS USED

In this section we describe our proposed methodology and concepts related to its behavior, involving polygon approximation, sequence pair, longest common subsequence and simulated annealing.

A. Polygon approximation

Since sequence pair methodology applies only on rectangle packing problem, irregular polygons used in this research are approximated using bounding box representation. A bounding box of a polygon is a rectangle circumscribed around a polygon, i.e. the smallest rectangle that contains all points of a polygon as seen in Fig. 1. Each bounding box rectangle is represented with its reference point (coordinate of a lower left corner is used), width and length.

B. Sequence pair

A placement can be presented directly as a list of polygons. Each polygon is thereby presented with coordinates of its vertices which can potentially result with an overlapping placement. Therefore, many heuristics use abstract representation techniques whose goal is to present a placement by describing the relationship between elements rather than dealing with elements' coordinate positions. The abstract representation is later subjected to a decoding algorithm to reconstruct a placement [3]. In this research a sequence

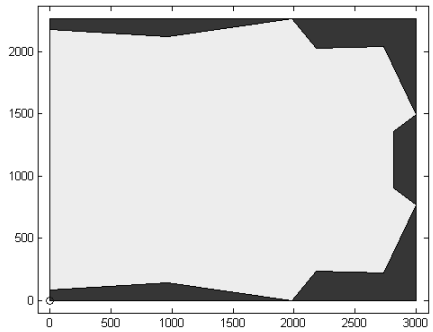

Figure 1. Bounding box representation

pair abstract representation is used and applied on rectangle packing.

Sequence pair is a pair of permutation lists consisted of m indexes where $m = \{1, 2, ..., n\}$ and n is the number of rectangles. Each index m represents one rectangle.

The relationship between polygons is decoded using the following rules [8]:

$$(< ..m_i..m_j..>, < ..m_i..m_j.. >) \Rightarrow m_i \text{ is left of } m_j \quad (1)$$

$$(< ..m_j..m_i..>, < ..m_i..m_j.. >) \Rightarrow m_i \text{ is below of } m_j \quad (2)$$

Example of a packing for a sequence pair (X, Y) is shown in Fig. 2. In this paper a packing is reconstructed with longest common subsequence method.

C. Longest common subsequence

Longest common subsequence (LCS) method is used to reconstruct a rectangle packing from a sequence pair. By applying it, we are able to find the position of a reference point of a rectangle and to find its position in a placement [8]. Using LCS method the dimensions of an overall placement can also be calculated [3].

For two weighted sequences X and Y, a sequence Z is a common subsequence of X and Y if Z is a subsequence of both X and Y. In example in Fig. 2 a subsequence (5 1 4) would result as a LCS of (X, Y).

To obtain the length of a packing a LCS(X, Y) needs to be performed. Height of a packing is calculated as LCS(X^R, Y), where X^R represents inverted X permutation. Based on this relation coordinates of a rectangle can be calculated.

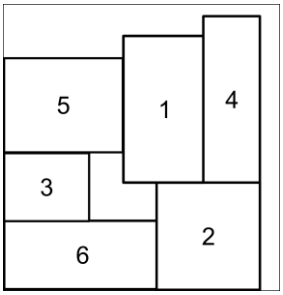

Figure 2. Packing represented by sequence X = (5 3 1 4 6 2) and sequence Y = (6 3 2 5 1 4)

```
Initialize P and L to zeros
FOR each element i
  b ← X(i)
  p ← index of element b in sequence Y
  P(b) ← L(p)
  t ← P(b) + width of element b
  FOR j = p to n
    IF t>L(j)
      L(j) = t
    ELSE
      Break
    END IF
  END FOR
END FOR
LCS width = L(n)
```

Figure 3. LCS algorithm for obtaining a width of a packing based on sequence pair (X, Y)

If sequence pair (X, Y) is represented as (X_1bX_2, Y_1bY_2), b is the rectangle whose coordinates are calculated, X_1 and Y_1 are the predecessor of rectangle b in a sequence pair and X_2, Y_2 are successors of rectangle b in a sequence pair. The x-coordinate of polygon b can be reconstructed by calculating LCS(X_1, Y_1).

If sequence pair (X, Y) = (X_1bX_2, Y_1bY_2), then (X^R, Y) = ($X_2^RbX_1^R$, Y_1bY_2), so y-coordinate of a rectangle b in a packing is reconstructed by calculating LCS(X_2^R, Y_1).

The pseudo code of a LCS algorithm implemented in this research is shown in Fig. 3.

D. Simulated annealing

Simulated annealing is a metaheuristic local search technique inspired by a process of cooling metal which is known as annealing. Simulated annealing searches a set of neighborhood solutions to a certain problem in a randomized manner. Each solution is said to have a neighborhood, i.e. a set of solutions in the close area of a current solution. Neighborhood of a solution is expressed by a criteria depending of a problem. For e.g. if a solution is presented by a permutation, a neighborhood of a solution is a set of permutations where distance between permutations is two (permutations differ in positions of two elements).

In simulated annealing the neighborhood of a solution is searched in a randomized manner. If a better solution is found in the neighborhood it is always accepted and the search process continues from that solution. This method is also used in hill climbing algorithm. One of the main drawbacks of this heuristic is that it can get easily stuck in a local optimum. To escape local optimum some worse solutions from the neighborhood are also accepted, but with a certain probability.

The probability of a downward move is based on the temperature factor T. Factor T is decreasing over the course of the algorithm according to a cooling schedule. If a new solution X_{i+1} has worse fitness value than the current solution X_i, X_i is replaced with X_{i+1} if a random number r $\in$ [0, 1] is lower than probability $e^{-D/T}$. Otherwise, it is always accepted. Temperature T is decreasing in each iteration according to the problem specified formula.

Downward move serves as a mechanism to better explore the search space because sometimes the best solution can be found in the neighborhood of the worst solution. Initially, the probability of allowing a downward move will be relatively large, but later in the algorithm, closer it gets to the optimum, downward moves are permitted with smaller probability [12].

E. Proposed methodology

The proposed methodology is described by pseudo code in Fig. 4. After initializing SA parameters, bounding boxes are created for a set of irregular polygons. The rectangle packing is obtained using sequence pair and SA.

After randomly choosing the initial sequence pair, a neighborhood solution needs to be found. A neighborhood of a sequence pair is a set of permutation pairs in which at least one sequence within a pair differs in positions of two elements from its neighbor. For e.g. if a sequence pair is X = (1 2 3 4 5), Y = (5 4 3 2 1) then a possible neighbor can be X_1 = (5 2 3 4 1), Y_1 = (5 4 3 2 1). Function that calculates (X_1, Y_1) permutes only two elements in a permutation in sequence X, or in sequence Y, or in both sequences X and Y. The option is randomly selected by the algorithm. After selection solutions are evaluated by calculating the fitness of each solution according to (1). A polygon packing is obtained by removing bounding boxes from a layout.

```
Initialise: SA parameters t0, ts, number of iterations
Create bounding boxes from a set of polygons
polyArea ← area of polygons
Randomly choose initial sequence pair (X, Y)
Calculate the fitness of (X, Y)
FOR each iteration
  Find the solution (X1, Y1) in the neighbourhood of (X, Y)
  Calculate fitness f(X1,Y1) to evaluate the (X1, Y1)
  IF f(X1,Y1) is better than f(X,Y)
    Accept it
  Else
    Choose random number r
    Calculate temperature factor T = 1 / (t0 + ts * a)
    Calculate fitness ratio factor D = (f(X1, Y1) − f(X, Y)) / f(X, Y)
    IF r < e^(−D/T)
      Accept solution
    END IF
  END IF
  IF solution is accepted
    X ← X1, Y ← Y1
    a = a + 1
    bbArea ← area occupied by rectangles using LCS algorithm
    IF bbArea is smaller than minimum area so far
      Minimum area ← bbArea
    END IF
  END IF
END FOR
```

Figure 4. Proposed algorithm

IV. RESULTS

In this section experimental results and discussion on obtained results are presented.

A. Environment

The experiments have been carried out on a personal computer with the following configuration: Intel Core i5-2400@3.1 GHz, 10 GB DDR3, 500 GB HDD. An application has been implemented in MATLAB environment.

B. Parameters

Simulated annealing parameters initial temperature t_0 and temperature step t_s are initialized to empirically chosen values 0.1 and 0.01 respectively.

A series of experiments have been conducted on 4 benchmark datasets available on EURO Special Interest Group on Cutting and Packing (ESICUP) website [13]: ALBANO, MARQUES, MAO and DAGLI all of which are real instances from textile industry. The data sets are described in Table II. Although rotations of polygons for these data sets can be allowed, we have not included experiments with rotation in our research.

TABLE II. DATA SET CHARACTERISTICS

Data set	**Number of different pieces**	**Total number of pieces**	**Orientation (degrees)**
Albano	8	24	0, 180
Dagli	10	30	0, 180
Mao	9	20	0, 90, 180, 270
Marques	8	24	0, 90, 180, 270

For each data set a series of ten experiments with 10000 (10k), 50000 (50k), 100000 (100k) and 500000 (500k) iterations of SA have been conducted.

C. Discussion

Experimental results for packing density of a rectangular packing (column RECT) obtained by sequence pair, and its corresponding polygon packing (column POLY) are presented in Table I. For each data set (column *DATASET*) and for each iteration count (column *ITER*) a minimum and maximum value of ten experiments is recorded in column MIN and MAX respectively while an average value of ten experiments is recorded in column AVG. The values are calculated in percentage.

From Fig. 5 a visualization of a fitness function can be interpreted. The blank space between items and a rectangular bounding box that represent a container is considered as waste area. The goal of a fitness function is to decrease the amount of waste area.

Since the waste between items wants to be minimized, fitness function is defined as:

$$f(X,Y) = bbArea - polyArea \quad (1)$$

$$polyArea = \sum_{i=1}^{n} area(p_i) \quad (2)$$

$$bbArea = \mathrm{LCS}(X,Y)*\mathrm{LCS}(X^R, Y) \quad (3)$$

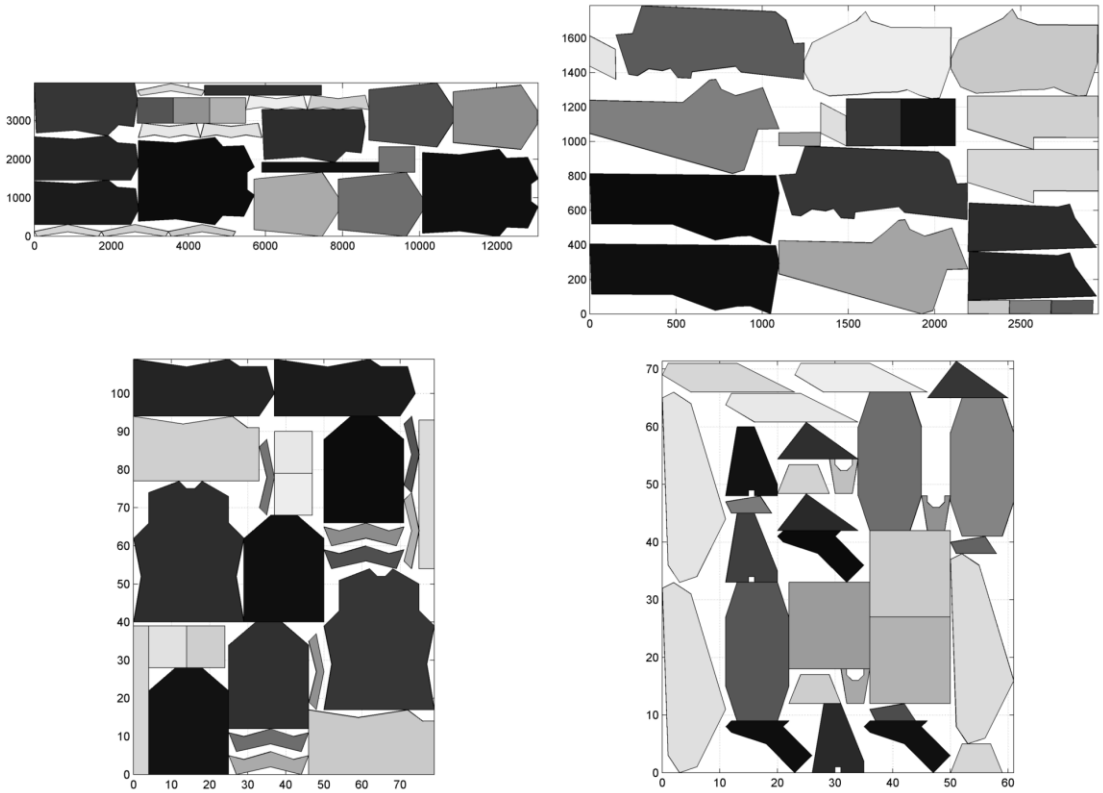

Figure 5. Best packing obtained for ALBANO (upper-left), DAGLI (upper-right), MARQUES (bottom-left) and MAO (bottom- right) dataset

The (*X*, *Y*) is a sequence pair, *polyArea* is the sum of area of all items in a data set, and *bbArea* is an area of a bounding box that is surrounding current packing. Value of *bbArea* is calculated using LCS algorithm.

In this research we tried to examine the efficiency of a rectangular polygon approximation and the ability of applying a rectangular packing method on 2D irregular polygon packing problem. We performed experiments with various iterations count in order to examine the rate in which the number of iterations influences packing density.

The best obtained packing density for the dataset ALBANO is 82.02%, for DAGLI 69.86%, for MAO 71.26%, and for MARQUES 83.54%.

Some of the best results for current algorithms are presented in [6] and [14]. For ALBANO dataset, packing density of 89.96% has been obtained by SAHA algorithm, 84.60% by BLF, 86.96% for 2DNest, 87.88% for BS, and 88.40% for AM.

For DAGLI dataset 87.15% has been obtained by SAHA, 83.70% by BLF, 87.05% by 2DNest, 87.99% by BS.

For MAO dataset 82.54% has been obtained by SAHA, 79.50% by BLF, 85.15% by 2DNest, 84.07% by BS, and 82.69% by AM.

For MARQUES dataset 88.14% has been obtained by SAHA, 86.50% by BLF, 89.17% by 2DNest, 88.92% by BS, and 87.80% by AM.

Some of our results are not comparable with the ones in literature since they allow rotation of polygons and we do not. We would also like to note that any compaction method has not been performed on our final packing so the results are expectedly worse than the ones in literature.

When analyzing the quality of a bounding box approximation we conclude that the effectiveness of an approximation depends on the shape of items in a dataset. The results for data sets ALBANO and MARQUES versus data sets MAO and DAGLI indicate this hypothesis. As it can be seen in Fig. 4, in data sets MAO and DAGLI the degree of irregularity of elements is higher than in MARQUES and ALBANO in terms that the elements are more similar to rectangle in MARQUES and ALBANO than in MAO and DAGLI.

The results in column DIFF record the average decrease in packing density of 10 experiments between rectangular packing and its corresponding polygon packing. These values confirm the above mentioned hypothesis that the waste contribution is greater the more the items are not similar to a rectangle. The DIFF value for MAO and DAGLI is roughly 24% while for MARQUES and ALBANO roughly 13%.

Overall we can conclude that a bounding box representation produces a lot of waste area between rectangular and polygonal packing. To make improvements some other sort of approximation might be considered such as convex hull, but the sequence pair method can only be applied on rectangles so we would not be able to implement this method.

Regarding the influence of iteration count on packing density, from Table I it can be seen that the most significant leap in packing density occurs between 10k and 50k iterations. Experiments with 50k and 100k

obtained similar results. Significant improvement in results between 100k and 500k iterations is not seen for any data set but there is significant time savings in time since the algorithm after with 100k iterations finishes 5 times faster.

Execution time for our experiments with 10k iterations varies from 20 to 30 seconds. With 50k iterations the execution time varies from 100 to 150 seconds, for 100k iterations from 200 to 300 seconds and for 500k iterations from 1000 to 1500 seconds. All results are dependent of the number of polygons in a set. In [15] and [16] the execution time of MATLAB code is compared with other programming languages. The execution of MATLAB code is from 10 (in [16]) to 500 times slower (in [15]) than the execution time of the same code in C++. This is seen as an opportunity for future performance optimization.

Overall it can be concluded that iterations count influences packing density. With the increase of iterations count the denser the packing is obtained. The best packings were obtained for 500k iterations for all data sets. These packings are shown in Fig. 4.

D. Future work

As it can be seen in Fig. 4, if items are irregular, bounding box approximation produces more waste, therefore leaving a lot of gaps between items. Applying some compaction method might be able to solve the problem. A compaction method based on non-linear programming (ILSQN) as described in [17] that solves the overlap optimization problem and controls the container size based on the success in each iteration might be used.

In [18] a group of sliding algorithms (*BLi*, *BLPi*, *BLDPi*, *BLFi*) commonly known as bottom-left which packs polygons by a series of downwards and leftwards movements is described.

In our experiments rotation of items has not been taken into account. We believe that allowing items to rotate would obtain better results even though the search space will be significantly increased.

A further adjustment of our proposed model might be implemented in terms of making the width of a container a fixed value as defined by the strip-packing problem.

V. CONCLUSION

In this paper an approach that uses sequence pair abstract representation is used to solve strip packing problem. Irregular polygons are approximated using rectangular bounding box and simulated annealing is then used to obtain a rectangle packing from a sequence pair. A polygon packing reconstruction is obtained by removing bounding box approximations.

Proposed methodology is test on 4 benchmark datasets from textile industry and the following best packing densities (in brackets) have been obtained: ALBANO (82.02%), DAGLI (69.86%), MAO (71.26%) and MARQUES (83.54%). The improvements to obtain a tighter packing can be implemented such as bottom-left heuristic and compaction strategies.

teo.manojlovic@gmail.com

Abstract - Stock market prediction is considered to be a challenging task for both investors and researchers, due to its profitability and intricate complexity. Highly accurate stock market predictive models are very often the basis for the construction of algorithms used in automated trading. In this paper, 5-days-ahead and 10-days-ahead predictive models are built using the random forests algorithm. The models are built on the historical data of the CROBEX index and on a few companies listed at the Zagreb Stock Exchange from various sectors. Several technical indicators, popular in quantitative analysis of stock markets, are selected as model inputs. The proposed method is empirically evaluated using stratified 10-fold cross-validation, achieving an average classification accuracy of 76.5% for 5-days-ahead models and 80.8% for 10-days-ahead models.

I. INTRODUCTION

Consider the following scenario. You are currently in possession of a substantial amount of money. Additionally, you do not completely approve the behavior of the late W.C. Fields, actor and writer, who has claimed to have spent half of his money on gambling, alcohol and wild women, and the other half he has wasted. Quite the opposite - you would like to save some of that money (the wasted bit, at least). What would be the best choice of investment for the future? You cannot just keep it in a drawer, because the inflation will reduce its actual value. One of the investment possibilities is buying specific stocks, bonds, or mutual funds from certain markets. But, how to be (almost) certain, that this investment will pay off? How to choose markets and exact paper assets, and put up an exact portfolio investment plan for the near(-er) future?

These questions are the reason why the analysis of stock market price movement has been in the focus of both investors and researchers for quite some time. Predicting stock price movement is considered to be a rather challenging task, according to the efficient-market hypothesis [1], which states that one cannot consistently achieve returns in excess of average market returns, given the information at the time the investment is made. To beat the average, in the absence of expert knowledge, we resort to using machine learning for predicting stock price movements. We are, of course, interested in the technical analysis of the markets, i.e. using historical market data to create actionable intelligence, which could be used to make a portfolio investment plan.

There are two common ways of predicting stock market behavior. The first one is based on the prediction of future *price values* of a stock. This approach usually requires treating the historical data as time series data, feeding the distinct time frame signals to an algorithm and trying to model the future time points in the signal, e.g. using ARIMA models. The second is based on predicting the future *price direction* of a stock, i.e. guessing whether the price will rise or fall the next day, or in a couple of days (trend forecasting). There are considerably less studies dealing with the prediction of future price direction of a stock [2].

Previous research showed promising results on the possibility of correctly predicting the price direction of a stock or market index. We mention some of that work here. Kim [3] was the first to apply support-vector machine (SVMs) to predict the next day stock price direction of Korea composite stock price index (KOSPI), using twelve technical indicators. Kara et al. [4] applied SVMs and artificial neural networks (ANNs) for building the model used to predict future movement on the Istanbul Stock Exchange (ISE) National 100 index. Hajek [2] proposed a 5-day-ahead prediction model of NASDAQ Composite Index using prototype generation classifiers. Masoud [5] applied artificial neural networks (ANNs) for building the model used to predict future direction of the Libyan Stock Exchange.

Further improvements in stock direction prediction research were made more recently, using hybrid machine learning models, selecting fundamental indicators [6] (price/earnings ratio, return on equity, etc.) and by discretising technical indicators. Choudhry and Garg [7] proposed a hybrid genetic-algorithm SVM-model for predicting the direction of stock price movement in the Indian stock market. Chandwani and Singh Saluja [8] used a combination of both fundamental and technical indicators and applied genetic-algorithm SVM- and ANN-hybrid models to predict the direction of 25 companies listed on the Bombay Stock Exchange. Patel et al. [9] discretised technical indicators by representing them as trend deterministic data and then trained predictive models using random forests, ANNs, naïve Bayes and SVM models on CNX Nifty, S&P BSE Sense indices and

The work presented in this paper is partially supported by the University of Rijeka research grant 13.09.2.2.16.

Reliance Industries and Infosys Ltd companies on the National Stock Exchange of India.

Concerning the prediction of future behavior of the Croatian stock market, most of the reported work involved is based on forecasting the future value of the stock prices and indices [10,11]. We are unaware of any studies dealing with the prediction of their future direction. In this paper we propose using a random forests model for predicting the trend direction of stocks and index values. We demonstrate its efficiency on the CROBEX index and on several companies listed at the Zagreb Stock Exchange (ZSE) from various sectors, namely HT-R-A, KRAS-R-A and PBZ-R-A. Predictive models were built and evaluated using stratified 10-fold cross-validation.

Structure of this paper is as follows. In the following section we describe the historical data and input parameters used for building the proposed models. In section 3 we give details on the machine learning model used. In section 4 we present the results of empirical evaluation. Finally, in section 5 we give a conclusion and present several ideas for future work.

II. RESEARCH DATA

Data used in this paper was gathered following the CROBEX index and a few companies listed at the Zagreb Stock Exchange from different sectors, namely HT-R-A (telecommunications), KRAS-R-A (confectioner) and PBZ-R-A (finance). They consist of several calculated technical indicators and 5-days-ahead / 10-days-ahead direction for each respective company or the index. Selected datasets cover the period from January 2008 to December 2013. Each time point in the selected datasets consists of the following features, used to calculate the technical indicators: open, close, high and low price. Their movement is shown in Figure 1.

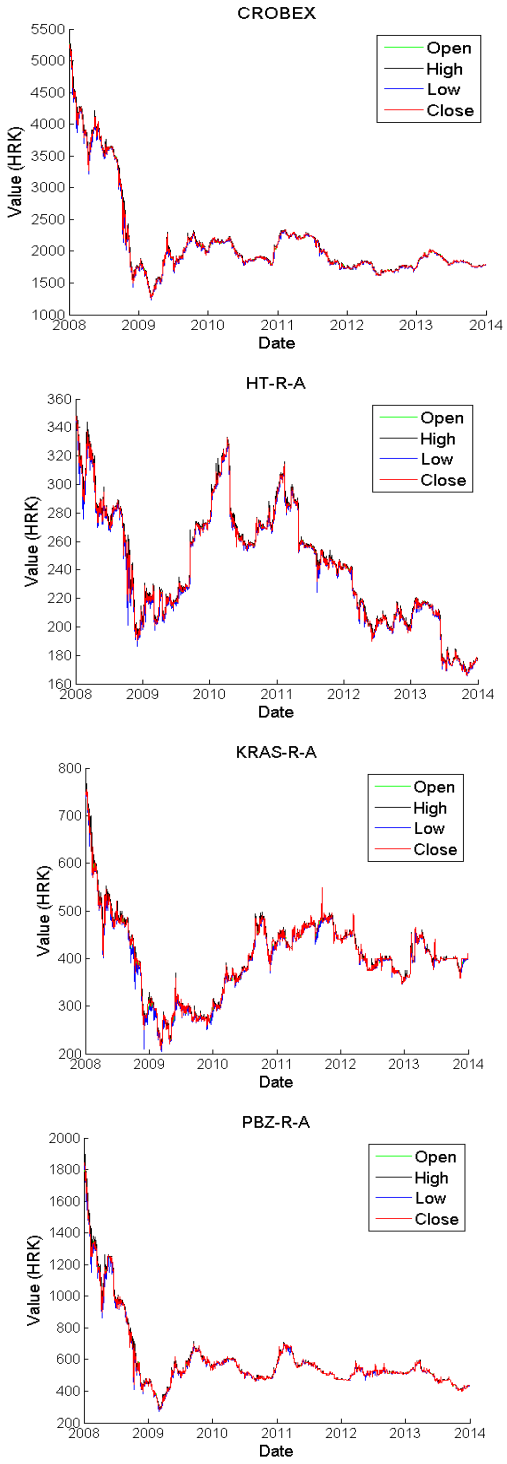

Figure 1. Price movement (open, high, low and close) of the CROBEX index and of the selected stocks: HT-R-A, KRAS-R-A and PBZ-R-A.
Can you spell "recession"?

Twelve different technical indicators were selected for model input, based on prior research [2,3,4,5]. Formulas for calculating the selected indicators are described in Table I. Some technical indicators used in [2,3,4,5] (such as Williams R%) are not used in our model because they show similar properties with respect to class as already used indicators. First two indicators are moving averages. They are used to smooth the stock price signal, making it easier for an investor to identify trends. Next two indicators are stochastic oscillators (*%K* and *%D*). Stochastic *%K* is used to compare the closing price at time *t*, relative to high-low range, over a period of *n* days, and stochastic *%D* is a simple moving average of *%K*, over a period of *n* days. Value of stochastic oscillators is varying from 0 to 100. If their value is higher than 80, it is generally believed that this means that the stock price is overbought. On the other hand, if their value is lower than 20, this means that the stock is oversold. Another indicator, *MACD*, is calculated by subtracting the slow exponential moving average from the fast exponential moving average, and it is commonly used in combination with the technical indicators mentioned above to suggest buying or selling of specific stocks. *CCI* is another indicator, used to detect whether the selected stock is overbought or oversold. It is calculated by subtracting the *n*-days simple moving average from the typical price, and then dividing it by the mean absolute deviation of the typical price. If the *CCI* value is greater than 100, then the stock is considered to be overbought. Otherwise, if the *CCI* value is lower than -100, selected stock is considered to be oversold. *RSI* is yet another indicator, used to detect whether a stock is overbought or oversold.

TABLE I. TECHNICAL INDICATORS USED AS MODEL INPUTS

Names	***Formulas***	***Parameters***
5-days and 10-days moving average ($SMA(5)_t$, $SMA(10)_t$)	$\frac{C_t + C_{t-1} + \cdots + C_{t-n+1}}{n}$	$n = 5$, $n = 10$
5-days and 10-days weighted moving average ($WMA(5)_t$, $WMA(10)_t$)	$\frac{(n)C_t + (n-1)C_{t-1} + \cdots + C_{t-n+1}}{(n + (n-1) + \cdots 1)}$	$n = 5$, $n = 10$
Stochastic %K ($\%K$)	$\frac{C_t - LL_n}{HH_n - LL_n}100$	$n = 14$
Stochastic %D (%D)	$\frac{\sum_{i=0}^{n-1}(\%K_{t-i})}{n}$	$n = 3$
Moving Average Convergence Divergence ($MACD$)	$EMA(fast)_t - EMA(slow)_t$	$fast = 12$, $slow = 26$
Commodity channel index (CCI)	$\frac{M_t - SM_t}{(0.015D_t)}$	$n = 20$ (see description below)
5-days and 10-days disparity	$\frac{C_t}{SMA(n)_t}100$	n=5, n=10
Price oscillator ($OSCP$)	$\frac{SMA(fast)_t - SMA(slow)_t}{SMA(fast)_t}100$	$fast = 5$, $slow = 10$
10-days Rate of change (ROC)	$\frac{C_t}{C_{t-n}}100$	$n = 10$
10-days momentum	$C_t - C_n$	$n = 10$
Relative strength index (RSI)	$100 - \frac{100}{1 + (\frac{\sum_{i=0}^{n-1} Up_{t-i}}{n})/(\frac{\sum_{i=0}^{n-1} Dw_{t-i}}{n})}$	$n = 14$
5-days standard deviation	$\sqrt{\frac{\sum_{i=0}^{n-1}(C_{t-i} - SMA(n)_t)^2}{n}}$	$n = 5$

The original time series inputs description: C_t denotes the closing price at day t, H_t denotes the high price at day t, L_t denotes the low price at day t, HH_n denotes the highest high price in n days, and LL_n denotes the lowest low price in n days. Calculated terms: $EMA(n)$ is the exponential moving average, $EMA(n)_t = EMA(n)_{t-1} + \alpha(C_t - EMA(n)_{t-1})$, α is a smoothing factor $\frac{2}{n+1}$, n is the number of data points used to calculate the exponential moving average, M_t is a typical price, $M_t = \frac{C_t + H_t + L_t}{3}$, SM_t is a simple moving average of typical prices for n days, D_t is a mean absolute deviation of typical prices for n days, and Up_t is the upward and Dw_t the downward price change at day t.

Its value ranges from 0 to 100. If the *RSI* value is above 70, this indicates that the stock is overbought, and if the *RSI* value is below 30, this indicates that the stock is oversold. *Disparity* and *ROC* are similar indicators. *Disparity* is the ratio of closing price at time *t* and the *n*-days simple moving average, and *ROC* is the ratio of the closing price at time *t* and the closing price at time *t-n*. If the values of these two indicators are both above 0, this is a signal for an investor to buy the selected stock. On the other hand, if the values of these two indicators are below 0, this is a signal for an investor to sell the selected stock. *Price oscillator* is a technical indicator that displays the difference between the fast and the slow moving average, divided by the fast moving average. It generates the buy signal if the value of the fast moving average rises above the slow moving average, and generates the sell signal otherwise. *Momentum* is calculated as a difference between the stock price at time *t* and the stock price at time *t-n*. Negative momentum is often used by investors to generate the buy signal, and positive momentum to generate the sell signal. Last indicator used is *standard deviation*. It is used to measure volatility in a period of *n* days. Technical indicators, used in this paper, were calculated using MATLAB and R.

5-days-ahead direction of selected stocks and the index used is labeled "1", if the closing price at time *t*+5 is greater than the closing price at time *t*. 10-days-ahead direction of selected stocks is labeled "1", if the closing price at time *t*+10 is greater than the closing price at time *t*. Otherwise, the directions are labeled "0". The ratio of 5-days-ahead directions is shown in Table II and the ratio of 10-days-ahead directions is shown in Table III.

III. MODELS AND METHODS

Predictive model used in this paper is based on the random forests algorithm, firstly introduced by Breiman [12]. Random forests algorithm belongs to ensemble learning methods. The main idea behind ensemble learning methods is that a single classifier is sometimes not sufficient for correct classification of test data and that multiple classifiers can increase model correctness.

The principle of random forests is simple. First, a set of *k* bootstrap samples *D* is created. Bootstrap samples are samples of same size that are created using sampling with replacement. This means that every sample can be used again, even if it was already used. Then for every bootstrap sample, a decision tree is built using *n* randomly chosen features. The most common algorithms for building decision trees are ID3 [13], C4.5 [14] and CART [15]. When inferring its class, every new instance is classified by *k* trees and the prediction that gains the

TABLE II. PERCENTAGE OF 5-DAYS-AHEAD INCREASE/DECREASE

Symbol	***Increase***	***Decrease***
CROBEX	45.5%	54.5%
HT-R-A	45.6%	54.4%
PBZ-R-A	43.1%	56.9%
KRAS-R-A	44.8%	55.2%

TABLE III. PERCENTAGE OF 10-DAYS-AHEAD INCREASE/DECREASE

Symbol	***Increase***	***Decrease***
CROBEX	45.6%	54.4%
HT-R-A	45.8%	54.2%
PBZ-R-A	43.2%	56.8%
KRAS-R-A	45.7%	54.3%

majority of votes is selected as the class label.

There are several advantages of random forests. For one, they are easily parallelised, which means they can be used for large scale machine learning. Their performance is comparable to other ensemble learning algorithms, such as Adaboost and often it performs even better. Random forests are also faster than boosting and bagging. Finally, they perform well on noisy data containing outliers.

In this paper, we used the random forests algorithm, implemented in the WEKA (Waikato Environment for Knowledge Analysis) toolkit [16], for performing the classification task. WEKA uses a combination of simple random trees as simple classifiers, which are then used for voting to obtain class label. WEKA uses a combination of a bagging algorithm and random trees for the random forests algorithm. Bagging algorithm is used to perform bootstrapping and random tree algorithm is used to train decision trees with randomly chosen features.

For building the predictive models used in this study, we tested multiple parameters for WEKA random forests. Best results were obtained by setting the maximum depth of trees to unlimited, setting the number of features used in random selection to 5 and setting the number of trees to 100. Model used in this paper is illustrated in Figure 2.

IV. EMPIRICAL EVALUATION

For evaluation of the used predictive models, classification accuracy and F-measure were used. Classification accuracy is calculated by dividing the number of correctly classified instances with the overall number of instances. In other terms, formula for calculating the classification accuracy is given by

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN}, \quad (1)$$

where TP stands for the number of true positives, TN stands for the number of true negatives. True positives are positive instances classified as positive and true negatives are negative instances classified as negative. FP stands for the number of false positives and FN stands for the number of false negatives. False positives are negative instances classified as positive and false negatives are positive instances classified as negative.

For calculating the F-measure, it is necessary to calculate precision and recall:

$$Precision_{positive} = \frac{TP}{TP+FP}, \quad (2)$$

$$Recall_{positive} = \frac{TP}{TP+FN}, \quad (3)$$

$$Precision_{negative} = \frac{TN}{TN+FN}, \quad (4)$$

$$Recall_{negative} = \frac{TN}{TN+FP}. \quad (5)$$

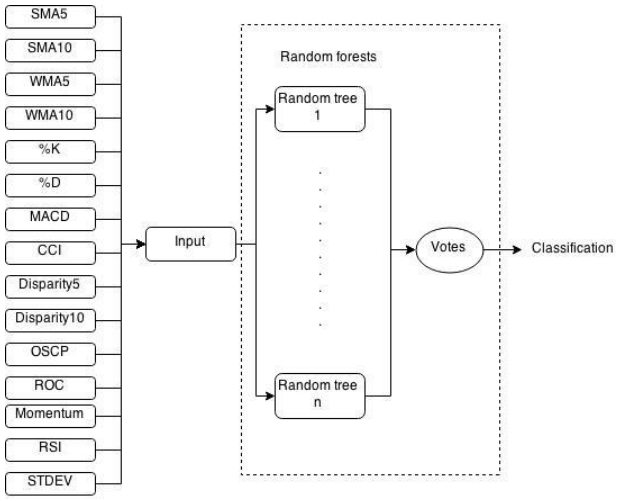

Figure 2. Visual representation of the model used in this paper

F-measure, also named the F-score, is defined as the harmonic mean of precision and recall:

$$F_{positive} = 2\frac{precision_{positive} * recall_{positive}}{precision_{positive}+recall_{positive}}, \quad (6)$$

$$F_{negative} = 2\frac{precision_{negative} * recall_{negative}}{precision_{negative}+recall_{negative}}. \quad (7)$$

Given the negative and positive F-measure, we can now calculate the weighted average F-measure.

Proposed models were evaluated using stratified 10-fold cross-validation. In stratified 10-fold cross-validation, data is divided into 10 randomly partitioned subsamples of approximately equal class distributions. Nine out of ten subsamples are then used to train the model and the remaining subsample is used for validation. This procedure is repeated 10 times, every time using a different partition for validation. The result is then calculated as the average of results obtained for every model. Results of 5-days-ahead direction predictions are shown in Table IV and the results of 10-

TABLE IV. PERFORMANCE OF 5-DAYS-AHEAD MODELS

Symbol	*Accuracy*	$F_{positive}$	$F_{negative}$	*Weighted average F-score*
CROBEX	0.767	0.726	0.797	0.765
HT-R-A	0.772	0.739	0.798	0.771
PBZ-R-A	0.761	0.711	0.797	0.76
KRAS-R-A	0.76	0.721	0.789	0.759

TABLE V. PERFORMANCE OF 10-DAYS-AHEAD MODELS

Symbol	*Accuracy*	$F_{positive}$	$F_{negative}$	*Weighted average F-score*
CROBEX	0.816	0.79	0.836	0.815
HT-R-A	0.825	0.804	0.842	0.825
PBZ-R-A	0.81	0.767	0.84	0.808
KRAS-R-A	0.787	0.758	0.81	0.787

days-ahead predictions are shown in Table V.

Experimental results suggest that random forests achieve significant performance accuracy in stock market trend prediction. Average accuracy of 5-days-ahead models is 0.765 (76.5%) and weighted average F-measure is 0.763. Average accuracy of 10-days-ahead models is 0.808 (80.8%) and weighted average F-measure is 0.808. If we compare our models with those of Hajek [2], who has trained models for predicting 5-days-ahead direction of NASDAQ Composite Index, we can see that our models perform somewhat better than most of the alternative models. Inspecting the calculated results, we can safely assume that the proposed predictive models can be successfully applied for portfolio management on the ZSE market.

V. CONCLUSION AND FUTURE WORK

In this paper, we used the random forests algorithm to build a model used to predict 5-days-ahead and 10-days-ahead directions of the CROBEX index and selected stocks. Our results show that random forests can be successfully utilised for building predictive models for predicting the direction of stock market trends.

From the cited papers, mentioned in introduction, it can be seen that empirical prediction results vary greatly. For example, if we compare different attempts of building 1-day-ahead models using SVMs, on one side, we have Kim [3] with very bad average accuracy (less than 60%) and, on the other side, we have Kara et al. [4], with much higher average accuracy (71.52%). We too have tried to build 1-day-ahead models on CROBEX and selected stocks using SVMs, ANNs and random forests, but only managed to achieve accuracy similar to that reported by Kim [3]. This could be explained with the inherent market volatility and with the fact that the influence of some technical indicators can be seen only a couple of days in the future.

There are several research directions that should be pursued in the future. One of them involves additionally improving the predictive accuracy of the model. We believe that this can be done in two ways. First, other technical indicators, not mentioned in [2,3,4,5], should be explored, especially the indicators that include volume. Next, hybrid models could be used to further improve the model accuracy. Regardless, we plan to continue our work on constructing an algorithm for automated trading, based on our predictive model, and use it for portfolio management.

Abstract - The purpose of this study is to present novel GA-ANFIS expert system prototype for tar detection in cigarettes during manufacturing process. The proposed system combines capabilities of Adaptive Neuro-Fuzzy Inference System (ANFIS) and Genetic Algorithm (GA).The data recorded for different type of cigarettes are collected by special control quality equipment in real conditions inside cigarette factory. GA-ANFIS system performs optimization in two steps. In the first step it generates six different ANFIS structures, and after that, we have second level of GA optimization using given ANFIS structures resulting in optimal fuzzy model structure. Modeling and validation of the GA-ANFIS system approach is performed in MATLAB environment using validation data set that were not used in the process of training. Our earlier research results based on two different approaches (ANFIS and High-performance liquid chromatography (HPLC)) are also introduced. Performances of these three approaches are compared and novel expert system prototype shows better result related to training, testing and validation errors. It also more precisely shows that low yield tar cigarettes contain similar levels of nicotine opposite to high yield tar cigarettes while benzene, toluene, and xylene (BTX) levels rise along with increasing tar yields.

I. INTRODUCTION

Three main tobacco smoke components harmful to health are nicotine, carbon monoxide and tar. Tar is the term used to describe the toxic chemical residue left behind from burning cigarettes. In 2010, a law that bans tobacco manufacturers from using the terms “light,” “low,” or “mild” in tobacco product labeling, went into effect. Tar is present in all cigarettes and tends to increase as the cigarette is burnt down, which can mean that the last puffs on a cigarette may contain as much as twice the amount of tar as the first puffs. The exact composition of the tar that smokers inhale is uncertain. Produced cigarette is not consumed in the state it is presented, but in the form of smoke which is the basic product being formed in a complex combusting process. When lighting a cigarette, at the end of smoke pillar is formed combusting zone. The material within cigarette is exposed to high temperatures, with a presence of certain amount of oxigen, so it does not burn completely. Two burning processes take place while the cigarette is "burning" [11]. One process takes place when inhaling smoke (Main Stream), while the second one appears in the intervals between two smoke inhaling - so called smolder (Side Stream). Combusting starts with the presence of oxigene, while reactions are reflected in creating certain gasses. Chemical characteristics are now measured on "smoker's machine" that operates under standardize conditions. When the smoke is "cought' according to ISO method, components being fully deposeted on the filter are marked as a total smoke condensate. By removing water and nicotine from the total smoke condensate we get a substance that is marked as TAR. When analyzed by special High Performance Liquid Chromatography (HPLC), the smoke from a so-called light cigarette has a lower yield of tar than the smoke from a regular cigarette. However, a machine cannot predict how much tar a smoker inhales and need 12 hours to determine tar content in any cigarette. Cigarette quality process has a lot controllable variables and we use in our study four: porous cigarette paper diameter, ventilating filters, nicotine and CO.

There have been suggested many approaches to nonlinear system control. However, the problem gets more complex when uncertainties are considered.

In research paper [1], authors used ANFIS in their recent works, to train the mathematical models and provide short-term load forecast. At the same time, GA was responsible to analyze database and possible correlations with consumption. Some authors suggested combination of Adaptive Neuro Fuzzy System, Genetic Algorithm and Singular Value decomposition [9]. The incorporation of genetic algorithm into ANFIS model design starts by presenting the real value parameters as antecedent part of fuzzy system. Authors in research study [12] suggested hybrid GA-ANFIS model in which GA optimizes structure and the number of fuzzy IF-THEN rules by finding best value of sub-clustering method. On the other hand, ANFIS is used to optimize initial FIS based on the clustering parameter generated by GA.

A novel GA-ANFIS expert system prototype for tar prediction in cigarettes is presented in our study. The purpose of this study is to reach smaller prediction errors (in regard to ANFIS model) by developing new GA-ANFIS expert system. Our novel GA-ANFIS system approach is trained with a subset of different parameters of cigarette data. The effectiveness of the GA-ANFIS

system approach is tested and verified by the use of validation data. Modeling and validation of the novel GA-ANFIS system approach is performed in MATLAB environment. The results are compared with ANFIS and HPLC [7], and they show the effectiveness of the proposed approach.

GA-ANFIS system performs optimization in two steps. In the first step it generates six different ANFIS structures, and after that, we have second level of GA optimization using given ANFIS structures resulting in optimal fuzzy model structure. The time spent in searching for the correct configuration by GA-ANFIS and also the amount of training samples utilized to train the ANFIS are optimal and less than time spent in ANFIS..

The paper is set up as follows; in section one, we have described the process of different cigarette components and described process of tar detection. In section two, we have explained the methods used in our research along with the description of Adaptive Neuro Fuzzy Inference architecture (structure of each layer) and Genetic algorithm covered in this work. Section three is about novel GA-ANFIS system approach where we have described GA-ANFIS system design architecture. We have explained the steps taken in using GA-ANFIS Matlab user interface that contains several subsystems. Section five gives the numerical results about training, testing and validation error compared with ANFIS and HPLC results. Discussion is summarized in section five. Finally, the conclusion is summarized in section six.

II. MATERIALS AND METHODS

A. Data preparation

A different kind of laboratory test stations for cigarette parameters measuring are used in different phases of cigarette production. Chemical characteristics are measured on "smoker's machine" that operates under standardize conditions. When the smoke is "cought' according to ISO method, components being fully deposeted on the filter are marked as a total smoke condensate. By removing water and nicotine from the total smoke condensate we get a substance that is marked as TAR. Each data sample consists of five values: the diameter of a cigarette, filter ventilation, nicotine and CO.

The total number in the base was 1020 data samples. The group is divided in two parts. In the developing phase, we used 950 data that were used for training, testing and checking. 70 separated data did not participate in the training and testing, but were applied on the finished model in the application phase. We used as an output parameter tar results collected from about 1020 cigarette samples that Quality control measured during the last two years by HPLC.

B. Anfis

Adaptive Neural-Fuzzy Inference System (ANFIS) was proposed by Roger Jang in 1992 [4][5]. We used ANFIS architecture with four - input - one output and sixteen rules (Fig.1).

ANFIS has five layers within which node functions of the same layer have the same function type as described below.

Layer 1: Every node i in this layer is an adaptive node with node function refer to equation in the text as (1) - (4):

$$O_{1,i}=\mu_{Ai}(D),\ i=1,2 \quad (1)$$

$$O_{1,i}=\mu_{Bi-2}(FV),\ i=3,4 \quad (2)$$

$$O_{1,i}=\mu_{Ci-4}(N),\ i=5,6 \quad (3)$$

$$O_{1,i}=\mu_{Ci-6}(C),\ i=7,8 \quad (4)$$

where D (diameter), FV (filter ventilation), N (nicotine), C (carbon monoxide) are premise parameters and A_i, B_i, C_i, D_i, $i=1,2$ are the linguistic label associated with node function.

Layer 2: Every node i in this layer is a fixed node labeled Π, whose output is the product of all the incoming signals refer to equation in the text as (5).

$$O_{2,i}=\omega_i=\mu_{Ai}(D)\times\mu_{Bi}(FV)\times\mu_{Ci}(N)\times\mu_{Di}(C),\ i=1,..16 \quad (5)$$

Layer 3: Every node i in this layer is a fixed node labeled N. The i-th node calculates the ratio of the i-th rule's firing strength to the sum of all rules' strengths refer to equation in the text as (6).

$$O_{3,i}=\omega_i=\omega_i/(\omega_1+\omega_2+...+\omega_{15}+\omega_{16}),\ i=1,..16 \quad (6)$$

Layer 4: Every node i in this layer is adaptive node with node function refer to equation in the text as (7),

$$O_{4,i}=\omega_i(p_i(D)\times q_i(FV)\times r_i(N)\times s_i(C)+z_1,\ i=1,..16 \quad (7)$$

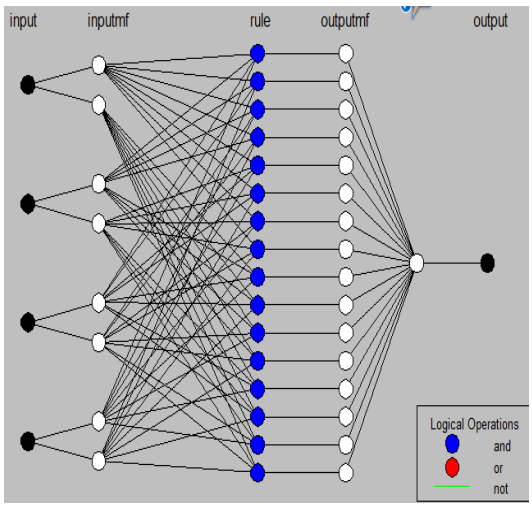

Figure 1. ANFIS architecture utilized in this work.

where { *pi qi ri si zi*}are consequent parameters [3,4], updated through Recursive Least-Squares Estimation.

Layer 5: The single node in this layer is a fixed node labeled Σ, which computes the overall output as the summation of all the incoming signals refer to equation in the text as (8) (*i=1,..16*).

$$O_{5,i}=\sum_i \omega_i f_i=(\omega_1 f_1+\ldots+\omega_{16} f_{16})/(\omega_1+\ldots+\omega_{16}), \quad (8)$$

C. Genetic Algorithm

Genetic algorithm (GA) is an optimization algorithm that incorporates the process of evolution. GA uses a population of chromosomes, each representing a solution to the problem that has been solved. It is assumed that a potential solution to a problem may be represented by set of parameters [10].

After initialization, the population is evaluated and stopping criteria is checked. If none of the stopping criteria is met, new population is generated again and the process is repeated until one or more of the stopping criteria are met. Crossover is a genetic operator that combines two chromosomes to produce a new chromosome.

The idea behind crossover is that the new chromosome may be better than the chromosomes of both parents, if it takes the best characteristics from each of the parents. Crossover occurs during evolution, according to a user-definable crossover probability.

We used different types of crossover: one point, two point, heuristic and arithmetic. We use Gaussian mutation to increase the performance of genetic algorithm.

Fig. 2 shows the genetic algorithm implemented in the experiment.

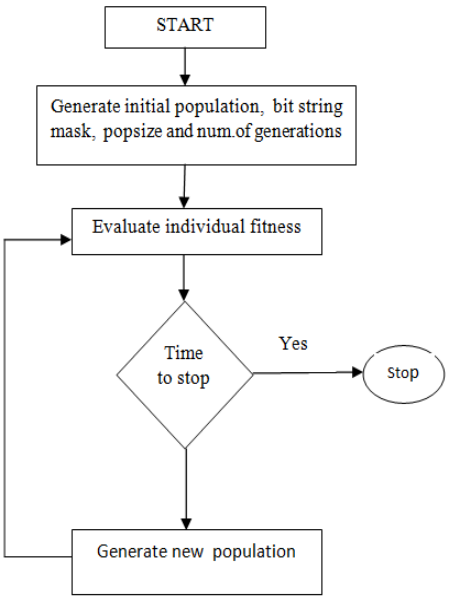

Figure 2. GA flowchart

III. GA -ANFIS SYSTEM DESIGN AND MATLAB IMPLEMENTATION

The GA-ANFIS system application was developed in MATLAB. The size of chromosome structure- fuzzy structure was generated by ANFIS computational complexity (Table I)[8].

For NumIn=4 (input variables) and NumMf=2 (number of membership functions) we have concrete chromosome structure (Fig. 3). The process flow chart is shown in Fig. 4.

TABLE I. ANFIS COMPUTATIONAL COMPLEXITY

Layer type	Nodes	Parameters
$O_{0,i}$ Inputs	NumIn	0
$O_{1,i}$ Values	(NumMf*NumIn)	3*(NumMf*NumIn)
$O_{2,i}$ Rules	$NumMf^{\wedge NumIn}$	0
$O_{3,i}$ Normaliz.	$NumMf^{\wedge NumIn}$	0
$O_{4,i}$ Lin.func..	$NumMf^{\wedge NumIn}$	$(NumIn+1)*NumMf^{\wedge NumIn}$
$O_{5,i}$ Sum	0	1

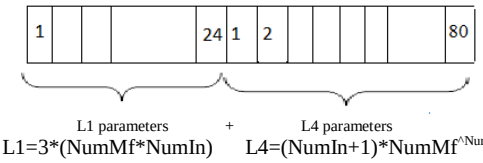

Figure 3. Ga - Anfis Chromosome structure

First part of the system is data base initialization where four different cigarette parameters data sets are created (no.1 in Fig.5). We used one set data for training and another for testing. Half of testing data are used for checking. Validation set of data is used for prediction.

Second step (no.2 in Fig. 5) is ANFIS modeling where we made initialization parameters for ANFIS network. Different fuzzy structures are generated by choosing one of the following partitioning techniques: Sub-Clustering and Grid Partitioning, in combination with two optimization methods (hybrid and back propagation).

Third part (no.3 in Fig. 5) of the system is GA-ANFIS modeling where we defined GA parameterization: defined population size, number of generation, fitness limit and type of crossover operation.

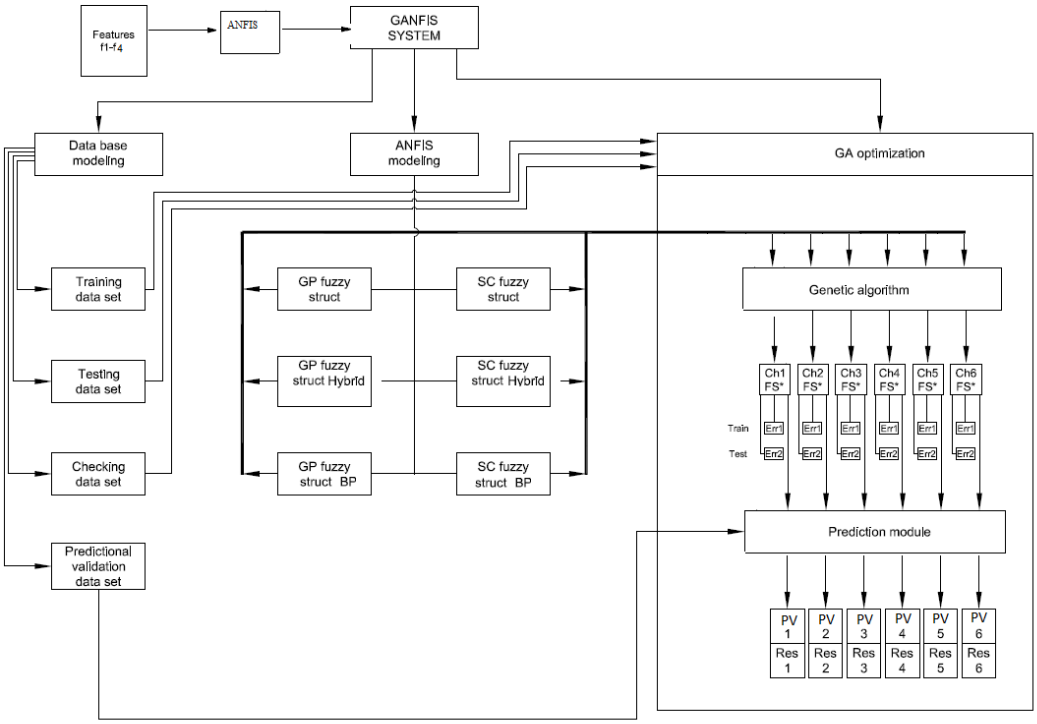

Figure 4. Process flow chart GA-ANFIS system algorithm; GP-Grid Partitioning, SC-Subtr.Clust CH-Chromosome, FS- Fuzzy structure, PV-Predicted

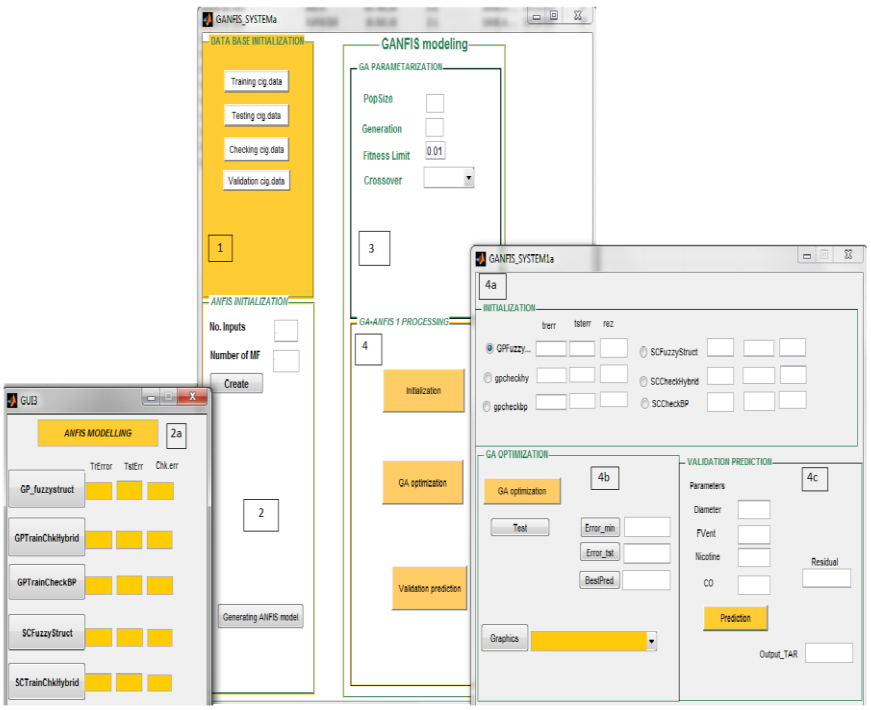

Figure 5. GA- ANFIS System GUI

Fourth part of the system (no.4 in Fig. 5) is GA-ANFIS processing where we initialized fuzzy structures (4a) and optimized them by genetic algorithm (4b). Different chromosome-fuzzy structures are created on GA-ANFIS system output, and used for testing and obtaining training and testing errors.

Validation of the novel GA-ANFIS system approach is performed in MATLAB environment by using validation data set (4c).

IV. TESTING AND RESULTS

In data base processing, we have divided sample data in four groups: 1020 different kind of cigarette samples is used for training, testing and checking (from 2013 till now) and one independent set of data (70 individuals) is used for model validation. In each experiment were 20 individuals for the GA initial random populations, 200 generation for the GA and fitness limit 0.01. When process training is completed, real prediction of the system takes place. As you can see the prediction is very accurate in most of the cases (Fig.6). RMSE error is shown in Fig. 7.

The results of the collected data give the best residual of prediction 0.02. Table II-IV shows the results of the test success of GA-ANFIS versus ANFIS and High Performance Liquid Chromatography (HPLC) for different optimization method used in ANFIS.

ANFIS	0.36	1.50	0.61	0.38

V. DISCUSSION

The comparison results show that our novel approach has better performances than approach based on single ANFIS model in our previous study [1]. It is an approach based on cascade optimization. Physical cigarette parameters have great impact on the TAR content in the cigarette smoke. As the amount of tobacco in cigarette increases, so the TAR production slightly rises. By decreasing TAR amount, concentration of harmful substances is also decreased, because of which is tar subject of legal restrictions and standards. The amount of nicotine and tar is linked with ventilation of filter and cigarette paper, so it could be even two or three times smaller in ventilated cigarettes. Analysing various cigarrete samples, we determined that nicotine in the main smoke stream (inhalation) did not much differ from the nicotine in the mixture, which confirms the fact that the tar depends more on technological parameters and cigarette construction than on the amount of nicotine.

On the other hand, the results we have achieved by this novel approach are more useful for the Quality control during the manufacturing process, because they can get information about tar during processing.

With these results, one can make some changes on physical parameters being used as input variables for ventilation control inside range, in order to increase the reduction of smoking components level, primarily tar.

The training of the Root Mean Squared Error via GA-ANFIS is 0.57; the checking of RMSE is 0.02. Prediction results of the amount of tar in manufacturing process require a

number of additional chemical analyses. The results of nicotine and tar measured via HPLC are detectable with 1,07 % error. GA-ANFIS access enables faster prediction of tar amount with a permitted deviation which is less than 0.02%.

VI. CONCLUSION AND FUTURE WORK

In this paper we built a novel GA-ANFIS system approach using ANFIS modeling and Genetic optimization technique for tar detection. The experiments have demonstrated that this novel algorithm is suitable for the training, testing and prediction for tar detection in different types of cigarette data acquired from different types of machines.

The study shows that tar reduction in light and non-light cigarettes remains identical by increasing values of one of the inputs (cigarette filter ventilation). We also concluded, by analysing impacts and other input variables being trained and tested through our model, that low yield cigarettes contain similar levels of nicotine as compared to high yield cigarettes while BTX levels increase with increasing tar yields.

The following can be inferred from the experiments:

- The basic cigarettes features are used as inputs to classifiers based on Adaptive Neuro - Fuzzy Inference Systems (ANFIS) for first level of fuzzy model optimization.
- GA performs optimization in two steps: in the first step it generates six different ANFIS structures. Each of these ANFIS structures combines one of partitioning techniques: Sub-Clustering and Grid Partition, one of two optimization methods: hybrid and back propagation, and training or checking data set, which is six combinations in total. The results from ANFIS models are inputs to the second level of the optimization that outputs and optimized fuzzy model structure.
- Optimized fuzzy structure, which is a result of the novel GA-ANFIS system approach, is validated in MATLAB environment by using validation data set. Training, testing and model validation errors are collected during fuzzy model structure creation.
- Three functions are created to give answer for best result - least training, testing and validation error.

In this study, we tried to predict tar concentration in different type of cigarettes. We did not have any information about tobacco or other additive components in cigarette rod. We compared our GA-ANFIS system with ANFIS and HPLC.

In our approach we use two-stage cascade optimization, where six types of ANFIS were parallel processed. Originality is in the approach that uses global optimization of the genetic algorithm, so to find ANFIS structure whose parameters give the best preciseness, from the aspect of model accuracy.

If it had worked without GA, finding of ANFIS optimal structure would have taken very long time, and we would not have objective results (because we did not do through research, as GA did).

The next phase of our research will be focused on fusion GA-ANFIS model with chromosome configuration composed of three parts: six ANFIS parameters, L1 parameters as in presented approach, and L4 parameters as in presented approach.

ACNOWLEDGMENTS

The support of "Tobacco Factory Sarajevo" company in data collection is acknowledged. Any opinions, findings, and conclusions or recommendations expressed in this paper are those of the authors and do not necessarily reflect the views of the company mentioned above.

Abstract - Feature selection (FS) methods can be used in data pre-processing to achieve efficient data reduction. This is useful for finding accurate data models. Since exhaustive search for optimal feature subset is infeasible in most cases, many search strategies have been proposed in literature. The usual applications of FS are in classification, clustering, and regression tasks. This review considers most of the commonly used FS techniques. Particular emphasis is on the application aspects. In addition to standard filter, wrapper, and embedded methods, we also provide insight into FS for recent hybrid approaches and other advanced topics.

I. INTRODUCTION

The abundance of data in contemporary datasets demands development of clever algorithms for discovering important information. Data models are constructed depending on the data mining tasks, but usually in the areas of classification, regression and clustering. Often, pre-processing of the datasets takes place for two main reasons: 1) reduction of the size of the dataset in order to achieve more efficient analysis, and 2) adaptation of the dataset to best suit the selected analysis method. The former reason is more important nowadays because of the plethora of developed analysis methods that are at the researcher's disposal, while the size of an average dataset keeps growing both in respect to the number of features and samples.

Dataset size reduction can be performed in one of the two ways: feature set reduction or sample set reduction. In this paper, the focus is on feature set reduction. The problem is important, because a high number of features in a dataset, comparable to or higher than the number of samples, leads to model overfitting, which in turn leads to poor results on the validation datasets. Additionally, constructing models from datasets with many features is more computationally demanding [1]. All of this leads researchers to propose many methods for feature set reduction. The reduction is performed through the processes of feature extraction (transformation) and feature selection. Feature extraction methods such as Principal Component Analysis (PCA), Linear Discriminant Analysis (LDA) and Multidimensional Scaling work by transforming the original features into a new feature set constructed from the original one based on their combinations, with the aim of discovering more meaningful information in the new set [2]. The new feature set can then be easily reduced by taking into consideration characteristics such as dataset variance coverage. Feature selection, on the other hand, is a process of taking a small subset of features from the original feature set without transformation (thus preserving the interpretation) and validating it with respect to the analysis goal. The selection process can be achieved in a number of ways depending on the goal, the resources at hand, and the desired level of optimization.

In this paper, we focus on feature selection and provide an overview of the existing methods that are available for handling several different classes of problems. Additionally, we consider the most important application domains and review comparative studies on feature selection therein, in order to investigate which methods perform best for specific tasks. This research is motivated by the fact that there is an abundance of work in this field and insufficient systematization, particularly with respect to various application domains and novel research topics.

Feature set reduction is based on the terms of feature relevance and redundancy with respect to goal. More specifically, a feature is usually categorized as: 1) strongly relevant, 2) weakly relevant, but not redundant, 3) irrelevant, and 4) redundant [3,4]. A strongly relevant feature is always necessary for an optimal feature subset; it cannot be removed without affecting the original conditional target distribution [3]. Weakly relevant feature may not always be necessary for an optimal subset, this may depend on certain conditions. Irrelevant features are not necessary to include at all. Redundant features are those that are weakly relevant but can be completely replaced with a set of other features such that the target distribution is not disturbed (the set of other features is called Markov blanket of a feature). Redundancy is thus always inspected in multivariate case (when examining feature subset), whereas relevance is established for individual features. The aim of feature selection is to maximize relevance and minimize redundancy. It usually includes finding a feature subset consisting of only relevant features.

In order to ensure that the optimal feature subset with respect to goal concept has been found, feature selection method has to evaluate a total of $2^m - 1$ subsets, where m is the total number of features in the dataset (an empty

feature subset is excluded). This is computationally infeasible even for a moderately large *m*. Therefore, putting completeness of the search aside, many heuristic methods have been proposed to find a sufficiently good (but not necessarily optimal) subset. The whole process of finding the feature subset typically consists of four basic steps: 1) subset generation, 2) subset evaluation, 3) a stopping criterion, and 4) validation of the results [5]. Feature subset generation is dependent on the state space search strategy. After a strategy selects a candidate subset, it will be evaluated using an evaluation criterion in step 2. After repeating steps 1 and 2 for a number of times depending on the process stopping criterion, the best candidate feature subset is selected. This subset is then validated on an independent dataset or using domain knowledge, while considering the type of task at hand.

II. CLASSIFICATION OF FEATURE SELECTION METHODS

Feature selection methods can be classified in a number of ways. The most common one is the classification into filters, wrappers, embedded, and hybrid methods [6]. The abovementioned classification assumes feature independency or near-independency. Additional methods have been devised for datasets with structured features where dependencies exist and for streaming features [2].

A. *Filter methods*

Filter methods select features based on a performance measure regardless of the employed data modeling algorithm. Only after the best features are found, the modeling algorithms can use them. Filter methods can rank individual features or evaluate entire feature subsets. We can roughly classify the developed measures for feature filtering into: information, distance, consistency, similarity, and statistical measures. While there are many filter methods described in literature, a list of common methods is given in Table I, along with the appropriate references that provide details. Not all the filter features can be used for all classes of data mining tasks. Therefore, the filters are also classified depending on the task: classification, regression or clustering. Due to lack of space, we do not consider semi-supervised learning feature selection methods in this work. An interested reader is referred to [16] for more information.

Univariate feature filters evaluate (and usually rank) a single feature, while multivariate filters evaluate an entire feature subset. Feature subset generation for multivariate filters depends on the search strategy. While there are many search strategies, there are four usual starting points for feature subset generation: 1) forward selection, 2) backward elimination, 3) bidirectional selection, and 4) heuristic feature subset selection. Forward selection typically starts with an empty feature set and then considers adding one or more features to the set. Backward elimination typically starts with the whole feature set and considers removing one or more features from the set. Bidirectional search starts from both sides - from an empty set and from the whole set, simultaneously considering larger and smaller feature subsets. Heuristic selection generates a starting subset based on a heuristic (e.g. a genetic algorithm), and then explores it further.

The most common search strategies that can be used with multivariate filters can be categorized into exponential algorithms, sequential algorithms and randomized algorithms. Exponential algorithms evaluate a number of subsets that grows exponentially with the feature space size. Sequential algorithms add or remove features sequentially (one or few), which may lead to local minima. Random algorithms incorporate randomness into their search procedure, which avoids local minima [17]. Common search strategies are shown in Table II.

TABLE I. COMMON FILTER METHODS FOR FEATURE SELECTION

Name	Filter class	Applicable to task	Study
Information gain	univariate, information	classification	[6]

TABLE II. SEARCH STRATEGIES FOR FEATURE SELECTION

Algorithm group	Algorithm name
Exponential	Exhaustive search Branch-and-bound
Sequential	Greedy forward selection or backward elimination Best-first Linear forward selection Floating forward or backward selection Beam search (and beam stack search) Race search
Randomized	Random generation Simulated annealing Evolutionary computation algorithms (e.g. genetic, ant colony optimization) Scatter search

B. Wrapper methods

Wrappers consider feature subsets by the quality of the performance on a modelling algorithm, which is taken as a black box evaluator. Thus, for classification tasks, a wrapper will evaluate subsets based on the classifier performance (e.g. Naïve Bayes or SVM) [18,19], while for clustering, a wrapper will evaluate subsets based on the performance of a clustering algorithm (e.g. *K*-means) [20]. The evaluation is repeated for each subset, and the subset generation is dependent on the search strategy, in the same way as with filters. Wrappers are much slower than filters in finding sufficiently good subsets because they depend on the resource demands of the modelling algorithm. The feature subsets are also biased towards the modelling algorithm on which they were evaluated (even when using cross-validation). Therefore, for a reliable generalization error estimate, it is necessary that both an independent validation sample and another modelling algorithm are used after the final subset is found. On the other hand, it has been empirically proven that wrappers obtain subsets with better perfomance than filters because the subsets are evaluated using a real modelling algorithm. Practically any combination of search strategy and modelling algorithm can be used as a wrapper, but wrappers are only feasible for greedy search strategies and fast modelling algorithms such as Naïve Bayes [21], linear SVM [22], and Extreme Learning Machines [23].

C. Embedded and hybrid methods

Embedded methods perform feature selection during the modelling algorithm's execution. These methods are thus embedded in the algorithm either as its normal or extended functionality. Common embedded methods include various types of decision tree algorithms: CART, C4.5, random forest [24], but also other algorithms (e.g. multinomial logistic regression and its variants [25]). Some embedded methods perform feature weighting based on regularization models with objective functions that minimize fitting errors and in the mean time force the feature coefficients to be small or to be exact zero. These methods based on Lasso [26] or Elastic Net [27] usually work with linear classifiers (SVM or others) and induce penalties to features that do not contribute to the model.

Hybrid methods were proposed to combine the best properties of filters and wrappers. First, a filter method is used in order to reduce the feature space dimension space, possibly obtaining several candidate subsets [28]. Then, a wrapper is employed to find the best candidate subset. Hybrid methods usually achieve high accuracy that is characteristic to wrappers and high efficiency characteristic to filters. While practically any combination of filter and wrapper can be used for constructing the hybrid methodology, several interesting methodologies were recently proposed, such as: fuzzy random forest based feature selection [29], hybrid genetic algorithms [30], hybrid ant colony optimization [31], or mixed gravitational search algorithm [32].

D. Structured and streaming features

In some datasets, features may exhibit certain internal structures such as spatial or temporal smoothness, disjoint/overlapping groups, tree- or graph-like structures. In these datasets, features are not independent. Therefore, it is a good idea to employ specific algorithms to deal with the dependencies in order to increase performance of the selected feature subsets. Most of the algorithms dealing with feature structures are recent, and are based on some adaptation of the Lasso regularization method to accomodate different structures. Good overviews of these methods can be found in [2,33].

Streaming (or dynamic) features are features which size is unknown in advance; they are rather dynamically generated, they arrive as streamed data into the dataset and the modelling algorithms has to reach a decision whether to keep them as useful for model construction or not. Also, some features may become irrelevant over time and should be discarded. This scenario is common in social networks such as Twitter, where new words are generated that are not all relevant for a given subject [2]. The most important feature selection methods in this category are: the Grafting algorithm [34], the Alpha-Investing algorithm [35] the OSFS algorithm [36], and dynamic feature selection fuzzy-rough set approach [37].

III. Feature Selection Application Domains

The choice of feature selection methods differs among various application areas. In the following subsections, we review comparative studies on feature selection pertaining to several well known application domains. Table III summarizes the findings from the reviewed studies.

A. Text mining

In text mining, the standard way of representing a document is by using the bag-of-words model. The idea is to model each document with the counts of words occurring in that document. Feature vectors are typically formed so that each feature (i.e. each element of the feature vector) represents the count of a specific word, an alternative being to just indicate the presence/absence of a word without specifying the count. The set of words whose occurrences are counted is called a vocabulary. Given a dataset that needs to be represented, one can use all the words from all the documents in the dataset to build the vocabulary and then prune the vocabulary using feature selection.

It is common to apply a degree of preprocessing prior to feature selection, typically including the removal of rare words with only a few occurrences, the removal of overly common words (e.g. "a", "the", "and" and similar) and grouping the differently inflected forms of a word together (lemmatization, stemming) [38].

Forman [38] performed a detailed experimental study of filter feature selection methods for text classification. Twelve feature selection metrics were evaluated on 229 text classification problem instances. Feature vectors were formed not as word counts, but as Boolean representations of whether a certain word occurred or not. A linear SVM classifier with untuned parameters was used to evaluate performance. The results were analyzed with respect to precision, recall, F-measure and accuracy. Information gain was shown to perform best

TABLE III. SUMMARIZED FINDINGS OF RELEVANT FEATURE SELECTION METHODS IN VARIOUS APPLICATION AREAS

Application area	Subfield	Datasets	Feature selection methods	Evaluation metrics	Best performing	Study
Text mining	Text classification	229 text classification problem instances gathered from Reuters, TREC, OHSUMED, etc.	Accuracy, accuracy balanced, bi-normal separation, chi-square, document frequency, F1-measure, information gain, odds ratio, odds ration numerator, power, probability ratio, random	Accuracy, F-measure, precision, and recall	Information gain (precision), bi-normal separation (accuracy, F-measure, recall)	[38]

with respect to precision, while the author-introduced method bi-normal separation performed best for recall, F-measure and accuracy.

Liu et al. [39] investigated the use of feature selection in the problem of text clustering, showing that feature selection can improve its performance and efficiency. Five filter feature selection methods were tested on three document datasets. Unsupervised feature selection methods were shown to improve clustering performance, achieving about 2% entropy reduction and 1% precision improvement on average, while removing 90% of the features. The authors also proposed an iterative feature selection method inspired by expectation maximization that combines supervised feature selection methods with clustering in a bootstrap setting. The proposed method reduces the entropy by 13.5% and increases precision by 14.6%, hence coming closest to the established baseline, obtained by using a supervised approach.

B. Image processing and computer vision

Representing images is not a straightforward task, as the number of possible image features is practically unlimited [40]. The choice of features typically depends on the target application. Examples of features include histograms of oriented gradients, edge orientation histograms, Haar wavelets, raw pixels, gradient values, edges, color channels, etc. [44].

Bins and Draper [40] studied the use of filter feature selection methods in the general problem of image classification. Three different image datasets were used. They proposed a three-step method for feature selection that combines Relief, K-means clustering and sequential floating forward/backward feature selection (SFFS/SFBS). The idea is to: 1) use the Relief algorithm to remove irrelevant features, 2) use K-means clustering to cluster similar features and remove redundancy, and 3) run SFFS or SFBS to obtain the final set of features. The authors found that using the proposed hybrid combination of algorithms yields better performance than when using Relief or SFFS/SFBS alone. In cases when there are no irrelevant or redundant features in the dataset, the proposed algorithm does not degrade performance. When the goal is to select a specific number of features, it is suggested to use the R+K+B variant of the algorithm if the number of relevant and non-redundant features is less than 110, and otherwise R+K+F. If the number of selected features is allowed to vary, authors suggest using

R+K. The authors also note that Relief is good at removing irrelevant features, but not adequate for selecting the best among relevant features.

Muštra et al. [41] investigated the use of wrapper feature selection methods for breast density classification in mammographic images. Five wrapper feature selection methods were evaluated in conjunction with three different classifiers on two datasets of mammographic images. The best-performing methods were best-first search with forward selection and best-first search with backward selection. Overall, the results over different classifiers and datasets were improved between 3% and 12% when using feature selection.

C. Industrial applications

Feature selection is important in fault diagnosis in industrial applications, where numerous redundant sensors monitor the performance of a machine. Liu et al. [22] have shown that the accuracy of detecting a fault (i.e. solving a binary classification problem of machine state as faulty vs. normal) can be improved by using feature selection. They proposed to use a global geometric model and a similarity metric for feature selection in fault diagnostics. The idea is to find feature subsets that are geometrically similar to the original feature set. The authors experimented with three different similarity measures: angular similarity, mutual information and structure similarity index. The proposed approach was compared with distance-based and entropy-based feature selection, and with SVM and neural network wrappers. The best performance was obtained by combining the proposed geometric similarity approach with a wrapper, so that top 10% of feature subsets were preselected by geometric similarity, following by an exhaustive search-based wrapper approach to find the best subset.

D. Bioinformatics

An interesting application of feature selection is in biomarker discovery from genomics data. In genomics data, individual features correspond to genes, so by selecting the most relevant features, one gains important knowledge about the genes that are the most discriminative for a particular problem. Dessì et al. [42] proposed a framework for comparing different biomarker selection methods, taking into account predictive performance and stability of the selected gene sets. They compared eight selection methods on three benchmark datasets derived from DNA microarray experiments. Additionally, they analyzed how similar the outputs of different selection methods are, and found that the outputs of univariate methods seem to be more similar to each other than to the multivariate methods. In particular, the SVM-embedded selection seems to select features quite distinct from the ones selected by other methods. When jointly optimizing stability and predictive performance, best results were obtained using chi- square, systematic uncertainty, information gain and ReliefF.

Abusamra [43] analyzed the performance of eight different filter-based feature selection methods and three classification methods on two datasets of microarray gene expression data. The best individually performing feature selection methods varied depending on the dataset and the classifier used. Notably, using Gini index for feature selection improved performance of an SVM classifier on both datasets. Some feature selection methods were shown to degrade classification performance. However, Abusamra demonstrated that classification accuracy can be consistently improved on both datasets using a *consensus* of all feature selection methods to find top 20 features, by counting the number of feature selection methods that selected each feature. Seven features were selected by all the methods, and additional 13 features were randomly selected from a pool of features selected by seven out of eight methods.

IV. Conclusion

The current research advancement in this field is identified in the area of hybrid feature selection methods, particularly concerning the methodologies based on evolutionary computation heuristic algorithms such as swarm intelligence based and various genetic algorithms. Additionally, application areas such as bioinformatics, image processing, industrial applications and text mining deal with high-dimensional feature spaces where a clever hybrid methodology design is of utmost importance if any success is to be obtained. Therein, features may exhibit complex internal structures or may even be unknown in advance.

While there is no silver bullet method, filters based on information theory and wrappers based on greedy stepwise approaches seem to offer best results. Future research should focus on optimizing the efficiency and accuracy of feature subset search strategy by combining earlier best filter and wrapper approaches. Most research tends to focus on small number of datasets on which their methodology works. Larger comparative studies should be pursued in order to have more reliable results.

Abstract - When evaluating the process of building classification decision trees, it is necessary to assess the performance of constructed trees, as well as the speed and efficiency of the algorithm. Top-down induction algorithms are relatively simple and can quickly generate good solutions, however their deterministic nature often prevents them from finding globally optimal solutions. On the other hand, the evolutionary approach to decision tree building has yielded promising results by exploring and exploiting the entire search space. However, the standard evolutionary method of building decision trees uses the fitness-based selection of two trees for crossover, which can lead to premature convergence to a local, often sub-optimal solution. In order to maintain the diversity of the population over the course of evolution, we propose a novel method of selection that takes into consideration the similarity of trees in the crossover process, to prevent inbreeding. Several different approaches to evaluate the similarity between trees were designed and implemented. The approaches of both similar and diverse tree crossover were compared to the standard induction algorithm on twenty different data sets to determine the impact of similarity on the effectiveness and efficiency of the genetic algorithm.

I. INTRODUCTION

As one of the most important machine learning tasks, classification is widely used in the context of many real-world problems, both in the fields of social and natural sciences. In literature, many classification algorithms have been presented, having developed from simple extensions of statistical models to complex algorithms.

Decision trees, being one of the first and even to this day most commonly used classification techniques, have become popular due to several advantages. Among them, the concept of their building can be exposed as a relatively simple process, where understanding how the trees are built is trivial matter. The transparency of the constructed trees is another prominent advantage responsible for their popularity, especially in fields like medical diagnosis, as black-box solutions like neural networks and support vector machines cannot yield as interpretable and easy-to-understand results [1]. Furthermore, their accuracy is comparable to other classifiers', though it has been shown to be affected by the method of tree construction. Whereas the traditional, top-down approach excels at the speed of tree construction and is insensitive to missing data, its deterministic nature often leads to non-optimal solutions.

Alternative approaches of tree building attempted to overcome the aforementioned disadvantages of induction algorithms. Evolutionary decision tree design has been shown to yield promising results, with the trees gradually and incrementally approaching the optimal classification accuracy, using genetic mechanisms such as selection, crossover and mutation.

An important prerequisite for successful evolutionary design is the constant development of trees. Often, fitness-based functions are used to guide the evolution by giving more favorable trees a higher chance of being selected in the next generation. Despite such an approach being relatively successful at a continuous progression towards the global optimum, it can be quite resource- and time-consuming. In addition to that, diversity between the trees begins to deplete with the number of generations, effectively slowing down and eventually stopping further development, as breeding very similar or even identical trees cannot produce significantly better offspring.

To prevent only the best (e.g. most accurate), though often very similar, decision trees from being selected for crossover, the proposed solution introduces an alteration to the selection process: while the first tree remains to be selected by the fitness function, the second tree is chosen depending on its level of similarity with the first tree. By breeding mutually different trees, we aimed to preserve the population diversity by allowing unique and promising genes to advance to the next generation and consequently prevent the evolution from getting trapped in local optima.

II. EVOLUTIONARY DECISION TREES AND THE ROLE OF SIMILARITY

Inspired by the process of natural evolution, following the key principles of natural selection and genetics, the evolutionary algorithms provide a promising framework for the non-trivial task of optimal decision tree creation. As opposed to the traditional induction algorithms, which build trees using complex statistical models or information theory, the evolution-based building approach allows for the development of a population of individuals, depicting final solutions, and then gradually adapting them to the environment [2].

Fig. 1 presents the basic idea of evolutionary decision tree building, using a genetic algorithm. After the initial generation of the population that the given algorithm will operate on, each individual tree is evaluated by a fitness

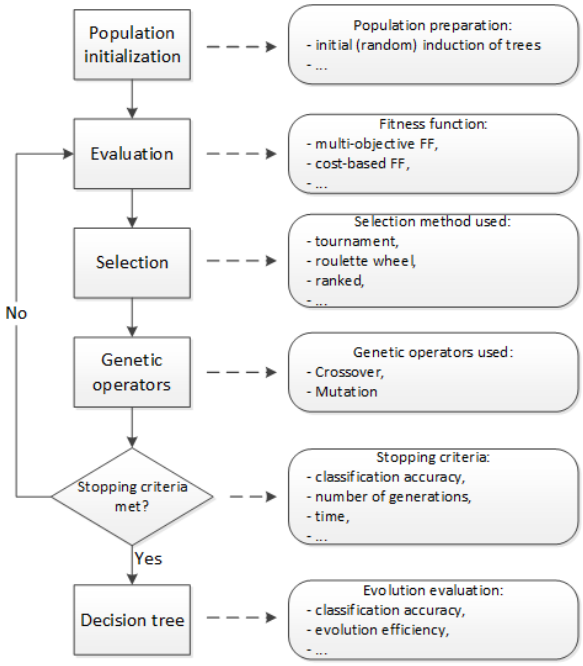

Figure 1. General structure of a genetic algorithm

function – a measurement taking into consideration one or several criteria, trying to assess the general quality of the said individual (i.e. chromosome). Most often, the fitness function considers the tree's classification accuracy and complexity, though it has to be emphasized that this is by no means the best evaluator; with quality being an elusive concept, fitness functions should attempt to measure it by capturing all desired characteristics of a decision tree that are included in the globally optimal solution as well [3].

In every consecutive generation, the individuals that have been evaluated as the best by the fitness function, have a higher chance of being selected for the production of new offspring. That indicates how crucial the selection process is in determining the further course of evolution. Without a good mechanism for selecting the parents, the generated offspring will likely not be as successful as their predecessors, effectively stagnating the evolution through the generations.

The selected individuals are then subjected to various genetic operations: **crossover**, which is responsible for the exchange of genetic material between two parents, and the optional **mutation**, which results in the substitution of a part of the child's genetic material with a new, randomly generated genetic material. The execution of mentioned operations produces new individuals, which replace their parents and consequently create a new generation of individuals. The entire process is then iteratively repeated until the stopping criteria is met [4].

The general idea of evolutionary algorithms is as such very simple, and can be drawn on a parallel with the well-known concept of natural evolution. In nature, species are constantly evolving, which allows them to progressively adapt to the environment. In the context of evolutionary algorithms, the individuals can be described as decision trees, whereas the environment denotes the classification problem they are solving [4]. That reasoning exposes the key difference between the induction- and evolution-based decision tree designs: while the former follows a specialized deterministic algorithm which focuses on building a single solution based on pre-determined rules, the latter has the potential of exploring the entire available search space of solutions.

Unfortunately, two aspects of evolutionary algorithms – selection pressure and gene flow – can quickly cause the nature of the evolution to lean more towards exploitation rather than exploration of search space. In turn, the focus of the algorithm is shifted to a particular subset of the entire search space, effectively ignoring the remainder of the possible solutions. While ideally, we indeed want the algorithm to be able to determine the best solutions in a given set, doing so too early in the course of the evolution can prevent it from considering potentially promising solutions that could represent the global optimum.

Because of that, it is essential to maintain a healthy balance between exploration and exploitation, allowing for the algorithm to *explore* and *identify* promising subsets of the entire search space, and then *exploit* and *select* the optimal solutions. Doing so requires an appropriate level of selection pressure and controlled gene flow. Too strong selection pressure greatly increases the probability of the best solutions being selected for advancement to the next generation. Consequently, after several generations of the same or very similar trees being selected for breeding, the population is quickly filled with similar variations of the successful individuals, preventing further improvement. Likewise, high gene flow also leads to eventual stagnation of the evolution. Algorithms that do not implement a more refined type of selection but instead allow each individual to breed with any other individual in the population, most often cause the same genes to quickly spread throughout the population. As a result, the previously diverse genetic material begins to dilute and as such decreases the range of possible solutions the parents could produce [5].

Both unsuitable selection pressure and high gene flow, resulting in the problem of imbalance between exploration and exploitation, cause progressive loss of gene diversity, hinting at the importance of similarity in the process of evolution. When the individuals of the population become too similar to each other, the population begins to quickly converge towards one of the possible solutions. This phenomenon, known as premature convergence, usually brings the search for the best decision tree to a merely locally optimal solution [6]. Any further exploration of the available search space is from thereon unnecessary – mutually similar parents will continue to produce similar offspring, whose traits will not significantly differ from those of their predecessors [7].

III. SIMILARITY-BASED SELECTION

Typical crossover methods used in genetic algorithms combine parents that had been selected based on their fitness. By considering only the measured "quality" of solutions, such traditional genetic algorithms simulate a process that is in biology more commonly known as random mating: a type of selection, ignoring differences in genotype and phenotype between the individuals [8].

As random mating is not the only existent mechanism of sexual reproduction in nature, the idea of non-random mating has also been considered in the context of genetic

algorithms. It introduces a certain level of intelligence into the selection process by basing it on certain characteristics of the parents. Such non-random and preference-oriented mating schemes are capable of introducing new as well as preserving existing genetic material in the population to maintain or increase diversity between the individuals. By doing so, they lengthen the exploration phase in order to consider all possible neighborhoods of good solutions. A thorough initial exploration of the search space allows the algorithm to avoid premature convergence towards one of local optima traps due to ignoring the subset of promising solutions in which the globally-optimal tree is included. Such approach, focusing on the sustainment of genetic diversity within the population, is particularly relevant for dynamic environments, in which adaptation to change is often more important than convergence towards the currently optimal solution [8].

To preserve genetic diversity, various restricted mating techniques have been introduced, including: assortative and dissortative mating, seduction, evolving agents, tabu genetic algorithm and correlative tournament selection. They incorporate the ideas of *fitness sharing* and *incest prevention*. The former assumes the maintenance of several niches within the search space, each including high-fitness solutions clustering around local optima. By promoting inbreeding between the individual members of each niche, these solutions simultaneously evolve until the globally optimal solution is selected from all sustained niche local optima. On the other hand, incest prevention encourages the recombination of mutually different individuals, as breeding two very similar instances cannot produce solutions containing new genes. In order to select the parents depending on their genetic dissimilarity, this method quantifies the genotypic or phenotypic difference and select the most diverse solutions for crossover [9].

Several studies examining the impact of similarity in the process of selection have been conducted. De, Pal and Ghosh have compared the selection of parents, based on their genotypic or phenotypic similarity, to the traditional, fitness-based selection method, showing the superiority of the novel approach on the problem of complex function optimization [10]. Another study supports the notion of a genetic algorithm, using adaptive dissortative mating scheme, outperforming several other genetic algorithms on a variety of dynamic optimization problems [11]. To an extent, these and other dissortative mating techniques have been inspired by the CHC algorithm, which restricts the crossover between similar solutions, whose Hamming distance is not above a certain threshold [12]. The honey-bee mating optimization algorithm and its enhancements, presented in [13], have shown the algorithm's capability to explore and exploit the search space simultaneously while maintaining population diversity. A comprehensive study describing the most prominent non-random mating techniques, focusing on dissortative mating, was presented by Fernandes and Rosa, emphasizing their effectiveness in maintaining population diversity in comparison to random mating schemes [8]. The results of the study complement Goldberg's, as well as Eshelman and Schaffer's findings showing a more effective exploration of the entire search space by similarity-based non-random mating approaches, both in fitness sharing and incest prevention [9].

A. *Similarity-based mating strategy*

Numerous other similarity-based restricted mating approaches have also been presented in literature [14-16], however none have been observed in the context of classification with decision trees. The purpose of this paper is as such to apply a particular non-random mating scheme based on similarity and diversity between decision trees to an evolutionary algorithm, and compare its performance to a traditional evolutionary algorithm on a given set of classification problems.

A similar mating strategy that was implemented in the context of classification with decision trees and is shown in fig. 2, has already been presented on the problem of vector quantization, indicating the significance of this research [14]. It differs from the conventional genetic algorithm in the way parents are selected for crossover. The first parent tree remains to be selected depending on its fitness, in order to promote the transition of successful genes into the next generation. Any traditional selection method can be used, including but not limited to: ranked, roulette wheel and tournament-based selection. The latter is one of the most commonly used selection methods, due to its efficiency, as well as simple implementation [17], and was therefore used in our case as well. From the entire population, a set of α decision trees was then randomly selected. Each of the candidate trees was evaluated by the fitness function, which quantified the fitness of the trees based on their classification accuracy and size. Of the subset of trees, the one with the highest fitness value was selected as the first mating parent.

Usually, the second parent would have been selected in a similar manner, either as the second-best tree from the already executed tournament, or as the best tree from a new tournament of β randomly selected trees (where, in most cases, but not necessarily, $\alpha = \beta$). Whereas a β-sized tournament could still be held to randomly select a subset of candidate trees, the evaluation and subsequent selection of the second parent was based on the similarity between the first tree and the candidate solutions, rather than the fitness, however. Firstly, similarity indices measuring the difference and/or similarity between two given trees, were calculated for all β pairs. Then, depending on whether we wanted to use assortative or dissortative mating scheme, the most similar or different decision tree from the first one was chosen, respectively.

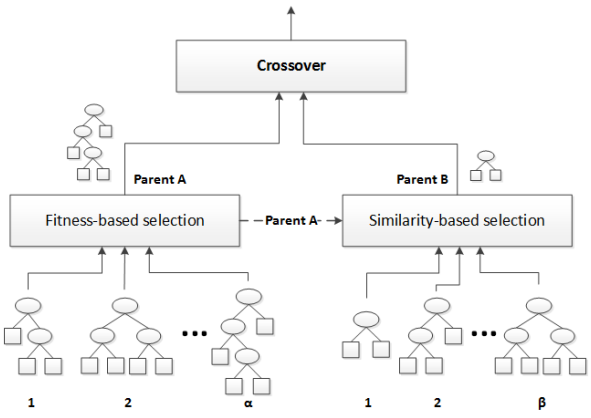

Figure 2. Similarity-based selection of decision trees

Measuring similarity between two trees is not a trivial task. There are several possible characteristics of trees that can be considered, and depending on these contradictory perspectives, different estimates of similarity between decision trees can be derived. Furthermore, any observed differences have to be appropriately quantified, producing a single numeric value as an output – that is necessary so that all similarity scores can be compared to each other, making it easy to determine the most similar or diverse pairs. While fitness score can be computed with relatively small effort, as it is simple to identify the most accurate or the smallest trees as the best (even in the case of several criteria being considered simultaneously, simple weighted formulas can provide a rather straightforward approach to multi-objective optimization) [18], it is very difficult to arbitrate how different two trees are from each other.

Identical trees can be unambiguously labelled with a score of 0, whereas the measure of difference between two trees can theoretically rise to infinity, since we can always find a pair of trees that is more different from each other than the previous one. For computational purposes and ease of comparison and understanding, most studies have placed the limit of difference at 1, with the more different trees gradually approaching the limit without ever actually reaching it, as two trees can never be the *most* different [19, 20]. Even though normalizing the differences in order to limit the score in between the designated boundaries can distort the severity of differences between two given trees, we have decided to follow the above mentioned approach because we are ultimately interested only in the highest and lowest-rated pairs.

B. Implementation of similarity-based evaluation

There is a number of possible ways similarity between trees can be measured. For example, decision trees can be transformed into rule sets, following a particular pattern: "*IF* $attr_A > x$ *AND* $attr_B <= y$ *AND … THEN* $Class_1$". The similarity measure can then be obtained by comparing substructures of particular rules composing two observed decision trees, and finding identical patterns in them [19]. Another study investigates the issue of splitting attribute selection, proposing a technique that takes into account the similarity between any two instances in a given subset, choosing the attribute with the greatest similarity score as the splitting attribute [20]. Finally, with the intention of observing semantical rather than structural differences between the trees, allowing for possible meta-analysis and meta-mining, a semantically-driven similarity measure has been developed [21].

In our work, we present five independent measures of similarity that were designed for the purpose of capturing several different, possibly contradictory features that trees could differ in:

Tree complexity. Representing one of the aspects that affect the tree's performance, complexity should generally follow the Ockham's razor principle, stating phenomena should be explained with as few variables as possible. Smaller and simpler trees are not just easier to interpret, but achieve a high level of generalization and are prone to overfitting [22]. As such, we aimed to breed similarly-sized trees in order to maintain a low level of complexity. We observed the complexity of decision trees on two levels: horizontal and vertical. The former constitutes the tree's comprehensibility and interpretability, and can be easily measured as the number of all nodes. The latter, on the other hand, denotes the maximum number of decisions a tree has to make in order to classify an arbitrary instance into one of the classes, and is represented by the tree's depth. The implemented similarity measure considers both as a balanced weighted difference between two trees.

Number of used attributes. Selection of numeric and nominal attributes, based on which decision trees classify instances, is already performed by the induction algorithm building said trees. Nonetheless, the complexity of trees is, to some degree, dependent on the number of attributes used: more complex trees often use most, if not all of the available attributes describing instances, whereas simple trees classify instances, considering only a few attributes. The metric evaluates similarity by calculating the absolute difference between the numbers of unique attributes used in both decision trees. Despite that being another measure of complexity, it was not included in the previous metric because it is not directly related to tree size. While we are aware the two metrics could have been combined, our aim was to consider several simple measures of similarity, although multi-criteria similarity-based selection methods remain as a possible research direction for future work.

Attribute values. As pointed out in ref. [20], splitting criteria affects the tree's classification accuracy, as well – despite having two equal trees in terms of size and even used attributes, the instances can be classified in different classes depending on the attribute values. The idea behind the implemented metric is therefore the crossover of trees with dissimilar attribute values, to create offspring that would, despite similar tree structure, classify instances in a different (and hopefully better) way. Naturally, it cannot be expected of the descendant decision trees to outperform their parents in every generation. However, since the principles of natural evolution speak in favor of the more successful trees advancing into the subsequent generation, they will only be replaced by their children when the latter surpass them, while the diversity within the population can be maintained by the similarity-based crossover that considers differences in attribute values.

Attributes can be either numeric or nominal, meaning that the differences in both types of attributes had to be considered. Numeric attributes were evaluated simply by calculating the absolute difference between the two tree's attribute values. In case a tree splits the data set using the same attribute multiple times, the sum of that attribute's values is taken instead. To determine the differences in nominal attributes, the different values for that specific attribute were counted. Since every attribute was assessed separately, partial similarity scores were produced, finally being added up to the final score.

The most prominent flaw of this method can be seen on data sets containing attributes, whose values have an extensive range. In such cases, the final scores are heavily influenced by just a single attribute. In order for every attribute to have the same amount of impact on the final score, feature scaling method was used to normalize every sub-score into the closed interval between 0 and 1 [23].

Confusion matrix. The implemented similarity metric focuses on the matrix's diagonal. For every class, the difference in the number of correctly classified instances was calculated, with the final similarity index represented by the sum of all partial scores.

Instance classification. A rather promising approach considers the differences in the way two trees classify the instances. For every instance in the data set, classified into two different classes by the compared trees, the similarity score is incremented by 1. The final score is represented by the number of differently classified instances. With the differences in instance classification, it can be expected that the two parents are structurally different as well. By combining two decision trees that classify the instances in a different manner, the created offspring could inherit the parts of the parent trees that are responsible for correctly classified instances, making the newly created tree even more accurate in turn. It should be noted, however, that such a scenario is greatly dependent on coincidence, due to the crossover points being selected randomly. Since the evolution runs through many generations, the probability of favorable children being constructed in such a manner, is still relatively high, however.

IV. EXPERIMENT AND RESULTS

The similarity-based mating strategies described in the previous section were implemented within a Java program "GaTree", which served as a framework for the execution of our experiment. The program was previously developed with the intention of conducting studies in the field of evolutionary-based decision tree construction. In addition to the standard evolutionary building approach, it offers a wide variety of functionalities, including several selection, crossover and mutation methods, as well as novel fitness functions. An extensive range of the available control parameters was especially useful for proper configuration of the environment, in which the experiment was run. The used parameters, crucial for the experiment, are presented in table 1.

Since we aimed to ensure the validity of the executed experiment, we compared the conventional, fitness-based selection method to the five implemented similarity-based selection methods on twenty benchmark datasets, obtained from the UC Irvine Machine Learning Repository. The selected data sets differed in the number of attributes and instances, type of attributes, existence of missing data and the field of study. Additionally, due to the initial decision tree induction, as well as several genetic operators being based on randomness, the experiment was repeated ten times on each of the twenty data sets. Thus, the probability of the results being as such due to random chance, was accordingly mitigated.

The experiment was run on the 64-bit server operating system Windows Server 2008 R2 Standard, with a 2.4 GHz Intel Xeon E5645 processor and 25 GB of RAM, taking 439,644 seconds (or 5 days, 2 hours, 7 minutes and 24 seconds) to complete. The resulting data consisted of simple metrics, measuring the effectiveness and efficiency of the standard evolutionary algorithm and five similarity-based approaches for all ten repetitions on all twenty data sets. Efficiency was thus measured by the number of generations necessary to obtain the best decision tree in the evolution, whereas effectiveness was determined by the best tree's accuracy, size and F-score.

TABLE I. USED CONTROL PARAMETERS AND THEIR VALUES

Control parameter	*Value*
Number of repetitions on a single data set	10
Size of the population	200
Maximum number of generations	2000
Maximum tree depth in the initial population	10
Maximum number of possible non-final nodes in the initial population	20
Mutation probability for a particular node	0.1
Parent tree selection method	Tournament
Number of randomly selected trees for the execution of the tournament	5
Evaluation of selected parent trees	1st tree: fitness 2nd tree: similarity
Crossover method	Random

In the analysis phase, the obtained data associated with the standard approach was compared to the data from each of the other five, similarity-based approaches. Due to the data not being normally distributed ($D(200) \approx 0.152$, $p < 0.001$, for all six approaches), the Kruskal-Wallis non-parametric test was performed, although no significant difference between the standard and any one of the five implemented approaches has been observed. Since these tests were run on all data sets at once, we repeated them on each data set and noted significant differences on 6 out of 20 individual data sets. On four of these data sets, the standard approach was significantly better than the others in terms of classification accuracy and F-score, while the similarity-based approaches considering tree complexity and the number of used attributes were significantly better than it on another four of the data sets in terms of tree size.

Statistical significance greatly depends on the sample size (which was, in our case, only 10 repetitions per data set, due to computational complexity of the process), so we calculated the effect size that represents a standardized measure of the observed difference's magnitude [24]. On fig. 3, the graph shows the number of data sets, on which at least a weak effect size has been observed. Individual columns represent the implemented approaches that were more successful than the standard approach, with respect to the observed metrics. Yellow color denotes weak, green

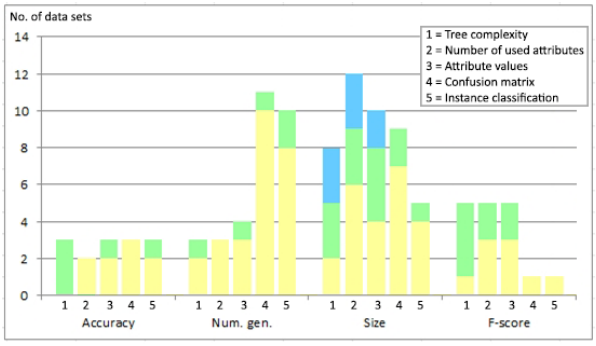

Figure 3. No. of data sets on which one of the similarity-based approaches was better than standard with at least weak effect size

denotes medium and blue denotes strong effect size. As it can be seen, the implemented approaches seemed to be better than the standard approach mostly in respect to the size of the tree, which was consistent with our previous findings that pointed at the most significant improvements being in relation to the size. On ten and eleven data sets, the similarity-based approaches considering differences in the instance classification and confusion matrix appeared to find the most successful tree faster than the traditional approach. Improvements of classification accuracy and F-score were less common, with weak and medium effect size of the implemented approaches' improvements being observed on only one to five data sets.

V. CONLUSION

Evolutionary algorithms, with the idea of mimicking natural evolution and simulating the development and reproduction of organisms in nature, present a promising framework for construction of successful decision trees. Despite that, their features have been observed to lead to premature convergence. With the implemented similarity-based crossover approaches, we aimed to address the problem of diversity loss, one of the main reasons for the evolution getting trapped in one of the local optima.

Although the five selection approaches that consider similarity between trees do not significantly outperform the standard evolutionary approach, at least weak effect sizes, hinting at possible improvements of the similarity-based methods in comparison to the standard one in regards to the tree size, have been noted on up to twelve data sets. Furthermore, the mating strategy considering differences in the confusion matrix and the classification of instances, have been shown to improve the number of generations to the final solution with weak to medium effect size on over half of the data sets. We believe that the significance of these findings would have been shown, had the sample size been bigger. One of the possibilities for future work is thus to observe one of the implemented approaches (or a combination of them) on fewer data sets, by executing a greater number of repetitions. Likewise, new approaches evaluating similarity between trees could also be developed.

It has been established that, while the similarity-based selection does increase diversity within the population, the final result still depends on chance, due to the crossover points being selected randomly. As such, it would have also been plausible to consider adding an additional level of intelligence into the process by determining the most optimal crossover points in both trees to breed even more successful offspring.

***Abstract*—The described investigation proposes an approach to overcome known problem of site developers' participation in the real development of Semantic Web content. The site integration in a way of the Semantic Web is too hard to be used in a regular site maintenance. This results in the necessity of development of site content management software integrated by means of semantic web as knowledge acquisition systems, where developers and users have to play a role of an information source for a system-integrated decision-making engine inducing formal knowledge on the base of data analysis.**

The logical layer is generated on the base of analysis of changes introduced by user, which are analyzed and interpreted. The variant of the interpretation (e.g., error correction of a value or a new statement definition) is determined by means of user interview and other factors. The theoretical basis of the technique is based on a polysystem representation of ontologies describing the domain. The presentation is a hierarchically fibered structure of concepts and relations, which are mapped between fibers by means of interpretation relations.

I. Introduction

In 2001 Tim Berners-Lee proposed a blueprint [1] of web development that is aimed at the implementation of network services with reasonable integration of logical layer of the information presented. The information is to be marked up semantically and the program agents are to take advantage of the markup as the logical layer for the information consumption and processing. The blueprint is called Semantic Web (SW).

One of the main problems of SW is the fact, that the regular users of web resources are not fond of the complex technological aspects of SW. They are interested in their practical problems solutions. In order to involve users in SW content development these aspects must be completely hidden. This results in the necessity of development of document and site content management software exploited within SW as knowledge acquisition systems, where user is to play a role of an information source for a system-integrated decision-making engine inducing formal knowledge on the base of data analysis.

To be more comprehensible consider a content of a legal document, which in most cases contains meaningful information on legal entities relationships that is usually passed to other documents in a derivative forms. This suggests an idea to develop a form of the logical layer representation in a reasonably detailed form, which can be rendered as a regular text pages by means of context-depended (in sense of a legal document) text templates. The SW approach could supplement the idea with data formats and technologies of their storage and processing. SW represents logical layer as a network graph of notions and relations between the notions. For example, individuals mentioned in a legal document relate to the document as "part-whole", unless to speak even more explicitly in a meaningful context.

At present most of the use cases of domain ontology models are refining search results. Automatic procedures of ontology extraction from the documents are based on crawling documents in a warehouse, running data mining procedures on text content and metadata attributes of the documents. Simple observation of human behavior in the process of a document preparation will result in the confidence that meaningful parts of the document, which are usually expressed with the logical layer, are located at the points of document changes. Hence, a programming system automating the document preparation should track the changes and analyze them in time to extract ontology structure, i.e., objects, concepts and relation between them.

The logical layer is induced during content edition by means of data mining and user interview. The context of the knowledge acquisition consists of a polysystem [2] of ontologies describing the domain, the source document (its text representation and current logical structure), its list of modifications in transaction, user's action history, and answers to the interview questions clarifying meaning of text content changes and properties of the relations constructed. As a result, new or modified triples `<subject, relation, object>` are constructed. Collected triple data, metadata and knowledge of the logical layer can also be crawled on a regular basis to grasp patterns and functional relations between attributes (triple's objects). In the last case a relational table could be induced to rise the efficiency of data storage and processing.

The present trends of internet information system development show that the systems become a web-services and are oriented to support social networks [3]. The data flow processing there in most cases is input, storage, filtering and transmitting data, i.e., the social networks integrate rather than aggregate data, e.g., to produce reports. Hence, the usage of special design techniques for the middle-ware layer of the software, such as object-oriented design, is not a significant technological advantage. Social network (SN) agent software are interconnected with standardized protocols and data structures, and have the same way of integration with other social networks.

Let us emphasize the properties of social network software:

- there are no predominant common global task to be solved by agents (computer and human) of the SN;
- each agent solves its special task acquiring data from other data sources and agents, hence, the agent's APIs and supported data format must be standardized;
- human users of the social network do most of the aggregation tasks personally including subconscious joint processing of unstructured and semantic information;
- a good practice is to use cheap virtual hosting to run the a SN node, therefore, the information system itself must be written according to the restrictions of a server-side programming language, like PHP, and utilize the computational and data storage resources of client workstation and its browser environment.

In this paper, we continue the development of the approach [4] of document and site content management and integration within a general study [5], and briefly consider the procedure of polysystem ontology usage in the process of user dialog maintenance.

II. Document Markup

Resource description framework (RDF) standard describes informational resources with triples `<subject, relation, object>` in a context. A set of triples forms a graph (network) of data and relations reflecting knowledge. It is convenient to divide graphs to subgraphs and construct hierarchic complexes [5], resulting a hierarchy of contexts. In a general case, a context affects the interpretation of the set of triples coupled with it. For example, in a legal notary document family name and passport data are presented as texts in different parts of the document, but they related to the single person in the context defined by the document. So the parts of the document form the contexts of text rendering for the passport data.

The rendering engine we considered in [4]. According to this approach, all the template data for document rendering is also stored in the ontology graph. We also represent the views and algorithms implementing controllers in the sense of MVC (Model View Controller) [6] pattern with triples. The content of the document from a general point of view is based on a tree graph, where almost each node is both subject and object of their corresponding relations. The root node in a document can be only a subject, and the leaf nodes are objects only. The document root node becomes object node as being referred from document sets and hierarchies organized in a warehouse.

III. The Outline of Markup Scheme

The proposed way of semantic document markup is to track and interpret the results of document editing. Let's suppose that a document body change affects the meaning of the document, hence, alters its logical layer. The following trivial modifications that are the elementary error correction are not considered to be a valuable information for the markup: a field value change (object of a triple), paragraph text editing that might imply its original template correction. The changes of our interest result in a new triple relation construction between context subjects and old/new object value. The content management system and a built-in editor play an active role in the markup process, and user is a source of supplementary information.

The first question that user have to be asked is to determine weather a change is an above mentioned trivial one. If it is not, then the semantic layer enrichment procedure is carried on. The source of data to decision-making procedure of a triple formation/modification is an environment containing a) logic structure of the previous version of the document; b) the source version of the document content as text, c) a text modification expressed in diff format [7]; d) user answers to the question stated by the system, refining the semantics and structure of the modifications; e) user actions prior the modification done. The list of the previous user's actions can reveal a general intention, e.g., if user made a copy of document and changed an individual name, this would imply the necessity to fill in the passport data, which, in turn, implies filling in a number of triples with new values representing the new individual (subject) of the document.

At the next step of markup the extent of the modified value is determined. It could be a word, a phrase, a sentence, the whole object value, or an extent of a text markup (e.g. HTML tag value). A resulting variant is specified by user.

The simplest way of the triple formation procedure is to allow the user to choose subject and relation from list of all relevant subjects mentioned in the document and their relations and construct a new triple `<subject,relation,old object>`. The list of subjects is constructed from a tree of all the subjects of the edited document and the edited object itself. After the first choice is made, a list of all available relation is constructed from all known relation of the chosen subject, its class and parent classes. User must choose one relation to form the triple. In the case, when the list contains no adequate relation, a new one could be defined. New relation is always a subclass of an already existing on, which is also chosen from the list. New relations defined by inexperienced users must be periodically analyzed by knowledge engineers to get rid of semantic inaccuracy, contradictions, redundancy to the equivalents, and, hence, be refactored.

If a value of a triple is removed, then the triple must be removed too. The situation is acceptable if the minimal structural and semantic completeness of all the subjects of the documents holds, otherwise either the user delete action is prohibited or the chain recursive deletion of the subjects is initiated. To control this behavior each subject class have to be accompanied with a list of minimal valuable triples that define the basis of the subject meaning. Partial text removal, if it is not an error correction, is processed analogously to modification, with removed part being the object value. Addition of characters to text is an action similar to modification.

Addition of a triple might result in extending the document with new subjects and relations. For example, let one construct a new tripartite agreement from an existing bilateral one. In the new agreement the third individual appears, so the addition of a new family name of the individual results in construction of a) subject for the individual, b) filling in the necessary triples, as well as c) definition of a new relation between document and

the third individual as a subclass of `structuralElement`: relation. This stage is necessary as all new subjects must be in a relation.

IV. Theoretical Generalization of the Acquisition Process

The above described approach is a simplified step-wise implementation of the procedure of polysystem analysis and synthesis [2] (PPAS). This is a general procedure for system analysis of domains. The essence of the approach is that domain and any its object or process can be fibrated and represented in multidimensional space of fiber-coordinates. The fiber consists of concepts and morphisms between them. This approach is used in decomposition, analysis and synthesis of complex systems. For each concepts of a fiber there exists another concept in all the fibers, which is identical to the former concept via an interpretation (e.g., substitution mapping). All the fibers are element-wise mapped to the abstract system fibers. The same is true for the morphisms. In comparison to the widely known system approach, where the principle of interconnection of the elements is fundamental, polysystem analysis assumes the hypothesis of fibration, i.e., it supposes a possibility of representation of the object under investigation as disjoint fibers, thus, mutually unbound fibers (subdomains). So, in a generalized insight a polysystem is a system itself, and polysystem analysis is a new form of system analysis.

Now then, according to PPAS [2] each concept of an aspect should be presented via interpretation morphisms in all other fibers as well as its relationships with adjacent concepts. For each of the fibers, a complete theory of the domain can be constructed. Each theory differ by their fundamental concept, but they are similar to all other via concept substitution via interpretation. This allows us to induce new axiomatic theories of domains in the image and likeness of the known ones. Each system domain (fiber) of knowledge fibrates multiply and sequentially, giving raise of the polysystem of representation of an object under investigation. All the system theories are combined in the unified model describing the domain and the object under investigation.

The application of the PPAS to the process of data and knowledge acquisition in the documents expressed as simultaneus polysystem fibering the domain in various coordinate systems (aspects) such as follows: structural organization of a document (mereological aspect), expressing domain of activity area, hierarchical inheritance of various kind of documents (domain system concept inheritance), people and organization relationship, deontic logic representation of the document meaning, etc. Having established new class or new relation between two classes, the concept or relation should be reflected as a substituted (interpreted with) one in other ontologies (e.g., mereological). To make the polysystem to be easily understandable to users, definitions for the concepts and relations in a natural language must be supplemented in terms of those ontologies. The traditional requirement of affiliation of an object to a class, and inheritance between classes and relations reflects the idea of hierarchical polysystem fibering. The relations of inheritance and affiliation are the examples of concept interpretation between the fibers.

The conceptual methodological basis of PPAS allows us to a) control the completeness of the system of objects in a document with respect to their interpretation to a predefined abstract system fiber, which we roughly call “template fiber”; b) verify the soundness with respect to the semantics of the relation defined again via interpretations; and in a distant future c) automatically produce program implementing the fiber theories via interpretation and combination of the existing algorithms of other fibers.

V. Maintaining a Dialog With User

The through interpretation feature of the polysystem layers could be used to maintain user interview dialog on the base of an inference by analogy represented as movement along relations, morphisms and interpretation in a polysystem of ontologies.

In order to realize the dialog procedure, there should already exist system fibers representing “part-whole” relations, class hierarchies of the abstract concepts, correspondence of objects to classes. The aspects of the domain is represented by set theories and necessary domain layers, e.g., the fiber defining that “man” and “woman” are disjoint concepts. The user dialog is used to determine that the object belongs to a context (fiber), recognize its interpretations into concepts of other fibers, and to provide all the context to be complete and sound with respect to their template fibers. The dialog is maintained on the base of analysis of known properties and restrictions (relations) of the subject: type of data representing the subject, its location in the context hierarchy, existing relations with subjects and objects, etc.

Let’s consider simple family relationships in fig. 1, where most of the obvious relations are hidden to make the figure more readable. There showed a part of the domain polysystem consisting of four main layers, which model various aspects of Bob’s family. Layer 1 represents the family itself, it is the only layer having objects as concepts; layer 2 represent main roles of individuals in a family; layer 3 shows genders as two opposites; and later 4 corresponds to a rough mereological model “part-whole”.

Let’s construct a sequence of questions to determine a role of Jul in Bob’s family. It is supposed that we know only that Jul is a woman, and she has been mentioned in a document related to Bob’s family. To put Jul in layer 1, in a edited context of a document, we must ask a general question: “Is Jul a part of Bob’s family?” The question is constructed according to a following intuitive inference. All members of a family are “partOf:” the family. This fact is shown as an arrow from relation “hasFather:” of Layer 2 to “partOf:” of Layer 4, other four arrows are hidden. So, in order to determine the fact that Jul is a member of Bob’s family, it is sufficient to ask “Is Jul partOf: Bob’s-family?”. The identifier of the example family is devised from the tradition to name families after their master of housekeeping (MOH) person, that is denoted by arrow from individual Bob (layer 1) to concept MOH (layer 2). Note, that layer 1 interpreted by layer 2 by means of a functor of theory of categories.

If user answered positively, i.e., Jul is a part of the family, then we must refine her role further, as role “partOf:” is not allowed in layer 1, and, hence, layer 1 is not complete yet with respect to template layer 2. Jul is a female by definition, so she cannot be father and son. If she is, she must be male,

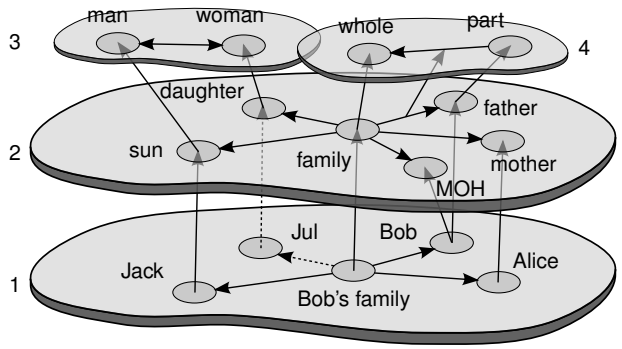

Figure 1. A Usage Example of an Ontology Polysystem

but it is impossible as male and female are formally opposite concepts. If multiplicity of relation "hasMother:" in the layer are defined as one, then we will also know, that the family already has mother. The only possible choice is Jul is daughter, resulting in another general question:"Is Jul a daughter?" If the answer to the question is also positive, finally a new triple constructed <Bob's-family, hasDaughter:, Jul>. Now the layer of Bob's family is complete with respect to the template layer 2.

If, e.g., Jul's gender is unknown, then the second question is constructed as a special question "What role does Jul have in Bob's family?" and a list of two possible answers is shown: "hasDaughter:" and "hasSon:". Another variant of the question can be synthesized if only two alternatives exist: "Which of the following two roles does Jul play in Bob's-family: hasDaughter: or hasSon: ?".

In fact in the original example the question about a role of Jul is redundant as there exist only one role for a woman being a part of Bob's family. If we remove mother Alice from the family then the question have to be asked, even for incomplete families. The general questions are asked when we could narrow a list of alternatives in further questions. The queue of the questions being asked could be defined at runtime by analogy to decision tree construction procedure, e.g., by analyzing entropy gain [8].

VI. A Notary Office Usage of the Technique

One of the applications of the technology under development is document preparation automation of a notary office. Notary office in Russia generate vast amount of printed documents. The documents contain both formalized and unformalized data in a balance reasonable for our study. For example, formalized data are the passport data of individuals, registration data of vehicles. This kind of data are normally stored in rational databases, passed from one document to other documents mostly structured and unchanged, raising a bundles of related documents and patterns of document flows. The final document content structure significantly depends on entry fields data filled in, e.g., form of notary signature field depends on legal capacities of the individuals mentioned in the main document body. Unformalized data are various enumerations of legal empowerments of the individuals, article codes, and explanatory text.

At present most of notary legal documents are generated

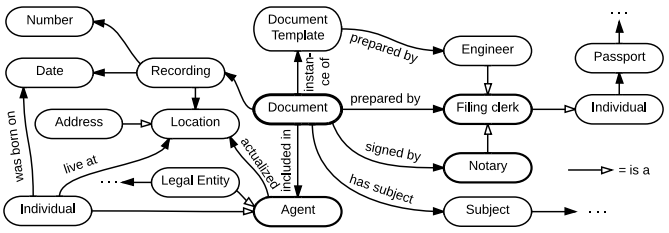

Figure 2. Upper Layer of Notary Office Ontology

from templates. In experimental office, the document templates are prepared by engineer in collaboration with a secretary having necessary experience of use of the existing software. Templates are HTML forms dispersed in the text of document. Logical structure of a document is defined by field names, and the procedures of information processing are implemented as simple form processing routines. The output document is rendered by means of value substitution instead of fields. The field names are defined by identifiers according to a special rules so that fields implicitly combine into a subject. This simple formalization allows one to carry on basic transformation operations on roles of the individuals by means of renaming or exchanging values of the field sets. Application of semantic approach to the logical layer representation of the notary document content is aimed at involvement of the secretaries (office stuff with low engineering skills) into development of the templates and constructing hierarchical arrangements of documents.

In new approach, logical layer of a notary document consists of hierarchy of subjects. The subjects relate to each other on various abstraction levels, e.g., in a letter of attorney there are at least two individuals, the first one is principal, and the second one is trusted (proxy). For each individual passport, data and place of residence are defined. The letter can contain other person data, e.g., for partially capable children. As we just noted, all the individuals are in explicit relation to the document. The triples <letatt998 containsPrincipal: indiv_78> (commas are omitted) and <letatt998 containsProxy: indiv_79> could define a principal and proxy of the document. The mentioned relations are specifications of abstract hasIndividual: and structuralElement: relations. This polysystem approach allows us visually represent hierarchical structures of the document, having interpreted the relations as structural elements, and in the same time to associate individuals with other roles in new documents, swap roles during editing. The role swap function is implemented as user interface widget generated as a result of recognition of certain subject-to-subject relations indistinguishable in a fiber, or specific patterns of relations in the document body. A general graph structure of the abstract level of a notary office automation ontology is drawn in fig. 2.

VII. The Software

The software developed within the project will include two major versions. The first one will be a client and server combination, where client will drive the data mining and visualization procedures, and server will control storage and access rights to a graph of the domain. The second version of

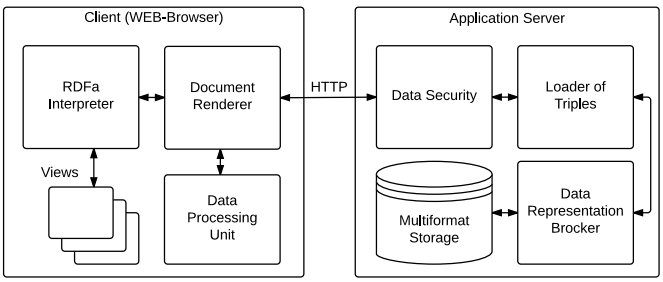

Figure 3. Program System Architecture

the software is a desktop application that is a fusion of the client and server functionality. The application is intended for corporate and personal off-line usage. The following are the requirements of the software to be fulfilled in our investigation:

1) the software should be developed as an open-source project, and we hope to involve in our project a free community of engineers and users;
2) server software must be not too consumptive of computational and memory resources of a shared hosting service;
3) in accordance to 2, a support of various database back-ends are to be implemented to store triple data.

We orient our efforts of implementation to a popular hosting environments that include PHP as programming language and operational environment, MySQL- and PostgreSQL-servers as a storage, functioning under Linux operation system. As a primary client, Firefox web browser has been chosen, and its JavaScript implementation is being considered as a client programming language.

Architecture of the first variant of the software is presented in fig. 3. Server side deals with data storage and security. “Multiformat Storage” module supports various techniques of data representation, it could be a SQL-server. The purpose of “Data Representation Broker” module is to convert triples in a format that is better support special tasks, such as aggregations, and pass the conversion result to the storage. In the backward direction, the broker restores triples from the storage as RDF entities. In order to render a template the data model instance should be loaded through module “Loader of Triples”. The instance is represented as a set of triples. The security is supplied by Data Security module.

At client side the triples are rendered as HTML texts and combined into a document by “Document Renderer” module. The result is either interpreted further by “RDFa interpreter” or processed in “Data Processing Unit”. New concepts and relations are sent back to server as RDF- and RDFa-content.

A. Implementation details

Representation of domain graph and PHP’s access to graph components is implemented on the base of EasyRdf library. The library supports loading RDF-files and represent them as PHP’s objects. The objects can be accessed in a usual object-oriented way and by means of the special standard query language SPARQL.

Storing RDF-triples in MySQL is to be implemented with ARC2 library, which also supports SPARQL-queries. ARC2 is a development platform with SW functionality, allowing one to extend the standard set of routines by means of plug-in modules as well as to create trigger functions fired as soon as SAPRQL query finished.

Text composition library Zope Page Template (ZPT) [9] is used as a generic text rendering engine out of the logical layer. ZPT is cross-platform and allows representing templates and rendering the triples inside. The templates also stored in RDF. ZPT technology and its descendants, like Chameleon [10], allow programmers and designers to share their common work on a dynamic HTML page because of ZPT is based on a declarative approach to template definition.

ZPT engine includes interpreters of several query expression languages to a logical structures of model and template: TAL (Template Attribute Language) and METAL (Meta TAL). There are also tools for internationalization (I18N) support. Developers of ZPT successfully solved the following standard web problems:

- separation application logic and user interface;
- utilization of existing HTML-page design software and editors (e.g., Dreanweaer) for manipulation of template content with conserving TAL and METAL expression;
- trivial cycle programming structures are replaced with a declarative constructions;
- thanks to METAL templates are manipulated in a powerful manner — cutting and pasting subtrees of a HTML page — using model data.

To date there are many implementations of TAL and METAL for various programming systems, including PHP (PHPTAL). The same templates can be used in all of them if programmer uses only the basis syntax and semantics of TAL. For client-side language JavaScript, ZPT has been implemented by Distal library, which can also dynamically load model data into rendered template, resulting consumption more CPU resources of client workstation and less of server.

The storage module of desktop application should not be too resources consuming, that’s why we propose usage of in-process database libraries which are also do not require special configuration and engineer’s periodical maintenance. One of the outstanding in-process database engine is Kyoto Cabinet library [11], which is high-performance implementation of BerkeleyDB standard. The library maps blocks of bytes, i.e., a key to a value, and the mapping is realized by means of B+-trees and hash tables. Kyoto Cabinet supports protection against data loss even due to partial physical damage of hard disks. The protection is achieved by special file format and data replication among a cluster of workstations.

Thus, the nowadays open-source software of internet application development and relatively cheap server computational resources completely cover all the requirements of the software under development.

VIII. Similar Projects

Among existing projects of ontology based document management the project Semantic MediaWiki can be emphasized. A basic Wiki text editing is extended with semantic annotations represented in a special markup format. The annotations are used by search engine of the Wiki pages [12].

In comparison to Semantic MediaWiki the project OntoWiki [13] obtained the similar results from an opposite starting point. OntoWiki is based on the predominantly usage of logical representation of the information as semantic network. The logical structure is edited with entry forms generated on the base of predefined vocabularies (term sets). User is allowed to change just one text property lod:content, which can contain HTML markup. The HTML markup does not relate to the logical structure of the subject to be visualized as web-document. The text is modified with WYSIWYG editor integrated into OntoWiki. The project is aimed at social networks developed under control of Linked Data technology.

Our project can be positioned as a further development if the OntoWiki engine to support a natural representation of the document content, visual editing of the content, conserving the logical layer; implementation of the data and knowledge acquisition on the base of modification analysis. The templates for OntoWiki subjects rendering are stored beyond the ontology and separately from the main content of the document. In our case the templates are auxiliary elements of ontology, it can be logically inferred from inheritance. Most of the interrelations between text content and its logical structure are expressed in RDFa.

IX. Conclusion

The research is aimed at support of Semantic Web with algorithms and software automating text document markup and its logical model induction. The approach is based on polysystem representation of the domain and document content (e.g., web site) as an evolving ontology. The usage of polysystem of ontologies and the procedure of polysystem decomposition [2] allows us to solve a number problems in the activity related to knowledge acquisition in the domain. New knowledge are represented as fibers of categories with property of through cross-fiber interpretation. In the future, the possibility will arise for automatic construction of algorithms and programs implementing a fiber theory in the image and likeness of an already constructed ones. At present the polysystem of ontologies allows us to rate and categorize facts on the domain by analogy with the already known structures, as well as obtain new interpretations of new recognized concepts.

The main part of the paper is devoted to a general description of a technique of maintenance of an interactive process of logic model induction of document content on the base of data mining of changes of various versions of the document. A problem solution outline for user dialog conduction aimed at modification and extension of the logical model with new objects and relations has been considered. The dialog is maintained by analyzing the completeness of the constructed model and logical inference in the polysystem representation of the domain ontology. A pilot software architecture has been presented as well as brief overview of used modules and libraries, their properties and features have been assessed.

As a testing ground for the technologies under development we decided to automate a notarial office, where the legal document representations has both well formalized and unformalized text fragments. On the base of the technology a social network of document data exchange can be devised. The security of the document transfer can be provided as off-line data streams: each physical document is accompanied with its bar or QR-code encoding the corresponding RDF-data of the document.

Acknowledgment

The research is carried on under support of Integration multidisciplinary project of Siberian Branch of Russian Academy of Sciences N 17 Development of services and infrastructure of scientific spatial data for supporting complex multidisciplinary scientific research of Baikal nature territory.

***Abstract*—Software development technologies evolved from concrete algorithm design and their programmatic implementation to modeling the whole information systems (IS). The modeling approaches allows developers to describe the system in terms of a domain, software design, properties of implementation platforms, and standard ways of the IS development such as programming traditions in a concrete firm. In the case if a new IS is being constructed, having an already implemented database, Data Driven Engineering (DDE) is used. The model for IS is constructed by importing database structure and adding a semantic layer description reflecting the database structure to the domain terms.**

We describe a DDE-approach based on declarative specifications of existing database schema and properties of the target application, as well as interpretation of the description into IS components. The interpretation in various aspects allows developer to construct user interface for database modification, subsystem of SQL query construction in terms of domain, etc. An example of the technique application is presented.

I. Introduction

Software development technologies evolved from concrete algorithm design and their programmatic implementation to modeling the whole information systems (IS). The modeling approaches allows developers to describe the system in terms of domain, engineering and software design, features of implementation platforms and tools, and standards of the IS development of a software firm such as programming traditions, used modeling and instrumental tools, etc. Very simplified techniques of the modeling usages are infiltrated into nowadays production developer "philosophies", e.g., referred to as DRY (Do not Repeat Yourself), where each concept in a system must be defined only once. DRY is a basis of many open-source web development frameworks such as Django [1].

The theoretical basis of the modeling approach is model transformation theories and their software implementations, which are developed in the field of Model Driven Engineering (MDE) [2]. The transformations construct ultimately either source code modules realizing modeled structures or an operator interpretation of the models of an intermediate level like virtual machine byte code, SQL queries execution plan synthesis, and executable UML. Model transformation is based on recognition of a pattern structures in the source model, relating them to the model of development platform rules of transformation. The results of transformation are structures of a model of more specific (concrete) level of abstraction. At the lowest level the code generation routines are executed, which use source code templates. Thus, from the point of view of generative programming, one of main function of the transformation process is an intelligent configuration generation for the source code generators.

In the case if new IS is being constructed, having already designed and deployed database, Data Driven Engineering (DDE, a kind of MDE) is used. The model for IS is constructed by importing database structure, e.g. DDL-queries, analyzing it, and adding a semantic layer of the database structure description in IS's domain concepts and relations. In Laboratory of Complex Information Systems of Institute of System Dynamics and Control Theory at Siberian Branch of Russian Academy of Sciences, a number of DDE approaches has been developed based on declarative specifications and their run-time interpretations, as well as techniques automating the description process. The interpretation in various aspects allows developer to construct user interfaces for database modification, subsystem of SQL-queries construction in terms of domain, plugin integration, etc.

The report describes an DDE-approach of IS development based on a special specification language describing database properties, interpretation of the description in various IS components, resulting in automatic user interface construction and layouting; a configuration generation for constraint-oriented database editor, SQL-query builder, OLAP subsystem, etc.

II. The Description Language

The DDE-modeling of an IS starts either from description of a general view of data structures used by business-logic or from loading schema of already existing database. The second case has important value in practice, when customer requires a new implementation of an exiting IS with new features and with conserving exiting data in its warehouse.

The structural description allows developers implementing routine functionality via transformation and generation, e.g., data input forms; user interface and business-logic interaction; import, export and integration operations. Adding a domain description allows one to refine user interface with notions familiar to user, as well as construct various query-answering subsystems like SQL-query builders and OLAP operating in terms of the domain.

In Institute of System Dynamics and Control Theory at SB RAS a number of DDE technologies has been developed within economic contracts activities supported by necessary theoretical investigations. One of the recent description format

is based on mix of the `.ini`-file and SQL-query languages. The first format is used to describe database structure and semantic of attributes and their relations, the second part is used to describe the rules of user interface generation, and interaction with geographical information systems and other applications.

A. Development Stages

In the proposed approach, in a general case on the first stage of IS development, system engineer carries on structural analysts of the domain, resulting in description of concepts and their basic relations, business-processes and software requirements. After that, at the second stage, the database design follows, which produces database schema ad its implementation as database server. Common design tools (such as Sybase Power Designer, IBM Rational Rose) are used on this stage. The second stage is carried on if IS is designed from scratch, and there are no database already implemented.

On the third stage, the model of IS database is constructed by loading the implemented database schema and extending it with the description of the following special database object classes: `TABLE`, `VIEW`, `RULE`, and so called *superstructure*. The `TABLE` objects describe IS database structure and relations, attribute names and data types. These object are automatically constructed by loading and analyzing IS database schema, if it is literally devised (it must be at least in third normal form). The lack of schemata data is compensated manually with the description language and the following interpretation.

The `VIEW` objects, which are more complicated than `TABLE` ones, used to generate user interface. Here we define properties of the attribute and table relations, for example, for each foreign key a look-up widget can be used to select a record from a foreign table (a reference book). For a complex reference book and transitive references, the key attribute sets must be specified to increase generated user interface usability. There are other special cases of foreign key interpretations, like "master-details", and all of them can be described with the specification language.

The superstructure objects support interaction of developed IS with foreign modules and libraries, processing information with methods beyond the standard of rational databases and SQL, e.g., computer simulation and complex data visualization.

The `RULE` objects are responsible for expression of functions implementation in generated IS specific to its business-processes. By means of the rules, one can describe input field logic (enabling and disabling them), implement uniqueness check routines and plug-in modules interaction, i.e., rules provide declarative means of describing and implementing relationships between objects and components in business-logic layer of IS. The rules also affect the generated queries to IS database during editing, as well as creating special widgets in user interfaces, which connect input data with spatial tables and render cartographic. For all the object classes a formal set model is devised and investigated, resulting in a theoretical basis of the technology under development.

On the fourth stage, the IS functionality is generated at run time as a result of the specification interpretations. It integrates foreign software subsystems according to the rules.

B. The Description Language

Our specification language is reasonably simple whereas complete with respect to expressive abilities. The language has LL(1) grammar class. Its syntactic structures describe elements of IS and a general options like database connection properties. The specifications written in the language are *precise*, *understandable* and *complete* according to [3], [4]. The language clauses have the following general structure:

```
<Start keyword> <List of mandatory statements>
[ list of optional statements ]
```

The `Start keyword` can be one of the following: `ADO`, `BDE`, `CFG`, `TABLE`, `VIEW`, `PLUGINS`, `USES`, `INCLUDE`, `MENU`. First two are used to describe properties of database connection. Keyword `CFG` used to describe general application settings of IS. Keywords `TABLE`, `VIEW` describe the database schema and view widgets. Keyword `PLUGINS` describes interaction with outer systems; `USES` and `INCLUDE` allow developer to break an IS description into source modules. Keyword `MENU` controls the main menu of IS application.

Let's consider a part of an example description.

```
TABLE ADR FOR SP_ADDR AS 'Address' READONLY
```

This statement describes table `SP_ADDR` of IS, the table will have an alias `ADR` for usage in the rest of the specification. The table will have also a user-friendly alias `'Address'` in user interface forms, table editor, etc. The following language construction describes table fields.

```
FIELDS (ID_BUIL_G P AS 'Building Code',
        ID_NREG ^SP_NREG AS 'Region Code',
 ID_MK_GM ^SP_MK_GM AS 'Microdistrict Code',
        ID_STREET ^vSP_STR AS 'Street Code',
        BUIL=S AS 'Building',
        ANN=S AS 'Annotation');
```

Identifiers `ID_*`, `BUIL` and `ANN` are table fields. Sign `^` creates a reference to a table or a view, in particular, `^SP_NREG` is a table referenced by field `ID_NREG`, and `^vSP_STR` is a reference to a view. Expression `ANN=S` denotes that `ANN` is a string field. At the first line of the example, `ID_BUIL P` denotes that the field is a key field.

There are also more sophisticated ways of various reference denotation, expressed with a general `REFS(...)` construction. Its parameters allows one to define references of various IS business-logic interpretations including "master-details", special cases of "reference book" and so on.

III. Interpretation of Database Description

All current implementations of the interpretation of the specification language are run-time. After preparing the specification of the IS database, the IS developer must run the IS environment with the specification an the database as its input. The specification is translated, and the translator creates two data structures. One is stored in process memory as complex data structures and used by form and query builders. Another one is a technical database of tables, describing IS database

structures. The technical database is used by database editor and OLAP modules. The translator also checks whether the specification is changed and corrects the database accordingly.

A. User Interface Generation

One of the important IS quality characteristics is its input forms, and layouting the widgets in the forms is the question of usability. From one hand side the widgets must efficiently consume the area of a form, and on another hand side, the user interface must be convenient and fit to application functionality requirements.

We considered a number of approaches of user input form constructions, such as [5] and [6], and come to the conclusion: in order to improve usability of user input forms, we must account the domain properties of attributes. For the purpose, a rule-based engine has been developed, which uses the database specification to access the attribute properties. The engine interprets the database specification, adjusts Database Editor widget, and generates form for database records modification.

a) Database Editor: Database Editor controls a dynamic user interface operating over IS database records. Its layout includes three areas (panels): menu of entities, operations, and data table itself. Menu of entities (fig. 1, left panel) consist of database and view table names described in the specification. The entities are joined in semantic groups according to their roles and functions.

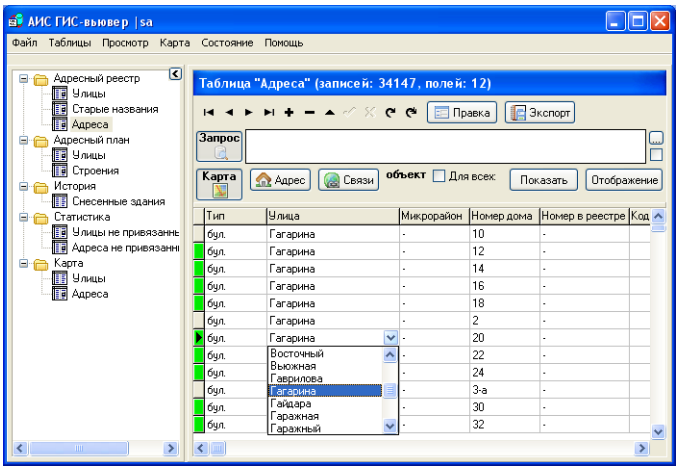

Figure 1. Database editor

The operation area (fig. 1, top panel) displays widgets for construction and execution of data processing operations. The set of widgets for each table (view) is controlled by the specification. The minimal set contains table navigation buttons, “Edit”, “Export” and “Query” buttons. Optional buttons are “Options” and “Cartographic”. The layout of the widgets is under control of layout manager.

The table area (fig. 1, bottom-right panel) displays the chosen entity. The data is represented in two views: tabular and as a form. Tabular form supports standard data editing operations, but they adjusted according to specification: reference fields are choice boxes and look-up widgets. Dependable (in sense of the specification) fields are changed as soon as their ascendant become edited. For example, in fig. 1 street name in an address record is chosen from a look-up list of streets. The street `ID` is stored in an address reference field, this results in changing address `TYPE` (boulevard or street) field according to the type of chosen street.

The order and widths of the table columns can be adjusted according to user’s preferences. The customization is stored in user profile `.wsf`–file.

b) Form Mode: In form mode, user input form is generated. The form widget set is created in accounting table’s references to other tables, views and visual components. The form is activated from Database Editor with a mouse click on “Edit” button, or when a creation of new record is requested. The layout of the widgets of the form is generated according to the database specification and run time context: whether this record belongs to a main table or a reference one. Each attribute editing widget is accompanied with a label showing user-friendly attribute alias from the specification. The label can signify attributes uniqueness, non-null condition and a membership in the primary key.

For each widget, placement, order, widths and width adjustment are controlled by layout manager component. The order and layout of the form must conform to criteria of usability. Upon form size change or screen resolution the widgets must be reordered, resized, and so on, conversing the usability criteria. The layout manager extends ideas of FlowLayout [7] (Java): the widgets a placed in rows from left to right.

FlowLayout manager implies that each widget has fixed size. We took over the restriction, and our layout manager takes advantage of some heuristics based on minimal (`szMin`), best (`szBes`), and maximal (`szMax`) sizes of a widget. Maximal size is equal to field data size, e.g., for `VARCHAR(150)` field, the `szMax` is equal to 150. Experience shows that it is more ergonomic to display about 70 % of `szMax`, and it is `szBest`. Minimal size for strings is taken about 10 characters.

The layout manager arranges the widgets according to the following strategy. At the first stage all three sizes are queried from the widgets, and the manager tries to figure out a layout,

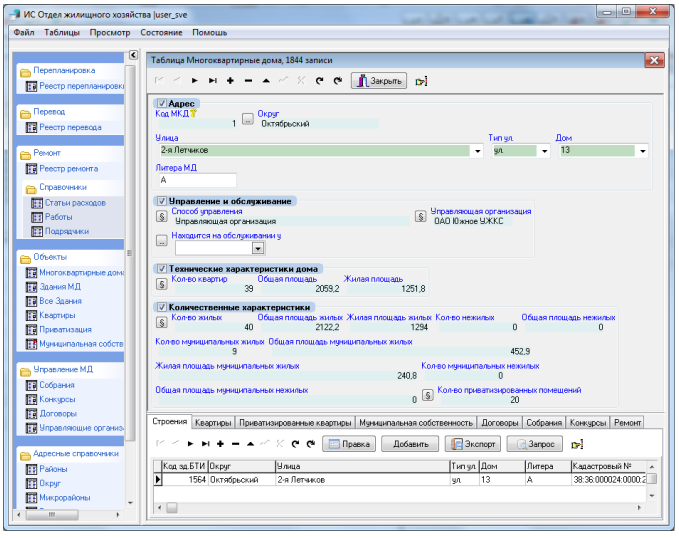

Figure 2. An example of autolayout form

where all the widgets have maximal sizes and placed in rows from left to right. If a widget is not shown in the form, the layouting immediately restarts the process, with `szBest` used as widgets sizes. If the layout process finished successfully and there are some free space, then the layout manager tries to extend significant widgets to their maximal sizes. In the wort case, when the second try has failed, the manager uses `szMin`.

Attributes can also be grouped according to a logical record structure, which a also defined in the specification. The groups are placed in the form as tab containers or group boxes, arrangement of the fields inside tabs is made analogously. An form generation example from "Address Plan" IS instance (described further) is shown in fig. 2.

B. Query Builder

Most of IS applications require components for data search and filtering. We developed an expressive user-friendly search engine module that allows one to quickly jump to a specific record and also allow a subject specialist to query record data from database without programmers assistance.

Query constructor of Microsoft Access allows user to design a complex SQL-queries for aggregating and modifying data. The query builder supports definition of complex conditions for the `WHERE` and `HAVING` sections of the query. The query builder also does not account the domain, and, thus, it is intended for programmers and experienced users accounted with database technologies. Another problem is the availability of SQL-query designer utilities for web projects.

In our work we proposed an engine that supports interactive specification of field value criteria and construction of combinations of logical and filter operations sufficient to describe common user queries. Query builder is a form that is configured in accordance to the specification and the table especially. The logical condition is a tree structure, which is drawn horizontally to allow long field names being displayed correctly without overlapping.

To control the tree editing, a special widget has been developed. The widget placed inside a dialog window is shown in fig. 3. The widget allows to construct tree from elementary operations, move the operations between various levels of nesting, operand switching, editing criteria values.

Extended mode of Query Builder widget supports referencing subordinal tables. Processing such references requires recursive call of the builder. For example, the query "Which streets of Leninsky and Sverdlovsky city districts [of Irkutsk] has more than two gas stations?" can be expressed by means of Query Builder as the following sentence: "City district is in 'Leninsky', 'Sverdlovsky' and Table 'Address' row count [is taken] from (Table 'Address building' has records from (Building type is in 'GS')) >=2." In this example two level of referencing is used: streets include addresses, at the same address can be situated several buildings. This results in generation of correlated subqueries interpreted as "master-detail" relations. The query builder generates SQL-query as follows:

```
SELECT T.id Id, T.reg_id reg_id, T0.type ST,
  T.name name, T1.name Distr, T2.name mk,
  T.BTI_id BTI_id, T.IsNew IsNew,
  T.IsChanged IsChanged from dbo.street T
LEFT OUTER JOIN dbo.street_type T0 ON
  (T0.Id=T.street_type_id)
LEFT OUTER JOIN dbo.distr T1 ON
  (T1.id=T.distr_id)
LEFT OUTER JOIN dbo.mkr T2 ON
  (T2.id=T.mkr_id)
WHERE (T1.id IN (8,10) AND (select count(*)
  from dbo.buildings S
WHERE (T.id=S.street_id) AND (exists
  (select * from dbo.bld R
WHERE (S.Id=R.ADDRESS_ID) AND (UPPER
  (R.HOUSE_TYPE) IN ('GS'))))))>=2)
ORDER BY T.id
```

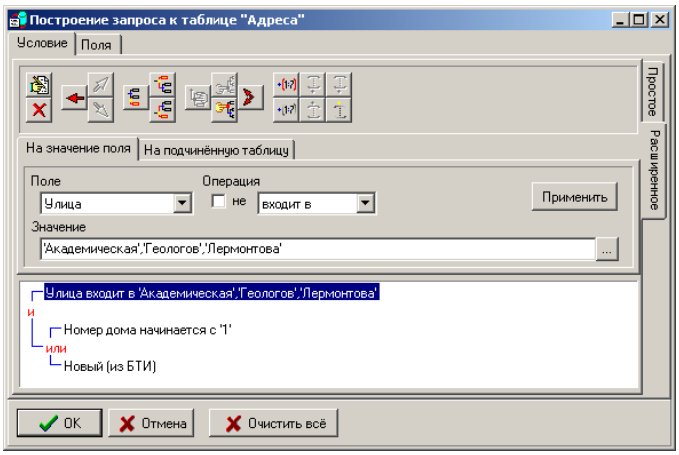

Figure 3. Subject specialist controlled query builder

C. On-Line Analitical Processing

Another valuable usage of specifications is to implement import routines of IS database data for On-Line Analitical Processing unit (OLAPu). OLAPu allows user to store, select and analyze numeric indicators. The indicators are considered as funtions of a set of attributes. OLAPu user interface aids selection of indicators in various attribute projection combinations.

OLAPu's design is a classic client-server architecture, where server is a rational data storage, and client provides a flexible access to the indicator data by means of intuitive user interface. The interface is configured specially to support the multidimensional OLAP. User selects and adjusts projection and indicator aggregation configuration by means of interface widgets, the results of the selection are presented as interactive tables and can be stored in Microsoft Excel spreadsheet files.

To convert IS data into a database of indicators suitable to be processed by OLAPu, `TABLE`, `VIEW` and superstructure objects are used. The data is converted into a tree of indicators. Each node of the tree corresponds to data selected in a projection. Each projection is characterized by a set of attributes. The sets are referred to as dimensions. They could describe regions, industries, types of ownership, etc. A special case of the dimensions is time intervals, such as year, half a year, quartal, month. Most of the indicators are tied to time intervals.

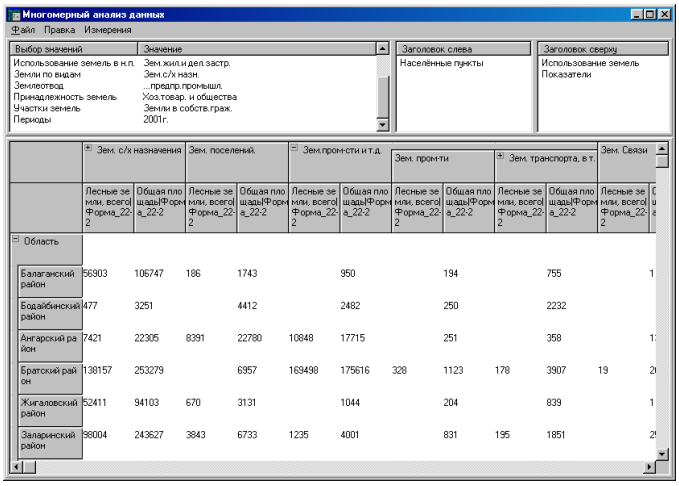

Figure 4. Main window of OLAP unit

The indicator data usually have more complex structure than just a linearly ordered set. In a general case, the set is a tree structure, where one indicator aggregates data of a set of subordinal indicators, e.g., state indicator aggregates state regional data. The same is true for industries. The indicator database includes all the index dimension attribute references to the original tables of the IS database and the index value itself.

The main windows of OLAP unit is shown in fig. 4. The window has been divided on two parts. The upper part consist of three panels with dimension lists, and the lower part is the resulting table. User must select an indicator from the left list of dimensions as well as the dimensions associated with columns and rows of the resulting table. The headers of rows and columns may contain combinations of dimensions. In this case for all the combination a row (column) is inserted into the resulting table widget. The combinations of dimensions and attribute value filters are adjusted with mouse clicks.

Time intervals are selected with a special pop up dialog widget on mouse click. User can drag dimensions between lists and reorder them, this results in regeneration of the resulting table. When editing is allowed, user can change values of indicators directly in the resulting table cells. The changes are immediately stored into the intermediate database of IS and written into a journal for eventual import into original IS database. The table widget allows exporting data and table structure into system clipboard in a table format recognizable by Microsoft Excel, the same is implemented in the opposite direction.

D. Report Builder

Report Builder unit is a plug-in module, that has access to internal representation of the specification via API. Report Builder functionality is based on Microsoft Word documents. The report templates are constructed as texts with special placeholder identifiers (mark points), which are replaced with data. Report Builder templates are listed in the specification as well as the associated `TABLE` and `VIEW` objects. The mark point language is as follows:

```
<Mark Point> ::= <# <Data Domain>
                 <Place Holder> [ <Format> ] >
<Data Domain> ::= TF | PN | IMG | DETAIL
<Place Holder> ::= <Field Name> | <PN> |
                 <Detail Reference>
<FN> ::= SN=<Field Name> FN=<Field Name>
         MN=<Field Name>
<Field Name> ::= N=<Char>+ | <Digit>*
<Detail Reference> ::= <Field Name>
<Format> ::= <Case> | SHOW
<Case> ::= CASE= ( N | G | D | A | I | P )
```

In the report engine, a conditional processing has been implemented. The following special case of mark point construction is used:

```
"<#" IF <Field Name> <Value> ">"
     <Output> "<#ELSE>" <Output> "<#END>"
<Value> ::= V=<Char>* | <Digit>*
<Output> ::= <Mark Point> | (<Char>*|<Digit>*)
```

IV. GIS Integration: a Usage Example

The developed technologies are applied in GeoAW (Geological Automatized Workplace) environment, which is aimed at construction of GIS for municipal authorities. Its derivative GIS systems allow one to represent data accumulated in departments as GIS cartographic. In order to construct such system developers must go through the steps described early to describe data sources and filter data to be represented in new GIS applications. The main attention should be paid to spatial related attributes, as the attributes are used in connecting the table rows and graphics shapes of topographic base.

GeoAW environment is an instrumental tool to create stand-alone Windows GIS applications. Its architecture is shown in fig. 5. GeoAW consists of the following main software components: Specification Management, System Kernel, Database Editor, user Query Builder, Plugin Interface, and GIS as external application.

The GeoAW GIS module is implemented on the base of authors' extension of GIS Toolkit, which is popular in Russian government "Panorama" [8]. Panorama is a COM-server incorporated in applications. The COM-server object can be configured so that the user of IS could reach only allowed GIS data on the cartographic base, namely by running under a special Windows user account. The IS data are transferred to the COM-server process and shown as cartographic (fig. 6).

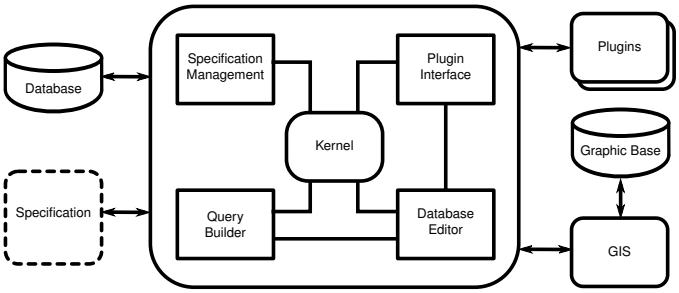

Figure 5. GeoAW instrumental environment architecture

The resulting integration of Address Plan IS and GIS Toolkit has functions relating to selection of objects on the map and showing tabular data with main IS module. At the same time, filter queries over tables having spatial attributes can affect the semantic layer presentation on cartographic.

Therefore, the example showed that the instrumental GeoAW environment fully supports all the functions for specification development, their interpretation as configurations of all modules related to IS data aggregation, storage and processing. The developed technique and software technologies allows one to organize robust and productive IS development. The resulting application is generated dynamically without compilation of any source codes.

V. Further Development

In further work the description should be extended with an additional superstructure, which could be used to extend the capabilities of SQL-query constructor to allow user formulating the query in a natural language in terms of modeled domain. The superstructure expands the description of the database entities and their relationships with abstract notions of domain and relations, resulting in fibered representation of the domain of two fibers: abstract domain and database structure [9], [10].

Another direction of development is further extension of the interpreter and creating a code-generating version of the description language on the base of nowadays techniques of language-oriented programming [11].

VI. Conclusion

The nowadays techniques of application software development are aimed at close cooperation of developer and customer. To shift some responsibility to the customer's users and to extend the maintainability and usability of software, it is necessary to develop techniques, which produce some processing according to a domain description. This description is to be connected to the models of various aspects of the software, in particular, database schema.

In this report we considered such description language, which allows programmer to express database schema in terms of domain via human-readable aliases for the database structure elements, references (foreign keys) can be classified as "master-detail", "reference book" and other relationships. The language is interpreted into configurations of modules for database editing, record adding and modification, query construction, report generation, OLAP and so on. The language expressiveness is sufficient to support development of municipal GIS software. As a part of programmer efforts within the proposed approach are aimed at extending language interpreter, user interfaces generated out of the description have good usability characteristics. Very frequently it is much better than the original software.

Importance of Network Nodes for Navigation with Fractional Knowledge

Denis Helic, Florian Geigl

***Abstract*—Due to sheer size of today's information and social networks people and algorithms are limited in their knowledge about those networks. Since this knowledge is important in many processes taking place on such network, e.g. search and navigation, an interesting question is how this fractional knowledge should be constituted and structured. For example, when agents navigate an information network the question is what are the most important nodes for an efficient navigation. In this paper we apply machine learning techniques to learn an optimal division of network nodes into two classes: nodes that are important for navigation and nodes that are not important for navigation. We learn this optimal classification by maximizing the correlation between global and fractional knowledge about a network. For learning we resort to MCMC methods such as Simulated Annealing and a simple approach for random assignment of nodes to classes. We perform a series of experiments by applying our optimization algorithm to synthetic networks with different community structures to shed more light into the relation between network structure, the node structural properties such as various centrality measures, and node classes produced by the algorithm.**

I. Introduction

Search in a network is a dynamical process in which an agent (a human or an algorithm) moves along the links between the nodes in search for a given target node or a given set of target nodes. In an informed search the agent possesses global or fractional background knowledge of the network, which guides it towards selecting specific links. In both cases, background knowledge is a certain numerical representation of the quality of a link (or the destination node incident to that link) with respect to reaching given target node(s). The distinction between global and fractional knowledge can be summarized as follows. In case of the global knowledge the numerical representations are calculated from the complete knowledge of the network, i.e. the agent knows about every node and every link in the network, whereas in the case of fractional knowledge the agent knows only about some selected nodes and links.

Due to sheer size of today's information and social networks people as well as algorithms are typically limited in their knowledge about those networks. For a typical network it is only possible to have knowledge about certain nodes and links, e.g. in a social network people only know their local friend circle, and additionally a couple of very famous and popular people. In a typical case they will lack knowledge about other people's friends with whom they do not share friends. Similarly, in a information network such as Wikipedia users have knowledge about their topic of expertise or interest, and about some general and well-known concepts, however they will typically lack knowledge in the areas that they are unfamiliar with.

This situation raises an interesting research question. In a situation with limited time and resources to learn about the networks, their nodes, links and structure how can we optimally invest those resources. In other words, what nodes and/or links are the most important ones to know about to efficiently navigate the networks even with a fractional knowledge about those networks. For example, if an agent has resources to learn about a few of currently unknown network nodes, which nodes should she learn about? Which strategies should we apply when learning about a network? Should we first learn about e.g. high-degree nodes, or about nodes with a high local clustering?

In this paper we set out to answer this question by:

(i) Defining a global criteria for assessing the quality of fractional knowledge,
(ii) Applying machine learning techniques to learn an optimal division of network nodes into two classes: nodes that are important for navigation and nodes that are not important for navigation, and
(iii) Analyzing the properties of important nodes and generalizing our findings to a heuristic for learning about new network nodes.

The paper structure follows approximately the presented questions. In the next Section we give a short overview of the related work in this field. In Section III we describe the objective function for the quality of fractional knowledge. Section IV gives the details about our optimization experiments with fractional knowledge of synthetic networks. In addition, we present the experimental results and shortly discuss them in that Section. Finally, we conclude the paper and provide directions for further research.

II. Related Work

Search has been an important concept in theoretical and empirical studies of networks. For example, in Web search the famous PageRank calculation [1], which determines the importance of Web pages is based on a random walk on

the Web network. In a so-called Random Surfer model a hypothetical user navigates the Web by clicking randomly on the Web links. In the limit of large number of clicks the fraction of visits to each Web page gives its PageRank.

Research on decentralized search in social networks started with Milgram's seminal small world experiment [2] in which he aimed to study the connectedness of the US society. Milgram found that people in such a large social network are connected by short chains of acquaintances. Moreover, he found that people are able to navigate large social networks efficiently, i.e. that they are able to find those short chains even if they only possess the local knowledge of the network. In the subsequent research, Kleinberg analyzed the second result of the Milgram's experiment – the ability of humans to find a short path when there is such a path between two nodes [3]–[5]. Kleinberg concluded that social networks possess certain latent properties that humans are aware of. This background knowledge of network structure allows humans to find a short path between two arbitrary network nodes efficiently. Independently, Watts [6] introduced the notion of social identity as a membership in a number of social groups organized in hierarchies and showed the existence of efficient decentralized search algorithms by simulation. Finally, Adamic [7] and others applied such a model to explain search in e.g. professional social networks.

All of these models have been based on the assumption that an agent navigating the network possesses a complete background knowledge on distances or similarities between pairs of network nodes. Contrary to that, in [8] the authors argued that distances between nodes are typically available only for some of the node pairs and that the assumption that an agent possesses a complete background knowledge is unrealistic. Thus, the authors analyzed an informed search algorithm that bases its decisions on the node degree (the number of nodes adjacent to a given node), a quantity that is always available locally. The algorithm performed better in comparison with a random walk but could not reach the performance of an agent having a complete background knowledge.

Additionally, decentralized search can be used to model user navigation in an information network, e.g. the Web or Wikipedia [9]. In that model the user navigates from a Web page to a Web page by following her own intuition and her own knowledge about the topics of various Web pages.

A crucial element of an informed search is the notion of distance or similarity between the pairs of network nodes. Mathematically, we may represent the background knowledge with a distance or a similarity matrix. The rows and columns of the similarity matrix represent the network nodes and the elements of the matrix give the similarity score between corresponding network nodes. If the similarity function is symmetric we obtain a symmetric similarity matrix. Partial background knowledge may be easily represented by blank elements in the matrix for those node pairs where the agent's knowledge is missing.

Different similarity measures have been previously discussed in the literature for various tasks. For example, [10] gives an overview and evaluation of various similarity measures for the link prediction task. In general, similarities in networks can be calculated from external or exogenous information about the networks (e.g. textual content in an information networks), or from internal or endogenous information (internal linking patterns). There are two possible similarity measures based on the network linking patterns: structural equivalence measures and regular equivalence measures. Structural equivalence is based on the simple idea that two nodes are similar if they share many of the same network neighbors, whereas regular equivalence between two nodes is given if they have neighbors who themselves are similar. Since absolute numbers of common neighbors are hard to interpret, this number is typically normalized. Different normalizing constants give rise to different similarity measures such as cosine similarity, Pearson correlation coefficients, or Euclidean distance ([11] gives a nice overview and comparison of various normalization methods). In contrast, regular equivalence between nodes is established when two nodes do not necessarily share same neighbors but rather they have neighbors who themselves are similar, or in a more simple case two network nodes i and j are similar if j is similar to other neighbors of i. In past, several simple algebraic measures have been developed to measure regular equivalence [12], [13].

III. Methodology

A. Katz Similarity

In this paper we represent the knowledge about network as a similarity matrix. We denote the similarity matrix with $\boldsymbol{\sigma}$ – the element σ_{ij} of the matrix gives the similarity between nodes i and j from the network. Further, we concentrate on a particular measure of similarity called Katz similarity [10].

Let us now first introduce the basic quantities relevant for measuring this similarity. Let us denote the adjacency matrix of a graph $G(V, E)$ with $\boldsymbol{A}$:

$$A_{ij} = \begin{cases} 1 \text{ if nodes } i \text{ and } j \text{ are connected by a link} \\ 0 \text{ otherwise.} \end{cases} \tag{1}$$

We define Katz similarity recursively as [14]:

$$\sigma_{ij} = \alpha \sum_k A_{ik}\sigma_{kj} + \delta_{ij}, \tag{2}$$

where δ_{ij} is Kronecker delta ($\delta_{ij} = 1$ if and only if $i = j$, otherwise $\delta_{ij} = 0$).

The idea is that the term σ_{kj} is large if the neighbor k of i is similar to j. We then sum over all neighbors of i, which is ensured by the product $A_{ik}\sigma_{kj}$ since A_{ik} equals 1 only if i and k are neighbors. Finally, the term δ_{ij} assigns a high value of "self-similarity" of a node to itself. The constant α weights the influence of neighbors as compared to the influence of the self-similarity to the nodes similarity.

We can write the expression for the Katz similarity in the matrix form as:

$$\boldsymbol{\sigma} = \alpha \boldsymbol{A}\boldsymbol{\sigma} + \boldsymbol{I}, \tag{3}$$

where $\boldsymbol{I}$ is the identity matrix.

We can now solve this equation for $\boldsymbol{\sigma}$, which gives us the following:

$$\boldsymbol{\sigma} = (\boldsymbol{I} - \alpha \boldsymbol{A})^{-1}. \quad (4)$$

In case of large networks with e.g. millions of nodes, inverting a matrix is computationally expensive. Therefore, we may want to evaluate the Equation 3 recursively. We would typically start by assigning initial values for similarity to zero, e.g. $\boldsymbol{\sigma}^0 = 0$. We then obtain (for the first three iterations):

$$\boldsymbol{\sigma}^0 = 0, \boldsymbol{\sigma}^1 = \boldsymbol{I}, \boldsymbol{\sigma}^2 = \alpha \boldsymbol{A} + \boldsymbol{I}, \boldsymbol{\sigma}^3 = \alpha^2 \boldsymbol{A}^2 + \alpha \boldsymbol{A} + \boldsymbol{I}. \quad (5)$$

Thus, in the limit of large number of iterations m we have:

$$\boldsymbol{\sigma} = \sum_{m=0}^{\infty} \alpha^m \boldsymbol{A}^m. \quad (6)$$

The elements of matrix $\boldsymbol{A}^m$ at index i and j, i.e. $[\boldsymbol{A}^m]_{ij}$ give the total number of paths of length m between nodes i and j. The Katz similarity can be seen as a weighted count of all paths between the nodes i and j with paths of length r getting weight α^r. As long as $\alpha < 1$ longer paths obtain less weight than shorter ones.Thus, two nodes will be similar if they are connected either by few short paths or if they are connected by many longer paths.

The inverse of $(\boldsymbol{I} - \alpha \boldsymbol{A})$ does not exist for $det(\boldsymbol{I} - \alpha \boldsymbol{A}) = 0$, which is exactly the characteristic equation for eigenvalues of $\boldsymbol{A}$, i.e. in the matrix form $\boldsymbol{\lambda} = \mathbf{1}/\boldsymbol{\alpha}$. Thus, the inverse does not exist whenever $1/\alpha$ equals λ_i. If we start with $\alpha = 0$ and gradually increase it, we first hit the equality $1/\alpha = \lambda_i$ for the largest eigenvalue λ_1, and then again every time when we approach the next eigenvalue. Thus, if we pick an $\alpha < 1/\lambda_1$ we ensure that the inverse exists (or that $\sum_{m=0}^{\infty} \alpha^m \boldsymbol{A}^m$ converges).

B. Correlation between global and fractional knowledge

A nice property of the Katz similarity is that with the parameter α we can control the amount of knowledge that we have about a particular network. For example, setting α closely to the upper bound $1/\lambda_1$ weights also even very long paths significantly. For example by setting e.g. $\alpha = 0.5$ paths of length 4 are weighted with 0.0625 and even paths with with length 8 are weighted with 0.00390625. Thus, we may argue that the similarity is calculated with a complete global information about the network. On the other hand by setting a small value for α, e.g. $\alpha = 10^{-8}$ even path of length 2 are negligible since their weights are 10^{-16}. In other words for smaller values of α the information kept in the Katz similarity matrix is only local. In an extreme case where only paths of length 1 obtain a significant weight the Katz similarity matrix is equal to the adjacency matrix up to a constant and the diagonal entries.

Thus, a possible global criteria for comparing the global knowledge (Katz similarity matrix with a large α, e.g. $\alpha = 0.99/\lambda_1$) and a local knowledge (Katz similarity matrix with a small α, e.g. $\alpha = 10^{-12}/\lambda_1$, or even the adjacency matrix) can be a correlation (Pearson correlation coefficient ρ) of those two matrices. The correlation would be high if we observe links between two very similar nodes according to the Katz similarity and it would be low if that is not the case.

For example, suppose that we have two nodes in the network that are not directly connected to each other but are connected by many paths of length 2 and more. Those two nodes will have a high Katz similarity with a strongly weighted long paths. Because they are very similar we would expect that they are connected to each other where in fact they are not. If we have many such pairs in a network than the network would be non-navigable with the local information only – we would need the global information to navigate this network efficiently. For such network the correlation between the Katz similarity matrix and the adjacency matrix would be low.

Let us now formalize the notion of the correlation between the global and the fractional knowledge. Let $\alpha_{max} = 0.99/\lambda_1$ be the α parameter for calculating the Katz similarity matrix with the global knowledge. Let us call this global knowledge matrix $\boldsymbol{\sigma}^g$. With $\boldsymbol{\sigma}$ being a similarity matrix for an arbitrary α from the permited interval we define the Pearson correlation coefficient ρ as:

$$\rho_{\boldsymbol{\sigma}^g, \boldsymbol{\sigma}} = \frac{cov(\boldsymbol{\sigma}^g, \boldsymbol{\sigma})}{\sqrt{var(\boldsymbol{\sigma}^g) var(\boldsymbol{\sigma})}}, \quad (7)$$

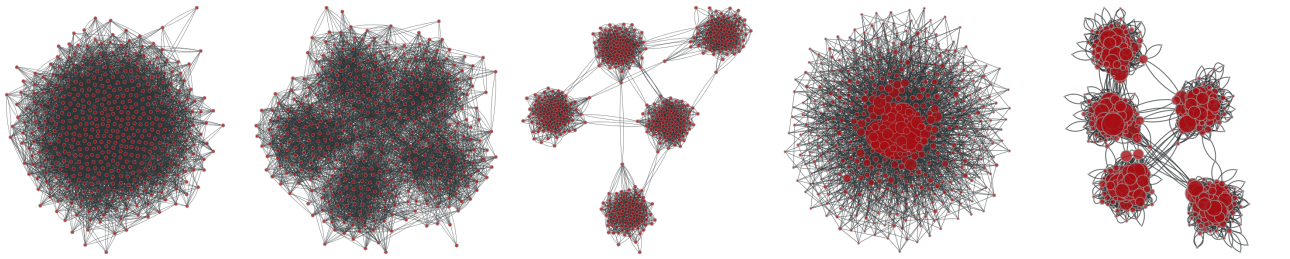
where we first vectorize the similarity matrices to calculate covariance and variances.

After we calculate the correlation between the global knowledge and adjacency matrix we may calculate further correlations by adjusting the parameter α. Thus, we start with a small α and slowly increase it until we reach the α for the global knowledge. The correlation will slowly start to increase until we reach 1. By comparing the current value of the parameter α with the maximal one we can deduce the fraction of knowledge that we need to have to reach a certain level of correlation with the global knowledge.

C. Illustration on synthetic networks

We now illustrate this correlation coefficient on synthetic networks. The goal is to generate networks that structurally closely reflect a typical social or an information network. Although the real networks exhibit a wide range of interesting structural properties we concentrate on two which have been observed in the majority of networks from different domains: (i) degree heterogeneity (where we typically have only a few of high degree and mid degree nodes that keep the network connected), (ii) and modular or community structure (with various groups of nodes that are tightly connected with each other and only loosely connected to other communities – typically via high and mid degree nodes). Such networks reflect also typical search scenarios such as search for a similar node within the same community and search for a distant target node in another community. We generate the following networks:

(i) random networks using the standard Erdős–Rényi [15] or Bernoulli graph model as a random baseline,



(a) Random Network (b) Weak Communities (c) Strong Communities (d) Power-Law Network (e) Power-Law Net. with Comm.

Fig. 1. **Synthetic networks.** The networks have 500 nodes and 2500 links. The structural differences between networks are clearly visible. In the visualizations of the power-law network as well as the power-law network with the communities the node size corresponds to its degree clearly depicting the heterogeneity of the node degrees in these networks.

(ii) networks with weak communities using Stochastic Block Models [16],
(iii) networks with strong communities again using Stochastic Block Models,
(iv) power-law networks using Barabási–Albert model [17],
(v) networks with strong communities with degree-corrected Stochastic Block Models [18].

We generate 6 groups of networks: the first three groups with 500 nodes and 2500, 5000, 10000 links respectively and the second three groups with 1000 nodes and 5000, 10000, and 20000 links. Networks with communities have always 5 communities of equal sizes. Additionally, we repeat generation 10 times and report always average values with the standard error of the mean in our diagrams. Figure 1 visualizes examples of the generated networks.

In Figure 2 we report the results for the networks with 1000 nodes and 10000 links. We observe similar results in all other networks. The results may be summarized as follows. The random networks exhibit consistently the lowest correlation between global and local or between global and fractional knowledge. This corresponds to our intuition about the random networks. Since the links are created at random there are no structural clues in these links that could steer our local decisions during the navigation. The correlation between global and local as well as fractional knowledge in networks with weak communities is slightly higher than for the random networks. The weak communities represent the structural clues that we can utilize when navigating locally, e.g. within a community we will have more links to other similar nodes from the community. The situation improves even more if the communities become stronger – the correlation is higher in networks with strong communities. A similar phenomenon can be observed in power-law networks. The existence of highly connected hubs provides structural clues that correspond to the links in the network, i.e. a hub is similar to many other nodes in the network and a hub has indeed many links to other nodes. Finally, the highest correlation can be observed in networks with degree-corrected communities. Here we have structural clues related to the node degrees as well as to the similarity of nodes within a community. For example, the correlation between the adjacency matrix and the global knowledge is already around 0.6 and improves steadily to e.g. correlation of almost 0.8 with only 50% of the global knowledge.

IV. Experiments and Results

In our experiments we are now interested in the following question. Suppose that we have available resources to learn global information about a given fraction of nodes in a network, e.g. 1%, 5%, or even 10% of nodes. The question is then which nodes are "good" or "optimal" nodes to know about. Having defined the correlation between the global and fractional knowledge ρ in the previous section we may use this quantity as a reasonable global criteria for selecting informative nodes to learn about. We can now think about this node selection procedure as an optimization problem. Thus, we want to know about global information for a given number or fraction of nodes such that the correlation between the global and the fractional knowledge constituted with the selected nodes is maximized.

Let us now formalize the optimization problem in the following way. We first introduce a division vector $\boldsymbol{s}$ as:

$$s_i = \begin{cases} 1 \text{ if we have global information about node } i \\ 0 \text{ otherwise.} \end{cases} \tag{8}$$

With k we denote the number of nodes about which we have global information, i.e. it is the number of 1s in $\boldsymbol{s}$.

Further, we define $\boldsymbol{\sigma^s}$ as the fractional knowledge matrix. This matrix is constructed in the following way. We start with the adjacency matrix $\boldsymbol{A}$ and replace those rows and columns in the adjacency matrix with the corresponding rows and columns from the global Katz similarity matrix $\boldsymbol{\sigma}^g$ for those nodes where we have global information. Formally, we have:

$$\boldsymbol{\sigma}^{\boldsymbol{s}}_{ij} = \begin{cases} A_{ij} \text{ if } s_i, s_j = 0 \\ \boldsymbol{\sigma}^g_{ij} \text{ otherwise.} \end{cases} \tag{9}$$

Finally, we may formalize the optimization problem as follows:

$$\boldsymbol{s}_{max} = \underset{\boldsymbol{s} \in D(k)}{\operatorname{argmax}} \rho_{\boldsymbol{\sigma}^g, \boldsymbol{\sigma}^{\boldsymbol{s}}}, \tag{10}$$

where $D(k)$ is the set of all divisions with k 1s in $\boldsymbol{s}$. Now, D has the cardinality of $\binom{n}{k}$, where n is the total number of nodes in a network. With increasing k the number of possible divisions grows rapidly and reaches the exponential limit with

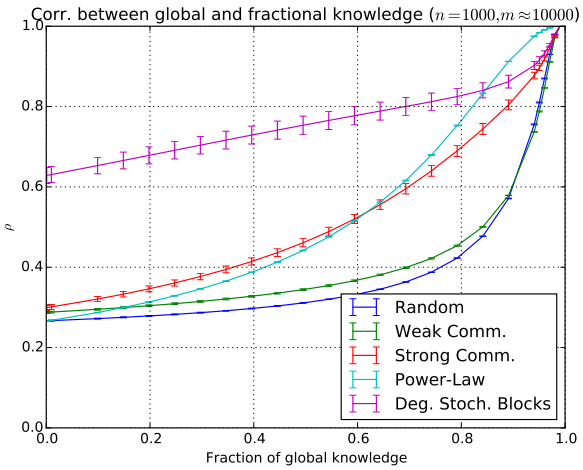


Fig. 2. **Correlation between global and fractional knowledge.** The diagram depicts the correlation between global knowledge and increasing fractional knowledge. The correlation is low in networks where the structural clues in links are weak such as random networks or networks with weak and blurred community structure. In networks with stronger clues such as power-law networks or strong community structures the correlation increases quickly with increased amount of knowledge. The highest correlation can be observed in networks which are rich in structure in that they exhibit both: heterogeneity in node degrees as well as a rich and strong community structure.

e.g. $k \approx n/2$. Thus, to solve the optimization problem we will need to resort to a heuristic optimization strategy.

For our experiments we adopt a stochastic approach, in particular a well-known Markov Chain Monte Carlo optimization algorithm called Simulated Annealing [19]. In this algorithm we start be exploring the configuration space by randomly moving around that space. In our case a random move corresponds to randomly selecting a given number of nodes (e.g. 1 to k) and setting their corresponding s_i to 1. To satisfy the condition that the total number of nodes that we know about is always k we then randomly select the exact same number of known nodes and unlearn them by setting their s_i to 0. We then evaluate the Pearson correlation coefficient (ρ_{new}) with the new matrix $\boldsymbol{\sigma}^{\boldsymbol{s}}$ and accept the move if the correlation (ρ) has increased from the previous iteration step. Otherwise if the correlation is smaller than previously we can still accept it with some small probability. In our experiments we use the standard Metropolis-Hastings acceptance scheme and accept with the probability:

$$p_{accept} = min(1, e^{\frac{-\Delta E}{T}}), \tag{11}$$

where:

$$\Delta E = \rho - \rho_{new}, \tag{12}$$

and T is the control parameter or temperature. By slowly adapting the control parameter, i.e. by cooling the system we become more restrictive and accept less and less random moves concentrating in this way around an optimal solution. In general, this optimum is only a local maximum, however by a proper configuration and multiple starts we almost always find the global maximum in practice. The only drawback of the method is that it is typically very slow as it requires a large number of iteration steps and a large number of different temperature levels.

We generate 10 networks with strong communities with degree-corrected Stochastic Block Models with 500 nodes and approximately 2500 links as described previously. By Simulated Annealing we then select optimal $\boldsymbol{s}$ with 5 nodes for which we have the global knowledge. The progress and the results of the optimization algorithm, as well as the comparison with the $\boldsymbol{s}$ where 5 nodes are selected according to a specific centrality measure are shown in the Figure 3. We show examples of two networks with all other networks having similar results.

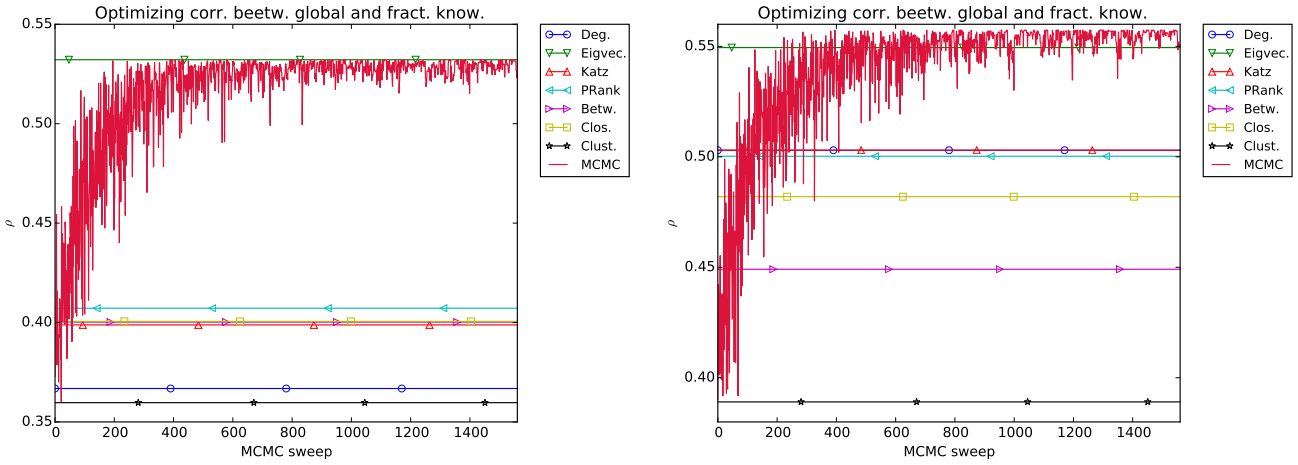
The results may be summarized as follows. With Simulated Annealing we are able to find an optimal solution that increases the Pearson correlation coefficient significantly. For example, the correlation between the global and local knowledge is typically in the interval [0.3, 0.35]. By optimizing for only 5 globally known nodes we are able to raise the correlation coefficient to range [0.55, 0.65], which seems as a great improvement over a local knowledge. Thus, we may assume that by knowing only 1% of "important" nodes we may already have a 60% fraction of the global knowledge. This assumption would need to be confirmed experimentally, e.g. by simulating navigation with the optimal fractional knowledge.

Another interesting experimental result is the comparison of the optimal results with 1% of nodes selected by a given selection criteria. For selection criteria we resort to a wide range of well-known and established centrality measures including degree, eigenvector, Katz, PageRank, betweenness, and closeness centralities, as well as clustering coefficient. Our results suggest that only the eigenvector centrality used as a criteria for node selection can match the optimal solutions obtained by our MCMC method. Thus, selecting 5 top nodes according to their eigenvector centrality will either provide the optimal solution or come very close to the optimal solution (cf. Figure 3). None of the other centrality measures can provide consistently good correlations with the global knowledge. On the other hand, clustering coefficient consistently produces the worse results and should be avoided as a selection criteria.

These results can be explained in the following way. Eigenvector centrality of a given node is high either if this node has a lot of neighbors or if that node is connected to other nodes with high eigenvector centrality. In other words, a node has many links that can steer navigation in various directions and therefore this node is important for navigation, or a node has a few links but all of them to other "important" nodes that may have many links themselves. Thus, either a node can lead a search agent into a proper direction or it can lead an agent to a neighbor that herself has an appropriate link.

V. Conclusions

In this paper we: (i) defined a global criteria (Pearson correlation coefficient between the Katz similarity matrix with the global knowledge and a Katz similarity matrix with a



(a) Random Network

(b) Weak Communities

Fig. 3. **Optimizing fractional knowledge.** A typical correlations obtained by Simulated Annealing. With only 5 optimal nodes globally known (that is with 1% od nodes globally known) we are able to reach correlation values above 0.55 in those two networks. We observe similar or even better results in other simulated networks. We compare the correlation obtained by Simulated Annealing with correlations with 5 globally known nodes which are 5 top nodes according to a given centrality measure. Thereby, the eigenvector centrality perform much better than other centrality measures, i.e. by selecting 5 top nodes corresponding to their eigenvector centrality we are in almost all cases at the optimal (left) or nearly optimal (right) solution. Other centrality measures can not be categorized consistently with the clustering coefficient as being always the worse criteria for selecting globally known nodes.

fractional knowledge) for assessing the quality of fractional knowledge for navigation, (ii) applied MCMC techniques (Simulated Annealing) to select nodes that are important for navigation, and (iii) compared the important nodes according to various centrality measures with the nodes selected by the optimization algorithm. The eigenvector centrality is consistently the best indicator for the quality of nodes for the navigation task.

The main limitation of our work is the theoretical nature of the analysis. Specifically, we performed all of our experiments on synthetic networks. The next step would be to conduct experiments with empirical networks and compare the results with the synthetic networks. However, we leave these experiments for the future work.

Using latent features to measure the diversity of recommendation lists

M. Kunaver*, Š. Dobravec* and A. Košir*
* University of Ljubljana/ Faculty of Electrical Engineering, Ljubljana, Slovenia
matevz.kunaver@fe.uni-lj.si

Abstract - One of the well-known issues with content recommender system is that they tend to become over-specialized, which often has a negative influence on user experience. This can be solved by diversification of the recommendation list, a process that implements a tradeoff between accuracy and diversity of recommended items. Normally, item metadata is used in the diversity measure. In certain cases however, the item metadata may not be available thus a different approach to measure diversity is required. The aim of this preliminary study is to determine whether latent features can be used to measure the diversity of recommended items. In order to resolve this we generated recommendation lists for 43 different users using the LDOS-CoMoDa dataset. We then evaluated the diversity of these lists using the standard intra-list diversity measure. In addition we calculated the diversity of each list by comparing the latent features (calculated using the matrix factorization approach) of each item on the list. The comparison of both value sets showed that they show similar characteristics which implies that latent feature space offers an alternative method of evaluating item diversity when no metadata is present.

I. INTRODUCTION

The rapid development of recommender systems (RSs) has led to a change of focus from simply generating recommendations for the user to generating recommendations that consider the user's context [1][2] and personality in order to improve the recommendation results[3]. In addition most of the existing recommender systems are encountering the problem of overspecialization which can have a negative impact on the user experience.

This led to the search for improvements that would help RSs present the user with a selection (a subset) of results that would be the most appropriate for the situation in which the user desires to review the selected results.

One of such improvements is the diversification [4][5][6][7] of recommendation lists that specifically aims to correct the overspecialization problem.

A. Motivation and goal

One of the problems with the diversification of recommendations lists is the measure used to determine the diversity of these lists. One of the more frequently encountered diversity measures is the intra-list diversity (ILD) [7] that was for instance used as one of the comparison parameters in the ESWC diversity challenge [8].

After participating in the challenge and a further development of our diversification approach [9] we focused on the evaluation measure itself. One of the problems of ILD is that it relies on having access to the meta-data (categories and attributes) description of each recommender item. This also implies that the accuracy of this method depends on the level and complexity of meta-data available – the more data available the more accurate the measure. Last but not least this also opens the question of using this measure in collaborative systems that i.) do not need metadata for the recommendation procedure and ii.) can contain items of different types (movies and music for example) which can be described with different metadata ontologies.

The aim of this study is therefore to determine whether we can use alternative item features such as Matrix Factorization (MF) latent feature vectors [10] to evaluate the diversity of recommended item lists. For this purpose we revised our previous research [9] and re-evaluated our results using ILD and our proposed latent feature based measure.

II. MATERIALS AND METHODS

In this section we describe the dataset, the baseline RS used to generate recommendations, the diversification methods and the compared evaluation methods.

A. Dataset

For the purposes of our research we used the Context Movie Dataset (LDOS-CoMoDa) [11], that we have acquired in our previous work. The dataset was collected using an on-line application for rating movies (www.ldos.si/recommender.html) that enabled the users to track the movies they have watched and to obtain recommendations from several RS algorithms. In addition, the application features a questionnaire whose purpose is the collection of the contextual data describing the situation during the item consumption.

The dataset currently consists of 4237 ratings given by 184 users to 1782 items. Each rating is also annotated with associated contextual variables. Each user is described with basic demographic data (age, sex, location) provided on a voluntary basis. Each item is described with several attributes: genre, director, actor, language, country, budget and release year.

The on-line application is still available and in use. Additional information about LDOS-CoMoDa can be found in and.

B. Recommender systems

For this paper we used two different RSs: a hybrid RS to generate the diversified recommendation lists and a Matrix Factorization RS to generate the latent feature vectors for each item in the dataset.

Hybrid RS [12]: The hybrid RS used for this experiment was developed as part of our previous research [12]. It is a collaborative RS that selects nearest neighbors based on genre preferences instead of their ratings. Each preference indicates the user's interest for one specific genre (25 in total). By using these preferences we are able to select nearest neighbors who perfectly match the active user in preferences without having a single overlapping item (i.e. item rated by both users). This increases the recommendation pool and the overall quality of the RS.

The hybrid RS generates recommendations for each user by performing the following steps: (i) Calculate genre preferences for the user based on his/her previous ratings, (ii) Find 20 users whose preferences are the most similar to the active user, (iii) Create a pool of potential recommendations from all of the items rated by these users, (iv) Calculate the predicted rating for each item using the Bayesian estimator, (v) Present the user with the top 20 items.

Matrix Factorization RS [10]: The MF RS was used in this experiment was based on the algorithm that was developed and deployed in [10]. For this experiment the algorithm was used solely for the purpose of calculating latent features vectors for each existing item in the dataset. We plan to use the diversification methods described below on the MF RS as well, but decided to leave this for future work as the recalculation of latent features proved to be too time consuming.

The MF RS calculated 7 latent features for each existing items and stored them in a vector. A set of all item vectors was then used as input for our diversification measure (see below).

C. Diversification methods

The three diversification methods used in this research can be implemented in any existing RS without requiring a direct change in the way that RS work. The methods focus on diversifying the top 20 lists generated by the RS. In our case the diversification process follows the next steps for every user's list of recommended items: (i) prepare ordered (descending) list of recommendations and split it into top 20 recommendations list and the remainder of the set, (ii) find exchange candidates in such manner that the diversity of the top 20 items increases without significant harm to the accuracy of the system, and (iii) exchange the selected items to yield a diversified list of recommended items. The second and the third step can be performed iteratively.

As mentioned above, we used three diversification methods that mainly differ in the way how the exchange candidates are picked.

The first method swaps up to three items in a single step (no iteration). It starts by assessing the worst items in the top 20 list. It calculates the ILD value of the list while excluding one item (exchange candidate) of the list at a time. Effectively this means calculating ILD@19. Higher values of ILD@19 indicate better exchange candidates. Next, it searches for the best replacement candidates from the first 20 items of the remainder of the set. The method calculates the ILD@20 after exchanging every combination of up to three items. Final result is the top 20 list with best ILD@20 score after the exchange.

The second method uses the same approach as the first one to determine exchange candidates in the top 20 list. The best item, which yields highest ILD@19 is then replaced with an item from the first 20 of the remainder of the set. The final exchange is done using the replacement candidates that gives best ILD@20 score. In this case we shuffle only a single item at a time, but repeat the process K-times. It can be expected that increasing value of K would favor list diversity in trade-off to lowering list accuracy.

The third method, just like the second one, replaces single item at a time. The difference is, it considers a joint score in form of (1) instead of a pure ILD value.

$$a \cdot avgPR + b \cdot nILD \qquad (1)$$

$avgPR$ stands for the average prediction rating of the list and $nILD$ for the normalized ILD value of the same list. The $nILD$ is calculated using the ILD@20 measure, described in the next chapter. The sum of both parameters is 1. A combination of $a = 1, b = 0$ therefore means that the system creates non-diversified recommendation lists, while $a = 0$, $b = 1$ creates as diverse recommendation lists as possible with total disregard to the final accuracy of recommendations. The shuffling procedure is repeated until best top 20 list (in terms of joint score) is achieved.

D. Diversity measures

We used two measures to determine the diversity of the generated recommendation lists.

The first was the intra-list diversity [7] (ILD@20) which calculates the diversity value of each top 20 list based on the metadata descriptions of each item on the list, that consist of: genre, director, actor, language and country as shown in equation 2.

$$ILD@20 = \frac{1}{2}\sum_{n=1}^{20}\sum_{k=1}^{20}\left(1 - \frac{match(n,k)}{\sqrt{size(n) * size(k)}}\right) \qquad (2)$$

$match(n,k)$ represents the number of metadata description in which items n and k match. $size(n)$ is the number of medatada used in the description of item n.

The second was our proposed measure "latent feature diversity" (LFD@20) which was calculated using the following equation:

$$LFD@20 = \frac{1}{2}\sum_{n=1}^{20}\sum_{k=1}^{20} ldiv(n,k) \qquad (3)$$

Each item is represented with a feature vector composed of 7 latent features [2]. The diversity ($ldiv(n,k)$ of items n and k is therefore calculated as the Euclidian distance between the two latent feature vectors. The greater the distance the more diverse the two compared items.

E. Evaluation

The evaluation of our proposed diversity measure was performed for two experiments.

In the first experiment we focused on the first diversification method since it does not include any additional parameters (number of iterations, weights etc.). We first collected top 20 lists for each user – the original list and the diversified list. We then calculated the diversity 'before' and 'after' using both diversity measures. The aim of this stage was to determine if both measures show similar behavior (for instance if ILD@20 shows an increase in the list diversity does LFD@20 do the same?).

In the second experiment we focused on the second and third diversification method. The aim was to diversify the top 20 list as much as possible while retaining high recommendation accuracy. To achieve this we measured the accuracy of the system (using the F-measure [13]) at different parameter values (number of iterations for the second diversification method and weight values for the third). We then calculated the accuracy, ILD@20 and LFD@20 for each parameter value. The aim of this stage was to compare the trend of each diversity measure in order to determine whether we could achieve the same results using the proposed diversity measure (LFD@20) as when using the measure that was successfully used in our previous experiments (ILD@20).

III. RESULTS

A. First experiment

In the first experiment we created and diversified the top 20 recommendation lists of 44 different LDOS-CoMoDa users. We then calculated the diversity of each diversified and non-diversified list using both ILD@20 and LFD@20 measures.

Since we wanted to compare the behavior of each measure we then calculated the relative change of each measure during the diversification process as shown in table 1.

TABLE I. TYPE SIZE FOR CAMERA-READY PAPERS

	ILD@20	LFD@20
avg. change	5.6%	16.2%
std. dev.	3.6%	27.8%
min. change	1.3%	-21.8%
max. change	14.6%	99.6%

The values show that both measures show a change however the ILD@20 always shows an increase in the list diversity (which is expected since ILD@20 was the measure used to diversify the list) while LFD@20 sometimes actually shows a decrease in the diversity of the items contained in the 'diversified' recommendation list. The negative value of minimum change LFD@20 shows that there were cases where the ILD@20 diversity

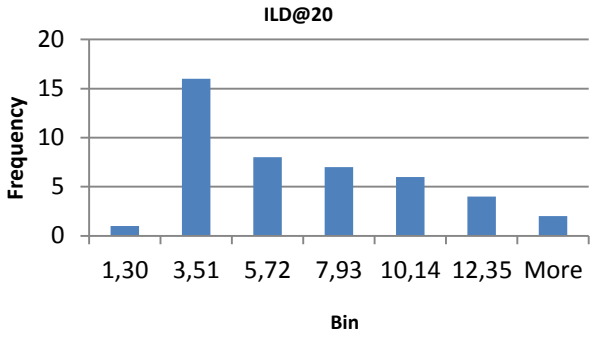

Figure 1. ILD@20 value change in the first experiment.

of the list increased while the LFD@20 value decreased. This was possible as our diversification methods used ILD@20 in the diversification procedure.

Another detail that can be observed from the presented

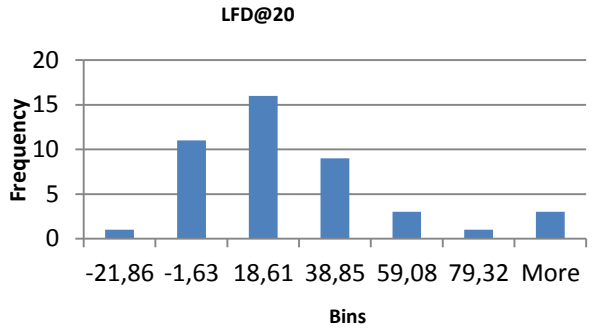

Figure 2. LFD@20 value change in the first experiment.

numbers is the fact that LFD@20 seems to be a lot more dynamic as it's changes range from -21% to as much as 99,6% while the greatest change in ILD@20 value only amounts to 27.8%.

In order to further observe this we performed a data analysis of each set and created a histogram where all 44 values are divided into 7 bins. The results are shown on Fig, 1 and 2. The bin value represents the relative change of the list diversity while the frequency value shows how many of such changes we detected during our experiment.

A comparison of Fig. 1 and Fig. 2 shows that LFD@20 values change in a broader spectrum (from -1.6% to 38.8%) while most of ILD@20 gather around 3.5%.

As we lack the information about how actual users perceive the diversity of these diversified top 20 lists (see further work) we cannot say which of these two measures performs better or is a better reflection of the actual list diversity.

B. Second experiment

In the second experiment we used the recommendation list of 44 different LDOS-CoMoDa users obtained from hybrid RS. We then diversified the list of top 20 items using second and third diversification method (as described in materials and methods section) at different diversification level. At each step we calculated both diversity values, the ILD@20 and the LFD@20. It is important to note that in the diversification procedure, the

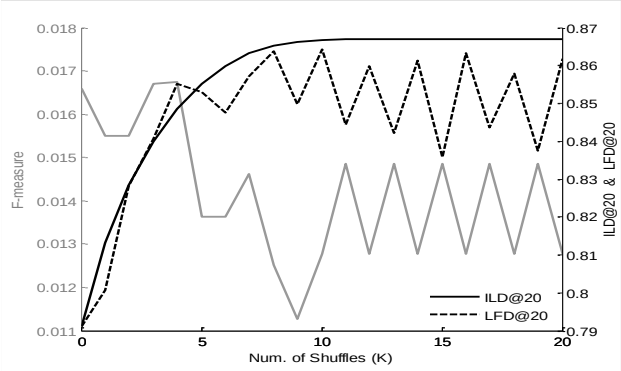

Figure 3. ILD@20, LFD@20 and F-measure values when using the second diversification method.

ILD measure and not the LFD measure was used to find candidates for shuffling step.

Fig. 3 shows the results when using second diversification method (iteratively shuffling single item). It can be seen that as we increase the number of shuffled items, the list accuracy drops, while the diversity, measured as either ILD@20 or LFD@20, increases. Note however, that for the purpose of graph plotting, the LFD values are scaled to the range of ILD values (using ILD@20 at k=0 as the scaling factor). We justify this scaling by our interest in shape of the plot rather than in actual LFD values.

Similarly, the results when using third diversification method (evaluating joint rating/diversity score) are presented on Fig. 4. Again, the LFD values are scaled to the range of ILD values to observe the shape of the plot.

In both cases, we can observe a similarity in the ILD and LFD curves, which in worst case differ by less than 5%. This does not mean that the diversity measures are automatically interchangeable, but they do show similar tendencies.

IV. CONCLUSION AND FURTHER WORK

The aim of this paper was to evaluate whether a latent feature based diversity measure could be used to evaluate the diversity of lists of recommended items. Such a measure would have the advantage of being insensitive to the content type used in the system as well as to the type and complexity of the metadata ontology used to describe the content items stored in the system.

Our results show that LFD@20 shows a different value dynamic when used to evaluate the diversity of each individual user's recommendation list (see experiment one, described above) as compared to ILD@20 which seems to be a more 'conservative' measure showing only

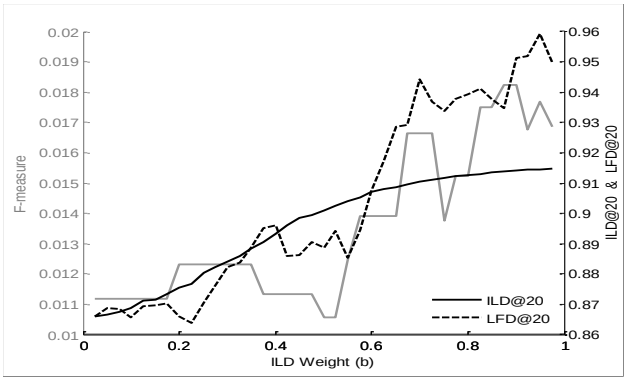

Figure 4. ILD@20, LFD@20 and F-measure values when using the third diversification method.

small relative changes during the diversification process while LFD@20 claims a much larger relative change in the diversity of the same list.

The results of the second experiment on the other hand show that the two measures could be more alike since they both show similar behavior when used to select the best diversification parameter values.

Regardless of this we need to perform additional experiments and evaluations if we wish to confirm that LFD@20 is a viable diversity measure. In order to achieve this we plan to perform a series of experiments:

- The most important experiment that needs to be performed involves a live user trial which would determine which of the evaluated measures best reflects the actual user preferences and would also establish a 'ground truth' about how the users actually perceive recommendation list diversity.
- We should also explore the latent features themselves – in the experiment above we used 7 latent features since this was the number used in our previous experiments. We need to perform a statistical analysis in order to determine whether this number should be adjusted.
- Experiment with different latent diversity measures – for this paper we only used the Euclidian distance. We should also consider other methods such as correlation, p-norm etc.
- Last but not least perform a series of A/B test to determine the user satisfaction with the diversification method.

Efficient Profiling and Distributed Synchronization of Statistical User Models for Content-Targeting and Real-time Applications

Lj. Mercep
Cognizant Technology Solutions, Munich, Germany
Ljubo.mercep@cognizant.de

Abstract – This work presents an efficient approach for managing distributed user profiles in the use-case of the semi-autonomous or fully autonomous connected car. A user profile is a collection about user's personal preferences and statistical data on user's previous interactions with all compatible connected systems outside and inside the car. Managing the user profile practically means dynamically updating the profile based on the interaction with the vehicle's human-machine interfaces and using it to answer complex queries placed by the vehicle's applications. The queries can range between user interface personalization queries (what is the user's favorite radio station), over product-placement related queries (are we going to pass next to a restaurant the user might be interested in) to safety-relevant queries (is the senior driver paying adequate attention to the direction of a detected obstacle). The focus is placed on reducing the computational complexity of user profiling and synchronization of distributed user profiles.

I. INTRODUCTION

Semi-autonomous or autonomous connected cars have the potential to reshape the automotive human-machine interfaces and several business concepts deeply rooted inside the automobile industry. As the automobiles become more autonomous in the upcoming decades, the driver's workspace of a connected car is assumed to change in its purpose and the driver will be able to use the human-machine interface for other non-driving related tasks. The value added through personalized content delivery in the new driver's workspace can be used to offset the increased design and construction costs of the future semi-autonomous connected automobiles and the surrounding intelligent traffic systems. The basis of such business model is efficient management of a large number of user profiles, which can be used for driver workspace personalization and targeted content delivery [1]. User profile is defined in detail later on, but can be summarized as a collection of statistical data on user's preferences generated during hers/his interaction with other systems and a collection of certain known facts about the user.

This work presents a solution to the problem of keeping a large complete user profile in sync with all distributed applications which are using smaller models of the complete user profile to perform complex queries or extensive user profile analysis. The applications are running on remote embedded platforms, such as in-vehicle computing units. It is advantageous to cache the parts of full user profiles on a local embedded platform inside the vehicle, as opposed to performing all the operations remotely on a centralized user profile management platform. Caching is performed indirectly, based on observing the user profile queries of different applications running inside the vehicle. The applications present user-targeted content to the passenger(s) inside the vehicle based on the vehicle location i.e. its vicinity to various product and service profiles on the one side and passengers' user profiles on the other. There are several advantages to distributed handling of user profiles and their local caching in the vehicle - reduced computational complexity and a well-defined interface towards the users of the user profiles and the central user management platform. Once an application inside the connected car requests and retrieves relevant parts of the user profile, it can internally perform custom queries, which might contain business-sensitive data.

The user profiles are generated during everyday interaction with connected handheld devices and other human-machine interfaces and contain static user data (such as gender) as well as learned/observed statistical data about the user's preferences. Bayesian network representation has been chosen as the underlying model of the customer profiles, after performing the analysis in the preceding work of the author on this topic [3]. *Using* the user profile model practically means:

- Updating the statistical user data in the model
- Extending the model structurally by adding new nodes and new dependencies between the new or existing nodes
- Placing questions or queries on the user profile model – this is described as user *profiling*

The first step of the approach is based on an existing improvement of the efficiency of exact querying or exact inference on Bayesian models, which is performed with well-known secondary structures known as junction trees [2]. The user profiles which are stored in this form can be distributed over multiple spatially separated systems and can be queried with different quality-of-service requirements. A query with quality-of-service requirement

The opinions and the evaluations of research topics and business concepts expressed in this work are those of the contributor alone and do not necessarily reflect the views of Cognizant Technology Solutions.

is a pair of query Q and a requirement R where Q can carry the value of "is the driver tired?" and R can carry a set of restraints on the inference procedure of Q. R can, for example, contain the restraint that the query frequency has to be 1 Hz and that the maximal allowed latency in answering the query is 100ms. The impact of quality-of-service requirement, the important quality-of-service dimensions and a further optimization for exact inference with quality-of-service requirements are given in previous work [3].

A proposed metric for evaluating the efficiency of the approach is composed out of two components:

- The computational complexity necessary for the application using the user profile to answer its query and start acting towards the user
- The computational complexity of synchronizing the distributed statistical user models in order to minimize the drift between different copies of the same user profile

This work is organized as follows. In Section II the theoretical background of the approach is present. In Section III the approach is evaluated against the known alternatives. Finally, the work is concluded and the future steps are discussed in Section IV.

II. Proposed Approach to User Profile Management

The first logical step when designing a system for user profile management based on Bayesian representation is designing the underlying Bayesian networks. This work does not evaluate specific Bayesian networks and their effectiveness in practice, apart from using the INSURANCE network to measure computational complexity. Table I. presents the mapping between the user-data-related concepts used in this work and the proposed implementation methods, which are all explained in the following.

The first suggested optimization principle is storing and exchanging the user profile data in the form which is optimized for querying, that means for its practical usage, and not in the more explicit form used during the learning process or during the manual knowledge base design. Secondary knowledge structures such as junction trees, which can be constructed using statistical analysis of queries (through observation) and using the explicit metadata attached to the query (such as query priority or maximal latency allowed for answering the query in the case of strict real-time inference), can drastically reduce the computational complexity of inference. In some cases, meeting the real-time requirements on knowledge updating and parallel inference is not feasible at all without constructing the secondary knowledge structures [7]. This is even more the case if exact inference is required, meaning that the entire knowledge base stored in or available to a particular agent has to be evaluated before answering a query, eliminating the possibility for heuristic approaches [8].

As shown in [3], large computational reduction of exact inference can be achieved after identifying the most commonly used variants of user profile models, meaning the optimal query-optimized junction trees. Identifying these co-called hot-spots also enables high efficiency of information transfer between the central user profile management platform and remote applications, since the remote applications receive a small-scale query-optimized model of the entire user profile. This eliminates the need for intensive remote querying and "internalizes" the machine-machine interface by replacing it with a local user profile model inside the borders of the remote application. To summarize, the distributed applications which need to perform queries on the user profile receive a reduced model of the user profile, optimized for performing exactly the requested queries.

TABLE I. Mapping between Abstract User-Data-Related Concepts Used in this Work and Proposed Implementation Methods

User-Data-Related Concept	*Implementation Method*
Full user profile	Bayesian network stored at the central user profile management platform (CUPMP)
Single property of the user or the minimal non-divisible unit of knowledge about the user	Single node in a Bayesian network
Querying a user profile	Performing exact inference on a set of nodes in Bayesian network
Query-optimized user profile or an optimized non-complete user profile model	Junction tree constructed upon the Bayesian network
Remote application which is querying the user profile	Any application capable of sending a query to CUPMP or performing exact inference
Syncing user profile data after user interaction with the remote application	Updating the Bayesian network in CUPMP and all affected junction trees with the new content of nodes
Syncing the local query-optimized user profile model with the fresh user profile data	Retreiving the content of the nodes inside the appropriate junction tree stored at CUPMP

The internalized user profile model (i.e. the query-tailored junction tree) represents the basic meaning or the utility of the entire user profile, since the optimized models are generated by many real-life queries placed on the complete user profile over a long period of time by real-life remote applications. Exchanging information by the means of directly usable query-optimized knowledge structures makes for a very efficient machine-machine interface, since no time is lost in data encoding or interpretation. Since the user profile information is used for querying very often and since the query profiles change very rarely, the bulk of computational effort is invested into optimizing information consumption and synchronization between all remote applications.

A remote application which uses a user profile has the primary purpose of placing queries on the user profile, reacting to the answers and updating the user profile with new information stemming from the user interaction.

The necessity to construct the secondary knowledge structures around the complete Bayesian network can be positively seen as chance to better understand the system's usage patterns, identify these patterns and properly distribute the computational complexity of querying over all user profile users. Fig. 1 shows the main elements of

the proposed architecture, based around query-optimized user profile models. In the figure, the junction trees are either being used remotely (inference engine used on CUPMP) or locally (inference engine used inside the remote application).

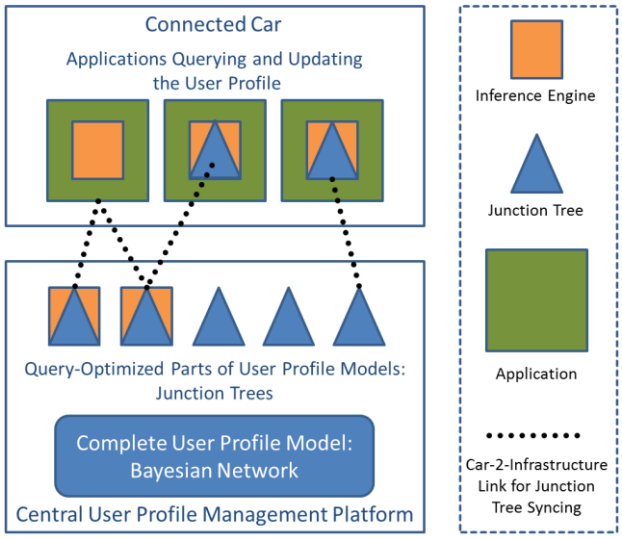

Figure 1. Proposed architecture for user profile management

This work builds upon the following levels of optimization, out of which the first one does not represent a new contribution:

- Queries from users generate query-optimized junction trees to reduce complexity of exact inference
- Similar queries can be answered by the same already generated junction trees, further reducing computational and sync effort on the CUPMP
- Information syncing between the junction trees is perform by write-through the underlying Bayesian network on CUPMP and updating all junction tree bottom-up

It is important to note that all the structural changes on the junction trees have to be controlled by the central user profile management platform (CUPMP), since such changes invalidate all already deployed junction trees for a specific query. A structural change in the underlying Bayesian network would cause invalidation of all distributed junction trees which build upon this network. On the other hand, content changes in junction trees (syncing data between junction trees) can be performed in a completely distributed manner.

Remote applications might be interested in very rapid profiling of the user which has started interacting with it, in order to present her/him with the most appropriate product offer or to customize the driver's workspace. An example is a driver whose vehicle is approaching a shopping center. The application executes a series of important queries, which answers have a high-value utility function. Using the query-optimized secondary knowledge structure is the fastest way to perform wide-range and intensive querying / profiling over the relevant data.

Following procedure for user profile management is suggested:

Applications $a_1,a_2 \ldots a_n$ contained in the set **A** request the profile for the user u_k from the set of users **U**, for the purpose of answering the queries $q_1,q_2 \ldots q_n$ from the set of possible queries **Q** (set contains all nodes inside the Bayesian model representation of user's profile) with the associated quality-of-service requirements $r_1,r_2 \ldots r_n$ from the set of possible requirements **R**.

In the first step, CUPMP checks for existing junction trees for this query profile. If there are none, the service checks how many times this query has already been placed. Based on a fixed threshold, which would be determined in practice, it performs inference directly on the user profile stored in Bayesian network form or it constructs a query-optimized junction tree. The applications receive either the answers to their queries or the generated junction tree.

Alternatively, the applications from set **A** can place a direct request for generating a junction tree for their query-QoS pair (**Q**,**R**). This is a clear statement to the CUPMP that this query-QoS pair will be used for more intensive profiling or more intensive and longer interaction with the user. This type of interaction also provides the application with the freedom to query or profile the user profile without exposing the content of the queries to the central management service. This might be important in the case of business-sensitive queries or performing a passive survey which is relevant to an upcoming, in-the-works, service or product.

After the remote applications have finished using their junction trees and/or after the interaction with user is finished, there are several possible ending steps:

1. The applications delete the junction trees and request a new one when the user interacts with the system next time.
2. The applications cache the junction tree for future use to avoid placing load on the CUPMP. The applications are aware that this will cause a drift between the cached user profile and the actual one, stored on the CUPMP, so they have to re-sync with CUPMP before the next interaction with the same user.
3. The applications wish to sync the possible changes in the junction tree, which happened during the interaction with the user, with the central user profile management service.

The last step, which provides valuable new user data to all applications using the system, has to satisfy at least the following requirements:

1. Applications have to be trusted in order to be allowed to update the central user profile data. Otherwise, one application which injects false user data could compromise all other remote applications.

2. All junction trees which are affected by the change of the synced junction tree should be immediately updated with the new knowledge

A balance between computational and communication complexity and content drift between affected junction trees has to be considered in the last step. In practice, the values of allowed margins for the drift between individual variables in the junction tree representation of the user profile have to be defined based on their impact on most important queries.

III. Evaluating the Approach

One important prerequisite has to be met in order for the following evaluation to hold: A common ontological system or a standard for semantic marking of nodes in the Bayesian representation of user profiles has to be defined. An interesting practical approach is integrating an existing semantic sensor standard, such as Open Geospatial Consortium Software Web Enablement (OGC SWE), with a Bayesian decision making engine [4][5][6]. Please note that the notion of quality-of-service used in the related work does not correspond with the one used in this work. In this paper, quality-of-service is used as an alias for non-functional requirements on a data-centric platform. In the aforementioned publications, quality-of-service is mapped to the quality of data, such as its resolution.

As shown by Thomas and Green in their work on enumerating the junction trees in decomposable graphs, the number of available junction trees is strongly related to the graph structure [11]. A decomposable graph used as an example in their paper, with 23 vertices and 4 components, was shown to have more than 9000 distinct junction forests. They summarize that the conservative upper bound for complexity of enumeration of junction trees (in other words, for calculating the number of distinct junction forests) is $O(n^2)$. The cost for searching for the optimal junction tree in regards to a specific query profile is therefore dependent on the underlying graph's size and structure and on the size and structure of the query. The author is not familiar with any work in this area which attempted to bound the computational complexity of this calculation, based on the properties of the graph and the query. Multiplying the number of the enumerated junction trees with the number of combinations of all vertices which can be meaningfully queried in graph (without taking vertex weighting inside the query into account) would yield an overly pessimistic estimate, since the actual practical combinatorial space is determined by a relatively small number of pairs of nodes which act as data sources and the nodes which are being queried. Low-cost heuristics, such as the average graph distance between the nodes which are members of data sources and the nodes which are members of nodes which are being queried, can be used to eliminate solutions which have a very high probability of being far from optimal. For most practical applications, the optimal solution is not necessary, but rather a good enough or the first solution fitting in the time boundary for both upwards and downwards propagation of the junction tree's message passing protocol.

The first level of optimization in this work is focused on building optimal junction trees based on a specific query profile and is defined in the author's previous work on exact inference on Bayesian networks with quality-of-service requirements. The second and third levels of optimization are the contribution of this work and are based on exchanging entire query-optimized junction trees as opposed to using a central database of junction trees at one location for answering queries. This means that the remote application using the user profile model has to execute the protocol shown in Fig. 2.

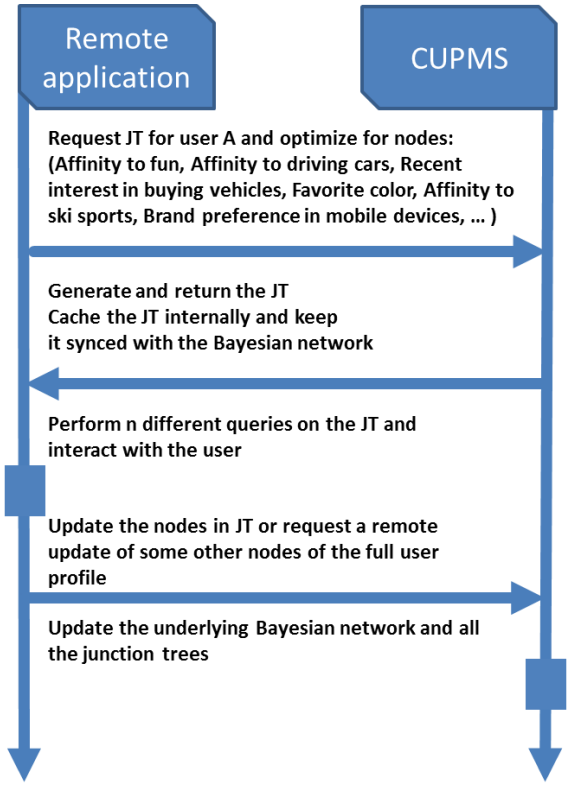

Figure 2. Protocol between a remote application and CUPMP

A. *Computational Complexity of User Profiling*

Important factors to consider:

1. Amount of queries on the junction tree needed to profile the customer
2. End-to-end communication delay with the CUPMP
3. Ratio of high-performance computational power of the CUPMP and the local embedded processing power of the remote applications
4. The computational and delay cost of re-synchronization of distributed user profiles

End-to-end communication delay is not an issue with profiling, since all the queries can be stacked together and sent to CUPMP as a single large query. The delay becomes an issue if a real-time and responsive interaction is necessary or if the application performs user profile updates very often. Even though offloading the entire

computational complexity to the high-performance CUPMP has the advantage of relieving the underpowered embedded platforms, this approach obviously limits the reactivity of the remote applications and exposes the entire user profiling process to the CUPMP.

The hardest element to estimate is the amount of queries on the junction tree which is needed to profile the customer. The ranges of different queries on the junction tree are not only dependent on the range of services or products offered by the data consumer, but also on the desired level of personalization or personalized presentation of information to the customer. Customer profiling can also be related to future products or trends. It could be expected that the depth of customer profiling will increase drastically as the profiling becomes easier to perform.

The well-known INSURANCE [10] Bayesian network is taken as a simple practical example of the complexity of customer profiling. The network has 27 nodes and was designed to calculate the expected claim costs for a car insurance policyholder. Let us assume that the network is expanded into a dynamic Bayesian network, with n history steps where n=3 [9]. Expanding the Bayesian network representation into an "unrolled" dynamic Bayesian network representation enables the application to capture the dynamic of the development of a user profile over the course of time. A customer whose theoretical expected claim costs have been falling over the course of time might be exactly the target audience for a new type of insurance product. Unrolling a Bayesian network in a simplest way means that the number of nodes is increased n times, or 3 times in this example. With a conservative estimate that the company only offers 5 different insurance products whose attractiveness should be evaluated using the current user's data, we assume that 5 different variations of dynamically unrolled INSURANCE network have to be evaluated for this specific user and that each time only one query is performed – the one on the **proposed cost** node. The insurance company however wants to offer a personalized experience to this user and analyzes the models of the car this user is interested in or would possibly want to purchase in future, based on the previous interaction with online car comparison platforms. Nine nodes in the INSURANCE network are directly impacted by the user's current vehicle data. Further assuming that the user was looking into three different vehicles from three different manufacturers in the same price class, it means that each network has to be instantiated with different values of the nine vehicle-dependent nodes at least three times. Varying the vehicle data and the vehicle equipment is where the number of necessary queries starts rapidly increasing, since some variables, such as **mileage**, have no correlation with variables such as **airbag**. Finding the most attractive insurance option for this user includes going through all the variable instantiation combinations and performing inference on **proposed cost**. Let us assume, for the sake of simplicity of this analysis, that the number of relevant variants of each vehicle is not bigger than 5. Total number of queries for this conservative use case is therefore 5 x 3 x 5 = 75. The example for the computational costs of querying the INSURANCE network using junction trees is given in [3], but for the purposes of this analysis it is enough to assume the constant cost **c** which is repeated 75 times. In other words, a single application incurs a computational cost of 75**c** on the central user profile management platform before any interaction with the user took place. If the user, by chance, chooses to select one of the products offered to him on the screen or over another human-machine interface, the application's interest in this specific user grows immensely and it becomes imperative to perform much deeper profiling. User's action of "paying attention" to the first offer can also be seen as permission for deeper profiling. As a side note, since the user's interaction has the potential to create value for the insurance selling company, the company might choose to pay a small fee for this additional or complete user profile. Performing a two-step or n-step profiling based on the level of interaction with the user is very important for such approach. The computational complexity of profiling will increase from the entry-level 75**c**, not only because more user data is now taken into account, but also because wider ranges of variables will be tested. Just like in the simple INSURANCE network, a combinatorial explosion follows from the growing number of variables with impact of user decision which has growing ranges of values.

Compared to the approach where all the profiles are kept on one place and all queries are answered by a massive centralized platform, the advantages of the proposed approach are the following:

- Responsiveness or on-demand real-time reactivity during the interaction with the user, regardless of connectivity issues with the central management platform
- Black-box approach to own profiling, protecting own business-model-related data / data about future products
- Caching local updates in user profile without putting load on the car-to-infrastructure communication

Having all knowledge-update and knowledge-query operations running on a central platform would incur massive performance issues. The proposed approach is highly parallelizable and robust against short-term connectivity losses.

B. COMPUTATIONAL COMPLEXITY OF SYNCHRONIZATION OF DISTRIBUTED USER PROFLE MODELS

Once a junction tree has been retrieved once, it only needs be synced with the currently same junction tree cached at CUPMP. It is important to consider a limit on allowed difference or drift between the information in the previously used and newest junction tree, to reduce the cost of constant minimal-updates or frequent user profile pulling.

The second part of syncing is pushing the new information about the user, acquired during the just-finished interaction, back to CUPMP. The simplest approach is to update the underlying Bayesian network in CUPMP containing the full user profile, and let the CUPMP populate the other junction trees bottom-up. The junction tree construction is now "for free", since it was

already performed once. This provides more predictable timings and forces one central sync point – the Bayesian network – to be constantly up-to-date. The cost of this operation is split over three different phases.

The first phase is updating the underlying Bayesian network, what is linear in the size of the junction tree.

The second phase is updating all other affected junction trees carries the complexity of **(num_nodes * num_trees)**, where num_nodes represents number of average nodes in a junction tree and num_trees represent the total number of junction trees. Lookup tables must exist, keeping track of which nodes are present in which junction tree.

The third phase consists of one pass of upwards and downwards propagation according to the junction tree algorithm. This is bounded by the depth of biggest junction tree.

To put the cost of the three phases into perspective, let us assume 1000000 drivers being on road in a given country – on a daily average. Let us make an estimate on the size of full user profiles in the form of Bayesian networks, containing 100 nodes. Let us assume 1000 different remote applications, with each having own junction tree (no sharing of profiles between applications) with an average of 30 nodes per junction tree. Complexity for syncing remains bounded only by linear complexity of 30x1000.

IV. Conclusion

Exact inference, which is one of the key elements of this work, offers the advantage of perfect reproducibility of the inference results, but at a very high computational cost. Heuristic approaches to Bayes inference, which are going to be the focus of future work on this topic, can result in a drastic reduction of the cost of inference.

One advantage of the proposed approach is a clearly-definable interface towards CUPMP, which enables the consumer to place arbitrary queries freely after receiving the entire junction tree. During the proposed system's operation, it will be possible to indirectly (by observing the usage of various junction trees) valorize different parts of the user profiles based on the frequency of their usage and the impact of their usage on the user behavior.

Driver assistance systems can also tap into the user profile data, at least in the phase of semi-autonomous vehicle operation, and profit from system reactivity and the lack of need for constant connection. Extending the proposed approach from content targeting to safety-critical vehicle systems would further increase the importance of exact inference. The reason is the perfect reproducibility of the results of inference, given the same starting conditions.

One important difference in this approach as opposed to generic user profiling and target content delivery is the fact that the connected car cannot be assumed to have perfect connectivity, but it is required to have perfect reactivity to user interaction.

Junction tree generation is a well-known NP-hard issue which is dependent on Bayesian network size. Cost of the junction tree construction is bounded by the size of the underlying Bayesian network, but this even happens extremely rare and can be performed in parallel to answering other queries. In this sense, the biggest shortcoming of this work is the lack of field trials with evaluation against existing big data, to measure in-the-field computational complexity. The pro and contra argumentation has only been provided by comparing the theoretical computational complexity of the approach.

Abstract - This paper proposes the algorithm for text skew estimation based on the entropy calculation. The method consists of three stages. In the first stage, it calculates the horizontal projection profiles. In the second stage, the horizontal entropy for the rough angles is calculated. In the last stage, the horizontal entropy calculation for the smooth angles is performed. The calculated entropy creates the cost function. The position where the cost function has an absolute minimum represents the estimated text skew angle. The experiment on DISEC'13 document database confirms that the method correctly estimates text skew. Besides, it is robust and time efficient.

I. INTRODUCTION

The digitization of documents is typically carried out by a scanner, which usually introduces the text skew [1]. Hence, a some degree of text skew in digitized document image is an unavoidable. Readers are very sensitive to any text skew. They can register the text skew of at least 0.1° [2]. Furthermore, the text skew is undesirable in all stages of the optical character recognition (OCR) system, because it enables that system makes errors. It is valid, because any existence of the residual skew can lead to improper character recognition. If the text skew in document image is not corrected before further recognition processing, then the accuracy of these steps may be significantly reduced. Hence, the text skew detection and correction is indispensable prior to any recognition step in the OCR system. As a consequence, the text skew detection represents a mandatory stage in the OCR system [3].

Many different methods have proposed for the text skew detection in document images [4]. They can be classified into the following groups: (i) methods based on projection profiles, (ii) clustering of nearest neighbor's methods, (iii) cross-correlation methods, (iv) methods based on the Hough transform, (v) Fourier transforms methods, (vi) moment based methods, (vii) straight-line fitting methods, and (viii) other methods.

From all aforementioned methods, we choose to explore the extension of the projection profiles method. A method based on the projection profiles is widely used to detect the text skew angle. It is an easy method which sums up the pixels in the rotated document image creating a histogram at each possible angle. Then a cost function is applied to these histograms. The optimization of the cost function detects the text skew angle. The extension of this method is given in [5] by introducing the entropy concept.

The aim of this paper is to describe the algorithm for the text skew estimation based on the entropy. Furthermore, we suggest the optimization of previously proposed entropy method [5], which leads to speeding up the algorithm by the factor 2 to 4 times. Then, we tested the proposed algorithm on a document database DISEC'13. At the end, the results of the experiment are compared to the well-known Chou's algorithm [6] and validated according to the widely accepted method [7].

The paper is organized as follows. The Section 2 describes the proposed method. Sections 3 defines the experiment. Section 4 shows the experimental results and discusses them. Section 5 makes conclusions.

II. PROPOSED METHOD

The proposed algorithm detects the text skew angle in a document image by calculating entropy of the horizontal projection profiles. The preprocessing stage, which includes cleaning of documents, extracting blocks and denoising images [5] is out of the scope of our approach. Figure 1 shows the flow diagram of the proposed algorithm.

The method is applied to the binary image. Suppose that we have the binary image $B(i, j)$ with M rows and N columns. The horizontal projection profile of the binary image **B** is calculated as:

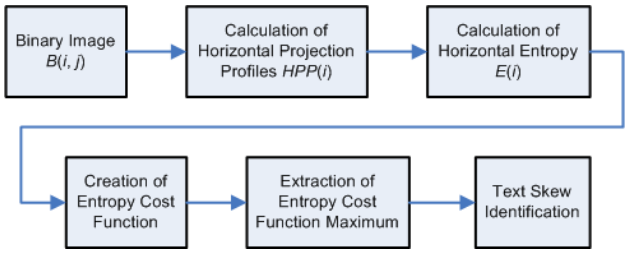

Figure 1. The flow diagram of the proposed algorithm

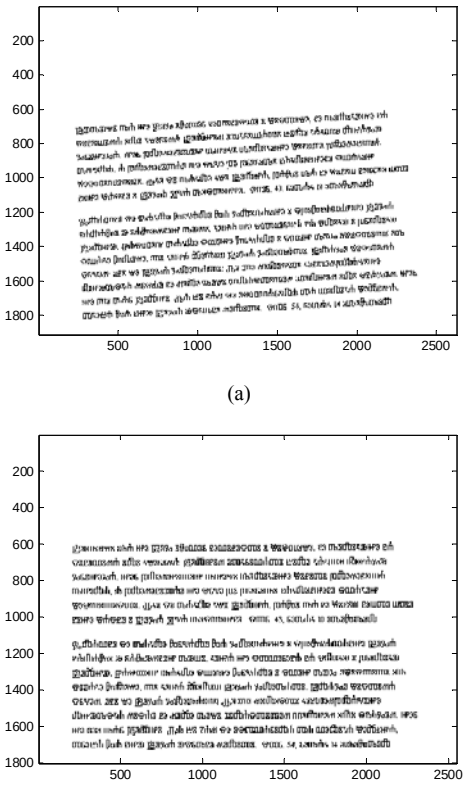
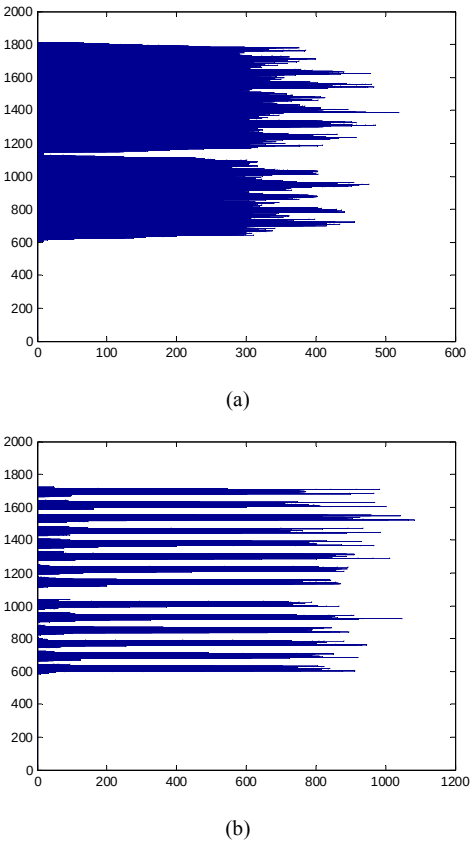


(a) (b)

Figure 2. Initial binary image: (a) skewed for the angle of 2.6°, (b) unskewed



(a) (b)

Figure 3. Horizontal projection profiles (*HPP*): (a) for skewed image (2.6°), (b) for unskewed image

$$HPP(i) = \sum_{j=1}^{N} B(i,j), \qquad (1)$$

where i represents the row and j represents the column of the image **B**. Each element of the horizontal projection profiles $HPP(i)$ represents the sum of the pixel values in the corresponding rows.

Figure 2 shows the initial binary image **B** ((a) skewed, (b) unskewed). Figure 3 (a) and (b) shows a corresponding horizontal projection profiles according to Figure 2 (a) and (b), respectively. If the number of calculating pixel per row (horizontal projection profiles) is under observation, it is clear that highest value will be received when the text is unskewed. Hence, the procedure of rotating skewed image in the range of angles with certain angle step will establish the *HPP*, which receives its highest value among all rotated images. This angle represents the position where the skew is the closest to 0° [6]. In this way, the text skew can be identified.

Using horizontal projection profiles as a basis, we introduce the concept of entropy. The entropy is determined as a statistical measure of image randomness. The horizontal entropy, i.e. entropy per row is calculated as [5]:

$$E(i) = \sum_{i=1}^{N} -HPP(i) \cdot \log\big(HPP(i)\big). \qquad (2)$$

If the text-line has more randomness in its texture, then $E(i)$ will receive higher values. In the original algorithm [5], the full range of $E(i)$ is used for calculation of the cost function E. However, we introduce an optimized approach, which consists of the two-stage calculation of the entropy function E. In the first stage, the image is rotated from θ_{start} to θ_{end}, where θ_{start} is equal to -15° and θ_{end} is equal to +15°. The step of rotation is $step_{start}$, which is equal to 1°. As a result, the entropy cost function E is obtained. The lowest value of entropy means that it can be considered as the starting (prefinal) estimated text skew angle, i.e. $\theta_{prefinal}$. However, the accuracy is given by the step of rotation equal to 1°, which is too coarse. Hence, some additional justification is needed. In the second stage, the subrange around the prefinal text skew angle $\theta_{prefinal}$ is used for additional testing. Currently, the image is rotated from $\theta_{prefinal} - step_{start}$ to $\theta_{prefinal} + step_{start}$ with the step of rotation $step_{final}$. This step is much finer, i.e. it is equal to 0.1°. The newly obtained result for the minimal entropy represents the final estimated text skew, i.e. θ_{final} with the accuracy of 0.1°.

Figure 4 illustrates the entropy cost function. Figure 4 (a) shows the entropy cost function obtained in the first stage (θ_{start} = -15°, θ_{end} = +15°, $step_{start}$ = 1°), while Figure

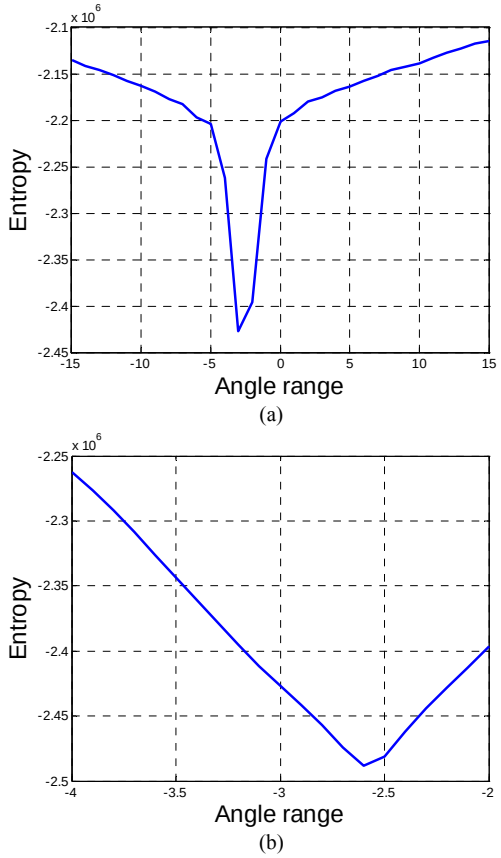


Figure 4. Entropy cost function E for the skewed image (2.6°): (a) established by rotating image using angles from -15° to +15° with the step 1°, (b) established by rotating image using angles from -15° to +15° with the step 0.1°

4 (b) shows the entropy cost function obtained in the second stage ($\theta_{start} = \theta_{prefinal} - step_{start}$, $\theta_{end} = \theta_{prefinal} + step_{start}$, $step_{final} = 0.1°$) of the proposed algorithm. Figure 4 (a) illustrates the so-called coarse detected minimum, while Figure 4 (b) shows the so-called fine detected minimum. The fine detected minimum of the entropy cost function represents the estimated text skew obtained by the proposed algorithm (See Figure 4 (b)).

III. EXPERIMENT

The experiment related to text skew detection needs to evaluate the quality of the algorithm to correctly predict the text skew embeeded into the document image. In this way, the algorithm is applied to the skewed document images from a database. Usually, the document images are randomly rotated at different angles ranging from -15° to +15°. The result of the experiment shows the deviation of the estimated text skew obtained by the tested algorithm and correct text skew value.

As a document database, a part of Document Image Skew Estimation Contest (DISEC'13) [7] is used. It is recognized as a standard tool for unbiased testing of the algorithms for the text skew detection. Document images included in DISEC'13 are extracted from various sources consisting of document images with figures, tables, diagrams, architectural plans, electrical circuits, etc. They are written in different languages like English, Chinese

Figure 5. A few document image samples from DISEC'13 database

and Greek or some multilingual combination. Our part of DISEC'13 consists of 100 images. Figure 5 illustrates a few document images from DISEC'13 database.

To measure a performance of the results obtained from testing algorithm, the following criteria is proposed [7]:

$$AED = \frac{\sum_{n=1}^{N} \Delta(n)}{N}, \quad (3)$$

where $n = 1, ..., N$ is the number of document images from a database, and $\Delta(n)$ is the absolute deviation error (ADE). ADE for document image n is given as:

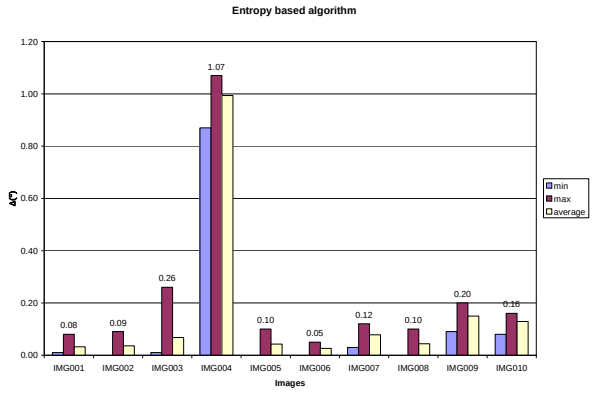
$$\Delta(n) = \left| \theta_{gt}(n) - \theta_{est}(n) \right|, \quad (4)$$

where θ_{gt} is the skew angle of the document image n from a database, commonly called ground-truth, and θ_{est} is detected or commonly called estimated skew angle obtained by testing algorithm.

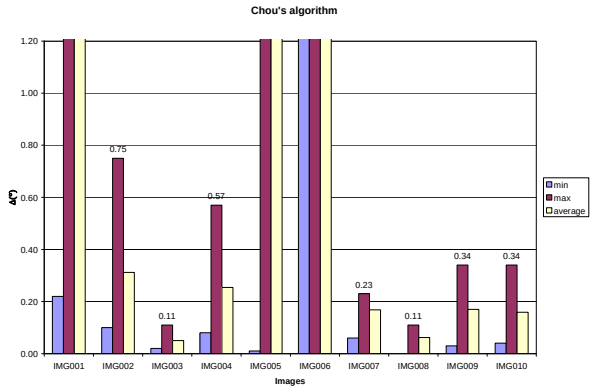
IV. RESULTS AND DISCUSSION

We make a comparison between our algorithm and well-known Chou's algorithm [8] to show the quality of the proposed text skew detection approach. The results of the experiment for the entropy based and Chou's algorithm are shown in Figure 6. Because the text skew of 0.1° may be visible to a human observer, it is chosen as comparison criteria [2].

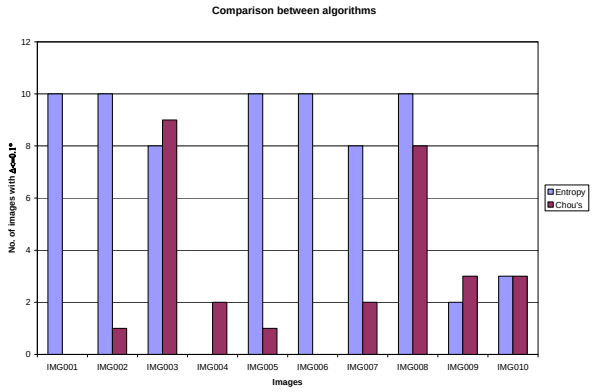
The application of the entropy based algorithm to the DISEC'13 database shows that three out of ten document images are characterized with the highest maximum level of ADE equal to 0.26°, 0.44° and 1.07° with corresponding average ADE level equal to 0.16°, 0.18° and 0.99°. The aforementioned ADE values are quite



(a)



(b)



(c)

Figure 6. (a) ADE for entropy based algorithm, (b) ADE for Chou's algorithm, and (c) Number of images with the skew detection <= 0.1°

moderate. Furthermore, it should be noted that document images with highest ADE level represent so-called multi-column document images.

The application of the Chou's algorithm to the DISEC'13 database shows that three out of ten document images are characterized with the highest maximum level of ADE equal to 9.53°, 20.87° and 22.63° with corresponding average ADE level equal to 2.70°, 10.86° and 8.24°. These values are rather extreme. Two of them represent the comic document images. Obviously, Chou's algorithm is completely unsuitable for text skew detection of such type of document images.

Finally, the comparison between two algorithms is made by counting the number of images with ADE less or equal to 0.1°. The proposed algorithm has a success rate of 71/100, while the Chou's algorithm has a success rate of only 29/100. From all above it is clear that the proposed algorithm has the real potential and it shows the advantages compared to well-known Chou's algorithm for text skew detection.

V. CONCLUSION

The paper proposed the entropy based algorithm for the text skew estimation. The basic entropy method which was previously proposed in [5], we optimized by incorporating two stages with so-called rough and fine step rotation of the analyzed image. In this way, the proposed algorithm was speeding up compared to the basic version at no cost on its accuracy. The algorithm was tested on a part of DISEC'13 database, which contains a variety of document images written in different scripts, including different elements like images, comics and so on. At the final stage, the proposed algorithm was compared to well-known text skew estimation method proposed by Chou et al. [8]. Our method proved to be robust and accurate. It showed much better results than Chou's method in terms of accuracy. Future research will be toward improving the algorithm estimation of the text skew in the multi-column document images.

Abstract - Solving complex combinatorial optimization problems using classical algorithms is not efficient related to resources and time. To overcome the problem, we used optimal parameters selection based on Ant Colony Optimization (ACO) algorithms. In this paper, we present algorithm for solving telecommunication network using ACO for searching optimal ring star network topology. We analyzed ant's optimization ability based on shortest path between the nest and food location. In our research we used: Ant System, Elitist Ant System, Rank-Based Ant System, and MAX-MIN Ant System. The program is developed using GNU C++ to prove the algorithm theoretical convergence through simulation on variety of topologies regarding to node numbers. The algorithm was adapted to solve design of telecommunication network, which connects terminals to concentrators using point-to-point connections. The algorithm's output is a star topology showing connections of concentrators in a ring creating Digital Data Service. Algorithm uses seventeen parameters, with thirteen metrics to evaluate configurations. Program validation is performed using three different network node configurations for all four ACO algorithms, only changing two control parameters: speed of pheromone evaporation and existence of local search. The best path was evaluated based on: total time, number of iterations, ring size, and value of topology.

Key words: ant colony, optimization, ring-star problem

I. INTRODUCTION

Worldwide, telecommunication companies spend billions of dollars to replace copper lines with new transmission medium - optical lines, and for reasons of increasing the flow of data and information, as well as customizing communication networks for simultaneous transmission of multiple types of these data, including video signals.

Rapid growth of design paradigms for large optical networks is evident, including connecting the clusters of nodes, the synchronized optical network (Synchronous Optical Networking – SONET [1]) in large rings, as building blocks for design of communication systems. Ring is a popular topology for these systems and attracts a lot of research attention.

Optical links are installed along with the rest of the infrastructure of telecommunications equipment and facilities, and using the latest technology they are integrated in an intelligent and transparent transmission network, characterized with high capacity, automatically monitored and controlled.

The ring is separated as a kernel of the network, to which, in accordance with the needs, other parts of the system are connected. Such a solution is transparent for all telecommunication nodes, regardless of whether they are located in the local, regional or some remote telecommunication level.

Prevailing technical standard in the USA is the SONET. Within the SONET ring, the most common node is a telephone exchange, with optical connection into the ring. The topology enables every node to send, receive and forward data. The nodes are available for every edge of the SONET ring thorough the Add-Drop Multiplexer (ADM). The SONET standard has an important role in optical transmission because it helps to prolong survival of legacy networks and their faster transformation into contemporary and functional optical telecommunication networks.

Node symmetry of the ring ensures that each node in the ring has the same role with the all necessary equipment provided. The circular connection of the node protects it from unwanted traffic disruptions. An important problem of telecommunication network optimization is to find a balance when minimizing the sum of routing and connection costs in the network.

The objective of the ring star problem is to find a simple cycle, referred to as a ring, connecting a subset of nodes of a graph. The problem includes two minimization objectives: of a cost associated to the ring connecting the subset of nodes and the minimization of a cost associated to the arcs connecting out-of-the-ring nodes with the nodes within the ring. The problem was introduced by Labbé et al. [2]. The ring-star problem is used in designing telecommunication networks, and in planning fast transport systems. The problem is considered as extension of the classic location-allocation problem from the early 60s, including several comparative versions studied by several authors. One of the recent studies proposes solution based on evolutionary methods [3], and there are methods that employed meta-heuristic and treated the ring star problem as a bi-objective problem [4]. For solving the problem we used optimal parameters selection based on Ant Colony Optimization (ACO) algorithms, a metaheuristic approach proposed by Dorigo et al. [5]. To

our knowledge this approach was not used before for solving the ring star problem.

Typical telecommunication network traffics content from various sources with dramatic increases in system capacity [6]. In order to answer the increasing size of networks, many telecommunication companies support hierarchical structure of the network, built out of different interconnected layers. The various services (voice, video and data) are structured in several layers, allowing telecommunication companies to solve network design problems focused only on a part of the network.

Solution to the network design problem is to connect terminals and concentrators. Design solution presents a set of nodes forming a ring and a set of direct connections from each non-included terminal to a node included in the ring. The solution should also meet the network requirements at the minimum cost.

II. DATA AND METHODS

The Ant Colony Optimization is used in a way to let Ant Agents visit the graph nodes, until they return to the starting node. Upon their return on the starting position we calculated cost of the cycle as a sum of the ring route cost and the assignment costs. Depending on the quality of the cycle pheromone is laid on the branches belonging to the ring.

We had chosen this approach for pheromone trailing, because we did not have *a priori* knowledge about the number of nodes belonging to the ring, and the number of assignment nodes. This approach provided that ant colony had decided about the ring size and which nodes were part of the ring and which not.

Due to a single path nature of the assignments, their costs are 4 to 5 times lower compared with the ring connection costs. This is the reason for the importance of the resulting topology, and significance of the selection which nodes to include in the ring, and which to leave out of the ring and assign separately to respective node in the ring. In case that assignment cost was higher than the cost of the connection within the ring, algorithm would have tried to connect all the nodes into the ring and the problem would be reduced to the classical Travelling Salesman Problem (TSP). Accordingly the Ring Star problem can be considered as a generalization of the TSP.

The program was tested using files Bosnia62.tsp, att532.tsp and d1291.tsp. Files att532.tsp and d1291.tsp are part of TSPLIB95 [7]. File Bosnia62.tsp was created using geo coordinates from 62 municipalities in Bosnia and Herzegovina, and in compliance with the rules for the library TSPLIB95 (in Appendix).

The program comprised four ACO algorithms: Ant System, Elitist Ant System, Rank-Based Ant System and MAX-MIN Ant System. The program was executed using different parameter values and results achieved were captured.

In addition, we have used to algorithms for local search and the following pseudo-random-proportional rule for the next node selection:

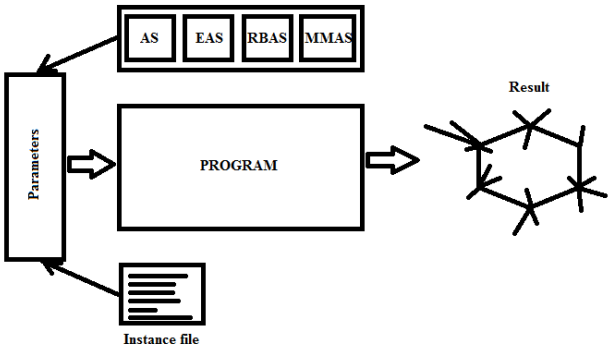

Figure 1. System block diagram

$$p_{ij}^{k} = \frac{\tau_{ij}^{\alpha} \cdot \eta_{ij}^{\beta}}{\sum_{l \in N_i^k} \tau_{il}^{\alpha} \cdot \eta_{il}^{\beta}}, \quad (1)$$

III. SYSTEM DESCRIPTION

The system we built to utilize the four selected ACO algorithms is shown in Fig. 1. The system was capable to execute the program without user intervention, using the default values for the parameters, otherwise user needed to change the parameter values. After parameters initiation, program calculated or read data about the nodes and their respective distances.

After that initiation phase, the system was searching for solutions. The first solution was saved as a candidate for the result. Every time the system had found a better solution it was saved for reviewing the solution in process and to monitor advancement in a search for a better one.

The system utilizes modified standard ACO algorithms described in detail in [8]. In the following section we shall describe only differences with respect to the original algorithms. In respect to the TSP, pheromone evaporation rate calculation is changed. The evaporation in solving the TSP starts when all ants return to the starting point. In this work, the evaporation is started after the Ant makes more steps than the double maximal ring size. The evaporation implementation is the same for all four ACO implemented in the system.

A. *Ant System (AS)*

1. The Ant System algorithm starts with positioning the Ant Agent at the random node.
2. The Ant Agent moves along the path selecting the next node to visit using the pseudo-random-proportional selection rule (1).
3. If parameter defining the maximum number of nodes in the cycle is equal total number of nodes, the Ant Agent is obliged to visit the starting node again.
4. If the starting and the destination node are the same, the Ant changes the move direction, and traverses the cycle backwards.

5. The Ant checks the quality of the cycle and, if needed, improves it using the local optimization.

6. On its way back, Ant lays pheromone, and the quantity of the pheromone is inversely proportional to the cost of the cycle.

7. The cost of the cycle is calculated as a sum of the ring route cost and assignment costs.

8. After laying pheromone on the branches traversed, the Ant repeats the algorithm.

9. After every few steps, program trigger evaporation of pheromone trail.

B. *Elitist Ant System (EAS)*

Elitist Ant System algorithm differs from Ant System in a way how pheromone quantity is calculated.

The algorithm in accordance with the description in [8], before step 6. (in A. Ant System), assigns extra reword for the best cycle. This is accomplished using the specific parameter that multiplies the pheromone trail.

C. *Rank-Based Ant System (RBAS)*

Rank-Based version of the ACO algorithm for the Ring Star problem has a significant difference in implementation, compared with the previous algorithms. Step 6. (in A. Ant System) is replaced with three new steps.

6a. Whenever the Ant Agent constructs a ring of nodes, that results is captured in the temporary array, until the all Ants complete the task.

6b. After that, the system selects the r best rings and assign to each ring respective rank starting with the r for the best towards 1 for the last ring in the selection.

6c. Pheromone trail is updated for these rings, and quantity of the pheromone is multiplied with the rank of the ring.

D. *MAX-MIN Ant System (MMAS)*

In this algorithm the Ants also construct the path, again by selecting the next node using the pseudo-random-proportional rule (1). The difference is regarding the pheromone update (Step 6. in A. Ant System).

6. The MAX-MIN algorithm limits the upper and lower boundary for the pheromone quantity. After the Ant constructs the cycle, the pheromone is updated according to the calculated boundaries, and the Ant starts its task again from the beginning.

IV. RESULTS

The system was tested using the workstation with core2duo processor and 2GB RAM, with the MS Windows XP operating system.

In the beginning the program was executed to establish input parameter: evaporation rate. The parameter was changed thorough several iterations, and final values for the parameter is presented in the Table I.

TABLE I. INPUT VALUES FOR EVAPORATION

Algorithm	***Evaporation parameter***
Ant Colony System	0,03
Elitist Ant System	0,03
Rank-Based Ant System	0,05
MAX-MIN Ant System	0,018

Each of the four algorithms was tested in duration of 20 minutes, with previously presented parameters and for the four data files. The results are presented in Fig. 2 for data from the files att532.tsp and dl291.tsp [7], and Fig.3 for data from the file Bosnia62.tsp.

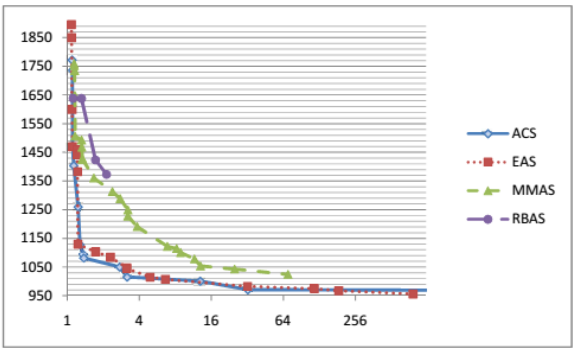

Figure 2. Results for the file: Bosnia62.tsp

Presented results were obtained with system using the following parameters: Number of Ant Agents: 32, Minimal percentage of nodes to be included in the ring: 30%, Maximal percentage of nodes to be included in the ring: 70%, Maximal time interval for program execution: 1200s, Number of nodes in neighborhood: 10, Assignment cost was 20% of the ring route cost.

During construction phase of algorithm, while Ant construct the ring it is not allowed to close ring if he did not include, due to Minimal percentage of nodes, minimal number of nodes in his path. Similarly, if he reach Maximal percentage of nodes, next node which he will chose is his starting node.

Analyzing the results obtained, the MAX-MIN Ant System (MMAS) is constructing the best solution, what is in compliance with [9]. However, it can be noted that in respect to convergence, other algorithms after additional time period construct the better solution.

V. CONLUSION

Presented results bring into attention several issues worth the further investigation. As a next step we would like to build a solution employing a hybrid of the two algorithms: ACO and the Neural Networks algorithms, such as backpropagation .

We expect that this hybrid approach combining the advantages of the ACO with the ability to search for the

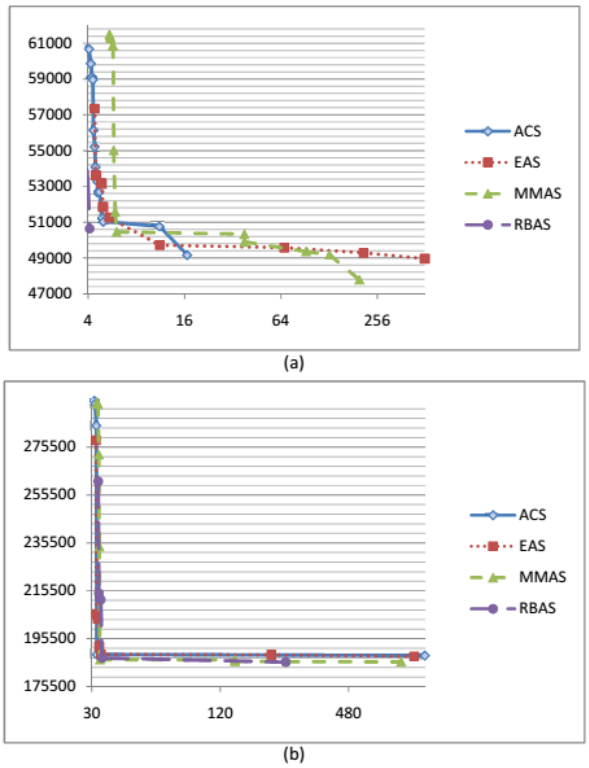

Figure 3. Results for the files: (a) att532.tsp (b) d1291.tsp

global optimal solution, and the backpropagation algorithm with the ability of convergence to the local optima, can be successfully applied for solving the Ring Star problem.

Using String Similarity Metrics for Automated Grading of SQL Statements

I. Štajduhar* and G. Mauša*
* University of Rijeka, Faculty of Engineering, Department of Computer Engineering, Rijeka, Croatia
istajduh@riteh.hr

Abstract - Manual grading of structured query language (SQL) statements after an exam can be tedious and time consuming for the teaching assistant. Additionally, it can also be subjective to her current state of mind and, thus, prone to errors. In this paper we propose an automated method for grading individual SQL statements. The method uses several common and simple string similarity metrics for comparing the student devised statements against the reference statements. These are then used, along with the manually assigned grades, for building the predictive logistic regression model. The proposed method was evaluated on a dataset consisting of 314 pairs of student-reference statements, along with the discretized average grade assigned by three independent evaluators. The model achieved the expected classification accuracy of 78% on a binary class, thus exhibiting its potential for real-life application. The model can be used as is with the suggested calculated features and reported learnt parameters, or adapted to other examiners' evaluation criteria, presuming their willingness to build manually graded datasets of their own.

I. INTRODUCTION

Sitting in a dark and cold office, working late hours, performing a mind-numbing choir, one cannot help oneself but not to ask himself: "What have I done to deserve this?". The authors of this paper are no strangers to this scenario during midterm and final examinations at their home university, when they are overwhelmed by a large number of SQL exams that need to be manually graded. Here, an SQL exam usually consists of several assignments, custom made for a distinct toy database (one not too simple, or too difficult to grasp), each of which requires an answer in a form of an SQL statement. Although the answer statement might not necessarily be unique for a distinct question, it does need to generate the exact relation, as was prescribed by the assignment, to be correct. Verifying the equivalence of the answer statement output relation to the reference statement output relation is trivial, if done using information technology. Two years ago we developed an SQL examination system in the form of a web service, allowing us to evaluate our students' understanding of SQL in a more grading-friendly and fair way, than it was when we conducted the examinations solely on paper. Additional benefit of such a system is that the students now gained the ability to check their progress during this problem-solving process and correct syntactic errors on the fly, which is a desirable property of a teaching system [1]. This system would automatically test for equivalence between the student relation and the reference relation and automatically grade such cases as correct. Moreover, it would discard syntactically incorrect statements, grading them as incorrect. Yet one problem remained. What was to be done with all the syntactically-correct "close, but no cigar" answers, ones that were automatically graded as incorrect?

Automated grading of SQL statements has been in the focus of the scientific community in the last decade or so. There exist several interesting interactive SQL tutoring and/or grading systems [2,3,4,5,6,7]. The automated tutoring systems, such as [2,3], are focused on improving student learning, and usually provide on-line automated feedback to the student, with guidance based on a personalized assessment. Other systems [4,5,6,7] also include the (partially-) automated grading component, but with some limitations. For example, *AsseSQL* [4] provides query grading, but only on rather simple queries. *SQLator* [5] allegedly uses a heuristic grading engine, but no details are specified in the proceedings paper. *SQLify* [6] introduces other manual grading mechanisms, like peer review, for coping with the problem of continuous grading. The most thorough automated grading system was recently presented in [7], including also the statement cost and style grading, but, again, lacking the option of evaluating partially correct answers.

Recent work done, towards developing a system for fully automated grading of SQL exams, mostly involved mechanisms for thorough semantics parsing. These approaches exploited the SQL semantic specifics to formulate simple rules, to be applied for automated grading. They are, however, mostly limited to simpler statement formulations, which is understandable, since the language semantics are extremely difficult to reasonably bind in a fair SQL understanding-evaluation-system model. For more complex statements, manual grading is usually necessary.

In this paper we demonstrate that simple string similarity metrics can be successfully used for comparing the student-devised SQL statement against the reference statement, without specific knowledge or understanding of the underlying semantic intricacies of SQL. We believe that these could be used to further improve the accuracy of existing, semantic aware, automated grading systems, or as an add-in to the systems that lack soft grading entirely. The prerequisites for this are using a live database management system (DBMS), a nonempty toy database

The work presented in this paper is partially supported by the University of Rijeka research grant 13.09.2.2.16.

and a list of assignments with corresponding solutions in the form of SQL statements.

Structure of this paper is as follows. In the following section, we describe the data used for evaluating the model. Being aware of the structure of the data used is necessary for understanding the workings of the feature transformations and the learning setup, described in section III. In section IV, we report and interpret the results obtained through empirical evaluation of the proposed model, using good machine-learning practice. Our findings are summarized in section V, additionally giving some insight into our probable future efforts in this field.

II. DATA

Exam data was gathered during the summer semester in the academic year 2013/2014, at the course Database Systems, held at the Faculty of Engineering, University of Rijeka. Part of the exam used to assess students' knowledge of SQL was performed on computers, using a live database-interactive system devised here. This system produces an individual exam for each student, generating it by randomly selecting a total of 5 assignments from 3 pools of questions of varying difficulty, tied to an exam database: 2 easy, 2 moderate and 1 question of hard difficulty. For the purpose of this study, we used the "Library" example database, consisting of 13 assignments of varying difficulty, each of which requires an answer in the form of a SELECT statement. The entity-relationship model for this toy database is presented in Fig. 1. During the midterm and term exams in the semester, a total of 393 student answers were gathered for this database. A summary of gathered data is presented in Table I.

A. Old grading process

Each of the 393 student answers was first automatically graded by the system, using a rigid evaluation principle, and then manually regraded by the teaching assistant, to somewhat soften the criteria. If the student-devised statement gave the same resulting relation as the reference statement, it was then marked as completely correct and graded 100%. This equality was compared automatically and reported back by our system using the following expression:

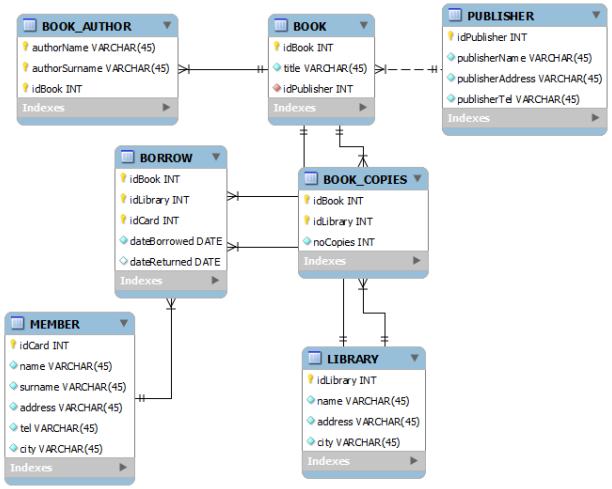

Figure 1. ER model of the "Library" toy database

$$(R_S \text{ UNION } R_R) \text{ MINUS } (R_S \text{ INTERSECT } R_R), \quad (1)$$

where R_S represents the relation returned by the DBMS when running the student-devised statement, and R_R represents the relation returned by the DBMS when running the reference statement. If the expression returned an empty relation, then we could assume that R_S and R_R were equal. The actual implementation of the equality checking function required manual implementation of binary set operations MINUS and INTERSECT, because the MySQL DBMS does not support them directly. If, on the other hand, the student statement was noninterpretable, or far from the correct answer, it was marked as completely incorrect and graded 0%. This was also done automatically.

All of the interpretable statements were manually inspected afterwards for softening the grading principle and detecting cheating attempts. In some cases, when the student-devised statement was semantically close to the reference statement, but not entirely correct, the answer was manually labeled as partially correct and graded 50%. If not for this step, it would remain graded 0%. Cheating would occur when a student would use several statements to come to intermediate results and then use their output manually to achieve the desired resulting relation, instead of writing it as a single, standalone, statement. Detected cheating attempts were then graded 0% (instead of previously automatically assigned 100%).

B. New grading process

To allow a more flexible grading method and to account for the possible teaching assistant bias during the assignment grading, three independent expert reviewers were engaged in a triple blind, fully-manual, grading of the entire answer dataset from scratch. Each of the reviewers was given a spreadsheet, consisting of all of the 393 student-reference statement pairs, along with the assignment difficulty label, access to the live database and several grading guidelines for correctly assessing the knowledge. These were as follows: if the statement cannot be interpreted by the DBMS, i.e. reports an error parsing the statement, label it **N** (noninterpretable); otherwise, if the statement is interpretable, then use the appropriate exclusive scenario:

- If the relation returned by the student statement, R_S, equals the relation returned by the reference statement, R_R, then grade it 100% (1). If the student statement is regarded a cheating attempt, label it **C** (cheating).
- If the student statement is completely meaningless (e.g. SELECT * FROM tblname), label it **M** (meaningless).
- If the student statement is not entirely correct, i.e. $R_S \neq R_R$, then try to assess the amount of knowledge needed for devising such a statement, in regard to the question asked, and grade the answer accordingly in a continuous scale [0%, 100%]. Be strict when grading the answers in the easy category, and be lenient when grading the answers in the hard category.

This last scenario is, obviously, the hardest and most time consuming part of the entire grading process. Separate labels for special cases of noninterpretable, meaningless and cheating attempts were introduced (and used instead of grades) in order to allow later use of various record filtering methods for tidying up the data, e.g. for possible outlier exclusion. The reviewers were advised against sharing the grades they assigned and subjective policies they practiced between them, to retain the correctness of the experiment.

C. Tidying up the data

After the grades have been assigned for every student answer, by each reviewer independently, a mean of those estimated grades was taken as ground truth. Special cases detected during the grading process (i.e. records labeled **N**, **C**, or **M**) by at least one of the reviewers were handled in the following manner. After the grading assignment process, 76 pairs were excluded from the dataset due to their noninterpretability (**N**) by the DBMS. These would (and should) be automatically graded with 0% in our live system, and are, thus, not interesting for the prediction problem. Additional 3 pairs were excluded because they were labeled as cheating (**C**). They were omitted purposefully because they are outliers in the data. If they were more numerous, however, they could be automatically detected by the predictive model learnt and then excluded. Pairs labeled meaningless (**M**) were only graded 0%, and were not excluded from the dataset. This yielded a new dataset of reduced size, consisting of 314 instances. A clearly bimodal grades distribution for this dataset is presented in Fig. 2. Discrepancies between reviewers' grade and label assignments were not taken into account for outlier detection.

Estimated grades distribution on the used dataset clearly suggests that the prediction problem is not solvable via regression. The obvious imbalance of occurrence frequencies of grades, ranging from 10% to 90%, makes it almost impossible to build a good regression prediction model, i.e. one that would estimate the exact grade percentage, ranging from 0% to 100%, based on the given answer statement. This is, clearly, an unfortunate consequence of the rather small exam database used, consisting of a majority of assignments too simple or too difficult for the average student (not justifying the obvious lack of knowledge and skill herein). Summary of the average assigned grades statistics for each question are presented in Table I.

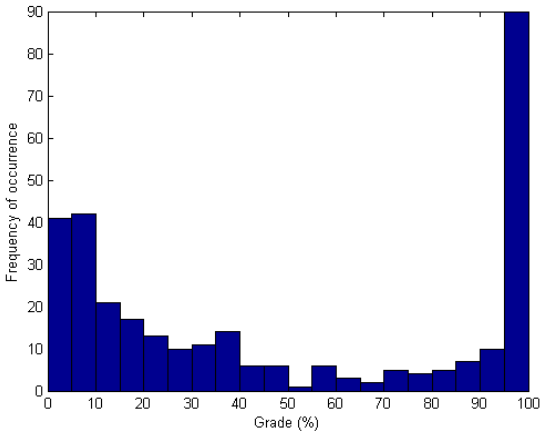

Figure 2. The average grade distribution for the dataset

TABLE I. FINAL EXAM DATASET AND GRADING SUMMARY

Question difficulty	Question ID	Number of answers	Average assigned grade summary			
			Minimum grade	Maximum grade	Median grade	Binary grade distribution 0/1 (%)
Easy	1	24	0	100	15	75 / 25
	2	24	0	100	93.33	33.33 / 66.67
	3	37	10	100	83.33	16.22 / 83.78
	4	29	0	100	96.67	27.59 / 72.41
	5	20	0	100	56.57	50 / 50
	Subtotal (134 answers)				86.67	37.31 / 62.69
Moderate	6	17	0	23.33	13.33	100 / 0
	7	28	0	100	21.67	71.43 / 28.57
	8	28	0	100	45	53.57 / 46.43
	9	28	0	100	21.67	85.71 / 14.29
	10	18	0	100	23.33	61.11 / 38.89
	Subtotal (119 answers)				18.33	73.11 / 26.89
Hard	11	19	0	100	45	57.89 / 42.11
	12	21	0	100	35	57.14 / 42.86
	13	21	0	100	18.33	90.48 / 9.52
	Subtotal (61 answers)				28.33	68.85 / 31.15
Total					35.83	57.01 / 42.99

That being said, we decided to use a binary grading system instead, based on the 50% threshold: answers graded 50% or higher were assigned label 1 (correct) and label 0 (incorrect) was assigned otherwise. This way, all the answer statements that were estimated as being closer to the true solution, were labeled as correct. Unfortunately, this grading system does not include the third, intermediate, grade, because the frequency of the grades around 50% is rather small, thus not providing enough data points for this third label. This binary system is not entirely fair for real-life application, but in this paper serves its purpose for demonstrating the general idea.

Finally, the statement dataset consisted of 314 records, each of them described with the following features: question difficulty, question ID, reference SQL statement, student-devised SQL statement and binary label (0/1). Before these could be used for building a predictive model for automated grading, additional steps were needed to ensure the provisioning of suitable metrics based on SQL statements comparison. These are described in the following section, along with the details on the predictive model used.

III. MODELS AND METHODS

In this section we first describe the data preprocessing techniques that were applied to the SQL statements in the dataset, in a stemming-like manner. The goal was to get rid of the noisy constructs in the statements, thus preparing them for the input to several string similarity metrics functions. Finally, we present the methodology used for learning the predictive model from data.

A. SQL statement preprocessing

SQL statements normally consist of a variety of different constructs and keywords, such as SELECT, FROM, WHERE, GROUP BY, HAVING, variations of JOIN, arithmetic operators, punctuation characters, brackets, table and column names, aliases, etc. Subsets of these form an integral part of every SELECT statement. Some of these constructs and keywords were removed from the statements, in order to insure greater generalization performance, e.g. to lower the noise in the data.

In each SQL statement string, both in the answer from student and in the reference statement, the following characters were omitted: ",", ";", "(", ")", "=", "<", ">", "!", "+", "-", "*". Additionally, newline characters were replaced with whitespace, and all leading and trailing whitespace was removed. Finally, all SQL aliases preceding the table column names with a dot were removed from the statements. This preprocessing step is the only one partially aware of the SQL semantic intricacies.

The choice of activities to be performed during the SQL statement preprocessing heavily depends on the type and content of statements that can be expected. The activities chosen here are far from optimal, but were more than adequate for the preparation of the used dataset.

B. Calculating learning features

Building an accurate prediction model for grading student SQL statements required developing a number of various metrics for measuring the similarity of the student-reference statement pairs. These metrics were adopted and adapted from several well-known information theory concepts [8]. We used the following functions for computing the features (S_S stands for the student-devised statement and S_R stands for the reference statement; function names in the equations are self-explanatory):

- **Normalized absolute length difference (ALD)** is the absolute difference of string lengths between the statements, divided by the length of the reference statement,

$$ALD = \frac{|\,length(S_R) - length(S_S)\,|}{length(S_R)}. \quad (2)$$

- **Normalized character Levenshtein distance (CLD)** is the smallest number of single-character edits (i.e. character insertions, deletions or substitutions) required to change one string into another string (also known as edit distance [8]), divided by the length of the reference statement,

$$CLD = \frac{LevDist(S_R,S_S)}{length(S_R)}. \quad (3)$$

- **Normalized word Levenshtein distance (WLD)** is the smallest number of single-word edits (i.e. word insertions, deletions or substitutions) required to change one string into another string, divided by the number of words in the reference statement,

$$WLD = \frac{wordLevDist(S_R,S_S)}{noWords(S_R)}. \quad (4)$$

  Whitespace is the only token used for retrieving the ordered word list from a statement.

- **Euclidean word frequency distance (EWFD)** is a distance between statement word frequency vector points in the Euclidean space, in regard to the unique words occurring in the reference statement,

$$EWFD = \sqrt{\sum_i (f_i(S_R) - f_i(S_S))^2}. \quad (5)$$

  $f_i(S_R)$ stands for the frequency (number of occurrences) of the i[th] unique word $w_i \in S_R$ and $f_i(S_S)$ stands for the frequency of the word w_i in S_s.

Only the values of the features, normalized to their respective reference value, were used, because experimental results suggested that better model generalization properties were achieved using them, as opposed to using nonnormalized values. Asymptotic runtime of the described feature calculating functions is rather small, varying from O(n) to O(n^2), where n can be the length of the longer string or the larger number of words in two strings. As the last step, values for each of the calculated metrics (separately) were linearly scaled to fit the interval [0,1], whole dataset wise, enabling us later better interpretability of the model parameters learnt.

C. Learning the predictive model from features

After the SQL statement preprocessing step, following the calculation of learning features, the adapted statement dataset consisted of a total of 314 instances, described by 6 features (question difficulty, question ID, ALD, CLD, WLD and EWFD) and a binary class, representing the estimated correctness of the student-devised statement. First two features were handled as categorical, and the remaining four as numeric (values ranging in the [0,1] interval).

We chose to use a binomial logistic regression model to illustrate the applicability of the string similarity metrics for correctly predicting the class value. This was a logical step following the abandoned multiple linear regression idea, highly capable of utilizing the linearity in the calculated string similarity metrics. Inferring the class y from a logistic regression model is done using a simple expression:

$$h_\theta(x) = \frac{1}{1+e^{-\theta^T x}}, \quad (6)$$

where x represents the input feature vector, θ represents the model parameters vector and $h_\theta(x)$ is the probability that the inferred estimate equals 1, given x and θ. In the inference phase, classification is done simply by choosing the more probable class, i.e. if $h_\theta(x) \geq 0.5$, then $y = 1$, otherwise $y = 0$. Model parameters are learnt from data by maximizing the log likelihood,

$$L(\theta) = \sum_i (y_i \log h_\theta(x_i) + (1 - y_i) \log(1 - h_\theta(x_i))) + \\ + \lambda \sum_j {\theta_j}^2, \quad (7)$$

in respect to the actual class value of the i^{th} instance, y_i, considering the ridge regression regularization penalty λ to prevent overfitting. The actual implementation of the algorithm used a quasi-Newton method for parameter estimation, with $\lambda = 1$ [9].

IV. EMPIRICAL EVALUATION

To explore the predictive power of calculated features, we performed several experiments on their subsets, bearing in mind their usefulness for future real-life application. The experiments were conducted using stratified 10-fold cross-validation, to test the models generalization properties. Data preprocessing was performed using MATLAB, and model learning and testing using Weka [10]. The learnt models predictive efficiency was estimated calculating two well-known model evaluation measures: classification accuracy and area under receiver operating characteristic (ROC) curve. Classification accuracy is calculated as the percentage of correct predictions against the total number of predictions tested. Estimated classification accuracy that is lower or equal to the percentage of the majority (more numerous) class means that the learnt model is useless. Everything higher than that is pointing out to a possibly useful model. ROC curve is a graphical plot, commonly used for illustrating the models predictive power under various discriminative threshold values [11]. It represents the relationship between the true-positive rate, against the false-positive rate, at a given threshold. Area under the curve (AUC) is commonly used to evaluate the robustness of the model learnt. In regard to the ROC threshold value, classification accuracy is calculated for the discrimination at the threshold value of 0.5. Experimental results obtained through various feature subset setups are presented in Table II and Fig. 3.

In the first experiment, all 6 calculated features were used for grade prediction. Highest classification accuracy was achieved using this exact setup, due to differences in samples belonging to each distinct assignment (question). Good generalization properties are, however, not to be trusted here, because the class distribution balance varies significantly in the data (deviates from its mean), thus contributing to the overall accuracy with trivial models. For example, the percentage of incorrect answers for question ID 13 is 90% (compared to the mean number of incorrect answers, which is 57%). Of course, this also means that for this exact question databank, inclusion of the question ID feature is useful. Anyhow, it would make far more sense to train separate models for each question ID separately, if the data were more abundant.

TABLE II. EXPERIMENTAL RESULTS OBTAINED THROUGH 10-FOLD CROSS-VALIDATION FOR THREE DIFFERENT FEATURE SUBSETS USED

Features used	Classification accuracy (%)	Area under ROC
question difficulty, question ID, ALD, CLD, WLD, EWFD	78.66	0.853
question difficulty, ALD, CLD, WLD, EWFD	71.97	0.735
ALD, CLD, WLD, EWFD	62.10	0.664

In the second experiment, all calculated features, except question ID, were used. The exclusion of the feature led to a significant drop in calculated classification accuracy, as was expected. The overall model usefulness was retained, however, because the class distribution balance has also settled nearer to the dataset mean. The model learnt by using this feature subset is the first one that could be used on other (yet unseen) question databanks, if one was prepared to assign prescribed difficulty levels (easy, moderate or hard) to the questions contained in them, in the same manner as we did. Regression coefficients estimated from the entire dataset are presented in Table III. It is interesting to note that, although individual feature contribution implies the estimation of negative thetas (smaller values should mean higher probability of answer correctness), the model learnt suggests otherwise.

In the third experiment, which was also the last, only string similarity metrics were utilized for model learning. If one is not able to ascertain the correct level of difficulty for questions contained in the databank, this is the way to go. The additional, even more significant, drop in the estimated accuracy suggests that this model is not by far ready to be exploited in this form. We made a comment on this in the following section.

V. CONCLUSION AND FUTURE WORK

Manual grading of SQL exams is a tedious and mind-numbing ordeal, usually done by teaching assistants (those poor sods). Although some effort was made by the scientific community, towards eliminating the need for manual grading of SQL exams, none of them completely succeeded in this task. Unlike these attempts, which are highly aware of the underlying SQL semantics, we

TABLE III. ESTIMATED LOGISTIC REGRESSION COEFFICIENTS FOR THE SECOND EXPERIMENT. INPUT DATA WAS SCALED TO [0,1] INTERVAL, PRIOR TO MODEL LEARNING.

Feature	θ
question difficulty = easy	-0.9984
question difficulty = moderate	0.7057
question difficulty = easy	0.4993
ALD	1.6415
CLD	3.8415
WLD	-0.8138
EWFD	0.3033

decided to use a different approach.

In this paper we present a way of using simple string similarity metrics for comparing the student-devised SQL statement against the reference statement, for the purpose of engineering cloddish, yet useful features, which are then used for supervised learning of a predictive model from data. This model could be used for automated grading of SQL exams. String metrics used in this paper include the difference in character length of statements, the statement Levenshtein distance in terms of characters and words and, finally, the Euclidean word distance between statements. These were used for building a logistic regression model, along with two other, dataset specific features. Empirical evaluation of the proposed procedure was performed on a dataset consisting of 314 manually graded statement pairs. Obtained experimental results suggest, that the procedure shows promise, seeing that the metrics used are able to contribute to the overall predictive accuracy of the model, but is not yet usable (in this form, at least).

What could be done to further improve the predictive efficiency? For one, we should start by building a larger exam databank. Using only a handful of student solutions, for a handful of question assignments (in turn), for only one database sandbox (toy dataset) is not nearly enough for building a good predictive model, nor for the said database, nor for any other, yet unseen, database. A larger exam databank would allow us to exclude the instances, highly-disagreed upon by the reviewers during the manual grading process (these would be the outliers in the data), thus eliminating a significant amount of noise. Additionally, a larger exam databank would probably consist of a more uniformly distributed grades in percentages, or at least a larger number of grades concentrated around 50%, probably allowing us to learn a multiple linear regression model for the continuous grading scale, further increasing the usefulness of such a predictor in real-life application.

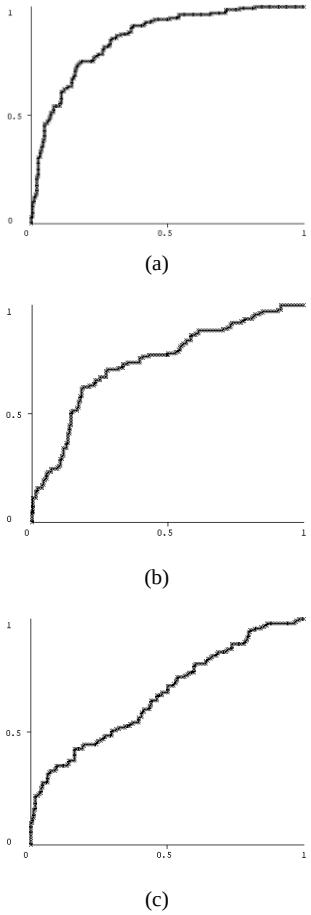

Figure 3. ROC curves plotted for the three feature subset experimental setups used: (a) question difficulty, question ID, ALD, CLD, WLD, EWFD; (b) question difficulty, ALD, CLD, WLD, EWFD; (c) ALD, CLD, WLD, EWFD. Horizontal axis represents the false positive rate, whereas the vertical axis represents the true positive rate.

Utilization of other string metrics for engineering of additional features would most likely lead to further improvements in the model's predictive accuracy. Finally, comparing the ungraded student-devised statements against those student-devised statements that are recognized as completely correct by the system in the early processing stage, in a nearest-neighbor manner, could also improve the model performance. These are the steps that we intend to follow in the future.

ACKNOWLEDGMENT

We would like to thank I. Todorović for his work on developing the original SQL exam system. A very special thanks goes to S. Jugo, F. Hržić and M. Burul, for their invaluable help with the exam statement grading.

***Abstract*—Massively Multi-Player On-Line Role-Playing Games (MMORPG) give us the opportunity to study two important aspects of computing: (1) large-scale virtual social interaction of people (players) and (2) the design, development and coordination of large-scale distributed artificial intelligence (AI). A common denominator for both aspects are the methods used to study them: social interaction can be described and simulated using agent-based models (ABM) whilst distributed AI is commonly modeled in terms of multi-agent systems (MAS). The important question to ask in both perspectives is how do agents organize in order to perform their tasks and reach their objectives? In the following paper we will present and overview of agent-based approaches to modeling MMORPG's agents including human players, artificial players (bots) and non-playing characters (NPCs). We will put a special accent on useful agent behaviors, coordination and consensus mechanisms as well as organization and social network structure of agent societies.**

***Keywords*—MMORPG, multi-agent systems, modeling, npc, bot, agent behaviors.**

I. Introduction

Role-playing computer games (commonly referred to as role-playing games or RPGs) are a computer game genre in which the player controls the actions of a protagonist (or several party members) in some world which is well defined [1]. A massively multi-player on-line game (MMOG) is a computer game that supports a great number of players playing the game on-line simultaneously often causing interaction among them [2]. Massively multi-player on-line role playing games are thus a mixture of the RPG genre with MMO allowing players to control the action of their avatar (protagonist) by interacting with a potentially large user-base on-line [3].

MMORPGs have become enormously popular during the last two decades. According to Wikipedia [4] numbers of players on some popular MMORPGs are given below:

- Dofus – 10,000,000
- World of Warcraft – 7,600,000 (on average 34,000 simultaneously on-line)
- MapleStory – 5,000,000
- Knight Online – 4,250,000
- Start Trek Online – 3,200,000
- Guild Wars 2 – 3,000,000
- Final Fantasy XIV – 2,500,000 (avg. 30,000-45,000)

The global MMO market [5], [6] is growing continuously with 2011 $\approx$ 8.5 billion €, 2012 $\approx$ 10.2 Bn€, 2013 $\approx$ 11.7 Bn€ and 2014 $approx$ 15.0 Bn€.

While the importance of MMORPGs in economic terms is obvious, another aspect is of equal importance: it allows us to study two aspects of large-scale computing - social interaction of (large numbers of) players through a computing platform as well as the design and implementation large-scale distributed artificial intelligence (in form of non-player characters – NPCs, mobs – various monsters to be fought, as well as artificial players – bots). Both of this aspects can and should be studied using agent-based techniques the former by ABM (social science perspective of agents) and the latter by MAS (computer science perspective).

In the following work in progress paper we will present an overview of agent based modeling techniques which can be applied to study MMORPGs some of which have already been applied in the ModelMMORPG project[1]. Basically we will describe three sets of methods that allow us (1) to model NPCs (finite state machines), (2) user behavior (agent based modeling of social network structures), and (3) bots (agent behaviors, automated planning techniques, consensus and coordination techniques). Our objective in future research is to study user behavior using social network analysis and natural language processing in order to establish agent based models of their behavior that will be mapped into an ontology of organizational design of large-scale MAS (developed partially in [7], [8], [9], [10]) to be used in the implementation of bots to foster organizational behavior among them.

MMORPGs have various subgenres, but a usual setting is that a protagonist is placed into a world in which he interacts with various NPCs and mobs which give out quests that have to be resolved in order to proceed to higher levels, buy better equipment or learn new skills like magic and similar. For the sake of the ModelMMORPG project the MMORPG The Mana World (TMW)[2] has been selected in order to conduct our research. It was selected due to a number of reasons: (a) it is open source (GPL licensed)) allowing us to modify code and add additional functionality, (b) it has a supportive community, (c) it supports a number of interaction techniques which can be studies (e.g. trade among players, IRC based chat, organizing teams called parties, social network functions e.g. friends, enemies, parties etc.), (d) it is a (more or less) finished game featuring lots of quests that can be analyzed.

[1] See http://ai.foi.hr/modelmmorpg for details.
[2] See http://themanaworld.org for details.

In order to study organizational behavior of players, apart from existing quests, we have partially developed a quest which fosters players to organize called "The quest for the dragon egg". The basic idea of the quest is that players have to establish parties of at least three players to transport a dragon egg to their castle to hatch it. Additionally, they have to gather a number of ingredients scattered across the Mana World to create a hatching potion. The catch is that time limits exist for each of the tasks, so they cannot be performed by a single player by himself. An egg hatches on a random location every 24 ± 1 hours, the egg has to be hatched in an hour or it goes bad. The hatching potion has to be available at the moment the egg is transported to the castle. Ingredients can be acquired by fighting mobs or by trading with other parties. Since all of these constraints are in fact (more or less) simple to implement, we use finite state machines to model NPCs needed for the quest.

The rest of the paper is organized as follows: in section II we give an overview of related work. In section III we show how NPCs can be modeled using finite state machines in TMW. In section IV we give an introduction on how to model social network behavior of players using an agent based technique. In section V we provide AI agent formalisms for modeling artificial players - bots. In the end VI we draw our conclusion and give an outline to future work.

II. Related Work

Since MMORPGs are a relatively new phenomena, there are consequently only few studies that investigate MAS and ABM approaches in MMORPGs. Most studies deal with the design of individual AI agents (NPCs). For example Eckschlager et al. [11] try to model emotional behavior through artificial neural networks and a Five-Factor Model of Personality. Tychsen & Hitchens [12] deal with the limited abilities of MMORPGs in story-telling and identify agent based story-telling [13] as a possible solution. Eladhari & Mateas [14] describe a technical framework for modeling personality and emotion for both players and NPCs called the Mind Module. They describe a semi-autonomous agent architecture built to be used in a multi-player environment, employed as a part of the player's avatar. Brom & Lukavsky [15] focus on the usage of full episodic memory in contrast to ad-hoc, or special purpose, memory, and how it can be contributed to the agent's believability.

Some investigations deal with a MAS oriented design of MMORPGs. Robert et al. [16] clarify why classifier systems (CS) are good candidates for action selection mechanisms of NPCs. CSs are used as control architectures for simulated animals or robots in order to decide what to do at each time. The authors describe different classifier systems and introduce a new CS architecture, acting in a MAS environment, which is adapted to the specific constraints of the MMORPGs. Fairclough & Cunningham [17] deal with the area of computer-mediated storytelling, and describe the "development of an expert case-based character director system which dynamically generates and controls a story, which is played out in a multi-player networked game world". The proposed system includes a story director system which utilizes the case based planning paradigm, and facilitates multi-player stories. Stories are modeled as cases, and their planning and scheduling is the primary activity of the system. This work is story-centered, and the notion of AI for the most part refers to the story director agent. Modeling of the NPCs is performed in a layered structure, from low-level behaviors to higher level targeted goals (low level such as collision detection, followed by social simulation, idle behaviors, targeted behaviors, attitudes etc.). Berger et al. [18] describe "an integrated, game-like e-Business environment that follows the role model of (...) MMORPGs", and essentially is a 3D virtual world based on game engine technology. This environment provides a platform for conducting business, and is based on MAS ideas, composed of many autonomous individuals - both human and software agents, which constitute avatars in the 3D virtual world. The goal of this environment is to support the complex interaction patterns between the members in an e-Business setting, and provide grounds for a lively and sustainable on-line community composed of providers and consumers.

Other studies employ ABM techniques to study player behavior. For example Lehdonvirta [19] is trying to apply concepts and techniques from economics to study the complicated interactions inside game worlds and is asking the question if techniques and theories from real economics be applied to virtual economics? Basic motivation for Lofgren & Fefferman [20] was a software update released into the MMORPG World of Warcraft, which created a full-blown epidemic. Players of this game encountered an extremely virulent and highly contagious virtual disease, which caused high rates of mortality and social chaos within gaming population that comes from a large-scale outbreak of a deadly disease. The authors conclude that the virtual outbreak in WoW game was both a missed opportunity to study epidemics, and a new direction for future epidemiological research. Ang & Zaphiris [21] have proposed a new method for sociability design and research through the use of simulation, and have developed an ABM to simulate and study the formation of social networks in a MMORPG guild community. Fishwick [22], on the other hand, introduces personal aspects of agents through first person perspective, inside an open-source, multi-user, virtual environment system called OpenSimulator.

While these studied do analyze the social structure and dynamics of players (trough social network analysis for example) they do not particularly target the question of how players organize in order to perform their tasks.

From this reasoning follows that there are two important aspects which aren't covered in contemporary MMORPG studies: (1) organizational techniques of artificial player's societies development, (2) study of organizational behavior of players.

III. Modeling NPCs

An NPC is an in-game character which is, most usually, used for communication with the player, serving the purpose of delivering all kinds of information to the player, e.g. basic information for new players, introduction to new areas, simple server-wide or local news service, information about a certain quest, etc. An NPC can range from a simple reactive agent to a completely interactive, environment and history immersed agent, based on the purpose it serves. Here we will consider simplest and an agent of average complexity, modeled as a finite automaton.

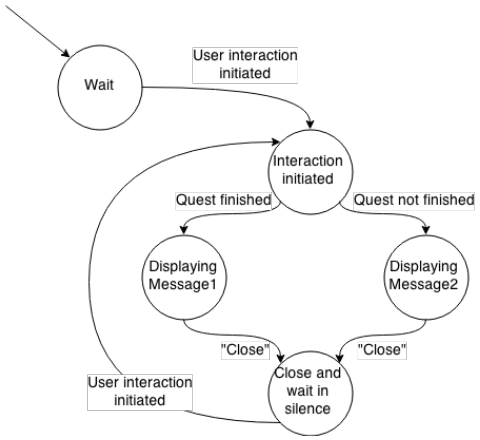

Fig. 1. Graph representation of the described agent

Fig. 2. In-game representation of the two simple interaction examples, dependent on the state of the quest

This finite state-machine needed for our goal is defined by six elements $(\Sigma, \Gamma, S, s_0, \delta, \omega)$, as follows: Σ is a non-empty symbol set called the in-alphabet, Γ is a non-empty symbol set called the out-alphabet, S is a finite non-empty set of states, s_0 is the initial state, δ is transition function defined as $\delta : S \times \Sigma \rightarrow S$, and ω is an exit function defined as $\omega : S \times \Sigma \rightarrow \Gamma$. This more general definition, when specialized for defining agents, is adapted as follows: in-alphabet is a set of possible experiences, out-alphabet is a set of possible actions, set of states is a set of agent's inner-self states, the initial state is the initial inner-self state, transition function is the next internal state function of the agent, whilst the exit is the action function that will be performed by the agent.

The less complicated version is a simple reactive agent which reacts to user-initiated interaction. Based on the status of the quest the user started with another NPC, the NPC delivers simple, static, information about the state of the world. As defined, the NPC has several defined states, activated by user interaction. Figure 1 shows an example of possible states and the transitions needed to reach them.

The in-alphabet of this agent consists of possible variable values, out-alphabet, considering it is a set of actions, gathers all the actions the NPC can take, i.d. send one of the messages to the player, set of inner NPC states are the states of this NPC, as visible in Figure 1, etc.

User interaction is started by clicking on the NPC or other

Fig. 3. In-game representation of the choices a player can make

ways of conversation initiation. The graph on Figure 1 depicts the possible state transitions, e.g. from *Interaction Initiated* state, in order to move to the *Displaying Message1* state, the quest status has to be checked. Based on this action, the agent changes its state, showing either *Message1* or *Message2*, as seen in Figure 2. Similarly, player has to click the Close button, so as to finish interaction with the NPC, and to get it ready for interaction with the next player, NPC or mob.

A more complex example is an NPC which gives out a quest, and is the sole authority on the state of the quest, depending on user interaction and a more dynamic environment, considering it interacts with the player on a more active level, and depends on some environment events, such as a timer. TMW NPCs are implemented using an domain specific scripting language, where quest process is tracked using a variable, and several code segments to be defined. These segments are accessed based on player decisions or status of variables or special elements of the environment. For example, an NPC, the Knight of Ni, after sending a default greetings message to the player, checks if this particular player is a part of a player party, and proceeds accordingly, as is shown in the code listing below.

```
if (getcharid(1)==0) goto L_Deny;
if (getcharid(1)) goto L_Allow;

L_Deny:
    (...)
L_Allow:
    (...)
```

The whole process of interaction between the user and the NPC is manipulated by using conditional expressions, such as in the following piece of code.

```
if (countitem(663) > 0 &&
    $@KnightNiShrubberyQuest == 3)
        set $@KnightNiShrubberyQuest, 4;
if ($@KnightNiShrubberyQuest == 0)
    goto L_Start;
if ($@KnightNiShrubberyQuest == 1)
    goto L_QuestState1;
```

In the code listing above, the first line checks if the player concerned has the needed item, defined by ID 663 (named *Black Rose* in the game), and if the quest state variable has value 3. If those are fulfilled, then the engine will set the value of variable *$@KnightNiShrubberyQuest* to 4. Other lines of code work in a similar manner, since the value of the quest state variable is checked, and a certain action is taken, e.g. the engine is instructed to go to the label *L_Start*, where some other code follows.

These mentioned labels are markers throughout the NPC script, which allow for non-linear script execution, and interactive communication with the user. For example, label *L_Start* contains the code which will try to attract the player to accept a quest. Although in a rather guided fashion, a player can choose the path they want to take, as shown in the code below.

```
L_Start:
    mes "We are
        Keepers of the sacred words.";
    next;
    mes "Ni!";
    next;
    mes "I shall say Ni! again if you do
        not appease me.\"";
    menu
        "You are a what?!",
            L_Ni,
        "All right!  What do you want?",
            L_Describe;
```

Figure 3 depicts the example communication done in the game environment, at the moment when the player is offered to choose their move. Direct interaction with player data, such as player inventory content, is something this game genre cannot do without. The example NPC will proceed to direct player data interaction only if the quest state variable has a certain value, which is, in turn, set by checking the player's inventory. In case of a successful check, the NPC will proceed, taking an item from the player's inventory (*delitem*) and giving them another item (*getitem*). More specifically, when certain conditions for an action are met, the NPC is going to proceed to this defined action, hence producing an effect affecting the player, as shown in code listing below. This example represents a prime example of the finite state automaton, since there is an input, a condition for an action, the action and a certain effect this action has on the environment (i.e. the player).

```
L_Next4:
    mes "[Knight of Ni]";
    delitem 663, 1;
    mes "\"Very good,
         that is a nice shrubbery.";
    next;
    mes "You shall be awarded
        with this mighty gift!";
    getitem 742, 1;
    mes "Now go!\"";
    set $@KnightNiShrubberyQuest, 5;
    close;
```

Non-player interaction with NPC is enhanced by using NPC timers and special code which activates when this timer reaches a defined point in time. In this example, the NPC is going to change value of the quest variable exactly sixty minutes after the second part of the quest is started, as seen in code below.

```
L_Next2:
    (...)
    initnpctimer;
    close;

OnTimer3600:
    set $@KnightNiShrubberyQuest, 11;
    end;
```

This particular action allows for more unpredictable and non-linear NPC behavior, when observed by the player. Introducing a random number generating function would further increase unexpected, yet completely foreseen NPC behavior.

IV. Modeling Player Behavior

In order to model the behavior of players in an MMORPG one needs to acquire statistical data about them using the game. Such logging data in TMW is available in form of chat logs, user (social) behavior logs, user inventory logs, trade logs and other logs that can be collected and analyzed. The collected data can be analyzed using various methods, but two approaches are of particular interest: social network analysis (SNA) and natural language processing (NLP) with possible help of sentiment analysis (SA) [23], [24]. SNA allows us to study the social structure of the players (interactions including chat, trade, fight etc; friendships; antagonisms; parties and similar [25]) as well as processes on networks (the dynamics of network creation [26], spreading of information [27], mixing patterns [28], [29] etc.). While SNA is very insightful in the construction and analysis of player networks, the actual meaning (semantics) of the interactions as well as their intensity can more efficiently be analyzed using NLP and SA techniques. In this way a comprehensive study of behavior can emerge that can be the input to the construction of agent based models of player behavior (see [30] for detailed examples).

A very interesting method to be used here is the so called recipeWorld brought forward by Fontana & Terna which is "an agent-based model that simulates the emergence of networks out of a decentralized autonomous interaction" [31]. The main of their approach is that modeled agents are given so called recipes that represent variable numbers of steps, some of which might run in parallel, which ought to be taken in order to achieve a given result. In this way the social network of agents emerges as a side effect of agent behavior which use recipes to achieve attended objectives. The model of recipeWorld is founded on four distinct sets: A the actual world populated by entities and their actual network; B an ABM with agents that base their behavior on the objectives and recipes derived from A; C the social network generated by B, D the data exchanged on the network. Fontana & Terna proposed that it is possible to populate sets A, B and C, by knowing D with use of inference and an approach similar to reverse engineering.

From our perspective recipes can be patterns of interactions (e.g. message passing, trade transactions and other actions) that lead to well connected subnets over some observed periods

TABLE I. THE STRIPS ALGORITHM

If on top is	Then
A complex or atomic goal which is satisfied	Remove it
A complex goal which is not satisfied	1. Leave it on top 2. Put its subgoals on top in a different order
An atomic goal which is not satisfied	Find a rule which adding list includes the goal 1. Exchange the goal with the rule 2. Put the rule's preconditions on top If no such rule exists put the preconditions on top in a different order If no such order exists find an alternative rule. If no such rule exists the, goal is not satisfiable.
A rule	1. Remove the rule 2. Update the state using the rule 3. Write down the rule (solution)
Nothing	Stop

of time. These patterns of interaction could be extracted using adequate SNA and NLP techniques and then used for simulation experiments to construct artificial agent networks. Such simulated networks could then be analyzed and compared to empirical data to see if they actually conform to real processes by using various network metrics for example. In this way automated organization techniques for agents could be established.

V. MODELING BOTS

The previous contemplation brings us to the most complex part of the project which deals with implementation of artificial agent players. In order for a an artificial agent to play a MMORPG a number of MAS and AI techniques have to be employed. The agent has to have the ability to connect to the game server, learn about its environment, understand instructions from NPCs and mobs, solve quests and interact with other (possibly artificial) players and organize to solve harder (social) quests. For the first part, we have partially implemented a low level client to the TMW server in the Python scripting language that allows us to connect an agent to the server, move around, collect items and interact with other players, NPCs and mobs.

In order to implement intelligent agents we will use the Smart Python Agent Development Environment (SPADE) [32] that provides a FIPA (Foundation for Intelligent Physical Agents) compliant development environment for Python and features a number of predefined agent behaviors, advanced knowledge bases and agent organization facilities like group chat and organizational units. We will use SPADE to build an agent layer above the low level interface that will allow agents to understand their surroundings (by using some of the provided advanced knowledge bases), solve quests (by implementing a belief, desire, intention – BDI agent model and an automated planning algorithm e.g. STRIPS [33] see table I) and interact with their environment (using the integrated communication and organization facilities).

Individual agents are usually defined by a number of behaviors which might be [34]:

- **role factory** (a role added at runtime and then enacted by the agent);
- **itinerary** (allows mobile agents to travel across various locations and perform tasks);
- **periodic** (looped behavior possibly with a given period of time intervals between iterations);
- **observer** (an agents awaits an event in order to perform its actions);
- **listener** (a special type of observer in which an agent awaits a special message of some other agent);
- **client/server** (resembles the client-server model);
- **one-shot behavior or task** (represents a simple task or activity);
- **finite state machine** (resembles a finite state machine in which every node is an activity to be performed);
- **sequential behavior** (a sequence of other behaviors);
- **parallel** (various behaviors are run in parallel).

Most of these behaviors will have to be used to implement a working bot (except maybe for itinerary, since our agents will not have to travel across the network). Role factories come to use in organizational behavior of agents. For example when an agent joins a party he might be assigned a role to act as the carrier of some item (e.g. the dragon egg) and has to enact this role (e.g. has to keep line of sight with two other party members). The periodic behavior can be used in multiple different occasions for example to harvest a given resource mobs of a given type have to be fought. The agent will loop this behavior until it has enough of a given resource. An observer behavior is likewise important – an agent will observe its environment and in case of an event (e.g. an attack of some mob) react accordingly. The listener behavior is similar – if a bot receives a message from another player it might choose to react. Client/server behavior are especially important for trading – (server) agents will offer some items and wait for other (client) agents to pay for them in order to deliver the good. Task behaviors are ubiquitous – every action (moving, attacking, talking etc.) are simple tasks to be performed. FSM behaviors on the other hand might come in handy to deal with various states of quests – e.g. when the player solves one part of the quest (by for example bringing some item to some NPC) it moves to another state (e.g. finding some other item). Sequential behaviors are important for the planning system – all plans will be sequences of (simpler) actions. Parallel behaviors on the other hand are obvious – while solving some task an agent has to be alert about events in the environment, thus the task behavior will run in parallel with some kind of observing behavior.

VI. CONCLUSION

In this work in progress paper we have shown some important agent based modeling techniques that allow us to study MMORPGs with a special accent on techniques to be employed in the ModelMMORPG project in which the TMW MMORPG has been chosen for study. We have firstly shown how to implement NPCs using finite state machines and how they can be implemented in the scripting language of TMW. Later we have provided some recommendations on how to collect, analyze and model behavioral and social player data using SNA, NLP, SA and ABM techniques. Based on the proposed ABM technique to model the social and organizational behavior of players, we have contemplated that artificial agents might implement their consensus and coordination techniques

in the same way by using the recipeWorld approach. In the end we have shown some important modeling techniques for implementing artificial players – bots – by providing important agent behaviors as well as examples of their usage.

Out future research is aimed towards implementing the (dragon egg) quest that will foster organizational behavior of players. Afterwards we will conduct a large scale study with the developed quest by collecting server logs that will be analyzed in the described way. The analysis will yield agent based models of organizational behavior among players that we will embed into an ontology of organizational design techniques for the development of large-scale MAS. In the end we shall implement artificial agent organizations and test their performance against human players on the TMW platform.

ACKNOWLEDGMENT

This work has been supported in full by the Croatian Science Foundation under the project number 8537.

***Abstract*—Using contextual information in recommender systems is a subject of continuous improvement of rating prediction accuracy. Among others, information on temporal rating dynamics contain valuable data that establish foundation for discovering changes in both individual and group user's preferences. Such changes can be caused by multiple factors such as changes of individual user interests, changes in item popularity or other hidden patterns or events. In this paper an improved user-based collaborative filtering algorithm is presented that utilizes changes of group user's preferences over time. We also investigate temporal dynamics of changes in user's preferences within different item categories and propose time weight function that improves prediction accuracy of recommender systems.**

***Index Terms*—Recommender systems, collaborative filtering, contextual information, temporal dynamic, user preferences, hybrid model**

I. Introduction

The general task of recommender systems is defined as finding item i_j that maximizes a given user's utility or optimizing the lifetime of user's utility [1]. The recommendation systems differentiate themselves by the type of knowledge they exploit, e.g. product knowledge or some other domain expert's heuristics or by different strategies the apply. The common strategies in recommender systems are [1]: *Content-based* (CB) recommendation, that recommends items similar to those preferred by the user in the past; *Collaborative filtering* (CF), which recommends items preferred in the past by similar users, using approaches with item-based or user-based filtering; and *Hybrid recommenders*, that combine both CB and CF in order to overcome particular limitations of each individual strategy.

Most of the traditional recommender systems exploit only user and item profiles associated to known ratings in order to predict ratings of unseen items [1], and they consider data collection as static. In such scenario, the ratings produced in the past used to predict future preferences are weighted equally. The fact that user preferences are naturally changing over time is not taken into consideration, leading to a reduced accuracy of recommender systems. The occurrence of changes in user preferences is known as the concept drift or concept shift [2].

Over the recent years, various approaches that cope with this kind of problems have been developed. The most common approach is discounting old rating data with a certain weight depending on the rating time. In collaborative recommender systems, the change of individual user preferences also affects preferences of the neighbor's users used to predict the unseen ratings of individual user, and vice versa. They affect each other indirectly due to fact that the group of similar users in CF is selected based on the user's individual ratings. By adding the item content or item preferences into the consideration, it's also possible to trace and exploit temporal dynamics of individual and group user's preferences over different item content, e.g. item categories. The item content adds an additional dimension to CF approach, and moves the model from pure CF to a hybrid recommender.

In this work is presented an improved user-based collaborative filtering recommender system using temporal dynamics combined with hybrid model that traces the ratings over item categories, thus embeds the item content into the user-based collaborative filtering model.

The rest of the paper is organized as follows: in Section 2 is provided background on the temporal dynamics problem in CF and hybrid recommender systems and its solutions. In Section 3 are described details of the proposed model for improvement. Section 4 explains experimental settings, evaluation metrics and results of different experiments conducted in order to evaluate accuracy of the proposed model. The results are evaluated on a movie data set using movie genres as item categories. The Section 5 presents conclusion remarks with a discussion and directions for future work.

II. Related work

Examples of previous work identify repetitive patterns over time using periodic or discrete time information [3]. There are also works that do not predict ratings based on the future recommendation time. Instead of considering the future prediction time, they simply adopt some of the parameters according to changes in rating data over time.

The most common approaches for adoption of concept drift in CF models generally penalize older ratings presuming them as less relevant at the recommendation time. The set of different models is used, based either on discrete time windows [4], or as a weight function in [3] and [5].

The weight function is defined in [5] as a monotonic decreasing time-function $f(t) = exp(\lambda t)$ in the recommendation step, thus giving more weight to recent item ratings. In function f, t is the time of the rating and λ is a parameter that controls the decay relative to rating time in item-based CF.

Other approaches deliver a series of user ratings, establishing current user interest for individual items or group of items. In [6], ratings are grouped using an interest measure that takes into account item similarity, leading to a unique time series for each user. The users' rating history is divided into several periods and then quantizied by each user's interest in [7], setting a time-window to find users' recent interest. A time-driven filtering strategy is presented in [8] that links items and their features to time functions corrected by temporal curves built from individual user consumption histories. In [9] is proposed weight function dependent on changes in group user's preferences in user-based CF approach.

On the other side, hybrid approaches bring item content to CF methods. In order to select different neighbors for each different target item, a new similarity function for item-based CF is proposed in [10], giving a weight depending on the similarity between the item and the target item. Another hybrid approach is provided in [11] using matrix factorization technique in implementation of item-based collaborative filtering algorithm. In [12] is also proposed item-based collaborative filtering algorithm by combining the information of items categories with item-item interestingness.

However, the most of the related work and models that include temporal information are based on item-based CF methods and do not consider concept drift within a group user's preferences.

III. Proposed Recommender System

Our proposed recommender system considers temporal dynamics in user-based CF recommender system within item categories and proposes model that improves prediction accuracy. The basic idea includes the following assumptions:

a) similar users follow the same concept shift in an item ratings,

b) similar users also follow the same concept shift within the item categories,

c) the recent ratings are more relevant.

Suppose all ratings on an item i during a time period are presented in Fig.1, where the x-asis is the rating time in days, and y-asis represents the given ratings. From all of the ratings, we can mark out the neighbors' ratings N for an user u.

We can see that all neighbor's ratings follow a certain rating trend over time until τ_0, that is a recommendation time in an ideal case. Since an item can belong to one or more item categories, each neighbor's ratings can be divided into corresponding set of ratings over item categories. In Fig.1, from all of the neighbor's ratings, we recognize subsets of ratings $N(C1)$ and $N(C2)$ for categories $C1$ and $C2$ of the item i.

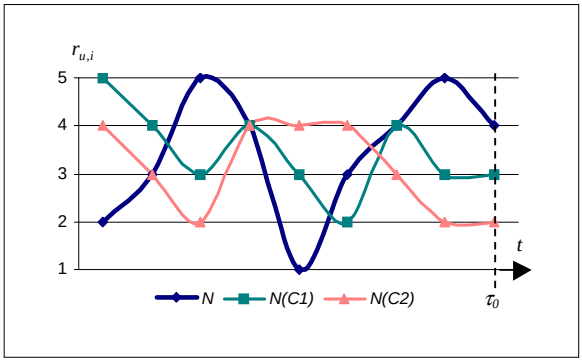

Fig. 1. Trend in neighbors' ratings over item categories

We can see that they also follow a certain trend over time until recommendation time τ_0, but obviously different than the ratings N.

Our goal is to recommend items based on the recorded ratings until the recommendation time τ_0. Based on the assumptions above, we propose an improved user-based collaborative recommender system built from following the steps.

A. Selecting a set of neighbors within item categories

We first find a set of neighbors for each user calculating similarity between users. The common approach for finding similarity P between two users a and u in standard user-based CF is calculated using Pearson correlation coefficient [13]:

$$P_{a,u} = \frac{\sum_{i=1}^{m}\left(r_{a,i} - r_a\right)\cdot\left(r_{u,i} - r_u\right)}{\sqrt{\sum_{i=1}^{m}\left(r_{a,i} - r_a\right)^2 \cdot \sum_{i=1}^{m}\left(r_{u,i} - r_u\right)^2}} \quad (1)$$

where $r_{a,i}$ is rating given to an item i by user a; $r_{u,i}$ is rating given to an item i by user u; r_a is mean rating given by user a; r_u is mean rating given by user u; m is a total number of items.

To accomplish our assumptions a) and b), instead of calculating similarity between users using the common user-item rating matrix, we deliver a set of particular similarity measures for each item category:

- $P_{a,u}(C1)$, $P_{a,u}(C2)$, $P_{a,u}(C3)$, ..., $P_{a,u}(Ck)$

where $C1$, $C2$, ..., Ck are the item categories. The particular similarity measures are used in the following step.

B. Modifying prediction function

The prediction function in traditional user-based CF recommender system is [13]:

$$p_{a,i} = r_a + \frac{\sum_{u=1}^{n}\left(r_{u,i} - r_u\right)\cdot P_{a,u}}{\sum_{u=1}^{n} P_{a,u}} \quad (2)$$

where $p_{a,i}$ is rating prediction for active user a for item i; r_a is the mean rating given by active user a on all items; r_u is the mean rating given by neighbor user u on all items; $r_{u,i}$ is rating

given to an item *i* by neighbor user *u*; $P_{a,u}$ is similarity between users *a* and *u*, and *n* is a total number of neighbors.

To extend our assumptions a) and b) on the prediction step, we use the similarity measures between users from the previous step. Instead of using a global similarity measure between users $P_{a,u}$ in the prediction step, we use a linear combination of calculated similarity measures depending on item categories to which an item *i* belongs:

$$P_{a,u}(i) = \sum_{j=1}^{k} a_j \cdot P_{a,u}(C_j) \tag{3}$$

where C_j are categories of the item *i*.

In case all item categories are equally relevant and there is no declared relationship between them or item taxonomy, the coefficients a_j are equal to 1.

For example, if categories of an item *i* belong to a set *{C1, C2, C3}*, and similarities between user *a* and the neighbor's user *u* over categories C1, C2 and C3 are:

- $P_{a,u}(C1)$ = 0.23,
- $P_{a,u}(C2)$ = 0.08,
- $P_{a,u}(C3)$ = -0.11,

respectfully, then the corresponding similarity is:

- $P_{a,u}(i)$ = 0.23 + 0.09 - 0.11 = 0.21.

The other values from the Equation 2, such as the mean rating r_a and r_u are taken over all available item ratings, without considering the item categories nor other item content. The prediction function from Equation 2 is then modified as:

$$p_{a,i} = r_a + \frac{\sum_{u=1}^{n} \left(r_{u,i} - r_u\right) \cdot P_{a,u}(i)}{\sum_{u=1}^{n} P_{a,u}(i)} \tag{4}$$

C. Adding time weight function

As previously stated in our assumption c), we assume that the recent ratings are more relevant then those given in the past. Consequently, we conclude that the most recent ratings from neighbor's users are closest to a future preference of an active user a. As proposed in [9], we also add time-dependent weight to each neighbor's rating in the preference prediction step as a function of neighbor's rating time. The Equation 4 is then modified as:

$$p_{a,i} = r_a + \frac{\sum_{u=1}^{n} \left(r_{u,i} - r_u\right) \cdot P_{a,u}(i) \cdot W(t(r_{u,i}))}{\sum_{u=1}^{n} P_{a,u}(i)} \tag{5}$$

where $W(t(r_{u,i}))$ is the time-dependent weight function. The function is calculated on the base of difference (in days) between recommendation time τ_0 and the time of actual rating of neighbor *u* on an item *i*. Consequently, the weigh function is expressed as:

$$W(t(r_{u,i})) = \exp[-(1/\lambda) \cdot (\tau_0 - t(r_{u,i}))] \tag{6}$$

where $t(r_{u,i})$ is the time of actual rating of neighbor *u* on an item *i*, and λ is a parameter for accurate performance tuning. As in [9], where the weight function is a monotonic time decreasing function based on the neighbor's rating time, we introduce the same function, but here dependant on the recommendation time, and also combined with the item content. The weight function takes values from the range [0,1]. The more the neighbor's rating time deviate from the recommendation time, the lower is the weight of the rating. The λ parameter and its impact on the weight function and prediction accuracy are discussed in the further section.

IV. Experiments and Results

Following creation of the proposed recommender model as described in previous section, a set of experiments is performed in order to examine accuracy of the system. The main goal in experiments is to compare accuracy of the proposed model with standard user-based CF model.

A. Experimental Setup

In this section experimental design and settings are described for validating the proposed recommender model with temporal dynamics over item categories, including the overview of the used data, selected variables, and performance measures.

Data. We used data from HetRec2011[1] data set that is broadly used in recommender systems research projects. The HetRec2011 data set contains 855,598 ratings from 2,113 users for 10,197 movies. Each movie is categorized by one or more of 19 genres, e.g. Action, Animation, Documentary, Drama, Romance, Sci-Fi, Thriller, etc. The genres assigned to movies are considered as the item categories in the experiment.

Data adjustment. The data set is prepared in order to adjust to a nature of the model that utilizes temporal dimension. The data is ordered by the time of the rating. The frequency of the ratings across the time is analyzed and then chosen the subset of the entire ratings data. The rating frequency is presented in Fig.2.

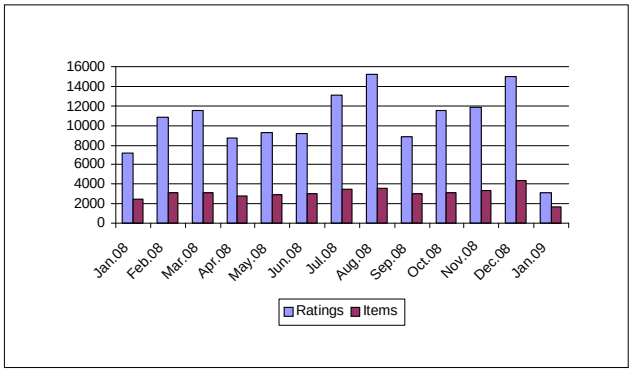

Fig. 2. Rating frequency

From the entire set of the ratings, a newest subset is selected for experiment with 135,555 ratings for period between 20-Jan-2008 and 05-Jan-2009. The subset is

[1] http://grouplens.org/datasets/hetrec-2011/

partitioned into the training and testing data. The training data used to build correlations between users contains 90% of the ratings in order to provide as much closer recommendation time to the rating time. The testing data used in the prediction step contains remaining 10% of ratings. The full description of the data set is presented in Table I.

TABLE I. DATA SET ADJUSTMENT

	Period		Ratings	Users
	From	*To*		
Training – Correlations	20-Jan-08	12-Dec-08	122,297	1,141
Testing – Predictions	13-Dec-08	05-Jan-09	13,258	443

Variables. For each experiment, the following variables are tested to ensure the most accurate predictions in the preference prediction step:

- Neighborhood size,
- Minimum number of contributing neighbors which affects the coverage of the predictions, and
- λ parameter which controls the slope of the weight function.

Performance measures. The performance measures used in experiments are based on two common evaluation metrics: Mean Absolute Error (MAE) and Root Mean Squared Error (RMSE). The MAE is defined as the average absolute difference between predicted ratings and their true user-specified values [13]:

$$MAE = \frac{\sum_{i=1}^{N} |p_i - q_i|}{N} \tag{7}$$

where p_i represent the predicted rating of an item i; q_i represents the user-specified rating values; N represents the number of user's ratings.

The RMSE metrics that puts more emphasis on large absolute errors [13]:

$$RMSE = \sqrt{\frac{\sum_{i=1}^{N} (p_i - q_i)^2}{N}} \tag{8}$$

The prediction results are compared with standard user-based CF recommender system in two steps. In first step, only the time-dependant weight function from Section III.C is added to the proposed model (CF-Td) and compared to CF. Thereafter, the linear combination of similarity measures over item categories is added and tested as the final proposed model (CF-Td-IC).

B. Experimental Results

Based on the experimental setup, a set of experiments is performed across different values of input parameters in order to provide the best performing model. These resulted with 30 comparisons for the given data set. The first set of experiments is performed across different values of λ parameter for CF-Td model and compared to traditional CF model.

The second step of experiments is performed on CF-Td-IC model with a subset of experiments testing different values of neighborhood size. The adjustment of different values resulted with conclusion that accuracy increases with the size, as presented in Fig. 3, which is opposed to most of the previous work [13].

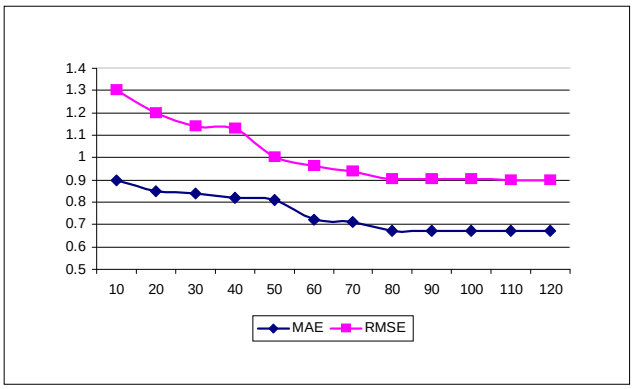

Fig. 3. Testing accuracy on neighborhood size for CF-Td-IC

Having the satisfied results with the given neighborhood size presented in Fig. 3, for all final experiments this variable is set to 100.

The minimum number of contributing neighbors is also tested with different values that affects the prediction accuracy and the coverage of the predictions. For each user-item pair that can not find the given minimum number of contributing neighbors (MinCN) due to sparse rating matrix, the prediction is rejected. Although the condition increases accuracy, the prediction coverage consequently decreases. For final experiments, the variable is tested with two values: 5 and 10, to present changes in MAE, RMSE, and recommendation rating coverage.

Although the λ parameter has less impact on the performance, it's also tested on different values and finally set to 40.

The results presented in Table II show that the CF-Td model outperforms CF model with the given MinCN values. The coverage is same in both models, but becomes poor with MinCN = 10.

TABLE II. EXPERIMENTAL RESULTS

Model	MinCN	MAE	RMSE	Coverage
CF	5	0.8017	1.0677	72%
	10	0.7524	0.9921	60%
CF-Td	5	0.7185	0.9598	72%
	10	0.6887	0.9226	60%
CF-Td-IC	5	0.6993	0.9320	52%
	10	**0.6702**	**0.9049**	43%

The CF-Td-IC model also outperforms CF and CF-Td models in prediction accuracy, especially for value of MinCN = 10, as presented in Fig. 4.

Although the prediction coverage is less than good if compare with CF and CF-Td, the prediction shows very good result with MAE = 0.6702 and RMSE = 0.9049.

Fig. 4. Results for MinCN = 10

V. Conclusions and Future work

In this work is presented an improved user-based CF recommender system that exploits changes of group user's preferences over time. It also utilizes temporal dynamics of changes within different item categories and proposes time weight function for prediction of ratings for unseen items.

The main contribution in this work is in utilizing changes of group user's preferences over time. The proposed model has shown improved results over previous work.

The future challenge of our work is to deal with the future prediction time by utilizing different item content and different recommendation context.

Predicting sports results using latent features: a case study

Stefan Dobravec
University of Ljubljana, Faculty of electrical engineering, Ljubljana, Slovenia
stefan.dobravec@fe.uni-lj.si

Abstract - Predicting sports results is normally a challenging task, even more in case of a sport that shows a highly stochastic nature. In football, for example, numerous features are tracked and combined with expert knowledge, yielding various predicting algorithms. Our work however, is based on a case where there is no expert knowledge available and the only data comes from previous match results. We built a goal score prediction model that uses latent features obtained from matrix factorization process. We also added a Naive Bayes Classifier to be able to predict outcome of the match. The algorithm has been tested on results of the FIFA World Cup 2014. We also built a match result predictor based on the betting quotas. As these are derived from a complex algorithms that encompass also the expert knowledge, our algorithm can be used to estimate accuracy of an expert knowledge-based system. This case study shows that there is no significant difference between the two algorithms that we tested and that the latent features may provide a valid substitute for real features, when the later ones are not available.

I. INTRODUCTION

Sport result prediction can be viewed as one of the objectives of sport analytics, which aims at helping decision makers (e.g. team managers, odds traders, etc.) to gain competitive advantage. The difficulty of this task depends on many factors, like the availability of data for the past events, the ability to gather data for future events, the knowledge needed to interpret gathered data, and others. In some cases, like in football, the task becomes even more challenging due to the highly stochastic nature of the game. At the same time, however, strategies of a team can be approximated by crisp logic rules [1].

Various techniques for modelling a football match exist that yield different result prediction algorithms. According to [2] the modelling can be put under the four generic categories: (i) empirical models, (ii) dynamic systems, (iii) statistical techniques, and (iv) artificial intelligence (including expert systems). The most basic approach in the category of statistical techniques is to use Poisson distribution for goal-based data analysis [3]. While Poisson distribution is used to predict the number of goals conceded and scored, the other statistical models restrict their prediction to match outcome. However, it has been shown in [4], that both approaches yield similar performance. In the artificial intelligence category there are several approaches that focus on Bayesian network modelling [1] [5] [6]. In most cases these approaches are highly complex, based on numerous assumptions, and require large statistical data [7]. On the other hand, they enable inclusion of expert knowledge, thus making them in general more accurate [5]. The remaining two categories are poorly represented in recent years.

A comparison of the described approaches is hindered due to the fact that they do not use a common dataset. In fact, neither a standard nor an agreed dataset exists. An analysis of football match parameters is performed in [8] pointing out features that influence the game, however various approaches use various sets of parameters. This is at least partly due to the high dynamics of a football match, which makes it hard to systematically gather statistical data. Also, different competition formats (league, tournament) emphasize different parameters or their combinations.

Our research, in contrast, is based on latent features of a matrix factorization model instead of relying on a real (observed) features. We assume that it is better to use latent features that in best way possible reflect the variability of the observed facts, than to rely on a poor set of real features that can't be properly assessed. The proposed method is thus based solely on results of past matches (the number of goals scored by each team), which represent the fundamental data that is recorded in all cases. No other statistical data or expert knowledge is used.

The Matrix factorization technique became very popular in the field of multimedia content recommender systems where it showed good scalability and predictive accuracy [9]. The idea behind using the latent features in our case is to be able to build a successful model even when expert knowledge is not available or when large statistical data is not available.

The proposed method has been tested on the case of FIFA World Cup 2014 tournament. Since different approaches use different techniques to measure the success, direct comparison with our method would be misleading. Instead, we used cross-folding to statistically evaluate the prediction success of our method. We also compared the proposed method to a match result classifier that is based on betting quotas, which indirectly encompass the expert knowledge of odds traders.

In the following sections first the methodology for predicting match results is explained. Following is the explanation of the validation procedure. Next, the results are presented, followed by discussion and conclusions.

II. MATERIALS AND METHODS

A. FIFA World Cup 2014 Dataset

Using World Cup tournament results as the dataset allowed us to observe the short-term performance of competing teams. Thus we were able to exclude time factor from our model, in contrast to a league-type competition where teams compete over long period, which increases the importance of the time factor. We assume that teams enter the tournament in peak condition, with a fixed set of players, and team strategies planned ahead. Therefore major changes in team's performance are not expected.

A major drawback of the dataset is its size, which is quite small. The dataset could be increased by including results of previous World Cup tournaments, however the list of competing teams varies through tournaments. Thus only the number of teams would increase and the number of matches per team would increase only for those teams that qualify regularly. Additionally, the time factor would play an important role as the players, coach, and strategy may change significantly in-between the two tournaments. A sophisticated strategy for handling such dataset, requiring significant research on its own, would be required.

In the World Cup teams compete in the tournament format. In the group stage 32 teams are put in groups of four (altogether 8 groups). Each team plays three matches (rounds) against their group adversaries, which accounts for 48 matches overall in the group stage. Best two teams from each group proceed to elimination stage, where 16 matches are played (8 in the eight of the final, 4 in the quarter-final, 2 in the semi-final, and 2 in the final). The tournament therefore consists of 64 matches.

Additionally, 56 matches played in the preparation period of one month before the World Cup tournament were taken into account.

The data was obtained from the official FIFA World Cup page (http://www.fifa.com/worldcup/). In the elimination stage the match can't end as a draw, therefore overtimes (and optionally penalties) are required to determine the winner. As this rule has huge impact on the final result of the match, we ignored the final score and considered only the score after the regular period, which is also a standard practice with 3-way bets (home win, draw, away win).

Betting quotas for the World Cup matches were obtained on the day of the match from online betting service bwin (https://www.bwin.com/). Betting quotas are in form of 3-way bets and reflect the probability of the three possible outcomes: home team wins, draw, away team wins. Lower quota (approximately) corresponds to higher probability of the given outcome.

B. Matrix Factorization Model

In the field of multimedia recommender systems the matrix factorization model showed robustness and accuracy when predicting user experience [9]. The interaction between users and items is modelled on the base of known ratings that were given by the users to the specific items and that correspond to the user's satisfaction. The model is then used to predict the user's satisfaction with an unknown (unrated) content.

In our case the model is based on the observation of number of goals scored by a given team (T) to its opponent (O) in previous matches - $g_{T,O}$. Every observed match yields two goal score observation:

$$\text{team } A : \text{team } B - \text{scored } G_A : \text{scored } G_B$$

$$first\ observation:\ g_{A,B} = G_A$$

$$second\ observation:\ g_{B,A} = G_B$$

The observations can be arranged in a table (see Table 1), displaying the number of goals scored by a team (T) against its opponent (O). Initially, such table is highly sparse. New values are added as the tournament progresses, however even in the final stages the table remains sparse.

TABLE 1. THE TABLE REPRESENTATION OF GOAL SCORE OBSERVATIONS

$T \setminus O$	A	B	…
A	■	$g_{A,B}$	
B	$g_{B,A}$	■	
…			■

The model is then used to predict the number of goals scored in a match to come $-\hat{g}_{T,O}$. As in the case of observing past matches and match observations as above, in every match there are two goal score predictions, one for each of the two paired teams.

Additional parameters, besides the goals scored by both teams, may be included in the model in the similar way as [10] included the time component. However, this is not straightforward, as the parameters may not be directly correlated to goal score predictions, and an expert knowledge is therefore required. For example, if key player is injured this should influence the match outcome, but you need an expert to point out key players. Since the time factor was excluded in our case due to a short-termed data set, and we avoid using any expert knowledge, we use the matrix factorization model with biases:

$$\hat{g}_{T,O} = \mu + b_T + b_O + \mathrm{q}_O^T \mathrm{p}_T. \quad (1)$$

In the model the team and its opponent are represented using latent feature vectors p_T and q_O and their interactions are modeled as inner products of the corresponding vectors in the latent feature space. By implementing biases b_T and b_O we model the team's inclination towards scoring/conceding goals, while μ represents an overall 'goals scored' average. Bias b_T is calculated so that $\mu + b_T$ represents the average of goals scored by the team. Similarly, the bias b_O is calculated so that $\mu + b_O$ represents the average of goals conceded by the opposing team.

In the learning phase the model is fitted to the known match results, or more precisely to the number of goals scored by one team to its opponent (note again that every match provides two observations). The stochastic gradient

descent algorithm is used to loop through the training set (κ_T), where for each given training case $g_{T,O}$, the prediction $\hat{g}_{T,O}$ is calculated and the model parameters are modified to minimize squared error function:

$$\min \sum_{\kappa_T} \left(g_{T,O} - \hat{g}_{T,O}\right)^2 + \lambda\left(\|p_T\|^2 + \|q_O\|^2 + {b_T}^2 + {b_O}^2\right), \quad (2)$$

where the second part of the sum serves for regularization and it is controlled by the parameter λ.

C. Match Outcome Prediction

The described model predicts the number of goals scored by a team against a given opponent. For a match outcome prediction another step is required. First we need to pair the two predictions, one for home team ($\hat{g}_{H,A}$) and one for the away team ($\hat{g}_{A,H}$), and compare them to predict the outcome. There are three possible outcomes, commonly noted as 1-home team wins, 0-draw, 2-away team wins:

$$\hat{g}_{H,A}, \hat{g}_{A,H} \overset{\mathcal{C}}{\rightarrow} \{1,0,2\}\,. \quad (3)$$

The easiest way to predict the outcome using the pair of goal-scoring predictions is to simply round the predictions to nearest integer to get predicted match score:

$$\mathcal{C}: c = \begin{cases} 1; & round\left(\hat{g}_{H,A}\right) > round\left(\hat{g}_{A,H}\right) \\ 0; & round\left(\hat{g}_{H,A}\right) = round\left(\hat{g}_{A,H}\right) \\ 2; & round\left(\hat{g}_{H,A}\right) < round\left(\hat{g}_{A,H}\right) \end{cases} \quad (4)$$

Such approach, however, proved to be unfavorable to such pairs of predictions, where the two are close together but on different side of rounding threshold. Better results were expected when deploying a standard classifier, trained on a set of prediction pairs. We deiced to use the Naive Bayes classifier, which proved to be robust and performs well in most cases, despite the fact that it builds on the assumption that the input parameters are uncorrelated [11]. As the input parameters for the classifier, the $\hat{g}_{H,A}, \hat{g}_{A,H}$ pairs were used, and the match outcome was used as a label.

While in the first case no training is needed and the prediction is possible 'on the fly', this is not the case with the Naive Bayes classifier. Due to the small size of the data set (64 matches altogether), the classification has been done 'post festum', using the cross-folding technique to train and to test the performance of the classification.

D. Evaluation

Overall classification success rate, which gives the percentage of correctly predicted (classified) samples, is insufficient, as in most cases we need more insight into the classification performance. Thus a confusion matrix is commonly used (see Figure 2). In our case there are three possible classes (match outcomes), predicted classes are marked with 'hat' sign (^), actual (achieved) classes without it. Values p_{ij} represent shares of samples originating from class *j* and classified as *i*.

Several performance measures were developed on basis of the confusion matrix that vary over different research areas. However, in most cases simple and easy to understand measures, like the overall success rate, precision and recall, should be used [12]. Overall success rate (OSR) is used to measure the percentage of correctly classified samples. In our case it is calculated as:

	1	0	2
$\hat{1}$	p_{11}	p_{12}	p_{13}
$\hat{0}$	p_{21}	p_{22}	p_{23}
$\hat{2}$	p_{31}	p_{32}	p_{33}

Figure 1. Confusion Matrix for 3-class classifier

$$\mathrm{OSR} = p_{11} + p_{22} + p_{33}. \quad (5)$$

To get more insight into how the classifier is performing according to a specific class, the precision and recall are used. Both are used to measure percentage of correctly classified samples, however while precision (P) is used for a given prediction class, recall (R) is used for a given actual class:

$$P_i = \frac{p_{ii}}{p_{i1} + p_{i2} + p_{i3}}, \quad R_i = \frac{p_{ii}}{p_{1i} + p_{2i} + p_{3i}}. \quad (6)$$

Fawcett [13] proposes usage of ROC (Receiver Operating Characteristics) graphs as a performance graphing method as they are especially useful for domains with skewed class distribution and unequal classification error costs. ROC graphs show relationship between two ratios: (i) the rate of correctly classified samples from the given actual class (same as recall), named true positive rate (tp rate), and (ii) the rate of incorrectly classified samples that do not belong to the given actual class, named false positive rate (fp rate). In case of perfect classification, the tp rate would be 1 and the fp rate would be zero. ROC graphs allow us to find the point on the curve (which corresponds to a certain classification threshold) closest to the 'perfect case'. The diagonal line represents the 'random classification' where the two rates are equal. The same author also proposes the area under ROC curve (AUC) as the measure for a classifier performance. Higher AUC represents better performance. The performance of a random classifier in terms of AUC is 0.5.

In cases with a small dataset (like ours) it is a common approach to use the cross-folding technique. The correct way to calculate AUC is such cases is to obtain the ROC curve for each fold and represent the classifier with the average curve and the corresponding AUC [14].

In their basic form, the ROC graphs are used for two-class problems. With more classes the situation becomes more complex. One method for handling such cases is to produce several different ROC graphs, one for each class, where reference class is treated as positive and all others as negative [13]. For the multi-class AUC, the weighted sum

approach can be used, where the weights $p(c_i)$ correspond to prevalence of the reference class [15]:

$$\mathrm{AUC}_{\mathrm{total}} = \sum_{c\_i \in C} \mathrm{AUC}(c_i) \cdot p(c_i) \qquad (7)$$

III. EXPERIMENT

On Figure 1 flow of the experiment is presented. Known match results are stored in the local database. In the start only the results of friendly matches were known, the results of the tournament matches were added as the tournament progressed. After every tournament round, the known data was used to (re)train matrix factorization model. Betting quotas were obtained on the day of the match and stored for later comparison.

Due to the small size of the data set the latent feature predictor (classifier) performance evaluation was performed 'post festum'. We used cross-folding of the data set, more precisely the 8 bin folding stratified sampling approach. The 8-fold approach was used instead of more commonly used 10-fold, as this allowed the same size of all bins (64 samples divided across 8 bins).

For comparison, a classifier based on betting quotas was developed and evaluated using the same approach as the latent feature match predictor. In this case, the three quotas (one for each possible outcome) were used for the Naive Bayes classifier input, and the match outcome was used as the label. Betting quotas are (for obvious reasons) prepared using sophisticated proprietary algorithms, backed also by an expert knowledge of the odds traders and others. Such comparison of the two classifiers (the latent feature based and the betting quota based) gives a latent feature approach usability estimation.

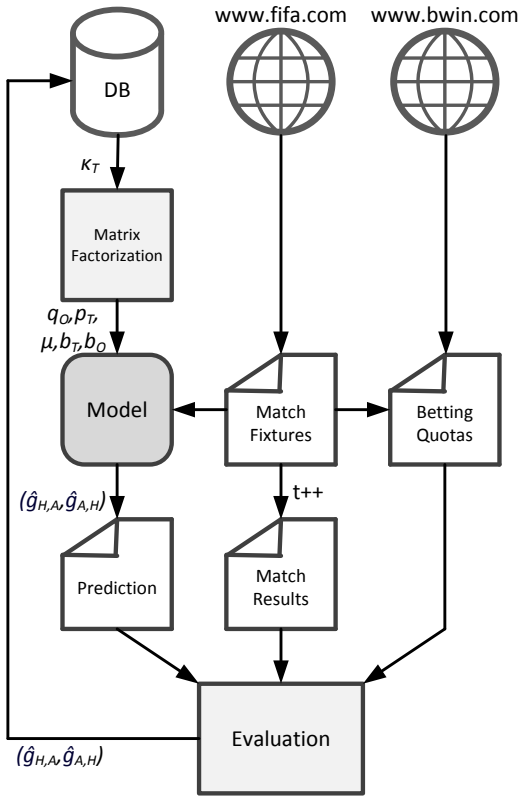

Figure 2. Flow of the experiment

IV. RESULTS

The match prediction performance using the 'rounding' approach (4) yielded 44% overall accuracy (OSR= 0.438). Confusion matrix on Figure 3, as anticipated, shows very poor precision and recall values for the 'draw' class. Using Naive Bayes classifier improved overall accuracy to 50% (OSR= 0.5). Closer look to confusion matrix on Figure 4 shows that prediction value of the 'draw' class improved, as also the recall value of the 'away win' class. There were less candidates for the 'draw' outcome as in the first case, but those were picked better. Consequently we managed to find more 'away wins' and also 'home wins' as in the case of 'rounding' approach.

Figure 5. Confusion Matrix for 'betting quotas' approach

Figure 6 is showing ROC graphs for the classifier that uses matrix factorization model output. The curves represents average over eight folds, used for cross-folding. Shaded areas mark the 95% confidence interval for the averaged curves. In our case the following class prevalence was observed: $p_1 = 0.375, p_0 = 0.266$, and $p_2 = 0.359$. Using (7) we obtained:

$$\mathrm{AUC}_{\mathrm{lf}} = 0.677$$

To estimate the performance of an expert knowledge-based algorithm, we tested Naive Bayes classifier using betting quotas. We achieved the 50% overall accuracy (OSR= 0.5), which is the same as with 'latent features' approach. However by inspecting the confusion matrix (Figure 5) some differences may be observed, for example more candidates for 'draw' outcome at the cost of lower precision, but much higher hit rate (relevance) for the 'home win' outcomes, and also lower hit rate for the 'away win'.

Furthermore, ROC graphs on Figure 7 show superior performance in terms of classifying 'away win' class but at the cost of extremely poor classification of 'draw class'. In this case, we obtained the following AUC value:

$$\mathrm{AUC}_{\mathrm{bq}} = 0.562$$

The AUC that we obtained for latent feature-based classifier is actually higher than the one obtained for betting quotas-based one. However the fact of high measuring uncertainty (shaded areas on Figure 6 and Figure 7) cannot be overlooked. Thus we cannot conclude that the former classifier performs significantly better than the latter.

V. CONLUSION

The prediction algorithm presented in this paper is based only on the base of previous results and does not require any form of match statistics or expert knowledge. We propose to use the described approach in cases when statistics and expert knowledge are not available or when they cannot be imported, interpreted, or evaluated properly.

As football shows highly stochastic nature it is difficult to evaluate any prediction algorithm. The only correct way would be to test all relevant algorithms against each other on the same (reasonably) large dataset. However, it is practically impossible to perform such comparison as various algorithms use various statistical data and knowledge, and a standard dataset for testing purpose containing all required data does not exist yet. The comparison between two classifiers (the latent features-based and the betting quotas-based), performed in this study, can be used only to estimate the possibility to substitute real features with latent ones. This case study showed no significant difference between the two approaches, showing that such substitution is possible.

The major issue with our case study lies in the size of the dataset. We used a short-termed dataset, where 64 matches were played in a period of two months, therefore drastic changes in teams' performance (e.g. due to player injuries) were not expected. It is known that the matrix factorization approach towards latent features extraction

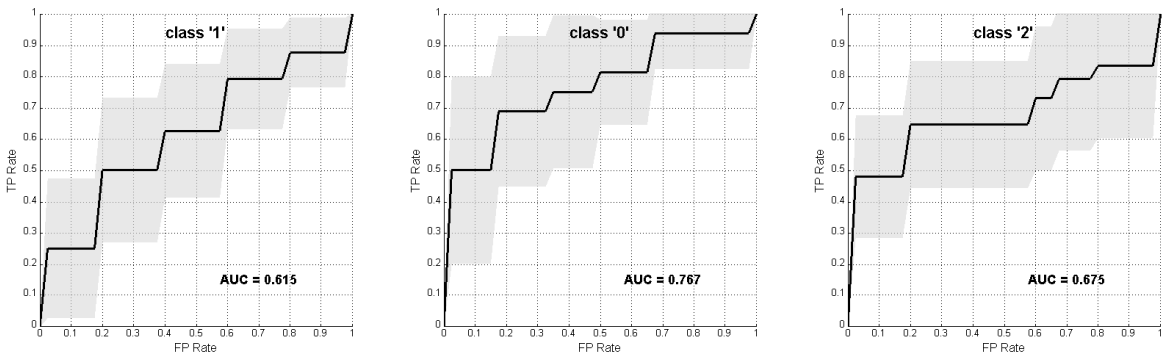

Figure 6. ROC graphs for Naive Bayes classifier using Matrix Factorization model

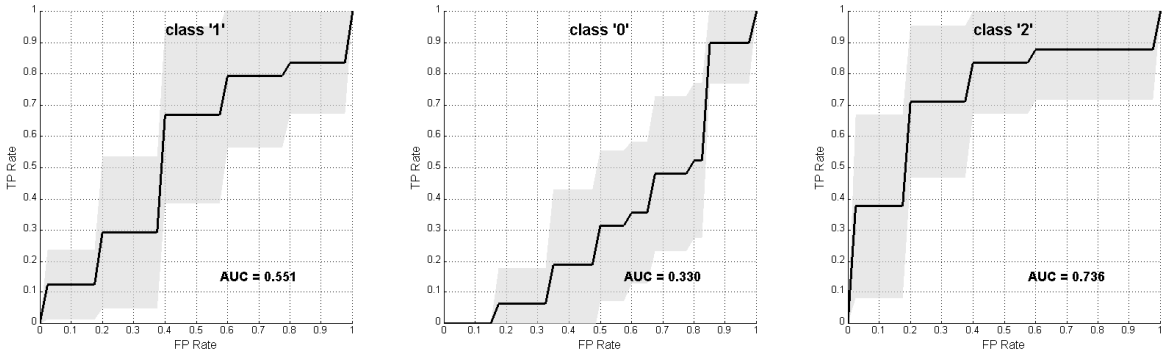

Figure 7. ROC graphs for Naive Bayes classifier using betting quotas

performs significantly better on large datasets. However, larger dataset would require long-term observation bringing (at least) time factor into the equation.

We believe that the prediction process can be further improved by inclusion of expert knowledge into the matrix factorization model training, exposing parameters that do not encompass teams' interaction (e.g. motivation, fatigue…) On the other hand, the parameter selection step would introduce another level of complexity into the matrix factorization process.

Another possibility to improve the prediction success, is to append regression model that would be used to improve latent feature model based predictions. This would allow us to include various 'real' match features into the regression model, where are easier to handle. However, as already pointed out in the paper, the expert knowledge would be required to point out the important features.

Abstract – Role-playing, besides its use as a gaming media, can also be used as a powerful simulation tool. Due to its versatile nature and all the possibilities that it can offer us in building imaginary worlds and situations, we can also apply that technique to simulate real life and realistic behaviour. In project and knowledge management it is possible to use Role playing for optimization and building specific knowledge. Applying the simulation in advance, can greatly help us to recognize, prepare and solve most problems that may occur, reducing overall cost and time of any project.

I. INTRODUCTION

Despite its humble beginnings as a gaming system, Role-playing (RP in further text), has also developed over the years as a simulation system worthy of our attention. In its very core, RP is a system that combines setting, a variety of entities that coexists in it and all interactions among those entities and its surroundings. A setting is a specific environment in which we can create our simulation, making a copy of a real world we would like to simulate, with all its legalities and factors that influence it. Entities, on the other hand, can be all the participants active in the simulation process, events that we wish to study, along with all the tasks and problems presenting goals of our RP simulation. In establishing a simulation by defining its setting, entities and goals, we are able to conduct optimisation processes of real life events, building specific knowledge usable in future projects.

This kind of RP simulation can be used as an optimisation tool in project management. Before actually conducting a project, RP simulation can help us anticipate various problems and situations, explore different phases of our project and optimise them to accomplish better overall results. In every project there are key factors defining successfulness, like the project end time, cost and efficiency. Every step of the way, conducting our simulation, we can explore different solutions to every problem and situation we could come across. Keeping in mind our end goal, exploring different options and solutions and documenting the course of the simulation, we are able to anticipate, and eliminate, a variety of problems that could occur later when a real project starts to develop. With combined knowledge and experience of participants involved in the simulation, and later the real project itself, we can accomplish a high level of optimisation resulting in immense resource benefit. We can even choose the optimisation path making some resources primary and other resources secondary. For example, making time our primary resource, we can reduce overall duration of the project by finishing it prior to the originally planned time. In this example we are making finance one of our secondary resources, not going over the budget but coming to its limits.

II. ROLE-PLAYING SIMULATION IN PROJECT MANAGEMENT

A. Introduction to RP simulation

Project management in its surveillance, optimisation and conduct, treats every project as a system. Each and every project is carefully dissected in order to organise, analyse and optimise all of the components making the system. For every new system that we build, first we need to understand its overall purpose and the way it interacts with its surrounding environment, as every system is part of some already existing larger one. With that in mind, dynamic equilibrium of this new system and control of its parts are essential components on which project the management is focused. In essence we first need to establish the system a structural code of elements and the rules by which the elements correspond to one another so that we may later, when simulating operate the structure and determine specific process codes optimised to our needs. [5]

This step is crucial because once we establish the rules – code of the systems structure the objectives we have in the project and knowledge management in general are process operations of that structural code. The

very structure is the one which will enable us to analyse specific parts of the system, ask different questions, select, make different elements, or attributes pertinent in order to restructure and therefore optimise the system. **The use of RP in simulation in this level is therefore an easy to manage transparent way of producing code (rules) for system optimisation.**

Using RP simulation as an additional tool in project management, we are able to further understand, optimise and achieve that dynamic equilibrium needed in order to successfully build a new system. Applying the simulation it the earliest stage of project development, right after setting up the main idea and general system guidelines, is the best way to use all of its potential. Of course, due its flexibility, we can run the simulation again in every phase of the project and apply different objectives and gain information. If we imagine project management as a surveillance tool when building a new system, we can think of RP simulation as a preparation tool for all our actions during building and implementation phase. Project manager as head figure in project, should choose various relevant field experts which will contribute and be part of simulation process. It is noteworthy that in the case of RP simulation it is desirable to have multiple experts from the same field contribute from various roles. With their combined knowledge and experience put into the simulation, the simulation process creates a knowledge base for solving particular problems. During simulation, participants are looking for different solutions to known problems, and in the end choosing answers that best suit any given occasion. It is necessary to point out that the very RP simulation model preparation should be made in with the problem solving process in mind. The human aspect of the role from which the participants play is crucial and it's where the brilliance of RP simulation lays. Therefore a problem solving approach frequently used in group communications is particularly applicable. [6] There we use a slightly modified classic eight step process for problem solving. The process is modified in the sense that each participant posing the questions is a specific role with a specific perspective. That role is determined in the process of system creation and typically firstly played by a field expert. We say firstly because it is encouraged and welcome that the same role is afterwards played by different experts and non-experts alike as they can provide valuable insight in the whole process of approaching the system from the perspective of playing a specific role. The process is as follows:

1. ***Defining the problems*** – we ask the problems as questions from the perspective of our role in relation to the system structure.
2. ***Identifying the meaning of the problem for the system structure (from our role)*** – what does the problem impact, what can we foresee changing as a result of the problem solving process in general etc.
3. ***Further problem analysis (from the perspective of our role)*** – How long does the problem last? What caused the problem? Does it have any consequences? Is the problem recognised within the system? Does it impact other parts of the system in a known way that is currently managed?
4. ***Identifying the criteria for solution evaluation from the perspective of our specific role***: What would make a solution practical? What are the specific effects a proposed solution could/should have (cost efficiency, time etc.)? If there are multiple solutions what would my criteria be for ranking them?
5. ***Identifying possible solutions*** – this is the phase where the participants should brainstorm. Thus when encountering problems, participants should try to find as many solutions to each specific problem they can, observing them from different angels and exploring additional options. Besides obvious solutions that come from knowledge and experience, simulation itself forces participants to think and look for other unorthodox answers. When brainstorming is concerned the wilder the ideas the better. Each participant should answer these questions from their specific standpoint: what is a solution to our particular problem? How does it impact the system (or my specific part of the system)? How do I view it from my role? Does it create new problems or difficulties for me?
6. ***Solution evaluation*** – each participant should evaluate all solutions according to step 4.
7. ***Selecting the best solutions*** – ones where most participants agree, most relevant criteria are met and the system as a whole reaches the particular goal in the most efficient manner.
8. ***Simulation*** – testing the solutions. From this point on we can return to any of the prior steps.

During simulation, the main point is to explore any relevant solutions recommended by any specific participant/role or defined by an **actant** [7] and research different approaches to encountered problems. Given results are created with all the roles and actants in mind producing different directions in problem solving, ones that are normally difficult to brainstorm. In that way, we can say that **RP simulation itself is in fact an "idea generator".** By documenting problems and given solutions, the RP simulation model provides a base of knowledge, and experience on problem solving, regarding any given situation (project, system), before they occur. Apart from common brainstorming, RP simulation in the end gives us a transparent, precise and well documented workflow on specific problem solving, knowledge base applicable in real situations, time and environment, produced by a group of chosen field experts.

A well-documented simulation workflow gives us a high level of preparedness to almost any situation that could occur during project implementation. Of course, there could always emerge some unpredictable situations, but as soon as those situations appear, we can input them into simulation and develop new steps for solving them. It also helps us that we already have a multitude of other solutions and experience which may relate to this unpredictable one, so the simulation had

already given us general guidelines on how to resolve it, or at least we know the direction to solve this new problem.

B. Simple example of RP simulation

Every project consists of three main components: events or milestones, activities and time. Events are different phases of project that we are trying to achieve through our activities in some estimated time. In order for a project to be successful, each of these components should be done on a predetermined schedule with optimal path (activity) between events. Time needed to finish the project is also divided in four categories. Most likely time, expected time, optimistic and pessimistic time. Most likely time is the best estimate of the time required to accomplish a task, assuming everything proceeds as normal. In reality, we will almost always have some kind of problems and delays to cope with, in the end achieving expected or pessimistic time. Therefore, RP simulation offers us a tool to achieve this most likely time, which is the minimum possible time to finish a project, or maybe even go for optimistic time. By optimising every event and activity in project through simulation, we are able to balance all of our recourses, specially finance, in order to achieve time that we would like. With simulation, we are absolutely trying to avoid pessimistic time and immensely reduce resource consumption.

For example, when building a fifty story skyscraper, one of our events could be building first ten storeys in one month (expected time), with all the activities (physical work, material delivery etc.), in optimal condition to do so. With all of that in mind, a selected group of experts with roles defined and derived from their specific area of expertise should when conducting RP simulation, with their knowledge and experience put into the simulation, be able to optimise the process in order to achieve optimistic time with maximum savings in resource consumption.

On Figure 1 we can see an example of PERT network chart for a seven-month project with five milestones (10 through 50) and six activities (A through F).[1]

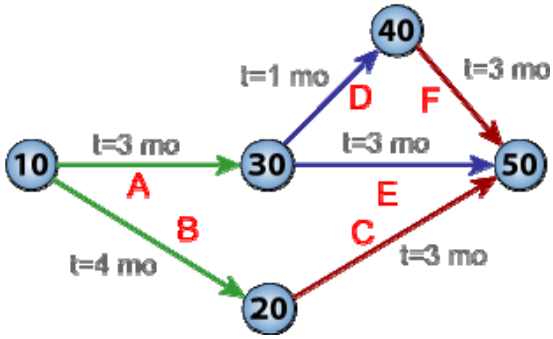

Figure 1: PERT network chart for a seven-month project with five milestones (10 through 50) and six activities (A through F).

In the example above, we know our milestones which are something that generally does not change and activities that up until now were something that we knew had to be done. Using RP simulation, we can take one fragment of the chart, expound one activity and question its parts in order to optimise it. During simulation we are able to in example discover reasons to introduce a new milestone in-between, reorganize the order of some milestones, adjust specific times etc.. By doing so, we guide ourselves through simulation, in order to achieve a better finish time, reduce costs or other resources. In the end, we are trying to find a new or different way of accomplishing our work goals, creating and expanding our own knowledge on the substance. That way, by documenting our newly found knowledge, we are in fact creating a learning system which can be not only applied during project implementation, but also as a teaching method for others.

[1] Source: Wikipedia web page: http://en.wikipedia.org/wiki/Project_management, accessed 30. January 2015.

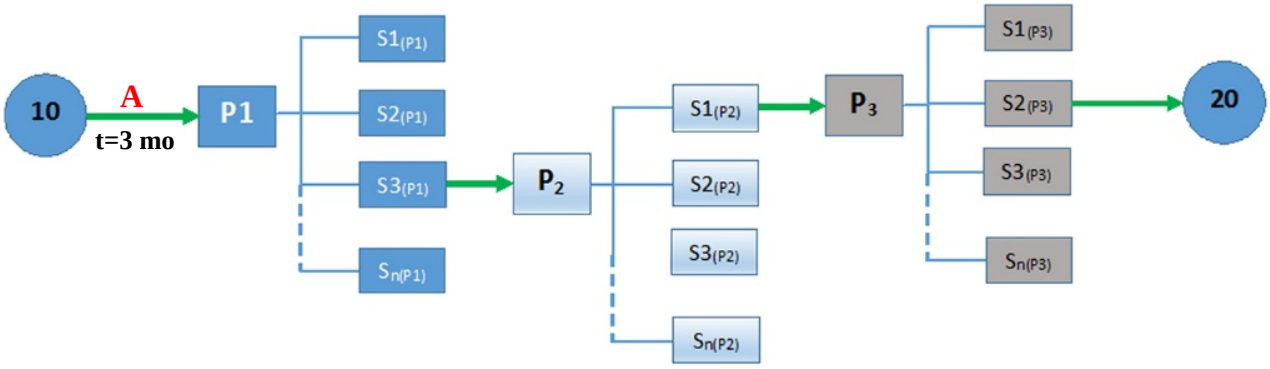

Figure 2: An example of one activity divided by three separate problems with a number of solutions for each

In our second figure, we can see one activity divided by three problems. Problems can also be questions that experts in specific roles ask in order to optimise and improve a course of chosen activity. If the chosen activity is a simpler one, maybe only one question will appear, but with complex activity there could be many. A project manager with his team of experts involved in simulation, using their knowledge and experience, should try to come up with as many questions needed in order to improve given activity (we believe the best approach is using our proposed 8 steps method). Likewise, more answers to each question or problem, gives them more options and paths to direct optimisation process the way they imagined, in the given process, saving resources of their choosing (money, time, material etc.). Picture shows us that on first problem ($P1_{)}$, solution ($S3_{(P1)}$) was chosen. It means that in that particular time in our simulation, one answer seemed most logical and valid in order to be chosen, based on judgement of experts running the simulation. That is of course a specific process code "recommended" by the system and chosen in this particular case but whether or not it is the best solution can only be discovered once the course of the simulation is complete. Let's say that time is the resource we wish to optimise, so in that case answer $S3_{(P1)}$, gives us a course of action with which we will reduce activity time. There are probably other answers that also save time, but may produce other disadvantages, greatly higher costs or similar. The chosen answer leads us to a new problem or question and we repeat the optimisation process.

If we would like to reduce time of our activity, from four months to three months, we should ask relevant questions as part of the 8 step process, and imagine problems that we need to solve from each role in order to achieve our time reduction. In our earlier mentioned example, in order to build the first ten storeys in three rather than in four months, maybe we should apply some new building technique. By introducing that new technique, perhaps we will spend more money on material or mechanisation but reduce manpower needed for construction and achieve our time saving plan. Right there, in our simulation, in that moment we can research all of our options and influence on all later milestones and activities, optimising our overall project plan. Some solutions will open new problems, some will bypass existing ones, but our goal in simulation is to try to imagine all the possibilities we can in order to optimise the project the way we want. That way we also accumulate knowledge and acquire a well developed execution plan for project deployment. In the end, balancing resources but emphasising the one crucial for our overall success, is the right way to approach the process of simulation.

For every project that is being built in a real word environment, we can consider it to be a part of highly dynamic and ever-changing bigger system. After conducting our RP simulation and having it all optimised the way we wanted, taking into consideration all the possibilities that could happen during real life project implementation, since being the part of this bigger dynamic environment, some absolutely unpredictable things could always happen. In that case, we can always go back to our simulation and make necessary changes. This unpredictable problem, in most cases should not represent too big an obstacle, since we already have the optimised project and our resources rather reduced. By introducing that new problem into simulation, the course of affected activity might change and influence all other actions after, but also that might not be the case. It really depends on the scale of that new moment introduced in our project and simulation likewise. Unpredictable problems could cost us a great deal of time and money when encountering them. Best way to reduce their appearance and minimise the damage they could cause, is to have experienced experts running the simulation, but as we stated earlier also include people of different knowledge and background, to have more perspectives on the matter and gain more insight. An architect will know how to solve construction problems, but an economist will promptly adjust the course of an activity in case of a

market fluctuation, while a work safety expert will contribute and likely end up changing the activities attributes (time, finance etc.) as a result.

III. ROLE-PLAYING SIMULATION AS A KNOWLEDGE MANAGEMENT TOOL

Similarly as shown in the example of the project management, RP simulation can be also used as a knowledge management tool. If we imagine a situation or a project that has never been done before, including a field expert research, with RP simulation we are able to explore and develop a knowledge base on the subject. It is very problematic to create a knowledge base and thus develop training or educational means for something that has never been done before. RP simulation is a tool that gives us the needed environment in order to explore our ideas and expand our imagination. Working closely with other experts, it provides us an opportunity to share our ideas and develop them further than we would be able alone. RP simulation gives us the opportunity to expand our ideas even to borderline fiction with various experts as interdisciplinary as possible. In order to create a new knowledge base or learning tool, we usually reach for an already existing situation, review it, optimise and document it. That way others could be trained for that situation and the gathered knowledge can be expanded. The problem occurs when we are faced with a project for which, in order to conduct, necessary knowledge simply does not exist. In that case, RP simulation can provide us means to explore and test our ideas in simulated close to real environment. By using existing knowledge provided by experts, the ones that are related in the field of our research, we are able to build our simulation and put it to test. By doing so, we are creating absolutely new knowledge that could be used later in real-life situations. It is an ideal tool for techno-centric knowledge management perspective, since in its core Role-playing in general is focused at interpersonal interaction in order to share information and ideas and together create new knowledge. Knowledge management is already using storytelling as an instrument for accumulation and sharing information. Since RP simulation is actually an evolved and advanced form of storytelling, it would be wise to further explore it and its use as a valuable tool in knowledge management.

RP simulation is truly unique as it not only educates with the results of its simulation it educates all the participants in the process of role playing. Different experts and non-experts face varying situations from different role perspectives expanding the ways they view and deal with problems. RP is not only interactive it is immediate in the way it affects the participants expanding the way they approach and analyse systems, situations, and problems. When using RP simulation the whole process is a rewarding educating experience which helps participants to develop in various ways within their formal education frame as well as out of it. Not only that but it participants learn to understand different role types tied with different systems and the intricate ways of structural - process relations which stem from interpersonal actor - actor - actant - environment relations. **The usage of RP therefore thrives in longevity and creates a constantly evolving and growing knowledge base which ties knowledge and experience in dealing with knowledge in special roles and situations in ways no other method can.**

IV. CONCLUSION

RP as optimisation tool presents a specific environment in which we can create our simulation, making a copy of a real world we would like to simulate, with all its legalities and factors that influence it. Every step of the way, conducting our simulation, we can explore different solutions to every problem and situations we could come across. The use of RP in simulation is therefore an easy to manage transparent way of producing code (rules) for system optimisation. The human aspect of the role from which the participants play is crucial and it's where the brilliance of RP simulation lays. Therefore a problem solving approach frequently used in group communications is particularly applicable, and we use a slightly modified classic eight step process for problem solving. The process is modified in the sense that each participant posing the questions is a specific role with a specific perspective. RP simulation gives us a transparent, precise and well documented workflow on specific problem solving furthermore it produces a knowledge base applicable in real situations, time and environment, produced by a group of chosen field experts. As we show in the example of the project management, RP simulation can also be used as a knowledge management tool. If we imagine a situation or a project that has never been done before, including a field expert research, with RP simulation we are able to explore and develop a knowledge base on the subject, because a true RP session enables the equivalence of discourse and determines a community of knowledge. RP is a unique tool that establishes the ontology of knowledge for individual projects, defining the context in which we need to think about the problems we face. [8] Therefore RP ties knowledge and experience and can be used as a mighty tool for project management and knowledge production and application of RP to the problems of the project and knowledge management. Therefore RP remains a challenge to maximize the use of human creativity in creating new values, goods and practices.

Nadogradnja inteligentnog sustava aerodromskog održavanja serijskih strujnih krugova

Zdenko Balaž*, Ivo Puhalović**, Goran Bjelić*

*Tehničko veleučilište Zagreb, Elektrotehnički odjel, Zagreb, Hrvatska

**Hrvatska agencija za civilno zrakoplovstvo, Odjel aerodroma, Zagreb, Hrvatska

zbalaz@tvz.hr, ivo.puhalovic@ccaa.hr, gbjelic@gmail.com*

Sažetak -Model inteligentnog sustava koji se nalazi na raspolaganju studentima stručnog specijalističkog studija Elektrotehničkog odjela i polaznici Programa edukacije AERO TVZ za stjecanje licence aerodromskih specijalista, na Tehničkom veleučilištu u Zagrebu, nadograđuje se za potrebe „rada u oblacima". U radu je prikazan koncept nadogradnje inteligentnog sustava koji obuhvaća i prezentaciju baze podataka s rezultatima obrade provedenih istraživanja na aerodromima i ispitivanjima u laboratoriju za potrebe baze znanja. Referentni parametri aerodromskog sustava svjetlosne signalizacije između ostalog se odnose i na stanje otpora izolacije aerodromskih primarnih kabela serijskih strujnih krugova. Redovnim održavanjem, ali i provjerom održavanja inspekcijskim nadzorima utvrđuje se stanje tih vitalnih komponenti sustava koje su u funkciji sigurnosti zračne plovidbe.

Znanjem iz inteligentnog sustava razrađeno je i primijenjeno unapređenje održavanja, koje se kao model usluge dobavljive na tržištu nudi krajnjim korisnicima. Ispitivanje i mjerenje otpora izolacije na serijskim strujnim krugovima aerodromskog sustava svjetlosne signalizacije moguće je povjeriti specijalistima. Uz ekspertni sustav koji služi za edukaciju, postavljena je paralelna agentska platforma koja obuhvaća procedure i uređajem nove generacije koristi se za ispitivanje na terenu. Posebna sofisticiranost ispitnog uređaja uz agentsku platformu je njegova mogućnost da osim sveobuhvatnog ispitivanja, prikupljanja i obrade, relevantne podatke može trenutno, (online), dostavljati na bilo koje zahtijevano mjesto uz punjenje u bazu podataka.

I. UVOD

Sustav aeronautičkih svjetala na zemlji, (*engl. Airfield Lighting System*), pruža pilotu informacije o lokaciji, orijentaciji i poravnanju u nepovoljnim vremenskim uvjetima i noću. U funkciji je sigurnosti zračnog prometa te ovisi o razini opremljenosti zračne luke, (kategoriji prilaza - instrumentalni precizni prilaz CAT I, CAT II-III, A, B, C, slika 1.), može biti kreiran s više podsustava. Ispravnost i pouzdanost cjelokupnog sustava uvelike utječe na sigurno provođenje operacija, (slijetanje, uzlijetanje, taksiranje) zrakoplova na zračnim lukama. Ocjene ispravnosti i pogonske pouzdanosti rezultat su zadovoljavajućih parametara o stanju, koji se nadziru i arhiviraju u baze podataka, a o čemu svjedoče prethodno provedena istraživanja i prezentirani rezultati, [1-2]. Otpor izolacije aerodromskih primarnih kabela serijskih strujnih krugova utječe na izlazne (fotometrijske) karakteristike sustava aeronautičkih svjetala na zemlji, a time i na sigurnost operacija, te ga je potrebno nadzirati i analizirati u svrhu što kvalitetnijeg održavanja sustava.

Slika 1. Aerodromski sustav svjetlosne signalizacije, sustav aeronautičkih svjetala na zemlji

Nastavak istraživanja na aerodromima i ispitivanja u laboratoriju, vezano na stanje otpora izolacije aerodromskih primarnih kabela serijskih strujnih krugova, uz učenje iz inteligentnog sustava potvrdila su mogućnost unapređenja procedura preventivnog i predikatnog održavanja, [3-6]. Nabavljena nova ispitna oprema omogućuje sveobuhvatno ispitivanje, prikupljanje i obradu relevantnih podataka koji se mogu trenutno proslijediti na zahtijevano mjesto, bez prijenosa na računalo. Model inteligentnog sustava koji je na raspolaganju studentima specijalističkog studija Elektrotehničkog odjela i polaznici programa edukacije za stjecanje licence aerodromskih specijalista na Tehničkom veleučilištu u Zagrebu nadograđuje se za mogućnost „rada u oblacima" s navedenim specifičnim zahtjevima, [7-8].

A. Održavanje aerodromskog sustava svjetlosne signalizacije

Za specijalističke aerodromske sustave u funkciji sigurnosti zračne plovidbe, kao što je sustav svjetlosne signalizacije, legislativnim zahtjevima definirani su uvjeti eksploatacije, način održavanja, mjerenja i kontrole stanja otpora izolacije u serijskim strujnim krugovima, [9]. Praćenje parametara kroz duži niz godina ukazalo je na niz važnih spoznaja iz kojih se ocjenjuje pouzdanost ali i strategija održavanja, [10].

Na temelju raspoloživih baza podataka prikupljenih tijekom gradnje fakultetskog ekspertnog aerodromskog sustava, "ExSys AERO TVZ", ali i obradom konkretnih

aerodromskih primjera eksploatacije složeni su algoritmi za koncept odabira održavanja, [11]. Strategije održavanja moraju biti povezane s kreacijama baza znanja kao dijela inteligentnog sustava koje su rezultat praktičnih spoznaja. Ta se unapređenja elaboriraju kroz pripreme specijalističkih programa održavanja i na temelju razmjene iskustava kreiraju nova znanja, [12-13]. Primjer obrade prijašnjih iskustava pretočenih u bazu znanja pokazuje Tablica 1, koja prezentira vrste kvarova na serijskim strujnim krugovima, (ukupno analizirano 166 kvarova na šest zračnih luka, [1]. "Korisnik instalacija, opreme ili uređaja najbolje poznaje njihovo stanje", konstatacija s kojom dvije od pet legislativnih podloga o održavanju započinju poglavlje, kojim se definira plan održavanja, [13]. Kada se radi o planovima održavanja vezanim uz aerodromske specijalističke

TABLICA 1. STATISTIKA KVAROVA IZ BAZA PODATAKA

Red. br.	**Pregled kvarova iz baze podataka**		
	Vrsta kvara		***Vrsta kvara***
1	Kvar na kabelu - oštećenje uslijed atmosferskog pražnjenja, (udar groma)	3/1,8	odstranjen dio oštećenog kabela
2	Kvar na kabelu - mehaničko oštećenje izolacije, starost kabela ili prekid kabela	12/7,3	nadomješten dio oštećenog kabela
3	Kvar na konektoru - nedovoljno čvrst spoja vodiča u spojnici konektora	5/3	zamijenjen konektor
4	Kvar na konektoru - prekid spoja vodiča kod pina konektora	6/3,6	zamijenjen konektor
5	Kvar na konektoru - oštećenje izolacije konektora ili neispravno izrađen konektor	95/57,2	zamijenjen konektor
6	Kvar na konektoru - nečistoća unutar kontaktnih površina oba kontakta konektora	23/13,8	saniran konektor
7	Kvar na transformatoru - proboj unutar namota transformatora	5/3	zamijenjen transformator
8	Kvar na transformatoru ili primarnom konektoru transformatora izvana	12/7,3	saniran konektor
9	Kvar na transformatoru - uzrokovan probojem na strani sekundara transformatora	2/1,2	zamijenjen transformator
10	Kvar na transformatoru i kabelu zbog prodora vode iz zdenca	3/1,8	ispumpana voda i osušen transformator
	UKUPNO	166/100	

sustave, korisno je napomenuti kako su već više od tri desetljeća radne stanice - dio sustava svjetlosne signalizacije u službi za održavanje, opremljene dijelovima ekspertnog sustava - bazama podataka, koje su u početku nazivane "Arhive". One su u početku isključivo služile za "arhiviranje podataka", i značilo je da se utvrđeni podaci mogu arhivirati, pohraniti odnosno spremiti. Danas, u novije vrijeme, razvojem ekspertnih sustava uz baze podataka korisnici uređuju i grade vlastite baze znanja pa se s podacima može zaključivati i stjecati nova znanja, kao što su primjeri provedenih radionica uz edukacijske programe AERO TVZ, [12-13], u skladu s aktualnom legislativom, [14].

Prilikom obrade navedenih primjera za koje su korišteni arhivirani podaci službe održavanja s određenih aerodroma, eliminirani su slučajevi u kojima su greške i kvarovi na serijskim strujnim krugovima bili posljedica greške u proizvodnji kod određenog proizvođača. Također su eliminirani kvarovi i greške za koje je nakon reklamacije proizvođač priznao svoj propust i eliminirani su kvarovi nekih prototipova opreme koji su bili tretirani kao razvojni projekti, i kvarovi koji su bili posljedica nestručnog postupanja - neposjedovanje radne rutine i rad needuciranog osoblja za određene radne postupke, kao i propusti koji su kasnije bili pripisani montažerima opreme. Suradnja s proizvođačima opreme rezultirala je kod korisnika ostvarivanje bonusa i značajne uštede, a tijekom daljnjih eksploatacijskih spoznaja neki od proizvođača su promijenili i svoj pristup u proizvodnji nekih tipova opreme i izdanim uputama za ugradnju, montažu i održavanje.

Navedeni kvarovi obrađeni u Tablici 1. direktno ili indirektno su utjecali na stanje otpora izolacije serijskih strujnih krugova, odnosno utjecali su na ispravnost i pogonsku raspoloživost sustava svjetlosne signalizacije. Utvrđeno stanja otpora izolacije, kroz procedure održavanje, spoznaje su i pomoć aerodromskim stručnim službama. Naime u postupcima održavanja sa stečenim spoznajama moguće je kvalitetnije i kompetentnije održavanje odnosno raspoloživost kontinuirane funkcionalnosti što je direktni zahtjev vezan uz sigurnost zračne plovidbe. Iz opisa dijagnosticiranih kvarova prema Tablici 1. utvrđeni su uzroci na kojima su stečena znanja za buduću eliminaciju, preventivno djelovanje i otklanjanje kvarova.

Tako na primjer zbog udara groma i prolaska prenaponskog vala na instalaciju serijskog strujnog kruga uslijedile su poboljšane verzije prenaponskih zaštita. Najviše mogućih uzroka, (a mogući su i na svim drugim komponentama serijskog strujnog kruga) kada se eliminiraju gore navedeni u obradama su:

- greške i propusti završnih ispitivanja
- hodanje po kabelima postavljenim u i na metalne police u objektima ili zdencima prilikom montaže
- neprimjereno uvlačenje i navlačenje kabela tijekom izvođenja radova na kabelskoj kanalizaciji
- kritičan polumjer savijanja primarnih kabela prilikom uvlačenja i polaganja u zdence
- neadekvatno odabrana vrsta kabela - nemogućnost polaganja za određena projektantska rješenja
- prve tehnologije finožičanih kabela bez ekrana

Velik broj kvarova posljedica je i neadekvatno korištenog alata kojim se preša, (moguća greška u debljini pina konektora), greška dimenzije skinute izolacije, (neuredno uvijen snop žila vodiča, problem promjera primarnih kabela), oštećenje izolacije konektora prilikom nestručne izrade konektora, konektori koji se nakon nekog vremena odvoje zbog nečistoća, zarobljenog zraka i dimenzije dijelova konektora. Sve navedene spoznaje raspoložive su u bazama podataka ExSys AERO TVZ.

II. INTELIGENTNI SUSTAVI ODRŽAVANJA

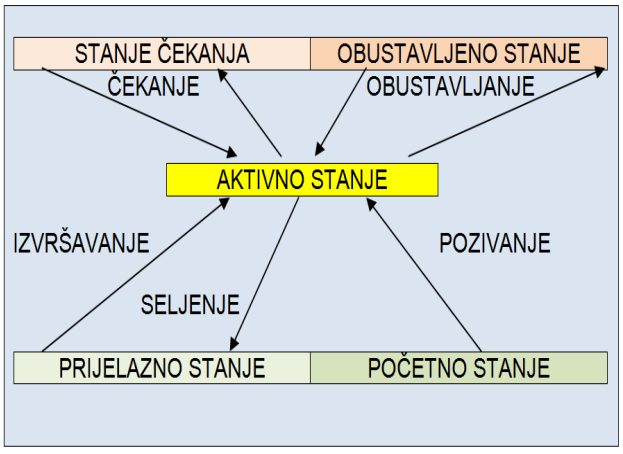
Na tim je osnovama specijalističko održavanje usmjereno na upravljanje kvalitetom, koje podrazumijeva prepoznatljivu i ujednačenu kvalitetu proizvoda i usluga, usmjerenost prema korisnicima, kreativnost i inovativnost, upravljanje procesima, resursima, troškovima i rizicima, komunikaciju i edukaciju. Upravljanje kvalitetom usmjereno je i na stvaranje zadovoljstva zaposlenika i poslovnog entuzijazma, poboljšanje uvjeta i kvalitete rada te razvoj svijesti o kvaliteti pojedinca i cjelokupne organizacije, tvrtke. Uvođenje i praćenje ključnih pokazatelja uspješnosti koja generiraju inteligentni sustavi, koristan je alat za smanjenje troškova održavanja, koje je moguće ostvariti kroz dobru strategiju održavanja, optimalne preventivne ili korektivne aktivnosti, optimalnu raspoloživost doknadnih dijelova, svrsishodnu organizaciju i kvalitetan menadžment. Praćenje ostvarenih ušteda moguće je kroz ekonomske pokazatelje iz baza znanja i baza podataka ekspertnog sustava. Koristan je primjer predstavljenih i standardiziranih ključnih pokazatelja uspješnosti u norma EN 15341:2007, koju je objavio Europski savez nacionalnih društva održavatelja, *(engl. European Federation of National Maintenance Societies)* .

Na tom tragu provedena su i različita dodatna istraživanja na hrvatskim aerodromima, kojima su prikupljeni stvarni podatci o troškovima održavanja i uporabe prema strukturi troškova. Za svaku od navedenih skupina troškova održavanja i uporabe popisane su sve ostvarene stavke spomenutih troškova koje su se javile tijekom promatranog vremenskog razdoblja. Obradom u ekspertnom sustavu došlo se do spoznaja o ostvarenim aktivnostima u održavanja i uporabi kao i implikacije na specifične skupine troškova.

Svakako da je održavanje serijskih strujnih krugova aerodromskih specijalističkih sustava u direktnoj vezi s troškovima, pa tako i postupanje aerodromskih specijalista se veže uz imperativ njihovog racionalnog postupanja. Poznate su razne krivulje troškova održavanja, koji se uglavnom žele svesti na najmanju moguću vrijednost a istovremeno da razina pouzdanosti ostane visoka. Kvalitetnim edukacijama i profesionalnim postupanjem to se i postiže kod aerodromskih specijalista. No u novije vrijeme otvaraju se i nove mogućnosti racionalnog postupanja u pogledu održavanja, naročito kada podaci o kvalitetnom održavanju mogu biti podloga za ostvarivanje određenih bonusa. Iako najčešće policu osiguranja određene opreme zračne luke ugovara ekonomsko-financijski sektor, konačna odluka o mogućem ostvarenju bonusa, (konkretno za dio opreme ALS), u kompetenciji je aerodromske službe održavanja. Primjeri ovih postupanja potvrđeni su u razmjeni iskustava s nekim europskim aerodromskim službama održavanja. Konkretan je primjer investicija s police osiguranja u opremu prenaponske zaštite na temelju koje je ostvarena bonifikacija u razdoblju eksploatacije bez havarijskih posljedica s naslova prenaponskih pražnjenja, a koja je korištena kao model za investicije zamjene primarnih kabela i konektora serijskih strujnih krugova s permanentno lošim otporom izolacije koji je izazivao ispadanje serijskih strujnih krugova. Stoga se može zaključiti kako unutar sofisticiranih održavanja, svi sustavi nadzora i prikupljanja velike količina podataka, omogućuju korisnicima stjecanje novih znanja između ostalog o racionalizaciji održavanja. Za to je vrlo bitno približiti takav sustav korisnicima i omogućiti im lakše snalaženje u toj masi podataka, što je inače i imperativ osnovne, bazne, zrakoplovne legislative, [15], kao i aktualnog unapređenja, [16-17].

A. Koncept nadogradnje inteligentnog sustava za obradu serijskih strujnih krugova

Koncept kreacije rješenja nadogradnje inteligentnog sustava za obradu serijskih strujnih krugova odvija se u fazama. U svakoj fazi inteligentni sustav ne prolazi kroz sva navedena stanja razvoja, već će neka stanja biti vezana sa ciklusima trajanja. Faze stanja mogu se prikazati međusobnim interakcijama, Slika 2.
Globalno shvaćanje kreacije koncepta kroz razvoj temeljeno je na raspoznavanju, sustava, podsustava i



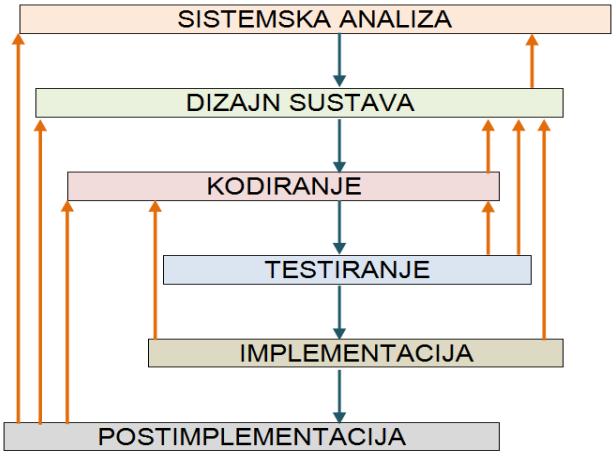
Slika 2. Faze stanja razvoja inteligentnog sustava

platformi. Pa tako u konkretnom slučaju imamo:

- Raspoloživi ekspertni aerodromski sustav iz kojeg učimo - (ExSys AERO TVZ

- Inteligentni sustav u kreaciji za nadogradnju – (InSys AIRPORT TVZ)
- Potrebu za pripadajućim agentskim platformama – (AgPlat AIR TVZ)

Koncept slaganja rješenja nadogradnje inteligentnog sustava aerodromskog elektro održavanja**,** svodi se na slijed koji započinje sistemskom analizom a završava postimplementacijom, Slika 3.



Slika 3. Slijed koncepta nadogradnje inteligentnog sustava

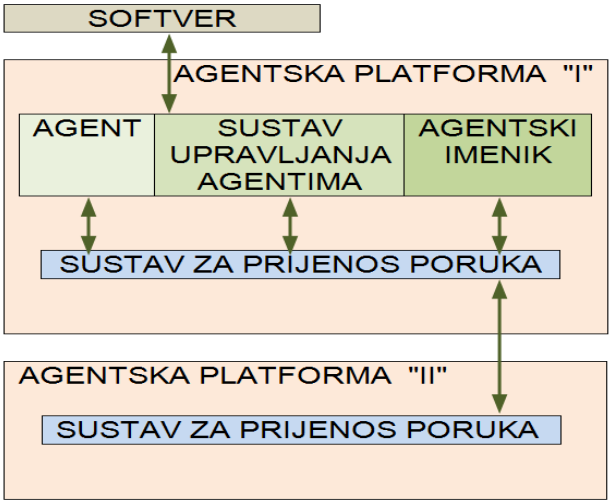
B. Arhitektura agentske platforme za održavanje

Ono, na što će biti stavljen akcent u finalizaciji nadogradnje inteligentnog sustava jest utvrđivanje potrebe za određenim agentskim platformama. U samoj definiciji, Agent, (*lat. agere)* znači voditi, djelovati, raditi. On se razaznaje kao entitet kojim se mogu „opažati" promjene i povratno „djelovati". To je netko tko djeluje ili ima mogućnost djelovanja ili zastupanja nekoga drugoga. Definira se kao sredstvo kojim se djeluje (instrument) ili pozicija s koje se djeluje pa je stoga uvriježen naziv – platforma.

Pojednostavljeno, agentska platforma, (opaža i djeluje), definira se kao nešto što djeluje u ime nekoga kako bi izvršio povjereni mu zadatak. Ona uključuje ljude, virtualne karaktere i računalne komponente, sustava upravljanja i sustava za prijenos podataka, Slika 4.

C. Nadogradnja agentskim entitetom

Svaki inteligentni agent, odnosno agentska platforma, pokazuje elemente inteligentnog ponašanja. On ima sposobnost djelovanja i u situacijama za koje nije unaprijed pripremljen, ima mogućnost učenja i samoispravljanja. Racionalnost agent postiže kao posljedicu svog djelovanja rezultirajući napretkom koji je potrebno vrednovati mjerom uspješnosti *(engl. Performance Measure).* Ta se mjera ponekad naziva i funkcija korisnosti *(engl. Utility Function),* koja



Slika 4. Agentski sustav prijenosa poruka i upravljanja agentima

predstavlja preslikavanje sa skupa ili sekvence stanja na skup realnih brojeva. Cilj je postići dobro ponašanje agenta, njegovu racionalnost (razboritost) o kojoj ovisi konačan uspjeh, što je moguće postići što boljim određivanjem okružja zadatka, i ocjene uspješnosti provođenja, koje definiraju inženjeri znanja, [18].

Prema namjerama ostvarenja unapređenja pogona i racionalizacije potrebno je osim same definicije i razlučiti djelovanje agente.
Agentska platforma se može postaviti kao složeni računalni sustav (budući je sastavljena iz više dijelova), smještena u okolinu iz koje može primati podražaje i koja može fleksibilno, autonomno djelovati u svrhu ostvarivanja vlastitih ciljeva. Dobro ponašanje agenta vezano je uz njegovu pronicljivost, *(engl. Clairvoyant)* i uspješnost, *(engl. Successful)*, pa se od njega očekuje fleksibilnost koja uključuje sljedeća svojstva:

- pristupačnost (prepoznaju svoju okolinu i odgovaraju na promjene u njoj)
- aktivnost (iskazuju i ponašanje usmjereno kroz preuzimanje inicijative)
- društvenost (sposobnost djelovati zajedno s drugim agentima i ljudima u svrhu ostvarivanja svojih ciljeva i u svrhu pomoći drugima u ostvarivanju njihovih ciljeva).

U ciklusima prema slici 2, početno stanje agentske platforme mora biti precizno definirano, odnosno moraju ga karakterizirati:

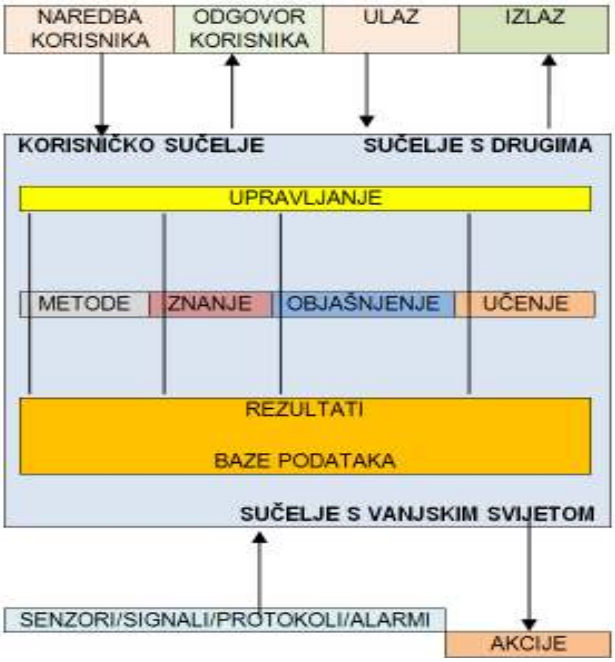
- mjere njegove uspješnosti
- njegovo okruženje
- stvarne akcije i rezultati

Raspoloživi ekspertni demo sustav iz kojeg se uči, dizajniran je i ima već ugrađene svoje senzore i aktuatore te kroz rad u praktikumu moguće je simulirati stvarno stanje serijskih strujnih krugova na aerodromu. Na terenu obradu serijskih strujnih krugova agentska će platforma proći određivanjem trenutnog stanja, koje neće uključiti čekanje, obustavljanje i prijelaz, već raspoloživost parametara utvrđenog stanja. Nadogradnja inteligentnog

sustava za obradu serijskih strujnih krugova obuhvaća samostalno djelovanje agenta. Akcent je stavljen na tehničku napravu, (u našem slučaju sofisticirano mjerilo otpora izolacije) koja samostalno rješava zadatke distribucije utvrđenih parametara u online sustavu. Na tim osnovama agentska platforma je proaktivna u dobro definiranom okružju i uz pomoć inženjera znanja ispunjava svoj zadatka, [19].

Njeno je okružje – operativna površina aerodroma i ona:
- utvrđuje trenutno i stvarno stanje otpora izolacije
- dijagnosticira kritične parametre
- šalje protokol o stanju sustava na temelju utvrđenih parametara na striktno zahtijevano mjesto
- ocjenjuje sigurnost zračne plovidbe na zračnoj luci i
- puni baze podataka

Tako u fazama razvoja, osim prikupljanja parametara broja i vrste modula koji se povezuju važna je interakcija i povezivanje unutar pa i s drugim inteligentnim sustavima ili perifernim jedinicama, kao što će biti nastavak integracije s ekspertnim sustavom u laboratoriju, Slika 5.



Slika 5. Sučelja za komuniciranje agentskih platformi i ekspertnog sustava

D. Kontrolna mjerenja – povjerenje u agenta

Za mjerenje i obradu otpora izolacije serijskih strujnih krugova korištena je agentska platforma oslonjena na ispitni uređaj nove generacije.

Njegove karakteristike su osim razine ispitnog napona koji u potpunosti može udovoljiti zahtjeve legislative, (10.000 V), i mogućnost online dostave izmjerenih podataka. Mogućnost trenutnog slanja podataka znači da se podaci direktno iz samog instrumenta šalju bez posredovanja računala ili bilo kojeg drugog pomagala. To je njegova posebna prednost koja dolazi do izražaja kada su zahtjevi za provjerom stanja vezani uz inspekcijske nadzore jer u tim slučajevima nema mogućnosti manipulacije podacima a niti uključivanje funkcije vremena za koju je dokazano da ima utjecaj na strujne krugove sa starijom i oštećenom izolacijom. To u pogonskim uvjetima znači da je moguće stvarno provjeriti stanje otpora izolacije u nekim ekstremnim klimatskim uvjetima, prilikom puštanja u pogon novih sustava, uključujući i fazne nadogradnje kao i akcidentnim događajima.

Osim slanja, velike količina podataka mogu se prikupljati i obrađivati kroz mehanizme zaključivanja u ekspertnom sustavu. Ta je mogućnost ostvariva pod pretpostavkom da mjerenje i obrada za bilo koji slučaj budu u kompetenciji, inženjera znanja, odnosno da se ima povjerenje u agenta. Elektrotehnički odjel, posjeduje odobrenje Hrvatske agencije za civilno zrakoplovstvo kao licencirana institucija za edukaciju, a odgovornost za dosljednost provedbe u rukama je Voditelja i Instruktora koji su svoje funkcije također potvrdili dobivenom licencom. To bi trebala biti garancija povjerenja uključujući i potvrdu o umjeravanju, [20].

Originalnost i inventivnost sustava potvrđena je razradom agentske platforme, primjenom nove generacije uređaja koji se koriste za provedbu ispitivanja, rezultati kojeg se online protokoliraju i dostavljaju na željenu adresu. Među parametrima moguće je izdvojiti osim stanja otpora izolacije i vrstu, tip, dimenzije, proizvođača kabela serijskih strujnih krugova, način polaganja, (kabelska kanalizacija ili zemlja), stanje zaštitne uzemljivačke trake i drugo. Da bi sve bilo povezano i uzeto u obzir, sudionici u izgradnji IS su osim eksperata, inženjera specijalista, inženjera znanja, i korisnici i osoblje na prikupljanju i obradi podataka. Svi oni sa svojim znanjem pomažu kreiranju algoritama, punjenju baza znanja i baza podataka, i u funkciji su podrške donositelju odluke.

Na tim osnovama, uvođenjem ekspertnih sustava u proces edukacije na TVZ-u pomalo prerasta u vizije rada u oblacima *(engl. Cloud Computing)*. Pokretanjem inicijative i suradnjom s privredom u namjeri konkretizacije ovakvih specijalističkih aktivnosti uključuju se i specijalističke tvrtke. Svojim iskustvom, spoznajama i djelovanjem one također sudjeluju u razvoju ekspertnih sustava ali istovremeno postaju i njegovi korisnici ili pružatelji usluga a vezano za npr. održavanje njegovih specijalističkih sustava. Takav angažman, prema predviđanjima razvoja i primjene ekspertnih sustava, bit će prihodovno orijentiran i prihvaćen, uvođenjem i pružanjem takvih usluga koje još uvijek očekuju višu razinu definirane zaštite intelektualnog vlasništva, [21].

III. ZAKLJUČAK

Sustavu svjetlosne signalizacije na zračnim lukama u funkciji sigurnosti zračnog prometa kroz mjerenje i ispitivanje ocjenjuje se pogonska pouzdanost. Rezultati parametara o stanju, koji se nadziru i arhiviraju u baze

podataka, moraju biti zadovoljavajući u skladu s propisanom legislativom.

Istraživanja na aerodromima i ispitivanja u laboratoriju, vezano na stanje otpora izolacije aerodromskih primarnih kabela serijskih strujnih krugova, uz učenje iz ekspertnog sustava potvrdila su mogućnost unapređenja procedura preventivnog i predikatnog održavanja, ali i ponudu online raspoloživosti izmjerenih podataka. Nabavljena nova ispitna oprema omogućuje sveobuhvatno ispitivanje, prikupljanje i obradu relevantnih podataka koji se mogu trenutno proslijediti na zahtijevano mjesto, bez prijenosa na računalo. Model inteligentnog sustava koji je na raspolaganju studentima specijalističkog studija Elektrotehničkog odjela i polaznici programa edukacije za stjecanje licence aerodromskih specijalista na Tehničkom veleučilištu u Zagrebu nadograđuje se za mogućnost „rada u oblacima“. Specifičnim zahtjevima, bit će moguće udovoljiti kada se ostvare zaštite intelektualnog vlasništva, ali i potvrde povjerenja u agentske platforme koje se u funkciji tih provođenja. Ideja budućnosti takvog rada u virtualnim okruženjima u osnovi podržana ekspertnim sustavima, osim mogućnosti uporabe baza podataka i baza znanja u "bezgraničju" razvijat će se u smjeru pružanja usluga s naslova pouzdanih, provjerenih i zaštićenih podataka.

TECHNICAL TRACK

Disabling Same Origin Policy for Automatization of Webform Data Entry

Samir Ribić*, Adnan Salihbegović * and Alvin Huseinović**
* University of Sarajevo, Faculty of Electrical Engineering, Sarajevo, Bosnia and Herzegovina
** Enit d.o.o., Sarajevo, Bosna i Hercegovina
samir.ribic@etf.unsa.ba, adnan.salihbegovic@etf.unsa.ba, alvin.huseinovic@enit.ba

Abstract - There is often a need enter data in online documents. Web based interface is popular, but sometimes there is a need to fill the data using scripting and automation. JavaScript may enable automatic data entry, but it requires that script written in JavaScript executes on the same server where the form is being processed, due to protection mechanism of "same origin policy". If needed, some browsers support disabling this policy, or there is alternative method to bypass it. The paper describes this method and includes a sample JavaScript code for automated data confirmation.

I. INTRODUCTION

There are different ways to interact with a computer: command line interface, textual interface, graphic user interface, web interface, gaming interfaces, voice recognition, pen and tablet interface, etc. Inserting large amounts of similar data in online document can easily be automated by using scripting tools and languages developed for command line, although the main disadvantage of using command line is that it is inappropriate for users with lack of experience, and it is considerably prone to errors. Textual and graphical dialogs made the data entry less error prone, but also harder for automatic data entry. It is especially a case when data entry is simple, for example, if one needs to approve large amount of records. The discrepancy between ease of use and possibility to automate the data entry is present also in web interface.

In the second section of the paper will review typical methods for automating data entry in web applications. Web has one ubiquitous scripting language JavaScript, but it has one security property, which makes the automation difficult, called "the same origin policy". The third section of the paper will review popular methods for avoiding this policy. In the fourth section we will illustrate one method of save origin policy avoidance, here is a JavaScript source sample, developed by us, which performs mass data approval on the web site used for the co-ordinated localisation and translation of software. The empirical results for modified workflow will be also given.

II. WEB INTERFACE AUTOMATION

The development of web technologies has created web applications that execute in a web browser. The scripts can execute on the client or server side, depending on the application appliance. Web applications are quite flexible, as they can be quickly changed on the server side without client side interventions. Initially, web interface was designed for entering a minimal amount of data (such as registration forms), but it soon became used for entry of different kind of data. However, when entering a large amount of the similar data, typical data entry process (entering the form, submitting and waiting for server response) might be tedious and slow.

Sometimes this problem is not only related to the design of web application, but also to the application workflow. For example, in a web shop, an officer needs to approve the orders, by clicking check boxes, each of them, separately. After the previous review the officer concludes that all pending orders are correct, and wishes to confirm all of them at once, but the user interface allows only approval one order at the time.

To avoid described situation, web servers offer web services or other kind of API to facilitate automated data entry. An officer who often repeats same queries in web searches may prepare locally hosted web pages which aggregate the queries, as in the following example.

```
<!DOCTYPE html>
<html>
<body>
<iframe width=100% src=
"http://www.bing.com/search?q=weather+paris">
</iframe><br>
<iframe width=100%
src="http://finance.yahoo.com/q?s=TSLA">
</iframe>
</body>
</html>
```

The officer can refresh the page to retrieve the actual data without re-entering the data over and over again. Unfortunately, in web applications, this kind of interface may be unavailable, too complex, and available only for a charge or undocumented. When implementation of such interface on server side is not possible, it is often necessary to try with different approaches to simulate data entry and achieve automatic entry on the web forms. Such approaches might be tried on client side or on proxy.

There are three obvious approaches. The first approach would rely on APIs in the local operating systems. For example, Windows program which sends `WM_MOUSEMOVE` and `WM_KEYPRESS` messages to the web browser window could simulate data entry into the form.

The second approach is based on modified HTTP requests. Instead sending the form data from web browser, it is possible to programmatically prepare a set of HTTP requests with content similar to those generated from the entered data. By using tools (ex. `curl`), one can send the packets.

The third approach would use JavaScript and analyse the remote web page. Document Object Model[1] allows access to each part of the web page, including all elements of web forms. A JavaScript program fills up the web form and simulates required mouse clicks and keyboard actions. For example, one can write this piece of code :

```
var nm=window.document.getElementById("name");
nm.value='John Smith';
```

However, there are obstacles to implement all three approaches. The first approach is quite vulnerable to web page layout and size. It is difficult to predict the exact location on the screen where the button or data entry field will be located. Furthermore, a web browser may intercept system messages or render web pages differently.

Modified HTTP requests have also some obstacles. If they are sent from external software, they need to simulate complete login procedure in a way a browser did it (or to reuse an existing session with browser). Server often checks `Origin` and `Referer` HTTP header as a security measure against Cross site request forgery[2] to be sure that request came from browser, not the external tool. The programmer needs to correctly fill these fields in request. Additionally, the external tool needs to cope with certificates and protocols if HTTPS is used, which makes writing of the external tool more difficult. This is not problem if HTTP request is sent from JavaScript inside browser, using `XMLHttpRequest` object, because SSL library is transparent, but `XMLHttpRequest` object is subjected to Same Origin Policy.

III. Same Origin Policy And Avoidance Methods

A. *Same Origin Policy*

There is one security rule that makes it difficult to use JavaScript as a tool for data entry. It is called the Same Origin Policy. It was introduced early in JavaScript history, with Netscape Navigator 2.0 and it prohibits websites from different domains to interact with each other, except in a limited way [3]. For example, there are popular sites (Amazon, Facebook, PayPal, Ebay), and it is not uncommon that the user opens the tab or window containing session to them. At the same time, this user opens another site in a different window, without knowing that it contains JavaScript code, which reads credit card information from Amazon session or sends an embarrassing message from user's Facebook account. On the other hand, it is desirable that JavaScript initiated from Facebook server is aware of all Facebook windows opened on the client's computer.

Same Origin Policy is established on the client side. It is a purely web browser capability. It allows JavaScript to access the DOM contents of the other web page only if it belongs to the same server, domain, port and protocol, as defined in the standard proposal [4]. Directory and file names need not to be the same. So, `http://www.ex.com/test.js` may access structure from `http://www.ex.com/a/h.htm` but not from `http://www.sam.com/hello.htm` (other domain), `http://w2.ex.com/h.htm` (other host) or `https://www.ex.com/h.htm` (other protocol).

This limitation means that web page influenced by JavaScript and the file with a script needs to be on the same server. This is often not possible to implement.

Two common situations when the same origin policy limits the software usability are JavaScript access to document structure and AJAX request using `XMLHttpRequest` to access web services through JavaScript.

With caution, same origin policy can be avoided if it is necessary. This is not a recommended activity, and should be used with care. This means there is a need to disable same origin policy only during specific activities and re-establish thereafter. While the browser is in insecure environments, it is prohibited to visit the other sites except the ones planed one for data entry scripting.

B. *Macro recording and testing tools*

An approach, which sometimes does not require programming, relies on software that records keys on keyboard and mouse movement and clicks. They can be saved in macro and then replayed, although the use of this method is limited to cases where the same action needs to be repeated many times and if screen layout remains unchanged during the whole web session. Some macro recorders are expanded to full IDE, like Selenium IDE, a Firefox plugin for editing macros in browser, and Selenium WebDriver, a set of language bindings for web browser automation, both of them are available at http://www.seleniumhq.org.

C. *Browser Option*

The easiest method to switch off the same origin policy is to utilize browsers which have this as an option. This also means that one has to avoid these browsers or options in other situations. One example of such a browser is Google Chrome in versions 5 to 20. This browser can be started with an option

```
chrome.exe --disable-web-security
```

This option initially was intended for testing purposes during web development, but here it will be used for automating scripts on sites where automation is not possible by default. In a similar way, in the Mozilla Firefox, it is possible to open `about:config` page and change `security.fileuri.strict_origin_policy` setting to `false`[5].

The disadvantage of this approach is a limitation to a specific web browser version, and need to start it temporarily in non-secure environment. When this is not acceptable, there are other possibilities to avoid the same origin policy.

D. *Change Document Domain*

One approach [6] is designed for the case when the JavaScript program and the web form have the same domain, but not the same host. For example, an university has a common information system, but each department also has its own system. The university system is located at `univ.edu/info.php` while CS department has a system at `cs.univ.edu/start.php`. A program at the CS department (for example data export program) in JavaScript program may contain the line

```
document.domain = "univ.edu";
```

After this statement is executed, the page would pass the origin check with http://univ.edu/info.php. However, it is not allowed to change the domain to otheruniv.edu.

E. *Policy Files for Flash Applications*

The applications in Macromedia Flash can allow cross-domain access using configuration file `crossdomain.xml`[7]. Inside the XML element one can put the tag to allow flash applications to modify data locally, which come from a specific domain.

F. *Proxy Servers*

For frequent web form filling on a remote domain, one can use proxy server. The user can host a proxy server locally to access a web page `http://www.rem.com` using ex. `http://www.local.ba/co/www.rem.com`. A script at `http://www.local.ba/script.js`, from a perspective of web browser will not void the same origin policy.

G. *Cross Origin Resource Sharing*

One recent approach is called Cross Origin Resource Sharing (CORS).[8] It is suitable for AJAX requests. During request, an additional HTTP header may be set as in the following example.

```
Access-Control-Allow-Origin: http://www.srvr.com
```

The browser performing an Ajax request should now ignore the origin.

H. *JSONP*

JSONP stands for JavaScript Object Notation with Padding[9]. Assume that the call to the server `http://www.srvr.com/act.php` results with a JSON document `{"name":'milk',"price":1.8}`. Servers, which return data in JSON format, can also call a callback function when submitted.

On these kind of servers a call to `http://www.srvr.com/act.php?jsonp=Process`, will result with calling the function

```
Process({ "name": 'milk' ,"price":1.8}).
```

This method requires that the server is aware of cross-domain requests.

I. *Use of XdomainRequest and JSONRequest*

In addition to standard `XMLHttpRequest` for Ajax calls Internet Explorer from version 8 has `XDomainRequest` object.[10] This object allows an asynchronous call to HTTP server located on a different domain from the one where the JavaScript program is executed.

```
var obj = new XDomainRequest();
obj.open("post","http://www.serv.com/act.aspx");
obj.send();
```

`JSONRequest` is similar object, installed as additional library but supported by a wider variety of browsers.

J. *Use of GreaseMonkey*

There is a plugin for Firefox called GreaseMonkey [11]. It has `GM_xmlhttpRequest`, a version of the `XMLHttpRequest` which does not use the same-origin policy, object unsafeWindow which provides access to the raw JavaScript window scope of the content page. The unsafeWindow is most commonly used to access JavaScript variables on the page. Usage of this plugin is similar to browser option approach, except for different names of used objects. It is recommended to switch it off when not used.

K. *Use of window.postMessage*

Calling `window.postMessage` method is useful for selectively cross origin scripting [12]. This method causes a `MessageEvent` at the target. The script that receives the data should install the listener using the method `window.addEventListener("message", handler, false);`

In the handler function, it is possible to check for `event.origin` property if it matches allowed domains. The message can be sent using the `postMessage` method over the window opened with `window.open` method.

IV. EXAMPLE

As an example of the situation where disabling the same origin policy might simplify data entry, we will present here our real world JavaScript code. It is used here as an illustration of accessing a form data in JavaScript on remote server, with mouse simulation.

During the localization project of Linux operating system for Bosnian language, we used Launchpad Rosetta[13] system. Typically, such projects might have bigger number of the contributors (translators) than the

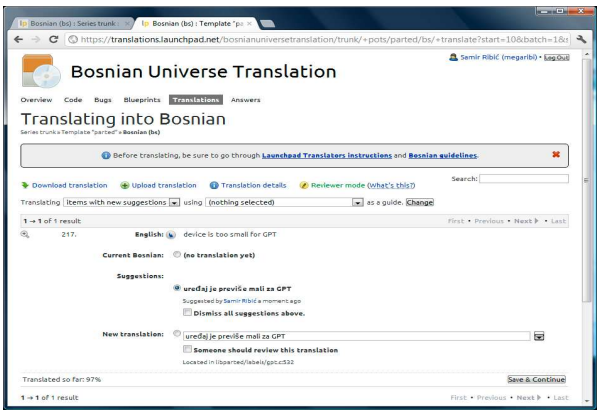

Figure 1. Translation suggestion in Launchpad Rosetta

approvers. In our project, we have had about 70 translators and one approver, who needed to check about 80000 strings. When the approver wants to remark that the contributor works satisfactory, he may start accepting his translation proposals, by clicking radio buttons, and submit buttons. It seems that the job was trivial, just to look at the text and click one radio button, then one submit button (as shown in the screenshot, Fig. 1).

However, due to the fact that the majority of the contributors work just before the deadline, this might result in tedious job for the approver to complete his part in a limited time. Launchpad servers are often overloaded and manual clicking and confirming fails and require resubmitting. Manually, one approver could confirm up to 2000 strings daily. It would be easier to confirm with one script all the proposals from reliable contributors and then to fix only small percent of the strings, which contain translation errors. However, writing such JS string, without accessing the server, is prevented by the Same Origin Policy.

After surveying the different methods for the same origin policy avoidance, we have chosen the browser option method. We decided for it because: it was easiest to implement, it is intended for general JavaScript programming (not only AJAX), it does not require proxy servers, and the JavaScript program can be executed from the local machine. The major drawback was the need for searching older version of Chrome browser. The server side will not recognise it as malicious attack, because the browser will continue to send usual HTTP payload, here we simulate only client side activities.

After the browser Chrome is started with disabled web security, a JavaScript program similar to the following might be used locally.

```
<!DOCTYPE html>
<html>
<head>
<script>
var myWindow,myInterval,finished,poz,tries;
/* chrome.exe --disable-web-security  */
urls=[
"https://translations.launchpad.net/ubuntu/trunk
/+pots/gcc/bs/+translate?show=new_suggestions&ba
tch=1",
"https://translations.launchpad.net/ubuntu/trunk
/+pots/dpkg/bs/+translate?show=new_suggestions&b
atch=1",""
]

function isEmpty( variable ) {
  if ( typeof( variable ) == 'undefined' )
    return true;
  if ( variable  == null )
    return true;
  return false;
}

var dispatchMouseEvent=function(target,var_args)
{
  var e = document.createEvent("MouseEvents");
  e.initEvent.apply(e,
    Array.prototype.slice.call(arguments, 1));
  target.dispatchEvent(e);
};

function afterSubmit() {
  if (isEmpty(myWindow))
    return;
  var u=myWindow.document.URL;
  if (isEmpty(u))
    return;
  window.focus();
  clearInterval(myInterval);
  if (urls[poz]!='') {
    myWindow=window.open(urls[poz], 'scripted');
    myInterval=setInterval(function(){
      doModify() },2000);
  }
  else  {
    myWindow.close();
  }
}

function doModify() {
  if (isEmpty(myWindow)) return;
  if (isEmpty(myWindow.document)) return;
  var all = myWindow.document.
     getElementsByTagName("input");
  for (var i=0, max=all.length; i < max; i++) {
    if (all[i].id.search("bs_suggestion")>0 &&
     all[i].type=="radio") {
       b=all[i];
       b.focus();
       dispatchMouseEvent(b,'click',true,true);
       break;
    }
  }
  var b=myWindow.document.getElementById
   ("save_and_continue_button");
  if (!isEmpty(b)) {
    b.focus();
    dispatchMouseEvent(b,'click',true,true);
  }
  var all = myWindow.document.
    getElementsByTagName("div");
  for (var i=0, max=all.length; i < max; i++) {
    if (all[i].innerHTML.search
      ("There are no messages")>0) {
       poz++;
       break;
    }
  }
  clearInterval(myInterval);
  myWindow.focus();
  myInterval=setInterval
    (function(){afterSubmit()},2000);
}

function startScripting() {
  poz=0;
  if (urls[poz]!='') {
    myWindow=window.open(urls[poz], 'scripted');
    myInterval=
      setInterval(function(){doModify()},2000);
  }
}

function stopScripting(){
  poz=0;
  clearInterval(myInterval);
}

</script>
</head>
<body>
<p>Click the button to trigger a function.</p>
<button
onclick="startScripting()">Start</button>
<button onclick="stopScripting()">Stop</button>
</body>
</html>
```

The array `urls` contains a list of HTML files with translation suggestions. This array can be generated automatically by filtering Launchpad web page, which shows new translation proposals using `grep` and `sed` tools. The approver may remove translation proposal URL

from the array if he concludes that it comes from unreliable translator.

Function `startScripting` fetches the first element from `urls` array, and opens it in another tab. In the Chrome, JavaScript calls are asynchronous and there is the `setInterval` function to repeat calling `doModify` function.

The function `doModify` will check if the page is ready and it will find the HTML element with tag name INPUT and type RADIO, send the mouse event, which will simulate the mouse click. This will confirm the translation suggestion and the next mouse event will click the `save_and_continue_button`. The script will stop with periodical calling of `doModify`, and it will start checking the response by repeated calling the `afterSubmit` function. In the `afterSubmit` function, when response is received, the script will process next `url`. The function is specific to HTML structure of the web page we want to update.

The function `stopScripting` disables the interval calling and therefore stops webpage data populating. Both `startScripting` and `stopScripting` are linked to HTML buttons.

With an automatic confirmation, started from ten client machines, it was possible to confirm 20000 strings in just three hours, the biggest part of this time being attributed to the server delays. Although the translation review is postponed, the list of accepted translations in Launchpad is quickly generated, since it was not overloaded with the GUI part of HTML. The approver finally watches the translations and fixes only those translations that were necessary. The similar script, but intended for situations where edit fields are involved was presented in [14].

V. Conclusion

Web browsers that are in use today, include the Same Origin policy as a security measure for the system by preventing the execution of unwanted scripts on the remote server. This makes the Same origin policy an important part of Web application security. Generally, it is bad practice and dangerous to avoid this policy. However, there are situations that can improve web application usability when this policy is disabled. Examples are the situations when we need to automatically enter big amount of data, but we have only web interface available. In that case the user has to ensure that the application runs in the controlled environment, which cannot in any way execute malicious scripts.

Towards a Rule-based Access Control Framework for Distributed Information Systems

Sergey Afonin
Institute of Mechanics, Moscow State University
Michurinskij av., 1, Moscow, Russian Federation
Email: serg@msu.ru

***Abstract*—Rule-based access control is a powerful and flexible paradigm for specifying security policies in information systems. Access may be granted or denied depending on object's and subject's properties, or the context of the request, such as current time. Complex access control rules are typically implemented at application level. In this paper we describe a framework targeted to separation of access control rules from the main application logic. It is assumed that access policies are managed in a distributed fashion (discretionary access control), objects are stored in relational database, and requests are independent. Such assumptions correspond to a RESTful web application. We describe a proof of concept implementation and discuss efficiency and decidability issues of access checking and policy verification problems.**

I. Introduction

In many information systems access control rules are hard-coded into main application logic. This is typically so for Web-centric systems. When page request arrives, the server first validates that the requested operation can be executed by the requester. Application level access control rules could be quite complex and depend on various parameters, including object's and subject's properties and context of the request. For example, one can define that a user is allowed to modify document if he belongs to some group (subject's property) and the document was signed (object's property) no more than two days ago (request context). Such rules can be easily implemented in the target programming language (PHP, Python, Ruby or Java in case of web application) and typical application contains code like "return an error message when access conditions are not met, or process the request". The obvious drawback of hard-coded access control rules is that application code should be altered each time the security policy changes. Any modification of the source code, in turn, requires repeated testing, and so on. Moreover, if access control rules are implemented in a Turing-complete language one can not automatically validate any non-trivial property of the implemented security policy.

Classical and the most frequently used in real systems Role-based Access Control (RBAC) model [1] separates application logic form users grouping. It is based on the assumption that roles of an organization are static, while users and their responsibilities might change frequently. RBAC standard provides mechanisms for reducing cost and potential for errors when assigning users to roles within an organization. Static nature of RBAC model makes it less useful for web applications characterized by dynamic access control rules. In basic RBAC model it is difficult to express many natural constraints, such as rule "registered users can modify *their own* objects".

In order to overcome limitations of RBAC model, a number of extensions have been proposed in the literature. These extensions form an actively developing research area frequently referenced to as *attribute-based access control* (ABAC) or *rule-based access control*, allow one to specify security policy by means of *rules* that depend on application level objects' *attributes*. According to [2], [3] such extensions fall into following three classes:

- Dynamic roles. Roles are assigned to user dynamically, depending on user's and/or context's attributes.
- Attribute-centric. Roles are considered as subject's attributes. In contrast to RBAC model this approach does not assume permission to role relation.
- Role-centric. Attributes are used to constrain RBAC roles. Constraint rules can only reduce user's permissions.

Rule-based access control appears in many domains, including information systems, database systems, GRID and Cloud computing, Linux kernel, social networks, XML document-security and many others, see e.g. [4]–[9]. For the moment there exists no commonly adopted model for attribute-based access control. In this paper we discuss a framework motivated by the development of a real system. We believe that methods and tools could be abstracted from the needs of that particular system, yielding a general framework suitable for wide class of information systems. Our goals are: separation of security policy from application logic and ability to perform static analysis of the policy.

It is worth noting that development of a general rule-based security framework requires number of complex issues to be solved. First of all, security policy should be defined in terms of application-level objects, so a kind of object-relational mapping (ORM) have to be supported. In many research, e.g. [5], [10], rules can use fixed number of application level objects' properties, and these properties are computed by dedicated functions or services written in general purpose programming languages. Application developers need to implement appropriate set of functions, so this approach can not be considered as a general solution. The second issue that should be addressed, is the efficiency of an on-line permission checker. As final decision depends on database state, permission checks might produce undesirable database workload, so permission checker's efficiency may be measured in terms of number of database queries. Finally, static validation of specified policy for redundant or conflicting rules, similar to [11], [12], has to be done.

The paper is organized as follows. Next section contains brief description of key properties of information system that triggered this research. We also formulate main goals of the proposed security framework. In Section III we describe rule definition language. Algorithmic issues related to policy enforcement and verification are discussed in Section IV.

II. Motivation and Goals

A. Motivating Example

This research was motivated by the development of a Current Research Information System named ISTINA[1] for Moscow State University. Let us briefly describe its properties and security-related issues.

The system is used to collect information about research and teaching activities (publications, research projects, participation in scientific conferences, membership in program committees, awards, etc.) of university's staff. Some information, such as list of publications in scientific journals, may be imported or verified by accessing external resources, but significant amounts of data are not available from other sources in unified form. As a result, researchers registered in the system are allowed to maintain their own pages. In order to perform more or less reliable scientometric reporting, most critical information is manually verified by authorized users. An authorized user can modify any object authored by anybody from his area of responsibility.

Our access control rules are heavily based on authorship relations, object's ownership information, and organization hierarchical structure. For example, "an article can be edited by any of its authors", or "an authorized user can modify any object created or authored by researchers from his department or its child departments". Some information, such as financial data, may be inaccessible to anybody but authorized users. Role membership, e.g. who are considered as authorized user, may be parameterized by department or other data. For example, membership of a user in *administrative staff* role is limited to department and its descendant departments.

Both permissive (or positive) and restrictive (or negative) rules, defining who are allowed (or not allowed) to perform an operation on specified object are used. Access to individual objects should also be managed. For example, one can grant or revoke editing permissions on specific object to someone who is not in the list of authors, or in the authors list, respectively. Time constrained access is also important, for example, when an administrator wants to be sure that no objects will be modified after the specified deadline.

Another usage scenario of the security framework is related to reporting subsystem [13]. Roughly speaking, a report is a parameterized SQL query. Depending on supplied parameters' values, a user may be granted access to the report, or not. For example, a dean can access data about his department and its parts, but should not access information about other departments. In both cases, the same report is requested, and this problem can not be resolved by standard access control approaches.

In this paper we address only one scenario when all access requests are treated independently and each request is performed on only one object. In other words, there is no interaction between subsequent requests from the same user. This assumption is reasonable for RESTful web applications. If a web page contains information collected from several objects, then this page may be protected as a whole.

It is assumed that each department, or each university that uses the system, can define its own security policy and these policies are managed independently. This distributed nature can produce conflicts in case of joint work. For example, if department A allows anybody to delete any object, and department B does not allow to delete objects at all, is it possible to delete a paper authored by researchers from both A and B? At runtime restrictive rule would take precedence as a safer option, but system's behavior will be surprising for some users, regardless of the decision made.

Finally, some rules of the policy defined at top administrative level, e.g. university, may be redefined on lower levels, e.g. faculties and departments. The list of rules that may be redefined or overwritten by a "subordinate" policy writers should be defined by the top level administrator. From the other hand, policy writers from hierarchically unrelated administrative units could produce any rules. Policy conflicts, similar to conflicts caused by coauthored objects, arise when a user has relation to several administrative domain, for example, as a coworker in two institutions. Such conflicts should be resolved dynamically (at runtime), or statically, during policy validation step.

B. Goals and Requirements

The main goals of the security framework are:

- Separation of access control logic from application's code. Modifications of security policy should not lead to any changes in application's source code.
- Static policy checking. In a distributed environment, when several organizations manage their own policies affecting common database, an automated testing for potential conflicts should be possible.

It is assumed that application developers provide "atomic" permissions that are checked in appropriate points. For example, if a user sends a request for object deletion, then application checks that this user can delete this object by issuing function like

```
has_permission(user, object, "delete").
```

If an object consists of several parts, e.g. paper title and authorship information, access to that parts could be controlled by additional rules and verified by dedicated calls to above mentioned function. For example, a policy could specify that every author of a paper can update title, abstract, and his own authorship information but can not update information about his coauthors. In any case, all checks for specific permissions must be hard-coded, because providing fine-grained access to object's parts can not be realized without programming efforts.

Specific security policy should not be defined or implemented in application's source code. When application calls *has_permission* function providing it with information about

[1] http://istina.msu.ru/

current user, object and requested operation, that function should perform all necessary checks in accordance to specified policy. In order to guarantee policy enforcement, such calls to *has_permission* function may be performed automatically when the request arrives to application server. This can be done by variety of means, including preprocessing of incoming HTTP requests, defining appropriate middleware of application server framework, or using programming language tools, such as Python's function decorators. The actual implementation of policy enforcement in real application depends on available software or hardware tools, and should be as much mandatory as possible.

Another typical problem that arise in Web-centric information system is generation of links available to the user. If user has no rights to perform some operation, e.g. object deletion, then it should be reflected by user interface, for example, by removing or disabling corresponding links. Clearly, generation of a set of active links can be done on top of has_permission function. From the other hand, if we know that several permissions have to be checked in a row a more efficient solution could exists. So, from the programming point of view, the framework should support two functions:

- *check for specified permission*,
- and *list of all operations* that user can perform on given object.

Input parameters for check operation are *subject* (user), *object*, and requested *operation* label (required permission). Second function returns list of valid operations for given *user* and *object*.

We can also specify following additional requirements:

- rules should be defined in a human-friendly formal language (XML-based languages, such as XACML, is not a suitable option);
- both permissive and restrictive rule should be supported;
- if an access is denied, then it should be possible to identify the rule leading to that decision;
- modification of security policy should be controlled by the same access control system.
- administrative domains should be separated in the sense that policy writer from one organization can not specify a policy affecting another organization; all conflicts, caused by existence of coauthored objects or coworkers, should be identified at runtime, or discovered statically.

III. Rule Definition Language

As access rule may refer to object's attributes, rule definition language consists of three parts: definition of objects, roles, and rules itself. First part defines set of entities, attributes and relations that can be used in other parts. Parameterized roles are listed in roles definition. Access control rules defines under what constraint a user has permission to evaluate action on specified object.

Our proof of concept implementation is performed in Common Lisp (due to Lisp's ability of rapid development of domain specific languages), so we use lisp-friendly syntax for all three parts.

A. Definition of Objects and Attributes

Objects definition is a kind of Object-Relational Mapping that reflects database structure. Each statement in this section defines an "object" – an access control entity. In terms of target application, objects correspond to a *classes* or types. In order to simplify descriptions in our proof of concept implementation we associate an object with database table only.

```
(defobject department
  (table department))
```

All other relevant information, including attributes, identifiers and related objects, is extracted from the database dictionary. If a table associated with object A contains a foreign key to a table of object B, then an attribute named "As" (plural form of A's name) is added to B. It is assumed that every database table is equipped with surrogate primary key, so foreign key references are simply integers.

In addition to database table name, a list of possible operations on that object can also be specified:

```
(defobject article
  (table article)
  (operations (read update delete)))
```

This definition means that only that three operations are relevant for *article* objects.

B. Roles

In many applications, user's membership in a role depends on administrative structure of organization, or other parameters. Technically, one can specify the set of roles as a Cartesian product of "real" roles by departments and manage hierarchical department's structure by means of roles inclusion. Clearly, such system is extremely difficult to support and security policy has to be modified every time department's structure changes.

In this work we adopt notion of parameterized roles. User-to-role relation is computed dynamically because the decision on whether or not a user belongs to a role depends on current state of the database. Roles are defined by the following statement.

```
(defrole dean
  (parameters department))
;; membership is limited to department
```

C. Rules

Rules are used to define conditions what should be satisfied in order to perform operation on object. In terms of [2] this models follows role-centric approach: attributes are used to constraint permissions assigned to roles.

Each rule is characterized by:

- access type (allow/deny),
- associated object,
- list of operations,
- grantees (roles or users), and
- access conditions.

Formal grammar for rule definitions is presented in Table I. For the lack of simplicity some "syntactic sugar" constructions are omitted. Let us consider the following example:

```
(rule
  (comment "Delete articles.")
  (access allow) ;; allow/deny
  (object type "article" alias "a")
  (operations ("delete"))
  (grantees
     (roles "admin"
            ("dean" a.authors.department))
     (users "root"))
  (conditions
    (and
      (= a.journal.publisher.name
         "Springer")
      (< 2010 a.year))))
```

Here we define that user "root" or any member of "dean" or "admin" roles are allowed to delete articles that were published in Springer's journals after year 2010. The role "dean" is a parameterized role, so not every dean can delete articles: at least one author of the article should be from the dean's department. When this rule is evaluated during permission checking procedure, object alias "a" is assigned to the object from user's request. Similarly, a predefined name "user" is assigned to the structure representing the requester.

Two points should be noted. First, a rule may be associated with a parameterized role, and values of role's parameters are related to target object's attributes. Second, conditions part of the definition consists of a list of logical expressions that define conditions required for treating this rule as *applicable* to given object. Each atomic expression has form (relational-operator operand operand).

Operands are XPath-like expressions defining access path to desired property of target object. The above example may be rewritten as a oneliner:

```
(= a[year > 2010].journal.publisher.name
   "Springer")
```

Here, filtering condition "[year > 2010]" applied to the object. Filtering condition may contain standard logical connectors and may refer to deeper attributes by means of dot notation.

Possibility to overwrite a rule in subordinate administrative unit is controlled like in [10]: a rule has special boolean property "strict" that states whether or not this particular rule can be redefined. The value of this property itself can be redefined (lowered from True to False) by a subordinate writer. It should be noted that set of objects affected by top-level and low-level rules may differ due to differences in specified

RULE	::=	'(rule' {'(' clause ')'} ')'
clause	::=	'comment' string
		| 'object' 'type' string ['alias' string]
		| 'access' ('allow' | 'deny')
		| 'operations (' operation {operation} ')'
		| 'grantees (' grantee {grantee} ')'
		| 'strict' ['True' | 'False']
		| 'condition (' expr ')'
operation	::=	string
grantee	::=	'(users' user {user} ')'
		| '(roles' [role | '(' role {selector} ')'] ')'
user	::=	string
selector	::=	('object' | alias) [filter] { '.' attribute [filter] }
alias	::=	string
filter	::=	constant relation (attribute [filter] { '.' attribute [filter] })
		| '(' filter ')'
		| filter ['and' | 'or'] filter
expr	::=	'(' relation constant selector ')'
		| '(' ['and' | 'or'] expr {expr} ')'
relation	::=	'>' | '<' | = | '<=' | '>=' | 'like' | 'in'

TABLE I. RULE DEFINITION GRAMMAR.

constraints. For example, top level constraint may by stated as `year > 2010`, while lower level rule may be redefined using `year > 2012`.

More than one rule may be defined for the same object type. In this case access is granted if there exists at least one rule that allows the access, and there are no rules that denies it.

IV. ALGORITHMIC PROBLEMS

In order to make the system useful in real situations, a number of algorithmic issues have to be resolved. First of all, due to highly dynamic nature of access control rules and high rate of such operations, efficient access checking methods should be designed.

A. Checking for Access

In this section we describe a straight forward algorithm for checking access of a user to specified object and discuss possible improvements. The general idea is to find all *applicable rules*, i.e. rules that are assigned to specified object and user, and verify whether an access should be granted, or denied.

Rules are associated to users or roles. In order to compute a set of candidates of applicable rules, i.e. a set containing all correct items and some false positives, membership of the requesting user in roles has to be verified. Membership in a parameterized role depends on current state of the database, so user-to-role relation should be computed dynamically. Given an expression like

```
(grantees
  (roles ("dean" a.authors.department))),
```

where "a" stands for a reference to accessed object (effectively, this is the value of a primary key in corresponding database table), one should verify that current user is a member of any roles "dean x", where x runs over the set of all departments accessed by path expression "a.authors.department". The set of applicable rules candidates consists of all rules associated with such roles.

Once the set of candidates is computed, additional constraints imposed by rule's conditions section will be verified

for every candidate rule (this step is a subject to optimization). Each condition consists of number of expressions of the form (relational-operator value selector), e.g.

```
(<= a[year = 2011 and
      journal.name like "Int.*J.*"].issue
    2)
```

Such expression can be translated into SQL statement naturally. Dots correspond to table joins, and filtering constraints yield conditions in WHERE clause of the SQL query. Consequently, whole constraints section may be represented as an SQL query.

Let us recall that access is granted if and only if there exists at least one positive rule and there are no negative rules for given user, object, and operation. Final decision can be trivially made on basis of applicable rule set. If there exist an applicable rule that denies access, then the finial decision is negative. Otherwise, the decision is positive if an only if the set of applicable rules is not empty.

Our proof of concept implementation supports automatic generation of SQL queries for checking rule's conditions and user's membership in parameterized roles. Checking that a rule matches request parameters is performed in statically defined order. First, matching between request's and rule's object and operation is validated. If this string equality check succeeded, role membership and additional access conditions are validated. This order based on assumption that last check is more complex and time consuming, because corresponding SQL query generated from a potentially complex expression. As long as the number of rules associated with each object and operation pair is small, this simple strategy produces reasonable performance: checking one or two extra rules yields only a couple of extra SQL queries. In general, one can expect that the number of rules will increase over time, so more sophisticated algorithm has to be developed. In the rest of this section we discuss possible improved to the described simple strategy.

One possible approach to performance optimization based on the observation that, if the access was granted, then all candidates for applicable *negative* rules had to be checked. It is worth noting that long lists of negative rules could be inefficient in principle. Positive candidate rules have to be checked only until first match occurrence. Choosing the "right" order of search space exploration can speed up overall performance. Preference may be given to rules that

- do not require to much time to verify, and
- yield positive result with high frequency.

Both values may be estimated using statistics of previous calls to the same rule. Frequency of positive results reflects the quantity of objects satisfying rule's conditions.

Other directions of optimization include:

- choosing the right order of conditions processing, based on the similar statistics on hit rate and efficiency of SQL queries, and
- finding common sub-queries in rules and organize rules hierarchically.

The latter approach is related to view selection techniques in relational database that allow to identify frequently used "patterns" in a set of queries. If conditions, or parts of conditions, of two or more rules are similar, they are probably may by approximated from above (with false positives) by a single query. If this generalized query produces negative result, then none of dependent rules can not be evaluated to positive result. Otherwise, some compensation queries are to be evaluated.

B. Policy Validation

Static validation of security policy is one of the goals of our work. In distributed environment searching for possible conflicts between access rules created by independent administrators is extremely important. Conflicts of two types are possible.

- Explicit conflict: there exists a triplet (user, object, operation) and two applicable rules such that one rule is positive, and the other one is negative.
- Implicit conflict: there exists an object, user, and applicable positive rule defined by a subordinate policy writer, such that there exists no applicable positive rule defined by a higher level administrator.

Both types of conflicts can be detected at runtime. Dynamic detection is, certainly, a useful feature in practice, but static analysis is required for elimination of possible errors in advance.

Methods for static analysis of access control systems were developed for classical RBAC model, e.g. [11], [12]. In [11] authors consider similar problem of collaborative editing of security policy under Administrative RBAC model. The decision problem in this case consists of establishing if a user can be assigned to certain role by a sequence of administrative actions. The problem is reduced to the reachability problem in some infinite transition system.

Decision problems for attribute-based models should be harder because wider range of objects should be considered. Searching for explicit conflicts in some cases may be reduces to a well studied NP-complete problem of checking containment of conjunctive query in a union of conjunctive queries [14]. Indeed, suppose we are checking one particular rule for consistence with a policy. A conflict appears if a conjunctive query corresponding to the rule under consideration is not contained in union of all other queries generated by rules defined for the same object.

In a more general case, policy checking problem may be reduced to a problem similar to [15]. A conflict appears if some counter-example object can be constructed under the specified policy.

V. CONCLUSION

In this paper a very basic role-centric attribute-based access control framework, motivated by the development of a real distributed application, is presented. It is targeted to support RESTful web application where each request is treated independently from all previous requests from the same user.

Attribute-based rules restrict permissions assigned to parameterized roles. Additional constraints, specifying whether or not a rule is applicable to the request, are stated in an XPath-like language that automatically mapped into SQL statements during access checking stage. As access control rules are defined using special language, automated policy validation is possible.

We briefly describe possible research directions in the areas of efficient implementation of decision procedure and static policy validation. Despite principal inefficiency of some operation, such as checking an access in presence of large number of negative rules, we believe that the described framework, which is in the very early stage of development at the moment, may be used in wider class of web-based application.

***Abstract*—Android is one of the most popular operating systems for mobile devices in the world today. One of its greatest advantages, being an open source operating system, represents also one of its major drawbacks. There exists a number of malicious programs that can harm devices running any operating system, including Android. In accordance to that, having a system that is secure presents a goal of a paramount importance. However, the fact that the improvements in the security often come with a penalty in the usability can present a problem. Furthermore, it is difficult to give a good answer to a question when a system is secure enough since that heavily depends on the user's needs.**

In this paper we investigate several ways on how to improve the security of Android devices through various customizations of the operating system or third-party applications.

I. Introduction

When discussing the role of mobile phones in the world today, one could reach the conclusion that they became almost a necessity. Of course, today a mobile phone represents almost a synonym for a smartphone. Although a primary purpose of a phone should be the ability to send and receive voice calls and short messages, it seems that is not enough anymore. Nowadays, characteristics like high resolution screen, high speed multi-core processors or a high quality camera also seem to play a very important role in the choice of a mobile phone. Furthermore, with an increase of Internet speed and availability coupled with a drop in the prices, it is common to be connected to the Internet the entire time. With a number of applications that enable VoIP (Voice over IP), the primary purpose of a mobile phone (calling and receiving voice calls) became almost of a secondary importance. Naturally, this does not mean that people do not call anymore, but only that their phones' GSM modules are becoming less and less important as the primary communication channel.

However, one important question is whether the people think about their phone security. To use a phone, one doesn't need to know its inner workings, but to actually understand various threats one should possess a certain level of knowledge that is less common. The first thing that comes to mind when discussing the security of smartphones is the ability to have a secure, confidential communication (regardless if that is over a voice or a data channel). Such a "need" for secure (encrypted) communication proliferated after the Snowden's revelations [1]. In an effort to fill that need, we are evident of several applications that offer encrypted communication like Skype, Viber or WhatsUp.

However, is a secure communication all that people need to be secure and protected when using smartphones? The answer to this question is a definitive no. Some objectives of importance are also the ability to securely delete data from a phone and to securely store data. Furthermore, the knowledge whether an application has some security weaknesses or does it keep one's location private represents relevant objectives. Out of the aforementioned objectives, securely storing data on the phone is currently the only option readily available in the Android OS, which only requires that a user enables it.

Perhaps the easiest way to achieve all of the aforementioned goals is to use an operating system that is custom tailored to be secure. However, that is often impossible, since such operating systems are usually delivered only with dedicated devices and they are also expensive.

In this paper we concentrate on how to improve the security of smartphones against various malware. Furthermore, we examine only Android OS since it is an open source system that is extremely popular and widespread. When experimenting how to increase the security of a smartphone, we consider two scenarios. The first one deals with the customization of an OS where we do not consider fully custom operating systems, but rather small changes to the official Android OS. We note that such small changes cannot compare with the security of a custom made Android OS, but are much easier to implement. The second scenario concerns with various applications that one can use to improve the security of a mobile device. Since we are only concerned with the security improvements that can help against the malware, this should not be considered a complete study. Indeed, for example one can consider the location data. It is relatively easy to forbid the transmission of data that are sent by the GPS or network. However, recent research showed that even battery consumption can be used to determine phone's location [2]. Similarly, it has been shown that various sensors can be used to identify the device [3] or even to recognize speech [4].

The rest of this paper is organized as follows. First, in Section II, we give a short overview of various malicious

programs and Android OS architecture with a focus on security aspects. Section III deals with the Security-Enhanced Linux for Android as a more general approach to the security of a device/OS. Next, in Section IV, we concentrate on the security of Android applications and how to improve it. Finally, Section V offers a short conclusion.

II. Background

A. Malicious Software

Here, we introduce several classes that various malware can be classified in. We emphasize that this taxonomy can differ from those found in other literature. Here we strive to present various threats, while the exact division of those threats is of secondary importance.

Malware, or malicious software is any program which sole task is to cause destruction of data, steal personal information or gain access to system resources. Therefore, a malware is written with an intention to do harm [5]. Term malware encompasses all classes of malicious software like viruses, trojans, worms, spyware, etc. Note that many malware programs are actually capable of performing various tasks and therefore have elements of several malware classes.

Trojan represents a program that looks like a legitimate one, which after it is activated causes some damage to a user. Examples of Android Trojans are NotCompatible and Trojan-SMS.AndroidOS.Opfake.a.

Worm is a malicious program that makes copies of itself. An example of a worm is Selfmite.b, which spreads with a help of a text message that contains a link to the url address with the malicious code.

Spyware is a malware whose primary purpose is to access and exfiltrate personal or private data from a device [5]. An example of a spyware is ShrewdCKSpy.

Adware is a program in which advertising banners are displayed while different programs are running. An example of an adware is Durak application.

Besides those more common malware classes, there also exists **ransomware** which locks out a device from a user until he pays to unlock his device. An example of a ransomware is ScarePackage.

Chargeware is an application that charges users for content without a clear notification. One example of such an application is SMSCapers.

It is important to emphasize that most of the malicious applications come from small third-party application stores and not from the official Google Play store. For additional information about various malware and threats in general, we refer interested readers to [5], [6].

B. Android Architecture

Android uses a type of UNIX sandboxing method to run its applications [7]. Each application in Android is connected to a separate user and has a unique user ID (UID) and group ID (GID) associated with it. This means that Android security relies primarily on discretionary access control (DAC) provided by the kernel. Under discretionary access control, access to data is controlled at the discretion of the data owner or creator. Therefore, Android application security model is based on application sandboxing and isolation enforced by the Linux kernel through the user and group identities.

An application runs in the context of its own user and has a separate area of storage space reserved for it to store its private data. Besides the sandboxing provided by the Linux kernel, Android also uses a permission model. This model makes sure that only applications with necessary permissions can access system critical resources and resources of other applications. System resources like Camera, Wi-Fi, GPS, etc. are considered system critical resources and an application needs permission to use them. Similarly, if an application wants to access resources of another application, then it must have the necessary permissions required to access them.

The Android architecture defines mechanisms by which an application can communicate with another application outside of the sandbox. This secure cross-application communication is facilitated using inter-process communication (IPC) mechanisms. Primary mechanisms for IPC on Android are Intents and Remote Procedure Calls (RPCs). Intents are messages that components can send or receive. Intents are usually used to send a command to a component. RPC is implemented using binders that are used to directly invoke methods on a remote component.

The user defined permission architecture in the Android permission model enables a developer to define new permissions to certain components of the applications he creates. Furthermore, he can safely export those components to be used outside of the sandbox.

There are four different types of components for an Android application, through which IPC mechanisms are acquired.

- **Activities**. These are the visual elements of an application which users can see. They provide the graphical user interface (GUI) for the application.
- **Services**. Services provide no GUI for the application, but instead they represent the background processes. Usually long running tasks like downloading a file, etc. are implemented through services.
- **Broadcast Receivers**. Responses to system-wide broadcast announcements are accomplished with broadcast receivers. Examples of such responses are when the battery level is low or a picture is captured.
- **Content Providers**. Content provider is an encapsulation over the persistent data storage options available in Android (SQLite) database file system, etc., to facilitate data sharing among applications. Data stored via content providers can be exported and made available for other applications with a proper security channel restricted by the Android permission model.

Intents and Intent-filters are used to perform IPC through activities, services and broadcasts. Content providers use insert, update, query and delete operations to perform their operations. Content providers implemented in an application can be accessed by another application using content resolvers. If one application wants to communicate with another application, it

can accomplish that only through one of the above mentioned components.

One of the main issues with Android permissions, in their current form, is that a user has to approve every permission that a certain application requests before he can install that application. Currently, it is not possible to selectively approve or deny specific permissions to applications, at least not in the official Android builds. Applications also cannot request additional permissions at a later time, so application developers are left with no other choice than to request all permissions during the installation. This can make even legitimate applications look suspicious, because they sometimes require unexpected permissions. This also makes it even more difficult for users to detect which applications could be malicious before installing them. Because applications submitted to Google Play store are not reviewed, ultimately the only way to make sure that applications have no vulnerabilities is to test them.

As an example, a game may require access to user's contacts. That request can be very suspicious to the user that is trying to install that game, but the game developer could use contact information to find which friends of that user are also playing the game, and recommend that they play together. The user cannot know if the game will use this information for a legitimate feature or, for example, share it somewhere on the Internet. A much better approach would be if the game could request only the basic permissions that it needs to function during the installation, and all other permissions could be requested at the time when they are actually needed. In our example this could be when the user wants to invite his friends to play the same game.

For further information about the Android security architecture, we refer readers to [8].

III. Security-Enhanced Linux for Android

Security-Enhanced Linux for Android (SEAndroid) is a project initiated by the US National Security Agency (NSA) in order to identify and address critical gaps in the security of Android [9]. The initial plan of the project was to enable the use of Security-Enhanced Linux (SELinux) in Android, but several additional SELinux extensions specific to Android operating system were added over time. The motivation for the project was the increasing desire to use mobile devices throughout the US government. Android presented itself as a good candidate because of its open source nature that allowed easy customization, and its wide market adoption.

SELinux introduces mandatory access control (MAC) that is based on a system-wide security policy [9]. This security policy is enforced over all processes, even the processes running with root/superuser privileges [9]. The default action in SELinux is denial, which means that everything that is not explicitly allowed is automatically denied. Security rules in the policy are defined by domains or labels. Every process is labeled with a domain, and all processes labeled with the same domain are treated identically by the security policy.

SELinux was included in the Android 4.3 release in a permissive mode, which means that policy denials were only logged and not enforced [10]. In Android 4.4 (KitKat), SELinux was in enforcing mode on a set of crucial domains, and finally, starting with the Android 5.0 (Lollipop) release, SELinux is in full enforcing mode on all domains [10].

One of the most important benefits of SELinux on Android is strong isolation and sandboxing of applications and privileged daemons. SELinux can be used to protect the privileged daemons from misuse, and limit the damage that can be done through them. This means that malicious applications that users can install on their devices can do much less damage to other applications, or to the operating system itself. This, however, does not mean that applications cannot abuse the permissions granted to them by the user during the installation process.

A. AppOps

A step towards allowing users to selectively control application permissions was the AppOps application included in the Android 4.3 release. AppOps was a hidden application that allowed users to deny permissions to installed applications [11]. AppOps application was removed afterwards, but the code used to control the application permissions still exists in the Android open source project.

We display several screenshots of AppOps application in Figure 1. The first screenshot shows the permission that the Facebook application requires, and allows users to selectively deny access to those permissions. The second screenshot lists the applications that recently accessed user's personal information, and the third screenshot shows a list of the applications installed on the device.

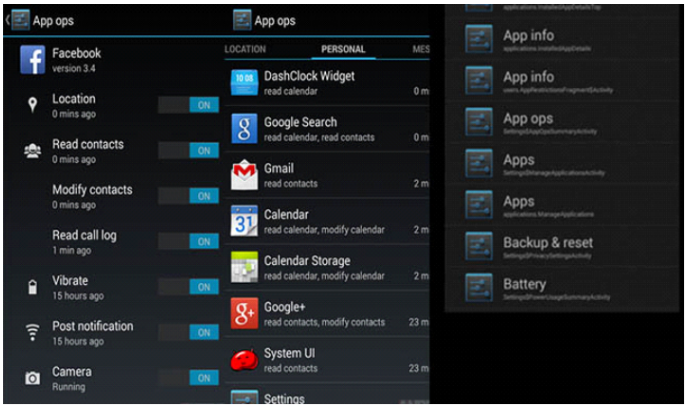

Fig. 1. Screenshot from Appops.

B. EnterpriseOps

An extension to the SELinux called EnterpriseOps (EOps) was developed as a part of the SEAndroid project in order to allow an enterprise like control to application permissions [11]. EOps provides a way to define a policy that can explicitly deny certain permissions to a group of installed applications. This extension relies on the code developed for the AppOps feature, and the primary problem is that the AppOps code is still incomplete [11].

When a permission is denied, an empty data set should be returned to the caller to ensure that applications continue to function correctly. The Android code that handles permissions doesn't currently support those empty data sets, so it completely blocks the operation. Because of this, some applications might crash or behave unexpectedly when some of the permissions they require are blocked. In some cases, the code that checks the policy isn't implemented correctly, and the operation is permitted anyway. Because of those issues, both AppOps and EOps features are not ready for general use. Next, we give an EOps policy example that denies the CAMERA permission [11]:

```
<?xml version="1.0"?>
<app-ops>
    <debug/>
    <seinfo name="default">
        <op name="CAMERA"/>
    </seinfo>
    <seinfo name="system">
        <op name="CAMERA"/>
    </seinfo>
</app-ops>
```

The *seinfo* element of the EOps policy files is used to target applications labeled with a specific name, and the *op* elements inside are used to remove permissions from those applications. The above policy removes the *CAMERA* permission from applications in *default* and *system* domains. Because of that, if a user would start the camera application that comes with the Android OS, the application would launch, but he would not be able to take photographs.

The code and the policy developed by the SEAndroid project has been merged to Android open source project repository as of Android 5.0 release [12]. While this includes the SELinux support, middleware MAC mechanisms, like the EOps extension used for managing application permissions among other things, are still not merged. Developers that want to use or test those features need to create a custom Android build that includes those features.

C. Intent Firewall

Intent firewall is a component of the Android operating system designed to control and enforce intent based inter-process communication in Android. Intent firewall was developed as a part of the Android open source project, and not as a part of the SEAndroid project. Only the tools that simplify the process of deploying intent firewall policies to target devices were developed as a part of the SEAndroid project.

Every intent created in the Android operating system goes through the intent firewall, which means that the intent firewall has the power to allow or deny any intent [13]. Intent firewall can be configured using an XML file with rules that specify how activity, service and broadcast intents will be handled. Rules in this XML file can be used to target one or more intents, and control if those intents will be blocked or allowed. An example of the intent firewall policy that blocks access to settings menu [13] is presented below:

```
<?xml version="1.0"?>
<rules>
  <activity block="true" log="false">
    <component-filter
    name="com.android.settings/.Settings"/>
  </activity>
</rules>
```

The above policy blocks all intents to the activity named *com.android.settings/.Settings*, i.e., the default settings menu activity of the Android operating system.

Intent firewall is implemented in Android, but it is not officially supported or documented [13]. This means that it requires going through the Android source code to determine how to use it properly, and it could also change significantly in the future versions of Android. Intent firewall configuration can currently be modified only by system applications and root users. Because of that, users who wish to enhance the security of their device using intent firewall must first obtain root access on their devices.

D. Customizing Policies

Default SELinux policy is deployed on the device with the operating system build itself, and is loaded during every boot. It is possible to create additional policies and deploy them to devices using tools and the SEAdmin application developed as a part of the SEAndroid project. Those tools will produce a bundle zip file with the policy, suitable for installation using the SEAdmin Android application. SEAdmin application currently looks for policy bundle files on the SD Card device. To deploy a new policy to a device, it is enough to copy the bundle file to the SD Card device, and run the SEAdmin application. After that, the application will detect and install a new policy. The policy bundle file must be signed with the key that was used to build the Android OS. SEAdmin application can also be used to deploy EOps, and intent firewall policies to devices. The procedure to deploy those policies is similar to the procedure to deploy SELinux policies [11]. The main difference is that different tools must be used to create the zip file that will be deployed to the target device.

SELinux for Android introduces a more flexible security model to Android operating system, and increases overall security of the system, provided that the default policies deployed with the OS are good. The main problem for more advanced users who would like to customize the security of their devices is that those policies cannot be easily customized. SELinux policies can be customized by creating a custom Android build and flashing it to a device, or possibly using an exploit to gain root access on the device, if it exists. On the other hand, SEAndroid together with EOps extension may prove to be a good way for organizations to enforce their security policies on a large number of devices using custom Android builds.

IV. Security of Android Applications

In this section, we first deal with the reverse engineering of Android applications. In the second part, we examine several applications that are able to conduct the security analysis of the Android OS or an application.

With Android OS, anyone can create an application and upload it to the Google Play store. Most often, it is necessary to know how to code in order to be able to develop an application. However, tools like App Inventor are available and they make it possible to develop Android applications without any coding knowledge [14]. Inexperienced developers can create applications with substandard code quality and with many vulnerabilities. Such vulnerabilities can become a threat to the user's private data. The most common vulnerabilities are:

- Insecure data storage, which can lead to cross-application data stealing.
- Exported Intents, which can lead to confused deputy problems.
- Insecure network transmission, which can cause user's private data to be sniffed by attackers.

To battle such problems, user can either reverse engineer an application to check what does it do or use some ready-made application to test/change the application of interest.

A. Reverse Engineering APK

Android application installation files (.apk) are quite easy to reverse engineer. Here, we present several tools which make it possible for any amateur to reverse engineer an .apk file in a relatively short time. APK files can be reverse engineered using the following applications:

- apktool [15].
- dex2jar [16].
- Java decompiler tool (e.g. Jd-gui [17], JAD [18]).

Apktool is a tool for reverse engineering third-party, closed, binary Android applications [15]. This tool can decode resources to the nearly original form and rebuild them after making some modifications; it makes it possible to debug Smali (assembler) code step by step. Also it makes working with applications easier because of project-like files structure and automation of some repetitive tasks like building APKs, etc. It transforms binary Dalvik bytecode (classes.dex) into Smali source. Apktool is a multi-platform tool, based on the Apache 2.0 license.

Dex2jar is a multi-platform tool that converts Dalvik bytecode (DEX) to Java bytecode (JAR) [16].

Apktool helps extracting binary resources and allows repacking after which dex2jar converts Dalvik bytecode to Java bytecode.

A better solution are pure Android decompilers, unfortunately there are not as many of them as there are Java decompilers. We mention several popular Android decompilers:

- Open Source: Androguard [19], APK Studio [20].
- Commercial: JEB [21].

Next, we present several publicly available tools one can use to analyze Android applications.

B. TAINTDROID

Enck et al. proposed an analysis system called TaintDroid, which is an extension to the Android mobile phone platform that tracks the flow of privacy sensitive data through the third party applications [22]. The primary goals of this application are to detect when the sensitive data leaves the system via untrusted applications. TaintDroid automatically labels (taints) data from privacy-sensitive sources and transitively applies labels as sensitive data propagates through program variables, files, and inter-process messages. When tainted data is transmitted over the network, or otherwise leaves the system, TaintDroid logs the data's labels, the application responsible for transmitting the data, and the data's destination.

C. SCANDROID

Fuchs et al. developed a tool SCanDroid for the static analysis of Android applications [23]. SCanDroid's analysis is modular in order to allow incremental checking of applications as they are installed on an Android device. It extracts security specifications from manifests that accompany such applications, and checks whether data flows through those applications are consistent with those specifications.

D. X-RAY

Duo Security developed an application, X-Ray, which scans for OS vulnerabilities on the Android device [24]. This application can be directly installed to an Android device. X-Ray scans an Android device to determine whether there are vulnerabilities on it. The X-Ray application presents the user with a list of vulnerabilities that is able to identify and allows him to check for the presence of each vulnerability on their device.

E. APPVIGIL

Appvigil is an advanced security loophole scanner for Android applications [25]. It is a cloud based security scanner that can scan security loopholes in applications. Created by Indian company IIT Bombay, it offers free trial for application scan. Through its audit report, Appvigil provides exact location of loopholes with patch recommendation.

F. ANDROID Application Vulnerability Scanner Tool

Android application vulnerability scanner tool (AAVST) helps to alter applications by disabling some of the permissions they ask and by fixing some of the vulnerabilities that such applications possess [26]. This tool offers significant capabilities whether one is an application developer or a normal user. For an application developer it offers the following functionalities:

- Scanning of Android applications for vulnerabilities.
- Interactively fixing the detected vulnerabilities.
- Generating keystores.
- Building applications.
- Signing application and making it ready to upload to the hosting servers.

As a normal user by using AAVST one has the following options at his disposal:

- Make an “APK" ready for editing (decompile the APK).
- Scan and fix vulnerabilities in the decompiled application.
- Disable undesirable permissions requested by the application.
- Make the application ready to be installed to devices (build and sign the application).
- Generate certificate (important step because only signed applications will run on Android device, when you decompile application it’s signature is removed).

Out of the aforementioned options, one especially interesting is disabling undesirable permissions requested by the application. Many users experience that applications require too many permissions and they would prefer that permissions were more restricted due to the privacy issues. AAVST tool can help the users to deny some of the permissions that an application asks for, and still run the application. Step by step routine to do this is:

1) Run the AAVST tool.
2) Choose the *Decompile application* option where one sets up the output directory for the application source code.
3) Select static analysis with decompiled directory and press the scan button. After that, select *Uses permission* radio button and a choice to disable permissions which one doesn’t want for an application appears. After that, click the update button and check *Re-Build apk* which will build the APK for the modified application.
4) Only signed APK’s will work in an Android device so once the application is rebuilt, one must sign it to make it ready to be deployed to an Android device. In this step one selects *Generate Key* and fills in required parameters to generate a keystore.
5) After that it is necessary to select *Sign application* where one chooses application and a keystore that he generated in the previous step. After the signing step is complete, the application is ready for the installation to an Android device.
6) The final step is installing the permission modified APK to a device.

V. Conclusion

In this paper we discuss the security of Android operating system where we identify several objectives one needs to consider. We disregard the secure communication objective and concentrate on several methods that can be used to improve the security of the Android OS and applications against malware. In order to do that, we present several improvements that are within a reach of an average user. The first set of improvements considers the customization of Android operating system and the second set considers several ready-made applications that can help to improve the security of a system. We note that some of the improvements currently achievable through the third-party applications should become available within Android OS itself in newer releases.

***Abstract*—Digital Enhanced Cordless Telecommunications (DECT) is an European Telecommunications Standards Institute (ETSI) standard for short-range cordless communications with a large worldwide installed customer base, both in residential and enterprise environments. As in other wireless standards, the existence of active attacks against the security and privacy of the communications, involving identity spoofing, is well documented in the literature. Although the detection of spoofing attacks has been extensively investigated in the literature for other wireless protocols, such as Wi-Fi and GSM, very limited research has been conducted on their detection in DECT communications. In this paper, we describe an effective method for the detection of identity spoofing attacks on DECT communications, using a radio frequency fingerprinting technique. Our approach uses intrinsic features of the front end of DECT base stations as device fingerprints and uses them to distinguish between legitimate and spoofing devices. The results of measurement campaigns and the related analysis are presented and discussed.**

I. Introduction

In wireless communication networks, spoofing is a serious attack where a malicious attacker masquerades as a legitimate mobile device and transmits false information. Device identity spoofing is often used as part of larger and more complex active attacks that require sending forged information originated from the identity of a legitimate device of the network.

DECT, Digital Enhanced Cordless Telecommunications [1], is a radio frequency protocol developed by ETSI, widely used in residential and enterprise environments for the transmission of voice in cordless telephony. It is considered by ETSI as its second most successful protocol after GSM, with an estimated install base of almost 820 millions of cordless phones world-wide [2]. DECT is largely widespread in Europe, where it is commonly used by citizens in residential environments as wireless access protocol for fixed telephony. It is also commonly found in enterprise environments, usually integrated into Unified Communication systems.

Despite the security features foreseen in the standard, several attacks against the security and privacy of DECT communications have been described in the literature. In addition to passive attacks against both non-encrypted [3], [4] and encrypted communications [5], [6], a set of active attacks, involving the injection of spoofed DECT packets into the network, has also been described in the literature. In [3], the authors demonstrate how the lack of mutual authentication in some implementations of the standard, can be exploited to perform a Man-In-The-Middle attack able to intercept the voice communications of the victim. In order to do so, the attacker impersonates the identity of the legitimate DECT base station (Fixed Part - FP), spoofing its identity in such a way that the Portable Part (PP) of the victim will eventually connect to it, instead of the legitimate one. In essence, this attack is similar to the one described in the literature [7], [8] for GSM networks, where the identity of the Base Station (BTS) is spoofed by the attacker.

The application of DECT identity spoofing has also been proven to be effective attacking encrypted communications, as part of a more complex active attack. In [9] the authors demonstrated an active attack that sends spoofed DECT packets into the network in order to progressively decrypt an encrypted communication.

The identification of device identity spoofing on DECT networks is an effective way to generically detect a big percentage of active attacks that rely on the injection of spoofed packets into the network. To this end, several approaches can be followed. One approach would be the detection of the spoofed packets based on anomalies in the data and metadata contained in the spoofed packets. This technique could be effective in certain cases where differences between the legitimate and the spoofed packets can be appreciated by looking at their content, as it has been demonstrated in GSM networks for the detection of rogue base stations [10] and in Wi-Fi for the detection of MAC address spoofing on the basis of the analysis of the sequence numbers [11].

In many cases, these detection methods can be circumvented by an attacker, by carefully imitating or jamming the data transmitted by the legitimate station, given the fact that the features used in the detection can be easily modified by the attacker to match the legitimate ones.

In order to tackle this point, the radio frequency (RF) fingerprinting of mobile devices has been proposed as a method for the detection of active attacks in other protocols such as GSM [12] and Wi-Fi [13].

The basic idea behind the RF fingerprinting technique, is that each electronic device has unique features, also called Radio-Frequency Distinctive Native Attributes or (RF-DNA), which can be extracted from its spectral emissions and can be used to uniquely identify the specific model or mobile device. The RF pattern cannot be manipulated at the software level by the attacker, and is therefore hard to forge, even using customisable transceivers, such as those based on Software-defined radio.

In other words, the term RF-DNA is used to embody the coloration of RF emissions (both intentional and unintentional) induced by the intrinsic physical attributes of a unique device and related to components like filters, amplifiers, Integrated Circuits (IC) and so on. While other authors have focused their research efforts in the unintentional emission as in [14], in this paper we focused on the intentional emissions of the DECT base station during transmission and/or signal broadcast.

The use of fingerprinting to detect spoofing has been also proposed in other wireless communication technologies other than DECT. In [15], the authors have applied RF-DNA fingerprints to IEEE 802.16 WiMax-based airport communications by using both Time Domain (TD) and Wavelet Domain (WD) techniques.

Another popular application for fingerprinting is related to Wi-Fi technology. In [16], the authors used unique features extracted from RF-components or from the timing behavior of the MAC-chips to attest the uniqueness of a dedicated wireless station. The authors argue that Wi-Fi Protected Access (WPA) or IEEE 802.11i (WPA2) are not a complete protection against MAC address spoofing because WPA and WPA2 can provide data-frame authentication to prevent clients from being spoofed but unfortunately they do not provide authentication for management frames. The authors applied different approaches for fingerprinting. In one case, Discrete Wavelet Transformation (DWT) was applied to signal phase and signal amplitude to generate features used for the classification process. In another approach, the analysis of the distribution of delay values between 802.11 packets and the corresponding acknowledgment frames was used for fingerprinting as delay values differ in various chipsets.

Still on Wi-Fi technology, Sheng and others [17] applied the analysis of received signal strength (RSS) for fingerprinting on the basis of the RSS patterns (e.g., their Gaussian profile). This approach has the merit to avoid the need for sampling the RF signals, as in [14] and [16], even if this need has become less costly with the latest generations of sampling devices (e.g., the RTL-SDR).

In [18], the authors applied RF-DNA fingerprints to mitigate the risk of impersonation of authorized network devices. The fingerprinting was implemented using Multiple Discriminant Analysis (MDA) for training and authorised device classification and Multivariate Gaussian (MVG) likelihood values to identify rogue devices attempting to gain unauthorized network access by presenting false bit-level credentials. Finally, in a recent paper [19] the authors have applied Support Vector Machine (SVM) to identify GSM phones based on their uplink RF emissions. The analysis in [19] is similar to what done in this paper because the fingerprinting method was based on instant amplitude as in this paper and GSM have some similarities to DECT (e.g., modulation scheme).

As we described above, fingerprinting analysis has been applied to various widespread wireless communication technologies like Wi-Fi, WiMax, GSM and Zigbee but we are not aware of similar analysis for DECT. The purpose of this paper is to cover this gap and provide some preliminary results to mitigate the spoofing of DECT by using a simple, yet effective, RF fingerprinting technique.

The structure of the paper is the following. In section II, we describe the DECT standard. In section III we provide a description of the measurement setup and the definition of the algorithms for classification and identification, which have applied to provide the results in section IV. Finally, V describes the conclusions and potential future developments of this paper.

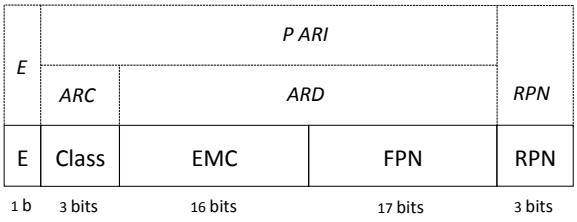

Fig. 1. Radio Fixed Part Identity (RFPI)

II. Digital Enhanced Cordless Telecommunication standard

In Europe, the DECT protocol operates in the range of 1800 Mhz to 1900 Mhz, where a total of 10 physical channels are allocated, using Frequency Division Multiple Access (FDMA), leading to the creation of a total 120 logical channels by dividing each physical channel into 12 logical channels using Time Division Multiple Access (TDMA), with separate time slots for the reception and transmission of data following Time Division Duplexing (TDD). Each DECT device will only transmit in its assigned time slot, producing bursts that will be clearly identifiable in the DECT channel assigned for the transmission.

A typical DECT installation will be composed of one or more cordless phones, denoted as Portable Parts (PP) in the standard, registered to a DECT base, named Fixed Part (FP). In a residential installation, the FP is typically connected to the fixed telephone line and also acts as a battery charger for the portable parts. In enterprise installations, the portable parts are registered to the FP, which is, in many cases, integrated into a Private Automatic Branch eXchange (PABX) system. In recent years, a new generation of residential Unified Communication systems have started to integrate DECT devices for the Smart Home ecosystem. The Generic Access Profile (GAP) of the DECT standard ensures the interoperability of fixed and portable parts from several manufacturers.

Each FP is identified by a RFPI (Radio Fixed Part Identity), which is a 40-bit number mainly composed of a 16-bit Equipment Manufacturer's Code (EMC), a 17-bit Fixed Part Number (FPN) and a 3-bit Radio fixed Part Number (RPN). The first 4 bits of the RFPI, reserved for the E bit and the class type, are set to zeros in residential and small corporate DECT installations (Class A). Figure 1 depicts the composition of the RFPI and the formal relation of each part with the Access Right Class (ARC), Access Right Details (ARD) and Primary Access Rights Identity (PARI) fields.

The EMC code determines the specific manufacturer of the FP. The FPN and FPN codes are assigned by the manufacturer and will uniquely identify a specific FP device. Unless an ECO mode is enforced, a FP will continuously advertise its

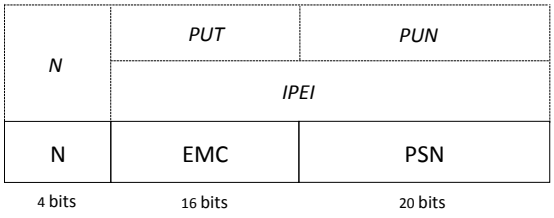

Fig. 2. International Portable User Identity (IPUI)

presence by broadcasting its RFPI, sending 100 DECT frames per second. Due to this fact, a physical channel with a single FP and no active PP communications, will show short bursts in regular intervals of 10 milliseconds. Each burst is a DECT frame that is composed of a preamble, the A field data where the RFPI is located and an optional B field in case there is voice being transmitted in the frame.

On the other end, the PP is uniquely identified by a 40 bit number called IPEI (International Portable Equipment Identity) that is composed of a 4-bit identity type field (type N for residential and small corporate set-ups), a 16-bit EMC and a 20-bit Portable equipment Serial Number (PSN) code. Both EMC and PSN are known as the Portable Part Equipment Identity (IPEI) and uniquely identify the specific PP device, with the EMC uniquely identifying the manufacturer and the PSN the specific device. Figure 2 depicts the composition of the IPEI.

When a PP is registered into a given FP, the RFPI of the FP is known to the PP and it is stored in its permanent memory. Similarly, the IPUI of the PP is registered in the permanent memory of the FP. A PP will monitor the available DECT channels and identify the corresponding FP on the basis of the RFPI code transmitted in the DECT frames.

The DECT standard foresees the usage of authentication, by using the DECT Standard Authentication Algorithm (DSAA), and encryption, by means of the DECT Standard Cipher (DSC). The Generic Access Profile (GAP) part of the standard ensures the interoperability between different DECT models and manufacturers and establishes a pairing process in order to register a DECT handset (PP) into a base station (FP). As part of this process, a long term key, named User Authentication Key (UAK), will be exchanged and permanently stored by both PP and FP.

The DSAA algorithm will use the UAK key for authentication and negotiation of temporal session keys, named Derived Cipher Keys (DSC), which will be used by the DSC algorithm for the encryption of the communications between FP and PP.

It shall be noted that DSC encryption, which protects the confidentiality and up to a certain point the integrity of the data, is only applied against the B-field (voice) and C-channel data (control information). The RFPI and IPUI identities included in the A-field of the FP and PP frames respectively, are not protected.

In that regard, for the purposes of this paper it is sufficient to say that there are several weaknesses on the security of the DECT GAP communications and, as described in section I, various active attacks against DECT communications that involve spoofing of the DECT devices identities have been described in the literature.

III. Fingerprinting analysis

A. Measurement setup

A schema of the measurement setup is provided in Figure 3. The correspondent image of the measurement setup used to collect the radio frequency emissions is provided in Figure 4.

The test-bed is in a shielded semi-anechoic chamber (i.e., absorbers are only partially covering the walls of the chamber). The DECT handset and the base station are separated at a distance of four meters and at a height of one meter from the ground. In the experiments performed, a total of 4 DECT models were analyzed from 2 well known manufacturers of DECT cordless phones.

The receiver used to record the radio frequency samples is an Universal Software Radio Peripheral (USRP) N210 with a configured sampling rate of ten mega samples I/Q per second. The receiver is located in the middle between the DECT handset and the base station (i.e., two meters from each DECT component) and it is also at an height of one meter from the ground. The antenna is a vertical omni-directional full wavelength monopole. The USRP N210 is connected to a desktop computer for the recording and the processing of the samples. To avoid possible biases, the USRP and its antenna inside the shielded semi-anechoic chamber, were the same for all the signal acquisitions.

The experiments were focused on the scenario where the identity of the DECT base station (FP) is spoofed by an attacker, so the recordings of the samples took place with and without PP transmissions. As described in section II, the FP transmits 100 frames per second, even in the absence of a call or PP activity. This was the case for all the DECT models analyzed.

The signals were acquired in 2 rounds for the 4 DECT devices and stored in I/Q format. The signals acquired the first day for all the devices became the training dataset and the set recorded the second day (also for all the devices) was used for testing, as it will be described in the next section.

B. Algorithms for fingerprint verification

Formally, the detection of a spoofing attack can be modeled in the same way of biometric fingerprint *verification* [20], i.e., an one–VS–one comparison of two fingerprints. The first one is the *template* fingerprint of the target DECT base station B, the second one is the fingerprint of the base station who "claims" to be B.

The template fingerprint of a base station is constructed, as follows, from a recorded radio transmission originated from that base station. First, we process in MATLAB the samples recorded by the USRP N210 in I/Q format, in order to identify and process the bursts.

In order to do so, we first calculate the modulus of the I/Q signal. Then we apply a low pass filter to ensure that only the in-band DECT signal is used to fingerprint the DECT device. In our case, we adopted a 2nd order Butterworth filter with a

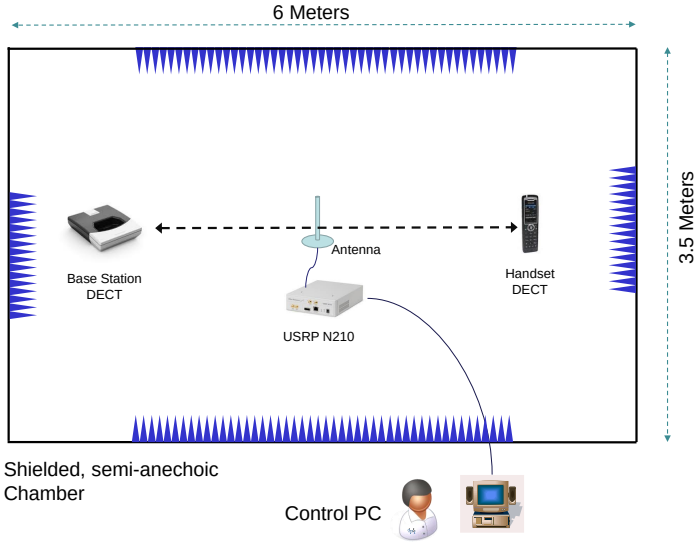

Fig. 3. Schema of the test bed used to collect the radio frequency emissions

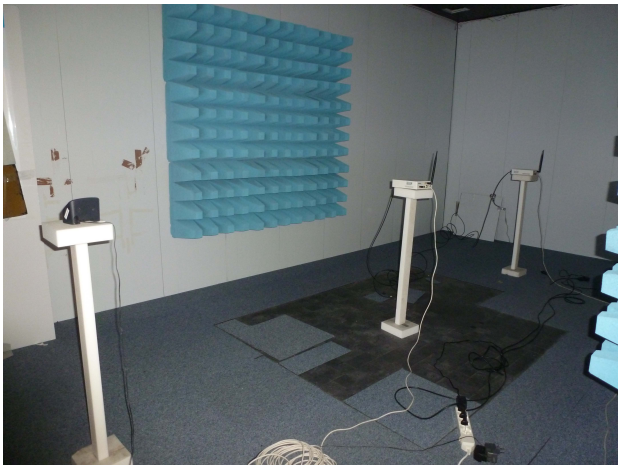

Fig. 4. Image of the test bed used to collect the radio frequency emissions

normalized cutoff frequency of $10e-5\ \pi$ rad per sample in normalized frequency. The Butterworth filter is used because it provides a flat response in the DECT frequency bands. A flat response is more appropriate because we did not know a priori which frequency components of the DECT signal could be more valuable for fingerprinting.

Once the Butterworth filter is applied, the bursts are identified by detecting the ramp-up and ramp-down of the signal. Each burst is normalized to the maximum amplitude of that specific burst and extracted using a fixed thresholding to synchronize it with the others.

We are interested only in the part of the burst which is not related to the content being transmitted (e.g., the voice during the DECT call), in order not to fingerprint content differences rather than the DECT device itself. The content invariant parts in the bursts are the ramp-up and ramp-down sections of a burst plus the preamble. Apart from being content invariant, these sections are appropriate for fingerprinting because they are more related to the physical properties of the front-end of the wireless devices [15].

The ramp-up and ramp-down sections plus the preamble of each burst are then stored in arrays, which are the primary source of data for the fingerprinting algorithms described in the following paragraphs. For simplicity, the combination of ramp-up and ramp-down and preamble are called mini-bursts in the rest of the paper to differentiate them from the initial raw bursts.

The mini-burst of both datasets are normalized into the interval $[0, 1]$, to make their signals comparable. In an initial training phase, a template T_B of the base station B is created by calculating the average of all the mini-bursts stored in the training dataset for that specific DECT device.

Verification of a given mini-bursts b^* of the validation dataset is then performed by computing a *burst similarity score* $S(T_B, b*)$, defined as the Normalized Cross-Correlation between T_B and b^* (both real vectors of the same length):

$$S(T_B, b^*) = \frac{(T_B - \bar{T_B}) \cdot (b^* - \bar{b^*})}{\|T_B - \bar{T_B}\| \cdot \|b^* - \bar{b^*}\|} \quad (1)$$

where $\bar{T_B}$ and $\bar{b^*}$ are the means of T_B and b^*, respectively. The value of $S(T_B, b*)$ measures the likelihood that b^* is a mini-bursts transmitted by the base station B. NCC was chosen as likelihood measure as it evaluates the similarity of the *behaviour* of the two signals (i.e., to which extent the vary in the same way over time) rather than the similarity of their values as it would be done e.g. by the Euclidean distance.

In order to obtain a sharp Yes/No decision, a threshold Th is applied so that b^* is deemed as coming from the base station B only if $S(T_B, b*) \geq Th$. The value of Th impacts on the False Positives (i.e., false alarms triggered by the spoofing detection systems) and of False Negatives (i.e., spoofing attacks not detected). In particular, the higher the threshold, the lesser False Positives, and the more False Negatives. It is worth to point out that False Positives and False Negatives can be reduced by verifying more than one mini-burst, and then decide on a majority vote (provided that the initial number of errors is lower than 50%). In this paper, we measure the accuracy when only one mini-burst is verified.

IV. Results and Discussion

Figure 5 shows the mini-burst templates calculated for each of the four classes, generated by taking the average of all the mini-bursts extracted out of the training data. This is the result of the training phase, where the mini-burst templates of each DECT device are calculated.

Distinct patterns can be appreciated visually in the transient part of the signal, particularly in the ramp-up, possibly generated by front-end components of the DECT device including filters and amplifiers [15].

The verification scenario was carried out with the signals acquired a second day (validation dataset). Figure 6 reports False Positive and False Negative ratios with respect to the selection threshold, as well as the Equal Error Rate (EER), i.e., the point at which the two errors are equal.

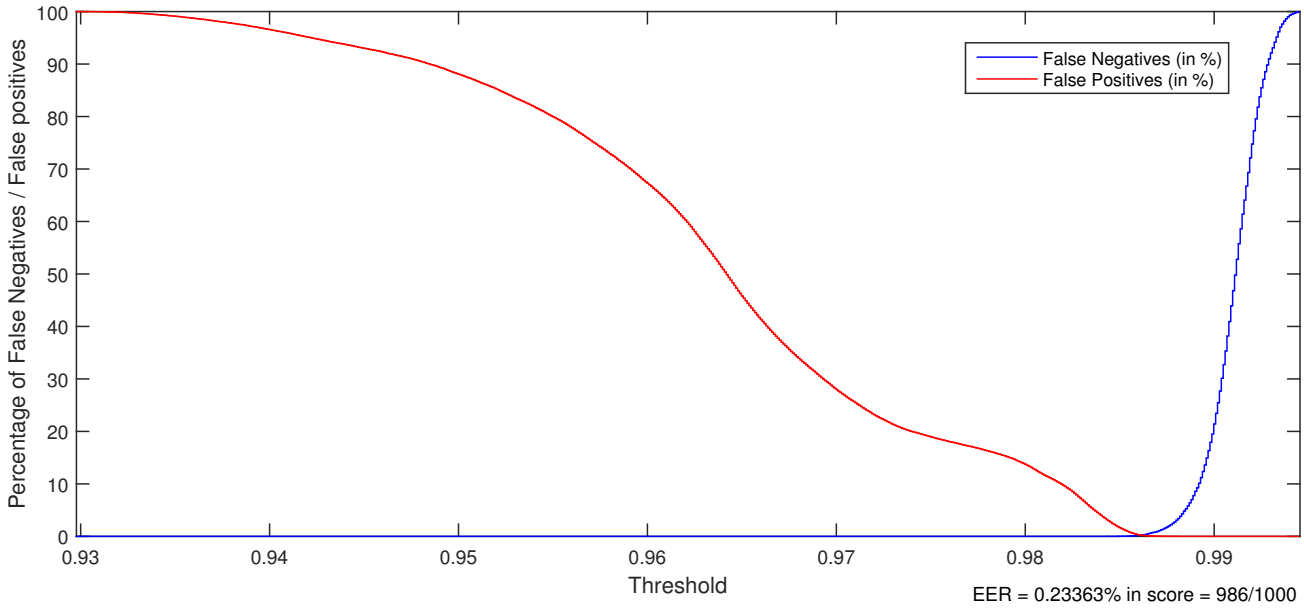

Fig. 6. False Positive and False Negative rates versus decision threshold Th. The Equal Error Rate (EER), i.e., the point where False Positive and False Negative rates are equal, is also reported.

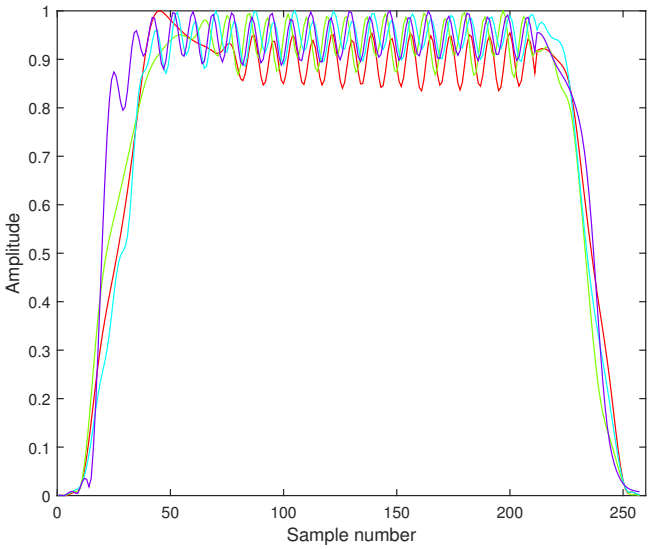

Fig. 5. Averaged Mini-bursts

The results of burst verification clearly show that it is possible to achieve almost 0% Equal Error Rate, i.e. a perfect discrimination between legitimate bursts and attacks. However, it is worth to point out the limited extent of our evaluation, which was limited to a small data set of bursts coming from four base stations. A more fair evaluation should average the results attained with several devices. Nevertheless, as highlighted in III-B if necessary the accuracy can be easily increased by classifying several bursts in place of only one, and then apply a majority voting rule.

In most of the actual spoofing scenarios, the hardware used by the attacker will be sensibly different from the one of the legitimate DECT FP whose identify is being spoofed. This is specially the case where the attacker uses a Software-Defined Radio device as a DECT transmitter and receiver, but also when specific DECT RF chip, completely different than the legitimate FP, is employed to launch the active attack.

The results obtained in the experiments demonstrate that the proposed fingerprinting technique can directly be used to detect such active attacks which involve device identity spoofing, in the probable scenario where the hardware used by the attacker does not perfectly match the one of the spoofed DECT device.

V. Conclusion

In this paper we have described an approach for the detection of device identify spoofing attacks in DECT communications based on the fingerprinting of the radio-frequency signal. We have demonstrated that the proposed RF fingerprinting technique, based on the analysis of the transient parts of the DECT signal, is effective in the detection of active attacks that impersonate the identity of the DECT base station, assuming that the RF hardware use by the attacker is not exactly the one of the legitimate station.

Unlike other techniques usually employed in intrusion detection, the RF signature is intrinsically linked to the RF circuit used by the transmitting device and therefore it is not easily manipulable by an adversary.

On the basis of the results obtained, we think that RF fingerprinting is a promising technique for the detection of active attacks on DECT communications and could be considered, in combination with other approaches, for its practical application by intrusion detection systems specialized in this type of wireless communications.

The proposed approach only takes into account the transient part of the signal and it uses a single burst for the classi-

fication. In order to handle more complex spoofing scenarios, where the same RF hardware than the legitimate DECT station is used to conduct the attack, future work will consider the usage of sequences of bursts in combination with other more complex RF fingerprinting techniques.

***Abstract*—With the interconnection of devices becoming more widespread in society (e.g. internet of things), networked devices are used in a range of environments from smart grids to smart buildings. Wireless Sensor Networks (WSN) have commonly been utilised as a method of monitoring a set processes. In control networks WSN have been deployed to perform a variety of tasks (i.e. collate and distribute data from an event to an end device). However, the nature of the wireless broadcast medium enables attackers to conduct active and passive attacks. Cryptography is selected as a countermeasure to overcome these security vulnerabilities; however, a drawback of using cryptography is reduced throughput. This paper investigates the impact of two software authenticated encryption with associated data (AEAD) security constructs on packet throughput of multiple hop WSN, being counter with cipher block chaining and message authentication code (CCM) and TinyAEAD. Experiments were conducted in a simulated environment. A case scenario is also presented in this paper to emphasise the impact in a real world context. Results observed indicate that the security constructs examined in this paper affect the average throughput measurements up to three hops.**

***Index Terms*—Networked Control Systems, Wireless Sensor Networks, AEAD constructs.**

I. Introduction

Wireless Sensor Networks (WSN) have commonly been used in control and instrumentation tasks such as obtaining measurements to transmitting data across multiple wireless devices. The application for WSN have been deployed in control systems to remote monitor; however, due to the nature of the wireless broadcast medium utilised , potential attackers could conduct passive and active attacks to compromise the operation of the system [1].

Many challenges and issues have been documented outlining the current vulnerabilities and constraints associated with WSN, including limited computational power, trust of intermediately devices and the physical medium utilised to broadcast data [2]. The requirement for reliability in WSN is critical with a variety of security challenges that require addressing whilst maintaining the operation of the system [3]. High throughput applications are currently utilised over wireless mediums (e.g. video streaming), with emphasis on quality of service (QoS). WSN can be deployed to relay streaming data to devices outside the range of the broadcasting node and maintain an acceptable quality of experience (QoE) for the end user.

This paper investigates the effect of two software security measures on WSN with focus on Authenticated Encryption with Associated Data (AEAD) concept and how their implementation influences packet throughput of a WSN. Reasons for undertaking this investigation is to record the behaviour of packet throughput dependent applications (i.e throughput measures the successful message deliveries over a communication medium) with AEAD constructs implemented over multiple wireless hops. A mathematical model is proposed to predict packet throughput for multiple hop WSN communications.

The structure of this paper is organised as follows: Section II introduces the terms and phrases discussed in this paper and a relevant case scenario. Section III introduces relevant literature, Section IV introduces the proposed mathematical model. Section V discusses the experimentation methodology. Section VI analyses the results obtained from the simulation conducted with comparison against the proposed mathematical model. Section VII examines the mathematical model as a predictive tool. Section VIII discusses the impact in relation to the case scenario Section IX concludes.

II. Preliminary

This section defines the terms used throughout this paper and presents the context of the case scenario. The Authenticated Encryption with Associated Data (AEAD) concept provides symmetric cryptographic security services to transmitted packetised data. AEAD combines confidentiality and integrity resulting in a secure communication channel. Confidentiality as an encrypting function is thought secure if an adversary is unable to distinguish the ciphertexts from a bit string chosen uniformly at random, from the set of all possible bit strings of a specified length, under a chosen plaintext attack. For the purpose of this paper, an integrity check function is thought secure if it is computationally infeasible to perform an existential forgery under an adaptive chosen ciphertext attack.

Two AEAD paradigms are presented in this paper, they are Counter with cipher block chaining (CCM) and

TinyAEAD. CCM is a National Institute of Standards and Technology (NIST) standardised AEAD construct designed to provide integrity and confidentiality using a 128-bit block cipher [4]. The TinyAEAD construct is designed to provide confidentiality and integrity services using block ciphers of various bit lengths [5]. This construct can be configured to run at a reduced specified number of block cipher iterations in order to enhance the processing speed of the construct. In addition TinyAEAD provides flexibility and adaptability that can be applied to a broad range of contexts.

The case scenario selected focuses on a circuit switched WSN multi-hop communication link viewed as using a linear logical network topology. It is assumed that nodes in the link are 100m due to limited battery power to transmit data over this distance, therefore multiple intermediate nodes are required to relay data between the source and destination nodes [6]. Figure 1 illustrates the case scenario.

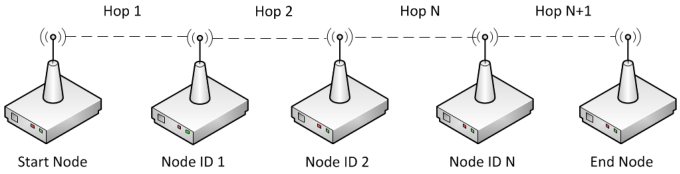

Figure 1. Illustrative concept of a circuit switched linear WSN multi-hop topology

In reference to Figure 1 the Start Node transmits a continuous flow of packets to node ID 1; the data is then transferred over *N* intermediate nodes before reaching the End Node. To secure the data being transmitted between each node, confidentiality, integrity and authentication is applied to prevent adversaries from viewing and modifying data in transit on the communication link; however, a drawback of introducing security is reduced throughput due to the additional processing time of the cryptographic process undertaken at each node during packet propagation.

III. Literature Review

This section introduces relevant literature related to the context of this paper with focus on confidentiality, integrity and authentication for WSN and the current mathematical models utilised to predict packet throughput over multi-hop networks.

Research conducted by Diaz et al [7] examines the attack vectors used against WSN with focus on the impact on power consumption and software execution time. The security vulnerabilities examined by the authors focuses on attacks against the physical and data link layer of the open systems interconnection (OSI) model. Three attack vectors are examined; link-noise, packet injection and direct attacks. Experimentation was conducted using SystemC to model the software execution time. A virtual WSN platform was created to examine collision, interrogation and Sybil attacks to analyse the effect on the power consumption and system performance. Two network topologies were also evaluated in this simulation; linear and mesh networks with each node utilising an ARM 926 processor and 802.15.4 transceiver (Zigbee). Results reported suggest that display power consumption varied depending on the network topology and attack selected.

A journal article presented by Pan et al [8] investigates WSN for healthcare. The main security vulnerability investigated in the article was providing confidentiality and integrity of patients data over a wireless broadcast medium as an attacker can conduct passive and active attacks to monitor and modify confidential data before arriving at its destination. The authors proposed solution uses a Feistel structure with two different methods, the first method incorporates an substitution box (Sbox) and the second method without a Sbox. Each Feistel cipher uses four rounds with a unique 32-bit key called at each round for encryption and decryption. Experimentation of the two Feistel constructs were conducted on an Atmel ATMega128L 8-bit microcontroller operating at 8 MHz crystal frequency. Comparative results against the Data Encryption Standard (DES) cipher suggests that the two Feistel ciphers are more suited to computational constrained WSN as the time taken to operate the encrypt and decrypt functions were faster than DES and memory consumption was also reduced.

An approach undertaken by Vu et al [9] presents a concept for simulation modelling of secure WSN. The focus of the research conducted in this paper examines their own bespoke simulation environment for modelling WSN, with emphasis on secure connectivity between each WSN. The security vulnerability discussed by the authors concentrates on active attack vectors (e.g. man-in-the-middle attacks) to determine what proportion of the WSN links remain secure. Five areas have been configured in the simulator being physical deployment, key establishment, node capture model, network analysis and a graphical user interface. Experimentation conducted by the authors suggests the results obtained for resilience against node capture for model and simulation correlate; however this methodology only take into consideration cryptographic key distribution only.

Research conducted by Marzi and Marzi [10] propose a security model for WSN using trust and reputation models (TRM). The issues highlighted by the authors emphasise the security vulnerabilities incurred by incorporating WSN into a networked environment (e.g. sinkhole attacks) and the computational constraints associated with WSN devices. The proposed solution utilises a Enhanced Bio-inspired Trust and Reputation Model (EBTRM) to calculate which node on the network is the most trustworthy before selecting the node to communicate with. The node also take into consideration if the communication was successful or unsuccessful and factor this into their computational model. Experimentation conducted reviewed the performance of the EBTRM against the Peer Trust System (PTS) and Bio-inspired Trust and Reputation Model (BTRM-WSN) using the TRMSim-WSN simulator. Results indicate that the EBTRM is suited for

selecting the correct trustworthy node in comparison to BTRM-WSN and PTS, even with a high percentage of malicious sensor deployed on the network; however, when compared to the average path length and energy consumption utilised the EBTRM consumed the most energy and took longer wireless paths than the BTRM-WSN approach.

Summary of the literature review undertaken suggests there is a requirement to investigate modern software security constructs suited for WSN as current approaches utilise constructs that are no longer standardised. Secondly, the current models for predicting throughput do not take into consideration the influence of the security constructs selected on the impact of packet throughput; suggesting an approach taking security into consideration is required. This suggests that an investigation is required to examine how modern cryptographic paradigms influences throughput over WSN.

IV. Proposed Mathematical Throughput Model

In this section we propose a mathematical model for predicting the total throughput of packets transmitted across multiple node WSN. The mathematical model presented in this paper utilises the exponential decay function to calculate the change of packet throughput over time (packets per second) for each wireless hop. This model takes into consideration that the wireless nodes would have no knowledge of the previous packet arrival (i.e. the amount of packets arrived at the previous hops), thus making the process memoryless. In addition it is assumed that the packet arrivals do not occur simultaneously, therefore, orderliness has been factored into this model.

The model is calculated by adding the initial packet throughout value for the initial start hop (N_o) divided by the time frame selected in seconds (e.g. per minute) (t) to calculate the packet arrival rate. The inverse of the value is obtained using -1/($\frac{N_o}{t}$) before using the value with the exponential function (e). The value obtained is then multiplied by the total throughput value of the previous wireless hop packet throughput (N_o) to calculate the rate change in packet throughput (r).

$$r = N_o e^{(-1/(\frac{N_o}{t}))} \quad (1)$$

Equation 1: Exponential decay calculation for estimating throughput rate of change per wireless hop

The final calculation is to subtract r from N_o to derive the new packet throughput measurement for N_{o+1} as formulated in Equation 2.

$$N_{o+1} = N_o - r \quad (2)$$

Equation 2: Calculation for estimating throughput per wireless hop

V. Experimentation Methodology

This section discusses the apparatus, metrics and context selected for the experimentation methodology. The programme selected is Proteus ISIS 8 professional with an emulated Microchip PIC18F45K22 selected as the microcontroller. The Serial Peripheral Interface (SPI) is selected as the physical layer (e.g. OSI model) to transmit and receive messages between each microcontroller on the WSN. The AEAD security algorithms used are CCM and TinyAEAD running AES (128-bit key variant). The communication channel for this experiment is simulated.

The experimentation methodology is used for observing packet throughput for ranging multiple nodes with and without software security measures applied. Packets are sent continuously and counted by the last hop device to measure how many packets have arrived at its destination within one minute time sample. All timings and packet throughput counts were taken from the simulator used. It is assumed for this scenario that no noise is present on the wireless channel and consequently all packets transmitted are received without loss or corruption.

Metrics used for the experimentation are seconds for the time frame of the experiment. The packet throughput is counted to measure how many packets arrived in the time frame and number of nodes to state how many intermediate devices were between the start and end node.

Configuration of the components selected are as follows, the crystal frequency selected is 4 MHz to replicate low powered industrial microcontrollers with packet sizes of 36, 52 and 84 bytes. A SPI divisor of 16 is chosen to replicate bandwidth of a wireless link of 250Kbps [11] as calculated using the formula obtained from previous research [12]. It is assumed that a 100m distance is between each wireless node. The experimentation methodology varied the number of intermediate nodes on the linear network, starting from one node to the maximum of five nodes.

VI. Results and Analysis of Experimentation

This section analyses the results obtained from the experimentation methodology discussed in the aforementioned section. Figure 2 illustrates the total throughput for a packet size of 36 bytes. Results presented in Figure 2 suggests that the number of intermediate nodes influences the total amount of successful packets being received within the time frame for a 36 byte packet with one hop showing the largest throughput count and five hops showing the smallest throughput count. The packet size has minimal impact based on the data presented. TinyAEAD at three rounds has a smaller impact on throughput than CCM.

Figure 3 presents data obtained from increasing the packet size to 52 bytes. The data indicates that security has reduced the throughput up to three nodes with CCM having the least throughput recorded. The larger hop counts show a minimal effect on the total throughput readings.

The data in Figure 4 represents results obtained for a 84 byte packet size. The results indicate CCM has a greater impact on

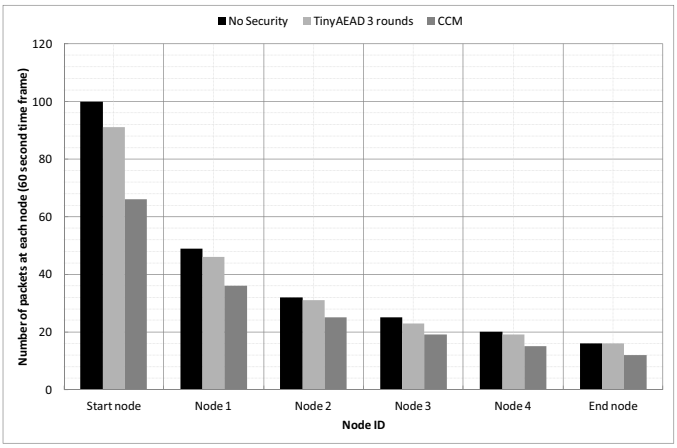

Figure 2. Simulation results for 36 byte packet lengths over multiple intermediate nodes for a sixty second time frame

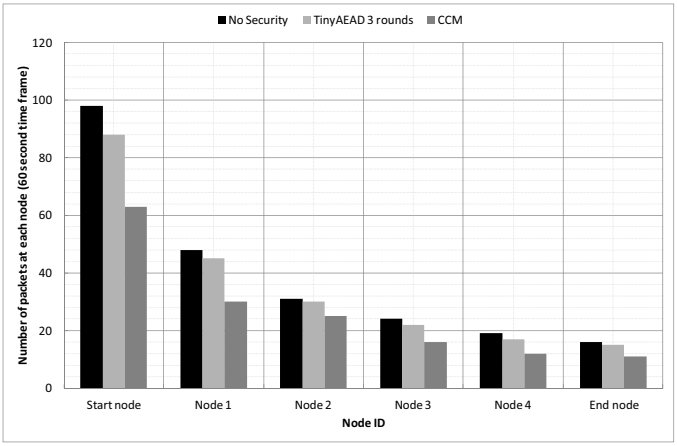

Figure 3. Simulation results for 52 byte packet lengths over multiple intermediate nodes for a sixty second time frame

the total throughput; it is also illustrated that larger packet sizes has ta larger decrease on throughput values in comparison to smaller packet sizes.

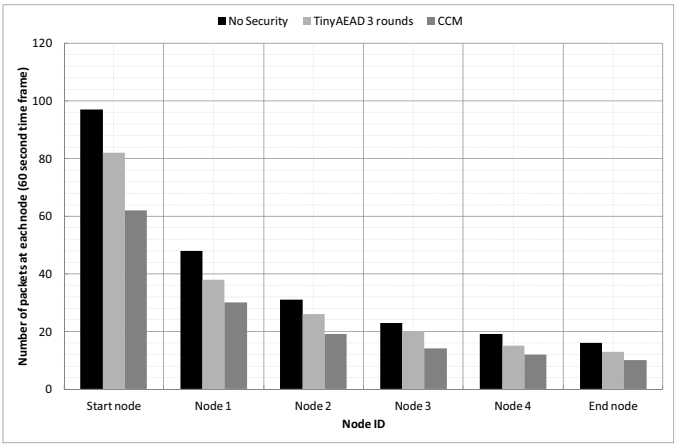

Figure 4. Simulation results for 84 byte packet lengths over multiple intermediate nodes for a sixty second time frame

The number of rounds utilised by the underlying block cipher used by the AEAD algorithms has a direct effect on the throughput values generated as the AEAD algorithms operating at reduced number of rounds outputted more packets in comparison to specified maximum number of rounds.

The quantity of intermediate nodes between the source and destination also has an influence on the total throughput value as the more nodes that were present in the network, the larger the reduction in the packet throughput; however, the AEAD algorithms had a greater impact for nodes closest to the Start Node, whilst nodes further away from the Start Node endured a minimal impact, suggesting that multiple hop wireless propagation over three nodes are suited to operating at stronger security configuration as the degradation of the packet throughput is reduced, whilst lower hop counts below three nodes are suited to lower security parameters as the effect on throughput is more noticeable.

Analysis of the results obtained from the simulation and the results acquired from the mathematical model is presented in Table 1. Table I compares the results for a 36 byte packet size over varying hop counts using a 250Kbps link.

Table I
NO SECURITY THROUGHPUT COMPARISON OF MATHEMATICAL MODEL VS SIMULATION (36 BYTES)

NUMBER OF NODES	SIMULATION RESULTS (PACKETS)	MODEL RESULTS (PACKETS)	CORRELATION COUNT
Start node	97	97	0.9998
1	48	52	
2	31	35	
3	23	28	
4	19	24	
5	16	22	

Data displayed in Table I suggests that the mathematical model correlates with the simulation results obtained up to three nodes. Correlation analysis indicates that the mathematical model and simulation results have a positive linear correlation. Table II shows the comparison data obtained from using TinyAEAD at three rounds.

Table II
TINYAEAD THREE ROUND THROUGHPUT COMPARISON OF MATHEMATICAL MODEL VS SIMULATION (36 BYTES)

NUMBER OF NODES	SIMULATION RESULTS (PACKETS)	MODEL RESULTS (PACKETS)	CORRELATION COUNT
Start node	91	91	0.9989
1	46	47	
2	31	33	
3	23	27	
4	19	24	
5	16	22	

Results in Table II indicates that the mathematical model correlates with the simulation up to three nodes. Correlation analysis suggests a positive linear correlation between the simulation and mathematical model. Table III compares data

obtained from simulation and modelling for CCM.

Table III
CCM THROUGHPUT COMPARISON OF MATHEMATICAL MODEL VS SIMULATION (36 BYTES)

NUMBER OF NODES	SIMULATION RESULTS (PACKETS)	MODEL RESULTS (PACKETS)	CORRELATION COUNT
Start node	66	66	0.9605
1	36	26	
2	25	23	
3	19	21	
4	15	19	
5	12	18	

Data illustrated in Table III indicates that the mathematical model is suited up to three nodes before difference increases. The correlation count between the simulation and mathematical model indicates a positive linear correlation between the two data samples.

Reviewing the comparison between the mathematical model and the simulation results, data obtained indicates that the mathematical model is better suited for calculating the throughput expected up to three nodes, this indicates that the mathematical model error increases as the number of nodes increases. Correlation analysis of the data obtained suggests the model and simulation have a positive correlation with no security and adjustable AEAD algorithms, whilst fixed AEAD algorithms have a lower positive correlation.

VII. PREDICTIVE MODELLING

This section utilises the mathematical model as a prediction tool for the total packet throughput over a select number of nodes over a period of time. Two experiments were conducted, first the prediction of throughput values over six nodes for varying packet sizes and security algorithms. A second experiment assesses the viability of the model as a predictive tool by varying the packet size, time frame, number of hops and rounds used by TinyAEAD. Table IV displays the data obtained for packet throughput values over six hops for a time frame of sixty seconds. The predictions were obtained using the first hop packet throughput value for each packet size and security construct obtained in Figures 2, 3 and 4 as a base reference for the variables used for the calculation.

Table IV
MATHEMATICAL MODEL VS SIMULATION RESULTS FOR THROUGHPUT MEASURED OVER INCREASED MULTIPLE NODES

NUMBER OF NODES	SECURITY CONSTRUCT	PACKET SIZE (BYTES)	PREDICTIVE MODEL RESULTS (PACKETS)	SIMULATION RESULTS (PACKETS)
6	CCM	36	11	16
7	TINYAEAD 3 ROUNDS	52	12	19
8	TINYAEAD 5 ROUNDS	84	7	12
9	TINYAEAD 10 ROUNDS	36	8	14

Results obtained from the predictive model and the simulation results suggest that the results do not correlate, this suggests that the mathematical model is not suited for predicting over five nodes. Table V tabulates data obtained from varying the time frame, rounds used for the underlying block cipher for TinyAEAD, size of the data packets and number of nodes were selected to indicate the viability of the mathematical model as a predictive tool.

Table V
MATHEMATICAL MODEL VS SIMULATION RESULTS FOR THROUGHPUT MEASUREMENTS OVER VARYING PARAMETERS

	TINYAEAD 3 ROUNDS	TINYAEAD 5 ROUNDS	TINYAEAD 10 ROUNDS
NUMBER OF HOPS	2	3	4
PACKET SIZE (BYTES)	36	52	84
SAMPLING TIMES (S)	120	180	240
PREDICTIVE MODEL RESULTS (PACKETS)	93	76	62
SIMULATION RESULTS (PACKETS)	92	80	63

Data presented in Table V indicates that the predictive results obtained from the proposed model correlate with the simulation results.

VIII. DISCUSSION

This section discusses the results obtained from experimentation and how they influence the case scenario of WSN previously discussed in Section II. To clarify how security impacts on packet throughput, Figure 5 graphs the instantaneous throughput measurements for a packet size of 36 bytes.

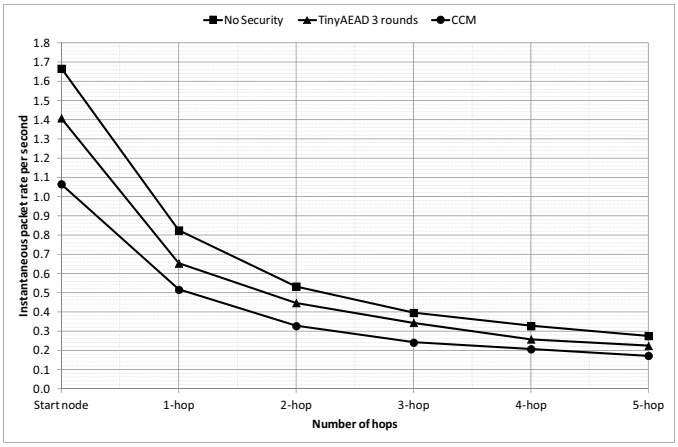

Figure 5. Instantaneous throughput measurements for 36 byte packet lengths over a sixty second time frame

Trends graphed in Figure 5 suggests that implementing security algorithms influences the initial rate of packets received

in the given time frame as no security has the highest throughput rate per second, however, the selection of the security algorithms also influences the instantaneous packet rate as TinyAEAD at three rounds outputs 0.3 packets per second faster than CCM from the initial start hop. The percentage difference between no security and CCM from the start node is 35% whilst the percentage difference between TinyAEAD and no security is 19%. This suggests that the initial impact of security algorithms on throughput is offset from the start node and propagates over multiple hops.

IX. Conclusion

The proposed mathematical model presented in this paper is suitable for calculating the impact of security algorithms using varying packet lengths and security algorithms up to four nodes in length. The amount of intermediate nodes on the network has influence on packet throughput measurements obtained with the number of packet arriving at each hop decaying exponentially; this indicates that the rate of throughput decreases with the increase in intermediary nodes.

Concluding from this investigation undertaken, it has been identified that the use of current standardised fixed AEAD algorithms impact on the throughout of WSN in comparison to adjustable AEAD algorithms, suggesting that current standardised AEAD algorithms using fixed parameters are not as suited in comparison to adjustable AEAD algorithms if packet throughput is a priority.

The mathematical model proposed contributes towards predicting the effect of security algorithms for variable sized WSN for a range of sampling time frames in simulation. Future work will validate the findings obtained on real world platform.

Abstract - In this study, a practical card-emulated relay attack is implemented on Near Field Communication (NFC) equipped mobile devices. NFC is a promising communication technology which is also used in smart mobile devices. As an effective and flexible communication technology, NFC is frequently used in innovative solutions nowadays such as payments, access control etc. Because of the nature of these transactions, security is a critical issue that should be considered in system design and development phases. Although inherited from Radio Frequency Identification (RFID) technology, NFC security needs, requirements and solutions differ in terms of its usage areas and solutions. Based on these parameters, security precautions in communication layer of RFID technology do not prevent relay attacks occurred in the application layer NFC solutions. This study is conducted to prove relay attack practicability with using only mobile phones for relaying credentials instead of RFID based smart cards in an access control application. The Host Card Emulation (HCE) mode also eases relay attacks in NFC communication. The study explains the conceptual description of proposed relay attack, development and operating logic of mobile applications working based on card emulation mode and server software and also data communication basics between modules and web services descriptions.

***Keywords*- NFC, Relay Attack, Mobile, Card Emulation**

I. INTRODUCTION

Daily communication devices such as computers, mobile phones etc. have evolved in the last decades in terms of both size and functionality. Although they are small in size, they became very capable devices in terms of performing complex and critical processes. This state is defined as the third era of computing [1] and named "Ubiquitous Computing" or "Pervasive Computing". In this stage, standard computer perception changes both in appearance and logic.

In the last decade, the communication and life style of people have completely changed. People have started to use smart mobile devices for their daily routines such as mailing, dealing with documents, entertaining etc. As a result, production and sales of smart mobile devices, mobile operating systems, mobile marketing and mobile solutions have extremely increased. According to the research conducted by Collins, there are 7.3 billion mobile devices in the world which exceeds world population. These numbers also show the impacts of mobile ecosystem.

Near Field Communication (NFC) technology is one of the communication conveniences that emerge from mobility tendency and device interaction concept. The main function of NFC is to establish connection between two mobile devices or NFC tags and reader. Data exchange or access requests can be easily performed with this concept. NFC enabled smart mobile devices are used in daily applications and create smart solutions. For example; NFC technology is used for contactless payments which are also the most popular NFC applications, loyalty couponing, transport systems (bus, train etc.), data exchange, gaming, location based services and access control systems.

This paper has five sections: After introduction, Section 2 explains Near Field Communication basics and Section 3 includes literature review about the study. Relay attack is described in Section 4 and finally Section 5 concludes the paper with summary and possible future works of this study.

II. NEAR FIELD COMMUNICATION

With the invention of mobile phones, the intent was to enable making voice calls via wireless instead of using traditional wired phones. After Second Generation (2G) GSM technology, mobile phones have been equipped with not only to perform voice but also to send/receive text messages and also to have internet experience capabilities. In addition to standard cellular network connection over base stations, mobile devices have started to establish connection to other electronic devices for data exchange and interaction. The infrared technology was used in first wireless communication trials, then Bluetooth and Wi-Fi wireless technologies have been developed for connection between interactive mobile devices.

1) Basics of NFC

After the studies of hardware developments, Near Field Communication (NFC) technology was introduced in 2002 by Philips and Nokia [3]. In 2004, NFC Forum was established in order to foster cooperation and standardization by Nokia, Microsoft,

This study is supported by the Scientific and Technological Research Council of Turkey under 2211 program.

Sony, and Philips. In early 2010s, NFC Forum has started to introduce NFC standards such as: Logical Link Control Protocol (LLCP) Specification, NFC Data Exchange Format (NDEF) Specification and NFC Record Type Definition (RTD) Specification etc. Then, mobile device manufacturers have been influenced from these developments and started to produce smart NFC products which are NFC enabled mobile devices, tags and readers. Finally, NFC became a standardized short range, easy to use and set up, flexible and stable communication technology.

NFC provides short range (up to a few centimeters) wireless communication between two electronic devices. In order to establish communication, at least one active (energy provider) device should initiate communication process. NFC enabled mobile devices and NFC readers such as contactless payment readers are active devices, whereas NFC tags and NFC posters are passive devices.

NFC operates in 13.56 MHz High Frequency (HF) unlicensed frequency band that is available to all manufacturers with range of up to 4 cm. Data transfer rates of NFC are 106, 216 and up to 424 Kbps which is higher than RFID data transfer rates, however much lower than 3G and Wi-Fi rates. The reason of that is the main purpose of NFC operations is not transfer high volume data to destination.

2) Operating modes of NFC

NFC devices interact via three different modes according to application types and needs. This flexibility creates a customizable environment for developers and manufacturers.

a) Peer-to-Peer Mode

In Peer-to-Peer mode, two active NFC enabled mobile phones interact with each other in two directional data exchange paradigm. Firstly, one mobile device initiates communication set-up process using request-response mechanism, and other mobile device replies its response. The connection is established according to Logical Link Control Protocol Specification (LLCP) created by NFC Forum and data exchange is performed based on Simple NDEF Exchange Protocol (SNEP) protocol basics. The data, picture, URL exchange operations between two mobile devices use this mode of operation.

b) Reader/Writer Mode

Active mobile devices can both read and write passive NFC tags in Reader/Writer mode. Similar to RFID cards, NFC cards respond to requested data sent from initializer mobile device or write demanded data. Passive NFC tags are operated according to NDEF and RTD message format standards. Location based services, information tags or smart posters use this operation mode.

c) Card Emulation Mode

In this mode, two active NFC devices which are mobile device and reader are used. The mobile devices act as smart card based on ISO/IEC 14443 Type A, Type B and FeliCa standards in the application. When mobile phone gets close to reader, similar to RFID applications, reader initiates interaction and reaches mobile phone's NFC module and Secure Element if available. Payment and Access Control applications use this mode for granting access.

III. RELATED WORK

The Near Field Communication (NFC) technology is relatively a new technology which is introduced within the current decade [4]. The first versions of related standards have been released in last five years by NFC Forum and ISO [5], also device manufacturers have started to develop more NFC devices after these developments.

After mobile payment systems have been launched especially after Google Wallet solution, the popularity of NFC has increased. As a result of this popularity, trials of practical attacks on mobile payments were conducted in research [6], [7] and [8]. These studies demonstrate the applicability of security problems in mobile payment domain.

The implementations of NFC relay attack examples were conducted successfully in [6] and [7]. A mobile application installed on mobile device is used in attack; however, no security precautions are discussed in the study [9]. In the studies [6], [8] and [10], ISO/14443 based RFID cards were exposed to relay attack and successfully relayed. As countermeasures, protocols of distance bounding and Frame Waiting Time were offered in [6] and [8], however, they cannot provide sufficient precautions for attacks.

In the ISO/14443 standard, Frame Waiting Time (FWT) is defined for standard smart card and reader communication. FWT variable defines maximum response time after the end of the reader's data. FWT is defined as $(256 \cdot 16/ f_{carrier}) \times 2^{FWI}$, where FWI is a value from 0 (FWT = 300 μs) to 14 (FWT = 5 s) with a default of 4 (FWT = 4.8 ms). The control of this variable was offered in the literature for avoiding relay attack in [6] and [8]. This variable can be modified by attacker or some additional readers may be placed between reader and card in order to overcome this variable. However, the main reason of its unsuitability is that mobile devices are used in the proposed model instead of smart cards and when a relay attack occurred, only NFC based mobile phones

communicate with each other. There is no timing limitation between two NFC based mobile phone communications, because two devices are active not like in the ISO/14443 based passive cards. This problem should be solved with application layer security methods.

Location based control is also offered as another countermeasure in the studies [8] and [11]. Distance-bounding protocols use FWT values for calculating round trip time and finally comment on requester's location. As it is mentioned, using FWT is not a suitable solution for avoiding relay attacks especially where NFC enabled mobile device are used. These studies also show the significance of this research, because, it proves relay attack practicability with using only mobile phones for relaying credentials instead of RFID based smart cards and any other intermediate devices.

IV. Relay Attack

In addition to other security threats such as eavesdropping, data modifications etc. in the short range wireless communication, relay attacks are frequently used for performing interventions.

Attacker captures and forwards relayed message to proxy device and this device delivers the message as if the real owner in a typical scenario. Similar to relay attacks, man in the middle attacks also influence wireless medium, however, the method and also purpose of relay attacks have completely changed. These attacks are frequently used in ISO/IEC14443 based passive smart card communication environment. Since these cards are used in critical payment and access control systems, relay attacks in this environment result in important security threats. For example; in the research [7], ISO/IEC14443 based smart contactless credit card is successfully relayed over proxy devices. In this application, relay mobile phone records debit card data in reader mode and forwards this data to another phone via wireless communication such as Wi-Fi or Bluetooth. Proxy NFC based mobile devices send credentials to reader as the real owner in card emulation mode. If the reader cannot detect the fake sender, relay attack is completed successfully. This activity flow is illustrated in Fig. 1.

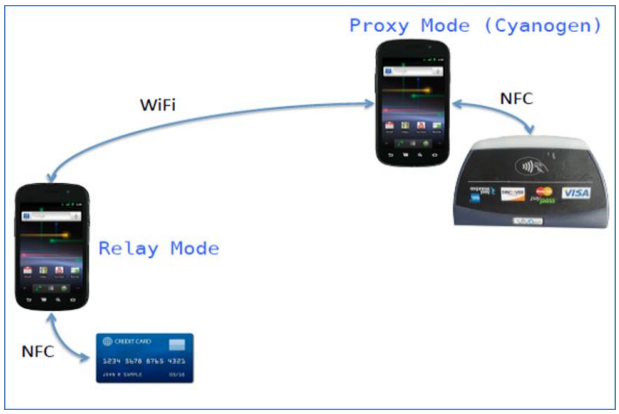

Figure 1. Typical Relay Attack scenario using contactless credit cards.

In the literature, NFC enabled mobile phones are generally used for relaying smart cards, in other words mobile phones read and send the data only. Credit cards, debit cards, and even electronic passports are used in relay attack experiences, however, in the access control systems proposal; mobile devices are used in card emulation mode instead of using smart cards. On the other hand, smart cards are limited and just reply the requested data

A. *Host Card Emulation Mode (HCE)*

NFC devices basically operate in three different implementation modes, Reader/Writer, Peer-to-Peer and Card Emulation mode. Although three modes are specified, developers could use only two of them, Reader/Writer and Peer-to-Peer in Android operating system because of Google policies. Only Google Wallet [12] application could use this operation mode for its transactions. With release of Android 4.4 (API Level 20), developers have started to use Host Card Emulation Mode [13] in their solutions and users have started to use their mobile phones like smart cards. We have also moved to that operation mode in our system because of its functionality and flexibility compared to its other modes.

The use of HCE in solutions also eases the practicability of relay attacks in the applications. Shifting between Reader and Card Emulation modes on same mobile device provides great chance to relay attackers instead of using different intermediate devices. HCE has also been used in practical relay attack scenario of the study.

B. Implementation

The relay attack setup in this study shows differences in transaction methods and relaying medium. As it is illustrated in Fig 3, the high level components of NFC based access control systems are NFC Enabled mobile device, NFC reader, access control panel and central server.

The general activity flow of NFC based access control system begins with controlling whether NFC unit of the mobile device is active or not. If NFC is enabled, user registers to the system with his/her mobile operator number, username etc. using application that is installed on the device. Once user is registered to the system, central server activates his/her account and sends activation key to authenticated mobile device. The activation key is checked based on predefined parameters. After registration process is completed successfully, user can now send access requests with his/her user name, password and expiration time of key parameters.

After getting key from the server using JSON based web services infrastructure, user can now send authentication requests to NFC reader with acquired key. At that time, relay phone can interfere NFC communication between reader and mobile phone. Relay phone can read the key that stored in the real mobile phone by getting close to phone in reader operation mode. In other words, relay phone imitates the NFC reader. If requester cannot identify the real

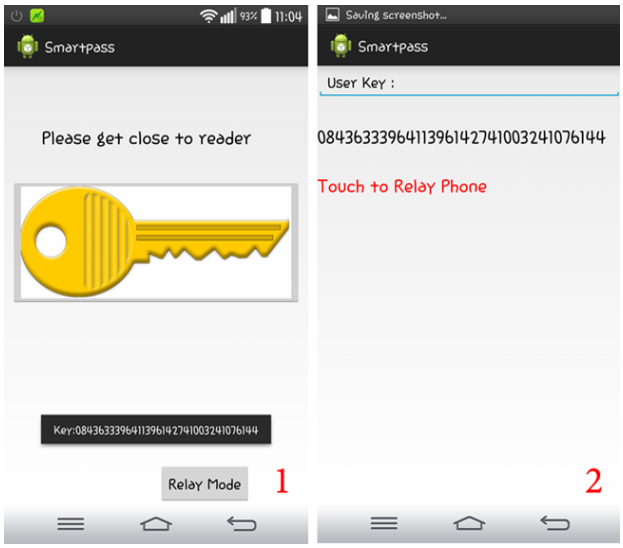

Figure 2. Screenshots of mobile application

NFC reader, relay phone gets the user key from real owner with operating peer-to-peer mode.

In order to complete the attack successively, relay phone should send access request to NFC reader with the key that captured from real phone. In order to do that, relay phone shifts its operating mode to Host Card Emulation Mode, by doing this; it now acts as a smart card and sends requests. These processes are illustrated in Figure 4. After these transactions, NFC reader gets the key and forwards to the server. Because of the validity of the key, unauthorized attempt can access to resource.

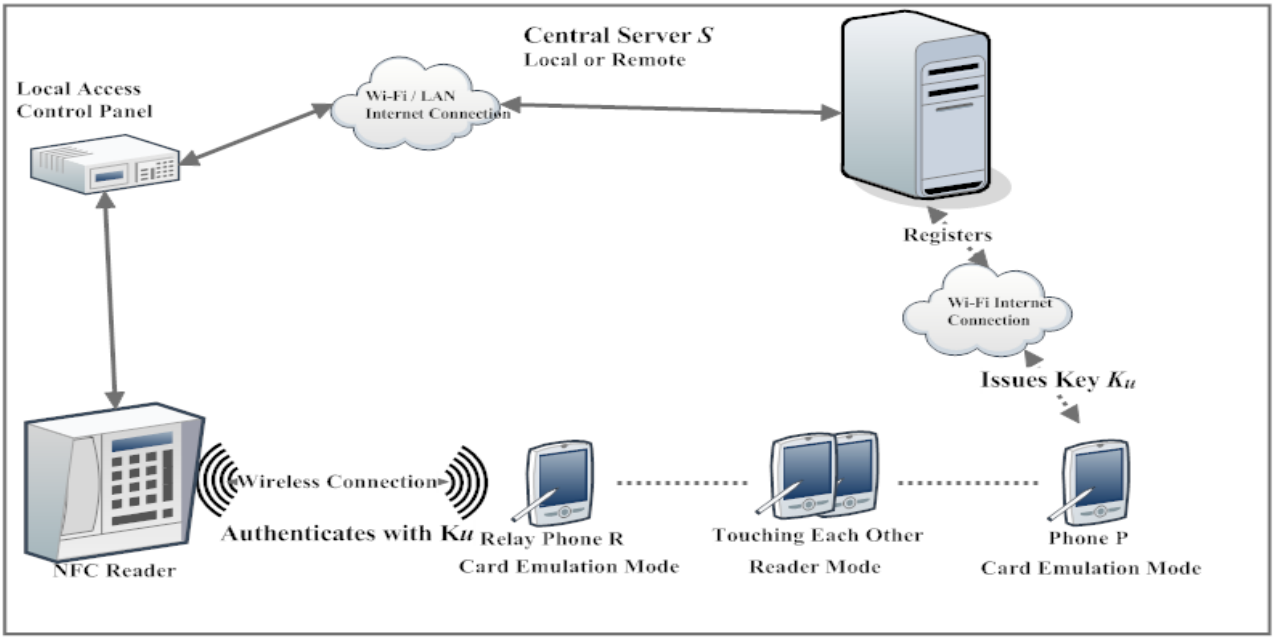

Figure 3. NFC Relay Attack scenario for access control system

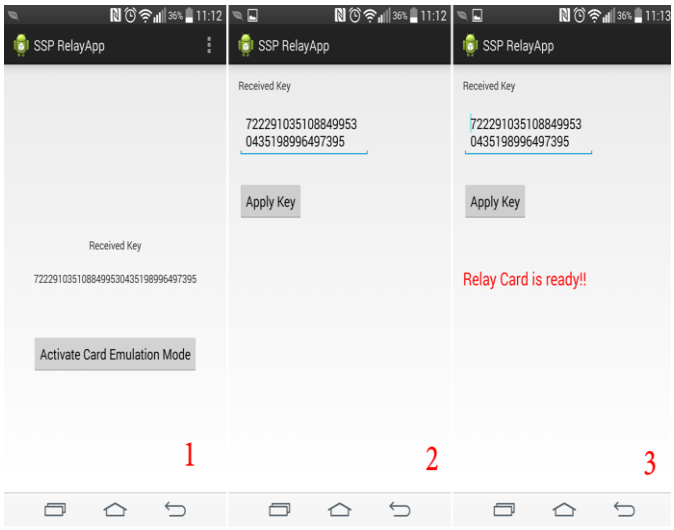

Figure 4. Screenshots of relay application

The whole process is illustrated in Figure 3. In the attack environment, relay phone has no wireless connection to server; therefore any key exchange occurred between server and relay phone. It captured the key from user mobile device using peer-to-peer operating mode and then changed its mode to card emulation mode. After this change, it created a virtual smart card using captured key from user device and requested access. NFC reader, access control panel and central server could not realize the relayed mobile device and attack is successively performed.

In a typical relay attack scenario which is also illustrated in the Figure 1, at least two mobile devices are used for relaying credentials. However, in this study, only one mobile device performs attack with the help of ability of switching operating modes of NFC. This is the main originality of the study. Also this convenience provides flexibility to attackers, because, in this kind of environments, attackers do not need to place between devices physically at the same time. Once he captures the credentials from real phone in reader mode, then he can use them another time after switching NFC mode to card emulation mode. Critical part of this type of relay attacks is whether relayed sender mobile device is detected or not by reader during authentication.

V. CONCLUSION & FUTURE WORK

Practical and successful relay attack scenario on mobile device using card emulation mode and its implementation steps are described in this study. NFC is a relatively new and popular wireless communication technology especially on mobile devices and used in critical solutions frequently. As well as its functionality, it is exposed to the relay attacks. Because of inheritance from RFID standards, the proposed precautions of communication layer such as defining FWI for transactions between receiver and transmitter do not prevent relay attacks in NFC environment. The study proves NFC communication security gap in access control systems using mobile devices. This type of relay attacks occur in the application layer, therefore, the real-time precautions that work on this layer and able to detect real sender should be developed for prevention as a future work.

Honeytokens as active defense

A.B. Robert Petrunić, bacc.ing.comp.,
Algebra university college for applied computer engineering, Zagreb, Croatia
robert.petrunic@racunarstvo.hr

Web applications are one of the mostly attacked platforms today, and because of that new ways to break into the web applications are being invented almost on a daily basis, allowing attackers to steal user's personal data, credit card numbers, and conduct many other frauds related to data and applications hosted on the Internet servers and databases.

Some of the reasons that web applications are constantly attacked is 24/7 availability, mix of technologies used to provide needed functionality, interesting data in the backend databases and easy way to avoid punishment for crimes committed against web sites and website users/owners. There is also an aspect related to cybercrime and cyber warfare that is marching throughout the planet in the last few years, exposing more and more personal data in highly sophisticated and targeted attacks.

This paper will try to summarize few different ways that web application could be written in order to identify, isolate and track the hacker during the attack process. The concept presented in this paper is so called honeytoken – a value the application is using in databases, files, parameters, etc., which should never be changed or touched by the application in normal application lifecycle.

Index terms – Web application security, honeytoken, active defense

I. INTRODUCTION

The reason for writing this paper is because the methods explained inside are only partially being used in the enterprise grade web applications, and because there are not so many papers related to this kind of malicious user protection.

Today, we have to fight against various threats on the Internet that will try to break into vulnerable web site. This threat might come from criminal organizations, trying to infect as much computers a possible in order to build powerful botnets that will be used to steal money, credit card numbers, send spam messages, provide bandwidth for DDoS (Distributed Denial of Service), etc. It might also come from Government sponsored hackers that will use this as Cyber weapon, from hacktivists that will try to use it as a tool to prove they cause, and from other hacker types. It's almost impossible to fight against all of this threats by using traditional methods and tools, and in order to raise the bar a little bit higher for them, one has to write the web application that will be capable of self-protection of some kind. This self-protection is covered throughout the paper discussing the cons and pros for every available method.

In most of the cases, the attack starts with scanning and vulnerability scanning of web application, that consist of testing all of the parameters the application uses, against the database of well-known attack vectors (for example, OWASP project TOP 10 [1]) and vulnerabilities. This is really loud process and it is easily recognizable on the server side and in most of the cases it could be stopped by using WAF (Web Application Firewall [2]). The problem is that WAF could only prevent known attack vectors, and additional protection is mandatory in modern web applications.

The Section "Honeytokens explained" is focusing on basic concepts behind honeytoken and their usage followed by Section "Honeytoken implementation options" that is focusing on different approaches and possible practical honeytoken implementation inside web applications. "Logging and reporting" Section explains the importance of log management, while "Implementation example" is showing the code excerpts one could use to implement proposed functionality.

II. HONEYTOKENS EXPLAINED

In most of the cases, web application is exchanging data with user part of the communication channel by using parameters, and this is the perfect place to use the honeytoken (canary) value in order to fight against attackers and automated tools. The purpose of honeytoken is quite simple: this is the value that should never be used by the application in normal usage scenario. It means that at the same time the value of honeytoken has changed, someone has done something that is not allowed in the current application context, and the session should be disconnected or isolated. Honeytoken could be anything from the web application parameter, through the data inside the database to the file on the file system. Depending on the needs it could be implemented on any or all possible layers of the application and application data. That being said, honeytoken value inside web application parameter will help to identify automated or manual scanning procedures and it could be used as the early warning system that could also be used to prevent the further system compromise. If the system has been compromised (even though the previously explained web application parameter honeytoken has been used) honeytoken inside the database could be used as additional breach identification and possible evidence in forensic investigation. The same logic applies to the files used as honeytokens. Honeytoken implementation is not enough in order to have in depth view on the attack process. In order to track the attacker during and after the attack SIEM (Security Information and Event Management) or centralized log management system had to be used. This system will collect all the related logs (application, web server, operating system, database, etc.).

Conceptual idea of honeytoken based protection inside web application, DBMS (Database Management System) and file on the file system is presented in Figure 1.

Zone 0 is related to firewall and IDS/IPS protection and it is not covered in this paper. This is usually the first line of defense that could be composed of the packet filtering firewall and/or WAF (Web application firewall). This is the zone that could be used to identify classical network attacks (IDS) and prevent them (IPS). If the WAF is being used, it is possible to identify and prevent most of the web application attacks such as SQLi (SQL injection), XSS (Cross Site Scripting), directory traversal etc. OWASP top 10 is ideal place to look for additional information about possible and mostly exploited web application vulnerabilities.

Zone 2 is the zone where web application based honeytokens [3] should be implemented. In this zone it is possible to identify and automatically react against any web application based attack.

Zone 1 and 3 are used to implement file system and database [4] based honeytokens. This is used in case zone 0 and zone 2 are compromised. If the zone 2 has been penetrated, it means that the web application is compromised and collecting as much data about the attacker as possible is mandatory in order to be able to conduct successful forensic investigation.

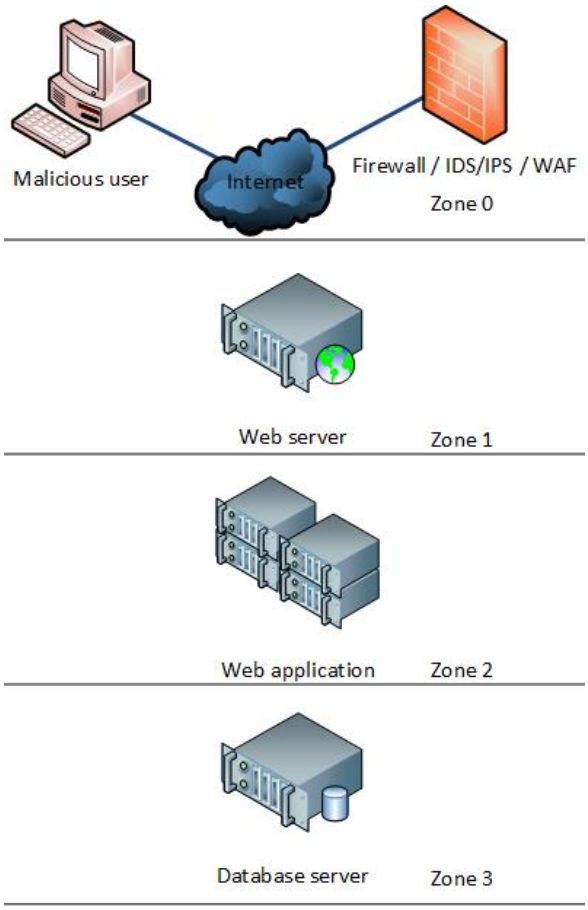

Figure 1: Conceptual honeytoken protection by layers

Logging and centralized log collection should be used in order to correlate the data, identify the attacker, to learn, to support computer forensic investigation, to be able to recognize attack vectors and trends, etc.

Let us define simple honeytoken parameter inside web application. For example, the following URL has one parameter called ID:

https://www.example.com/Site.aspx?ID=1

This link will return the data related to user with ID 1. In order to implement honeytoken value in the previously shown link, we should add additional parameter, and now the example could look like this:

https://www.example.com/Site.aspx?ID=1&Admin=false

Parameter "Admin" is honeytoken, with the value defined as "false". If the value is changed to "true" (or anything else) honeytoken event should be triggered inside the web application that will actively fight against the attacker by disconnecting user session, or allowing further access by placing the user session in the sandbox mode that will partially or fully change the results being sent to the user. This could allow for data collection that might be useful during the forensic investigation and it could be used to collect the crucial evidence that could be used to catch the perpetrator. It can also be used to change the firewall, IDS/IPS, and/or WAF settings in a fully automated manner.

III. HONEYTOKEN IMPLEMENTATION OPTIONS

There are many tools available for web application security scanning [5], and most of those tools (if not all) have spider functionality that is being used as the starting point in application parameter identification. Spider results are later used for vulnerability scanning and identification, by executing known exploits and vulnerability tests against every identified parameter in the application. As an example, SQLi , XSS, parameter tampering and modification, to mention only the few of the possible tests. Some of the tools have additionally modified spider that allows for so called forced browsing that will allow spider to identify existing files and folders even if they are not linked anywhere on any of the existing web pages. By using this functionality it is possible to identify application entry points usually hidden from the end user and one could easily go around the protection of this kind. One of possible options to prevent modified spider is to identify application entry points by using above mentioned functionality is to modify the application logic to response with 200 OK HTTP answer no matter if the web page exists or not. This will slow down the spidering process and it will prolong the process and reliability, thus making it both unreliable and incorrect. If the spidering process is unreliable and incorrect, the whole vulnerability assessment procedure is unreliable, thus it is unusable. As already mentioned, after spider process has identified all the entry points, the tool will try to find all the well-known vulnerabilities and/or ways to breach the system. This portion of the tool's logic could also be tampered

with in a way the results are inconclusive and incorrect, by modifying the application to respond with previously prefabricated answers when the application logic recognize the usage of spider. The proposed methods that could be used in order to actively fight against automated vulnerability scanning tools and hackers are:

Using honeytoken (canary [5]) parameters is one of the easiest way to implement above mentioned logic inside any web application with little or no effort. Developer has to implement parameters with sound and interesting names (in order to fool the hacker also), and those parameters are not supposed to be changed by the client. Should any of the honeytoken parameters be changed, the application logic has to assume that the parameter was modified by malicious user or scanning tool. If this is the case, application will enter highly secure mode that will actively fight against the attacker, no matter if the attacker is automated tool or hacker. The options application developer can use in order to implement this functionality are the following:

I. **Session termination.** This approach has its own advantages and disadvantages. The advantage is that the attacker session will be terminated and it will have to reestablish session again, and disadvantage is that by analyzing the packets that forced the system to terminate the session the attacker could easily identify honeytoken parameters and ignore them during the rest of the scanning or attacking procedures.

II. **Session isolation with 200 OK answers for every possible request.** This method is fairly successful, and it could be easily identified by the attacker if the answer for nonexistent pages is always the same, and it could be much more resilient to detection if the answers are tailored and modified with every single response. The problem is that when the hacker or the tool recognize this pattern it will realize that it is being fooled and in the long run this is just a partial solution to the problem.

III. **Session isolation with 200 OK answers for randomly chosen client requests.** This method is almost the same as the previous one, but in log run it could be more effective, because it will be much more difficult to identify that the server side is fabricating false web pages. Especially if the fabricated results are from prepopulated dictionary that make sense, So it will never respond with the 200 OK for request like this one: http://domain/This_app_does_not_exist_no_way.aspx, and it will respond to the request like this one: http://domain/AdminPage.aspx.

IV. **Session continuation in isolated (sandbox) mode.** This is the option when application does not offer real functionality anymore and attacker will receive preconfigured or dynamically generated fake pages. This could prove to be the most effective way but the problem is that it requires large amount of prefabricated fake results that could prove to be hard to implement.

V. **Throttling the connection between the identified attacker and the server.** Maybe the easiest protection to implement. The attacker will be slowed down to the point when the application will be unusable, thus, it could prove to be the easier and most effective protection that could be implemented. The consequence is: the attacker will need much more time than usual to finish the job and the administrators on the other side will have more time to identify and prevent the attacker.

VI. **Responding with timeouts.** This option is special case of previously explained throttling method, and it could be used as an add-on to this method or as a standalone protection, that will sporadically send timeouts to the hacker, preventing him from finishing the scan, attack, or whatever he is trying to accomplish.

Storing honeytoken values inside databases is method that is being used in order to identify web application protection method breach. Should this happen the decision has to be made in the application whether to terminate the session and prevent further data leakage, or continue the session in order to be able to identify who the attacker is. In order to use this type of honeytokens, the system has to be equipped with the SIEM or centralized log management system that will be utilized in the detection and alarming process.

Storing honeytoken values on the file system. This is the method similar to the one explained before, with the only difference being that the honeytoken is the file on the file system instead a value inside the database table.

Using intentionally generated vulnerabilities. This method is using prefabricated vulnerabilities that will show as the real vulnerabilities (SQLi, XSS …), but they will be isolated and contained. For example, the attacker and/or automated tool will identify this fake vulnerability, and it will try to exploit it further. This could be used to "keep the attacker happy" by giving him fake vulnerabilities, and it could give the system administrator enough time to isolate the attacker and contain his traffic.

Robots.txt entries could also be used as honeytokens. Robots.txt is file used in the root of the website that will inform spiders what should and what should not be indexed. By storing honeytokens (links to the nonexistent web pages) in robots.txt, one could easily isolate misbehaved spiders should the honeytoken link marked in robots.txt as "do not index" be touched by the spider. In this case, the honeytoken is the link itself, because well behaved spiders will obey the entries in the robots.txt, while misbehaved will not.

Active attacks against the attacker. If the attacked web application owner wants to actively fight against the attacker and attack the attacker, this is the option that could be used in order to identify the attacker's real IP address (if the address is masked or hidden by using proxy or proxy chaining software). In order to attack the attacker, web site owner could use XSS vulnerability that will trigger the request from attacker's computer via

direct communication channel, thus circumventing the protection the attacker is using in order to prevent the IP address identification. Of course, the same method could be used to steal the attacker's cookies, hijack his mail account etc.

Above mentioned methods should actively prevent an attack that is utilizing automated tools and/or being additionally watched by malicious users. On a first sight it looks that the database and file system honeytokens are not needed because everything should be stopped on the application layer but the point is that the application layer could always have a vulnerability, even the protection itself, so one have to implement as much of methods as possible in order to be as secure as possible. All the methods provide the administrator, developer, security personnel and others with comprehensive and complete insight into attack itself, methods and techniques being used and it allows for active countermeasures implementation that could be automatically embedded into application or that could be manually started after the attack has been identified.

IV. LOGGING AND REPORTING

In order to be able to identify and prevent the attacker from further attacks it is imperative to have active and correctly configured centralized log management system[7]. This system could be SIEM or "normal" centralized log management with custom made dashboards that will graphically present the active attacks, types of the attacks, attacker's IP addresses, etc. Some additional functionality could be added, like geolocation, routing information, amount of traffic generated, etc. There are many free and commercial tools that could provide some of this functionality out of the box, but usually none of the tool will be able to provide all of the required information without fine-tuning and additional modifications. The most important portion is that all the logs of interest have to be collected and visualized with the tool. Just to mention some of the logs of interest: Operating system logs, Web server logs, Web application logs, database logs, etc.

V. IMPLEMENTATION EXAMPLE

The excerpts of code written as a PoC (Proof of Concept) and as an example how a developer could implement above mentioned protection is written in ASP.NET. Basic ASP.NET knowledge is required to understand this code, though on the conceptual level familiarity with any programing language should be enough. The code presented here is not self-contained protection, it's just an example of where and how the protection could be implemented. In order to track the user sessions the PoC code is using Global.asax file and session_start and session_end functions. "Global.asax file is an optional file that contains code for responding to application-level events raised by ASP.NET or by Http modules" [6]. When new session starts it will be added to a session pool and this is the way of tracking the unique users. When session ends it will be deleted from the sessions pool. Example code of session start follows:

```
protected void Session_Start(object sender,
EventArgs e)
        {
            if
(!Sessions.ContainsKey(HttpContext.Current.Session.S
essionID))
            {

Sessions.Add(HttpContext.Current.Session.SessionID,
new SessionInfo());
                }
```

SessionInfo() contains all relevant and interesting information related to the session, like, whether this user is identified as an attacker, user IP address, UserAgent, Hacking type recognized etc. Anything could be added to this portion of code. This code will create a session, or identify the request with existing session making the user tracking possible. The example function follows:

```
    public SessionInfo()
        {
            //defaults
            IsHacker = false;
            SessionCreated = DateTime.UtcNow;
            LastRequest = DateTime.UtcNow;
            IP = "";
            UserAgent = "";
            RawURL = "";
            HackingType = "Peace"; // Peace - no
attack, CPT - canary Parameter tampering, COSFS - OS
canary tampering, DB canary tampering, SQLI - SQLi,
XSS - XSS//
        }
        public bool IsHacker { get; set; }
        public string Username { get; set; }
        public DateTime SessionCreated { get; set; }
        public DateTime LastRequest { get; set; }
        public string IP { get; set; }
        public string UserAgent { get; set; }
         public string RawURL { get; set; }
        public string HackingType { get; set; }

      }
```

This function is populating variables with the data relevant to the session, like user data, IP address etc.

Function that might be used to recognize hacker by using parameter based honeytoken could look like this one:

```
protected void Page_Load(object sender, EventArgs e)
        {
            if (Request.Params.Keys[1] == "admin")
            {
                if (Request.Params[1] != "false")
                {
Global.Sessions[Session.SessionID].IsHacker = true;

Helpers.MyFunctions.WriteInTheLog(Global.Sessions[Se
ssion.SessionID].Username, Session.SessionID,
Global.Sessions[Session.SessionID].IsHacker,
Global.Sessions[Session.SessionID].IP,
Global.Sessions[Session.SessionID].UserAgent,
Global.Sessions[Session.SessionID].RawURL,
Global.Sessions[Session.SessionID].HackingType);
                    Panel2.Visible = true;
                    Panel1.Visible = false;
                }
              }
```

So, if the parameter admin was tempered with, the user session is identified as malicious one and it will be dealt with appropriately. In this particular example it will only

write the data in the log for later audit, or for direct audit by SIEM, or centralized log management system solution. It could also break the session, isolate the user in specially written sandbox, etc.

An example of function that will write data to the log file could look like this one:

```
public static void WriteInTheLog(string user, string
sessionID, bool Hacker, string IP, string UserAgent,
string RawURL, string HackingType)
        {
            StreamWriter sw = new
StreamWriter("log.txt", true);

sw.WriteLine(DateTime.Now.ToShortDateString().ToStri
ng() + " " +
DateTime.Now.ToLongTimeString().ToString() + " " +
user + " " + sessionID + " " + Hacker + "  " + IP +
" " + UserAgent + " " + RawURL + " " + HackingType);
            sw.Flush();
            sw.Close();
            return;
          }
```

It is not possible to provide the entire code listing in this paper, but the point is that by using few simple functions like the ones shown above, one can start to implement proposed protections.

VI. Conclusion

The future of Internet security is in the hands of developers and security researchers that will add on the security in general, thus raising the bar or preventing the malicious users from compromising the remote systems. It has to be clear to every party included in the web application development that web application will always be vulnerable to some kind of vulnerability, and that the implemented protection could have vulnerabilities of their own. Knowing that should be enough to write the web applications in more responsible way that will make them less exposed to the attackers.

Proposed honeytoken implementation could be used as an additional protection against the above mentioned threats together with firewalls, web application firewalls and various filtering platforms, raising the bar and making it more resilient to intrusions. By using the proposed solution, one could identify, contain and deflect the automated tools and hackers more efficiently than by using the traditional approach only (firewall/IDS/WAF). This is because firewall will not be able to prevent parameter tampering and to recognize the important parts of the application one wants to protect. The same issue is with IDS/IPS, which has to be reconfigured with every new version of application in order to be able to identify what's important. With WAF, which is capable of recognizing variety tampering attacks, there is always an issue of going around the WAF protection itself. The proposed solution will implement the honeytokens inside the application logic, thus making the application resilient no matter if the other protections are implemented or not. Of course, this does not mean that all the other protections are not necessary anymore, it is additional protection with one simple task – to make the web application more resilient to the hacking attempts.

POLICY AND RISK TRACK

Artificial Intelligence in Network Intrusion Detection

M. Stampar* and K. Fertalj**

** Faculty of Electrical Engineering and Computing, Zagreb, Croatia
mstampar@zsis.hr, kresimir.fertalj@fer.hr

Abstract – In past, detection of network attacks has been almost solely done by human operators. They anticipated network anomalies in front of consoles, where based on their expert knowledge applied necessary security measures. With the exponential growth of network bandwidth, this task slowly demanded substantial improvements in both speed and accuracy. One proposed way how to achieve this is the usage of artificial intelligence (AI), progressive and promising computer science branch, particularly one of its sub-fields – machine learning (ML) – where main idea is learning from data. In this paper authors will try to give a general overview of AI algorithms, with main focus on their usage for network intrusion detection.

I. INTRODUCTION

Today, lack of network access is unthinkable in both business and personal life. With unrestrained and ever-increasing number of electronic devices connected to the Internet, attackers never had such large attack surface. This brings up the question how to successfully defend from both known and unknown dangers. The answer is not so straightforward, especially having in mind that the number of threats is rising every year [1].

Valuable resources having network access should be permanently protected from all attempts to destroy, expose, alter, disable, steal or gain unauthorized access and/or usage. Resources' confidentiality, integrity and availability have to remain intact. Intrusion detection system (IDS) is a system specially designed to detect such malicious attempts.

As traditional IDS's are mainly signature-based, detecting only known attacks, their biggest problem is the inability to detect new or variant attacks [2]. One topic that intuitively stands out as a potential solution for solving this problem is ML, a type of AI that provides computer the ability to learn without being explicitly programmed for particular purpose.

The rest of this paper is organized as follows. In Section 2, we discuss the basic concepts of AI and ML. In Section 3, we discuss the basic concepts of intrusion detection. In Section 4, we thoroughly discuss the usage of AI for network intrusion detection, including the brief overview of most popular AI algorithms and mutual comparisons found in literature. In Section 5, we present results for conducted research of topic related literature trends, while in Section 6 we offer concluding remarks.

II. ARTIFICIAL INTELLIGENCE

AI is by definition the study of mental faculties through the use of computational models [3]. Main fields of AI research include reasoning, knowledge representation, automated planning and scheduling, ML, natural language processing, computer vision, robotics and general intelligence (strong AI). This paper is mainly focused on ML as it seems to be the most promising AI sub-field for intrusion detection task. Nevertheless, other non-ML methods will be mentioned too.

ML deals with the construction and study of algorithms that can generalize (i.e. learn) from limited sets of data. Such algorithms operate by building models based on input and using those models to make predictions or decisions, rather than following only explicitly programmed instructions. Having such characteristics makes them ideal candidates for intrusion detection tasks.

There are three common problems that ML tries to solve: classification, regression and clustering. Classification means identifying group membership, regression involves estimating or predicting a response, while in clustering a set of inputs is divided into groups, where members have similar characteristics. Depending on output, if the output variable takes class labels, we are talking about classification, if the output variable takes continuous numerical values, we are talking about regression, while if the output values are subsets (i.e. *clusters*) we are talking about clustering. Thus regression is applicable for prediction type of problems as opposed to classification and clustering.

Depending on ways of learning, ML can be further split into three main categories: supervised, unsupervised and reinforcement learning. Supervised learning is commonly used in classification problems where the goal is to get the computer to learn a classification system that we have created. Unsupervised learning seems much harder. The goal is to have the computer learn how to do something that we do not explicitly tell it how to do. It is a powerful tool for identifying structure in unlabeled data, reflecting the statistical properties of the overall collection of input patterns. Reinforcement learning is performed by interacting with an environment, where learning agent learns from the consequences of its actions through trial and error, rather than from being explicitly taught.

There is no single AI algorithm achieving best accuracy for all situations. Hence, one way to improve

results is the usage of combined multiple algorithms to obtain better quality of reasoning than from any single one. There are generally two approaches: ensemble and hybrid. In case of ensemble classifiers, multiple but homogeneous weak models are combined, typically at the level of their individual output, using various merging algorithms (e.g. majority voting) [4]. Hybrid algorithms, in turn, combine completely different, heterogeneous AI approaches (e.g. through cascading).

III. INTRUSION DETECTION

Intrusion detection can be defined as the act of detecting actions that attempt to compromise the confidentiality, integrity or availability of a resource [5]. IDS is a device or software application that gathers and analyzes information from various areas within a computer or a network to identify possible security breaches, including data for both intrusion (i.e. attacks from outside the organization) and misuse (i.e. attacks from within the organization). IDS come in a variety of "flavors" and approach the goal of detecting suspicious behavior in different ways.

Based on a running location, IDS can be network-based (NIDS), inspecting network events at single collecting point, or host-based (HIDS), inspecting system events at individual device(s). NIDS is used to monitor and analyze network traffic, collected using a network tap, span port or hub, to protect a system from network-based threats. HIDS attempts to identify unauthorized, illicit, and anomalous behavior on a specific device. HIDS generally involves an agent installed on each system, monitoring and remotely alerting on local OS and application activity. In this paper we will mainly focus on NIDS systems.

Based on an underlying detection logic, IDS can be signature-based (misuse) or anomaly-based. A signature-based IDS monitors suspicious behavior and compare its characteristics against a database of signatures or attributes from known malicious threats. Main issue is the lag between a new threat and the signature for detecting that threat being applied to the IDS. During that lag period IDS is unable to detect the threat. An anomaly-based IDS monitors behavior and compares its characteristics against an established baseline. The baseline will identify what is "normal" for that subject and alert when anomalous behavior is detected, or significantly different than the baseline. Main issue is the higher false positive rate.

Based on how it reacts to a detected threat, IDS can be passive or reactive. Passive IDS simply detects and alerts, leaving decision to administrator to take action and block the activity or respond in some way. Reactive IDS, also known as intrusion prevention system (IPS), will take predefined proactive actions to respond to the threat. Typically, this means blocking any further network traffic from the source IP address or user.

IV. USING ARTIFICIAL INTELLIGENCE FOR NETWORK INTRUSION DETECTION

A. Datasets

The Cyber Systems and Technology Group (formerly the DARPA Intrusion Detection Evaluation Group) of MIT Lincoln Laboratory, under Defense Advanced Research Projects Agency (DARPA) and Air Force Research Laboratory (AFRL) sponsorship, has collected and distributed the first standard corpora for evaluation of NIDS's [6]. Such efforts have been carried out in both 1998 and 1999, resulting with DARPA 1998 and DARPA 1999 datasets respectively, with DARPA 1998 being more popular one.

KDD Cup is the annual Data Mining and Knowledge Discovery competition organized by ACM Special Interest Group on Knowledge Discovery and Data Mining. The task for the classifier learning contest organized in conjunction with the KDD'99 conference was to learn a predictive model (i.e. classifier) capable of distinguishing between legitimate and illegitimate connections in a computer network [7]. Dataset used during the competition was based on a DARPA 1998 dataset and has become widely accepted as just KDD'99.

Both DARPA and KDD datasets consist of nearly 5 million training connection records (i.e. events) labeled as an intrusion or not an intrusion, and separate testing dataset consisting of seen and unseen attacks. Each connection record consists of 41 different attributes that describe the different features of the corresponding connection, categorized as follows: basic TCP features, content features, time-based traffic features and host-based features. All the forms of attack fell into one of three categories: Remote-to-Local (R2L), User-to-Root (U2R), Denial-of-Service (DOS) or Probing [8].

As already mentioned, KDD'99 is based on the DARPA 1998, which by itself has been strongly criticized by McHugh [9], mainly because of having the characteristics of the synthetic data. As result, some of the existing problems in DARPA 1998 remain in KDD'99 too.

Currently, as there are only few public datasets like DARPA 1998 and KDD'99, much related work considers these for their experiments, while very few studies use non-public or their own datasets. From literature overview results by Tsai et al. [10] it can be concluded that those two datasets are recognized as de-facto standards in intrusion detection field of study.

B. Evaluation

While evaluating IDS, for every possible test value there are two kinds of error: false positive (FP) and false negative (FN). FP occurs when an event is predicted as intrusive but it is in fact normal, while FN occurs when a truly intrusive event occurs without being recognized as one. In the other hand, true positive (TP) measures the proportion of actual positives which are correctly identified as such, while true negative (TN) measures the proportion of negatives which are correctly identified as such. The performance of each classifier can be quantified using the detection rate (DR) and overall accuracy (OA) measures. DR shows the percentage of the true intrusions that have been successfully detected:

$$DR = \frac{TP}{TP + FN} \times 100\% \quad (1)$$

OA is calculated as the total number of correctly classified intrusions divided by the total number of observations:

$$OA = \frac{TP + TN}{TP + TN + FP + FN} \times 100\,\% \tag{2}$$

Efficient IDS necessitates high degree of DR and OA, while maintaining low false alarm rates. Accuracy is critical to develop effective IDS, since high FP rate or low DR will make it practically unusable.

C. Neural network

When used without qualification, the terms "neural network" (NN) and "artificial neural network" (ANN) usually refer to a multilayer perceptron (MLP). MLP is a supervised learning algorithm based on the feed-forward neural network with one or more layers between input and output layer. Feed-forward means that data flows in one direction from input to the output layer (i.e. forward). This type of network is trained with the error back-propagation learning algorithm. The true power and advantage of MLP lies in its ability to represent both linear and non-linear relationships and in its ability to learn these relationships directly from the data being modeled. Traditional linear models are simply inadequate when it comes to modeling data that contains non-linear characteristics [11].

Ghosh et al. [12] used MLP for anomaly detection, where the proposed model is a single hidden layer neural network. The performance of this model tested on the DARPA 1998 dataset was a DR of 77% with 2.2% FP. Lippmann et al. [13] used selected generic keywords to detect the attack preparations and actions after the break-in. Results were used to train the MLP using back-propagation algorithm. This approach ensured a DR of 80% when it has been tested on the DARPA 1998 dataset. Debar et al. [14] stated that NNs are very slow in converging, they suffer from dimensioning and stability problems, training takes a lot of time to achieve a reasonable level of performance, and their adaptability is low because a partial retraining can lead to a network that forgets everything it has learned before.

D. Genetic algorithm

Genetic algorithm (GA) is a search algorithm that works similar to the process of natural selection. It begins with a sample set of potential solutions which then evolves toward a set of better solutions. The algorithm repeatedly modifies a population of individual solutions. At each step, the genetic algorithm randomly selects individuals from the current population and uses them as parents to produce the children for the next generation. Over successive generations, the population "evolves" toward an optimal solution. Within the sample set, solutions that are poor tend to die out while better solutions mate and propagate their advantageous traits, thus introducing more solutions into the set that boast greater potential (the total set size remains constant; for each new solution added, an old one is removed). A little random mutation helps guarantee that a set won't stagnate and simply fill up with numerous copies of the same solution.

Li [15] proposed IDS with 57 genes in chromosomes, where each gene represents single connection feature, like: source IP address, destination IP address, source port, destination port, duration, protocol, number of bytes sent by originator, number of bytes sent by responder, etc. Due to the effectiveness of the evaluation function, the succeeding populations are biased toward rules that match intrusive connection. Mukkamala et al. [16] achieved 97.04% OA on DARPA 1998 dataset for their implementation of IDS based on linear genetic programming (LGP). However, Teodoro et al. [17] concluded that main disadvantage of this kind of IDS is the high resource consumption involved.

E. Fuzzy logic

Fuzzy logic (FL) is a form of many-valued logic where one deals with reasoning that is approximate rather than fixed and exact. Compared to traditional binary sets where variables may take on true or false values, FL variables may have a truth value that ranges in degree between 0 and 1. FL proponents claim this generality allows greater flexibility, freedom, accuracy and compactness when representing real world situations. All the usual properties of Boolean algebra can be extended to FL, and probability's degree of belief in a Boolean variable becomes a fuzzy variable's degree of truth. It provides a principled way to encode expert knowledge or heuristics into algorithms that mimic a human's approach to solving challenging problems by weighing different sources of information and making judgments based on a preponderance of the evidence [18].

Chimphlee et al. [19] proposed IDS based on rough sets theory and fuzzy c-means. Proposed system achieved a total of 93.45% OA on KDD'99 dataset, while reduced number of features resulted with enhanced performance. Dickerson et al. [20] developed FIRE IDS which uses simple data mining techniques to process the network input data and expose metrics that are particularly significant to anomaly detection. These metrics are then evaluated as fuzzy set for every observed feature and later used to detect network attacks.

F. K-nearest neighbors

K-nearest neighbors (kNN) is one of the most simple and traditional non-parametric supervised learning algorithms. It stores all available cases and classifies new ones based on a similarity measure (e.g. distance function) calculated between feature vectors. Classification is made by a majority vote of object's k nearest neighbors, where k is typically chosen to be a small positive integer (e.g. 3). For example, if k is chosen to have a value 1, then object is assigned to the class of its nearest neighbor. It has to be noted that if k is chosen to be considerably large, it will result with greater classification time.

Ma et al. [21] proposed kNN IDS based on similarity as a quantitative measure for distance and achieved DR of 90.28% (k=1) on KDD'99 dataset. Liao et al. [22] achieved DR of 91.70% (k=5) on DARPA 1998 dataset with their implementation of IDS based on kNN. They

also concluded that kNN works well in dynamic environments where frequent updates of the training data are required, which makes it attractive for intrusion detection tasks.

G. Naive Bayes

Naive Bayes (NB) is a supervised learning algorithm based on Bayesian theorem with the "naive" assumption of independence between every pair of features. Classification is made by combining prior probabilities and likelihood, to form a posterior probability using the so-called Bayes' rule. Despite its simplicity, NB can often outperform more sophisticated classification algorithms in both speed and accuracy [23]. Also, they are particularly suited when dimensionality of the input is high [24].

Panda et al. [25] proposed NB based IDS and achieved OA of 94.90% on KDD'99 dataset. Amor et al. [26] made a similar proposition and achieved 91.52% OA.

H. Decision tree

Decision tree (DT) is a supervised learning algorithm based on flowchart-like structure in which internal node represents a "test" on an attribute (e.g. whether a coin flip comes up heads or tails), each branch represents the outcome of the test and each leaf node represents a class label. Decision is taken after computing all attributes. The paths from root to leaf represent classification rules. The goal is to create a model that predicts the value of a target variable by learning simple decision rules inferred from the data features (i.e. attribute). DT is simple to understand and to visualize, making its explanation for the resulting value easily explainable by Boolean logic.

Abbes et al. [27] compared DR of rule-based Snort and IDS based on DT on a custom dataset based on collected RPC protocol traffic. Snort detected only three, while proposed IDS detected all 46 different forms of attacks. Bouzida et al. [28] made comparison of DT with and without principal component analysis (PCA), a mathematical procedure that transforms a number of (possibly) correlated variables into a (smaller) number of uncorrelated variables called principal components. They reduced computation time on dataset KDD'99 by a factor of approximately thirty, with slight loss of OA from 92.60% to 92.05%.

I. Support vector machine

Support vector machine (SVM) is a supervised learning algorithm based on concept of decision planes that define decision boundaries. An SVM constructs the hyperplane, or a set of hyperplanes in a high-dimensional space, that separates all data points of one class from those of the other class. The best hyperplane for an SVM is the one with the largest margin between the two classes. It often happens that classes can't be linearly separated. For this reason, the original finite-dimensional space can be mapped into a much higher-dimensional space, using what is called the "kernel trick", presumably making the separation easier [29].

Laskov et al. [30] concluded that the best performance is achieved by the non-linear methods, such as SVM, MLP and rule-based methods. Khan et al. [31] presented results where their solution, utilizing dynamically growing self-organizing tree (DGSOT), enhanced the training time of SVM on DARPA 1998 dataset from 17.34h to 13.18h and improved OA from 57.6% to 69.8%. Chen et al. [32] achieved OA of 86.79% on KDD'99 dataset by using rough set theory (RST) to preprocess data and reduce the number of dimensions before forwarding it to SVM for intrusion detection. Mulay et al. [33] concluded that the integration of DT and SVM model gives better results than the individual models.

J. Random forest

Random forest (RF) is a supervised learning algorithm that is based on a collection (ensemble) of tree predictors, rather than a single classification tree, where to grow each tree a random selection is made from the examples in the training set. Each tree gives a classification and we say that the tree "votes" for that class. The forest chooses the classification having the most votes (over all the trees in the forest), with basic principle that a group of "weak learners" can come together to form a "strong learner".

Kim et al. [34] concluded that their approach based on RF has been able not only to show high DR, but also to figure out stable output of important features simultaneously. Also, they stated that performance of RF based IDS turns out to be comparable to that of SVM. Zhang et al. [35] achieved average DR of 92.58% on original KDD'99 dataset and 99.86% on balanced dataset, where minority classes have been over-sampled and majority classes down-sampled to increase the DR of minority intrusions.

K. Self-organizing map

Kohonen's self-organizing map (SOM) is an unsupervised learning algorithm producing a low-dimensional (typically two-dimensional), discretized representation of the training samples' input space, simply called a map. It consists of components called nodes or neurons. Each node is associated with a weight vector of the same dimension as the input data vectors and a position in the map space. Nodes in a 2-D layer learn to represent different regions of the input space where input vectors occur. In addition, neighboring neurons learn to respond to similar inputs, thus the layer learns the topology of the presented input space. They provide a way of representing multidimensional data in much lower dimensional spaces, where this process of reducing the dimensionality of vectors is essentially a data compression technique known as the vector quantization [36].

Srinivasan et al. [37] proposed an agent-based SOM IDS called SAPID, designed especially for wireless networks. They achieved an average DR of 97% on an undeclared dataset. Lichodzijewski et al. [38] achieved DR of 94% on DARPA 1998 dataset with conclusion that hierarchically built unsupervised neural network approach is able to produce encouraging results. Rhodes et al. [39] analyzed SOM's potential for intrusion detection. Their experiments shown that even single SOM, when trained on normal data, will detect anomalous behaviors. Also, the ratio by which normal and intrusive packets differed has been greater than an order of magnitude. Their conclusion was that IDS based on SOM should be particularly

powerful because it never needs to be told what intrusive behavior looks like.

L. *Comparisons*

Li et al. [40] compared SVM, NN and kNN based IDS, where SVM had best, while kNN had worst OA on KDD'99 dataset. Chen et al. [41] compared SVM and NN based IDS and concluded that SVM performance is superior to that of NN. Bouzida et al. [42] concluded that while NN is very interesting for generalization and poor for detection of new attacks, DT has proven efficiency in both generalization and new attacks detection.

Amor et al. [43] conducted an empirical investigation on the KDD'99 dataset, comparing NB and DT based IDS's. IDS based on DT obtained a higher OA, while IDS based on NB obtained better DR. Peddabachigari et al. [44] conducted similar study for SVM and DT. IDS based on DT gave better results for both OA and performance.

Wang et al. [45] compared DT, NB and NN based IDS. While OA has been similar for all three cases, with DT having slightly better results, training time of NN based IDS has been by far the worst (couple of orders of magnitude). Chen et al. [46] compared SVM and RF based IDS and concluded that IDS based on RF has better both OA and DR, with slightly worse training time and by far better performance From results presented by Sindhu et al. [47] it can be concluded that NB and DT (having similar values) outperform RF in both DR and OA.

V. LITERATURE TRENDS

For literature trends overview purposes quantitative analysis was done in form of scientific publication search for topic related terms. Each chosen term was inquired in combination with term "intrusion detection" to narrow down results to only the respective field. Google Scholar was used to perform searches through scientific literature, mainly because of its simplicity and openness. Total number of publications (excluding citations and patents) was recorded depending on different search objectives. Main goal of presented results is the outline of current trends provided in a comprehensible format.

In Fig. 1 trends for terms "artificial intelligence" and "machine learning" are shown for period 2010-2014 in form of a number of intrusion detection related publications for each particular year. From given results it is visible that the usage of AI, and ML as its most prominent sub-field, has an increasing tendency. Greater values for ML can be explained by lack of references to

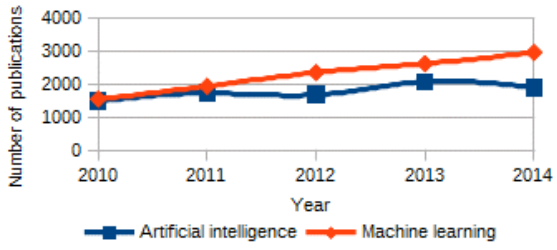

Figure 1. Intrusion detection trends for AI and ML

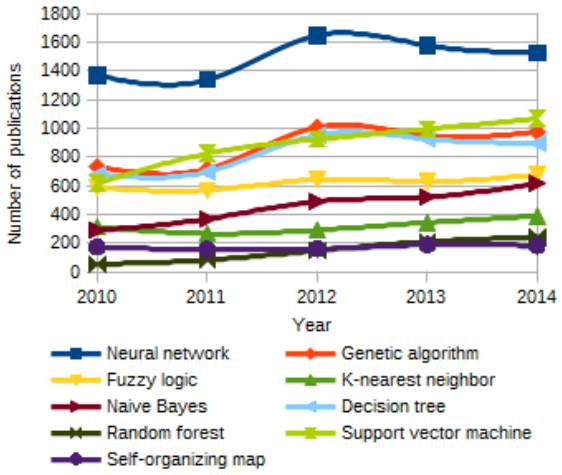

Figure 2. Intrusion detection trends for different AI algorithms

AI in related studies.

In Fig. 2 trends for different AI algorithms are shown for period 2010-2014. It is clear that NN is the most popular AI algorithm used for intrusion detection compared to other algorithms, but with slight decrease in popularity over the last couple of years. Then there are GA and SVM, where SVM is constantly increasing in popularity. Out of the rest, SOM seems to be the least popular, which could be explained by the lack of an intuitive approach to solution of intrusion detection problem. It is clear from observed trends that AI composes a significant part of the intrusion detection study, becoming more and more popular tool of choice.

VI. CONCLUSION

As faster and more effective countermeasures are required to cope with the ever-growing number of network attacks, AI comes as a natural solution to the problem. This paper, albeit briefly, discusses the foundations of AI in intrusion detection field. Most popular AI algorithms are presented along with the review of related studies, showing the maturity of the subject.

From comparisons found in related scientific literature it can be concluded that IDS's based on NB and DT seem to be the most promising, having best overall results for both accuracy and performance when compared to other single-classifier solutions. From presented results for conducted quantitative analysis of scientific literature it can be concluded that AI plays a significant role in the intrusion detection field of study, with NN being most extensively researched.

Further research in this field is necessary as there are very promising results that are obtainable from related algorithms, especially in the area of their combined usage.

Advanced Persistent Threats – Detection and Defense

J. Vukalović, D. Delija
INsig2 Ltd., Buzinska cesta 58, 10010 Zagreb, Croatia
jakob.vukalovic@insig2.eu, damir.delija@insig2.eu

***Abstract* – The term "Advanced Persistent Threat" refers to a well-organized, malicious group of people who launch stealthy attacks against computer systems of specific targets, such as governments, companies or military. The attacks themselves are long-lasting, difficult to expose and often use very advanced hacking techniques. Since they are advanced in nature, prolonged and persistent, the organizations behind them have to possess a high level of knowledge, advanced tools and competent personnel to execute them. The attacks are usually preformed in several phases – reconnaissance, preparation, execution, gaining access, information gathering and connection maintenance. In each of the phases attacks can be detected with different probabilities. There are several ways to increase the level of security of an organization in order to counter these incidents. First and foremost, it is necessary to educate users and system administrators on different attack vectors and provide them with knowledge and protection so that the attacks are unsuccessful. Second, implement strict security policies. That includes access control and restrictions (to information or network), protecting information by encrypting it and installing latest security upgrades. Finally, it is possible to use software IDS tools to detect such anomalies (e.g. Snort, OSSEC, Sguil).**

I. INTRODUCTION

One of the main challenges in information security today is a new type of threat that has become a significant concern for various organizations. Organizations now face advanced groups of attackers who are determined to gain access to their resources. They are not just opportunistic criminals. Instead, they are well organized and possess enough resources to launch prolonged and sophisticated attacks. That is how they got the name – *Advanced Persistent Threat* (APT).

Over the last few years, there has been a significant increase in the amount of APT attacks. FireEye, a US based network security company detected 4,192 attacks associated with APT groups during 2013 [1]. That amounts to 11.48 unique daily attacks. FireEye also reports that APT groups caused 17,995 unique malware infections. Command and control servers that APT groups use to coordinate attacks have been found in 206 countries, most of them in the USA, Germany, South Korea and China. During 2013, they have produced over 22 million control messages. Most often, APT groups target organizations in the USA, South Korea and Canada. Most of these organizations belong to education, finance, government or high technology sector [2].

Exploitation of zero-day vulnerabilities in APT attacks is particularly worrying. During 2013, FireEye reported 11 attacks of that type. Most exploited were Java's zero-day vulnerabilities, followed by Internet browsers and Adobe Reader.

APT attacks cause damage to business operations of organizations affected by them. A study [3] conducted by Ponemon Institute shows that victims of APT attack are most likely to experience downtime of information technologies, loss of sensitive information, and disruption of business processes. Even though all these events cause significant losses, the worst and most expensive consequence is damage to brand and reputation. Ponemon Institute's research shows that, on average, damages to organization's reputation caused by APT attacks amount to $9.4 million.

APT attacks often remain undetected for a long period of time. Some of them, however, gained media recognition. For example, operation Aurora that resulted in loss of Google's intellectual property in 2009, or Stuxnet, a worm discovered in 2010 that infected uranium enrichment plants in Iran.

APTs bring changes in attack methodology. New attack methodologies mandate that organizations change their approach to information security. While there is no such thing as a completely secure system, it is possible to establish countermeasures that will greatly reduce the risk of falling victim to APT attacks.

This paper explains the nature of APTs and provides an overview of appropriate methods of countering attacks. The second chapter gives an overview of APTs, a definition and description of the term, their lifecycle, mode of operation and tools they use to exploit weaknesses in information systems. The third chapter lists some characteristic detection points for APT attacks, particularly outgoing traffic. It also contains a summary of tools that can be used for purposes of detection. The fourth chapter lists basic countermeasures in order to establish proactive defense in an organization.

II. ADVANCED PERSISTENT THREAT

A. What are APTs?

The term *Advanced Persistent Threat* refers to a well-coordinated group of people (typically controlled by an organized entity such as a government, terrorist group, corporate entity or other) with malicious intent that targets

a specific organization, government or company. APTs perform persistent prolonged attacks until they gain access to organization's computer systems, sensitive data or other resources. Individual hackers and opportunistic criminals are not APTs. They either do not possess the resources or abilities to execute complex and prolonged attacks, are rarely well organized, or they are not targeted. Traditional hackers attack for financial gain, because of social and economic issues, or just for fun and to gain recognition. APTs, however, have a very specific target. They are after the target's intellectual property, and they do not just try several methods to get access and then stop trying if they are unsuccessful, but attack continuously. If they are unsuccessful on the first few attempts, they will keep trying until they find a way to compromise the organization.

A description of an advanced persistent threat can be inferred from its name. Traditional attacks lack one or more of these characteristics.

Advanced – the attacks are coordinated by a group of people that possess advanced resources and knowledge, and are often well funded. The attacks themselves do not necessarily have to be highly sophisticated for the breach to be successful. Attackers often use phishing and widely available tools for malware creation [4] [5]. However, if needed, they can also develop their own tools to target specific vulnerabilities (such as zero-day exploits), and use multiple types of attacks in order to breach the target. Therefore, the term *advanced* refers to attackers' capabilities and knowledge which makes it different from traditional attacks.

Persistent – the attackers persist, they repeatedly try to compromise the victim's systems until they gain access to their resources. Then, the attacker maintains access. They create backdoors and, when one connection is severed, another one can be opened and used to continue extracting sensitive information. If the attacker loses access to the victim's system, he will repeat the whole process until he reestablishes access.

Threat – a threat is a possible source of harm or danger. Since APTs possess both the intention and the means to harm their targets, and are not just automated pieces of software, they present a threat.

APTs have a very specific target, and their main objective is to maintain **prolonged access to the target's intellectual property**, sensitive information, or otherwise interesting data that is useful to the attacker. To achieve that, the attack needs to remain concealed.

Even though APT most often attacks target computer systems, attackers can also use other, more traditional and simpler attack methods, such as social engineering or intercepting phone calls. APTs also perform attacks in order to acquire data that may help them execute more attacks in the future.

B. Life Cycle of APT Attacks

APT attacks are complex and consist of several stages. Each step of an attack is carefully adapted to attack the specific victim's vulnerabilities. Although these steps are not a rule, but a general scheme of an APT attack, their existence is vital in maintaining stealthiness and prolonged access to sensitive information, and it is expected in most attacks (**Error! Reference source not found.**).

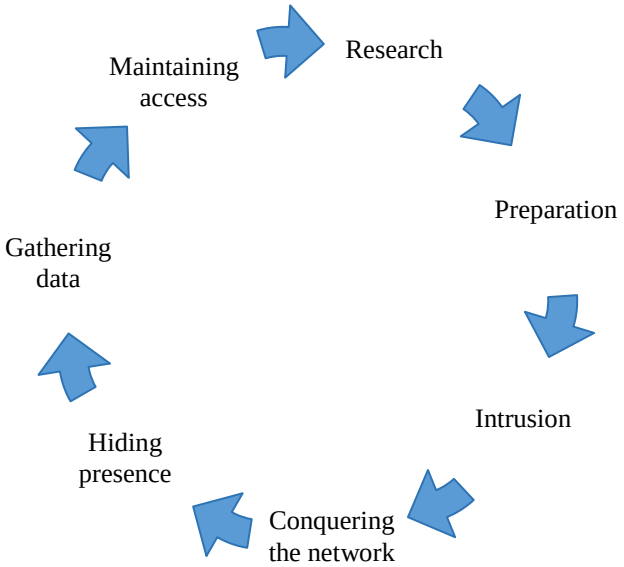

Figure 1 Life cycle of an APT attack

1. **Research.** The attackers gather information about the victim, trying to find weak points to exploit. The information that attackers search for is often publicly available. The attackers research employees' social network profiles and personal information, organization's website, technologies, communications, hierarchy, and premises. APTs differ from traditional attackers at this point. Since traditional attackers (individual hackers, *script kiddies*, inadequately organized hacking groups) do not target a specific organization, or at least do not do so persistently, over a prolonged period of time, they do not care if some of their attacks are unsuccessful, because they know there will be other, successful cases. APTs target a specific organization, therefore they must conduct extensive research if they want to find a vulnerability that can be exploited. Chances of a successful attack increase with the amount of information researched. The attackers will also search for individuals to be targeted (e.g. with phishing messages). At this phase, the attack is almost impossible to detect because it does not involve interaction with the organization's systems. Once the target has been identified, attacker moves on to the next phase.
2. **Preparation.** Using information they acquired in the first step, attackers prepare the attack. In this step they perform active extraction of specific information about the victim. They also prepare and test methods and tools that will be used to exploit found vulnerabilities. Activities in this step include scanning the network, ports, and running services, finding or creating customized malware that will exploit the victim's vulnerabilities, and planning malware

deployment (e.g. phishing messages, removable media). During this stage, APTs also have to prepare the infrastructure that will be used to manage and control attack flow. This includes taking control of servers to use as command and control centers, modifying DNS entries, creating fake domains and email accounts etc. At this phase, the probability of detecting the attack is very low. Once the attack methods and command-and-control infrastructure have been set up, the attacker proceeds to the next step.

3. **Intrusion.** Attackers launch first attacks. Most often, it is done using phishing email messages. These emails contain a message that will convince a gullible employee to open a document or a URL that contains malicious code. The attackers can impersonate a coworker, business partner, or any other person that the employee trusts. Assuming that the attacker gathered enough information in previous steps, and since people are typically the weakest link in the security chain, this approach is probably the easiest way to compromise an organization, and very likely to succeed. Other possible methods are exploiting vulnerabilities in organization's systems, including zero-day vulnerabilities, and spreading malware infections using removable media. Smartphones and tablet computers also present a security risk in this context. Since employees use their personal devices to connect to their workplace network, these devices can be used to spread malware in the organization's network. Absence of security policies and protocols increases the probability of success for this stage of attack. After the attack has been launched, the attacker monitors command and control infrastructure waiting for a sign of successful breach.

4. **Conquering the network.** If the attack has been successful, that means the attackers have gained access to one or more computers in the organization's network. If possible, they will try to obtain administrative (*root*) privileges on victims' systems. After initial breach, they install additional malware and create backdoors (e.g. remote administration tools – RAT) to act as a convenient way to remotely access and control the system. They also try to spread through the network identifying other machines susceptible to compromise, and trying to find valuable data that will be extracted. In this phase the attacker actively controls computers in the network, therefore the intrusion is easiest to detect. Some APTs also execute fake and easily detectable attacks against the organization in order to keep system administrators busy while the real attack takes place quietly.

5. **Hiding presence.** One of the main goals of the attack is to maintain prolonged access to organization's network and, consequently, their data. In order to avoid detection, APTs need to conceal their presence in the system. For traditional attackers this component is not crucial for the same reason it is not crucial for them to research their potential victims – even if they lose access to some of the machines they have infected, they can always find other vulnerable machines. For them, it is a numbers game. On the other hand, APTs have a specific target, which makes it harder to reestablish connection every time they are detected. Because of that, APTs install rootkits, modify event and audit log entries, periodically enter a sleeping state for some time, and delete traces of their own files on the system.

6. **Gathering data.** While exploring the organization's network, attacker searches for data of interest. When found, the data is gathered and, most often, encrypted to conceal its true identity on the way out of the network. Then, the data is masked to resemble legal traffic and slowly extracted from the organization's network. Using the command and control infrastructure that has been set up, it is then routed back to the attacker.

7. **Maintaining access.** In order to extract the maximum possible amount of data from the victim without getting caught, the attacker needs to maintain prolonged access to the victim's network. The attacker needs to make sure the backdoors are working as expected, the infected systems are accessible, and that command and control infrastructure is working, so he periodically checks their status. He could also update existing or install new malware in order to exploit other weaknesses or improve stealthiness, reconfigure the malware, and expand or reconfigure the command and control infrastructure. If, despite everything, the communication is severed, the attacker has to persist and go back to step 1.

C. Attack Toolbox

Attackers employ a variety of tools and methods when trying to access the organization's systems. One of most used techniques is **phishing**. It involves sending a specifically crafted message with an embedded malicious document or link to employees of an organization via email or social networks. In case of **spear phishing**, the attackers send such messages to specific people within an organization, after obtaining their personal information to increase the probability of success. Attackers also spread malware using **infected removable media**, or embedding it into **installation files** of popular programs. **Zero-day** vulnerabilities in commonly used programs or operating systems are targeted as well.

In the second phase, and while spreading through the network, attackers use **network scanning and enumeration tools** to discover computers and other devices connected to the network, their operating systems, open ports, running services and possible vulnerabilities.

When the system has been infiltrated, the attackers create **backdoors**. Backdoors enable the attacker to evade normal security controls and get remote access to the

system. They are created as modifications to the operating system, or they can be installed as a service. Attackers use **rootkits** to hide the presence of unwanted programs in the system. They also use **malware generators** to quickly and easily create customized malware.

In order to facilitate remote access to the machines, the attackers use **remote administration tools** (RATs). While such tools are often used in legal activities, they can also give the attacker complete control of infected systems.

APTs utilize **command and control infrastructure** to communicate with the infected machines, pass control messages, and extract data. Command and control servers are most typically infected servers under attacker's control. The communication is **encrypted** to make it harder to detect and block.

D. Notable Cases

1) Operation Aurora [6]

Operation Aurora was a sequence of multiple hacking attacks in 2009 that targeted Google, Adobe Systems, Rackspace, Juniper Networks and probably many others. The attacks originated from China, and exploited several zero-day vulnerabilities in Internet Explorer. Google's intellectual property was stolen. As a result, Google left the Chinese market.

2) Stuxnet [7]

Stuxnet is a worm, discovered in 2010, that infected industrial control systems, mostly in Iran. The worm propagated through infected USB thumb drives, exploited several zero-day vulnerabilities in Windows OS, and then corrupted PLC control software. The worm destroyed nuclear centrifuges in Iran's uranium enrichment facilities. It is speculated that creation of Stuxnet was a joint effort between Israel and the USA.

3) Operation Shady RAT [2]

A sequence of attacks that started in 2006 and continue to this day. McAfee, a cyber-security company, claims that the attacks targeted more than 70 organizations, most of them in the USA. The attacks utilize RATs and encrypted HTML comments that are used to pass commands to RATs. The attack most likely originates from China.

4) GhostNET [8]

A cyber espionage operation, discovered in 2009, that targets computer systems in more than 100 countries. The attackers use phishing and remote administration tools. The attacks originate from China, and target governments, ministries, and embassies. China's government denies involvement.

5) Darkhotel [9]

An active APT that targets guests using wireless networks in high-end hotels. The APT misuses hotel's check-in data and targets very specific individuals. It offers them software updates for frequently used packages, bundled with trojans and key loggers. It also possess some unusual features. The programs were signed with stolen certificates. Most of the attacks occurred in Japan.

6) RSA [10]

In 2011 it was reported that RSA Security was a victim of an APT attack. The attackers used phishing messages which contained an Excel document which exploited a vulnerability in Adobe Flash Player. The attackers used a RAT tool to control the infected computers and access data on company's servers. This incident caused $66.3 million damage. It is probable that the attackers stole information about RSA SecurID token seeds.

III. DETECTION

Even in the best of circumstances, systems get compromised and computers become infected. Attack vectors are numerous, and covering each option is almost always impossible. If the breach happens, there are several options that can help detect and remove the threat. With APTs, well-timed detection is very important.

Traditional methods of detection rely on examining the signature of unknown files to determine if they correspond to known malware, examining protocols or blocking specific network ports, and intrusion prevention systems (IPS) that can detect a very small subset of threats. APTs, however, rely on masking and encrypting network traffic, port hopping, newly created malware that does not exist in malware databases, malware with mutating code etc. For that reason traditional methods of detection are ineffective. Since malware has developed from infecting individual machines into organized networks of *zombies*, organizations need to implement not just endpoint security mechanisms, but also network security mechanisms.

Since one of the main activities of APTs is to extract data from an organization, analyzing data that leaves the network can help in discovering the command and control messages of an attack. The following characteristics of outgoing traffic can be used to discover malicious activities and should be analyzed:

- **Amount of data and packet quantity.** When normal users establish connections, they typically send out small amounts of data and receive large amounts of data. Since APTs extract data *from* the organization, this is one of key areas to monitor. Infected machines may generate large amounts of outgoing data that looks unusual (encrypted or masked). However, when analyzing outbound data, it is necessary to consider organization's common data flow in normal circumstances. It facilitates adjusting the monitoring engine precisely and decreasing the number of false positives it might produce.
- **Connection duration.** Normal connections are rarely established for longer periods of time. APTs establish connections that last longer when extracting larger amounts of data from an organization. Again, when monitoring connection duration it is necessary to consider types and duration of connections that normal business activities use.
- **Transmission period.** If the machines generate a certain type of outgoing traffic consistently in regular periods of time (a pattern which does not

correspond to normal usage), it could indicate presence of malware that regularly extracts data from the network.

- **Malicious sites.** Network monitoring system should keep a list of sites that have hosted malicious content. Existence of machines that communicate with such sites could indicate the existence of an attack. It will not prevent communication with newly established malware servers, however such communication will stand out from usual and can be detected by other means.
- **Internet Relay Chat (IRC) communication.** Botnets often use IRC to pass control messages between command and control servers and infected machines.
- **Destination IP addresses.** It is possible to determine the country in which the destination IP address resides. If there are outgoing IP packets with destination addresses in countries which have no association with the organization, it is possible that these connections were established by malware.
- **New domains.** In order to create command and control infrastructure, APTs often register new domain names and use dynamic DNS to route traffic between multiple infected machines which makes such traffic hard to track. Frequent communication with a previously unknown new domain could indicate presence of malware.
- **DNS cache.** Normal users typically do not use IP addresses when establishing network connections, they use URLs (uniform resource locators). When the user types a URL or clicks on a hyperlink, their DNS resolver must find the matching IP address for the URL. The domain name and its IP address are then stored in the DNS cache for some time. If outgoing connections do not have a corresponding entry in the DNS cache (which means someone established a pure IP connection), that could indicate malware infection.

Detection of network security breaches can be done using various IDS and SIEM (Security Information and Event Management) tools. It is important to note that these tools do not exempt users from using traditional endpoint security tools, such as personal firewalls and antivirus programs.

Various tools exist which can automate network monitoring tasks, correlate events and help detect breaches in network security:

- **OSSEC [11].** OSSEC is an open source host based intrusion detection system which detects intrusions by examining logs generated by various applications. OSSEC has two work modes, *local* (monitoring only one system) and *agent/server* (collecting and monitoring logs from multiple sources across the network). OSSEC can read and analyze log files of over 40 different programs and devices. It has separate components for collecting, reading, analyzing logs, and sending email alerts. It is also possible to install OSSEC agents on network devices. These agents collect logs on devices and send them to the central server for analysis using UDP. When logs are received, their field values are extracted, crucial information contained within logs is identified, and checked against pre-set or manually created rules. If needed, it sends email alerts. OSSEC works on most operating systems.
- **Snort [12].** Snort is an open source network intrusion detection and prevention tool. It is capable of performing packet analysis and logging on the network. Snort works in one of three modes: sniffer mode, packet logger mode, or network intrusion detection mode. The first two modes are simpler modes used for displaying or storing network packets. The last mode is used for traffic analysis according to a predefined set of rules, and generating alerts. Snort consists of several components which capture packets, decode and preprocess information in packets, analyze extracted information, find patterns within this information, and perform logging, alerting and outputting data. It is also possible to filter generated events in order to reduce false positives (e.g. by rate, number of events, or completely hiding events).
- **Sguil.** Sguil is a set of network monitoring tools that combines an IDS (Snort), network connection security profiling (SANCP), TCP connection analyzer (Tcpflow), stores results from multiple tools in a database (MySQL), and provides a GUI. When deployed, a system consists of a Sguil server and several Sguil sensors which monitor the network and send collected data back to the server. Sguil clients receive and display data from the server. Sguil improves common IDS systems by integrating different data sources and analysis solutions, thereby improving detection rate and reducing workload.
- **Splunk.** Splunk is a tool for processing machine-generated big data [13]. It provides searching, analyzing, indexing, correlating, visualizing and reporting capabilities. Splunk is used in various information technology domains, e.g. web analytics, internet of things, operational analysis, and security [14]. When used for security monitoring, Splunk can collect, index and analyze data from logs, firewalls, IDSs, perform statistical analysis of events within the network and thereby detect threats that would otherwise escape rule-based systems.

IV. DEFENSE

It is possible to undertake actions that can reduce the probability of system security breach. Of course, these efforts should be focused on critical areas – those which

present a high risk of security breach or high cost of repairing the damage. For that reason it is important for organizations to recognize their critical data and potential weaknesses which may present an attack vector.

In order to stop attackers from breaching the system, and discover those who have succeeded, both prevention and detection of attacks is important.

Some basic prevention measures are:

- **User education.** People are often the weakest link in organization's security. Due to the lack of knowledge and understanding of the threat employees become a critical point that attackers exploit. Educating users can greatly improve organization's level of security. It is necessary to educate employees about good password practices, social engineering (particularly phishing messages), malware, and other dangers.
- **Implementing access and usage policies.** Organizations should implement strict access policies and permissions for wired and wireless networks, files and other data. Access should be granted to users at the lowest necessary permission level. When authenticating users, TFA (Two-factor Authentication) should be used and strong passwords should be enforced. Detailed authentication logs should be kept.
- **Controlling external media.** All external storage media (USB drives, optical disks etc.) should be controlled in order to prevent spreading malware infections or losing valuable data.
- **Protecting valuable data.** Valuable data should be encrypted, with limited access. The most critical data should be kept on machines without network connection.
- **Managing endpoint security.** It is important that all operating systems and other programs used by organization's employees have all the latest security updates installed and enabled. It is also important that they have personal firewalls and antivirus programs installed and updated. When detecting or preventing security incidents, endpoint security must not be disregarded, but not exclusively relied upon.
- **Implementing NAC (Network Access Control).** Network Access Control is a method of enforcing network access policies for client devices. Non-compliant devices can be automatically repaired or upgraded when they are first connected. Network access is granted only to devices which satisfy certain security requirements such as security patches or antivirus protection. Other devices are given limited access until they are updated. NAC can also be used to control access based on assigned roles.
- **Blocking high risk applications.** Organizations should block usage of known high risk applications which could be used to spread malware or facilitate data leakage, such as P2P (peer-to-peer) programs, encrypted tunneling applications, and proxies.
- **Blocking known malware servers.** Organizations should keep a list of known malware sites, block access to them, and alert system administrators of any requests to these sites.
- **Analyzing security breaches.** Finally, if an attack does penetrate organization's security, it is necessary to thoroughly analyze how it happened, which parts of the system were compromised, and what data was lost. That way organizations can get a complete picture of the incident and protect themselves from future attacks.

V. CONCLUSION

APTs have become a significant concern for organizations from various domains. This trend is not showing signs of slowdown. Due to their stealthiness and focus on data, APTs present a growing danger that is very hard to prevent, detect and defend against. In the recent years, we have witnessed numerous cases where APTs have caused significant damage to various organizations, not only in form of data theft, but immediate physical damage.

APTs have an advanced approach to attacking organizations, they have the resources and knowledge, they do not stop give up when they are unsuccessful, they conceal their presence, and they target organization's valuable resources. Because of that, new security approaches are needed. Organizations cannot rely on traditional firewalls and malware detection. They need to employ various advanced intrusion detection tools and, based on their activities, develop new methods of detecting anomalies in a specific network, and correlate them in order to discover security breaches.

Even though there is no guarantee that any network is completely secured, organizations can implement tools and security policies that can greatly reduce the risk of an attack. However, doing that requires knowledge, resources and time.

Security Risk Management in Complex Organization

Ivan Sedinić, Tamara Perušić
Croatian Telecom, Cyber & Data Security Section
ivan.sedinic@t.ht.hr, tamara.perusic@t.ht.hr

Abstract: Security Risk Management is foundation and starting point for implementation of security measures in any organization and challenge by itself. But in complex organizations there are additional challenges, how to align IT Security Risk Management with overall Security Risk Management and later with the Company's overall Risk Management. When organization is part of some international corporation, corporative rules also need to be followed in addition to legal and regulation rules. In telecom industry in regular operations also is very important that security assessment could be performed in short timeslot as support for operational decisions. Croatian Telecom as a part of Deutsche Telecom Group is facing all of this issues in addition to ISO 27001 requirements against which the Company is certified. To solve the challenge, the Company developed three methodologies for Information Security Risk Management. All of these methodologies are merged in common Risk Register as well as aligned with the Company's Risk Management. In this paper each Information Security Risk Management methodology will be described including its application area, as well as how recognized security risks are shown in common Risk Register and how they relate to the Company's Risk Management.

I. INTRODUCTION

The goal of this paper is to describe a way to align different Information Security Risk Management methodologies caused by different business requirements. These methodologies are supporting operational decisions process and in the same time are also supporting central risk reporting. Practical way of such approach is described in this paper.

In section I is given introduction to Risk Management and significance of having Risk Management in place. Section II briefly described some of the most popular Risk Management methodologies that are used worldwide. In section III is shown the Company's Risk Management process in the Group as well as three various methodologies that are used for Information Security Risk Management in the Company. Finally, in section IV is described Risk Register that is used in the Company for tracking information security risks.

The Company is Telecommunication Company that provides fixed, mobile, Internet and TV services. It has approximately 5.000 employees and is a part of the International Telecommunication Group. The Group is comprised of European Telecommunication Companies with joint governance and consolidated financial report. At the Group level are defined umbrella policies and guidelines that have to be applied in all group members. The Group and the Company are on different Stock Exchanges and are subject to different Stock Exchange rules.

Careful handling of risks is a fundamental condition for commercial success in today's complex and dynamic environment. Early detection and management of opportunities and risks should be an integral part of any management activity within each company. This also includes instilling awareness of the Risk Management system to all employees as part of the tasks assigned to them. Having well managed Risk Management process provides ongoing support to successful business performance. Focus should be placed on following aspects:

- creating transparency over opportunities and risks,
- early detection of material risks and opportunities,
- precise and careful handling of opportunities and risks,
- risk reporting,
- documentation and management and
- increasing enterprise value in order to recognize risks in early stages and make decisions which enable to focus on activities with the most favorable risk-return profile [1].

IT risk is the potential that a given threat will exploit vulnerabilities of an asset or group of assets and thereby cause harm to the organization. It is measured in terms of a combination of the probability of occurrence of an event and its consequence [2].

II. DIFFERENT RISK MANAGEMENT MODELS

Many risk frameworks have been developed and each of them has its own advantages and disadvantages. All have in common that they require organizational discipline to define assets, list of threats, evaluate controls, and conclude with an estimate of the risk magnitude. Bellow will be shortly described some of the most popular methodologies.

OCTAVE, probably the most well known risk framework, comes in three sizes depending on the organization size (small, medium or large). One of the benefits of the OCTAVE series is that each of the frameworks provides templates for worksheets to document each step in the process. Templates can be used directly or customized for a particular organization [3].

The NIST framework, described in NIST Special Publication 800-30, is a general one that can be applied to any asset. It follows a similar structure like OCTAVE, but uses a little bit different terminology. NIST doesn't provide plenty of templates such as OCTAVE but it is relatively easy to follow. Since it has a focus on concrete components as systems, it can be easily used for organizations that are new to risk assessment. Also because the methodology is defined by NIST, it is approved for the use by US government agencies and organizations that work with them [4].

ISACA's COBIT is IT management framework while the ISO 27xxx are security frameworks that require organizations to have a risk management program. They recommend repeatable methodologies and specify when risk assessments should take place. Risk assessment in COBIT described in RISK IT goes beyond security risks and includes development, business continuity and other types of operational risk in IT [5], whereas ISO 27005 concentrates on security exclusively.

ISO 27005 follows a similar structure to NIST but terms are defined differently. ISO 27005 includes annexes with forms and examples, but like other risk frameworks, it's up to the organization implementing it to evaluate or quantify risk in ways that are relevant to its particular business.

Organizations that do not have a formal risk assessment methodology could firstly review the risk assessment requirements in ISO 27001 and 27002 and consider the 27005 or NIST approach. The ISO standards provide a good justification for formal risk assessments and outline requirements, while the NIST document provides a good introduction to a risk assessment framework.

In this article we will use telecom company listed on Stock Exchange and which is part of international telecom group, as a model.

Described organization's Security Risk Management is based on ISO 27001, 27002 and 27005 frameworks. The Company has decided to certify Information Security Management System according to ISO 27001 standard. Because of it, Security Risk Management System has to be compatible with the ISO 27001 standard.

III. SECURITY RISK MANAGMENENT IN THE COMPANY

Company's Risk Management process

For the purpose of early recognizing and reporting significant risks within the Company, the Company's Risk Management process is established.

This process encourages early identification, analysis and risk assessment, timely communication to decision-makers and implementation of measures and activities that lead to optimal outcomes in relation to objectives of the Company. This process also established additional business transparency for Management and Supervisory Board through reporting process about significant risks.

Management and reporting system of the Company's risks is an integral part of the Risk management and reporting system of the Group. Also, the Company is obligatory to manage and timely report on significant risks according to Capital Market Act [6] and Accounting Act [7].

According to business requirement and obligations the Company's reports have to be prepared quarterly, and every organizational unit in the Company is obliged to ensure continuous monitoring and timely reporting of all risks that may affect the future business as well as work towards promoting awareness of risks at all levels.

The Company reports significant risks:

- *within mandatory periodic financial statement reporting* of the Company for stakeholders,
- *to external auditors* (Audit of financial statements of the Company [8]),
- *to the Group* (Consolidation of risks portfolio for the whole Group),
- *to the Audit Committee* (monitoring efficiency of internal controls of the Company referred to Risk Management system, compliance operations, internal audit, etc.)

The Company's Risk Management process has 6 major sub-processes:

- *identify risk* where risk is recognized,
- *assess* where risk is assessed in relation to its business objectives (plan),
- *correlation and aggregation* where assessment of risk appearance interdependence to other organizational units and processes is done,
- *response to risk situation* where measures for risk management are defined,
- *implementation of action plan* and
- *monitoring* that includes monitoring of residual risk and development of risk circumstances.

All company units have to take care on risks within their jurisdiction and they are following this process when some risk occurs.

This process is shown in Figure 1.

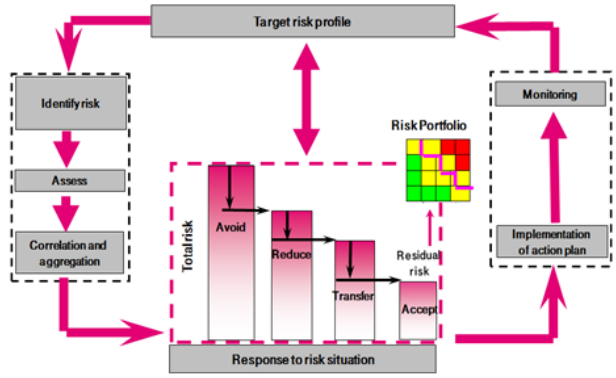

Figure 1: Company's Risk Management process

In Figure 2 is presented reporting line, who reports to whom within Risk Management Process.

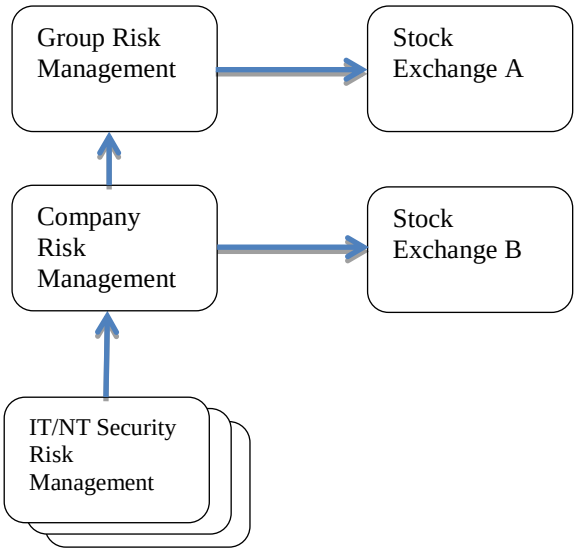

Figure 2: Reporting line

Risks are presented in Risk Portfolio matrix by mapping evaluated impact of recognized risk which is expressed in financial terms and estimated likelihood of occurrence as shown in Figure 3.

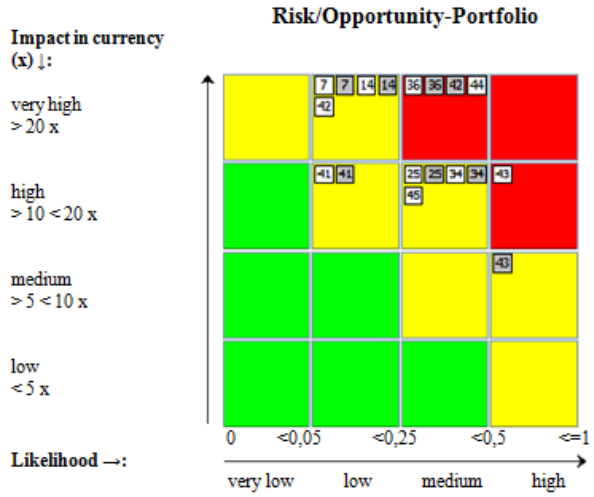

Figure 3: Risk Portfolio matrix

For the purpose of managing information security risks in the Company, three Security Risk Management sub methodologies are developed. All of them are aligned with the Company's Risk Management. Each of them will be described.

A. ISMS Security Risk Management Methodology

This methodology is used in the Company for evaluation of all kind of information security risks. It is developed to support implementation of Information Security Management system (ISMS) according to ISO 27001 standard [9].

ISMS Security Risk Management ensures identification of the critical Company's assets and related risks, and also manages identified risks. In that way, overall security of business processes in the Company is properly considered. Also, by conducting Security Risk Management, continuous increase of security in the Company is ensured.

Methodology that is used in ISMS Security Risk Management process is aligned and very similar to the Company's Risk Management process methodology. Risk matrix is also similar in both processes (4x4) and visually presented in traffic light colors, but scores are calculated slightly different as can be seen in Figure 3 and Figure 5.

ISMS Security Risk Management process consist of the next 5 sub-processes shown in Figure 4.

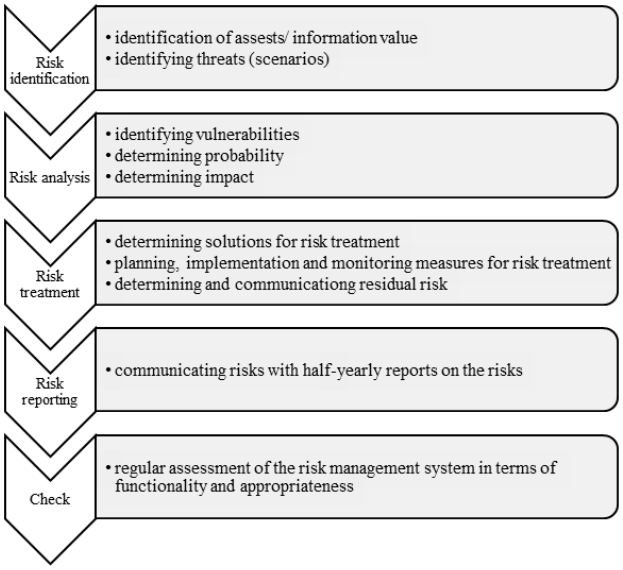

Figure 4: ISMS Security Risk Management sub-processes

Brief description of each ISMS Security Risk Management sub-process is given bellow:

A.1. Risk identification - this sub-process includes identification of assets (people, technology, processes and information) where attention also should be paid to the transmission of information from source to the destination. Scenarios of threats that may have an impact on the identified assets have to be recognized and noticed. Example how it is done is presented in Table 1.

Type	Example of vulnerabilities	Example of threats
Software	Disposal or reuse of storage media without proper erasure	Abuse of rights
	Incorrect parameter set up	Error in use
	Poor password management	Forging of rights
Hardware	Lack of efficient configuration change control	Error in use
	Unprotected storage	Theft of media or documents

Table 1: Examples of some vulnerabilities and threats

A.2. Risk analysis - within risk analysis any threat (scenario) associated with the identified asset is necessary to check from the perspective of certain risk dimensions (availability, integrity, authenticity, confidentiality) and to identify vulnerabilities. The probability of occurrence and impact on asset has to be determined in this step if risk occurs.

In Table 2 are criteria that are used when determining the probability of occurrence.

Category	Probability	Value	Definition
Very low	0-0,05	1	The appearance scenario is very rare (once in the time period of >5 years)
Low	0,05-0,25	2	The scenario appears once within 5 years (based on previous experience)
Medium	0,25-0,5	3	The scenario occurs annually
High	0,5-1	4	The scenario occurs often (several times over a period of one year)

Table 2: Criteria for determining the probability of occurrence

In Table 3 are criteria that are used when assessing the impact.

Category	Value	Impact (Confidentiality, Integrity, Availability)	Financial impact
Very low	1	The impact is rarely felt. The impact is limited to a certain part of the observed process.	No financial impact
Low	2	The impact is limited to the observed process.	Moderate financial impact (<100.000 kn)
Medium	3	The impact can be felt in other processes/ outside the scope of observation.	Significant financial impact (>100.000 kn)
High	4	A major impact within the process and out of processes/ inside and outside the scope of observation; impacts on users	Major financial impact (>1.000.000 kn)

Table 3: Criteria for impact assessment

Risk level is derived from multiplying determined impact value (taking into account financial impact) and probability value (scenario occurrence) and is shown in risk matrix (Figure 5).

Low risk includes risk levels 1 and 2 and is green colored. Middle risk includes risk levels 3, 4, 6, 8 and 9 and is yellow colored. High risk includes levels 12 and 16 and is red colored.

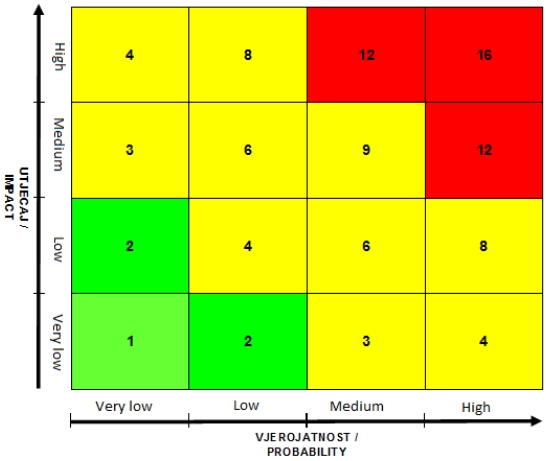

Figure 5: Risk matrix for ISMS Security Risk Management

A.3. Risk treatment - within this sub-process, possible solution for the treatment of risk are determined. After solution is chosen, next step is to plan, implement and monitor measures for risk treatment. Finally residual risk has to be determined and communicated.

The following risk treatments are possible:

- *risk mitigation* in which appropriate controls to reduce the risks are applied,
- *risk acceptance* where organization decides will not to take action and that the risk clearly satisfies the organization's policy and criteria for risk acceptance,

- *risk avoidance* where risks are avoided by not allowing actions that would cause the risks to occur and
- *risk transfer/sharing where risk* are transferred to other parties e.g. insurers or suppliers.

A.4. Risk reporting - risks are communicated half-yearly (internal regulation) within the Report on risks.

A.5. Check - as a final step in ISMS Security Risk Management process, regular assessment of the Risk Management system in terms of functionality and appropriateness has to be done.

B. Basic Security Evaluation (BSE) Methodology

BSE methodology is used for basic security evaluation of all IT/NT systems in the Company against 20 predefined security risks by going through defined check list called BSE questionnaire. Limitation of this methodology is that it is based on a set of basic security measures and therefore it is primarily used for initial security screening of particular system. Advantage is that it gives a solid security insight of IT/NT system as well as possibility to compare levels of IT/NT systems' security risks in the Company.

Following risks are included in BSE methodology:

- inappropriate system location (e.g. in office)
- unsecure access to system from internet,
- administration without Jump-Hosts and/or dedicated admin network,
- possible external access not using approved 3rd party access,
- manual file upload/download,
- missing segregation from office network,
- testing with production data,
- missing central user management,
- missing auditable process for user management,
- missing or insufficient control of given rights,
- missing regular backups incl. recovery tests,
- missing patch process,
- missing continuous scans,
- missing logging and/or log analysis,
- not compliant to near offshore requirements (security rules for offshoring to companies in neighborhood),
- missing agreement for commissioned data processing,
- disaster recovery plan is missing,
- missing system description,
- group accounts used,
- missing data privacy and security concepts

Main goal is to identify security risks in IT/NT systems and create risk repository in short time. Risk repository enables IT/NT management to easily determine systems with the highest risk level from a security point of view.

This methodology is adjusted to needs of the Company and aligned with ISMS Security Risk Management system by using same risk levels and criteria for risk acceptance as well as the Company's Risk Management.

Technical System Owner or his/her representative with assistance of Security Expert has to fill-in BSE questionnaire for particular IT/NT system. Given results are imported in excel tool for security risks assessment and scoring. Risk score is calculated combining impact value and probability value in Risk matrix from ISMS Security Risk Management (Figure 5). Further steps are basically the same as in methodologies shown previously. Results are analyzed and report created about risks found. Given results are presented to management and open issues discussed. Risk treatment plan is created, measures with defined deadlines are agreed and progress of implementation is monitored.

C. IT Security Risk Management

Third methodology is IT Security Risk Management used for evaluation of specific security risks in IT area. Assessment of IT security risks is done within the excel risk assessment tool called RAST. It is an in-house solution where risk estimation is done into nine steps. In each step are entered some data about the treat scenario that is considered. Risk index is calculated by the tool as soon as all required fields are filled-in.

In scope of this methodology are complex IT projects where are evaluated specific IT related assets, processes and solutions. Threats that are considered are:

- threats to confidentiality and integrity of information assets resulting from accidental and deliberate malicious acts done by authorized and unauthorized human threat actors,
- threats to availability of information assets and services provided by technology assets, as long as they are endangered by deliberate malicious acts or human (operative) mistakes. [10].

Risk methodology is very similar to previous ones. Main difference from others is that impact, likelihood of occurrence and risk are expressed as index values on a scale from 1 to 10 (see Figure 6).

The *impact index* is assessed separately for three protection goals – loss of confidentiality (C), loss of integrity (I), and loss of availability (A). Overall impact index is a maximum value of impacts for C, I, A. Impact index has the scale 1-10. The likelihood index is assessed for a described threat scenario and has a scale 1-10.

Risk index = f (impact, likelihood) or in this case
Risk index = sqrt(impact* likelihood)

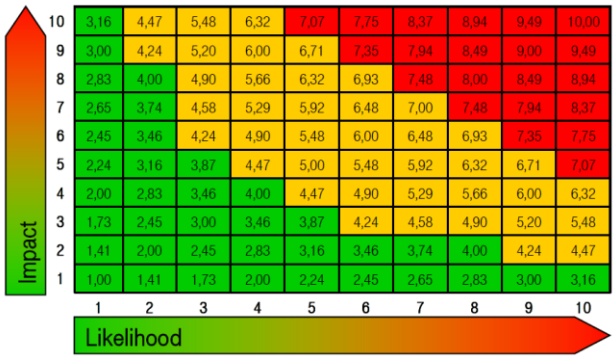

Figure 6: Risk matrix for IT Security Risk Management

This methodology has 5 sub-processes as shown in Figure 7.

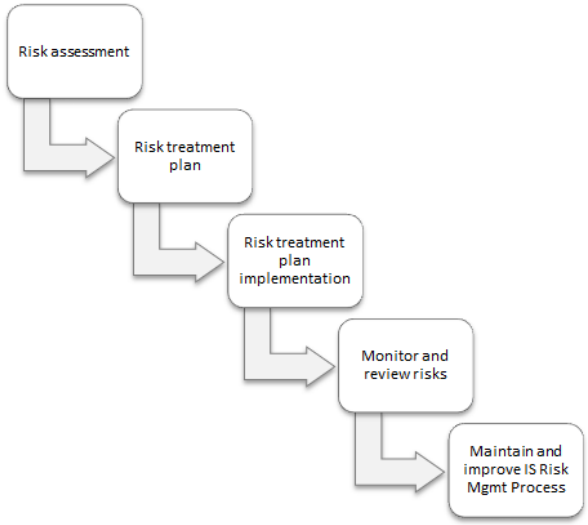

Figure 7: IT Security Risk Management sub-processes

Further is shortly explained each sub-process of this methodology.

C.1. Risk assessment – this sub-process starts with risk identification where vulnerability, threat scenarios and potential impact are documented. Findings have to be confirmed by System Owner. After confirmation, Security Expert estimates the risk index.

C.2. Risk treatment – within this sub-process next options are possible:

- *risk retention* where risk is acceptable according to Risk acceptance criteria and no further action is required,
- *risk reduction* that consists of a list of possible controls to reduce impact or likelihood, cost & benefits, priority of implementation and timeframe for implementation,
- *risk avoidance* in case that risks are too high, or costs of control exceed benefits,
- *risk transfer* where risk is shared with external party and
- *risk acceptance* - where management decision is required for accepting the current level of risk without implementing security measures. This is done in situations where the cost of implementing protective measures exceeds the benefits or risk cannot be decreased with implementation of security controls (it is not possible to decrease threat or vulnerability) nor it is possible to decrease it by propagation or avoiding.

C.3. Risk treatment plan implementation – consists of list of possible controls to reduce impact or likelihood, costs and benefits, priority of implementation and timeframe for implementation.

C.4. Monitor and review risks - All risks in status "open" are monitored in regular intervals.

C.5. Maintaining and improving information security risk management process – regular check of information security risk management process.

IV. RISK REGISTER

In addition to Risk portfolio which is managed within the Company's Risk Management process, Risk register is developed and maintained within IT/NT Security Risk Management process. Its main purpose is to track information security risks within the Company.

Risk register contains all information security risks that are identified in any of 3 above described Security Risk management methodologies, as well as all risks that have been recognized during various internal or external audits and system scans (e.g. penetration scanning, vulnerability scanning, and source code scanning).

In cases where different method for Risk Management scoring is used (like in external audits or system scans), translation tables are designed in order to have comparability of risk levels.

The following information is tracked in Risk register:

- Information asset name – affected assets
- Threats – possible threats to confidentiality, integrity and availability of information assets
- Vulnerability – described weakness in information asset that could expose the system
- Probability/ Likelihood of occurrence – estimation on how easy it is to exploit a threat
- Impact – assessed consequences of risk events if they are realized
- Risk value – value calculated based on assessed probability and impact
- Risk evaluation date – date when risk evaluation is performed
- Recommended measures – proposed risk treatment options for affected information asset

- Deadline – agreed date until risk will be mitigated
- Risk Owner – name of person that is responsible for implementation of measure.

Risk register is updated each time when new risk is identified and assessed or some changes related to risks in evidence occurred.

Risk register is half-yearly reviewed and report on residual risks prepared. Report is discussed with Risk Owners and further activities defined.

V. CONCLUSION

In situation when it was necessary to fulfill requirements and obligations toward different stakeholders in different timeframe and on different detail level, we found that optimal way for us is to design different risk management methodologies which are interconnected at least through same risk levels and risk acceptance criteria. Concept was to have overarching risk management methodology which is capable to cover all area in the Company and plug in results from other, area specific methodologies. On the next level were developed specific risk management methodologies appropriate for dealing with specific problems in information security overall, fast and simple reaction to operational requirements and detail assessment of complex IT projects.

Such approach has numerous benefits as are:

- Practical way to integrate different risk methodologies using bottom up principle
- perform risk assessment in short period when operational requirements dictate it,
- perform risk assessment in very deep and detail level for technologically specific risks,
- unification of results for different area in which risk management tools are used,
- optimization of time spent on risk management.

PRIVACY TRACK

Violation of User Privacy by IPTV Packet Sniffing in Home Network

Siniša Vukojević, univ. spec. secur. inf.
HAKOM, R. F. Mihanovića 9, 10110 Zagreb
Sinisa.Vukojevic@hakom.hr

Abstract - The aim of this paper is to determine the possibility of learning about and the quantity of collected information about the habits of users of Internet Protocol television (IPTV) in Croatia on the basis of unauthorised monitoring of the IPTV traffic in the users' home network.

The experimental part of the presented work includes collecting IPTV traffic in home networks of IPTV users of the two largest electronic communications operators in Croatia while preforming ordinary user activities (initiating the Set Top Box (STB) devices, switching TV channels, using EPG, program recording, using video on demand etc.). The paper does not explore the possibility and the manner of achieving the unauthorised access to the users' home network itself; instead, it is assumed that it has already been obtained.

Based on the gathered data, each user's action is analysed from the aspect of indicating users' behavioral habits and the violation of their privacy. The results of the conducted analysis presented in the paper provide an overview of gathered information and some concluding remarks regarding the possibility of violation of privacy by IPTV traffic sniffing in the user's home network.

I. INTRODUCTION

Internet Protocol Television (IPTV) is a system which enables delivering the digital television services over the internet using Internet Protocol (IP). The usage of IP technology enabled interactivity, more versatile and higher quality content and the development of numerous new IPTV services.

IPTV services are usually offered via closed networks by electronic communications operators, which control the technical parameters and ensure an adequate Quality of Service (QoS) and Quality of Experience (QoE) to its users. However, apart from international standards and recommendations, there is a lack of publicly available documents which describe the network architecture or its operation, thus leaving several open questions, including the level of users' privacy protection, which is unknown.

Due to that fact, this paper addresses the possibility of IPTV users' privacy violation and what types and amount of user, content or system data can be obtained by an unauthorised IPTV traffic monitoring of user's home network. The aim of the paper is to determine the possibility of IPTV data collection and investigate the quantity of gathered information regarding the behaviour and habits of IPTV users in Croatia based on the IPTV packet sniffing.

The study presented in this paper is performed in home networks of IPTV users of the two largest electronic communications operators in Croatia. The possibility and mode of establishing the unauthorized access have not been explored; it is presumed that sniffing is already established. The protection of protected content and network, as well as IPTV service provider's network security are also not explored, although results of the analysis suggest some aspects of those questions as well.

The experimental part of the study consists of collecting IPTV traffic during usual user actions: initiating the Set Top Box (STB), switching TV channels, using program guide etc. Collected data are analysed with regard to two aspects - user behaviour and the violation of users' privacy.

The paper is organized as follows. In order to provide a better insight into the IPTV functioning, Section II provides a brief overview of the IPTV technology based on the publicly available data. Section III describes the methodology of data collection and Section IV the analysis of IPTV data. Section V analyses gathered information, while Section VI comprises discussion and some concluding remarks.

II. INTERNET PROTOCOL TELEVISION (IPTV)

A. General

IPTV is defined and confirmed by the International Telecommunications Union (ITU) focus group ITU-T FG IPTV as follows [1]:

"IPTV services are multimedia services such as television/video/audio/text/graphics/data delivered over IP based networks managed to support the required level of quality of service (QoS) and quality of experience (QoE), security, interactivity and reliability"

As a term, IPTV was first used in 1995 by the company Percept Software as the title for the application for audio/video traffic transmission via unicast and multicast using IP [2]. In 1998, Precept Software was bought by Cisco, which kept IPTV as a trademark. First IPTV services via Digital Subscriber Line (DSL) ware available in 1999 in UK and it is estimated that today there are approximately 110 million subscribers worldwide [3]. The number of connections in Croatia in 2013 was 393 thousands [4].

B. *Architecture*

Several organisations have been involved in the standardisation of IPTV systems, architecture and services [5]. General IPTV architecture (Fig. 1) consists of four main parts: content provider, IPTV service

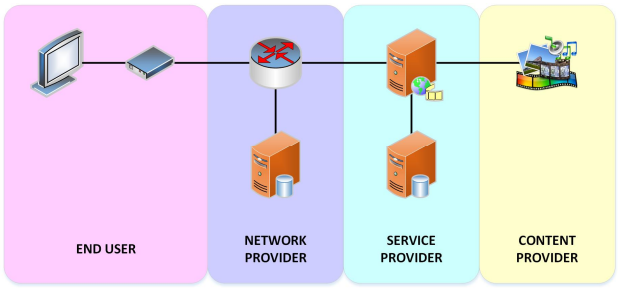

Figure 1. General IPTV architecture [6]

provider, network service provider and the end user. Each operator can be present in more than one entity.

More details on IPTV architecture and its basic elements can be found in the following standardization documents:

- FG IPTV-DOC-0181: IPTV Architecture
- ITU-T Y.1910: IPTV functional architecture
- ETSI TS 182 027: IPTV functions supported by the IMS subsystem
- ETSI TS 182 028: NGN integrated IPTV subsystem Architecture

C. *Protocols*

Providing *end-to-end* IPTV service (from the content provider to the end user) is achieved by the large number of protocols which enable and support different applications and functionalities of IPTV services. ITU document "IPTV related protocols" [7] identifies and categorizes relevant IPTV service protocols (Table I).

In the observed systems the most used protocols are:

- **HTTP** for the communication from the end user STB device to IPTV middleware servers placed in service provider's network
- **RTSP** for the establish and control media sessions (play, pause, rewind and fast forward etc.), acts as a "network remote control"
- **RTP** for the real-time transmission of media content (audio and/or video), and **RTCP** for reporting on the performance and control of the RTP session
- **IGMP** for the TV channels switching

In IPTV networks unicast communication is used for processing unique requests from a single user (e.g. video on demand), while multicast is used for delivering the same content to a large number of end users. Due to the requirements for network bandwidth for every video signal, i.e. TV program, IPTV service would not be possible without using multicast for content transmission.

TABLE I. IPTV PROTOCOLS [7]

TCP/IP LAYERS	*PROTOCOLS*
APPLICATION LAYER	DHCP, DNS, DVB-IPTV, FEC, FLUTE FTP, HTTP, IPDC CDP, LC, MBMS RTP, RTSP, SIP, SNTP, TLS
TRANSPORT LAYER	TCP, UDP
NETWORK LAYER	BGMP, ICMP, IGMP, IP, MLD MSDP, PIM-SM, Anycast-RP, SSM

D. *Services*

IPTV enabled numerous new IPTV services. ITU document "Service scenarios for IPTV" [8] classifies services into content, interactive and communications services (Table II).

TABLE II. IPTV SERVICE LIST [8]

Content Services	Linear TV (audio, video and data)
	Linear Broadcast Audio
	Linear TV with Trick Modes
	Multi-View service
	Pay Per View (PPV)
	Personal Broadcast Service
	PVR service (network or client-based)
	Time-shift TV
	Video on Demand (VoD)
	Near Video on Demand
	Content Push
	Music on Demand (MoD)
	Content download service
	Service Information (EPG, ECG, …)
	3rd party content services
	End-user Originated content
	Regulatory Information services
	Advertising
	Hybrid services
Interactive Service	Interactive TV (iTV)
	Learning services (education, languages, ...)
	Information services (news, weather, traffic, …)
	Entertainment services (photo, games, karaoke, blog)
	Portal services
	Commerce services (security, banking, shopping, …)
	Interactive Advertising
Communication Service	Communication services (e-mail, IM, SMS, Chat, ...)
	Communications Messaging
	Presence services

E. *Market Overview*

At the end of the third quarter 2014 there were around 108.2 million IPTV subscribers, which represents 18.9% annual growth of the number of subscribers, i.e. 17.2 million new subscribers [3]. At the same time, there were 393 104 IPTV subscribers in Croatia [9], i.e. 0.22% lower quarterly rate and 2.06% annual growth, which is significantly lower than 18.9% of global growth (Fig. 2).

IPTV services in Croatia are used in 26.14% households [4], while a major part of 53.07% households uses digital terrestrial television, which is a great potential for the further development of IPTV.

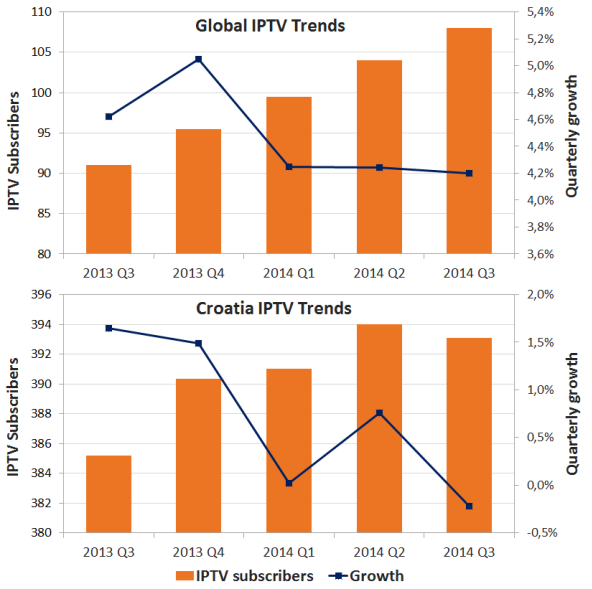

Figure 2. Number of IPTV subscribers and their growth globally [3] and in Croatia [9] for Q3 2014

III. IPTV Data Collection

A. Tools and Method

To determine the amount, type and the content of data which are exchanged when using IPTV service, it is necessary to collect information from the end user's home network. For that purpose the home network has been adjusted: instead of directly connecting ADSL modem and STB, they are connected via switch (Fig. 3). Using Port Mirroring properties of switch, a copy of their communication was forwarded to the computer which collected and stored IPTV packets for the further usage and analysis. For collecting and storing data, as well as for their analysis, a free tool *Wireshark* and Linux operating system *BackTrack 5* have been used. Data were collected in the third quarter 2013. The study included two major operators in Croatia, which are compared in the results of the analysis.

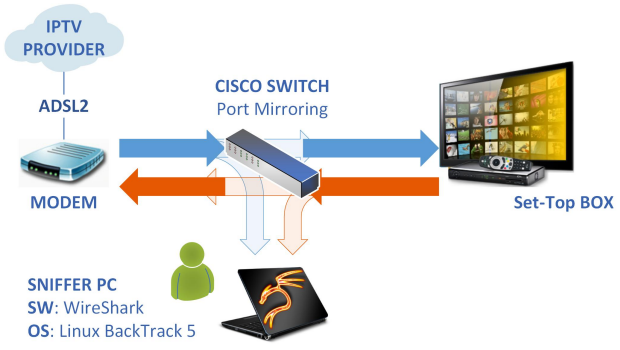

Figure 3. Modified home network for experiment

B. Use Cases

In order to enable faster and better quality collection and later analysis of IPTV packets, the ordinary user activities has been classified into several use cases, which are described and explained in subsequent steps (Table III).

TABLE III. Use Cases

USE CASES	*STEPS*	
Initiating the STB device	1	STB device is not connected to the power, but is connected to the TV and to the ADSL modem
	2	After 30s, power-up the STB device
	3	Monitor the process of initiating the STB device on TV
	4	After image appearing on the TV screen, wait 5 min
Switching TV channels	1*-2	Every 30s user switching TV channels HRT1 → HRT2 → HRT3 → HRT1
Using EPG	1*-2	After 30s, the user open the EPG guide
	3	After 30s, the user presses the button "DOWN" on the remote, and positions to the current show on the channel below HRT1
	4	After 30s, the user presses the button "DOWN" on the remote, and positions to the current show on the channel 2 places below HRT1
	5	After 30s, the user selects "Show description"
	6	After 30s, the user closes the EPG guide
SNIMALICA – recording video content	1*-2	After 30s, the user opens the EPG guide and clicks on next show
	3	After 30s, the user presses "RECORD" and confirms the record TV shows
	4	After 30s, the user closes the EPG guide
SNIMALICA - watching previously recorded content	1*-2	After 30s, the user selects "Snimalica"
	3	After 30s, the user selects one of the pre-recorded shows, starting with watching
	4	After 30s, the user temporarily stops the watch by pressing the "PAUSE"
	5	After 30s, the user continues to watch by pressing the "PLAY"
	6	After 30s, the user interrupts watching by pressing the "STOP" and exits
SNIMALICA - erasing previously recorded content	1*-2	After 30s, the user selects "Snimalica"
	3	After 30s, the user selects one of the pre-recorded shows, and option "DELETE"
	4	Confirms deletion of show and exits
VIDEOTEKA - renting the video content	1*-2	After 30s, the user selects "Videoteka"
	3	After 30s, selects one of the offered programs and clicks the "PURCHASE"
	4	The user enters the PIN and confirms purchase
Youtube	1*-2	After 30s, the user selects "Youtube"
	3	After 30s, selects and starting with watching one of the available video content
	4	After the completion of video playback exits
Facebook	1*-2	After 30s, the user selects "Facebook"
	3	A user logs with username and password (Sinisa.Vukojevic@gmail.com / LoZinka.123)
	4	After 30s, the user selects "FRIENDS"
	5	After 30s, sets the message "Test IPTV" on the wall
	6	After 30s, the user is logged out from "Facebook" and exits
Telefon - Call	1*-2	After 30s, the user receives an external telephone call
	3	After four (4) rings , the user answers the call and hangs up after 10s
Telefon – List of calls	1*-2	After 30s, the user selects "Telefon" and the sub-option "All Calls"
	3	After 30s, the user exits

1* - Start: The user watching TV channel HRT1 (initial step)

C. Description of user IPTV services

IPTV users from operator A and B are subscribed for the following services:

- triple play (Internet, telephone, television)
- Snimalica - TV program recording and watching on demand
- Videoteka - Video on demand

Operator A user is additionally subscribed for:

- Application "Telefon" which allows list of calls overview and current call notification on TV device
- Youtube and Facebook applications via TV

IV. IPTV Traffic Analysis

The IPTV traffic analysis was performed using Wireshark tool. Based on the captured data, each use case is analysed in order to investigate how the observed IPTV system works from the aspect of indicating users' behavioral habits and the violation of their privacy (more detailed technical information are available in [10]).

A. Initiating the STB device

Traffic tracking while booting the user STB provides the most information about the IPTV system, service, content and user under study. Fig. 4 depicts a simplified process of starting user STB.

1) Operator A

After starting, using DHCP protocol, STB device obtains IP address and other network data, as well as the information about multicast UDP flow with IPTV system configuration data - InfoCast. After that, STB connects to InfoCast and downloads configuration data: boot files for its device type, current time and time zone, user interface homepage, IPTV middleware servers. Using boot files configuration data, STB reads files for kernel boot and boot splash, which gives graphical representation of the device start up.

After the kernal boot, follows the download of files necessary for IPTV user interface, based on the homepage *index.svg* whose URL is taken from InfoCast flow. Scalable Vector Graphic (SVG) is an open standard based on XML format and in observed system is used for the graphical representation of the user interface. Besides SVG files, graphical PNG (Portable Network Graphics) files are downloaded, as well as JS script files which consist program code written in JavaScript language.

In parallel with running graphic user interface, based on the JavaScript files content, STB sends multiple HTTP POST requests (26 requests), and receives responses from provider's servers with metadata. Metadata describe user device and GUI interface characteristics, IPTV service and video content. They also contain user, i.e. IPTV subscriber data. Data are written in simple and open text standard format for the exchange and transmission of data, JSON (JavaScript Object Notation).

Initiating the STB device is finalized by registering in the multicast flow containing Promo TV channel video content, i.e. by image appearing on the TV screen. A video stream is transmitted over IP network as MPEG-2 Transport Stream encapsulated into RTP/UDP/IP, and in experiment is observed that is possible to reproduce captured video stream (Wireshark: Telephony – RTP – Stream Analysis – Save payload).

2) Operator B

Using DHCP, STB gets the IP address and other network settings, as well as additional boot files data. Based on the obtained data, STB registers and reads UDP multicast flows with boot files and configuration parameters. By using boot files, STB is restarted, DHCP request repeated and then the current time is set using TIME and NTP request to the current time providers.

Using RTSP DESCRIBE request STB device gets configuration parameters of TV channels present in the IPTV service. After that, it is registered in SAP/SDP flow which contains configuration parameters or IPTV service data, i.e. it redirects to other UDP flows (there are 24 flows in total) with configuration parameters or IPTV service data.

Although UDP flows seemed unreadable, detailed analysis showed that data are sent through UDP in parts and in cycles (UDP Carousel), with the first 8 bytes of UDP load describe its position inside the file. Merging separate parts into one single file, based on the first two bytes (0x1F and 0x8B), showed that it is a GZIP file, which is decompressed into an easily read XML file.

STB device loads configuration parameters first, and then it retrieves device, service, content and user metadata in XML format using several HTTP requests and registering in multicast UDP flows.

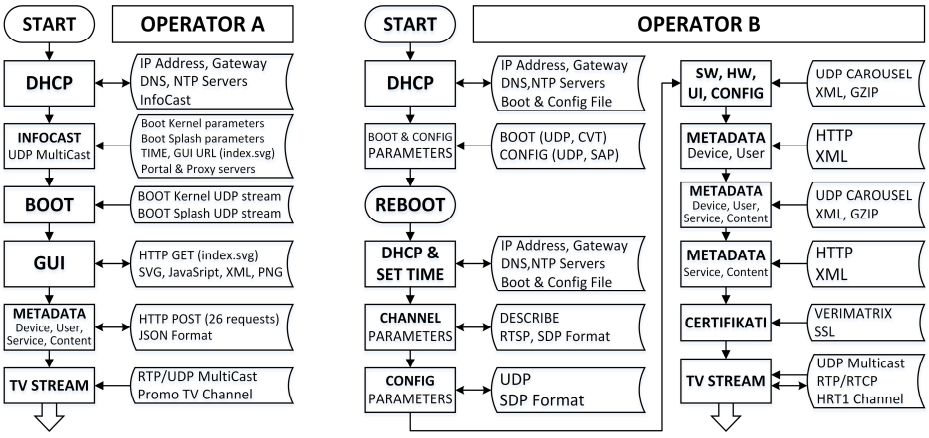

Figure 4. Simplified diagram of initiating the STB device - based on a detailed analysis of traffic in Wireshark

After retrieving metadata, a protected SSL communication occurred for the first time. Typical SSL/TLS handshake and key derivation was observed and the negotiated cipher suite was TLS_DHE_RSA_WITH_AES_256_CBC_SHA. Based on the usage of Verymatrix system, it can be concluded that SSL communication occurred probably due to exchange informations between STB and provider's servers in order to protect video content and digital rights.

Starting the device is finalized by multicast HRT1 TV channel as MPEG-2 Transport Stream encapsulated into RTP/UDP/IP and corresponding RTCP flow, resulting with the image of the channel appearing on the TV device.

3) Analysis of initiating the STB

Analysis of the traffic obtained while initiating the STB showed that it is possible (for both operators) to obtain extensive information about the device, IPTV service, user and the content, such as TV channel list and description of the program content. However, it must be emphasized that it is also possible to obtain the user PIN code (it can be found within the XML file as MD5 hash at Operator A and it can be obtained by hash comparison; at Operator B, it can be found in plain text).

B. Switching TV Channels (Operator A and B)

Switching channels is done using IGMP messages. For each channel switch, the user STB must generate one IGMPv2 Leave Group message and one or more Membership Report messages. Knowing the list of TV channels with the corresponding multicast addresses (it is possible to get them by sniffing traffic when starting STB device) and tracking IGMPv2 messages in the home network, it is possible to track user habits when watching live TV programs.

C. Using EPG

Using EPG (program guide) of Operator A, the information retrieval about the program content is done using HTTP requests, and data are in JSON format.

Operator B does not have an instant communication between the STB and middleware. Information describing program content for the specific time interval is in XML format and they are loaded during device booting, as observed in subsection A: Operator B.

D. Using "Snimalica"

Snimalica is used for recording and later reproduction of video content stored on servers in provider's network (Networked Personal Video Recorder - nPVR). Data collection is done for three use cases: video content recording, watching and erasing previously recorded content.

Both operators use HTTP requests for retrieving all necessary information and starting the actions of recording, erasing or reproduction. Establishing and control of the reproduction of pre-recorded video material is done via RTSP. As arguments to those requests, identifiers of program, i.e. recorded content, are used.

Taking into account that HTTP and RTSP requests are used, it is possible to track habits of using *Snimalica* and subsequently reproducing the content previously displayed to the user.

E. Using "Videoteka" - Video on Demand

Video on demand enables renting multimedia content by using remote control. Data collection is done only for the process of shopping, i.e. renting the video content, omitting the other use cases. Shopping process is verified by user's PIN code at both operators.

HTTP requests with corresponding arguments are used for getting all necessary information and carrying out the renting transaction itself. This enables tracking users' habits and rented content.

By observing details of shopping transactions, we have noticed that Operator B does not provide any safety mechanism from malicious transaction repeating. Operator A has some data from the request cookie which are seemingly safety mechanism, but they can be found in all other HTTP requests, meaning that they are not unique for the transaction itself.

By repeating HTTP requests, with changes of video content identifiers, malicious attacker on user's home network could cause a significant financial damage to the user because the middleware would consider it a legal shopping transaction made by the user.

F. Using application Youtube (Operator A)

Youtube application is used for watching video content on Youtube service. The IPTV user chooses from the given video content or searches the content using keywords. Information about the available content, searching the content and all necessary parameters for carrying out the service, are retrieved via HTTP requests, the same way as the video content itself. Therefore it is possible to keep the track of using Youtube service and later reproduce displayed video content.

G. Using application Facebook (Operator A)

Facebook application within IPTV service enables user to access Facebook profile and most of its functionalities via web browser using the interface adjusted to be displayed on TV device and for using the remote control. Before using the application, it is necessary to sign in using eligible Facebook username and password.

The same as for Youtube application, the data traffic between the application on STB and the rest of IPTV system is done via HTTP protocol and it is fully readable, which enables insight into all exchanged data. Username and password are sent as plain text during the authorization request and can be seen by anyone with the access to the network communication.

Sniffing IPTV traffic enables finding out all exchanged data: personal data, friends' data, photos, messages, Likes etc., including the user's Facebook profile password.

H. Using application "Telefon" (Operator A)

Application "Telefon" enables the possibility of displaying the notification of the current phone call, with the caller's phone number, and checking the phone call lists (list af all, missed, received, outgoing calls) on TV device.

For the current call notification the IPTV system sends STB at TCP 8080 port a file in JSON format which contains the information about the time of the call and caller's number.

For the list of calls overview the communication is performed via HTTP requests. Lists are in JSON format and they contain information about the time and duration of a call.

Sniffing IPTV traffic it is possible to see current phone communication, as well as user's phone call history.

V. GATHERED INFORMATION

The following table summarizes gathered information, relevant for this research, based on the analysis of the data collected via sniffing communication between end user STB and the rest of the IPTV system during the ordinary user activities.

OPERATOR	A	B
STB DEVICE		
Device model	✓	✓
SW – UI version	✓✓	✓✓
IP - MAC address	✓✓	✓✓

List of all calls	✓	

✓* - in the case that the collected content that is displayed to the user is not protected

VI. CONCLUSION

The paper provides insight and the analysis of the communication between end user STB and the rest of the IPTV system with an aim to investigate the possibility for the violation of user's privacy and see the amount and type of user, content or system information that can be obtained by sniffing IPTV home network.

Analysis of the collected traffic for both chosen operators has shown that it is possible, and rather easy, to find out user's personal data including their PIN codes, habits of watching television program and video content etc. In case user is subscribed to more advanced IPTV applications, like Facebook or Telefon, it is possible to get additional personal or friends' data, phone call records etc. Besides privacy violation, it is possible to get extensive information regarding the operation of IPTV system, mode of service implementation and available content. Large number of information can be obtained due to the fact that most inter-system communication is performed without the additional protection, using protocols and formats which are easily read (HTTP, RTSP, SAP/SDP protocols, XML, JSON formats). Once known HTTP or RTSP requests can be repeated, with the same or changed arguments, and thus obtain information without waiting for the user's action.

From the network security aspect, the fact that user's PIN code can be easily retrieved at both operators, that at Operator A Facebook username and password are in plain text and open for everyone who monitors the network communication, that shopping/renting transactions are done without the additional protection via simple HTTP requests, is very dangerous for users. Using wireless STB in the future is likely to increase the possibility of abusing described security and privacy issues.

It can be concluded that IPTV service providers should additionally protect delicate communication of user services and assure better user privacy protection, at least at the level of protecting video content, regardless the low possibility of unauthorized access to the user's home network and potential degradation of QoE due to the additional protection measures.

Have we been monetized and become commodity without our consent – Privacy in the time of Big Data Technology

Marinko Žagar, Dubravka Mendeš Poljak
Polytechnic of Zagreb, City of Zagreb

According to Eric Schmidt, Google CEO, the quantity of data which is now generated in only two days, equals the quantity of data which was generated since the beginning of civilization until 2003. Aggregation of technologies which are used for storing and the analysis of huge quantity of data are called Big Data, and are used in many aspects of human activity. Since both structured and non-structured sources of data are used in Big Data technology, there is a question of personal data and privacy protection. Are and in what ways various companies, agencies and services collecting and analyzing personal data from social networks in order to increase their efficiency, make profit or to increase general safety of citizens? Law on Protection of Personal Data regulates the protection of personal data of citizens as well as the supervision of the collection, processing and use of personal data in the Republic of Croatia. Provisions of this Law are applicable to the processing of personal data by state authorities, local authorities, as well as legal entities and private persons who process personal data. Has personal data which is stored and analyzed on daily basis become commodity without our consent?

I. INTRODUCTION

Over the years, the quantity of information available on the Internet has become bigger and bigger. Facebook is an excellent example which illustrates this point. Over 500 TB of data is processed daily in this social network; 300 million photos and 2.7 billion "likes". In the article titled "Big Data Just Beginning to Explode", it is said that the quantity of data expands at the astonishing rate and that the annual growth of data by the year 2020 will amount to 4300%. [1]. Due to continual development of new technologies, as well as trends such as Cloud Computing and Big Data, we are more than ready to store and use all this information for various purposes. Depending on what purpose the information is analysed and used for, ethical issues regarding such use emerge, as well as the need for the protection of customer's privacy.

The term "Big Data"appeared for the first time in the article of NASA investigators M. Cox and D. Ellsworth in 1997. They emphasized the occurance of problems as the result of generating huge quantities of data. At that time, the existing computers with its memory and disc capacities were not able to accept such quantity of data. Nowadays, the technology in use excludes such limitations. The term "Big Data" has been kept until these days, however, it is no longer referring only to marking big quantities of data but active use of tools and procedures for analyzing and obtaining values; that is quality information out of that data

II. BIG DATA TECHNOLOGY

A. *Where is Big Data Technology used?*

World most famous examples of Big Data Technology use are Google, Yahoo, Amazon, Facebook, Netflix and Hadoop.

Google is definitely the leader regarding the quantity of data it processes and is taking number one place as Big Data Technology user. They were one of the pioneers who developed their own method of analysis, known as MapReduce.

By developing its software Hadoop, Yahoo! has brought such analysis closer to a broader circle of users. Hadoop is Java-oriented frame of open code which is used for processing big blocks of data in distributed computer systems.

Another famous global example of using Big Data Technology is Netflix; an American company which provides video content on demand. They have developed the most complex analysis of films and series, based on users' preferences. They have developed algorithms by which they can accurately predict what their users like, what their interests are, what they want to watch and at what time. In this way, Netflix offers their customers exactly what they want. Thanks to such successful model of prediction, they know what a successful film or series should look like and what actors and qualities are expected in such film.

Inspired by Netflix's success, Hrvatski Telekom signed a contract with data analysis company called TVbeat which would monitor viewing statistics of its IPTV platform [2]. By this, HT will get an insight into the viewing habits of its customers. Access to data in limited and entirely anonymous form will be given by HT to third parties (advertisers). The use of this technology will be visible through the definition and adjustment of new or modification of the existing services for the targeted user groups, all based on the conducted analysis.

Apart from the listed examples, there is a range of different areas where Big Data Technology can be applied. However, its biggest application is in companies such as Netflix, which have the need to understand the needs and

preferences of its targeted groups and users. We are talking about marketing agencies with high probability analysis, which give their recommendations to companies regarding the choice of products ideal for a group of customers.

American trading house Target, by using this high probability technology, can know when one of their customers is expecting a baby and can, in accordance with that information, offer them targeted products.

Search engines are another useful source of information. By gathering and analyzing searched terms, one can get very useful data as well as link the person with the inquiries they made.

Smart phones, tablets, smart bracelets and similar devices enable us to monitor and record everything, including the tiniest details of our daily lives such as calories intake, workout time and intensity, sleep rhythm, emotional state etc. When all this data is collected and analysed, one can get very useful recommendations. Simply by observing activities on social networks and from statements like this one: "Today I am feeling terrible, I'm lying in my bed with high temperature", one can predict the outbreak of flu infection in a certain geographical area. In 2009 Google correctly predicted the course of swine flu epidemic spread simply by monitoring swine flu-related searches on the Internet. This technology has been in use in the world of sports for some time now with the purpose of improving sports achievements.

They have come up with a service called MyMagic+ in Disneyland where users effectuate various benefits by wearing smart bracelets. In return, the park monitors all the user's activities, including his/her spending pattern.

In cities, by monitoring traffic, one can predict traffic jams and organize alternative routes, plan major events and more successfully manage the local infrastructure.

Surveillance cameras, private or public, are all around us. This method of monitoring and recording people is the most concerning regarding privacy isssues.Cameras can monitor our movements and if a face recognition algorithm is applied, a person can easily be identified.

The town of Zagreb, by signing a cooperation agreement with Microsoft on Microsoft CityNext project has made their first step towards the use of this technology, with the purpose of fast management of bureaucratic needs and better data management in all its operational segments.

Banks use Big Data technology not only to predict and prevent the abuse of credit cards and other financial malfeasance but to analyse their clients' behavior, their needs and, as consequence, to create specific, personalized offers through their products.

American National Security Agency, NSA, has been collecting huge quantities of metadata from all types of communication and has been using Big Data analytics in order to (among other things) uncover and prevent terrorist attacks and other security threats. Through the Boundless Informant[1] programme 96 billion intelligence units have been collected from servers and telecommunication channels throughout the world in March 2013 alone. [9]

As can be seen from the examples listed above, Big Data technology is more and more in use in a growing number of various systems benefiting individuals directly or indirectly. Crisis management systems have proved to be very efficient and show that the use of personal data without the consent of its owners is crucial in rescuing operations, whereas data owners do not support the use of personal data for commercial and marketing purposes without prior consent.

Analysts predict the future of the Internet closely linked to the term of Internet of things[2]. Internet will simply disappear. There will be many IP addresses, devices, sensors and things which we will carry around and which will be connected, yet we will not even notice that."[3]

The responsibility of each individual when it comes to sharing personal data is often crucial because some individuals ignore EULA[4] which warns the user what software manufacturers will use personal data for. Very often users give their consent without reading the terms of use.

B. Data collection

Information which is used for various Big Data technology analysis is collected from numerous sources. These sources may or may not be private or public, structured or non-structured. The number of users is continually growing, social networks are becoming more and more popular and therefore habits and user activity on the Internet is present in abundance. State and local institutions are becoming more and more aware of the importance of sharing information, partly due to Law on Freedom of Information, partly due to pressures from the European Union, and partly due to the need to provide better services to its citizens. However, all those information, without unification, joint analysis and pattern definition do not have any great value. Picture 1 shows the basic concept of Big Data technology which covers data collection and filtering, storing, sharing and analysis of data, as well as taking actions based on the analysis results of the collected data.

Privacy is becoming an asset based on the laws of supply and demand. Information is a highly valued commodity nowadays, and the information we are willingly sharing on the Internet are being "traded for" certain services. If we want to use some of the services of a webpage we accessed, for example to fill out a questionnaire, play a game or leave a comment, etc., in most cases we are not able to do so unless we accept the terms of use. In this way webpages or applications which potentially collect personal data meet the legal regulation

[1] Boundless Informant – Secret NSA programme which enables collection of information of worldwide communication conducted via phones and computers. A programme called PRISM has been used for this purpose.

[2] Internet of things – IoT – interconnection of uniquely identified devices with the Internet.

[3] Eric Schmidt, the president of Google, Davos 2015.

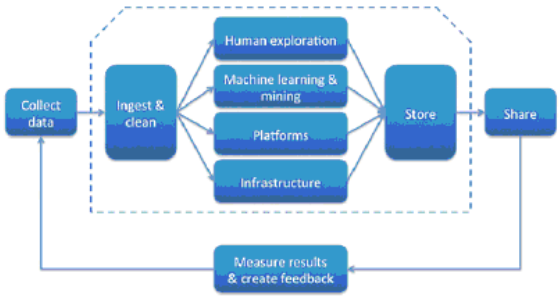
[4] EULA – End-user License Agreement

regarding data collection and processing, as stated in Article 6 and Article 7 of the Law on Protection of Private Data.

"Privacy Policy"is an integral part of every webpage. It defines the terms of use as well as ways in which the service provider will use the data and to whom the data will be available. To sum up, privacy policy is entirely defined by those who offer certain services and the user has a choice whether to accept it or not. Due to the fact that those terms of use are in most cases extensive and elaborate, the users are rarely aware of what they contain and in what ways their personal data is managed, even if they had accepted them. Marketing agencies are very skillful at using this way of "informing" their users. The data used in Big Data technology comes from different sources for which perhaps we gave our consents, but the new set of data emerging from the analysis and obtained through the combination of various sources may not be what we gave our consent to.

Apart from accepting the terms of use, the use of cookies is also regulated. Setting cookies, software which monitors and records computer user's activities when they access webpages is no longer allowed without the consent of the computer user.

Current legislation is not able to entirely protect the privacy rights and therefore individuals should get more involved and assume control over the protection of their data. Individuals should act responsibly during their Internet searches, they should refrain from sharing their data and always read the terms of use of the webpages they visit as well as EULA.



Picture 1. Data flow used in Big Data Technology

Legislation

Thanks to the rapid growth of the Internet users and available services, there is a growing concern regarding the protection of their privacy and personal data. In 90 countries all over the world they have passed laws which regulate personal data access. Nearly all those laws are based on specific measures adopted on the level of individual countries. In Croatia there is a Law on the Protection of Private Data, a Law on Freedom of Information and a Law on Electronic Media. As bylaws in Croatia, the following is in use: Regulation on Keeping Records and the Form of Personal and Regulation on the Procedure for Storage and Special Technical Protection Measures for Special Categories of Personal Data.

The right to protection of personal data is a fundamental human right and, as such, is guaranteed by the Croatian Constitution (Article 37 of the Croatian Constitution). As for the personal data protection, these rights are regulated by law in Croatia. Article 6 of the Law on Protection of Personal Data stipulates that personal data may be collected for the purposes of which the user has been informed on, which have been clearly stated and in accordance with the Law and may further on be processed only for its originally stated purposes. Provision of Article 7 of the same Law provides the legal basis for the collection and processing of personal data. Therefore, personal data may be, among other things, collected and further on processed with the consent of its owners only for the purpose for which the owner gave their consent, in cases specified by law, for the purpose of carrying out legal obligations of the supervisor of collection of personal data and the other enumerated cases. In the case where the individual gave their consent or shared the data themselves, they have the right to withdraw their consent. Croatian Laws conform to the highest European and international norms and standards and fulfill the obligations arising from international conventions that the Republic of Croatia signed and ratified. International law defines data protection: Convention 108 of the Council of Europe - The Law on Ratification of the Convention for the Protection of Individuals with regard to Automatic Processing of Personal Data and the Additional Protocol to the Convention (MU no. 04/05), Directive 95/46 / EC of the European Parliament and the Council - Directive protection of individuals with regard to the processing of personal data and on the free movement of such data, Directive 2002/58 / EC of the European Parliament and the Council - Directive on the processing of personal data and privacy in the electronic communications sector and the Manual on European legislation on data protection. As the document states, it is very important to understand that the right to data protection is not an absolute right, but it has to be balanced against other rights, national legislation and individual cases. For this reason, for example, publication of photos in some cases may be interpreted as a breach of privacy, while in some cases this may not happen. All these laws share the concept of consent. Consent means "each voluntarily given, special and informed expression of will." In many cases it is the legal basis for the lawful processing of data[5]. According to Article 2 of the Law on Personal Data Protection of the Republic of Croatia, the subject's consent is freely given and it is a specific manifestation of the subject's will by which they express their agreement to the processing of their personal data for specific purposes.[6] This means that the consent must be clear, unambiguous and free statement, given by the individual and regarding the use of data which this individual can withdraw at any time. The individual must also have the right to choose in order to make their consent valid, and the withdrawal of such consent should not invite any type of sanctions.

[5] Directive on Data Protection, Article 2. Act (h).

[6] Directive on Data Protection, Article 2. Act (h).

However, the problem arises when it tries to answer the question of how to regulate the collection, storage and exchange of information on the Internet, especially when all that is spread throughout different countries and continents.

Current research regarding the issues of privacy concerns on the Internet shows that most respondents feel concern about that. According to research conducted by Tech Pro Research, 84% of the total number of respondents confirmed their concerns regarding privacy violations [8]. Similar results were obtained through extensive research conducted by the committee formed by order of the President of the United States Barack Obama on Big Data and privacy, ie. how this technology affects the way we live and work [10].

Picture 2. Most occurred words regarding Big Data technology inquiries [10]

Despite that, the users of smart phones, social networks and the Internet, generally speaking, do not think about these issues as they use various accessible and widespread services and publish their statuses or opinions on the Internet. Awareness about the violation of privacy is only perceived after all those opinions, comments and data typed in various search engines, profiles etc. are displayed back to their originator. There was a case like that in a divorce hearing when an ex-wife was faced with a document containing all her online activities collected in several large files [4]. It contained information on how much time she had spent on the Internet, which webpages she had visited, what opinions and comments she had shared and how she had felt every day. All that data was used as character traits of the person in question. Certainly, this felt like the violation of privacy and it caused great discomfort for her. Regardless of the fact that all such activities are recorded in the vastness of the Internet, the users do not think about who may see or use such data due to the falsely created feeling of anonymity on the Internet. On one hand the Internet promotes the freedom of expression and it has become the largest civil force that has emerged in recent years, and citizens have a voice that can be heard[7], on the other hand we try to protect and restrict all these information. The protection of such information and privacy is still the responsibility of each country. Therefore, this is more or less (depending on the country) regulated by law. EU members are trying to secure the highest level of privacy protection for their citizens. On the other side, the USA is not placing emphasis on the protection of privacy, whereas in countries such as China or India privacy as such does not even exist. However, regardless of laws, interpretations of the right to protection of personal data and privacy are very elastic.

In addition to incomplete definition of the protection of privacy in the Internet environment, virtually no or very small penalties are prescribed for the violation of it. The European Parliament currently adopted only a formal proposal for a new legislation on data protection of citizens which provides much greater sanctions of companies which will be violating this[4].

C. What does Big Data know about us?

It is easy to conclude that, based on the areas where Big Data technologies are used, the collected and processed data can easily identify individual persons. In order to placate concerns regarding the privacy violations, the organizations which use and publish analysis based on Big Data information harvesting claim that all information by which an individual could be identified have been removed. They claim that it is impossible to link records with actual persons who made those records. In the article titled Data Issues, Pete Warden gives several examples to prove the opposite. One of these examples is Netflix, who released an anonymous list of film rentals. This list was correlated with and analyzed along with IMDB reviews, which made it possible to determine the identity of certain individuals and view their entire rental history. Another example is the analysis and the comparison of two different social graphs, the result of which also led to the identification of the persons in question [7]. Information such as user names, e-mail address, webpages visited, inquiries done, comments left, IP addresses, times of action and many, many more are sent through web browsers. We leave traces. Regardless of that, individuals voluntarily give up their privacy in order to participate in all the services provided on the Internet. It is very easy to monitor the location and movement of persons via their smart mobile phones, however such knowledge does not diminish the number of smart mobile phone users.

III. BIG DATA AND PRIVACY

A. Data management in the public sector

Our data can be found in various data collections which are stored and kept at data centres of ministries and government bodies. Government agencies and services have our personal data and use them to improve their services towards us, in order to make government services more efficient. The use of personal data in the times of crisis, natural disasters or terrorist threats is absolutely justified and to citizens quite understandable. The use of personal data in such situations is legally regulated by the Law on the protection of personal data, if the data processing is required for the purposes of protection of life, preventive medicine and the like. The systems of predicative policing, based on Big Data analytics use both structured and non-structured data from various public

[7] Eric Schmidt, Google, The World Economic Forum in Davos 2015.

services. The analytics of such complex and enormous quantities of data is extremely efficient. Crime rate in cities where such systems have been implemented have been decreased by approximately 20% [11]. Apart from the above listed situations, our data is used in situations which are not predicted by laws, nor did the citizens give their consent to it. For example, during the political campaigns, some politicians send personalized messages to their voters and ask for their votes in text messages or via post. Apart from this, seemingly innocent example, every day we witness the use of someone's personal data for the political purposes, and the sources of such data are government agencies or services. We are in particular sensitive to the abuse of our health-related data as well as data of underage persons.

The use of personal data from such databases in combination with the data from social networks and services can be used for various purposes and their latent value is huge.

Data management in the private sector

Private sector is becoming more and more aware of the value of their databases. The implementation of CRM systems has become the condition for the provision of the efficient service to their customers and clients, and company owners and management are aware of this fact. Such systems bring certain benefits to their owners as well as to their clients. Significant benefits to both sides are brought by the use of Big Data technology, which can analytically manage both structured and non-structured data from various sources. The value of data is best illustrated through the example of company Facebook, which is a classic example of a company whose business is entirely based on data. We can see a big discrepancy between the estimated market value of $ 104 billion and the value of company's physical assets estimated at $ 63 billion. This enormous discrepancy in value represents the data the company works with. Doug Laney, the president of company Gartner, was the first one who warned us about the lack of data value in presenting the book-keeping value of Facebook. In his research he pointed out that even though Facebook owns "just data", in a value sense they own 2.1 trillion units of tradable goods, such as likes, uploaded materials and comments, which have been collected in the period between 2009 and 2011. This number is even more impressive nowadays. In the same research, he highlighted the actual value of each such data item at 5 cents, which sheds a totally different light on Facebook, where every user is worth $ 100[12].

Daily use of technology brings many advantages but also reveals many details which we would rather keep private. How to harmonize these apparently opposing facts?

B. How to protect privacy?

Even though continual efforts are invested into solving this issue, measures that have been adopted and in force are failing at protecting the privacy. This is the result of several things: lack of help, poor awareness, and in many cases the lack of interest of the individuals. The individuals are the persons who share and manufacture "products" in big quantities and should therefore get informed about where and how their data will be used. On the other hand, terms of use and consents on websites should be clearer, more concise and concrete regarding management methods of the data they provide. Luckily, data and privacy violations are not used in order to cause certain damage or malicious actions. Regardless of that, the individuals are feeling threatened when they receive personalized e-mail messages for which they know they had not given their consent. People are also unwilling to share their information in order to help third parties to make profit. One of the proposals of privacy protection in this case is that organizations which use data inform their users about where, when and how they would use their personal data [6]. The negative side of this method is that persons might be swamped with a large number of notifications in cases where many organizations would use their personal data and there would be very little they could do about that.

The largest challenge today, in times of Big Data when large sources of data are available, is the prevention of any kind of data leakage and securing that organizations which have access to private information do not use them for commercial purposes.

IV. CONCLUSION

Even though the benefits of using Big Data technology are, by far, great and useful, it is clear that this way of data collection and data analysis violates privacy in all its segments. Laws do exist, however, regulations and provisions are not able to protect privacy and at the same time enable the free use of Big Data technology. Despite the fact that it is the individuals who share their data and who should be more responsible for what they do, they do not want to be the ones who think about such issues and expect legislative control of organizations which collect and process data and therefore it is expected from states to reinforce their activities in this area.

SECURITY AWARENESS AND EDUCATION TRACK

Impact of Security Education on Password Change

Viktor Taneski*, Marjan Heričko* and Boštjan Brumen*
* University of Maribor, Faculty of electrical engineering and computer science/Institute of Informatics, Maribor, Slovenia
viktor.taneski@um.si, marjan.hericko@um.si, bostjan.brumen@um.si

Abstract - Users and their passwords are the weakest link of security, because they tend to create passwords that are not strong, easy to remember and contain words that are familiar to them. Users' lack of security consciousness and their behavior can be influenced by security education. Our research explores the effect of password security training on the strength of the passwords chosen by the users. The objective of this paper is to explore possible differences in the quality of passwords between students from different faculties with different foreknowledge and education about passwords and security. In this paper we analyze the passwords of the students from the Faculty of Tourism and compare the results to the ones from the Faculty of electrical engineering and computer science at the University of Maribor. We collected the data by means of an online questionnaire, performed among undergraduate and graduate students. Despite our efforts to educate the users about the importance of frequent password change, a large percent of users did not change their passwords following the lectures. The overall conclusion of this preliminary study is that users still lack security knowledge regarding password change and need to be further educated in this direction.

I. INTRODUCTION

The combination of a username and password is the most common method for gaining a legitimate access to a computer system. Alternative authentication methods such as biometrics (based on "what you are"), smart cards (based on "what you have") and two-step verification are becoming more available, but passwords remain the most common method for authentication for computer systems, despite the fact that they suffer from a number of problems. Password-related problems are firstly identified by Morris and Thompson [1]. In their experiments they noticed that users of the system chose passwords that are short, simple and contained only lowercase letters and digits, or appeared in various dictionaries. 20 years later Zviran and Haga [2] concluded that one of the biggest vulnerabilities to a computer system's security is the user. Almost 50% of the users surveyed in their study reported passwords composed of five or fewer characters, 80% used only alphanumeric characters, and 80% never changed their password.

Many approaches and solutions, for increasing the security and usability of textual passwords, were proposed through the years but none have proven widely acceptable [3]. Users and their textual passwords are still considered "the weakest link", because they still tend to choose weak passwords and passwords that can be found in a dictionary [4], use a very small number of passwords and are likely to use words that are familiar to them as their passwords [5]. Users create the easiest-to-remember passwords regardless to any recommendations or instructions and tend to trade security for memorability [6], [7]. These problems can arise as a result of users' lack of security motivation and the fact that users tend to circumvent password restrictions for the sake of convenience [8]. This indicates a deficit in user's consciousness about security and this user behavior can be influenced by information security training [9]. Educating users about password security and assisting them with creating secure passwords can raise the security consciousness of system users and can help achieve greater security [2].

This study, which is research in progress, explores the recommendation of Zviran and Haga [2] by analyzing the effect of password security training on user's practices regarding password creation, frequent password changes and their consciousness about security and the importance of creating strong and hard-to-guess passwords. We performed a pilot study among undergraduate and postgraduate students from the Faculty of Tourism and the Faculty of electrical engineering and computer science at the University of Maribor. We investigated their password practices, attitudes and knowledge about password creation and password security. The survey consisted of two phases over one month period along with several lessons on password security between the two phases. The first phase of the survey was performed among students that had no password security training. The second phase of the survey was performed one month later on the same group of students. For a period of two weeks, between the two phases, the students were educated about the importance of password security and how to manage their passwords. Following the lectures there was a two-week period for learning decay. The contribution of this study in this manner is that we succeeded in educating the participants about some password practices, in contrast to some previous studies [10], [9] that have not proven to be quite successful.

The rest of the paper is organized as follows: In Section II we review and analyze related work, Section III describes the research method, Section IV presents the results of the survey and a discussion, while Section V concludes the paper.

II. Related Work

Research on passwords has been active for almost 35 years [3]. Zviran and Haga [2] in their paper on password security investigated in more details the characteristics of user-selected passwords and the relationships between key password characteristics. They used a questionnaire as an instrument to investigate users' password characteristics. After finding that user-selected passwords are relatively weak and easy to guess, Zviran and Haga propose a further investigation of the effectiveness of educating users about passwords security and raising their security consciousness.

There have been a few previous attempts to research the effect of education on users' password practices. Delber Hart in [10] presents the results of an experiment performed to determine the effect of a brief presentation of password security best practices on users. The methodology used was a survey, which was administered five times among different student groups along with some password education. The results of the study show that the education had no significant effect, even possibly had an opposite effect: students realized they do not want any more information about password security best practices.

The study by Horcher and Tejay [9] follows the recommendation by Zviran and Haga and examines the use of cognitive load theory to design the information security training on password strength. It is a study in progress involving employees in a chemical company with different level of technical expertise and work location. The preliminary results show that after twelve hours of cracking users' passwords, 93% of the passwords were compromised, using the dictionary of pre-computed passwords.

Our approach can be viewed as a combination of the aforementioned approaches. Our questionnaire is an improved version of the one created by Zviran and Haga in [2]. Furthermore, our education was conducted over a longer period of time compared to that of Hart in [10], and in addition to the password strength we also analyzed the general password characteristics and the password change frequency.

III. Method

A. The Survey

Data for this study were collected by means of an online questionnaire. The main objective of the questionnaire was to determine the characteristics of textual passwords used by individuals to log in, mainly to a university account, but also to other accounts, such as Facebook, Twitter, Google, or their own mobile devices and phones. Because asking users about their passwords is a sensitive topic, we did not ask them about their actual passwords, but rather about the characteristics of their passwords for different accounts. We classified the questions into six categories:

- Account information – which services or devices does the student have a password for (desktop computer, notebook computer, mobile phone, tablet, University account, Facebook account, Twitter account, Google account)
- Password information – the characteristics of the selected passwords (first character, length, how did the user choose the passwords etc.)
- Password recall – how often do users forget their passwords, how often do they change them and how often do they write their passwords down
- Frequency of password use – information about how often do users log in by using the password, and whether they use the password to log in to multiple accounts
- Data importance and data sensitivity – how important and how sensitive are the data to users they are protecting
- Demographic data about the user – gender, year of birth, university, faculty, postal code etc.

TABLE I. Number of Participants in the Study

Faculty	Initial results		Filtered results	
	Phase 1	Phase 2	**Phase 1**	**Phase 2**
Tourism	43	37	34	34
EE&CS[a]	33	30	30	30
Total	76	67	**64**	**64**

a. Electrical engineering and computer science

For creating our questionnaire, we drew inspiration from the questionnaire that was performed by Zviran and Hagga [2]. Our questionnaire has additional questions and additional answer options about password characteristics for different accounts for different services or devices, thus allowing us to compare characteristics of different passwords for different accounts. The completion of the questionnaire took between 15 and 20 minutes.

B. Procedure

The survey was conducted in the spring term of 2014 and consisted of two phases. The first phase of the questionnaire was performed among students that did not receive the lessons. After the first phase of the survey, the students attended lectures dedicated specifically to passwords and related issues, like password creation, management and security. The education consisted of topics about the importance of creating strong and secure passwords, how to choose such passwords and how to manage them (frequent changes, no writing down, no reusing one password for more than one different accounts etc.). After the education part followed a two-week period of learning decay, followed by the second phase of the survey. We slightly modified the questionnaire by adding an additional answer option "I prefer not to disclose" to every question in the "Password information" section. The goal is to see if there will be any significant difference in the general password characteristics and the frequency of password change, before and after the students attended the lectures.

TABLE II. SUMMARY OF COMMON PASSWORD CHARACTERISTICS – FACULTY OF TOURISM

Account	Common password characteristics			
	Phase 1	Count	Phase 2	Count
desktop account	lowercase letters only	4 (26.7%)	lowercase letters only	4 (26.7%)
notebook account	mixed case letters and 3 or more digits	3 (20.0%)	lowercase letters only	6 (37.5)%
	mixed case letters and 1-2 digits somewhere	3 (20.0%)	I prefer not to disclose	3 (18.8%)
mobile phone	digits only	11 (64.7%)	digits only	6 (37.5%)
			lowercase letters only	3 (18.8%)
tablet device	digits only	2 (50.0%)	digits only	2 (33.3%)
University account	lowercase letters only	5 (19.2%)	single case letters and 1-2 digits in front	4 (14.8%)
	mixed case letters and 1-2 digits somewhere	4 (15.4%)	I prefer not to disclose	5 (18.5%)
Facebook account	lowercase letters only	7 (22.6%)	mixed case letters, several special characters and several digits	4 (14.8%)
			I prefer not to disclose	5 (18.5%)
Twitter account	mixed case letters and 3 or more digits	1 (33.3%)	long sentence, mixed case	1 (25.0%)
			I prefer not to disclose	1 (25.0%)
Google account	lowercase letters only	7 (25.0%)	mixed case letters, several special characters and several digits	2 (10.0%)
			I prefer not to disclose	4 (20.0%)

C. Participants

The participants were undergraduate and postgraduate students from the Faculty of Tourism and the Faculty of electrical engineering and computer science at the University of Maribor. Table I presents the number of participants in the first and the second phase of the study. As shown in the Table I, a total of 76 students participated and completed the first phase of the web-based survey (43 students from the Faculty of Tourism and 33 from the Faculty of EE&CS). 67 of them also completed the second phase of the study (37 from the Faculty of Tourism and 30 from the Faculty of EE&CS). As we can observe from Table I, the number of participants is not equal in the first and second phase, which means that not all participants completed the two phases of the study. Having the same sample/participants in the two phases of the study is crucial in order to properly analyze the data and determine whether our education had any significant effect. For this matter, before we proceeded with analyzing the data, we excluded those participants that did not complete one of the two phases (either the first or the second phase). Thus, we used a total of 64 records, as legitimate answers for performing our analysis. The last two columns in Table I represent the number of total participants in the study, after we filtered the results. Ages of the participants range from 21 to 51 years for the Faculty of Tourism ($M = 28.50$; $M_d = 24.50$; $SD = 9.046$; a Shapiro-Wilk test of normality indicates a deviation from normality at $p << 0.05$) and from 21 to 26 years for the Faculty of electrical engineering and computer science ($M = 22.93$: $M_d = 23$; $SD = 1.172$; a Shapiro-Wilk test of normality indicates a deviation from normality at $p = 0.015$). Ten participants were male and 24 were female at the Faculty of Tourism, and 26 were male and 4 were female at the Faculty of electrical engineering and computer science.

IV. RESULTS

We were interested in the general password characteristics and password change frequency before and after the lectures. We were also interested in finding out whether there is any significant difference in the general password characteristics and the password change frequency between users' passwords from both faculties.

A. General Password Characteristics

Since asking about the actual users' passwords is a sensitive subject, we asked our participants about their password characteristics and did not inquire their actual passwords. The question that we asked in both phases was "What are the characteristics of your password?". The most common answers to the question for both phases and both faculties are summarized in Table II and Table III for both faculties, respectively. In the tables, the first column denotes the specific account, the second column represents the most common answers about password characteristics for every account in the first phase. The third and the last column represent the most common answers and the percentage of users who chose that specific answer in the second phase.

We were interested to investigate whether there is any significant difference in the general passwords characteristics for the accounts before and after the lectures, first for the Faculty of Tourism, and second for the Faculty of EE&CS. A before and after measurement of password characteristics was taken on a categorized ordinal scale, from 1 = "digits only" to 23 = "long sentence, digits and special characters" and 24 = "I prefer not to disclose". We ordered this scale by calculating the number of possible password combinations for every

TABLE III. SUMMARY OF COMMON PASSWORD CHARACTERISTICS – FACULTY OF ELECTRICAL ENGINEERING AND COMPUTER SCIENCE

Account	Common password characteristics			
	Phase 1	Count	Phase 2	Count
desktop account	lowercase letters only	4 (28.6%)	mixed case letters and 1-2 digits somewhere	5 (31.3%)
			I prefer not to disclose	2 (12.5%)
notebook account	lowercase letters only	6 (23.1%)	mixed case letters and 1-2 digits somewhere	7 (25.9%)
			I prefer not to disclose	2 (7.4%)
mobile phone	digits only	12 (63.2%)	digits only	11 (57.9%)
tablet device	digits only	2 (66.7%)	digits only	2 (66.7%)
University account	single case letters and 1-2 digits behind	9 (33.3%)	mixed case letters and 1-2 digits somewhere	5 (17.9%)
			I prefer not to disclose	2 (7.1%)
Facebook account	mixed case letters and 3 or more digits	7 (25.0%)	mixed case letters, several special characters and several digits	6 (21.4%)
Twitter account	mixed case letters and 3 or more digits	4 (44.4%)	mixed case letters and 1-2 digits somewhere	3 (33.3%)
			I prefer not to disclose	2 (22.2%)
Google account	mixed case letters and 3 or more digits	7 (28.0%)	mixed case letters and 1-2 digits somewhere	4 (17.4%)
			I prefer not to disclose	2 (8.7%)

password category. For the purposes of this paper, we presumed that the average password length is approximately 9 characters, as stated in [11], a long sentence would have at least four words, and we have the English language and the English alphabet as a dataset (e.g. for a "one letter uppercase, other lowercase" type of password the number of possible combinations would be $26^1 \times 26^8 \times 9$).

The data for the Faculty of Tourism were mostly not normally distributed (Shapiro-Wilk test of normality indicated a deviation from normality for nearly every account password, except in the case of tablet account passwords where the data were normally distributed. Therefore, we performed non-parametric Wilcoxon Signed-rank test for dependent samples to compare the two dependent samples (before and after). In the case of tablet account passwords we performed a Paired samples t-test. The results indicate that there is a significant difference in password characteristics after the lectures for the mobile, University, Facebook and Google accounts (p-values: 0.043; 0.004; 0.013; 0.011 respectively, at significance level 0.05). If we take a look at Table II we can observe some changes in users' passwords for the mobile, University, Facebook and Google accounts, which we find significant. The passwords for the University, Facebook and Google account in the first phase mostly consist of lowercase letters only. The results from the second phase demonstrate that the passwords for these accounts are slightly stronger (according to our ordinal scale): consist either of single case letters and 1-2 digits in front, or mixed case letters, several special characters and several digits. We can also observe changes in the password characteristics for other accounts, but our statistical analysis shows that these changes are not statistically significant and may be due to chance alone.

The data for the Faculty of EE&CS were also not normally distributed (Shapiro-Wilk test of normality indicated a deviation from normality for every account passwords). As previously, we performed a Wilcoxon Signed-rank test for dependent samples to compare the two dependent samples before and after. The analysis shows that there is no significant difference (the significance level is 0.05) between password characteristics before and after the lectures, for none of the accounts. By looking at Table III we can, however, observe certain changes in the characteristics of users' passwords, but the statistical analysis shows that these changes are not significant. According to our ordinal scale of password characteristics, passwords for the desktop, notebook, University and Facebook account are slightly stronger in the second phase. But, this is not the case with the passwords for the Twitter and Google account where we can clearly notice that passwords in the second phase are weaker than the ones in the first phase.

We can provide at least two possible explanations for this unexpected behavior. First, there is a possibility that participants did not quite understand our lectures about what makes a good and strong password. The second explanation may lay in the fact that a large percent of the participants from both faculties, as we can notice in the both Table II and Table III, chose not to disclose any information about their password characteristics. It is most likely that after attending the lectures the awareness of users about the importance of their data and the importance of not disclosing information about the passwords for their accounts, increased; thus participants in the second phase deliberately falsified data about their password characteristics.

TABLE IV. FREQUENCY OF PASSWORD CHANGE – FACULTY OF ELECTRICAL ENGINEERING AND COMPUTER SCIENCE

Accounts	Frequency of password change	Count
desktop account	never changed it since first use	5 (35.7%)
	less than once a year	5 (35.7%)
notebook account	less than once a year	11 (42.3%)
mobile device	less than once a year	8 (40.0%)
Tablet device	never changed it since first use	1 (33.3%)
	less than once a year	1 (33.3%)
University account	never changed it since first use	17 (63.0%)
Facebook account	less than once a year	11 (39.3%)
Twitter account	never changed it since first use	5 (55.6%)
Google account	less than once a year	7 (28.0%)
	up to three times a year	7 (28.0%)

TABLE V. FREQUENCY OF PASSWORD CHANGE – FACULTY OF TOURISM

Accounts	Frequency of password change	Count
desktop account	less than once a year	11 (64.7%)
notebook account	less than once a year	10 (62.5%)
mobile device	never changed it since first use	6 (35.3%)
	less than once a year	6 (35.3%)
Tablet device	less than once a year	2 (50.0%)
	four to six times a year	2 (50.0%)
University account	never changed it since first use	13 (48.1%)
Facebook account	less than once a year	16 (51.6%)
Twitter account	never changed it since first use	2 (66.7%)
Google account	less than once a year	13 (46.4%)

B. *Password Change Frequency*

We educated the participants about the importance of a frequent password change in order to ensure that a stolen password can not be used to compromise other passwords and accounts of other users in the system. The frequent password change is considered a basic security measure [2]. On the other hand, the rapid growth of the popularity of the Internet and the increased number of online accounts, can lead to users having to maintain many different passwords [11]. Because of this, the forced and too frequent password changes can have negative effect on the users [12]. Users may quickly forget which password restrictions apply to which system, which password is current, and this may lead to users tempting to write their passwords down or to reuse an old one. Despite such claims, the research in literature still supports frequent password changing in order to reduce predictability and suggests that a realistic time for password change should be 90-120 days [13].

We were interested in finding out whether our lectures and recommendations about frequent password changing had any effect on the participants and whether they changed their passwords after attending the lectures. For that matter, in the first phase of the questionnaire we asked our participants "How often do you change your password (when not required by the system?)", and in the second phase, following the lectures, we asked them "Have you changed your password since the last survey or not, and why?" The most common answers to the first question are summarized in both Table IV and Table V for the students from the Faculty of Tourism and the Faculty of EE&CS, respectively. By observing Table IV we can notice that many students at the Faculty of Tourism never change their passwords since the first use, or change them very rarely (less than once a year). We find a statistically significant difference between the answers to this question from the first and the second phase of the study, for the desktop (Wilcoxon Signed-rank, p=0.031), notebook (Wilcoxon Signed-rank, p=0.014), mobile (Wilcoxon Signed-rank, p=0.039), Facebook (Wilcoxon Signed-rank, p=0.023) and Google (Wilcoxon Signed-rank, p=0.012) accounts. This significant difference indicates that there are some changes and effects of the lecturing. When asked whether they changed their passwords since the first phase, some percent of the students answered that they did not change their passwords since the first phase (especially for the University account – 59.3%). On the other hand, overwhelming are the results about the students who changed their passwords after attending the lectures: 43.8% for the desktop computer, 43.8% for the notebook computer, 50.0% for the mobile phone, 33.3% for the tablet device, 44.4% for the Facebook account, 50.0% for the Twitter account, and 42.1% for the Google account. These students stated that they changed their passwords because they realized that the old passwords were very week and could compromise their other passwords and accounts.

Table V summarizes the most common answers to the question about the frequency of password change, for the students from the Faculty of EE&CS. The table shows that most of the students from this faculty change their passwords very rarely (less than once a year) or never change them since the first use, which was also the case with the password change frequency at the Faculty of Tourism. A Wilcoxon Signed-rank test for dependent samples shows no statistical difference (at significance level 0.05), between password change frequency before and after the lectures, for none of the accounts (desktop – p=0.248; notebook – p=0.560; mobile – p=0.850; tablet – p=0.317; University – p=0.431; Facebook – p=0.739; Twitter – p=0.705; Google – p=0.059). By analyzing the answers to the question "Have you changed your password since the last survey or not, and why?" we find that a large percent of the students (desktop 52.9%; notebook 57.1%; mobile 57.9%; tablet 66.7%; University 75.0%; Facebook 50.0%; Twitter 66.7%; Google 52.2%) reported that they have not changed their passwords after attending the lectures. However, we find some promising

results (desktop 35.3%; notebook 32.1%; mobile 26.3%; tablet 33.3%; University 21.4%; Facebook 28.6%; Twitter 22.2%; Google 30.4%) where students decided to change their passwords because they realized that the old one was very weak and could compromise their other passwords and accounts.

V. CONCLUSION

We investigated the effect of password security training on user's practices regarding passwords creation and password change frequency. We performed a pilot study with university students as participants to explore their password characteristics and habits regarding password creating, using, managing and security. We collected our data by means of an online questionnaire. The survey consisted of two phases. Between the two phases, the students received lectures about the importance of creating strong and secure passwords, how to choose such passwords and how to manage them.

We find significant changes and an improvement in the characteristics of the passwords for the University, Facebook and Google account at the Faculty of Tourism. The passwords for these accounts in the first phase mostly consist of lowercase letters only. The results from the second phase demonstrate that the passwords for these accounts are slightly stronger: consist either of single case letters and 1-2 digits in front, or mixed case letters, several special characters and several digits. However, we find no significant changes in the characteristics of users' passwords at the Faculty of EE&CS. We also noticed that a large percent of the participants from both faculties chose not to disclose any information about their password characteristics during the second phase. Our deduction is that the awareness of users about the importance of their data and the importance of not disclosing information about the passwords for their accounts, increased after attending the lectures.

The results regarding the frequent password change from the first phase at the Faculty of Tourism show that many students never change their passwords since the first use, or change them less than once a year. On the other hand, we find an increased percentage of students that changed their passwords after attending the lectures (43.8% for the desktop computer, 43.8% for the notebook computer, 50.0% for the mobile phone, 33.3% for the tablet device, 44.4% for the Facebook account, 50.0% for the Twitter account, and 42.1% for the Google account). These students stated that they changed their passwords because they realized that the old password was very weak and could compromise their other passwords and accounts. Our analisys also shows a simillar behaviour about the frequent password change at the Faculty of EE&CS: students very rarely change their passwords (less than once a year) or never change them since the first use. A large percent of the students reported that the have not changed their passwords after attending the lectures.

The lectures and recommendations had a positive effect regarding users' password characteristics and password change at the Faculty of Tourism, but not quite positive at the Faculty of EE&CS. Despite our efforts to educate the users about the importance of frequent password change, a large percent of users did not change their passwords following the lectures. The overall conclusion of this preliminary study is that students at the Faculty of EE&CS still underestimate security risks and need additional security knowledge. As paradox as it may seem, students studying computer science may have a false feeling that nothing can happen to their accounts. Lax security behavior regarding rare password change and password write-down, still exists, but compared to the results from the research made by Zviran and Haga [2], our the results show some improvements.

For future research we are interested in determining the reasons for the students behavior related to password characteristic (choosing passwords with lower quality in the second phase of the study) and low frequency of password change, even after attending our lectures. This work will serve as a starting point for our further research in this area where we want to determine how students choose their passwords, and what other factors can affect the choice of passwords (data importance, data sensitivity, log on frequency, field of study, etc.).

Abstract - In this study authors gathered information on ICT users from different areas in Croatia with different knowledge, experience, working place, age and gender background in order to examine today's situation in the Republic of Croatia (n=701) regarding ICT users' potentially risky behavior and security awareness. To gather all desired data validated Users' Information Security Awareness Questionnaire (UISAQ) was used.
Analysis outcome represent results of ICT users in Croatia regarding 6 subareas (mean of items): Usual risky behavior (x_1=4.52), Personal computer maintenance (x_2=3.18), Borrowing access data (x_3=4.74), Criticism on security in communications (x_4=3.48), Fear of losing data (x_5=2.06), Rating importance of backup (x_6=4.18). In this work comparison between users regarding demographic variables (age, gender, professional qualification, occupation, managing job position and institution category) is given.
Maybe the most interesting information is percentage of questioned users that have revealed their password for professional e-mail system (28.8%). This information should alert security experts and security managers in enterprises, government institutions and also schools and faculties.
Results of this study should be used to develop solutions and induce actions aiming to increase awareness among Internet users on information security and privacy issues.

I. INTRODUCTION

The importance of ICT system's users' knowledge and awareness about information security issues should be acknowledged when dealing with user's privacy and information security in general [1-3]. Users with potentially risky behavior can significantly affect overall security level of different information and communication systems [4-6].

Generally, main goal of empirical studies is to produce some new knowledge based on gathered data analysis. In that manner aim of this work was to produce some new conclusions about ICT system's users' knowledge, behavior and awareness regarding information security issues. For purpose of collecting data authors used previously validated Users' Information Security Awareness Questionnaire (UISAQ) [7]. Total of 701 participants included in this study were ICT users from different areas in Croatia with different knowledge, experience, working place, age and gender.

Other empirical studies with similar aim in their research examined only certain segments of ICT users' awareness or behavior, mostly focused on password usage and password quality [8-13]. However, by using UISAQ questionnaire when examining ICT users this empirical research covers wide range of awareness, knowledge and user's behavior. Additional quality of empirical research was succeeded by using UISAQ questionnaire as statistically validated measuring instrument.

The UISAQ questionnaire has two main scales and six subscales, each with five or six items. Associated abbreviations are used in further text and tables:

- Potentially Risky Behavior (PRB; k=17)
  - Usual Behavior (UB; k=6)
  - Personal Computer Maintenance (PCM; k=6)
  - Borrowing Accessing Data (BAD; k=5)
- Knowledge and Awareness (KA; k=16)
  - Security in Communications (SC; k=5)
  - Secured Data (SD; k=5)
  - Backup Quality (BQ; k=6)

These subscales describe user's behavior, knowledge and awareness. Participants should evaluate their agreement with the statement on a 5-point Likert-type scale where five means excellent from aspect of information security. At the end of UISAQ questionnaire there were two additional questions about behavioral security of users and one part with demographic data.

For statistical analysis in this work statistical software tool MedCalc 14.12.0 was used. Statistical significance, when comparing differences among groups was defined as $p<0.05$, using nonparametric tests Mann-Whitney U Test and Kruskal-Wallis Test with Bonferroni correction when needed.

II. PARTICIPANTS

In this research a paper version of UISAQ questionnaire for data collection was used. Sample was defined in a way to be as similar as possible to general ICT user in the Republic of Croatia restrictive to adult users, but covering different regions (Dalmatia, Slavonia,

Zagreb area), both rural and urban areas, both government institutions and business organizations and also including students, unemployed and retired users with different background knowledge and experience regarding information security issues.

Participants (n=701) in total were 32.0 ± 11.5 years old (arithmetic mean ± standard deviation), youngest participant was 18 and oldest was 66 years old. Among participants there was 61.6% of female participants and 31.4% of all participants were working at private sector meaning business organizations. Regarding professional qualifications most of the participants were with high education (masters) 36.8%, while there was similar percentage of those with high school (25.2%) and bachelor degree (24.5%). The 28.8% of all participants revealed their password for professional e-mail systems' access by writing it down on the questionnaire.

Analysis outcome of the whole sample represents average results of ICT users in Croatia regarding 6 subareas (mean of items): Usual risky behavior (x_1=4.52), Personal computer maintenance (x_2=3.18), Borrowing access data (x_3=4.74), Criticism on security in communications (x_4=3.48), Fear of losing data (x_5=2.06), Rating importance of backup (x_6=4.18).

III. COMPARISON RESULTS

In order to compare ICT users, authors made groups regarding gender, age, workplace in government or private sector, professional qualification, managing job position and regarding revealing password. Following results are more interesting part of total results, depending on existence of statistical significant difference.

Comparing results regarding gender are showing that female ICT users got generally better results, except in subscale "Usual Behavior" (Table 1). There is no statistically significant gender difference regarding password revealing (p=0.547, Chi-Square Test).

Comparing results regarding age, where four groups were defined, are showing that middle age and older ICT users got generally better results (Table 2). For analysis between each group was used Mann-Whitney U Test with Bonferroni correction (with p<0.0125) Analysis results have shown that youngest group of users is significantly different of all other groups in total and most other subscales (UISAQ, PCM, KA, SC) while significant difference among other three groups of users is found only regarding subscale "Personal Computer Maintenance".

TABLE I. GENDER DIFFERENCES IN USERS' INFORMATION SECURITY AWARENESS

gender	Male (n=269) x±SD	Female (n=432) x±SD	p*
UISAQ	3.68±0.37	3.71±0.32	0.237
PRB	4.17±0.40	4.15±0.34	0.409
UB	3.30±0.96	3.14±0.87	0.018
PCM	4.45±0.48	4.58±0.38	<0.001
BAD	4.75±0.38	4.72±0.39	0.050
KA	3.18±0.54	3.27±0.46	0.013
SC	3.33±0.83	3.57±0.81	<0.001
SD	2.06±0.84	2.05±0.76	0.734
BQ	4.16±0.72	4.20±0.65	0.667

* Mann-Whitney U Test

Regarding workplace of ICT users, working in government institutions or in private sector, results have shown that both groups of ICT users got similar results, except in subscale "Secured Data" where users working at private sector got significantly lower result (p=0.015; Mann-Whitney U Test with Bonferroni correction). However, ICT users that work in private sector significantly more often reveal their password (p<0.001, Chi-Square Test), 48.2% of them.

Results of comparison between groups of ICT users with different professional qualification have shown that participants with masters got total result and two subscales regarding behavior (UISAQ, PRB, UB) significantly better than all other groups (with p<0.001; Mann-Whitney U Test with Bonferroni correction) (Table 3). Most significant differences (with p<0.0125; Mann-Whitney U Test) were found between users with masters and users with high school (UISAQ, PRB, UB and SD) while users who attended gymnasium are more skeptical in securing data than users with high school (SD).

Results of comparison between groups of ICT users regarding managing job position have shown significant difference between top management and the rest of employees and also significant difference between employed and unemployed users (Table 4). Statistical analysis between each group (p<0.0125; Mann-Whitney U Test with Bonferroni correction) has shown that

unemployed users are significantly different from all other groups in total and in several other subscales (UISAQ, PCM, KA, SC, BQ). Significant difference was also found between top and middle management regarding "Borrowing Accessing Data", while there was no difference found between each management group and employed users.

Comparing results between ICT users that did or did not reveal password for accessing professional e-mail system are shown in last table (Table 5). ICT users that revealed their password got significantly lower overall result and results for three subscales that examine "Potentially Risky Behavior" (UB, PCM and BAD). Also there is significant difference regarding age, where younger ICT users significantly more often reveal their password.

However, ICT users with lower level of education significantly more often reveal their password ($p<0.001$, Fisher's Exact Test).

IV. CONCLUSION

Some general conclusions about ICT user's behavior and awareness emerging from analysis results are:

- Female users are generally more careful and more skeptical comparing to their male colleagues;
- Regarding age difference, middle age and older ICT users got better results in total and in most of the subscales;
- ICT users that work in private sector significantly more often reveal their password;
- Comparison of users with different professional qualification has shown that participants with masters got overall result significantly better than other users. Most significant differences were found between users with masters and users with high school;
- Unemployed users got significantly lower results than all other groups in total and in several subscales, both regarding behavior and awareness. Significant difference between three groups of employed users was only regarding borrowing access data;
- Participants who did not reveal their password generally got better results than participants that did reveal their password.

Regarding gender, age and different professional qualification results are expected. However, top management participants achieved surprisingly well results, which is very important as that kind of ICT users is most often target in direct phishing hacker attacks.

Maybe the most interesting information is percentage of users that have revealed their password for professional e-mail system (28.8%) and they are working in private

TABLE IV. DIFFERENCES IN SUBSCALES OF UISAQ REGARDING MANAGING JOB POSITION OF USERS

job position	Top management (n=24) x±SD	Middle management (n=126) x±SD	Employee (n=495) x±SD	Unemployed (n=55) x±SD	p*

sector significantly more often. This information should alert security experts and security managers in companies, government institutions and also schools and faculties.

There are few possible drawbacks of this study. It was not possible for authors to check out if the revealed password is true and active, and also there would be higher amount of revealed passwords if some employees in some departments were not warned in advance. Other recommendations for future studies would be additional questions in demographic section of UISAQ questionnaire and bigger sample size.

Results of this study should be used to develop solutions and induce actions aiming to increase awareness among Internet users on information security and privacy issues.

Moore's Curse on Textual Passwords

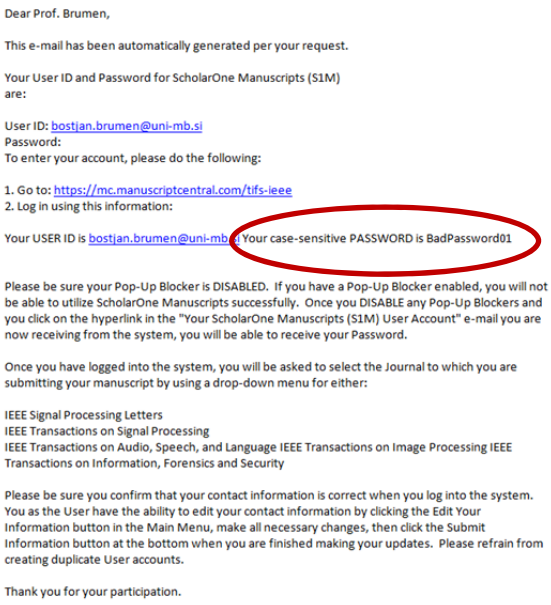
Boštjan Brumen* and Viktor Taneski *
* University of Maribor, Faculty of Electrical Engineering and Computer Science, Smetanova 17, Si-2000 Maribor, Slovenia
bostjan.brumen@uni-mb.si

Abstract - Background: Passwords are still the predominant way of authentication in information systems, and are mostly at user's responsibility. They conceive, use, re-use, abuse and forget passwords. In absence of strict password policies and at minimum required user training, passwords tend to be short, easy to remember, connected to the user's personal or professional life and consequently easy to break. The additional problem with passwords is their aging: Moore's law is affecting the available computing power to crack passwords and those deemed secure today may easily be broken in the near future. Objective: The aim of this paper is to study various scenarios of the effect the Moore's law is having on passwords and their security. In addition, advancements in other fields, e.g. quantum computing and Internet of Things, are taken into the account. Method: We analyzed various password types and the lengths required to withstand an off-line brute-force attack. The analysis was performed under various scenarios and combinations thereof: the Moore's law will continue to be in the effect for years to come with varying parameters, quantum computing will become feasible, improvements in hash tables computations will speed up the cracking process, and others. Results: The paper shows the minimum password length in characters for each password type under various scenarios. Even the most optimistic scenario shows that the minimum required password length today should be of 11 randomly drawn characters, rendering most of the passwords inappropriate due to their poor memorability. Conclusion: The current textual passwords are cursed by the Moore's law and other advancements in the field. Soon, classical textual passwords will need to be replaced by other mechanisms, which are, fortunately, already emerging.

I. Introduction

The ability to authenticate the identity of a user via passwords continues to be basic and the most relied-upon security mechanism in information systems. Weak passwords have led to very serious breaches, exposing millions of users and/or causing billions in damages. The history of password-related problems pre-dates the seminal paper written Morris and Thompson in 1979 [1] – it goes way back to mid-1960s and to the CTSS operating system exposing all the passwords as a daily welcome message [2]. A comprehensive list of breaches since 2005 can be found at [3].

Sadly, with all the years passing and evidence against bad password practices piling up, such practices continue. For example, the ScholarOne Manuscript system[1], used by many IEEE societies and journals, is storing passwords in plaintext. To upload a manuscript, a user must first create an account by selecting a username and a password. If the password is forgotten, the system is able to re-send it back to the user, meaning the system stores the passwords in original plaintext, or in best case it stores them encrypted but still able to decrypt upon request.



Dear Prof. Brumen,

This e-mail has been automatically generated per your request.

Your User ID and Password for ScholarOne Manuscripts (S1M) are:

User ID: bostjan.brumen@uni-mb.si
Password:
To enter your account, please do the following:

1. Go to: https://mc.manuscriptcentral.com/tifs-ieee
2. Log in using this information:

Your USER ID is bostjan.brumen@uni-mb.si Your case-sensitive PASSWORD is BadPassword01

Please be sure your Pop-Up Blocker is DISABLED. If you have a Pop-Up Blocker enabled, you will not be able to utilize ScholarOne Manuscripts successfully. Once you DISABLE any Pop-Up Blockers and you click on the hyperlink in the "Your ScholarOne Manuscripts (S1M) User Account" e-mail you are now receiving from the system, you will be able to receive your Password.

Once you have logged into the system, you will be asked to select the Journal to which you are submitting your manuscript by using a drop-down menu for either:

IEEE Signal Processing Letters
IEEE Transactions on Signal Processing
IEEE Transactions on Audio, Speech, and Language IEEE Transactions on Image Processing IEEE Transactions on Information, Forensics and Security

Please be sure you confirm that your contact information is correct when you log into the system. You as the User have the ability to edit your contact information by clicking the Edit Your Information button in the Main Menu, make all necessary changes, then click the Submit Information button at the bottom when you are finished making your updates. Please refrain from creating duplicate User accounts.

Thank you for your participation.

Fig. 1: A ScholarOne system message on lost password request

Because the "lost" password is sent by a plaintext e-mail, it becomes vulnerable in the system of origin, in all the passing systems, and in the end-user's e-mail box system and probably also on the user's hard drive. Such a password management system is very vulnerable to all kinds of attacks.

In such cases when a password is used for an on-line system with a lockout policy (e.g. "three times and you are out"), the stored (and later compromised) user credentials (username/email, password) become available offline for attacks without lockouts. The transition from an on-line password to an off-line one is very common [4].

Based on the survey by Brown et al [5], almost all respondents reuse passwords, and about two thirds of password uses are duplications. Passwords have been forgotten by a third of respondents, and over half keep a written record of them. Despite all the warnings and research in the last 50 years users continue to have bad passwords and practices and are thus easiest targets [6-10], while passwords continue to be the predominant way to authenticate the identity of a user.

[1] A product by Thompson Reuters, http://scholarone.com/products/manuscript/

Without the mentioned problems, yet another one is slowly but surely dooming the textual passwords: the effect of Moore's law on computing speed and consequently on password cracking.

A. Aims and Scope

In this paper, our research goal is to find out the length of a randomly generated password to withstand the brute force attacks using future computing power. Namely, passwords may be long enough today to protect valuable information, but what about in 10 years and beyond? The scientific contribution of this paper is to give guidelines for the password selection and evaluation criteria, e.g. for the password meters.

II. Related Work

Typically, a user is authenticated based on one of the three underlying principles (or combinations thereof): "what you know", "what you are" and "what you have" [11, 12]. "What you know" is based on secrecy known only to authorized user, "what you are" is based on user's physical characteristics (e.g. retina image, fingerprint) and is better known by the term biometrics, whereas "what you have" is based on smart cards or other tokens.

The passwords that are generated based on "what you know" principle can be divided into textual passwords and graphical passwords [13, 14]. In our contribution we focus on textual passwords as graphical ones require a different user interface for entering passwords [14] and are thus not directly comparable to our study. In addition they require a redesign of user interface for entering a password [14].

There are several alternatives to (nearly) random long textual password:

- passwords based on personal data or characteristics (e.g. birthdate, names, pets, addresses, etc.) [1, 15, 16].
- cognitive passwords require user to answer a randomly selected set of personal questions which only an authorized user can answer correctly [17]
- pass-sentences and pass-phrases which are composed of long, grammatically correct phrases [18, 19].
- randomly generated but pronounceable passwords made up of concatenated pronounceable syllables [20, 21].
- mnemonic passwords are those where a user chooses a memorable phrase and uses a character – often the first letter – to represent each word in the phrase [17, 22].

Each of these passwords types has several security issues, as discussed in the relevant references.

When protecting the data using passwords, one needs to observe one of the underlying principles of security in computing: "*Principle of Adequate Protection: Computer items must be protected only until they lose their value. They must be protected to a degree consistent with their value*." [12]. Namely, different data have different life spans. For example, stock exchange data have a short life span between their creation and publication date; for medical data this time span easily reaches 60 or more years. These data need to be protected even when processed, as discussed in [23-26].

It is to notice that present paper deals only with randomly generated passwords; further detailed studies are needed to make comparisons between each of password types with respect to issues covered in this paper.

III. Moore's Law and Other Effects on Password Security

The general rule is that passwords strength is proportional to their length and the size of the symbols space – i.e. the pool from where the password characters can be used from. This is true only if the process of the character selection is truly random [11]!

The number of possible combinations in a random password can be expressed by

$$s=b^{le}, \tag{1}$$

where s is the total number of combinations, b is the total number of symbols in a domain and le is the length of the password in number of characters.

The longer the password, the stronger and more resilient it is to the attacks. The speeds for unlocking a plaintext password from a given (unsalted) hash value are today about $v=10^9$ combinations/second [27-30], up to 10^{12} combinations/second [11].

Because the Moore's Law [31] is still doubling the computing power roughly every 18 months, we can expect the speeds to increase in 10 years by a factor of $2^{(10*12/18)} = 2^{6,67} \approx 100$. The increase factor in 60 years is amazing 1.099.511.627.776, or 10^{12}; the computers in 60 years from now are assumed to be one trillion-times faster than those today. Although Moore's law was doomed decades ago [32], recent studies show that it will still be in force for a few coming decades [33].

Other improvements in the field of computer science, besides improvements in hardware, make password cracking easier. The most important improvements are quantum computing [34, 35], improvements in parallel and GPU farming computations [36], improvements in hash computations [37] and applying Markov model preprocessing and filtering [38]. All these improvements have had and will have an impact on the password cracking process, while new improvements are, obviously, on the way.

Quantum computing is already a reality [39]. We can compare its state-of-the-art as being in late 1930s and early 1940s for computers based on Von Neumann's architecture. If today's quantum computers are not yet faster than conventional, we can assume their speed growth will be following the Moore's law too. In our model, we suppose that quantum computing will be generally available in 20 years from now [34] and its leap in password security will be one thousand-fold [34, 35], with standard exponential increase in eighteen months.

Other advancements in the field, e.g. construction of graphical processing units (GPU) farms, have further

increased the cracking speeds. It was shown that GPUs can speed up the cracking by a factor of 100 compared to the conventional systems; in addition, GPUs as electrinic circuits follow the Moore's law. Next, by using the Markov models and filters in modelling the password probability, the speed-up improvements are again substantial. For the purpose of our model we asume that all such improvements in the field (aside the hard computing power increase due to hardware improvements) will cumulatively increase the speed of password cracking by 10 % every year.

A user, when creating a password, needs to observe one the following principle: (1) a password is considered secure if the cost of breaking it exceeds the value of the protected information, or (2) the time required to break the password exceeds the lifetime of the protected data [11]. Today, we cannot rely on the costs because the ratio of bits processed per unit of currency is continuously sinking making the password cracking machine affordable [27, 29, 30]. One can only increase the time required to break a password. Thus let us assume a typical 60-year time span of usefulness of stored personal information [23, 25, 26, 40, 41].

Under the mentioned assumptions we calculated the time needed to crack various passwords using brute-force technique today and in a time line from today on. We assume that data have a useful life span of 60 years [23].

In other words, a safe password today (in 2015) would be made of at least ten characters from upper and lowercase letters, numbers and symbols, but it would not be safe in 10 years from now.

For the purpose of modelling, we asume that users use characters from the symbol space of approximately 50 when no possword creation policy is in place (i.e. uppercase and lowercase letters) and from 80 characters when such a policy is enforced (uppercase & lowercase letters, at least one digit and a symbol). Table I lists the models and their descriptions.

TABLE I. LIST OF MODELS

Model No	*Description*
1	Moore's law, 50 characters in symbol space
2	Moore's law, 80 characters in symbol space
3	Same as model 1 plus improvements in the field add 10 % annually
4	Same as model 2 plus improvements in the field add 10 % annually
5	Same as model 3 plus quantum computing
6	Same as model 4 plus quantum computing

For each model we first calculated the number of combinations using different password lengths and the then the worst time required to crack them using brute-force attack.

For each of the model the equations are as follows:

Model 1: $$t_i = \frac{b_1^{le}}{cs \cdot 2^{\frac{i*12}{18}}} \quad (2)$$

Model 2: $$t_i = \frac{b_2^{le}}{cs \cdot 2^{\frac{i*12}{18}}} \quad (3)$$

Model 3: $$t_i = \frac{b_1^{le}}{cs \cdot 2^{\frac{i*12}{18}} \cdot f^i} \quad (4)$$

Model 4: $$t_i = \frac{b_2^{le}}{cs \cdot 2^{\frac{i*12}{18}} \cdot f^i} \quad (5)$$

Model 5: $$t_i = \frac{b_1^{le}}{cs \cdot 2^{\frac{i*12}{18}} \cdot f^i \cdot q}; q = \begin{cases} 10^3; i \geq 20 \\ 1 \end{cases} \quad (6)$$

Model 6: $$t_i = \frac{b_2^{le}}{cs \cdot 2^{\frac{i*12}{18}} \cdot f^i \cdot q}; q = \begin{cases} 10^3; i \geq 20 \\ 1 \end{cases} \quad (7)$$

where *cs*, the initial cracking speed, equals to 10^9 passwords / second and b_1 and b_2 are set to 50 and 80, respectively. As mentioned, other improvements add 10 % each year (f=1,1). Another assumption is that (general-purpose and publicly available) quantum computing will be a fact in 20 years (parameter q).

IV. RESULTS

We have calculated the time needed to break a password for each of the models. The results of calculations for Model 6 are presented in Table II (for reasons of space other detailed results are not shown).

From the Table II can be seen (see row 1: "year 0" and column 1: "length 10") that a password consisting of 10 randomly drawn characters from a pool of 80 (lower and upper case letters, digits and symbols) is considered safe. With today's computing power it takes approximately 340 years to brute-force attack it. However, in only 5 years from now the computing power will increase (based on the assumptions built in the Model 6) and it will take only 25 more years to break such a password. In other words, if someone waits for 5 years and utilizes then-available computing power, the password cracking will be done in 30 years from now; for 20-year wait it will be done in seconds.

TABLE II. RESULTS OF CALCULATIONS FOR MODEL 6

length / years	10	11	12	13	14	15	16	17	18	19	20	21	22

For these reasons passwords of length 10 are not adequate for future use. The same hold true for all passwords shorter than 19 characters (in model 6). With 19 characters and 60 years from now it will still take 136 years to break such a password. "Safe" password lengths for the given time frames are shaded.

It is interesting to notice the quantum leap that is modelled to happen in 20 years from now: it will take 500 years to break a 12-character password with computing power in 15 years from now on, but only roughly two weeks in 20 years from now.

Table III summarizes the calculations for all the models. It can be seen that required password lengths today are 10 to 11 characters, randomly drawn. In 10 years, they will need to be 2 characters longer, in 30 years approximately 4-5 characters longer and in 60 years their required length will need to be double of today's length. Today, a typical password has (only) 8 characters [42].

TABLE III. COMPARISON OF RANDOM PASSWORDS RESILLIENCE TO BRUTE FORCE ATTACKS

Model	*Required length today*	*Required length in 10 years*	*Required length in 30 years*	*Required length in 60 years*
1	11	12	14	18
2	10	11	12	16
3	11	13	14	20
4	10	11	13	18
5	11	13	16	22
6	10	11	14	19

The table shows that what is safe today will not be safe tomorrow [11], this especially holds true for off-line files which will remain unchanged for years, containing interesting medical data about an important person. The breach of privacy of data in such a file has a timelessness property [23] – no matter when in the lifetime of data the breach happens, it poses a problem.

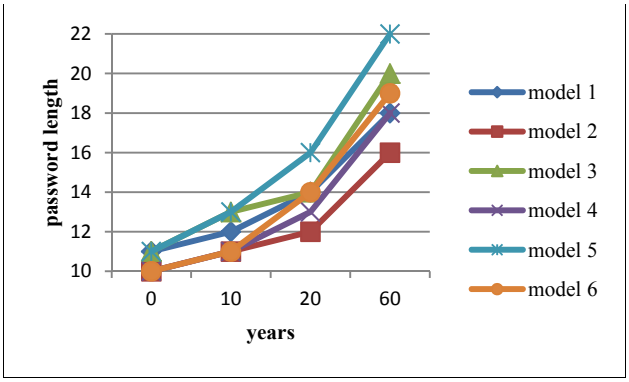

Fig. 2: Required password length with respect to time

The graph in Fig. 1 depicts the dependency of the required password lengths and the time.

V. DISCUSSION AND CONCLUSION

Egelman et al [43] have calculated that 10-character passwords are required today to be safe tomorrow (i.e in 10 years) as well. This is somehow true; however, the value of data has a longer time span. Computing power will continue to increase exponentially and what is safe tomorrow due to unavailable computing power can easily be affordable in 10 years from now. In the most pessimistic scenario regarding the power increase we need to use 16 random characters in password (base 80), and in the most optimistic one 20 or 22 for base 50 and 80, respectively. For example, the following password consists of 20 characters: "Q€Tu!3%7|rZu2$6(oPŁL".

This amount of characters to remember constitutes a much larger corpus than is the capacity of human memory, the well-known 7±2 principle [44]. Human memory in addition is temporally limited (short-term) when it comes to memorizing sequences [45] and has a limited capacity with a fixed final error rate [46-48]. For

this reason good passwords that are consisting of an abundant number of randomly selected characters are doomed: the users will either forget them [49] or write them down, or both [50-52]. In this paper we have shown that already today's password lengths are inadequate and that tomorrow's speed improvements will make security in computing even worse. What are the alternatives?

For one, special cognitive methods should be used to compose passwords. The required length of cognitively-generated passwords exceeds the randomly generated ones for a comparable resilience; however, they are much easier to remember [23]. But, users will have to be educated about proper password generation and management very early, possibly already in the primary school, but certainly not later than in the first year of secondary education.

Secondly, the industry will have to start replacing textual passwords as the predominant way of authentication with other means, such as keys [53], two-phase authentication and biometric. But, each of these replacements has some disadvantages. Common to all is the possibility to disclose the user's real identity [24].

DIGITAL FORENSICS TRACK

Concepts and Methodology in Mobile Devices Digital Forensics Education and Training

Damir Delija
INsig2 d.o.o, Zagreb, Croatia
damir.delija@insig2.hr

Abstract - This paper presents various issues in digital forensics of mobile devices and how to address these issues in relation to the education and training process. Mobile devices forensics is a new, very fast developing field which lacks standardization, compatibility, tools, methods and skills. All these drawbacks have an impact on the results of the forensic process as well as a deep influence in the training and education process. In this paper real life experience in training is presented, with tools, devices, procedures and organization with the main purpose of improving the process of mobile devices forensics and mobile forensic training and education.

I. INTRODUCTION

Some interesting issues and situation were noticed while providing digital forensic services, especially during training and education. These situations are part of the whole digital forensic process but usually not stressed enough, it is worth mentioning them and analyzing them. Most of these issues are coherent with the current state of the mobile forensics, some are specific while some of the problems already recognized and reported in mobile forensics field "Is Mobile Device Forensics Really Forensics?" [3], others are specific but still rooted in the same basic issues.

Experience comes from the business position such as digital forensics service provider, which covers the full life cycle from defining solution proposal, development, implementation, support, consulting, training, improvements, and upgrades. This is a project oriented life-cycle where training and support holds the biggest share of it with the aim of improving the solution and keeping it operational.

Basically all projects in mobile digital forensics include the introduction of new functions in existing system (law enforcement, business etc) through providing forensic tools and methods. In such setups training and consulting is essential for success. From the client's viewpoint it is often very challenging because the personnel don't usually have the basic training or skills, also there is usually no infrastructure for quickly setting up internal training and skill distribution. In a few words this means you actually fail if you provide only tools and installations without training, since everything will be shelved because no one will be able to efficiently use it.

Experience stresses on the education and training as the most important part of mobile forensics projects. Aim is to improve ability of users to work independently and in a forensically acceptable manner while dealing with various mobile devices. This conceptual goal, with both firm understanding what tools and procedures can and can't do, is essential for any acceptable mobile forensic practice.

The profession of digital forensics requires continuous education, training, and practice based on all above mentioned concepts. It is necessary to define methodology which can fulfill these requirements in the context of projects (law enforcement environment, military, governmental). This must provide training in basic forensic science, basic computer science and engineering, understanding of forensic tools and procedures

Mobile forensics is a very dynamic field in digital forensics which is, by itself, a new field in forensic science. This concept is taking to extremes where it is presented in recent 2014 paper "Is Mobile Device Forensics Really "Forensics"?", [3] which addresses some open questions and gives clear definitions on mobile forensics and digital forensics. Fast development rate, and actually a slave position to development in other fields, puts mobile forensics into a very unpleasant position where lack of standardization stands among other problems [3].

As an excellent overview into tools, skills, knowledge and procedures required for mobile forensics is the presentation "Cell Phone and GPS Forensic, Tool Classification System, (2009 Update)" done by Sam Brothers in 2009 which defines classification of tasks, tools and skills [5].

II. MOBILE FORENSICS SPECIFICS

It is important to stress that mobile forensic is a specific field, it is even hard to find coherent definitions as to what is a mobile device and what is mobile device forensics. There are various definition for mobile devices most of them defining mobile device as „small size device which is mobile and with network connection" [3]. Even if the definition of mobile forensic is more straightforward, it is sill biased enough because due to the ambiguous definition of mobile devices. As early as in definition there are problems with regards to procedures, tools, methods and compatibility with the rest of the digital forensics. Key issues to be solved are with relation to essential principles of digital forensics. The simplest firm relation in mobile device forensics is a „sub-science of digital forensic science" [3], while digital forensics is a computer and engineering science [3]. In precise terms, forensics are the application of scientific knowledge to

legal problems [3]. Still it is possible to argue about this definition based on Vietse Wenema definition of digital forensic "Gathering and analyzing data in a manner as free from distortion or bias as possible to reconstruct data or what has happened in past of the system" [6] which is used by SANS Institute. It is crucial to see it as a scientific and engineering process which is wide a enough concept, in that sense mobile forensics is a digital forensics applied on the mobile devices.

No one actually can count the number of mobile device, let alone the number of different models and types. The only sure thing is constant the arrival of new devices. Mobile devices has short lifespan models soon become extinct, while all of them are on the market as not sufficiently finished devices, as in not always working correctly. To complicate things even more, it is impossible to get data from mobile service providers with regards devices used and connected to their infrastructure, while this data surely exists and it is not confidential or illegal, but it is often under nondisclosure or privacy rules.

Table 1: Mobile device evidence extraction process – mobile device forensic process [2] [5].

Preparation Step	1. Device Intake, device is taken into forensic process 2. Device Isolation from mobile and WIFI network 3. Device Identification, type, model, features 4. Device Preparation, preparation for extraction and manipulation
Analyses Step	1. Processing extracting data 2. Verification of extraction and findings 3. Documentation/ Reporting of findings
Finalization Step	1. Presentation of findings and reports 2. Archiving device and results 3. Tools calibration and maintenance

One very distinctive mobile forensics trait is how commercial vendors approach mobile forensics. We can roughly separate vendors in specialized in mobile forensic and those general purpose digital forensic tool vendors. Among these groups there are no common tools nor standards from the mobile devices viewpoint. What is even more interesting is the separation among vendors based on how they handle mobile devices. Digital forensics vendors usually only support smartphones and provide very limited support for other mobile phones, while mobile forensic vendors almost completely ignore anything other than mobile devices. What is also stunning is the lack of compatibility and standards among mobile vendors and lack of using existing established forensic data formats.

From a practical point of view, of conducting investigations or just using forensic tools and methods, it is important to recognize real work tasks and address them properly in training and education. Basic steps in mobile forensic processes are defined in Table 1, it is the same process as any other digital forensic process, with a few difference among stressing preparatory steps and having very specialized tools, almost on data recovery level. Skill-sets and mobile forensic analyses levels are related to mobile forensic process as presented in Table 2, skills are hard to achieve and requires a lot of practical work [5], [2].

From our current experience gathered trough training and support, data made available, through logical level extraction or even manual level extraction, is sufficient for closing the investigation. Only in a small number of situation, about 10%, requires phone memory dump (physical extraction) or more complex extraction methods. The same happens with a number of mobile devices included in one investigation process; mostly only one or two mobile devices are included (basic communication among two people), often related to one or two computers forensic images. This estimates are hard to confirm since statistics data for ex-Yugoslavia area are not possible to access, law enforcement organization currently does not have such statistics publicly available.

Table 2: Mobile forensics analyses types and skills levels [5].

	Operation	Skill level	Description
1.	Manual Analysis	Introduction / beginner	taking picture of device screenshots, manually accessing reading data
2.	Logical Analysis	Introduction / beginner	extracting data from mobile devices by logical synchronization commands, usually done by forensic tool
3.	Hex Dump (Physical Analysis)	Intermediate	extracting bit by bit copy of mobile device memory, done by forensic tool or specific usage of non forensic tools (flash boxes, jtag)
4.	Chip-Off (Physical Analysis)	Expert /advanced	extracting flash chips from devices and reading chip contest, required dedicated laboratory equipment
5.	Micro Read (Physical Analysis)	Expert /advanced	extracting chips and reading logical gate states by electronic microscope

III. EXPERIENCE IN MOBILE FORENSIC TRAINING AND EDUCATION

There are many possible classifications of digital forensics training processes. In theory it can be vendor specific or vendor independent, academic or professionally oriented, certified or uncertified, practical or theoretical. In reality it is always a compromise especially in the case of mobile forensics. As for any digital forensics education training devices and tools are essential, because of possible varieties of models and scenarios. With mobile forensics it is essential to provide practical methods of configuration for mobile devices in order to provide same set of artifacts and same results during different training steps. Being unable to provide relevant training environments, with up-to-date tools and configurations, render training process ineffective and sometimes counterproductive, since outdated methods usually compromise evidence and results.

Methods used by various vendors are different from academic and no-tool specific trainings, in most situation academy is not capable with keeping up with development, while vendors always get concentrated on their tools lacking general knowledge and skills.

Mobile forensic tools become part of our portfolio (INSIG2) in 2009, with now defunct EnCase Neutrino. Since 2009 many other products have been accepted like Cellebrite UFED [7], MicroSystemation XRY [8], and Oxygen provide with full service. With such a wide product range, vendor independent mobile forensic services and support is provided, based on the requirements and current state of the market. Full mobile forensics training infrastructure was implemented and added to the training curriculum in 2012. Since 2012 each training is evaluated and analyzed for valuable actionable data, but because of contracts data is under nondisclosure clauses, so just general observations can be presented.

Table 3: Number of mobile forensic trainings provided

	Attendees	Region	Type of training
2012	40	Croatia	vendor specific/ law enforcement
2013	30	Croatia	vendor specific and / or vendor refresher / law enforcement military
2014	30	EU	vendor independent / law enforcement / military

To present the volume of activity in mobile forensics training, training events are presented in Table 3. Each training event is fully documented, analyzed and evaluated for lesson learned, but not only from the attendees' viewpoint but also from the trainers and logistic viewpoint. It is crucial to acquire such data to understand the practices of different vendors and how these practices and tools fit into the current environment. Such data is necessary in order to keep the quality and understand what should be improved or modified, also the whole process must formalized to prevent overseeing important factors. Based on this data, and data acquired through vendor products trainings and usage, the process is developed which keeps the necessary skills and ability to teach mobile forensics.

The key concept is understanding that the training event is specific and unique, since version and tools are changing fast. For demonstration we can use data about UFED family of products. Just since 2012 UFED forensics portfolio has substantial changes both in hardware and software, while continuously being upgraded with new supported mobile devices and analyses capabilities. All volume and type of changes have to be incorporated into the training process to keep it efficient. Supported phone models grow in the hundreds per year, not only as a new device model, but also with support for new applications, functionalities and operating systems.

Very important chat tool Skype can be used as example. In 2009 Skype was not supported as an analyses feature in automated analyses on smartphones, while in 2013 it is a standard part of the analyses. Since Skype artifacts are extremely important, that new functionality has to be introduced and supported in the training, with examples, drawbacks, practical issues etc. This is typical for feature and application support in mobile forensics. To show the volume of work required for only one application, in this case Skype analyses, in 2012 extraction was done through cooperation with other forensic tools [4], while in 2013 generic support was introduced. Again, during training, both methods were presented. General methods of using other forensic application, to verify artifacts' findings, is mentioned since it is an example of common practice. Application evolves and it is always possible to find a new version which is not supported on the current tool, but is supported by some other tool like Belkasoft, InternetEvidenceFinder, or by custom developed script [5].

It is the same for all features and applications on mobile devices, especially about encryption support, geolocation information and other new developments. Available forensic methods have to be presented, while optional solutions must also be provided at least at the conceptual level, as shown in Table 10.

Since changes are in all steps, each step has to fully include both the theoretical and practical parts of the training, with appropriate training mobile devices and artifacts on mobile devices. Maintenance and troubleshooting issues are key to making training kits operational, it must also be included. These topics are emphasized since they are usually overlooked in trainings.

Other mobile forensic tools are close to UFED example since mobile phone development forces forensic vendors to keep up with the change. With general purpose forensic tools vendors' situation is different, since the tool has limited mobile forensic capabilities, mostly only smartphone support. Good illustration for general forensic tool is EnCase from GuidanceSoftware. With introduction of EnCase version 7 in 2011 former mobile forensic version of EnCase, Neutrino, was discontinued. Its functionality later was added as special smartphone module into main EnCase v7 product. Since 2011 EnCase v7 got 26 versions and subversions with various upgrades, functionality changes and bug fixes.

IV. PROCEDURES AMD METHODS FOR MOBILE FORENSICS TRAINING AND EDUCATION

Preparation of training for mobile devices and forensic images requires forensically sound approach, method and tools which will guarantee that the training results are reliable and useful. As for specific vendor training, forensic images and artifacts are usually provided by the vendor, the same goes for the training materials. In reality it can happen as it was for early UFED situation where there were only forensic images of mobile devices provided by the vendor, but no officially approved training materials.

Training process varies in duration, usually from 3 days to 5 (24 or 40 hours) depending on the type of training. Duration for the tool specific trainings it is usually up to 3 days with 1/3 time for practical work.

Each skill level from Table 2 usually has its own skill level training, which deeply depends on the previous trainings. No-tool specific and general purpose trainings follow the same idea being more concerted on general skills than specifics tools. Training materials are copyrighted and protected from any kind of distribution or usage out of contract limited trainings that even goes for trainings result analyses data.

Preparing training materials, mobile devices and forensic images is an important and complicated task. It is common for any type of practical computer training, but because if nature of mobile forensic it is crucial part of training. Basically, for each new current or future versions images have to be recreated and reinstalled on the mobile devices. This process is independent from the training and unusually covers three basic steps and some additional logistics steps.

Basic steps

- **Initialization of mobile devices to known state**: Resetting mobile device to factory defaults, then installing the image from backup or other source, depends on mobile device model, operating system etc. After this step the mobile device is ready for the next training event
- **Creating mobile artifacts for each specific mobile device platform:** complex step which requires using application, tools on mobile device in real life scenario. For example for each supported mobile phone real chat sessions were done, emails sent and received, sms's going through town, images taken, video, connecting to WIFI etc. Each action is documented and time stamped so that the artifacts can be compared and verified in preparation for the training. It is a lengthily task requiring a lot of time and resources, usually done by students as part of their internship work.
- **Creating mobile device images:** when mobile devices have all necessary artifacts, forensic images and backups are created as baseline images from which other mobile devices - of the same types - will be cloned. Methods of cloning are different depending on mobile devices models, varies from backup/restore, synchronizations methods or using dedicated cloning tools like Ufed. It is also important to remember creating relevant forensic clones of SIM cards, to prevent mobile devices from changing installed images. Forensic SIM clone is SIM copy of user data but without data required for GSM connection, so mobile device can not connect to network while keeping it configuration and artifacts unchanged. This SIM copy is done with mobile forensic devices like UFED through the specialized SIM cloning function.

Additional logistic steps

- **Preparing and maintaining training documentation:** keeping manuals and documentation up to date, depends on the source of the documentation.
- **Acquiring and maintaining the necessary fleet of mobile devices**: mobile devices are changing and to keep with these changes typical models and functionalities must be obtained. From experience, this means having about 5 devices of the same type in the training kit. At the moment it is about 60 mobile devices, 30 smartphones and 30 of other phone models some of them ageing. From this kit about 5 devices are in various states of degradation, being replaced by new models. Also it is important to keep some broken devices to show techniques and methods available for partially functioning devices.
- **Acquiring and maintaining sets of SIM cards**: SIM cards from various mobile service providers have to be obtained, initialized, used and cloned, in order to provide realistic usage patterns. Each SIM has a limited lifetime so it has to be regularly maintained, subscription renewed and replaced if necessary. For each event it is necessary to have a set of SIMs in specific condition, even locked or damaged to provide realistic training scenarios.
- **Maintaining forensic equipment:** forensic kits for mobile forensics have different elements, but it must be maintained and kept in order as any other tool, basically it is keeping with the vendor updates and changes.
- **Maintaining versions of forensic images and backups and documentation:** each mobile device forensic image, backup or configuration must uniquely named, documented, listed and stored. Without these administrative practices the training process can not be reliable.
- **After each training event forensic image of each used mobile device can be created and compared with baseline image**. Forensic images should be created with available forensic tools and procedures. This is not a mandatory step, however, it helps to keep track of changes and possible bugs or malfunctions in the forensic software or equipment. Also it presents the patterns of how the trainees work with mobile devices as well as the efficiency of the training, since any change in mobile device configuration or content out of planned actions shows failure in training procedures. Up to now such failures were detected in forensic images.

As for the no-vendor trainings and education, it is almost the same situation but with specifics issues. This

type of training and education covers general issues about mobile devices and presents specific tools and tasks to solve them with such tools. In a typical training curriculums, there is a list of topics with expected interval for renewal and change as presented in Table 4.

Each of these changes require a full cycle of preparation and training refreshing both for trainers and specialists who already have attend a previous training. Since each topic has very fast update rate, special type of training refreshers are needed. To keep with this lifecycle and requirements, efficient organization and logistic processes must be established, with well defined procedures for each step in the training process.

Table 4: Topics in mobile training curriculum and its life cycle influences

Training Topic	How often has to be updated	Specific forensic image required or specific device
Introduction to mobile devices, technologies	Yearly	No
Introduction to mobile networks	Yearly	No
SIM Cards and key serial numbers	Yearly	SIM cards and forensic images
Common challenges with Devices	For each version or event	No
Forensics of the mobile devices	For each version or event	example of locally used devices
Seizure of Mobile Devices	Yearly	example of locally used devices
Types of extractions with mobile devices and comparison to regular computer extractions	For each version or event	example of locally used devices
Tools for mobile forensics – Analysis, Searching, Reporting	For each version or event	New devices and tools with updated kits, connection cables, flash boxes etc
Introduction to Smartphones and other "Smart" devices	yearly	example of locally used devices
Introduction to mobile devices operating systems	For each version or event, forensic images have to updated	example of locally used devices and forensic images of devices, forensic images have to updated, same for the mobile devices
Key features challenges with "Smart" devices in forensic sense	yearly	example of locally used devices
recovering deleted data from a wide range of mobile devices, including locked devices	For each version or event	example of locally used devices and forensic images of devices, forensic images have to updated, same for the mobile devices
understand how forensic software extracts and decodes data	For each version or event	, forensic images of devices, forensic images have to updated
understand how you can approach a forensic problem, defining a forensic strategy which may use a combination of tools and techniques to obtain evidence from a mobile device	For each version or event	example of locally used mobile devices, forensic tools
Understand the different challenges in the field of mobile device forensics compared to those in traditional computer forensics	For each version or event	example of locally used devices and forensic images of devices, forensic tools, forensic images have to updated, same for the mobile devices
Understand the different acquisition methods available when examining mobile devices	For each version or event	example of locally used devices and forensic images of devices, forensic tools, forensic images have to updated, same for the mobile devices
Understand how and when to use the different approaches	For each version or event	example of locally used devices and forensic images of devices, forensic tools, forensic images have to updated, same for the mobile devices
Awareness of the limitations of each method forensic method	For each version or event	example of locally used devices and forensic images of devices, forensic tools, forensic images have to updated, same for the mobile devices
Know how to approach defining an acquisition strategy for a new device	For each version or event	example of locally used devices and forensic images of devices, forensic tools, forensic images have to updated, same for the mobile devices

I. LESSON LEARNED AS DIGITAL FORENSIC TRAINING PROVIDER

II. Lessons we gained trough provided trainings and education since 2012 are in fact very disappointing, even on European level and especially for former Yugoslavia countries. Lack of ability for any type of digital forensic is astonishing also lack of investing into required infrastructure, training and education are overwhelming. It is the same for governmental, academic and business communities. At the moment most crucial problem is in law enforcement because it seriously influence ability to protect community. For the long term prospects lack of programs, funding and related knowledge in academic community is also worrying, but

it is not so important because of growing numbers of excellent online academic resources. The most astonishing lesson is that internal organization on client side is key for success, a fact which one will take for granted since organization is sending members to training. These lessons are worthwhile for anyone included in digital forensics training and education.

III. Based on our experience gathered trough delivered training, it can be said that mobile education and training is a key part in keeping forensic skills, especially in law enforcement and military organizations. In such organization there is a dichotomy among needs and ability to implement organizational structure which keeps skills and expertise. This dichotomy must be constantly addressed and remedied with various formal and informal methods of training and education. Such methods as conferences, workshop, and refreshers etc, while are not efficient as full set training, provide at least minimal necessary updates for skills and knowledge.

IV. For organizations sending personnel to training and education, it is important to emphasize the fact that it is actually skill set and internal organization that must be acquired, implemented and maintained. This should be done by establishing internal organizational structure, career path through continuous education and training for organization members [1]. It is often that internal organizational structure that is missing while need for specific skills are recognized, which is a very common scenario in law enforcement and defense organization as well as any other organizations which have a strict legally defined structure. Methods and practical solutions on how to cope with such problems are presented in "Digital Forensic Triage" [1]. Definition of such organizational structure is not part of the training and education, it is important to deliver the message about it's importance, because without it, the skills and knowledge are lost thus nullifying the training results.

V. As for the personnel receiving training, it is important to stress on the necessity of continuous working and keeping with current developments, which again leads back to the internal organizational structure of the trainee's organization. Again, without such organization, personnel will probably get only one minimal introduction training, there will be no upgrades and no career path. Skills and forensic capabilities will soon be lost.

VI. In some organization, informal internal keeping-up events can be organized, but this is sometimes double edge situation which is often maintained for a short period of time and later fails. Another key element for such organizations is implementing an internal communication network among personnel to keep skills and knowledge active. There are many possible models; the right model depends on the structure of organization and legal requirements, since it is not the same for the law enforcement, military or business environment. What is often seen as good model is kind of help desk or internal forum type of organization which works well in most situations. There we have experts helping others and keeping knowledge and skills alive with very simple computer infrastructure for support.

V. CONCLUSIONS

As a general conclusion we can say that training processes must be tailored for the needs of the organization and attendees. To cope with this conclusion very efficient, but resource consuming, processes must be implemented where trainings are kept up to date with various inputs: vendor development, user requirements, current best practice and client abilities (mostly budget restrains). This means that vendor / tool specific trainings and educations should be customised for specific needs and abilities, it is impossible to directly apply it without adaptation. Adaptations must be carefully prepared and examined since for example what is proposed by vendor or it is best practice in another country is not applicable in local context because of various technical or even legal reasons. Major goal for any mobile forensic trainig and education should be:

- to improve expert level of knowledge and skills for a usually small number of expert users and
- to keep growing number of user able to efficiently apply basic mobile forensics.

Jerko.Buric@insig2.eu

Abstract **- In present modern times when operating systems require larger amounts of RAM or Random Access Memory, we usually come across computers with 4 GB RAM, but given the price drops, it is quite usual to come across computers with 64 GB of RAM as well. By imaging this part of computer memory and by performing forensics analysis of the data located in RAM, it can be easily concluded that performing RAM imagining and analysis should be one of the essential steps in any forensic investigation.**

This paper will give a short introduction to digital forensics and the role of live data forensics. Furthermore, the mail goal will be to show and explain the importance of forensics of live machines and artefacts which can be found as well as methods and tools which are used for extracting and analyzing data from RAM. In addition, it will be shown that sometimes in forensic investigations, data contained in RAM can contain enough evidence to solve the whole case and actually be everything a digital forensics investigator really need.

Index Terms **- RAM, Live data forensics, Imaging, Volatility, Batch scripts, Windows processes, Network connections, Passwords, Windows registry, Extraction, Malware.**

I. DIGITAL FORENSICS

Digital forensics is a relatively new area which is constantly spreading and progressing quickly. Accordingly, it requires continuous monitoring of new technologies in order to be up to date. The development of technologies such as smart phones, tablets as well as the constantly changing operating and computer file systems requires an exhaustive analysis in order to determine the best way how to get information required in investigations. Additionally, forensic investigation techniques on existing and new technologies are constantly developing.

In such a dynamic working environment a forensic analyst must be aware of all changes and developments of technologies. Many techniques are complex, they require a lot of time, specialized trainings and often special tools. It is exactly due to the frequent changes and developments that certain fields i.e. divisions of investigations emerged within the digital forensics itself such as computer file systems, mobile device forensics, operational systems forensics and the like. It is common that a forensic analyst opts for just one of these areas. One of these areas is the Live Data Forensics [1].

II. WHAT IS AND WHY IS LIVE DATA FORENSICS IMPORTANT?

Live Data Forensics

One of the new tools of a digital forensic analyst is also the Live Data Forensics. It is defined as the procedure of analyzing volatile or partially volatile computer data i.e. data which disappear upon shutting down the computer or data that is not persistent – often changed. In digital forensics, the analysis of such live data is important due to accessing data and evidences which are not reachable otherwise. In reality it often happens that the procedure of acquiring data includes solely the analysis of data-storage media such as hard disks, USB memories, CD/DVD media and other, better known as post-mortem analysis. The analysis of live data includes saving and analyzing volatile data such as Pagefile, Hibernation file, Crash Dump files and most importantly RAM - Random Access Memory.

III. RANDOM ACCESS MEMORY – RAM

In order to understand the importance of analyzing RAM data, it is first necessary to explain where such data are located and what information's does it contain. All data "travelling" through the computer have to pass through RAM at one point. Regardless whether we are referring to network traffic, working with hard disks, copying files from or to a certain medium or simply displaying pixels on the screen, all information are recorded in RAM memory blocks. Information will be present in RAM as well as on the computer hard disk, the only difference being that RAM is telling us what was happening on the computer at a certain period of time i.e. at the moment we recorded RAM while data on the hard disk are telling us what was happening in general. It is important to note that a huge quantity of data and information are never registered on the hard disk but solely in RAM. Common example being internet data [1][9][10].

IV. IMPORTANCE OF RANDOM ACCESS MEMORY ANALYSIS

Volatile data are constantly changing, they often are not structured in the same way as the computer file system and it is considerably more difficult to analyze and interpret the same. However, exactly such data are often the basis for continuing an investigation since certain data can be obtained solely from RAM. Currently, the analysis of volatile data is

still not defined as the analysis of hard disks drives or USB memory. Hard disks have a predefined structure and we can always find certain data at the same place which is not the case when analyzing RAM. Random Access Memory may but doesn't need to be allocated in the same places, depending on the type of memory in question. It is not possible to anticipate where a certain data can be found. It is obvious that the analysis of this data requires higher expertise and that it is a more demanding than post-mortem analysis. What also needs to be emphasized is that collecting such data also requires a certain expertise and work flow. Since the data is constantly changing, the moment and the way in which they are collected can greatly influence the final result. In Table 1 it is shown how RAM data will change (degradation of data) in time while the computer is in sleep mode (turned on but not in use).

TABLE 1 How RAM data changes with time in sleep time – data degradation

Activity	% Changes in RAM	
	256 MB RAM	512 MB RAM
Start	100	100
Sleep mode 1h	90,4	96,7
Sleep mode 2h	79,7	96,1
Memory dump	76,9	89,8
Sleep mode 15h	74,8	85,6
Memory dump	67,2	69,4

Information in table one was gathered by performing 2 tests in a lab environment. An older PC machines was used with single core AMD processor, Win XP SP3 and one 256 MB DDR 1 RAM module. After boot process, the following steps were taken:

1. Start MS Office and open one document
2. Start IE and log in to an online email account
3. Open CMD and run ipcofing command and ping google.com
4. Open Windows Explorer and copy one file

After the last step, RAM imaging was performed as stated in the Table 1. The second test was performed on the same machine only with two DDR1 RAM modules.

By analyzing RAM we can considerably contribute to the progress of every forensic investigation in which it is possible to take over RAM. Forensics of RAM is also of utmost importance because it bypasses several restrictions of traditional forensic analysis such as encryption which can completely stop the investigation in case it is not possible to get the password. Since technologies continue to advance, RAM analysis will become more and more important in order to collect all information necessary for any case.

Traditional post-mortem analysis is restricted in several ways. The most important one is the encryption. Investigators cannot access encrypted data if they are not able to crack the password or recover the key used for encrypting data. Such keys are rarely stored on hard disks, however, when the user enters his password or when the data is decrypted, data is being stored in RAM. The subsequent analysis of RAM enables finding these keys. Another restriction is the inability to analyze processes which were initiated on the computer at the moment of taking over the same. The inability to review processes which were initiated on the computer makes it impossible for the investigator to get an insight in the way the computer was being used. In addition, it is also possible to hide data in RAM itself as well as to initiate processes which are endangering the functioning of the system or stealing sensible data.

Nowadays, more and more we have cases where malware was used for endangering systems. Most malware is placed exclusively in RAM and it doesn't leave any trace whatsoever on the hard disk. Consequently, by traditional forensic analysis it is challenging to detect most malware or to make it possible for the analyst to better understand the way in which the computer was used. A good example would be Stuxnet, the first computer virus which was used as a military weapon. It was placed in the computer RAM, it left very little traces on the system itself and on the hard disk, and its goal was to disable centrifuges of nuclear reactors in Iran [1].

V. INFORMATION AND DATA THAT CAN BE FOUND IN THE RANDOM ACCESS MEMORY

There is a lot of information that can be found by analyzing RAM depending on the computer and the operating system used. Most valuable being: active processes, information on open files, registry entries, information on network activities, drivers used, logged in users, passwords and cryptographic keys, hidden processes and data, malware, temporary data, portable apps (apps which are not installed on the computer itself but they are solely initiated), used dlls, open sessions and many other vital information [3][9][10]. In this section we will address only some of these information and their importance.

A. Processes

There are various types of processes which can be found in RAM. All currently active processes are stored in RAM and they can be recovered from data structure in which they are located. Additionally, hidden processes can be recovered as well. For example, malware is known for hiding its activities, therefore its activities cannot be traced by regular methods or by simply reviewing active processes through the task manager of an active computer. By analyzing processes from RAM, we can search in their Headers and Footers thus making their hiding more difficult. Additionally, advanced code or malware can hide nevertheless by changing that information as well, but with additional analysis of blocks in which these processes are located, that information can be recovered as well. The aforementioned methods are exceptionally advanced and long-lasting and they require a deep knowledge of the operational system functioning. It is important to emphasize that this data can be obtained solely by analyzing RAM and that it is not possible to get it by regular forensic procedures ("dead box analysis").

Furthermore, processes which were stopped can also be found in RAM since the computer was not restarted from the moment when a certain process was shut down, so it is possible that the process still exists in the memory because its working environment was not yet assigned to another process. This shut down processes can be singled out from RAM and analyzed just like currently active processes [2][10].

B. *Open files and "registry handles"*

Files for accessing an individual process as well as registry entries are also stored in RAM. Information about files used by the system can be of great importance. In case the process is part of a malware code, open files can point out to the investigator where the code itself is placed on the hard disk, where the data is possibly being sent to or files which were changed. By monitoring these indicators it may be possible to reach the author of the malware code and to find out what his ultimate goal is. Also, it is possible to establish which omissions the code is using and to improve the safety of the overall system by correcting the same [2][9].

C. *General files*

As already mentioned, all files used (opened, read, modified) on a PC have to pass through RAM. Usually what happens is that the program creates a temporary copy of the file, stores it in the RAM and later when modification is complete, the files is saved on the media. This temporary file can later be recovered in full or just its fragments form the RAM. This is only one of the many possible scenarios but what is important that depending on the RAM size, can in some cases hold large number of files that were opened or used on the PC. Depending on the case, information that a files was used on a certain PC can have big significance. Furthermore, one of the most basic operations done on any given PC is the copy/paste feature. Each time sometime is placed in the clipboard, it is stored in RAM and therefore it is possible to recover it [1][2].

D. *Information on network traffic*

By analyzing RAM it is possible to identify all established network connections and open ports which existed at the moment of acquiring RAM as well as local and remote information on such connections. This possibility allows the investigator to analyze the programs which were initiated on the computer itself and which can be a target of malware code that can give false information on the network status. When receiving information directly from RAM, it is much more difficult for the offender to hide his open connections or planted processes. Information on network traffic is among the most important information which can be obtained from the computer that is the subject of investigation and it is more reliable when it comes from RAM analysis or from independent scanning of IP traffic [2][10].

E. *Internet data*

In this modern times, it is very common for everybody to use the Internet in their daily work or surf the web in their spare time. All research, networking, communication and similar is usually done via Internet. Additionally, it is also very common for people to store their data in the Cloud[1] and not locally on their computers. As previously mentioned, data that is being downloaded from the Internet will always pass through RAM. Because of this fact, it is possible to retrieve Gmail or Yahoo emails, Skype conversations and many more. All this very valuable data would be impossible to recover by "dead box" analysis since it is deleted as soon the PC is turned off.

F. *Passwords and cryptographic keys*

One of the main advantages of live data forensics is the possibility to recover passwords and cryptographic keys which were potentially used for decrypting data of interest and user accounts. Passwords and cryptographic keys are generally never stored on the hard disk without additional protection. However, when they are used, they have to be stored in RAM and they remain stored there until they are overwritten with another data or until the computer is shut down. When investigator performs a RAM dump (process of obtaining data form RAM), by reviewing collected data it is also possible to find online account passwords, which can have significant impact on the case itself. As an example, we can take online data or computer storage in clouds (cloud computing) which can store up to several terabytes of data.
Many BIOS (Basic Input/Output System) will write their plain text password to the BIOS keyboard buffer during boot which automatically suggest that it is possible to retrieve from RAM [2][10].

G. *Decrypted content*

The search for passwords and cryptographic keys in RAM can often lead investigators to decrypted data which can be recovered. When the user decrypts a certain file, the same file is temporarily being stored in that unencrypted form in Random Access Memory. By analyzing RAM it is possible to find parts of documents and even whole documents that were once encrypted. Files found by post-mortem analysis of the computer, will always be encrypted.

H. *Other data that can be found in RAM*

Since it is very common to have multiple users on one PC, by analyzing RAM it is very easy to determine which user was logged on, at what time and what was he doing or what files was he using. If Microsoft Windows were used for the operating system, a complete event log can be extracted and shown through a time line view. This can create a very clear picture for the investigator what was happening on the PC at what time. This can be crucial information for multiusers workstations and while investigating malware or virus infections. Windows will by default log software, security and system related events such as plugging in a USB device. In the latest analysis of the RAM, analysts have discovered that it is possible to retrieve a screenshot of the desktop and therefore all opened windows, time and work being done at the time the RAM data was retrieved [3][9].
All before mentioned information's can be also applied to multiple operating systems such as Microsoft Windows, Apple OSX or various Linux distributions. Not all operating systems will have the same results since each operates on its own way, but the most valuable information's such as network info, processes or files can be retrieved from the RAM data. Furthermore, RAM analysis can be performed even within the virtualized environment. In this types of cases, it can be very easy to obtain virtualized RAM data since it is commonly being stored as a single file on the hard drive of the hosting machine [1][2][10].

[1] A model of data storage where the digital data is stored in logical pools, the physical storage spans multiple servers (and often locations), and the physical environment is typically owned and managed by a hosting company.

VI. RANDOM ACCESS MEMORY ACQUIRY AND ANALYSIS

Acquiring Random Access Memory

In order for an investigator to be able to analyze RAM, he must have certain tools and knowledge in order to get all information contained in RAM. There are two methods for acquiring RAM: hardware and software method.

A. Hardware method

The hardware method includes installing a special card in the computer in order to gain Direct Memory Access (DMA). Usually this process involves installing PCI or PCMCI card with FireWire connector. Once the card is installed properly, other computer is used to image the RAM of the target machine. Generally, this method is more reliable than the software method since, in case the computer is compromised, we can still obtain a copy of RAM because there is no dependence on other computer components. In addition this method is the only way to image the RAM of a live machine that is password locked. Of course, this method has its deficiencies too – the price of the hardware component is higher and more expertise is required for performing extraction and especially installing the additional card in a live machine [10][11].

B. Software method

Software extraction is a much more common way for obtaining data from RAM and it is recommended to perform it during every computer acquisition in case the computer is active. Tools used for acquiring RAM can be commercial tools such as FTK Imager, Foremost, Helix, Belkasoft Live RAM Capturer and the like and there are also many non-commercial tools such as dd, memdump or Dumpit [4][5][6][7][8][9]. The main problem of software solutions occurs in case the computer is already compromised, the offender can easily additionally hide his data from such tools or give incorrect i.e. false data. Another deficiency of software solutions is that, when they are initiated, they themselves are using RAM just like all other programs and thereby they are potentially erasing other, possibly important information. With software tools we need to pay attention that they leave the smallest possible footprint, receptively that they occupy the least possible memory space. Another important fact is that they are operating in the so called "Kernel" mode. This means that the application itself has more rights in the system and that it can reach more information in the system. The main advantage of software tools is that they are free of charge and that they simplify the takeover of RAM so that it can be performed by untrained personnel [12].

Data analysis

Among commercial tools it is possible to use tools such as AccessData FTK, Belkasoft Evidence Center, X-Ways or Digital DNA –HBGarry, however, each of these tools contains only certain options and does not provide sufficient flexibility respectively adaptability[4][5][6][7]. As already mentioned several times, in order to analyze RAM a high level of expertise and experience is required [2][3]. Volatility Framework became prominent as the main tool for "deep" respectively thorough analysis [3][4].

VIII. CONCLUSION

It can be conclude that Live data forensics and therefore RAM data analysis should become a part of regular forensic procedures. During every computer analysis (in case the situation allows it) it is necessary to acquire RAM. The acquisition itself takes much less time than the acquisition of other types of memories and the possibility that it contains information important for the case which would otherwise be unavailable, is very high. Even though the procedure itself, the methodology and analysis are neither sufficiently examined nor documented, the potential results always make up for it. As described in this paper, the data that can be found in the RAM can sometimes contain enough evidence to solve the whole case. Special attention should be given to the fact that, even though there are deficiencies in the methodology, there are ways of preventing forensics analysis (the so-called anti-forensics) and therefore, while performing RAM dump, attention should be paid to anti-forensic tools.

Competencies and Skills needed for Digital Forensic Trainer

D. Foit, J. Vukalović, K. Hausknecht
INsig2 Ltd., Zagreb, Croatia

davorka.foit@insig2.eu

kresimir.hausknecht@insig2.eu

Abstract - Today we live in a time where everything is digitalized and technology moves rapidly forward. This big technology progress is closely linked to increase of cybercrime. In an effort to fight e-crime and to collect relevant digital evidence, law enforcement agencies are incorporating the collection and analysis of digital evidence, also known as computer forensics, into their infrastructure. They are challenged by the need to train officers and specialists to collect digital evidence and keep up with rapidly evolving technologies such as computer operating systems and mobile devices. With a lack of resources to send new people to the trainings, very often recently trained officers and experts become trainers to their colleagues. This role demands specific competencies and skills that can be learned on specialized courses. Based on an empirical analysis done on specimen of 20 experienced digital forensic specialists, this paper shows results of this research, offers explanation of competencies and skills needed for digital forensic trainer and helps law enforcement agencies to recognize potential trainers in their ranks, and helps them in their fight with the e-crime.

I. INTRODUCTION

Based on a long term experience in holding specialized trainings for the digital forensic specialists and law enforcement agencies, we've noticed that there is a big lack of methodology and approach in dealing with adult learning. The same thing happened when we participated some of official, vendor's trainings. The main reason to that is that people that hold trainings are not college educated people, but regular employees of companies or government agencies. Aldo this may seem strange, the explanation of such procedures lies in the fact that due to the world crises, many government institutions were forced to decrease their budgets. Because of that, companies usually send only one or two people from the department to educations and then it is on them to transfer gained knowledge to their colleagues and coworkers.

In this paper we will show what skills and competencies a digital forensic specialist needs to develop and improve to become a digital forensic trainer.

Methodology: We conducted empirical researches in January 2015 during Train the Trainers training in Pasadena. Research was conducted on a focus group of 20 experienced digital forensic specialists. Some of them work as a trainers for 5 or more years so they have enough of practical experience. Research was conducted by questionnaires, quantitative and qualitative analysis.

At the very beginning we set 3 hypothesis about digital forensics trainers that this paper should confirm or decline:

1. Digital forensic trainers understand how adults learn and acquire new skills
2. Digital forensic trainers can determine goals and purpose of a training
3. Digital forensic trainers understand and use different learning methods in order to transfer their own knowledge to participants who have different learning styles

II. ADULTS LEARNING

The main problem that appears with teaching adults lies in the fact that people who are not college educated teachers or who didn't attend some sort of train the trainers course, don't have skills and capabilities needed to perform good and successful education of adults. An important part of being an effective educator involves understanding how adults learn best. The principles and rules for adults learning are much more different than with children education with which are we all familiar. The theory that covers and handles adult learning principles is called "andragogy" (adult learning). Andragogy uses approaches to learning that are problem based and collaborative and emphasis more equality between the teacher and learner. It was defined as a study in Europe in 1950s and pioneered as a theory and model of adult learning in 1970's by Malcolm Knowles. [1]

At the beginning we asked the group what is an adult learning and what they know about adult learning principles. From 20 persons just one person knew the

term; others have never heard about the term and were not aware of adult learning principles.

III. EMPIRICAL ANALYSIS –TASK ONE: WHERE IS THE MAIN FOCUS OF THE TRAINING

The main goal of the first task is to discover where the trainer's main focus is when it comes to digital forensic trainings. It is well known that there are four main parameters on which focus can be set – trainer, participants, content, organization, – and all four of them are of equal importance to the training [2]. The purpose of a research was to determine on which of those four parameters digital forensic specialists focus the most, is that enough to improve their training performance and does this qualify them as a digital forensic trainers or they need to work more on improving their skills.

We told the members of a focus group to decide which one of four above mentioned parameters is the most important to them. When they decide, they need to go in one of four possible corners of the room and write down on flipchart (4 flipcharts on easels were already set up in four corners of the room) parameter for who they decided: TRAINER, PARTICIPANTS, CONTENT or ORGANIZATION. Focus group was composed of 20 active digital forensic specialists who have experience in holding trainings but they never got any formal education in that area. After that, members of the focus group were asked to write down list of reasons why they think that the chosen parameter is the most important for the training. The results are shown in the table below:

TABLE I. WHERE IS THE TRAINING FOCUS?

Focus on	Number of participants
Trainer	8
Participants	6
Content	3
Organization	3

Two participants remained "neutral" because they considered that all 4 parameters are of equal importance. The reason for this assignment is to discover how people think, what are their main priorities when they come to training, and what when they decide to educate other people.

Besides choosing where the focus should be, they also need to give some arguments to support their choice. Group that put focus on TRAINER listed their reasons as follows (I intentionally left original version of their handwriting):

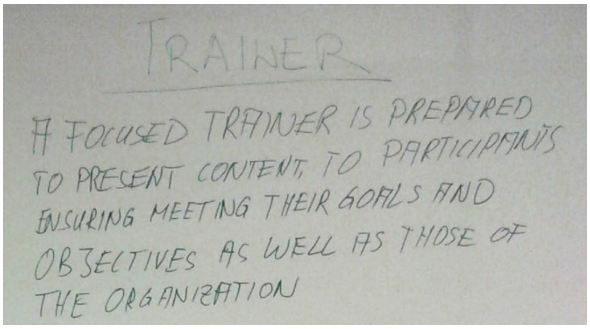

Figure 1. Arguments for "trainer" as the main focus of a training

Here is also group that decided that PARTICIPANTS are the most important for the training and list of arguments:

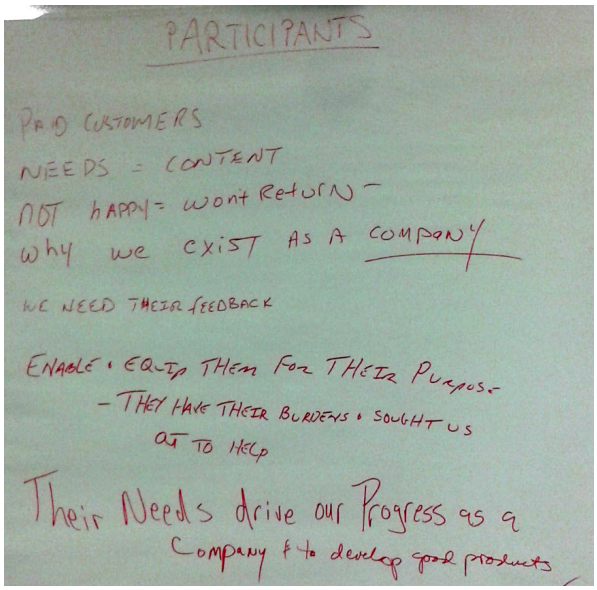

Figure 2. Arguments for "participants" as the main focus of a training

Also, in the same way are two other parameters (CONTENT and ORGANIZATION) added and described.

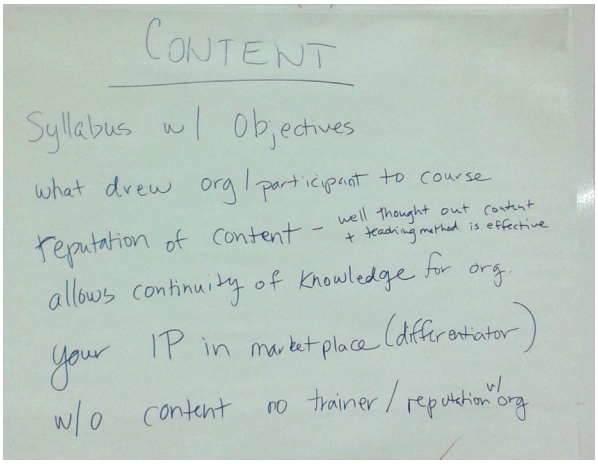

Figure 3. Arguments for "content" as the main focus of a training

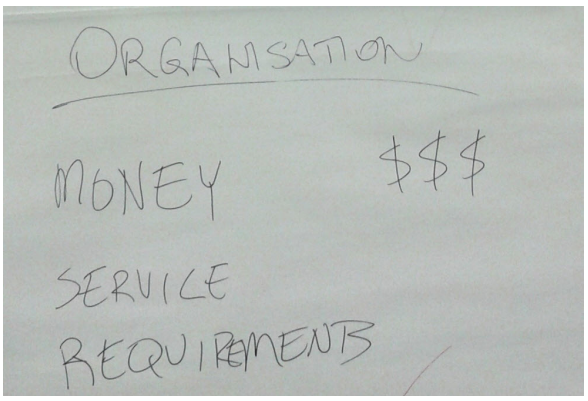

Figure 4. Arguments for "organization" as the main focus of a training

As we can see, all 4 parameters are well – reasoned.

The task was a little bit tricky, because there is no wrong answer. All four parameters are of the same importance for the training and all four need to be implemented in the adult training. Trainer needs to be focused on the organization and its need to accomplish its mission. It focuses on content that he delivers to ensure that it's accurate and practical. It also needs to be focused on himself to ensure that he is skilled and knowledgeable about the subject in hand. And finally, trainer focuses on his participants to ensure that all their expectations as a group and as individuals have been met during the training.

A. Results

The results of an empirical research show that, without proper education about adult learning principles, digital forensic specialist put their focus on trainer and participants, while content and organization are not of such importance to them. Hence, digital forensic specialists assume their own knowledge as absolute, and don't take into consideration that trainings which they perform are held in behalf of their employer or organization.

For the other part of research where thy needed to argument their decision, members of a focus group gave good explanations and arguments for each parameter.

IV. EMPIRICAL ANALYSIS – TASK TWO: LEARNING STYLES IN THE CLASSROOM

Besides determination where the training focus is, another important fact in andragogy are learning styles in the classroom. There are many modules that can be used as a reference for the learning styles, from Kolb's experiential module [3], Peter Honey and Alan Mumford's model [4], Anthony Gregorc's model [5] and many others. Module that will be used in this paper as a reference module is VAK module [6]. It is one of the most effective module of individual learning style, especially easy to applicable to adults who have already developed their own learning and working preference. This a module consists of carefully mixing all three dominant learning styles – Visual, Auditory and Kinesthetic – according to participant's preference [6].

For a good trainer, it's important to accept the fact that participants may have different learning styles, so it is important to consciously design content that is balanced between all styles. Trainer should always use a variety of approaches, techniques and activities that address the different VAK preferences such as:

Visual: creating graphic models, drawing concepts, taking notes, viewing slides and flipcharts.

Auditory: utilizing spoken words, allowing them to talk, panel discussions and music.

Kinesthetic: things to manipulate, such as modeling clay, crayons, Koosh balls and papers feels good [2].

Visual	Auditory	Kinaesthetic
Posters	YouTube clips	Note taking
Mind maps	Dictaphone	Copying out notes
Post it notes	Discussions	Games
Note taking	Question/Answer sessions	Talking-Walking Study
YouTube clips	Mnemonics	Re-enactments
Colour coding	Revision songs/rhymes	Trace words with finger
Timelines	TV Programmes	Doodling
Grids/Tables/Charts	Revision Videos	Trips and Visits
Fact Lists	Listening to music whilst revising	Construct posters and other revision resources
Facebook Profiles	Study Groups	

Figure 5. Some of techniques and activities characteristic for different learning style

It is also really important that trainer doesn't use its own preferred learning style. For instance, some people are active learners. They like to be constantly challenged, can think on their feet and enjoy the challenge of being thrown in the deep end, learning best 'on the job' through practical exposure, trial and error and direct experience. Other people are more reflective learners, they need time to plan, prepare, research and to have time to reflect on their learning before being confronted with a new challenge. They may like to be thoroughly briefed before proceeding. Some people are theoretical learners, and are stimulated by abstract ideas and concepts. They like to consider numerous viewpoints and theories and to analyze situations before selecting options and approaches to a task. They learn through observation, discussion, analysis, and enjoy logical and sophisticated reasoning. Whilst others are pragmatic learners, they enjoy learning from qualified demonstration, and need to see the practical advantage of all that they are doing. They need to know that what they are doing works and is realistic [7].

In this research we had a focus group of 20 people that work as a digital forensic specialists and, as a part of their job, hold training for their colleagues and superiors.

The group had to fill in given questionnaire (Figure 6) with a list of 25 statements that describe some behaviors during learning process. The goal was to determine learning styles of digital forensic specialists that are active and good in digital forensic investigations, and see what skills and competencies, which are related to training

performance, they need to improve or change in order to become digital forensic trainers. Assumption that was taken in this research was that the members of a focus group will expect that their learning styles are similar to those of their colleagues and supervisors (potential participants) and that, in that case, they will not have to adjust or change their skills.

The questionnaire was designed in a way that members of a focus group had to put checkmarks next to the statements that correctly and most accurately describe things they like and don't like to do while adopting new knowledge. At the end, they had to sum all the checkmarks in each column. Each column was representing one learning style [2]:

- VL (*Visual Language*) – This is the person who learns the best from reading words in books, on the chalkboard, charts or workbooks. The individual may even write down the words that are given orally in order to learn from seen them on the paper
- VN (*Visual Numerical*) – The person has to see the numbers on the board, on the paper or in the book in order to work with them. They are more likely to remember and understand number facts if they have seen them. They don't seem to need to much oral explanation.
- KL (*Kinesthetic Language*) – Learning takes place by the student actually carrying out a physical activity, rather than listening to a lecture or merely watching a demonstration. It is also referred to as a tactile learning.
- AL (*Auditory Language*) – this is the person which learns from hearing words spoken. You may hear them vocalizing or see their lips or throat moving when they read, especially when they are trying to learn some new materials. They are more capable of understanding and remembering words or facts they could only learn by hearing.
- AN (*Auditory Numerical*) – this is the person that learns from hearing numbers and oral explanations. They may remember phone and locker numbers easily and be successful with oral numbers, games and puzzles. They can probably solve problem in their head. Trainer my see participant's lips moving and hear them talking while they are trying to understand a problem.

At the end, column for which they have the highest score is their preferred learning style.

In the picture below is an example how one page of the questionnaire looked like:

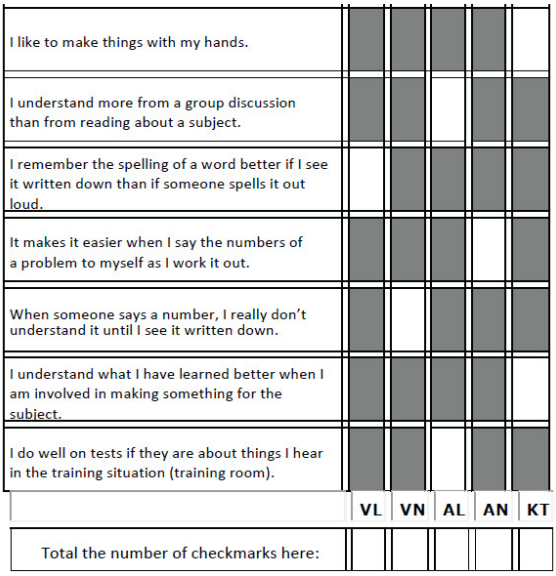

Figure 6. Part of VAK learrning style questionanire [6]

At the end we asked them to plot a spider web connecting the points with the scores on each line. We created a similar spider web based on the scores of all 20 participants.

A. Explanation of the questionnaire results

The result that focus group achieved is shown on the Figure7:

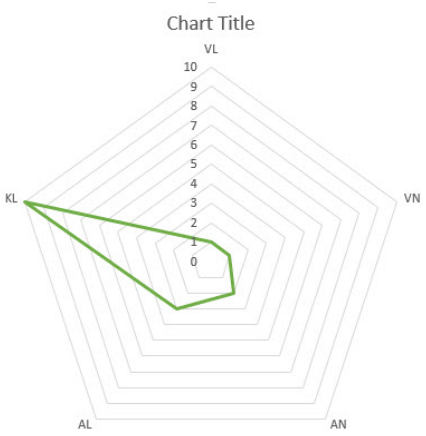

Figure 7. Spider web with connected points of scores on each line

VL stands for Visual Language and it was preference learning style for only 1 person. **VN** is Visual Numerical learning style and was represented by 1 person. **AN** is Auditory Numerical and it was preference learning style for 2 persons, and **AL** is Auditory Language and is preference learning style for 3 persons. As expected for this group of people – the most represented learning style was **KL** (Kinesthetic Language) with 10 representatives.

It is recommended for every trainer to conduct such testing at the beginning of a lecture because it gives them opportunity to combine all learning styles, but also to

encourage participants to use learning style that is not preference to them.

B. Results

With conducted research was established that the dominate style which digital forensic specialists use in their learning process is **Kinesthetic Language**.

The result is important because it shows connection between jobs that members of a focus group perform in their everyday life and learning style that they use. Digital forensic trainers have to work on understanding how to train people who have different learning styles.

Kinesthetic represents repetition of procedures and *Language* represents written part. If we look globally, that is exactly what digital forensic investigators do - they spend much of their time in laboratory settings, analyzing physical evidence from crime scenes and at the end of analysis, they write official reports on the subject.

V. Digital Forensic Specialists – General Skills and Competencies

In their everyday job, digital forensic experts should be proficient in conducting many types of tests, analyzing the results and reporting them. They are all insatiably curious about how and why computers work. They spend much of their time reading about software, hardware, registry keys and root kits. Exploration is their daily job.

Communication and learning skill which are emphasized: tenacity, persistence, dedication, patience, integrity, curiosity, investigative skills, desire to learn constantly, self-motivation, interest in researching new things.

College education is not the most important in this job – it is desirable to have a degree from a technical college to prove your competencies and expertise in the courtroom. However, the most of the knowledge that digital forensic specialists have, they obtained through professional certifications that legitimately demonstrate training, testing and practical experience and at the same time have value in helping courts, clients and potential employers assess qualifications. The ability to construct illuminating experiments and the patience to elicit the data is another hallmark of skilled computer forensic examiners. If you need to know how a file or metadata changes when a user does something or what digital evidence is left behind, you'll be best prepared to testify if you've proven your theory by competent experimentation.

Knowledge that is emphasized with digital forensic specialists: good formal education, good math aptitude, good computer background, basic computer knowledge.

Another thing that characterize digital forensic specialists is experience and sharing that experience with other colleagues. Every examiner benefits from the exchange of ideas with skilled, experienced colleagues. However, the computer forensics community has its own rules that need to be followed:

- show respect for others by first doing your homework;
- don't waste time with a question that's been asked and answered in a prior posting or one you took no steps to address on your own;
- be a learner, not a leech

And finally, all digital forensic experts know all about the tools and techniques they use in their cases. It is not enough only to know how to use some tool, but also to know how to explain and defend your report in the courtroom, in front of the people that are not familiar with digital forensic evidence and examination of the same.

The job of a computer forensics expert doesn't end when the digital evidence has been obtained and analyzed. They must document their findings in the form of one or more reports that detail not only what they found, but how they found it. It's really important that they are able to articulate the process and procedures they followed so there will be no doubt that the evidence was legally obtained, that its integrity was preserved throughout the process, and that there was no opportunity for it to be tampered with [8].

Social and cognitive skills that are emphasized with digital forensic specialists: ability to write a report on findings, ability to link one part to the whole case, ability to receive criticism.

VI. Conclusion

By empirical researches conducted on a focus group in this paper, it is determined that digital forensic specialists have some of the skills and knowledge that are necessary to become trainers in digital forensic field, but they need to change some of them in order to fulfill all prerequisites needed for digital forensic trainers.

By going back to the 3 hypothesis from the beginning of this paper, we can conclude:

1. Digital forensic specialists don't understand how adults learn and gain new knowledge. If they want to become successful digital forensic trainers, they need to learn about adults learning principles and about ways how adults adopt new skills. So, hypothesis no.1 was not confirmed by researches in this paper.
2. Digital forensic specialists can determine goals and purpose of a training. In this case they can become digital forensic trainers without any big adjustments or changes so the hypothesis no.2 is confirmed by researches in this paper.
3. Digital forensic specialists use their individual learning styles, but, at the same time, are not aware of other learning styles which their colleagues use. They need to become more aware of other's learning styles in order to be able to provide adequate knowledge and skills to their future participants. In this case, hypothesis no.3 was not confirmed by the researches in this paper.

Next research should be based on this one and it will be done in Orlando on 2 different focus groups. Groups are composed of 20 skilled and well trained digital forensic specialists who come from all over the world and are of different age.

ACKNOWLEDGMENT

I would like to thank the trainers from Guidance Software Inc. for their participation in my research and for sharing their experiences and their thoughts with me.

Challenges in Network forensics

J. Burić*, D. Delija **
INsig2 d.o.o., Zagreb, Croatia
jerko.buric@insig2.eu, damir.delija@insig2.eu

Abstract - Network forensics is a branch of digital forensics that focuses on monitoring, capturing, recording, and analysis of network traffic. More accurately, it is the use of scientifically proved techniques to collect and analyse network packets and events for investigative purposes. Network forensics is an extension of the network security model which traditionally emphasizes prevention and detection of network attacks. Current network forensics approaches are costly and time consuming. However, unlike other areas of digital forensics, network forensics deals with volatile and dynamic data. It helps organizations to investigate attacks that originated from outside and inside of the company. It's also important for law enforcement agencies when solving crimes. Paper presents different challenges that are facing investigators due to the rapid growth of network and attacker's skill, and possible framework solutions that would help to solve or minimize problems.

I. INTRODUCTION

The Internet is constantly changing, where evidences are located all over the network, there is no enough time nor staff. Expectations are unrealistic, various differences within organizations, and above all, mishandling of evidence. Network forensics investigations can be and is a very demanding process. With all challenges that traditional forensic investigators are faced, network forensic investigators need to work/interact with expert and non-expert people, learn to handle different types of equipment, both hardware and software, theirs' various versions, more than often capture evidence that exist only for a brief moment, and unfortunately, investigative teams find themselves in situations where it is not clear who's in charge [1].

An organized approach is a key to a successful investigation. With the continuous growth of the Internet, cyber-attacks and crimes are happening every day [2], with addition of increasing intruder's skills. Everything has gone that far, that it raises the fact: It's not IF you are going to be attacked, it's WHEN. Traditional tools used in investigations, such as firewalls and Intrusion Detection and Prevention Systems (IDPSs), are no longer enough since they can't provide all required evidence or data [3].

Current network forensic approaches are costly and time consuming. In addition, these approaches normally use active and reactive processes to resolve cyber-crimes, and such processes start after cyber-crime has been identified, which makes identifying useful evidence difficult [4], making network forensic investigation a post-mortem incident handling.

II. NETWORK FORENSICS

Network forensics is an act of capturing, recording, and analysing network audit trials in order to discover the source of security breaches or other information assurance problems [5]. The term "network forensics" was introduced by the computer and firewall expert Marcus J. Ranum in early 90s, but borrowed from legal and criminology fields where "*forensics"* is related to investigation of crimes.

In 2001 DFRWS (Digital Forensic Research Workshop) defined network forensics as *"The use of scientifically proven techniques to collect, fuse, identify, examine, correlate, analyse, and document digital evidence from multiple, actively processing and transmitting digital sources for the purpose of uncovering facts related to the planned intent, or measured success of unauthorized activities meant to disrupt, corrupt, and/or compromise system components as well as providing information to assist in response to/or recovery from these activities"* [6].

In essence, the concept of network forensics deals with the data found across a network connection going to and from one host to another. Network forensics analyses the traffic data logged through firewalls or intrusion detection systems or at other network devices such as routers. The goal is to trace back to the source of the attack in order to discover perpetrators [9]. One note has to be emphasized; the traffic or data which is being monitored is live so in network forensics we are no longer talking about post-mortem analysis.

The following table presents network devices and their value in network forensics.

Table 1. Network devices and their forensic value

Tool name	Value to Network forensics
Switches	Contain Content Addressable Memory (CAM) - determines which port on a switch corresponds to which MAC address.
Routers	Networking devices that forward data packets between computer networks. They store routing tables that maps ports to connected networks. They can also function as a packet filter.
IDPSs	Network security appliance that monitors network and/or system activities in real time and alerts for malicious traffic.
Firewalls	Control incoming and outgoing network traffic based on predefined rules. Analyse and log the source and destination addresses, packet payloads, and port numbers to make decision about certain traffic to help forensics in process of investigation.
Web proxies	Act as an intermediary server for requests from clients seeking resources from other servers. Can be

	configured to maintain special logs for extended period of time. Such logs store the web surfing for an entire organization.
Special type servers	The main types are DHCP, Name, Authentication, Application, and Central log servers. Data stored on each of these servers can be of the great value and can provide help in forensic investigations.

Back in 2002, Simon Garfinkel introduced two network forensic systems called "Catch it as you can" and "Stop, look and listen" [7]. "Catch it as you can" system captures and writes all the packets passing through a particular traffic point. This approach requires large amounts of data storage. On the other hand, "stop, look and listen" system, analyses each packet in a rudimentary way in memory and only certain information is saved for future analysis. This requires a faster processor to keep up with incoming traffic [2]. Network forensic systems are designed to identify unauthorized use, misuse, and attacks on information systems which were previously identified manually or in most cases, unidentified [8]. Most network forensic systems are based on audit trails. System relying on audit trails try to detect known attack patterns, deviations from normal behaviour, or security policy violations. They also try to reduce large volumes of audit trail data to small volumes of interesting data. Most of the current techniques are passive monitors, which heavily rely on network traffic, CPU usage, or I/O usage with human intervention [8]. The main focus in the area of cyber and network forensics is to automate the process of detecting the attacks and to prevent the damage caused by future security breaches.

Network forensics is not another term for network security, but it is an important part in network forensics. Data for forensic analysis can be collected from various security products which are placed onto the network to detect and prevent intrusions. Network forensics ensures that the attacker spends more time and energy to cover his tracks making the attack costly and time consuming [9].

The IT industry's ever-growing concern with security is the primary motivation for network forensics [10].

A. Network Forensic Analysis Tools (NFATs)

Although not the final-solution for security administration, NFAT is capable of saving both time and money and help administrator watch everything in the network, gather all information about suspicious traffic, and help in network forensics. Basically, NFATs capture network traffic and send data to the engine, which analyses that data and shows results. NFATs correlates with IDSs and firewalls making preservation of network traffic in long period of time possible and allows quick analysis of concerning points in the network identified by IDSs and firewalls [11, 12]. Some of the NFATs functions are:

- Intellectual property protection
- Detection of employee misuse/abuse of company networks
- Risk assessment
- Network forensics and security investigation
- Exploit attempt detection
- Data aggregation from multiple sources, including firewalls, IDSs, and sniffers
- Incident recovery
- Prediction of future attacks
- Anomaly detection
- Network traffic recording and analysis
- Network performance

Some of the commercial NFATs available in the market are: NetIntercept, NetDetector, NetFlow, SilentRunner, EnCase, and VisualRoute [11].

The open source NFATs are: TCPDump, Libpcap, WinDump, Wireshark, Snort, Nmap, P0f, Tcpstat, Tcptrace, and Tcpflow [11].

Following commands are inbuilt in many modern OSs and are very useful for Network forensics: nslookup, traceroute, netstat, nbtstat, whois, ping, wget, dig [11].

B. Network forensic Process (Generic) Model

In the paper called *"A survey about network forensic tools"* [2], the authors propose a generic framework for network forensic investigation. The proposed framework consists of many phases which are already imprinted in digital forensic model, on which they built new phases specific to network forensics. As illustrated on figure 1, generic framework consists of nine phases, which are going to be closely explained.

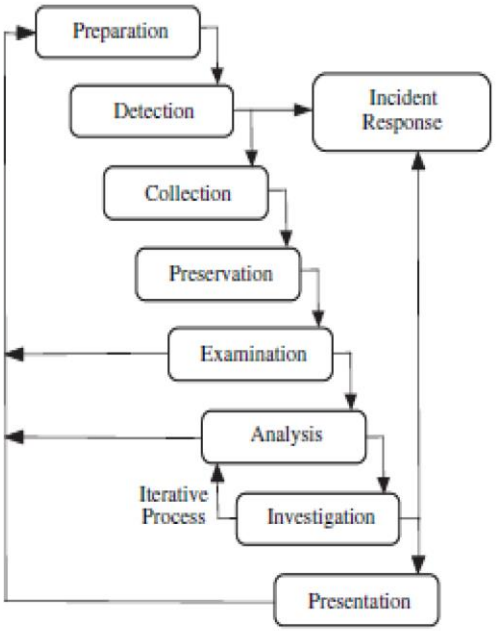

Figure 1. Network forensics Process Model [13]

- *Preparation phase* – since many tools need to be deployed (IDPSs, firewalls, packet analysers) on various points on the network, the prime duty is to obtain required authorization and legal warrants to ensure privacy.
- *Detection phase* – deployed tools generate an alert or a warning which indicates a security

breach or policy violation. A quick validation is done to assess and confirm the suspected attack.

- *Incident response phase* – the response initiated in this phase depends on the type of attack identified and also by organizational and legal policy. This phase is applicable only when investigation is initiated during the attack.
- *Collection phase* – the most difficult part because data that flows over a network changes rapidly and it is not possible to generate the same trace at later stages. It is crucial to have reliable hardware and software, along with well-defined procedures to collect maximum evidence with minimum impact on the network.
- *Preservation phase* – original data is kept safe along with computed hashes. Another copy of data will be used for analysis. This is done to ensure that there is no unauthorized use or tampering.
- *Examination phase* – this phase examines previous phase. This is done in a methodical way so no key information is lost. All hidden or altered data done by attacker needs to be uncovered. Reduction of high volume data is necessary in order to identify the least information holding the highest probable evidence.
- *Analysis phase* – collected evidence is analysed in order to find specific indicator of an intrusion. Also, statistical analysis and data mining is performed to search for data and to match it to attacking model. The attacking patterns are put together and reconstructed to understand the purpose and methodology of the attack.
- *Investigation phase* – this phase uses information gathered through analysis phase, and concentrates on identifying attacker, which is the most difficult part of analysis phase. Attacker may use many different techniques to hide their intentions or their identity, such as IP spoofing or stepping stone attack [1]. Actual approach in investigation phase depends on attack type.
- *Presentation* – is the final stage in processing model. Systematic documentation, along with observation with explanations are presented in readable and understandable format. Everything that has been performed needs to be presented in accordance to applicable legislation and security policy, along with recommendations on how to prevent future attacks.

This framework for network forensics shows how methodical and precise approach an investigator needs to take in order to have valuable, legally acceptable and forensically sound evidence to present.

III. NETWORK FORENSIC CHALLENGES

The main idea of network forensics is to identify all possible security violations and threats, and build the signatures into IDPS mechanisms to prevent further losses [8]. Many tools allow network administrators or forensic investigators to observe network traffic in real-time, but real-time monitoring at any level requires significant human and hardware resources, and doesn't scale to networks larger than a single workgroup. It is generally more practical to archive all collected traffic and then analyse it per needs [10].

When conducting network forensics, investigators frequently work with live systems that cannot be taken offline. These systems can include routers, switches, firewalls and other equipment all the way to critical servers. In network forensics, investigators also work to minimize effect on system modification due to forensic activity. However, in those cases investigators do not have luxury of an online copy. Furthermore, network-based evidence is more than often highly volatile[2] and must be collected through active means that essentially modify the system which holds necessary evidence. This impact on the system can be minimized through careful selection of appropriate tools and acquisition techniques, but it can never be eliminated entirely [1].

Network-based evidence poses special challenge in several areas [1]:

- *Acquisition* – it can be difficult to locate specific evidence in a network environment. But, even when you know where a specific piece of evidence is located, you may have difficulty gaining access to it for various reasons.
- *Content* – unlike file systems, which are designed to contain all the files and their metadata, network devices may not store evidence with that level of diversity.
- *Storage* – network devices normally do not employ secondary or persistent storage, and often have very limited storage capacity
- *Privacy* – depending on jurisdiction, there may be legal issues involving personal privacy that are unique to network-based acquisition techniques.
- *Seizure* – seizing a hard drive can inconvenience an individual or organization. Seizing a network device can be much more disruptive. In the most extreme cases, an entire network segment may be brought down indefinitely.
- *Admissibility* – file system-based evidence is now regularly admitted in both criminal and civil proceedings. In contrast, network forensics is a newer approach to digital investigations. There are sometimes conflicting or non-existing legal procedures for admission on various types of network based digital evidence.

[1] Stepping stone attack – technique used by attackers to attain anonymity and complicate their apprehension [15]

[2] Volatile – information that changes frequently and is often lost upon powering down the PC [16]

As the main idea of network forensics being to identify all possible violations and threats, a key challenge in network forensics is to ensure that network is forensically sound. That means that network needs to be properly configured, maintained, and updated by network administrator, and possibly have infrastructure that supports network forensic tools - hardware and software. When conducting network forensic investigation on a network infrastructure, following challenges should be taken in considerations:

- *Data sources* – typical network has several possible data sources, ranging from raw data to logs from network devices. The best situation would be to collect all data from all sources but this is very often not possible, especially when dealing with large networks. Therefore, selection of proper source of data is of the essence.
- *Data granularity* – as related challenge to data sources, deciding how much details we want to collect is another problem. While in smaller networks we can collect whole packets that contain packets' headers, IP addresses, port numbers, protocols, TTL, etc., collecting that much data in larger network doesn't seem to be practical or manageable.
- *Data integrity* – probably the crucial part or challenge in network forensics. The whole forensic process can be dismissed or court disproved if data collected from a network is altered or changed in any way, deliberately or accidently. Therefore, forensic investigator needs to ensure and guaranty data integrity during and after collection and analysis.
- *Data as legal evidence* – Data collected internally for different purposes within organization differs from data collected for court of law. Data/evidence as it is needs to pass strict legal procedures needs to be acceptable in the court.
- *Privacy issues* – data collected during an investigation always contains some form of personal information, whether it is an email, personal files, or metadata of a person. Collateral intrusion can also be a privacy issues, when investigators discover personal information about people who are not subject of an investigation.
- *Data analysis* – a huge challenge in an investigations due to complexity of network environment and data involved during collection process. It is quite difficult to find, analyse and present useful information or data. Therefore, investigators use variety of tools and techniques to make job easier and more accurate.

Challenges regarding network-based evidences and network infrastructure have been presented in relation to network forensic investigation. Network forensic investigators are searching for a clue or piece of evidence buried deep in a pile of data, something like searching a needle in a haystack. Keeping that in mind, following challenges occur almost every time when a network forensic analysis is taking place:

- *Time* - whether is it a deadline they must honour, or to find what actions were taken at a specific time, or just to synchronize date and time information with events being analysed, time is very important aspect in every forensic investigation.
- *Performance* – speed and accuracy are one of key components of network forensic investigations. It's all about how fast an investigator can react on alert of a security breach, and/or policy violation, and how punctual is he in his assignment. Of course, it is not all about human competence and skill; both hardware and software need to be capable of performing at top level.
- *Complexity* – bigger network, bigger problems; bigger complexity. Although not a general rule, since sometimes smaller networks can cause large problems in numerous ways, bigger networks tend to have more network devices, more end users, more IDPSs and firewalls and very large infrastructure, where investigator or team of forensic investigators can be overwhelmed by the size of data they need to process and analyse. In addition, servers can be located in different geographical areas which increases complexity and makes the job more difficult to perform.
- *Collection* – in correlation with complexity, it is true skill of an investigator to separate valuable data from terabytes of normal network traffic.
- *Law* – as being a young area of expertise, network forensics tends to have legal and court issues. They could be related to the lack of applicable legislature, a country's internal decision-making organization associated with law.
- *Hiding a breach* – many companies try to minimize exposure to the public regarding their network breaches, and 'ask for help' only when they see that there is no other option. This is another major challenge in network forensics simply because, if an attack or security breach has occurred, a skilful attacker is long gone and has successfully covered his tracks.
- *Network systems* - as already mentioned, network forensic systems are based on audit trails. One of the main setbacks with these systems is their price, which can be extremely high. In order to analyse logs, system must keep information, which results in large amount of data requiring even larger amounts of disk space with very powerful CPU resources.

Even after you have collected everything necessary for network forensic investigation, the next step is processing and converting logs in manageable format, and then comparing them with known attacks patterns and misuses,

to possibly identify security breaches can be extremely demanding. Furthermore, stored patters of attacks need to be regularly updated, which requires a lot of human expertise. A network tool that is capable of performing this automatically is the goal of a researches in cyber/network forensics.

IV. CONCLUSION

Network forensics is an art and skill. It takes a lot of knowledge and patience to learn networking, how it operates and functions, networks flaws which skilful attacker can use, as well as advantages which forensic investigator can turn into his favour. Network forensics gives an investigator an ability to trace the source of the attack to its origin and possibly to identify the perpetrator. This paper presented only some challenges concerning network forensics. Attackers, and their rivals, network investigator/administrators, constantly battle around dominance over the network. That battle is what challenges are all about: time, speed, accuracy, complexity, integrity, performance, etc. Paper also presented NFATs, collection of network tools, which investigators can use to monitor, maintain, and trace back attackers if needed. A generic framework was also presented, which provided a visual overview how network forensic procedure should look like and what are the key stones and challenges.

Abstract – Computer forensic is the practice of collecting, analyzing and reporting evidences in a way that is legally admissible "in open court" or "public" as a part of criminal investigation process. It can be used in the detection and prevention of crime and in any dispute where evidence is stored digitally. In this paper we presented case of criminal activity in progress where forensic using hacker tools helped to proactively prevent criminal act of blackmail in progress. This approach was acceptable to company owner because public case would bring negative publicity and because incident resolution time was very important criteria for this case. Many organizations suffer great losses because of missing implementing standards for information security that includes segregation of duties, and active monitoring. In this paper we described how we used network hacking for forensic investigation for the right cause which is to prevent criminal activity in progress. This paper shows how different techniques and tools can be jointly used in step by step process to successfully perform forensic analysis and reporting.

I. INTRODUCTION

Computer forensics follows a similar process to other forensic disciplines, and faces similar issues. Purpose is to give answer to questions of a legal system related to computers. Forensics has it's role in any sort of legal issue, trial, civil court cases or any other legal processing that has computer involved.

"Computer forensics usually refers to the forensic examination of computer components and their contents..." [1]

A. Presenting the case before forensic investigation

The case presented in this paper started when forensic team was called by company's IT manager with company's owner permit with request to investigate if data base (DB) administrator was hiding important organisation's data on PC computer. There was fear that data DB administrator collects and use company information without permit. Another reason for believing that stealth blackmail is in process was the fact that DB administrator initiated negotiation for changing salary terms and conditions and refusing to provide system password to IT manager. The PC that was used by DB administrator was database administrator's device because company allows bring your own device (BYOD) and bring your own technology (BYOT) policy. The database administrator's PC was password protected at all time. Other issues included fear that database administrator will permanently destroy entire hard drive with data of the system which he manages or just quit the job and leave company without important company and user's data. Knowing that, and because there were still no elements for criminal prosecution, data or hardware was not destroyed, nor there were no formal blackmail request, it was decided to acquire access to all data without knowledge of database administrator. This case was more prevention of the possible crime. Because no one was able to tell any information regarding what operating systems, type of the software and version DB administrator used on his PC.

Decision was made with company owner that forensic team will work after office working hours. In order to keep low profile it was decide to keep the contact only with IT manager, to avoid that the other employees inform DB administrator that forensic process in progress. Because DB administrator's PC was running all the time, the idea of shutting it down and creating forensic image was out of the question. Reason for this is that DB administrator would probably be able to detect if PC was rebooted without his presence.

Network presented in this case was structured UTP wired infrastructure with central router, IP addressing of local network communication was configured by using DHCP server service located at the router.

B. Rationale for documenting the forensic case

The main reason for documenting and presenting whole process of forensic analysis was to show how hacker techniques can be used for right purpose which is stopping criminal activity in progress. Criminal are usually aware of this possibilities and they are trying to mitigate detection and prevention of their activities. While hacker tools are used to fight with criminals it is possible

to find arguments for, and against the use of "malicious" tools or code for "righteous" purposes [2].

II. PROCESS OF COLLECTING AND ANALYSING NETWORK DATA

Typically, at the crime scene first step is collecting and labelling all evidences, but in this case priority was to leave entire LAN hardware up and running so that DB administrator will not be aware that forensic process is in progress. The forensic team has arrived after working hours to use approach common to intrusion attacks shown in Figure 1. steps of intrusion attacks [3].

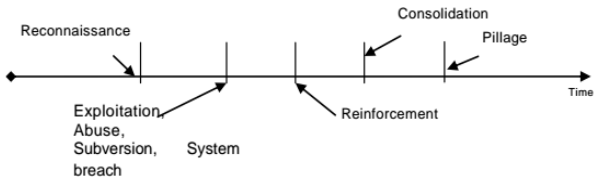

Figure 1. Steps of intrusion attacks

The first step was collection of all network which is followed by [3] of reconnaissance, exploitation, reinforcement, consolidation, and pillage to:

- Detect computers in the company network
- Detect IP addresses of devices in the network
- Detect any other type of attached network devices
- Sniff network traffic for passwords
- Gain access to PC and stored data

Because no one in the company was able to tell what software is installed on DB administrator's PC as BOYD / BYOT policy, it was decided to use available hacker tools such as Angry IP Scanner 2.16 [4] and Nmap [5] to detect DB administrator's PC. In the network diagram shown in Figure 2. presented is simplified company network diagram with several workstations, one router, and a DB administrator's PC that was a prime goal of the investigation.

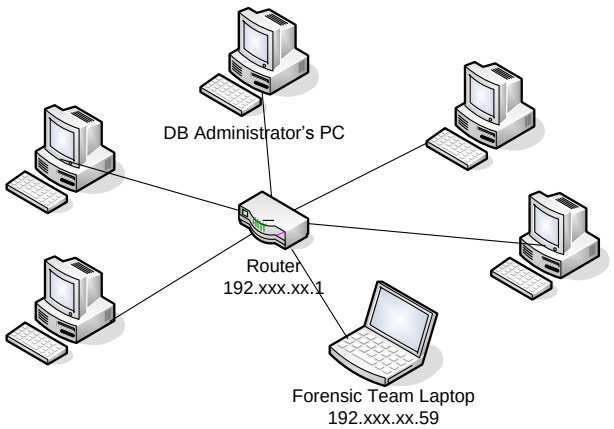

Figure 2. Simplified company network diagram segment

A. *Network scanning*

In order to scan entire Local Area Network Angry IP scanner 2.16 [4] was used and Nmap [5], with goal to find DB admin PC IP addresses. Angry IP scanner [4], and Nmap [5] are able to scan IP addresses, open ports, to detect running operating systems. They can be installed on Linux, Windows platforms

With nmap it was decide to use intense scan, and slow and comprehensive scan by using below stated nmap commands:

nmap -T4 –A –v 192.xxx.x.xx

nmap -sS -sU -T4 -A -v -PE -PP -PS80,443 -PA3389 -PU40125 -PY -g 53 --script "default or (discovery and safe)" 192.xxx.x.xx

Angry IP Scanner (or simply ipscan) is an open-source and cross-platform network scanner designed to be fast and simple to use. In Figure 3. is shown level of details which are used to gain information on available devices attached on network.

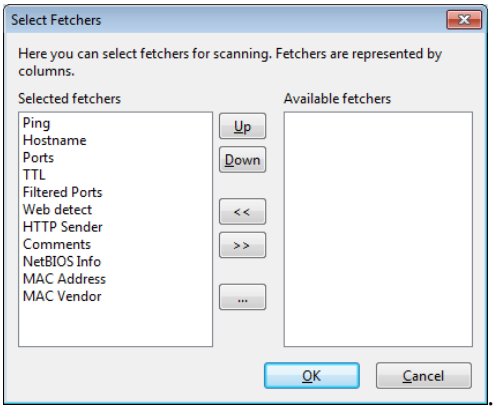

Figure 3. Result after scanning LAN with Angry IP Scanner

In Figure 4. is presented screenshot with results of IP scanning network segment with IP addresses.

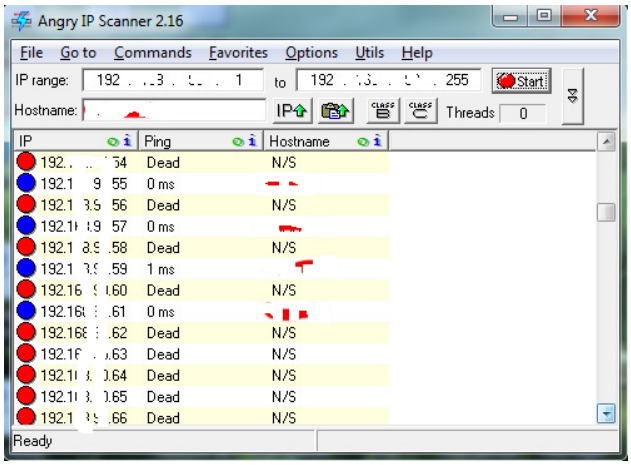

Figure 4. Result after scanning LAN with Angry IP Scanner

Result didn't show a logical host names, and it was not clear which IP addresses belongs to DB administrator's PC that forensic team was trying to investigate.

Next step was to shut down all other active computers, except a default gateway on IP 192.168.xx.1 and DB administrator PC. It was clear that only three IP addresses after all other devices were powered off were active: forensic team laptop, router and DB administrator's PC.

All scanning activities were finished in time window less than one minute.

After this step, the problem with DB administrator's PC IP address was resolved and all other network devices were again switched on. Using Nmap [5] it was detected that on this PC MS Windows operating system is installed, as shown in Figure 5. Nmap scanning results.

After reconnaissance activity which included scanning network segment where DB administrator's PC resides network topology became populated with new information.

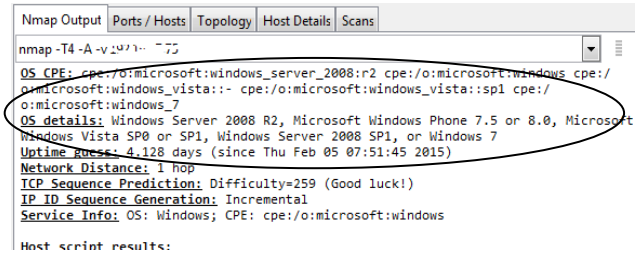

Figure 5. Nmap scanning results

After scanning network segment new information became available about network which included DB administrator's PC IP address as it is shown in Figure 6. and other network segment details with relevant IP addresses for all connected devices.

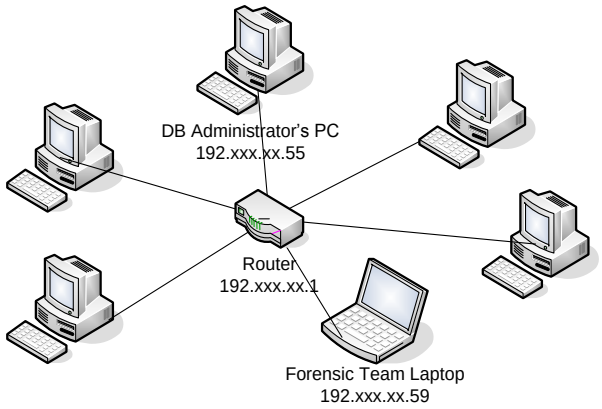

Figure 6. Network segment with relevant IP addresses

Because DB administrator worked every day, it was assumed that he will use his PC to logon with credentials at web pages, web mail, or other service. Next steps were to capture traffic and to recover passwords.

B. Network sniffing

After successful target determination another step was to capture network traffic which can be usually done by using tap device with an open source tool such as Wireshark [6] on wired networks. Tool Kismet [7] as open source can be used on wireless links, and tool called Cain (Cain and Abel) [8] which is also open source can be used on wired and even on wireless networks [9].

Next step was to choose approach to sniff LAN in order to collect all traffic between DB administrators PC and the rest of the network. For this purpose forensic team has Wireshark [6] and Cain [8]. While Whireshark [6] offers options for passive sniffing Cain [8] offers hacker tools for active attack and break security features.

This time it was agreed to use Cain [8] because it is resourceful tool for ARP poisoning [10] and is used for other purposes such as research in WIFI security [11]. Cain [8] is a well-known password cracking tool that is capable of handling different type of tasks. This tool is only available for Windows platforms. It can work as network sniffer, to crack encrypted passwords using the dictionary attack, to record VoIP conversations, to execute brute force and cryptanalysis attacks, to reveal password boxes, to uncover cached passwords, to decode scrambled passwords, and analyze routing protocols.

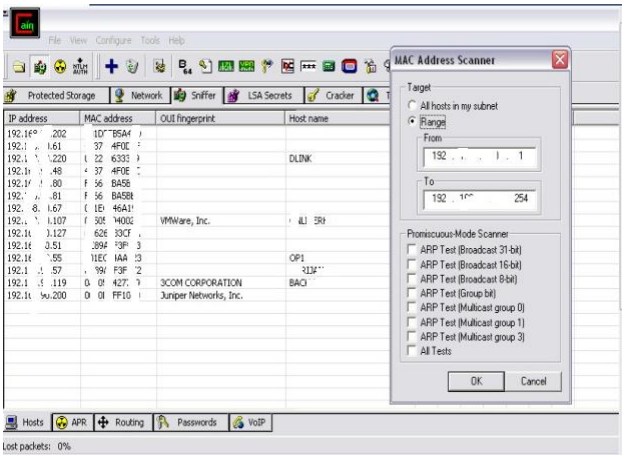

Figure 7. MAC address scanner

Cain [8] is not created to exploit any vulnerability or bug, it is created to use weakness of security I network protocols to gain passwords. After starting the program it is configured to scan MAC address of all hosts in the subnet, and then to resolve host names, just to be sure that forensic team has right information of LAN devices. Figure 7. shows active MAC address scanner in the Cain [8], same process was performed with Wireshark to confirm Cain [8] findings. Now when program collected MAC and IP addresses, host names, it was time to start with "Man in the middle attack".

III. PROCESS OF EXPLOITING PRIVILEGES

First step in process of exploiting privileges was reconnaissance and enumeration of IP and MAC address of DB administrator's PC. Second step was gaining user name and password credentials to be able to exploit privileges. One of easiest methods to gain information such as passwords is ARP poisoning [12].

A. APR poisoning

It is possible to change the Media Access Control (MAC) address of NIC card and attack an Ethernet LAN

by changing the target's computer ARP cache with a forged ARP reply packets [10]. The forensic team sends frames that are created so that they contain wrong MAC address.

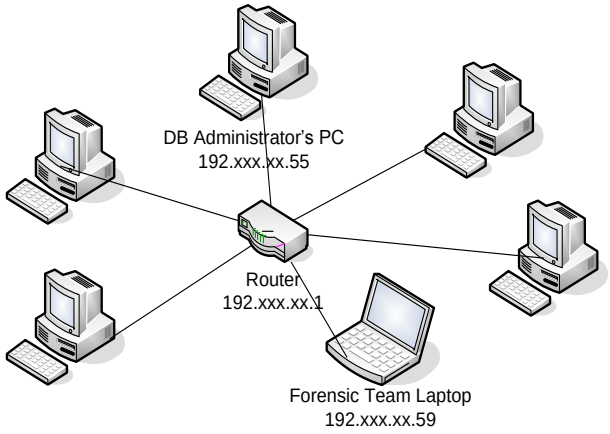

Figure 8. ARP poisoning

Because the ARP replies are forged, the target computer unintentionally sends the frames to the attacker computer instead of sending it to the genuine destination. An effective ARP poisoning attempt is undetectable to the user.

Next step was to start Cain [8], select IP address of the target devices and the gateway, and start ARP poisoning. After this step is finished system was left with running Cain [8] on the system in order to collect as more network traffic data as it is possible with goal to collect DB administrator's user name and password credentials.

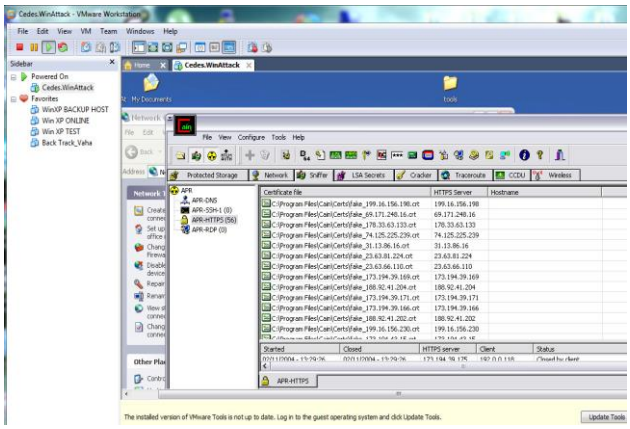

Figure 9. - Providing fake certificate by ARP poisoning [13]

B. Password collection retrieval

Four days after forensic team started with ARP poisoning using Cain [8], forensic team members came to examine what information were captured by Cain [8], it was found that program captured HTTP, POP3 and SMB encrypted passwords.

The great news for the team was that for the first two protocols, HTTP and POP3 passwords were captured in clear text format, password and username were the same for two different services.

For the SBM, sniffer captured one encrypted password used by Windows-based computers that allows systems within the same network to share files or access to other network resources. It allows computers connected to the same network or domain to access files from other local computers.

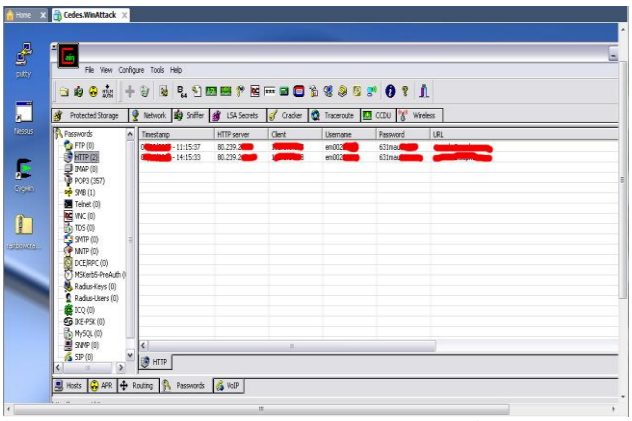

Figure 10. Captured password in clear text format

As it is shown in Figure 11. there is information available such as: timestamp, HTTP server IP address, client IP address, and the most important for the forensic analysis, username and password. The Cain [8] provides information about URL location with authentication type. Now focus of forensic team was to gain knowledge of SMB protocol and it's user-level authentication. It indicates that the client attempting to access a share on a server must provide a user name and password. When authenticated, the user can then access all shares on a server.

The only thing that's left is to try decrypt SMB hash. For this purpose Rainbow Crack [14] were used by [15, 16, 17, 18] with Rainbow table size of 64GB. This is a hacker tool that uses a large-scale time-memory trade off process for faster password cracking compared to traditional brute force tools. Time-memory trade off is a computational process in which all plain text and hash pairs are calculated by using a selected hash algorithm.

After computation, results were stored in the rainbow table. This process is very time consuming. Once the table is ready, it can crack passwords much faster than brute force tools. There is no need to generate rainbow tables every time, they can be used if someone else prepared them. Developers of Rainbow Crack have generated LM, NTLM, MD5, and SHA1 rainbow tables [19]. In the Figure 11. are shown three steps taken from article "Capturing and cracking SMB hashes with Cain [8] and Half-LM rainbow tables" [19] of loading the hashes into Cain [8], by selecting the Cracker tab step 1. then the plus symbol – step 2. to add hashes from a list – step 3.

Like Rainbow Crack [14], these tables are also freely available. It is possible to download these tables and use them for similar password cracking processes. The great thing about rainbow tables is that they can be imported in to Cain [8] in order to perform hash crack attack. This

approach was used by forensic team as an attempt to discover SMB password.

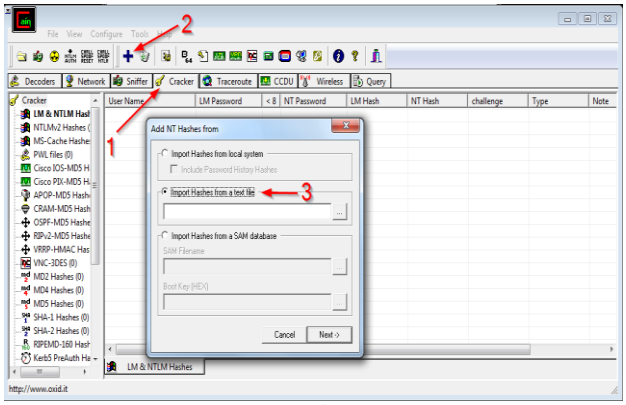

Figure 11. Adding HASH file to CAIN cracker [19]

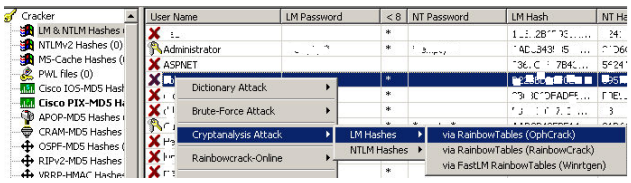
Assuming that DB administrator was using the same password for Windows shares as he used for other two protocols, quickest solution was to convert discovered password in to hash and putting that in to rainbow table – Figure 12. After this the crypt analysis attack was started and after couple minutes program finished with analysis and it was confirmed that password was the same for all discovered network services used by DB administrator.



12. Cryptanalysis attack with rainbow tables

IV. PROCESS OF REINFORCING DATA EVIDENCES FOR FORENSIC REPORT

In order to have enough time, forensic team members came first day of the weekend to create digital copy of entire hard drive. Following procedure, DB administrator's PC was unplugged from power supply and the battery was removed. After this, hard drive was removed, labelled and placed in to antistatic bag and then carried away to forensic team office where digital image was created using EnCase [20]. Luckily, all retrieved data from digital image that were protected by password had the same password that was discovered in previous days.

This forensic analysis task was finished by returning hard drive into original place and giving system password which was object of dispute to company manager in order to set a new one.

V. CONCLUSIONS

As is the case with all evidence, it is very important to maintain a chain of custody for computer evidences. Each person who handled evidence may be required to testify that the evidence presented in court is the same as when it was processed during the investigation. Although it may not be necessary to produce at trial every individual who handled the evidence, it is best to keep the number to a minimum and maintain documentation to demonstrate that digital evidence has not been altered since it was collected. Forensic investigators must do everything possible to preserve the integrity of the digital evidences. Any mistake in the forensic process can make forensic evidence into question and it can be worthless if forensic principles were not followed. The way the forensic team handled integrity issues are numerous and include the way of seizing, labelling, transporting, coping, analysing and ate the end presenting results at court trials or for organisation needs.

It was advised by forensic team to company owner because organisational and technical vulnerabilities were detected that information security standards shall be used to prevent future problems.

INVITED PAPER

Spatial OLAP for agri-environmental data and analysis: Lessons learned

Sandro Bimonte
Irstea, TSCF
9 Avenue B. Pascal, 67178, Aubiere, France
Sandro.bimonte@irstea.fr

Abstract - Spatial Data warehouses and Spatial OLAP (SOLAP) systems allow analyzing huge volumes of georeferenced datasets. SOLAP has been successfully applied in several domains such as marketing, health, urbanism, etc. Few of SOLAP applications in the agricultural context have been proposed. The analysis of work reveals specific issues related to spatio-multidimensional analysis of agri-environmental data. Therefore, in this paper, we present our theoretical and implementation framework for agricultural SOLAP applications.

I. INTRODUCTION

It has been estimated that about 80% of the data stored in corporate databases integrates geographic information [12]. Spatial Data Warehouses (SDWs) and Spatial OLAP (SOLAP) systems allow analyzing huge volumes of georeferenced datasets [1][11]. SOLAP has been successfully applied in several domains such as marketing, health [2], urbanism, etc. The success of SOLAP technologies is mainly based on the capabilities of such systems to analyze large datasets in an interactive way, and provide simple and user-friendly visual analytics interfaces [2]. By a deep study of most important related work about SOLAP analysis of agri-environmental data, and our several years' experience in such kind of projects (EnergeTIC [3], EDEN [4], DispEAU [5], Fresqueau [6], VGOLAP [7], STORI [8], Myriphique [9], and FieldSOLAP [10], VagueSOLAP [17]), we describe in this paper main questions related to multidimensional analysis of agri-environmental data, highlighting theoretical and implementation issues. To remedy to these problems, we have proposed a new framework for the integration of agri-environmental data in SOLAP systems. In particular, our framework supports *conceptual modeling for vector and field spatio-multidimensional data*, and *handling quality issues related to spatial data precision and logical coherence*. Secondly, we propose a generic SOLAP architecture to deal with some implementation issues (i.e. integration, warehousing, analysis and geovisualization). Finally, to take into account skills of agri-environmental decision-makers and the complexity of their applications, we have proposed a *rapid prototyping methodology* based on our conceptual model.

The paper is organized in the following way: Section 2 presents main concepts of spatial data and SOLAP; An overview of existing work on SOLAP for agri-environmental data is detailed in Section 3; Lessons learned are detailed in Sec 4; Our framework is presented in Section 5. Section 6 concludes the paper and presents open issues.

II. MAIN CONCEPTS

In this section we provide main concepts of spatial data (Sec 2.1) and Spatial OLAP (Sec 2.2).

A. Spatial data

Geographic information is typically represented according two models: vector and field [13]. The former represents geographic data using points, lines and polygons. Vector model is well suited for representing human-built geographic objects such as parcels, buildings, etc. Vector model allows spatial analysis by means of topological, metric and ordinal predicates. Field model represents the space as a continuous field. Fields have to be discretized to be represented into computers. These representations can be grouped into two categories: incomplete (e.g. grid points) and complete (e.g. raster). Fields are very adapted for modeling spatial phenomena such as pollution, temperature, etc. They allow a point by point analysis through the Map Algebra operators [13]. Geographic Information Systems (GISs) (such as Qgis, ArcGIS, etc.) allow storing, querying, analyzing and visualizing (vector and field) geographic information [14]. Usual end-users of those technologies are first and foremost decision-makers who are rarely fully aware of the issues related to spatial data quality [15]. The (spatial) data integration of multiple heterogeneous data sources such as remote sensing systems, sensor networks, etc., may easily lead to a number of data quality problems [15] such as imprecision, incompleteness, logical inconsistencies, etc. And yet, vector data are primarily "false but useful" models about the reality of interest since they define geographic phenomena by means of crisp boundaries even if it is not always possible to define exactly where objects begin and end (due to spatial vagueness) [16]. With such a choice of representation, a clear gap is created between majority of real world phenomena and their formal representation in spatial databases [17]. Decision-makers are then exposed to erroneous analysis due to the uncertainty issues on data sources.

B. Spatial OLAP

SDW and SOLAP systems integrate GIS and OLAP functionalities in a unique analysis framework [1]. Usually, warehoused vector data are stored according to the spatio-multidimensionnal model (i.e. data cube) [11].

Data is organized in (spatial) dimensions and facts. Spatial dimensions represent the analysis axes, and are organized into hierarchies with spatial levels (for example cities, departments and regions). A spatial level is a level with geometric data. Facts represent the analysis subjects and they are described by numerical attributes, called measures (for example quantity of sold products). Measures are explored with the SOLAP operators that allow navigating into the SDW [2]. Common operators are Spatial Slice that allows select a subset of warehoused data using topological predicates, and Spatial Drill that allows navigating into hierarchies aggregating measures values with SQL aggregation operators (i.e. MIN, MAX, …) [2]. For example, in a retail application a SOLAP query can be: "*What is the total quantity of sold products by year, product and city at 50km far from Paris?*". Spatial OLAP extends OLAP technologies integrating the spatial representation of the geographic information to enhance multidimensional analysis with spatial analysis and the OLAP visualization with cartographic representations, as shown on Figure 1 using the SOLAP tool presented in [18].

Figure 1. Retail SOLAP application visualization

A typical SOLAP architecture is composed of a Spatial DataBase Management System (DBMS) to store (spatial) data (for example Oracle, PostGIS, etc.); a SOLAP server, which implements the SOLAP operators (for example GeoMondrian, etc.); and a SOLAP client (e.g. Map4Decision), which combines and synchronizes tabular, graphical, and interactive maps to visualize and trigger SOLAP queries [18]. In particular, data collected by means of several heterogeneous data sources are integrated in the SDW tier by means of Spatial Extraction, Transformation, and Loading tools (Spatial ETL) (such as Spatial Data Integrator), which provide a set of operators to work with spatial data (e.g., rename, spatial union, etc.). This kind of SOLAP architecture is called "OLAP-GIS integrated". Indeed, three kinds of SOLAP architecture have been defined [2]. "GIS dominant" SOLAP tools do not present the SOLAP server, and they define SOLAP queries using classical spatial SQL queries. Therefore, they don't take advantage from hierarchical navigation and advanced calculation features of SOLAP servers. "OLAP dominant" tools do not provide advanced GIS functionalities. They allow only simple cartographic visualization, limiting spatial analysis capabilities. Finally, it has been recognized that "OLAP-GIS" solutions are best suited for an effective SOLAP analysis [2]. Finally, SOLAP applications are based on complex multidimensional models and systems, which require particular effective design methodologies [11]. Indeed, it has been recognized that (S)OLAP projects fail usually for two reasons: data quality and correctness of the multidimensional implemented model [26]. Indeed, several DW design methodology taking into account available data sources (i.e. data-driven), users decisional needs (i.e. users driven), and both (hybrid) have been proposed [26].

III. Related Work

In this section, we detail most relevant existing work on SOLAP for the analysis of agricultural and environmental data.

In the agricultural context, the authors of [19] analyze cotton productions. They define 13 data cubes about analysis of crops according to different aspects, such as soil resources, socio-economics resources, etc., using a hybrid design methodology. Quality problems related to dimensional modeling are deeply studied. In particular authors point out the problem of multi-granular data, which consists in data sources that are not all available at the same dimensions levels. They overcome this problem by disaggregating data, when possible, using interpolation functions. The data cubes are implemented in a "OLAP dominant" solution. [20] provides a SOLAP system for the analysis of animal and crop resources. Authors conceive their multidimensional model by taking into account available data and decision-makers' needs, and validate it using a usability test (e.g. "Does the data warehouse provide sufficient information for decision-making?"). Therefore, they adopt a hybrid methodology. The authors define several data cubes providing a constellation schema based on classical dimensions (such as the product dimension) and complex dimensions such as the spatial and the temporal dimensions, which rise multi-granular problems as previously described. The multidimensional model is implemented in a "OLAP-GIS integrated" architecture. [21] studies precision dairy farming (for example the analysis of quantities of produced milk per year and farm). They define two data cubes: one for the milk analysis and another for the treatments of the animals, pointing out the versioning problem (for example cows can change groups during time). To provide decision-makers with "usable" indicators they associate some metadata (such as description, unit, etc.) to measures. Their work is based on an hybrid methodology where decision-makers exchange with DW experts using a multidimensional conceptual model (mE/RM), which is an extension of the Entity Relationship (ER) model. The implementation is based on relational data model and some examples of decisional SQL queries are described. The analysis of forestry data is briefly described in [22], where authors propose a complex multidimensional model with classical temporal and spatial dimensions to measure the area of forest. The main issue described in this work is (yet) the versioning problem related to the dependence of the spatial dimension according time.

In the environmental domain, [23] provides air and water pollution monitoring. The authors define a spatio-multidimensional model with a spatial dimension and some measures representing pollutants values. An example of SOLAP query is "What are pollutant values per year and zone?". On the top of the spatio-multidimensional model, a risk model is used to create

alerts when pollutants exceed tolerable values. [24] proposes a spatio-multidimensional model for the analysis of coastal risk erosion. They provide a complex model with several spatial, temporal and thematic dimensions, and measures. Their model allows answering queries like: "What is the total number of houses at risk, per year and municipality?". Authors define complex dimensions composed for example with alternative hierarchies and raster data (i.e. field model). Aggregation of risk measures is based on a complex risk model. A classical logical model based on the star-schema model is described. [25] also studies water quality. For that goal, authors propose a spatio-multidimensional model with seven dimensions and several measures, conceived using an ad-hoc new hybrid design methodology centered on the decision-makers. For the spatial data integration, they propose using GIS routines, and they implement the model using a ROLAP architecture coupled with a web-based GIS.

We have also conducted some projects in the agricultural and environmental domains, addressing some particular research issues. For example, in the EnergeTIC [3] and EDEN [4] projects, we investigate using SOLAP to analyze energy consummation data of agricultural farms, which comes from sensors installed on farms' agri-equipment (for example a tractor). Sensors data presents several quality problems (for example missing and incoherent data). Quality issues related to vague data (Sec. 2.1), geometries with not well defined boundaries, have been studied in a project aiming at the analysis of usage of sewage sludge produced by wastewater treatment plant used as crop fertilizer in agriculture [17]. Finally, in the FieldSOLAP project [10], we analyze urban odor propagation. Since odor is a continuous phenomenon, we represent it using grid points (i.e. field model) (Sec. 2.1).

IV. LESSONS LEARNED

In this section we discuss multidimensional modeling and architectural issues of previous described work. In particular we address issues related to dimensions (i.e. *What kind of dimensions are defined?)* to facts (i.e. *How many facts are defined?*), analysis (i.e. *What aggregation functions and derived measures are defined?*) and design (i.e. *How the spatio-multidimensional is designed?*). From an analysis of related work emerges that in the most of them dimensions are spatial and temporal ones, since agricultural and environmental data are strongly related to space and time. Dimensions and SOLAP operators are usually complex since agricultural and environmental domains need complex indicators having impacts of aggregation methods and hierarchies design. Moreover, to define a multidimensional model that answers to decision-makers needs, a hybrid design methodology is needed. We also study issues about implementation and data sources. Quality is an important issue since data source is usually "bad" quality data needing ad-hoc methodologies. About implementation, the need for a ROLAP architecture coupled with GIS also emerges, as well as adopting ad-hoc tools for the integration and loading data in the SDW. To resume, warehousing and OLAPing agri-environmental data is a complex task implying a set of design and implementation features that are at an embryonic stage yet, and consequently they are the focus of research work. In detail, warehousing and OLAPing agri-environmental data need:

- Using advanced spatio-temporal multidimensional conceptual models to allow decision-makers and DW experts to discuss and design complex dimensions, facts, and aggregation methods [11][24][27];
- Supporting vector and field data [24][10][28][29];
- Adopting a hybrid methodology to define successful multidimensional model taking into account decision-makers functional requirements and complex data sources [26] [30];
- Handling quality issues (spatial precision, logical coherence, etc.) [4] [9] [11] [15]
- Implementation in commercial OLAP-GIS systems. Integration of OLAP and GIS systems is necessary for an effective spatio-temporal analysis. However, this integration requires important implementation efforts (time, money and human resources), implying that an ad-hoc solution is not always feasible. However, actually SOLAP systems have finally reached a good maturity in terms of stability and functionalities. They move in recent years from prototypes to commercial-industrial systems [31].
- Using extendible Spatial DBMS and/or Spatial OLAP server for the integration of complex calculation methods in OLAP analysis. Indeed, some work propose to extend OLAP aggregation functions in the DBMS tier using native SQL methods [32] or in the (S)OLAP server tier using MDX user-defined functions [10], or in the SOLAP client with new advanced visual analytics features. In this way, agri-environmental decision-makers can represent their analysis indicators as aggregated measures, and transparently analyze their data by the simple exploration of warehoused spatial data.

V. SOLAP FRAMEWORK

In this section we present our framework for integration of agri-environmental data into SOLAP systems, developed in the COPAIN team of Irstea. The EDEN project aims at the multidimensional analysis of energy-use [4]. Energy data is acquired using mobile sensors, installed on the different farms' equipment (i.e. tractors), to retrieve fuel consumption. The implemented SOLAP application allows decision-makers to manage their farm activities.

A. Advanced spatio-temporal multidimensional conceptual model: ICSOLAP UML Profile

In order to support advanced conceptual modeling as described in Sec. 4 we use in our framework the ICSOLAP UML Profile presented in [27] [33]. Our UML profile allows modeling advanced multidimensional issues [27]: complex dimensions (non-covering, non-onto and multiple hierarchies) [11], spatial dimensions [11], multi-granular facts [11], complex aggregations, etc. ICSOLAP

allows representing spatial dimensions modeled using the vector [27] and field models [33].

The UML profile defines a stereotype for each multidimensional element. For example a fact is represented with a stereotyped <<Fact>> class, whose attributes are measures (<<NumericalMeasure>>). A spatial vector level is represented using the stereotype <<SpatialAggLevel>> class that designs spatial dimension levels whose geometries are represented with geometric attributes (point, line, polygon, etc.) (stereotyped <<LevelGeometry>>). An example is shown on figure 2 where (a simplified model) the SOLAP application of the EDEN project is represented. Here the spatial level "Plot" represents the plots of the agricultural farm.

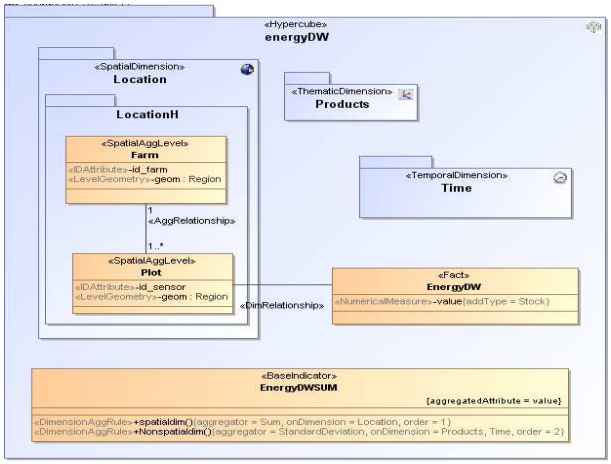

Figure 2. ICSOLAP: vector model

In order to represent field data we define <<FieldAggLevel>> as an extension of <<SpatialAggLevel>>. <<FieldAggLevel>> presents a interpolation function as a tagged value "Continuity Interpolation". It allows estimating the measure values in any point of the space. Figure 3 shows an example of a regular grid points where the *bicubic interpolation* method is used to represent the temperature phenomenon.

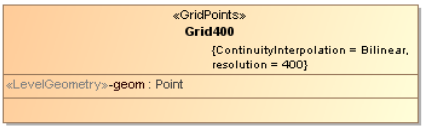

Figure 3. ICSOLAP: field model

Although, some very expressive spatio-multidimensional conceptual models based on extensions of ER have been proposed yet such as [11], we prefer to adopt the UML formalism for several reasons. Indeed, using UML eases the exchange between decision-makers and DW experts since UML model is easy to read and interpret. Moreover, UML has been adopted by the software designers' industrial community and a growing number of the UML-based tools allows for easier and quicker developments of software applications (by automating certain tasks) have been developed. Computer-aided software engineering (CASE) is the scientific application of a set of tools and methods to a software system which is meant to result in high-quality, defect-free, and maintainable software products. These tools allow automatic translation of UML models into errors free code and implementation routines (SQL, Java, etc.). In our framework, we have implemented our profile in the commercial CASE tool MagicDraw.

B. Quality: Logical coherence and spatial precision

As described in Sec 3 addressing spatial data quality issues is crucial for SOLAP projects. In this context, Integrity Constraints (ICs) play a key role in improving consistency, accuracy and completeness of the stored data [34]. ICs are assertions that can be defined in conceptual models to identify incorrect data and prevent their insertions in the database. For example, in the vector context, these constraints could be used to define the expected topological relationships between spatial objects. In order to handle with logical coherence issues in SOLAP, in [4] we propose a framework, using the ICSOLAP profile, to express IC using Spatial OCL. Spatial OCL is an extension of OCL with topological predicates [16]. The Object Constraint Language (OCL) is a declarative language for describing rules that apply to UML models. ICs are expressed at a conceptual level, and then automatically implemented in the "OLAP-GIS" architecture. An example of IC representing that the geometry of a plot must be contained in the geometry of the farm using Spatial OCL is the following:

```
context Plot inv DataIC1:
self.geo.isInside (self.Farm.geom)
```

Another important quality issue of spatial data is the geometric precision: geometries do not have exact boundaries (i.e. spatial vague data). Supporting vague data in DBMS is an open research question [37]. Since, existing SOLAP systems do not provide any tools for handling spatial vague data, in [17] we propose a new design methodology where analysis problems related spatial precision issues are replaced by risk usage policies. In particular, to each vague member we associate a risk usage in the multidimensional analysis (level risk, aggregation risk, etc.). Consequently, these risks are handled by some actions on the spatio-multidimensional model that aim at eliminating (such as delete spatial level action) or communicate the risks (for example visualize risk aggregated value). As for ICs, [17] allows to define the elements of our methodology at a conceptual level using the ICSOLAP profile. After that, the new spatio-multidimensional model is automatically implemented. An example is shown on figure 4 where the analysis problems related to plots vague geometries is handled by a visualization policy.

C. Hybrid methodology: ProtOLAP

As highlighted in the previous sections, designing SOLAP models is quite difficult because spatial data and analysis are complex. Secondly, it needs hybrid approach since data and decision-makers knowledge should be taken into account for an effective SOLAP analysis. Thirdly, agri-environmental decision-makers usually are (S)OLAP and Information Technology unskilled users. In this context in order to define a design DW methodology tackling above described issues, in [35] we propose a new methodology and a tool called ProtOLAP (Figure 5).

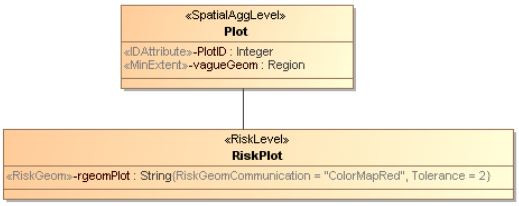

Figure 4. ICSOLAP quality: vague data

ProtOLAP supports the easy and rapid design of spatio-multidimensional models. In details, decision-makers and DW experts define their conceptual model using ICSOLAP UML Profile. After that, the schema of the SDW and the SOLAP Server tiers are automatically generated. The data warehoused is consequently fed with sample data, allowing decision-makers to play with warehoused data in an SOLAP client to validate the spatio-multidimensional model. ProtOLAP is well adapted to agri-environmental applications since: (i) automatic prototyping allows for a free-error implementation of complex spatio-multidimensional models; (ii) visualization of the resulting analysis easies unskilled decision-makers to translate (and validate) their tacit analysis needs on a spatio-multidimensional model. The integration of vector and field data as well as the support for logical coherence and spatial precision quality issues have also been integrated in ProtOLAP since these features are based on the conceptual design in ICSOLAP UML profile with its automatic implementation. Consequently, ProtOLAP can also remediate to projects failure due to spatial data quality problems. We have successfully tested ProtOLAP in the context of the EDEN project.

D. Implementation

In this section, we detail implementation issues. The architecture used in our framework is described in Figure 5. As described in section 3, agri-environmental analysis needs more complex aggregation than classical SQL ones. In a "OLAP-GIS integrated" architecture two possibilities to solve this issue can be implemented. The first one is to implement complex aggregation inside the Spatial DBMS. Indeed, when the Spatial DBMS allows for extension mechanisms, it is possible to add new functionalities directly accessible as native SQL functionalities. In our framework, we use PostGIS. PostGIS is a Spatial DBMS extending Postgresql to natively support spatial data storage and querying. PostGIS allows to defined SQL user-defined functions written in SQL, C, PL/SQL, etc., which are then usable as native SQL functions. Therefore, we implement decision-makers agri-environmental methods, such as percentile, using user-defined aggregation functions (Boulil et al., 2014). After that, these aggregation functions can transparently be used by any SOLAP server and client. The main advantage of this approach concerns performance since the Spatial DBMS natively provide optimization calculation techniques, but when analysis methods require complex navigation and calculation methods, their implementation becomes difficult. Indeed, as for the "GIS dominant" architecture, the functionalities of the SOLAP server cannot be used. The SOLAP server can be also used for the definition of such complex method. Indeed, some SOLAP servers such as GeoMondrian, which we use in our framework, allow defining user-defined functions that can be transparently used in MDX queries. GeoMondrian is a open source java-based OLAP Server that extends Mondrian with spatial operators. Indeed, GeoMondrian allows defining using Java ad-hoc user defined aggregation functions [10]. Contrary to the Spatial DBMS-based approach, this approach allows using SOLAP server functionalities for the calculation, but it presents a main limitation: calculation are performed in the main memory, which can represent an important drawback when the number of facts to aggregate is huge since response answer time becomes intolerable for on-line analysis.

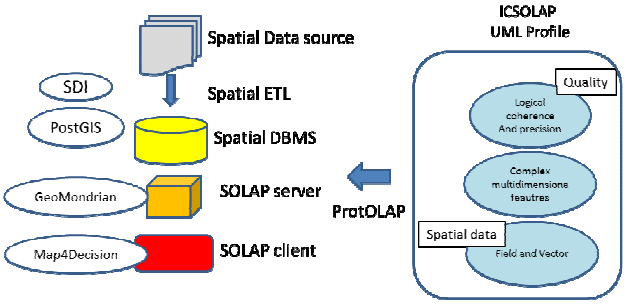

Figure 5. Architecture

As described in [31] few commercial OLAP-GIS integrated tools are available. In our framework we use the SOLAP client provided by Map4Decision (Map4Decision, 2014). According to the visual analytics mantra [38], Map4Decision integrates intelligent cartography concepts that support the automatic creation of maps while conforming to the rules of visual communication and semiology (colors, symbols, patterns, etc.). The user can easily navigate from one type of map to another (simple maps, multimaps, multivariate maps, temporal maps, etc.), explore geographic data at various levels of detail (e.g. from countries to provinces, to cities, or vice-versa), while keeping a coherent semiology. Map4Decision client configuration is very easy and it is provided by a simple "point and click" user interface. Map4Decision supports XMLA, which is the de-facto standard web-service for OLAP tools. Therefore, in our framework we connect Map4Decision on the top of GeoMondrian to provide advanced cartographic visual reports using XMLA.

VI. CONCLUSIONS AND FUTURE WORK

Spatial OLAP systems are effective GeoBusiness Intelligence technologies. Their application in agri-environmental context is few studied and is quite recent. In this paper we highlight main problems related to spatio-multidimensional analysis of agri-environmental data. We provide an overview of our new framework for this kind of SOLAP projects. (Un)lucky several issues rest unexplored. These issues represent our current work. Although, conceptual modeling is quite advanced, physical and logical modeling for SDW are not studied enough [36]. Indexes, materialized views have to be defined to take into account all particular aspects of geographic information (e.g. continuity, spatial predicates,

etc.). Finally in [18] the first generic model of geovisualization in SOLAP systems has been provided. But, an exhaustive study of well-suited geovisualization methods, and/or their adaption, should be provided to fully exploit visual analytical capabilities of SOLAP clients.

***Abstract*—The problem of time series subsequence matching occurs in a wide spectrum of subject areas. Currently Dynamic Time Warping (DTW) is the best similarity measure but despite various existing speedup techniques it is still computationally expensive. Due to this reason science community is trying to accelerate DTW calculation by means of parallel hardware. There are implementations of DTW-based subsequence matching on GPU and FPGA but there none for accelerators based on the Intel Many Integrated Core architecture. This paper presents a parallel algorithm for time series subsequence matching based on DTW distance adapted to the Intel Xeon Phi coprocessor. The experimental results on synthetic and real data sets are presented and confirm the efficiency of the algorithm.**

***Index Terms*—data mining, time series, subsequence matching, dynamic time warping, parallel computing, OpenMP, Intel Many Integrated Core architecture, Intel Xeon Phi coprocessor**

I. Introduction

A time series represents a collection of data points, measured chronologically. Currently, time series data mining touches upon a wide spectrum of scientific and applied tasks in various subject areas, e.g. medical monitoring [1], economic forecasting [2], climate modeling [3], etc. Being one of the most important problems of time series data mining, subsequence matching assumes that a query sequence and a longer time series are given, and the task is to find subsequences in the longer time series, which match the query sequence.

To measure the similarity between two time series, a number of Euclidean-based distance measures have been suggested but currently the Dynamic Time Warping (DTW) [4] is the most popular similarity measure in many applications [5]. DTW is computationally expensive and there are many approaches that have been proposed to solve this problem, e.g. pruning the subsequences using lower bound of distance [5], computation reusing [6], data indexing [7], early abandoning [8], etc. However, DTW still takes a large part of the total application runtime. That is why there are researches devoted to accelerating subsequence matching by means of parallel hardware, e.g. computer-cluster [9], multicore [10], FPGA and GPU [6].

This work was financially supported by the Ministry of education and science of Russia ("Research and development on priority directions of scientific-technological complex of Russia for 2014-2020" Federal Program, contract No. 14.574.21.0035).

In this regard, in our opinion not enough attention is paid to the Intel Xeon Phi coprocessor based on Intel Many Integrated Core (MIC) [11] architecture. This paper presents a parallel algorithm for time series subsequence matching based on DTW distance adapted for use on a central processor unit (CPU) accompanied with the Intel Xeon Phi coprocessor.

The rest of the paper is organized as follows. Section II gives the formal definition of the problem and briefly considers the Intel Xeon Phi architecture and programming model. In section III a description of the proposed algorithm is given. The results of the experiments evaluating the algorithm are presented in section IV. Section V discusses related work. Section VI contains concluding remarks and directions for future research.

II. Research Background

A. Problem Definition

A *time series* T is an ordered sequence $t_1, t_2, ..., t_N$ of real data points, measured chronologically, where N is a length of the sequence.

A *subsequence* $T_{i,k}$ of time series T is its continuous subset of length k starting at i position.

A *query* Q is a certain subsequence to be found in T.

Subsequence matching problem aims to finding all the subsequences $T_{i,j}$ such that distance $D(T_{i,j}, Q)$ is minimal.

Dynamic Time Warping (DTW) is a similarity measure between two time series which may vary in time or speed. DTW distance between two time series X and Y, where $X = x_1, x_2, ..., x_N$ and $Y = y_1, y_2, ..., y_N$, is denoted as $D(X, Y)$ and defined as follows.

$$D(X,Y) = d(N,N),$$

$$d(i,j) = |x_i - y_j| + min \begin{cases} d(i-1,j) \\ d(i,j-1) \\ d(i-1,j-1), \end{cases}$$

$$d(0,0) = 0; d(i,0) = d(0,j) = \infty;$$
$$i = 1, 2, \ldots, N; j = 1, 2, \ldots, N.$$

B. The Intel Xeon Phi Architecture and Programming Model

The Intel Xeon Phi coprocessor is an x86 many-core coprocessor of 61 cores, connected by a high-performance on-die bidirectional interconnect where each core supports 4×

hyperthreading and contains 512-bit wide vector processor unit (VPU). Each core has two levels of cache memory: a 32 Kb L1 data cache, a 32 Kb L1 instruction cache, and a core-private 512 Kb unified L2 cache. The Intel Xeon Phi coprocessor is to be connected to a host computer via a PCI Express system interface. Being based on Intel x86 architecture, the Intel Xeon Phi coprocessor supports the same programming tools and models as a regular Intel Xeon processor.

There are three programming modes to deal with the Intel Xeon Phi coprocessor: native, offload and symmetric. In native mode the application runs independently, on the coprocessor only. In offload mode the application is running on the host and offloads computationally intensive part of work to the coprocessor. The symmetric mode allows the coprocessor to communicate with other devices by means of Message Passing Interface (MPI).

III. Subsequence Matching on the Intel Xeon Phi Coprocessor

A. Research Roadmap

Development of the parallel algorithm of time series subsequence matching adapted for the Intel Xeon Phi coprocessor consists of the following steps, which will be discussed in detail further.

Firstly, we had developed a parallel version of the UCR-DTW serial algorithm [8]. Using OpenMP technology, we have obtained a parallel algorithm for CPU, keeping in mind a possibility of running this algorithm on the Intel Xeon Phi coprocessor in *native* mode. However, experiments have shown that, despite the one-order speedup of parallel algorithm, it works *slower* on the Intel Xeon Phi coprocessor in native mode than on CPU. This results from low operational intensity of our algorithm, i.e. insufficient FLOPs (floating point operations) per byte of data to be effectively processed on the Intel Xeon Phi coprocessor.

Next, we modified our algorithm combining CPU and coprocessor to process time series. In this version of the algorithm both CPU and the Intel Xeon Phi run the parallel version of the UCR-DTW algorithm developed at the first step. Here we used *offload* mode to transmit code and data to the Intel Xeon Phi. Experiments, where we varied the portion size of data to be transmitted to the coprocessor, show results similar to those obtained at the first step due to the same reason.

Finally, we developed an advanced version of the algorithm. The key point of this version is to support a queue of subsequences on CPU that are offloaded to the coprocessor to compute DTW. This significantly increased the operational intensity of the calculations on the coprocessor and experiments show acceptable performance of the algorithm.

B. Parallel Algorithm for CPU

The UCR-DTW algorithm proposed in [8] is one of the fastest existing subsequence matching algorithms. This algorithm (see Fig. 1; hereinafter, we use UML activity diagrams) uses a cascade estimation of the lower bound of DTW distance. If the lower bound has exceeded some threshold, the DTW distance also exceeds the threshold, so the subsequence can be pruned off.

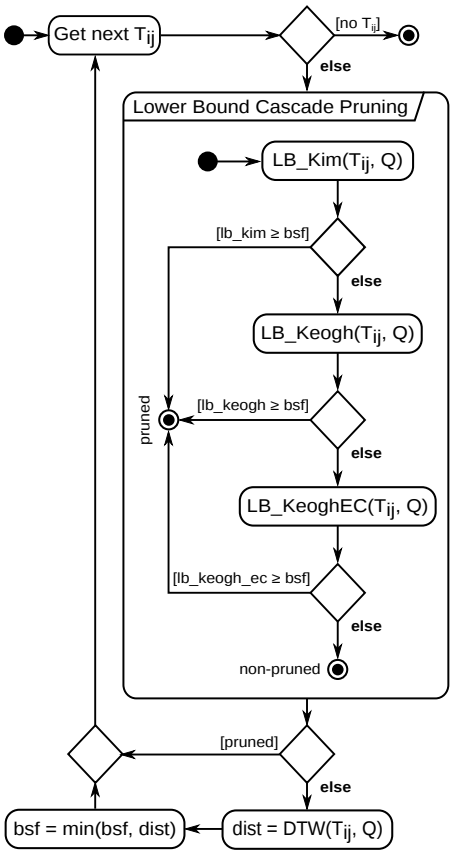

Fig. 1. Serial algorithm

A parallel version of the UCR-DTW algorithm is depicted in Fig. 2. We parallelize the original algorithm using the OpenMP technology. The time series is splitted into equal portions and each portion is processed by a separate OpenMP-thread. Here `UCR-DTW` is a subroutine that implements the original serial algorithm. It uses the `bsf` (best-so-far) shared variable that stores the distance to the nearest subsequence. This allows each thread to prune off unpromising subsequence using lower bounding. Master thread reads new data from a file simultaneously with processing of data that have been read.

We evaluated the obtained algorithm on synthetic time series both on CPU and on the Intel Xeon Phi coprocessor in native mode (see Fig. 6). Although parallel algorithm expectedly surpasses the original algorithm it works slower on the coprocessor in native mode.

This was a result of low operational intensity of our algorithm, i.e. insufficient FLOPs per byte of data to be effectively processed on the Intel Xeon Phi coprocessor.

C. Naïve Parallel Algorithm for CPU and the Intel Xeon Phi

Fig. 3 depicts the modified version of the algorithm. This version is called "naïve", because in comparison with the previous version it only distributes work among CPU and

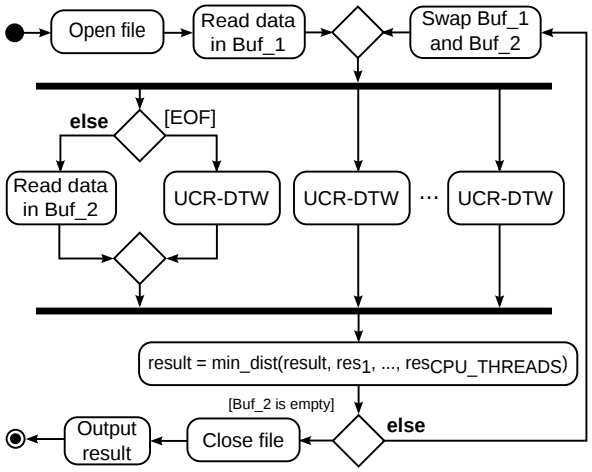

Fig. 2. Parallel algorithm for CPU

coprocessor. Here `ALPHA` is a parameter that determines a portion of data to be transmitted to the coprocessor. We use offload mode to organize data exchange between CPU and the coprocessor. The `min_dist` subroutine chooses subsequences with minimal value of DTW.

As well as in the previous step we evaluated the obtained algorithm on synthetic time series (see Fig. 6). Regardless of the `ALPHA` value this algorithm has worse performance in comparison with the parallel algorithm for CPU.

This is because we still have not increased operational intensity of calculations on the coprocessor. Additionally, `bsf` shared variable can not be synchronized between the CPU and the coprocessor while offloading is performed (the synchronization is possible at the beginning and at the end of offload section). That is why we have more non-pruned subsequences to calculate DTW.

D. Advanced Parallel Algorithm for CPU and the Intel Xeon Phi

The advanced version of the algorithm obtained at the previous step is depicted in Fig. 4.

The idea of the advanced algorithm is to support a queue of subsequences on CPU. Subsequences of the queue are candidates to be offloaded to the coprocessor to calculate DTW. One of the CPU threads is declared as a master and the rest as workers. When the queue is full master offloads it to the coprocessor.

Worker's activity looks like the following. A worker calculates cascade estimates for the subsequence. If it is dissimilar to the query then the worker prunes it off otherwise worker pushes this subsequence to the queue. If the queue is full (and data previously transmitted to the coprocessor have not been processed yet), the worker calculates DTW by itself.

The `UCR-DTW*` (see Fig. 5) subroutine implements worker's behavior as described above.

At the end of offload section the information about most similar subsequences found on the coprocessor is transmitted

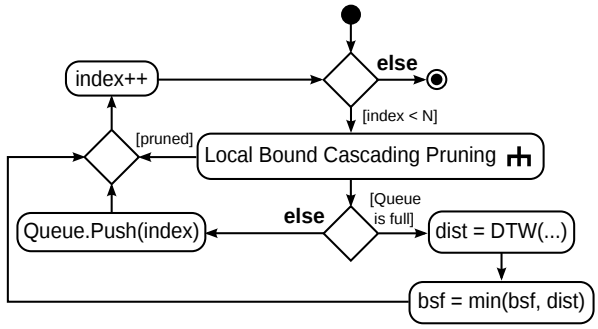

Fig. 5. UCR-DTW* subroutine

to the CPU. The final result is calculated among the most similar subsequences found on the CPU and on the coprocessor.

Additionally, we slightly modified the original source code of DTW calculation to provide vectorization of operations inside the `for` loop.

IV. Experimental Evaluation

To evaluate the algorithm developed we performed experiments on a Tornado SUSU [12] supercomputer's node (see Tab. I for its specifications). In these experiments subsequence matching runtime was measured while varying query length. Experiments have been performed on synthetic and real time series. We also investigated usage time of the coprocessor, impact of queue size on the speedup, and compared our algorithm with analogues for GPU and FPGA.

TABLE I
Specifications of Tornado SUSU supercomputer node

Specifications	Processor	Coprocessor
Model	Xeon X5680	Xeon Phi SE10X
Cores	6	61
Frequency, GHz	3.33	1.1
Threads per core	2	4
Peak performance, TFLOPS	0.371	1.076

A. Performance on Synthetic and Real Data Sets

In the first set of experiments we used synthetic time series generated by one-dimensional random walk comprising of 100 million data points.

Fig. 6 depicts the experimental results on synthetic data sets. The results show that our algorithm is more effective for longer queries. In case of shorter queries the algorithm has the same performance as parallel algorithm for CPU only.

The second set of experiments investigates the algorithm's performance on real electrocardiographic (ECG) data with about 20 million data points (approximately 22 hours of ECG sampled at 250 Hz).

Results of experiments on real data are shown in Fig. 7. Our algorithm shows a three times higher performance than the parallel algorithm for CPU only.

We evaluate what was the contribution of the coprocessor in computations as well. Fig. 8 depicts that increasing the query

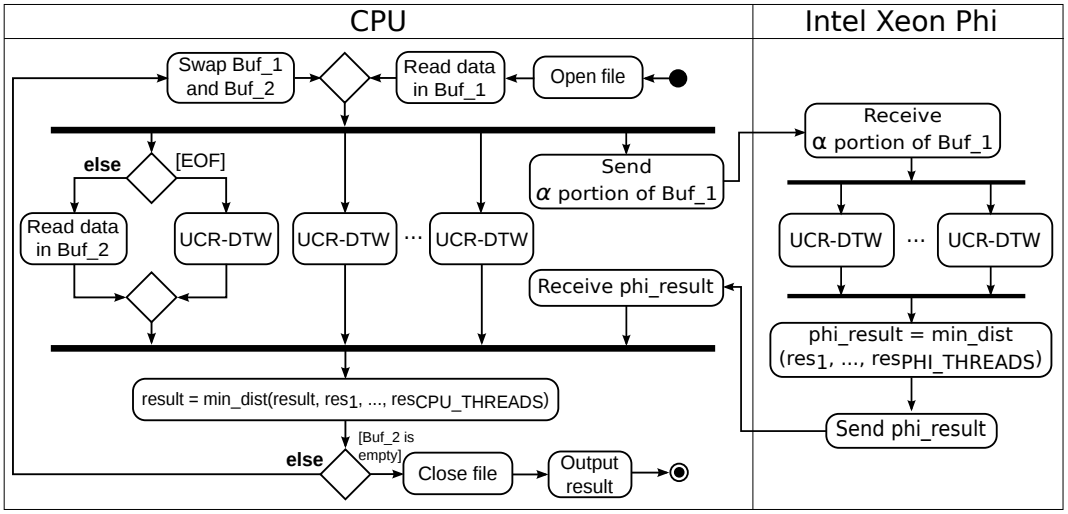

Fig. 3. Naïve parallel algorithm for CPU and the Intel Xeon Phi

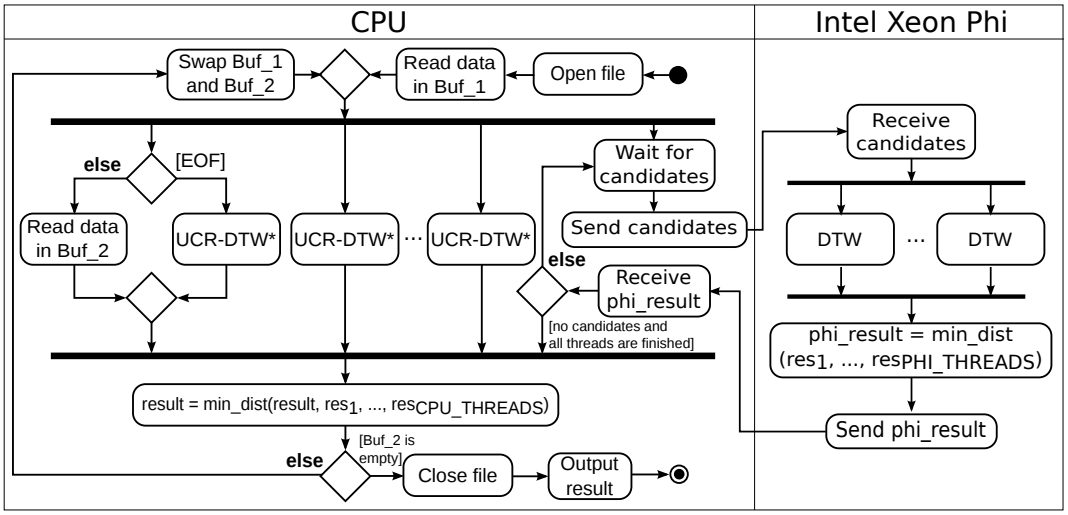

Fig. 4. Advanced parallel algorithm for CPU and the Intel Xeon Phi

length greater than 4000 leads to almost 100% usage of the Intel Xeon Phi coprocessor for both synthetic and real data sets.

B. Impact of Queue Size

The results described in subsection above have been achieved when queue size was 2400. We empirically select this value having performed some experiments beforehand (see Fig. 9).

C. Comparison with Algorithms for GPU and FPGA

We compared the performance of our algorithm with analogues for GPU and FPGA developed in [6]. We repeated the experiments presented in that paper keeping the same length of the time series and query length. The results of the experiments are depicted in Fig. 10.

We took into account that the peak performance of the hardware we used is significantly greater than its counterparts of that paper, i.e. overall peak performance of our hardware was 1.44 TFLOPS whereas GPU as NVIDIA Tesla C1060 had 77.8 GFLOPS and FPGA as Xilinx Virtex-5 LX-330 had 65 GFLOPS.

To provide a "fair" experiment we added to the chart *hypothetical* results for NVIDIA Tesla K40 (1.43 TFLOPS) [13] and Xilinx Virtex-7 980XT (0.99 TFLOPS) [14] multiplying real results of NVIDIA Tesla C1060 and Xilinx Virtex-5 LX-330 by a respective scaling factor. As we can see our algorithm provides significantly higher performance.

Finally, we compared relative costs of performance (see Fig. 11). The charts show that Intel-based solution is a bit more expensive than the latest one from NVIDIA but at the same time provides significantly higher performance.

V. Related Work

A substantial amount of work has been done in the area of time series data mining, including subsequence matching

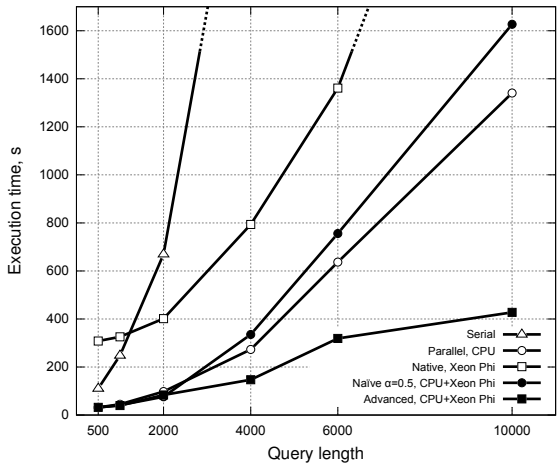

Fig. 6. Algorithm's performance on synthetic data set

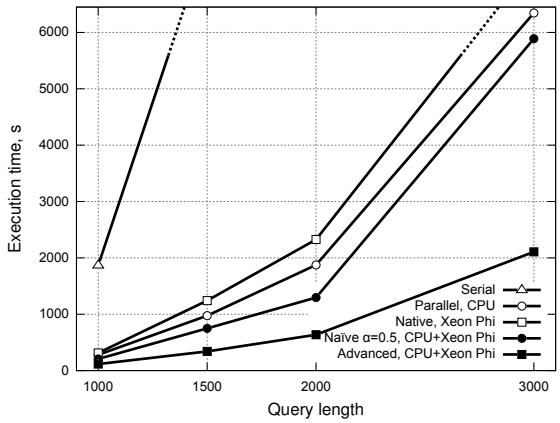

Fig. 7. Algorithm's performance on real data set

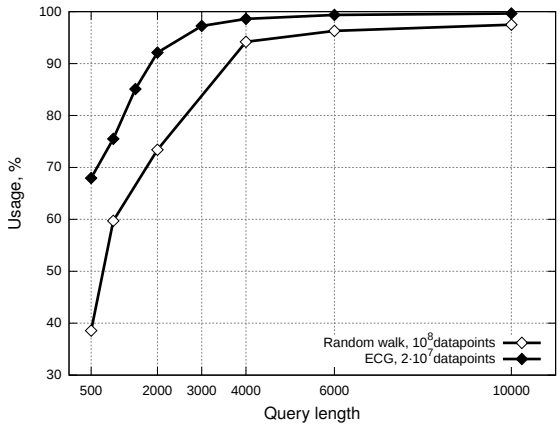

Fig. 8. Usage of coprocessor in experiments

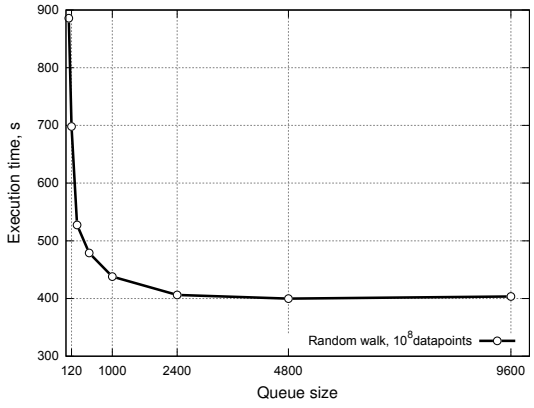

Fig. 9. Impact of queue size on the speedup

problem [15].

One of the earliest researches [16] considers the time series as a set of multi-dimensional rectangles and constructs its spatial index to perform search of subsequences as spatial queries to the index. This work serves as a basis for many researches devoted to improving subsequence matching performance. For instance, the DualMatch algorithm [17] and its improved version, the GeneralMatch algorithm [18], split the time series into non-overlapping windows and query pattern into sliding windows. In [19] and [7] an index interpolation to overcome the storage and CPU time overhead is used. All the former techniques are based on lower bounding of the

Euclidean distance.

Nowadays the Dynamic Time Warping (DTW) [4] measure is recognized as the best similarity measure for many time series subject domains [5]. DTW-based subsequence searching techniques include a suffix tree [20], a segment-based approach based on piecewise time warping [21], an index-based approach based on prefix querying [22] and a comparison optimization approach [23]. An algorithm proposed in [8] integrates all the possible existing speedup techniques and most likely it is the fastest of the existing subsequence matching algorithms.

All the aforementioned algorithms basically focus on reducing the calling times of DTW calculation, not accelerating DTW itself. However, because of its complexity, DTW still takes a large part of the total application runtime. Due to this reason science community tries to exploit the effectiveness of parallel hardware to accelerate subsequence matching. Existing researches assume allocation of DTW calculation of different subsequences into different processing elements, e.g. computer-cluster [9], multicore [10], FPGA and GPU [6].

Despite the existing research devoted to use of the Intel Xeon Phi coprocessor in data mining [24] in our opinion not enough attention is paid to applying this coprocessor for time series subsequence matching. In this work we adapt the algorithm [8] to the Intel Xeon Phi coprocessor (what was done for the first time, to the best of our knowledge).

VI. Conclusion

In this paper we have described the parallel algorithm for time series subsequence matching adapted for CPU accompanied with the Intel Xeon Phi coprocessor. The algorithm uses data parallelism and OpenMP technology. To establish interaction between CPU and the coprocessor the *offload* execution mode is used, when the program is run by the CPU while some code and data are transmitted to the coprocessor. To provide high operational intensity of the calculations on the coprocessor the algorithm supports a queue of subsequences on CPU, where subsequences are candidates to be offloaded to the coprocessor to calculate DTW. Experiments on synthetic and real data sets have shown that our algorithm outperforms analogous algorithms for GPU and FPGA.

As future work we plan to extend our algorithm for the case of a cluster system based on nodes equipped with the Intel Xeon Phi coprocessors.

Outlier Detection as the Primary Step for Promotion Planning in Retail

Abstract - Forecasting the increase of customer demand during discount promotions is a fundamental business assignment in retail, which can nowadays be performed by sophisticated data mining algorithms. The calculations are based on data gained during previous promotions. Apart from choosing the right mining algorithm, the quality of prediction models strongly depends on the quality of the training data. Outliers are points of data that do not conform to a defined notion of normal behavior and are therefore either excluded from the training set, or their impact on the model is weighted in a manner different from other data. In this paper we propose a new approach to outlier analysis, with the aim of distinguishing between the outliers associated with an outlier-generating store or product and the outliers that can be classified as noisy data. Outlier analysis is performed with a multidimensional perception of the dataset typical for data warehousing and OLAP. We also introduce measures that estimate the probability of store or product being an outlier generator and conduct experiments to determine their critical threshold values.

I. INTRODUCTION

Business information systems serve as the source of new, added-value information either by means of analytical processing (OLAP) or data mining. The work of data mining scientists is mostly aimed at constructing predictive models (by using regression, neural network, naive Bayes classifier, k-nearest neighbor classifier, support vector machines, random forests, etc., see [1]) or descriptive models (by using clustering, association rules, hidden Markov models, principal component analysis, self-organizing maps, etc., see [1]). However, modeling is just one step of the process: according to the well-known CRISP-DM process model [2], modeling is preceded by the steps of Business Understanding, Data Understanding and Data Preparation and then followed by Evaluation and Deployment. Data understanding and data preparation are frequently observed as a single process called Data Analysis or Exploratory Data Analysis [3]. The analyst first gets familiar with the data, studying attributes and their distributions as well as identifying possible quality problems, and then chooses the optimal subset for model construction, performing data transformations if necessary.

A principal task related to data quality is outlier detection. According to Anscombe and Guttman [4], "*an outlier is an observation which is suspected of being partially or wholly irrelevant because it is not generated by the stochastic model assumed"*. Hawkins [5] defines an outlier in a similar fashion, as "*an observation which deviates so much from the other observations as to arouse suspicions that it was generated by a different mechanism*". Based on the domain of application and motives for outlier detection, two general perspectives of outliers can be taken [6,7]. The first perspective is taken when the primary goal is to remove dirty data. Outliers are understood as noise that "spoils" the data and hinders further analysis. Once the outliers are detected, the easiest way is to exclude them from the dataset. However, simple exclusion may sometimes not be the best solution since the resulting dataset may become unrepresentative: in such case it is better to calculate some interpolation value for the outlier records [8,9,10]. From the second perspective outliers are understood as a useful indicator of the different ("abnormal") mechanism that creates them [6]. Thus, outliers themselves are not the purpose of the detection process, but only serve as means to detect their generator mechanism. Outliers in credit card transactions or insurance claims are strongly related to fraud attempts [6], while outliers in meteorological data may suggest a dangerous event such as storm or hurricane [6].

A part of our team has been involved with constructing predictive models of promotion sales demand for a major retail corporation in Croatia [11]. The models have been based on linear regression and support vector machines. During the exploratory analysis process it became clear that outliers occur as a result of several mechanisms and each outlier group should be processed in a different manner (i.e. not all outliers should be discarded). For instance, very low sale result for several products in a particular store during a particular promotion campaign in January, which differs from the mutually highly correlated results for the same products during other promotions and which is accompanied with the out-of-stock flag is a result of shipping problems due to a snow blizzard. A much-higher-than-usual sale result for beer in a countryside store in June is a result of a camping rally. Such cases do not express regular behavior pattern and should be discarded. On the other hand, some stores express outlying behavior (in comparison with other stores i.e. according to statistical outlier detection parameters) for many products and many promotions. Likewise, some products are outliers across the majority of stores. Stores and products can be understood as some kind of outlier-generating mechanism, obviously different from unexpected events

such as a camping rally or uncontrollable ones, such as blizzards. Removing particular stores and products from the training dataset would result in a general model that could likely be inapplicable for those particular stores and products: we would need to construct additional models (or possibly many models) or apply some heuristics. Keeping the data in the dataset and using some additional engineering (e.g. introducing of some additional parameters) may be a better solution.

In this paper we propose a new approach to outlier analysis, with the aim of distinguishing between the outliers associated with an outlier-generator store or product and the outliers that can be classified as noisy data. We adopt the multidimensional perception of the dataset typical of data warehousing and OLAP [12]. In the first step we detect outliers using the multivariate statistical technique MCD [13]. In the second step we analyze the entire dataset, understanding each record as a single OLAP cell. We introduce outlier ratio and total number of outliers as OLAP-like measures of the fact and aggregate their values across multiple dimensions.

The paper is structured as follows. Basic terms and formulae considering outliers are given in Section II. Related work is elaborated in Section III. Techniques for multivariate outlier detection are explained and applied in Section IV. Multidimensional analysis of the outlier data is performed in Section V. Conclusions are drawn in Section VI.

II. BASIC TERMS AND FORMULAE

Let the data be characterized by a set of one (*a univariate set*) or more attributes (*a multivariate set*). Each data record may be represented by a point in the *N-dimensional space* (*N* being the number of attributes). Outliers are points that are according to some distance measure "far away" from other points (Fig. 1).

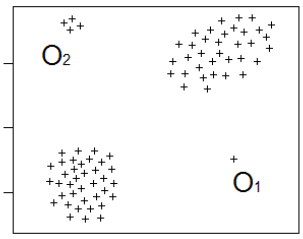

Figure 1. Outliers in two-dimensional space. A single point O_1 and a cluster of several points O_2. Adapted from [7].

In a very large number of cases attributes are continuous variables with Gaussian distribution. Considering univariate instances as the most simple case, the most common notion of outliers in statistics was long perceived in relation with the mean μ and the standard deviation σ of the population (or sample) and the confidence coefficient α (most commonly for α=0.05, 0.01, 0.005 etc.) [14]:

$$\text{out}(\alpha, \mu, \sigma^2)=\{x : |x - \mu| > z_{1-\alpha/2}\sigma\} \quad (1)$$

However, outliers themselves strongly influence the values of μ and σ. Hampel [15] suggested to use median and median absolute deviation (MAD) instead. A similar concept was used by Tukey [3], who introduced Boxplot as a convenient graphical display for outliers. Tukey's robust estimator for σ is based on the difference between the third and the first quartile also known as the interquartile range, *IQR*:

$$\hat{\sigma} = IQR = Q_3 - Q_1 \quad (2)$$

Outliers are observations smaller than $Q_1-1.5\cdot$IQR and larger than $Q_3+1.5\cdot$IQR. Fig. 2 shows the boxplot for an example dataset consisting of 12 members. The box stretches from Q_1 to Q_3. The thick line is the median. "Whiskers" denote the smallest and largest non-outlier values (50, 70). Outliers (38, 85) are represented by small circles.

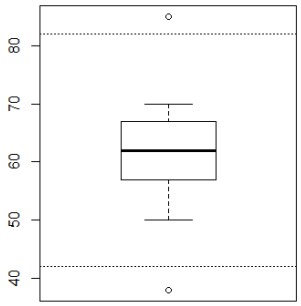

Figure 2. Boxplot for dataset {38, 50, 57, 57, 58, 61, 64, 64, 67, 67, 70, 85}. Median=62.5; Q_1=57; Q_3=67; IQR = 10; ($Q_1-1.5\cdot$IQR) = 42; ($Q_3+1.5\cdot$IQR) = 82.

III. RELATED WORK

Outlier detection became a popular topic in computer science in 1990s, with the emergence of many domain-specific classification techniques based on neural networks [16], support vector machines [17] and Bayesian models [16]. Rule-based classification techniques (i.e. classification based on pre-defined heuristic rules instead of machine learning) have also been widely adopted [18]. The main difference between "standard" classification and outlier detection is the fact that instances labeled as outliers occur very rarely in the dataset, which makes the training process particularly challenging. Certain techniques successfully solve the problem by injecting additional artificial outliers into the original dataset in order to increase their ratio [19]. Neighbor-based approaches combine the idea of calculating distance from other object in the space (which is specific for clustering), with the idea of doing the calculation locally, i.e. only for *k* nearest objects [19,20,21].

Principal component analysis (PCA) uses an orthogonal transformation to convert a set of observations of possibly correlated variables into a set of values of linearly uncorrelated variables called principal components. Since the top few principal components capture the largest portion of variability in a given dataset, the smallest principal components are expected to result in constant values. A data point that violates this expectation for the smallest components is an outlier [22].

Up to the present date outlier detection has remained in the permanent focus of scientific research in manifold and mutually diverse application domains. Price estimation in real estate market is addressed in [23]. The well-known particular case of credit card frauds can be extended to any kind of relationship between a business

provider and a consumer [24]. New visualization techniques used for clustering and outlier detection in high-dimensional spaces are proposed in [25]. Further possibilities of applying non-Gaussian models in outlier detection, with application in enterprise resource planning (in particular, executive benefits) are investigated in [26].

Particular examples of outlier detection in retail or retail promotions are [27] and [28] from the long-term econometric perspective of a marketing department, [9] from the perspective of statisticians collecting data for a government, and [29] from the perspective of an agency affiliated with the US Department of Healthcare.

IV. MULTIVARIATE OUTLIER DETECTION

A. Dataset description

The promotion planning dataset upon which the retail demand prediction models are built [11] consists of more than 50 attributes. We may adopt a multidimensional perspective of the data identifying three basic dimensions: **product**, **store** and **promotion** (Fig. 3; this is not a model of a data warehouse, since it lacks the *sine-qua-non* time dimension). Each dimension contains one or more hierarchies (for instance, there is a four-level hierarchy of products imposed by the internal organization of the retail corporation: single_product → group → subcategory → category).

A single data record i.e. a single OLAP-cell contains numerical data on the promotional performance of a single product in a single store during a single promotion campaign. There are seven numerical measures (Fig. 3).

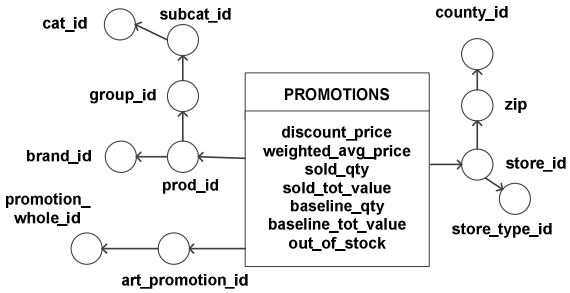

Figure 3. Dataset attributes observed from the multidimensional perspective.

Weighted average price is calculated across all stores during a longer time period. *Sold total value* is the product of *sold quantity* and *discount price*. *Baseline quantity* is the interpolated value of the sold quantity expected in case there was no promotion. *Baseline total value* is the product of baseline quantity and average price. The values of baseline quantity and baseline total value are expected to be smaller than the actual sold quantity and sold total value. *Out-of-stock* is an integer defining how many days during the promotion the product was unavailable (in case of good organization and planning it should be zero).

The purpose of the demand forecasting model described in [11] is to predict the quantity sold during promotional campaigns. Thus, our observation of outliers will be performed with respect to the values of two attributes: *sold_qty* and *baseline_qty*. We did not observe prices, since the resulting space would be very strongly influenced by the product dimension (in comparison with stores and promotion campaigns).

Observing the histograms in Fig. 4, (all the processing is performed in the R programing language), we see that the distribution of both variables is exponential, while the standard definitions of outliers (Eq. 1, 2) refer to the normal distribution. Quantile-to-quantile plots comparing the distributions of the two variables with the normal distribution display large discrepancies (points of QQ-plots for two corresponding distributions do not fit the red line; see Fig. 4). Intuitively, taking the logarithm of the variables would produce results that conform to the normal distribution. We use the Box-Cox transformation [30] which works for many distributions and turns the original variable x into normalized value:

$$x \to \begin{cases} \dfrac{x^{\lambda}-1}{\lambda}, & \lambda \neq 0 \\ \ln(x), & \lambda = 0 \end{cases} \qquad (3)$$

R calculates the optimal value of the λ parameter by an iterative computation for values within the interval [−2, 2]. In our case the optimal values of λ are −0.02 for *sold_qty*, and −0.06 for *baseline_qty*. Histograms and QQ-plots for the transformed variables are shown in Fig. 5 (the majority of values now conform to the normal distribution). All further work is performed with the transformed values.

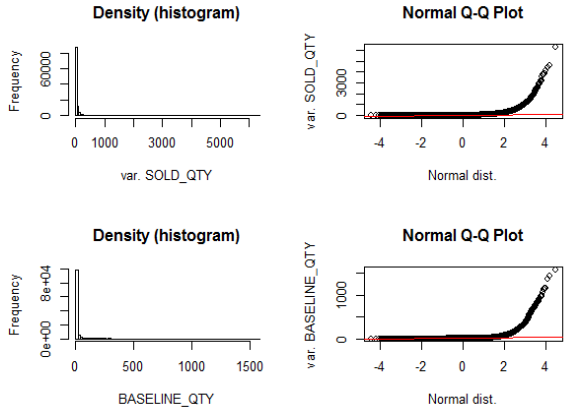

Figure 4. Histograms showing distributins of variables *sold_qty* and *baseline_qty* and quantile-to-quantile plots comparing their distribution with the normal distribution.

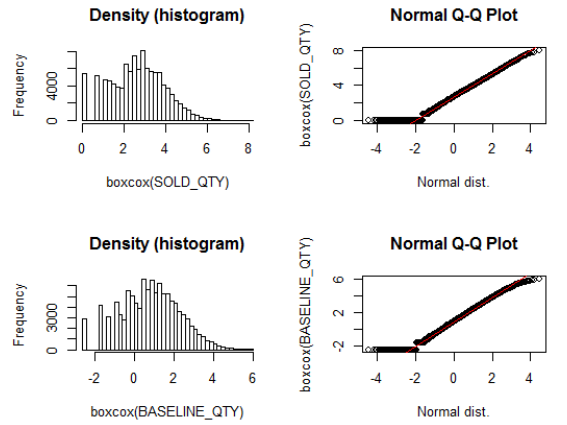

Figure 5. Histograms and quantile-to-quantile plots for variables *sold_qty* and *baseline_qty* transformed by the Box-Cox tranformation.

B. *Mahalanobis distance and MCD*

In many cases multivariable observations cannot be considered outliers when each variable is observed independently. For instance, a height of 187 cm for a grown-up male person makes him taller than average but not an outlier. Likewise, a male person with (European) shoe size 41 is not an outlier, although this is smaller than the average male size. However, a person 187 cm tall with shoe size 41 would by most people be observed as an outlier.

Given a multivariate (N-dimensional) space where all variables conform to the normal distribution, it is easy to calculate the centroid, but each of the variables has a different value of σ. Intuitively, the space is not spherical but shaped as an ellipsoid, and each dimension has to be normalized by $(x - \mu)/\sigma$ in order to achieve a spherical space using the *Mahalanobis distance*. Let $x^i = (x_1^i, x_2^i, \ldots, x_N^i)^T$ be a vector representing the *i*-th *N*-dimensional observation (let the total number of observations be *M*). Let the centroid $\boldsymbol{\mu} = (\mu_1, \mu_2, \ldots, \mu_N)^T$ be the vector of univariate mean values for each dimension. Mahalanobis distance is defined as [13]:

$$D_{MAH}(x,\mu) = \sqrt{(x-\mu)^T S^{-1}(x-\mu)} \tag{4}$$

where $\boldsymbol{S}^{-1}$ is the inverse of the covariance matrix $\boldsymbol{S}$ for observations $\boldsymbol{x}^{(1)}, \boldsymbol{x}^{(2)}, \ldots, \boldsymbol{x}^{(M)}$, which is defined as [13]:

$$S = \frac{1}{M-1}\sum_{k=1}^{M}(x^k - \mu)(x^k - \mu)^T \tag{5}$$

The covariance matrix determines the ellipse which is at $D_{MAH} = 1$ from the centroid (the axes correspond to the square roots of its eigenvalues; its eigenvectors define the rotation angle). Since the distribution of the Mahalanobis distance behaves as a chi-square distribution for a large number of instances, the cutoff threshold to distinguish outliers from other data is $[D_{MAH}(\boldsymbol{x}, \boldsymbol{\mu})]^2 = \chi^2_{N,1-\alpha}$ (the number of degrees of freedom is equal to the number of dimensions in the space, *N*). The preferred value of $1-\alpha$ is 0.975 [13] which for $N=2$ gives the threshold value of $\sqrt{7.3777} = 2.716$.

Similar to the non-robust basic formula (Eq. 1) for univariate outliers that had to be replaced with a more robust estimation (Eq. 2), a group of outlying instances may skew the mean and covariance estimates towards itself. A robust estimator of the centroid and the covariance matrix is the minimum covariance determinant (MCD) [13], which instead of the original *M* observations uses its most dense subset of size $\lceil 0.5 \cdot (M + N + 1) \rceil$, which is smaller than *M* since $N < M$.

Our dataset contains 109284 records (35 promotion campaigns, 300 products, 744 stores). The scatterplot is shown in Fig. 6. Only 414 records are univariate outliers, above the horizontal line and right to the vertical line, which both denote the Q_3+1.5·IQR value. In both cases there are no outliers for Q_1−1.5·IQR. Basic multivariate method detected additional 2219 outliers (i.e. five times more than the number of univariate outliers). The threshold is denoted by the larger ellipse in Fig. 6. In comparison, the robust MCD method detected a much

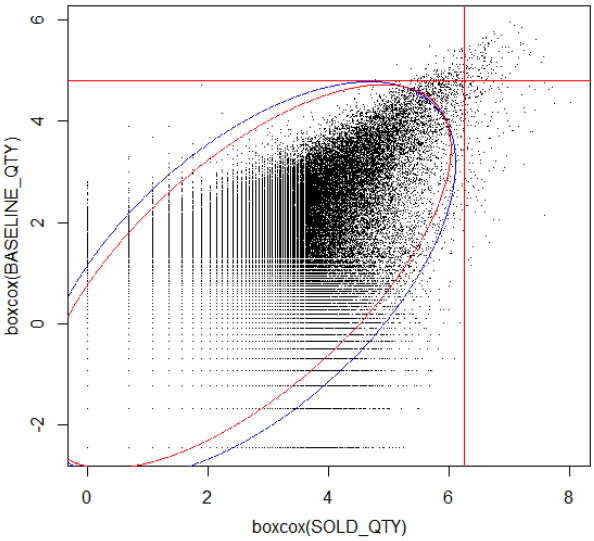

Figure 6. The scatterplot for the transformed variables *sold_qty* and *baseline_qty*. Lines denote univariate outlier thresholds. Ellipses denote multivariate threshold for basic Mahalanobis distance: the larger one for the basic calculation method, the smaller one for the MCD estimate.

larger total number of 4445 outlying points (the smaller ellipse, with a 1.15 times smaller area in comparison with the larger ellipse). When natural logarithm was used to normalize the values instead of Box-Cox transformation (Table I) the number of points identified as outliers is smaller (the normalization is of lesser quality, hiding outliers that skew the distribution parameters). It is important to note that the set of algorithms held in the literature as optimal (Box-Cox transformation and MCD) produced the largest number of outliers.

		BASIC	**MCD**
LOG	386	1996	2219
BOX-COX	414	3224	4445

V. OUTLIER ANALYSIS FROM MULTIDIMENSIONAL PERSPECTIVE

Outlier analysis from the multidimensional perspective is performed with the three dimensions already described in Section IV.A: product, store and promotion (Fig. 3). Thus, the minimum granularity corresponds to a single dataset record. Instead of the measures proper to the dataset, cells now contain two measures:

- the number of outliers, ***NO*** (in the particular cell),
- the total number of points, ***NP*** (in the cell).

Both measures are additive across all dimensions. We aggregate *NO* and *NP* and group them by each of the three dimensions: store, product and promotion, as well as by two of the three dimensions jointly (i.e. by store and product, store and promotion, product and promotion). For

each group we calculate the principal measure of *outlyingness*: **outlier ratio** (**OR**) i.e. the ratio of the number of outliers and the total number of points:

$$OR = \frac{NO}{NP} \tag{6}$$

This measure is by its definition non-additive and has to be calculated separately for each aggregated multi-cell. The outlier ratio for the entire dataset is OR_{DS} = (414+4445)/109284 = 0.0445.

Total number of outlying points is not a good measure of *outlyingness*: a large number of outliers for a particular group may correspond to an even larger total number of points i.e. a low outlier ratio. Indeed, many promotions refer to a limited number of stores, which makes *NP* for those stores larger in comparison with other stores. Table II shows that products with IDs 37 and 40, respectively, are associated with almost the same number of outliers (19 and 18, respectively). However, while the *NP* of the former is 27 points in total (making the ratio of outliers very high), the *NP* of the latter is 975, making the outlier ratio smaller than 0.02 and more twice smaller than OR_{DS}. Thus, only the former product is indeed an outlier-generator, while in the latter case the product is considered regular (the related outliers may arise due to an outlier-generator store or promotion or may even more likely be considered noise).

TABLE II. OUTLIER MEASURES AGGREGATED ACROSS THE PRODUCT DIMENSION

PROD_ID	NP	NO	OR
335	1	1	1
243	166	160	0.9639
37	27	19	0.7037
…	…	…	…
40	975	18	0.0185
…	…	…	…
72	607	1	0.0016
13	56	0	0
…	…	…	…

High outlier ratio alone can be deceiving when the total number of points is small. The highest ratio in Table II is associated with a single record for product ID 335, which happens to be an outlier. Based on the total number of detected outliers, we declare a minimum threshold of 10 outlying points (about 0.2% of the total of 4859 outliers) to consider a store or a product an outlier-generator candidate (due to a small number of promotions in comparison with stores and products, all promotions cross the threshold by far). Considering the products in Table II, only those with IDs 243 and 37 (shadowed rows in Table II) are outlier generators.

For the aggregations by two dimensions it is very useful to compare their outlier ratio with the ratios for the corresponding aggregations by a single dimension. We divide the former value with the latter two values obtaining two coefficients that illustrate whether the particular combination produces a higher *OR* than each of its parts observed separately. Table III shows several records for the joint aggregation by product and promotion. When both coefficient values (the last two columns in Table III) are significantly larger than 1 (e.g. 1.5 at least), the combination itself is a strong outlier-generator (e.g. promotion 27 and product 91). When one coefficient value is slightly larger than 1 and the other is much larger (e.g. promotion 25 and product 78), or when one coefficient is smaller than 1 (e.g. promotion 34 and product 184), the outlier-generator candidate is in the dimension related to the coefficient close to 1 or smaller than 1 (i.e. promotion 25, product 184), whereas the other one is not a candidate (product 78 and promotion 34 generate outliers only in dependence with the other dimension).

Summary characteristics of the aggregated data are shown in Table IV. We measure the size of each group, the number of groups with at least one outlier, the number of groups with at least ten outliers, the third quartile value for *OR* in each aggregation, the number of groups with *OR* higher than 0.2 and 0.3 respectively, and the maximum *OR* within the entire aggregation.

Given the minimum threshold of 10 outlying points in total (0.2% of the total number of outliers in the dataset) we decide that *OR* value of 0.2 (which is more than 4 times greater than OR_{DS}) is a good threshold to distinguish outlier-generating products and stores from the outliers that occur as result of unpredictable or uncontrollable events.

Considering higher aggregation levels, we grouped data by all cities (level *zip* in Fig. 3) with two or more stores. The highest *OR* was 0.0905, two times smaller than the critical threshold value of 0.2. The highest two *OR* values for product groups (level *group_id*) with two or more products were 0.1655 and 0.1377, respectively. The groups consisted of 2 and 14 products, respectively. The first *OR* value is smaller than the suggested threshold

TABLE III. OUTLIER MEASURES AGGREGATED ACROSS TWO DIMENSIONS: PROMOTION (PRM) AND PRODUCT (PRD)

PRM ID	PRD ID	OR	OR_{PRM}	OR_{PRD}	OR/OR_{PRM}	OR/OR_{PRD}
27	91	0.570	0.125	0.184	4.544	3.094
36	301	0.128	0.103	0.080	1.245	1.592
25	78	0.127	0.099	0.034	1.276	3.747
34	184	0.058	0.026	0.070	2.237	0.826

TABLE IV. SUMMARY PARAMETERS FOR ALL AGGREGATIONS

value of 0.2, although quite close to it. However, looking backward at the product level we discovered that all outliers were generated by a single product. Hence, in order to classify a group at a higher aggregation level as an outlier generator, there should be an additional threshold: at least *K* of *N* group members at the basic level should be outlier generators themselves. Focusing on this threshold is a challenging task for future work.

VI. CONCLUSION

In this paper we proposed a new approach to outlier analysis based on the multidimensional conceptual model and OLAP. We analyzed the datasets used for training promotional sale forecasting models, with the primary goal of distinguishing between outliers occurring for stores and products that behave as outlier-generator mechanisms and outliers occurring as a result of unpredictable events.

We constructed two-dimensional space and detected outliers using the MCD estimator. We counted the points (*NP*) and the outliers (*NO*) across three dimensions: product, store and promotion. Then we aggregated the data and grouped them across dimensions, associating each group with its outlier ratio (*OR*), a non-additive measure we proposed in this paper as the one that best describes outlier behavior of an aggregated group of points: a store, a product or a promotion. The analysis led to a conclusion that, regardless of its *OR* value, a group cannot be considered an outlier generator mechanism unless its absolute number of outliers (*NO*) exceeds a threshold.

Through the conducted experiments we established the threshold values to consider a group an outlier generator: the *NO* threshold is 0.2% of the total number of outliers in the dataset, whereas the *OR* threshold is 4 times greater than the outlier ratio of the entire dataset.

Our future work will be directed at studying higher aggregation levels as possible outlier generators. We also plan to analyze the outliers in the same or similar dataset from the perspective of income (i.e. sold total value measure instead of sold quantity).

Data Warehouse in era of Big Data platforms

Tomislav Križan, Mladen Družetić
Poslovna Inteligencija d.o.o., Zagreb, Croatia
{tomislav.krizan, mladen.druzetic}@inteligencija.com

Abstract - One of emerging questions in analytical space is difference between implementations of traditional Data Warehouse systems and those based on Big Data technologies. Also, what about Data Warehouse appliances in era of fast evolving Big Data systems? Within this paper overview will be given of differences and/or similarities between traditional and Big Data option in analytic space, with focus on relevant cases for each of them.

I. INTRODUCTION

For almost over 40 years, data management solutions typically meant focusing on relational data processing and use of relational database management systems (RDBMS's). Within last decade, industry moved to a data-driven world with explosion in the data volumes generated not just with human interactions, but even more of those originating from machines communicating with other machines (M2M). With those data volumes came need to analyse underlying data sets to find information for statistical and/or legal reporting, but even more to gain insight into previous behaviour pattern within data set to predict future outcome(s) of *our* actions.

In computing, a data warehouse (DW or DWH) is a system used for reporting and data analysis. DWs are central repositories of integrated data from one or more disparate sources. They store current and historical data and are used for creating trending reports for senior management reporting such as annual and quarterly comparisons [1]. DW guru's try to define meaning of DW as „A data warehouse is a subject-oriented, integrated, time-variant and non-volatile collection of data in support of management's decision making process“ [2] or „A data warehouse is a copy of transaction data specifically structured for query and analysis.“ [3]. In essence, the DW concept was intended to provide an architectural model for the flow of data from operational systems to decision support environments.

There were many problems related to analysis of large data volumes, but the term “Big Data” which spans computer science and statistics/econometrics, probably originated in lunch-table conversations at Silicon Graphics Inc. [4]. Term meant something different in 90's than in current days and moreover, we are now talking completely different scales of used data volumes which were unthinkable in 90's. Trying to solve problems related to Big Data, Apache Hadoop came to life and became most common platform for distributed storage and distributed processing of very large data sets (e.g. Big Data). The core of Apache Hadoop consists of a storage part (Hadoop Distributed File System (HDFS)) and a processing part (MapReduce, Yarn, Spark) [5]. Hadoop was created in 2005 to support distribution for the Nutch search engine project [6].

II. DATA WAREHOUSE IN PRACTICE

The enterprise data warehouse (EDW) is the backbone of analytics and business intelligence for most large organizations and many midsize firms. The tools and techniques are proven, the SQL query language is well known, and there's plenty of expertise available on the market. Over the time, many applications and concepts arose around DW with different maturity levels and use-cases.

Currently, majority of DW implementations are based on use of RDBMS's from existing mega-vendors (e.g. Oracle, IBM, Microsoft, SAP, etc.), but there is also highly rising trend of replacing general-purpose built RDBMS with appliances designed exclusively for analytical purpose (same mega-vendors compete even in this space as well).

At same time, until year 2014. use of Big Data platforms as replacements for DW was not even considered due architectural and/or conceptual differences behind major distribution of those solutions (Cloudera, Hortonworks, and MapR to name some of them). Necessary components within common Hadoop distributions, gained high level of maturity and some major obstacles to use those platforms as DW, were solved within 2014. thus allowing them to step into *ad-hoc* analytical spectrum as first-line-of-defence.

In following segments of this paper we will briefly describe use of RDBMS and analytical appliance approach and put more focus on use of Big Data platforms as sole DW provider for days to come.

A. Traditional DW

Relational databases (RDBMS) are the most common choice for data warehouse implementations. Even more, record-based structure is the most common choice of data storing within RDBMS’s. Since entire records are physically written and read as single units, this means that selecting any field requires reading the entire record, and changing a single value requires reading and rewriting the entire record unless there is other mechanisms to prevent

this behaviour, but then we can end up with result where we have same attribute spanned across multiple locations on storage level (e.g. Chained Rows problem) and additional maintenance is needed to fix this issue [7]. Over time, some vendors start introducing column-based structure along record-based structure, and some of them completely switch to column-based structure and benefited from query performance and lower storage costs. To cope with always rising data volumes, from early days, RDBMS's started to introduce indexing mechanisms which would allow quicker response to ad-hoc queries (classical use of DW systems consists of set of "static" queries from reporting tools and ad-hoc queries which can span across whole DW). Also, clever method of data pruning like partitioning, field maps, etc., were introduced to further enhance analytical needs from DW system, but at same time to speed even loading mechanisms into DW.

Constant problem in majority of DW implementations is how to effectively partition tables to support any kind of ad-hoc queries on large data volumes. This is due to different partition level limitations in traditional RDBMS's implementations (in almost all cases it stops either on partition or sub-partition level). There are methods how to overcome those limitations but it means need for specific implementation of Business Intelligence solutions on top of those DW implementations (like combining multiple attributes into single one and partition on that column/attribute, etc.). Even so, DW systems are mostly designed and implemented on top of traditional RDBMS's due to their wide use in many different applications and organizational need to have only one team managing and maintaining different instances and use-cases of same RDBMS engine.

B. *DW on appliance*

In a traditional DW implementation, the database administrator (DBA) can spend a significant amount of time tuning and putting structures around the data to get the database to perform well for large sets of users. As enhancements of existing DW implementations, new generation of specially built software and/or software/hardware combinations arise to deal with analytical problems on top of rising data volumes. A data warehouse appliance consists of a DBMS mounted on specified server hardware with an included storage subsystem specifically configured and optimized for data warehousing. They were named *appliance* because first implementations came in enclosed HW with embedded implementation of RDBMS's designed and optimized for analytical purposes. Term data warehouse appliance (DWA) defines a new category of computer architecture for data warehousing (DW) specifically targeted for Data Analytics and Discovery that is (a) simple to use (not a pre-configuration) and (b) very high performance for this workload. A DWA includes an integrated set of servers, storage, operating system(s), and DBMS [8].

Most obvious difference between traditional DW implementation and DW appliance is in scaling out whole system. When you need to scale traditional DW, you need to migrate all the data to a larger and more robust server. When using appliances it is necessary to have an additional components which connects into existing environment and auto-balance data across new components, thus scaling processing power and speed. Other differences are based on storing and retrieving data from storage components. While traditional RDBMS rely on indexes, partitions and/or statistics to speed up data retrieval, DW appliances rely on massively parallel processing (MPP) and full-table (or segment in smarter implementations) scanning complete data sets, including clever pruning mechanisms based on use of appropriate data type definition for underlying tables. Traditional RDBMS's also introduced data caching in memory to speed query responses, but only repeating queries benefit from that feature. At same time, DW appliances do not rely on statistics, in majority of cases they do not even rely on index use, thus allowing controllable and linear execution times over any data volume.

Introduction of DW appliances was a great leap in analytical capabilities of DW systems but it still needs to fight for its *place-under-the-sun* from DW's built on traditional RDBMS's and overcome common fear-of-new (which can manifest as the unwillingness to try new things or break from routine) from people who will maintain DW appliances.

C. *DW on Hadoop*

New-born. Newcomer to DW scene. Needs to prove a lot and to show its strength and benefits not just towards traditional DW, but also towards DW appliances. From technological aspects, it shares the same strategy as massively parallel processing (MPP) engines used within DW appliances, but whole philosophy around MPP implementation is different. For organisations and persons going into analytical spectrum without predetermined preferences towards traditional RDBMS's, major clash will be between DW appliance and DW on Hadoop.

Figure 1. Magic Quadrant for Data Warehouse and Data Management Solutions for Analytics [31]

Original aspects and technology foundations for Hadoop implementation were around processing large number and volumes of textual files. Thus new purpose

built file system arose (HDFS - Hadoop Distributed File System). On top of HDFS, different processing engines were created ranging from batch processing towards real-time processing capabilities which consumed data stored in HDFS. Some of them focused on implementing DW solutions on top of Big Data platforms and this paper will focus on those components.

Gartner Inc. (world's leading information technology research and advisory company) started to introduce different Hadoop distribution Vendors to their Magic Quadrant for Data Warehouse and Data Management Solutions for Analytics (as show on Figure 1). Entering 2015, the DW has expanded to address multiple data types, processing engines and repositories. This is creating new demands on the data warehouse market - for broader data management solutions for analytics, with features and functionality that represent a significant augmentation to existing enterprise data warehouse strategies.

III.HADOOP AND DW

Hadoop was engineered to rely on the schema on read approach, in which data is parsed, reformatted, and cleansed at runtime in a manually written program, whereas RDBMS enforces schema on write approach. In RDBMS's, a table's schema is enforced at data load time. If the data being loaded doesn't conform to the schema, then it is rejected. This design is called *schema on write*. Schema on read makes for a very fast initial load, since the data does not have to be read, parsed, and serialized to disk in the database's internal format. The load operation is just a file copy or move. Schema on write makes query time performance faster, since the database can index columns and perform compression on the data but it takes longer to load data into the database [27].

Initial processing engine created at same time as HDFS was based on paradigm of parallel processing of distributed file sets (e.g. MapReduce). MapReduce is a programming model on top of HDFS for processing and generating large data sets which was developed as an abstraction of the map and reduce primitives present in many functional languages [9]. A MapReduce program is composed of a *Map()* procedure that performs filtering and sorting (such as sorting students by first name into queues, one queue for each name) and a *Reduce()* procedure that performs a summary operation (such as counting the number of students in each queue, yielding name frequencies). The "MapReduce System" (also called "infrastructure" or "framework") orchestrates the processing by marshalling the distributed servers, running the various tasks in parallel, managing all communications and data transfers between the various parts of the system, and providing for redundancy and fault tolerance [10]. The term MapReduce actually refers to two separate and distinct tasks that Hadoop programs perform. The first is the map job, which takes a set of data and converts it into another set of data, where individual elements are broken down into tuples (key/value pairs). The reduce job takes the output from a map as input and combines those data tuples into a smaller set of tuples. As the sequence of the name MapReduce implies, the reduce job is always performed after the map job. This is show on Figure 2.

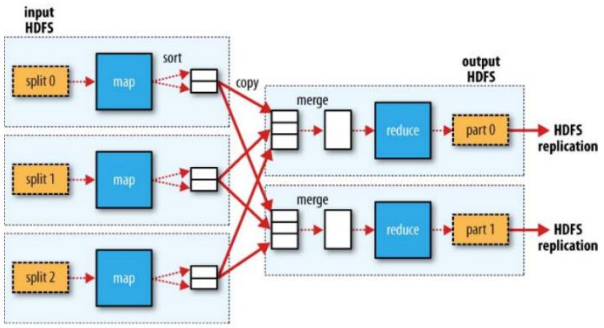

Figure 2. Map Reduce Programming Model [30]

By utilizing parallel computing and processing techniques like MapReduce, Hadoop is able to reduce long computation times to hours or even minutes. This is suitable for analytics over large volumes of historical data stored on disk, but it is not suitable for operational use of underlying data in real-time. Nevertheless, existing programming skills and infrastructure with parallel architecture of Hadoop itself can be leveraged to gain real-time data analytics on live data. Over the last few years, Hadoop has emerged as a popular way to handle both the storage and analysis of these increased volumes of data. Even so, Hadoop's parallel architecture can accelerate analytics over vast volumes of data. When it comes to real-time data, Hadoop's native batch processing and disk overheads are harder to overcome. One of the options to have real-time analytics using Hadoop is by combining an in-memory data grid (IMDG) with an integrated, stand-alone Hadoop MapReduce execution engine. With this technology fast results can be delivered for real-time data at same time as speeding-up analysis of large, historical data sets. Basically, IMDG is a data structure that resides entirely in RAM (random access memory), and is distributed among multiple servers [11]. First step from Apache community to overcome batch legacy of MapReduce were under project MapReduce 2.0 which was later renamed to YARN [12] due extensible enhancements and changes in logic than initially envisioned. On top of YARN, new extensible framework for building high performance batch and interactive data processing applications was created (Tez) [13]. This enabled new generation of Hadoop platform to appear (e.g. Hadoop 2) and at same time enabled DW solutions to be built on top of Hadoop platform.

IV. HADOOP DBMS'S FOR DW

Initial architecture over Hadoop platforms for a generic, scalable and fault-tolerant data processing architecture on distributed data processing systems was envisioned by Nathan Marz [14] and it's shown on Figure 3. This established robust architecture for distributed system with both batch processing and real-time processing capabilities, capable for long running queries over massive amount of historical data and also insight into operational real-time data events. End-user could combine those two sources without need to wait batch processing to end and get quicker results to *ad-hoc* queries.

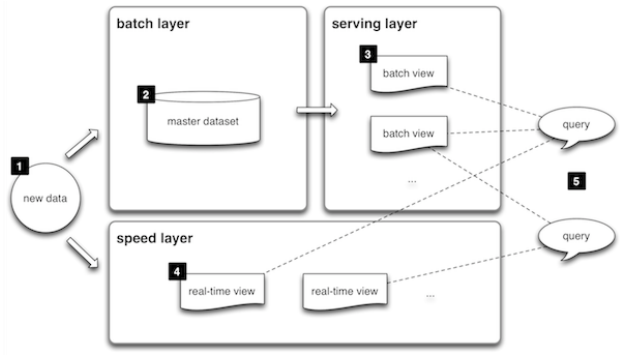

Figure 3. Lambda Architecture [14]

Better representation of Lambda Architecture is shown on Figure 4 which aligns real-time view of data with batch view. All other components prior to Serving Layer can be logically represented as Data Integration processes or ETL within traditional DW systems and will be discarded from future elaboration, thus focusing only on combined Serving Layer and different Hadoop DBMS's.

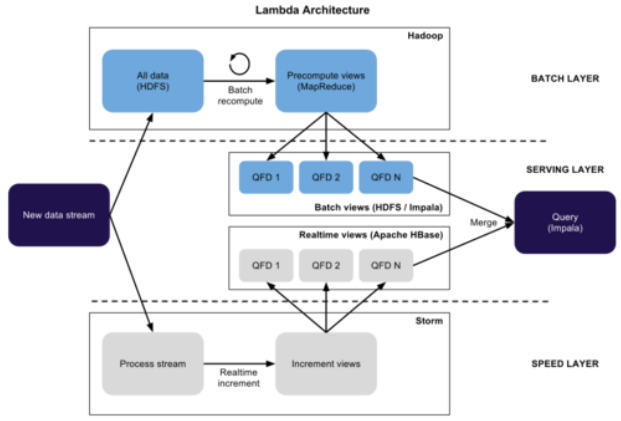

Figure 4. Consolidated Lambda Architecture [15]

Today's IT systems and networks can cause delays in capturing the data and delivering the data to a traditional DW for processing. With the explosion of data, DW's become data processing bottlenecks themselves, causing delays in processing and providing decision recommendations. As a result, the business misses an opportunity to take action (Figure 5). Major imperative is to move decision making much closer to the business event itself (e.g. to source data).

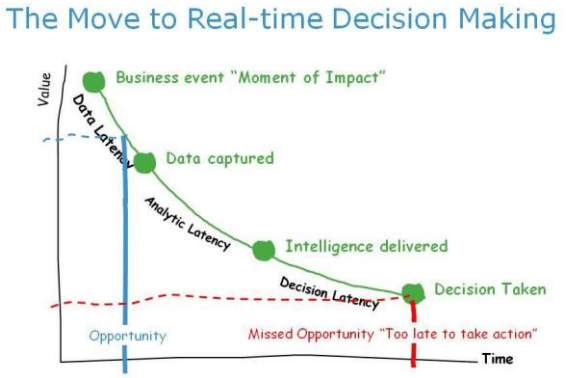

Figure 5. Correlation between Business event and Decision [28]

Some of providers within analytical appliance stack (like EMC) are starting to recognize that centralized, behemoth traditional DW are going the way of the dinosaur. For the purpose of big data analysis, they are too massive, too rigid and too far removed from the „moment of business impact"[28], so they start to evolve their business by moving analytics and decision-making to the edge of the network. They introduced solution for Real Time Intelligence (RTI) as a new kind of real time big data platform for a wide range of environments including telecom operators. The RTI system is based on the Pivotal One technologies and provides the ability to access and reason over large, diverse data sets ranging from subscriber databases to billing systems and network information. Together with in-memory real-time analytics, system is able to capture and process huge volumes of events coming from the carrier infrastructure. Those are one of many steps of existing vendors towards Hadoop platform but still with legacy within traditional spectrum which can be more of a burden than opportunity.

Newcomers without excessive technology baggage are introducing new platforms and components on daily basis with clear intent to tackle with traditional systems and take over large portion of DW business. Leading data integration vendors are already supporting Hadoop as native environment for data processing with even complete push-down capabilities to Hadoop for all functionalities. Due to large number of different solutions and implementations of DBMS engines on top of Hadoop (at the moment there is more than 80 different types of database solutions for Hadoop, e.g. Graph, Document, Object, etc.), next segments of this paper will focus on two of them that are more suitable for Data Warehouse implementations on top of Big Data platforms:

- Impala (developed by Cloudera)
- Hive (developed by Apache Foundation)

A. Impala

Cloudera Impala is a query engine that runs on Apache Hadoop. It brings scalable parallel database technology to Hadoop, enabling users to issue low-latency SQL queries to data stored in HDFS and Apache Hbase (open source, non-relational, distributed database modelled after Google's BigTable) without requiring data movement or transformation [16][17]. It features full SQL 2003-compliant analytic window functions together with external joins and aggregations using disk, sub-queries, incremental statistics and vast number of built-in functions, thus making it one of candidates for DW implementations over Hadoop. Introduction and enhancements on Impala were done by utilizing lot of underlying technologies like introduction of columnar storage format (Parquet) which can be aligned with partitioning capabilities to completely speed up *ad-hoc* query execution. Comparison of Parquet file storage format towards other file formats (with or without compression) is shown on Figure 6.

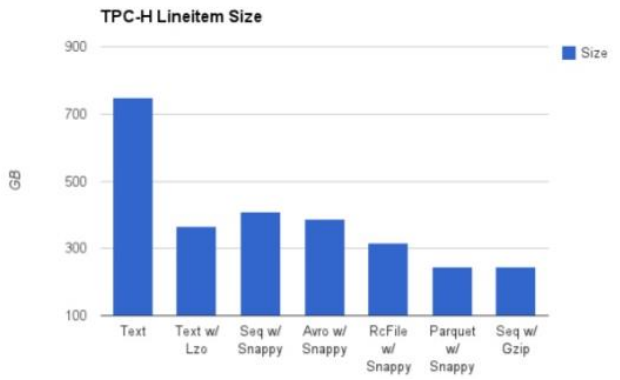

Figure 6. Parquet Storage Efficiency [29]

By utilizing Parquet storage engine with default Snappy compression, original text documents were shrink by a factor of 10, but at same time, data were redistributed based on columns within those textual documents. Performance gain based on TPC-DS like benchmark [18] is shown on Figure 7.

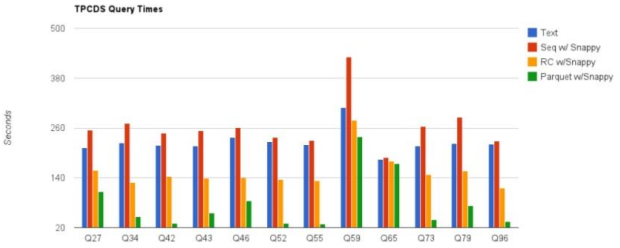

Figure 7. Parquet Scan Efficiency [29]

Currently there are obstacle related to DML SQL statements which prevents wide use of Impala as DW DBMS. It's not something that can't be overcome by modelling all phases of DW implementation (including data integration phase), but currently users of DW systems are accustomed to those features (e.g. ACID transactions). Because Impala reads data from HDFS or HBase, it can potentially have ACID support. Data in HDFS is immutable and thus ACID is unavailable unless complete files are changed, so HBase is roughly ACID for single-row transactions [19], and there are several projects to make HBase ACID for multi-row transactions. In DW implementations, fact tables are almost always immutable but *almost* part of this sentence needs to be stressed, which basically means that our fact data sometimes needs to be changed so ACID-like compliance is necessary. Impala is not a good choice for a mature enterprise DW's with strict security requirements and heavy use of exotic SQL features or proprietary extensions. In that case, Impala aims to augment the existing data warehouse by offloading high volume, low value data and workloads from the expensive enterprise data warehouse.

B. *Hive*

Apache Hive is a data warehouse infrastructure built on top of Hadoop for data summarization, query, and analysis [20]. It provides an SQL-like language called HiveQL and transparently converts queries to MapReduce, Apache Tez and, in the future, Spark frameworks. Transactions with ACID semantics were introduced to Hive in late 2014. which allowed users to easily modify data with inserts, updates and deletes. This extend Hive from the traditional write-once, and read-often system to support analytics over changing data and thus enabled reporting with occasional corrections and modifications and allowed operational reporting with periodic bulk updates from an operational database [21]. Most major players in BI segment are already implementing Native Hive connectivity and support for HiveQL together with traditional ANSI SQL support. Until recently, optimizing Hive queries focused mostly on data layout techniques such as partitioning and bucketing or using custom file formats [22]. Driven by Stinger initiative [23][24][25], Hive query time has improved dramatically, enabling Hive to support both batch and interactive workloads at speed and at scale. With Stinger.next initiative [25], Hive should support both transactions and SQL:2011 analytics as shown on Figure 8.

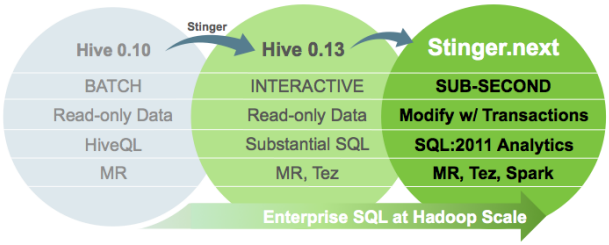

Figure 8. Stinger.next delivery [21][25]

Some of Stinger.next initiative goals are already in place, like transactions with ACID, allowing insert, update and delete, temporary tables, Cost Based Optimizer for star and bushy join queries, thus enabling Hive to become standard for DW implementations on top of Hadoop. On top of all technological advances, there is even methodological approach of optimizing queries and analytics on top of Hive. They focus on choosing appropriate execution framework (e.g. Tez in this v1.0.0, Tez or Spark in v1.1.0), selecting storage format like ORCFile [26] that sports fantastic speed improvements through techniques like predicate push-down, compression, using vectorised query execution (e.g. perform demanding operations in batches instead of single row each time), using cost-based query optimizer and most of all, write efficient SQL (same result can be achieved with different SQL statement and some of them may not be as efficient as they should be).

V.CONCLUSION

At the moment, different Hadoop distributions are implementing or have already implemented the same architecture supported by the traditional DW systems (including appliances). In next years, they will have competitive performance with much lower price tag. Analytic projects on top of Hadoop platforms are new, but the results of early projects have been impressive. The early projects have been completely business driven, and have focused on new ways of increasing revenue and reducing costs. Accelerating time-to-value has been a business imperative.

Stable and mature enterprise DW's will continue to exist due the fact that it can be cumbersome and time consuming (money as well) to migrate something which is

not broken. They will use Hadoop platforms for offloading data processing, minimize storage costs (major RDBMS vendors started to support HDFS for data storage), develop and test on Hadoop prior migrating result into traditional DW, etc.

From author's point of view, currently the best solution for DW on Hadoop and across different distribution is Apache Hive. This is due to comprehensive roadmap of new functionalities and enhancements and ANSI SQL standard implementation including analytical window functions. Other solutions are add-on on top of native Hadoop components thus adding some uncertainty to adoption of latest Hadoop features and/or visionary aspects of companies who are developing those solutions.

Nevertheless, DW on Hadoop is still not imaginable by majority of users and they will continue to use Hadoop for offloading tasks and processing for traditional DW until Hadoop platform gains some maturity.

Delta View Generation for Incremental Loading of Large Dimensions in a Data Warehouse

Igor Mekterović*, Ljiljana Brkić *
* University of Zagreb, Faculty of Electrical Engineering and Computing, Zagreb, Croatia
igor.mekterovic@fer.hr
ljiljana.brkic@fer.hr

Abstract - Incremental load is the preferred approach in efficient ETL processes. Fact tables are the ones who benefit the most from this approach, since they are large in terms of row count. For the sake of simplicity, dimension tables are often ignored and populated in a full reload manner. However, big dimensions (e.g. Client) can also have a significant impact on the ETL process and should also be considered for incremental load. Although they have much smaller cardinality than a typical fact table, it usually takes much more resources to calculate one dimension table row than to calculate one fact table row. Large dimension tables are based on multiple source tables, and it is not trivial to determine the changed records that should be considered for the incremental load because changes in any and all of underlying source tables must be considered. In this paper, we present an algorithm for the dimension's delta view generation. Delta view for a dimension encompasses all its source tables and produces a set of keys (e.g. ClientIds) that should be incrementally processed. We have employed this approach in a real world project and have noticed a significant reduction in the loading time of big dimensions.

I. INTRODUCTION

While OLTP systems are focused on supporting operational business processes requiring short response time, the intention of data warehouses (DW) is strategic planning and decision-making based on data integrated from heterogeneous systems. Multidimensional database technology is the key factor in interactive analysis of large amounts of data for decision-making. A multidimensional data model is commonly used in data warehouses that integrate enterprise's data from several sources into large repositories. The data acquisition process represents one of the most technically demanding and one of the most expensive parts of building a data warehouse. The data needed for the data warehouse are being extracted from their sources during an extract, transfer and load (ETL) process. According to [1], ETL design and development work consumes 60 to 80 percent of an entire BI project, therefore it is essential to optimize this layer of BI environment. Typical DW architecture includes a data staging area where the extracted data are stored temporarily, and subsequently, upon cleaning and transformation phase, transferred into the data warehouse. Commonly, there is no real-time connection between a DW and its data sources, since the massive read in decision support systems would conflict with the continuous update of operational systems and result in poor response times.

After the first or *initial loading*, DW must be periodically refreshed to keep up with source data updates. DW loading is usually done periodically, by a background process. The update patterns (daily, weekly, etc.) for traditional data warehouses and data integration process result in outdated data to a greater or lesser extent [3]. The naive approach to refreshing a data warehouse is referred to as *full reloading.* Possible refreshment scenario is to repeat the initial loading process using modified source data, compare the results with the current DW in order to determine changes that need to be done and finally perform the changes. This strategy is known as full DW reload. With the increasing size and complexity of DW, full reloading becomes inadequate, and in some cases inapplicable. More appropriate approach is a gradual change of DW in accordance with the changes that have occurred in the data sources since the last synchronization. Only the data that has changed since the previous reload needs to be transformed and processed. This approach is known as *incremental reloading*. The volume of modified data is always small compared to the entire dataset, thus, incremental reloads can be assumed to work quicker and more efficiently than full reloads. In most cases, the content of a DW is updated once a day. However, there are businesses such as health systems, e-business, stock brokering and others where such level of freshness of data is not sufficient, since they operate in a business time schedule of 24x7 and need relevant information as fast as possible in order to react in a near real-time manner. Real-Time Data Warehousing refers to an approach where DWs are updated as frequently as possible, greatly reducing data accuracy and availability gap.

The basic assumption of incremental and real-time loading is that the changes of source data can be captured and later on propagated to the data warehouse. There is a number of known techniques for changed data capture. The most commonly used ones are discussed in chapter III.

II. RELATED WORK

Incremental warehouse reloading is evidently related to incremental maintenance of materialized views [2] [3] as both areas cope with same issue – how to update physically integrated data under a given time constraint [4].

The core idea of materialized view incremental update stated in [4] assumes computing new content using materialized parent view (the outdated view needed to be refreshed) and its incremental update, often referred to as

delta view. Finding tuples constituting the delta view is addressed in a number of papers [5] [6] dealing with so called CDC techniques. This concept of capturing information about changed tuples is valuable later in the extract phase of incremental ETL process [7] [8]. Work described in [6] is to some extent similar to ours, but we go further with optimization of extract phase. The authors presented a tool for automatic creation of all necessary structures for altered data capture and subsequent extraction. They track changes by storing changed tuples identifiers (primary keys) in a special CDC tables and later on use stored identifiers for fast retrieval of tuples relevant for the next ETL cycle. Complementary to their work we addressed the issue, and proposed the solution, for finding identifiers of tuples responsible for refreshment of a particular dimension table. Since the contents of denormalized dimensions are refreshed based on the contents of numerous source tables, finding such identifiers can be a challenging task.

III. CHANGE DATA CAPTURE TECHNIQUES IN DBMS

Change Data Capture (CDC) is a generic term for techniques that monitor data sources in order to detect and capture necessary data changes [9] [10]. Different CDC techniques are used in practice. All CDC approaches assume that a complete changed record will be available to the requesting target.

The following is an overview of three most popular CDC techniques applicable in DBMS environment.

A. Timestamp based Capture

Timestamp based data capture is performed by adding a timestamp column (specifying the time and date when observed row was last modified) to each table of interest. These timestamps provide the selection criteria for the capture of changed records. The need to change the structure of each table of interest, by adding a single timestamp column, is the first disadvantage of this approach.

Second, it is not possible to capture intermediate states of data. If a record changed state more than once since the last ETL run, only the current (precisely the last) state of the respective record would be at disposal. Accordingly, when using this method, the inserted records cannot be distinguished from updated ones.

An additional problem with this technique is a lack of possibility to detect deleted records. Possible solution to detecting deletions is to label these records as inactive until they have been processed [10]. This concept leads to other problems in operational systems. For example, all applications working with operational data have to treat inactive records as deleted ones.

This method causes frequent writes of timestamp attributes on the operational systems and frequent reads whenever ETL process runs. Indexing timestamps can speed up reading but on the other hand can slow down INSERT and UPDATE operations [11].

B. Trigger-Based Capture

This approach involves the usage of triggers to track changes in the source database. Whenever a modification takes place in the source database corresponding log record is written into a dedicated log table. These dedicated log tables serve to determine rows changed since the last ETL processing.

The log tables usually contain a timestamp column that provides the exact time and date when a given row was last modified. The statements that are executed when trigger is fired, maintain the timestamp column accurate i.e. update the timestamp column with the current time.

This technique assumes that the DBMS supports active behavior i.e. triggers. The set and granularity of the events and conditions that cause a trigger to fire are database specific.

This approach enables capturing all types of events (INSERT, UPDATE, DELETE, MERGE). For UPDATEed rows both before and after image can be available.

One shortcoming of this approach is that it might significantly affect performance on the source systems. For example, if all INSERTs, UPDATEs and DELETEs are captured, this method creates twice the workload for the database [10]. This technique imposes a considerable operational overhead at the source system. This impact should be carefully considered prior to implementation on a production source system.

C. Transaction Log Capture

This technique employs the logging and recovery capabilities of a DBMS [9]. Since transaction logs are utilized by < DBMS to store transaction information for logging and recovery, these logs contain all information required to capture changed data. A specialized vendor-specific application must be written to monitor the log files and capture the data of interest.

One of the shortcomings of this approach is that it assumes that the transaction logs remain available until the changes of interest are captured. In order to prevent transaction loss, the database administrator must constantly monitor the transaction log area. The problem can occur when the recycling of the transaction log takes place, that is, when a part of the transaction log, containing transactions already committed, is reused by the DBMS [12].

The log capture method is probably the most efficient approach to incremental capture due to the fact that log writing is already well optimized and available on most DBMS platforms today [10].

IV. DELTA VIEWS

Once we know what records have changed in the source system, we can use that information to incrementally populate fact and dimension tables in the data warehouse. Incremental loading of fact tables is rather trivial and will not be further discussed. Fact tables are also the ones that benefit most from the incremental loading style since they typically contain a huge number of records. On the other

hand, dimension tables are usually relatively small and can be populated in a full reload manner. However, there are cases when dimension tables are also fairly large, both in terms of number of records and number of attributes. Such dimensions are sometimes referred to as "monster dimensions", "whose size exceed 100 million rows" [13]. Typically, those are customer or client dimensions in large enterprises. In our case, out client dimension is of 10^5 order with more than a hundred attributes. Such dimensions may take a long time to load, since they are both large in record count and have a considerable number of attributes that need to be calculated along the way (e.g. student's Grade Point Average, rank, etc.). We believe that, for such large dimensions, it is beneficial to construct the "delta view" – a view that will contain keys of records that need to be addressed in the ETL procedure. Delta view contains the keys of deleted, updated and inserted records of the relational source table, and that information is then used in accordance with the dimension type to update the dimension. For instance, for type 1 SCD (Slowly Changing Dimension), one would simply delete all dimension records that are members of delta view, and then reload those updated delta view records as well as the new ones. Type 2 SCD would handle updates and inserts differently, etc.

Unlike fact tables, delta view records are deduced not only from the base source table (for the dimensions), but also from many other tables that are being used in the dimension's ETL process. In our, real-world case, our dimension table is based on 23 relational tables. A change in any of those 23 tables can impact the content of the dimension. In the following chapter, we elaborate on the prerequisites and algorithm for the delta view construction.

A. Delta view construction

Algorithm for the delta view construction will be explained with the help of the running example. Figure 1 shows a simplified version of the relational database subset used to populate dStudent dimension table:

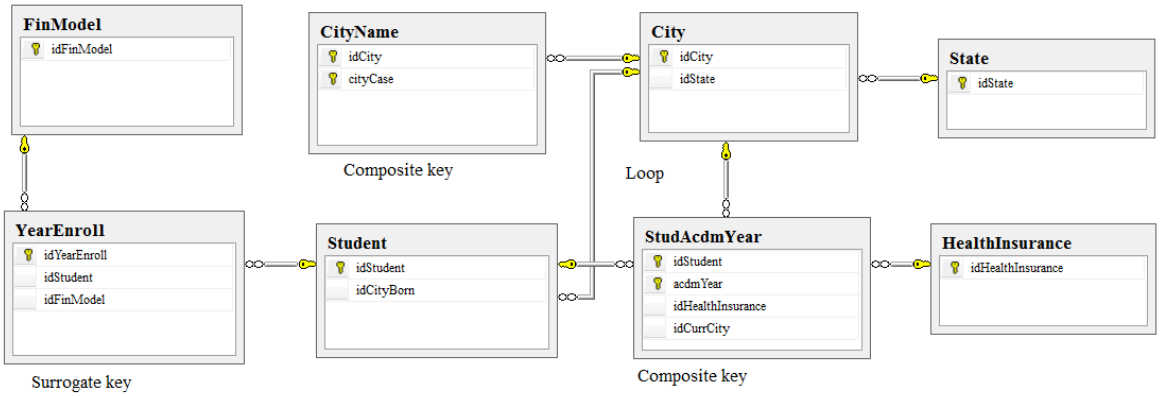

Figure 1 Relational model used to populate dStudent dimension table

For the sake of simplicity, all attributes except primary and foreign keys have been removed. Student enrolls in 0..N years using one of the supported financial models (scholarship, self-funded, etc.). Also, for each academic year we keep track of current city (and state) of residence and student's health insurance. CityName is specified in different word grammatical cases (in Croatian language there are seven different grammatical cases) because different cases are needed for different contexts (in various reports). Similar constructs appear in multilingual databases where a name for an entity is specified in various languages.

From this model, various dimension attributes are calculated. Some are trivial (e.g. dStudent.currCityName), while others have to be calculated with stored procedures (e.g. a flag indicating whether student repeated/failed any academic year, whether the first/last year enrollment was funded by the Ministry of Science, etc.). Granulation of dStudent dimensional table is the same as Student – one record per one student. So, the goal is to determine all primary keys (idStudent) that have changed in between two loads. We assume that all tables have accompanying CDC tables, having the same name but with the underscore prefix, i.e. _Student, _City, etc.

Any change in tables referenced by student, branching out, will affect the denormalized dStudent table. For instance, if the name of the city or state changes, this will affect dStudent dimension content both directly (via CityBorn relationship) and indirectly (via StudAcdmYear table, and current City/State attributes). At first, it might appear as if it is enough to start from the Student table and follow the referenced tables, however that is only part of the solution: referencing tables might also have an impact on the base table, e.g. YearEnroll is such a table. The same is true for all other tables that are iterated with the algorithm, e.g. CityName references and affects City table (in this context). These directions or ways that data from a table affects another table and consequently the base table used to populate the dimension table, cannot be determined just by inspecting the foreign key relationships. They have to be manually assigned by the domain expert. A tool can be used to assist in this task: using the foreign key relationships a graph can be constructed with default directions assigned according to the foreign key cardinalities. After that, a domain expert only has to correct directions of certain, if any, "arrows". Figure 2 shows such a graph for the example used. Arrow directions can be interpreted as "data flows" in the context of

dimension table being considered. That is, data from CityName "flows", via City, to the dimension table dStudent.

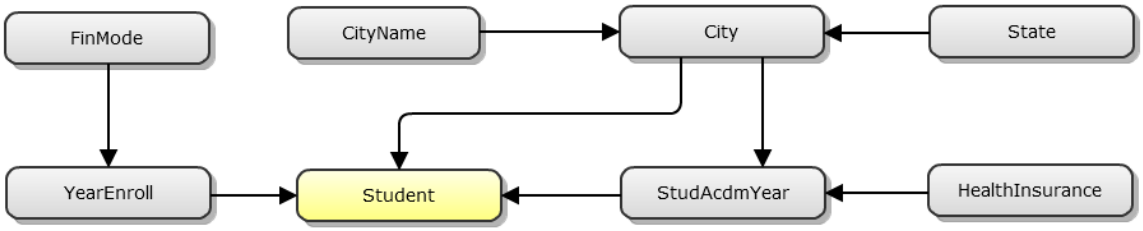

Figure 2 A data flow graph for the relational model in Figure 1

In terms of metadata, to support such setup, one only has to add a single flag to the metadata table describing the foreign keys: a flag that indicates which way the data is "flowing". In the conclusion, the standard metadata information (tables, primary key, foreign keys) enriched with a single flag in foreign key metadata table is enough information to construct the delta view for the dimension table.

Note that though we refer to relationships between tables as "foreign keys", in general, they don't have to be. The graph in fact represents ways in which tables have been joined throughout the ETL process to produce the dimension table. These can be arbitrary joins. Furthermore, the relational database might not even employ foreign keys for some reason. This only makes metadata definition process a bit less trivial, since design expert has to manually connect the tables, rather than leveraging the foreign key relationship information read from the RDBMS's system catalog.

The delta view construction idea is to, starting from the base table (e.g. Student), recursively traverse the graph and gather primary keys of the related tables. The related tables are divided in two sets:

- **REFD** – a set of tables **referenced** by the current table (e.g.
  REFD (Student) = {City},
  REFD (City) = {State})
- **REFING** – a set of tables **referencing** the current table (e.g.
  REFING (Student) = {YearEnroll, StudAcdmYear},
  REFING (City) = {CityName, StudAcdmYear, Student})

Also, we assume that every table t has a corresponding t' CDC table that contains at least primary key attributes (denoted with PK(t)) and operation attribute (update, insert or delete), e.g. for t = Student, t' = _Student and PK(t) = {idStudent}. For the sake of simplicity, in the definition of delta view we omit the operation attribute, though it should appear on every projection operation where PK(t) is used. Finally, the delta view $\boldsymbol{delta(t)}$ for the dimension table **t** is given with:

$$delta(t) = cdc(t) \bigcup_{r \in REFD(t)} refdcdc(t,r) \bigcup_{r \in REFING(t)} refingcdc(t,r) \quad (1)$$

where:

$$cdc(t) = \pi_{PK(t)}\, t' \quad (2)$$

$$refdcdc(t,r) = \pi_{PK(t)}\, \mathrm{t} \rhd\lhd delta(r) \quad (3)$$

$$refingcdc(t,r) = \begin{cases} \pi_{PK(t)}\, delta(r), & if\ PK(t) \subseteq PK(r) \\ \pi_{PK(t)}\, delta(r) \rhd\lhd (\mathrm{r} \cup \sigma_{op='del'}\mathrm{r}'), & \text{otherwise} \end{cases} \quad (4)$$

Obviously, calling $\boldsymbol{refdcdc}$ and $\boldsymbol{refingcdc}$ results in recursive calls that traverse the entire graph. We have divided the related tables in two sets because they produce different SQL constructs to attain the primary keys: **Referenced** tables must be joined to the base table to get the base table's primary keys as stated in (3). For **referencing** tables, as stated in (4), there are two possible scenarios:

- Referencing table has a composite primary key whose subset is a foreign key referencing the current table (e.g. StudAcdmYear has {idStudent, acdmYear} primary key, where {idStudent} is used to reference the Student table).
  In this case, it is superfluous to join the referencing table to the current table since current table's CDC primary keys can be attained using referencing table only, e.g.
  $\pi_{idStudent}\ (delta(StudAcmdYear))$
  We denote this case in the final delta view example with the comment /* -ABBREV- */, as this is the abbreviated SQL construct, without the current table join.
- Referencing table has a surrogate key and references the current table via the foreign key attribute that is not a part of the primary key. In this case, the CDC set for the referencing table has to be calculated and then

joined with the same table to extract the foreign key. For instance, for the YearEnroll table:

$$\pi_{idStudent}(delta(\text{YearEnroll}) \rhd\lhd (\text{YearEnroll} \cup \sigma_{op='del'}(\text{YearEnroll})))$$

We denote (alias) the table with "exp" as in "expanded", since we are using the self-join to "expand the primary key" to get the foreign key. However, since we are using the *current* data to get the foreign key, we must also include (UNION) the deleted records. We denote this case in the final delta view example with the comment **the delete exception**.

Note that, when traversing the chart, certain nodes are reached more than once (e.g. City). *cdc* function for that node returns the same keys (SQL) so there is no need to execute (traverse the subgraph) more than once. More precisely, our primary concern is not with the algorithm execution time or complexity in that respect, since these charts are small – it is hard to imagine more than few hundred nodes (tables) which presents no problem.

```
WITH WCity (idCity) AS (
      SELECT _City.idCity
        FROM _City
      UNION                          /* - REFING ABBREV- */
      SELECT CityName111.idCity              /* -ABBREV- */
        FROM  (
         SELECT _CityName.idCity, _CityName.cityCase
           FROM _CityName) AS CityName111
      UNION    /* REFD UNION */
      SELECT City.idCity
        FROM City
        JOIN  (
         SELECT _State.idState
           FROM _State) AS State112
          ON City.idState = State112.idState)
SELECT _Student.idStudent
  FROM _Student
UNION                  /* - REFING ABBREV- */
SELECT StudAcdmYear1.idStudent               /* -ABBREV- */
  FROM  (
   SELECT _StudAcdmYear.idStudent, _StudAcdmYear.acdmYear
     FROM _StudAcdmYear
   UNION    /* REFD UNION */
   SELECT StudAcdmYear.idStudent, StudAcdmYear.acdmYear
     FROM StudAcdmYear
     JOIN  WCity AS City11
       ON StudAcdmYear.idCurrCity = City11.idCity
   UNION    /* REFD UNION */
   SELECT StudAcdmYear.idStudent, StudAcdmYear.acdmYear
     FROM StudAcdmYear
     JOIN  (
      SELECT _HealthInsurance.idHealthInsurance
        FROM _HealthInsurance) AS HealthInsurance12
       ON StudAcdmYear.idHealthInsurance =
HealthInsurance12.idHealthInsurance) AS StudAcdmYear1
UNION                  /* -REFING JOIN- */
SELECT Student_Exp_Student.idStudent
  FROM  (
   SELECT _YearEnroll.idYearEnroll
     FROM _YearEnroll
   UNION    /* REFD UNION */
   SELECT YearEnroll.idYearEnroll
     FROM YearEnroll
     JOIN  (
      SELECT _FinModel.idFinModel
        FROM _FinModel) AS FinModel21
       ON YearEnroll.idFinModel = FinModel21.idFinModel) AS
YearEnroll2
  JOIN  YearEnroll AS Student_Exp_Student
    ON Student_Exp_Student.idYearEnroll = YearEnroll2.idYearEnroll
 UNION (SELECT idStudent FROM _YearEnroll WHERE operation = 'd')
/* DEL EXCPTN */
UNION    /* REFD UNION */
SELECT Student.idStudent
  FROM Student
  JOIN  WCity AS City3
    ON Student.idCityBorn = City3.idCity
```

Figure 3 Final delta view for Student dimension table

We are concerned with creating more compact and readable SQL which is, hopefully, more beneficial to the relational engine in terms of query optimization. To that end, when implementing the above algorithm, we use the ANSI SQL-99 WITH CLAUSE to define reusable SQL statements or "local views". Every node that is reached more than once will create a WITH CLAUSE that will be used more than once in the main SELECT statement. With clauses may be referencing each other, so it is important to order them properly. Nodes further from the base table should be ordered first. For the node's distance from the base table we take the maximal distance, since a node can be reached via different routes, e.g. City has distances 1 and 2 (via *StudAcmdYear*), therefore its distance is 2

Finally, **Figure 3** shows the final delta view for the Student dimension table.

We have applied this incremental loading technique to the real world project dimension table consisting of 62 attributes and two accompanying minidimensions (31 and 19 attributes), that is, 112 attributes in total. Dimension itself is based on 23 relational tables and trigger based change data capture is used to detect changes in the data.

Table I shows the average dimension load times accumulated over the years (N is the number of load times, where one load corresponds to one day). When we switched from full reload to the proposed delta load, the average duration was about 89 minutes. Currently, using delta load the average duration is only 4 minutes. We've continued to perform full reloads occasionally (on weekends), for testing purposes, and the full reload duration with the current data volume averages roughly 127 minutes. Obviously, by employing incremental loading approach we have significantly reduced the time spent to populate the dimension.

Table I Average load times in a real world case

Load type	N (loads)	Average (min)
Full	707	88,67
Delta	1276	4,03
Full (test)	170	126,97

Initially, we have constructed the delta view by hand and spent several days writing and testing the query. Using the proposed algorithm, we were able to describe and generate the same delta view in less than an hour. The view spans 227 lines of SQL using the same formatting as shown in Figure **3**.

V. CONCLUSION

In this paper we have presented an algorithm for delta view construction that enables incremental loading of dimension tables. This method is suitable for large, complicated (both in terms of attribute and row count) dimensions, , because they can have significant impact on the ETL process. We have shown that delta view, yielding the keys of records that need to be incrementally

(re)processed, can be constructed from the graph of data flow dependencies that can be fairly easy assembled.
Obviously, incremental loading of large dimensions can significantly shorten the ETL process, but writing (and maintaining!) large delta views manually is complex and error prone. On the other hand, data flow graph is simple to define, especially with the help of a tool that, for instance, uses RDBMS's metadata. We therefore find this algorithmic approach to delta view generation to be the apt solution for the given problem. Finally, we have verified it by applying it to the real world case and achieved significant reduction in loading times.

Abstract - In this study, SimBusPro, a novel business process modelling and optimisation tool that runs on Cloud, is introduced. The tool is developed during a project called SCI-BUS (Scientific Gateway-Based User Support) under the seventh Framework of the European Commission. SimBusPro has a visual editor that uses BPMN 2.0 notation. A wide range of commercial and academic workflow processes can be modelled, simulated and optimised using SimBusPro. The distributed computational architecture of the tool is capable of completing complex simulations in reasonable times. In addition to these features, with the alternative resource planning module, SimBusPro allows optimal resource assignments to be made for the processes that have been modelled.

I. INTRODUCTION

In the contemporary business world, it is necessary for firms to operate in a manner that is both cost-effective and responsive to changing conditions so as to ensure their existence. Thus, firms must continually analyse their business processes in their pursuit of continuous improvement, thereby bringing about continual improvements in their resource utilisation efficiency. One of the most prominent ways in which this continuous improvement can be achieved is via the use of business process modelling, and simulation and optimisation software [1].

SimBusPro [2], which was developed during a project called SCI-BUS (Scientific Gateway-Based User Support) under the 7th Framework of the European Commission, is an example of such a software program. In essence, SimBusPro is a simulation and optimisation-based decision support tool that can be run on cloud [3]. By using SimBusPro's modelling editor, it is possible to design and develop workflow diagrams that are in line with BPMN 2.0 [4, 5] standards. Once such a model has been established, its simulation, using parameters defined and entered by the user, can be carried out, which, in turn, will yield highly accurate and precise simulation reports containing various graphs representing miscellaneous information about the process that has been modelled. Via the results that are displayed in these reports, it is possible to make analyses that will lead to the achievement of increased efficiency in the utilisation of the resources of the processes that have been modelled.

Business process modelling software programs, despite having the ability to model business processes with consummate ease, are typically limited by their ability to attain simulation results in reasonable times. SimBusPro is an exception to this and can generate simulation reports of complex models rapidly as it is compatible with Cloud technology. SimBusPro uses a scalable, distributed architecture in its calculating infrastructure. As a result, besides possessing the capability to perform simulations rapidly, SimBusPro eliminates any need for setup and updating, meaning that it is always readily available for use. SimBusPro makes use of a pay-per-use model, thereby allowing multiple users to benefit simultaneously in a secure environment.

In July 2014, from the results that were obtained from a modelling and simulation competition in which SimBusPro was used as the modelling and simulating tool, users provided feedback about the software, thereby enabling its weaknesses to be identified. Since then, the problems identified have been addressed and SimBusPro has become more capable of successfully responding to the needs of its prospective users. SimBusPro is now extremely accomplished in the modelling and simulation of a very broad spectrum of processes [2]. Thus far in the paper, SimBusPro's various proficiencies have been discussed. In the second part of the paper, SimBusPro's programming design and architecture will be discussed. The third section of the paper will discuss the simulation-based optimisation of a pizzeria, whilst the fourth section will discuss results, and planned actions of the future.

II. SIMBUSPRO'S PROGRAMMING ARCHITECTURE

Business process modelling, simulation and optimisation software programs are designed to model the service and manufacturing processes of business and firms, and to subsequently optimise their resource utilisations. Using SimBusPro, it is possible to obtain simulation data about processes in a virtual environment [6, 9]. This will enable those who opt to use SimBusPro to test certain hypotheses about their business processes without actually having to carry them out in real-life, which, effectively, will enable them save a lot of time and money.

A. *BPMN 2.0 Based Visual Editor*

BPMN is a universal modelling notation through which businesses are presented with a means with which they can display their internal procedures [4]. BPMN is a model established by an organization called OMG (Object Management Group Inc.) in which businesses and other such entities are presented with a means, or a platform, through which their internal business procedures in a graphical notation. This model was established in the hope of giving organization a means to communicate these procedures in a standard manner, thus facilitating the business transactions and performance collaborations between different organizations. This model will ensure that businesses understand themselves and the participants in their business more clearly and will enable them to adjust to new business circumstances quickly and with ease.

The SimBusPro editor was developed using Eclipse's BPMN 2.0 library. Using this editor, it is possible to model a broad spectrum of business processes using all elements that are present in BPMN 2.0. In Figure 1, the fundamental elements of BPMN 2.0 are shown:

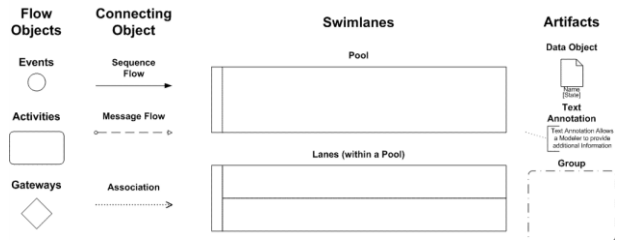

Figure 1. Fundamental elements of BPMN 2.0

Three basic elements are events, activities and gateways. Events are occurrences cannot be controlled internally - such as the arrival of a message. Events trigger the start or end of activities within a business process. Tasks are planned activities that are carried out by using the resources of business process. They may be manual based on service tool or based on the sending or receiving of messages. Gateways indicate decision points within processes where the work flow is effectively split.

B. *Infrastructure of SimBusPro*

The SimBusPro Gateway is used for optimizing business processes through simulation by utilizing the SCI-BUS framework. To simulate multiple models simultaneously, the application sends models to the portal, which are then transferred grid machines via the gUSE system. The SimBusPro gateway has used the BOINC Desktop Grid as its Distributed Computing Infrastructure [7, 10, 11, 12, 13]. SimBusPro's architecture can be seen in Figure 2:

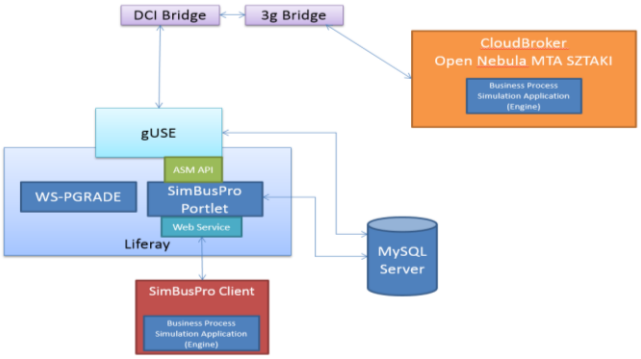

Figure 2. *SimBusPro*'s architecture

C. *Resource Utilisation Optimisation*

One prominent feature of SimBusPro is its ability to generate alternative solutions of models. This allows users to evaluate the performance of a given system under certain induced and controlled changes. SimBusPro enables users to toggle with the parameters of an existing model and display the results of the simulations of different versions of this model simultaneously on the Cloud. This endows users with the ability to easily identify superior models, thereby providing them with a means to improve their processes or systems. These capabilities will provide a multitude of benefits to firms who are seeking to improve their existing business processes or systems, and also to those who are planning the development of some system but have several alternative versions to choose from.

Thus, SimBusPro can be used to optimise the number of resources that are used in a modelled system. To illustrate the way in which SimBusPro finds an optimal solution among various alternative models, let us imagine a fictional pizzeria. Let us assume further that the number of employees is not fixed and that 1 to 10 waiters, 1 to 8 delivery boys and 2 to 4 chefs can be employed. In such a case, SimBusPro would calculate all of the possible resource combinations and identify the best model with respect to some key performance indicator – such as cost or customers served. In this scenario, SimBusPro must evaluate 240 separate models (number of waiters * number of delivery boys * number of chefs) and identify the best one among the lot. Due to the fact that SimBusPro makes use of a multitude of processors upon the Cloud in carrying out its calculations, it can generate the simulation reports corresponding to alternative models in reasonable times.

D. *Multi-Objective Optimisation Capability*

SimBusPro has the capability of carrying out both single-objective and multi-objective optimisations [8]. Multi-objective optimisations may be carried out with respect to any parameter including cost and process times (both of which it would typically seek to minimise). In the formula for multi-objective optimisation, each measure that is aimed to be optimised is multiplied by some weighted coefficient, the size of which depends on its importance. The formula is as follows:

$$\min\left(\sum_{i=1}^{n} w_i r_i\right)$$

where n is the number of measures that are to be optimised, w_i is the weighted coefficient of measure i and r_i is the value that is assumed by measure i.

III. SOLUTION OF AN OPTIMISATION PROBLEM

In this section of the paper, the optimisation of the business processes of a pizzeria will be discussed. The business processes of this pizzeria were modelled and simulated using SimBusPro. Alternative models were then generated by running simulations on the Cloud, after which an analysis of the alternatives was carried out in order to identify the optimal solution.

A. Optimisation of the Business Processes of a Pizzeria

The problem is as follows: A pizzeria is open for 10 hours (600 minutes) a day. When a customer arrives (once every 2 minutes) he/she chooses whether to eat in (80%) or take away (20%). The restaurant also accepts orders via phone or internet (which arrive once every 5 minutes). The details of the different processes that take place within the restaurant are given in Tables 1-3.

TABLE I. EAT IN

Activity	Duration	Resources used
Take a seat	1 minute	
Order	5 minutes	1 waiter
Pizza made	15 minutes	1 chef
Dine	15 minutes	
Pay and leave	5 minutes	1 waiter

TABLE II. TAKE AWAY

Activity	Duration	Resources used
Go to counter	0.5 minutes	
Order	2 minutes	1 clerk
Payment	1.5 minutes	1 clerk
Pizza made and exit	10 minutes	1 chef

TABLE III. ONLINE/ PHONE ORDERS

Activity	Duration	Resources used
Order	2 minutes	1 telephone operator
Pizza made	10 minutes	1 chef
Delivery and payment	15 minutes	1 delivery boy
Return to restaurant	13 minutes	1 delivery boy

The restaurant currently employs 5 waiters, 10 chefs, 1 clerk, 1 telephone operator and 5 delivery boys, all of whom are paid $6 per hour. Assuming that the restaurant can spend up to $1,400 daily on wages, find the optimal combination of employees that is required to maximise the number of customers served during the course of a day.

From the problem description, the following BPMN 2.0 diagram may be constructed as in Figure 3.

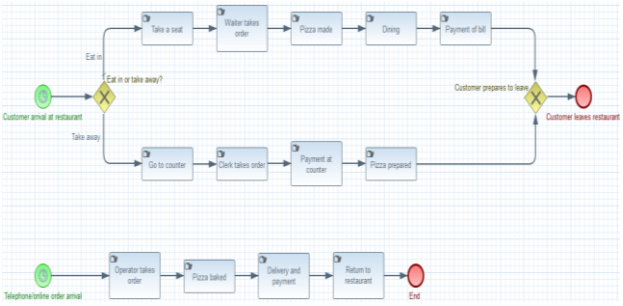

Figure 3. BPMN Diagram of the Pizzeria

Once this model was constructed on SimBusPro and the simulation data corresponding to the problem description were filled in, the model was simulated, yielding simulation reports containing miscellaneous information about the process.

B. Analysis Results

Before alternative models were developed and simulated in the search for the optimal solution, the simulation results of the existing system were analysed. The fundamental information regarding the simulation of the existing system is displayed in Table 4.

TABLE IV. SIMULATION RESULTS OF THE EXISTING SYSTEM

Simulation period	600 minutes
Tokens entering the system	420
Tokens existing the system	376
Total cost	$1,320

Of the 420 customers that entered the system, whether it be in person either to eat in or take away, or via orders placed by telephone or internet, 376 managed to get served within the simulation period, which corresponds to 89.5%. Thus, in the existing system, 89.5% of customers who enter the system get served during the course of a working day, whereas the remaining 10.5% do not. This is due to the fact that they must await the resources (the employees) that have been occupied by prior customers. The expenditure on daily wages can be seen from the table to be $1,320. The objective of this optimisation problem is to ultimately serve the maximum amount of customers without exceeding the daily wage budget of $1,400. In order to achieve this goal, simulation results from the existing system must be analysed.

The resource utilization rates must be analysed to determine which resources are being used efficiently, and which are not. The resource utilisation rates can be seen in Figure 4.

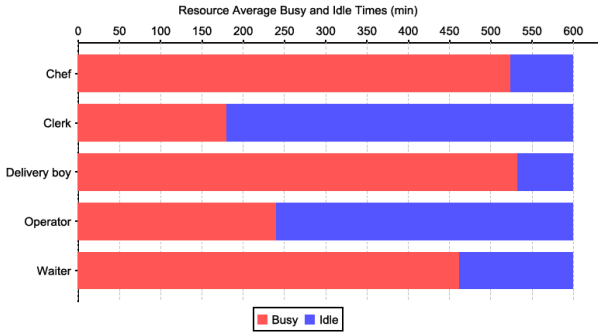

Figure 4. Utilisation Rates of the Pizzeria's Resources

From this graph, it can be seen that the waiters, chefs and delivery boys are extremely busy whereas the clerks and telephone operators are not. This shows that in the prevention of the formation of queues and as per the objective of serving the maximum amount of customers, ideally, more waiters, chefs and delivery boys should be hired. However, the management must take heed not to violate the budget constraint. Thus, the resource for which most customers are waiting for must be determined, and its numbers must be increased.

Figure 5 shows the total time waited for each resource by the customers throughout the simulation time span.

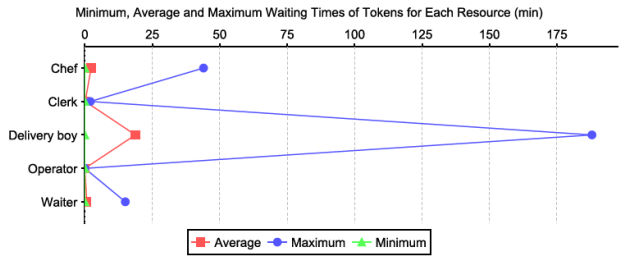

Figure 5. Minimum, Maximum and Average Times Waited by Tokens for each resource

One can see from this graph that it is the waiters, chefs and delivery boys for whom the customers wait the longest periods of time. This reflects the information shown previously in the utilisation rates graph. The total time waited for the delivery boy is particularly high (assuming an average value of approximately 20 minutes and a maximum value of over 180 minutes), thereby once again hinting at the fact that the hiring of new (a) delivery boy(s) ought to be priorities in order to improve the existing system.

In Figure 6, the total number of customers that wait for each resource throughout the simulation duration is displayed.

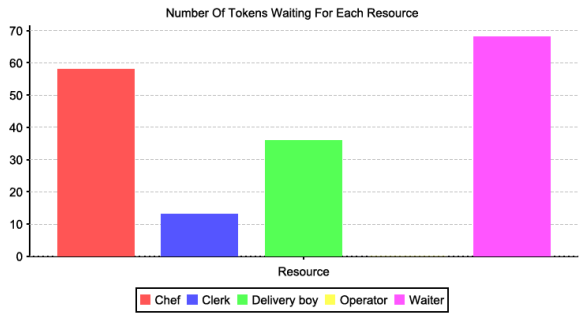

Figure 6. The Number of Customers that wait for each Resource

The graph shows that most customers are waiting for waiters, chefs and delivery boys. There are also some customers who wait for the clerk. However, the number waiting for this resource is far less when compared to the 3 aforementioned resources. This graph also shows that none of the customers wait for the operator, who is always readily available.

To summarise, the resource utilisation graphs show that the chefs, delivery boys and waiters are extremely busy, whereas the clerk and operator are not. The waiting times of tokens for each resource graph shows that tokens do not wait for clerks or operators for prolonged periods of time, whereas queues may sometimes be formed where they sometimes have to wait for the other 3 resources. This graph shows that it is the chefs, delivery boys and waiters for which most tokens have to wait. This information shows that, in the establishment of alternative models, the numbers of the chefs, waiters and delivery boys have to be modified, whereas the numbers of the operators and clerks should be kept constant.

Our analysis shows that in our search for alternative solutions, the number of chefs will either be 9, 10 or 11, whereas the numbers of the waiters and delivery boys will take the values of 4, 5 and 6. Thus, this corresponds to 27 alternative solutions. SimBusPro will generate simulation reports of the different resource combinations. Among these alternative solutions, the one that serves the most customers whilst meeting budget constraints will be chosen as the optimal.

It takes approximately 7 minutes to run each simulation. 27 separate processors were used in order to carry out the simulation of the alternative solutions, corresponding to a total simulation time of 7-8 minutes. Among the 27 alternatives, the optimal solution was identified as the one having served the most customers whilst not breaching the budget constraint. In this new system, the restaurant is to employ 5 waiters, 10 chefs, 1 clerk, 1 operator and 6 delivery boys. In this solution, the only difference from the original system is that 1 more delivery boy has been hired. The basic information corresponding to the simulation of the new system is displayed in Table 5.

TABLE V. SIMULATION RESULTS OF THE OPTIMAL SOLUTION

Simulation period	**600 minutes**
Tokens entering the system	420
Tokens exiting the system	395
Total cost	$1,380

When compared to the previous system, it can be seen that the number of customers served during a typical working day has increased to 395, which corresponds to a 5% increase and that the daily wage budget of $1,400 has not been exceeded.

Figure 7 shows the number of tokens waiting for each resource in the optimal system.

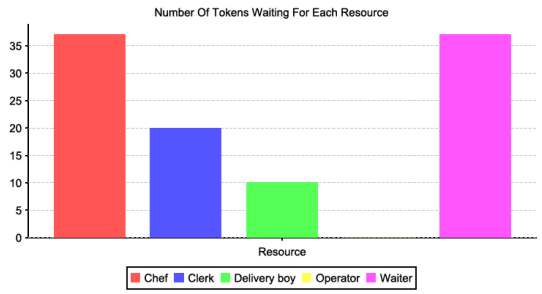

Figure 7. The Number of tokens that wait for each Resource in the Optimal System

When compared to the original system, the numbers of the customers waiting for the chefs, delivery boys and waiters have decreased by 38%, 71% and 47% respectively, whereas the number waiting for the clerk has increased by 66% (due to the fact that he/she is now being kept busier by serving an increased number of customers). The mean queue length in the system has therefore decreased by 41%.

Figure 8 shows the maximum, minimum and average time waited by tokens for each resource in the optimised system.

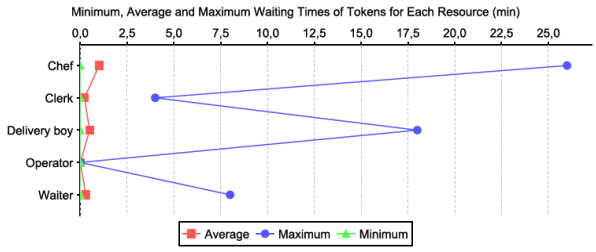

Figure 8. Time Waited by Tokens for each Resource in the Optimal System

When compared to the original data, the average waiting times in the queues of the system can be seen to have decreased by 90%, whereas the decrease in the maximum waiting times is 78%. Thus, in the new system, customer satisfaction can be expected to rise significantly as a result of no longer having to wait as much to be served.

IV. CONLUSION

In this paper, the description of SimBusPro, a simulation-based decision support tool that makes use of BPMN 2.0, has been discussed, and an optimisation problem has been solved. SimBusPro is proficient in the modelling and simulation of a broad spectrum of business processes. Being compatible with Cloud technologies, SimBusPro offers end users a plethora of advantages including the ability to perform rapid simulations. In the future, a new optimiser module that can solve integer programming and linear programming problems is planned to be added to the software. This module will allow for rapid optimisation, and will pose an alternative to the already-present simulation module.

This paper is the result of a research project carried out by three teams of bachelor and master programme students. The research analyzes the possibility and usability of connecting different technologies. The project resulted in a system prototype based on a web application with a relational database, mobile application using a CouchDB database and data warehouse for business intelligence purposes. The three parts of the system communicate through a web service based on a node.js environment and MongoDB database. The developed system provides real-time reporting that helps decision making during handball matches and, by using online analytical processing and data mining, detailed post-match data analysis. The advanced handball statistics system offers a complete perspective of match dynamics and cumulative player and team efficiency by game segments in the time domain. This way it provides coaches with highly usable data, allowing the analysis and adaptation of training methods, coupled with efficient game dynamics monitoring and the detection of players' behavioral patterns during matches. Finally, the paper presents the challenges concerning distributed software development in the team with various levels of member's knowledge, teamwork and organization.

I. INTRODUCTION

The Advanced Handball Statistics system was envisioned as a group of several projects that would, as a whole, provide an efficient way of tracking and processing all the actions that occur during handball matches, as well as managing administrative data connected to handball.

In section II, the system architecture is presented. Section III gives the overview of web application for data administration structure and development. Section IV illustrates design and development of the mobile application. Section V presents the data warehouse design with accompanying web application and ETL processes. Section VI describes the web service components and finally, section VII depicts challenges in project management.

II. THE SYSTEM AS A WHOLE

The system consists of three parts: a web application with a transactional database, a mobile application and a web application connected to a data warehouse as shown in Fig 1. The web application with the transactional database is used for data administration, while the mobile application is used for real-time action logging, generating data that is then transferred into the data warehouse. The application connected to the data warehouse is used for calculating the statistics of different partitions (team, player, match) and generating statistical reports.

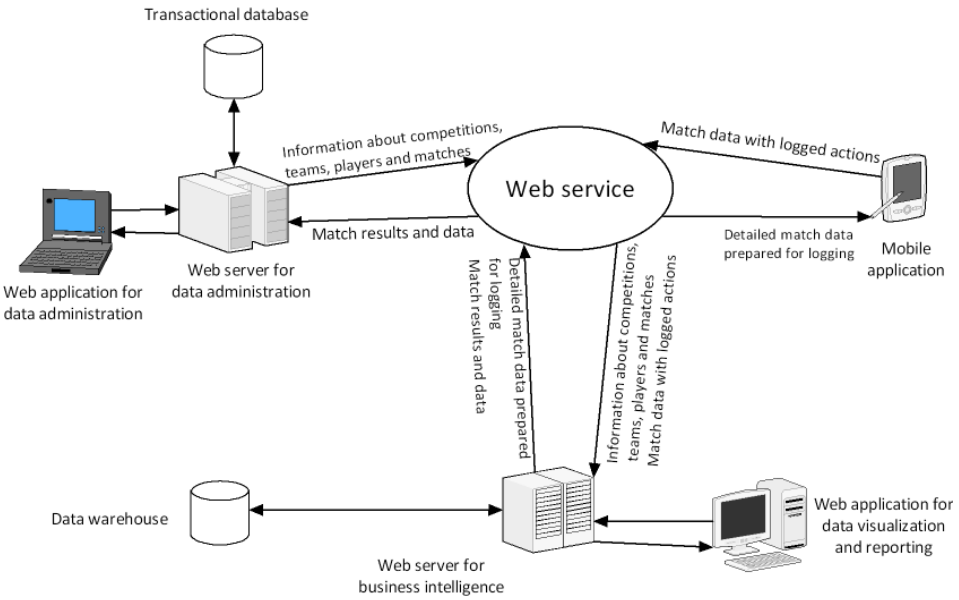

Figure 1. System diagram

None of the applications can function without the other; the one with the transactional database is used to generate a record about a match, containing basic information about it (the teams playing, the season, the competition…), which is then transferred into the data warehouse for further processing. Afterwards, the record is sent to the mobile application in order to provide the data necessary for action logging during the match. The data recorded through the mobile application is afterwards deployed into the data warehouse and it is used for statistical views provided by the application connected directly to the data warehouse. All of the communication between the applications goes through a web service.

III. WEB APPLICATION FOR DATA ADMINISTRATION

The web application for data administration is used to collect and manage administration data related to handball. Therefore, the application was connected to a corresponding transactional database.

The web application allows the user to enter data about handball clubs, competition organization and the information about players and officials. This data is then transmitted to other modules (data warehouse and mobile application). The main parts of the application are the SQL database and MVC web application, described in the following sections.

A. Used tools and technologies

The application was implemented using the object oriented programming language C# along with the development framework ASP.NET MVC [1] and view engine "Razor".

The relational database management system used was Microsoft SQL Server [2]. The database was built using the user interface provided by the program SQL Server Management Studio. For object-relational mapping the open source framework Entity Framework was used.

Also, the presentation language for web page creation called HyperText Markup Language [3] (abbrev. HTML) and the style sheet language for HTML documents - Cascading Style Sheets [3] (abbrev. CSS) were used along with the above listed main technologies.

B. Transactional database

The transactional database was organized through the relational model of data and was fully normalized in order to protect the data and to optimize the database by eliminating redundancy and inconsistency. The focus was also on choosing the appropriate type and size of data attributes within relations. Generally, smaller data types were used where possible. For example, the attributes height and weight from the table "Player" are of type tinyint which uses 1 byte instead of 4 bytes for integer values.

When deciding whether to use a variable or fixed length of character data types, the approximate average, the minimum, and maximum data length were observed.

A fixed length was used for strings whose length does not vary. Variable length was used where the average length was greater than four bytes and where the length of data often varies.

An auto-increment field was created in all tables and was declared to be the primary key. To ensure no duplicate values are entered in specific columns that do not participate in a primary key, unique indexes were created. Relations between database tables were created by specifying corresponding foreign keys.

In case of inheritance (e.g. an official person can be of the supervisor or judge subtype) one table per subclass strategy was used, meaning the common data was stored in a parent table and subclass specific fields were stored in subclass tables.

C. MVC web application

As mentioned earlier, the web application was built using the ASP.NET MVC application framework [1]. MVC is an abbreviated name for the Model-View-Controller architectural pattern which separates applications into three main components: the model, the view, and the controller.

Model objects help implement the logic needed for the applications' data domain. In this project, model objects retrieve and store data in the earlier described relational database. Entity Framework is used for mapping database entities with corresponding model classes. In this case a database first approach strategy was used, i.e. Entity Framework generated data access classes for the existing database. Entity Framework also provides an automated mechanism for accessing and storing data in the database.

Views handle and display the applications' user interface. Almost all the views in this application are created from the model data, i.e. the views are based on them. Razor syntax [4] was used for their creation. For almost each model class there are five views implemented: Index, Create, Edit, Delete, and Details. The Index view displays the main data (the data that should interest most users) from a certain table in the database and the rest of them are used according to their name.

Controllers manage user interaction. Based on user input, they can process and store entered data or retrieve data from the model, select a view to render and provide that view with the data that needs to be displayed. There are over twenty controllers in this application, each for managing a particular model entity and the views based on it.

Validation rules were created upon the database and transferred to model objects. Data types are automatically checked in views and the rest of the validation is done in the controllers.

When using the web application the user can see a sidebar menu containing links to all the relevant entities like "Player", "Club", "Club competition" etc. as shown in Fig. 2.

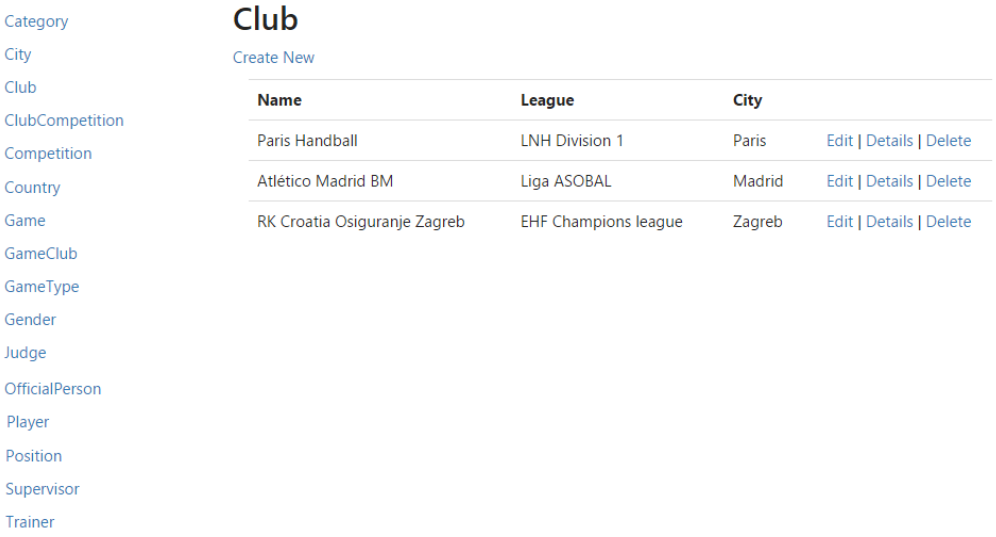

Figure 2. Screenshot of the MVC web application for data administration

Each of the links navigates to the Index view of the corresponding controller. By clicking on the chosen link, the user will be presented with all the data from the database related to that entity. In addition to that, links leading to the Edit, Create, Details and Delete view of a particular entity will also be displayed and placed in an intuitive place. When entering data, the user will be provided with user-friendly input fields like dropdown lists (where appropriate), fields for integer numbers, etc. In case of entering invalid values or not filling the required fields, the user will get corresponding validation messages.

IV. MOBILE APPLICATION

The Android operating system was used as a base for the development of the client side of this application. Through the flexibility and capabilities of Android OS the user is offered a host of options not found in comparable mobile operating systems regarding handball game analysis and statistics. The simplicity and the ease of use of the application are secured through a drag and drop graphical user interface.

The application is run on a tablet and its initial execution request asks for an internet connection. Through a web service, an updated version is received which contains the list of games whose data the user would like to analyze, monitor and process.

Despite the fact that the application communicates with other parts of the system through a web service, after loading the data from the database on the server side and a synchronization with it (if needed), further work is possible without an internet connection.

After the match has been selected, at each initial launch of the application the first step the user has to take is to select and set the player to a certain predefined position in order to help the user react faster to the action which happened on the field.

After choosing the position, a list of players appears, from which the user can select the player playing at that position.

The logging of the events during a game can begin as soon as the user clicks on the Start button, which in turn starts the timer that counts down time. The basic operation of the application is based on two cases, the first case being when the selected team attacks the goal and the second when the relevant team defends or focuses on the defense of their own goal. Depending on which selected functionality is in progress, the actions based on the user's activities in the application are generated. An example of the most often used action is a shot to the goal by a player at a specific time of the match, additionally described by shot side and height, position of the player from which he took the shot and in the case the player scored the goal from the shot, a flag marking the positive actions is set.

Every action or event is closely connected to a particular player, and all the changes are stored in a local database.

The right choice of an adequate database was essential in the design of the system. Since the data collected through the application is structured and distributed, a non-relational database called Couchbase [4] was chosen, which allows easy data loading for web services.

Data is stored in a local database on the device in JSON format, which can later be synchronized with the main database on the server. Considering that the data is presented in a very detailed way, it tends to be of very low granularity. The expandability of the system is secured through the class with defined attributes which is generated by the user in order to store data and describe the events.

V. WEB APPLICATION FOR GENERATING REPORTS

The statistical analysis of match actions is based on business intelligence tools. The basis for it is the data

warehouse, built on Kimball's bottom-up approach with a star scheme [5], part of it shown on Fig. 3. In the initial stage of system development, the data warehouse was used for generating simple reports from available data, leaving the selection of query conditions to the user's previously entered data.

The idea behind handball statistics powered by business intelligence is to enable simple access to data during and after the match through an interface which allows a fast and precise choice of data. The choices of reports differ by their depth and data scope, varying from a single match report to player and team statistics.

The match report is a list of match events (actions), entered through the mobile application and modeled through ETL (Extract-Transform-Load) [5] processes for storing in the data warehouse without any further processing. The other two reports (player statistics and team statistics) process the stored match action data to calculate the players' efficiency by game segments. Player statistics was designed to show all the data related to a specific player, whereas team statistics used only aggregated player data.

As a part of the distributed system, this application uses data from both the mobile application and the data administration application, thus completing the communication in the system. The details about matches, players, teams and competitions are gathered from the web service, which serves as an interface, and stored before they are ready to be used in the mobile application. Such a procedure not only ensures the integrity of data throughout the whole system, preventing double data entering, but also allows the restriction of data access if privacy is needed.

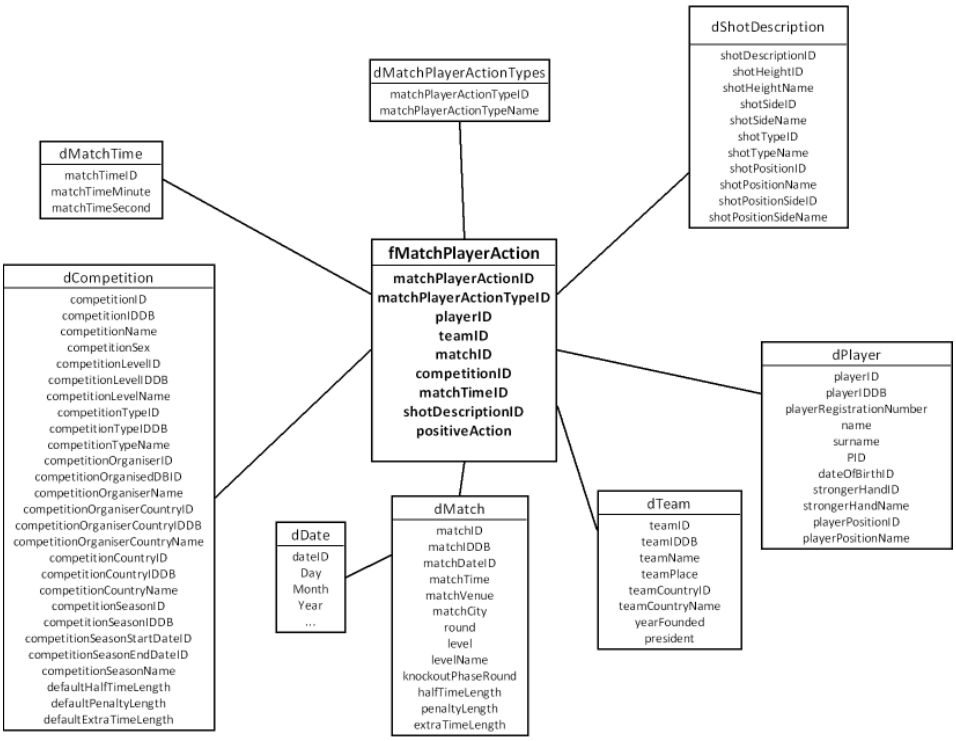

Figure 3. Diagram of the fact table fMatchPlayerAction with relevant dimension tables, in which the data with match actions is stored

Data processing was initially implemented in the web application with the processing functions developed solely as functions in the code. In the second stage of the development, detailed data analysis is enabled by introducing OLAP (Online Analytical Processing) [4], allowing slicing, dicing and drill-down operations to be executed over the data, making the initial code-based data processing implementation obsolete. OLAP, in terms of the match data analysis, give more flexibility by allowing users to focus on one or more dimensions of the game (e. g. the directions of player's shot through one or more matches and following the shots by game segments, how many goals team or player scores after the passive attack signal or who takes most responsibility for shots after the passive attack signal), thus giving more precise information suitable for adapting the game tactics.

The web application that provides the user with data access was developed in ASP.NET MVC, connected to the data warehouse through an interface on the middleware's business logic layer, which provides access to data through predefined methods, accessible in the controller part of the web application.

As the system consists of the three modules, ETL processes [5] are needed in order to store consistent data into the data warehouse. They are executed as the new data appears on a web service interface, where the extraction matches the process of collecting the data from the web service, where it's stored in JSON format.

In the transformation process, a function takes the data from JSON structure and adjusts it to suitable classes in the application's core layer, without the need for integrity checking which is ensured as previously described.

Data collected from the web application for data administration loads into all dimension tables and fact tables which follow the processes of team personnel changes (player transfers, coach assignments etc.) and assigning the match official personnel (referees, supervisors etc.). As for the data originating from the mobile application, it is loaded only into fact tables related to processes of match actions (as described before) and team match events, such as choosing team officials, following timeouts during the match and progressive penalties given to the team officials.

VI. WEB SERVICE

The web service is the main method of communication between the mobile application and the database. It is used to provide the option of update to the mobile application or synchronize data with it, and provides a way for the mobile application to enter gathered data into the database.

A. Used tools and technologies

The web service is established as a combination of a NodeJS[8] platform and a MongoDB[9] database implemented on MongoLab[10]. The RESTful[11] style was used and implemented via a node-restful library[12]. The data is sent as a JSON[13] encoded object which provides great flexibility of data type transferred, and is the favored way of transferring data while providing cross-domain flexibility by JSONP if necessary. The web service is located on the Azure server[14].

B. NodeJS and RESTful

NodeJS is a platform built on Chrome's JavaScript runtime[13] for building fast, scalable network applications easily. Its event-driven, non-blocking I/O model makes it lightweight, efficient and highly responsive. It does not matter how "complicated" the request is, the response will be instant, with a possible follow-up data stream.

RESTful is a software architecture style consisting of guidelines for creating scalable web services. Its main properties are performance, scalability, simplicity of interfaces, modifiability of components (even when the application is running), visibility of communication between components, portability and reliability. The communication with the client should be stateless – no client context should be stored on the server between requests. The communication is established via the HTTP protocol which is an application layer protocol based on the TCP transport protocol.

C. MongoDB on MongoLab

MongoDB is an open-source document database implementation of the NoSQL[5] database model made in a combination of C++, C# and Go. Its implementation of JSON-style documents is a perfect fit for JavaScript and the communication with the mobile application. It's hosted on MongoLab that manages the MongoDB database as a service.

A NoSQL database provides a mechanism for the storage and retrieval of data that is modeled in means other than the tabular relations used in traditional relational databases. That results in a simpler design, horizontal scaling and finer control of availability. Data structures in NoSQL databases (key-value, graph, document to name a few) differ from the ones used in relational databases, making some operations faster in NoSQL, and making some of them slower. Depending on the particular problem to be solved, it's crucial to select a suitable data structure. Data structures chosen in web service correspond with data structures in the system's application, making the transforming process easier without big refactoring of the previous code.

VII. PROJECT MANAGEMENT DURING DEVELOPING

The development of the advanced handball statistics project was a challenge on several levels. First of all, almost all of the members had their first contact with developing a sport statistics application, without any prior knowledge of the sport itself. By that, the students got in touch with typical development outside of the academic world, where the developed software usually is not in a domain which their knowledge covers.

Other important segments of the project were teamwork and workload distribution among the teams. Since the system was divided into three applications that could have been developed independently, only with prior given specifications, not only did the team leaders have freedom to focus just on their team, but it also allowed the teams to give more attention to the development itself, rather than data modeling for interoperability purposes.

Of the twelve students involved in the project, three are master program students and the rest are undergraduate (bachelor) program students. Each master program student became a team leader, while the undergraduate students had the opportunity to choose the part of the project which they found most interesting, thus creating four-member teams.

One of the project goals was to test whether the students that never came across technologies used in system development, but have basic programming skills, could adapt to the new development environment under the mentorship of more experienced students. The process started with gathering online materials, mostly tutorials, after which the team leaders helped the students utilize their newly gained knowledge to solve specific tasks, starting from smaller ones. By the end of the project, the undergraduate students were able to cope with more demanding tasks, which consequently led to a bigger mentors' involvement in debugging. The outcome

was satisfying, resulting in the undergraduate students being able to develop their own applications in the future.

Regarding project management, several tools were used to track the project's status and completeness of tasks. From the very beginning, the main communication method was a mailing list where all team members got the general information on the project's status and future tasks, complemented with Dropbox [16] as a main document repository, through which the members got access to system specifications, diagrams and tutorials. As for task management, Trello [17], an online application, provided enough possibilities that covered all the needs, where different project areas got their independent cards, with the possibility of restraining access to a specific card only to the team to which it belonged. It also allowed the tasks to get their deadlines assigned, according to a previously established schedule, and milestones to be set, which, in combination with the later mentioned GitHub [18], helped decision making regarding the reallocation of development resources.

Another important aspect of the development process was the usage of a distributed revision control system. Owing to the latest academic initiative, the choice got down to GitHub. From the very beginning, all team members were encouraged to track their development through their own branches, while checking for updates on the project's master branch. In order to prevent possible crashes of the master branch, a workflow of development was established, where only team leaders pushed code they previously approved through testing to the master branch, while other team members pushed their code only to their own branches, which later got merged to the leader's branch. This multiple-level hierarchy of code approving proved to be successful, since the team leaders had the opportunity to fix issues in the code or do small changes that did not require major refactoring. Also, a subsequent outcome was the development of a habit of tracking even the smallest changes during the development process, which gives opportunities not only to rollback possible errors, but also to track the status and progress of the development and, if possible, relocate development resources to project parts which require more attention or are left behind schedule.

VIII. Conclusion

The project encompassed the development of a system that provides an efficient way of tracking all handball matches, teams, and players, as well as all the player actions during a match. The system generates relevant statistics on demand.

The bachelor students learned how web applications and distributed systems are created and what the process of software development looks like. They developed their programming skills and discovered what it is like to work in teams.

The master program students honed their leadership and programming skills. They integrated several applications into one system via a web service, thus perfecting skills needed when dealing with distributed systems.

This project proved to be a challenge due to the vastness of the work involved and the number of participants, but it has also been an invaluable experience.

Further research in the project will lead to a self-learning system based on machine learning techniques which would detect and show various anomalies, usable in handball team optimization.

Acknowledgment

The authors would like to thank Microsoft Croatia for their help in acquiring access with academic benefits to the Azure platform, which ensured the system's complete functionality. Also, they would like to thank Marina Brebrić, Leon Fadljević, Ivan Golik, Velimir Lisec, Martina Martinović, Ana Matić, and Ana Šarčević for all the hard work they put into realizing this project.

Planiranje i nabava energije za pokriće gubitaka u distribucijskoj mreži

Igor Žarkić*, Zdravko Lipošćak* i Matjaž Malovrh**
*HEP-Operator distribucijskog sustava d.o.o., Zagreb, Hrvatska
** Landis+Gyr, Šenčur, Slovenija
igor.zarkic@hep.hr, zdravko.liposcak@hep.hr, matjaz.malovrh@landisgyr.com

Gubici električne energije u sustavu distribucije električne energije jednaki su razlici energije koja je ušla u distribucijsku mrežu i energije predane kupcima. HEP–Operator distribucijskog sustava d.o.o. dužan je osigurati električnu energiju za pokriće gubitaka u distribucijskoj mreži, nabavom na otvorenom tržištu električne energije.

Analizom dosad primjenjivanog postupka utvrđena je potreba izrade složenijih algoritama predviđanja potrošnje te osiguranja kvalitetnije informatičke potpore, primjerene uvjetima poslovanja na tržištu električne energije. Provedeno je nekoliko studija načina potrošnje energije krajnjih korisnika distribucijske mreže, utjecaj distribuiranih izvora električne energije, predviđanja ukupne satne potrošnje s ciljem izgradnje sustava što točnijeg predviđanje iznosa gubitaka električne energije u distribucijskoj mreži. Ovim radom dan je pregled izgradnje sustava predviđanja iznosa energije gubitaka u distribucijskoj mreži, izrada plana nabave potrebne energije na tržištu te izračun ostvarenja energije gubitaka.

I. UVOD

HEP–Operator distribucijskog sustava d.o.o. dužan je osigurati električnu energiju za pokriće gubitaka u distribucijskoj mreži. Gubici električne energije u distribucijskom sustavu jednaki su razlici energije koja je ušla u distribucijsku mrežu i energije predane kupcima. Pritom se za ulaz u distribucijsku mrežu uzimaju u obzir izmjerene vrijednosti energije na ulazu u distribucijski sustav (iz prijenosne mreže, susjednih distribucijskih sustava i elektrana priključenih na distribucijsku mrežu) i izmjerene vrijednosti potrošnje energije na mjestu priključka kupca. Tako definirani gubici električne energije dijele se na dvije grupe: tehnički gubici i netehnički gubici.

Tehnički gubici (gubici u užem smislu) nastaju isključivo u elementima mreže svih naponskih razina (vodovima, transformatorima, potrošnja komponenti sustava), a netehnički gubici nastaju zbog pogrešaka uzrokovanih složenim poslovnim procesom očitanja i obračuna potrošnje električne energije te neovlaštenim korištenjem električne energije (krađa energije). Pitanje točnog izračuna razine tehničkih gubitaka složeno je zbog velikog broja elemenata mreže i vremenske promjenjivosti opterećenja koja ovisi o velikom broju potrošača energije i njihovim trenutnim potrebama te problema nemogućnosti mjerenja velikog broja izlaza energije u isto vrijeme. Parametri elemenata mreže isto su tako ovisni o radnim uvjetima i promjenjivi su s vremenom, ali se utjecaj ovih promjena zanemaruje u kratkoročnim (satnim, dnevnim, mjesečnim) analizama potrošnje i gubitaka energije u distribucijskoj mreži.

Rad ukratko opisuje osnovne korake i rezultate složenog, višegodišnjeg procesa definiranja modela planiranja ukupnog opterećenja i gubitaka energije distribucijskog sustava. Autori rada sudjelovali su u kreiranju i povezivanju pojedinih faza projekta od definiranja istraživačkog uzorka, izgradnje sustava daljinskog očitavanja brojila te u konačnici u definiranju modela i pravila izračuna gubitaka energije iz predviđenog opterećenja sustava. Tijekom projekta provedeno je nekoliko studija s ciljem analize načina potrošnje energije koje su ukratko opisane u radovima [2] i [3]. Iz ovih studija kreirana su pravila primjene nadomjesnih krivulja opterećenja [4] za potrebe rada tržišta električne energije koja omogućuju i izradu plana satne potrošnje kupaca električne energije. U konačnici provedena je i studija za definiranje matematičkog modela kratkoročnog predviđanja satne potrošnje električne energije [5].

II. ANALIZA NAČINA POTROŠNJE KUPACA ELEKTRIČNE ENERGIJE

Ukoliko je moguće predvidjeti potrošnju energije korisnika distribucijske mreže u određenim vremenskim periodima, bilo bi moguće i na velikom skupu elemenata mreže s dovoljnom točnošću predvidjeti iznose tehničkih gubitaka. Mjerni intervali u kojima se najčešće mjeri potrošnja kupaca je 15 ili 60 minuta, a nabava energije na tržištu je u 60 minutnim intervalima. Da bi se točno predvidjela energija koju je potrebno nabaviti za kupce ili za gubitke na tržištu potrebno je imati povijesne mjerne podatke u odgovarajućim intervalima. Budući se radi o velikom broju mjernih mjesta troškovi opremanja brojilima koja imaju mogućnost mjerenja potrošnje u intervalima od 60 minuta su značajni, a za provedbu cijelog projekta potrebno je i značajno vrijeme, koje je u pojedinim zemljama procijenjeno na 5 do 15 godina. Trenutno se potrošnja energije u 15-minutnim intervalima mjeri na 19.500 obračunskih mjernih mjesta na srednjem naponu i niskom naponu priključne snage iznad 30 kW. Na ovim mjernim mjestima registrira se oko 40% ukupne potrošnje svih 2,3 milijuna kupaca [1].

Dosadašnja slika pasivne distribucijske mreže postaje složenija priključivanjem sve većeg broja distribuiranih obnovljivih izvora energije. Broj ovih malih elektrana koji je danas oko 1.500, nema značajniji utjecaj u odnosu na potrošnju energije 2,3 milijuna korisnika distribucijske

mreže. Kako bi se ograničila količina podataka potrebna za planiranje ukupne potrošnje kupaca na osnovu koje se u drugom koraku izračunavaju gubici energije u distribucijskoj mreži, bilo je potrebno grupirati kupce prema sličnosti u načinu potrošnje energije. Za potrebe definiranja karakterističnih skupina kupaca kreiran je istraživački uzorak od 1.500 obračunskih mjernih mjesta koja su opremljena brojilima s mjerenjem potrošnje u 15-minutnim intervalima.

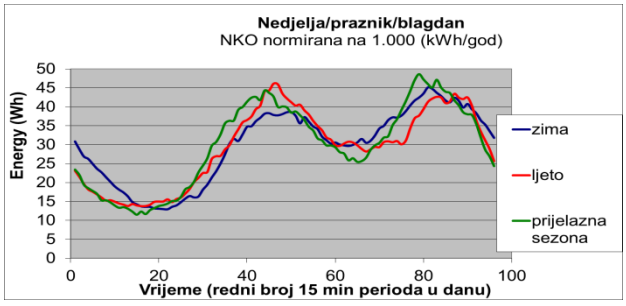
Grupe se oblikuju tako da je sličnost objekata unutar grupe veća od sličnosti između grupa. Kao mjera sličnosti udaljenosti dvaju objekata (obračunskih mjernih mjesta, OMM) koristila se Euklidova udaljenost [2].

Neka su $P_i(t)$ i $P_k(t)$ cjelogodišnje krivulje opterećenja dvaju objekata (OMM) „i“ i „k“. „t“ je brojač po svim 15 min razdobljima u promatranoj godini. Euklidova udaljenost između dviju krivulja opterećenja definirana je sljedećim izrazom (1):

$$d(i,k) = \sqrt{\sum_{t=1}^{35040} (P_i(t) - P_k(t))^2} \quad (1)$$

pri čemu je 35.040=96*365 broj 15 minutnih intervala u jednoj kalendarskoj godini (ukoliko je godina prestupna 35.136=96*366), a 96=24*4 je broj 15 minutnih intervala u jednom danu. Prepoznate su sljedeće karakterističnih skupina kupaca: K0–Kućanstva, P1–Poduzetništvo priključne snage manje ili jednake 13 kW, P2–Poduzetništvo koje ne pripada u P1, JR0–Poduzetništvo–javna rasvjeta.

Promatrajući tijek opterećenja kroz jednu godinu, svakoj karakterističnoj skupini kupaca pripada 9 dnevnih nadomjesnih krivulja opterećenja (NKO) koje su osnova za utvrđivanje godišnje krivulje opterećenja OMM: zima – radni dan, zima – subota, zima – nedjelja (slika 1), ljeto – radni dan, ljeto – subota, ljeto – nedjelja, prijelazno razdoblje – radni dan, prijelazno razdoblje – subota, prijelazno razdoblje – nedjelja.



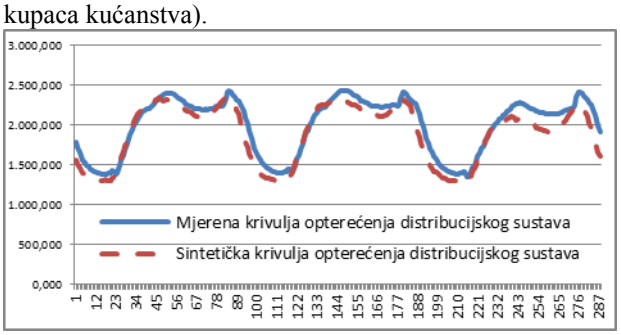
Slika 1. Nadomjesna krivulja karakteristične skupine kupaca – K0 Kućanstvo normirana na 1.000 kWh/godišnje

Analizom obilježja vremenske slijednosti opterećenja kupca kategorije kućanstva, zaključeno je kako se potonji, za razliku od ostalih karakterističnih skupina kupaca, ne mogu vjerodostojno opisati samo uporabom 9 dnevnih NKO. U tu svrhu istraživane su vremenske slijednosti dnevnih potrošnji OMM kako bi se odredila takozvana funkcija (polinom) dinamiziranja (2):

$$F_t = -2{,}454 * 10^{-10} * t^4 + 2{,}586 * 10^{-7} * t^3 - 5{,}135 * 10^{-5} * t^2 - 3{,}261 * 10^{-3} * t + 1{,}602 \quad (2)$$

gdje je **t** redni broj dana u kalendarskoj godini (t=1 za 01. siječnja) [3].

Izravnim zbrajanjem nadomjesnih krivulja opterećenja karakterističnih skupina kupaca pomnoženih s prosječnom godišnjom potrošnjom dobiva se sintetička krivulja ukupne potrošnje kupaca koji nemaju mjerenje 15-minutnih potrošnji (intervalno mjerenje). Dobivenoj krivulji dodaje se zbirna krivulja kupaca s ugrađenim intervalnim mjerenjem te dobivamo sintetičku krivulju ukupne potrošnje svih kupaca (slikom 2 prikazana je usporedba ove krivulje u odnosu na mjerenu krivulju opterećenja). Razlika dobivene krivulje potrošnje kupaca i izmjerene krivulje opterećenja cijelog sustava predstavlja krivulju gubitaka energije. Ukoliko bi se za nabavu energije koristila krivulja gubitaka dobivena na opisani način rezultat bi u sebi sadržavao netočnosti predviđanja potrošnje energije na nivou karakterističnih skupina kupaca i netočnosti određivanja nadomjesnih krivulja opterećenja (jedna krivulja K0 za 2 milijuna kupaca kućanstva).

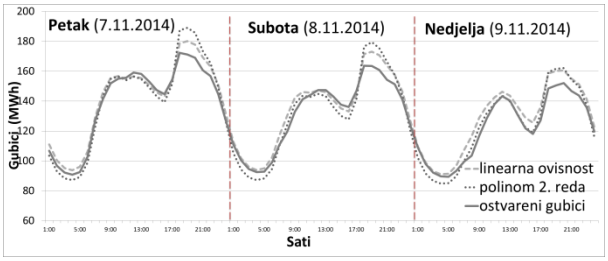


Slika 2. Usporedba mjerene i sintetičke krivulje opterećenja distribucijskog sustava (MW) za tri dana (96*3=288 15-minutnih intervala) - četvrtak, petak, subota

III. IZRADA KRIVULJE PLANIRANIH SATNIH GUBITAKA

Prema postojećim Pravilima primjene nadomjesnih krivulja opterećenja [4], gubici se računaju u linearnoj ovisnosti o opterećenju distribucijskog sustava. Dakle, za predviđanje satne krivulje gubitaka potrebno je predviđati satnu krivulju opterećenja distribucijskog sustava. Za potrebe analize gubici su se računali i u kvadratnoj ovisnosti o opterećenju distribucijskog sustava korištenjem polinoma drugog reda. Koeficijenti polinoma drugog reda dobiveni su analizom tehničkih karakteristika cjelokupne distribucijske mreže, analizom rezultata kontrole neovlaštene potrošnje električne energije i usporedbom s višegodišnjim rezultatima izračuna gubitaka.

Slika 3 prikazuje sličnost krivulja planiranih satnih gubitaka za tri karakteristična dana (radni dan, subotu i nedjelju) koje su dobivene upotrebom dva modela ovisnosti gubitaka o opterećenju (model linearne ovisnosti i model ovisnosti preko polinoma drugog reda), te stvarno ostvarenih gubitaka.



Slika 3. Ovisnost korištenog modela za planiranje gubitaka o opterećenju distribucijskog sustava uz prikaz ostvarenih gubitaka

Kao posljedica liberalizacije tržišta električne energije, predviđanje potrošnje električne energije dobiva sve veći značaj u sektoru distribucije električne energije. Točno predviđanje potrošnje električne energije omogućava značajne uštede za elektroenergetski sektor ako se vođenje elektroenergetskog sektora zasniva na (točnom) predviđanju potrošnje.

Osnovni je problem kod predviđanja potrošnje električne energije njena stohastička i nestacionarna priroda, kao i činjenica da je uvjetovana velikim brojem čimbenika poput: ekonomskih čimbenika, vremena, dana, godišnjeg doba, te hidrometeoroloških uvjeta. Postoji više različitih pristupa problemu predviđanja potrošnje električne energije, a eksperimentalni rezultati koji su dobiveni na modelima neuronskih mreža su se pokazali zadovoljavajućima i primjenjivima [5]. Privlačnost neuronskih mreža leži u pretpostavci da mogu naučiti model sustava na temelju povijesnih podataka pa je nužno poznavati potrošnju i druge čimbenike koji utječu na opterećenje do nekoliko godina unazad.

Analizom dosad primjenjivanog postupka koji se temelji na procjeni potrošnje kupaca korištenjem nadomjesnih krivulja opterećenja, utvrđena je potreba izrade složenijih algoritama predviđanja potrošnje te osiguranja kvalitetnije informatičke potpore, primjerene uvjetima poslovanja na tržištu električne energije. Cilj je bio izraditi aplikaciju za točnije predviđanje satne potrošnje i gubitaka električne energije u distribucijskoj mreži kako bi se smanjili mogući troškovi odstupanja planiranih od stvarno potrebnih količina energije. Predviđanja ukupne potrošnje i gubitaka električne energije obavljala bi se na razini pojedinog distribucijskog područja i na razini cijelog distribucijskog sustava.

IV. APLIKACIJA ZA PREDVIĐANJE SATNE POTROŠNJE ELEKTRIČNE ENERGIJE I PRORAČUN GUBITAKA

Programsko sučelje izvodi se u programskom okruženju Matlab tvrtke MathWorks sa sljedećim modulima:

1. Matlab – osnovna programska podrška.
2. NeuralNetworkToolbox – modul za modeliranje, simulaciju i učenje neuronskih modela sustava.

A. Opis osnovnih funkcionalnosti modula

Osnovne funkcionalnosti modula su:

- predviđanje potrošnje električne energije za sljedeći dan i tjedan, za pojedina distribucijska područja i za cjelokupni distribucijski sustav, na satnoj razini, na temelju povijesnih podataka, kalendarskih podataka i na temelju meteoroloških prognoza,
- predviđanje gubitaka električne energije po distribucijskom području i za cjelokupni distribucijski sustav na temelju predviđene potrošnje, gdje HEP ODS osigurava matematičku formulu za računanje koja povezuje potrošnju električne energije i gubitke.

Potrebne spomenute povijesne, meteorološke i kalendarske podatke modulu se osiguravaju iz baze podataka u informatičkom sustavu HEP ODS-a.

Na zahtjev korisnika, modul za zahtijevano distribucijsko područje može prilagoditi postupak predikcije koristeći odabrane arhivirane podatke (adaptacija parametara predikcijskog modela), tj. njihovo odabrano povijesno razdoblje. Kvaliteta predviđanja modela može se kvantificirati na povijesnim podacima prema dogovorenim kriterijima. Korisnik ima mogućnost pohranjivanja modela u svakom trenutku, te je pritom predviđena mogućnost paralelnog rada više predikcijskih modela i promjena aktivnog modela u bilo kojem trenutku. Predikcija se obavlja centralno na jednom računalu za sva distribucijska područja.

B. Opis kompletnog ulaznog prostora za svaki sat u danu

Za rad modula, čiji je mogući model kratkoročnog predviđanja satne potrošnje električne energije prikazan u sljedećem poglavlju (vidi sliku 4), potrebno je osiguravati sljedeće ulazne podatke:

1. temperatura zraka $T(i)$ za $i = 0\ldots-14$ (Pritom oznaka $T(0)$ označava temperaturu zraka u danu za koji se provodi predikcija opterećenja, $T(-1)$ označava temperaturu zraka u danu ranije, $T(-2)$ dva dana ranije itd.).
2. naoblaka $N(i)$ za $i = 0\ldots-14$.
3. potrošnja električne energije $P(i)$, za $i = -2\ldots-14$ (potrošnja $P(0)$ se ne koristit u predikciji jer je to upravo vrijednost čija se predikcija traži, dok se pretpostavlja da podatak o potrošnji od dana ranije $P(-1)$ neće biti dostupan u trenutku kad će se provoditi predikcija.
4. vremenski indeks τ_2;
5. tip dana τ_3;
6. sat za koji se radi predikcija τ_4.

Vremenski indeks τ_2 označava koje je doba godine i računa se preko formule (3):

$$\tau_2 = \sin(2\pi t/365) \quad (3)$$

gdje je t redni broj dana u godini. Pošto je sporo promjenjiv kroz godinu, njegova vrijednost uzima se samo za dan za koji se radi predikcija. Tip dana τ_3 označava je li riječ o radnom danu, suboti, nedjelji ili blagdanu.

Predikcijski model predviđa ukupnu potrošnju za odgovarajuće distribucijsko područje te će se ispadi velikih potrošača iz mreže, kao i prilagodba pripadajuće predikcije, uzimati u obzir izvan aplikacije.

C. *Vremenski horizonti*

Prema Pravilima djelovanja tržišta električne energije (NN 90/12, VII. Planiranje rada tržišta za dan unaprijed) HEP ODS obvezan je:

- najkasnije do 14:00 sati u danu trgovanja dostaviti Operatoru tržišta svoje ugovorne rasporede za dan isporuke.
- Operator tržišta do 14:30 sati u danu trgovanja izrađuje tržišni plan te u slučaju potrebnih ispravaka ugovornog rasporeda traži ispravak od tržišnog sudionika na kojeg se ispravak odnosi.
- do 14:45 sati u danu trgovanja tržišni sudionik dostavlja Operatoru tržišta ispravljeni ugovorni raspored.

Prema Pravilima djelovanja tržišta električne energije (NN 90/12, VIII. Izmjene ugovornog rasporeda tijekom dana isporuke):

tržišni sudionik može tražiti od Operatora prijenosnog sustava izmjenu ugovornog rasporeda tijekom dana isporuke najkasnije dva sata prije početka razdoblja na koje se izmjena odnosi [6].

Modul osigurava predviđanje potrošnje na satnoj razini za svako distribucijsko područje počevši od ponoći nakon dana trgovanja za sljedeća 24 sata i sljedećih 7 dana. HEP ODS će za svako distribucijsko područje iz niza modela koje će biti moguće naučiti za odabrana razdoblja povijesnih podataka odabrati jedan predikcijski model koji će time postati aktivnim. Odabir aktivnog modela omogućuje se putem korisničkog sučelja u Matlabu.

D. *Detaljne specifikacije korisničkog sučelja programskog modula*

Korisničko sučelje sadržava sljedeće funkcije:

- pokretanje i grafički prikaz predviđanja potrošnje i gubitaka za aktivni model
- pokretanje i grafički prikaz predviđanja potrošnje i gubitaka za po volji odabrani model
- spremanje predviđanja potrošnje i gubitaka u Excel (*xls*/*xlsx* format) datoteku
- kvantifikacija kriterija za ocjenjivanje predviđanja modela za odabrano razdoblje
- pokretanje prilagodbe modela za odabrano povijesno razdoblje
- odabir aktivnog modela za određeno distribucijsko područje

Sustav omogućuje memoriranje i kasniji dohvat ulaznih podataka, parametara predikcijskog modela, dobivenih rezultata te izlaznih datoteka za period od najmanje zadnja 24 mjeseca. Korištenjem povijesnih podataka moguće je ponovo generirati predviđanja za određeni dan ili tjedan u zadnjih godinu dana.

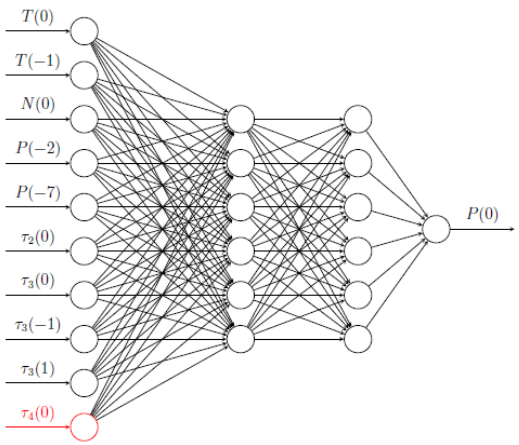
E. *Razmjena podataka*

Komunikacija modula s drugim programskim sustavima HEP ODS-a (odgovornim za podatke o potrošnji i meteorološkoj prognozi) provodi se korištenjem Excel datoteka (*xls*/*xlsx* format) formatiranih prema unaprijed utvrđenim pravilima. Pritom aplikacija provodi kontrolu potpunosti ulaznih podataka te pretpostavlja ispravnost ulaznih podataka.

V. NEURONSKA MREŽA

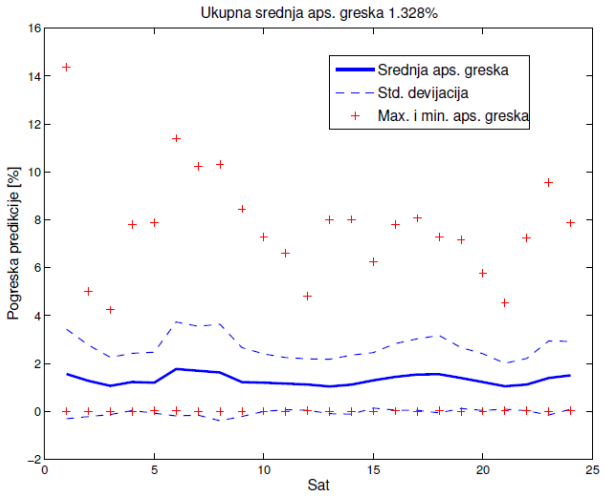
A. *Prijedlog modela predviđanja potrošnje električne energije*

Modeli predviđanja satne potrošnje za pojedina distribucijska područja dobiveni su uspoređujući rezultate predviđanja za pet različitih neuronskih mreža. Uzimajući u obzir složenost strukture, vrijeme učenja te količinu primjera za učenje na raspolaganju, zaključilo se kako je najbolja struktura dvostruka MLP (engl. *MultiLayer Perceptron network*) mreža koja koristi dva tipa predviđanja (24 i 48 sati unaprijed). Ideja ovog pristupa jest da se ne koristi jedna mreža po satu, već da jedna mreža radi predviđanje od 24 sata unaprijed, a druga 48 sati unaprijed. Potom se iz te dvije mreže dobiva predviđena dnevna krivulja. Koriste se dvije mreže zato što je pretpostavka da prilikom predviđanja za prvi sat postoji informacija o potrošnji prije 24 sata, dok za ostale sate u danu mora se koristiti mreža koja predviđa s horizontom od 48 sati, iako je najsvježiji podatak od prije 25 sati, ali sve do 48 sati unazad podaci nisu frekvencijski relevantni. Prednost ove mreže jest u tome da na raspolaganju ima 24 više primjera za učenje što bi trebalo rezultirati boljim učenjem oblika dnevne krivulje te robusnijim ponašanjem za blagdane. Nedostatak je znatno duže vrijeme treniranja te zahtjevi za memorijom. Struktura mreže prikazana je na slici 4 iz koje se može vidjeti da je dodan jedan parametar τ_4 u regresor koji označava za koji se sat u danu računa predviđanje.



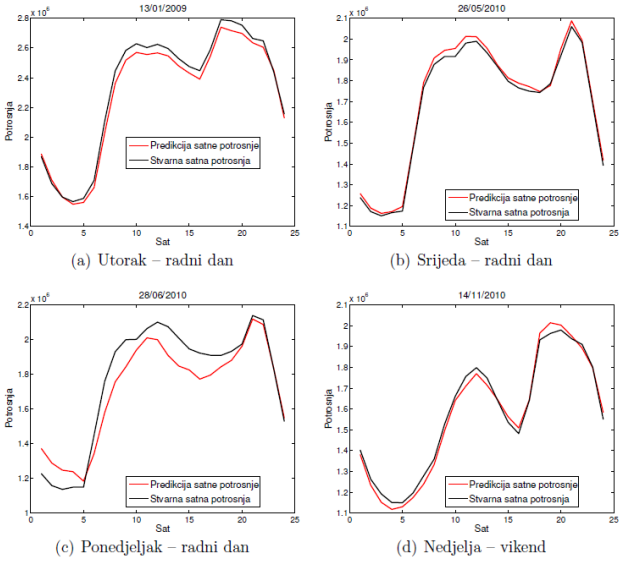
Slika 4. Struktura neuronskih mreža s horizontima od 24 i 48 sati.

Dobivena srednja apsolutna pogreška za cjelokupan sustav iznosi 1,328% (slika 5), a rezultati simulacije za nekoliko odabranih dana prikazani su slikom 6. Razlog dobrome rezultatu za cjelokupan sustav vjerojatno leži u nešto većoj robusnosti cijelog sustava na nenadane događaje te u činjenici da se predviđanje računalo za cijeli sustav zbrajanjem predviđanja za pojedine grupe distribucijskih područja od kojih su neki mogli procijeniti preveliku, a neki premalu potrošnju što u konačnici zbrajanjem može rezultirati manjom pogreškom.



Slika 5. Srednja apsolutna greška za sve sate u danu za cjelokupan sustav

Iako je odabir strukture mreža napravljen na temelju rezultata za distribucijsko područje Elektre Zagreb, pretpostavka je da se struktura modela uči radi opisivanja nelinearnog odnosa između ulaznih parametara (kalendarski, hidrometeorološki i podaci o potrošnji) te izlazne veličine (predviđena potrošnja) neovisno o strukturi distribucijskog područja. Parametri modela će se svakako mijenjati ovisno o distribucijskom području, jer različiti čimbenici utječu na potrošnju. Međutim, to ne utječe na samu strukturu modela te je korišteno jedno distribucijsko područje za usporedbu.



(a) Utorak – radni dan (b) Srijeda – radni dan

(c) Ponedjeljak – radni dan (d) Nedjelja – vikend

Slika 6. Primjer cjelodnevnog predviđanja potrošnje (u Wh) električne energije po satima za cjelokupan sustav

Također, veće netočnosti kod manjih distribucijskih područja mogu se očekivati zbog veće osjetljivosti na promjene u sustavu, ali sam izbor modela ne bi trebao imati utjecaja. Sukladno tome, za svako distribucijsko područje provodilo bi se učenje za taj slučaj te bi dobivena mreža opisivala najbolje što je moguće naučen odnos između odabranih ulaznih veličina i predviđene potrošnje [5].

VI. ZAKLJUČAK

Predviđanje potrošnje električne energije dobiva sve veći značaj u sektoru distribucije električne energije. To je ponajprije posljedica sve razvidnijeg tržišta električne energije u Republici Hrvatskoj, ali i činjenice da točno predviđanje potrošnje električne energije omogućava značajne uštede za elektroenergetski sektor. Čak i relativno mala poboljšanja u točnosti predviđanja potrošnje električne energije mogu rezultirati uštedama od nekoliko stotina tisuća do više milijuna kuna.

Da bi se postiglo što bolje predviđanje potrošnje električne energije važno je imati što točnije ulazne varijable (hidrometeorološki podaci, potrošnja električne energije prethodnih dana te tip dana i doba godine), jer neispravno odabrani skup ulaznih varijabli može znatno narušiti kvalitetu predviđanja potrošnje električne energije. Ako ulaznim skupom nisu obuhvaćene neke značajne varijable, bit će nemoguće u potpunosti opisati funkciju potrošnje električne energije. S druge strane ako ulazni skup sadrži preveliki broj (redundantnih) ulaznih varijabli, postupak učenja modela i predviđanja postaje pretjerano složen te može dovesti do toga da funkcija potrošnje električne energije ne bude ispravno naučena.

Gubici u distribucijskoj mreži predstavljaju jedan od ključnih čimbenika koji ukazuju na stupanj ekonomičnosti poslovanja i kvalitetu obavljanja djelatnosti distribucije električne energije. Ovim radom dan je pregled izgradnje sustava predviđanja iznosa energije gubitaka u distribucijskoj mreži, izrada plana nabave potrebne energije na tržištu te izračun ostvarenja energije gubitaka.

Automatska monotona kategorizacija numeričkih varijabli

Valeria Horvat i Krešimir Bokulić
Multicom d.o.o., Zagreb, Hrvatska
valeria.horvat@multicom.hr , kresimir.bokulic@multicom.hr

Sažetak - Rad se bavi područjem kategorizacije (engl. *Binning*) varijabli za dubinsku analizu podataka (engl. *Data mining*). U radu je opisano automatsko rješenje pronalaženja granice kategorizacije kontinuiranih numeričkih varijabli s obzirom na ciljnu varijablu. Rješenje se koristi u slučaju kada ciljna varijabla poprima dvije vrijednosti. Svakom razredu pridružena je WOE (engl. *Weight of Evidence*) težina, te je raspodjela težina monotona. Algoritam ima dva moguća rezultata: monotonu kategorizaciju s najvećim mogućim brojem razreda i kategorizaciju s maksimiziranom IV (engl. *Information Value*) vrijednošću. Rješenje je razvijeno u programskom jeziku R koristeći Rstudio. Sastoji se od R paketa i R skripti, koje je Oracle PL/SQL upitom moguće pozvati na Oracle Data Miner alatu.

I. UVOD

Diskretizacija, tj. kategorizacija varijabli može pružiti robusno, interpretativno rješenje u prediktivnim modelima. U području financija su to često varijable poput dobi, prihoda, nenaplaćenih zajmova. Dob je tipična karakteristika u bankarstvu, pogotovo u modelima kreditnog bodovanja(engl. *Scoring*). Takva karakteristika je podijeljena u različite razrede i svakom razredu je dodijeljena ili količina bodova ili težina, a može biti i WOE vrijednost. Na primjer, dvadesetsedmogodišnji podnositelj zahtjeva za kredit bi mogao pasti u dobnu skupinu od 24-30 godina. Na taj je način varijablu „dob“ lakše interpretirati, čak i ako osoba koja koristi model ne razumije modeliranje kreditnih rizika. Diskretizacijom kontinuirani atributi, tj. varijable postaju diskretne. Postoje razne metode pronalaženja granica diskretnih razreda: razredi iste širine, razredi po kvantilima, itd. Originalne vrijednosti atributa mogu se zamijeniti s raznim vrijednostima, npr. oznaka intervala, redni broj intervala, srednja vrijednost ciljne varijable unutar intervala, s WOE vrijednošću, itd.

Ovaj rad u drugom poglavlju daje definiciju WOE i IV vrijednosti. Zatim u trećem poglavlju opisuje općeniti problem smislenog grupiranja jedne varijable i uvjete, tj. ograničenja koja se najčešće pojavljuju prilikom traženja optimalne kategorizacije. U četvrtom upoznaje čitatelja s nekim alatima za dubinsku analizu podataka. Te u zadnjem pruža uvid u rješenje mBinning za automatsko pronalaženje monotone kategorizacije, tj. pronalaženje razreda, granica za grupiranje varijabli uz koje se dobivaju optimalne monotone WOE vrijednosti te se maksimizira IV vrijednost. U tom poglavlju detaljno je opisana implementacija rješenja. Tako je pokazano da su riješeni problemi i poteškoće koje se mogu javiti prilikom automatske kategorizacije numeričke varijable u odabranim alatima.

II. WOE I IV

Prije spomenuta metoda zamijene s WOE (engl. *Weight of Evidence*) vrijednošću uzima u obzir i ciljnu varijablu. U slučaju diskretne ciljne varijable koja može poprimiti dvije vrijednosti, npr. iz skupa (0, 1), („dobar“ , „loš“), („događaj se nije desio“, „događaj se desio“) i slično. WOE se za svaku grupu *i* dobivenu diskretizacijom računa sljedećom formulom (vidi u [2]):

$$WOE_i = \ln\left(\frac{\frac{dobri_i}{Ukupno\ dobrih}}{\frac{lošI_i}{Ukupno\ loših}}\right). \quad (1)$$

Nakon kategorizacije može se izračunati IV (engl. *Information Value*) vrijednost i druge metrike za izračun prediktivnosti varijable. IV vrijednost se za neku varijablu s *k* razreda može dobiti sljedećom formulom:

$$IV = \sum_{i=1}^{k}\left(\frac{dobri_i}{Ukupno\ dobrih} - \frac{lošI_i}{Ukupno\ loših}\right) * WOE_i\ . \quad (2)$$

III. PROBLEMI GRUPIRANJA

Proces kategorizacije je često ograničen nekim pravilima, stoga se na traženje optimalnih granica koje zadovoljavaju zadana pravila može izgubiti podosta vremena. Na primjer, kako bi se osigurao statistički značajan i primjenjiv model u nekim slučajevima, može se dati zahtjev da svaki razred sadrži obje vrijednosti ciljne varijable i „dobre“ i „loše“. Treba pružiti alternativan izračun u slučajevima kada to nije moguće. Drugi zahtjev može biti da svaki razred smije sadržavati samo određen broj opažanja, a isto tako i minimalan broj zapažanja.

Mogu se zadati i zahtjevnij uvjeti na kategorizaciju. Na primjer, u zakonu Sjedinjenih Američkih Država, točnije u Equal Credit Opportunity Act (USDOJ 2006) (vidi u [3]) zakonu, nameće se ograničenje koje kaže da se starijim podnositeljima zahtijeva za kredite ne smije dodijeliti manja količina bodova, tj. manja težina od onih dodijeljenih mlađim podnositeljima. To ograničenje zahtijeva monotonost WOE vrijednosti. Primjer, pretpostavimo da je varijabla *godine* podijeljena na tri razreda: $a = \langle 18, 25]$, $b = \langle 25, 40]$ i $c = \langle 40, 60]$, razredu a pridružena je vrijednost WOE_a , razredu b WOE_b , razredu c WOE_c . Pretpostavimo da WOE vrijednosti nisu monotone, ali da je maksimalna WOE

vrijednost u razredu s najvećim godinama, tj. WOE_c je maksimum. Kako je WOE_c maksimum, znači da su WOE_a i WOE_b manji od WOE_c, a kako WOE vrijednosti ne rastu monotono, znači da je WOE_a veće od WOE_b. No, tako je razredu s manjim godinama pridružena veća težina, odnosno Equal Credit Opportunity Act nije zadovoljen. Sličan zaključak dobiva se i kada WOE nisu monotone ali imaju minimum. Odavdje slijedi da WOE vrijednosti trebaju biti monotone. Ovakvo ograničenje je posebno zahtjevno zbog nelinearne veze između varijable koju je potrebno grupirati i ciljne varijable.

Ukratko, tražimo rješenje koje zadovoljava sljedeća ograničenja:

- maksimalan broj razreda
- minimalan broj razreda
- maksimalna veličina razreda
- minimalna veličina razreda
- monotonost WOE vrijednosti po razredima
- alternativno rješenje za razrede koje nemaju zastupljene obje vrijednosti ciljne varijable.

Kada je inicijalna podjela varijabli velika, proces nalaženja optimalnih granica može potrajati zbog mogućih kombinacija i velikog broja iteracija. Moguće je da je skup zahtijeva toliko restriktivan da ne postoji rješenje koje može zadovoljiti sve tražene uvjete. Sam postupak kategorizacije ima negativne strane, te nije primjenjiv u svim situacijama. S kategorizacijom mogu se izgubiti korisne informacije, pa tako i sam model može izgubiti na prediktivnosti.

A. *Spajanje susjednih razreda*

Jedan od pristupa pronalaženju optimalne kategorizacije je da svaku vrijednost proglasimo jednim razredom, zatim ih spajamo sa susjednim razredima dok svi zadani zahtjevi ne budu ispunjeni.

Primjerice, u tijeku kategorizacija neke karakteristike nije ispunjen uvjet minimalne veličine razreda za neki razred *k*. Rješenje bi bilo spojiti taj razred s *k+1* ili *k-1* razredom, no pritom treba paziti da se ne prijeđe uvjet maksimalne veličine razreda ili minimalnog broja razreda, te treba paziti da WOE vrijednosti rastu ili padaju monotono. Takvo spajanje razreda ima utjecaja i na druge razrede. U slučaju kada *k* i *k+2* razred ne zadovoljavaju zadane uvjete, rješenje je spajanje sa susjedima, no pitanje je s kojim razredom krenuti. Razred *k+1* je susjedni od oba prije spomenuta razreda. Ako se krene s jednim razredom, može se dogoditi da se drugi neće moći spojiti tako da su ograničenja kategorizacije zadovoljena.

Broj mogućih kombinacija raste s brojem početnih razreda inicijalne podjele. Kod neograničenih kontinuiranih varijabli taj broj može biti velik. Iz tih razloga bi trebalo bolje promisliti o inicijalnoj podjeli varijable.

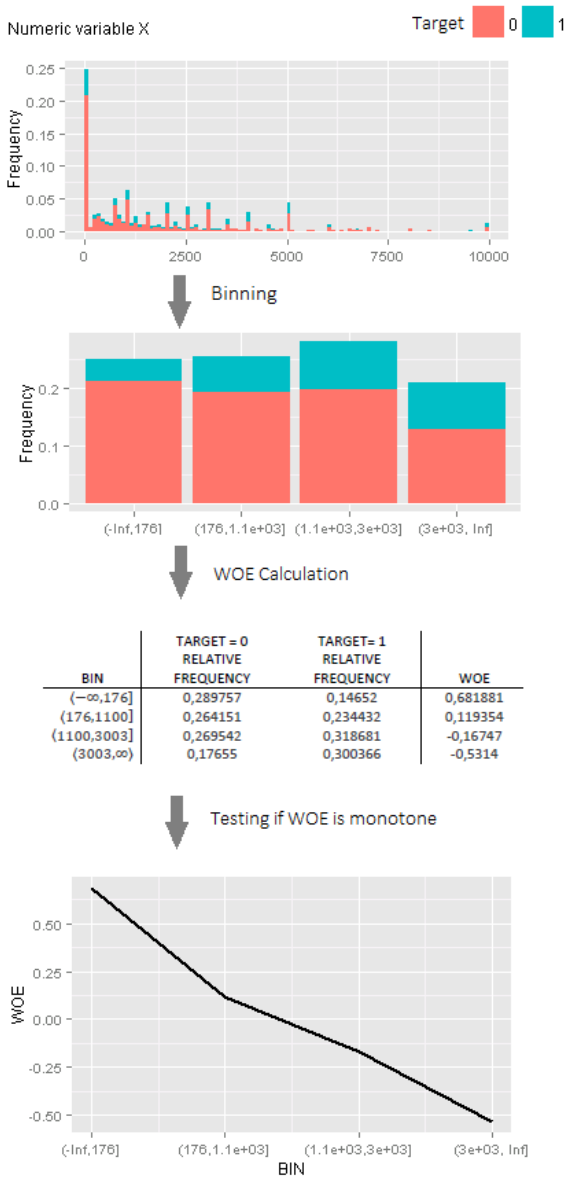
B. *Pronalaženje granica koristeći kvantile*

Umjesto prethodno spomenute inicijalne podijele, raspon varijable moguće je dijeliti na jednake razrede, odnosno razrede iste širine. No ovdje se javlja problem odlučivanja o širini razreda. Ako se uzmu preširoki razredi postoji mogućnost da se neće moći naći optimalno monotono grupiranje koje zadovoljava zadane uvijete. Ukoliko se uzmu preuski razredi, pronalaženje optimalnog grupiranja bi moglo potrajati sukladno tome dulje. Jedna od mogućih metoda je podjela na razrede s jednakom količinom podataka. Takva metoda koristi kvantile (*n* kvantila dijeli varijablu na *n* razreda pri čemu svaki sadrži najviše (100/*n*)% opažanja neke varijable) .

Nakon što se podaci podijele (Slika 1) računa se WOE vrijednost za svaki pojedini razred, provjerava se da li su početni uvjeti zadovoljeni. Ako nisu, podaci se dijele po novim kvantilima, manjem broju.

IV. R, ORE I ODM

R je programski jezik i softverska okolina za statističke obrade podataka te njihov grafički prikaz. R je GNU projekt, samim time je open source i dostupan pod



Slika 1: Prikaz procesa traženja optimalne kategorizacije za numeričku varijablu X koja poprima vrijednosti iz intervala od 0 do 10000.

GNU General Public License licencom. Izvorni kod za R okolinu je napisano prvenstveno u C, Fortranu, ali i u R-u. R koristi sučelje naredbenog retka, postoji i nekoliko alata kao Rstudio, kojim je programiranje u R-u olakšano. Prednost R-a je lako proširivanje kroz pakete, te jednostavna definicija vlastitih paketa. Njegov nedostatak je upotreba memorije. Jednostavne naredbe koje se u SQL brzo izvršavaju, ovisno o dostupnoj količini radne memorije, u R-u mogu razmjerno duže potrajati.

OAA (engl. *Oracle Advanced Analytics*) je proširenje na Oracle bazu podataka. OAA se sastoji od dva dijela: ORE (engl. *Oracle R Enterprise*) i ODM (engl. *Oracle Data Mining*).

ORE povezuje R sa Oracle 11g bazom podataka. Točnije, R je direktno instaliran na server na kojem se nalazi i baza podataka. Instalacijom se omogućuje tzv. transparentni sloj (engl. *transparency layer*) što znači da se naredbe iz klijentskog R engina na bazi izvršavaju kao SQL naredbe ukoliko postoji njihov ekvivalentni transparency oblik. Transparentni sloj omogućuje jednostavan prijenos podataka, uz to i korištenje tablica i pogleda (engl. *View*) definiranih u R-u sa ore.frame tipom koji je ekvivalent R-ovom osnovnom data.frame tipu. Zbog toga je moguće i definirati vlastite ORE skripte, koje se tada čuvaju na bazi.

ODM je skup algoritama potrebnih za dubinsku analizu podataka, klasifikaciju, predikciju, regresiju i sl. ODM se može koristiti kroz grafičko korisničko sučelje Oracle Data Miner. U tom sučelju se grade procesni sljedovi (engl. *workflow*) s raznim čvorovima ponuđenim u alatu.Oracle Data Miner se može povezati i sa ORE-om u SQL čvoru definirajući ulaznu tablicu, parametre i izlaznu tablicu ORE funkcije, odnosno skripte.

Primjer u (Slika 2) daje procesni slijed izgrađen nad INSUR_CUST_LTV_SAMPLE tablicom koja dolazi s instalacijom Oracle Data Miner repozitorija. Tablica sadrži umjetno stvorene podatke vezane uz klijente nekog fiktivnog osiguravajućeg društva. Ciljna varijabla daje informaciju o tome da li je pojedini klijent kupio osiguranje ili nije. Osim ciljne varijable tablica sadrži i identifikacijsku kolonu, broj godina klijenta, broj djece, iznos plaće, stanje na računu i slično.

V. MBINNING RJEŠENJE

U ovom poglavlju je dan opis mBinning rješenja. Opisane su pojedine komponente, važniji dijelovi njihovih algoritama, ulazni parametri i izlazni rezultati. Sve komponentne su razvijene od strane autora.

Rješenje mBinning koje služi za grupiranje kontinuirane numeričke varijable moguće je zbog svoje konstrukcije koristiti kroz R, ORE te kroz ODM pozivom skripti u SQL čvoru (Slika 2). Sastoji se od sljedećih komponenti:

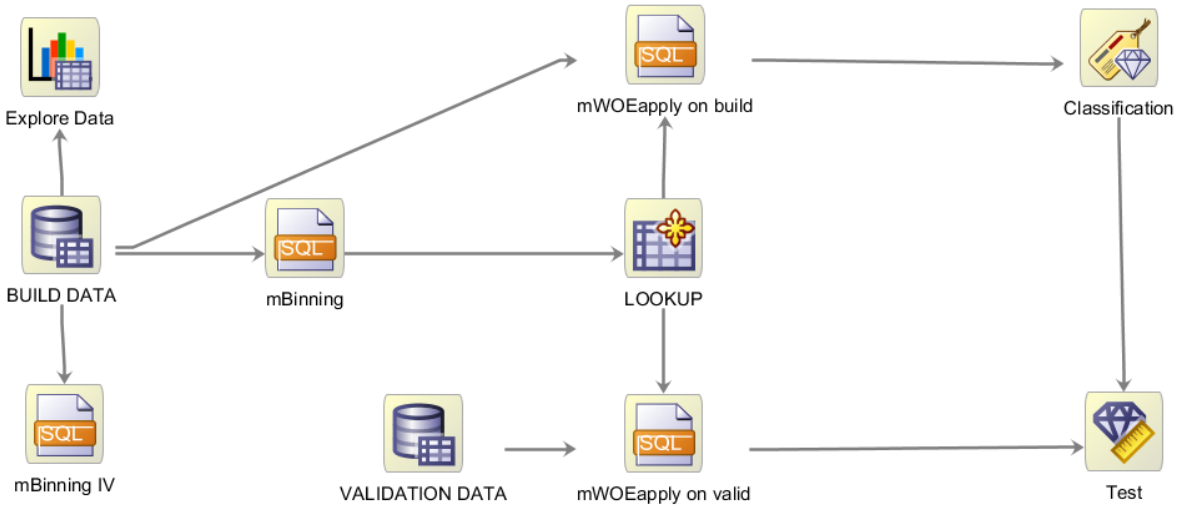
- mBinning R paketa
- m.Binning ORE skripte
- m.BinningIV ORE skripte
- m.WOEapply ORE skripte

Sve ORE skripte se čuvaju u bazi podataka. Transparency sloj omogućuje njihovo izvršavanje, koje se odvija u R-u na serveru. R mBinning paket se nalazi u R-u na serveru i tamo se izvršava (Slika 3). Moguće je paket imati na lokalnom stroju, tada transparency sloj služi za prebacivanje podataka s baze na lokalno klijentsko računalo.

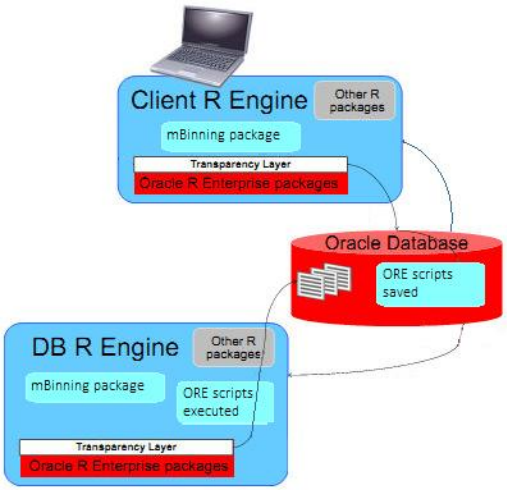
A. *mBinning R paket*

mBinning R paket je skup R funkcija. Funkcija koja se poziva iz gore navedenih ORE skripti je m.Binning funkcija. Ta funkcija za numeričku varijablu nalazi kategorizaciju koja zadovoljava zadane uvjete. Algoritam je napisan tako da iskoristi sve prednosti koje pruža R , te izbjegava moguće poteškoće koje bi se mogle javiti u ORE i ODM okruženju. U daljnjem tekstu slijedi detaljan opis rada funkcije.

Funkcija traži optimalnu kategorizaciju na način kako je opisano u poglavlju III.B (Slika 1). Slijedi detaljniji



Slika 2: Primjer procesnog slijeda iz Oracle Data Miner alata i načina poziva i redoslijeda ORE skripti iz mBinning rješenja u SQL čvorovima.



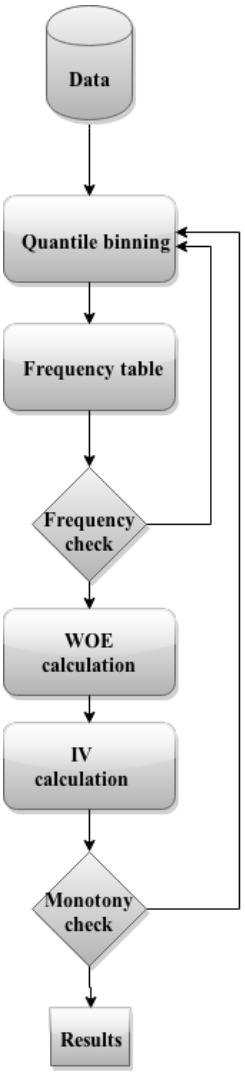
Slika 3: Prikaz transparentnog sloja i arhitektura mBinning rješenja

opis postupka (Slika 4) :

1. Da bi se odredila varijabla nad kojom se želi primijeniti kategorizacija treba navesti tablicu u kojoj se nalazi, naziv kolone, tj. varijable, naziv ciljne varijable. S dodatnim parametrima osigurava se da su prije spomenuti zahtjevi zadovoljeni. Pomoću njih se može podesiti maksimalan broj razreda, maksimalna i minimalna veličina pojedinih razreda te je moguće zadati vrijednost za korekciju razreda u kojoj nisu zastupljene obje vrijednosti ciljne varijable. Dva dodatna parametra određuju algoritme kojima se traži kategorizacija ulazne kolone. To su parametri percents i max_IV , a biti će objašnjeni u daljnjem tekstu.
2. Kategorizacija kreće od maksimalnog broja razreda *n*. Traže se granice za *n* razreda po kvantilima. Za svaki zapis traži se razred kojem pripada. Prazni zapisi se posebno tretiraju. Takvi zapisi se smještaju u *n+1*. razred. Tako korisnik može sam odlučiti kako će tretirati takve zapise, odnosno kojim razredima će ih se pripojiti.
3. Sljedeći korak je izrada frekvencijske tablice. Frekvencijska tablica u sebi sadrži informaciju o raspodjeli ciljne varijable po razredima. Jednostavnije, za sve zapise koje se nalaze u *k*-tom razredu provjerava se vrijednost ciljne varijable te se izračuna frekvencija za obje vrijednosti u tom razredu. U frekvencijskoj tablici također se nalazi informacija o relativnoj veličini razreda u odnosu na sve zapise. Ta tablica je potrebna iz dva razloga: koristi se za provjeru uvjeta na kategorizaciju (sada se lako iz tablice vidi da li su uvjeti maksimalne i minimalne veličine razreda zadovoljeni) i služi za izračun WOE vrijednosti.
4. Prije nego se krene u izračun WOE vrijednosti, u frekvencijskoj tablici potrebno je zamijeniti sve vrijednosti koje su jednake nula s vrijednošću zadanom u ulaznom parametru. Tako je zadovoljen uvjet za razrede koje nemaju zastupljene obje vrijednosti ciljne varijable. Kada bi se prethodni korak preskočio, došlo bi do greške prilikom izračuna WOE vrijednosti zbog njegove definicije. Dijeljenje s nulom nije moguće. Nakon izračuna WOE vrijednosti, može se izračunati IV metrika. Ukoliko nisu zadovoljeni uvjeti vezani uz veličinu razreda, daljnji koraci se preskaču. Sada se može provjeriti monotona raspodjela WOE vrijednosti po razredima.

Ako monotonost nije postignuta, koraci 2., 3. i 4. se ponavljaju za *n-1*. Ako se ne može ni za jedan *n>=2* naći kategorizacija koja zadovoljava zadane uvjete, tada funkcija vraća rezultatnu tablicu s posebnim ćelijama. Kolona koja daje razred grupiranja će biti prazna, a ostale kolone imat će nule.

Ulazni parametar *max_IV* utječe na algoritam tako da određuje trenutak u kojem potraga za kategorizacijom završava. Postoje dvije mogućnosti: u prvoj se nalaze sve moguće kategorizacije neke varijable koje zadovoljavaju zadane početne uvjete, te se na kraju odabire ona za koju je IV vrijednost najveća, u drugoj algoritam stane kada naleti na prvu kategorizaciju koja zadovoljava uvjete. Na



Slika 4: Blok dijagram redoslijeda radnji unutar m.Binning R funkcije

taj način ulazni parametar *max_IV* ima utjecaja na brzinu izvršavanja cijelog postupka.

Parametar *percents* također utječe na brzinu izvršavanja. Ovisno o njemu uvjeti maksimalne i minimalne veličine razreda se uzimaju u obzir ili ne. Taj parametar može usporiti cijeli proces. Ako se uvjeti o veličini razreda ne uzimaju u obzir, tada će se WOE vrijednost izračunati za svaki *k*.

Zbog parametara *max_IV* i *percents* postoji četiri različita algoritma. Razlika je vidljiva u brzini izvršavanja (Slika 5) i u rezultatu.

B. *m.Binning ORE skripta*

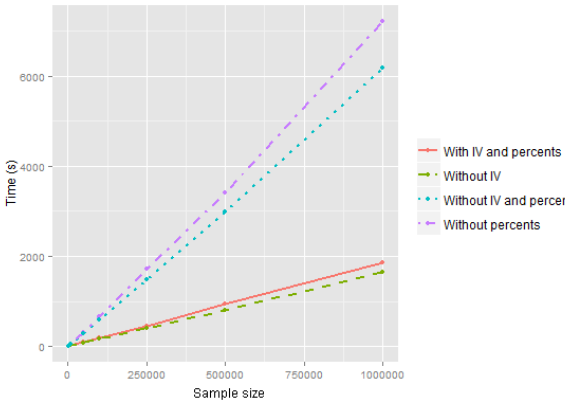
Skripta omogućuje primjenu prethodno spomenute funkcije iz mBinning R paketa na cijeloj tablici, a ne samo na pojedinoj numeričkoj koloni. Petlja prolazi kolonu po kolonu ulazne tablice te primjenjuje funkciju za nalaženje optimalnog grupiranja, s kojim se osigurava monotonost WOE vrijednosti, na svakoj koloni pojedinačno. Kolone koje nisu numeričke jednostavno se preskaču.

Rezultat skripte je tablica koja sadrži kolonu s nazivom numeričke varijable, redni broj razreda, WOE vrijednost pojedinog razreda, gornju granicu razreda, donju granicu razreda. Ako se koristi algoritam za maksimizaciju IV vrijednosti, izlazna tablica će sadržavati kolonu s IV vrijednošću grupirane varijable. Ako su zadani uvjeti na veličinu pojedinih razreda, rezultat će još sadržavati kolone s informacijama o veličini razreda te strukturu ciljne varijable u tom razredu (Tablica 1). Varijable za koje nije moguće naći grupiranje koje bi zadovoljilo zadane zahtjeve, biti će navedene u izlaznoj tablici. Sve kolone za takve varijable biti će nule, osim kolone s njihovim nazivom i razredom grupiranja. Tablica dobivena ovom ORE skriptom može služiti kao pregledna (engl. *Lookup)* tablica za primjenu u m.WOEapply ORE skripti, koja je niže objašnjena.

C. *m.BinningIV ORE skripta*

U toj ORE skripti koristi se glavna funkcija iz mBinning R paketa nad cijelom tablicom. Petlja koja to omogućuje je slična onoj iz m.Binning ORE skripte. Ona koristi spomenutu m.Binning funkciju iz mBinning R paketa na svakoj pojedinačnoj koloni. Primjenjuje funkciju nad numeričkim kolonama, kategorijske i datumske kolone se preskaču.

Razlika između ove ORE skripte i prethodne je u rezultatu. Rezultat m.BinningIV ORE skripte sadrži



Slika 5: Usporedba brzine algoritma nad tablicama s različitim brojem zapisa (*Sample size*) za sve moguće kombinacije postavki ulaznih parametara *max_IV* i *percents.*Tablice su dobivene repliciranjem kolona iz spomenute INSUR_CUST_LTV_SAMPLE tablice.

kolonu koja daje ime numeričke varijable, broj razreda za koje je nađeno monotono WOE grupiranje koje zadovoljava tražene uvjete, te rezultat sadrži i IV vrijednost takvog grupiranja. Jedna varijabla može biti navedena više puta, ukoliko za nju postoji više mogućih grupiranja koje zadovoljavaju tražene uvjete. Ako za neku numeričku varijablu nije moguće naći ni jedno grupiranje, tada je ona samo navedena, ali ostale ćelije će sadržavati nule.

D. *m.WOEapply ORE skripta*

Ova skripta služi za primjenu prethodno dobivenih preglednih tablica na tablicu koja se koristi za modeliranje.

Rezultat ove skripte je tablica s identifikacijskom kolonom i još onoliko kolona za koliko varijabli je originalna vrijednost zamijenjena s WOE vrijednošću. Dakle, kolone koje nisu numeričke i numeričke kolone za koje nije nađena kategorizacija koja zadovoljava zadane uvjete se preskaču. Njihove vrijednosti se ne zamjenjuju, te niti nisu dio rezultata skripte.

VI. ZAKLJUČAK

U području financija, pogotovo u području kreditnih rizika, kontinuirane varijable često se pretvaraju u

Tablica 1: Primjer rezultatne tablice poziva m.Binning ORE skripte.

VAR_NAME	VAR_LEVEL	WOE	LOWER_LIMIT	UPPER_LIMIT	IV	P0	P1	PTOTAL
NUM_VAR_1		0	0	0	0	0	0	0
NUM_VAR_2		0	0	0	0	0	0	0
NUM_VAR_3	1	0,6819		176	0,1752	0,2898	0,1465	0,2512
NUM_VAR_3	2	0,1194	176	1.100	0,1752	0,2642	0,2344	0,2562
NUM_VAR_3	3	-0,1675	1.100	3.000	0,1752	0,2695	0,3187	0,2828
NUM_VAR_3	4	-0,5314	3.000		0,1752	0,1765	0,3004	0,2099

kategorijske. Taj proces poznat je kao binning, kategorizacija ili grupiranje. Iako to može smanjiti moć predikcije konačnog modela, ako je učinjeno razborito gubitak je mali.

Postoje razne metode za kategorizaciju. Jedna od mogućih pristupa je dan u mBinning rješenju. U sebi sadrži automatski monotoni binning numeričkih varijabli koje se dijele po kvantilima. Omogućuje zamjenu originalnih vrijednosti varijable s pripadnim WOE vrijednostima. Korisnik ovog rješenje može birati između dva pristupa: kategorizacija s maksimalnom IV vrijednošću i kategorizacije s najvećim mogućim brojem razreda. Štoviše, ako se odluči za prvi pristup, ima uvid u preostale moguće kategorizacije za pojedinu numeričku varijablu. Ulaznim parametrima dobiveni rezultat može se podesiti tako da zadovolji neke zahtjeve na kategorizaciju poput: maksimalnog broja kategorija, veličine pojedinih kategorija itd. Rješenje mBinning može se koristiti u R-u ili ORE-u, može se pozvati kroz procesni slijed Oracle Data Miner alata.

INVITED PAPER

Public e-Procurement as a Key-Impact Factor in the UE Welfare Context

-The Italian Public e-Markets: Research Findings and e-Solutions Analysis-

Francesco Bof*, Gianmaria Casella **
* Bocconi School of Management, Milan, Italy
** CSAmed, Cremona, Italy
Francesco.bof@sdabocconi.it, francesbof@hotmail.com

Abstract

"*For Governments thinking about the competitiveness of nations and states has focused on the overall economy, with national-level policy as the dominant influence*" (Porter, 2000).

The goal of the present paper is to help Governments Decision Makers, Public Buyers, Private Markets Representatives, and ICT Companies to understand the opportunities and the present challenges of the public processes digitalization strategy for the EU Welfare goals. Evidences on the Italian experience in public (health) e-procurement and e-markets will be brought forth.

Public (E)-Procurement of goods/services, in the EU context, is strategic because of five main reasons: a) economic relevancy (public expense can be from 10% to 20% of EU Countries GDP); b) impact on citizens' service quality c) impact on markets competitiveness and innovation capacity, d) necessity to guarantee transparency and security of transactions and e) improvement of its processes efficiency. In particular, e-procurement models and solutions play a major role in the present EU digitalization strategy. Moreover, it seems that none of them has emerged as the optimal yet.

After an analysis of the updated relevance, main factors and dynamics effecting public (e)-procurement of goods/services and public-private in the EU and in the Italian context, in particular: transactions data analysis in a four years' period on the Italian Public e-Marketplace will be presented. As the findings give evidence of criticalities connected with A. ICT infrastructures capacity of territory and, B. Public segment (specifically the Public Health), consistently, a case-study identifying potential (although partial) solutions will be presented.

I. INTRODUCTION

Nations' competitiveness depends, among the other factors "on the Government influences to act as sophisticated buyer which provide needed inputs and upgrade local demand conditions" (Porter, 1990). In particular, Public Procurement of goods and services in a public Governments context is a strategic activity aiming to provide needed inputs for improving the citizens' conditions and, so doing, to reach the welfare level goals.

In the EU, specifically, the Public Procurement strategy aims to increase EU countries' and citizens' welfare levels. Public Procurement affects the public debt, being quantitatively from 10% to 20% of a EU country public expense; consequently public debts contingencies often consider Public Procurement as a priority in the Governments Agendas. Public expense management and Public Procurement Systems should generally aim to reduce bureaucracy and administrative costs (process reengineering), to negotiate effective prices with the different market sector, increasing the quality of goods and services in a medium-long term.

Centralization of Procurements stations and tender processes, and e-procurement tools and are two strategic pillars of today's EU strategy. Centralization should reduce tender procedure and administrative costs and increase the power of demand; consequently contract prices of public-private transactions should decrease, and in the medium term, should contribute to lower the Public expense without affecting the quality of needed factors, tangibles (goods), intangibles (services).

E-procurement has a huge potential in term of administrative cost reduction, bureaucracy simplification, optimization of the employees and resources involved in the process, of time constraints, transparency level. Transparency, in particular, can help in fighting corruption and misbehaviours and in building dataset and database feeding public policies information needs and requests.

With respect to these goals, and strategy pillars, policy makers must, at first, identify the role of Central Departments in the long-term, and so doing define guidelines and mandates of the single procurement station (e.g. cities, hospitals), of possible alliances models among them (e.g. Consortium), following geographical and demographic criteria, economic parameters applied to tender models (e.g. min or max economic tender volumes per each production input), and guidelines/mandatory norms to address different public segment issues. Nevertheless the capacity of evaluating Public Procurement systems in term of socio-economic performances and, so doing, to compare different Public Procure ment models and organizations, is a complex activity, because 1. it needs a process management approach, and so the integration of different organizational professionals and tools, (e.g. in HCOs, in order to provide drugs, team of doctor, nurses, pharmacists, public procurement officers administrative employee and budget manager must work in team and often negotiate with the strategic board), 2. the expected performance can vary depending on external factors. Among these, the Nation's economic and financial "state of health" in the global context, the public services strategy and priorities, the legal set and bureaucracy impact, the politics and policy makers goals and targets, especially during electoral campaigns etc. A Public Procurement strategic management, in other words, is by definition complex and moreover it is effected by different rapidly evolving influences.

The topic of Public Procurement is worth studying for the following reasons:

a) It is economically relevant in a Public State Government balance sheet, and it contributes to its capacity to compete (see point c);

b) It has a substantial impact on Governments' public activities, and on the quality of public services (quality intended as the capacity to respond to citizens' outcome standards and specific target needs);

c) It affects competitiveness and innovation capacity of markets and companies, (as well also Nations' competitiveness and citizens' welfare).

d) Given the high management complexity, there are different institutional and management models none of which has emerged as the optimal one yet,

e) The potential improvement of its processes' efficiency, whose juridical panorama has strongly evolved in the last ten years, is extremely high, in the most of the public context of the EU;

f) research did not produce enough to substantially help top manager who are in charge of it, the academic literature on public procurement is quite poor compared with other management fields.

In particular, with respect to this last aspect (see f, above), and to the previous considerations, the debate and the research fields should aim to understand both drivers and barriers for economic and quality results of public procurement systems and tools also by improving the way to collect, and then by collecting, qualitative and quantitative data concerning the main aspects influencing the process execution and results of a Public Procurement Hub. These can be summarized as follows:

a) Public country (procurement) system,

b) Stakeholders' map,

c) Governance and organizational mission, criteria, structure, indicators (size, competences, costs etc.), swot analysis, human resources systems,

d) Financing model,

e) Legal framework,

f) Core activities processes,

g) Public clients (or users) identification and management,

h) Suppliers and bidding selection criteria,

i) (E)-business to government relationship,

l) Performance measurement and quality monitoring,

m) E-procurement solutions adoption and the evaluation of their capacity in intermediating between demand and offer, that is, between their own clients (i.e., individual public administrations) and the different market sectors.

In the present paper, after A. a review of the literature concerning the recent public procurement evolution, and B) an overview of the (E)-Public Procurement experiences in Italy and in the EU, with a specific focus on the most relevant Public Sector (Health Care), two empirical case will be presented:

The first one will present a results sum up of transactions data analysis on the Italian Public e-Marketplace in a four years' period.

II. REVIEW OF LITERATURE

In today's highly competitive business and global environment, public procurement and e-procurement need to be well equipped with all necessary knowledge, skills, and abilities, as well as innovative technologies and ICT solutions in order to survive in the regional and global markets. Researchers, practitioners and professionals continue to emphasize the need to align the curriculum, competences and ICT solutions with the needs of

national and regional economics. When the public cover a fundamental role for the territorials socio-economic growth they believe in executive education and partnership as tools for developing the capacity and flexibility to adjust highly bureaucratic systems, meet the challenges of the rapidly emerging knowledge-based global economy, and respond faster to changing needs. Therefore, rules in their different declinations (organizational regulations, regional norms, national laws, directives, International guidelines etc.) are not the only way to cope with advancing technology, transforming economy, changing demography, and more importantly dealing with the informational revolution. It is required to develop highly educated workforce and citizens who can contribute and participate in their country's economic development.

Procurement, in particular, is now seen not only as a strategic player in the value chain, but also as a major driver in the extended supply chain (Kalakota and Robinson, 2001). There is some literature expounding the benefits of innovative solutions through procurement systems, mostly connected with ICT implementation (Heywood, 2001; Minahan and Degan, 2001; Konicki, 2001;). For our field of analysis, we have outlined the benefits related to the organizational impact of efficient procurement management as follows:

- Accelerated flow of important information between buyers and suppliers, thereby shortening delivery timelines and leading to greater discounts and better services from suppliers;

- Reduced paperwork and administrative hours;

- Improved accuracy through the elimination of transaction errors and improved financial controls which match orders better;

- Improved auditing and security controls which enable staff and auditors to verify and track the movement of orders throughout the system;

- Reduced inventory levels, hence the costs associated with inventories.

Whilst these drivers provide a measure of success, it is important to consider the possible barriers that organizations may experience when adopting new procurement solutions (e.g. through ICT). A summary of these barriers (Attaran, 2001; Gebauer, 1998; Hawking et al., 2004) are the lack of specific procurement competences, the lack of relationships management with suppliers, and, related to ICT solutions, the security of transactions, the high cost of technology and the lack of technical expertise. With respect to the above, the literature (Andersen, 2004; Henriksen and Mahnke, 2004) reveals that these barriers and requirements tend to increase within the public sector, mainly because of the impact of different economic, institutional and social factors which influence the public domain with respect to the private sector (Gichoya, 2005; Maniatopoulos 2004; Tonkin 2003; Zulfiqar et al. 2001). These differences have resulted in a number of specific regulations and standards developed for public (e)-Procurement and requiring bureaucratic procedures. The bureaucracy, also related to the nature of the institutions involved, (Somasundaram and Damsgaard, 2005) embraces audit, accountability and compliance standards with national and international rules to ensure supply competition and transparency in the awarding of contracts.

Furthermore, Governments' agendas are typically more extensive and complex than the private organizations' ones, where efficiency, cost reduction and time saving are sufficient justifications for the adoption of specific procurement and e-procurement solutions (Coulthard and Castleman, 2001). The relevance of this reality means that one of the first challenges for a procurement policy and standards framework is to recognize that within a public sector context, procurement is more complicated than in the private sector and e-procurement becomes a tool for wider socio-economic goals. At the international level, public procurement rules depend on the country's legal setting and on purchase players (Central and Local Governments, public agencies, Health Care Organizations, etc.). International agreements on public tendering and procurement (WTO, OECD, EBRD) aim to regulate goods, services and work trade opportunities between public buyers and private organizations across different countries and aim to create a common framework based on social goals and key principles (e.g. Maastricht Treaty). These principles, in and of themselves, have proven to be necessary and insufficient in guaranteeing the development of a single and transparent European public market, in improving public services and, so doing, in enforcing Governments social role.

Following EU and EU countries' rules and orientations new ICT tools have been produced at a European level to facilitate the match between demand and offer (e.g., Simap website, Electronic Tendering, Directives to stimulate the use of ICT, etc.); the more the public service impact on individuals and communities is relevant (for example, health care services, environmental issues, creation of job opportunities), the more public procurement rules and ICT tools should be effectively managed. Moreover, the EU harmonization process can face difficulties depending on the different national context and the political, juridical, cultural and institutional profile of each country. The EU countries' public procurement models are basically identified by their grade of centralization/decentralization and by the extension of their public mandate (i.e., their scope and if it is mandatory or not), and on the different typologies of goods/services.

III. E-PROCUREMENT OVERVIEW (FOCUS ON HEALTH CARE)

The 2004 European directive regarding public calls for tender has been acknowledged only in 2006 in many European countries (just Denmark incorporated the European Directives in before – in 2004). However many countries have been considerably active and interested in the subject since the '90s, and have been investing resources in the adoption of e-Procurement databases/platforms for Public Administration purposes.

The Member States of the EU need organisational structures to carry out public procurement functions. These tasks range from the drafting of relevant legislation and development of public procurement policies to the training of procurement officers and publication of contract notices, ending with the structural targeted mission, and mandates delegation processe to new and already existing public procurement bodies. Particularly, many EU countries have adopted a model with a Central Procurement Department aiming to purchase goods and services for the public bodies like Cities, Regions, Provinces, Health Care Organizations (HCOs), Central Ministers etc etc. And the number is seemingly increasing due to the necessity to act more effectively on the public expense, and to optimize the public processes reducing the related costs. Still not all the European governments satisfy their needs through a central procurement agency given that there should be defined criteria, parameters and economic levels in order to identify when a procurement body is centralized and when it is not (10 institutions out of 19 were considered, Piga & Zanza, 2004, and more than 15 in year 2015 following different sources). In Italy, for example, there exists CONSIP Spa one of the biggest, most active and most representative European bodies and platforms, (around 250 employees). Moreover only Tuscany Region, out of 20 Italian Regions, has been developing a stable central procurement model since the very beginning of the territorial centralization process started in the early years of the new millennium. Although differing in terms of responsibilities, functions and tasks, as well as in implemented e-procurement projects, in Europe these bodies have several features in common. European countries tend to choose an external technology for the creation of an e-Procurement platform: The platform of a large number of projects is supplied by a provider that supplies the necessary technology whereas the purchase of a license is less frequent. Only in rarest cases European countries choose to produce internally the platform using their own resources to create the code owned by the Government. The platform organization is usually managed by agencies appointed by central entities: such agencies manage the relationships with public entities and promote the use of the platform.

The analysis of all the various instruments available on the public e-Procurement portals reveals a preference for auctions and calls for tender rather than catalogues and electronic markets. In all assessed countries there is project for the realization of an e-Sourcing platform, although such projects are all at different stages: if on one hand the initial phases of the process are all covered in most cases, (especially the phase of the call for tender publication), on the other hand the number of operating projects decreases as the further phases of the purchasing process are approached (Finland, Greece, Sweden, Ireland). However, in Europe there is a large number of public platforms that allow online negotiation and show more interest for calls managed with an open procedure. Electronic Catalogues are more and more widespread, although not as much as Calls and Auctions: these catalogues allow public entities to purchase directly from suppliers which published their proposal on the web following an authorization by the catalogue manager.

Electronic markets are becoming more relevant and strategic in EU approach to increase efficiency in public mgmt. E.g. E-market enable public entities to ask suppliers for direct orders or quotations saving time and costs.

It is interesting to assess how the different European portals offer their services to users. In some cases such as in Italy, the use of the national e-Procurement system is for free both for entities and suppliers. In other frequent cases in Europe there are several examples of platforms that charge for their services more frequently users, but sometimes also suppliers. There are different revenue policies also within each country, where different payment methods are applied to different e-Procurement instruments (in some cases suppliers pay for a catalogue update, in some others entities are requested for a fee for the use of the platform; some other time suppliers are requested for a percentage fee on the goods sold.

Italian Governments, local or not, are living a turbulent and rapidly evolving period in which the transformation of Government management (and procurement) is passing through many political, institutional and regulatory changes that began in the late ‘90s and are now still far from a stable solution. In particular, in 2006 the new legal setting concerning public procurement (“Nuovo Codice degli Appalti Pubblici”) has been approved by the Italian Parliament with the goal, among the others, to conform and align the national rules to the European ones. The Public System changes led to a model in which many central actors on a regional base are developing after the formula developed at the National level by CONSIP (Public Contracts and ICT Solutions Services Agency) for all public entities across the country (Hospitals and HCOs for which operates a specific Business Unit, Central Governments, Regions, Provinces, and other local administrations). CONSIP is a public company created by the Ministry of the Economy and Finance in 1997 in order to set up both the traditional procedures and the IT platform to carry out public acquisition processes at the central-national level in order to rationalize public expenditures, with a special focus on the Public Health Care Sector, whose national debt is extremely high, and whose public expenses are particularly critical in term of impact on welfare states. The key issues of today’s Italian National Healthcare System (SSN) are below summarized:

Constancy of changing dynamics

Institutional reintegration process

Regionalization (meaning centralization and differentiation mix)

Centrality of operations

Tension in searching Economic and financial equilibrium

In Figure 1 a representation of the health care public expense following economic classification (2012) showing how good and services (second column of Fig. 1 from left) is about a third of the Total; another third is represented by salaries, rewards and other expenses for personnel (first column from left).

After many juridical and organizational changes, today CONSIP is providing e-procurement solutions through electronic tools like the electronic catalogue, the electronic marketplace and the on-line auctions, still their mandate seem to be too challenging because of A. Italy's dimension and territory, population (60 million people), B. public administration numbers (8100 just the cities), C. welfare level and dimensions gap among the 20 Regions, especially between the Southern and Northern, D. the specificity of the Public Health Care sector in term of needs of minimum quality level requested (to the input factors). This last aspect is the most critical as Centralization imply standardization efforts on the demand needs, brought up by the different target client tipologies (Cities, HCOs, Regiones etc etc). Health care need cannot be completely standardized, especially considering the demography trends and consequent epidemiology trends (social and health care needs changes together with the population structure change).

	e. level of aggregation of demand,
	f. organization-execution; critic point,
6. Uncertain/variable centralization process	g. ICT technologies and tools
	h. potential impact on care services;

IV. METHODOLOGY

The methodology is a case study approach. The research case study has been defined as a method for learning the "right" questions to ask (Hoaglin et al., 1982). That is, the purpose of case studies is said by some researchers to be to generate hypotheses rather than to test or confirm them. The method involves an in-depth, longitudinal examination of a single instance. In our research, we used the research case study as a method for learning about a complex instance, like public e-procurement, describing extensively the whole context in order to clarify its goals and give a comprehensive understanding.

We've adopted an "illustrative approach" to case studies, which primarily describes what is happening and why, to show what a situation is like. This can help in the interpretation of public e-procurement phenomenon, particularly because we have reason to believe most experts, professionals, business man and academics know too little about the Italian context.

We have been conducting 1. Data analysis on the Italian National Public Administration e-Marketplace transactions for the last four years, through the elaboration of transactional data and, 2. Case-study methodology (Yin, 1984; Eisenhardt, 1989) on the Calabria Italian Region Procurement Model, combining different data collection methods: archives' analysis, interviews, secondary sources, direct observation and transactions data analysis.

In the first analysis, the data compiled relate to the following dimensions:

1. value and number of transactions by six-monthly intervals and by geographic area;
2. value and number of transactions divided by modes of acquisition, specifically, Request For Quotation (RFQ) transactions and direct transactions or Direct Order of Acquisition (RFO) over half-yearly intervals and by geographic area;
3. average value of RFQ and RFO as well as the flow over six-monthly intervals;
4. number of active suppliers by geographic area and the flow over six-month intervals;
5. number of active suppliers by catalogue type (ICT, office, services, health materials, others) and the flow over six-monthly intervals;
6. number of active suppliers by type of catalogues that cover a single area per catalogue (e.g. ICT only), 2 areas per catalogue (e.g. ICT and services), etc.

In the second part, the focus will be on the single contracting office of Calabria Region, with a focus on the transactional data analysis, provided by the Calabria Contracting Office most widely used e-procurement ICT platform (Albofornitori", now Net4Market), managed by CSAmed Company.

V. THE ITALIAN E-PUBLIC MARKET STUDY (2004-2008)

The analysis here presented is divided in parts, depending on the above mentioned dimensions.

The first part of the analysis has as dimension the number of the transactions (figure 1). The first illustration shows this dimension semester by semester over the period running from January 2004 through September 2008.

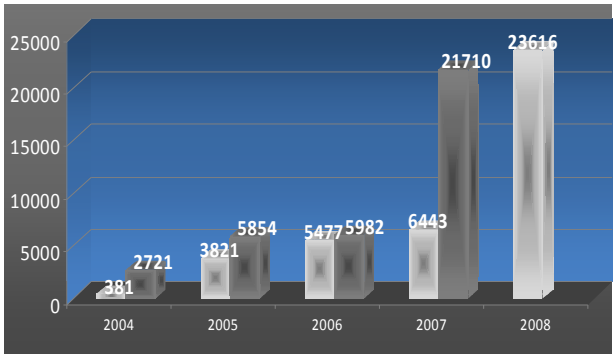

Figure 1 Number of transactions semester by semester from 2004 to 2008

Up from the first semester of 2004 - the starting point of the analysis - to the second semester of 2005, the trend in the number of transactions has always been on the rise, going from 381 to 5.854 transactions by the end of 2005. This process of steady growth has slightly decreased by the first semester of 2006 just to recover during the second semester of the same year and carry on till June 2008 - the month in which the analysis concludes. Taking into consideration the time scope that runs from the second semester of 2005 through June 2008, two different situations emerge. Up until June 2007 the process of growth in the number of transactions was slightly closer to a situation of stability, while in the second semester of 2007 witnessed acceleration tripled the number of transactions. The first half of 2008 marked another increase of the number of transactions; it may seem that, as in 2006, there was a movement towards a situation close to the stability but at a higher level, which in 2006 was around 6.000 transactions per year while in 2008 is around 22.500 transactions a year.

This reading shows a gradual learning process on the part of the supply and demand elements, leading to a stability, still, with a high growth potential of the market in late 2005, the date by which transactions had been stabilized until 2007, when a new Law (296/2006) introduced the compulsory membership to the system of conventions for Central Public Administrations (Ministers etc) and certain categories of private assets identified annually by the P.A. Electronic market. With the same budget, the P.A. Electronic Market became a binding instrument for purchases made by the central institutions. Hence the reason of the large increase in transactions since the second half of 2007 was clear.

The second illustration has still as dimensions the amount and number of transactions, divided into demand RFQ (request for quotation) and RFO (request for order), through an annual scope of time (Table 1).

RFO allows public institutions to purchase directly from the e-Catalog at pre-set prices. There is the possibility to choose a product from this catalog, by investigating the general conditions of contract, filling the order form (number, place of delivery) and signing the form with the digital signature that must then be sent to the supplier through the system. The contract is automatically and immediately a binding agreement between the parties in question; therefore the supplier is obliged to implement the agreement respecting the terms and conditions laid down.

RFQ is a more complex purchasing procedure. The RFQ is a competitive selection process through which public authorities make a request of supply to certain groups of suppliers or to all qualified suppliers so that they are able to make their bids. The suppliers in question should satisfy the money criterion and provide details related to the supply, including the technical ones from a quality point of view. The contract is awarded to those who fulfill the price-quality combination. The assignment of RFQ is carried out at the discretion of public authorities. They can, for example, pick suppliers that charge the lowest prices and promptly deliver on post-sale services.

	Numbers		Amount	
Year	RFO	RFQ	RFO	RFQ
04	2.520	426	4.391.716	4.947.443
05	7.721	1.253	12.699.547	17.144.210
06	9.862	1.597	12.920.627	24.971.498
07	23.393	4.760	30.593.134	53.021.577
08 (1°Sem)	19.199	4.507	20.861.319	42.528.345
Tot.	62.695	12.543	81.466.345	142.613.075

Table 1 Amount and number of transactions for RFO and RFQ

This table demonstrates that public institutions has been using since 2004 most of the RFO tool more than RFQ one. On the opposite the total amount of transactions through RFQ is decidedly higher than through the RFO, (just in 2004 it was slightly higher).

According to the characteristics of the two types of e-Procurement, RFO is more prompt and straightforward than RFQ, which explains why the number of transactions through RFO that supersedes the ones done through RFQ. Even if RFQ allows the making of requests on suppliers, it will require a greater commitment from both the requesting and the supplying party, which affects the element of immediacy. Public bodies seek to obtain from suppliers offers tailored to their needs and therefore buy more expensive products because of the greater focus in the purchase and willing to spend more money. RFQ transactions are of higher value than the RFO ones. Public bodies seek to obtain from suppliers offers tailored to their needs therefore linked to more expensive products. The greater focus is on the purchasing process and therefore will be at disposition to spend more money.

The third report refers to the number of suppliers in each geographic area considered for every semester from January 2004 to June 2008 (figure 2). Data were grouped by five geographic area (Central, Islands, North East, North West, and South). From the graph we see that the number of providers has been increasing in every geographic area over time. Considering the entire time horizon, the area with the largest number of providers has been the Central with a share of 37%, followed by the North West that has 24% of the number of suppliers then the areas of South and North East that each has 15% of the number of suppliers and last come the Islands with 9%. From the second half of 2007, as anticipated, there was a proliferation of suppliers and this is due to transactions occurring within that period as a result of regulatory requirements.

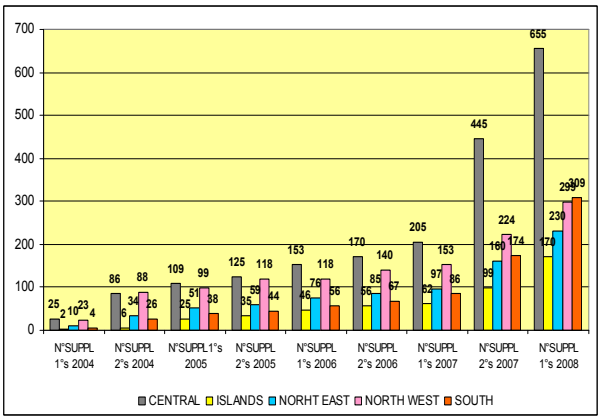

Figure 2 Number of suppliers per geographical area per semester

We can notice the growth in the number of active suppliers has been slow and steady up until June 2007 in all areas, with the Center and the North-West that stepped onto a higher level than the other areas due to the quick "sprint" made in the second half of 2005. During the second half of 2007, it is clear that it was a crucial period showing strong growth in the number of suppliers for each active area. The most significant growth occurred respectively in Central and Southern areas. The reason of the growth in the Central areas is linked to the compulsoriness of the public contracts below the EU threshold for Central Governments. The trend of growth of other areas, however, developed at a rate substantially lower (and similar) among them. Finally it is to be noted that the North West until the second half of 2005 has kept the pace of growth of the Center but paved the way after a period of stability in the first half of 2006.

The fourth report has as a dimension the number of active suppliers for each category with half-yearly flow (figure 3). Every catalog is defined according to the product it refers to. The product areas covered include ICT, Services, Health, Office supplies and "others". The total number of suppliers to be considered is 6248 that runs from January 2004 through June 2008. From the graph we see that the number of active suppliers has increased overtime for each catalog (apart from health). The product area in which the number of suppliers growth rate has increased less is Health that has been constant by that time ranging from nine to fifteen units; the second product area in which the number of suppliers growth rate has increased less is ICT (see also Figure 5). On the other hand, the office supplies area has been marked by the highest rate of growth. Other areas have instead seen both the number of suppliers and their growth rate increasing. Once again, the most growth rate was scored in 2007 (see also Figure 5). The total number of suppliers (83%) is active for Office Supplies and ICT catalogs (respectively 45% and 38%), with the remaining 17% divided among others (8%), services (7%) and Health (2%). Finally, it should be added that the services are considered from 2005 onwards, as there have been no previous data available and for the same reason Health is considered by the second half of 2004 onwards. In the following chart, catalogs have been separated from each other in order to highlight the flow in the number of suppliers during the semesters of the same period (figure 4).

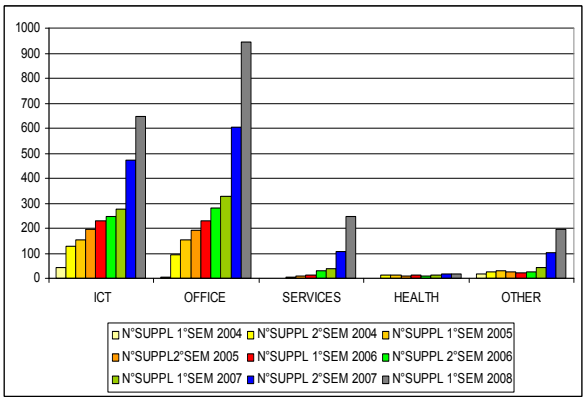

Figure 3 Number of active suppliers per category, per semester.

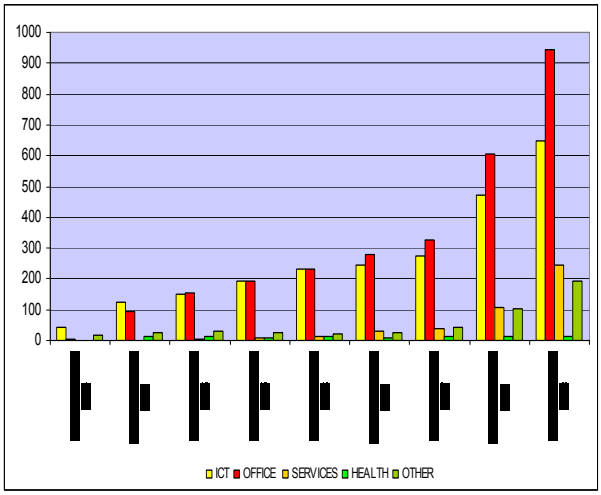

Figure 4 Evolution in the number of suppliers per semesters.

The national public bodies can be divided in Central Governments, 20 Regions, 109 Provinces, 8100 Cities, almost 276 Health Care Organizations, more then 50 Universities, Public Agencies, etc. In particular, the minimal e-transactions numbers and amounts of Health area (and related market number of suppliers) show us that the Public Health Sector and its Health Care Organisations are resistant to use the P.A. Electronic Catalogue.

The fifth illustration is the number of active suppliers catalogs by type (figure 5):

1. Mono-catalogue: suppliers that cover a single product area, are identified by the orange columns (one per catalog);
2. Bi-catalog: suppliers that cover two areas, are identified by the brown columns (one per each pair of catalogs);
3. Multi-catalog: suppliers that cover three or 4 areas, are identified by the blue columns (one for each triad of catalogs).

The graph shows that of 1.519 the considered suppliers, the major part (1.187) is operating in a single product area and thus provides a single catalog. 78% of the suppliers is mono-catalogue and focuses mainly on Office, ICT and (mostly related) Services. Bi-catalogue suppliers are the 19% that corresponds to the 288 suppliers of which 227 are involved in ICT products and Office. Only 3% of multi-catalogue suppliers (44 suppliers) are mainly engaged in ICT, Office and others.

The last illustration shows the suppliers divided in terms of regional, cross-regional and national areas (figure 6). It also shows the size of the firms which supply according to the number of employees:

⇒ Micro: less than 7 employees,

⇒ Small: from 7 to 13 employees,

⇒ Medium: from 14 to 62 employees,

⇒ Large: more than 62 employees.

You may notice that the number of suppliers on a national scale is rather small compared to those that operate on a regional or cross-regional. Providers operating at a national level represent 7% of the sample considered. The weight of the suppliers on a regional scale is 28%. 65% of the providers acted on a territorial area called multi-region, as it has embraced at least two regions. Such reasoning can be found in the size of firms that provide - especially micro and small - that are sufficiently large to provide for public entities located in at least two regions, uSUAlly neighboring, but not so much to cover the whole country. The micro-suppliers accounted for 60% of the supplying companies, small businesses 28%, those of medium size 8%, while large companies 4%.

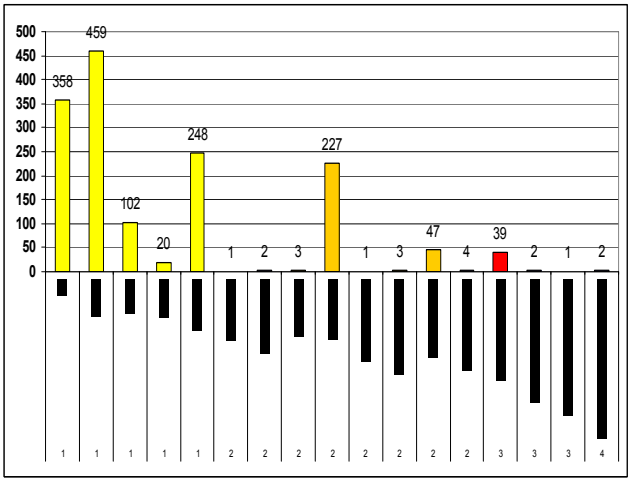

Figure 5 Number of active suppliers catalogs by type Over four and a half years of analysis, we do understand that the level its development was good passing from the initial 381 transactions of the first half of 2004 to 23.616 transactions in the first half of 2008. A major impetus to the growth was given by the Finance Act 2007 which forecast the mandatory use of the public e-market for purchases below the threshold of central institutions. The growth according to 2008 data is ongoing but at a rate far below that of 2007. In confirmation of what we just wrote is the fact that the number of active suppliers by geographic area and by type of catalog (excluding the health area) has steadily increased in these four years and a half with a decisive leap forward during the second semester of 2007. The area that has made the greatest number of transactions is the Center in that it spent the highest amount. The catalogs are the most used of ICT and Office Supplies. Health care

In addition, it is noteworthy that the Electronic Marketplace offers member administrations the possibility of concluding contracts through two different procedures for the purchase: the direct order of purchase (RFO) and the request for tender (RFQ). The data analysis shows that the number of transactions through the RFO is higher than that the ones through RFQ but that the amount of transactions is higher in the purchases made through RFQ. The total amount of purchases through RFQ in the reporting period was 1.75 times greater than the value of purchases through RFO. This is also confirmed by the fact that the average value of transactions through RFQ is significantly higher than that the ones through the RFO.

It should also be noted that 78% (1.187) of the considered suppliers (1.519) is monocatalog and focuses on Office, Information Technology and Services. Bicatalog Suppliers is 19% which corresponds to 288 suppliers of which 227 involved in ICT products and Office. Only 3% of suppliers (44 suppliers) are multicatalog and mainly engaged in ICT, Office and Others. The conclusion is that most served catalogs are those relating to office supplies and ICT and that competition among suppliers in more than one catalog is fairly limited.

In Italy during the second half of 2007 – significant year due new legislations - suppliers were distributed among 60% of micro-sized companies, 28% of small-sized companies, 8% medium and 4% larger firms. Furthermore 65% of these companies operated on a cross-regional level, 28% on a single region while the remaining 8% on a national scale. Most companies were small and operated in most regions. A result in line with the tradition of the Italian market made up of small and medium enterprises.

VI. THE CALABRIA REGION CASE- STUDY

Calabria is a region of Southern Italy, normally represented like “the tip of the boot", with a population of about 1.9 million inhabitants, (out of the 60.millions of Italy) and with its administrative capital, Catanzaro, placed between two seas (Ionian and Tyrrhenian). In Calabria, as well as in Sicily and Campania, the two closest Regions, underworld and organized crime play a relevant role, also impacting on public procurement activities.

The fight against organized crime is one of its policies key pillars. A priority is given by the attempt to exclude from such public procedures their presence. In Calabria, in particular, the fight has been conducted trying to identify ways of managing public procurement which exclude criminal interference. In 2007 the Region Institution, with special regional law, established the Station Unique Contracting Authority, a public body which, in intention, should take care of all the public contracts of its administrations (HCOs, Region, Cities, Provinces etc), including contracts for goods and services.

The purpose of this approach is, moreover, to optimize the processes, to create economy of scale by purchasing common and standardized goods/services, and so doing increasing the control of criminal infiltration.

A. The Single Station Contracting (SUA - Stazione Unica Appaltante)

SUA has been established in 2007 and has begun to take steps, through an observatory of contracts in the region, both through the direct management of the contracts: normally this is done or at the request of a specific entity for a particular contract (the SUA provides its structure to manage the contract on behalf of the Entity) or by pooling the needs of various organizations for specific product categories (the SUA manages a contract for the sum of the needs of various entities).

As often happens in the low performing Italian areas, however, the allocation of resources, has been limited and, accordingly, the results, based on professionalism and dedication of officials, are lower than those that we had in the prefixes' institutions.

Procurement of ICTs is handled partly via traditional (paper) and in part by on-line purchase, with different platforms.

"Albofornitori" (now Net4Market) provided by CSAmed Company, has been widely used by the SUA, especially in the Health Sector.

B. The results

The SUA led from 2009 to 2014, seven races of considerable economic importance, with the platform albofornitori (literally ....), For a total of about 1,440 million of Euros for a total of approximately 4,800 lots.

Among other stand out, for particular conditions, as the amount per race (between 400 and 700 million), the number of lots (well above 1,000) and by the number of participants (more than 100 per race), the regional competitions drugs for all healthcare organizations in the region.

It is currently an ongoing SDA drugs, whose values will be in addition to those already reported.

The SUA decided to use for this new purchase drugs System Dynamic Acquisition, on which the European Union is pushing a lot, in order to avoid extreme market dynamics of drugs (much needs changing, patents expire and companies that change structure very easily).

The new SDA was posted on 27/11/2014, it lasts three years, covers a demand for drugs provided about € 140 million, although it is expected that this figure will grow significantly.

The Calabria Region has instituted a Commission Station (SUA – Unique Contractor Station) whose aim is to manage from a central office the tenders of the regional authorities, in particular as far as the healthcare enterprises are concerned. The main goals of the SUA institutions are the governments' processes optimization, the economies of scale and the fight of corruption..

During the last years, the SUA has convened some tenders for the purchase of drugs of all the healthcare enterprises of the Region: in this case study we are going to analyze the very last one. Its management complexity is related to:

– the necessity of coordinating in order to focus on the needs concerning the type of drugs as well as their amount

– the total number of drugs to be purchased (2.138 different types) and the whole budget for the tender (745.377.630,69 euros)

– the number of participating enterprises (127)

A tender like this uSUAlly lasts from ten to sixteen months, adopting the traditional technique.

A special procedure was adopted in order to collect data: it allows every healthcare enterprise to insert the amount of the previous drugs and to add the new ones; this phase lasted more or less two months and included the discussion concerning the healing features and their eventual overlap. After that the call for bids was electronically published (having the documents been prepared before), the forum was activated and 127 suppliers were accredited. Afterwards the offers were electronically collected through the "electronic sealed envelope". The procedure is composed by the following 3-? 4: phases

- First , …..and the first ranking was drafted.

- Second: a second round of offers' collection: these offers were supposed to improve the previous ones.

- Third: offers and drugs were compared and the third ranking was finally published.

After that, the technical paper forms were deposited at the SUA.

This whole phase lasted more or less 160 days: the whole tender therefore lasted more or less seven months. Moreover, all the documents were automatically producted and all the contracting data were automatically sent to every commission station.

The security question is really important in tenders and was solved by using the "telematic sealed envelope©": it is based on operations temporarily articulated that make the offer of every supplier 100% secure: in fact, there is no algorithm that can fully protect a file from being read; it can only decrease this likelihood. On the contrary, this system is not based on algorithms, but on a timing, and therefore it is useless to know the contents of the various offers. This opportinuty is deeply important in such a suspicious environment.

With this tender the 84% of drugs were awarded a contract (1.801 lots awarded upon 2.138 tendering), while the average percentage is settled on the 70%. The cumulative purchase prices were decreased of 14,60%, which corresponds more or less to 100 million of euros.

VII. CONCLUSIONS

Following EU and EU countries' approach, rules and orientations, ICT tools have been empowering their role at a European level to facilitate the match the efficiency and the transparency between demand and offer (e.g., Simap website, Electronic Tendering, Directives to stimulate the use of ICT, the public process digitalization etc.); the more the public service impact on individuals and communities is relevant (for example, health care services, environmental issues, creation of job opportunities), the more public procurement rules and ICT tools should be effectively managed.

Moreover the EU harmonization process can face difficulties depending on the different national context and the political, juridical, cultural and institutional profile of each country. The EU countries public procurement models are basically identified by their grade of centralization/decentralization and by the extension of their public mandate (i.e., their scope and if it is mandatory or not), and on the different typologies of goods/services. Many EU countries adopted a model with a Central Procurement Department aiming to purchase goods and services for the public bodies. The Italian one is one of the most active and representative. Still it seems that is not sufficient as being just a part of the plans to review public spending, e-Procurement entities and ICT Software Companies have now a key role in both modernization and increasing the efficiency of both monitoring of government accounts. The importance and impact that computerized purchasing tools not only stems from the fact that public procurement accounts for about 16% of GDP (on average in EU countries), but they can also bring benefits into the management of the P.A. evolution. The P.A. Electronic Market, the virtual site for demand & supply in the form of structured and dynamic electronic catalogs, for contracts below the threshold of Community importance, is undoubtedly among the most advanced B2G tools. In Italy it has been launched in 2003 and it has now e-Catalogs with over 400,000 products with technical data sheets on which they can be searched, with automatic, direct purchases and requests for bids through the use of digital signature. Additionally, these systems also enables the management and archiving of digital streams (the contracts and bid requests that occur between P.A. and Suppliers). They are a tool that offers no pre-negotiated bids, and allows local PMI to qualify and get in touch with customers who maintain complete autonomy to choose among different suppliers and products, because the same product can be sold by several vendors, as in any traditional market.

On the base of research results, we understand how E-Procurement Central Bodies can be a guiding tool for the promotion of organizational and procedural P.A. changes which impacts and provides opportunities not only on the part of public demand but also supply, still they need to identify ICT Companies with the capacity to help them in covering strategic and potentially key role in the welfare context. That means to identify first the specific areas, (geographical, technical, merchandising, functional, service areas) on which they may need assistance in order to develop partnership with small-medium Softaware Companies that since the beginning of their life have the vocation for understanding public clients' needs and for innovation.

The picture that has been traced thus highlights what is now the potential role of E-public markets in purchases under the threshold of the whole public administration, especially in light of the requirements dictated by legislations such as EU Directives, the various EU counties Codes of Contracts and the Finance Acts.

The research also shows us that the Public Health Sector is resistant to use the P.A. Electronic Catalogue. A reason, to be anyway more investigated, can be the high relevance of quality factors for health products, and the consequent reduction of price (and administrative costs) relevance; public health purchasers consider e-procurement solutions inadequate for selecting quality. More in general, Public bodies which seek to obtain from suppliers offers tailored to their needs, are willing to select quality aspects and, therefore, either not to be so much price-oriented or to acquire more expensive products.

Finally we can state that the need to reduce public expenditure, administrative costs and timing, and to increase transparency led to new public procurement institutional models; together with the ICT evolution a relevant institutional change may be connected to e-procurement solutions and realization of ICT platforms. The Italian situation show us a high growth potential connected to these models and solutions, even if strictly related to juridical changes (e.g. compulsoriness of public contracts).

Future steps can be the analysis of the e-transactions by Government typology to check differences among non-Central Administrations (Local, and Public Health Sector Administrations, Universities etc), and understandings of the potential margins of growth in the different market sector also depending on political, cultural, economic and organizational drivers and barriers.

Abstract - Widespread implementation and ubiquitous beneficial impact of ICT technologies is often praised as a decisive factor demarcating the frontier between "old" (classical), and "new" models of digital economies. However, exact quantitative analysis of such impact on a micro and macro level shows some surprising results. No unique conclusions could be applied to all countries and in all timespans. ICT technologies are subject to the law of diminishing returns more than any other, their impact is notoriously difficult to measure and carries a number of hidden and sunk costs and transfer effects. Furthermore, there is a distinctive difference in yields derived from ICT technologies in national economies depending on their use or development and production. On a microeconomic level of a single company, only investments in those ICT technologies that aim to preserve and increase value of the information capital can be economically justified. In this paper, the authors will research and elaborate the impact of implementation of ICT technologies on the corporate level and aggregate measures of national economies.

I. INTRODUCTION

ICT is an important part of the fourth, quaternary sector of the national economies, along with state and society management, culture, education and science. However, none of those activities are usually attributed with such intrinsic characteristics in regard to their possibility to positively influence aggregates of the whole national economies. Macroeconomics and ICT experts are well aware of the fact that ICT possesses a number of specific characteristics that have to be taken into consideration prior to reaching final conclusions on the subject issue.

In order to analyze the impact of ICT technologies as a driver of businesses and modern (digital) economies, it is important to study and outline characteristics of the quaternary sector of the national economy where ICT dominantly operates, to describe the impact of ICT on a company level, and then translate it to aggregates of the national economies.

II. ICT AND QUARTENARY SECTOR OF THE NATIONAL ECONOMIES

The main determinant of the quaternary sector is the usage of knowledge and skills in the final product, rather than raw materials, products or simpler forms of services. It is tightly connected with intellectual services and further with use of ICT, research and development in scientific fields and consultancy. Some theorists also include pure services (those services that are the highest form of services provided to end consumers in the marketing continuum, facilitating direct contact to customers) in this sector [1].

Quaternary sector has developed inside the process of further evolution of the three-sector hypothesis of industry, developed by Alan Fisher, Colin Clark and Jean Fourastié [2], and in fact it is a derivative of the tertiary (service) sector presented in that model. These sectors are illustrated in Figure 1 where percentages of a country's economy made up by different sectors based on its level of income or development are shown. The primary sector operates primarily on activities of extraction of raw materials. The secondary sector consists of activities converting the raw materials into manufactured goods. The tertiary sector is the provision of services rather than the manufacture of goods. Countries that have achieved higher levels of socio-economic development tend to have less of their economies made up of primary and secondary sectors and relatively more employment in economic activities in tertiary sectors (and consequentially, quaternary and quinary sectors) [3]. Underdeveloped and developing countries exhibit completely inverse pattern: majority of employees work in primary and secondary sectors of national economies. Consequentially, that is where majority of economic activity happens and most of GNP is created there instead of sectors with higher percentage of value-added economic activities. These facts are shown in the following Figure 1.

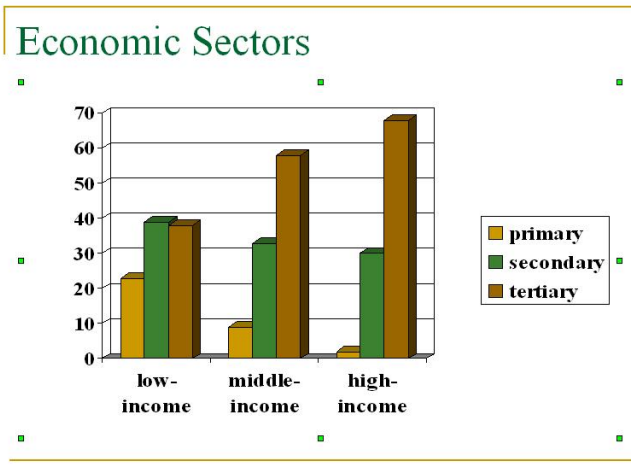

Fig 1. Economic sectors and income (adapted by the authors according to [4])

Generally, the emergence of quaternary economic sector requires significant levels of highly educated workforce. In developed countries, tertiary and quinary sectors usually make up the predominant part of the economy and employ between two thirds and three quarters of the workforce. On the microeconomic level, companies generally view investments in this sector as one of the possibilities of further expansion because returns on investments and margins are generally higher in this sector.

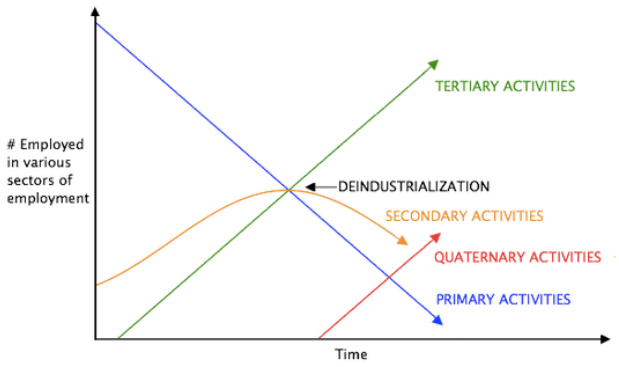

Fig 2. Visual representation of dynamics of modelled activity changes in relation to increase of tertiary and quaternary activities and decline of primary and secondary activities after peak of deindustrialization (adapted by the authors according to [5])

In Colin Clark's sector model of an economy during technological change shown in Figure 2, increase of the share of quaternary sector in national economies accelerates after the peak of the deindustrialization process and the decline of primary and secondary activities in the national economies (especially sharp decline of primary ones).

III. POSSIBILITIES OF MEASUREMENT OF INFLUENCE ON BUSINESSES AND NATIONAL ECONOMIES

Generally, the use of ICT technologies is considered to carry along significant levels of competitiveness, increased levels of employment and positive contribution to all economic measures. It is important to notice the verb "use" in previous sentence: very often, colloquially there is no distinction between "usage" and "production" or "creation" of ICT technologies; even the mere proximity of ICT technology to businesses is regarded as inherently positive. In this article, some clear delimiters will be set towards these attitudes, with the major goal of enhancing further considerations on the subject and fully understanding the fact that the impact of ICT technologies on national economies is a very complex topic, not just a sum of partial and superficial effects.

There is a total of ten considerations related to the influence of ICT technologies on the microeconomic level and the level of national economies that will be elaborated in the remainder of the paper.

1. *There are no unique conclusions about the influence of ICT technologies on national economies – conclusions can be made only based on analysis of individual national economies or groups (clusters) of similar economies.* Since the middle of the 1990s, factors of the growth productivity between Europe and USA have been divergent. The productivity rate in the USA has been growing constantly while in Europe it has been on the decline. The impact of use of ICT technologies on GDP growth and Total Factor Productivity (TFP) in the emerging and transitional economies is lower than in the developed countries [6]. Paradoxically, in some countries the increase of investments in ICT technologies and growth of GDP shows negative correlation. Furthermore, the impact of increased use of ICT technologies is different in various groups of countries, economic activities and in different timespans (decades).

2. *The impact of ICT on GDP and other aggregate indicators is notoriously difficult to measure.* On macroeconomic level, the fact that automatization of the businesses up to 1970s has caused measurable increase in productivity and direct transfer to productivity measures of the national economies is a well recognized fact. Some of the tools used to achieve this automatization were use of telephones, electronic calculators, fax machines, mainframe

computers for mass data processing and the use of vacuum transport tubes. However, this effect is not present in developed economies after 1970s. This seemingly contradictory concept is also known as Solow's paradox. Robert Solow, an American economist and Nobel prize winner, particularly known for his work on the theory of economic growth that culminated in the exogenous growth model, is also known for his phrase: "You can see the computer age everywhere but in the productivity statistics" [7]. There are several potential explanations for this paradox, one of them endorsed by Solow himself: the impact of ICT technologies on total factor productivity is difficult to measure. Other possible explanations are that ICT brings benefits on the microeconomic (company) level, but also adds cost to other stakeholders on the market, so total gains are small (or can be even negative). ICT is very complex, difficult and expensive to manage, so summary benefits are lower than initially and often subjectively expected. Furthermore, the decreased need for human labour caused by use of computers negates potential positive effects on the macroeconomic level [8].

3. *The impact of ICT technologies is visible with latency, and carries along significant sunk and hidden costs* [9]. This fact is aligned with problems of ICT technologies impact measurement: not only there is pronounced problem with multicolinearity and heteroscedasticity of variables used in quantification of impact of ICT technologies on gross national product, but the efect of their use is visible only in the long run. At the end of the investment cycle, significant new investments are required that are usually equal to the value of the initial investment, caused by technology's obsolescence. During the investment cycle, the use of ICT technologies carries significant operative costs (usually, it takes 4 to 5 years in current state of technological affairs for accumulated operative costs to reach the value of the initial capital investment).

4. *The use of ICT technologies is subject to the law of diminishing returns, both on the macro and microeconomic level.* "More" ICT does not necessarily mean "better", both in businesses and national economies. The question of optimum determination is always a very complex one. Economists typically tend to resolve it by applying an appropriate mix of labour and capital in the equation. Some go even a step further and claim that ICT is not a separate factor influencing the economic efficiency frontier, rather it can be attributed either to work or labour. There is a certain level of investments in ICT and operative costs where new additions do not produce added effects. Non- selective and literal application of the best practices and compliancy measures will certainly not create new ICT giants from micro businesses, and neither will indiscriminate investments in ICT technologies and infrastructure of national economies propel them to new levels. Every economy and business requires just exact amount of ICT investments, technologies and services and not less or more than that. Absorption capacity for ICT technologies is therefore quite rigid, and the only exception to this rule is production of ICT services and goods destined for export [10].

5. *ICT can be either used or produced: for national economies it is more beneficial if it is used.* This hard fact is not the best accepted among those who are proponents of indiscriminant increase of the native production of ICT technologies within national economies. In Figure 1., impact of the output and use effect on long term growth of GDP in a selected panel of countries is shown.

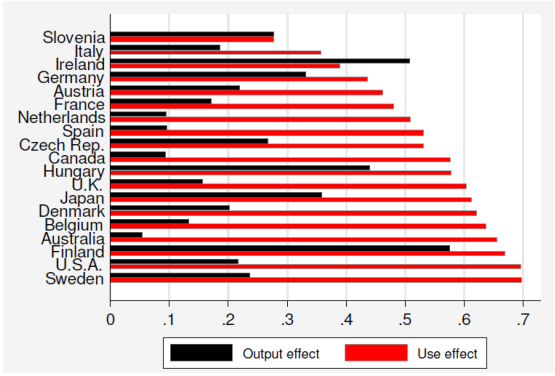

Fig 3. Effects of output and use of ICT technologies in a selected panel of countries [11]

From Figure 3 it is clearly visible that effects of production are less pronounced than use effects. Only in one country (Ireland), and caused by specific local conditions of

extremely high direct foreign investments in ICT prior to crisis eruption in 2008, the situation is inverse. In all other countries, benefits from ICT use compared to ICT production are much higher. In the case of USA or Great Britain, this ratio reaches approximately 1:3.

6. *Impact of ICT is visible in statistics of other parties (sectors and states).* Impact of ICT is not that visible in statistics of those countries that produce those technologies, but it spills over to statistics of other countries, with certain latency. Because of this reason, in macroeconomic terms ICT is considered to be so called GPT – „General Purpose Technology", a type of supporting or adjunct technology to other core processes and technologies [12]. This explains the already mentioned fact that increased levels of ICT investments in developed countries have resulted in decrease of total productivity because additional resources have to be engaged in implementation, reorganization or learning related to the adoption of new technologies.

7. *In most OECD countries, education in use of the new ICT technologies is the main cause behind their falling behind trends of business use of the same technologies.* Analysis of this apparent lag of the EU as a whole in comparison to USA shows that three main contributing factors can be identified:

   a) cost related to users' induction and implementation of systems,
   b) education, and
   c) lack of regulatory flexibility.

   These contributing factors are shown in Figure 4. for some selected developed countries.

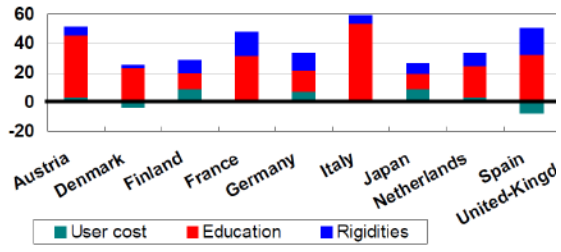

Fig 4: Factors contributing to ICT lag (adapted by the authors according to [13])

These three factors can be explained by a lower level of employed structural and organizational capital for use of ICT technologies in the EU compared to the USA. In most European countries, the main cause of the lag is education of the users, implying neccessity of additional investments in employee education and lifelong learning as support activities for successful implementation of the new ICT technologies in businesses. However, inflexibility of regulative requirements (laws and legislation related to ICT) also shows significant impact on the widening of this gap. More flexibility in law-making related to ICT, but also the labour legislation flexibility, has positive transfer effects to national level implementation of the new ICT technologies.

8. *Outsorcing enables focus to key areas.* Research that encompasses several countries and all sectors of national economies shows that those countries that use outsorcing of ICT services benefit from the increase of labour productivity in ICT intensive industries [14].

9. *Quantitative methods and econometrics can be used as a part of decision making process in ICT industries, especially related to telecommunications.* Research shows that 1% increase of broadband penetration in a general population of OECD countries between 2002 and 2007 caused direct GDP growth of 0,025% [15]. Therefore, it has been proven that on a given set of data, 40% increase of broadband penetration results in 1% increase of GDP through transfer mechanisms. In the years that have passed since this study, there has certainly been more saturation of the telecommunications market, so elasticity might have changed, but this is just an example of deployment of econometrics in decision making in ICT industries and creation of guideline for policy-makers on national levels.

10. *Conclusions related to the impact of ICT on microeconomic level cannot be directly translated to macroeconomic level.* If companies in two comparable national economies equally invest in ICT technologies, but differ in ability to introduce complementary organizational changes in order to optimally use them, increase in productivity that can be attributed to those investments will differ from one company to

another [16]. Consequentially, difference of ICT investment impact on productivity on individual companiy levels translates to macroeconomic level (national economies) in lower overall influence than the one measured or overall percieved for individual companies. Those companies that are lagging behind will either disappear from the market or catch up with respective niche leaders. However, total sector and national productivites reflect effects on both of those categories of companies: laggards and leaders.

Despite all the presented facts that might seem unexpected or contrary to the popular opinion, ICT is nevertheless a propulsive sector of national economies that proved to be very resistant to downwards trends of business cycles in the last decades. However, ICT possesses certain inherent specific characteristics and does not function well on a national level if regulatory framework is rigid, levels of employed regulatory capital are low, levels of implementation of ICT technologies are inadequate on a firm level, labor regulation is too strict and investments in employee education and training for use of new technologies is reduced.

IV. CONCLUSION

ICT technologies are typically a part of the tertiary sector of national economies and constitute most of the quaternary sector. The emergence of activities within this sector follows the peak of the process of deindustrialization and sharp decline in volume of activities in primary and secondary sectors of national economies.

However, there are some inherent specific characteristics of the ICT technologies, services and ICT based industries that separate them from other activities in the new, "digital" national economies, so it is not possible to analyze them by using the same toolbox of economic analysis that was used for previous, classical models.

The impact of ICT on national economies has to be analyzed inside the context set by overall timeframe, state of the economy and current model (transitional, mature, developed or underdeveloped countries). Usually, the countries in transition and those with underdeveloped technical penetration of ICT technologies benefit more from additional use than countries whose economies are in a more mature, developed state. However, it is important to underline that even between comparable state economies, those countries that are able to accommodate and adopt more ICT technologies because of higher deployed levels of structural capital will benefit more than countries and economies where the amount of engaged structural capital is comparably lower.

The use of ICT technologies exhibits significant spillover and transfer effects, so its impact on the levels of national economy macroeconomic aggregates is very difficult to measure, however it is indubitably tied with laws of diminishing returns, sunk and hidden costs, and especially those costs related to increased spending for education and implementation.

ICT technologies can be produced or used (implemented) to enhance business processes. National economies almost always benefit more from the use of ICT technologies than from their production. Because of aforementioned transfer effects, some costs and benefits of ICT technologies may spill across sectors or borders, so they may be present in balance sheets and accounts of other stakeholders, sectors and nations. However, it has been clearly demonstrated that econometrics and quantitative methods can be used for analysis of this phenomenon, so scholars should not be vary of deploying them in the field of analysis of the quaternary sector, while being very cautious in selection of the methods and interpretation of the output results.

Abstract - Information and communication systems in support of management to manage all business processes in the ports of nautical tourism, which means unification of business processes and information and communication technologies through the use of various methods and techniques for developing, managing and analyzing business processes involving human resources, organizations, applications, documents, and various other information as an integral part of the business process in nautical ports. The introduction of Service Oriented Architecture into existing or new information systems in the ports of nautical tourism, and ways of thinking that it offers new possibilities in terms of expansion of logistics solutions, lowering costs and increasing the quality of service end users - the sailor. Service-oriented approach is no longer projecting monolithic or multi-layer applications, but services that are autonomous with the implemented security, transaction processing and interoperability with other software services in a distributed environment.

I. INTRODUCTION

In Croatia, there are 56 marinas which are member of the Association of marinas and have over 16,000 berths and over 8,500 dry berths. Nautical ports (LNT) as traditional providers of services for boaters in recent times, are forced by the increasing competition in the tourism market, as well as by increased costs caused by the introduction of new services and raising the level of existing services. They look for new solutions and services in order to increase productivity and reduce costs. One of the solutions that are proposed is introducing the concept of orientation to the service. This term, service-oriented architecture represents a model in which the logic of the system breaks up into smaller, separate pieces of logic. These smaller parts can be independently distributed across the network.

In light of the major changes and the impact of information and communication technology on the services and strategy LNT - matter is primarily related to the globalization of business, reengineering business processes, speed of response to market conditions and the connections between all LNTs and other business entities.

The application of information and communication technology enables easier management of all resources, monitoring and controlling of all processes to improve business quality and forming services according to the wish of yachtsmen.

This paper analyzes the use of information and communication system (ICS) based on architecture-oriented services in the management of LNT at all levels of management.

Service oriented solutions are not closed, nor oriented only to one vendor of software equipment. Service oriented solutions can be integrated into different environments, different platforms and save big financial resources. There is no need to change existing software, and it is possible to exchange data between the new and old software. The introduction of the service oriented solutions in the LNT is not only a temporary solution and the aim, but can be seen from the perspective of the overall strategy, especially with the marketing plan of the marina.

2. SERVICE ORIENTED ARCHITECTURE

Service Oriented Architecture (SOA) is actually a new perspective on software architecture that defines the use of services to achieve the requirements set by the user. It is important to note that SOA does not have a universal definition valid. One definition that is consistent with the work, defines SOA as "software architecture for building applications that business processes or services, by using a set of loosely coupled components box, adjusts to provide a satisfactory level of services" [2]. Also, the SOA provides that any logic or data can be used in various ways, depending on who uses them. SOA is primarily arisen from the need to improve and rationalize business systems, which will reduce costs and increase company profit.

Architecture is subjected to changes that are often required until the structure can be observed at different levels in the business system, especially in the accompanying ICS. As the process, architecture is a set of activities of designing and constructing some physical or virtual structure but includes documented occurrence. The service is an essential element of any system based on the principles of SOA. SOA system actually provides a service that comprises one or more elemental services, often called components. The components are small

logical units that perform an operation. SOA components must ensure the level of abstraction of the business logic so that: *the message* indicates the information required to do the work or any part thereof, *operation* represents the logic required to process messages in order to carry out the unit of work, *the service* is a logical set of operations able to perform related work units and *process* contains business rules that determine which services are used to perform some task. Simplified basic concept of SOA architecture is shown in Figure 1.

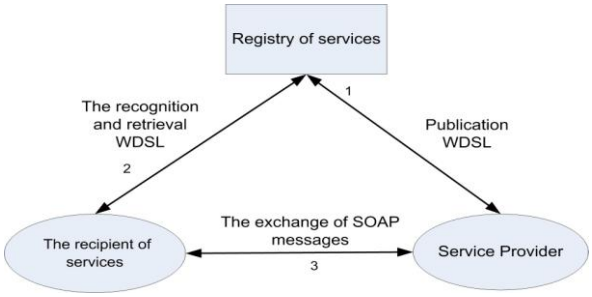

Figure 1. Main concept of SOA architecture

Figure 1. shows the way of work of Web services. The numbers on the axes indicate the order of execution of the determined steps. Step No1-service provider publishes a description of services. In step No2 a particular service on the Web is located. Step No3 is usually called a "connection with the service", and it allows SOAP (Simple Object Access Protocol).

SOA represents more than set of technologies. SOA is not directly affiliated with any technology, although it is often implemented by using Web services. Web services represent the most appropriate technology for the realization of SOA. According to available literature, the most important components of the SOA concept are: services, interfaces, messages, synchronous and asynchronous communication, registers (service provider), and the composition of services in the business process. SOA is primarily arisen from the need to improve and rationalize business systems, which will reduce costs and increase company profits. From the organization science it is well known that the business system can be divided into two levels: the level of business processes and application levels. The business level is process structured performance of business requirements along with the limitations, interconnections and external influences on these requirements. An application level solution automates business processes across different technologies. Application level contains solutions required for studying and successful flow of business processes and is usually realized through applications based on suitable technology platforms. SOA introduces the third level, the level of service interfaces. This provides the possibility of encapsulation and application and business level. Applications are separated through the platforms (.NET, J2EE, etc.) for which they are intended and reveal individual components, which now services can use through the interface. By SOA architecture, service is an essential element. SOA system actually provides a service that comprises one or more elemental services, often called the components.

To design a business process that enables the use of services by different service providers created are specialized languages that make it possible. The basis for all languages is an XML (Extensible Markup Language). Software companies that deal with this technology have become united and they created a Process Execution Language for Web Services (BPEL). BPEL is a grammar based on XML to describe control logic necessary for the coordination of services participating in a business process. Orchestration mechanism executes that grammar, coordinating and compensating the whole process in case of errors. BPEL process defines and describes the coordination of services with partners in order to achieve business objectives as well as state and the logic necessary for coordination.

Web services represent a technology that is relatively quickly and widely accepted as a way to integrate applications. Web services are based on open technologies such as:

- XML has emerged from SGML (*Standard Generalized Markup Language)* and is designed especially for Web documents. It allows users to create their own tags, allowing the transfer, validation and interpretation of data between applications and between organizations. Today is an XML language very widespread and is used for different purposes: the separation of data from presentation, data exchange, data storage, increase of data availability and creation of new specialized markup languages. XML provides an efficient, flexible and simple solution for electronic business.
- *SOAP (Simple Object Access Protocol)* is a protocol designed to transfer XML messages. SOAP is a communication mechanism for connection of Web service. SOAP consists of three parts: the first part provides a wrapper for sending Web service messages through the dormitory or an intranet, the second part has a set of rules to define special data types for the Web service, and the third part includes rules for the description of the Web service methods whereby the structure for a description of the call and corresponding Web service is included.
- *WSDL (Web Services Description Language)* is based on XML language for describing Web services. WSDL document describes how the Web service works and how to use it to communicate and where you to find it. Parts of description of a Web service can be located in multiple documents that provide more flexibility and increase the possibility of reuse.
- *UDDI (Universal Description, Discovery and Integration)* is platform-independent, based on XML, and is used to publish lists of services and mutual disclosure of the same. It also defines the way in which services or software applications collaborate over the Internet.

3. ORCHESTRATION AND CHOREOGRAPHY

In order to fully exploit the opportunities provided by the SOA architecture and provide connectivity services of different companies, it is necessary to describe in more detail the way in which services can be linked to each other. So far, there is no unified standard, but two were allocated, orchestration and choreography service (Orchestration and Choreography) [3].

The orchestration is the model for connecting various services in which all control is retained at one central process. Central process coordinates the execution of various operations of Web services according to the requirements of orchestration. Connections to Web services are being performed by the message. They contained the business logic and order of inclusion and work execution.

Choreography of service is a model based on cooperation. Choreography is not dependent on the central process. Each Web service involved in the choreography knows exactly when to execute its operations and with whom we should cooperate. It allows each Web service description part of your interaction. Choreography follows the exchange of sequences of messages between multiple parties, not just a business process that only one participant of interaction is interested in.

4. SOA APPLICATION IN BUSINESS MANAGEMENT OF NAUTICAL TOURISM PORTS

Modern and contemporary way of doing business offers to LNT huge trade and economic area, primarily related to e-business and business through the internet. Directing the business strategy of the marina to the service mode enables businesses to focus on core business and thus make improvements in competitiveness. Recognizing the importance of SOA, and the benefits that it provides (multiple service usability, scalability and manageability), in particular, a significant number of companies including also the management of the marina will have to introduce the re-engineering of existing information systems and thus fulfill expectations of sailors connected to the speed and quality of service (higher processing speed, lower cost, higher security). In this way boaters receive a completely new opportunities and the perception of service quality.

The primary objectives of the SOA in LNTs are to improve communication with subjects in order to be more efficient, more reliable, automatic exchange of information on reservations service which provides LNT and a shortened flow of business processes.

When business processes are electronically established, integrated and stored in a single database, the management of the marina is ready to orient their services to boaters through information and communication system.

A. Existing information systems in LNT

Almost all LNT management use information and communication technology in their operations. ICS are of modular construction, linked to a computer network and mostly on the Microsoft Windows platform. The main communication with guests takes place through the LNT reception. Boater can negotiate in advance, partial or total stay in the LNT, personally by direct contact with LNT (telephone, fax, e - mail or on line by filling out the form) or through an intermediary (tourist agency, agent).

Start of service execution is taken from the moment when a boater with his vessel arrives to the marina and fills in the application (information - communication center). The receptionist takes all the necessary information (personal information for boaters, vessel information, the estimated time of arrival, types of berth and determines (issues) free embroidery and turns certain supporting documentation with which boater acquires the right to use the rented berth or technical/general services. At the same time, the receptionist opens the account to pay for the agreed services. At the end of the stay, boater accesses the reception again and concludes documentation of the stay and the use of marine services, based on which he is delivered the account of the overall services for which payment is competent the reception.

Marines have their own website where they can view a detailed description of the marina (high quality images), price list, links to certain data and information (exchange rates, weather, etc.), the way of establishing the contact with the marina and others. In most marinas ICS supports i.e. available to operators are the following programming models: basic information for boaters and information on the vessel, record of berths, moorings issuance, registration fee-Ministry of Internal Affairs and tourist boards, guestbook, required reports, invoicing, cash register , subsidiary accounts, automatic accounts keeping documents, etc.). In most cases the plan of berths of marina is used i.e. visualization of state in the marina. The module is designed to control accommodation facilities and allows maximum use of capacity with a minimum number of moving vessels. In network operation, all users access the same database and can on their own computer see the data just entered or changed by the other users in the network.

B. Solution proposal

Rapid development of nautical tourism has forced the management of LNT to work continuously to improve and enrich the level of service and adapt to the modern needs and wishes of their guests. This paper proposes the introduction of SOA on existing ICS. Therefore it is necessary to create a new business process that we call ***"Reservation service",*** and it will contain all the elements necessary for the automation of marina operations. Newly created business process will support the functionality of the existing software support of ICS marina. Creating a business process consists of several models:

- Business process model, shown graphically by using BPMN diagrams.
- Ensuring communication between existing and new applications as well as adding automation of business processes by creating the following Web services:

- ✓ Web service that will allow booking and cancellation of berth in one of the offered LNT,
- ✓ Web service that will enable the booking and cancellation of technical services in one of the offered LNT,
- ✓ Web service that will enable the booking and cancellation of general services in one of the offered LNT,

- Code generating that will allow the execution of business processes, based on the created business process model.
- Creating new Web applications of portal type.
  - ✓ Web application that will provide a simple overview of the existing capacities (berths) in LNTs, organized to provide technical and general services,
  - ✓ Web application that will allow the operator: to choose the required marina, date and time of the service, enter the number of vessels that will be anchored, request for technical or general service, as well as other necessary information,
  - ✓ Web application that will allow initiating or starting a business process,
  - ✓ Web application that will be available only to authorized operators of reception and operators of agencies/agents.
- Creating BizTalk Server applications that will enable the execution and monitoring of business processes.

C. Microsoft BizTalk Server

Microsoft BizTalk Server is the leading technology platform used in manufacturing and service companies for business process automation and integration of business applications into a single business information system. In addition to Microsoft technology can be used Oracle or SAP technology. BizTalk Server enables the development, setting up, implementing, monitoring and management of business processes which are realized for the purpose of unifying the various divided applications. Such an information system is a prerequisite for the effective management of business processes, and thus to increase the competitiveness and profitability of the company, because the lack of simple ways to reach the information contained in a series of unrelated business applications is one of the main reasons for poor management of medium and large companies. An additional advantage of BizTalk is that it is, compared to similar solutions in the field of business application, significantly more favorable in price and requires less hardware resources. BizTalk communicates with the existing ICS without change of requests. The data from existing applications, BizTalk can accept in variety of formats and by using development tools, data from one format successfully convert to another, thus allowing communication between different systems. BizTalk coordinates complex business transactions and business applications by using orchestrations; it shortens the operation time, gives greater ability to update data which greatly reduces the cost of doing business.

D. Description of the execution of business process "Reservation service"

The execution of the business process "Reservation service" is done in several steps:

- The operator using a Web application, based on the demands of boaters selects information related to book berth in the marina (destination, arrival date, departure date and number of berths), reservation of technical services (servicing of the device driver, minor repairs, maintenance of vessels and cruising) and general services (parking place for car, sports and recreational services, catering and other services).
- Web application creates a corresponding XML messages and sends them to the BizTalk process machine.
- BizTalk application on the basis of the received message initiates the creation of a business process.
- Business process Web service calls to book the berth that in the existing database makes the reservation and returns information on the availability of the required berth.
- If there is a demand for technical and general services, business process calls Web service to book technical/general services that the existing database makes the reservation and returns information on the done booking.

E. Modeling of the business process "Reservation service"

Business Process Modeling (BPM) refers to the design, management and execution of the business process, and its strength lies in the unification and expansion of existing process-oriented techniques and technologies. In developing the model business processes used are standard, understandable graphic elements that significantly facilitate communication between different participants in their analysis. The model focuses attention on what is important and helps in understanding the way the business processes work. To create a graphical flowchart of the business process used are Business Process Modeling Notation (BPMN). BPMN is developed to ensure the notation for defining business processes easily understandable by all business users, from business analysts who need to outline the processes, to technical users who are responsible for implementing technologies that are executed for using the processes and ultimately to business people who will use and monitor business processes. BPMN allows you to make up the

gap between the business process design and its implementation. BPMN diagram is composed of a set of graphical elements. The elements allow easy development of simple diagrams; they are different with respect to another and look closely to the most of business analysts. To create a BPMN diagram for the implementation of the simplified process of berth booking and technical and general services in the marina which is shown in the paper, the ITP Process Modeler 5 for Microsoft Visio is used.

In a simplified model of the process "Reservation service" in the marina included are the following participants: the management of the marina/reception, boater and agency/agent. A simplified model contains all the elements necessary for the berth reservation and technical or general services at the marina (Figure 2).

The business process starts after receiving the request for insurance of services in the marina, why the start of the process is presented by Start Event element type Message. Receiving of requirements may consist of the following individual requests: berth reservation, reservation of technical or general service. Processing of the received applications is represented by parallel Gateway elements that allow passage through each branch for which the demand is fulfilled.

If the request is received to secure a berth in the marina, the task "Book berth" is performed, presented by the Task element, type Service, which calls the operation "BerthRequest" of Web service "Berth" , whose purpose is to reserve a berth in the chosen marina in the selected period of time. Web service returns a message on successful or unsuccessful completion of berth booking. In case of having to cancel already reserved berth, perform is the task "Berthcancel", presented by the Task element, type Service, which calls the operation "BerthCancel" of Web service "Berth".

If the request comes that it is needed to provide technical services, performs the task of "Technical Services", represented by the Sub - Process - the ad hoc element (a process that includes a set of activities that can be performed in any order) element, type Service, which calls operation "TechnicalServicesRequest" of Web service "TechnicalS ", whose purpose is to put aside some technical services in selected marina. Web service returns a message on successful or unsuccessful completion of booking technical services. If necessary to cancel already booked technical service, performed is the task "Cancel technical service", presented by the Task element, type Service, which calls the operation "TechnicalServicesCancel" of Web services "TechnicalS".

If there is request to provide general services, performed is the task "General Services", represented by the Sub - Process - ad hoc element, type Service, which calls the operation "GeneralServicesRequest" of Web services "GeneralS", whose purpose is to reserve a certain general service in the selected marina. Web service returns a message on successful or unsuccessful completion of booking of general service. In case of canceling already booked general service, perform is the task "Cancel general service",presented by the Task element, type Service, which calls the operation "GeneralServicesCancel" of Web service „GeneralS".

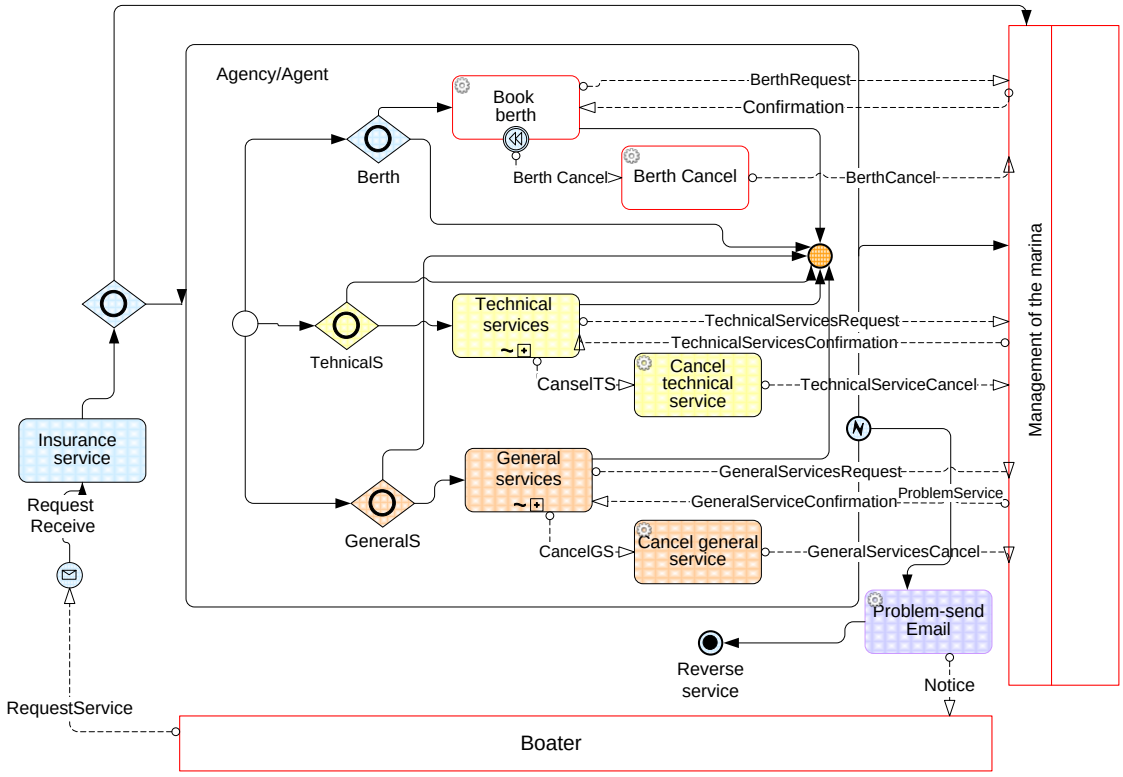

Figure 2. BPMN diagram for business process of berth reservation, technical and general service in the nautical tourism ports

Communication of Task elements, Service type, with Web Services is represented by berth objects type Message Flow, which is displayed as dotted lines with unfilled arrow. These elements are used to show the flow of messages between two separate participants in the business process. In case that happens some exception, related is the booking services, the event is raised, presented by Exception Event element. Event passes control task "Problem - Send Email to boater", who calls the operation "EmailInfo" of Web service "EmailNote", which sends an e-mail message about the existence of the problem.

E1. Web service creation

To ensure communication between existing and new applications as well as adding automation of business processes, several Web services are built. Descriptions of Web services are available through WSDL. WSDL document describes what the Web service does, how to use it and where to can find it. Parts of description of Web service can be located in multiple documents that provide more flexibility and increase the possibility of re-use. The proposed solution following describes the following Web services:

a) Berth in marina service

Web service "Berth" allows berth booking and cancellation in one of the offered LNTs. Web service "Berth" is done in several steps:

- Using a web application operator chooses: LNT, date of arrival, the size of the berth, date of departure,
- Web application creates an XML document and sends it to the destination where it will be read by BizTalk Server,
- BizTalk Server reads the received XML document and calls for the execution of Web service "Berth",
- Operation "BerthBook" of Web services "Berth" executes reservation in the required LNT ,
- Operation "BerthBook" of Web services "Berth" returns information on the availability of required berth in the LNT.

BerthBook is a synchronous request/response operation which for the required inputs (LNT, the size and number of berths, the date of the beginning of the berth's usage, date of leaving the berth) returns information of possibility of reservation of berth in Marina.

Operation Berth Cancel - using of Web services "Berth" for cancellation:

- Using a web application operator selects the number of berths in the marina,
- Web application creates an XML document and sends it to the destination where it will be read by BizTalk Server,
- BizTalk Server reads the received XML document and calls for the execution of Web service "Berth",
- Operation "BerthCancel" of Web services "Berth" cancels before created berth reservation.

Operation "BerthCancel" is the request operation that contains only the input (input) message. Operation of required inputs (LNT, the size and number of berths, the date of the beginning of berth's using, date of leaving the berth) cancels earlier created a berth reservation.

b) Technical service in marina

Web service "TechnicalS" allows booking and cancellation selected technical services in one of the offered LNT. Web service "TechnicalS" is done in several steps:

- Using a web application operator selects the offered technical service,
- Web application creates an XML document and sends it to the destination where it will be read by BizTalk Server,
- BizTalk Server reads the received XML document and calls for the execution of Web service "TechnicalS",
- Operation "TechnicalServiceRequest" of Web services "TechnicalS" does the reservation of technical services,
- Operation "TechnicalServiceRequest" of Web services "TechnicalS" returns information on the booking of required technical services.

Operation "TechnicalServiceRequest" is a synchronous request/response operation which for the required inputs (boater, number of connections, technical services) returns information regarding reservation of technical services.

Cancel technical service operation - Using Web services "TechnicalS" for cancellation of technical services:

- Using a web application operator selects the number of berths,
- Web application creates an XML document and sends it to the destination where it will be read by BizTalk Server,
- BizTalk Server reads the received XML document and calls for the execution of Web service "TechnicalS"
- Operation "Technical Service Cancel" of Web service "TechnicalS" reverses earlier created reservation of technical service.

General service will not be described in detail since it is exactly the same as the technical services.

c) Web service "EmailNote" enables sending e - mail messages to the boater. Web service has one operation EmailInfo.

Using of Web service "EmailNote" to send electronic messages:

- Using a web application operator chooses boater (number of berths),

- Web application creates an XML document and sends it to the destination where it will be read by BizTalk Server,
- BizTalk Server reads the received XML document and calls for the execution of Web service "EmailNote",
- Operation "EmailInfo" of Web services "EmailNote" sends an electronic message to the boater.

E2. Application creating

Web application "Reservation service" should allow independent berth booking and any technical or general service by the operator reception of marina or operator's agencies/agents. Functions of berth booking and technical or general services shall be executed in real-time, over a single database, which completely excludes the possibility of multiple sales of the same services. Besides the achieved consistency of database, web application development enables the following benefits:

- At any time, condition of available and rented berths and reserved services is known. That information allows the marina management to effectively manage resources, which is extremely important in the summer periods. On the other hand, agencies/agents sell only facilities that are currently available and real, which excludes cases of incorrect arrangements.
- The need for continuous oral and written communication of marina personnel/reception and agencies/agents disappears, in connection with the reservation of berths and technical and general services.
- ICS is available 7x24h week eliminating the problems of nonconformance of reception working hours, service offices and agencies/agents.

Access to the applications requires identification (username and password) users, because they are available only to certain users or registered agencies, agents and operators reception. Applications are of portal type because the main purpose of web portal is that it represents a centralized access point for finding and managing information and to execute various tasks via the Web portal Web browser is used. Also, Web portals are a very convenient way to collect information from various sources and their concentration in one place. The main window of the Web portal contains sections which allow by the operator, the selection of the required marina, date and period of the use of the berth or preferred service as well as the other necessary data.

5. CONCLUSION

By rapid development of information and communication technology, marinas have found themselves in a new environment and in order to remain competitive maritime market must adapt quickly. One of the models that will enhance and improve business is information communication systems whose architecture is based on service orientation.

This work represents the view of the model systems based on the orientation services in marina management. It describes what service oriented architecture and Web services are, that are enabling applications to communicate over the internet in an open and flexible way and the principles on which they are based. Finally, the simplified model of SOA applications in the management of the marina is given.

In developing the model it is essential to business process modeling because the goal of BPM is not just to copy the existing business processes in an information system, but also to improve them with what information technology has to offer, such as web services. Web services provide a generic, standardized client-server link to launch the application on the server. The most widespread way of using Web services is simply calling methods on remote computers.

SOA solutions can integrate in different environments, different platforms, that reduces LNT operating costs. There is no need to change existing software because it is possible to exchange data between the new and old software. In addition to financial savings, it is also a component of optimizing business processes in the proper application of SOA solutions. A key element of the SOA architecture is communication between different application services.

The application of SOA in the management of LNT obtained on flexibility, modularity, coverage of business activities, increased availability of data, easier management services and greater profits.

E-mail: ivabubanja@gmail.com,

Abstract – There is a growing trend of transferring commercials from print media to online format during the last decade. Rising number of users who are spending more time on Internet and social networks, are the main reason why print media are facing a problem of keeping advertisers in their media in order to provide resources for their survival. Newspapers are going through meager changes intending to adapt to business conditions in a digital environment. The conducted research showed the differences between commercials in online and offline versions of national newspapers.

I. INTRODUCTION

The media and publishing industry is undergoing a massive transformation thanks to the rise of digital technology. Over the past 30 years, changes in newspaper production have been significant: from linotype machines and hot lead type, typewriters and grease pencils, to computer terminals, satellite transmissions, digital cameras and online editions. The ability to get news online, instead of from the traditional printed newspaper, may be the most dramatic change of all.

This paper analysis how Belgrade daily newspaper industry is experiencing digital disruption process. The initial hypothesis of the performed research is that Belgrade daily print newspaper industry has to adapt to new advertising trends influenced by Internet and promotion capabilities of digital media by devoting full attention to their online versions of the daily papers in order to provide rising advertising income for their budgets.

Both retail and music are prime examples of sectors that underwent similar transitions. Many traditional retailers seamlessly translated their brick-and-mortar experience and built prosperous revenue streams through e - commerce. On the other hand, many of the traditional players in the music industry struggled to evolve and experienced a shrinking market once iTunes was born.

Digital publishing opens the door to additional income streams beyond advertising and subscriptions in content monetization. Readers will pay for content as long as it's compelling (feeds the intellect or fuels emotions) and can't be found for free anywhere else.

II. INTERNET IMPACT ON PRINT NEWSPAPER INDUSTRY

'Golden Age' for print media was a period between 1890 and 1920, when the industry grew and newspapers enjoyed the attention of being society's primary source of information. However, the Great Depression disrupted this and in the 1930s newspapers were severely hurt, hundreds of companies ended operations. This was escalated with the emerging broadcast radio, offering lower priced alternative news and as a result capturing a large portion of advertising revenues from newspapers [1].

Television was the next technology that disrupted the newspaper business. It was a more powerful medium to distribute information and it overtook the newspaper and majority of national advertising in the 1960s. In response, newspapers consolidated and existing newspapers got an opportunity to enjoy a semi-monopolistic position.

However, the early 1990s was the last time newspapers enjoyed profit margins of 20% to 25%. In 1995, the Internet was introduced to the public and by the millennium the Internet as a worldwide platform became evident. The Internet reached more people than any newspaper had and profits margins have dropped to an average of 5%. The mere ability to access information and receive instant updates threatened the purpose of a newspaper, and evidently the Internet has been a growing source of competition for the newspaper publishers [1].

The Internet opened to commercial interests in 1988, but it took a few years for the network to gain public recognition and in 1990's Internet began to take shape as the 'World Wide Web'. Against a backdrop of relentless growth, the Internet continues to change and evolve, as highlighted in Table 1. In the past ten years, the number of Internet users shot past one billion and is nearing three billion; users migrated their fixed Internet access from dial-

[1] This paper is the result of the research realized under the project 179038 „ Modelling of the development and integration of Serbia into world trends in the light of the economic, social and political commotions", Ministry of education, science and technology development of the Republic of Serbia.

up to broadband; and their usage shifted from text-based to predominantly video traffic. Globally, the number of users in developing countries now exceeds those in developed countries; there are now more mobile broadband subscribers than fixed; and mobile access has shifted to smartphones [2].

TABLE I. ICT AND INTERNET– FACTS AND FIGURES

Internet users (2014) - 2.893.587.260 Internet users worldwide. - 2/3 of Internet users are from the developing world. - Internet user penetration rate 40% globally, 78% developed countries and 32% in developing countries. - Households with Internet access: 44% globally, 31% developing countries, 78% developed countries.
Broadband Internet access (indicated years) - Global broadband subscriptions 93% of total global fixed Internet subscriptions (2012). - 673.295.648 fixed broadband subscribers worldwide and number of fixed-broadband subscriptions in developing countries overtook the number in developed countries (2013). - 2.3 bn. mobile-broadband subscription globally with penetration rate 32% (2014). - Mobile broadband connections 5.3 bn. - forcasts for 2018.
Mobile cellular subscription (2014) - The number of mobile-cellular subscriptions worldwide is approaching the number of people on the earth, almost 7 bn. - Penetration rate 96% (developing countries 90% compared with 121% in developed countries).

SOURCE:2 AND 3

The open Internet has become a medium like no other. It merges the most notable characteristics of traditional media such as broadcast and telecommunications, while also augmenting them in ways that have revolutionized aspects of civil society, business, and government [2].

As a result, the nearly 3 billion Internet users are both creators of information as well as consumers. Websites, blogs, videos, and tweets, can all be broadcast and accessed in the largest mass medium imaginable. Audio and video calls and conferences can be set up and received without regard to distance or cost.

This short analysis proves that the impact Internet has had on newspapers is two fold. Directly, the Internet has increased competition for the newspaper and revised the way news is distributed. Indirectly, the Internet has influenced advertising trends, consumer behavior and the rise of disruptive technologies. As a result, newspapers have been forced to integrate with the Web and now approximately 80% of newspaper publishers have integrated web and print operations [1].

The Internet has removed all geographical boundaries and as a worldwide platform, it has extensive global reach. Also it removed any barriers to entry in newspaper business. Initially, entry costs were very high because large investments were needed to set-up a publishing house, and so the number of players was restricted. However, the Internet gives anyone with a computer an opportunity to publish information. This has placed newspapers in an industry for news and information, and as a result they are now directly competing with all news sites online.

The Internet has revolutionized the way news content is distributed and consumed. It has the ability to deliver news immediately, thus the Internet allows readers to receive news in real time and stay constantly updated. Additionally, the Internet via e-mail and social media activity has led to news being distributed socially.

According to IAB Report for 2013 half of social network site users in US have shared news stories, images or videos, and nearly as many (46%) have discussed a news issue or event. In addition to sharing news on social media, a small number are also covering the news themselves, by posting photos or videos of news events [4].

It is evident that the existing newspaper business model necessitates change in the new digital environment whether this means: a) merely altering their existing model to include print and digital or b) a complete transformation of going purely digital what is still debatable.

III. CURRENT BUSINESS ENVIRONMENT FOR PRINT MEDIA INDUSTRY

Beside Internet, some other factors create very challenging environment for print media.

1) *Economic crises that begun in 2008/9* cause financial challenges for newspapers. On one hand, most newspapers were faced with cuts in revenues from declining subscriptions and single copy purchasers. Readers were looking for more cost effective alternatives and as a result increased consumption of online news. Since most newspapers do not charge for their online content, this shift in consumption did not drive any revenue increase for the publishers.

On the other hand, the recession resulted in deep cuts from marketing budgets in the majority of companies. Since the newspaper business model is largely dependent on advertising as a form of revenue, this advertising recession brutally hurt publishers.

In the US, the industry experienced a 23% fall in advertising revenues in 2007 and 2008 and revenue in 2012 was 45% of what it was in 2006. Print advertising losses continue to fall far exceed digital ad gains. In the US, for example, in 2012 the ratio was about $15 print lost for every digital dollar gained. In 2013 according to Newspaper association of America, print advertising revenues fell to $17.3b and they haven't been lower since 1950 [5].

In Europe the advertising share for the printed press has been decreasing continuously for more than 25 years, while the overall advertising market has increased temporarily. The financial crisis for the first time leads to a decline of advertising revenues for the press in real terms. It is expected that the level of 2007 (around $120.000 mil.), before the financial crisis will never be reached again. The revenue in 2014 was worth $88.105 mil [6].

Therefore, this overall plunge in revenue forced newspaper publishers to cut costs and scale back operations in order to survive. Internally, publishing houses began to lay-off staff and reduce the number of editors. Overall, the decade-long trend in newspaper job losses continues.

The best example of this growing phenomenon and effect of the Internet is reduction of journalists in print media. According to the annual American Society of Newspaper Editors survey, in the decade from 2003 through

2012, a total of 16,200 jobs were lost, and the similar situation is in Europe as well. [7].

2) *The Internet has played a big role in altering news consumption behavior for the average newsreader*. Today news is in a so much demand, but consumer wants to get them form different sources. In Europe 426.9 m people use the Internet (65%), and Internet was the second most popular news source in 2012. There was 25% rise of Internet users in Europe reading news online (91%). According to IAB/Mediascope Europe study each week Europeans spend 14,8h online, 16,8h watching TV, and only 4,6h reading print newspapers [8].

While newspapers with their web sites and online versions are definitely enjoying a portion of this growing online readership, the real problem is that most publishers are providing content for free. Thus, readers have become accustomed to consuming information at a zero cost, and this has resulted in subscription revenues to decline.

The rising percentage of consumer prefers news that is concise, with only the necessary information. Users have also developed a preference for a more personalized news experience as they only follow news for particular areas of interest. There are online tools that allow for such news customization.

Additionally, users have a preference for interactive tools and 36% of all Internet users take into consideration the interactive materials available on a website before selecting it as a news source [8]. Examples of interactive content are charts that users can manipulate, quizzes to test user knowledge, video news reports, and other. Internet users share the information they receive with others by forwarding links and stories. Online, sharing news is most easily facilitated via email and social media activity.

As a social media continues to be a grow space around the world, with roughly 29% of the world's population of active users (2.078 billion active social network users in the world), it is therefore important for newspaper publishers to make themselves visible to their newsreaders via social media portals as well. Research conducted by Global Web Index suggests that the average social media user spends 2,5 hours per day using social networks and microblogs. Facebook continues to dominate the global social media landscape, claiming 1.366 billion active users in January 2015. In Europe the social media penetration is 46%, what means that 387 million of Europeans are active social media users in January 2015. Among the social media users, 26% of them are accessing social media through mobile [9] [10].

There is growing trend of consumer participation in the process of online news creation and distribution. Certain publishers already adapted to this trend. For example, the New York Times launched a joint relationship with LinkedIn, where LinkedIn users are able to subscribe for news alerts on a specific industry and to share and discuss the news with users and experts via an industry specific blog.

3) N*ewspapers have a pressing need to accept the multiplatform consumption pattern that has emerged.* Digital platforms have been developed to keep up with transforming consumer demands and they include the computer, mobile and tablet. With respect to newspaper publishers, these technologies disrupt the newspaper business because they make online news more accessible for readers. Together, these devices aim to capture a larger readership for longer hours during the day. This is because now consumes are no longer limited to their work and have portable access to the news. While these devices are gradually increasing subscription and have the potential to strengthen the brand of a newspaper, they are simultaneously increasing the number of devices that users can select from. This is detracting from customer loyalty for any one device, platform or format. Newspapers are now competing in an open market for news and information sharing.

Consumers in Europe are constantly switching between devices: computer, tablets, smartphones, gaming platforms and other emerging devices are all used to access the web. This is a clear indication that European consumers are heading towards multiple platform media consumption. In fact, technology is driving the way Europeans consume media and interact with brands: 44% of all Europeans own a Smartphone and 50.9 million uses a Tablet to go online. Media multi-tasking is a large part of Europeans lives: a third (37%) of Europeans access the internet via more than one device and 48% are online while they watch TV [8].

This insight is essential to the newspaper industry because most publishers have to adapt their product to the technologies that consumers demand to ensure their presence on every available platform. In order to do so newspapers have to understand their customer segment, the news they demand and the device they prefer.

IV. PRINT AND DIGITAL ADVERTISING PRACTICE

While the Internet has severely threatened the traditional ways of news consumption, it has improved the business for an advertiser. With the Internet, advertisers are able to reach their target audience more effectively and efficiently. Marketers can accurately measure results and monitor their ad spends very closely. They can also engage with the consumer and interact with them to ensure the effectiveness of their campaignes.

With the economic recession in the world advertising also entered into the steep recession, but after 2010 media ad spending is in constant rise. According to e-Marketer media ad spending in the world rise from $475 bn. in 2010 to $575 bn. in 2014. Estimation indicates ad spending of $600 bn. in 2015 and $628 bn. in 2016 [11]. Newspapers saw a deep decline in overall advertising revenues proved statistics. On the global level there was a rising market share for Internet ad and declining for newspaper ad for the period 2005-2013. In 2005 Internet ad revenue were $13 bn. and raised to nearly $45 bn. in 2013, comparing with newspaper ad revenues declined from $47 bn. in 2003 to under $20 bn. in 2013 [11].

The same trends are present in European ad market where print ad spends per/capita fell from 60€ in 2007 to under 40€ in 2012 while online ad spends per/capita rise from 10€ to 30€ in the same period. The value of the European online ad market rise from 6,6 bn. € in 2006 to

27,3 bn. € in 2013. Online market share of ad budgets in Europe reached 25,6% in 2012 [12].

Online ad revenue in the United States grew to $42.8 bn. in 2013, according to the Interactive Advertising Bureau's Internet Advertising Revenue Report. Ad spending in US in 2013 was distributed as following: 45% TV, 22% Internet, 19% print media, 10% radio [13].

Although all the data indicate raising share of online ad in marketing budgets, newspapers can not depend on online ad as a revenue source in order to survive. In fact, online ad revenue which is approximately 10% of their total newspaper ad revenues is unexpectedly small and it therefore exposes online websites as a weak source of revenue for publishers [1].

One of the key reasons for this situation is the fact that the rate of online ads is drastically lower than the print rates. The online advertising model, unlike the newspapers flat rate, is based on the number of impressions (CPM: Cost pet 1000) and clicks (CPC: Cost per click). Since this billing model was first introduced with very low rates, the increasing competition has prohibited online rates to rise any further.

In addition, there is also evidence that news aggregators benefit disproportionately from the content they aggregate, link, index and present. This is because revenues from ad-space sold alongside re-distributed content are only paid to the news aggregators and not the news generators. As a result, newspapers have been losing a large portion of their online revenues.

V. Internet Challenges for Belgrade Daily Newspapers

The Belgrade daily newspaper industry is currently undergoing a much-needed transformation, battered and distressed by a severe recession, declining advertising revenues, major shifts in consumer behavior and emerging disruptive technologies. As a result, we have seen some major media companies face with the burden of heavy debts, while the others are still experimenting with new survival formulas to restore the equation between newspaper content and earnings. Moreover, Serbian print media are facing severe digitalization process, and every day more of them are becoming viral and providing online version of the same.

The research included media such as: Politika, Večernje novosti, Danas, Blic, Alo, Kurir, Informer, Naše novine and two specialized press Sportski žurnal and Sport. From ten analyzed national newspapers, eight of them have their online versions, and nine of them have their Facebook and Twitter accounts. On other social networks such as Pinterest, Instagram, Google+, only some of them have their profiles which are not regularly updated.

This transition of Belgrade daily newspapers to online version is closely connected with the increasing number of Internet users in Serbia, around 3.5m. They spend average 13.0 hrs online per week by IAB Europe research from 2012. The use of Internet in Serbian society keeps growing on daily basis especially among young generations, who are more mobile and informed, and who are searching for free information on the network [14].

TABLE II. INTERNET USE IN SERBIA

Facts and figures for 2014 - 3.500.047 Internet users in Serbia – penetration rate 48% - 3.800.000 Active Facebook users - penetration rate 52% - 9.138.000 Active mobile subscription - penetration rate 128% - 2.900.000 Active mobile broadband subscription, penetration 40% - 2.400.000 Active social media users accessing social media on a mobile device - penetration 33%,
The Serbian media consumption landscape 2012 - Hours per week used: TV 16,9hrs, online 13hrs, radio 13,1hrs, newspapers 4,4hrs, magazines 3,5hrs - 48% of Serbian Internet users watch TV online monthly - 61% of Serbian Internet users listen to the radio online monthly - 83 % of Serbian Internet users read news online monthly - 52% of Serbian Internet users visit news websites every day - 99% of Serbian Internet users communicate through email - 89% of Serbian Internet users have used a personal or professional Socail media website
Devices for accessing the Internet in Serbia 2012 - The computer is the most popular method, used by 3.0 million users, - 24% of all Internet users in Serbia (EU: 37%) go online via more than one device. - 2% of users go online by Tablet, - 21% of all mobile users own a smartphone.

Source: [3] for 2014 and [14] for 2012.

In line with this change in Serbian media consumption landscape are the research findings made by Gemius that the most popular websites in 2013 are online versions of national newspapers providing news from different spheres of life. The leader in 2013 in the online market was www.blic.rs, which is news portal that reached 53% of Internet population, and on the second place is www.kurir-info.rs, which is also a newspaper online portal that is providing news, after them the best ranked are www.b92.rs, www.telegraf.rs, 24sata.rs, novosti.rs etc [15].

The focus of the performed analysis devoted to commercial contents in ten Belgrade daily newspapers was to find out the relationship of their print and online versions concerning the volume and characteristics of presented commercials, as well as the possible contribution of commercial contents to print publisher's budgets and earnings. Daily newspapers are specific media with great circulation and massive and various audience what make them an efficient commercial medium.

The performed analyses included ten Belgrade newspapers of national coverage that can reflect the situation in Serbian advertising market of print media as a whole. Only small mismatches can exist. There are several reasons for this attitude. The first one is the fact that the print newspapers with national coverage are distributed all over the country and the main difference is that Belgrade news pages are not included in editions for other Serbian regions out of Belgrade. The second one is the absence of daily newspapers in local communities in Serbia, making press with national coverage the only source of daily information for the citizens out of Belgrade[2]. In this way commercials published in national daily newspapers reach the whole population of Serbia.

Final research results showed that there were only six commercials and two self-promotion contents per newspaper on a daily basis in their print version. Taken together for 10

[2] Local communities in Serbia usually have weekly newspaper editions.

newspapers there were about 62 commercials per day. Due to four time's smaller circulation compared to other newspapers, specialized press has 3 to 6 times less commercials than other daily newspapers [16].

On the same newspapers web portals situation is a bit different. There were 43 commercials and 52 self-promotion contents on daily basis. That was around 4 commercials and 5 self-promotion contents per newspaper in their on line edition. Taken together it is larger number of promotion contents in online version of the same print media. Specialized press is again in the worst position and has around 5 times fewer commercials than other daily newspapers in online form.

An increasing number of self-promotion indicates inability of a newspaper to sell its complete advertising space. Self-promotion is considered as an effective way of attracting new readership, which is necessary for the survival of newspapers. In fact, the number of self-promotion ads is rising and their contents and forms are so advanced that they are becoming equal to commercials. This opens the question regarding whether self-promotion steals readers' attention from the current commercial contents. Also large number of self-promotion in online newspaper form shows that newspaper companies are using increasing number of daily visits to increase the number of ridership by presenting a large number of self-promotion. The effect is even greater because online riders are active users and not just the passive audience.

The first conclusion from this two-month study of the selected press (online and print version) indicated small volume of the commercial content. This is not a good indicator for the Belgrade daily newspapers, having in mind that for the most print media selling advertising space is an important source of income. According to the estimation of print media publisher in researched newspapers participation level of ad resources to their budgets is around 20%. Comparing with newspapers in western developed economies where ad resources represent up to 80% of newspaper budgets, percentage in Serbia is very modest [16].

Concerning the characteristics of commercials presented in the Belgrade daily newspapers, the research results showed similarity of commercial contents in all newspaper type no matter do we talk about print or online edition. By comparing them it can be concluded the following: content types are repeated, there is a lack of variety of products and services, and narrowed choice is offered to potential buyers. Reasons for this are also connected with limited company budgets for commercials and the situation that the audiences of the different daily newspapers have the same preferences and tastes. In this way, newspapers create one public and a uniform products offer [16].

Research also showed that advertisers are choosing the same formats in online edition of different newspapers, and they place their ads in the specific page type. If advertisers' desire detailed processing of ad messages by consumers, they usually place their commercials on destination pages, even though the reach may be smaller than on navigational pages. The research identified several physical characteristics, such as visibility and time delay, as important factors in online advertising that affect perceived advertising level. Also the value of an audience to advertisers is determined by its receptiveness to advertising. Such emphasis on receptiveness towards advertising signifies the voluntary nature of media consumption and the importance of creating a receptive media environment for advertisers.

There is no regularity in repetition of commercial contents in online form. The characteristics of the texts and the photos are the same for online and print edition of newspapers commercials. The only difference is that in online world all commercials are in color no matter are they having a photo or they don't.

Besides indicated characteristics and volume relationship between commercial content in print and online version of daily newspaper, modest number of ads in ten Belgrade daily newspapers have to be considered in the respect with the current economic situation in Serbian economy.

There is significant reduction of producers' capability to allocate funds for advertising purposes due to reform and transition processes and other challenges connected with economic recession and stagnation. For this reasons, producers in Serbia choose more cautiously the media for advertising. They select media that can bring commercial message to the biggest number of potential buyers.

On the other side, complete society in Serbia has some new characteristics, as the high unemployment rate and lower monthly income force people to use the biggest part of their salary to satisfy their basic needs. Purchase of daily press became a luxury that many can not afford. Nowadays, middle and upper classes is still buying print media, but there are a growing number of readers that prefer to use online services for their news consumption what has clear impact of competitive position for commercial content between print and online version of selected newspapers [16].

General statistics of Serbian advertising market supports research results in the sample of ten Belgrade daily newspapers. Small number of ad in analyzed press is in line with the fact that Serbian advertising market is one of the poorest in Europe (average worth is about 170 million euros in the last three years). The share of print media in Serbian ad market is around 23%, what is also behind the European average [15].

Rising number of Internet users in Serbia and change in Serbian media consumption landscape opens new perspectives for digital media advertising and for online versions of print media. The Serbian online ad market is still in the phase of development, but advertisers are increasingly investing in Internet media and are becoming more interested in global advertising solutions. Rich media templates have become more popular, as well as mobile and video banners. Although the resources are limited, advertisers are trying to keeping in track with the global trends [15].

In 2013 it can be seen a positive growth of Serbian online advertising market. The total market value of digital and interactive advertising was estimated to € 16.32 million,

which includes advertising on mobile devices. The growth of the total market value is estimated at 13.41%, which means that they kept a positive trend of double-digit growth. The highest growth in 2013 had advertising on social networks, or social media marketing (27%). The market for mobile advertising in 2013 grew to as much as 150%, which means that the total value of this market segment amounted to €380,000. The total value of display advertising market segment is €8,230,000 and it remains the largest contributor of the Serbian online advertising market (50.68%) [17].

Comparing with Croatia and Slovenia as neighboring South Eastern Europe ad markets Serbia achieved in 2013 the highest growth rate in online advertising spends. The 13,4% growth rate of online advertising in Serbia was above European average growth rate of 11,9%, and higher than growth rate in Croatia of 6,2%, while Slovenian online ad spending decreased in analyzed year for 2% [17].

Regional comparisons of online ad markets are more complete by using online spend per capita across the region as an indicator that highlights the maturity of an online market irrespective of its size or absolute revenues incurred. Online ad spend per capita is a metric that helps to evaluate the maturity and scope for development of a market. By using this indicator results for 2013 are the following: 1) Slovenia with 42,6€ per capita is positioned above European average online ad spends per capita worth 37,4€; 2) Croatia spends 3,5€ for online ad per capita and is located in the lower part of the European countries list; 3) Serbia is penultimate with online ad spends of 2,3€ per capita; 4) Bulgaria with 1,5€ is the last on the list [17].

Despite positive dynamics Serbian online ad market still needs further development and maturation. Modern technology trends and new media consumption models support all traditional newspapers companies in Serbia to further invest in a digital strategy and focus their efforts on increasing their online ad revenue in future, as print ad revenues continue their decline.

VI. CONCLUSION

More than two decades after the adoption of the Internet by print media, newspaper publishers are still coming to terms with its implications. The Internet offers a novel platform for reaching audiences and has become a part of news gathering and news-processing routines. The new media ecology, with its additional agendas of interactivity, democracy, multimediality, and with a new domain of bloggers and citizen reporters, presents a set of new issues and opportunities for daily print newspapers, but also creates great challenges in the same time.

Statistics proves that the media and publishing industry is undergoing a massive transformation thanks to the rise of digital, which has made traditional revenue models based solely on subscriptions and advertising sales virtually obsolete. With an explosion of content seeking advertising support, and flat total advertising spend; publishers are scrambling to find new revenue streams and growth opportunities in digital media. The exact business model for the industry's future is still in flux, but one thing is for sure – the most successful and profitable companies will quickly find ways to capitalize on the enormous opportunities that digital offers [18].

Similar to the world trends, the competition between print and online media continues to intensify on the Serbian print media market. With decreased newspaper circulation, advertisers are turning their backs on print media in favor of the Internet. The connection between commercials and print media at the Serbian media market was researched by using a sample of ten Belgrade daily newspapers. The research results showed that the number of commercials in the daily newspapers dropped, while the numbers of ads in online version of daily Belgrade newspapers are in constant rise.

These two tendencies are connected with digitalization processes and challenges of domestic newspaper publishers, but also with general situation in the Serbian economy and society burdened with reform and transition processes, as well as economic recession and stagnation.

Research results definitely support the author's initial hypothesis that Belgrade print media need to include the Internet in their future advertising development strategy. It is also recommended that cooperation and synergy of print and digital media create a more effective way of presenting promotional contents to modern and choosy buyers, in Serbia as well.

The Success of Open Source Software: A Review

Domagoj Margan, Sanja Čandrlić
Department of Informatics,
University of Rijeka,
Radmile Matejčić 2, 51000 Rijeka, Croatia
Email: {dmargan, sanjac}@uniri.hr

***Abstract*—Open source software (OSS) is software with its source code available that may be used, copied, and distributed with or without modifications, and that may be offered either with or without a fee. In this paper we present an overview of the state-of-the-art OSS-related research from different fields and disciplines of the social and information sciences. The emerging work on understanding OSS has questioned what has led to its prosperity. We present an historical review of its success, and we discuss some of the key factors that contributed to the rise of the OSS, mainly from the perspective of the software engineering and economics. We conclude with some real-life business examples of companies that achieved their profit with OSS.**

I. Introduction

The open source software (OSS) movement has over the last two decades had a significant impact on the software industry, as well as on the software organizations in both the public and private sector. Similar as closed-software projects, one can notice that some OS projects fail, while other grow, prosper and take the leading position in the market. Considering specific OSS development environment and its properties in general, we were motivated to understand and evaluate the reasons for this behaviour.

In this paper we analyze the causes of OSS success trough an historical overview of research and literature. We investigate and discuss some of the most important factors crucial for the success of the OSS.

II. Open Source Software

Open source is a term generally used in a variety of different contexts. In this paper we use the term open source software to refer to software which is distributed under terms that comply with the Open Source Definition according to the Open Source Initiative [10]. The Apache License, BSD, MIT, GPL, and Mozilla Public License are all examples of licenses that conform to the Open Source Definition. The most important distinctions refer to the extent to which they allow public property to be mixed with private property rights. An open source license is certified by the Open Source Initiative, an unincorporated nonprofit research and educational association with the mission to own and defend the open source trademark and advance the cause of OSS.

The philosophy behind open source is based on the concept of free software. In 1984, Richard Stallman founded the Free Software Foundation [54] as a charity organization for free software development. "Free software" means software that respects users' freedom and community. Basically, it means that the users have the freedom to run, copy, distribute, study, change and improve the software. From the Free Software Foundations perspective, "free software" is a matter of liberty, not price. To understand the concept, one should think of "free" as in "free speech," not as in "free beer". This belief is founded on a social ideal of collaboration through information sharing.

Open source could be seen as a movement, where communities of skilled programmers collectively develop software, usually on virtual networking on Internet and the web. They are loosely coupled communities kept together by strong common values related to hacker culture. Work in the open source often seems to be totally distributed, delegated and loosely coupled.

West and Dedrick [36] state that the success of the open source movement reflected a confluence of three factors in the mid 1990s: i) users seeking an inexpensive Unix implementation free of licensing restrictions; ii) a philosophical movement rejecting the idea of software ownership and appropriability; iii) emergence of the Internet as both an enabler and objective for collaborative software development.

But, in reality, only a small percentage of open source projects are considered to be successful [28], [29]. Healy and Schussman [35] observe that it seems clear that for every successful open source project there are thousands of unsuccessful ones. According to Fogel [30], the failure rate for open source projects is as high as 90-95%. Schweik and English [59] found that only one in six OS projects (17 %) were successful. Almost half the projects (46%) were abandoned in the initiation stage before the first software release. More than a third (37%) were abandoned after the initial release [60]. On the other hand, Miller et al. [39] found that failure rates of commercial proprietary versions of UNIX utilities ranged from 15-43% in contrast to failure rates of 9% for Linux utilities and just 6% for GNU utilities (which are also open source). When a minority of the projects is extremely successful, but most fail, it is important to ask what makes the difference.

III. OSS Development Process

Eric Raymond describes the development of OSS as a bazaar-like activity driven by volunteers [1]. Ingrained in the hacker culture, open source appears to represent the contrast of standard software engineering practices. Consequently, open source is commonly disregarded as lacking any repeatable methodology. Despite this historical stereotype, a well organised OSS project has its own rules and strategies. Crowston and Howison [6] and Scacchi [7] claim that the development

The research has been conducted under the project Extending the information system development methodology with artificial intelligence methods (reference number 13.13.1.2.01) supported by University of Rijeka (Croatia).

in OSS communities is distinctly different from traditional software development. On the other hand, the view that the development of OSS is something radically different from traditional software development is questioned by Fitzgerald [4] and Fugetta [5]. Sometimes formal methods and processes are used in OSS development as well, but there is no push towards them, and there is evidence that they are not a requirement for success, unlike generally considered true for software engineering [33].

Open source movement is using the Internet as a basis for communication, collaboration, and storage of artifacts. In the open source movement, everyone capable of writing code is welcome to join in. The Internet inherently supports globally distributed product development. Open source practices and tools have proven to be highly effective for overcoming the many problems of geographically distributed software development [11]. Typically, an open source project starts with a single programmer solving a small problem (e.g. a malfunctioning system affecting his own work) that later turns out to be significant, and then make the solution available to others.

In Fig. 1 team model for OSS development proposed by Van Vliet [64] is shown. Core team is a small team of experienced developers that plays a role of anagement and makes decisions about updates and changes in main software components. Co-developers present a larger group that analyses sourcecode and solve bugs. Active users use recent releases and report bugs, but do not program. Pasive users use stable releases. Transition of team members between layers is based stricly on credits.

According to Ljungberg [55], coordination of work in OS projects can be performed in several different ways. One of the most common models in coordinating open source projects is that several contributors work under a single benevolent dictator who owns the project. Typically this organization evolves when the founder attracts contributors. The benevolent-dictator has the right to take decisions (e.g. of what to include for redistribution) and has an obligation to credit contributors fairly. By contributing to the project you earn part of its reputation in return. When a project grows it is common that it will be split in subsystems with subsystem-owners, i.e. introducing two kinds of contributors: ordinary contributors and co-developers. An alternative to one single benevolent dictator is rotating dictatorship. Yet another alternative is to form a voting committee with the co-developers.

In the corporate model, individuals or small groups of individuals quietly and reverently develop software in isolation, without releasing a beta version before it is deemed ready. In contrast, the open source model relies on a network of volunteer programmers, with differing styles and agendas, who develop and debug the code in parallel. From the submitted modifications, the delegated leader chooses whether or not to accept one of the modifications. If the leader thinks the modification will benefit many users, he will choose the best code from all of the submittals and incorporate it into the OSS updates [1], [56].

Related research

Gurbani et al. [11] present a case study of open source software development methodology adopted by a significant

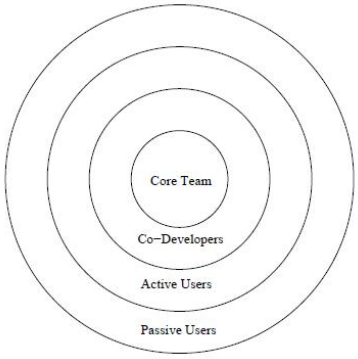

Fig. 1. Team model for OSS development

commercial software project in the telecommunications domain. Feller and Fitzgerald [50] defined a framework which is used to analyze the OS development paradigm in detail. Cowston et al. [22] made an review and empirical research of literature on development of free and open source software (FOSS) development. Weber [25] explains the open source process – how it came into being, how it works, and how it is organized. Scacchi [26] reviewed what is known about free and open source software development (FOSSD) work practices, development processes, project and community dynamics, and other socio-technical relationships. His work focuses on exploring how FOSS is developed and evolved based on an extensive review of a set of empirical studies of FOSSD projects that articulate different levels of analysis.

IV. Analysis of OSS success and quality criteria

Different measures to define the success of open source projects have been proposed in the literature. Crowston et al. [23] identified a range of measures that can be used to assess the success of open source software projects. They identified measures based on a review of the literature, a consideration of the OSS development process and an analysis of the opinions of OSS developers. They showed that the existing models of information systems success suggest a range of potential success measures for OSS projects, but a number of the measures are inapplicable, while others are difficult to apply in the OSS environment. Authors consider a software successful when its source code is of high quality, e.g. it is highly modular, correct and maintainable. In another work, Crowston et al. [52] address a key gap in Free and OS software (FOSS) research by seeking to define what ”success” means in a FOSS context. They derived a range of potential measures from the Information Systems literature, including system and information quality, user satisfaction, user experience, individual and organizational impacts, and then added a number of additional measures specific to the dynamics of the FLOSS development process.

Schweik and English [59] studied more than 174,000 open source projects shared on SourceForge, one of the largest and oldest repositories for open source code. According to them, a successful product achieves at least three software releases and has value for ”at least a few users.” As evidence of user value, they looked at project attributes such as the number of downloads and installations, the presence of continued development activity, posts to project discussion boards or

email lists and the addition of one or more developers. Midha and Palvia [51] examined two measures of project success: project popularity and developer activity, of 283 OSS projects over a span of 3 years, in order to observe changes over time. They made a comprehensive research model of OSS success which includes both extrinsic and intrinsic attributes. Maruer and Scotchmer [40] state that open source project success may depend on accident as much as quality. Comino et al. [45] provided the working definition of OS success and presented a survey of the literature describing the OS success phenomena. According to Comino et al, OS success can be classified into three categories: i) software use, ii) size of the community and/or its level of activity and iii) technical achievements of the project.

A. Software Quality Aspects

The development of open source is often perceived especially in business as being of low quality, due to its economy, team structure or philosophy. Yet, Raymond [1], [2] claims that OSS is cheaper, has fewer defects, gets improvements faster, and is generally better than other kinds of software. Kuan [44] argues that when open source programs are founded, software quality will surpass that of comparable closed source programs.

Boulanger [19] made the comparison of security and reliability between FOSS and proprietary systems, and showed FOSS systems can meet, or even exceed, the quality of their proprietary counterparts. Stamelos et al. [24] suggested that OSS code is generally of good quality, but, on the other hand, is not always as good as expected [9]. Mockus et al. [3] hypothesizes that the OSS products have lower defect density than commercial software and that OSS development rapidly responds to user requests.

Technical Aspects: Raymond [1] suggests that successful software development must be based on flexible approaches in opposition to rigid cathedral-like approaches. He states two laws for successful open source production paradigms. The first deals with the activity of bug reporting and fixing within open source projects. It states that given enough eyeballs, all bugs are shallow. The work of finding issues or solutions to them does not require much cooperation, and thus can be efficiently divided even to very large groups of people. Also finding issues doesnt require any special skills. Such practice may therefore lead to quick implementation of new features and solutions thank also to the interplay with the other open source development law: release often and release early. Early releases of the open source programs enhance the benefit of decentralized beta tests. Bug fixing and new features are quickly included in the official version of the program [14].

Johnson [38] argues that one reason the open environment can be successful is that there are many small tasks that can be completed for any particular project. With many small tasks it becomes more likely that any individual will find it worthwhile to contribute, increasing aggregate development.

Narduzzo and Rossi [43] argue that modularity, which can be regarded as an innovative manufacturing paradigm for the design and the production of complex artifacts, is a key element in explaining the development and the success of many FOSS projects, and it offers a comprehensive explanation of many key issues in FOSS development, such as how division of labor takes place within developers, how coordination is achieved and how code testing and integration is deployed, how innovation occurs, and so on. Similarly, Benkler [42] also claims that modularity is the key to making open source projects viable

Johnson [41] made a systematic investigation of the role of modularity in open source. He argues that the success rate of modular projects grows with the number of developers because programmers can self-select into working on the modules for which they are most proficient. The main drawback is that the project may founder if costs are badly distributed among modules.

Giuri et al. [49] show that modularity improves the performances of OS projects measured in terms of the number of bugs fixed, CVS commits, or files released to the community.

B. Community Aspects

According to the first two categories of OS success defined by Comino et al. [45], OS software is successful when it is widely adopted among users or when a large and active community of developers contributes to its production.

Ljungberg [55] states that the stories of the open source projects are full of descriptions of the importance of the founders as entrepreneurs, as dedicated persons, as technical innovators, and good designers. Johnson [38] claims that one major argument for why the open source system should be successful is that it engenders interactions and synergies between developers.

In Fershtman and Gandal [46] software success is measured in terms of output per contributor, i.e. the average number of source code lines written by each contributor. The analysis is based on a sample of 71 open source projects observed during a period of eighteen months, and it shows that output per contributor is significantly higher when the software is distributed under non-restrictive licensing terms. A similar result is obtained by Stewart et al. [47] in a study on 138 open source projects registered on Freshmeat. They measure project success based on the number of subscribers associated with a project, and find that this number is larger when the software is released under non-restrictive schemes and sponsored by non-market organizations.

Capiluppi et al. [8] provide evidence that the majority of OSS projects indeed struggle to attract contributors. Bonaccorsi and Rossi [14] made the comparison of motivations of individual programmers and firms to take part in the open source movement. They showed that the top reasons for firms to participate in the open source movement are the ability for small enterprises to afford innovation, contributions and feedbacks from the community, the reliability and quality of the open source software, and the independence of the price and license policies of the large software companies.

Capiluppi et al. [20] made a systematic analysis of around 400 projects from a popular OS project repository, statically and over time. They showed that only few projects were capable of attracting a meaningful community of developers, but the majority of projects is made by few (in many cases one) person with a very slow pace of evolution. Ghosh et al.

[27] showed that most open source projects are very small scale - 29% of projects have just one author, only 45% had more than two, and only one percent had more than fifty.

Fuggetta [34] argues that most of the success of products such as Linux is to be credited to the commitment and ability of the people who participate in their development.

West [37] states that one key variable for OS success may be the size of the user-programmer community. Anecdotal evidence suggests that the major reason open source projects fail is a lack of user-contributors to do the work. In this case, sponsors of open source projects (whether organizations or individuals) vendors face a particularly important adoption challenge: to attract enough of the right sort of users early enough to improve the quality and features of the software.

Kivekas suggests [33] that the successful work of a free and open source software development (FOSSD) team is largely based on creating and utilizing shared mental models. A shared mental model means that the team members have similar understanding on topics such as the project goals and limitations, the roles of different software modules, the target software architecture, the division of labor, etc. Crowston et al. [31], [32] propose that more highly developed and detailed shared mental models improve efficiency of cooperation by reducing the effort needed to collaborate.

Healy and Schussman [35] state that OSS projects are most often staffed by skilled professional software developers. They claim that the role of project leaders in mobilizing development is crucial and states that effective project leadership seems to us one of the most likely candidates for differentiating successful projects from unsuccessful ones. Authors also suggest that, despite the canonical image of OSS development as a free-for-all bazaar, hierarchical organization is central to the success of important projects. This hierarchy is not a formal organizational chart but rather a status-based pecking order which is known to project participants and serves as a way of policing members.

According to Raymond [16], the primary benefits that accrue to successful contributions of OS projects are good reputation among one's peers, attention and cooperation from others, and higher status in the exchange economy.

The so called gift economy [15] states that giving away goods and services for free allows to make and maintain social links and implies the duty to reciprocate [58]. In writings on the open source software development model, it is often argued that it is successful as a result of the gift economy that embraces activities in online communities. Raymond explicitly declares that the society of open source hackers is in fact a gift culture [16]. According to Raymond, gift giving practises rely on two factors: abundance of resources (as opposed to scarcity) and willing to signal social status. Gifting away the code allows getting new ideas and prototypes out into circulation [14], [17].

Weber [25] argues that open source software is not simply a non-rival good in the sense that it can tolerate free riding without reducing the stock of good for contributors. It is actually anti-rival in the sense that the system positively benefits from free riders. Some small percentage of free riders will provide something of value to the system, even if it is just reporting a bug out of frustration. The more free riders in this setting, the better. This argument holds only if there are a sufficient number of individuals who do not free ride - in other words, a 'core' group that contributes to the creation of the product. Open source projects have demonstrated that a large and complex system of code can be built, maintained, developed, and extended in a non-proprietary setting where many developers work in a highly parallel, relatively unstructured way and without direct monetary compensation.

C. Buisiness Aspects

Commercial businesses tied to open source projects provide additional resources for developing the free components of the software, but even more importantly it helps to promote the open source packages and drive them into the mainstream [13].

Companies make money out of open source software in at least three ways: on distributing the open source software; by adding value to the open source software by additional proprietary products; and by relating to open source software in different ways, such as bundling it with own products [12], [55].

Cook [21] argues that most of the success of open source software development is due to factors that ultimately cannot be transferred to closed-source software development in the business organization.

While traditional commercial proprietary software typically depends on monopoly support with one company providing support and "holding all the cards" (i.e., access to the code) for a piece of software, the publicly available source code for OSS enables many vendors to learn the platform and provide support [57]. Open source can create support that lasts as long as there is demand, even if one support vendor goes out of business.

An important economic incentive to take part in the open source movement deals with the emancipation from the price and license conditions imposed by large software companies. The business models of firms working with open source software are mainly based on the supply of software related services [18]. The open source framework, in fact, does not allow to profit from license fees. If these firms supplied services such as installation, integration, maintenance or support based on proprietary programs, they should pay license fees to the companies owning proprietary rights on such programs. Working with open source software these firms avoid license fees. This lowers down their production costs [14].

Foroutan [53] identified the risks of open source projects in the fields of development and licensing and offered suitable methods that can either prevent or minimize the damage inflicted by them. He states that, ultimately, it is the developers that will lead the project to success or failure. He argues that it is not that the correct license will absolutely ensure success, but rather that the wrong choice of license have a high chance of ruining a projects present and future plans for profit.

Fogel [30] states: "An open license does not guarantee that hordes of active developers will suddenly volunteer their time to your project, nor does open-sourcing a troubled project automatically cure its ills".

Fuggetta [34] states that there are particular market situations where open source is probably the only viable solution to

support successful and effective software development. Typical examples are research communities that need specific software products to support their research work. In this case, the expertise needed to develop this critical and specific kind of software, the cost of developing it, and the limited market base for the resulting products make it difficult to exploit a traditional approach to software development. Typically, in these situations software is cooperatively developed by a number of researchers worldwide. This is a situation where open source software appears to be the only viable solution.

V. Examples of Succesfull OSS

As many cases can demonstrate, open source software can also be a commercial success. Many open source software programs are widely used today. The best known is the computer operating system Linux and web server software Apache. RedHat Linux is probably the first ever corporate establishment to make it big with open source. According to Wikipedia [63], RedHat cloaked revenues of US$ 1,534.615 in 2014. Linux is the #1 server OS on the public Internet (counting by domain name), and the #2 web serving OS on the public Internet (counting by physical machine) [62]. Apache is a webserver software which can be called as one among the most important build block of Internet as we know it today. Since April 1996 Apache has been the most popular web server software in use. As of February 2015 [61] Apache served over 39.47% of all websites on the Web. Feller [50] cites O'Reilly who points out that although Linux and Apache are high profile, the more significant success of OSS can be seen behind the scenes, in the Internet "category killers" such as BIND, which runs the Domain Name Server (DNS) for the World Wide Web, and Sendmail, which is central to the Internet mail backbone [50].

VI. Conclusion

In this paper, we have conducted an analysis of various success criteria for OSS projects. We can conclude that the success of an OSS project depends on several crucial factors. Importantly, such project must attract a sufficient number of highly motivated and skilled contributors willing to invest their own time to the benefits of the project. The most successful open source projects are those not only with excellent code bases but thriving communities of users who have a need that can be met by the software. Successful OSS project must have an independent and powerful leader - a team or a individual - who will make prosperous decisions, and manage and supervise the project. A leader will have to establish well-articulated and clear goals for the project. It is crucial to have a relatively clearly defined vision and a mechanism to communicate the vision early in the projects life [59]. OS projects' collaborators can be part-time volunteers spread around the world, as well as the full-time employees (core-team) paid to develop key features and to maintain the software. For a successful OSS project, it is of vital importance to have a solid users community support and an active volunteers base. In the OS development process, volunteers play a vital role, especially in the area of software testing and bug discovery.

However, it it important to distinguish the success of the OSS project from a business accomplishments of a company which has started the OSS project.

The realization of significant business success is possible through OSS in specific business situations, where companies have developed the OS products interesting to the large number of customers, while achieving a superior quality, or have developed products of a unique value with no real business competition. For that matter, the nature of open source affects the projects' chances to thrive in the business market and achieve success. This is, to some extent, the prerequisite for the above-mentioned criteria of the OSS projects' success.

Commercially-oriented OSS can be successful and recognized as a software project, but that does not guarantee financial success for the company. Unlike proprietary software, where the success of a product usually implies the financial and business success of the company, success of a OSS do not necessary lead to the prosperity of a company or individual behind a project. If we ignore financial and time dimension of a success criteria, we can say that the OSS project is successful if it has a relatively large number of users satisfied with the quality and usability of the software. In this respect, it is of crucial importance to thoroughly understand the users' needs and demands, in a manner of improving old and implementing new product features.

Abstract - State governments, through the digitization of services that have been provided through conventional ways, have made possible to the citizens and businesses to find and use information and services electronically. Through the formation of e-government portal, as a single point of access to services, governments have greatly facilitate business and communication between relevant institutions and stakeholders. Subjects can be informed, they can download forms but also they can realize services using portal. The above is made possible with the clear objective of removing barriers that are an integral part of the administrative system.

In this paper, we will give a brief theoretical review of the concept of operations of the state administration in the provision of services through e-government portal, starting with the concept and definition of e-government, with the goals of this concept, to the benefits of its application from the perspective of the citizens and business as users, and the government itself as provider. Also, the paper aims to present and analyze the level of realization of services provided at e-government portal in Montenegro, and also to identify possible problems and give recommendations for further improvement of the same.

Key words: e-government, public services, one-stop-shop, portal

I INTRODUCTION

Significant changes that have occurred in the field of information and communication technologies development in the last two decades have influenced the change in the earlier paradigm of business. The development of the Internet and the emergence of a growing number of companies using the Internet as a means to reduce costs, but also to save time, was one of the main impulses that influenced the governments of a number of countries to launch a variety of electronic services that are needed to facilitate the operations of private business, and ultimately through the development of entrepreneurship and the private sector to become more competitive in a growing global market.

Realizing that the development of information and communication technologies opens up a space for exchange, by nature inefficient bureaucracy portals with modern electronic government, many states are deciding to withdraw the move to facilitate access to its services for a large number of citizens and companies. With digitizing a large number of processes and procedures the states have been able to influence the increase of efficiency and productivity of a large number of services, which ultimately had a positive impact on the development of the business environment in their economies as well in improving the competitiveness of the economy as a whole.

Modern public administration is significantly different from traditional public administration. Although many factors have contributed to the steady transformation of the work, it is clear that the initiator of the all changes was the use of information and communication technologies (ICT) in the daily work of the governments and its agencies. Traditional public administration is largely recognized under the concept of bureaucracy, and bureaucracy is by definition inefficient. The application of knowledge management in public administration leads to its higher productivity, and thus the competitiveness of the national economy. It is this shift that marked a new era in the work of public administration, which is now known under different terms, such as an electronic public administration, networking governance and the like. The aim of these efforts and initiatives is to move closer to services and intensifying communication of public administration with citizens and representatives of industry, bearing in mind above all, the increase of the efficiency and transparency of the process.

Governments and public sector organizations around the world are trying to combine basic, but often conflicting, demands: to provide better, more relevant public services that are focused on the needs of the citizens and businesses they serve; to reduce costs but also improve the efficiency of their operations; as well as to change and improve their supply chains in order to create processes that are quick, cheap and effective.

However, the application of technologies and advanced technological solutions is not the only solution to the implementation of electronic governance. The technology is now available especially when it comes to small countries which did not require large investments in

infrastructure and services. It is necessary to bear in mind the extent to which people own a computer, from which place they most commonly use internet services, what kind of equipment they use, which is the level of internet penetration, what kind of public key infrastructures is, whether digital certificates are available to the average user and the like.

If governments want to get liberated of the growing internal and external pressures, they need to review, redesign and optimize its services, and to put the users - citizens, businesses and NGOs - in focus, i.e. center of their operations, rather than the needs of government organizations and service providers. Also, they need to shift from outdated business models, management, culture, technology and processes that are inherited from some prior periods quickly and efficiently. This transition will involve destructive and very painful changes from closed, top-down, bureaucratic and paper-based transaction services to online, integrated digital offers that will encourage and enable a new way of interaction between citizens and the state.

II THE CONCEPT AND DEFINITION OF E-GOVERNMENT

e-Government or e-business in the public administration is the use of information and communication technologies combined with organizational changes and new skills in order to improve the delivery of public services, increase of democratic participation and involvement of the public in decision-making and policy-making processes [11]. So, e-government use modern achievements of information and communication technologies in order to provide greater productivity and heterogeneity of its activities, in order to meet the needs of citizens. Defining the concept of e-government, it is clear that it has adopted the famous marketing concept: in the focus of marketing management must always be the consumer himself, or transferred to the field of e-government: the focus of the public sector is a citizen. On that basis, it is clear that the modern public administration is highly qualified, initiative, solid, responsible and efficient network of public services. The most important consequence of the introduction of information and communication technologies in public administration is the elimination of physical contact between the users and service administration, and increased efficiency and transparency of the public sector. Performing numerous procedures online, either citizens or legal persons, represents a tremendous savings in time, and that is the most valuable resource in the possession of any individual or business entity. In addition to increasing efficiency, public administration with the introduction of ICT in the work contributes to the creation of new skills that are expected of employees in the public sector, thus changing the situation on the labor market.

There are different approaches when it comes to measuring the level of e-government development. If we focus on the concept of e-governance, it is possible to analyze the different levels of maturity of e-Services, e-Management, e-Democracy and the like. Most of the measurements tries to encompass all of these questions, but the scope of the analysis is often narrow and restricted. As long as it comes to the used methodology, the assessment is carried out by combining several techniques including web research, questionnaires, face-to-face interviews and the like. However, reliable and relevant measurements can provide key inputs to point to policy makers and practitioners to chances but also the problems they may face and to help them, in this regard, to focus in the right way.

One indicator of the level of development of e-government is e-government index, developed and administered by the United Nations, which is widely recognized as the authoritative measure of the capacity of the public sector in the provision of electronic and mobile services. According to research by the United Nations for 2014 [12], the index of development of e-government (e-Government Development Index -EGDI) for Montenegro has shown that Montenegro is in the category of high-income countries (High EGDI between 0.50 and 0.75). According to these data, it is considered that there is considerable scope and opportunity for Montenegro to continue the development of e-government. Government can achieve the development of e-government with implementation of clear strategy, continuous investments in primary, secondary and tertiary education, as well with the radical transformation in the offer of online public services available to citizens.

With the aim of easier facilitating the functioning in the world of internet, variety of platforms have been created. The purpose of their creation is to allow everyone access to services and portals. That is why it is necessery to allow everyone access to the Internet, and then make most of the work available online, for which it took a long time to finish in the real world, which will ultimately save time and make customers satisfied.

III DEVELOPMENT OF E-GOVERNMENT IN MONTENEGRO

In late 2010 the European Commission adopted the Digital Agenda for Europe as one of the seven most important initiatives of the European strategy 2020, which was established to define the key role of information and communication technologies in social and economic development of the country. In this context, the main goal of "Information Society Development Strategy 2012-2016. - Montenegro digital society", which is the most important strategic document that defines and provides a road map for Information Society Development in Montenegro, is planning activities that will maximize the social and economic potential of ICT, especially the Internet as an important means of economic and social activities [11].

As one of the priority areas of Information Society development, this document has recognized the development of e-government. Through the use of information and communication technology, substantially will be improved the delivery of public services with improvement of democratic participation and public involvement in decision-making and policy-making. The main goal of e-government is to increase the availability of public services to citizens and businesses. It should also enhance the effectiveness of state management, as well as to enable it to have better insight into the allocation of economic and social resources. Through efficient interaction of all participants - state, private and corporate customers - will stimulate political, social and economic development of the country.

Respecting the guidelines defined in the policy document for the development of information society in Montenegro [11] as well as EU standards, with a goal to implementing e-government, in Montenegro was developed web portal www.euprava.me who has aims to bring together in one place, consolidate, and enable electronic realization of services used by citizens, businesses and employees in the state administration.

IV ANALYSIS OF THE E-GOVERNMENT WEB PORTAL IN MONTENEGRO

Ministry for Information Society and Telecommunications of Montenegro has implemented the project of developement and realization of internet e-government portal - www.euprava.me. The institutions of state administration and local government units are providing via the aforementioned portal services to citizens and legal persons, as well as other institutions, by electronic means.

Web portal is a unique platform that provides (some) electronic public services offered by public administration. The basic principles on which web portal is built are: security, control, simplicity, transparency, services created by the user's needs, scalability, flexibility and adaptability looks, adapting to people with special needs, in person, and for anyone, anytime-anywhere, connect with other systems [15]. It is a unique place on the Internet where you can find all the public services offered by public administration. E-government services are available 24 hours 365 days a year. The aim of the implementation of the e-government portal is to provide an easier, cheaper, more transparent communication between government and citizens, government and companies and government agencies themselves. The government today operates through networked databases, and automated administration, which represents the essence of e-government. Therefore, the goal of e-government is to improve service delivery to citizens, and thus save time in a manner which will provide their services via the Internet.

e-government portal has started on 7th of April 2011 in cooperation with the five state institutions with the initial operation of the 12 services. Currently web portal provides 77 electronic services, which provide 25 institutions. The portal is based on a one-stop-shop system (all services in one place for the user), along with a complete or partial re-engineering processes and operations. In addition to the information and services on the portal grouped into three categories, such as services for: citizens, legal entities/businesses and government officials, information and services on the website are grouped in several ways, so that users can easily access the desired services. Information on this website is grouped according to the situations of life, in order to follow all significant situations of citizens (education, business, issuing documents, etc.) or legal entities (business and labor, document, finance, etc.).
Moreover, services within the portal euprava.me are defined through three "statuses" ie. the degree of realization, which are:

- informative services - services that provide users with information on how they can be implemented in a physical way, whether they are necessary and which documents, what it the competent institution which implements the service, etc. These services can not be realized electronically.
- electronic services that can be realized through the portal euprava.me, and can be done in two ways:
    - registering by e-mail adress
    - signing with the digital certificate

Depending on the type of the service, the portal supports the following system users: *anonymous users* - users who access the portal anonymously, without prior registration and they are allowed use of the services of the state administration on the level of information about procedures, contact details for the implementation of procedures and other necessary information about the institutions, as well as all the information of public importance which have the character of free access; *registered users by e-mail* - users who access the portal by registering the mail address, without the use of qualified and valid certificates; portal enables the use of government services, in addition to obtaining information, at the level applying for services that do not require digital signatures; *and registered users* - users who are accessing the portal with qualified and valid digital certificates. Registered users may be individuals, legal entities and civil servant who use the services of the portal as well as authorized officials of the relevant institutions (employees of public institutions) responsible for providing services and the provision of services on the e-government portal. Registered users can register via qualified digital certificates issued by any of the registered certification authorities (CA[1]) in Montenegro

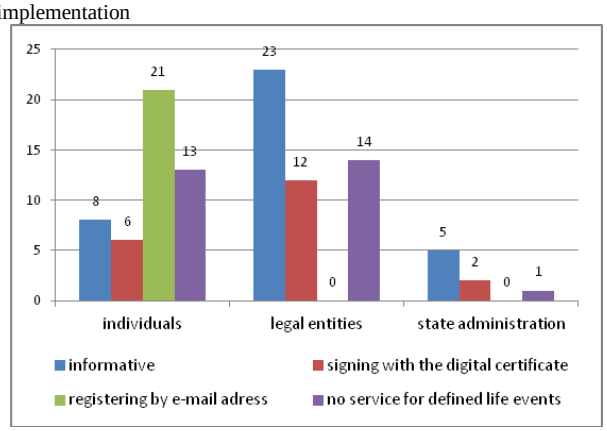
[1] Post of Montenegro is qualified Certification Body in Montenegro managing public key infrastructure (PKI-PoštaCG) for public needs of Montenegro. As part of the PoštaCG-PKI for the purpose of providing certification services is established certification body with a Single Rooted Certification Authority - PoštaCG-CA, which issues qualified

and can use the site's services at the highest level that has been implemented. For registered users, the portal identifies what type of users they belong to (citizen, business entity, employed in public administration, public administration) and assign rights that the user may get on the portal. Registered users can use the services of the Portal at the highest level of implementation, for example, citizens and businesses can, for certain services, request form necessary for receiving the services, fill it, sign electronically, electronically pay the administrative fee and electronically submit the request. Portal assigns each request to the competent institution, where it is processed classical and elecronically. Registered users can at any time check the status of their application. This procedure applies to both physical and legal persons. Registered users employed by the institutions in charge of public services have assigned corresponding rights that are recognized by the portal, and depending on the rights, they can set up the service of the state administration, create electronic forms on the site, track user requests, administer electronic public debates on the Portal and the like. Portal keeps a history of all activities and identities of all participants in the process [19].

Taking into account the level of development of e-government portal services, for this study was conducted web research of the euprava.me portal, through an analysis of the number of available services, as well as the extent to which the services are developed. Bearing in mind that the services can be informative, and that can be electronic services that can be implemented by logging with e-mail or using a digital certificate, we have, for this study, used these three categories for "evaluation" the level of implementation. In addition, we have analyzed it in terms of categories of users that use the available services.

Bearing in mind the above mentioned, although that 77 services are available on the portal euprava.me, information on the degree of realization of these services show that 36 service are developed just to the level of providing information, while the 41 service can be realized by electronic means (including 20 service using digital signatures and 21 service through registration by e-mail). When it comes to the services that are informative, 8 services are related to the services for citizens, 23 are services for business entities, while only 5 services are for employees in the state administration. For services that can be executed electronically and using a digital certificate, the six services are for citizens, 12 service are to local businesses and 2 are realted to the services of Public Administration. On the other hand, of the services that can be done electronically by registering by e-mail, 21 are for individuals while for businesses and government officials are still no services in this category. Although it is expected that the businesses are the main users of electronic services, more of such services (which may be executed electronically) are developed for individuals. On the other hand if we analyze the types of these services, it is not surprising, bearing in mind that the services on the portal and divided by the institutions that offer them, and that a significant number of these services for individuals that can be realized by registering an e-mail are just service *request for free access to information* (portal has 14 such services). The data are presented in Table 1.

Figure 1. Distribution of the services based on users and level of implementation



The fact that there are more services that can be implemented using digital certificates are developed for businesses and employees in the state administration is fully correlated with the current state of development and use of digital certificates in Montenegro, bearing in mind the high cost of certificates, as well as the level of use and the citizens need to use a certificate.

Thus, the same number of services is developed for individuals and legal entities, although the distribution by way of provision of services is different. In addition to these services, which can be implemented in any of the three modes, the portal also lists the services for which there is no information, following: 13 for individuals, 14 for businesses and one for employees in the state administration. Also noticeable is that the particular service in parts of legal entities and individuals coincide, as for example Statistical data. In the category of individuals this service is not developed while in the category of legal persons it is developed. When it comes to the category of administration that is employed in the state administration, there are many services that are supported by the portal, but the state administration only

certificates to interested individuals and corporate entities. PoštaCG-CA uses one registration authority, which operates within the Post of Montenegro Ltd. and is authorized to verify the identity of users in the Management of certificates such as first issue of the certificates, renewal of certificates, certificate revocation, to grant a request for the certificate. The registration authority forwards the approved requests to the operational. Certificates issued by PoštaCG-CA can be used for different purposes depending on the certificate policy. Certificate policy is in every issues certificate marked in the extension certificatePolicies in accordance with the specification in RFC (Internet X.509 Public Key Infrastructure Certificate and Certificate Revocation LICT - CRL Profile). Certificates issued by PoštaCG-Ca are allowed to be used for verification of digital or electronic signature, verification of identity and ensuring confidentiality [19].

needs to work on its expansion, which would imply better coordination between the state institutions.

Figure 2. Distribution of the services based on deegree of realisation for individuals

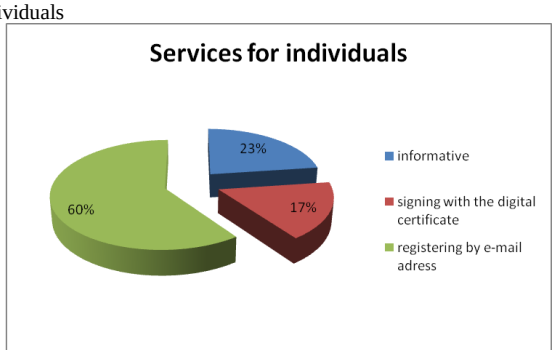


Figure 3. Distribution of the services based on deegree of realisation for legal entities

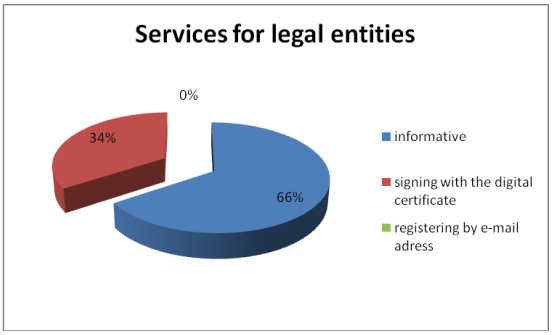

Figure 2. Distribution of the services based on deegree of realisation for state administration

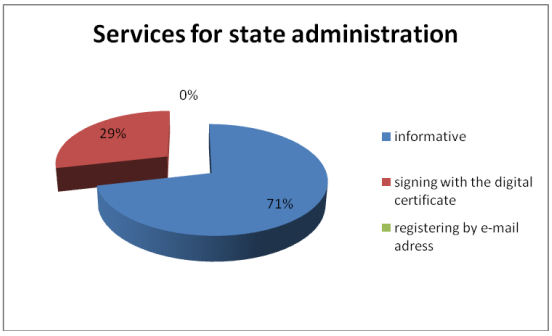

Analyzing Monstat data, which state that in Montenegro Internet penetration is 60.3%, this means that around 400,000 citizens of Montenegro have access to the internet and the possibilities it offers [17]. In accordance with these data, the number of laptops and PCs in households was around 80% and the number of mobile phone users as much as 90%. All these data suggest that in Montenegro all households do not own a computer, but has at least one mobile phone. When talking about the e-government portal, it can be concluded that the approach to it is not possible for about 40% of the citizens of Montenegro due to lack of internet access. However, the fact that the penetration rate of mobile telephony is constantly growing, and that penetration in the fixed-line declines, shows that an increasing number of users opt exclusively for the use of mobile telephony. Every citizen has an average of 1.6 mobile phone which, from the aspect of the e-government portal, is a good predisposition to increase the degree of usability services. Also, while retaining all the functionality of Web versions of the portal, there is developed a mobile version of the portal which give access to the portal via WAP and XHTML web browser with mobile phones. At this time, the portal offers access to the system via the email address and password. Full realization of the mobile version of the portal will be realized after such a system (electronic certificate on the SIM card mobile phone) is developed by some of the operators in Montenegro.

Action Plan for the development of information society [14], that follows strategic document, defines the objectives for the development of e-government, which implies that by 2016, 50% of the citizens of Montenegro and 80% of companies need to have benefited from e-government services. Also, one of the tasks defined in the "strategy of Information Society 2012-2016" is that the 100 most frequently used government services will be available on the website until 2014 and the 200 most commonly used services will be available until 2016 [11]. Although the portal of public administration is faraway from the defined guidelines and objectives, it is clear that such activities are conducted both in the promotion and improvement in order to be recognized as a unique access point, as well as to make portal and services available for all categories of users to use the services at the highest level. This is supported by the fact that the Government of Montenegro, in January 2015, adopted a "Program of Economic Reforms in Montenegro for 2015-2017" which defines specific objectives and measures towards the development of e-government in Montenegro. Although the analysis of the state of e-government from 2013 showed that the total level of sophistication of e-Services in Montenegro is below the average of all EU countries, the commitment to the realization of defined measures from the Program of Economic Reforms, technical and normative preconditions for its implementation (the portal of electronic government and the Law on e-government) that are created, are the guarantor for improvements in this area. In contrast to the positive trends stand resistance of the administration to change and resistance to centralized access to services in the state administration over the e-government portal as well as the identified risks to the achievement measures. According to the Law on e-government, state authorities, state administration, local government, public services and legal persons exercising public powers are obliged to, within about 18 months from the date of entry into force, all the services they provide to citizens and businesses traditionaly to make available and electronically through the e-government portal. Although there are currently available 77 services on the e-government portal, which provide 25 institutions, the structure of the services are not satisfactory, and insufficient number of services relating to business and civil rights is available, which is the most measurable in terms of administrative barriers. In this sense, through strategic documents, action plans, reports on implementation of action plans as well as economic reform plans, the intention is that the more

services (relating to key life events, both for individuals and for businesses and employees in the state administration) is available online through the e-government portal.

V Conclusion

Technological progress has influenced to a governments facing the challenges of maintaining and directing the development of e-government until there is great uncertainty to a rapid technological change. Therefore, it is very difficult to predict the detailed impact of future policies. New technologies are very attractive because they often promise better solutions and create an environment in which certain business changes can happen. More often may, however, they promise solutions that include facilitating the implementation of information technologies without changes of their own business processes. Experience shows, however, that systems that are built on the unknown and emerging technologies are very susceptible to failure. In some cases, potential benefits may justify taking such big risks; but in most situations this is not the case.

E-government is a government that recognizes the opportunities and impact of information technology on management in terms of the digital economy and that makes maximum use of them to improve internal processes in order to provide high quality services and the establishment of management oriented towards users. As such it has to provide: effective realization of the rights and interests of citizens, the protection of human rights, the protection of public interest, improving the quality of life of every citizen, efficient and professional self-control and quality preparation of the law.

Montenegro is following current trends in the information economy which is confirmed by a strategic documents and concrete activities on implementation of the objectives defined by these documents. However, in order to let the country became part of the information age it is necessary that in addition to the institution, which prepares and delivers strategy in the field of information society, there are other institutions that will focus on particular segments of the electronic development. No matter what the e-government portal now has 77 services, it can be concluded that the administrative authorities have not recognized the importance of this portal and the benefits it provides in communication with citizens and businesses. The number of existing services in Montenegro is not entirely satisfactory and requires dynamic development of electronic services. As for the assessment of public administration services, they can be improved by adding the most current information and forms on websites. However, for significant progress in the development of e-government it is necessary to develop the back-office applications, which are reflected in the fact that it will provide services for users, realization of registers, integration of information from databases as well as a larger number of users of a service which will ultimately increase the value of the portal.

Abstract - The paper presents the results of the level of adoption of e-commerce in Montenegro and provides an overview of the factors which slows the use of its full potential. The aim of the research is to create a picture of the perception of e-commerce in terms of consumer and to identify the determinants that can be affected in order to create a better environment for electronic transactions in Montenegro.
Quantitative research (conducted through survey) and qualitative research (conducted through assessment of web sites of companies that are on the supply side), are associated with the subjective judgment of the authors, in order to better examine the key issues that affect the decision on the online store.
Research has shown that the potentials of electronic commerce in Montenegro are great, but that there is still not a critical mass of users.
On the other hand, in companies that are on the supply side, there are ambitions, but there is not enough knowledge to further examine the potential of electronic commerce and properly direct the offer to the different categories of clients.

Key words: e-commerce, determinants, perception, consumers, factors

I INTRODUCTION

Two last decades have been marked by a significant penetration and dispersion of electronic commerce. If we exclude 2008, when the beginning of the economic crisis, which was met without preparation, reflected on the negative growth rate of electronic commerce, throughout all other years the growth rate of its application on the global level has been evident. Whereas at the beginning of this century the leading positions considering its acceptance belonged to highly developed countries of the world, especially to USA, nowadays the high growth rates are recorded in the developing countries as well [1]. The reasons for such state could be found in a large number of factors:

- Accelerated technological penetrations;
- Growth of trade volume within both national and international frameworks;
- Readiness of network configuration to support commercial transactions on all levels of different strength and complexity, which is followed by change in supply and demand in electronic environment;
- General economic terms favoring electronic commerce;
- Favorable world monetary and fiscal ambience for transferring business processes into electronic platforms;
- Change of legal regulation and its adjustment to technological changes;
- Activities of governmental bodies and certain international organizations and institutions to provide support to affirmation of electronic business and within it to electronic commerce as well;
- Development of strategies aimed at making effects of globalizations move into positive direction;
- Increased number of online payment methods designed to support business on open networks, primarily on the Internet.

From experience and all conducted researches so far, it is clear that delay in accepting electronic commerce may lead to isolation of national economies. On the other side, electronic commerce offers numerous advantages such as improvement of productivity, decrease in prices, cost savings, change of size and structure of the market, elimination of mediators and direct access to end-users [2].
For success in the electronic world, the first and most important step is planning to identify barriers to adoption of e-commerce [3].
The growth of electronic commerce has led to increased number of academic works that deal with this very issue and put focus on two interest groups – customers and companies. It has been noticed that other actors, such as suppliers, investors, regulation bodies etc, are disproportionally less treated in this field of research. On this degree of EC development their influence is not that considerable, but there is evidence that they will deserve more attention in the recent future [4].
Although it is believed that the electronic commerce is a global phenomenon, in the most of the studies the focus is on developed market economies [5]. We agree that the experience of developed countries is valuable, but we

think that developing countries should not be disregarded and that the complete picture can be gained only by parallel treatment of this issue on all levels of development. EC are seen in different lights in developed versus developing economies. The pattern of influence and use of EC differs according to a country's level of socio-economic development [6].

Montenegro, as a typical developing country, has an incentive environment and great economic potential for more massive usage of electronic commerce technologies, but the low degree of usage of those technologies and a great lack of awareness of potential benefits they offer.

The aim of this work is to identify factors that influence the low degree of acceptance of the electronic commerce in Montenegro from both perspectives – of consumers and companies.

This research has a triple purpose: 1) To create the picture of customers' perceptions about electronic commerce and recognize their expectations; 2) To identify factors determining degree of electronic commerce technology usage by companies; 3) To create data base pursuant to which the electronic transaction volume can be increased and strong base of satisfied internet users can be created.

II METHODOLOGY OF RESEARCH

We collected the data for this study during the one comprehensive research which had the goal to gain insight into the state of electronic business in Montenegro. For the purpose of this paper we used a part of that survey and analyze relevant data from submitted questionnaires.

In the survey we used two types of questionnaire, while one was forwarded to consumers (citizens of Montenegro), the other collected answers from companies, or precisely from employees and managers.

Perception and experience of different profiles of consumers about electronic commerce was important issue of this research. According to that, one of questionnaire made in way to collect as much as possible information about demographic characteristics of consumers (sex, age, employment, education, income level and geographic affiliation), their experience in using of the Internet, and electronic transactions, as well as their opinion about security in transactions and offers on the sites.

The second questionnaire consisted of two parts. The first section was intended for employees, and the second for managers of the company. The aim of this questionnaire was to gather information about organizational and technical factors which determine the degree of acceptance of electronic commerce technology from the perspective of supply.

During consumer survey, we used the method of random sampling, which proportionately included population of central, southern and northern regions. About 70% of the questionnaire is collected from the central region which can be considered as a representative sample. From 500 submitted questionnaires, we analyzed 350 properly completed.

From 100 questionnaires forwarded to the addresses of companies (randomly selected from the Central Registry of Companies), we received 87 completely filled. A total of 84 surveys were received from small and medium enterprises (SMEs). This fact justifies the efforts of the professional public to explore the acceptance of e-commerce technology particularly in the SME category.

The survey was anonymous in both cases and persons who participated in the survey were familiar with the purpose of research.

After collecting the data and their analyzing by a pre-defined plan, we approached to interpretation of research results.

For the purposes of this study, we used basic theoretical methods, appropriate to the social sciences: definition, classification, induction, deduction, analysis and synthesis.

III INTERPRETATION OF RESEARCH RESULTS

Although the Strategy for Information Society Development in Montenegro [9] that is currently in force sets the goals of digital environment development for operation of innovative companies, increase of the number of customers who are familiar with and use electronic commerce technology and growth of modern public sector participation that supports all of that, Montenegro is still at the bottom of the list of the European countries in the field of electronic commerce technology usage.

From aggregated data gained from the Montenegrin banks at the end of 2014, it could be seen that around 11 million euro was spent for online transactions in that year, which was about three millions more than in 2013, but the growth rate was still far from the one existing in neighboring countries.

From four examined categories of transactions (services of electronic banking, services of electronic tourism, electronic commerce and online auctions), online commerce occupies the penultimate position (Table 1).

The research has shown that 98% of citizens do the online purchase using foreign sites. As reasons for such decisions they state: poor offer on the sites of the Montenegrin companies, relatively high prices, bad functioning of sites and lack of confidence into companies that have no tradition of electronic commerce. Without doubt this leads to conclusion that the efforts made so far for implementation of electronic commerce in the Montenegrin companies are not sufficient and they give no significant results.

Participants in electronic transactions		Percentage
Use the services of electronic banking	Yes	15.14%
	No	84.86%
Use the services of electronic tourism	Yes	17.43%
	No	82.58%
Buy products over Internet	Yes	7.70%
	No	92.3%
Participate in electronic auctions	Yes	2.00%
	No	98.00%

TABLE 1. PERCENTAGE PARTICIPATION IN ELECTRONIC TRANSACTIONS

From the total number of those who do the online purchase, 81% of citizens belong to the group of highly educated, 14 % are students and 5 % accounts for other educational structures.

When it comes to online purchase, salaries exceeding 700€ are the breaking point. It has been shown that the amount of income is in direct correlation with participation in electronic transactions and by that, for now, the amount of income is in direct correlation with the level of education. Pursuant to the economic situation in Montenegro, 91% of those doing online purchase are employed, where difference in sector employment (public and private sector) has no statistical importance. If we analyze the number of online purchases done, it can be concluded that it is unevenly distributed from the aspect of age structure since 65% of online customers are people of middle age (35-50 years old). This is the category of customers who have more steady income. Besides 65% of online customers from that category, only 14% is from the category 18-25 years of age, 19% is from 25 to 35 years of age and less than 2% accounts for customers older than 50 years.

Differences between the sexes in Montenegro have no importance in examining the influence of sex on decision to carry out electronic transaction (from 58 YES answers, 27 gave women and 31 men).

Significant digital gap on relation north-central part-south of Montenegro is visible in gained data as well. From the total number of internet users doing online shopping 63% come from central region, 31% account for coastal region and only 6% for north region (which is recognized as the region with the smallest number of employees, lowest income and smallest number of educated inhabitants).

For ranging the importance of factors influencing satisfaction, trust and loyalty we used 9 criteria:

1. prices of service;
2. the quality of offered service;
3. the quality of information on services;
4. the quality of post selling service;
5. evaluation of previous experience;
6. brand effect;
7. design of user's interface;
8. perception of security;
9. perception of privacy of data.

In survey we used Likert-type scale as a criterion. The analysis has shown that when making decision on online purchase customers pay attention to (in the following sequence): trust, price, brand effect, the quality of offered service, the quality of information on service and the quality of post selling service. The trust is mostly influenced by belief about security and data privacy as well as the evaluation of previous experience. As it has been shown in previously published researches, in situation of greater space and time separation of the act of purchasing and the act of receiving goods the perceived risks grow higher. For that reason trust has the key role in developing this way of commerce and it is even more important than the price of the product to be bought [10]. Dehkordi and the associates have reached a similar conclusion [11]. In the research conducted in developed market economies they have shown that perceptions of customers regarding price and trust remain the same regardless of the level of development of the economy from which consumers come. Also, the information that 93% of customers from Montenegro give the highest grade (on scale from 1 to 5) to the importance of previous experience confirms the fact that the psychology of users on the web is the same regardless of demographic differences. [12].

Data gained for design of user's interface have shown the modest influence of this factor on the level of carried online purchases.

From the survey it can be seen that the examinees have been familiar with the importance of the Internet, they have modest knowledge about benefits of electronic commerce, insufficient knowledge about instruments of electronic payment and deeply rooted fear of negative consequences that can come out from such way of paying.

Generally, all reasons for inertness of citizens of Montenegro regarding participation in online commerce we can group into several units:

- There is a lack of trust into online transactions by consumers. In that regard, both companies and the Government must have understanding for consumers' perception regarding this issue. The problem must be approached at least from three aspects: a) electronic commerce should be promoted through development of training programs which can raise customer's awareness of problems regarding security and safety and which can inform consumers about the means that can be used for avoiding those problems; b) tools which customers can use to assess the reliability of service which is used during online commerce should be presented; c) national legal framework protecting rights to privacy and anonymity of online customers and punishing those who violate those rights should be secured.
- There are issues that arise from social differences. In Montenegro there is a huge difference in economic level of development on relation north – south part of Montenegro.

Government's programs should be used for removing digital gap existing on this relation, as well as on relation village – town so that all citizens could have the equal access to ICT and electronic commerce technologies. As long as telecommunication environment isn't promoted along with investments into Internet infrastructure by coordinated action in all regions, electronic business will remain at low level and in domain of conventional order.

- There is insufficient information regarding potentials of ICT in commerce. Promotional and educational activities should be used to help consumers understand the Internet environment, to realize new aspects of virtual economy (benefits and possible barriers) and to meet the so called Gift Economy on the Internet.
- There is an incomplete legal framework dealing with consumers and protecting their interests. Besides amendments to currently valid Law on Electronic Commerce and the Law on Electronic Signature, based on the model used in neighboring countries, the Law on Foreign Current Operations should be changed and a new law on payment transactions should be adopted. The Law on Foreign Current Operations could secure Montenegrin companies mechanism for sale on foreign markets. To the State it would secure foreign exchange revenue. To consumers it would bring trust into online commerce using national sites. Since the laws defining electronic business in Montenegro adopted so far do not define the concept of electronic money, this could be done by the law on payment transactions, by which citizens, besides a wide branch of instruments of electronic payment, would also get legal protection.
- There is a lack of purchasing power. This issue should be treated within overall economic policy aimed at creating conditions for reducing unemployment, increasing incomes and raising standard.

It is necessary to map the basic critical factors for the growth of electronic commerce from the consumers' aspect and suggest measures for resolving these problems so that companies by their activities could increase the base of satisfied online customers and the Government by strategic plans could create a favorable environment for acting towards other institutions and establish better cooperation with companies regarding mentioned issues.

After analyzing data gained from employees and managers in the Montenegrin companies on the side of offer we have got results which are not optimistic at all.

Companies are aware that on a long-term basis the usage of electronic commerce technologies is related to profitability and long-term growth of company, but the participation of electronic transactions in overall transactions is still very low. Reasons for such state managers see in discouraging economic environment and employees in feeble effort to attract and keep online customers.

More than 75% of persons surveyed on the side of offer have their own website, mostly informative and static one. Based on answers got from employees it could be concluded that in all companies maximum efforts have been made regarding designing and functioning of website. As regards quality, there is no backwardness in comparison to other companies that have online offer.

However, when we did a quantitative evaluation applying Web Assessment Index (WAI), we discovered that there were shortcomings and still a lot had be done regarding functionality and personalization of the sites.

WAI model was developed in 2001 and so far it has been used in a great number of researches aimed at evaluating the quality of websites of companies coming from different branches of industries [13,14].

The quality of websites of the surveyed Montenegrin companies we measured using 4 criteria: access, speed of access, navigation and site content.

As sub criteria for access we used the presence on search engines and link popularity. For measuring the presence on search engines we decided to use Google and for measuring popularity we used data got from AlexaWebsite.

For measuring the speed of access we carried out independent testing of the opening speed of websites of companies by approaching from one computer at the same time. We repeated testing three times in 15 days and got results which were slightly different.

For testing navigation we used a subjective standpoint of the authors, evaluating the presence of the site map, simplicity of navigation, linkage of the basic page with other site pages, easy orientation of users on the site etc.

For evaluating the content, following the pattern of previous works, we split content into three subcategories:

1. Information content
2. Content for the purpose of communication with consumers
3. Content related to transactions themselves

From the total of 100 points for evaluation of the site quality, 55 were intended for content (by subjective assessment as the most important criterion for site quality evaluation) and 15 for each – access, speed and navigation. From 15 points for access, 5 were given for presence on search engines and 10 for the number of visits on the site.

When the testing was done, we got the following results:

- Out of total of 100 points, only two companies have between 80 and 90 points, 4 companies are in the range of 70-80, 7 companies are in the range of 60-70, 21 companies are in the range of 50-60 and even 32 companies have less than 50 points.
- When analyzing the presence on search engines, none company appears on more than 60 search results previews, 14 companies have 50-60, 27 companies have 30-50 previews and the greatest number is of those having less than 30 search results previews;

- By measuring the speed of access we established the quickest access of 3.4 seconds and slowest of 41.6 seconds. The greatest number of companies has the speed of access between 6 and 8 seconds. We have also noticed that the speed of access is in direct correlation with quantity of content on the site.
- We have seen that the companies with a greater number of achieved points regarding access have a better navigation. Out of 66 companies 27 have and 39 do not have the site map.
- Regarding the content assessment, all companies got maximum points for information content and content related to contact and communication. Very small number of points has been given for content related to transactions and information on carrying out online transactions, which leads us to conclusion that the level of online transactions is very low. Regarding the assessment of content quality, 26 companies got between 40 and 50 points, 11 between 30 and 40 points and 29 between 20 and 30 points.
- 27% of analyzed websites support bilingualism (the English and Montenegrin language).

By comparison of these data with data got by other researches (by application of the same technique) it can be concluded that managers and marketing experts of the Montenegrin companies should make more efforts in order to improve the functionality of their sites. At the first place we think on more serious approach to SEO technique so that visibility could be increased, then on improvement of the quality of content in part of online transactions that can be offered to consumers, on improvement of quality of navigation, on more frequent refreshing of the available information and on higher level of encouraging customers on two-way direction.

Among the Montenegrin companies that have been analyzed there is a strong competition, for the purpose of gaining comparative advantage, employees in marketing sectors are currently focused on finding new products and services. On the other side, development of web presence strategy, on cite, forums, social communities etc, in 53 out of 87 companies is partially left to IT sector, where logically exists a lack of interdisciplinary knowledge.

Our impression is that all the efforts of managers and employees in the area of usage of electronic commerce technologies are aimed at stimulating customers to come to a physical location, point of sale, which is still considered as the most secure place for transactions.

As it is the case with a great number of companies from other branches of industry, in Montenegro, instead of adopting an insufficiently known ground, the management its development strategies mostly directs towards reducing costs of traditional business and traditional communication.

Answers of all persons surveyed on the side of offer show that there are expectations regarding support from the State.

Analyzing the experience from the area of electronic commerce in developed market economies, the support would be significant in the following fields [15]:

- The level of information on electronic services should be increased by educational activities, as well as the awareness of their potentials;
- Digital gap on the relation north – other regions, village – town, younger – older population should be reduced;
- Implementation of measures aimed at further cutting the prices of access to new technologies should be continued.

Also, in companies there is no ambition to separate the effects of traditional from effects of electronic types of communication and carrying out transactions, which leads to conclusion that there is no serious consideration of the role of ICT.

In all analyzed companies some mutual problems have been noticed:

- It frequently happens that important decisions on transition from traditional to electronic business are made by managers without cooperation with other experts for organizational and technological changes;
- Very often, decisions are made based on the feelings, intuition, bad experience and by neglecting key facts on business;
- Decisions are made without researching the market of customers and their needs, with no knowledge of competition and its activities;
- There is no knowledge of electronic commerce technology usage phases, and the importance of transition from one phase into another. Therefore, often there is unnecessary long or permanent remaining in the existing phase;
- After decision on transferring into electronic market is made, it often happens that affairs of transition are entrusted to persons or institutions out of company, which as a consequence can have a lack of knowledge of business processes, business climate, culture, mission and vision of a specific company and the problems may arise;
- None of the filled questionnaires gave positive answer to question on possessing methodology or any internal activity by which metrics of the importance of application of ICT in business is done.

It is clear that successful usage of ICT implies the existence of suitable stimulating politics that will be based on strong scientific basis, appropriate human and financial resources and adequate technological and business infrastructure, which is not the case in Montenegro.

Positive developments in the area of electronic commerce technologies usage can happen only if:

- Traditional business procedures and programs are continuously adjusted to new instruments of digital environment;

- Competence of all staff and management is adjusted to potentials of the Internet environment;
- Criteria for successful implementation of the Internet activities are defined;
- Requests of the clients are permanently observed and, in accordance with that, intuitive analyses are replaced by analyses based on micro segmentation;
- Benefits of existing "a large number of data" are used, and which can be gained by application of up to date instruments of marketing;
- The web offer is promoted amongst the clients;
- The experience of successful companies from developed market economies are used and bottlenecks in business practice of the Montenegrin banks are removed;
- The methodology for measuring the success of the usage of the Internet services is elaborated.

IV CONCLUSION

At this moment in Montenegro there is a need for better understanding of electronic commerce concept, its potentials and factors inhibiting its faster development. Also, there is no holistic approach of the analysis of the influence of the identified factors on adoption of ICT on national level, level of industry and level of organization.
There are many factors influencing slow adoption of ICT and consequently slow adoption of electronic commerce technology: a lack of technologies, insufficient usage of existing technologies, IT illiteracy, incomplete legal infrastructure, problems arising from economic potential of the country that belongs to a group of small and insufficiently developed economies etc.
Results of the analyzed data got from the companies on the side of offer show that the affirmation of electronic commerce can be achieved only by coordinated action aimed at solving the fundamental problems that can be divided into following groups:

- financial problems;
- organizational problems;
- technical problems;
- problems whose solving requires the assistance of the State;

On the other side, results of the analyzed data got from the individuals on the side of demand show that the growth of electronic commerce volume can be secured only when the following issues are solved:

- when a perceived digital gap is reduced;
- when the legal framework protecting the rights of customers in electronic environment is completed;
- when the purchasing power of customers is increased;
- when IT and telecommunications environment is promoted and programs of supports to the Internet users securing the system of information and education of participants in online transactions are designed

It would be illusory to expect that all perceived barriers would be removed in short time, but we think that identification of the problems can accelerate their resolving. If we consider the speed of solving these problems during last two decades, it could be concluded that the process of their removal or mitigation in Montenegro might last until the beginning of the second half of this century.

***Summary:** Network industries are very important in today's economy. The reason for this lies in the fact that in each network operates certain external or extra power so-called network effect. Bearing in mind that the laws are set for the value of the network, but not for the value of the users, this paper analyzes the possible functional value of the network and network users to another network.*

***Keywords:** network industries, fixed telephone network, the network effect, the value of the user.*

I. INTRODUCTION

Network industries play a vital role in the life and economy of modern society. Modern economy would be greatly impoverished without transportation, communications, information and network of roads and railways. This paper will analyze the specific features related to the networks and users. Yet the attention will be focused on the telecommunications network.

Specifically, each network has its own value (word "value" here means a functional value). Discovering the links between this value and the parameters of the network is for many years subject of scientific and expert analysis. It was found that the increase in the value of the network is a function of the number of its members or nodes. Furthermore it is logical that the increase in the value of the network is different for different networks. It is expected that one law is applied for a broadcast network, such as TV broadcasting, while for networks in which users communicate with each other it is faster than linear when number of nodes or members increases. But what is the speed of increase or what is the actual relation between the number of members and the value of the network has maybe finally been revealed. The importance of this relation is basis for making business models in development of network.

Let us remember the famous sentence: "Companies that leverage the power of networks will dominate the Internet in the future" - pronounced by Sean Parker, President of the Facebook. This brings us to the question of whether the network has something special or so-called "*power of the network*", what other business platforms don't have, and it brings us to to the next question: what is the real *power of the network* - or so-called *network effect*?

II. TYPES OF NETWORK EFFECTS

The best is to start from its definition: the network effect (also known as network externality) exists when the functional value of the product for the user increases and when the number of users of a given product grows. A classic example for this is the telephone. The more people own a telephone the functional value of telephone network for each of its owners is more valid.

When you buy a DVD player and a few DVDs, it encourages the industry to more DVDs marketed. In fact, the concept can be easily extended: perhaps the most dominant network effect exists in the language. If you are writing a website in a language of a small, fictional nation Kynuk, only few people (its members) can read it. If your targeted audience is in this community, that's fine. But if you want to increase attention, you'll probably write in English: scientific journals, for example, are now predominantly in English, especially because the Internet network has increased the network effect.

Network effects are fundamental to business strategies, intellectual property and technical applications in a wide range of industries [1], [2], [3], [4]. The main objective of any company is to immediately establish action network effects in its operations in the appearance on the market. The main issue, which is considered here, is how really is powerful network effect, namely how network effect influences quantitatively on functional network value for the user, and functional value of the user for the network owner maybe finally found [6], [7], [8], [9], [10], [11]?

Direct network effect: the simplest network effects are direct: an increase in the use of the product will lead to a direct increase in its functional value. The original example of telephone service is a good illustration of the product that shows the direct network effects.

Indirect network effects: network effects may be indirect, where an increase in the use of the product causes the production of more valuable complementary assets, resulting in an increase in the value of the original product. For example, although there are some direct network effects associated with Windows OS (arising from files' compatibility), probably more important network effects arising indirectly from an increase in the quality and availability of complementary software applications.

Two-sided network effects: network effects can be two-sided; increase in the use by one set of users, increases the value of complementary products for another different set of users, and vice versa.

Network effects occur in the platform mediated network - PMN, which includes networks of customers - often known as users - who want to communicate with each other, together with one or more intermediaries providing a platform, which includes infrastructure and rules to facilitate the mutual interactions of users. PMNs form the heart of computers, telecommunications, media and Internet sectors.

However, PMNs are not limited to the information and communication industry. They can be found in financial services (e.g., stock exchanges, credit cards, ATMs), health care, energy (e.g., connection to the electrical network), transportation (e.g. air transport, container transportation, gas stations) and retail (e.g., shopping centers, barcodes). There is a diverse range of appropriate business where network transactions mediate, including transportation, auctions and travel agencies.

Rank by market value, sixty out of the 100 world largest companies, which earn more than 50% of its revenue from online network - mediated platforms, include Apple, American Express, Cisco, Citigroup, Time Warner, UPS and Vodafone. In short, network-mediated platforms (PMN) are the essential characteristics of a modern economy.

Many beginners in the market entry aim either to build these new platforms (e.g. Facebook) or to profit by offering updated leverage of existing platforms (e.g. Zynga, which relies on Facebook as host of its game). Business models based on such a platform can be extremely complex, and the errors in their designs are often common.

III. LAWS OF FUNCTIONAL NETWORKS' VALUE

Each network has its own value. Discovering the link between that value and the network parameters has been, for many years, the subject of analysis, mainly in the American scientific community. It was found that the increase in the network value is a function of the number of its members or hosts. Furthermore, it is logical that the increase in the network value is different for different networks. It is expected that one law applies for a broadcast network such as a television, while for the networks in which users communicate with each other it is faster than linear when the number of participants increases.

But what is the speed of increase or what is the actual relation between the number of members and the network value is maybe finally established. The importance of this relation is the basis for making business models in the development and operation of the network. The fact is that the telecommunications network has never been isolated (at least not in the last 20 years), but has been connected with other networks through interconnections. It is expected that such a procedure increases the value of both networks but also is realized profit for the users of these networks [9], [12].

The network value is explained in Metcalfe's Law and in the Law presented by Bob Briscoe, Andrew Odlyzko, and Benjamin Tilly in their paper of 2006 [9], further referred to as Odlyzko's Law. Hereinafter we will try to provide answers to some questions about the value of the networks for users and users' value for the network owners.

IV. FRAMEWORKS FOR NETWORK EFFECTS AND THEIR VALUES

During the last 25 years, in the United States, an extensive academic attention has been dedicated to calculating the gains and benefits of connectivity in networks, which resulted in simple "laws" designed to capture the distributive effects of membership in the network, or "network effects" (Metcalfe's Law, Reed's Law, etc.) (Table I) [6], [7], [8], [9], [10], [11]. Currently proposed laws on network values, their inventors and chronology of proposals are listed in Table I.

All proposed "laws" show monotonous increase of network value, with the growth of the volume or the number of network members from linear (the slowest) to factorial (the fastest), but the Laws of Sarnoff, Metcalfe and Odlyzko are best-known ones. Like all such "laws", they are based on the application of simplification and assumptions. Key aspects of leading network models are identified and compared in Table I. [8].

Metcalfe's Law has been known for more than a decade, when it is was named as such by George Gilder in early 90's. According to Metcalfe's remembrance his intention was: "The original purpose of my law was to establish the existence of the price value of the critical coupling point - under which networks mutually do not pay to each other."

Metcalfe had an ideal opportunity for observation and analysis of the growth of networks and their profitability. In 1970, the first in his Harvard Ph.D. thesis, and then at the legendary Xerox Palo Alto Research Center, Metcalfe developed Ethernet protocol, which has managed to become dominant in the telecommunications networks.

The basis of Metcalfe's Law is the observation that in the communications network with n members, each member can make a connection with (*n-1*) other members. If all these connections are equally valuable - and there is a big "if", the total value of a network is proportional to $n^*(n-1)$, which is approximately n^2, for large *n*. So, for example, if the network has 5 members (Fig. 1), there are 20 different possible

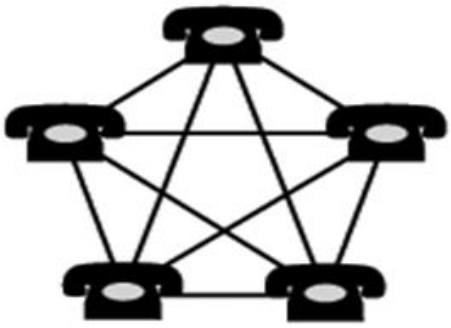

Fig.1. Illustration of a network with a network effect (the number of connections increase as the number of the network members increases).

connections that a member can make with the other one. If the network size increases four times, to 20, the number of connections increases not only four times, to 80, but increases to 380 - or in other words it is approximately eighteen times increase. This approach has helped the growth of dot-com companies, but also their collapse at the end of the last millennium in the United States, because, after all, this type of law was not appropriate, and used business models were mainly based on it.

Reed, on the other hand, introduced a law that recognized the value of the group within the network, not just couples, so certain group of four people can be connected not only to form pairs, but also in groups of three or even superset of all four persons. Adding 4 groups of 3, plus the entire group of four, all together as $2^n - n - 1$ and it is approximately proportional to a 2^n. This law is too optimistic and has no real stronghold in the telecom network, which mainly has communication between two members, but it partly has a stronghold in social networks, such as Facebook.

Briscoe, Odlyzko and Tilly [9] in their paper pointed out that presented network laws are probably too optimistic in their values, and it can be intuitively recognized that the growth rate of the network value must be reduced as future members join - because probably the most valuable connections have been formed first. This is parallel to the concept of "diminishing returns", the central position of neo-classical economics. Such a reduction in incremental values is modeled as total $n*log\ (n)$, (where the logarithm has base 2) where future membership reduces the growth rate values (but still ensures positive growth). This frame also coincided with visible power law in real-world of networks, which was highlighted by Barabasi and colleagues [5].

There is a big "but", because each member of the network establishes connection only with a relatively small number of members who are close to him and with whom he has a certain social relations, although there is the possibility of establishing a connection with each of the members of the network. Therefore it can be concluded that the value of the network is not proportional to the ability to establish a connection, but to established connections, or to be more precise, to the traffic realized when establishing connections. In fact, we all have definite directory in our phone, consisting of several hundred members, where some of them we call very rarely while some other close family members very often, and we belong to a network of over one million members.

Therefore, the paper [9] has proposed a new form of law on numerical value of network effects in telephony, in the form that the value of a network is proportional to $n*log_2(n)$ and it is much softer in the increase and it provides a new view on the issue of interconnections as analyzed in [12]. Fig.2. graphically illustrates increase in the network value in accordance with the laws listed in Table I. The paper [12] has shown that this law reflects well changes in the value of networks during their interconnection.

V. THE VALUE OF THE NETWORK FOR THE USER AND THE VALUE OF THE USER FOR THE NETWORK OWNER

There is a question: if the product or network is more valuable for the user when it is also used by others, should he pay accordingly? When it comes to material product, there is lot of such situations where one pays name/brand. When it comes to communications, then there is dealing with services. In the telecommunications network, there are different services and different payment models for using the services. Payment models can be compared with the parameter of functional network value and it can be seen whether models include the application of the network effect. As seen, in principle, there are two realistic models of the network value law: linear (Sarnoff) and logarithmic (Odlyzko) law.

Telecom operator can, in different ways and unconsciously, use the power of the network by application of some of network value laws in its business models of service provision. The most common model is the first service model, developed as broadcasting with TV and radio, and it applies linear law of network value. Therefore, the value of each member of the network is mutually equal and constant and it does not depend on the number of network members.

Total value (proportion. with)	***Hron-ology***	***Inventor***	***Model***	***Example***
n	1	Sarnoff	Broadcast	TV, Radio
$n*log(n)$	5	Odlyzko	Practical Metcalfe	Telephony
n^2	2	Metcalfe	Network	Telephony
n^c	6	Nivi	Practical Reed	Google, Facebook groups
2^n	3	Reed	Social networks	Google, Facebook groups
$n!$	4	Haque	?	?

TABLE I. THE PROPOSED NETWORK VALUE LAWS [8]

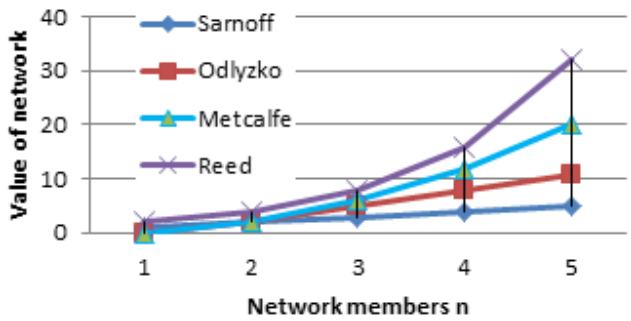

Fig.2. The increase in the value of the network

Historically, following service model that was developed and offered to the market is the voice service in fixed telephony. Such service completely follows a logarithmic (Odlyzko) model of the network value. In this case, the value of the network and each user increases as the number of connected users to the network increases.

In all business models where the principle of a flat rate charging (ADSL or other Internet access) is introduced, operates linear law of the network value. In the ADSL example, users have certain mean value of K_p and proportional to that value they pay to the owner of the network (you can put that monetary proportionality constant is 1 for easier calculation). In the network dominated by linear law of value of network connectivity, "content is king." In fact, in such networks, there are fewer sources of content that each user chooses from the available sources. There is a competition for customers based on the source of their content, i.e. based on the value of their content (published stories, published pictures, standardized consumer goods).

Where Odlyzko's Law dominates, the number of established connections, respectively transactions, becomes a central point. In cases where it is traded with transactions (either via e-mail, text mail or voice mail, money, securities, contracted services, or else) the transactions are key. It can be reasonably assumed that the average number of connections established by the user - member of the network is proportional to the logarithm of the total number of network members, proportional to a constant K_1 (Odlyzko's Law). It is evident that the value of member to the network increases as the number of members in the network increases. Direct examples include the provision of telephony and messaging services. From this it can be seen that the value of a network member increases by connecting new member to network, and it is clear that there is a network effect precisely operating in accordance with its definition.

However, in many cases with no lower limit of network user's payment to the owner, which is the case of telephony and all other services with Odlyzko's Law, network owners introduce a minimal fee for membership in the network, so - called subscription - K_{P1}. In such cases the value of the network member and the appropriate business model are determined by cumulative action of linear and logarithmic laws of the network value, with appropriate constant. From a business perspective, this is very favorable situation for the network owner. Table II. summarizes some typical cases of value related to the network and users and appropriate example of the telecommunications services.

Table II. shows:

- Column 1: the value of the network for the member;
- Column 2: the total value of the network;
- Column 3: the value of the member of the network;
- Column 4: the value of the network member in the business model of service; and
- Column 5: an appropriate example of the telecommunications services.

In principle, business models involving logarithmic law are economically better than linear, and the best business models are these where both laws operate simultaneously. It is evident that lately, operators in mobile communications use business models without subscriptions, which significantly reduces the value of a member itself, and then the overall economic effects of the network as well.

TABLE II. THE VALUES RELATED TO THE NETWORKS AND USERS

Value of the networks for members	***The total value of the network***	***The value of the networks member***	***The value of the networks member in the business model of service***	***Appropriate example***
Kp	$n*Kp$	K_p	$n*K_p$	ADSL Internet access, IPTV
$K_1*log(n)$	$n*K_1*log(n)$	$K_{p1}+K_1*log(n)$	$n*[K_{p1}+K_1*log(n)]$	Fixed telephony, VoIP, Postpaid mobile telephony
$K_2*log(n)$	$n*K_2*log(n)$	$K_2*log(n)$	$n*K_2*log(n)$	Prepaid and postpaid mobile telephony

With web access to the content on the Internet, network effects are actually closed-loops generating increasing feedback, the higher the number of users is. In the case of web, feedback results in more content and more possibilities for their users. Current Web 2.0 technology exactly allows such feedbacks, by allowing users to be editors, namely to place their own content on the Web. Such ideas has also started to follow business activities which aim to bring together its users in the business communities that share certain interest and create bigger value when having more members.

Regardless of the law used to describe the network effect, conclusion remains the same - all Web applications or services used daily by lot of people, allowing only passive usage for users, without any other value except just service or application (example of website that can only be browsed), lose a large part of the value, they could have if correctly use the network effects, for example, by allowing users' communications, or allowing users to change the very application or service. An example of such a service is Facebook, Digg or YouTube that not only attract an enormous amount of visitors every day, but also use a visitors as (the only) source of the content.

The question is how this phenomenon will affect further development of the telecommunications, the Internet and the Web in general, as well as business companies from this sector, but the fact remains that these who ignore it will have negative effects on their business.

VI. CONCLUSION

Modern economy would be very impoverished without transportation, communications, information and network of roads and railways. All these systems are based on a network-mediated platform. PMN can be found in financial services, health care, energy, transportation and retail.

Specifically, each network has its own functional value. This paper analyzed specific characteristics related to the telecommunications networks and users. In the analysis was used a new mathematical formulation of the network effect.

The development of the telecommunications operators is supported by strong externalities - network effect, which is more or less successfully implemented in their business models of individual services. In the telecommunications network, there are different services and different payment models for using the services. As seen, in principle, there are two realistic models of the network value law: linear (Sarnoff) and a new mathematical formulation of the network effect in the form of logarithmic or Odlyzko`s Law.

The business value of a network member is defined by various network value laws, only linear, only logarithmic, and in some business models both linear and logarithmic (best cases). In the case when a logarithmic network value law is applied in a network, presence of network effects is obvious.

It is expected that the content will get even more importance in the future. That is why more attention must be paid to the content and its creating, so own users should be involved in content creation, which is fully supported by existing Web 2.0 technology, and what in return, introduces activity of the network effect.

All Web applications or services used daily by lot of people, allowing only passive usage, without any other value than just service or application, lose a large part of the possible value they could have if correctly use the network effects, for example, by allowing communication among users or allowing users to change the application or service.

Open issues of open data in Croatia

Dalibor Bužić, Jurica Đurić
Visoka škola za informacijske tehnologije, Klaićeva 7, Zagreb, Croatia
dalibor.buzic@vsite.hr, jurica.duric@vsite.hr

Optimism and euphoria about open government data as a silver bullet which should lead economy and society to significantly higher levels have deflated after few years in collision with a reality. Expectations from open data usage were great, but in exploitation it is more than questionable at which rate open data generate new economic values. Many issues appear on both sides – government as a supplier and on demand side which lags behind the supply. In this paper we analyze and comment open data published by some of the public authority bodies in Croatia and we present an overview of mobile application based on those data.

I. INTRODUCTION

Governments all over the world generate large amounts of data. Movement for free access to government data is based on the fact those data are collected and processed by taxpayers' money. The goal of free access to data is enabling citizens, companies, media and academic community to use those data for economic and social progress. Published data should be in genuine form (without aggregation), up-to-date, ready for easy machine processing, available to everyone and license-free.

Open data promoters claim that the useful value of open government data can be created by citizens, associations, companies, academic community, and government itself. Citizens can find their interest in information which helps while making decisions such as choosing city for living with regard to air pollution or climate elements (areas with high average humidity, for instance) or choosing schools for children (based on the number of children per one teacher or a success in the later stages of education) and so on. Non-government associations can improve status of vulnerable civil groups. Academic community can conduct new researches. Companies can create new services and products based on open data. At the end, whole state can have benefits – new employments in the private sector, tax incomes, raise of the economy, and one entirely different spectrum of benefits such as increasing transparency or involving citizens in activities of wider social interest.

Economic gain of open government data usage one European commission study estimates on about 40 billion euros per year in the EU [1]. But this business activity domain is relatively new, and there is a lack of knowledge about potential economic effects of usage and creating new products and services based on open data. Some of the greatest challenges for existing and new companies interested in creating new values from open data are which precisely new products and services should they make, and how to make it lucrative. Applications related to meteorological data (such as temperature, humidity, wind speed and direction, UV index) and to traffic data (such as railway timetables, delays, road works and traffic jams) are well accepted by a wide range of users. Statistic data processed and presented in an attractive way (ecpecially graphics) can be a good opportunity. Information can be related to pupils' success in classes and competitions, water and air quality, police crime maps or government management (expenses share by type, supplier list, miscellaneous comparisons of cities or municipalities).

II. OPEN ISSUES

Optimism and euphoria about open government data as a silver bullet which will raise the economy and society on a significantly higher level had been deflated a few years after colliding with a reality. Web site data.gov, central place for publishing open US government data, was established in May 2009. when USA (and many other countries worldwide) experienced big crisis. Expectations from open data were large, but in practice it is very questionable at which rate open data generate new economic values.

The gap between promises and barriers are formulated in five myths [2]:

- publishing data will automatically yield benefits,
- all information should be published without any restriction,
- it is enough to publish data,
- everyone can make use of open data,
- open data will result to open government.

A. Supply-side issues

Issues arise at a very first part of the value chain: government. Bad design, flawed execution and adverse consequences are three main problem areas [3]. Bad design manifests in the initial uncertainty of a concept (what do open data really mean?), unrealistic goal of absolute transparency and focus on a technology as a transparency indicator.

Flawed execution reflects in three elements: resistance in agencies, data decontextualization and expense side. Resistance appeared, among other reasons, because of unrewarding extra work in preparation of data for publishing, but also because trading data were the significant income source. The question to be answered can be, for instance, what consequences brings public access to Croatian Meteorological and hydrological service (local acronym: DHMZ) which makes earnings from selling collected data? Decreasing income can lead to cutting down investment in equipment and decreased experts' salaries. That could result in negative employee

selection and, finally, in poorer service. DHMZ's income can be compensated from government budgets, but in that case, all taxpayers suffer that load. The serious question is then: who has benefits from free data? Right now some of DHMZ's data purchasers are largest media, telecom and insurance companies. On the other side, research about opening hydrometeorologic data in Netherland revealed that at the time when data has been sold, there were ten purchasers which brought income of four million euros. After data opening, number of users has increased, and government's tax revenue was about 30 million euros, which is 750% more [4]. In any case, cost-benefit analysis should be done before opening data which generate income to government agencies.

Decontextualization is the process of converting useful complete records into useless datasets by separating data from context. Agencies in the USA, just to fulfill the 'norm', often repacked data already published somewhere else. Data were sometimes without description, and in some cases even could not be opened.

Expenses side, as the third aspect of flawed execution, is conscious or unintentional ignoring of opening data costs. Some of the costs are related to adjusting data to new standards, employee training, improving the quality of data, but also hand-written and verbal data converting into digital records. Those expenses simply were not planned in agencies' budgets.

Among adverse consequences [3] emphasizes the fact that the open data programme did not decrease the information divide between developed and developing countries. Causes are in fact that developed countries have good mechanisms for data collecting and experts who use them. Undeveloped countries haven't enough such experts, and data are often of low quality or incomplete. In such countries citizens rarely participate in efforts about using of open data. It is a consequence of lack of knowledge and motivation. Of course, some kind of solidarity toward 'weaker' societies should not be obstacle in development.

Open data empower already powerful corporations and software companies who posses funds and skills for data usage. In other words, rich corporations (such as Lloyds of London, Google, Daily Mail, etc.) are subsidized by open data. It is almost absurd that sometimes government agencies buy its own data, but also there is a danger of corporative monopolization which could shape urban infrastructure guided by interests of profit [5].

Government bodies sometimes don't focus on processes outside their boundaries. That is why the process of opening data they don't see as interaction of government and public. While politicians are focused on stories about economic growth and citizen participation, officials are concerned about issues such as privacy, confidence, quality and data completeness.

Securing personal data privacy is a very sensitive issue. A fact is that most of open data (such as geo or budget data) are unrelated to people. But, personal data from which are deleted names, surnames and other identifiers don't guarantee absolute secrecy. Using only data about sex, date of birth and city in the USA, 53% of the population can be uniquely identified [6].

B. Demand-side issues

The issues are present also on demand side which lags after supply side. Part of causes lies in published data itself. Government agencies often under pression of data opening have taken passive-aggressive attitude by publishing minimal quantity of almost useless data. At first developers chose interesting data for new applications, but interest fell off quickly. Developers from New Zealand even refused to develop applications with useless data [7]. The second part of causes lies in lack of knowledge how to use those data which are pretty useless, until someone transforms it into something valuable. Lack of technical and statistical knowledge are serious barriers for exploiting potentials. Unknowing tools for effective open data processing is one more obstacle. That is why need for education in fields of statistics has appeared. It is necessary for avoiding erroneous analysis and results misinterpretations. Great Britain's Office for National Statistics, in cooperation with Durham University, trains interested journalists and politicians for using tools which enable data synthesizing from various sources, multivariate data interpretation, and so on.

Process of visualization, as a very important aspect of open data usage, demands special applications which should be easy to use, enable saving intermediate states of processing (due to repeatability), visual display of differences.

Even finding published datasets can be an issue. In New Zealand it is common that every agency publishes datasets on its own website. Since websites differ in design, finding data can be challenging [8].

III. TOWARDS OVERCOMING OF ISSUES

With a goal of relieved use and alleviation of some topical issues, dedicated infrastructure to work with open data are being developed. One of them is ENGAGE e-infrastructure. ENGAGE is based on literature, interviews, questionnaires and workshops, and is developed by Design Science Research methodology (DSRM). ENGAGE supports supply and usage of open data in five categories [9]:

- data provision – except data, it enables metadata acception, data cleansing, validation, conversion into other formats and metadata enhancement,
- searching and using data – uses SQL and SPARQL, has module for data demands and version management,
- linking data – manual and automated,
- user ratings – assessment system and quality control,
- user collaboration – user profiles, three user roles: supplier, consumer and coworker.

It is hard to understand how open data are used without previous understanding who are the users of open data and which are their motivations. Research conducted in Great Britain identified six motivation groups [10]: one has the government into focus, the second has focus on technology and innovation, third is focused on making a

profit, fourth deems that government digitalization will have reform of government as a consequence, the fifth represents users to whom open data will be a tool for achieving predefined goals, while the last group consists of entrepreneurs who cooperate with government.

Researchers in [11] identified six types of companies who are primarily oriented to:

- collecting and aggregating data,
- analytics as a service,
- creating data and analysis,
- knowledge discovering,
- data aggregation as a service,
- mult-source mash-up and analysis.

The main goal of a company is gaining a profit, which basically means making larger incomes relative to expenses. Web and mobile applications, as well as various services generate expenses in development phase, but also later on – during operation and changes. So, it is not only a matter of thinking about resources, what to offer, how to create it and who are the users. A company must think about profit side, i.e. how to charge a service. Income model exposed in [12] differentiates five main ways to generate an income:

- subscription model – recommended for frequently used service, but suitable for specialized or (semi) monopolistic information (such as geo maps in large scale) because internet users unwillingly pay online services,
- usage model - means service charge measured in bytes, time or session; suitable for ad hoc users who need access to services (possession is not important to them),
- royalty model – customer will pay a price (in the form of percentage or royalty) only after he creates and sells his product with added value
- free model – suitable especially for government services or products
- hybrid model – such as enticement model in which part of the content is free and the other part is to be charged, or community model (like Wikipedia or OpenStreetMap) where income is generated by subsidiary products/services or by donations.

Besides above-mentioned, income model that can be applied on mobile applications is one-time charge on download. Price admissibility combined with usefulness can generate significant income if application becomes popular. Mobile applications can find one exclusive buyer who will, by further free of charge distribution, create a new marketing channel. Web sites which offer free information generated by open data and have a large number of visitors can attract sponsors or advertisers and ensure income. Start-up companies or individuals can attract partners and find their place on the market. Therefore, the application itself doesn't create benefit, but enables easier finding jobs in the future.

IV. OPEN DATA IN CROATIA

Based on surveys, the Open Data Census has created Open Data Index for more than 100 countries worldwide. Table 1. shows ranking of Croatia and its neighbours according to mentioned index [13]. As we can see, of all Croatia's neighbours, only Bosnia and Herzegovina has poorer standing (no data exist for Monte Negro).

Table 1. OPEN DATA INDEX RANKINGS

Position	Country	Score
26.	Italy	545
28.	Slovenia	540
39.	Hungary	475
49.	Serbia	420
52.	Croatia	405
94.	Bosnia and Herzegovina	205
---	Monte Negro	no data

Information Commissioner (IC), as an independent government body for protection of the right of access to information, highlights following issues of open data in Croatia [14]:

- ignoring requests for information (2/3 of the complaints were about the silence of public authority bodies),
- tardiness of public authority bodies,
- information officers' lack of professionalism,
- overcharging of providing information (when actual material expenses incurred),
- insufficient proactive data publishing,
- low citizens' awareness about the right of access to information,
- uncoordinated regulations (about data privacy, trade secret etc.).

IC has a very important role in resolving complaints related to the right of access to information reuse. It also supervises the implementation of the Law on the right to access information. IC can submit an indictment proposal and can issue a misdemeanour order. At this moment, IC office is underfunded and understaffed. That fact negatively impacts on significant progress in realization of the right of access to information and information reuse.

At the time of finishing this paper (in mid-February) we are waiting for launching data.gov.hr portal (we can expect it in a few weeks, according to announcements). The portal is being developed by use of open source code of British data.gov.uk available at GitHub. It uses CKAN platform for data publishing. At the beginning, about 70 datasets will be published. Like in the USA or Great Britain, the intention is data.gov.hr would be the central portal for publishing open data, so all government bodies and agencies, every city and municipality will be able to put data in one place. This concept has advantages for

both publishers (no need for investment in infrastructure) and users (easier finding datasets). On Croatian open data portal there will be a request form for asking new (unpublished) datasets. The intention is to listen to datasets users' needs to avoid efforts about publishing datasets which will not be used.

Before presenting our findings it is important to emphasize that we analyzed only some publishers – so the list of datasets is not comprehensive. Municipalities and counties were not in our focus at all.

In the current situation, we found that some government bodies have a clear understanding of the need for open data. One of them is Ministry of administration which on its website https://uprava.gov.hr/ clearly states the terms of use for their 12 datasets published in CSV format. The Croatian public health institute publishes lot's of reports and publications in PDF format, and eight XLS datasets at http://www.hzjz.hr. The Croatian health insurance fund published more than 40 datasets in XLS format available at http://www.hzzo.hr/. Ministry of economy has recently developed web site for fuel prices tracking (http://www.min-go.hr) which helps citizens to find a cheaper gas station. It is expected that raw data will be available in acceptable formats for interested parties soon.

Geoportal is a service which is available for citizens recently. With it, we can see in every moment and examine everything related to cadastral and land registry business. Also via additional links, users can view documents such as proprietary and title deed, and view the history of documents.

Croatian bureau of statistics at http://www.dzs.hr/ provides national statistics about a large set of various data on a national level. They offer users to download and use their program for viewing and formatting datasets and downloading datasets directly from the website in the format they want.

Another site that offers open data to the public is Croatian waters. Croatian waters on their pages http://vodostaji.voda.hr/ offer information that is updated every hour. All data are complemented with graphical icons so it is very easily to notice water levels that are higher than normal limits.

Easy access to their data, gives Meteorological and hydrological institute of Croatia (DHMZ). On their site http://meteo.hr there are current weather data for a lot of cities in Croatia and Europe. Beside all the weather data that can be retrieved, data on water levels of rivers as well as information about the index danger of forest fires is also available. What DHMZ explicitly offers is dataset in XML format containing data about temperature, humidity, pressure, wind and condition for many Croatian cities.

The Croatian environment agency offers lots of data contained in Environment Information System at http://iszo.azo.hr/.

Croatian Automobile Club at http://www.hak.hr/ provides access to information about road conditions as well as other various services related to road trip with possibility of refreshing rate so it can be said that the data is updated in real time. There is also a map that offers a view of all information that are essential together with an estimate of travel time, toll rates, the list of restaurants, resorts, hotels and cameras that are installed on highways.

The HAK mobile application offers a very transparent access to all data that are essential for the journey. In addition to what has already been stated, that is available on the website, mobile application offers finding the car if it is parked in a place which is not known to the owner. It also provides reference assistance both on the road and at sea by giving the exact location of which can help in case of a damage or accident with the vehicle.

Croatian Railways at http://www.hzpp.hr/voznired provides monitoring service trains in real time. All data can be found on their website and is very easy to find the data that are important for the train journey. The HZnet mobile application provides more readable and easier information about trains in Croatia.

Jadrolinija provides sailing schedule for Croatian ferries across the Adriatic Sea at http://www.jadrolinija.hr/. The data is in pdf document so if developers want to use that information, they must convert this data in more accessible format.

Most Croatian bus carriers provide their timetables on their websites. Some of that data is on website as image so they can't be reused. Some of data is in PDF document so it can be reused but it requires reformatting.

Mobile application provides information about domestic and international intercity bus schedule of Croatian bus carriers. We can find departures from each bus terminal in Croatia and phone numbers, locations and other contact information of bus terminals and carriers.

Croatia Airlines provides on its website (http://www.croatiaairlines.com/) all information about timetable and flight statuses of planes. There is also a mobile application that mobile users can use for getting information and checking their flights.

All post codes and post offices can be found on the Croatian Post website http://posta.hr/. Mobile application of Croatian Post also provides information about post codes and all post offices in Croatia. Users can use their GPS to locate the nearest post office, which is very usable if user doesn't know the area.

All major cities in Croatia provide their city budget open to the public. Most of that data is in PDF or Word document so it is easy to read for the user, but for other purpose, users need to reformat data. All data are in low level of transparency because they show only a rough picture of real costs for some activities and for every kind of deeper data you need to contact city office to give you that data.

City of Zagreb at http://data.zagreb.hr/ has published 12 datasets. Five of them are related to (un)employment statistics. Two datasets are published in XLS(X) formats, while others are available in preferred non-proprietary CSV format.

Part of research about open government data mobile applications was also challenging. First few applications

we found on webpages of datasets publishers. Then we concentrated on Google Play app store because it has good search engine, some data of our interest (number of downloads, average rating) and last, but not least important, according to [15], Android operating system is present in 69,5% mobile devices in Croatia. Since there is no „open data“ category of applications, we searched terms like Croatia, names of Croatian cities, weather, travel, timetable, budget, health, ecology and many other terms in Croatian language (sometimes also in English). When we found application of interest, we also searched for other applications of same developer. Sometimes we found applications in „Similar“ category. When we exhausted search in play store, we used web search engines and we searched on few Croatian web portals. We stopped when we found 50 apps, because after about 40 apps found, every new was hard and time consuming to find. So we are aware the application list is not final, but it gave us some interesting findings.

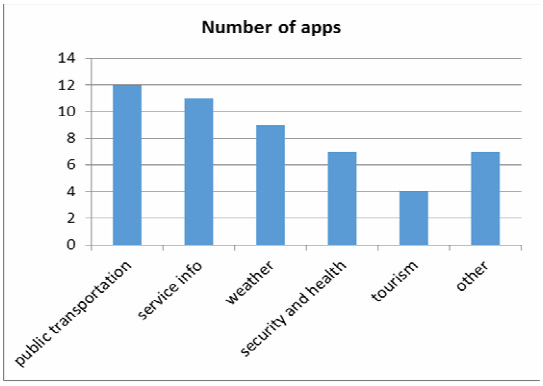

Figure 1. Number of apps per category

Figure 1 shows the number of applications within certain categories. Most of the apps are related to public transportation (bus and train timetables, delays, taxi and tram), various service information (holidays, post numbers and offices, road traffic, ATM machines etc.), weather, and security and health (emergency services, pollen forecasts, bike security, etc.). Our research didn't include classic tourist city guides, so number of tourist applications is quite low. All other apps are related to finance, ecology, city public services and social themes.

Table 2. Downloads and ratings of applications

Number of downloads range	Number of applications	Average grade
<100	4	4,0
100 – 500	7	3,9
500 – 1.000	2	4,6
1.000 – 5.000	9	4,0
5.000 – 10.000	8	4,1
10.000 – 50.000	16	4,1
>50.000	4	4,2

Table 2 shows that one third of apps are downloaded between 10.000 and 50.000, while only four are downloaded more than 50.000. Two of them are related to weather, one to road traffic and one to, interestingly, finding information about car (type, producer, insurance details etc.) based on registration plates. Only app about earthquakes didn't get any grade, but it is probably because it has been downloaded less than 50 times.

Only one app is not free of charge (it is related to Croatian marines), while all others are free to download. It is hard to say would it be different if Google allowed Croatian developers to sell their apps on Google Play. At this moment, Croatian developers can freely distribute apps, but if they want to sell, they have to open company in one of the countries which are acceptable to Google.

Fourteen apps were developed by individual users, and other by companies and institutions. Almost every app is in Croatian language, many of them are in English (and Croatian), and only a few are in Italian or German language.

V. CONCLUSION

Open data didn't empower economy as it was expected. Publishers of open data meet many issues such as unrealistic goals, expenses, decontextualization and lack of knowledge about what data is interesting to publish. Developers still have to learn how to use this data to create applications that are recognized and wanted in the market. They have to find an income model if they want to succeed. Developing mobile applications is not the only possible activity with open data; there are others – such as analysis creation, knowledge discovery, multi source mash-ups and so on.

Croatian IT specialists are still in a lack of valuable open government datasets, clear licenses and data formats. Despite that, they are quite active. They fight against hard-to-use formats, captchas, misunderstanding, and impossibility to charge app downloads on most popular app store. Portal data.gov.hr will make easier access to open data. About 70 datasets provided on portal maybe doesn't seem as a lot, but the quality (or better to say: usability) is more important than quantity. Developers should ask for opening other interesting data with understanding that publishers cannot always know needs for data in advance and also that publishers sometimes have rational constraints not to open every asked dataset.

Nowadays, most of the companies use cloud tools. Well-known services, such as Gmail, Google Docs and Dropbox are used every day. Salesforce is commonly used in companies' business routine. Through social networks (Facebook, LinkedIn, Twitter), significant part of personal and business data is collected and saved in the cloud. So, all these services and their data are easily accessible and available for different purposes.

On the other hand, users have to give up their privacy and control. Anyone with moderate analytical skills can research, profile and use all published data for their own gain and interest (advertising, sales, different analysis, etc.).

Nothing excites managers and marketers more than the massive application of cloud services and infinite flow of fresh information about consumers, which is then used to improve their products and services. In this paper we present process improvements in marketing automation, lead tracking, and inbound marketing as a result of cloud services.

No matter which cloud supported services are used, they are less time and money consuming and easier to access and manage. They are accepted by more users than traditional desktop tools. In the future, processes could be even more automated which could put businesses on autopilot. This might be the Holy Grail everyone is seeking.

I. INTRODUCTION

The theme of this paper is application of cloud services in business, especially in marketing. Our aim is to present how certain marketing concepts were not even plausible without cloud services.

Firstly, we present advantages and disadvantages of cloud services. So, we address issues of privacy and safety and then we present a couple of great implications of cloud services in marketing. We want to remind readers of all negative issues of cloud services, as we feel that users often embrace new applications of cloud services without taking these safety and privacy questions into considerations. We present marketing cloud implementations, because we want to show the vast area of cloud implication in business, and significant improvements it brought. We think that more and more services will migrate to the cloud in the years to come.

Our hypothesis is: "Marketing landscape has changed since cloud services were invented."

We use methods of description and compilation of secondary data to research the hypothesis.

Before we go any further, we would like to shortly define certain terms and terminology concerning cloud computing.

"Cloud computing is a model for enabling ubiquitous, convenient, on-demand network access to a shared poll of configurable computing resources (e.g. networks, servers, storage, applications, and services) that can be rapidly provisioned and released with minimal management efforts or service provider interaction. This cloud model is composed of five essential characteristics: on-demand self-service, broad network access, resource pooling, rapid elasticity and measured service [4]."

In the simplest terms, *cloud computing* and *working in the cloud* refer to performing computer tasks using shared resources for services running in public, private or combined cloud.

According to the reference [5], cloud model is composed of four service models. These services are referred to as:

- *IaasS* (Infrastructure as a service – servers, networks, virtual machines),
- *SaaS* (Software as a service – virtual desktops, Email, CRM),
- *PaaS* (Platform as a service – databases, development tools) and
- *UCaaS* (Unified communication as a service – instant messaging, audio, web & video conferencing, desktop sharing).

The lines between different service models are not always clearly defined as there is no universally accepted distinction between lower-level and higher-level infrastructure.

According to reference [4] cloud model is composed of four deployment models:

- *Private cloud* is used by an organization for its completely internal use. So, it is built exclusively for an individual enterprise. Private cloud may be owned, managed, and operated by the organization, a third party, or some combination of them, and it may exist on or off premises.

- *Community cloud* is provisioned for use by a specific community. It may be owned, managed, and operated by one or more organizations, a third party, or some combination of them. It exists on the premises of the cloud provider.
- *Public cloud* is made available to the general public. Customers benefit from economies of scale because infrastructure costs are spread across all users.
- *Hybrid cloud* is composed of two or more distinct cloud infrastructures (public, community, or private).

When the cloud's service is being sold, that is *utility* or *on-demand computing*.

So, cloud computing is the sum of service model (SaaS, PaaS, IaaS, or UCaaS), deployment model (private, public, community, or hybrid) and utility computing.

II. ADVANTAGES OF CLOUD SERVICES

Broad application of cloud technology in our everyday life, especially in terms of business, is often related to instant access to the tools used by the millions for affordable service fees.

Developing great IT solutions takes extensive knowledge, financing, risk taking and time. It is not an easy task. However, everyone wants to consume IT without constructing it – and finally, with cloud services, it is possible!

Businesses that use cloud implementations, no longer need to invest large capital in hardware or human resources to build their services. They can even choose among different solutions from several certified cloud service developers. Companies of all shapes and sizes are rapidly adopting cloud technology, since it is cost efficient and the usage of cloud services presents minimal risk for business. Cloud services are usually developed in a way that they can be applicable in different companies regardless of their size, shape or industry. Therefore, development costs are distributed over many users, positively influencing the pricing policy. So, prices of cloud services are relatively low.

Another benefit of cloud services is device and location independence. Modern cloud systems are constructed of sophisticated server geo-clusters. So, a specific piece of information is stored on several cluster nodes worldwide and on-demand, it is transmitted to the user as soon as possible. This system offers greater level of service comparing to the traditional system architecture. Moreover, it is also pretty common that cloud services offer application programming interface (API), allowing users to expand the functionality of the service and tailor it to their needs. Most of solutions are Web-based and even older computers can be used to access cloud services.

Cloud computing facilitates easier collaboration, since distributed teams or combinations of mobile workers and in-office staff can all work together on shared information stored centrally in the cloud. From the employee point of view, cloud's greatest beneficiaries may be remote workers, as Web-based applications empower them to be truly mobile and still accomplish their work.

Key characteristics of cloud computing mentioned above are just a few of many advantages cloud computing offers.

III. DISADVANTAGES OF CLOUD SERVICES

Along with pretty great advantages, cloud services have disadvantages, as well.

The first shortcoming of cloud computing is the fact that an Internet connection is necessary to take full advantage of a cloud service. Therefore, when users are offline, or if there are some disruptions with the cloud service the data may not be accessible at all. So, if the service is disrupted or stopped, it can result in additional costs.

However, there are applications, such as Evernote (note-taking application), that offer a good in-between or hybrid solution, with both desktop or phone software, and an online service that synchronizes data to the cloud. So, there are applications (e.g. Gmail) that offer some basic offline functionality, as well.

Far more serious and not easily solvable issue with cloud computing is security – both from providers' and consumers' point of view.

The location data processes and storage determinates the security in terms of data safekeeping. Organizations have a full control over data only when the data is stored on their own physical computers and servers. On the other hand, when organizations have service and data in the cloud, then they are not fully aware of where their processes are running or where their data is stored, as they have no control over it. They have to trust cloud service providers to respect their privacy and follow the regulations. So, individuals and/or companies may not be comfortable storing their information, especially proprietary or sensitive data, on someone else's server on the Internet.

End users have to agree to the privacy policies before they start using cloud services – it is "take it or leave it" contract. So, if it is not encrypted, cloud services providers have access to all the data and they could accidentally or deliberately disclose it to third parties or use it for unauthorized purposes. Of course, this raises privacy and confidentiality concerns.

The social networks' privacy issue is one of the biggest, as some applications are explicitly centered on "cyberstalking".

For instance, when Facebook recently announced changes to its default privacy settings regarding user's content sharing with friends, it was also revealed that Facebook can access smartphone's microphone to capture and analyze songs, TV shows and other content users listen to. This sounds disturbing.

Google suffered a court ruling in Europe last year, forcing it to allow petitioners to be "forgotten" by its search engine.

Yahoo recently changed its policy, so that it can deny users the ability to request that their behavior is not tracked, and called it an improvement in "personalized experience".

It is crystal clear that the main goal of cloud service providers is profitability which depends on users' shared data and on users remaining unaware of the extent to which their privacy is exploited.

Most of cloud service providers' profit comes from businesses, that want to acquire as much data as possible about their customers, because it enables them to not only better recognize customers' needs, but to anticipate them, ideally before they have been consciously acknowledged by customers themselves.

These issues of trust, confidentiality and reliability are critical for cloud services to resolve before everyone truly moves to the cloud. Certain security assurance is provided through service level agreements (SLA) or other standardized agreements. However, cloud services need way more reliable assurances of encryption technologies, privacy protection and solutions for offline accessibility.

There are a couple of suggested solutions to privacy issues in cloud computing. These suggestions include policy and legislation, as well as end users' choice for how data is stored [5]. The cloud service providers need to establish clear and relevant policies that describe how the data of each cloud user will be accessed and used. Cloud service users should be able to encrypt their data when it is processed or stored within the cloud, as encryption is one of the solutions for preventing unauthorized data access [3].

IV. CLOUD APPLICATIONS

According to reference [1], public services linked with cloud computing grew from $9 billion to $40 billion over the last five years. This convergence is aggravated by the increased usage of e-Commerce, social media, smart phones and mobile commerce.

Reference [6] has divided all cloud computing business models into eight types: (1) service provider and service orientation, (2) support and services contracts, (3) in-house private clouds, (4) all-in-one enterprise cloud, (5) one-stop resources and services, (6) government funding, (7) venture capitals, and (8) entertainment and social networking.

Today, companies can find almost all desired applications in the cloud. Following services are just some of many useful tools that can speed up daily work and lower operational costs, especially in small and medium enterprises (SMEs).

Solutions like Openstack offer private cloud building tools, so companies can create their own clouds. Such services often have strong online community, so users can get help and support quite easily.

Applications such as Gmail or Hotmail refer to software solutions provided over the Internet, or SaaS. They support communication within and outside the company. Other cloud computing services might include server virtualization and data storage, or IaaS, such application is Amazon Web Services, offering wide variety of services. If a cloud service includes software and product development tools then it is PaaS, e.g. Google Apps.

Mozy, Dropbox and Goggle Drive are online backup and synchronization services that continuously back up the files on a computer or server. They give small businesses the space to back up all their computer and server files for a very reasonable price, so owners of small or medium enterprises know their files are retrievable, even during a data loss crisis.

Finance cloud applications, like Outright help small businesses with their business accounting. They allow enterprises to track income, expenses, tax obligations, and profits or losses, in real time. This type of service is ideal for small companies or entrepreneurs that are looking to get a hold of their finances, as it provides access to finance data whilst on the move.

Here are other well-known cloud services that don't need much introduction:

- Salesforce – it supports most of company's marketing and sales activities and it can be easily expanded,
- Google Docs and Google+ – they support data storing, sharing and communication,
- Facebook, Twitter, Pinterest and other social networks – they support networking, communication, sharing, content marketing, etc., and
- Skype – it supports communication through instant messaging, video conferencing, as well as data sharing.

In spite of all the benefits these services offer, the integration of all different cloud services into the organization's core business software might not be possible or it might cost a lot of money, so organizations should choose their cloud services carefully.

V. APPLICATION OF CLOUD SERVICES IN MARKETING

In today's knowledge economy, the marketing landscape for businesses has changed dramatically especially thanks to the cloud services. Companies that hope to effectively: spread the word about their brands and products, attract customers, engage with them and ultimately retain them, need to adapt to mentioned market changes as soon as possible. Those that fail to do so will fall behind.

There are some marketing concepts that are impossible without cloud computing, and before cloud services, they existed only as mere ideas.

A. Marketing automation and lead tracking

Marketing automation is a process that enables marketers to nurture and quantify leads.

It includes: lead generation, segmentation, lead nurturing and lead scoring, relationship marketing, cross-sell and up-sell, customer retention, and marketing return on investment (ROI) measurement.

First and foremost, marketing automation software helps organizations discover more about their leads and customers. Organizations can track and expand their leads' profile data, including demographic and firmographic information that can be used to better segment and target the marketplace. Profile data can even include attitudinal information obtained from different surveys and form questions that provide powerful insights into leads' intentions and authority. By tracking what was previously invisible – the interactions leads have with organization's content – companies gain a much richer overview of the audience and how content meets their needs.

Armed with a greater understanding of their leads, organizations are in a position to expand their market reach. With automated outbound messages, whether in the form of newsletters, messages triggered by site registrations or complex automated nurture campaigns, they can reach more prospects in easier and more effective manner.

More touch points with leads mean more interactions and deeper understanding of leads, so organizations can prime them for engagement. The engagement starts with understanding the buyer's needs and the whole process buyer goes from awareness through research to a purchase decision. So, with marketing automation tools each customer step is carefully recorded by the IT infrastructure, and then compared to existing data, so next step can be predicted, often more accurately than sales personnel does it. Organizations can now create content to better meet their leads' information needs at every stage of their purchase decision process, and track their level of engagement.

Marketers' ultimate goal is to convert visitors to leads, leads to sales opportunities and finally, profitable customers. Marketing automation software enables organizations to convert anonymous visitors into qualified prospects using features such as reverse IP look-up and real-time website personalization with collaboration filtering. Organizations track and score these leads and convert them into sales opportunities.

Marketing automation is all about measuring. When using marketing automation service for sending out an e-mail (e.g. newsletter), firstly, companies can send it to more e-mail addresses, and they can also see how many e-mail receivers have actually opened the e-mail in question and/or specific (offer) link within the e-mail. They can also identify those receivers and keep records of them that can be used for personalization of future marketing activities. Companies can also measure the conversion of leads into potential customers, and finally buyers, which is their ultimate goal, of course.

Furthermore, before executing an e-mail campaign, several different versions of the e-mail can be prepared and tested, varying in title, content, day and time of sending. So, different versions of e-mail are sent out as a pilot testing, feedback is measured, analyzed and then the most successful scenario is chosen and used for the final e-mail campaign.

Services like MailChimp and Mandrill offer detailed analytics and control over sent e-mails and with their new mobile friendly templates they can reach almost everyone.

Well-known marketing automation cloud services with very similar sets of solutions offer wide application possibilities and they support many marketing techniques. Here they are:

- Oracle Eloqua – it offers content creation templates for e-mails, landing pages, social media marketing, lead segmentation, lead scoring/analysis, and personalization of marketing activities,
- Marketo – it also supports generating demand, building relationships with prospects, driving sales, measuring and optimizing,
- Google Analytics – it offers all web analytics, reporting and it measures conversions and sales,
- Adobe Marketing Cloud – it offers analytics, social, media optimization, targeting, web experience management, and cross-channel campaign management.

B. Inbound marketing

Marketing automation can be both outbound (e.g. e-mail marketing) and inbound (e.g. social media marketing).

Problems with some outbound marketing techniques include: difficulty in tracking return on investment (for TV or print ads), increasing blocking techniques ("do not call" list in phone marketing, spam filters in e-mail marketing, etc.) and high cost – low yield as a result.

The greatest advantage of inbound marketing lies in its extensive possibility of tracking and measuring. As mentioned before, the tracking of what was before social networking invisible, helped companies get a much larger picture of all their prospects and potential customers, and considerably richer view of their customers' needs, wants and interests.

Social networks tend to make users more open. Spending significant time online, using social networks, users become much invested in social media and they feel

connected through them with their friends. They follow their online friends' content and advices about products and services, which then consequently raises their level of trust in those products. Social network marketing campaigns are becoming more and more efficient, because it became easy to personalize those campaigns, lower marketing costs and improve conversions, all as a result of insights from considerable user data analysis.

Inbound marketing, in the simplest words, consists of creating content and posting it on the Internet. Inbound marketing strategy focuses on attracting customers, or leads with original content, thereby having potential customers come to the company themselves, rather than marketers vying for their attention. The beauty of inbound marketing lies in this very element that content readers are interested in the content and they voluntarily look for it, so they immediately become potential customers and even future promoters.

Inbound marketing is one of the hottest marketing techniques in business today. Be that as it may, managing outstanding marketing campaigns requires some human and technical resources and knowledge.

Quality content is not easily created and it takes much time and energy. Moreover, content marketing requires contemporary information sharing, active educational approach, significant general knowledge about product and related issues, and to top all up, excellent writing skills. All these competences are equally important, if marketers want users to perceive the content as reliable and significant, and to relate it to the product or company and get involved with the whole idea, so that they will share it with their friends and hence, become promoters the brand or product.

Inbound marketing content can be in form of: blog and blogging, forum activity, comment marketing, video and/or audio materials (webinars, online video, tutorials, etc.), podcasting, document or links sharing, questions and answers sites, social media marketing, self-published books, etc. With social networks, sharing such content is easy, as social networks facilitate user interactions.

The impact of the published content is usually measured in user interactions. Social networks offer different ways of sharing content, choosing right audience, choosing language, scheduling date and time of posts, reposting and post-editing, adding links, photos and videos, and performing descriptive statistics on users, posts, interactions, etc. As end users also have considerable set of tools to make their social network experience more agreeable, they can choose how they want to be served with the content. They can choose their interests and ways to get notified, as well as frequency and importance of the certain notifications and information, so basically, content can be personalized and with appropriate analytics and marketing skills, users can be served with targeted content and advertisements.

YouTube, Twitter, Pinterest and Facebook are all examples of cloud hosted services that have enabled the rise of inbound marketing.

Successful inbound marketing softwares simplify organizations' marketing efforts by automating content creation and distribution, lead capture and management, and measuring of ROI.

C. The art of engineering which makes it all work seamlessly

In general, marketing oriented cloud services address users that are potential customers and they promote users' engagement in company's content.

As mentioned, the most commonly used cloud services are Facebook, Youtube, and Twitter. They all allow users to share, comment and like the content. Sophisticated algorithms allow indexation of graphical, audio and video content, then they process the data in specific cloud services to extract all kind of metadata, from simple keywords, to human faces (Facebook acquired DeepMind, a small company that developed a software, which can recognize human faces with higher accuracy then a human being) and according to the results, algorithms can identify and "calculate" users' interests, personality and their mood [2].

Sophisticated algorithms can also perform predictions for larger group of people, and for the society as a whole [2]. So, well calibrated sophisticated prediction algorithms can, for example, predict society mood and satisfaction, and with high accuracy they can predict major world events such as strikes and protest, crises, even wars.

To increase the volume of analytics, social networks (e.g. Facebook), create widgets such as "Like", "Share" or "Comment" buttons which can then be integrated into external sites, as well. So, beside richer user experience and smooth content sharing mechanisms, these "buttons" facilitate monitoring of the user's activities all over the Internet. A user can be identified on the Internet in several ways. Most common way is through login, during which a cookie is saved on user's device, so each and every time specific user goes to pages with Facebook wigets, no matter from which device, the information about user's activity is gathered and saved. Furthermore, along with monitoring users' activity on the site, cookies also get information about which external pages are visited during and after Facebook sessions. Based on that, sophisticated algorithms can calculate user behavioral patterns.

With all the information gathered, marketers can thoroughly profile users, and according to all relevant information their experience can be nicely personalized. Personalization leads to one-to-one marketing or targeted marketing which is an extreme form of database marketing.

Marketing used to be based on product differentiation. Namely, marketers tried to differentiate their products from competing ones. Personalization has changed these marketing principles, since it tries to make a unique product offering for each customer individually. Consequently, users are served with the content, which is exactly what they want to see, hear or buy.

As these days most of the people from developed countries have smartphones – it is even simpler to perform personalization. Namely, smartphones send their location information when sending audio or video data from the phone to the cloud services, and new marketing strategies are based on proximity services, so users receive push notifications according to their current location. Smartphones represent a huge potential and great advantage for marketers.

With software platforms like HP Autonomy's HAVEn almost all the information can be extracted and categorized, forming unimaginable rich context for a specific user. As these platforms analyze and find meaning in "big data", this means that marketers can know more about users than users are aware of, which gives them a huge advantage in sales processes.

Thanks to "big data" and algorithms, it has become possible to anticipate individual's needs and tailor online advertisements and content according to a specific user. Additionally, services that help users personalize their devices and make it easier to automate tasks across applications are adding even more layers of functionality to mobile gadgets. In the future, these services will embrace emerging technologies such as augmented reality (AR) and then, the options for further development and application will be endless. For example, with AR all the data will be streamed directly from the cloud, according to user location and presented on next generation gadgets.

VI. CONCLUSION

The evolution of cloud computing over the past few years is potentially one of the major advances in computing.

Before cloud services, marketers used concept of four Ps (product, price, place and promotion), outbound marketing (TV and outdoor ads, direct marketing, etc.), segmentation of customers and differentiation of the products (figure 1) but now, they use new cloud based marketing activities that are build on completely different marketing philosophy.

Old marketing concepts were difficult to track and evaluate. Segmentation was long-lasting and never ending process that took place hand in hand with differentiation of the product, but was never flexible enough or quick enough to follow all market changes. Furthermore, it was quite demanding to calculate marketing return on investment (ROI).

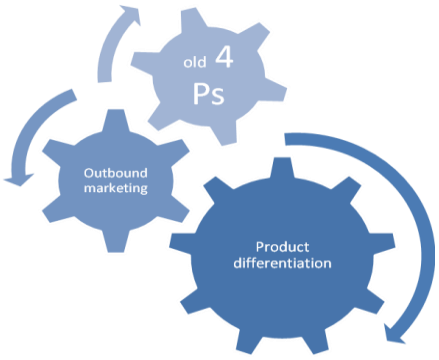

Figure 1. Pre-cloud marketing

These new concepts are less time and money consuming and more effective than older ones.

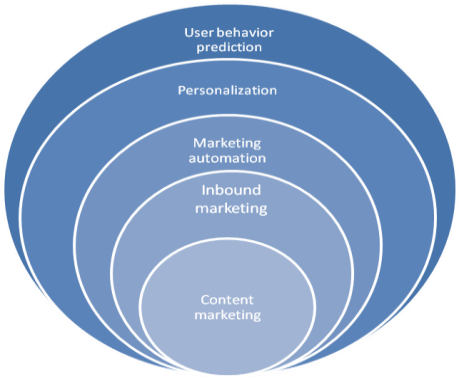

Figure 2. Post-cloud marketing

Cloud based content marketing, inbound marketing and marketing automation tools help organizations find out more about their leads and customers. They also provide great deal of functionality and measurement, so personalization and even user behavior prediction are possible (figure 2).

Cloud based marketing tools made it possible for organizations to bring customers on their sites, monitor their behavior, compare the results in real time and adjust marketing strategies accordingly. Furthermore, it is possible to create several different strategies and learn from a pilot test which one is the most effective. So, through better lead and customer analysis and personalization help organizations offer such products and services that are exactly what customers want. So, marketing principles have changed drastically. Marketers have adopted these new concepts and they exploit them in their everyday work. The philosophy has changed.

Therefore, we confirm our hypothesis: "Marketing landscape has changed since cloud services were invented."

Emerging technologies will blur the boundary between digital and real, and merge the two worlds together. Our every move, interaction and behavior will be recorded and processed in the cloud, and then used to augment our world.

For this reason, if cloud computing is to achieve its potential, everyone needs to research and address security and personal privacy issues with more care. It is much needed that various raised questions (both from the perspective of the providers and the consumers of the technology) are resolved, sooner rather than later.

Cloud services remain not just one of the most interesting contemporary computing issues, but one of the most challenging issues in general.

Abstract – Radio frequency identification (RFID) provides the ability for unmanned automatic real-time data acquisition. The aim of this paper is to open discussion about implementation of RFID technology in Croatian ports. The authors propose RFID as one of the technologies that can accelerate and improve ferry loading process and make it more efficient and reliable. Basic RFID system was built to introduce its capabilities to perform as one of the suitable solutions for ferry tickets check-in process within certain technical constraints.

I. INTRODUCTION

Radio frequency identification – or, as it is more commonly known, RFID – is an automated data acquisition technology. Nowadays, RFID technology has become integral part of our daily lives routines and process, such as: restrict access to buildings or rooms within buildings, livestock identification, asset tracking, pet ownership identification, warehouse management and logistics, product tracking in a supply chain, product security raw material tracking/parts movement within factories, automatic vehicle identification (AVI) systems, library books check-in/check-out, railroad car tracking, luggage tracking at airport, electronic toll systems, automobile ignition systems, tracking containers in an integrated traffic.

The developments in the semiconductor industry, as well cost decrease, trigger the mass usage of RFID in the global business world. RFID can be used for redesigning business processes, cutting costs, and improving the operational performance by increasing factors such as: efficiency, accuracy, visibility, and security [1].

Figure 1 presents applications of RFID by purpose in enterprises in the EU and Croatia, first quarter 2009

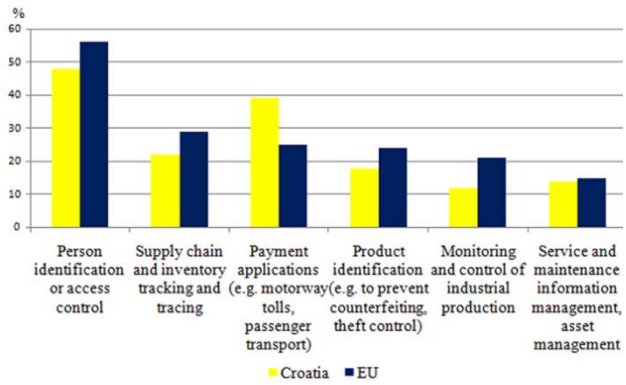

Figure 1. Applications of RFID usage in enterprises by purpose

(Eurostat- the statistical office of the European Union and Croatian Bureau of Statistics, 2010) [2][3]. RFID technology was mostly used in Croatian enterprises for person identification and/or access control and for payment applications (e.g. toll collection). Application of RFID technology is increasing in various industries while prices of RFID elements are continuously decreasing. According to data from Eurostat, the most common application of RFID technology in enterprises in the EU (in January 2009, sample size: 152 900 enterprises out of 1.6 million in EU-27 were surveyed) was in the area of person identification or access control (56%), supply chain management and inventory tracking and tracing (29%), payment (25%), product identification (24%), monitoring of industrial production (21%) and service and maintenance information management (15%). In 2011 (sample size: 146 000 enterprises out of 1.5 million in EU27 were surveyed), among all enterprises in the EU27, the use of RFID devices remained limited (4%) and at a similar level to 2009 (3%) [4].

RFID technology has been used in public transport for many years ago. RFID system, which is used in Helsinki, is the largest system and it comprises all sorts of public transport, as well ferry transport (e.g. M/S Suomentlinna II). Norwegian ship operator Fjord Line uses RFID technology to manage ticketing and cabin access on one of its ferries (MS Stavangerfjord), and plans to expand the technology's use to the other ferries and as well on other onboard services, such as at restaurants [5].

In the most applications RFID technology achieve from 99,5% to 100% accuracy of reading in first scan. Furthermore, without moving elements, maintenance of RFID resources is far simpler and more efficient [6].

Integration of RFID technology into integrated information systems of shipping companies enables: secure and real-time passengers/vehicles tracking, automated data entry, provides insight into real situation of passengers/vehicles on each ship, ticket control without presence of the ship's officers, increase the capacity of port in a way that accelerate the process of verification, monitoring and management of passengers/vehicles, reduction of operating costs, timely and accurate information's about passengers/vehicles in front of berths in order to plan the needs of port resources, increase control functions at all levels of managements and optimization of the vessel traffic in the port.

This paper presents the RFID technology, its practical application, with special emphasis on application in the ferry ticket check-in process.

A. Basic physics of RFID

Radio frequency identification is based in discoveries made by Faraday during the mid-nineteenth century, as well in discoveries made between 1900 and 1940 in radio and radar technologies. Faraday discovered the concept of mutual induction, which is the basic principle for powering short-range passive tags operating in the near field. During the first half of twentieth century, due to technological advances, the development of far-field tags occurred. Far-range passive tags must harvest energy to operate and backscatter the interrogation signal transmitted by the reader to communicate with it. The voltage induced in a coil consisting of N loops immersed in a time-variant magnetic field can be calculated with equation of Faraday's law (1):

$$V = -N\frac{d\Psi}{dt} \tag{1}$$

with Ψ being the magnetic flux.

The magnetic flux can be calculated as (2):

$$\Psi = \int B \cdot dS \tag{2}$$

where:

- B - the magnitude of the time-variant magnetic field,
- S - the surface area of the coil.

Reflection is a property of the matching of the impedance of the antenna to the impedance of the load (chip) on the RFID tag [7]. The reflection coefficient is calculated in equation (3):

$$\Gamma = (Z_L - Z_A)/(Z_L + Z_A) \tag{3}$$

where:

- Z_L – chip (load) impedance,
- Z_A – antenna impedance.

If the load impedance is shorted (0), $\Gamma_{short} = -1$. If the load impedance is open (∞), $\Gamma_{open} = 1$, and if the two impedances are matched, that is $\Gamma_{match} = 0$. Thus, all other variations of matching the antenna and load impedances result in a Γ somewhere between + 1 and – 1.

II. SYSTEM OVERVIEW

RFID technology does not require line of sight and provides fast and accurate reading from a great distance without human intervention. Besides hardware and middleware cost, service cost factors, including compliance cost, cost of training users, and transition cost make the total RFID system cost structure. Benefit factors are more complex and almost impossible to calculate than cost factors as the limited pilot studies or studies from other application areas are unable to reveal the full set of benefits. Also, intangible benefit factors such as increased customer satisfaction are not easily measured. A simple RFID system is composed from three main components (tag, reader and middleware) shown in Figure 2.

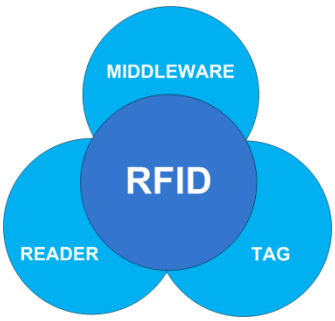

Figure 2. Three main components of RFID system

A. Tag

Tag (***trans***mitter/res***ponder-***transponder) is composed of a small microchip and an antenna and can be embedded into or attached to any kind of objects to be identified in an RFID system. Tags have different shapes and sizes and have a memory for data storage. These are specific data such as a unique identification number, ticket price, service location, date and time of transaction.

For such systems multi-application smart cards are mostly used. The card belongs to a group of passive RFID tags.

Passive tags are also called pure passive or reflective. Passive tags obtain operating power from the reader which sends electromagnetic waves that induce current in the tag's antenna and the tag reflects the RF signal transmitted and adds information by modulating the reflected signal. Chip cost and assembly cost define the tag cost and as the manufacturing volume increases chip cost decreases [8].

The advantage of RFID tag is that user can use one tag repeatedly (reusable) during many years. This advantage is significant for tourists who come every year. The data in the card can be changed only by authorized personnel. Devices for amendment are located at several locations in the port and/or at an authorized agency.

B. Reader

RFID readers communicate with tags through an RF channel to obtain identifying information. The basic components of the reader are: control unit (microchip), antenna and communication interface. In environments with many tags, a reader may have to perform an anti-collision protocol to ensure that communication conflicts to not occur. Anti-collision protocols permit readers to rapidly communicate with many tags in serial order. Readers often power what are called passive tags through their RF communication channel. These types of tags carry no on-board power and rely only on a reader to operate.

Reader cost, together with tag cost make up the hardware cost of an RFID system. Reader and related infrastructure cost are often regarded as fixed cost in contrast to tag cost which is variable. RFID readers may

also be integrated into hand-held mobile devices. Readers can have an integrated antenna, or the antenna can be separate device.

Communication between reader and computer takes place over communication interface, which can be RS-232 and/or RS 485, USB, WiFi and TCP/IP.

RFID readers are connected through the network (Ethernet protocol) with database server and application server. Furthermore, RFID readers can be connected with long range wireless connection (WiFi) or/and shorter – range wireless connection (Bluetooth). The choice of connection methods depends on depends on the configuration of berths and on the existing network in port. These solutions can be combined (wireless and wired devices at the same time in the network).

C. Middleware

Middleware software manages the readers and the data coming from the tags, and passes it to the backend database system. Figure 3 presents RFID system with middleware included. Middleware fills the gap in the middle of the data flow between the readers and the processing unit, and manages the flow of information between the readers and the processing unit. In addition to extracting data from the RFID tags and managing data flow to the processing unit, middleware performs functions such as basic filtering and reader integration and control. An RFID tag sleeps in normal mode: it does not perform any activities and does not use any power. This will change as soon as the tag moves through the reader's field. An RFID reader emits radio waves at a frequency similar to those of the tag. The tag antenna retrieves enough energy from waves so as to exit the tag from the sleep mode and to power the microchip. The tag's microchip initiates a wireless communication with the reader and receives a command. The chip will execute the command, resulting in a data transfer through the tag's antenna. In case of the passive tag, the data consists of the unique serial number of the tag in binary format emitted as radio waves. The antenna will pick up the data emission and sends it through a cable and in the form of

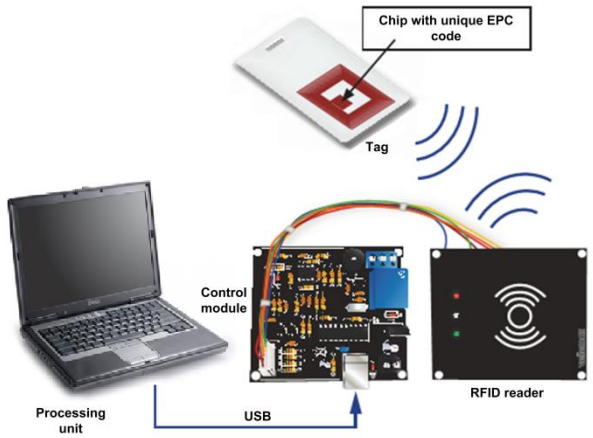

Figure 3. RFID system (including middleware)

electrical signals to the reader's control module. The module will in turn decode the radio signals and retrieve the binary data. The reader now has the tag's ID in digital format, which can be processed or printed immediately. This data will mostly be completed with additional data (e.g. time and location) and quickly forwarded to a processing unit or information system [9].

RFID middleware is software that facilitates communication between RFID readers and information system of enterprise. Middleware collects, filters, aggregates and applies business rules on data received from readers. It is also responsible for providing management and monitoring functionality - ensuring that the readers are connected, functioning properly, and are configured the correct way. Middleware may also contain a localized data store for data archives. Middleware may be implemented on a host computer, a central server, or on intelligent readers.

III. DISCUSSION

The authors propose RFID as one of the suitable ID technologies that can accelerate and improve ferry loading process and make it more efficient and reliable without burdening employees. Among automatic ID systems shown in Figure 4, RFID technology is optimal solution for check-in procedures. RFID technology provides support for e-ticketing and creating passenger and vehicle database.

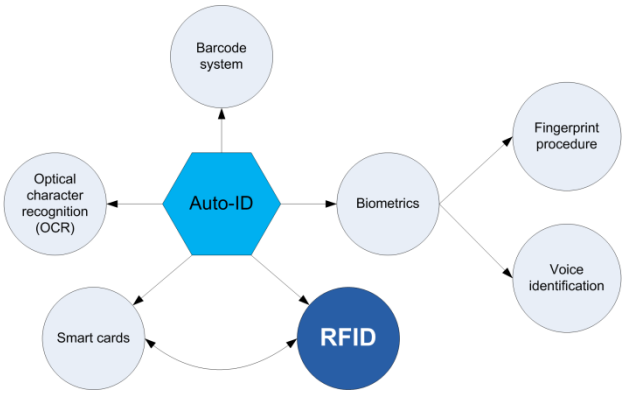

Figure 4. Overview of the automatic ID procedures

The barcode is a binary code comprising a field of bars and gaps arranged in a parallel configuration. They are arranged according to a predetermined pattern and represent data elements that refer to an associated symbol. Optical character recognition (OCR) systems have failed to become universally applicable because of their high price and the complicated readers that they require in comparison with other ID procedures. Biometrics is defined as the science of counting and (body) measurement procedures involving living beings. In the context of identification systems, biometry is the general term for all procedures that identify people by comparing unmistakable and individual physical characteristics. Voice identification systems have become available to identify individuals using speaker verification (speaker recognition). In such systems, the user talks into a microphone linked to a computer. This equipment converts the spoken words into digital signals, which are

evaluated by the identification software. Fingerprinting procedures (dactyloscopy) are based upon the comparison of papillae and dermal ridges of the fingertips, which can be obtained not only from the finger itself, but also from objects that the individual in question has touched. When fingerprinting procedures are used for personal identification, usually for entrance procedures, the fingertip is placed upon a special reader. The system calculates a data record from the pattern it has read and compares this with a stored reference pattern. Modern fingerprint ID systems require less than half a second to recognize and check a fingerprint. A smart card is an electronic data storage system, possibly with additional computing capacity (microprocessor card), which – for convenience – is incorporated into a plastic card the size of a credit card. Smart cards are placed in a reader, which makes a galvanic connection to the contact surfaces of the smart card using contact springs. The smart card is supplied with energy and a clock pulse from the reader via the contact surfaces. One disadvantage of contact-based smart cards is the vulnerability of the contacts to wear, corrosion and dirt. Readers that are used frequently are expensive to maintain due to their tendency to malfunction. RFID systems are closely related to the smart cards. Like smart card systems, data is stored on an electronic data-carrying device – the transponder. However, unlike the smart card, the power supply to the data-carrying device and the data exchange between the data-carrying device and the reader is achieved without the use of galvanic contacts, using instead magnetic or electromagnetic fields.

Contactless smart cards are designed for a lifetime of 10 years. Rain, cold, dirt and dust are not a problem for either smart card or reader. Contactless smart cards can be kept in a briefcase or handbag and are therefore extremely convenient to use. Although the purchase costs of a contactless smart card system are still higher than those of a conventional system, the investment should repay itself within a short period. Usually, in payment systems contactless smart cards apply standard ISO/IEC 14443 for data transmission [10]. The replacement of conventional paper tickets by a modern electronic fare management system based on contactless smart cards provides a multitude of benefits to all those involved.

Use of RFID technology facilitates automation of processes and improves operations management through reduction of workload and elimination of human errors. The most of Croatian enterprises still use labor-intensive methods (enter data manually and using bar-code systems) for products-related data acquisition. However, RFID technology has some advantages over the bar code:

- there is no need for line of sight (tags can be read through a different materials),
- suitable for harsh environments (e.g. dirt, moisture, dust, chemicals, high temperatures),
- the RFID reader could interact with multiple tags and automatically receive information from the tags,
- greater distances of reading with RFID readers,
- tags contain more data than bar codes,
- tags can have read/write memory capability, while barcodes do not (bar codes are not able to be modified once they are printed),
- form and dimensions of tags could be various, depending on the application.

Authors propose following main attributes as possible data composition for RFID ticket/tag:

- passenger ID,
- vehicle ID (e.g. license plate),
- maritime company ID,
- code of navigable area,
- credit balance,
- ticket ID,
- departure time of ferry,
- date and time of transaction.

Benefits of using RFID ticketing are presented in Table 1.

TABLE I. BENEFITS OF RFID TICKETING

Benefits for passengers
• cash is no longer necessary, RFID tag can be loaded with large amounts of money, passengers no longer need to carry the correct change • prepaid RFID tag remain valid even if fares are changed • the passenger no longer needs to know the precise fare; the system automatically deducts the correct fare from the tag • monthly tickets can begin on any day of the month, the period of validity begins after the first deduction from the tag
Benefits for the driver
• passes are no longer sold, resulting in less distraction of driving staff • no cash in vehicle
Benefits for the maritime company
• very secure against vandalism • it is easy to change fares; no new tickets need to be printed • ticket holders are known so passenger/vehicle reports can be created • expressive statistical data is obtained • waiting time reduction • transparency

Figure 5 presents overview of RFID ticket check-in procedure which is created by authors. RFID check-in procedure can be performed without impact of weather conditions, thus whole process become more robust and reliable. Authors suggest separate new user registration and check-in procedures to make concept smoothly and transparent. Without RFID ticketing roughly more than half ticket holders are unknown so passenger and vehicle reports created from known RFID ticket holders are of great importance for maritime company. Tags can be interrogated by RFID hand (mobile) readers or, more complex, by stationary fixed readers for realizing unmanned solution without employee burdening (human errors are reduced to minimum).

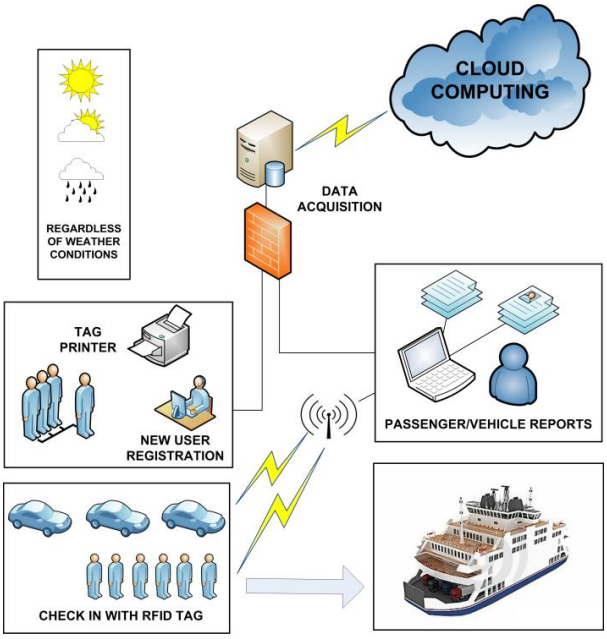

Figure 5. Overview of RFID check-in procedure

The collected data can be stored on the local database server (agency), on the maritime company's database server, or nowadays, more reliable way is to store data in the cloud. This paper gives detailed description of the data storage in the cloud.

Cloud computing storage is provided for backup of passenger and vehicle reports. Cloud computing offers maritime company back office online (real-time) data acquisition and inspection.

Cloud computing represents a combination of many different existing technologies comprising the virtualization, data storage, connectivity and processing power to create a new environment. Storing data in the cloud is an easy and automated backup mechanism for real-time storage of data to a remote location. This mechanism provides a reliable solution with a centrally managed backup that facilitates easy storage of data and enables company managers and owners to protect their data as the most important corporate assets. Furthermore, this mechanism provides a very efficient compression, global data deduplication, significantly reducing the time frame for storage, energy storage capacity and loading on the network infrastructure. Data deduplication eliminates duplicate data at the entire port, detached offices and mobile users. In addition, the mechanism verifies the integrity (Data Integrity Verification) with automatic recovery and the possibility of advanced rescue (Advance Recovery) that provides immediate availability and eliminates the need for manual data recovery activities.

Cloud system is an ideal way to effectively protect important data on a remote location against unexpected events such as theft, fires, earthquakes, floods, etc. Cloud systems are software solutions that perform storage of data at several remote locations at certain time intervals. In a secure manner the software collects, compresses, encrypts and archives data on the servers of the service provider, which are located at several different remote locations.

Before any piece of data is transferred, the data storage system in the clouds encrypts it with the most secure encryption mechanism. The data remain encrypted during storage and during all transfers. The system has a special module enabling that all data storage and recovery processes are registered, therefore allowing a clear overview of data operations. In addition, such a system features a multiple factor authentication of identity. In other words, the data storage system in the cloud is a set of regulations for digital storage and access to confidential data.

Data storage systems in the clouds are professionally maintained servers and disk systems, providing support 24 hours a day, seven days a week. Data are stored in three or more geographically remote data centers, thus providing unmatched availability and reliability. If there is a failure in the system, the data can be accessed in a secure manner until the re-establishment of the system's full availability.

Systems of data storage in the clouds will be increasingly present within the integrated information and communication systems because they are cost effective in financial and material terms. There is no need for a database administrator and there are no new or additional costs regarding the acquisition and maintenance of the software and hardware... The only cost is related to paying for the service which eliminates the need for any subsequent significant investment.

The advantages of storing data in the cloud include: fixed costs of space rental, expandability (scalability), saving to another location, speed of deployment, ease of administration, low energy consumption, reduction of electronic waste and decreased environmental impact. The disadvantages of storing data in the cloud include data security, control, openness, scalability, backup duration, making contract with the service provider, etc.

The implementation of storing data in the cloud requires lower initial costs and shorter time to achieve productivity compared to traditional ways of storing data. Storing data in the cloud will reduce costs, increase availability and reliability of computer resources and increase profits of maritime companies. The core concept of data storage in the cloud is that the customer pays only for the service of data storage in the cloud. Regardless of the advantages, users are still concerned about the security of their own data stored in the cloud. In the near future the security problems as well as ship-shore communication difficulties will be solved and the servers of cloud computing will enable the use of almost all IT services in the cloud [11].

Figure 6 presents economic impact, developments and application areas of RFID technology. Numerous factors make RFID technology the best choice for implementation in maritime company's business processes. RFID technology is suitable for monitoring and supervision of spare parts and technical equipment, access control, tracking, supervision and monitoring of container handling.

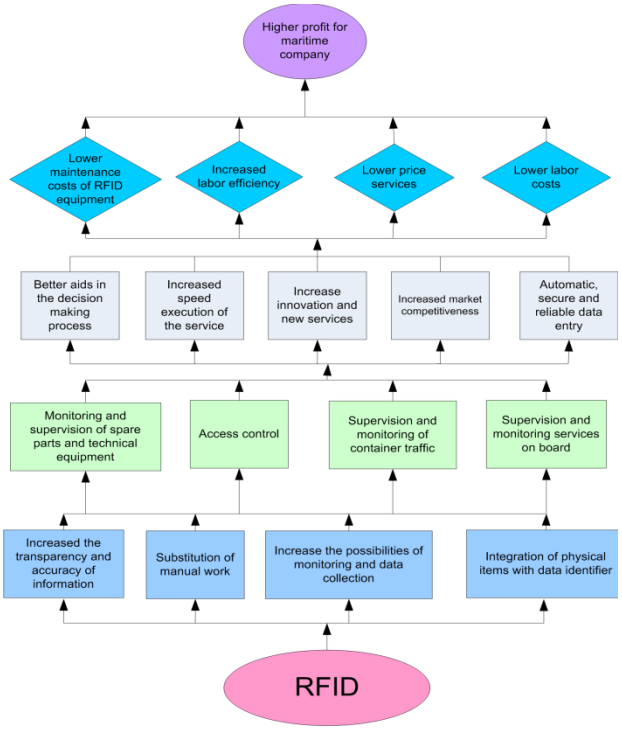

Figure 6. Economic impact and developments due to use of RFID

Monitoring and supervision of onboard services (such as cabin access control or restaurant services) could be also improved by implementing RFID technology. Individual and customized services (breakfast, Internet access, cocktails, etc.) can be offered via RFID prepaid solutions so there will be no need to use vouchers (additional discounts for frequent travelers are becoming available). All these factors contribute to reduction of human resources, paperwork, manual labor, accelerate the execution of business processes and contribute to increase of financial profits of maritime company.

IV. CONCLUSION

Although the market for RFID is already well established, because of the developments in the semiconductor industry, as well cost decrease, the mass usage of RFID will redesign existing processes in the global business world.

The advantage of using RFID technology in comparison to other technologies are: adaptability to working conditions (moisture, dirt, high temperature, mechanical resistance), long lifetime (standards prescribe a 10-year duration of RFID media with minimum 100,000 readings), protection of data on the card, all favorable price of RFID components, etc.

The aim of this paper was to start discussion about implementing RFID technology in Croatian ports by representing its capabilities to accelerate and improve ferry loading process and make it more efficient and reliable. RFID technology combined with advantages of cloud computing offers higher profit to maritime company. Additional promising features of RFID technology and its security aspects will be the subject of future work.

The use of cloud computing services (Database as a service -DBaaS) provides for cost savings in the costs of developing and maintaining an internal infrastructure, operating expenses such as those allocated for the maintenance of IT resources, administration costs and costs of scaling information infrastructure. In addition, it gives the shipping company a possibility of faster and greater development, a possibility of upgrading existing services or investments into new and thus further development of its IT sector.

***Abstract* - There are different types of bank statements offered by various banks. So far there are no standards, and each bank builds its own type of statements. Most of these statements given to the citizens are in pdf format, and lately several banks offer statements in excel formats. Very rarely one can find XML types of statements, which can be further processed.**

To use data from statements in other applications, one has to build their own interpreter of bank statements. To solve the existing problem with interoperability, as a main motivation for this paper, we introduce an adapter, which can read various types of statements and return an XML file as output. Our realization of the adapter works with statements offered by most of the banks in our country as a proof of concept. The adapter was efficiently used in a special program for analysis of consumer costs, where one can access accounts in several banks and calculate taxes, income statements and analyze the costs.

I. INTRODUCTION

The development of IT technology and its fast update and improvement enable an increased use of software solutions in businesses. All business transactions require extensive communication between the company and the banks. These financial transactions are usually recorded on the company's account. Similarly, the citizens too use financial transactions with banks and relevant data is stored on their accounts.

Internet allowed the banks to offer almost all the information and services online 24/7, including desk operations to their customers. This step contributed to the rapid development of modules that enable integration of e-business or ERP software with the banking systems. The final goal is recording and tracking of all realized transactions.

This paper analyzes some of the more familiar systems that enable management of expenses and bank transactions in a company. These systems also allow the users (companies or citizens) a complete insight into their banking transactions. Users can analyze, compare and make conclusions about the realized costs or give them an opportunity to perform management of the costs, which would lead to more rational spending of the funds.

Various banks deliver different types of bank statements. Since there is no recognized standard, each bank builds its own type of statements. Most statements are pdf documents, spreadsheet (excel) or word documents. These documents do not give a structural organization that can be used for automatic processing in computer programs, such as the xml format, used only by a small number of banks. This problem is mostly interpreted as interoperability problem, when two different systems exchange data.

When the problem is exposed only to two entities, then the solution can be realized as a simple interpreter between them, which processes the data coming from one system prior to use of the other. However, when one wants to build a more universal solution in cases when there is no official standard, one has to use other approaches.

To solve the analyzed problem with interoperability of bank statements we introduce a software adapter, which can read various types of statements and give XML file as output. The proof of concept is realized as a case study on examples of several banks in Macedonia. The realized solution uses an adapter to access various accounts in different banks and analyze the consumer costs.

The rest of the paper uses the following structure. Related work is presented in Section II and the analysis of existing solutions in Section III. Section IV presents the new interoperability framework and finally, the conclusion is given in Section V.

II. RELATED WORK

This section presents similar projects and approaches that tackle the analyzed problem. Later on we discuss interoperability solutions.

A. Similar ongoing projects

During work on this paper, we have tried to find some similar projects that are currently developed or operate in this area.

The first analyzed project is about integration of credit card transactions into a financial management system used by a company to track and control budgets [1]. The system realizes an accounting service for credit card transactions within the financial management system. The project uses various card transactions limits, regularly not available to a credit card issuer, and ensures that the transactions correspond with the financial system controls. The transactions can be obligated prior, to or during the actual transaction with the bank and thereby subjected to the controls of the financial management system. Obligated transactions can be authorized for immediate payment. The invention provides for the complete reconciliation of the credit card transactions with bank records after the transactions occur using the obligation function to capture

the transaction before it occurs, even the transactions that are immediately paid. The system reconciles the transactions recorded by the bank with those recorded in the financial system and updates budget, plan, project, and ledger entries accordingly. The system also allows cardholders to identify disputes and track the correspondence with the card issuer over the dispute.

The second analyzed project is about a system and method that automatically tracks player gambling transactions in a casino [2]. The system includes a casino database that stores betting summary records for multiple players, where each betting summary record is associated with a player identification code, and includes the player's betting rating. One or more gaming tables have multiple player positions and multiple code readers. A code reader initiates a betting session in response to reading a player identification card encoded with a player identification code. A communications network couples the casino database and gaming table to an automatic tracking and management unit (ATMU). The ATMU has a display unit, and is coupled to the code readers at the gaming table to receive a player identification code for a player at the initiation of a betting session. The ATMU retrieves from the casino database the betting summary record of the player, and displays it to pit personnel at the gaming table on the display unit. The ATMU also collects real time data of the player's betting transactions, including the player's identification code, and an average bet by the player during the betting session. The ATMU updates the betting summary record with the collected real time data for the player, and provides the updated betting summary record to the casino database via the communications network.

The next project is about control system and method for interfacing a control device to a vending machine having input/output control lines along which are transmitted signals to control the operation of the vending machine [3]. The control device includes means for connecting to the control lines of the vending machine; means for reading the control signal; means for determining operational responses/outputs of the vending machine, which correspond to the control signals; means for storing the control signals and information concerning the operational responses; and means for reading the stored information to control the vending machine. Control and monitoring of vending transactions comprises means for reading stored information from a magnetic card; means for obtaining an approved code for a specified authorization amount for a transaction; means for storing the approval code; means for operating the vending machine without exceeding the authorization amount; and means for storing transaction information.

The last project that was analyzed, and aligns with our goal of interest, is about a system and process for determining the terms of the transaction and establishing a function having a proper function identifier [4]. The function is adapted to be processed during a transaction such as a point-of-sale transaction that may involve a credit card. The system and process involve identifying an account having an account identifier, establishing a function having a function identifier, and receiving a transaction request including the account identifier, a transaction amount, and the function identifier. The system also processes the transaction in accordance with the function to affect the transaction and, possibly, the transaction amount. Additionally, the system and process are adapted to allow message to be presented by customers and credit card holders during a transaction for later appearance on a credit card statement or other notice.

All these projects work on a specific problem, but no one analyzes bank transactions per user from different bank documents.

B. Interoperability

Communication in this modern age is something that we take for granted. Interoperability is the ability of a system or a product to work with other systems or products without special effort on the part of the customer. Interoperability describes the extent to which systems and devices can exchange data, and interpret that shared data. In order two systems to be interoperable, they have to be able to exchange data and subsequently present that data in a way to be understood by a user [5][6].

In IEEE [5] dictionary interoperability is defined as the ability of two or more systems or components to exchange information and to use the exchanged information.

O'Brien and Marakas [6] define interoperability as the ability to achieve end user application, using different types of computer systems, operating systems, and application software, interconnected with different types of local and wide spacious networks.

The purpose of interoperability is calculated data exchange between computer systems that can be owned by different organizations that cooperate with each other in order to meet specific business process / workflow.

Interoperability can be distinguished on four different levels: technical, syntactic, semantic, and organizational [7]. The technical interoperability enables technical connection between entities needed to exchange information [8]. Syntactic interoperability enables appropriate format for data exchange [9]. Semantic interoperability ensures that meaningful exchange of data, i.e. the exchanged data are correctly understood by the entities included in the process [8]. Finally, the organizational interoperability deals with exchange information between entities with different internal structures and processes [8].

Interoperability commonly can be achieved in three ways: establishing a standard in the given area, accepting often used method/structure as a de-facto standard or building adapting software between different interfaces.

III. ANALYSIS

We have realized a detailed analysis of the files received via the system of e-banking of several banks in Macedonia (NLB Tutunska Banka, Ohridska Banka, Komercijalna Banka and Stopanska Banka). Further, these files are processed and inserted into database, from where then user draws the necessary data reports. The analysis will be categorized by various data formats, including spreadsheet and word documents, and XML formats.

Figure 2. Excel statement of "Ohridska Banka"

A. *Spreadsheet data format*

Most of the banks are using excel exports as a report with client transactions in a given period of time.

The first example is the bank statement provided by "NLB Tutunska Banka". Using the service for electronic banking, it is possible to make a report for a period of time. The user receives a document with sorted transactions, in html or excel format. An example of this excel document is presented in Figure 1. The following key data to be exploited by other applications for management of expenses and bank transaction:

- Field C6 contains information about user's name and surname
- Field C7 contains information about the user's transaction account
- All transactions are shown starting from the 20th row. Field B contains the transaction date, field G its description, and field I the transaction value.

The number of rows in the document is variable according to the given time range and the number of transactions that occurred in that period. The same layout of the fields is used for both the debit and credit cards.

Another example of use of Excel's reports as bank statement is the use of "Ohridska Banka", as presented in Figure 2. The used layout uses the following:

- Name and surname of the user account is recorded in the field H4
- Transaction account of the user is recorded in the field H6
- All transactions are shown starting from the 14th row. Field B contains the transaction date, field and its description, and field M the transaction value.

Similarly to the previous example, the number of rows is variable according to the given time range and the number of realized transactions.

One can conclude that although excel formatted documents give a relatively structured information each bank uses data in different positions. Structured information in this case means that the meaning of information is not described, so one needs to establish a mapping of the "meaning" and the value. For example C6 (or H4) identifies the user. This mapping of cells with their meaning is a file that has to be imported with each bank statements to enable information extracting from the corresponding statement.

Another problem is generated if the bank decides to change the layout, then all positions will be changed and the relevant information will be displaced.

B. *Swift related formats*

Some banks offer swift formatted bank statements using the MT940 format. An example is used by "Komercijalna Banka", which is shown in Figure 3. MT940 is Customer Statement Message international format used as digital equivalent of the official paper account statements. However, statement uses opening and closing balance on the book date, as well as specific information for all entries to the account. So the SWIFT MT940 structured format delivered by RCM is not fully compliant with SWIFT, i.e. the message starts with a specific value ':940:' and the allowed maximum length is more than the 2000 characters specified by SWIFT. The

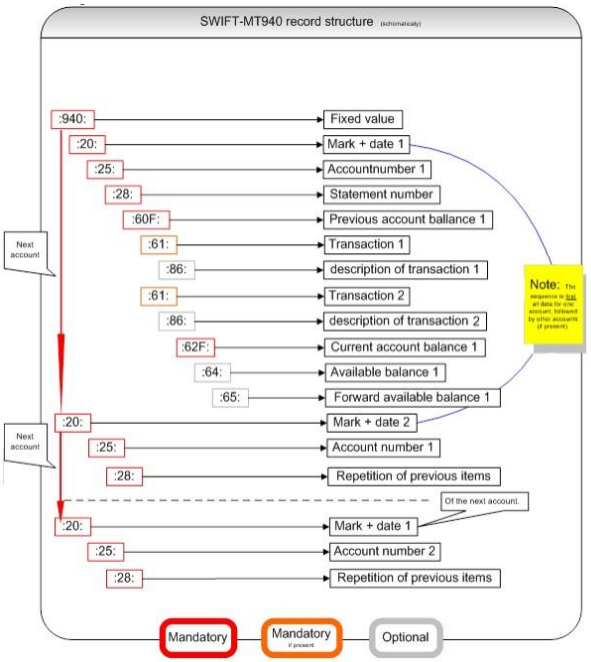

Figure 3. MT940 bank statement format of "Komercijalna Banka"

statements are empty if no entries are available for the specified entry date. The structured export format is adopted to provide additional information for SEPA orders. For example, Radobank will close any message with tag 62F, 64 or 65.

About format structure, each information block in an MT940 is preceded by a field (label, tag). The content of the field may consist of different elements. The file begins with a fixed value ":940:". Each statement in the file begins with field-20 and ends with the next field-20 or when the end of the file is reached. Within one statement the group consisting of field-61 and field-86 may occur several times. Field-65 may also occur more than once. Codes in field-86 are separated by a forward slash. These codes are used to provide structure in field-86 and to separate the various data elements [10].

This standard uses textual file with structured data and is better than the ordinary text based word documents. However, it does not offer flexible adaptation to new environments or processing of the files.

C. XML structured data

There are banks that use several document types for bank statements, including a XML format. An example is the use of "Stopanska Banka".

Figure 4 presents a typical example document. All information has explanation about its meaning and data values are described within the document using the following structure of XML objects:

- StatementRs is the main element in which are houses all XML objects from report
- StatementType, AccountInfo and ListOfTransactions are sub elements of the document, where in StatementType are given general information about the report, AccountInfo contains general information about the user's account and ListOfTransactions has data for all transactions made.
- In ListOfTransactions is described separately each transaction in element Transaction, and as the first element appears TranCount which containing information about how many transactions are described in the document.

The parser can easily analyze and further process the following XML data are:

- AccountInfo / AccountNumber - information about transaction account user
- AccountInfo / CustomerName - name and surname of the user
- ListOfTransactions / Transaction / ProcessDate - date when transaction happened
- ListOfTransactions / Transaction / Amount - value of the transaction
- ListOfTransactions / Transaction / OtherRefName – place where the transaction is made

```
<StatementRs>
    <StatementType>Retail
        <DateFrom>01.12.2014</DateFrom>
        <DateTo>31.12.2014</DateTo>
    </StatementType>
    <AccountInfo>
        <AccountNumber>1000000001</AccountNumber>
        <Currency>MKD</Currency>
        <CustomerID>2911</CustomerID>
        <CustomerName>IME i PREZIME</CustomerName>
        <CustomerAddress>ULICA 118-1</CustomerAddress>
    </AccountInfo>
    <ListOfTransactions>
        <TranCount>3</TranCount>
        <Transaction>
            <ProcessDate>2014-12-22T12:54:00</ProcessDate>
            <OrderId>-9655</OrderId>
            <ValueDate>2014-12-22T00:00:00</ValueDate>
            <Amount>-12.00</Amount>
            <Balance>1681.00</Balance>
            <RefTrans>FT14356580187257</RefTrans>
            <RefTime>1412221254</RefTime>
            <OtherRefName>СТОПАНСКА БАНКА АД СКОПЈЕ</OtherRefName>
            <OtherAccountNo>200000000099029</OtherAccountNo>
            <PurposeCode>666</PurposeCode>
            <Purpose>Провизија за трансакција: FT14356580187257</Purpose>
            <DebitReference></DebitReference>
            <CreditReference></CreditReference>
            <TransactionChannel>e-банк</TransactionChannel>
        </Transaction>
        <Transaction>
```

Figure 4. XML bank statement from "Stopanska Banka"

As a conclusion, XML bank statements offer the best suitable forms of documents that express the meaning of data and corresponding values. It allows easy further processing.

IV. INTEROPERABILITY FRAMEWORK

This section presents our solution of an adapter that can be used to communicate with different banks, presenting the software and hardware concepts.

A. Software concepts

The adapter analyzes reports collected by different banks and stores relevant data in the database using a pre-defined common format. Although various banks use different formats of bank statements, only common necessary data is extracted and inserted into the database. The output of the service is an XML file containing the pre-defined information. Our dedicated application form management of bank transactions uses these XML files to realize management of expenses and transactions.

The predefined common data extracted from all bank statements is using:

- Transaction Account
- Transaction date
- Transaction value
- Place / company where the transaction is made

These data should be read through for each transaction, respectively for any document submitted by a user. Furthermore, it should make connection between the user and the transaction. Accordingly, the display of table data is given at Figure 5. The special application for management of expenses and transactions is using an XML generated file and builds a database to store the information and generate various reports.

```
SELECT TOP 1000 [UserId]
      ,[TransactionId]
      ,[TDate]
      ,[Total]
      ,[MadeIn]
      ,[IsProcessed]
  FROM [MyMoney].[mm].[Transactions]
```

Figure 5. Display of the table in the database, in which are integrated necessary data from three different banks formats

B. *Architecture of solution*

The architecture of the interoperability process is presented in Figure 6. A user asks for an initial electronic bank statements transaction, the adapter transforms the statements into an XML recognizable file and send it to other applications (in our case to the application that manages the expenses). This application requires:

- Internet connectivity
- User's account for the electronic banking service
- User's account for the application that manages expenses and banking transactions

The adapter transforms all different types of bank statements into a pre-defined common XML statement that can be easily used by other software products.

Figure 6 presents the process of realized adapter and interoperability of bank statements. The adapter uses a configuration tool, where the user can configure the bank statement file specification and map relevant fields into pre-defined required data format.

V. DISCUSSION

A system that manages expenses and bank transactions faces a challenge to cope with various formats of bank statements. Although one can enter the relevant data by hand copying values from statements, we aim at automatic access to the bank statements. However, the main challenge is in recognition of various file formats.

Different approaches were used in similar systems, leading to several solutions of the problem.

In the first solution [1], it is a system that allows the integration of transactions made through credit cards in the system for financial management of a company, whose goal is to perform control over the budget of the company. The integration is done through the process of settlement of transactions. The bank captures every transaction for that company before it is processed. The recorded transactions and then sent to the company.

In the financial system of the company is done

A settlement between the recorded transactions from the bank and those who reported directly to the financial system of the company by employees.

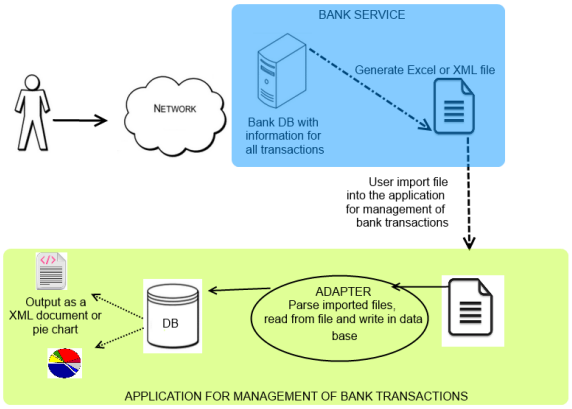

Figure 6. Interoperability process

Then based on the locked transactions, the system makes changes in the budget, plan, projects or books if such exist.

The second solution [2] is a system for monitoring and management of transactions in the process of using games in the casino. Namely, the system automatically monitors the transactions of gambling of the casino player. The system includes a casino database, which recorded the summary data for each of the many players, where each total field is associated with the identification number of the player, and includes the best rating of that player. One or more tables have multiple positions for the players and more readers' identification codes. Readers' codes initiate sessions betting in response to read the identification card of the player encoded with an identification code for that player. Communication network brings together a database table and casino gaming unit for automatic monitoring and management (ATMU). On this unit (ATMU) has a monitor and it displayed the related results. This unit (ATMU) collect data in real time of actual transactions, associated with casino database and makes settlement of transactions. Also with the data obtained from (ATMU) unit the player account is updated, according to transactions in real-time. In this way system monitoring the financial state of each player in real time and according to her system decides who has the right to play a particular game.

The third solution [3] is a system, which processes credit, debit and smart cards and related electronic transactions. The control system for the sale and the method used to connect the control unit for machine sales have input / output control lines that transmit control signals to control the operation of the machine for sale. Control devices include tools/ways to connect with the control lines of the machine for sale; means/ways for reading the control signals, tools/methods for determining an operative responses/outputs of the machine for sale, that corresponding to the control signals; means/ways for storage control signals and information for an operational responses; and means/ways for reading the stored information for control the machine for sale. The control and monitoring of transactions from the machine of sale include tools/ways for reading the magnetic data preserved by magnetic card; means / methods for keeping the approved code for specific authorized part of the transaction; means/ways for store the approved code;

means/ways for work with machines for sale without exceeding the authorized amount; and means/ways for store information about the transaction. Thus system manages transactions made between the bank and the corresponding cards issued by the bank.

In the fourth solution [4], there is a method for determining the terms of the transaction. The system and process that formed the function have a proper function identifier. This function is adapted to perform during the transaction, a point of sale transaction, which may include credit card. Systems and process include account identifier, the establishment of function that have function identifier and receipt of the request for a transaction involving account identifier, transaction amount and function identifier. Systems and process also processed transactions appropriate to the function that affects transactions, and perhaps the amount of the transaction. Also there is a consideration about the impact of the account. In addition, the system and the process are adapted to send messages to the user with the current state of the user card.

All analyzed solutions relating to projects with a specific problem, and all are doing some communication between two objects: a system of bank and system of company, the bank system with a device, functions, methods, etc. In none of these solutions there is no analysis of banking transactions per user from various bank documents.

XBRL (eXtensible Business Reporting Language) is a specially developed language to become a standard to exchange financial business information. It covers a much broader scope then the one we are analyzing in this paper. It is based on XML technologies to enable communication of business related information between business systems defined by appropriate metadata sets, taxonomies, and other relevant semantic meaning, concepts and relationships.

The scope of this paper is realization of a system that makes analysis of banking transactions per user from various bank documents. Our solution is based on building an adapter that is outside the application, and works as an independent service. It accepts different bank statement formats and outputs a pre-defined format that can be used for further processing by other applications, such as the one to manage expenses and transactions.

VI. CONCLUSION

The need for managing own finances is exposed a lot considering the dynamic lifestyle in the last decade. Banks in the digital society allow users to manage electronic transaction accounts, and control the finances. Users usually use several different bank accounts, which initiates the interoperability problem for a centralized solution and wish to control overall finances.

For this goal, we conducted research to analyze the existing solutions. We elaborated on the different approaches for the interoperability of bank statements. The existing solutions realize some analysis of the accounts, and perform connection with various devices, or produce confirmation reports of certain actions or data analysis. But none of these solutions makes data collection from different cards (debit or credit) of different banks, and provides summary reports based on the collected data.

Since our goal is to provide every user, regardless of that in which bank has his current account, to see his payments made in one place, grouped by certain criteria, we created a software solution that collects data from various formats from more banks, create a common format, then make different statements, according to which the user can see the analysis of his costs and implement a strategy for further management.

This paper analyzes the interoperability problem of different bank statement formats. The adapter solution we have developed, can understand various semi-structured formats, such as excel, MT-940 text or XML files, and also un-structured format files, such as textual files with pre-defined positions. The customization part enables the user to map the required fields onto specified formats. The Adapter is realized as a web service and can be used by other applications, such as those that manage expenses and bank transactions.

This application allows each user to analyze the transactions for a defined time period, and then to conclude a future spending strategy, which might set the proper and most efficient spending of analyzed finances.

SOCIAL NETWORKS IN THE CASE OF TOURISM IN CROATIA

Ljiljana Zekanović-Korona
Department of Tourism and Communication Sciences
University of Zadar
Franje Tuđmana 24i
ljkorona@unizd.hr

Abstract - Social networks in terms of communication are bidirectional and provide the opportunity to participate in shaping the product. In e-business social networks have made progress that will forever change the way the companies (large and small) create their image and overall performance. Social networks is a rather broad term, but what defines it in the context of e-business is the ability to communicate within the company itself and with other users. A carefully planned campaign, adjusted to social networks, can bring manifold benefits to the company business. Social networks should be mastered as they will become the primary basis for creating (and closing) future gigantic corporations and smaller companies. This paper analyzes viral marketing and the marketing of social and mobile networks through a series of examples. The development of social and mobile networks is influenced by advanced information technologies. The analysis of the results is based on the online research of social networks, where the TRI index of their users was tested together with the extent of their usage in tourism business. Further data analysis included a variety of statistical methods aimed at analyzing time and manner of using social networks in e-business.

Keywords: social networks, digital economy, Internet, information technology, e-business, accommodation.

I. INTRODUCTION

In the beginning of the 21st century the Web 2.0 technology was developed. Web 2.0 technology concerns a wide spectre of new technologies, mostly composed of blogs, Wikipedia, podcasts, tagging, predictable markets and social networking. In 2004, Mark Zuckerberg launched a web page called Facebook, later proven as a brilliant idea, because he wanted to enable virtual communication and reconnection with friends previously separated due to life circumstances. Facebook is simple to use and technologically sophisticated. The fact that Facebook is free contributes to its huge popularity. The success of Facebook encouraged other business people to try to imitate it. Existing similar web sites like MySpace, Delicious, Linkedln and Flickr had been founded before Facebook, but later they have implemented some of Facebook's characteristics. Twitter, Bobo, Ozone and Scispace.net were founded after Facebook and in their offer of Internet services they have added some other technological benefits. With the growth of social networking since 2005 until today, a large part of Internet has rapidly adopted characteristics of social media. Internet is turning into a first class social media of the 21st century, which does not reduce its business role and value. On the contrary, from the business point of view the virtual space of Internet is becoming more interesting because of the growth of its plurality and diversity, while the interest of users for the things happening in it is getting increasingly larger. From the moment the members of network see information from other members that they find interesting, they start using them as business users. The users exchange information about the business subjects they are interested in, search for a job or look for a partner which will work with them on a mutual project.

"...The amount of information on the web is really exploding. They say that from the beginning of human history all the way up thru 2003 you took all the information that has ever been recorded, you take all the books that have been written, all the films that's been produced, that's about 40 egzabytes of information that was produced in all human history up to 2003. This year (**2011**) the World is producing about **800** egzabytes of information... and all that lines up on the web...", [1]

Social networks as a form of online communication connect acquaintances and strangers in the great maelstrom of information and content, which includes all social groups. If social networks are wisely used, they can be a place where brands are created or otherwise destroyed. In order to master social networks, it is important to understand their modes of operation, and choose the one that best fits one's projects and plans of action.

B2C is the company that markets the products for the female population and has chosen Pinterest as its homepage Social Network. However, if the target population prefers to receive information in a concise text format, then Twitter is the right choice. Facebook has been so far the most widespread network with a wide range of users and companies doing businesses all over the world. LinkedIn is a great place to connect with other professionals of the kind, especially appropriate for B2B Company.

Regardless of the type of company, the way we start using social networking in doing business is always the same – identification of the target by asking four questions:

1. Who are the target customers?
2. What social networks are used by clients?
3. How much time do customers spend on social networks?

4. How do customers use social networks?

II. THE MOST FAMOUS SOCIAL NETWORKS

Facebook ranks as the world's largest social service, but it is also a very popular platform for advertising. The initial idea of a Harvard group of students was to create a network that will facilitate communication within the community of people who already knew each other. The company has existed for seven years and brings together nearly half a billion of users.

"Twitter is a microblogging service. It may also publish a variety of messages and notifications, known as the statuses of up to 140 characters. The Following are the people you follow and see their tweets / status, and the Followers are the people you have chosen to follow you. It is obvious that Twitter differs from Facebook, among other things, in the fact that if someone is your "friend", it does not mean that you are his or hers. It is not surprising that the majority of Twitter users are from the United States and that the Americans are leading in the number of tweets, but interestingly right behind them are the Japanese. Why? For the simple reason that with 140 characters a lot more can be said in Japanese than in English or another language. In terms of the market size, there are over two million Internet users in Croatia, and 1.2 billion in the world. According to the latest data there are 1.116.92010 Facebook users in Croatia, or about 50% of the Internet users, accounting for a quarter of the population."[1] [2]

Facebook and Twitter are closely linked with each other without ever having intention to do so. After first four years, Twitter, following the model of Google, introduced promotional messages on its site. A corporate Twitter account is an ideal opportunity to gain real-time feedback from the market. When in February 2009, Dell announced that they would offer exclusive benefits and promotions throughTwitter, the number of users rose sharply from 8000 in February, to 500,000 in mid-March.[2] [2]

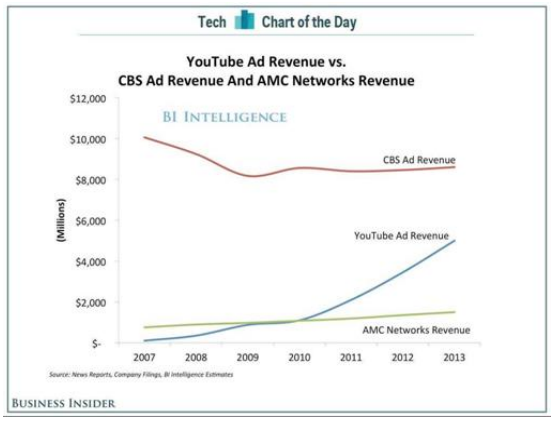
Pinterest is a relatively new social network compared to the already mentioned giants of the Internet marketing. It was launched in 2010, and promptly and significantly managed to change the structure of social networks. The emphasis is on the advertising photography and in such a way it initiated a new wave of advertising that focuses on textual minimalism. The principle of operation is a large advertising board, where users can pin the content they like and organize a themed collection.

The copies of Pinterest are appearing on daily basis. The most famous Chinese copies that generate turnover in millions for the companies being advertised on them are Mogujie and Meilishuo, and are directly associated with the giant of e-business: Taobao-m. According to the research of WhoIsHostingThis of 2014, Pinterest has more than 25, 000, 000 users and is one of the most popular social networks. 47% of online shoppers in the US have been influenced by the recommendations found on Pinterest. Each 'pin' generates approximately $ 0.78% on e-business pages - Pinterest generates four times more profits compared to Twitter does and 27% higher than Facebook.[3] [6]

One of the most popular social networks is YouTube, which daily publishes thousands of video clips. It was launched in 2005 by three former PayPal employees. Since its beginnings, the number of users, both individuals and multinational corporations doing campaigns on this platform, has been growing exponentially. "YouTube was acquired by Google in 2006 for $ 1.65 billion, which marked a new step in the evolution of the Internet. The first video 'uploaded' on YouTube in 2005 had only a few thousand views. Compare this with the most watched video of 2013 -PSY: Gangnam Style, which has had a staggering 1.3 billion views."[4] [3] The common feature of all social networks is non discrimination of users by the size of their income. YouTube is a platform that strives for constant development and integration with other social networks. In 2011 they confirmed the cooperation with the social network Google+ and moved into a new age of viral marketing.

Viral marketing is the attempt of creating an advertisement that will be orally spread online.

YouTube – ideal for viral marketing



Picture 1. YouTube and viral marketing

LinkedIn is a unique platform that has developed a special identity as a social network for professionals. But it has gone a long way since its beginnings (2003) as a forum that allowed employers to review one's resume and job seekers to see ads for vacancies.

„Engagement is rising fast on LinkedIn, as the social network becomes a content destination. The social network is also high-income and highly educated, and it has a big international presence. These factors will make LinkedIn increasing compelling to marketers. Already, a survey from Cogent Research finds that LinkedIn is the

[1] p.171.
[2] Ibid.

[4] Zarella, D.; *The Social Marketing Book*; O'reilly, Canada, 2010, p. 7

preferred social network by a wide margin for building a brand identity. “[5]

Nowadays, LinkedIn has a pseudo-monopoly in the sector of connecting employees and employers, and in the future we can expect its further growth and gradual monopolizing. It is important to note that LinkedIn is not blocked in the People's Republic of China as Facebook, Twitter, Google and YouTube are. In addition to the network itself, also available are the tools which contribute to building better relationships among the contact members. Fivehundredplus enables the sorting of contacts by the frequency of communication. The Rapportive is the extension of Gmail and displays the details of the LinkedIn profiles of the persons you communicate with and allows you to connect with them.

"According to the Jobvite Social Recruitment survey roughly 80% of companies use social media to locate a new labour force; 95% of them use LinkedIn."[6] [4]

Picture 2. The best choices of social networks for B2B and B2C[7]

III. TRI - Technology Readiness Index

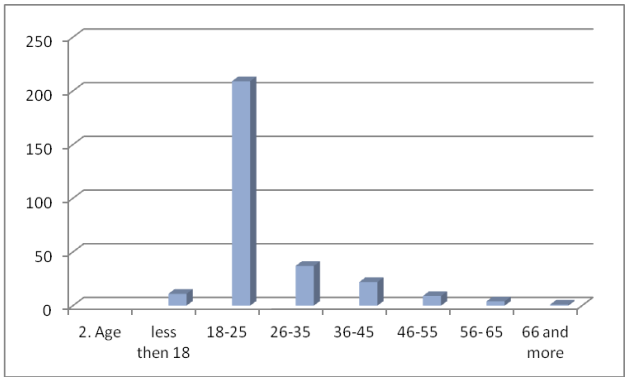
In the questionnaire there was a set of questions from which the TRI-index (*Technology Readiness Index*) was calculated for every respondent. Technology Readiness Index (TRI) is used to calculate the willingnes of respondents to adopt and use new technologies. This index is based on the scale of feelings that the respondents express towards new technologies. Components, i.e. feelings covered by the TRI-index are: optimism, innovativeness, discomfort and insecurity. The above feelings are measured by Likert scale as a series of statements in which the respondents can assess how much they agree or disagree with a given statement on a scale of 1 to 5. The obtained results can show us how much a particular individual or respondent is willing to accept new technologies. Readiness assessment includes the evaluation range of -20 to +20. If the above assessment scale is divided into five equal parts, it is possible to distinguish the following categories of respondents:

1) people reluctant to use new technologies (from -20 to -13)
2) paranoids (from -12 to -5)
3) skeptics (from -4 to +4)
4) pioneers (from +5 to +12)
5) researchers (from +13 to +20).

Therefore, if the level of TRI-index is higher, the tendency of respondents to the acceptance and use of new technologies is larger.[8] [5]

IV. The Questioning Method

The testing was conducted through an online questionnaire which was originally placed on the Facebook wall so that it could be accessible to the entire population of users. The online survey was opened during December 2014 and during that period a random sample of 293 respondents filled it out (245 females, i.e. 83,62% of the sample and 48 male respondents, i.e. 16,38% of the sample with the average age of 25 years). The age structure of respondents is showed in the picture 3. The online questionnaire consisted of 20 questions and all the questions in the survey were closed type with multiple choice answers. The limitation of this research is the fact that questionnaire was published on Facebook, and not on other social networks, as well as the fact that only the users of social networks were included.



Picture 3. Age structure of respondents

Picture 4. shows the age groups of Facebook users in the period between 2005 and 2010. Comparing these two pictures, it is obvious that our group of respondents, considering the size of sample, is correlated to the whole population of Facebook users.

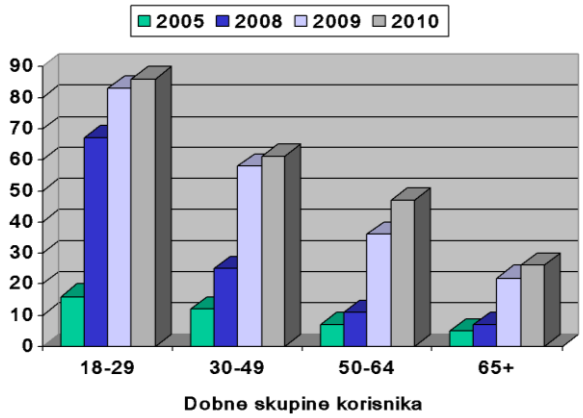
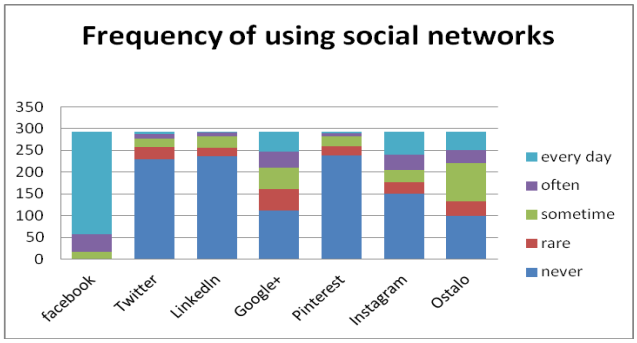
[8] Zekanović-Korona,Lj, Grzunov.J.: Evaluation of shared digital economy adoption: Case of Airbnb, MIPRO DE,Opatija 2014.



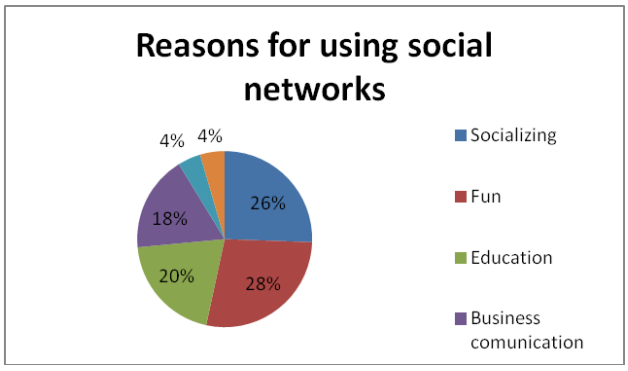
Picture 4. Age structure of Facebook users

The research results lead us to conclusion that the most popular social network is Facebook. In the tested sample there is not a single respondent that has never used Facebook, and 80% of the respondents use this social network on daily basis. The research results indicate that of all the networks the most common are Instagram and Google+, while the least preferable social networks are Pinterest and LinkedIn. (Picture 5.)



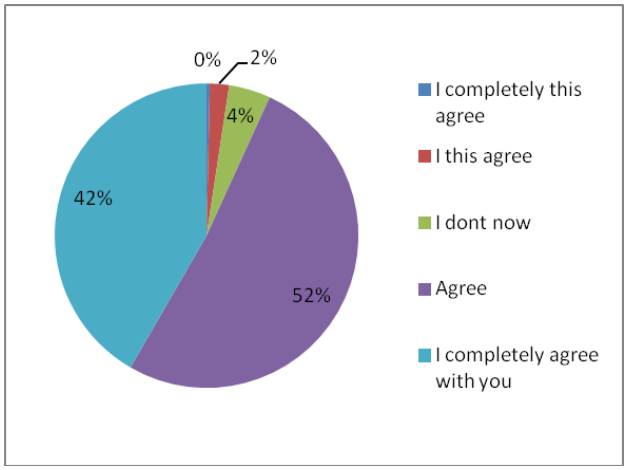
Picture 5. Frequency of using social networks

The Analysis of the survey results indicate that the respondents most often use social networks for fun and socializing, and they least use them without a clearly defined reason. As tourism covers travel, recreation and leisure, a logical conclusion would be that social networks are used largely for tourism. It can be said that tourism is one of the aspects of entertainment and socializing (Picture 6).



Picture 6. Reasons for using social networks

The survey was meant to determine the correlation between the use of social networks and tourism and it turns out that more than 50% of the respondents believe that they certainly facilitate access to information about people as well as tourist destinations. Only 2% of the respondents believe the opposite. (Picture 7)



Picture 7. Correlation between the use of social networks and tourism

The survey of the reasons, time spent on social networks and activities carried out on them was followed by measuring the satisfaction of the respondents with the quality of the content they consume on social networks. Although the largest proportion of the respondents (49%) are satisfied with the quality of the contents on social networks, a significant portion of them, slightly more than 40%, are only slightly satisfied.

Considering the age structure, we got the expected percentage of the respondents with respect to the TRI-index, i.e., sceptics 57,67%, paranoids 5,11 %, pioneers 33,79%, and researchers 3,4%.

The research results from this sample indicate that IT literate respondents use several different pages made for the purpose of accommodation renting and the review of the tourism offer. For example, the groups of Sceptics and Paranoids do not visit such sites, and the respondents from the group of Sceptics mostly use famous sites such as Booking.com and Airbnb for the purpose of accommodation renting while TripAdvisor, Booking.com, Futurama and Black egg are used for reviewing the tourism facilities. The respondents from the group of Pioneers, beside the above mentioned, also use some less known sites such as Couchsurfing, Hostelbook, Apartmanija, Galileo, Lonely Planet, Putovnica.net and the like. The least numerous group of Researchers, mostly use Booking.com in order to find accommodation and TripAdvisor for the reviews of hotels, restaurants, etc.

Today there are many social networking sites that offer a variety of activities to their users. One of the hypotheses of this study was to examine the association between the use of particular social networks and the basic activities performed on them. The questionnaire included a wider list of the most common and most popular social networks in the world today. The respondents in this study most commonly use the following social networks: Facebook, Google+ and Instagram. The testing of the hypothesis is based on three

most common social networks and the basic activities related to them.

The Chi-square test (χ 2) was 4.965 (p = 0.05, df = 6) and it found no association between the use of certain social networks and the basic activities that take place on them. Due to the multifunctionality of social networks it is very difficult to determine which network is suitable for the relevant activities (information sharing, publishing photos and videos, making friends, and communication and information about tourist destinations and travels).

With regard to the TRI indexes in this survey, the dominant groups are Sceptics and Pioneers. The testing hypotheses (χ 2) is the association between the level of computer literacy and the basic activities of respondents on social networks. The result is 9.267 (p = 0.05, df = 5), and we conclude that there is no mutual association, or regardless the level of computer literacy, the respondents use social networks for the same or similar reasons.

The level of computer literacy contributes greatly to respondents' views and attitudes towards social networks and the way they facilitate the availability of information about tourist destinations. It was also tested with (χ 2) test The result of the test was 9.49 (p = 0.05, df = 3), and we conclude that the higher level of computer literacy contributes to the wider use of social networks for getting information about tourist destinations. The higher degree of TRI means the openness of the respondents towards the acceptance of new technologies, and thus easier collecting of all kinds of information, including information on travel destinations.

The hypothesis on the association between the level of computer literacy and the time the respondents spend on social networks was also tested. The computer literacy variables and the time spent on social networks were used in calculating the chi-square. (Table 1)

Table 1: Time spent on social networks

	Less 2 ours	3-4 ours	more then 4 ours	∑
Sceptics	65	72	32	169
Pioneers	42	40	17	99
∑	107	112	49	268

The resulting value of the chi-square is 0.424 (p = 0.05, df = 2) and we can accept the null hypothesis that there is no association between the level of computer literacy and the amount of time spent on social networks. The lack of association between the level of computer literacy and the time spent on social networks can be interpreted by the fact that the time spent on social networks is more dependent on other variables such as free time and work status.

For most of the companies that conduct research in order to improve their business, an important part of the research is the satisfaction of users with their services. The study tested the hypothesis of association between the level of computer literacy and the satisfaction with the quality of the content the respondents consume on social networks. The resulting value of the chi-square is 9.49 (p = 0.05, df = 4), and we can conclude that the ICT educated people are more satisfied with the quality of the content they use on social networks. It is probably because they use particular social networks for the purpose they are meant for (eg. LinkedIn for business communication) and they know how to take advantage of all their possbilites while those with less computer literacy are more likely to use only a limited range of many possibilities offered by social networks.

IV. Conclusion

Social networks are increasingly gaining popularity among different age groups of users. A number of existing prejudices about the use of social networks were tested in this paper through different statistical methods.

The increased use of social networks for tourism purposes is proved by the fact that almost 50% of respondents answered that the information about tourist destinations and travel is one of the main activities they perfom on social networks.

Social networks made information about tourist destinations much more available to the largest part of the respondents. Considering a large number of social network users that is growing every day, social networks have beome an everyday source of first hand information about the whole offer of a tourist destination. All the users of social network will inform themeselves about accommodation and restaurants before the journey. The research results confirm that more ICT literate respondents frequently use online tourism offer. There is association between IT literacy of respondents and the use of technology for the puropose of getting information about tourist destinations. Tourism and e-business are strongly correlated and therefore we need ICT literate users. Population should be constantly educated so that information and communication technology can be efficiently used in tourism and other other related fields. In Web 2.0 environment and in business, various companies have their own on-line client communities that are showing tendencies toward social networking, which is understood as the improvement of e-business. For the purpose of tourism travelling, and especially for choosing a destination, it is important to know the experiences and impressions of the users that have already visited the same destination. Virtual client communities are groups of people in mutual interaction by means of ICT. The users of virtual communities share their concerns, problems, interests and passions toward particular issues. Numerous companies want to achieve active cooperation with customers and to collect data from them through the use of e-business and social networks. Computer literate users of social networks are more satisfied with the content offered by social networks because they know how to use all available opportunities they provide. The respondents mostly use Facebook, which was the expected result given the fact that the questionnaire was placed on it. The research should be repeated on a bigger sample and among older respondents, and the

questionnaire should be placed on other social networks in order to obtain a better dispersion of results. Almost 50 % of the respondents are satisfied with the quality of content on social networks (49%), 40% of the respondents want changes and improvements This research shows that there is still room for innovations in business communication, and they can be introduced in the domain of social networks through ICT.

Financial Agency FINA and Online Auctions in Croatian Amended Distraint Act

Anton-Jan Klasinc
Vertex projekt d.o.o.
Institute for Public Administration, Zagreb, Croatia
e-mail adresa: ajklasinc@gmail.com; vertexprojektmail.com

Abstract – This paper presents an analysis of the newly amended Distraint Act in Croatia, concerning foreclosure and sales of properties. The idea behind the act is that making sales of foreclosed properties more transparent by the means of online auctions can create gains for both the foreclosed and the state. The banks may also profit from better repayment of defaulted loans. The unamended act provided that the properties are put on sale by the court in execution proceedings, and those sales were conducted by dealers that saw their interest in lowering the prices. This apparently meant that properties were sold below the market prices and that loans were still not payed off when the sale of property was concluded, which also presented a useful opportunity for some buyers of properties to make profits, as well as for dealers themselves, while the state did not collect as much as it could have and the process of selling was slow. With online sales of properties the process becomes more transparent and it can reach larger number of potential buyers, which could increase the price and profits for both state and the former owners of those properties that are in debt. However, a similar act in the Netherlands provided that the properties should be sold through private online auction resellers, while in Croatia this is given to the government financial agency FINA. The problem is analysed from the perspective of principal agent theory, and from the perspective of supply and demand.

I. Introduction

Recent changes to the Distraint Act have been criticised by some for allowing too much discretionary power to FINA – executive Financial Agency in Croatia, and tranferring the issue from Commercial courts. A similar problem has already occured with the issue of pre-bankruptcy proceedings, where the main power has been transferred from commercial courts to the executive (Ministry of Finance). We analyse and propose a model for new Distraint Act based on principal agent theory, demonstrating that private companies have lost a significant amount of bargaining power arising from assymetric information allowing them to obtain significant gains in under-the-value sales of property. The ammendments were introduced in order to obtain better values for sold properties, or as close to the market value as possible, and on the other hand for the sake of preserving debtors' from being deprived of their property for a scarce value of the original debt, leving them still very much indebted after the sale of the property with which they guaranteed for the debt.

II. Theoretical Background and methodology

A common problem with real estate sales is that if buyer and sellers have some special relationship, they may agree on a lower price than the real price of property should be if the buyer and seller were strangers. This is generally known as principal-agent problem, where conflicts of interest and moral hazard may arise. The solution for this is to employ arm's length agencies that are supposedly indifferent and can not be influenced in transactions, acting in their own best interest as well as in the interest of their principal. In reality, situations which present moral hazard are quite common, especially in financial industry and real estate. In addition to this, they are also very difficult to control and prevent, and things are even more complex when the government is involved as principal or one of the parties.

We would like to begin by describing a simple model of an oligopolistic market with firms acting as principals trying to distribute their products through distributors acting as agents. This could be compared to the government acting as principal, trying to sell foreclosed properties through commercial courts which are then able to offer the property on auction s to private resellers as agents that offer them to final buyers on the market. The commercial courts are independent from the executive government in their operations and may offer the foreclosed properties on auctions. So far, the volume of sales was too low and the prices achieved also much lower than market prices, as the low provided for two auctions of 2/3 and 1/3 of market value, respectively. One reason could also be that the budget for commercial courts is fixed, with no possibility of extra bonus or motivation for judges conducting sales, or rewards for better performance, which could also lead to moral hazard on their part (e.g. bribes by resellers and/or debtors).

In the ammended act, the courts are obliged to transfer all requests for sales to FINA financial agency which then conducts online auctions. The argument for using online auctions instead of conducting sales directly through commercial court is that online auctions make sales available to a larger number of potential buyers, thus enabling larger competition and higher prices of foreclosed properties (near or equal to prices on the market), which in turn benefits the both creditors and debtors, as the latter are left with less debt to repay. It would also mean that the government investment into an

executive agency conducting the sales would provide for a faster and more effective sale process, which would result in larger volume of sales and consequently more income would be generated. However, this would hurt the private sector resellers that form an oligopoly and profit from the original Distraint Act. They would now have to appear as „ordinary buyers“ on online auctions with information readily available to everyone, so they would not be as motivated, as they would not be able to make profits from the difference between auction prices and market prices, and the government as a whole may also incur losses due to excessive and unnecessary investments that are not controlled by the market forces, as it would now have to conduct operations through its executive agency that may prove to be more expensive.

Monopolistic government firms replacing free market are not uncommon in Croatia, as on local level a recent study found a number of government owned firms (usually registered as ltd. - d.o.o.) doing business for local governments that could have been better left to the free market competition, except for, perhaps, community services (waste disposal, water, etc.).

From the above also follows that, the information about auctions being completely transparent and online, the absence of asymmetric information would allow for better volume of online auctions and fairer prices. This, of course, would increase the profits for all sides except for a few private real estate agencies.

On the other hand, it can be shown that in oligopolistic industry that consists of identical firms, a subset of firms may find it optimal to commit to face asymmetric information about their agents' operations. Therefore some firms may choose to incur informational agency costs, even though information is avilable at no cost. The commitment to face asymmetric information is also a commitment on the part of the firm not to extract the entire agent's surplus and so agents have incentive to make a specific investment that increases firms' expected profits. The level of this investment increases with the proportion of firms that are not informed.1

Uninformed firms always produce lower quantities than informed firms and the expected quantity of output in the industry is lower when there are uninformed firms. Informed firms' agents do not make any specific investment whereas uninformed firns' agents make a strictly positive investment. Since informed firms can extract all the agent's surplus, the latter does not have any incentive to make the investment. By deciding not to acquire information firms commit themsleves not to extract their agents' surplus and thus give a credible incentive to them to make specific investments.1

Therefore, in the case of uninformed commercial courts and oligopolistic resellers, the volume of properties sold at auctions would be lower and the output of debt repayment would be lower than if the information about auctions was readily available to everyone.

The level of investment in a government controlled or owned agency, such as FINA, is determined by its budget and not by market laws. In general, the level of specific investment in such agencies may be shown to rise in general, while not increasing efficiency and effectiveness at the same time, which presents a specific type of moral hazard where investment may be extracted through corrupt means or contracts with preferred suppliers (e.g. of IT equipment and services) as well as hiring preferred staff (cronies, party members).

The problem of online auctions and sales through private agents is essentialy a principal-agent model, which is also well known in the context of a monopolistic upstream market. Acquiring information has the benefit of eliminating asymmetry of information between each firm and its agent (reseller). 8However, it has the shortcoming of eliminating incentives to make specific investments on the part of the agent.

In our case, „upstream firm“ or the principal is the executive government and the debtor (as „producer“), and the „downstream firm“ or the agent is either (i) the judicial branch of the government with its commercial courts selling almost certainly below market prices to a certain limited number of firms, allowing them to profit from the difference between auction and market prices; or (ii) the monopolistic government agency FINA selling to virtually all potential buyers via online auctions; or (iii) an oligopolistic market of resellers which may be entirely owned by government (FINA) in which case there is no information assymetry, or private resellers that benefit from information asymmetry and need to make specific investments in order to facilitate sales, acquire greater volume of sales and speed up the process.

It has been shown that in considering a fixed cost of acquiring information, circumstances may arise under which one firm decides to acquire information, and the other does not acquire the information even when both firms are equally efficient. 1Therefore, even if the financial agency FINA has made information available to every potential buyer for a fixed cost, it is still possible that it would not be more efficient than several private oligopolistic resellers operating under information asymmetry and same fixed cost.

This, in turn, would mean that in the case of government monopoly on online auctions the cost to the government could rise due to lack of market control of specific investments that it is obliged to make, and the volume of sales may not increase as fast as if the operation were left to private sector that could be taxed and would still have incentive to make specific investments on their own, in order to make profits. The taxation and contributions from the private sector, however, could be greater than the amount that government agency FINA could earn as a sole operator.

In fact, the level of investment in FINA could in the end be equal to the surplus that would have otherwise been extracted from the agents (private resellers) in case of commercial courts as prinicpals, but as in this case the principal is informed about the results and targets, but not about the costs and FINA is allowed to project its own out-of-budget costs, the largest portion of increase in volume of sales would go to the repayment of debtors' debt to the banks and covering FINA's operational costs

and specific investments into equipment and human resources, that may exceed by far necessary levels.

As FINA is a public agency, it could be argued that with proper management and controlling it would not be motivated to make unnecessary investments and that it would operate at optimum level, allowing the maximum repayment of debt with government costs well covered. 2 However, actual examples of Croatian ministries and so called arm's length agencies show that they overspend if they are legally allowed to do so, even on very expensive and unefficient premises, vehicles, and other products and services, as well as on employees' benefits and unnecessary hiring of staff.

III. New Croatian Distraint Act, online sales and comparison of with Netherlands

The new amended articles of Croatian Distraint Act stipulate that:

- Agency conducts the sale of property. The request for sale is submitted by the court. The court is obliged to submit to the Agency the foreclosure act, deeds of the estate and the sale decision.
- Agency has the right to request advance covering its costs related to the sale of the property. The distrainor is obliged to pay advance to teh Agency within eight days from the day of receipt of the payment request. If the distrainor does not advance the costs, the Agency shall not conduct the sale of the property, and shall notify the court instead. In that case, the court shall terminate the foreclosure.
- Sale of the property is conducted by online auction (OA). Online public auction begins with the publication of the call for participation in the OA.
- »Online auctions shall be carried out even if there is only one bidder.«. (Article 48 amending Article 100)
- On the first OA, the property shall not be sold under 4/5 of the assessed value. (Article 49 amending Art. 102)
- On the second OA, the property shall not be sold under 3/5 of the assessed value
- Bid collecting shall last 10 workdays. If on the fist OA no valid bit is collected, the second OA shall start with the publication of call for participation, first day after the end of the first OA
- If even on the second OA no valid bid is collected, Agency shall notify the court about it. In that case, the court shall terminate the foreclosure.6
-

The main difference between Croatin procedure and a similar procedure in the Netherlands is that there is no centralised government agency that performs online auctions at the request of the court, but instead there is a market of reselling private agencies organising online auctions.

IV. Available Statistical data on distraints and foreclosures in Croatia

According to the Government Statistics Bureau, the average price of an apartment in Zagreb was 1460 euros for square meter, but in case of foreclosed properties, the price was as low as 775 euros, for an apartment of 90 m2 that was estimated at 2280 euros per square meter, or only 1/3 of the real price. The evidence of properties (*očevidnik nekretnina*) of Croatian Chamber of Commerce shows 140 foreclosed properties in August and 6658 in whole 2014., and 3038 of those were apartments (1170) and houses (1868), most of which are located in the city of Zagreb (601), Zagreb county (600) and Istria county (1455). Among them is an apartment estimated at 1950 euros per m2 that can be purchased for only 1300 euros.45

Table 1

Foreclosed properties – Year/Number	
2008	2106
2009	2579
2010	3664
2011	4266
2012	4784
2013	6733
2014	6658
Total:	**30790**

The old act allowed for properties to be sold at 1/3 of the real price, but new rules provide that price can not be lower than ½ of the real price, which is not true for apartments sold in bankruptcy cases.

Type of property	Foreclosed in 2014
House	1868
Apartment	1170
Building	332
Arable land	1034
Meadow	208
Business premises	213
Forest	213
Pasture	366
Apartmental and business space	42
Hotel	6
Total	**6658**

The judge on the first auction lowers the price to 2/3 and if it remains unsold, to ½ of the real estimated price in the second auction. In case of bankruptcies, on the first auction the real price is offered, which lowered by 10% on each subsequent auiction, and ½ of the price is than reached in 5 auctions – however, there is no lower limit for the price in this case.3

V. The model of the problem

The problem which should be solved requires the level prices achieved by the sales to be as close to the

market value (optimum), while repaying the maximum amount of the outstanding debt and achieving the best possible value for firms competing for the property, while also trying not to increase the cost to the state to much. This also means eliminating as much as possible the profits of those firms, in terms of difference between market value and the value achieved by the sales, but also limiting the cost of the Financial Agency FINA. As this is essentially a social measure requiring state intervention, it differs from similar models in other (market oriented) countries, where firms compete openly on private online markets, whereas in Croatia, the government FINA – Financial Agency is a mnopolist. In the case of private firms, they may acting as resellers, they may be motivated (and generally, are) to invest into human resources and equipment, while in this case it is the government that has to invest into these things – namely in its agency, FINA, in order to achieve the proposed results. The cost to the government including loss of employment in private sector and taxes to private sector should not exceed or should be at least equal to the increased repayment of debt to the lending institutions and guarantors, additional employment in lending institutions and the gains in terms of reduction of social welfare to debtors that are left without property (foreclosed).

In this case, it is a principal – agent problem in which the efficiency of the monopolistic state agency FINA should be greater or equal to the efficiency of several oligopolistic private resellers (some of which may be owned by the government).

The demand function relates price and quantity. It tells how many units of a good will be purchased at different prices. In general, at higher prices, less will be purchased. Thus, the graphical representation of the demand function (often referred to as the demand curve) has a negative slope. The market demand function is calculated by adding up all of the individual consumers' demand functions.

Assume n debtors that are trying to sell the same type of property (e.g. a house) through government auctions and face a linear demand function given by

$$P = a - Q$$

Where P is the clearing market price, q_h is the output of debtor h and $Q = \Sigma^{n}_{h=0} q_h$ is the output of properties. We assume that debtors compete in quantities and we normalize the production costs of properties to zero. It is also assumed that a is large enough for the equilibrium quantities to be always positive.

If the total number of debtors q_h is high, Q will also be high, and the clearing market price will be lower than it could be achieved on the open real estate market. So, a is actually a function of the number of prospective buyers, N and likewise n_h for each respective property.. With a larger N, both P and Q may rise, or just P, which than gets closer to the proposed clearing price.

$$P = xN - Q$$

Solving for x on a sum of all properties with its prospective buyers yields:

$$\Sigma (p_h + q_h)/ n_h = x \quad ; \qquad \Sigma n_h = N$$

Where x obviously depends on the amount of available money that each buyer n in n_h is willing to invest in a property h. With the rise of n_h, x should become greater, as more buyers will compete and have more incentive to invest money in order to buy property and not just to resell it, until they reach the threshold at which they have virtually no utility. P will rise simultaneously with the volume V of sales of Q (V = QxP), and after that point, P will start to drop again, although the number of sold properties Q may remain at the same level. This can be determined on the basis of statistical data over a period of time, where $P = \Sigma p_h$ and $Q = \Sigma q_h$. As the number of buyers is lower in the case of an oligopoly of private resllers than in the case of ordinary buyers, registered on online auctions, it is certain that the price P in that case would rise, even if the number of sold properties rises as well, and the volume of sales shall grow as P x Q. If the average number of available buyers N is increased by online auctions from 10 to 100, or even 1000 for some attractive properties, x would drop, but the product xN would still be higher than the original number, thereby increasing the price P closer to the value of market value of the property (above 1/2 of the market value, i.e. 4/5 or 3/5 of the market value instead of 2/3 and 1/3 respectively for first and second auction).

The average debt of all debtors q_h is the amount of D = Q x a/2, where P = a/2 is the equilibrium price which gives the real market value of foreclosed properties. The actual amount of debt repayment that may be achieved on sales is lower. By data analysis, a in Croatia is rougly equal to 5000, and a/2 (or equilibrium price) is 2500.

As we know, the sales are usually governed by power law or Paretto principle that says that 20% of properties make 80% profits to private resellers and 80% of properties make 20% profits. In case of auctions organised by courts, the prices are set at 2/3 in in the first and 1/3 of the market price in the second auction. If market price is 2500 euros per m2, that means that 2/3 is 1667 and 1/3 is 833 euros, respectively. In case that we have 4000 properties on sale, 800 properties make 80% of the profits for resellers, and 3200 make 20% profits. In fact, it is almost certain that those 800 making the most profits are large apartments (e.g. 100 m2) located in city centers or large houses. The other 3200 may be smaller apartments, or smaller houses in villages. Supposing that we have only 2 types of property, an apartment of 100 m2 and an apartment of 12 m2, the first should be sold in 800 sales and make 80% of profits, and the second in 3200 sales and make 20% profits. It is clear that the first would be sold in the second auction (for 1/3 market price, or 833 euros), and the second in the first auction (for 2/3 market price, or 1667 euros). In the first case, unpayed debt would be 133,365 million euros, where each property was deemed to be worth at least the amount of credit at market price of the property, or 250000 euros, as only

83300 euros would be payed for each such property. In the second case, each property worth 30000 euros of credit would be repayed with 20000 euros, which would leave only 3,2 million euros of outstanding debt, but the profit for resellers would also be considerably smaller, as they would not be able to make a large difference between actual price and market price, for a larger number of much smaller properties (12 m2). If the government took 10% on each deal, it would earn 10 million euros in the first and 6,4 million in the second. However, if sold at ½ market price, the sales for private resellers would be only 100 million euros, but the state would cover 10 million instead of 6,664 million euros, which is 3,337 million euros more, whereas in the second case private resellers would take 48 million euros, or 16 million more, but the state would take only 4,8 million euros, which is 1,6 million euros less than original 6,4 million euros. In total, the state would gain 1,737 million euros, or about 14,02275 million kuna, that it could use for financing the operations and specific investments of financial agency FINA, instead of employing private resellers, that would lose a total of about 17 million euros. If 1/3 was their profit, 1/3 used for investment in equipment and 1/3 in employment (human resources), and 1/3 is 5,7 million euros, than 20% of the first and ½ of the third would return to the government as profit tax and contributions for employment to the state, and income taxes, which means that the government would cover at least 1,14 million euros and 2,8 million euros or a total of 3,94 million euros from the private sector if online auctions were left to the private sector. On the other hand, if FINA was the sole monopolistic operator on the market, it would make only about 1,74 million euros for the government, or, in fact, government would lose about 2,2 million euros, or about 16,5 million kunas, which is an amount for which it could set up a whole new agency! However, if we looked at the budegt of the agency, we may notice that the government has taken this in the account and that it has already invested in both amounts, or about 30 mililion kunas, instead of 14 million kunas that it can actually cover from the operation. Actual budget for the actual FINA agency confirms this hypothesis.

In case the first auction is set at 4/5 and second at 3/5, the figures are even worse, and show greater loss for the private sector, and greater gain for the government and the banks, in terms of taxes and debt repayment. In this case, government would gain about 5,6 million euros, but it would lose about 13 million euros contributions from the private sector in taxes and contributions, which would amount to a loss of 7,4 mil euro, or about 55,5 mil kuna.

At the beginning of the game, executive government on behalf of the debtor employs a commercial court and its judge acting as an independent agent for the provision of reselling services on the open market, or a monopolistic government agency FINA, or a number of private resellers acting as agents, supposing that debtors may choose their preferred agent. It is assumed that except in the case of a monopolistic reseller there is a competitive market for identical agents and the equilibrium contract in this market is such that the expected utility of agents equals their reservation utility U, which is normalized to zero. At this moment in the game, the executive government cannot write a complete contract specifying the remuneration of the agent and the level of output (volume of sales) that must be delivered.

Since agents anticipate that informed government representing debtors will expropriate all benefits of their investment, they do not have any incentive to invest. In case the government is not informed, the situation is rather different: the executive government representing debtors must pay a rent to their managers when the good state is realized in order to maintain incentive compatibility.

The commitment to face asymmetry of information is also a commitment of the part of the government not to extract the entire agent's surplus and so agents have incentive to make a specific investment that increases governments' (and debtors') expected profits. The level of this investment increases with the proportion of cases in which government is not informed (such as particular debtors in forclosure cases on commercial courts).

In case of a monopolistic government agency, however, it is still a question what the optimum initial investment on the part of executive government should be and how to calculate it on the basis of available information

If the increase in sales volume is Q, the government may be able to collect a certain money per sale for its services. The total sum of this should not be lower than the initial investment that was made into FINA in order to perform online auctions of foreclosed properties, and all the proper registrars, and to to this instead of commercial courts, that are already prepared for this job better than executive government.

If the monopolistic government agency is used, the government also has to write a contract specifying the remuneration of the agent with the agent although it is not really informed, and it cannot specify the level of output that must be delivered. It just assumes that the level of output must be greater if it makes the investment in first place, but it doesn't actually know by how much. On the other hand, it cannot simply write off the previous investment in commercial courts, as the courts still have to exist, so it could lose all its investment if it doesn't meet the target in which whole loss would be covered by the extra output reuturns. In addition to this, it cannot have returns in terms of taxes, because Croatia doesn't have a property tax, so the government has deprived itself of one important way of covering back what it has invested, and can only use guarantees for bidders. The only real return it can actually have for its investment is to reduce the burden of debtors and creditors, hoping that this will somehow materialise in lower social costs to the government and higher level of contributions and taxes. However, if the initial investment is not well suited (if it is too high) it will be difficult for government to motivate the agent to achive higher output targets. If the investment is too low, the agent may entirely miss the target, and the operation will be a failure. Therefore,

without the market mechanisms working, it is almost impossible for the government to estimate what the optimum level of investment should be – and that is probably the reason why other countries would never opt for a monopolistic government agency to do the job.

In this model it can be shown that FINA is not necessarily more efficient in terms of cost to the government, although wtih the changed rules it may be more efficient in terms of increasing debt repayment to the banks because of better value achieved for sold property. Therefore, it may be concluded that the model is generally profitable for financial institutions (banks), somewhat less so for the debtors, and detrimental to the private sector and contributions of private sector to the government. In order to improve the efficiency of FINA and cover these contributions, it would be necessary to allow competition between FINA and private online resellers that would have to meet the same standards of transparency in online sales, as the government monopoly in reselling is not the optimum solution for this market in terms of cost of human resources and equipment.

VI. Policy recommendations

It would therefore be advisable to reduce the scope of operations of FINA financial agency and perhaps to stimulate private sector to make specific investments in online auctions, as it is done in Netherlands and other countries, although it could be necessary to leave a certain scope of operations to FINA in order to determinme whether the market forces are sufficient to handle the demand and supply and to intervene on the market as necessary. However, squeezing private market out with a bloated government agency seems to be a less efficient solution.

The fact that Croatia doesn't have a property tax makes it difficult to assess the exact amount of profit made by private agencies. Therefore, it would be necessary to introduce a property tax of at least 1,5 % to 3% in order to achieve the goal of government „breaking even“ or perhaps achieveing a small level of profitability with respect to the situation where no property tax exists and private resellers are not allowed to hold online auctions.

As the investments in human resources (employment) are among most important investments that provide a lot of resources to the state budget in case of private employment, it is necessary for the state to stimulate private employment and investment of private entrepreneurs in human resources by providing adequate measures and subsidies, which are more suitable than further employment in the public sector.

VII. Conclusion

In this paper we have proposed an analysis of a recently amended Croatian Distraint Act within the framework of a demand and supply model for online auctions in which in the first case we have a monopolistic agency acting as provider of auctions, in the second case an oligopolistic market of resellers without auctions and in the third case a market of private online auction agents together with the government agency. It is cleary the third case which is the most efficient and effective, and this has been shown by our modelling. The model in which commercial courts act as principals conducting the sales of property through an oligopolistic market of bidders - resellers and final buyers is vulnerable to conflict of interest and moral hazard, which can reduce the price of the property and lead to „power law“ distribution of profits, reducing debt repayment and government finances, whereas the model with a monopolistic arm's length agency is economically not viable, as it is practically impossible to determine the proper initial level of investment in order to obtain the desired output (results). The market element increasing the efficiency of FINA and more favourable to state budget could be introduced by allowing for private online resellers in auctions, that would serve as a benchmark for the government agency, which would in turn prevent moral hazard of employing more staff or spending on unnecessary equipment, while the government agency on its part could reduce the moral hazard of oligopolistic private reselling firms interested in lowering the price of properties on auctions too much in order to make more profits. As to possible uncstitutionality of the Act, it should be noted that it does serve some better than the others, such as banks and debtors, but not citizens in general or the private sector.

***Abstract*—Todays dynamic economy enforces the companies to dismiss their minor-business departments and to turn the efforts towards the main business. This is emphasized especially to small and start-up companies, which would like to order the issues as a service from third parties as OPEX (Operational Expenditure), rather than investing in their own departments as CAPEX (Capital Expenditure). Even more, they expect to achieve their orders as faster as possible. Since the number of such companies is floating, as well as the number of their employees, these requirements demand a scalable system for e-ordering. Such a system will allow the consumer companies to order some services from the sellers. In this paper we present scalable architecture in the cloud, which can be offered as a service both to the consumers (buyers) and clients (sellers), along with two business models according to the market in a particular region or state.**

***Keywords*-Business, cloud computing, e-Ordering, SaaS, services.**

I. Introduction

Until about a decade ago, a lot of enterprises hosted their software on servers in their own data centers. Enterprises conducted detailed analysis and developed a strategy on how to design and maintain the datacenter. The building of such a complex data center was usually conducted in several phases in a period of several months to several years. The dynamic life and ICT growth could not have been predicted easily and thus lead towards huge losses or even bankruptcies. Also, the board of directors spent a lot of effort on the non-business ICT issues, rather than on their main goal.

Small and medium enterprises usually did not have such problems since they could not afford to build and manage their own data center, which forced them to use third party hosting [1]. This approach offers them to be more flexible in choosing the hosting provider, but still other issues and challenges arise: vendor lock in, third party dependence, security and privacy issues, lack of elasticity, etc. Recently, the new paradigm cloud computing has emerged. The cloud removes the need for the user to install any software on premises [2]. Running software remotely can be more cost effective [3], because of the reduced man hours and days for maintenance and administration, power consumption, etc. In order to provide these cost savings, the cloud providers charge their customers on a subscription basis. As a result, companies can spread their budget more efficiently and focus on growing the business [4].

Cloud computing paradigm matured over time, attracting enterprises that are seeking to make the most of todays technology at lower costs. That is, enterprises are not obliged to invest in any software or hardware. They only pay for what they use. In general, the cloud services are divided into three layers: Infrastructure as a Service (IaaS), Platform as a Service (PaaS) and Software as a Service (SaaS) [5]. Each layer uses the services of the layers below. The IaaS layer is the lowest layer in the cloud architecture, while the SaaS layer is the highest. Going from IaaS to SaaS, the customers have less work and responsibility [6].

A typical deployment of a SaaS application does not require any hardware, because the vendors provide the entire cloud infrastructure. The SaaS model is designed to continuously and securely deliver applications anywhere and anytime. That is, the vendors need to have reserve capacity in order to handle any spikes in usage, outages or network mishaps. The cloud pricing model offers a company dynamic and elastic way to rent the resources where a SaaS application can be hosted. However, the SaaS application must have a scalable architecture, which can utilize the cloud elastic resources efficiently. Even more, the utilization will be more emphasized if the client requests are dynamic, but in some way predictive.

In this paper we present an architecture of an e-Ordering system, that is, a system that allows consumer companies to order some services from the sellers. We focus on a system for weekly orders catering. That is, the case where the orders are tightened in one or two days, while other periods the orders are minimized.

The rest of the paper is organized as follows. Section II elaborates on the motivation why the solution for e-Orders is selected and why a scalable architecture is proposed. Section III presents the details of the proposed scalable system concept for the e-Ordering system. In Section IV, the details of the system architecture and design are presented, along with detailed explanation of the systems modules and their agents. Section V presents the business models of the e-Ordering system. The system architecture challenges and benefits are discussed in Section VI. The last section, Section VII, concludes the paper and states future work.

II. Motivation

In this section we elaborate on the motivation why we analyze the system for e-Ordering. Also, some challenges are

analyzed about the performance and cost of such a system.

A. Main challenges

There are a lot of companies in the world that care about their employees, but only a few provide free food and other types of paid services to their workers. Every year, the Fortune magazine publishes a list of best companies to work for [7]. Last year, Fortune has once again ranked Google as number one. Google has always had a reputation for being the best employer and having a great office culture. As an employer who provides valuable benefits for its employees, Google has a profound influence on many small and start-up companies. The downside to this is that those companies dont have an approximate budget and resources as the tech giant. For example, they cant afford to have their own cafeteria and in order to satisfy their workers they order food from the local restaurants. Thus, the e-Ordering system comes to light, modernizing the ordering process of services and delivering them in one place. Because of this, companies can provide free food and other types of paid services to their workers in order to have higher employee satisfaction ratings, i.e. increased productivity and morale, healthier workforce, stronger and positive connections inside the company, etc.

The e-Ordering system must provide authorization and authentication for the users who are responsible for the administration of the profiles of both consumers (buyers) and clients (sellers), and those users who use the system to order some services from the sellers, i.e. the consumers employees. Their access rights are managed by the companys main user, who is also in charge of controlling and limiting the services they use. Those users are the most prevalent users in the system and also the ones who are responsible for slowing down the system.

The system performance depends on the total number of these active users and the most important factor that impacts the performance is their changing number. Thus, the system must be reliable and available during the e-Ordering periods in order to satisfy the increased number of orders that are tending to decrease the overall system performance. Security and data privacy are also important because the system stores sensitive user data, such as personal information of clients and consumers, and as well as their personal list of orders. All these requirements are essential to implementing a scalable and elastic system for e-Orders.

B. How to achieve a scalable system

SaaS vendors usually rent their virtual machines (VMs) on hourly basis [8]. The cost for a single VM is calculated by the hours the rented machine has been activated. On the other hand, the revenue that a given SaaS application receives from renting those machines, in our case that is the e-Ordering system, depends on the number of users and transactions made.

With exception of some sellers, most of the e-Ordering services are available for ordering just before the weekends start. That is, the system has increase in the number of orders every Thursday and Friday, as presented in Fig. 1. Since

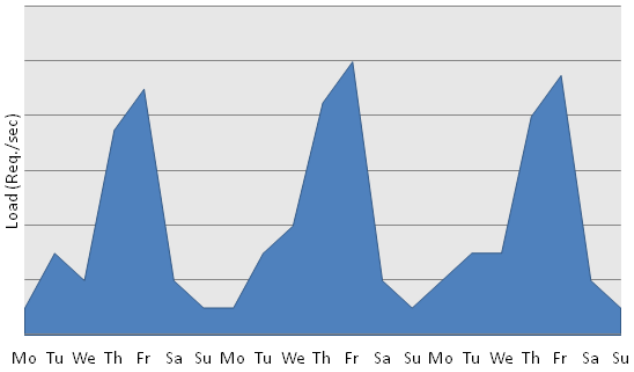

Fig. 1. System load in days per week.

both renting the VMs and consumers ordering most of the e-Ordering services from the sellers are happening at the exact time of the week, a business model needs to be created in order for the e-Ordering company to maximize the profit and grow its business. This will save the companys CAPEX and OPEX, and also resources needed for administration and management [9]. The details of the proposed business models are discussed in Section V.

As mentioned above, when the system receives the increased number of orders every Thursday and Friday, it should scale the resources in the cloud, either horizontally (utilize smaller VMs), or vertically (use greater VMs) [10]. A number of challenges of how to become a profitable provider by using the resources are discussed by Schwanengel and Hohenstein [11]. A few papers reported that the price for scaling the resources in a VM is linear [12], [13], i.e. using one VM with two cores is two times more expensive than one with one core, and so on.

In this paper we propose a scalable architecture of e-Ordering system in cloud which uses the cloud scalability and elasticity in order to achieve sustainable performance. The proposed solution will minimize the overall cost since it uses minimum resources utilized during the e-Ordering periods, thus better performance is expected to be achieved. The e-Ordering system requires huge amount of unpredictable resources only in small periods of time, while in most of the time it requires predictably much less resources. Using server-cluster architecture to create scalable and highly available solutions will only partially solve a performance peak problem since it is hard to be managed and administered, thus the proposed cloud hosted solution. However, although the peaks are unpredictable, the SaaS company still can predict the required resources in the peak period. That is, the SaaS company knows the total number of registered companies and the total number of their employees.

C. Service oriented architecture

A flexible and standardized architecture is needed to respond to the increasing demand for applications that support sharing resources and data. Service Oriented Architecture

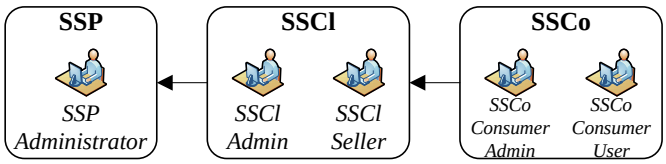

Fig. 2. Company roles interaction.

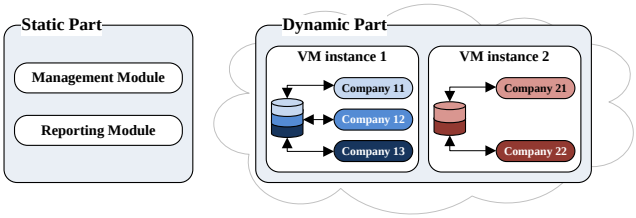

Fig. 3. Static and Dynamic parts of the system.

(SOA) is a flexible architecture that unifies business processes by structuring applications into services. SOA is being advocated as the next evolutionary step in software architecture [14], making a paradigm shift in architecture, i.e. from object to service oriented architecture.

SOA is based on the concept of a service [15]. Each SOA service is designed to perform one or more activities by implementing one or more operations. These services can be combined by other applications to provide the complete functionality of a larger application. Therefore, one service can rely on another to achieve its goals. These services communicate with each other by passing data or coordinating an activity between one or more services, allowing users to combine and reuse them in applications. Thus, the main benefit of SOA is the ability to mix together services from different systems.

Scalability feature of SOA is responsible for the wide adoption of this architecture. SOA enables interoperable communication among various systems, but has issues regarding the overall system cost and as well as resource utilization and provisioning. Therefore, on-demand infinite elastic resources are necessary to address these issues. Cloud providers are able to offer these resources using virtualization.

III. The Scalable System Concept

This section presents the details of the proposed scalable system architecture for e-Ordering system, along with various system roles and their interaction with the system modules.

A. System concept

The e-Ordering system is designed with three company roles: SaaS Service Provider (SSP), SaaS Service Client (SSCl) and SaaS Service Consumer (SSCo). The interaction among company roles, along with their users is presented in Fig. 2.

SSP offers the e-Ordering system as a service for SSCls to publish their services in a customized web site (service). SSCo interacts with one or several SSCls. That is, employees of SSCo can order services from different SSCls. The system roles of each company are elaborated in the next section.

B. System roles

SSP is represented with one user role: *SSP Administrator*, while SSCl is represented with two user roles: *SSCl Admin* and *SSCl Seller*. SSCo has also two user roles: *SSCo Consumer Admin* and *SSCo Consumer User*.

The *SSCo Consumer Admin* in the e-Ordering system is responsible for managing a given consumer company that uses the system to provide services from SSCls to its employees (*SSCo Consumer Users*). In order to provide these services, the SSCo needs to add or import its users into the system. *SSCo Consumer Admins* configure which SSCls are available to *SSCo Consumer Users*. Also, they can generate order reports and manage SSCl service rules, e.g. number of allowed orders per user, number of allowed items per order, periodical price limit for orders (daily, weekly, monthly), etc. On the other hand, the *SSCo Consumer Users* can only make orders from services per SSCl, predefined by their Consumer Admins. That is, they cannot order services that are not registered by their company administrators.

The *SSCl Admins* are responsible for managing the SSCl users - *SSCl Sellers*, which define the service menu items and their prices.

The *SSP Administrator* registers SSCl and SSCo companies and approves their administrators.

C. The scalable concept

Our main idea is to identify two subsystems of e-Ordering system, i.e. static and dynamic, as shown in Fig. 3. The first one will be active during a normal or a reduced system usage, while the other will be active at higher peaks of usage [16], [17].

The static part includes two modules: management and reporting modules, which do not require huge resources and can be predicted easily. This part can be hosted either on static physical server or VM with constant resources which can be predicted easily. The performance of this part depends directly on the number of SSCls only.

The dynamic part should be hosted in the cloud. The idea is to group, consolidate and host clients (those companies that offer) in separate VM instances according to the number of their consumers and their behavior. For example, one VM instance will host three companies and another VM instance two other companies, such that the total number of users per VM is balanced. The dynamic part depends on the total number of SSCo consumers, which is much greater than the number of SSCl clients. Additionally, the performance of this part is unpredictable because not only executes SELECT-queries,

but also performs a large number of INSERT, DELETE and UPDATE operations.

D. Architecture scalability

One of the main problems in this SOA architecture is lack of scalability, e.g. the administrator needs to upgrade the server infrastructure in order to satisfy the growing demand for orders. Thus, the administrator can either dedicate enough resources to host the system in order to handle the orders of all active employees in one moment or predict the average number of employees who are making orders in a specific moment and dedicate a required number of resources to host the system. The first solution is very expensive and the overall system will be underutilized most of the time. Also, the number of active employees varies from time to time, which introduces additional scaling problems. The second solution is less expensive, but it doesnt solve the problem, i.e. the system will be under or over utilized most of the time.

As the cloud computing paradigm emerged, the e-Ordering system will be hosted in cloud in exchange for better performance, optimal resource utilization and most importantly overall cost reduction. Because the cloud uses technologies that implement scalability, elasticity and interoperability between different systems, we propose a SOA based architecture that can be hosted on the cloud using all the benefits the cloud can offer in order to provide a working scalable solution as well as sustainable performance with minimal costs for hosting resources.

IV. System Architecture and Design

This section presents the details of the e-Ordering system architecture and design. Also, it explains the three modules of the system, as well as the agents with in these modules.

The e-Ordering system consists of three subsystems or modules, i.e. Management Module (MM), Reporting Module (RM) and Service Ordering Module (SOM), as presented in Fig. 4.

The latter is the dynamic part of the system, while other two modules belong to the static part. Each module has at least one agent. The e-Ordering system has total of four agents: Admin Agent, Infrastructure Agent, Reporting Agent and Consumer Agent. Each module and its agents are described in detail in the following subsections.

A. Management Module

This module is the core of the e-Ordering system, because it manages all resource provisioning in the cloud. The Management module can be hosted either on a bare metal server or VM instance in the cloud with constant resources. This module manages the system during inactive mode, providing user authentication and authorization, service menu items and categories, etc. Fig. 5 presents detailed design of this module.

Two agents are part of this module: Admin Agent and Infrastructure Agent.

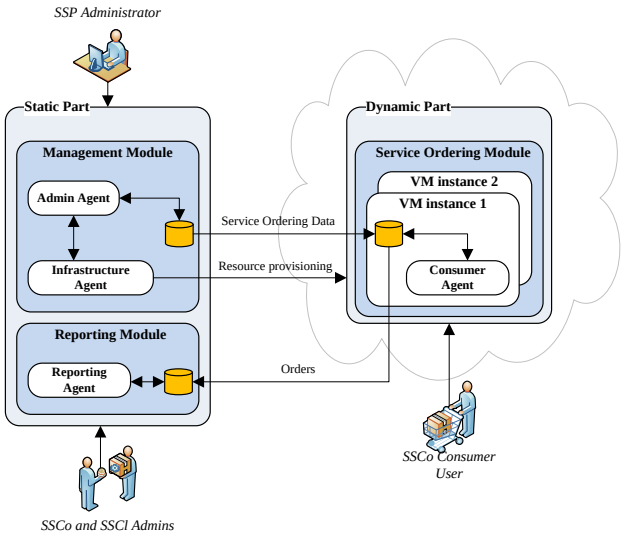

Fig. 4. System modules and roles interaction.

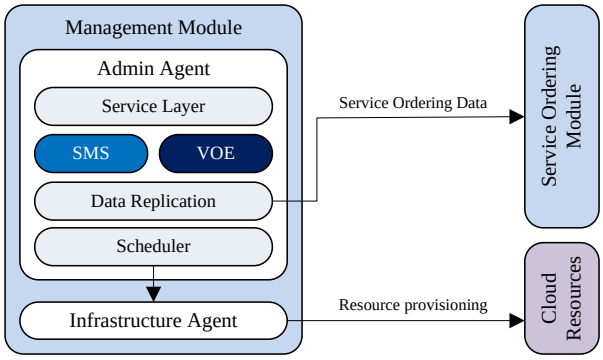

Fig. 5. Management Module design.

1) Admin Agent : The Admin Agent is responsible for authentication and authorization services of Service Layer, e-Ordering content administration, scheduling and data replication to the Consumer Agent in SOM. This agent is service oriented and contains Service Management System (SMS) and Virtual Ordering Environment (VOE). The former is used for SSCl management (menu and pricelists), while the latter is used for SSCo management (allowed SSCls for a particular SSCo).

The Scheduler communicates with the Infrastructure Agent for creating the SOM module. Through the VOE environment, SSCo Consumer Users can browse their personalized e-Ordering service menu. Based on the number of employees and the size of the allowed services from the menu, the Scheduler communicates with the Infrastructure Agent in order to supply the needed information for resource provisioning.

VOE as a subsystem communicates with the Data Replication subsystem in order to define the parts of data needed to be replicated to the SOM module.

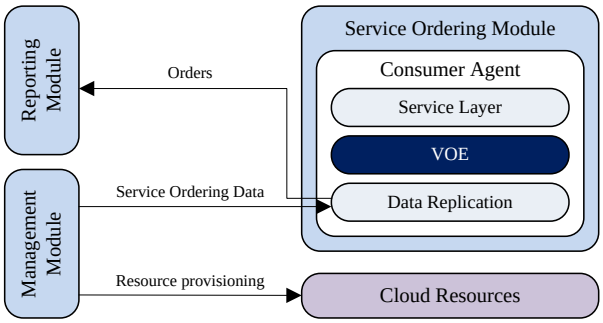

Fig. 6. Service Ordering Module design.

2) Infrastructure Agent: As we mentioned earlier, the Infrastructure Agent communicates with the Scheduler from the Admin Agent in order to create VMs in Thursday morning and shutdown instances in Friday evening, after the order data is replicated in the Reporting Module. Another important function is to choose an optimal algorithm how to organize SSCos in a single VM. This algorithm is out of scope of this paper.

B. Reporting Module

This module, similar to the Management Module, is the static part of the system. The main idea behind this module is dividing the purchased services from the e-Ordering system into a separate module for reporting and accounting. In Friday, after all orders have been purchased by SSCo Consumer Users, the order data is replicated for further management (accounting, reporting, business intelligence, etc.). Data privacy and security are very important for this part, because each order consists of a sensitive data.

This is a view-only module, i.e. only SELECT-queries are executed since both consumers and sellers view the executed orders. This module can be designed as OLAP part in order to speed up the report generation, where applicable.

C. Service Ordering Module

The Service Ordering Module is active only when the system is working in active mode (Thursday-Friday). Because its load varies depending on the number of orders and active users, we propose this module to have a dynamic resource allocation and therefore to be hosted in cloud in order for the system to be more efficient and cost effective. As a subsystem, SOM hosts only a small amount of data, i.e. SSCo Consumer Users can only order services from a small group of allowed SSCls. This makes the system more efficient and provides a better overall performance. Fig. 6 presents the detailed design of this module.

This module is specifically designed for the SSCo Consumer Users to order some services from the sellers. Because of its uniqueness, we can safely place the Consumer Agent in this module. The Consumer Agent receives the necessary data from the Admin Agent. It is a service oriented agent and contains only the VOE environment. VOE of Consumer Agent has significantly smaller database than VOE in Admin Agent. Each query in this module works on smaller data set improving the overall performance of the e-Ordering system, therefore making it more efficient. After all orders are committed, that is, after Thursday and Friday, the Consumer Agent copies the data of the orders in the Reporting Module as it can be viewed by the appropriate roles only.

V. Business model

In this section we propose two payment models for the e-Ordering system. That is, payment model per transaction (PPT) and payment model per consumer (PPC).

A. Payment model per transaction (PPT)

There are a number of SaaS applications where per consumer pricing makes sense, but it should never be the prime cause for choosing a payment model. For most applications it doesnt really matter how many users are using the application, but how many transactions they make. In order to grow the business we need to decide how to charge our clients. For example, if our clients are offering and selling food portions, then our payment metric will be - per food order transaction. As the consumers employees buy more food menus, our business (as SSP) will grow and expand.

We choose this payment model to be based on transactions, because the e-Ordering system does not only offer food but a various number of services. For example, when SSCo consumer orders some service from SSCl seller, the related seller is obliged to give a prearranged percentage to the SSP for every transaction that is made via the system. SSP helps SSCl clients to connect and sell their services to a countless number of SSCo consumers around the globe. Unlike SSCls, SSCo consumers in PPT are excused from paying a monthly fee to SSP for using the system.

B. Payment model per consumer (PPC)

Like most SaaS applications, this payment model is based on the number of active users a consumer company has. Unlike PPT model whose goal is to charge the SSCl clients for every transaction made via the e-Ordering system, the PPC as model intends to charge the SSCo consumers on a subscription basis, i.e. a monthly fee based on the number of their active employees. Thus, attracting more clients to come and use the e-Ordering platform because of its free SSCl access.

Depending on the market conditions and the business climate, the e-Ordering company can implement either one of these two models. Choosing an appropriate payment model for a particular region or state will help the e-Ordering company to maximize the profit and grow its business.

VI. Discussion

The e-Ordering system is designed to handle unpredictable peaks in the number of consumers and sellers. But, if the system starts spreading around the world as a proper SaaS

application, then a challenge for deploying additional VMs in different time zones arises. However, this is not a problem because the cloud service providers have several data centers around the world, which is enough to serve both the clients and consumers. Consumers usually order services from nearby warehouses, but they can also order services from sellers that are located in a different area, country or a continent. That is, a seller can offer services in different time zones, but its warehouse needs to be located closely to the consumers ordering location in order to distribute the ordered service to the consumer.

The e-Ordering solution is capable to instantiate as many VM instances as necessary. The communication with the cloud controllers is scalable and elastic. It creates and destroys VM instances during e-Ordering periods, with particular resources that can provide minimum system performance depending on the number of orders and active users.

VII. Conclusion and future work

In this paper we present a scalable architecture for e-Ordering system that is capable to retain its performance regardless of the peak periods. The architecture consists of two parts static and dynamic. The former is always active and charged for administration and reporting. The latter is active only during the period of active orders and it is charged for allowing the consumers to commit their orders. This part utilizes minimum resources to keep the performance at the required level.

The cost of this system is minimized since it uses the minimum resources only in active periods. Additionally, the performance is much better since each Consumer Agent works with its own small database, which has the data only for those companies (sellers and buyers) that are hosted within.

Our future work consists of developing such a system, with the described challenges and algorithms for consumer consolidation in a single VM.

Abstract - After joining the European Union, the Republic of Croatia became obliged to consolidate its laws and regulations with the EU's. European Commission's Regulation No 260/2012, obligatory for Croatia too, has set the 31st of October 2016 as the deadline for replacement of national euro credit transfer and direct debit schemes by SEPA Credit Transfer (SCT) and SEPA Direct Debit for the EU member countries that do not use euro as their currency. From that date, use of SCT will be obligatory for the credit transfers in euro, but it has been decided that it will be obligatory for national currency kuna, too. Since SEPA is based on ISO 20022 norm, which is built upon XML language, it is not realistic to expect from business subjects, i.e. future SEPA users, the understanding of XML technologies and ISO 20022 norm necessary for creating SCT electronic payment order. For that reason, we have built a web application, which provides for users a simple web interface with forms to fill and facilitate their transit towards SCT. This paper explains SEPA and describes its implementation in Croatia, structure of SCT electronic payment initiation order format and the web application we designed for its creation.

I. INTRODUCTION

Single Euro Payments Area (SEPA) is a project initiated by European Union and its main goal is creating an area in EU where the consumers, business subjects and government bodies can conduct their payments in euro currency under equal terms, regardless of their location. In the past few years SEPA payment tools have been slowly becoming mandatory for the EU member countries. Since it has joined the EU, Croatia is also obliged to implement SEPA until the deadline defined by the European Commission, which means that Croatian national euro credit transfer and direct debit system will have to migrate to SEPA until no later than November of 2016. This paper will describe the general purposes of SEPA, its brief history and standards it uses in the background, and SEPA activity called the SEPA Credit Transfer (SCT) along with its *pain* message format. This paper will represent a brief history of implementation of SEPA in Croatia and the main functionalities of an application developed in cooperation of Croatian Financial Agency (FINA) and Faculty of Electrical Engineering and Computing (FER) from the University of Zagreb, in order to facilitate a part of SEPA implementation in Croatia related to SEPA Credit Transfer.

Second chapter describes SEPA project into more details and the third chapter describes the norms on which SEPA is based. The fourth chapter explains SEPA Credit Transfer activity and the main document (payment order) by which a payment can be initiated. The fifth chapter brings the brief history of SEPA implementation project in Croatia and describes the application related to SCT made in cooperation of FINA and FER. Sixth chapter brings the conclusion of this paper.

II. ABOUT SEPA

Project SEPA is a part of a bigger project initiated by European Commission, which aims to unite national markets of the EU member countries into a singular European market. Creation of the united market was proposed in 1990 in the report *Making payments in the Internal Market*. The united market would have euro as a common currency, same payment operation costs regardless of the location within the area, same legal rules for national and cross-border payments, etc. The key prerequisite for such united market were cheap, fast and reliable money transfers across the area [1] and SEPA was meant to meet those requirements; SEPA payment tools would enable the users to conduct cashless payments to anyone within the SEPA area by using only their bank account and SEPA payment tools.

At the end of 2000 EU has defined SEPA as one of the main political goals and in the following years many legal acts have been brought in order to increase the integration of European market. One of the most important directives was *Payment Services Directive*, which has set the legal foundations for SEPA [2]. European Payments Council (EPC), which is consisted of European banks, created the necessary trading and technical schemes and frameworks. EPC's duty was also the creation of SEPA payment tools (schemes): SEPA Credit Transfer (SCT), SEPA Direct Debit (SDD) and SEPA Cards Framework, along with the belonging rulebooks and implementation guidelines. SEPA payment instruments became available for the first time in January 2008.

In 2010 SEPA payments became the most dominant payment type in EU and in 2011 it replaced national payment schemes of the Eurozone countries. SEPA includes 34 countries - 28 EU member countries, 4 EFTA members, Monaco and (as of February 2014) San Marino. On February 1, 2014, national payment schemes have been cancelled in all SEPA countries that have euro as the

main currency. On that date, all of the credit transfer and direct debit procedures have expired and afterwards all of the transactions can be conducted exclusively through SEPA instruments and using the IBAN bank account numbering system. For the rest of SEPA countries, which do not have euro as their main currency, the deadline for that same scenario is October 31, 2016.

III. NORMS USED IN SEPA

Any process that aims to integrate heterogeneous systems and processes has standardization as its key method for achieving that goal. SEPA was meant to be the standard that would unite heterogeneous national payment schemes of EU member countries. However, a new standard was not created, but a decision has been brought to build SEPA upon existing standards - ISO 20022, IBAN and BIC, which are described in the following subchapters.

A. ISO 20022

ISO 20022 is an industrial ISO standard for Financial Services Messaging that was decided to be the most suitable for SEPA [3][4]. This standard ensures consistency in the exchange of messages concerning the financial business. The messages of this standard suit the needs of the entire supply chain; from the clients to the banks, between banks, price and transaction reporting, money transfers, etc. Conceptually, this standard is organized in three layers. The upper layer provides key business processes and concepts, the middle layer provides logical models of the messages and the lower layer deals with the syntax and the actual implementation. The methodology of ISO 20022 is special because it differs business information and the way it is interpreted in the message [5].

The first step of the message modeling begins with modeling of the business process, activities and actors it includes. The business data are then organized into components, which contain the business elements. For instance, in the processes of credit transfer, the key terms are debtor, creditor, debtor agent, creditor agent and payment. For each of these terms, a data type is defined. However, these data types are not necessarily simple, but can be composed of more details (e.g. creditor data type contains name, address, identifier, etc.).

In the second step of message modeling, the defined types (components) model the message logically, while the third step is related to the lowest conceptual layer and includes physical implementation of the message model. For the purpose of the implementation, ISO 20022 is built upon XML language (Extensible Markup Language), even though using other language is also possible within special business domains and with mutual agreement. Consequentially, ISO 20022 business messages are XML documents and the term of message exchange means the exchange of actual XML files, whose structure complies the standardized format. In ISO 20022, the actual standardization mediators are XSD (XML Schema Definition) schemes that define the structure of the XML files and thus standardize their format. XSD files can be found in the ISO 20022 catalogue of messages, which is available online.

B. IBAN

IBAN stands for International Bank Account Number. It is an internationally agreed standard system for numeration and identification of bank accounts. It was developed by European Committee for Banking Standards and later as a part of ISO 13616:1997 standard. The current standard is ISO 13616:2007. IBAN was initially created to facilitate money transfers within the European Union and automate processing of payment orders, but due to its flexibility it has been globally applied. As of September 2014, 66 counties are using the IBAN system.

IBAN consists of 34 alphanumeric characters at most. First two characters have to be letters that denote the country code according to ISO 3166-1, a standard for representation of countries, dependent territories and special areas of geographical interest. The following two characters have to be digits, which have the role of control digits; they ensure the overall accuracy of the IBAN and thus minimize the possibility of error during transcriptions. Use of IBANs has reduced trans-national money transfer errors to under 0.1% of total payments. After these four characters come 30 alphanumeric characters at most and they are called Basic Bank Account Number (BBAN). BBANs are country-specific; each country can decide on its own how many characters will construct the BBAN and the only limitation is that all IBANs across a country must have the same length. For instance, Croatian IBANs must be 21 characters long. First two characters are letters "HR", denoting Croatia, and the following two characters are control digits. Of the rest 17 alphanumerical characters, the following 7 characters denote the leading bank number, and 10 remaining characters denote the account number.

Use of IBAN is mandatory within the European Economic Area and its usage is one of prerequisites for implementation of SEPA payment tools. Since February 2014 usage of IBAN is mandatory for all national systems for credit transfer and direct debit.

C. BIC

BIC is an ISO 9362 standard and stands for Business Identifier Code. BICs were originally introduced by the SWIFT Standard and they are still called SWIFT addresses of codes. It is a standard format for internationally unique business identifier applicable for both financial and non-financial institutions and is approved by the ISO organization. When it identifies a non-financial institution, it is also known as Business Entity Identifier (BEI), and when it identifies banks as financial institution, BIC can be interpreted as Bank Identifier Code.

BIC information is used for routing of the money transfers and exchange of messages between banks. The latest BIC version is ISO 9326:2009. It is made of 8 or 11 characters. In case of identification of primary bank office, BIC is an 8-character code; otherwise it is 11 characters long. The first four characters have the role of Institution Code (e.g. bank code). The next two characters are letters

denoting the country code according to ISO 3166-1, just like first two characters of IBAN. The following two characters can be either letters or digits and they denote the location code, and the last three characters are alphanumerical optional characters denoting the branch code.

At the moment, SEPA is based on IBAN account numbering system and SWIFT-BIC bank identification. However, an overlapping issue between ISO 9362 (BIC) and ISO 13616 (IBAN) has been noticed and discussed recently. Within the Eurozone, SWIFT network is not required for payment transmission because BIC information can be derived from IBANs. Consequentially, usage of BIC information will gradually become optional within the Eurozone (and thus the SEPA area). From the February 2014 BIC usage information became optional for the national transactions, and from February 2016 it will become optional for the cross border transactions, too.

IV. SEPA CREDIT TRANSFER

SCT is SEPA payment tool for non-urgent payment in euro currency within the SEPA area. SCT are used for Payment Initiation activities. They can only be sent in euro currency and its user, i.e. payment initiator, has to know the recipient's IBAN.

In order to achieve "straight-through processing" of the data, EPC has developed a subset of ISO 20022 XML standard messages that were suitable because they defined the structure of the messages exchanged in payment services. Consequentially, all SCT-related messages are exchanged as XML documents whose structure corresponds with the XSD schemas defined by ISO 20022 standard.

ISO 20022 provides packages of standardized messages for various bank communications performed during the conduction of SCT activities. For instance, in the processes of Clearing and Settlement, usage of message package *pacs* is mandatory. Package *camt*, designed for Reporting, is not mandatory, but the banks have to be able to offer it on demand. Package *pain*, used for Payment Initialization, is also not mandatory, but its use is recommended. Even though the mentioned packages define the structure of the messages, this structure is not ultimate. The basic message structure can be further restricted according to the specific needs. For instance, it is expected that several *pain* specifications will be developed among the SEPA members.

A. SCT PAIN

SCT Payment Initiation payments are national or cross-border euro payments from the clients' transactional accounts they have in their national banks toward transactional accounts of the recipient, which can be either national or within Europe Economic Area or EU. The client initiates the payment by giving the payment order to his bank.

SCT payment order is an XML document, whose structure is defined by a XSD schema found in the *pain* package of the ISO 20022 standard. The *pain* schemas can be found in various versions in the ISO 20022 archive, but they do not differ drastically. For the purposes of SEPA, commonly used version of the *pain* XSD schema is *pain.001*, i.e. *pain.001.001.03*, which is recommended by the European Payment Council and was also selected to be the basis of Croatian national *pain* schema. After creating the XML document, a good practice is to validate the created document against that schema definition.

SCT payment order (XML document) has two main parts - a group header and one or multiple payment instruction information elements [6].

Group header refers to all of these payment instruction information elements. It contains the general information about the payments, such as message identifier, number of transactions, control sum and information about the payment initiator. Payment initiator can either be a person or a business entity (organization), so it contains initiator's name and identification element, which is optional. For instance, organizations can be identified by BIC/BEI and a person can be identified by date, city and country of birth.

Payment instruction information is the key element for conduction of the transactions. It also contains some general information such as control sum, number of the transactions, identifier, required execution date and various codes which determine the way the payment will be conducted, e.g. urgency of the transaction, which SEPA instrument will be used, payment purpose, etc. Payment instruction information also contains information about the debtor, but it differs the debtor from the ultimate debtor. This comes practically in use in scenario when a parent is making a payment for the child's school trip, i.e. in its child's name. In that case, the parent is the debtor, but the ultimate debtor is the child. Debtor's and ultimate debtor's information set is very similar to the one previously described for the payment initiator in the group header. Since the debtor is the side that will ultimately transfer money, payment instruction information set contains information about debtor's account and debtor's agent (usually a bank). The account is identified by IBAN and the agent can be identified by BIC code.

It is important to emphasize that payment instruction information can refer to one or more actual transactions. Information for a transaction contains similar data set as the general payment information, e.g. codes which determine the way the payment will be conducted and an identifier. The actual transaction amount is also defined within this data set, as well as the currency and optional remittance information. In the transaction information part, creditor (recipient), creditor's account and agent, and ultimate creditor are defined, while ultimate debtor can be redefined in case that ultimate debtor in the payment instruction information data set is not defined. When all of the transactions have the same ultimate debtor, it is enough to define it in the payment instruction information and leave it empty in the transaction information. Creditor, ultimate creditor and ultimate debtor in this part are defined as either a person or a business entity, similarly to initiator in group header, or debtor and ultimate debtor in the payment instruction information part. Creditor's account and agent are defined similarly to debtor's account and agent in the payment instruction information part.

V. SEPA PROJECT IN CROATIA

After joining the European Union in July 2013, Croatian national payment system was incorporated into SEPA area. From that moment, the option to join SEPA Credit Transfer Scheme became administratively available to Croatian banks. Even though SEPA became available after Croatia joined the EU, it has still remained optional for the upcoming period which will last until October 31, 2016. This date is the deadline because Croatian main currency is not euro and for that reason the later deadline - defined by the European Commission - is applied to Croatia. Until that date, the national euro credit transfer and direct debit schemes will have to be replaced with SEPA Credit Transfer and SEPA Direct Debit. However, a decision has been brought that SEPA will be implemented not only for national euro transactions, but also for the national currency kuna and thus will be one of the first EU countries to implement ISO 20022 payments in non-euro currency [7]. Regarding the deadlines, Croatian banking community has decided that an earlier deadline will be applied for SCT, April 1, 2016.

In order to fulfill the obligation of implementation of SEPA in Croatia, Croatian National Payment System Committee initiated the SEPA project in Croatia [8] in 2012 and still governs it as the supervisor. In May, 2013 they formed the project's working bodies - Croatian SEPA Coordination Committee and Croatian SEPA Forum [9], whose main mission in the implementation of SEPA project in Croatia0. Both the Committee and the Forum are consisted of the representatives of Croatian Banking Association, Croatian National Bank, Croatian Chamber of Economy, Ministry of Finance and Fina. Croatian SEPA Coordination Committee deals with the migration of the national payment system to SEPA, including the credit transfers and direct debits, creates and conducts the solutions necessary for credit transfers and direct debits consolidation with the Regulation No 260/2012, etc. Croatian Banking Association leads the Committee, whose members are elected as its chairmen. Croatian SEPA Forum is oriented towards informing and educating the payment services users about SEPA and general promotion of SEPA payment services, and is presided by the Croatian Chamber of Economy. The Committee and the Forum can also found special workgroups (task forces) for the purpose of fulfillment of their objectives, whose goal will be proposing and finding the practical solutions for the set objectives and tasks. Figure 1. displays the general organization of the working bodies.

In the countries that have adopted SEPA, creating another national body called National Adherence Support Organization has been common practice. Its main purpose was giving support to the payment services providers during the process of transition to SEPA payment schemes. This body establishes contact between the providers and the European Payments Council and facilitates their procedures of collecting the documentation necessary for accessing SEPA schemes. On May 15, 2014 National Payment System Committee has brought the decision that Croatian Financial Agency (FINA) will perform the role of Croatian National Adherence Support Organization (NASO), as mediating body between EPC and payment service providers. As a part of the Croatian SEPA project, FINA will support the implementation of SEPA in Croatia, i.e. migration of the Croatian national payment system to SEPA payment tools, schemes and formats.

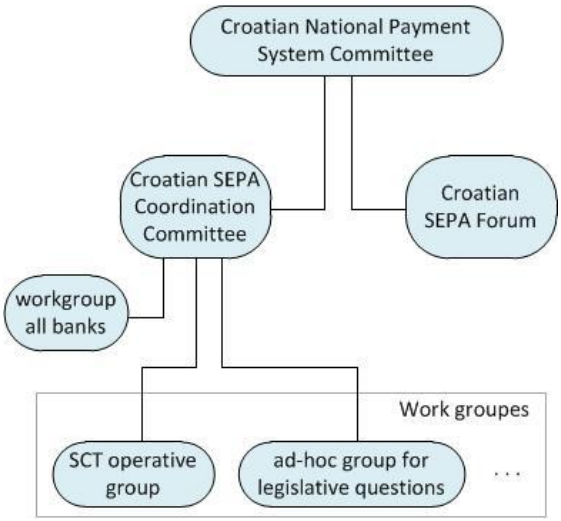

Figure 1. Organization of the SEPA working bodies [7][9]

In order to be able to participate in SEPA area, Croatian monetary institutions had to transit to IBAN account numbering system. Banks had to enable its usage until June 1, 2012. From that date started a two-year transitional period toward exclusive use of IBAN, during which the usage of IBAN was optional for either creditor's or recipient's account number field of the payment orders, and its purpose was to introduce the users to using IBAN. One year later, on June 1, 2013, IBANs became mandatory for the creditor's account number field. One year after that, on June 1, 2014, IBANs became mandatory for the recipient creditor's account number field too and that was the end of transition to IBAN account numbering system in Croatia. Since June 1, 2014 all of the transactions in Croatia can be conducted exclusively by using IBAN account numbers of the creditor and recipient.

A. FINA's Cooperation with University of Zagreb

As a part of SEPA project in Croatia, FINA and Faculty of Electrical Engineering (FER) from University of Zagreb have developed an application, whose purpose is creating one or more SEPA electronic payment orders (XML documents). Its goal is preparing business subjects for SEPA payments and using SCT formats and thus facilitate this transition which will become mandatory in 2016 for both currency of euro and kuna. FER helped FINA in specifying the user requests and modeling the application. The main functionalities of this application will be described in the following subchapter. In the nearer future, it is possible to expect that FINA will develop this web application further.

B. Web Application for Creation of SEPA Electronic Payment Order

The web application created by FINA and FER helps users to create a SEPA electronic payment order (XML

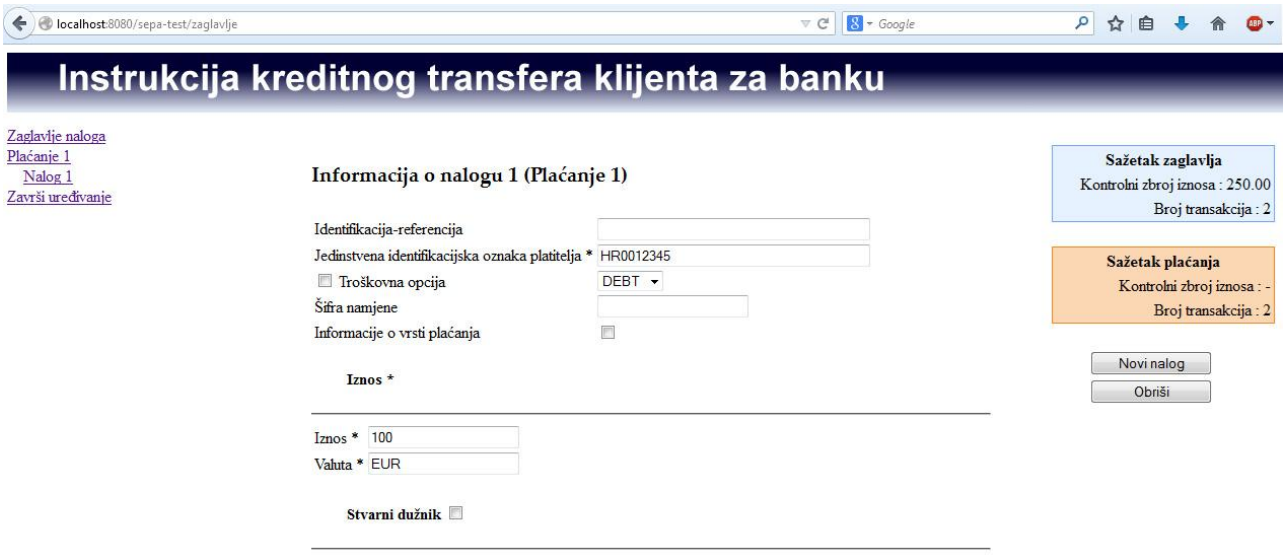

Figure 2. Screenshot of the web application for creation for SEPA electronic payment order

file) through filling and editing of simple web forms. Along with this main functionality, application enables user registration and authentication with basic built-in security mechanisms, validates user's inputs and generated XML file, and offers the generation and download of payment report in a PDF file.

The application has been developed in Java programming language using JavaServer Pages (JSP) and Java servlet web technologies. The servlets process HTTP requests and render the HTML code, acting as intermediary between the client and the actual JSP documents on the web server. This way, clients do not access the JSP documents directly and do not have to worry about the documents' actual location - which is hidden from them - but they access just the URL address, which is mapped to the corresponding servlet. The application provides bilingual interface - the users can choose whether they want the interface in Croatian or English language. The user's choice of language is stored in HTTP session attribute, and based on it the labels (displayed text) in the JSP page are built during the page rendering. The labels are dynamically fetched from a corresponding *property* file; for each of the offered languages one *property* file has been created. This way the application remains easily extensible with more interface languages by adding more *property* files and making few minor changes in the application code.

In order to be able to work with the application's web forms, users will have to be registered and logged in. Users register by their names and e-mails and they must define their password. The application stores the data necessary for the login in the database; the passwords are stored encrypted to keep them safe in case of database breach. The application communicates with the database by *Prepared statements* in order to avoid the possibility of *SQL Injection* attack. After the registration, the users will receive an e-mail from the application with the activation link and will be able to log in after opening that link in the web browser. However, the activation has to take place within the 20 minutes from the registration; otherwise the registration will be annulled. In the moment of registration, the application stores the timestamp so it could compute the time difference in the moment of activation attempt. If the time difference is greater than 20 minutes, the database record will be deleted and user will have to register again. Application will also enable redefinition of the password in case the user has forgotten it. The process is similar to registration process, but the user needs to provide the correct name and e-mail that were used for registration. Pages for login, registration and password recovery (i.e. publicly available pages) also implement CAPTCHA security mechanism so that application could be safe from *botnet* attacks.

After they log in, users will be able to access the electronic payment order form pages and fill the web forms for payment order group header, payment instruction information and the belonging credit transaction information. They will be able to manipulate the number of total payment instructions and the number of their credit transactions, i.e. add or delete them, and navigate through the filled data in order to check or update them. Figure 2. displays a web form for data input for credit transfer information. Navigation is on the left of the screen and helpful summary data, along with the buttons for adding or deleting credit transfer information is displayed on the right. During any kind of data manipulation, application will perform validation of the entered data; e.g. if the mandatory data are filled, if the order contains at least one payment instruction information and a payment instruction information contains at least one credit transfer, if the predefined codes are entered correctly, if IBANs and BICs have the correct form, etc. A part of user's input validation is conducted client-side (i.e. in the user's web browser) and is implemented by JavaScript functions. However, a part validation of the data policies concerning the elements' cardinality, such as number of payment instruction information elements in the group header element, can not be implemented by JavaScript functions and has to be conducted server-side, after the data are submitted from web browser to the application server. The submission

occurs when the users fill the form and want to save the data. After the reception of the data, the application performs server-side data validation and tries to store the data into the data model objects in the session attributes.

The application's main data model is derived from the XML Schema (*pain* XSD schema), meaning that the relations of the data model classes correspond to the relations of elements defined by the XML Schema. The model was generated by JiBX, a framework for XML data binding. After the users have finished their work with the web forms, application will offer them the download of the XML file or the PDF payment report. In both cases, an XML file will be generated based on the data stored in data model objects in the session attributes. In order to map Java objects to XML and generate the XML file, application uses JiBX marshalling methods that generate the contents of the XML file. Internally, once the XML file has been generated, application validates it against *pain* XSD schema by using common Java libraries for XML processing. If user chooses to download the payment report in the PDF, the application will use the generated XML file as a source to create a PDF report using JasperReports, a Java reporting tool.

After generating the requested file, the application sends it and the users can save it locally on their computer. Afterwards, they can either send the XML file by e-mail to their bank or agent, or bring it on a memory stick.

VI. CONCLUSION

SEPA offers potentially ultimate payment tools that could unite all of the EU member countries one step further. Deadlines for scheme implementation favor its success, especially with the fact that it was built upon existing standards which were partially used before they became imperative. This paper has explained the use of these standards and benefits SEPA would bring for each EU member country and SEPA area in general. Croatia has entered the SEPA area only recently and has a lot to achieve in the following two years to migrate to SEPA. However, Croatia's recent entrance is not such a bad thing, because in the meantime European SEPA project has developed to a decent state of maturity. FINA and FER have developed a web application for creation of SEPA electronic payment order in successful collaboration. This application will in future be provided as a service to business subjects and facilitate their transition to using SEPA Credit Transfer for the currencies of euro and kuna. This way SEPA will become one technical standard for payments both in currency of euro and kuna. The application will facilitate a part of the implementation of SEPA Credit Transfer in Croatia, which will be implemented by the beginning of April 2016.

Abstract - In today's global and continuously changing environment, companies are pressured to become more flexible, fast responding, customer oriented and to follow the fast technological development. To achieve these goals they should become business process oriented. Business process orientation (BPO) and process thinking help management to leverage the use of information and communication technologies (ICT) and the Internet, and hence to implement e-business more successfully. E-business strategies have made the need of streamlining, integrating and automating business processes even more pressing. Hence, efficient business processes and higher levels of process orientation are become elementary for organization's success in e-business environment.

Due to the potential of e-business technologies and organizational transformation towards process oriented organization in dynamic environment, the goal of this paper is to analyze business process orientation of Macedonian companies in selected industries and to estimate their level of business process maturity. For this purpose an empirical research was conducted based on the previously prepared questionnaire interviewing managers in Macedonian companies in the banking, telecommunication and IT sector.

I. INTRODUCTION

Today, e-business strategies have made the need to streamline, integrate and automate business processes even more pressing for organizations. Business processes are become elementary for organization's success. In order to maximize its competitiveness in the global, dynamic environment companies need to have business processes which are both efficient and effective. This requires process orientation and achievement of higher levels of process maturity.

In the e-business environment managing a business, means managing its business processes. In that sense, business process orientation – BPO has become one of the most important management paradigms in the new millennium.

But, being aware of its business processes is not enough. Managing mature business processes is the new challenge for contemporary management, since higher levels of process maturity promises better organizational performance. In this sense, maturity models have been proposed to gradually assess and improve business processes in organizations.

II. BUSINESS PROCESS ORIENTATION AND BUSINESS PROCESS MATURITY

A. *Business porcess orientation - BPO*

In the extensive literature on business process management, there are numerous definitions of business process orientation - BPO that vary. One that is more generic and comprises all of the basic elements of the concept is McCormack's and Johnson's [6] definition of process orientation. According to them, an organization that, in all its thinking, emphasizes process as opposed to hierarchies with a special emphasis on outcomes and customer satisfaction is considered as process oriented [6]. The concept of BPO is based on the assumption that the value to customers is delivered by streamlining and accelerating work patterns [6]. Placing the focus directly towards customer and managing end-to-end processes provides a strategic approach in achieving a competitive advantage in the current customer-centric e-business environment.

Organizational transformation towards process orientation for companies means numerous benefits like more efficient execution of work resulting in cost savings, improved customer focus, better integration across the organization, increased flexibility of the company accompanied with improved customer satisfaction etc. Another benefit from process focus is improved hand-offs between functions that leads to cycle time reduction. Process orientation reflected in processes that are broadly defined eliminates redundant activities, verifying inputs one time for all functions within organization. Further, it is indicated that investments in business processes and their management creates competitive advantage for companies and provides significant improvement to the overall system [5], [6].

The concept of BPO in the literature is considered as multidimensional and holistic. Hence, different authors have identified different elements that constitute BPO, each of them having different impact on BPO maturity level. As most relevant in the literature are models and frameworks defined by Kohlbacher, (2010), Škrinjar et al.,

(2010), Willaert et.al, (2007), Reijers (2006), Rosemann et.al, (2006), McCormack, and Johnson (2001). These models in general differ in the number of elements i.e. critical success factors influencing the level of BPO in organizations. Most common are the three elements present in the model of McCormack, and Johnson (2001).

According to McCormack and Johnson (2001), the BPO construct is defined through the following three basic elements: process view, process jobs and process management and measurement [6]. In addition to the basic components, they also discuss about the importance of two supporting components: organizational (process) structure and organizational culture referring to the process values and believes. These two elements enable the basic components to operate, interactively [3], [6]. The above mentioned BPO elements refer to the following:

Process view (PV) refers to the importance of the definition and documentation of business processes and their understanding from top to bottom and from the beginning to end of a process in the organization. w. Documentation of process steps, activities and tasks comes in both visual and written formats that allow people in different job functions and companies to communicate using the same vocabulary. This component includes broad understanding of the processes across the organization, not just documentation.

Process Jobs (PJ) refer to the definition of process related tasks and roles in the organization. These jobs include horizontal rather than vertical responsibility. People participate and take ownership of the entire process.

Process Management and Measurement systems (PMM). This component includes process measurement systems, rewards for process improvement, outcome measurements, customer-driven and team-driven measures, and rewards.

These individual dimensions of the BPO construct i.e. measured variables - PV, PJ and PMM in the model are measured by 3, 3 and 5 items respectively, as given in the table below.

TABLE I. OPERATIONALIZATION OF THE BPO CONSTRUCT

Process view (PV)	
PV1	The average employee views the business as a series of linked processes.
PV2	Process terms such as input, output, process and process owners are used in conversation in the organization.
PV3	The business processes are sufficiently defined so that most employees know how they work.
Process jobs (PJ)	
PJ1	Jobs are usually multidimensional and not just simple tasks.
PJ2	Jobs include frequent problem solving.
PJ3	Employees are constantly learning new things on the job.
Process management and measurement system (PMM)	
PMM1	Process performance is measured.
PMM2	Process measurements are defined.
PMM3	Resources are allocated based on process.
PMM4	Specific process performance goals are in place.
PMM5	Process outcomes are measured.

B. Business porcess maturity model

Extensive literature on business process management suggests that organizations could enhance their overall performance by adopting a process view of business. [5], [6], [8]. But, being aware of its business processes is not enough. Managing mature business processes is the new challenge for contemporary management. In this sense, maturity models have been proposed to gradually assess and improve business processes in organizations. Hence, business process management maturity models are becoming the new promising tool for managing successful companies in e-business environment. They become practical tools that assist organizations in achieving business (process) excellence, since organizational transformation towards business process oriented organization is an evolutionary pattern and as such is based on the concept of maturity.

As the topic became very popular, a proliferation of business process maturity models can be witnessed. A wide research on the topic reviled that most of them are based on the Capability Maturity Model developed by Software engineering Institute (SEI CMM) and differ among four or five maturity levels. Generally, in the literature are familiar maturity models that refer to three major process categories: general (core) business processes, supply chains and collaborative processes [1]. The first category of process maturity models further differ maturity models that refer to a specific process (CMM for example) and maturity models that refer to the overall BPM practice and process orientation of the organization.

Besides their popularity, maturity models have been a subject to a criticism as well. Mainly they are criticized for being a simple consultancy speech or step-by-step recipes that simplify the very complex reality of organizational transformation [4], [8], [11]. In spite they represent a basic road map for organizations in their attempt at moving toward process orientation.

For the purpose of this research the model of McCormack and Johnson (2001) comprising three BPO construct elements (as discusses previously) will be used that differ four levels of maturity: ad hoc, defined, linked and integrated processes [6]. Each step builds on the work of the previous steps to apply improvement strategies that are appropriate to the current maturity level. The following definitions for the stages that an organization goes through when becoming BPO are provided [4], [6]:

[1] *Ad hoc.* The processes are unstructured and ill defined. Process measures are not in place and the jobs and organizational structures are based upon the traditional functions, not horizontal processes.

[2] *Defined.* The basic processes are defined, documented and available in flow charts. Changes to these processes must now go through a formal procedure. Jobs and organizational structures include a process aspect, but remain basically functional. Representatives from functional areas (sales, manufacturing, etc.) meet regularly

to coordinate with each other, but only as representatives of their traditional functions.

[3] *Linked.* The breakthrough level. Managers employ process management with strategic intent and results. Broad process jobs and structures are put in place outside of traditional functions.

[4] *Integrated.* The company, its vendors and suppliers, take cooperation to the process level. Organizational structures and jobs are based on processes, and traditional functions begin to be equal or sometimes subordinate to process. Process measures and management systems are deeply imbedded in the organization.

The first level is estimated with the average score of 1,5; the second 2,5; the third 3,5 and the forth level with average score of 4,5. This measurement tool will help us to estimate on which maturity level are analyzed companies in our survey [6].

III. BUSINESS PROCESS ORIENTATION AND MATURITY OF COMPANIES IN SELECTED SECTROS IN THE REPUBLIC OF MACEDONIA

A. General characteristic of the sample

Competitive advantage of companies today is reflected in aligned and innovated business processes. This implies that successful implementation of e-business strategies requires companies to achieve higher levels of maturity in process orientation.

BPO is becoming promising concept for managing organizations and improving their organizational performance, not only in manufacturing sector, which is traditionally considered as process oriented sector, but in other industries like some high technology industries, telecommunications, finance and insurance etc. BPO is becoming common methodology for improving organizational performance in service industries as well [7].

Due to that, for the purpose of this research companies from sectors like telecommunication, IT sector and banking in the Republic of Macedonia which at the same time show higher level of e-business penetration in the country were selected for further analysis. The structure of the sample by industry type is given in Table II.

TABLE II. SAMPLE BY INDUSTRY TYPE

INDYSTRY TYPE	**Frequency**	**%**
Banking sector	37	54,41
IT sector	18	26,47
Telecommunications	13	19,12
Total	**68**	**100**

Although, the sample size is not sufficient to declare the sample as representative for complex statistical analysis, but it can certainly be considered informative for gaining insight into presence of process orientation in companies from selected sectors in the Republic of Macedonia, having in mind the specific structure of these sectors in the country.

Namely, the banking sector in the Republic of Macedonia comprises 16 banks (12 of them are in foreign ownership) and 4 saving houses (as at the end of 2013) in total. The Banks represent the most significant financial mediator, whereas, savings houses held an insignificant share. The concentration of the sector remains high, with 68, 8% share of the three largest banks in the total assets of the sector [15].

According AEC [2], the telecommunication market in the Republic of Macedonia, as in the third quarter of 2014, is represented by four companies which are FDI (foreign direct investments) (T-Mobile, VIP, ONE and Albafone). Three of them (T-Mobile, VIP and ONE) hold the 99% of the market.

The structure of the domestic IT market is represented by IT companies (which are mainly medium and small companies) including: software and IT services companies, hardware companies and distributors, as well as training providers and ICT consulting companies [14]. Most of the world's largest IT companies such as Microsoft, CISCO, IBM, Compaq, Hewlett Packard, Dell, Siemens, Sun Microsystems, Apple, Lotus, ORACLE are present in the Republic of Macedonia via branch offices, distributors, dealers, resellers, solution providers and business partners. In addition, there are a number of companies oriented towards assembling, sale and maintenance of their own computer systems [12]. Among these companies, of our interest were the ones that are engaged in software development i.e. software and IT services companies.

Due to this the sample of 68 responses from companies in the selected sectors, is considered representative for the task of the paper i.e. gaining the first insights of the process management maturity practices in these sectors in the Republic of Macedonia.

During the period from May to September 2014, an interview with 68 managers from companies in the selected sectors in the Republic of Macedonia was performed based on the previously prepared questionnaire. The questionnaire was consisted of three parts. The questions in the first part refer to the demographic characteristics of companies and respondents (managers). The second part contains question regarding the e-business strategy implementation, as well as major process characteristics of companies. The third part contains questions regarding the BPO construct which was based on the McCormack and Johnson (2001) model. Despite the questions in the first part and several questions in the second part, which were multiple choice questions, for questions in the third part a five point Likert scale was used.

Data gained from part I and part III from the questionnaire were basis for the analysis presented in this paper. The results show the following independent characteristics of the sample (Table III):

TABLE III. THE INDEPENDENT CHARACTERISTIC OF THE EXAMINED COMPANIES AND RESPONDENTS

A. Independent characteristics of the companies	**Frequency**	**%**
Number of employees		
10 - 49	13	19,12
50-249	14	20,59
250+	41	60,29
Market share		
up to 5%	13	19,12
6-10%	10	14,70
10 - 25%	18	26,47
more than 25%	27	39,71
B. Independent characteristics of respondents	**Frequency**	**Percentage**
Hierarchical position of the respondents		
Top management	5	7,35
Middle management	48	70,59
Lower management	9	13,24
Other	6	8,82

B. Data analysis

Regarding the BPO construct, the results of the survey are given in Table IV. For the measurement of the level of BPO, three measurement variables were taken into consideration: process view, process jobs and process management and measurement system which represent critical success factors of BPO in organizations. In the questionnaire they were represented by 3, 3 and 5 items respectively as in the original model [6].

TABLE IV. THE BPO CONSTRUCT – DESCRIPTIVE STATISTICS

BPO construct	**Mean**	**Std. deviation**
Process view - PV		
PV1	3,62	0,90
PV2	3,44	0,98
PV3	3,65	0,94
Process jobs - PJ		
PJ1	3,81	1,12
PJ2	3,43	1,06
PJ3	3,60	1,08
Process management and measurement - PMM		
PMM1	3,69	0,92
PMM2	3,57	0,85
PMM3	3,19	0,87
PMM4	3,29	0,88
PMM5	3,28	0,99

Based on the mean of analyzed critical success factors of the defined BPO construct (PV, PJ and PMM), an average process maturity level of the analyzed companies in the Republic of Macedonia can be estimated. The data showed that the average value for BPO is 3.51. This means that companies in analyzed sample are among second and third level of BPO maturity according the measurement tool of McCormack and Johnson (2001). This result cannot be generalized for all companies in the Republic of Macedonia since the sample was targeted based on the authors previous knowledge that this companies have some awareness about business process orientation and hence a certain degree of BPO. These companies as well have higher level of e-business penetration which is another indicator why a certain degree of BPO in these companies was expected, since e-business is recognized as one of the main driving forces of BPO [6]. Therefore it can be assumed that the overall process maturity of companies in the Republic of Macedonia will be different.

If we look deeper in the given descriptive statistics, based on the data given in Table IV, the lowest average value has PMM3. This means that in the analyzed companies in the Republic of Macedonia, resources are still allocated more on functional basis instead on processes. The highest average value has PJ1, which means that the jobs are more perceived like multidimensional and not simple tasks in most of the analyzed companies.

At the same time PJ1 has highest standard deviation i.e. variance in the answers. This means that there are companies where jobs are very multidimensional, but also there are cases where this statement is not true at all. The lowest standard deviation i.e. variance in the answers is evident for PMM2. This item refers to the definition of process performance measures, which means that most of the respondents recognize importance to this issue.

In the literature there is no significant indicator that there are differences in the level of BPO among companies from different sectors and different size. Even though large companies are making massive efforts to expand their BPO, in contrary, there is evidence that smaller companies tended to score better than larger ones [5]. Another question posed in the literature is the one of "natural BPO" concept which requires further investigation [5]. This means to test whether service companies, which by their nature have muchmore day-to-day contact with their customers, have naturally higher BPO scores than for example manufacturers, who tend to work further down the value chain

Regarding the tested sample that was carefully selected based on the authors expectations that a certain level of BPO exist in companies from selected sectors and size in the Republic of Macedonia, authors do not expect the data obtained from this survey to reveal differences based on these two criteria: industry type and company size regarding the level of BPO.

For that purpose, authors performed one way analysis of variance (ANOVA) to determine whether company size or industry type plays significant role in maturity of business process orientation construct. All assumptions for performing ANOVA like homogeneity of variances, absence of significant outliers and approximately normal distribution of the dependent variables for each group of the independent variable have been previously satisfied.

TABLE V. THE BPO CONSTRUCT AND COMPANY SIZE

Grouping variable - Company size	Small (10-49)	Medium (50+249)	Large (250+)	F ratio	F probability
PV construct	3.30	3.69	3.61	1.116	.334
PJ construct	3.74	3.71	3.53	.354	.703
PMM construct	3.15	3.52	3.44	1.193	.310

TABLE VI. THE BPO CONSTRUCT AND INDUSTRY TYPE

Grouping variable - Industry type	Banking sector	Telecommunications	IT sector	F ratio	F probability
PV construct	3.62	3.71	3.35	1.181	.313
PJ construct	3.47	3.53	3.94	1.672	.196
PMM construct	3.49	3.24	3.33	.791	.458

Based on the F probability statistics, no difference was found in business process orientation maturity constructs between the groups when the grouping variable is company size or industry type as given in Table V and Table VI.

Thus we conclude that company size or industry type does not play significant role in business process orientation maturity on our sample data, since we do not have enough evidence to reject the null hypothesis.

IV. CONLUSION

In order to take the advantage of business process orientation when implementing integrated e-business solutions i.e. automating business processes, companies and their managers have to understand that it is very important to start thinking and acting on a process way meaning to change the complete mindset of an organization.

Regardless the industry type and size, managers in all companies should focus on business processes and streamline their effort in achieving higher level of business process maturity since they promise higher organizational performance and hence better competitive position on the global market.

This research gave us important initial information on process maturity in companies in the Republic of Macedonia. As well, it showed that company size or industry type does not play significant role in business process orientation maturity on our sample data.

But in order to perform profound analysis, authors plan to extend the research in the following directions:

- to increase the number of companies in the sample by including companies from various sectors and from the overall territory of the country;
- to expand the original model by including more critical success factors in the analysis that have impact on BPO, since it is considered as multidimensional and holistic concept;
- to test the impact of BPO construct on organizational performance in companies in the Republic of Macedonia.

Business process orientation and business process management are strategic decisions and hence, require top management support, financial investment, time and commitment of all human resources in the company. BPO requires changes in the complete mindset in organizations.

The organizational transformation towards process focused organization is not a revolutionary but rather an evolutionary effort. This means that companies should join all of its resources and forces in order to gain the promised benefits from these undertakes. This counts for Macedonian companies as well.

The role of the public sector in defining the communication strategies in the Croatian tourism industry

Ph.D. Đani Bunja
University of Zadar/Department of Tourism and Communication Studies, Zadar, Croatia
gianni@unizd.hr

The paper describes communication strategies in the tourism industry. After an overview in the paper are discussed issues in tourist destination communication, i.e. the larger social, political, economic, and cultural climate in which tourist destinations creates their images and projects their voices, the "opportune moment" for communications, the need to understand and capitalize on the psychology of constituencies, the best mix of communication channels and the ethical dimension of tourism industry communication. Tourist destination needs to pay attention to communication strategies because missed opportunities and potentially dangerous threats to industry performance are the alternatives. In the paper then are described the possibilities for applying communication strategies on Croatian tourism industry. It is emphasized that the main characteristics of Croatian tourism industry are the inadequate quality level of services, unfavorable structure and low level of utilization. However, unclear identity can easily hurt tourism industry success and in order to bring about change (improvement the quality of Croatian tourism industry) the application of the communication strategies will be needed.

I. INTRODUCTION

Croatia earlier this year (2015.) chose a new tourism slogan, i.e. a new key message that will be used for its promotion on the international tourism market. The slogan reads: "Croatia, full of life" and will replace the previous one used for the last fifteen years, "The Mediterranean as it once was". Another slogan that Croatia also used for the purpose of tourism promotion was a "Small country for a big vacation", as the previous and the first slogan since Croatian independence and its appearance on the international tourism market under its own name "Croatia, a paradise on earth" practically had not been used.

The slogan is, according to the authors and the client, i.e. the Croatian Tourist Board and the Ministry of Tourism, applicable to all languages and in all communication channels, and summarizes all Croatian advantages - of natural beauty, cultural and historical sites, gastronomy, love, secrets and more.

The selection of a new key message will be followed by the design of a new logo, visual and other promotional materials accompanying it, as well as the elaboration of new concepts of advertising and overall marketing campaign of Croatian tourism for the next five to ten years, which is adjusted to the requirements of the last year adopted Strategic Marketing Plan for Croatian tourism in the period until 2020.

However, the adoption of this slogan, as most of other decisions related to the Croatian tourism, has caused many disputes.

The performance evaluation of tourism policy in a specific tourist destination is often a political issue, resulting in conflicts among political options, which is especially the case in Croatia.

II. ISSUES IN TOURISM INDUSTRY COMMUNICATION

Tourism industry communication is the voices and the images it projects of itself on the world tourism market by its various audiences. Included in this field are areas such as tourism industry identity, image and reputation, tourism industry marketing and advertising, investor relations, government relations, media management, change management, crisis communications, etc.

Tourism industry communication can be possibly observed from several vantage points. It is most visible as a function [19]. In addition, tourism industry communication is also the processes used to communicate all its messages to key constituencies. Finally, it is possible to see ethics as a necessary component of tourism industry communication.

In order to get the best results from communication there is a need to develop a communication strategy. An effective communication strategy involves process of setting objectives, analysis and synthesis, strategy implementation and its evaluation [7].

A developed communication strategy reduces the barriers to communication. The four main elements in an effective communication strategy are communicator strategy, audience strategy, channel strategy and message strategy [18].

Tourism industry communication can be one of the major ways to counteract the persistent scrutiny and negative attention that business has to face [19]. Secondly, a good strategy can set up the technological advances that enhance the scope of the publicity. Thirdly, numerous lessons from worldwide tourism industry demonstrate the harsh consequences of avoiding tourism

industry communication. And, finally, tourism industry communication can serve as a differential advantage on the international market.

As a result, the decision-making process should take into account which strategic direction a tourism industry will choose to take and ultimately how various tourism industry constituencies will react to new strategic initiatives.

The most relevant issues in the field of public relations [19] in general, but also in tourism industry, are the following:

- The larger social, political, economic, and cultural climate in which tourism industry creates their images and projects their voices;
- The "opportune moment" for communications, i.e. sensing the right moment to communicate messages;
- The need to understand the psychology of the market. Clients' constituencies seemed to be capable of rational decision making and so should be provided the facts on which to base decisions. The public was driven by primitive emotions. As a result, the public could be persuaded by symbols. Symbols, by their nature, appeal to the emotions, not to the judgment or intellect. The public was susceptible to the entertainment value of news events, even when they were contrived;
- The best mix of communication channels;
- The ethical dimension of tourism industry communication.

Tourism industry has to pay attention to communication strategies or otherwise missed opportunities and potentially serious risks to efficient and profit are rather costly alternatives.

III. TOURISM INDUSTRY COMMUNICATION STRATEGIES

The idea of communication strategy is taken from strategic management. However, while tourism industry strategic management deals with issues of productivity, profitability, efficiency and effectiveness, a communication strategies objective is development of tourism industry identity, image and reputation.

Generally, numerous examples from worldwide tourism industry demonstrate that tourism industry communication strategies by its nature are either offensive or defensive.

The different parts of a contemporary tourism industry communication function perform worldwide, activities such as tourism industry advertising, and the management of tourism industry identity, image and reputation.

Tourism industry identity is the various attributes, including names, brands, and symbols. A related concept, tourism industry image, is a reflection of that tourism industry identity. In other words, tourism industry image is how each constituency views specific tourism industry. Reputation represents the cumulative impact of the images all constituencies have of specific tourism industry. Both reputation management and tourism industry advertising should be handled in the tourism industry communication function because they have a direct bearing on how the tourism industry is perceived by its most important constituency's [19].

Activities of the tourism industry communication function are [19]:

- Strategy formulation and implementation
- Tourism industry identity, image, and reputation
- Tourism industry advertising and advocacy
- Customer relations
- Employee communications
- Investor relations
- Government affairs
- Community relations
- Media relations
- Crisis communication
- Management of new communication technologies

Not every tourism industry will be able to include all of the activities previously identified as parts of one strategy, but a majority of these functions must be included for the best operation. Indeed, the activities must be connected in some way for a tourism industry to speak with a single voice.

Along with a role in strategy formulation and implementation, tourism industry communication has recently expanded its scope of responsibilities in order to include the use of communication technologies.

The access to data is a crucial issue and therefore very important for managing worldwide communications. Through contemporary technology there is information available through the communication networks of a quality and a degree of sophistication that only, a few decades ago, was solely held by the largest multinational corporations.

With the technology ubiquity in tourism industry the functions of communication enabled by the given technology become ever more important.

Not only has the tourism industry communication function expanded to include responsibility for communication technology as it affects tourism industry communication, but the expansion of technology use in the broader society has given greater visibility and importance to the function of tourism industry communication.

IV. THE POSSIBILITIES FOR APPLYING COMMUNICATION STRATEGIES ON CROATIAN TOURISM INDUSTRY

The Republic of Croatia considers tourism as one of its main strategic guidelines of development. The tourism sector is undoubtedly one of the most significant sectors of the Croatian economy. However, regarding the

available resources, Croatia has not developed a product competitive enough. Croatia is in general unrecognizable as a destination. Croatia disposes of inadequate capacities, the inland, and the historical and cultural heritage are not evaluated enough [7].

Unfortunately, in spite of the country's hundred years of tourism tradition, we have to still speak of it as a new destination, primarily as its name is concerned [4].

Croatia on the international tourism market shares the faith of all Mediterranean destinations. Therefore tourism industry should also respect demand characteristics of customers attracted to this region. More frequently tourists' chief interest is in the quality of the product purchased. Croatia is facing the peril of market defeat in the case of untimely or inadequate inclusion into competition on Mediterranean tourist market. Therefore the immediate and most important aim of the Croatian tourism is qualitative transformation.

Tourism industry facilities in Croatia are mostly appropriate for mass-tourism, which nowadays is not an up-to-date option. The insufficient quality level of service is caused by the lack of standard in projecting, constructing and equipping its buildings. Unprofitable facilities prevail – those that cannot create income. Supply structure in this way cannot be efficient. With all this, the capacities of the Croatian tourism industry are becoming more and more uncompetitive on the international market. The consequence of inadequate tourism industry facilities is deficient utilization level in compare to competitors.

It is one of the reasons for a low occupancy rate. Other reasons can be searched in the context of the lack of identity of Croatia as a tourist destination, i.e. its poor offer unable to attract tourists and other consumers during the low season.

Neither the rate of capacity exploitation, nor the profit itself adequately indicates the successfulness in the modern tourism industry. A pleased customer should be the ultimate result of a well-done tourism-related enterprise.

An accelerated adoption of new strategy requires changes on the macro-level. The provision of additional investments in entertainment facilities and equipment in order to prolong tourist season is of great significance for Croatia. It is necessary to build small accommodation facilities adapted to the requirements of individual tourists. Investments may play an important role by investing in family and smaller tourist and hotel facilities. Innovative forms of investments involve long-term cooperation of partners' i.e. direct investments, joint investments, management controls and franchising. Foreign direct investments include know-how, and development of human resources. Franchising is particularly important for Croatia because it provides faster and easier internationalization of business.

The main tourism industry objective now is desirable identity configuration, and the way the potential customers perceive it [13]. In that respect, tourism industry should constantly expand their offer with new facilities and in such a way they can be more competitive and attractive to their clients.

Therefore, the turning point for Croatian tourism industry is not only in ownership and operative restructuring, but also in creation of a completely new identity and creation of destination's own image. The Croatian strategic communication goal has to be to develop a tourism promotion that will help Croatia create its own tourism identity and the image of a desirable tourism destination. Successful promotional activities are long-term and expensive, so penetration into international tourism market asks for a strategic decision, with clearly objectives.

Simply, success of tourist product and tourist destinations will not only depend on development of products in line with consumer demands and new trends but also on the more intensive marketing of their product and careful targeting of relevant market segments.

V. THE IMPORTANCE OF MEASURING TOURISM

Measuring tourism helps to understand some of the problems of those in charge of decisions related to plans for tourism growth. Statistics are needed for gathering the data which will enable an estimation of tourism importance to researchers, managers and other users, especially to public sector. The reasons for statistical measuring of tourism are as follows [26]:

- to estimate importance of tourism for tourist destinations;
- to make a quantitative analysis of contribution of tourism to economy, i.e. to society as a whole, and especially to define the impact of tourism on balance of payments;
- to help tourist industry and public sector in their process of planning and development of tourism infrastructure;
- to help in implementation of promotional activities;
- to help tourism industry in making decision related to future business activities.

However, there is an information gap between types of statistical data being offered to users and the real users' needs. [20] Actually, most of tourism statistics present measuring of tourist arrivals, overnight stays and spending by the use of questionnaires, the results of which are then interpreted to become representative for the real situation. Therefore, the questionnaires are liable to significant mistakes, depending on the size of the sample. While tourism sector requires reliable statistical data, which managers or decision-makers will be informed about, the public sector in Croatia often manipulates the data [9].

VI. THE ROLE OF THE PUBLIC SECTOR IN TOURISM DESTINATIONS DEVELOPMENT

Tourist destinations take part in a global tourism market competition. The market is characterized with a continually growing competitiveness. In this context, it is possible to speak about the so-called hyper competition [25] in tourism. According to Page, it is possible to define the following four processes, typical of modern tourism and contributing to hyper competition [25]:

- tourist require an improved quality at lower prices;
- implications of IT development;
- occurrence of very aggressive business entities ready to enter the market for a longer period with the so-called loss leader products aiming to destroy their competition;
- barriers of authorities towards competitions are progressively being removed worldwide.

Tourism management (elected by the public sector) requires certain measures to correct any deviations in accomplishing the objectives determined [9]. Unpredictability and taking risk are here unavoidable. In this context, managers of a certain tourist destination must ensure the destinations being able to adjust, which will allow for the destination's survival.

Authors of papers on tourism agree trends in tourism are influenced by a series of exogenous and endogenous factors not related with nor controlled by tourism. Managers must forecast the future to reduce risks and to increase possibilities for success. Therefore, tourism managers cannot avoid the need for a kind of forecasting the future trends in tourism. Those forecasts are results of guessing, teamwork or use of complex models and have a significant impact on managerial decisions. Jefferson and Lickorish in Marketing Tourism: A Practical Guide [2] point out the fact that forecasting is not a precise science as it tries to estimate the future potential and a series of possible scenarios related to possible level of changes in a certain category. According to Bull [1] there are two basic types of forecasting: forecasts based on qualitative techniques and quantitative forecasting methods using techniques deriving from statistics and economics.

Forecasting tries to determine the way the tourist flows influenced former trends and the way they can change in the future. Although forecasting will never be a precise science, it is one of the foundations for making plans about future changes in tourism.

Management of tourism destinations development is a complex question for the following reasons [26]:

- tourism sector is not a homogenous sector of economy as it consists of various activities included in tourism flows;
- certain business activities included in tourism sector are not always seen as an integral part of this sector;
- tourist destinations, i.e. the areas where tourism activities take place, are not controlled only by management of tourism sector but also of public sector, which coordinates the interests of the local community and business entities in terms of preservation of the resource basis they use;
- public sector is responsible for promoting development and marketing of tourism.

To formulate a successful developmental policy, all those connected with a tourist destination should be involved in different stages of this process. Developmental policy of a certain destination presents a smaller or a larger segment in formulating tourism policy within an integrated regional or national policy. The destination's surrounding is constantly changing; therefore the politics itself should be dynamic.

VII. CONCLUSION

The development of tourism needs to be managed and not left uncontrolled. The public sector approaches tourism with special interest due to its positive impact on the economy. However, in order to realize the benefits of the effects of tourism, the public sector must achieve certain prerequisites for the development of tourism. Ultimately, the development of tourism must stimulate the development of the economic activities that do not belong to the tourism sector [9].

Achieving a balance between the needs of each interested business and a sustainable development of tourist destinations is a real challenge. Therefore, the management of tourism is a complex task and there are good reasons why the public sector is usually in charge of its good functioning in society.

The fundamental role of the public sector in tourism lies in planning its development. The public sector by its intervening in tourism development seeks to achieve its long-term sustainable development, i.e. the maximization of benefits from tourism activities while preserving the attractiveness of tourist destinations.

The achieved level of development and utilization of capacities of Croatian tourism industry beyond any doubt require change. The one of possible options to achieve determined objective, i.e. qualitative improvement of Croatian tourism industry is defining the communication strategy. The communication strategy result, desirable identity and positive image in social and ecological environment, also require for an analytical research of competition.

Successful management of tourism as much as tourism planning and regulation of activities related to tourism, requires coordination between government bodies, interest groups, private sector and the involvement of local and regional government. The public sector, on the one hand, generally has a reactive role in terms of the regulation and control of tourist activities on the other hand, has a proactive role in planning and managing tourism.

Abstract – The basic function of accounting information system in local government is production of information on the basis of data processing as a result of financial transactions. This kind of information usually is the foundation and support of information systems management accounting and is conceived as a system for identifying, collecting, processing and exchange of financial and other data used to support decision making.
The main object of this paper is to analyse the importance and the impact of use of Accounting Information System (AIS), as well as use of information technology in accounting in whole. Also the authors will analyse the modelling of AIS, establishing quality of financial information, security of model of AIS in local government units, especially in decision making process in AIS and in internal control procedures.
The author's will also give and overview of standards in financial reporting with emphaisis on ISO/IEC 2510: 2011 and XBRL global standard as well as their assessment in use in local and regional governments.

Key words: accounting information system, control, quality, efficiency, financial reports, control, regional and local governments

I. INTRODUCTION

The standards of the European Union, in terms of local government, are clearly defined with European administrative space based on the principle of good governance and management, harmonization, development and codifying with it's convergence.

In most European countries, local authorities rely in an appropriate (usually higher) rate on financial grants from the central government and by budget planned accounting. [1] Although the constitutional basis for financial grants is not the same in all European countries is the central government grants to local budgets vary from 30% to 70% (United Kingdom, Netherlands, Ireland, etc.).[2]

In Croatia, the current issue is the issue of decentralization of the fiscal system and the transfer of authorities, responsibilities and funds from higher levels of government to the local level. Also this process has inevitably a political dimension which can be reduced to different ways of organizing economic and political institutions, which then define the financial strength of the local community. Local and regional governments in Croatia are characterized by a relatively weak financial capacity - share in GDP in budgetary spending is negligible; efficient use of public resources and effectiveness in achieving the objectives of relevant public policies are still not at a satisfactory level. In this context, reform of the part of the fiscal system, which regulates the relationship between central and local authorities is a necessary part of both economic and political reforms. Specifics of regional and local self-government in the Republic of Croatia speak in favor of greater decentralization, especially in order to stop the trend of depopulation of certain areas, but also to relieve the pressure of population on urban areas and attracting foreign investment. In this direction, in order to achieve the highest possible degree of fiscal decentralization, local governments must ensure that generous funding that will allow the provision of public services within their purview.

The next step in this direction is the establishment of a computerized accounting system which would enable a more efficient overview and insight into the current indicators of budgetary accounting. In favour of giving

[2] AULFIELD, J., „Local govermnent finance in OECD countries", University of New south Wales, 2008., p 4

the bigger efficiency and transparency as well as higher level of control and security – implementation of Accounting Information Systems (furthermore AIS) in the actual suggested process of decentralization which is discussed at this moment – can present the step forward in Croatia.

II. DECISION-MAKING PROCESS USING AIS

The goals of AIS differ depending on characteristics of organization which implements them. When speaking of companies, efficient usage of information through AIS can have various goals. However, in the end, entire set of goals converge to the fundamental goal every company has – profit maximization for the owners.

The situation with the local government units is somewhat different because they aim to provide the best possible service to the community and, accordingly, public benefit maximization tendency exists unlike companies which aim to maximize owner's profit.

One of the most important functions of AIS is to support decision-making at all organizational levels within a local government unit.

In addition to the function of providing periodical information to the external users through formalized financial statements, AIS also has function of providing relevant information at all organizational levels within an organization (in this case local government unit), especially to the highest management levels in process of decision-making. AIS handles both financial and non - financial transactions that directly affect the processing of financial transactions. [3] Besides traditional financial information (the amount of cash available, cost structure etc.), non-financial information is also needed for the more efficient decision-making process because certain information that can be very significant aren't contained in financial statements and attention should be paid to them.[4] When changes are made to customers' data, for instance change in next of kin and/or address, these changes provide vital information for processing of future data to such users/customers..[5]

Nowadays, „information overabundance" [6] is additional problem which can further complicate the decision-making process and because of which „computational procedures for decision-makers have been developed when using such information for specific decisions.". The same attention should bei also given to "data quality". The main understanding of this term is shown on Figure 1.

Dimensions	Definitions
Accessibility	The extent to which data is available, or easily and quickly retrievable
Appropriate Amount of Data	The extent to which the volume of data is appropriate for the task at hand
Believability	The extent to which data is regarded as true and credible
Completeness	The extent to which data is not missing and is of sufficient breadth and depth for the task at hand
Concise Representation	The extent to which data is compactly represented
Consistent Representation	The extent to which data is presented in the same format
Ease of Manipulation	The extent to which data is easy to manipulate and apply to different tasks
Free-of-Error	The extent to which data is correct and reliable
Interpretability	The extent to which data is correct and reliable
Objectivity	The extent to which data is unbiased, unprejudiced, and impartial
Relevancy	The extent to which data is applicable and helpful for the task at hand
Reputation	The extent to which data is highly regarded in terms of its source or content
Security	The extent to which access to data is restricted appropriately to maintain its security
Timeliness	The extent to which the data is sufficiently up-to-date for the task at hand
Understandability	The extent to which data is easily comprehended
Value-Added	The extent to which data is beneficial and provides advantages from its use

Figure 1. Data quality dimensions (Source: Wang & Strong 1996.)[7]

In the view of before mentioned information overabundance there is the question of utilization of certain information. Key characteristics when considering degree of information usability are:[8]

- Relevance,
- Reliability,
- Completeness,
- Timeliness,
- Intelligibility,
- Verifiability.

Accountability of leaders and groups that manage modern local government units is significantly increasing which indicates the requirement for efficient use of scarce resources and achieving planned goals.[9]

It is important to highlight that the manner of functioning of local government units in Republic of Croatia is significantly different than in the past. Political parties gain the trust of citizens on local level and, accordingly, legitimacy within a specified period to improve the local government unit in the different segments. If they fail, it is most likely that they will be „punished" at the following elections and their possibility of further local government unit management denied.

No. 4., November 2013 Issue., 2013., p 157.

Therefore, it is in the interest of local government unit leaders to ensure the quality information which enables them to bring optimal decisions and enhance the probability of retaining their political positions.

The Republic of Croatia belongs to the countries that experienced the transition and thoroughly changed economic system in the late 20th century. Accordingly, we can talk about „progressive environment“ and „the need of a more informative accounting information system“ in Republic of Croatia which went through significant changes similar to Poland in the same period.[10] Unfortunately, the crisis and the following experience of GDP falling (continuously) on the national level in Croatia didn't go in favour of getting the AIS on the higher level so in this matter the authors will disccuss on the best way to implement the AIS and AIS reporting in the public, reginal and local self-governments in order to harmonise their functioning and their level of use of modern information technologies.

The good example, in that area presents the reform conducted by Italian local authorities' also emphasized performance control of public managers with evaluation of „their ability to achieve stated objectives, both financial and non-financial, with the set of resources available and within their degree of autonomy and responsibility.“11

Speaking of local government units reforms, the case of Portugal can also be mentioned because Portuguese local governments improved their information system (and consequentially the quality of information and decision making) in a way that besides „traditional cash-based budgetary accounting, the system now includes accrual-based financial accounting and reporting, as well as cost accounting.“[12]

The research conducted in Indonesia showed that „information technology utilization has positive and significant impact on the quality of financial statements of the provincial government.“[13]

III. QUALITY CHARACTERISTICS IN ACCOUNTING INFORMATION SYSTEMS

The basic function of accounting information system is production of information on the basis of data processing as a result of financial transactions. This kind of information usually is the foundation and support of information systems management accounting and is conceived as a system for identifying, collecting, processing and exchange of financial and other data used to support decision making. There is no doubt that the function of AIS same in this case with local governments and with businesses as the quality of accounting information to ensure the achievement of the targets (as shown on Figure 1.) set by the idea that someone always has to be responsible for certain costs, otherwise it will cost to grow out of control.[14]

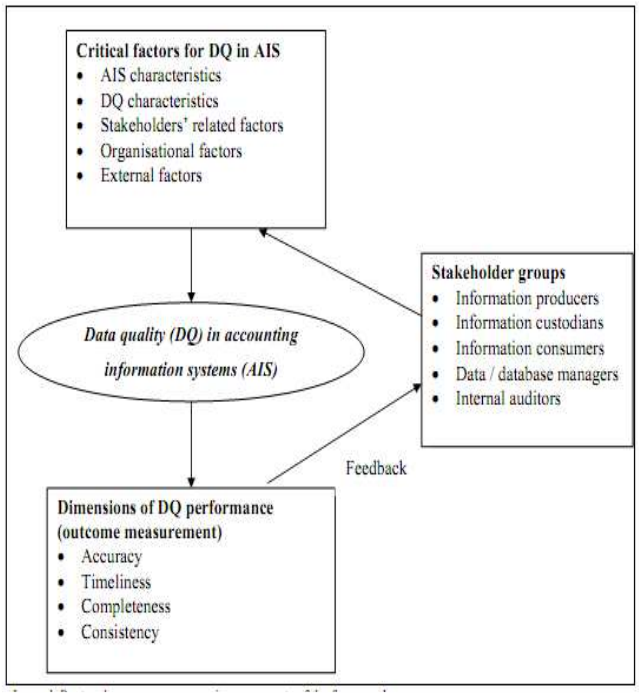

Figure 2. Data quality in Acounting information systems (AIS)[15]

If we are addressing to the quality characteristics in accounting information systems, several high-level approaches to modelling of the quality of software products have been proposed: these models are based on the idea that there are a number of important high-level quality factors of software products that should be measured. These factors are determined by lower-level criteria which are supposed to be much easier to measure than factors; for this reason, metrics are proposed as criteria. As a consequence, all the approaches proposed so far are based on the decomposition of a set of quality attributes in order to define a hierarchic structure of characteristics and a way to relate them to some technical aspects of the product.

These and other efforts have led to the definition of a number of draft standards which directly address software measurement issues. The main and most popular one, ISO/IEC 2510: 2011, gives standard definitions of quality attributes and proposed measures, together with a set of application guidelines.

[14] Peršić, M., Accounting inforamtion in management quality system, Praksa i daljnji razvoj urpavljanja kvalitetom / Bešker, Marko (ur.). - Zagreb : OSKAR, Centar za razvoj i kvalitetu , 2001. , p 259-267
[15] Availbale at Hongjiang Xu, M., Critical Success Factors for Accounting Information Systems Data Quality, https://eprints.usq.edu.au/1526/2/Xu_2003_whole.pdf p 29, (23. 02. 2015.)

The fundamental objective of the ISO/IEC 2510 standard is to address some of the well known human biases that can adversely affect the delivery and perception of a software development project. These biases include changing priorities after the start of a project or not having any clear definitions of "success."

By clarifying, then agreeing on the project priorities and subsequently converting abstract priorities (compliance) to measurable values (output data can be validated against schema X with zero intervention), ISO/IEC 2510 tries to develop a common understanding of the project's objectives and goals – as shown on Figure 2.[16] Also, it is important to mention that ISO/IEC 25012 contains a model for data quality that is complementary to this model .

In whole ISO/IEC 25010:2011 defines:

- A quality in use of model composed of five characteristics (some of which are further subdivided into subcharacteristics) that relate to the outcome of interaction when a product is used in a particular context of use. This system model is applicable to the complete human-computer system, including both computer systems in use and software products in use.
- A product quality model composed of eight characteristics (which are further subdivided into subcharacteristics) that relate to static properties of software and dynamic properties of the computer system. The model is applicable to both computer systems and software products.

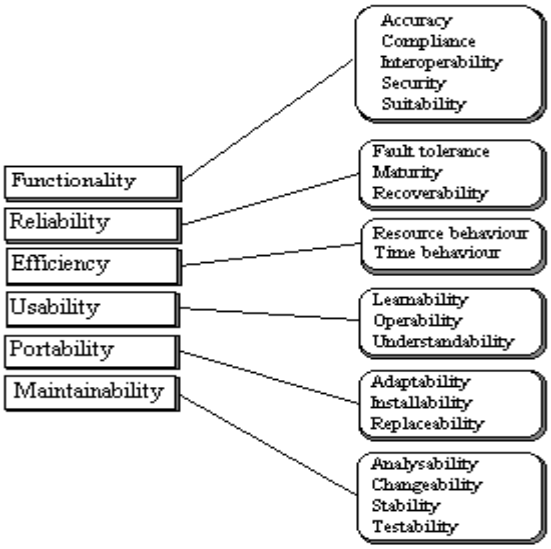

Figure 3. Software Quality Model (ISO/IEC 2510).[17]

[16] ISO/IEC 25010:2011Systems and software engineering -- Systems and software Quality Requirements and Evaluation (SQuaRE) -- System and software quality modelsat http://www.iso.org/iso/home/store/catalogue_ics/catalogue_detail_ics.htm?csnumber=35733 (21. 02. 2015.),

[17] Ibidem.

The characteristics defined by both models are relevant to all software products and computer systems. The characteristics and subcharacteristics provide consistent terminology for specifying, measuring and evaluating system and software product quality. They also provide a set of quality characteristics against which stated quality requirements can be compared for completeness.

Although the scope of the product quality model is intended to be software and computer systems, many of the characteristics are also relevant to wider systems and services as well at this example on accounting information system.

The main scope of the proposed model excludes purely functional properties, but it does include functional suitability. The scope of application of the quality models includes supporting specification and evaluation of software and software-intensive computer systems from different perspectives by those associated with their acquisition, requirements, development, use, evaluation, support, maintenance, quality assurance and control, and audit.

The importance of this model is that for example, it can, be used by developers, acquirers, quality assurance and control staff and independent evaluators, particularly those responsible for specifying and evaluating software product quality. Activities during product development that can benefit from the use of the quality models include:

- identifying software and system requirements;
- validating the comprehensiveness of a requirements definition;
- identifying software and system design objectives;
- identifying software and system testing objectives;
- identifying quality control criteria as part of quality assurance;
- identifying acceptance criteria for a software product and/or software-intensive computer system;
- establishing measures of quality characteristics in support of these activities.

These activities are of great importance for accounting information system so the suggestion will be that when modelling the AIS in local governments units it is proposed to be applied by the ISO/IEC 2510 procedures.

IV. INTERNAL CONTROL IN AIS

Internal control implies procedures „performed by management, executives and employees to ensure the provision of moderate guarantees with regard to the

achievement of objectives that can be grouped in the following categories:

- Efficiency and effectiveness of business,
- Reliability of financial statements,
- Compliance with applicable laws and other regulations."[18]

Control procedures imply methods for „recognition, prevention and elimination of irregularities that impede the fulfilment of the objectives of the enterprise", and the classification is as follows:[19]

- Preventive controls – they have the function of preventing irregularities,
- Detective controls – they are carried out with the purpose of analyzing deviations,
- Corrective controls – they are conducted after the irregularity has already emerged, with the aim of its removal and improving system functioning.

Control procedures are useful in all phases of accounting process:[20]

- Input – preventive control application when entering data,
- Processing – the control of the data and compliance with the relevant regulations,
- Output – checking the information through financial reporting.

Research has shown that, unlike positive impact of information technology on quality of financial statements of local government units, „internal control has no positive significant effect on the quality of financial reporting in work units of provincial government."[21]

In that area, the most famous global standard for exchanging business information is XBRL (eXtensible Business Reporting Language)[22]. It is freely available allows the expression of semantic meaning commonly required in business reporting. The language is XML-based and uses the XML syntax and related XML technologies such as XML Schema, XLink, XPath, and Namespaces. One use of XBRL is to define and exchange financial information, such as a financial statement.

As a proposed model, the positive aspects of XBRL is firstly the wiki repository of XBRL projects is available to be freely explored and updated.[23] Within the last fifteen years, the Securities and Exchange Commission (SEC) in the US, the United Kingdom's HM Revenue & Customs (HMRC), and Companies House in Singapore had begun to require companies to use it, and other regulators were following suit. The SEC's deployment was launched in 2008 in phases, with the largest filers going first: foreign companies which use International Financial Reporting Standards (IFRS) are expected to submit their financial returns to the SEC using XBRL once the IFRS taxonomy has been accepted by the SEC. In the UK in 2013, both HMRC and Companies House accepted XBRL in the iXBRL format. XBRL was adopted by the Ministry of Corporate Affairs (MCA) of India for filing financial and costing information with the Central Government. The only complaint on XBRL, is it's lack of accuracy. The study from April 2009, conducted by North Carolina State University Department of Accounting College of Management, which valuated the accuracy of XBRL filings for 22 companies participating in the SEC's voluntary filing program in 2006 showed it's lack of accuracy. Results of a comparison of XBRL filings to Forms 10-K revealed multiple errors in signage, amounts, labeling, and classification. The study considers that these errors are serious since XBRL data is computer-readable and users will not visually recognize the errors, especially when using XBRL analysis software. There was also a different conclusion, reached in a study in 2013 who argued that companies are going through a learning curve and are steadily improving.[24] However, the ocnlusion based on this studies, is that XBRL still needs improvements to be used as a recmmended model of financial data exchange used in the public, regional or local governments in the future.

CONCLUSION

Author's research and analysis security, control procedures and efficiency of accounting information systems and their use in regional and local Governments sector, has shown firstly that unlike positive impact of information technology on quality of financial statements of local government units, internal control has no positive significant effect on the quality of financial reporting in work units of provincial government. Also if we are addressing to the quality characteristics in accounting information systems, several high-level approaches to modelling of the quality of software products have been proposed: these models are based on the idea that there are a number of important high-level quality factors of software products that should be measured.

On the national level the future prospects for Croatia's strong recovery from recession and return to the pre-recession growth rates are slim unless the country vigorously moves forward in addressing the structural

[21] Nuryanto, Nur Afiah, 2013., p169.
[22] XBRL International (XII) is the international standards organization which develops and maintains the XBRL Standard and related specifications[1] in order to to improve business reporting for the public good. It is a global not-for-profit consortium of approximately 600 public and private organisations working together to support the collection, sharing and use of structured data for data reporting and analysis. More inofrmation available at http://specifications.xbrl.org/ (15. 01. 2015.)
[23] XBRL projects available at http://www.xbrlwiki.info/index.php?title=Main_Page (15. 01. 2015.)
[24] Du, H., Vasarhelyi, M. A. & Zheng, X. 2013. XBRL Mandate: Thousands of Filing Errors and So What? Journal of Information Systems, 27(1), pp 61-78. doi: http://dx.doi.org/10.2308/isys-50399

weaknesses of its economy, according to the World Bank's new Public Finance Review: Restructuring Spending for Stability and Growth report. The global financial crisis, coupled with a delay in the implementation of structural reforms, exposed the weaknesses of the Croatian economy which was especially emphesized on the process of fiscal decentralization. The most important role in this area should be on the Croatian Ministry of Finance which should be give directives and standards in the Public Finances by analyzing the key issues that are standing in the way of strengthening macroeconomic stability and of laying the foundations for a robust economic recovery. However, on streamlining the fact is that government of Croatia spends more on public administration than the new EU member states. Also, it has relatively weak performance in terms of effectiveness, rule of law, and administrative barriers to doing business. The public wage bill is close to 12 percent of GDP, with a tendency to increase further due to further decentralization, creation of new agencies, and the need to build additional capacity to absorb large EU funds. So giving the directives in the area of fiscal reporting and making accounting information systems as a standard on regional and local level should help in process of fiscal decentralization as well as funding based on EU funds.

Until the unique model on national public level in the process of fiscal decentralization is formed (or proposed) the regional and local governments, after the author's analysis of the most important procedures in AIS based on security, quality assurance and control, the suggestion of the author's is modelling the AIS in regional and local governments units based on ISO/IEC 2510:2011 procedures. Also the situation with the regional and local government units is somewhat different because they aim to provide the best possible service to the community and, accordingly, public benefit maximization tendency exists unlike companies which aim to maximize owner's profit, the model of AIS based on procedures of ISO 2510 meets all of the needed requests especially the most important function of AIS: to support decision-making at all organizational levels within a local government unit s described in paper.

Citybus mobile application

Jasmin Abou Aldan, Mario Lončar, Marina Ivašić – Kos
Department of Informatics University of Rijeka, Rijeka, Croatia
{jasmin.abou.aldanm, mario.loncar, marina}@uniri.hr

Abstract – Students, tourists and citizens are often confused by bus lines and timetables or get tired of running to catch their bus or looking for bus stops. This paper describes the mobile application that conveniently provides information about city bus lines. For a selected line, it can gives an overview of timetables, bus stop locations and estimated departures. It also calculates the shortest route from user location to a certain bus stop and can navigate the user to that bus stop. The prototype application is made for local bus lines in Rijeka.

Keyword: iOS application, navigations, maps

I. INTRODUCTION

The idea for this mobile application came in 2012 when we noticed a need for a better access to information about public bus transportation among university freshmen who came to the city for the first time, as well as among the citizens of Rijeka. Until then, available information about the bus lines were shown only on bus stations and on official website of the transporter, but information about exact locations of all stations was not available anywhere.

That kind of arrangement was rather impractical because to know when a bus would arrive to a particular station, one would have to be at that exact station and the problem gets bigger if one does not even know where the station is. We were encouraged to start this project by a frequent sight when people run after or miss a bus because they do not know the exact time when it will arrive at a station. Therefore, we started making various sketches and ideas to solve this problem.

In earlier versions, the application was reading a simple JSON format from Parse [1] because it was easier way to manipulate with data about local bus lines and stations than with the PDF document that was available on the official websites. The next functionality added in the first version of the application were coordinates of all the bus stations and the possibility to start a GPS navigation to a selected station.

II. APPLICATION DESCRIPTION

The main functionality of this application is to give information about local bus lines e.g., directions, locations of bus stations and timetables. To be as intuitive and easy to use as possible, the main applications screen contains a menu in which user chooses whether he needs information about locations of the bus stations or about the timetables (Fig. 1).

Figure 1: Main Screen

If a user selects the Stations button, a screen with all available bus stations will appear (Fig. 2). At first, all of the stations are shown on the map in form of pins, and the user can zoom the map to have a closer look at bus stations in the area of interest. When a particular station is selected, the information box appears on the screen and the user can see which busses pass through that station.

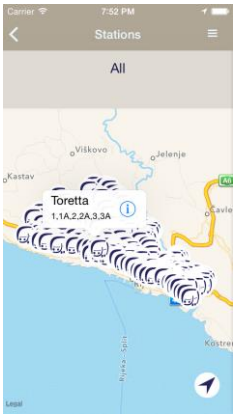

Figure 2: All Bus Stations

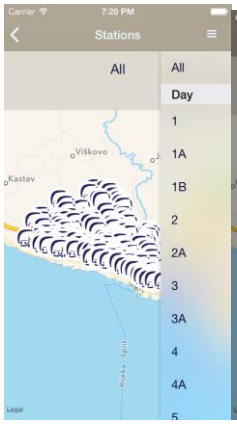
User can also select a side menu item to view all available local bus lines, e.g. 1, 1A, 1B, 2, 2A, etc. (Fig. 3). If the user needs all information about a particular bus line, he can select that line on a given list. Then, available directions will be shown in an alert view (Fig. 4). For each bus line, there are two directions: A direction, from the first to the last station and B in the opposite direction, from the last station to the first one.



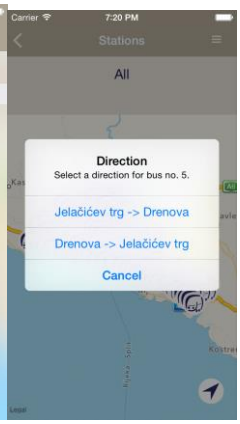


Figure 3: Side Menu Figure 4: Direction Alert

Then, for a given bus line and a selected direction, all stations will be indicated on the map (Fig. 5).

Additionally, by selecting a specific station, the user can start a GPS navigation by Apple Maps application (Fig. 6). Only navigation on foot is relevant, so for that navigation type several different routes are offered and time necessary to reach the station, from the current user location, is calculated.

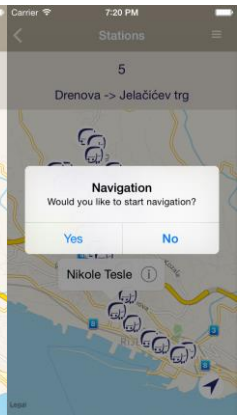

Figure 5: Single Line Figure 6: Navigation Alert

Figure 7 shows the selected route from the user location to the location of the selected station. By default, the walking route is selected, but the user can choose whether he/she wants the pedestrian or car route.

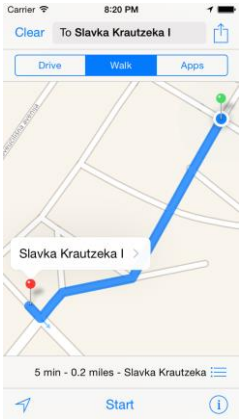

Figure 7: Navigation

For a selected route in the Apple Maps application, user has the ability to assign that route to any contact or to send it via SMS, e-mail, Facebook, etc. (Fig. 8).

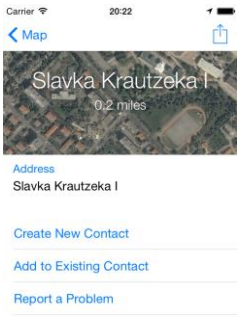

Figure 8: Navigation options

III. IMPLEMENTATION

A. General

The platform used to build the application is Apple iOS. The key feature of this application is manipulation with the maps service that provides a "turn-by-turn" navigation option for cars as well as pedestrians [2].

Both, Apple maps and Google maps can be embedded into an iOS application. Although Google maps where until recently the main maps used in iOS applications, we have decided to use Apple maps because of up-to-date application programming interface (API) and good support for iOS platform. Furthermore, it was shown that Apple maps work faster on the iOS platform than Google maps. However, as Apple maps were recently introduced, Google maps have better and more developed cartography. Since the performance was more important than accurate cartography, Apple maps were embedded in this application.

For the applications backend, Parse iOS software development kit (SDK) [1] is used. Parse iOS SDK is primary used to store data about the bus lines, directions and stations. It has proven to be a stable data storage that

can be easy accessed. Available functions for sending push notifications and statistics are implemented too.

The programming language used to develop this application is Swift [3]. It is a relatively new programming language introduced by Apple in 2014 [4] as a replacement to the former Objective-C language.

The Classes used within the application are part of the Cocoa Touch [5], a frameworks collection for creating native iOS applications. Used frameworks in this application are FoundationKit [6], UIKit [7] and MapKit [8].

Framework FoundationKit is a core framework in which classes for manipulation with strings (Class NSString), time (Class NSTime), numbers (Class NSNumber), arrays (Class NSArray), etc. are defined. All these classes are subclasses of the abstract class NSObject, and inherit their properties. Hierarchy of mentioned classes is shown on the Fig. 9.

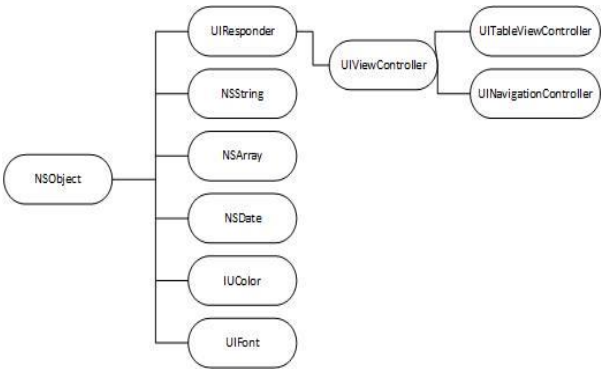

Figure 9: Class flowchart

Framework UIKit [7] contains all classes that are used to build user interface. This framework provides the window and view architecture with a view controller model to be able to encapsulate the contents of a user interface, event-handling infrastructure needed to respond to user inputs, and the application model needed to interact with the system.

To embed a fully functional map interface into an application and for working with maps, classes within MapKit framework [8] are used. The map support provided by this framework includes standard street-level map information or satellite imagery. In addition, automatic support for the touch events that let users zoom and pan the map display is provided. CoreLocation API [9] is used for locating current user position and for GPS navigation.

B. Maps

To represent distribution of bus station on the map and for side menu creation and filling with bus lines three classes are instantiated and overridden: *MapsViewController*, *SideMenu* and *SideMenuTableViewController*.

The *MapViewController* is the interface used to access the basic map services. It creates a map instance that can be displayed using methods inherited from its superclass *UIViewController*[10].

To manipulate with the map user can use finger gestures on the screen but map can also be manipulated by using methods for setting the display type, zoom level or a specific angle.

For example, the code snippet to set a standard map type with the possibility of 3D display and pitch is:

```
mapView.mapType = MKMapType.Standard
mapView.showsBuildings = true
mapView.pitchEnabled = true
```

First zoom is set to the Rijeka city. To specify a map data points that correspond to Rijeka, a latitude and the longitude coordinates of Rijeka on the spherical representation of the Earth is used to set values of the structure *CLLocationCoordinate2DMake*:

```
let zoomLocation = CLLocationCoordinate2DMake (45.337596, 14.426216)
```

Current zoom level is defined with structure MKCoordinateSpan where a smaller delta values correspond to a higher zoom level. For example, the amount of north-to-south distance and east-to-west distance (measured in degrees) that will be display on the map are set to 0.15 with a following code line:

```
let span = MKCoordinateSpanMake(0.15, 0.15)
```

To define and represent areas of interest around a given location (here the *zoomLocation*), with desired zoom level (here the *span*) a data in structures *MKCoordinateRegion* is set as follows:

```
let region = MKCoordinateRegion(center: zoomLocation, span: span)
mapView.setRegion(region, animated: true)
```

The pin that represents bus station is changed from standard red pin to a custom one, e.g. an image of a small bus:

```
pinView.image = UIImage(named:"pinstation.png")
```

Two functions of a *MapsViewController* class are used for customising the map. That is a *sideMenuDidSelectButtonAtIndex* that recognizesrecognizes which button is selected at the side menu and uses its index to call a function *makePins* responsible for drawing pins on the map for a selected bus line. Signature of function *makePins* is:

```
func makePins (coordinates1: Array <String>, coordinates2: Array <String>, linNumb: String, direction: Array<String>) { //code}
```

A *makePins* function opens a pop-up alert view *alertView* in which user can choose the direction of the selected bus line. For example if a direction A is selected, then, for every list item *el* in array *self.direction1*, function reads data and draws pins on the map. Data about bus lines and corresponding directions and bus stops are stored in an external database .plist [11] (a database similar to XML) in form of key – value data.

```
alert.addAction (UIAlertAction (title: dirA,
style:.Default, handler:
{action in
    for el in self.direction1 {
      let lat = tmp[0] as NSString
      let long = tmp[1] as NSString
      let name = tmp[2]
      let stations = MKPointAnnotation()
      let station_coordinates =
    CLLocationCoordinate2DMake(lat,long)

stations.setCoordinate(station_coordinates)
       stations.title = name

    self.mapView.addAnnotation(station1)
      }}))
```

Similar code is defined for the direction B, only difference is array self.direction2 used for data about stations in directions B.

```
alert.addAction(UIAlertAction(title: dirB,
style:.Default, handler: {action in
   for el in self.direction2 {
       //the same code
   }
}))
```

C. Navigation

After pins are created and shown on the map, the user can activate GPS navigation to the selected station.

For navigation, application uses MKDirections API within the Map Kit framework. MKDirections API provides route-based directions data from Apple servers and contains step-by-step walking or driving directions, travel time estimation, alternate routes etc.

When navigation is called, the application calls *provideDirections* function within which the part of the code responsible for navigation is executed. This function takes the user position and the position of the destination (selected bus station), generates direction request and sends it to the Apple servers where the route will be calculated.

```
let placemark = placemarks[0] as CLPlacemark
let destinationCoordinates =
placemark.location.coordinate
directions.calculateDirectionsWithCompletion
Handler {(response: MKDirectionsResponse!,
error: NSError!) in //code for starting the
navigation}
```

App server makes the calculations and sends them back to the application. The application should be able to accept directions response and should declare a document type to handle incoming routing requests. Then, Apple maps application opens and the navigation starts.

```
MKMapItem.openMapsWithItems([response.destin
ation], launchOptions: launchOptions)
```

D. Menus

Data about bus lines are shown on the side menu. To define menu, its size, position, colour and functionality Class *SideMenu* is used. The width of the menu is set to 100 pt (point). If the menu is opened, then the starting point of the menu is the width of the screen reduced by the width of the menu. If it is closed, then the initial point is on the edge of the screen increased by 1 pt to be sure that it does not appear on the screen.

SideMenu is a subclass of the *NSObject* [12] class. It uses *SideMenuTableViewControllerDelegate* that communicates with *SideMenuTableViewController* in order to fill out the menu with data. Data used to fill out the menu were forwarded with *MapsViewController* from .plist database.

The *SideMenuTableViewController* forwards the chosen index to the *SideMenu* class, which forwards it later to the main *MapsViewController* class.

MapsViewController class is a subclass of the *UITableViewController*[13] class that is usually used to display table data in different views.

For communication with a *SideMenu* class a *SideMenuTableViewControllerDelegate* protocol is used (Fig. 10).

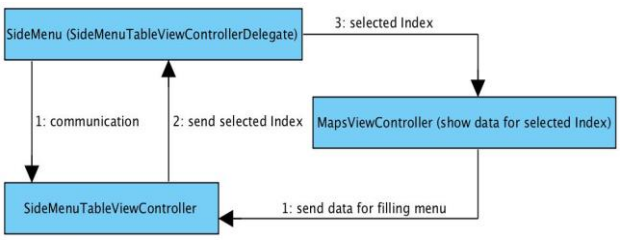

Figure 10: Communication flowchart

IV. CONCLUSION

The mobile application that conveniently provides information about city bus lines is displayed.

The application is available in beta test version for iOS, and it will soon be available for Android platform.

In the first upgrade, the number of bus lines will be expanded with nightlines and with suburb lines. In addition, for a chosen bus station estimated time needed to reach the station on foot from the user current location will be calculated as well as the calculation of closest bus departure from that station. As a new functionality, the application will deliver the latest news from the public transportation web site services that will be available in form of push notifications.

The application can be modified to provide useful information for other means of public transport and other transportation service providers in Croatia, and beyond.

ACKNOWLEDGMENT

On this occasion, I would like to thank my brother Damjan Abou Aldan for his contribution in creating design for the User Interface of the application.

Abstract – In this paper, the development of e-business in Croatia in the last decade has been researched, with special emphasis on legislation, organization and state influence, along with the influence of other relevant and potential stakeholders. The influence of Croatian inclusion into the European Union has been analyzed, both before and after the inclusion in 2013. The main directions of e-business development in Croatia are presented. Main segments of e-business have been analyzed (b2b - business-to-business, b2g - business-to-government and c2g - citizen-to-government). EU DESI, UN e-Government Survey, e-Participation Index (EPI), World Economic Forum (WEF) data, UN Open Government Data (OGD) and other relevant indices have been studied and interpreted. In the closing part of the paper, guidelines for development of e-business in Croatia are presented along with author conclusions, specifying e-business as a key element for the evolution of digital economy and digital society.

I. INTRODUCTION

The research started with three different relevant resources for analysis and recommendations of e-business development in Croatia:

- e-Domains observed in the paper: B2B & B2G, as being the most socially relevant,
- Nicholas Negroponte‘s vision outlined in the 1995 book: Being Digital, and
- EU 2010-2020 Digital Agenda for Europe.

Croatia has joined EU in the summer of 2013 and the object of our research is the achieved level of adoption of e-business and e-government paradigms one and a half years after the accession. To understand the current state of e-business in Croatia, available and published indices from relevant organizations have been identified, studied thoroughly, explained and conclusions were drawn based on them.

Finally, recommendations are given on how to improve the current situation in form of exact steps to be taken after identifying the main involved stakeholders.

II. ASSESSMENT METHODOLOGY OF E-BUSINESS DEVELOPMENT IN CROATIA

Digital economy and society results presented in the paper are assessed by using the latest indices and reports from reputable and up to date sources. These sources include the following:

- EU: Digital Economy & Society Index 2015 [1],
- UN: E-Government results assessed according to UN E-Government Survey 2014 [2],
- World Economic Forum: Global Competitiveness Report 2014-2015 [3],
- World Economic Forum: Global Information Technology Report 2014 [4].

III. RECENT DEVELOPMENTS IN E-BUSINESS AND E-GOVERNMENT AREAS IN CROATIA

In order to analyze various facets of achieved level of implementation of e-Business and e-Government systems in Croatia, selected aspects are presented including the most recent developments related to the implementation of such systems.

National PKI system provided by Financial Agency – FINA [5] is being used by public and private users. FINA is the only issuer of digital certificates in Croatia. Citizens are generally not using FINA certificates to access e-services. The eID project, which was promised by Ministry of Interior to include certificates for digital identification and signature is still not on the horizon. FINA is also serving some important applications related to e-Government and b2g, among them most notably HITRO.HR (Croatian Government’s service for quick communication between individuals and business entities and the state administration), Central Registry of Insured Persons (REGOS), Public Sector Employees Registry (RegZap), Blue Diesel Consumption Supervisory System, Registry of Court and Notary Public Securities, HITRONet end e-File.

The e-Citizen system [6] promoted by Ministry of Administration is in its initial phase, offering several services to citizens and business. Since there is no widespread national certification mechanism available, e-Citizen system is trying to temporarily fill the gap by using its own hybrid NIAS (*National Identification and Authentication System*) [7] consisting of combination of several local and partial identification and authentication solutions. E-Citizen is not expected to show its full potential until the 'real' NIAS is in operation and when a fully expanded set of useful and practical services is offered to citizens and businesses.

GS1 organization in the Republic of Croatia [8] is, among other activities, active in providing its members with electronic cataloguing GlobeCat service which is, thru built-in global synchronization network, offering far reaching possibilities for Croatian GS1 member companies.

The Eurostat eInvoicing data for Croatia's eInvoicing penetration in 2014 is about 10% which is, according to authors' opinion, also a statistically optimistic result. Slow take-up of eInvoicing in Croatia, in both public and private sector is a good indicator of the whole eBusiness implementation along both the supply and financial chains. Some good examples in supply-chain automation [9] clearly show what results could be reached on the larger scale if more companies in Croatia adopt similar development path. Croatia is lagging in adoption of eInvoice, being included into the lowest <15% penetration group [10].

IV. OVERVIEW OF EU DESI 2015. (DIGITAL ECONOMY AND SOCIETY INDEX)

On 24th of February 2015, EU has published the results of the new Digital Economy and Society survey with the appropriate scoring and rankings among 28 EU member states. All data contained in this paragraph is derived from the data presented in that survey [11]. Here the authors reproduce some of data presented by the EU. It should be noted that Croatia has been analyzed by the EU as a member of the low-performance cluster of countries.

DESI survey scores range from 0 to 1, the higher the score the better the country performance. Structure of DESI indices and composition factors related to principal policy area, sub dimension weights, indicators, units and ranges are shown in Table 1.

TABLE I. STRUCTURE OF DESI INDICES AND COMPOSITION FACTORS

Principal policy area (weight %)	Sub-dimension (weight %)	Indicator	Unit	Min	Max
Connectivity (25%)	Fixed BB (33%)	Fixed broadband coverage	% households	80%	100%
		Fixed broadband take-up	% households	50%	100%
	Mobile BB (22%)	Mobile broadband take-up	Subscribers per 100 people	25%	150%
		Spectrum	% of the target	25%	100%
	Speed (33%)	Next Generation Access coverage	% households	0%	100%
		Subscriptions to fast broadb.	% of subscriptions >=30Mbps	0%	75%
	Affordability (11%)	Fixed broadband price	% of individual gross income (EUR PPP)	0%	4%
Human Capital (25%)	Basic skills and usage (50%)	Internet users	% individuals	40%	100%
		Basic digital skills	% individuals	0%	100%
	Advanced skills and development (50%)	ICT specialists	% individuals	0%	5%
		Science, Technology, Engineering, Math graduates	Graduates in STEM per 1000 individuals (20-29 year old)	0	40
Use of internet (15%)	Content (33%)	News	% individuals who used internet in the last 3 months	33%	100%
		Music, videos and games	% individuals who used internet in the last 3 months	20%	100%
		Video on demand	% households with a TV	0%	100%
		Internet Protocol TV	% households with a TV	0%	75%
	Communication (33%)	Video calls	% individuals who used internet in the last 3 months	20%	100%
		Social networks	% individuals who used internet in the last 3 months	40%	100%
	Transactions (33%)	Banking	% individuals who used internet in the last 3 months	0%	100%
		Shopping	% internet users (last year)	0%	100%
Integration of digital technology (20%)	Business digitalization (60%)	Electronic information sharing	% enterprises	0%	50%
		RFID (Radio Freq. IDentif.)	% enterprises	0%	15%
		Social media	% enterprises	0%	50%
		eInvoices	% enterprises	0%	50%
		Cloud	% enterprises	0%	50%
	eCommerce (40%)	SMEs selling online	% of SMEs	0%	33%
		eCommerce Turnover	% turnover	0%	33%
		Selling online cross-border	% of SMEs	0%	25%
Digital public services (15%)	eGovernment (67%)	eGovernment users	% of internet users (last year)	0%	80%
		Pre-filled forms	score (0 to 100)	0	100
		Online Services completion	score (0 to 100)	0	100
		Open data	score (0 to 700)	0	700
	eHealth (33%)	Medical data exchange	% general practitioners	0%	100%
		ePrescription	% general practitioners	0%	100%

In the DESI 2015 survey, low-performing cluster of countries comprises of Bulgaria, Cyprus, Greece, Croatia, Hungary, Italy, Poland, Romania, Slovenia and Slovakia. As shown in Fig. 1, Croatia ranks better than EU's average in integration of digital technology. Croatia ranks better than low-performance cluster of countries in digital public services and human capital.

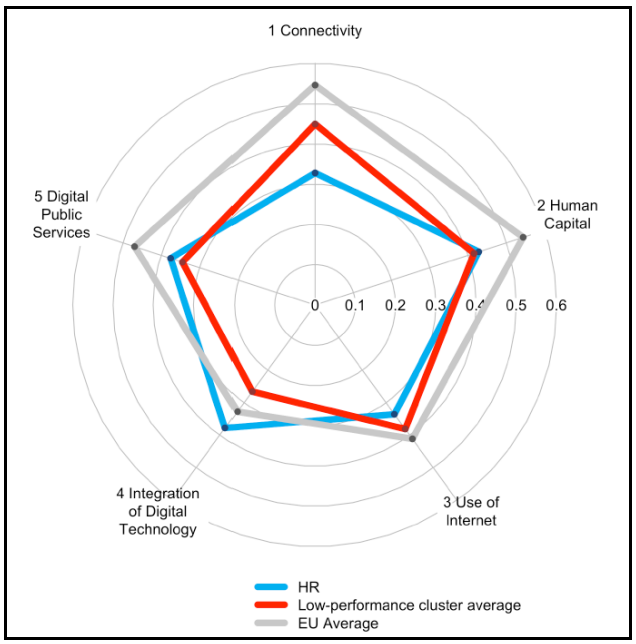

Figure 1. Croatia's DESI 2015 overall score

Croatia has a weaker rank than the representative cluster in use of Internet and connectivity, where it has the worst rank among all EU member states.

In the DESI 2015 survey, Croatia has achieved an overall score of **0.37** (the same as the previous year) and ranks **24th** (three places down compared to the previous year) out of the 28 EU Member States. Croatia falls into the low-performance cluster, ranking below EU's average (Fig. 2).

	Croatia		Cluster	EU
	Rank	Score	score	score
DESI 2015	24	0.37	0.38	0.47
DESI 2014	21	0.37	0.34	0.44

Figure 2. Croatia's DESI 2015 ranking within the EU

Data, ranks and scores related to different domains (Connectivity, Human Capital, Use of Internet, Integration of Digital Technology, and Digital Public Services) are shown in Table II.

TABLE II. CROATIA'S DESI 2015 RANKING COMPARED TO PREVIOUS YEAR, CLUSTER SCORE AND EU SCORE

		Croatia		Cluster	EU
		rank	score	score	score
1. Connectivity	**2015**	**28** ↓	**0,33** ↓	**0,45**	**0,55**
	2014	26	0,36	0,39	0,51
2. Human Capital	**2015**	**21** ↓	**0,43** ↓	**0,42**	**0,54**
	2014	20	0,45	0,38	0,52
3. Use of Internet	**2015**	**25** ↓	**0,34** ↓	**0,38**	**0,41**
	2014	22	0,35	0,33	0,39
4. Integration of Digital Technology	**2015**	**10** ↑	**0,38** ↑	**0,27**	**0,33**
	2014	17	0,31	0,23	0,30
5. Digital Public Services	**2015**	**19** ±	**0,38** ↓	**0,34**	**0,47**
	2014	19	0,36	0,33	0,45

In the year 2015 Croatia has achieved better score than in the previous year in Integration of digital technology and Digital public services, but other three DESI scores are lower than in the previous year. Better rank in the year 2015 than in the previous year Croatia obtained only in Integration of digital technology (+7), mainly because the e-Prescription service (ranking 3rd in EU, only behind Estonia and Denmark) entered in full operation and received maximal scores. All other rankings are lower than previous year, except for Digital public services where the score remained the same.

EU DESI data for the year 2015 are published accompanied with a very detailed Methodological note (68 pages) [1]. In addition to that, EU also provides interested researchers with raw data which can be used for further deep analysis of digital phenomena in EU member states, and EU as a whole.

As shown in Figure 2, in DESI 2015 Croatia ranks at 24th place among 28 EU member states. Denmark is at the first place with the DESI score of 0,68 and Romania is at the last place with the DESI score of 0,31.

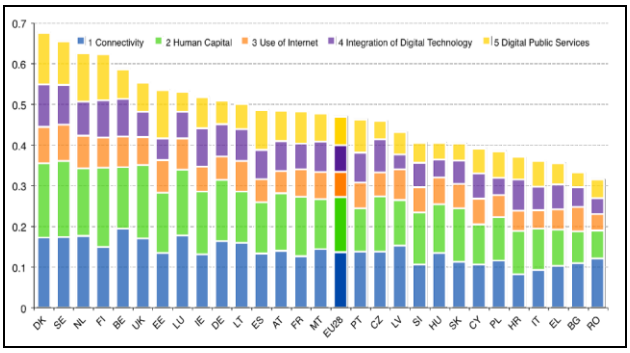

Figure 2. DESI 2015 EU main rankings

V. UNITED NATIONS E-GOVERNMENT SURVEY 2014

The UN has after two years published its new eGovernment Survey in New York in 2014 [2], so it is possible to compare similar data for the year 2012. The survey includes the Annexes with detailed survey methodological manual describing formulas used to calculate all relevant indexes. Croatia was ranked 47th in the survey, with EGDI (E-Government Development

Index) of 0,6282 (17 places lower than two years before when Croatia was ranked 30th). The survey, among other things, states:

"The small proportion of high scores in the Online Service Index (OSI), for example in the range of 0.7 and above, suggests that some governments with access to more advanced telecommunication infrastructures may be able to leverage existing technology more fully in public service delivery, especially in cases where human capital is high. To illustrate, consider on the one hand the case of Republic of Croatia that is well advanced in human capital and telecommunication infrastructure, but has an Online Service Index that is less than 0.5. On the other hand, consider Uruguay which has the same size and similar income levels to those of Croatia, as well as similar Human Capital Index (HCI) and Telecommunication Infrastructure Index (TII), but has invested more in online services, which is reflected in its OSI (0.8504) as shown in Figure. This shows that Republic of Croatia has great potential to improve its online services."

According to that, the comparison between two quite similar states, Uruguay and Croatia, shows some interesting results, as shown in Figure 3.

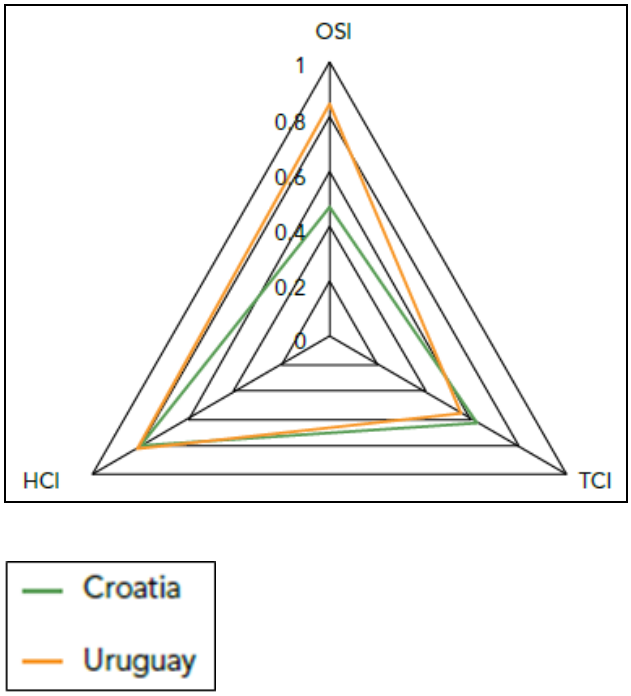

Figure 3. OSI, HCI and TCI comparison between Croatia and Uruguay

It is important to note that eGovernment eCentral State Office for eCroatia was three year ago transferred into a Ministry of Public Administration by a newly appointed government, becoming the Department for eCroatia.

Some more information from the UN E-Government 2014 survey can be extracted from component indices shown in the following figures.

	1.Online Service Component (OSI)	2. Telecomm. Infrastructure Component (TII)	3. Human Capital Component (HCI)
EGDI = 0,6282	**0,4646**	**0,6271**	**0,7928**

Figure 4. E-Government Development Index (EGDI)

	Stage 1 Emerging presence	Stage 2 Enhanced presence	Stage 3 Transactio-nal pres.	Stage 4 Networked (connected) presence
OSI = 0,4646	**59%**	**68%**	**26%**	**18%**

Figure 5. Online Service Index (OSI)

	% of Internet Users	Fixed telephone Subscr. per 100 inhab.	Mobile-Cellular Subscr. per 100 inhab.	Fixed BB Subscr. per 100 inhab.	WIFI BB Subscr. per 100 inhab.
TII = 0,6271	**63**	**38,07**	**115,41**	**20,67**	**53,9**

Figure 6. Telecommunication Infrastructure Index (TII)

	Adult literacy (%)	Gross enrolment ratio (%)	Expected years of schooling	Mean years of schooling
HCI = 0,7928	**98,99%**	**81,8%**	**14,11**	**9,8**

Figure 7. Human Capital Index (HCI)

Survey methodology for 2014 states: *„For the 2014 Survey questionnaire, the thematic subthemes identified are:*

- *Whole-of-government;*
- *Multichannel service delivery;*
- *Bridging the digital divide;*
- *Increasing usage;*
- *Open Government;*
- *E-participation."*

E-Participation Index (EPI) is derived as an important supplementary index to the UN E-Government Survey. It extends the dimension of the Survey by focusing on the use of online services to facilitate provision of information by governments to citizens ("*e-information*

sharing"), interaction with stakeholders ("*e-consultation*") and engagement in decision-making processes ("*e-decision making*"). Explanation of the principle of *E-Participation Framework* is the following*:*

• **E-information:** Enabling participation by providing citizens with public information and access to information without or upon demand.

• **E-consultation:** Engaging citizens in contributions to and deliberation on public policies and services.

• **E-decision-making:** Empowering citizens through co-design of policy options and co-production of service components and delivery modalities.

	Total %	Stage 1 % e-Information	Stage 2 % e-Consultation	Stage 3 % e-Decision-making
EPI = 0,333	**31,03**	**44,44**	**27,27**	**0**

Figure 8. E-Participation Index (EPI)

Regarding e-Participation, Croatia was not ranked among the top 50 global performers (ranked 97th) by the UN E-Government Survey 2014. Finally, the same is also valid for UN Open Government Data (OGD). According to UN's definition of OGD, *"data is considered open when it is shared with an open license in a way that permits commercial and non-commercial use and reuse without restrictions."* Furthermore, Croatia was not ranked among the top 50 global performers regarding the usage of Open Government Data by the UN E-Government Survey 2014. However, a large step towards data opening by the Croatian government was done on March 19th 2015 when *data.gov.hr* public portal was open. This portal will serve as a data hub for collecting, categorizing and distributing open data of the public sector in Croatia.

VI. WORLD ECONOMIC FORUM DATA

World Economic Forum data are sourced from two WEF reports: Global Information Technology Report 2014 [4], and Global Competitiveness Report, 2014-2015 [3]. As shown in Fig. 9, Croatia's Networked Readiness Index (NRI) for 2014 was **4,3** and it was ranked 46th out of 148 countries. For comparison, Croatia's NRI for 2013 was **4,2**, ranking it 51st out of 144 surveyed countries.

sub index	pillar	value (1-7)	rank (out of 148)
Environment	Political and regulatory	3,5	88
	Business and innovation	4,7	44
Readiness	Infrastructure and digital content	4,6	54
	Affordability	6,0	36
	Skills	5,6	36
Usage	Individual	5,0	39
	Business	3,5	81
	Government	4,1	65
Impact	Economic	3,6	40
	Social	3,8	66

Figure 9. WEF Networked Readiness Index (NRI) data

WEF Global Competitiveness Index (GCI) is shown in the Fig 10. According to GCI 2014-2015 index, Croatia's value is **4,1**, ranking it 77th out of 144 surveyed countries.

		score (1-7)	rank (out of 144)
Basic requirements	Institutions	3,6	87
	Infrastructure	4,7	44
	Macroeconomic environment	4,4	91
	Health and primary education	5,9	60
Efficiency enhancers	Higher education and training	4,8	53
	Goods market efficiency	4,1	105
	Labor market efficiency	3,9	106
	Financial market development	3,9	74
	Technological readiness	4,6	44
	Market size	3,6	79
Innovation and sophistication factors	Business sophistication	3,8	83
	Innovation	3,1	93

Figure 10. WEF Global Competitiveness Index (GCI) 2014-2015

For comparison, the data for the previous three year periods are shown here:

1. GCI 2013-2014 = 4,1 - ranking 75th (out of 148)
2. GCI 2012-2013 = 4,0 - ranking 81st (out of 144)
3. GCI 2011-2012 = 4,1 - ranking 76th (out of 142)

VII. CONCLUSION

Being late is not a good strategy in e-Business and e-Government, and it seems that Croatia is at least on the brink of being late according to researched and described indices.

On the whole, at the current level of the e-Business adoption Croatia is suffering from the following issues:

- Poor eRecords,
- Lacking and late e-Legislation (no national initiatives),
- Inadequate organization and management of national e-Bodies,
- Poor e-Governance,
- Automation of business processes is not included in the National Industrial Strategy,
- There are no national standards for e-business.

Development of e-business and its components, especially Internet and communications are stagnating in Croatia, which places Croatia at the very bottom of the EU and at the lower end of the first third of surveyed countries according to UN's methodology. There is no significant advance in ranking in the past years.

There are several very noticeable advances in implementation of some e-government services that are contributing to slight elevation of ranking (notable example is e-prescription, where Croatia is among European leaders, and data openness promoted by *data.gov.hr* portal).

However, the authors recognize the lack of government involvement to coordinate all e-business and e-Government effort. Creation of a new central governmental body (independent of specific ministerial domains, responsible for Digital Croatia strategic planning), and co-ordination between Government agencies and Industry (both public and private) is highly recommended and seems to be a prerequisite for further advances in Croatia's digital position.

The person appointed as head of the body for Digital Croatia should be a high positioned official at the level of State Minister (as in UK, for example) or minister for digital economy (as in France) or even two persons (like commissioners in EC), each responsible for digital economy and society and separately for digital market. No more 'silo' organizations should be allowed.

New and comprehensive national digital strategy should be proposed by the government and approved in Croatian Parliament, with clear goals to be reached by 2020, according to national and EU priorities.

Financial push should be given for research and development of digital competencies and knowledge through grant initiatives. Tax-reductions are highly advised for enterprises adopting new e-business practices. Available EU funding should be used in preparations, and maximal use of digital projects and programs should be endorsed in addition to own funds and grants.

In order to enhance the penetration of e-technologies in general population, national digital literacy program for "everybody to be included everywhere" should be devised, including but not restricted to the new European Computer Driving License.

Analiza sadržaja internetskih stranica županija, gradova i općina u Republici Hrvatskoj u prvoj polovici 2014. god.

Tomislav Lamut i Agneš Sarić
Digitalni informacijsko-dokumentacijski ured Vlade Republike Hrvatske
Zagreb, Republika Hrvatska
Tomislav.Lamut@digured.hr, Agnes.Saric@digured.hr

Sažetak - Nakon što je uočeno da na njihovim internetskim stranicama često ne postoje informacije koje bi po Zakonu o pravu na pristup informacijama trebale biti objavljene, Digitalni informacijsko-dokumentacijski ured proveo je analizu sadržaja stranica svih hrvatskih jedinica lokalne i područne samouprave. Na temelju odredaba čl. 10. Zakona, određeno je 20 kategorija informacija i dokumenata, čija se (ne)objava provjeravala na stranicama svake od 576 jedinica. Uz to, istražilo se i (ne)postojanje dodatnih sedam kategorija koje se smatraju bitnima za kvalitetu stranica. Nakon prve faze istraživanja, svim jedinicama je poslana obavijest s rezultatima analize njihovih stranica i molbom za povratnom informacijom u slučaju uočenih pogrešaka ili u međuvremenu izvršenih promjena. Nakon što su, na temelju naknadno izvršenih objava i uvaženih prigovora, izmijenjeni pojedinačni rezultati, prišlo se njihovoj analizi i interpretaciji. Rezultati su izračunati po pojedinim kategorijama i interpretirani na bazi međusobne usporedbe, te sveukupno, a potvrdili su pretpostavljane značajne manjkavosti u proaktivnoj objavi informacija. Kako su pri svemu tome uočene i velike razlike u principima strukturiranja sadržaja stranica, gdje su često mnoge informacije i dokumenti bili objavljeni na nedovoljno pregledan način, zaključeno je da bi napredak u proaktivnoj objavi informacija trebao biti potaknut putem prijedloga konkretnog standarda i procedure njihova objavljivanja.

I. Uvod

Digitalni informacijsko-dokumentacijski ured Vlade Republike Hrvatske (dalje: Digitalni ured), koji je nastavio djelatnost bivše Hrvatske informacijsko-dokumentacijske referalne agencije (HIDRA) koja je djelovala od 1994. godine, je stručna služba Vlade Republike Hrvatske nadležna za obavljanje informacijsko-dokumentacijskih poslova sa zadaćom osiguranja dostupnosti javnih službenih dokumenata i informacija Republike Hrvatske radi informiranja i ponovne uporabe.

Nakon što je u sklopu obavljanja svojih redovnih djelatnosti, što uključuje i rješavanje pojedinačnih izravnih zahtjeva, uočeno da na nekim internetskim stranicama županija, gradova i općina ne postoje informacije i dokumenti, koji bi po Zakonu o pravu na pristup informacijama [1] (dalje: Zakon) trebali biti objavljeni, Digitalni ured [2] proveo je analizu sadržaja stranica svih hrvatskih jedinica lokalne (općine i gradovi) i područne (županije) samouprave.

II. Analiza Sadržaja

Čl. 10. Zakona glasi:“ (1) Tijela javne vlasti obvezna su na internetskim stranicama objaviti na lako pretraživ način:

1) zakone i ostale propise koji se odnose na njihovo područje rada;
2) opće akte i odluke koje donose, kojima se utječe na interese korisnika, s razlozima za njihovo donošenje;
3) nacrte zakona i drugih propisa te općih akata koje donose, sukladno odredbama članka 11. ovog Zakona;
4) godišnje planove, programe, strategije, upute, izvještaje o radu, financijska izvješća i druge odgovarajuće dokumente koji se odnose na područje rada tijela javne vlasti;
5) podatke o izvoru financiranja, proračunu i izvršenju proračuna;
6) informacije o dodijeljenim potporama, bespovratnim sredstvima ili donacijama uključujući popis korisnika i visinu iznosa;
7) informacije o svom unutarnjem ustrojstvu, s imenima čelnika tijela i voditelja ustrojstvenih jedinica i njihovim podacima za kontakt;
8) zapisnike i zaključke sa službenih sjednica tijela javne vlasti i službene dokumente usvojene na tim sjednicama, te informacije o radu formalnih radnih tijela iz njihove nadležnosti;
9) informacije o postupcima javne nabave i dokumentaciji za nadmetanje te informacije o izvršavanju ugovora;
10) obavijesti o raspisanim natječajima te natječajnu dokumentaciju;
11) registre i baze podataka ili informacije o registrima i bazama podataka iz njihove nadležnosti i načinu pristupa;
12) obavijesti o načinu ostvarivanja prava na pristup informacijama i ponovnoj uporabi informacija s podacima za kontakt službenika za informiranje;
13) visinu naknade za pristup informacijama i ponovnu uporabu informacija, prema kriterijima iz članka 19. stavka 3. ovog Zakona;
14) najčešće tražene informacije;

15) ostale informacije (vijesti, priopćenja za javnost, podaci o drugim aktivnostima).

U skladu s time, određeno je 20 kategorija, odnosno vrsta informacija i dokumenata, čije se postojanje odnosno nepostojanje utvrdilo za svaku pojedinu jedinicu. To su sljedeće kategorije: predstavničko tijelo, izvršno tijelo, upravna tijela, kontakt, pravne osobe (ustanove), službenik za informiranje, službeno glasilo, opći pravni akti i druge odluke, statut, poslovnik, proračun, izvršenje proračuna, prostorni plan, dnevni redovi sjednica, prijedlozi i nacrti općih akata, zapisnici sa sjednica, programi, projekti, planovi i sl., izvješće o izvršenju programa, javna nabava te natječaji i potpore.

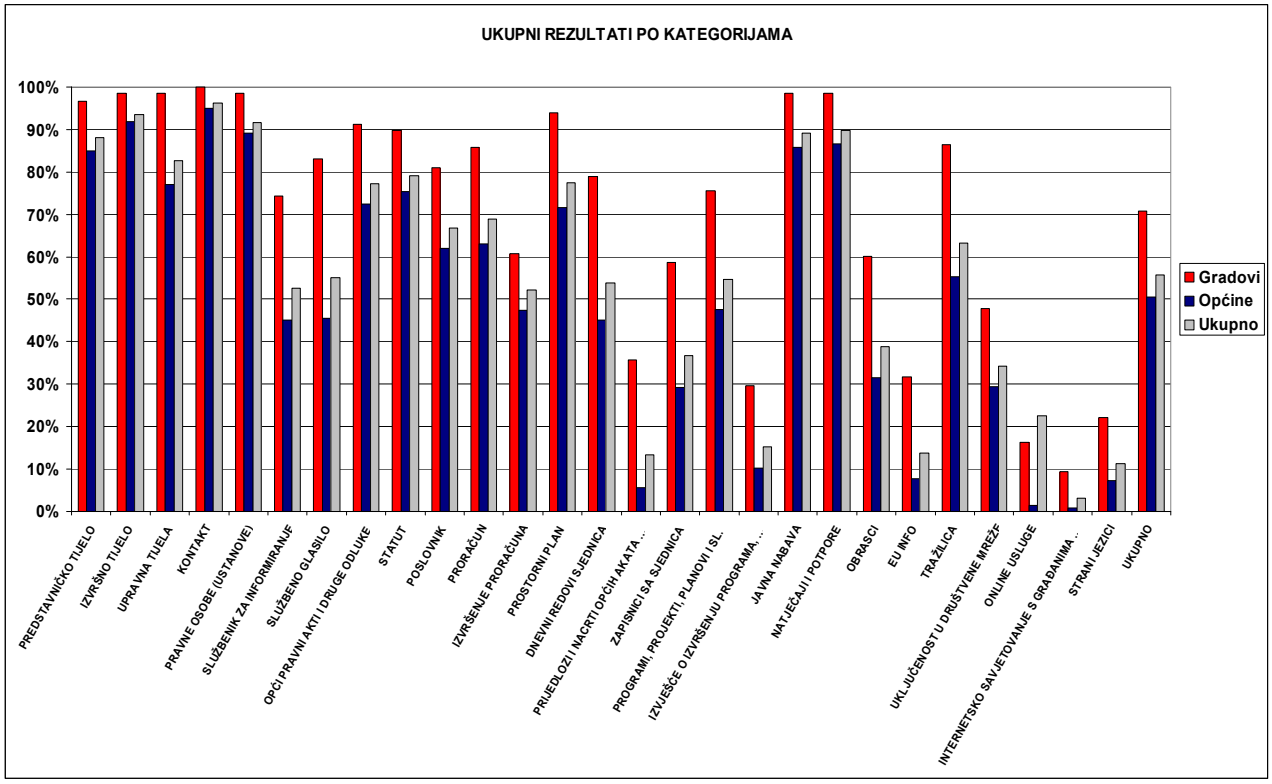
Ovdje treba spomenuti da čl. 62. st. 1. Zakona propisuje novčane kazne od 2000 do 4000 kuna za tijela javne vlasti u slučaju neobjavljivanja informacija u skladu s čl. 10., st. 1. i čl. 11. Zakona. Prema čl. 35. i čl. 41. Zakona, tijelo nadležno za nadzor i inspekcijski nadzor nad provedbom ovog Zakona jest Povjerenik za informiranje, koji također „podnosi optužni prijedlog i izdaje prekršajni nalog za utvrđene prekršaje“. U sklopu ovog istraživanja, nisu se prikupljale informacije o eventualnim kaznama izdanim od strane Povjerenika za informiranje.

Uz navedeno, istražilo se i (ne)postojanje dodatnih sedam elemenata, koji ne spadaju u ove izričito propisane Zakonom, ali se mogu smatrati bitnim za kvalitetu sadržaja internetskih stranica jedinica lokalne i područne samouprave. To su sljedeće kategorije: obrasci, EU info, tražilica, uključenost u društvene mreže, online usluge, internetsko savjetovanje s građanima i strani jezici. One su određene samoinicijativno od strane djelatnika Ureda, na temelju višegodišnjeg iskustva u pretraživanju internetskih stranica domaćih i stranih lokalnih jedinica.

Ukupni broj općina, gradova i županija u Republici Hrvatskoj je 576, od čega je 428 općina, 127 gradova, 20 županija i Grad Zagreb sa statusom županije. 15 jedinica, tj. općina nije u razdoblju istraživanja uopće imalo internetske stranice.

Nakon prve faze istraživanja, koju je dvoje djelatnika Ureda obavljalo kada je to bilo moguće s obzirom na osnovnu djelatnost i koja je trajala od siječnja do lipnja 2014. godine, svim jedinicama je poslana obavijest s rezultatima analize i molbom za povratnom informacijom u slučaju uočenih pogrešaka ili u međuvremenu izvršenih promjena. Odgovori su poslani iz 151 jedinice.

Najčešći prigovori su bili oni u kojima se navodilo kako je neki dokument objavljen u elektroničkom izdanju službenog glasila, što se nije uvažavalo jer se smatralo da time nije zadovoljen uvjet iz čl. 10. Zakona o objavljivanju „na lako pretraživ način“. Prethodno navedeno je ukazalo da u značajnom broju jedinica ne postoji spoznaja kako o nužnosti objavljivanja službenih dokumenata i informacija, tako i o omogućavanju preglednosti u njihovom pretraživanju. S druge strane, u značajnom broju dopisa kao i u nekoliko izravnih telefonskih razgovora, navodi se kako je nešto odmah po dopisu iz Digitalnog ureda bilo objavljeno i/ili će biti u „skorom roku“, što se zaista u većini takvih slučajeva pokazalo točnim, pa su takve, već obavljene nadopune, pribilježene u tablicama. Smatramo da je ovo jasno pokazalo kako je spoznaja da se kvaliteta sadržaja stranica prati od strane vanjske institucije, pozitivno utjecala na podizanje kvalitete stranica, pa čak i usprkos



Grafikon 1. Ukupni rezultati po kategorijama

tome što je Digitalni ured naveo, kako je ovo tek istraživanje u informativne svrhe. Nakon što su, na temelju u međuvremenu izvršenih objava i uvaženih prigovora, izmijenjeni pojedinačni rezultati, prišlo se njihovom zbrajanju i analizi.

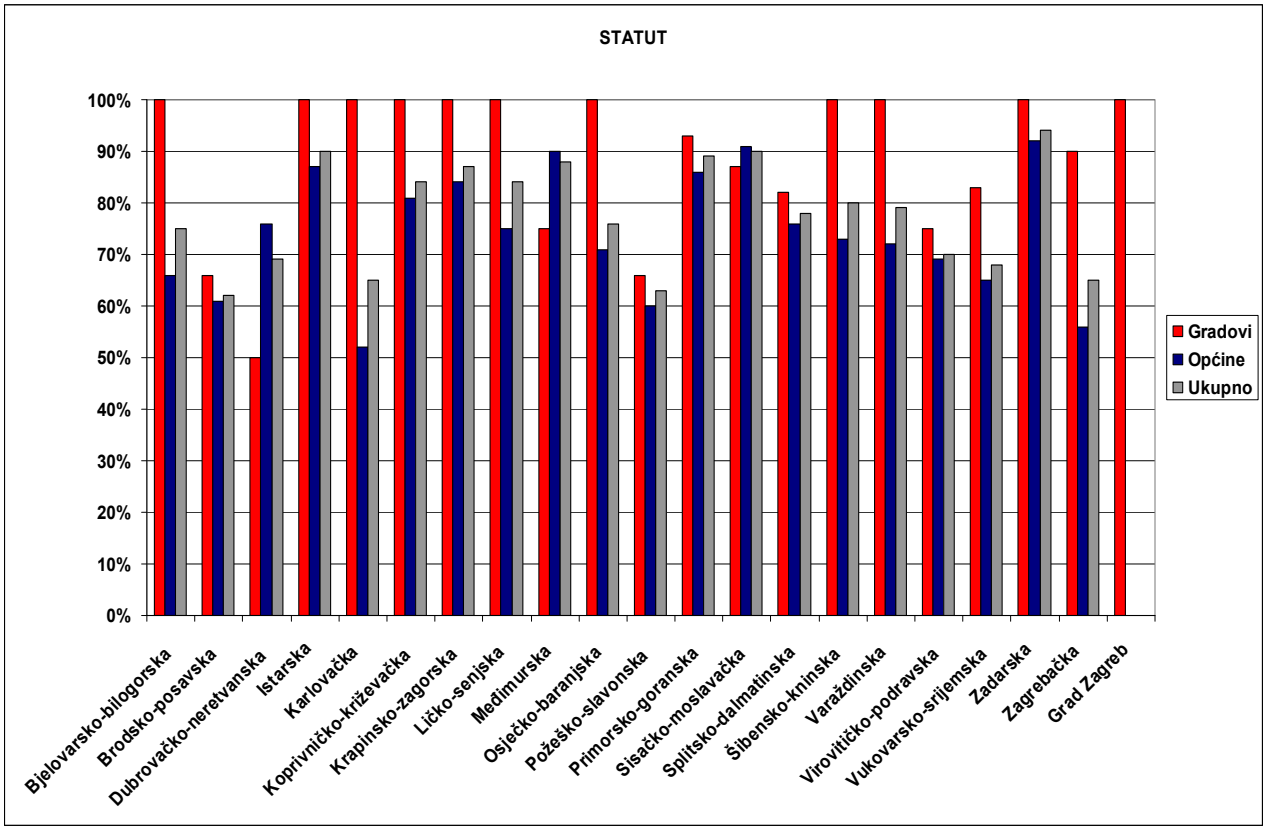
Rezultati su interpretirani na bazi međusobne usporedbe pri čemu su izračunati sveukupni rezultati te rezultati posebno za gradove i posebno za općine, uz napomenu da su rezultati županija pribrojani rezultatima gradova. Bitno je navesti da rezultati nisu vrijednosno interpretirani jer kada se radi o ispunjavanju zakonskih obveza, jedini zadovoljavajući rezultat je onaj stopostotni (takav je zabilježen za tri grada: Zagreb, Rijeku i Pulu). Po očekivanju, s obzirom na puno veći ljudski i tehnički potencijal gradskih i županijskih uprava, rezultati gradova su bili viši jer npr. u tijelima najmanjih općina, nije rijetko da su općinski načelnik i tajnik jedini profesionalni djelatnici.

Svi rezultati su prikazani u grafikonima, ali kako istih ima 28 (po jedan za svaku kategoriju i jedan sa sveukupnim rezultatima, koji su prikazani u grafikonu 1), nije ih bilo moguće sve uvrstiti u rad od maksimalno 6 stranica. Stoga su ovdje prikazani samo grafikon s ukupnim rezultatima i pet odabranih grafikona kao primjeri.

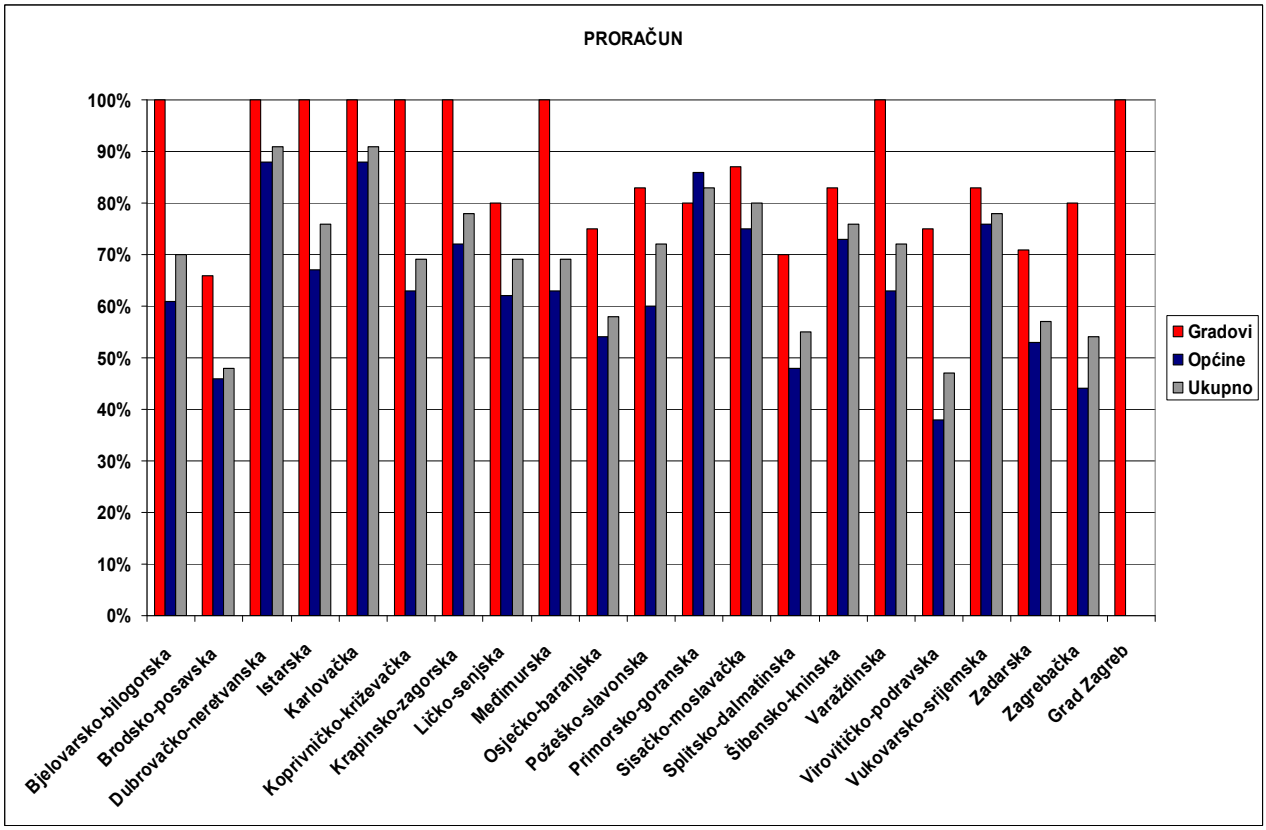
Što se tiče rezultata po pojedinim elementima, najviši rezultati su zabilježeni pri objavljivanju informacija vezanih uz kontakt podatke te ustrojstvo vlasti u jedinicama, ali već i kod toga su zabilježene prve manjkavosti. Tako je podatke o članovima predstavničkog tijela objavilo 96% gradova i županija, odnosno 85% općina, dok su podaci o sastavu izvršnog tijela bili objavljeni na 98% gradskih tj. županijskih, odnosno 91% općinskih stranica. Podatke o upravnim tijelima, odnosno djelatnicima, objavilo je 98% gradova tj. županija, ali u općinama je taj rezultat iznosio 77%. Podatke o raznim ostalim ustanovama, tvrtkama, organizacijama i udrugama u svom sastavu ili sa svog područja objavilo je 98% većih jedinica i 89% općina. Potpune informacije o ostvarivanju prava na pristup informacijama objavilo je 74% gradova i županija dok je kod općina rezultat bio puno niži i to 45%. Slični su rezultati (83% i 45%) vezani uz objavljivanje službenog glasila, pri čemu treba napomenuti da općine nisu obvezne imati svoje vlastito službeno glasilo, pa se u tom slučaju tražilo tek da na općinskim stranicama bude jasno objavljena poveznica na županijsko službeno glasilo što je velikom broju općinskih stranica nedostajalo. Dio prigovora iz pojedinih općina se odnosio upravo na negativni znak u rubrici „službeno glasilo“, uz obrazloženje kako imati ga, nije njihova zakonska obveza pri čemu se očito nije razumjelo da je u tom slučaju bilo potrebno isto navesti i korisnike uputiti na odnosno županijsko glasilo i osnovne općinske akte, koji su u njemu objavljeni. Osnovni akti poput statuta jedinice (grafikon 2) i poslovnika vijeća tj. skupštine su objavljeni u preko 80% slučajeva za gradove i županije (statut – 89%, poslovnik predstavničkog tijela – 81%), odnosno 75% (statut) i 62 % (poslovnik) za općine. Kriterije za ocjenu dostatnog objavljivanja tj. navođenja općih pravnih akata nije bilo moguće točno utvrditi pa se pozitivni znak upisivao tamo gdje je procijenjeno da je objavljen barem minimalan broj najvažnijih akata pri čemu je rezultat na taj način iznosio 91% za gradove i županije i 72% za općine. Zatim, zanimljivi su bili rezultati za objavljivanje proračuna (grafikon 3) i izvješća o njegovom izvršenju (grafikon 4); dok je proračun za tekuću godinu objavljen u 85% (gradovi i županije) odnosno 63% (općine) slučajeva, izvješće o njegovu izvršenju za prethodne godine je objavljeno na značajno manjem broju stranica (60% gradovi i županije, 47% općine). Prostorni plan (grafikon 5) je objavljen na 93% (gradovi i županije), tj. 71% (općine) stranica. Kod informacija vezanih uz sjednice predstavničkih tijela, dnevni redovi sjednica (grafikon 6) su objavljivani na 79%, tj. 45%, a zapisnici na 59%, tj. 29% stranica. Značajno niži rezultati su zabilježeni u objavljivanju prijedloga i nacrta akata (35% i 5%). Slična situacija kao s proračunom je uočena i kod objave raznih planova i programa rada, odnosno izvješća o njihovu izvršenju: planovi i programi su bili objavljeni na 75%, tj. 47% stranica, dok je rezultat vezan uz izvješća o njihovom izvršenju bio značajno niži: 29% i 10 %. U slučaju objavljivanja informacija o javnoj nabavi i raznim natječajima, rezultati su bili iznad 98% za gradove i županije, odnosno 86% za općine.

U drugoj grupi od sedam ostalih vrsta informacija i sadržaja, rezultati su po očekivanju, bili još niži pa su tako npr. informacije o EU objavljene na 31% stranica gradova i županija odnosno 7% onih općinskih. Obrasci i to uglavnom ne svi, objavljeni su na 60% stranica gradova i županija, tj. 31% općinskih stranica, a bilo kakve administrativne online usluge omogućuje tek 16% gradova i županija i nešto više od 1% općina. Internetsko savjetovanje s građanima vezano uz prijedloge akata je omogućeno u 9% gradova i županija i manje od 1% općina dok je pregled osnovnog dijela sadržaja na stranim jezicima (engleski i talijanski u Istri), omogućen kod 22% gradova i županija i 7% općina. Očekivano je bilo da mnoge, posebno manje jedinice nemaju informacije na stranim jezicima, ali se pokazao i neočekivano veliki broj jedinica iz turističkih područja, koje nisu imale informacije za strane turiste pa čak ni poveznice na neke druge takve stranice, poput onih npr. turističke zajednice i sl. Tražilicu na svojim stranicama ima 86% gradova i županija, te 55% općina, ali u mnogim slučajevima je njena funkcionalnost upitna. I na kraju, podatke o uključenosti u društvene mreže objavilo je 71% gradova i županija i 29% općina iako je broj u društvene mreže uključenih jedinica nešto veći, ali u nekim slučajevima podaci o tome jednostavno nisu bili objavljeni.

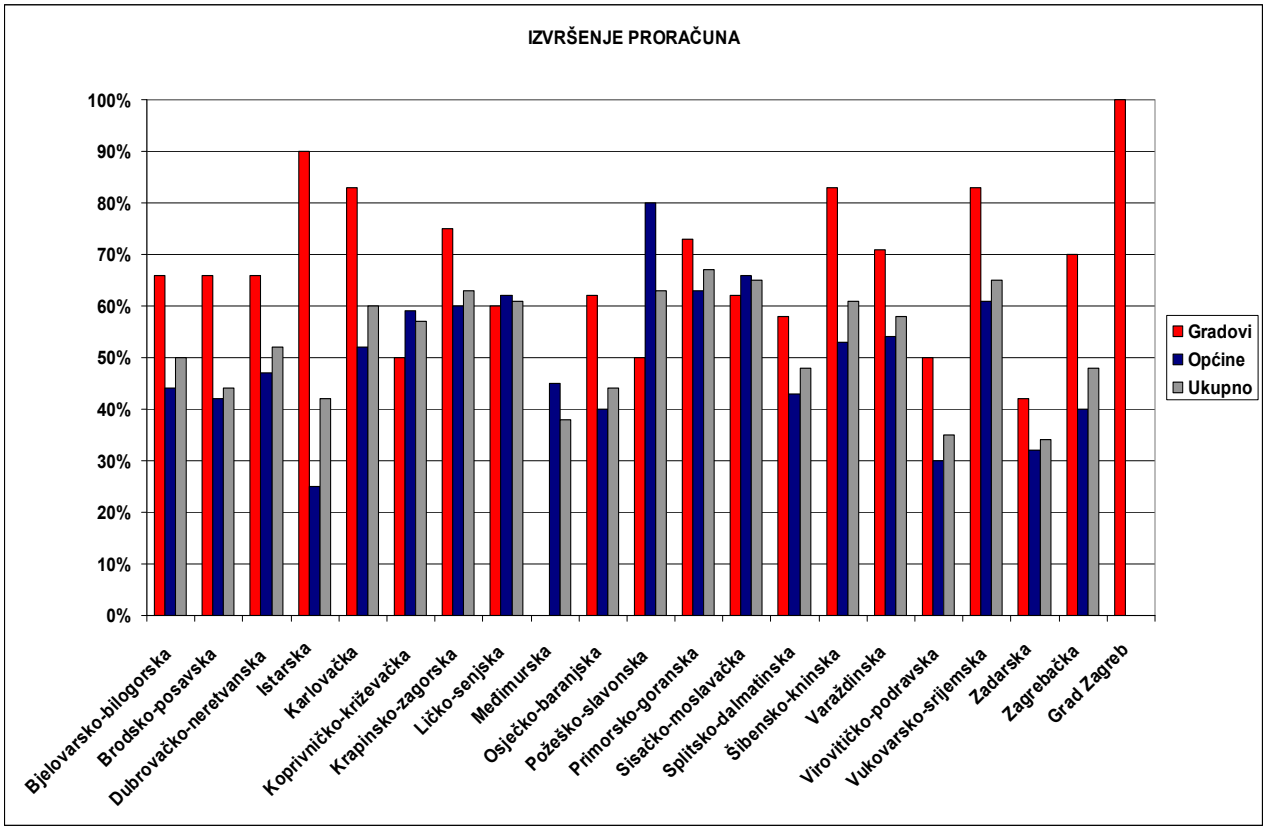
Sveukupni rezultati su grafički prikazani u grafikonu 1. Iz svega navedenog je jasno da su rezultati, s već navedenim razlikama između gradova i županija naspram općina, bili znatno niži kod onih vrsta dokumenata koji su mnogobrojniji, a aktualnost im je kraća, dok su viši bili kod pojedinačnih dokumenata, s dužim rokom važenja i pretpostavljano većom „važnošću“ poput npr. statuta ili prostornog plana.



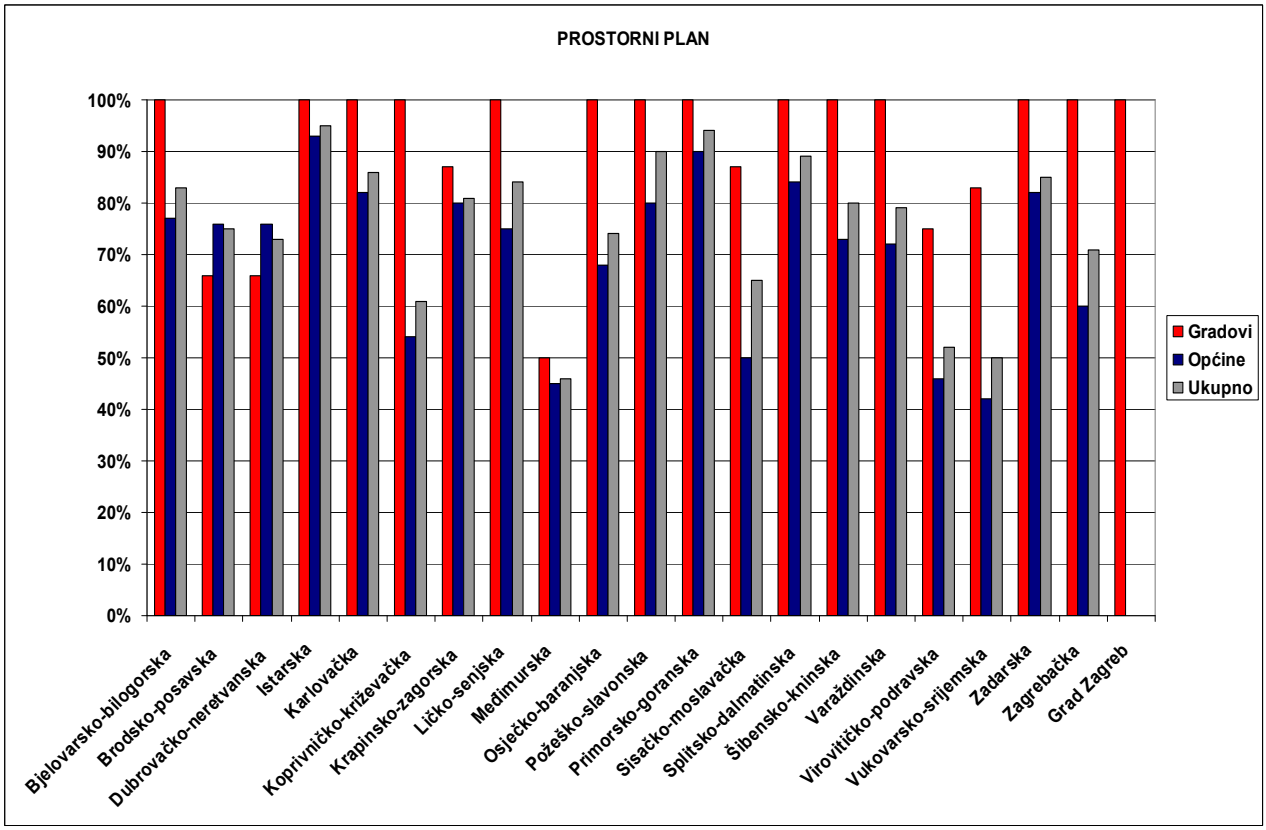
Grafikon 2. Statut



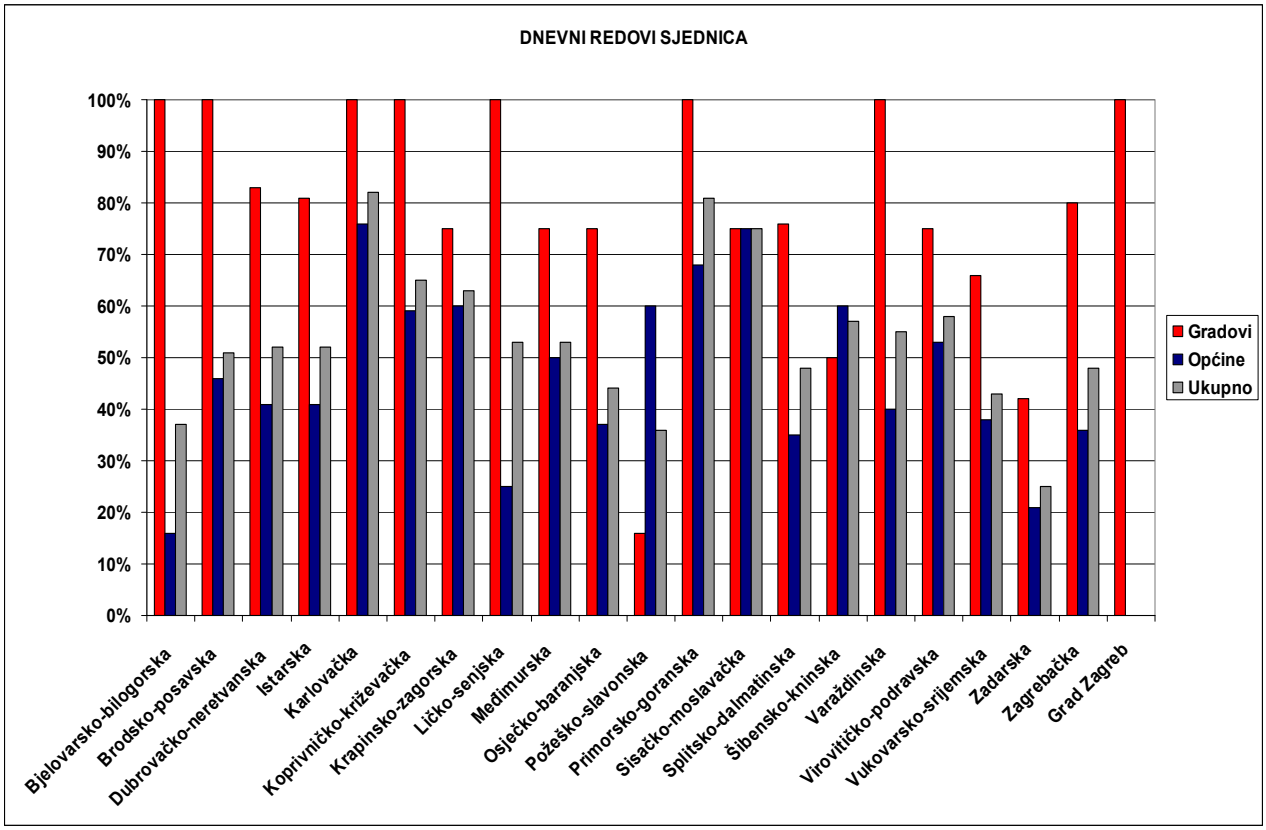
Grafikon 3. Proračun



Grafikon 4. Izvršenje proračuna



Grafikon 5. Prostorni plan



Grafikon 6. Dnevni redovi sjednica

Uza sve brojčano izraženo i vidljivo iz priloženih grafikona, uočeno je i da su mnoge informacije i dokumenti često bili objavljeni na neočekivanim dijelovima stranice i/ili pod upitnim naslovima. Takvi slučajevi jesu označavani znakom plusa, iako se može pretpostaviti da je kod dijela korisnika „laka pretraživost“ time bila više ili manje otežana. U svakom slučaju, također su uočene velike razlike u principima strukturiranja sadržaja stranica.

III. ZAKLJUČAK

S obzirom na sve navedeno što je ovo istraživanje pokazalo vezano uz nedostatno objavljivanje dokumenata i informacija u skladu sa Zakonom o pravu na pristup informacijama, mišljenja smo da bi napredak u proaktivnoj objavi informacija trebao biti potaknut putem prijedloga konkretnog standarda i procedure njihova objavljivanja, zamišljenog kao svojevrsnog jednoobraznog elektroničkog pretinca za unošenje odnosno objavu službenih dokumenata, pri čemu bi sa velikom vjerojatnošću, a nakon eventualnog ustrojavanja takvog modela, isti ne samo bio od izravne pomoći u lokalnim jedinicama, već bi dodatni pozitivni indirektni poticaj kod njihovih djelatnika bila i spoznaja da su „rezultati rada“ lako usporedivi u odnosu na ostale jedinice, tj. da je (ne)ispunjavanje zakonskih obveza na taj način puno lakše uočljivo. Naš zaključak se nalazi na tragu točke 3.5. Akcijskog plana za provedbu inicijative Partnerstvo za otvorenu vlast u Republici Hrvatskoj za razdoblje 2014. do 2016. godine [3] koja predviđa izradu uputa i priručnika za proaktivnu objavu informacija, čiji je nositelj Povjerenik za informiranje, sunositelj Ministarstvo uprave, a predviđeni rok srpanj 2015. god.

Implementacija informacijskog sustava za praćenje aktivnosti unutar jedinice javne uprave

O. Jukić, I. Heđi, I. Špeh
Visoka škola za menadžment u turizmu i informatici, Virovitica, Hrvatska
{oliver.jukic | ivan.hedi | ivan.speh}@vsmti.hr

Sažetak - U radu je opisana arhitektura informacijskog sustava čija osnovna zadaća je pružanje potpore prilikom odlučivanja, praćenja prijedloga i pritužbi građana te praćenja aktivnosti i stanja na određenim projektima jedinice javne uprave koja je implementirana na primjeru jedinice javne uprave. Funkcije sustava distribuirane su u tri sloja. Sloj medijacije daje potporu procesima prikupljanja podataka ili primanja aktivnosti iz različitih izvora. To mogu biti: postojeće baze podataka, baze podataka vezanih poduzeća, dopisi, telefonski kontakti ili kontakti elektronskom poštom, kontakti ostvareni putem web stranice i sl. Tako prikupljeni podaci se pohranjuju na sloju baze podataka, u više različitih baza podataka. Tipični primjeri su skladište podataka o radu jedinice samouprave, baza podataka o pritužbama građana, baza podataka o procesima koji su u tijeku (npr. zahtjevi za službena putovanja koji čekaju na odobrenje), baza podataka o projektima i sl. Iznad sloja baze podataka nalazi se prezentacijski sloj, čija osnova zadaća je kreiranje izvješća, njihov prikaz na grafičkim sučeljima te distribucija izvješća. Osim toga, arhitektura uključuje i *northbound* sučelje prema drugim informacijskim sustavima i tehnologijama, čija zadaća je omogućiti dostup podacima i izvješćima drugim sustavima i aplikacijama (npr. aplikacijama na pametnim telefonima). Implementacija ovako predložene arhitekture u tijeku je u jednoj jedinici javne uprave.

Ključne riječi: informacijski sustav, javna uprava, medijacija, baza podataka, izvješće

I. UVOD

Informacijski sustavi u jedinicama javne uprave s služe kao alati za povećanje učinkovitosti prilikom izvršavanja procedura javne administracije i upravljanju iste. Istraživanja su pokazala da informacijski sustavi pokreću modernizaciju javne uprave i dovode do organizacijskih promjena. Organizacije bez potpore automatskog procesiranja informacija imaju smanjenu učinkovitost zbog spore obrade tradicionalne "papirologije". Povećanje učinkovitosti je nemoguće bez automatskog procesiranja informacija [1].

Implementacija informacijskih sustava u javnoj upravi dovodi do poboljšanja kvalitete usluga prema građanima i poslovima. Prednosti dobivene implementacijom informacijskog sustava u rad javne uprave moraju se na neki način povezati sa ciljevima usluga koje se pružaju.

Ovaj rad je rezultat uvođenja informacijskih sustava u jedinicama javne uprave u Virovitičko – podravskoj županiji.

Te prednosti se postižu korištenjem usluga kako od strane građana, tako i od strane jedinica javne uprave. Prednosti prema građanima uključuju (1) pristup informacijama za javnost, (2) online usluge i (3) pristup pravovremenim, relevantnim i točnim informacijama. Prednosti za jedinice javne uprave su (1) standardizacija i redizajn procesa, (2) poboljšanje pri upravljanju projektima, (3) povećanje kvalitete te (4) povećana podrška i uključenost svih razina osoblja. Indirektna prednost implementacije informacijskog sustava u jedinice javne uprave je poboljšanje otvorenosti, transparentnosti i odgovornosti administracije te osvještavanje građana o lakšem pristupu uslugama javne uprave.

Implementacija informacijskog sustava u jedinice javne uprave rezultira sljedećim prednostima:

- Učinkovitu i logički smislenu cirkulaciju informacija među jedinicama javne uprave
- izvođenje operacija jedinica javne uprave koje su predefinirane procesima
- integraciju podataka
- lakši pristup podacima i informacijama za jedinice javne uprave
- pristup informacijama i uslugama putem različitih medija (računalo, tablet, pametni telefon) za građene.

Klasifikacija sustava implementirana u jedinicama javne uprave prema [2] je sljedeća: (1) Workflow Management System (WfMS), (2) Enterprise Information System (EIS), (3) Enterprise Application Integration (EAI), (4) Business Process Management System (BPMS), Business intelligence (BI) i (6) Enterprise Portals.

Sustavi za upravljanje tokovima su jedni od najvažnijih sustava koji pružaju podršku procesima javne uprave. Ovakvi sustavi djelomično ili u potpunosti automatiziraju definiranje, stvaranje, izvršavanje i upravljanje radnim procedurama koje se ne mijenjaju prečesto [3]. *Workflow* sustavi automatiziraju poslovne procese, djelomično ili u cijelosti pri čemu se informacije, dokumenti i zadaci prenose od jednog do drugog sudionika toka prema određenim pravilima [2].

Poslovni procesi, radne procedure i radni zadaci koji se mogu opisati *workflow* sustavom unutar jedinice javne uprave u radu su predstavljeni kao aktivnosti. Namjena

informacijskog sustava opisanog u radu je potpora za praćenje aktivnosti unutar jedinice javne uprave pri čemu su aktivnosti kategorizirane prema prirodi radnih procedura koje se izvršavaju. Prema tome razlikujemo (1) aktivnosti vezane za radne procedure unutar jedinice javne uprave, (2) aktivnosti vezane za pritužbe građana i (3) aktivnosti na projektima koje izvodi jedinica javne uprave.

Svaka aktivnost sastoji se od radnih zadataka, sudionika, dokumenata i informacija. Aktivnost može imati jedan ili više radnih zadataka koji se slijedno izvode. Svaki radni zadatak unutar pojedine aktivnosti u radu je definiran kao faza aktivnosti. Izvršavanjem svih faza aktivnost se završava.

II. ARHITEKTURA INFORMACIJSKOG SUSTAVA

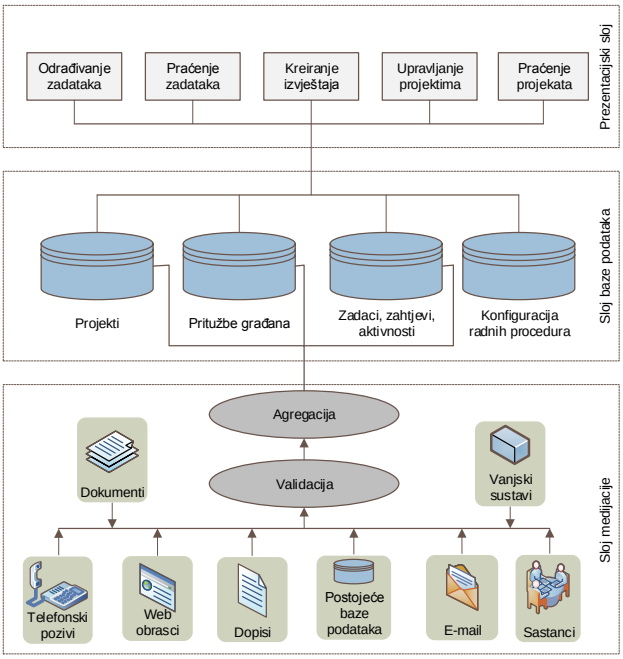
Za implementaciju informacijskog sustava potrebno je koristititi logičku konstrukciju (arhitekturu) sustava za definiranje sučelja i integraciju svih komponenti sustava [4]. Na slici 1 prikazana je arhitektura informacijskog sustava jedinice javne uprave čija je osnovna zadaća pružanje potpore prilikom odlučivanja, praćenja prijedloga i pritužbi građana te praćenja aktivnosti i stanja na određenim projektima. Funkcije sustava podijeljene su na tri sloja: sloj medijacije daje potporu procesima prikupljanja podataka ili primanja aktivnosti iz različitih izvora, sloj baze podataka te prezentacijski sloj.

Glavne funkcije sloja za prikupljanje podataka su:

- prikupljanje podataka od građana, djelatnika javne uprave ili drugih jedinica uprave
- validacija podataka
- agregacija podataka

Upravljanje poslovnim sustavom uključuje planiranje, organiziranje i kontroliranje aktivnosti poslovnog sustava, a u velikoj mjeri temelji se na donošenju odluke. Za donošenje dobre poslovne odluke potrebne su kvalitetne informacije (točne, potpune, primjerene i pravovremene). Zbog toga dobar poslovni sustav mora imati informacijski sustav koji će ga opskrbljivati kvalitetnim informacijama [6]. Za kvalitetno rješavanje problema potrebno je prikupiti informacije od građana na njima najprihvatljivi način. Na slici 1. prikazani su neki od načina prikupljanja podataka: web obrasci, telefonski pozivi, dopisi ili postojeće baze podataka. Prikupljanje podataka od građana putem web obrazaca odvija se putem modula web grafičkog sučelja otvorenog prema građanima ili putem web stranice javne uprave. U trenutnoj implementaciji građani ne koriste autenikaciju pošto pristupaju javnom sučelju i nisu dio sustava već su samo izvor informacija. Putem e-mail pošte građani pritužbe šalju na određenu adresu putem koje se prikupljaju informacije potrebne za rješavanje određenog problema. Postojeće baze podataka koriste se u slučaju da jedinica javne uprave već koristi određeni informacijski sustav. Tako prikupljeni prolaze proces validacije i agregacije (nepravovaljani i neprimjereni zahtjevi građana se odbacuju) i šalju se na pohranu i obradu u više slojeve.

Raznoliki unutarnji i vanjski izvori podataka "pune" skladišta podataka. Većina unutarnjih podataka (nastalih unutar javne uprave) rezultat je poslovnih aktivnosti. U



Slika 1. Arhitektura informacijskog sustava

sloju baze podataka (slika 1) prikazana su skladišta koja služe za pohranu pritužbi građana zaprimljenih na slojumedijacije, informacija o stanju na projektima, zadatke i rezultate pojedinih radnih procedura. Osim skladišta za prikupljanje podataka prikazana je i konfiguracijska baza podataka u kojoj su zapisani postupci izvršavanja određenih radnih procedura.

Korisničko sučelje obuhvaća mehanizme potrebne za unos podatka u sustav, izvođenje modela te izlaz podataka (sadržaj i grafički oblik ekrana). Ono je važna komponenta sustava za potporu praćenja aktivnosti jer je sučelje za korisnika zapravo sam sustav [7]. Grafičko sučelje implementiranog sustava sastoji se od modula koji su podijeljeni prema vrstama aktivnosti. Administrator sustava određuje koji moduli će se prikazati djelatniku na njegovom grafičkom sučelju. Npr. osoba zadužena za rješavanje pritužbi građana ne mora nužno imati modul za praćenje aktivnosti na projektima.

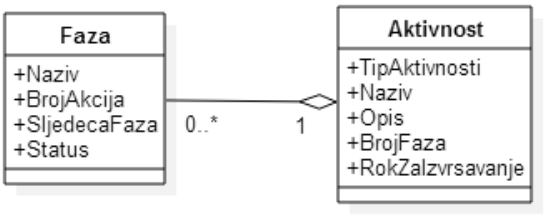
Djelatnici javne uprave pristupaju svom profilu putem web grafičkog sučelja koji se sastoji od dva glavna modula:

- grafičko sučelje za praćenje zadanih i primljenih zadataka vezanih za radne procedure unutar javne uprave, zadatke vezane za pritužbe i zahtjeve građana
- grafičko sučelje za praćenje stanja i aktivnosti na projektima jedinice javne uprave

III. PRAĆENJE AKTIVNOSTI

A. *Praćenje aktivnosti unutar jedinice javne uprave*

Radne procedure koje imaju isti slijed izvršavanja definiraju jedinstveni tip određene aktivnosti unutar sustava. Svaki tip aktivnosti, odnosno radne procedure karakteriziraju parametri zapisani u konfiguracijskim tablicama od kojih su najvažniji prikazani na UML dijagramu klase (Slika 2).



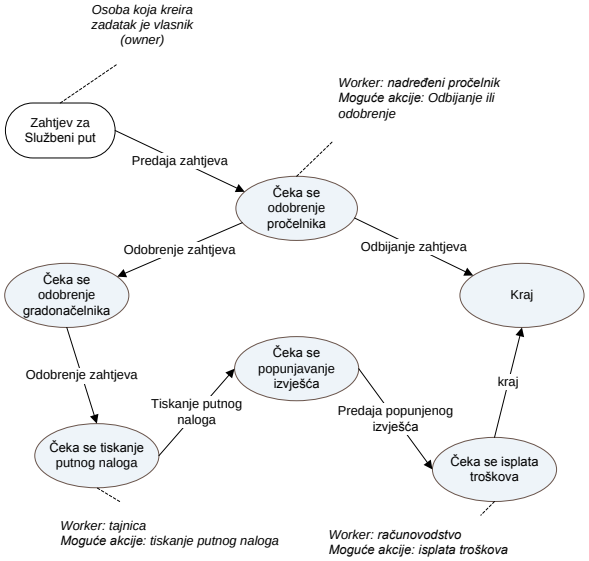
Slika 2. UML dijagram klase aktivnosti

Svaki korak izvršavanja radne procedure zapisan je u obliku faze. Radna procedura mora imati minimalno jednu fazu a ukupan broj faza određen je atributom "*BrojFaza*". U svakoj fazi definiran je djelatnik koji izvršava fazu - izvršitelj/radnik (*worker*). Izvršitelj može biti konkretan djelatnik u javnoj upravi ili određena funkcija (npr. pročelnik odjela). Rok za izvršavanje - datum do kojeg određena aktivnost mora biti odrađena. Ovisno o tipu aktivnosti rok može biti predefiniran (npr. izrada izvješća krajem mjeseca) ili se može birati prilikom kreiranja aktivnosti. Vlasnik aktivnosti može mijenjati rok za izvršavanje na grafičkom sučelju. Unutar svake faze definirane su akcije koje mogu izvršiti vlasnik zadatka ili izvršitelj zadatka. Ovisno o izvršenoj akciji, zadatak se završava ili prelazi u sljedeću fazu. Tipovi akcija mogu biti: (1) prijelaz aktivnosti u sljedeću fazu, (2) završetak aktivnosti, (3) završetak aktivosti sa negativnim ishodom (npr. odbijanje zahtjeva za odlazak na službeni put), (4) proslijeđivanje aktivne faze drugom djelatniku javne uprave, (5) otkazivanje aktivnog zadatka i zatvaranje njegove aktivne faze (akcija vlasnika aktivnosti koja rezultira zatvaranje aktivnosti) te (6) promjena roka za izvršavanje. Prilikom implementacije sustava akcije se prilagođavaju tipovima aktivnosti koje se nalaze u javnoj upravi. Tipični primjeri akcija za izvršitelja su "*Potvrdi*", "*Odbaci*", "*Proslijedi*" a za vlasnika aktivnosti su "*Otkaži*" i "*Promijeni rok za izvršavanje*".

Tijekom korištenja sustava korisnici kreiraju instance pojedine vrste predefiniranog zadatka, zahtjeva ili radne procedure (aktivnosti). Djelatnik javne uprave koji kreira novu instancu ujedno je i vlasnik zadatka (*owner*). Nakon kreiranja instance, zadatak postaje aktivan i spreman za izvođenje. Sve aktivnosti spremljene su u bazu podataka nad kojom se mogu kreirati izvješća o radu pojedinog djelatnika ili odjela, brzina reagiranja na zadane poslove, rezultati završenih zadataka i sl. U aktivnom stanju, zadatak prolazi kroz svoje faze izvršavanja pri čemu je u svakom trenutku aktivna samo jedna faza pojedine instance aktivnosti.

Vlasnik na grafičkom sučelju u svakom trenutku može vidjeti koje su faze zadatka izvršene te koja je faza trenutno aktivna. Svaki zadatak ima definiran rok za izvršavanje koji se postavlja prilikom kreiranja zadatka, a vlasnik ga u svakom trenutku može promijeniti (ukoliko tip zadatka dopušta promjenu roka za izvršavanje). Za svaku promjenu na zadatku (npr. istek roka za izvršavanje, promjena faze zadataka, završetak zadatka) obavještavaju se svi aktivni sudionici u zadatku putem notifikacije na grafičkom sučelju i/ili putem e-mail poruke.

Procedura izvršavanja jednog tipa radne procedure opisana je na slici 3. Djelatnik putem grafičkog sučelja odabire jedan od ponuđenih zadataka (u ovom slučaju



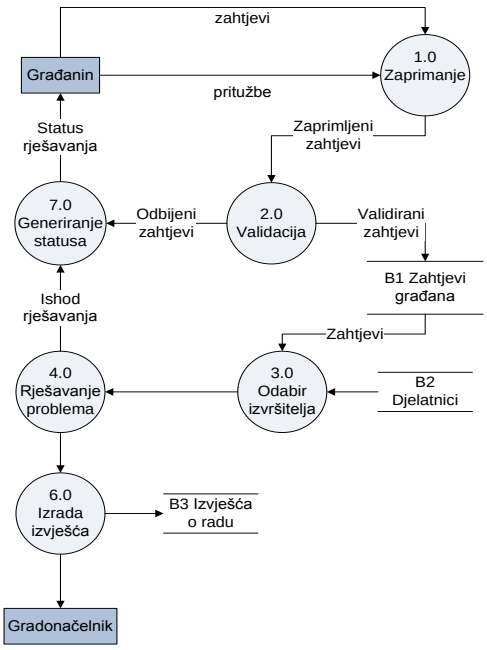
Slika 3. Workflow radne procedure službenog putovanja

"*Zahtjev za službeni put*"). Nakon popunjavanja web obrasca (sloj prikupljanja podataka) podaci o službenom putu spremaju se u bazu podataka službenih putovanja (sloj baze podataka) a nadređeni pročelnik na svom profilu dobiva notifikaciju sa novim primljenim zadatkom (prezentacijski sloj). Uz osnovne informacije o zadatku (tko, što, gdje, kada) pročelnik ima predložene akcije u obliku ikonica. Odabirom akcije za odobravanje završava se trenutno aktivna faza i zahtjev prelazi u novu fazu u kojoj izvršitelj postaje gradonačelnik nakon čijeg odobravanja zahtjev dalje prolazi kroz faze tiskanja putnog naloga, popunjavanja izvješća i isplate troškova. Svaka faza prikazuje se na profilu izvršitelja kojemu je zadano odrađivanje te faze Nakon što je zahtjev prošao kroz sve faze postaje neaktivan i sprema se u arhivu. Arhiva aktivnosti je podijeljana na aktivnosti u kojima je korisnik vlasnik i na arhivu u kojima je korisnik izvršitelj. Na temelju arhive moguće je izraditi izvješća na tjednoj mjesečnoj ili godišnjoj bazi (npr. koliko je djelatnik imao službenih putovanja u godini dana). Ovime je prikazana jedna od radnih procedura koja se može sresti u svakodnevnom djelovanju javne uprave.

B. Potpora za praćenje aktivnosti vezanih uz pritužbe građana

Rješavanje pritužbi i zahtjeva građana dio su svakodnevnih poslova djelatnika javne uprave. Dijagram toka podataka [5] prikazan na slici 4 prikazuje proces rješavanja zahtjeva i pritužbi građana putem informacijskog sustava. Građanin, kao vanjski entiteti u ovom procesu sustavu daje svoju pritužbu ili zahtjev na jedan od načina prikazanih na slici 1. Nakon zaprimanja pritužbe građanina i validacije ulaznih informacija (procesi 1.0 i 2.0), sustav dodjeljuje aktivnost određenom djelatniku na rješavanje koji će na svom profilu zaprimiti novi zahtjev sa opisom problema, rokom za izvršavanje i akcijama koje će odabrati nakon rješavanja problema (proces 3.0). Nakon što djelatnik odradi aktivnost vezanu za pritužbu građana generira se status u procesu 7.0, a on ovisi o ulaznim tokovima podataka koji mogu biti ishodi rješavanja problema ili rezultati validacije određenih

podataka. Gradonačelnik kao vanjski entitet zaprima izvješća o pritužbama građana i ishodima rješavanja istih.

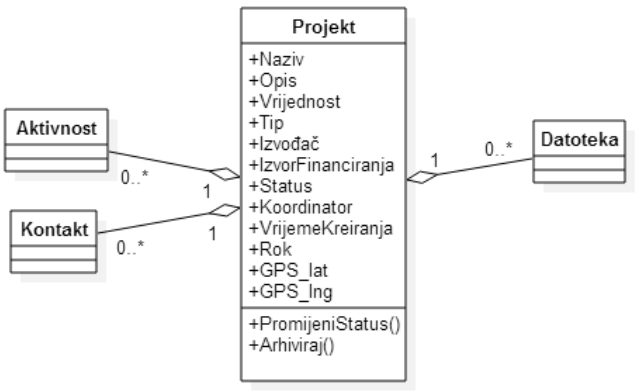


Slika 4. Dijagram toka podataka zaprimanja pritužbe građana

C. *Praćenje aktivnosti nad projektima*

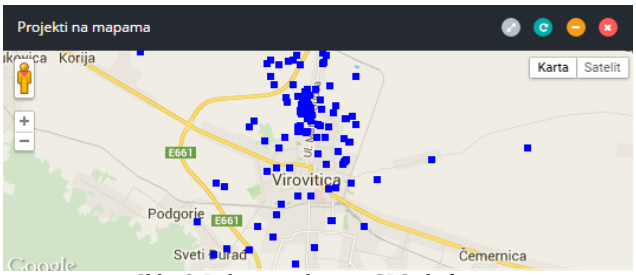
Jedna od glavnih zadaća jedinica javne uprave je provođenje projekata. Za projekte sa niskom dinamikom promjena i velikim brojem sudionika teško je uvijek znati trenutno stanje na projektu. Putem web grafičkog sučelja djelatnici javne uprave dobivaju brze i kvalitetne informacije o trenutnom stanju na pojedinom projektu kao i praćenje tijeka odvijanja projekta.

Svaki projekt karakterizira određeni broj atributa koji se mogu definirati tijekom prilagodbe sustava, na primjer: vrijednost projekta, tip (gradski, državni, privatni...), izvor financiranja, nositelj projekta, rok za izvršavanje, geografska lokacija itd. Njih unosi vlasnik projekta prilikom kreiranja novog projekta i vidljivi su na grafičkom sučelju. Za svaki projekt može se vezati i niz drugih atributa koji se ažuriraju kroz izvođenje projekta - to su aktivnosti na projektu, kontakti, prilozi, galerija fotografija i podsjetnici.



Slika 5. UML dijagram klase projekta

Projekt je logički okvir unutar kojeg se provode određene aktivnosti. Na primjer: projekt može biti 'Organiziranje proslave Dana Grada', na kojem će biti određeni broj aktivnosti (organiziranje koncerta, priprema domjenka, organizacija svečane sjednice i sl.). Premda te aktivnosti ne moraju imati direktne poveznice, one su logički povezane jer pripadaju istom projektu. Nakon što se odrade sve aktivnosti, projekt se zatvara. Kako na svakom projektu postoji čitav niz aktivnosti koje iziskuju kontakte sa djelatnicima jave uprave, ali i sa osobama iz drugih institucija (druge gradske tvrtke, ministarstva, državne tvrtke, dobavljači....) potrebno je za svaki projekt osigurati i rezime svih relevantnih kontakata koji su prikazani na grafičkom sučelju prilikom pregleda projekta. Uz sve informacije, projekt može imati i određene priloge u vidu različitih dokumenata: npr. ugovori, računi, skice, fotografije i sl. Nad projektom se mogu dodavati podsjetnici koji ukazuju na određene akcije koje se moraju izvršiti do određenog roka. Na grafičkom sučelju bit će prikazane u obliku led indikatora. Svaki projekt može se povezati sa geografskom lokacijom koja se na grafičkom sučelju prikazuje na GPS platformi (Slika 6).



Slika 6. Prikaz projekata na GPS platformi

IV. IMPLEMENTACIJA SUSTAVA

Svaka jedinica javne uprave (grad, općina. županija) predstavlja jednu domenu unutar koje se izvode aktivnosti vezane za pritužbe građana, unutarnje poslove ili aktivnosti vezane na projekt. Domene imaju jedinstveni identifikator po kojemu se međusobno razlikuju unutar sustava. Korisnici unutar jedne domene nemaju prava pristupa aktivnostima unutar druge domene osim ako politika praćenja drugačije ne nalaže, npr. administrator domene Virovitičko-podravske županije može imati pristup svojim *child* domenama. Cjelokupan sustav sa skladištima podataka izveden je u *cloud* okruženju.

Slika 7. Domene spojene na sustav u cloud okruženju

V. ZAKLJUČAK

U radu su opisane prednosti korištenja informacijkih sustava u jedinicama javne uprave sa naglaskom na workflow sustave. Predstavljena je arhitektura informacijskog sustava podijeljena na tri sloja: sloj medijacije koji daje potporu procesima prikupljanja podataka ili primanja aktivnosti iz različitih izvora, sloj baze podataka koji sadri više skladišta podataka o radu jedinice samouprave, baza podataka o pritužbama građana, baza podataka o procesima koji su u tijeku, baza podataka o projektima i sl. Iznad sloja baze podataka prikazan je prezentacijski sloj, čija osnova zadaća je kreiranje izvješća, njihov prikaz na grafičkim sučeljima te distribucija izvješća. Na primjerima je opisan workflow sustav za izvršavanje aktivnosti u jedinicama javne uprave. Opisana su grafička sučelja temeljena na web tehnologijama za prikazivanje workflow aktivnosti i projekata jedinice javne uprave.

slaven.bojko@fina.hr, Vesna.Kumpar-Tasevski@carina.hr, marino.mateljan@fina.hr, ana.topic@fina.hr

Sažetak - Ovaj rad analizira sustav za nadzor potrošnje posebnih goriva za namjene u poljoprivredi, ribarstvu i akvakulturi i za javne i gospodarske namjene u plovidbi kako su ga uspostavile Carinska uprava Ministarstva financija Republike Hrvatske i Financijska agencija. Pravni temelj ovakvog sustava nadzora potrošnje je europska Direktiva 2003/96 EZ o restrukturiranju sustava zajednice o oporezivanju energenata i el. energije, Zakon o trošarinama, Pravilnik o primjeni Zakona o trošarinama što se odnosi na plinsko ulje obojano plavom bojom za namjene u poljoprivredi, ribolovu, ribogojstvu i akvakulturi i Pravilnik o uvjetima i načinu oslobođenja od plaćanja trošarine na energente koji se koriste kao pogonsko gorivo za plovidbu. Sadašnjem sustavu nadzora prethodio je sustav posebnog poreza i knjižica goriva s neučinkovitim nadzorom.

Svrha uspostave sadašnjeg sustava je učinkovitiji nadzor i dostupnost podataka u realnom vremenu. Kako sustav mora omogućiti jednostavnu i brzu realizaciju korištenja prava na kupnju posebnih goriva velikom broju korisnika na velikom broju prodajnih mjesta, implementiran je pomoću tehnologija koje se koriste u sustavima plaćanja putem platnih kartica izdavanjem posebnih kartica goriva korisnicima, označavanjem plinskog ulja propisanim markerima i nadzorom samog korištenja plinskog ulja kod korisnika.

Ovaj rad će detaljno opisati način realizacije i učinke propisanog cjelovitog sustava nadzora.

I. UVOD

Predmet ovog rada je analiza utjecaja uvođenja naprednijeg sustava za nadzor potrošnje posebnih goriva. Novi sustav je uveden jer se pretpostavljalo da stari sustav ne sprječava adekvatno eventualne zloupotrebe posebnih goriva. Cilj ovog rada je, osim da opiše implementaciju novog sustava, kvantificirati efekt primjene sustava kroz promatranje relevantnih statističkih vrijednosti pojedinih pokazatelja kroz određeni niz godina prije i poslije uvođenja novog sustava.

II. ZAKONSKA REGULATIVA SUSTAVA

Nadzor potrošnje plinskog ulja obojanog plavom bojom korisnika u poljoprivredi, ribolovu i akvakulturi, kao i plovidbi uspostavljen je u svrhu kontrole potrošnje i sprečavanja zloporaba korištenja. Prethodni je sustav nadzora potrošnje plinskog ulja obojanog plavom bojom bio uređen putem Knjižica goriva svakog pojedinog korisnika, s obvezom popunjavanja od strane prodavatelja prilikom prodaje, a kontrola takve evidencije bila je uvelike otežana zbog pojedinačnog nadzora, s ograničenim opsegom uslijed nedostatnosti ljudskih resursa i relativne dostupnosti podataka. Današnji način kontrole potrošnje putem Kartica goriva uspostavljen je 1. srpnja 2010. godine.

Pravni temelj sadašnjeg nadzora potrošnje je pravna stečevina Europske unije koja između ostalih kategorija trošarinskih roba regulira i oporezivanje trošarinom energenata. Nadzor potrošnje plinskog ulja sa sniženom trošarinom do nule propisuje europska Direktiva 2003/96 EZ o restrukturiranju sustava zajednice o oporezivanju energenata i el. energije. Kako se sniženjem trošarine zadire u fiskalne učinke državnog proračuna svake države članice, plinska ulja koja imaju sniženu trošarinu moraju biti označena u svrhu smanjenja zloporaba i povećane učinkovitosti kontrole. Način i vrsta označavanja plinskih ulja propisan je Direktivom Vijeća 95/60 EZ o fiskalnom označavanju plinskog ulja i kerozina.

Nacionalni temelji ovog nadzora potrošnje su Zakon o trošarinama („Narodne novine“ br. 22/2013, 32/2013, 81/2013), Pravilnik o primjeni Zakona o trošarinama što se odnosi na plinsko ulje obojano plavom bojom za namjene u poljoprivredi, ribolovu, ribogojstvu i akvakulturi („Narodne novine“ br. 156/2013), te Pravilnik o uvjetima i načinu oslobođenja od plaćanja trošarine na energente koji se koriste kao pogonsko gorivo za plovidbu („Narodne novine“ br. 58/2013, 72/2013,69/2014, 157/2014).

Navedenim pravnim okvirom uspostavljen je sustav nadzora potrošnje plinskog ulja obojanog plavom bojom za namjene u poljoprivredi ribolovu, ribogojstvu i akvakulturi, te plovidbi, pomoću kartice goriva za poljoprivredu i ribarstvo, te plovidbu. Uređen je i izgled te sadržaj i oblik kartice goriva. Uređen je i način korištenja kartice goriva, te sukladno tome i programska podrška za sustav kontrole pri prodaji plinskog ulja obojanog plavom bojom. Uređena je mogućnost usporedbe zaduženja i odobrenih količina, te povezivanja odobrenih količina sa kvotama potrošnje plinskog ulja za te propisane namjene.

Osnove sustava implementirane iz europske pravne stečevine propisane u Zakonu o trošarinama sadržavaju odredbe koje se odnose na sniženje trošarine do 0,00 kuna, za plinsko ulje u tu svrhu označeno i obojano plavom bojom. Pravo korištenja navedenog ulja propisano je korisnicima prava u poljoprivredi, ribogojstvu, akvakulturi i ribolovu, te plovidbi. Da bi određeni subjekt postao korisnikom prava za namjene u poljoprivredi mora biti upisan u odgovarajući upisnik poljoprivrednih gospodarstava pri ministarstvu nadležnom za poljoprivredu. Korisnici prava u ribogojstvu, akvakulturi i ribolovu moraju posjedovati povlasticu sukladno posebnim propisima. Korisnicima prava propisani su pokazatelji prava na godišnju potrošnju. Pokazatelje utvrđuje ministarstvo nadležno za poljoprivredu uz zadovoljenje određenih uvjeta. Spomenuto ministarstvo prava na potrošnju goriva posebnih namjena, iskazuje putem kartica goriva, koje su javna i zaštićena isprava i obrazac namijenjeni za kontrolu. Na Kartici goriva, vidljiva je oznaka nadležnog ministarstva, naziv kartice goriva za poljoprivredu i ribarstvo, broj kartice goriva, OIB korisnika prava ili matični broj poljoprivrednog gospodarstva ili CFR broj plovila, kratki naziv korisnika prava i oznaka ispostave Agencije za plaćanja odnosno nadležnog tijela koje je izdalo povlasticu za ribolov ili za uzgoj ribe odnosno za akvakulturu. Kartica goriva za poljoprivredu i ribarstvo u vlasništvu je Ministarstva poljoprivrede.

Uvjet, propisan u naznačenim propisima, za stjecanje prava korisnika u plovidbi je upis fizičkih i pravnih osoba u odgovarajući upisnik odnosno očevidnik kao vlasnika, brodara, ili korisnika financijskog leasinga plovnih objekata ili plovila, registriranih za gospodarske svrhe sukladno posebnom propisu, a djelatnost je komercijalni prijevoz putnika ili tereta. Pravo na karticu goriva za plovidbu stječe se na temelju rješenja koje izdaje ministarstvo nadležno za plovidbu po službenoj dužnosti za svaki pojedinačni brod osim za brod koji plovi u međunarodnoj plovidbi i međunarodnoj unutarnjoj plovidbi. Ministarstvo je ujedno i vlasnik Kartice te utvrđuje i kriterije za određivanje najveće dopuštene količine godišnje potrošnje. Kartica gorivo za plovidbu sadrži podatke o nazivu ministarstva nadležnog za plovidbu, naziv kartice gorivo za plovidbu, OIB korisnika prava, ime odnosno oznaku plovnog objekta odnosno plovila, broj kartice goriva, ime ili naziv korisnika prava.

III. METODOLOGIJE NADZORA KORIŠTENJA PRAVA NA POSEBNA GORIVA

Cjelovit sustav nadzora mora omogućiti ograničavanje korištenja posebnih goriva kod pojedinog korisnika samo do odobrene količine i dokazivanje zloupotrebe posebnih goriva kada se koriste u neodobrene svrhe.

Prvi cilj nadzora može se ostvariti nadzorom proizvodnje posebnih goriva uspostavom odgovarajuće evidencije i usporedbom evidencije proizvodnje s evidencijom distribucije posebnih goriva krajnjim korisnicima. Stoga je [1] propisao vođenje evidencija kojima se evidentira ukupna proizvedena ili uvezena količina posebnog goriva, te distribucija posebnih goriva krajnjim prodavateljima. Posebno gorivo, već prilikom proizvodnje ili uvoza, sukladno [1] mora biti označeno propisanim indikatorom i bojom što se izvršava u posebnim trošarinskim skladištima ovlaštenog držatelja trošarinskog skladišta. Kontrolom navedene evidencije moguće je utvrditi koliko je svako prodajno mjesto zadužilo posebnog goriva u određenom periodu.

Kako bi se spriječilo da prodajna mjesta distribuiraju posebno gorivo neovlaštenim korisnicima, dužna su gorivo razdužiti evidentiranjem svake prodaje posebnog goriva kroz sustav nadzora potrošnje. Uspoređivanjem evidencije prodaje posebnog goriva krajnjim korisnicima s evidencijom distribucije opisane u prethodnom odlomku, moguće je ustanoviti da li je pojedino prodajno mjesto svu zaduženu količinu posebnog goriva prodalo ovlaštenim krajnjim korisnicima do pojedinačnih razina dozvoljenih količina, ili postoje razlike.

Mada je u [1] propisano da prodavatelji posebnih goriva prodaju moraju izvršiti izravnim utakanjem u poljoprivredne strojeve, ribarice ili plovila, postoji mogućnost da će zlonamjerne osobe posebno gorivo koristiti u strojevima za svrhe drugačije od onih propisanim zakonom. Odgovarajućim inspekcijskim nadzorom, moguće je analizirati pojavnost propisanih indikatora u spremnicima strojeva čija namjena nije propisana kao namjena za koju je moguće koristiti posebna goriva. Ovlaštene analize postojanja indikatora mogu se koristiti kao dokaznice u odgovarajućim prekršajnim ili kaznenim postupcima, te se time provode mjere sprječavanja zloupotrebe posebnih goriva.

U svrhu omogućavanja što učinkovitijeg nadzora, slijedeći postupci provode se sukladno opisanim pravilima:

- za namjene u poljoprivredi pravo na potrošnju plinskog ulja obojanog plavom bojom korisnici ostvaruju na temelju podnesenih zahtjeva za izravna plaćanja u prethodnoj godini odgovarajućem tijelu sukladno [1]. Pravo na karticu goriva za plovidbu stječe se na temelju rješenja kojeg izdaje ministarstvo nadležno na plovidbu.

- na temelju prethodno spomenutih zahtjeva korisnicima se izrađuju kartice. Karticu goriva korisnicima prava na potrošnju plinskog ulja obojanog plavom bojom u poljoprivredi izdaje Agencija za plaćanja u poljoprivredi, ribarstvu i ruralnom razvoju (u daljnjem tekstu: APPRRR), a korisnicima prava u ribarstvu nadležno tijelo koje je izdalo povlasticu za ribolov ili povlasticu za uzgoj ribe i drugih morskih organizama (u daljnjem tekstu: povlasticu za uzgoj) odnosno povlasticu za akvakulturu. Kartica goriva smatra se javnom i zaštićenom ispravom i obrascem kao kartica za kontrolu potrošnje goriva posebnih namjena čiji se sadržaj, oblik, način zaštite i obvezna primjena posebno uređuje. Karticu goriva za plovidbu izdaje ministarstvo nadležno za plovidbu. Kartica goriva za plovidbu smatra se javnom i zaštićenom ispravom i obrascem kao kartica za kontrolu potrošnje goriva posebnih namjena čiji se sadržaj, oblik, način zaštite i obvezna primjena posebno uređuje.

- svaki korisnik dobiva određenu količinu goriva za pojedinu godinu. Podatke o odobrenoj količini plinskog ulja obojanog plavom bojom za namjene u ribolovu, ribogojstvu i akvakulturi obračunava ministarstvo nadležno za ribarstvo koje je izdalo povlasticu za ribolov ili povlasticu za uzgoj odnosno povlasticu za akvakulturu, jednom godišnje. Podatke o odobrenoj količini plinskog ulja obojanog plavom bojom za namjene u poljoprivredi obračunava Agencija za plaćanja u poljoprivredi, ribarstvu i ruralnom razvoju jednom godišnje.

- korisnik prava koji je preuzeo karticu goriva dužan je prije kupovine plinskog ulja obojanog plavom bojom za namjene u poljoprivredi, ribarstvu, ribogojstvu i akvakulturi, prodavatelju predočiti:

1. karticu goriva i

2. identifikacijsku ispravu korisnika prava na potrošnju plinskog ulja obojanog plavom bojom propisanu posebnim propisima koja obuhvaća iskaznicu obiteljskog poljoprivrednog gospodarstva, ili rješenje o upisu u upisnik poljoprivrednih gospodarstava, ili povlasticu za ribolov, ili povlasticu za uzgoj, ili povlasticu za akvakulturu.

- plinsko ulje se može koristiti kao pogonsko gorivo za plovidbu ako:

1. se neposredno nabavlja iz trošarinskog skladišta te ako

2. korisnik prava pri nabavi podnese isprave kojima dokazuje komercijalno obavljanje plovidbe u međunarodnoj pomorskoj i međunarodnoj unutarnjoj plovidbi.

- prodavatelj koji prodaje plinsko ulje obojano plavom bojom korisnicima prava dužan je prije prodaje izvijestiti korisnika prava o raspoloživoj količini te izvršiti prodaju izravnim utakanjem do iznosa raspoložive količine.

- trošarinski obveznik i druga pravna ili fizička osoba – prodavatelj, koji prodaje plinsko ulje obojano plavom bojom za namjene u poljoprivredi, ribolovu, ribogojstvu i akvakulturi, dužan je voditi Evidenciju o kupcima plinskog ulja obojanog plavom bojom koji gorivo nabavljaju radi daljnje prodaje.

IV. TEHNOLOŠKA IMPLEMENTACIJA SUSTAVA

Za uspostavu učinkovitijeg sustava evidentiranja i nadzora potrošnje posebnih goriva za namjene u poljoprivredi, ribarstvu, akvakulturi i za javne i gospodarske namjene u plovidbi od onog koji je postojao do 2010. godine bilo je potrebno omogućiti kupnju posebnog goriva velikom broju korisnika na prodajnim mjestima diljem teritorija Republike Hrvatske, mogućnost za zloporabu prava korisnika svesti na najmanju moguću, osigurati da godišnja potrošnja korisnika ne premašuje odobrenu godišnju količinu te osigurati da proces provjere prava i evidentiranja kupnje traje što je moguće kraće.

Iz opisa zahtjeva može se zaključiti da je riječ o tipičnom slučaju dvostranog tržišta, odnosno, o usluzi koja mora zadovoljiti potrebe dviju potpuno različitih grupa korisnika usluge, u ovom slučaju korisnika prava na potrošnju posebnih goriva i distributera posebnih goriva.

U bankarskom sektoru slične zahtjeve već godinama ispunjavaju kartični sustavi koji se temelje na magnetskim i čip karticama izdanim korisnicima usluge plaćanja putem platnih kartica te EFT POS uređajima postavljenih kod trgovaca koji su voljni prihvatiti platne kartice kao sredstvo plaćanja. Kako je tehnologija kartičnih sustava dokazana u praksi, bilo je logično primijeniti istu za uspostavu učinkovitog sustava nadzora potrošnje posebnih goriva za namjene u poljoprivredi, ribarstvu, akvakulturi i za javne i gospodarske namjene u plovidbi.

A. Sudionici u kartičnoj shemi

Svako kartično poslovanje se temelji na reguliranim odnosima među sudionicima kartične sheme u kojoj svaki od sudionika imaju svoju ulogu, a informacijska i komunikacijska tehnologija je u službi kartičnog poslovanja gdje ima za cilj osigurati interakciju među sudionicima kartične sheme. U platnim kartičnim shemama prepoznajemo slijedeće ključne sudionike: izdavatelj (engl. Issuer), stjecatelj (engl. Acquirer), trgovac (engl. Merchant) i korisnik kartice (engl. Cardholder) kao shemu s četiri sudionika koja je primijenjena kod većine bankarskih kartica. Postoje i platne sheme s tri sudionika, gdje su izdavatelj i stjecatelj isti sudionik, te se ista primjenjuje kod kartica koje ne izdaju banke, već specijalizirani poslovni subjekti.

U kartičnoj shemi sustava za nadzor potrošnje posebnih goriva prepoznajemo Ministarstvo poljoprivrede i Ministarstvo pomorstva prometa i infrastrukture u ulozi izdavatelja i stjecatelja, distributere ili prodavatelje posebnog goriva koje prepoznajemo u ulozi trgovaca te poljoprivrednike, ribare i pomorce kao korisnike kartica. Ova shema spada u tzv. „zatvorene“ kartične sheme ili sheme sa tri sudionika. Dio poslova izdavatelja i stjecatelja, a temeljem odgovarajućih odluka i ugovora, u njihovo ime izvršava Financijska agencija (u daljnjem tekstu Fina) kao tehnički pružatelj usluge.

B. Izdavanje kartica

Izdavateljima kartica zainteresirani subjekti predaju zahtjeve s potrebnim podacima i temeljem kriterija utvrđenih u [2], [3] izdavatelji odobravaju korisnicima godišnju količinu posebnog goriva - kvotu. Podatke o korisnicima i godišnjim kvotama izdavatelji šalju na siguran način Fini, gdje se isti učitavaju u kartični sustav. Temeljem zaprimljenih podataka o korisnicima u kartičnom sustavu Fine kreiraju se računi korisnika s podacima o dozvoljenoj godišnjoj količini posebnog goriva – kvoti te se kreiraju podaci o kartici korisnika. U kartičnom sustavu Fine se također odrede podaci potrebni za izradu kartica i na siguran način dostavljaju ovlaštenoj ustanovi za izradu zaštićenih isprava Republike Hrvatske, tj. Agenciji za komercijalnu djelatnost (u daljnjem tekstu AKD).

Za potrebe izrade kartica, izdavatelji moraju prikupiti osobne podatke korisnika kartica. Stoga su kao voditelji zbirki osobnih podataka imenovane Agencija za plaćanje u poljoprivredi, ribarstvu i ruralnom razvoju, Uprava ribarstva Ministarstva poljoprivrede i Ministarstvo pomorstva, prometa i infrastrukture koji su zbirke prijavili u odgovarajući registar zbirki osobnih podataka koji vodi Agencija za zaštitu osobnih podataka.

AKD izrađuje kartice „Gorivo za poljoprivredu i ribarstvo“ (u daljnjem tekstu GPR kartica) i „Gorivo za plovidbu“ (u daljnjem tekstu GP kartica) koje su prema [4] standardu registrirane od ovlaštenog tijela „Bank of America“ i dodijeljen im je IIN broj – „Issuer Identification Numbers“. IIN broj GPR kartice je 639732, a GP kartice 637162. Kartice su izrađene sukladno [5], [6] i [7], s odgovarajućim prilagodbama u strukturi podataka kako bi se moglo zadovoljiti propisane zahtjeve. Izrađene kartice se distribuiraju korisnicima, a kako bi kartice bile spremne za korištenje iste je potrebno aktivirati.

Slika 1. Izgled prednje strane kartice „Gorivo za poljoprivredu i ribarstvo“

C. Prihvat transakcija

U ulozi stjecatelja Fina je dužna omogućiti prihvat kartica posebnih goriva na skoro 600 prodajnih mjesta diljem teritorija Republike Hrvatske. Kao i u svakoj kartičnoj shemi trgovci su dužni formalizirati svoju ulogu trgovca sklapanjem ugovora o prihvatu kartica te dostavljanjem podataka o prodajnim mjestima na kojima žele prihvaćati kartice posebnih goriva. Temeljem ugovornih odnosa s trgovcima podaci o svim prodajnim mjestima se unose u sustav nadzora potrošnje goriva te im se definiraju identifikacijski brojevi u sustavu, a sva prodajna mjesta potrebno je opremiti EFT POS uređajima na kojima je omogućen prihvat GPR i GP kartica.

Ukoliko trgovci imaju svoje vlastite EFT POS uređaje i kartičarske sustave, te su ih voljni prilagoditi za prihvat GPR i GP kartica, moguće je povezati takve sustave s kartičnim sustavom Fine. Komunikacija koja se odvija između takva dva sustava temelji se na „Host to host“ protokolu razmjene poruka kartičnih transakcija definiranom prema [8].

Za prodajna mjesta malih distributera posebnog goriva koji nemaju vlastite EFT POS uređaj, Fina je osigurala odgovarajuće EFT POS uređaje za prihvat GPR i GP kartica. Svaki EFT POS uređaj prije isporuke na prodajno mjesto prolazi kroz proces inicijalizacije u kojem je EFT POS uređaju na siguran način izdan i učitan X509 v3 certifikat kojeg koristi za ostvarivanje sigurne komunikacije sa sustavom u Fini putem Interneta. Pritom se koristi obostrana SSL/TLS autentikacija, tj. prilikom uspostave sigurne veze svojim certifikatima predstavljaju se klijent (EFT POS uređaj) i poslužitelj te se izmjenjuje jednokratni simetrični ključ kojim se štiti (enkriptira) sva komunikacija unutar uspostavljene sesije. Svi korišteni digitalni certifikati uređaja kreirani su sukladno X.509 v3 standardu, u kojem su definirane informacije koje se pohranjuju u certifikatu i sam format zapisa tih informacija.

Terminalska EFT POS aplikacija omogućuje trgovcu provođenje transakcija upita u stanje, prodaje, strona i naknadnog unosa te razmjenu kartičnih poruka sa sustavom u Fini koja se temelji na [8]. Prije samog istakanja željene količine goriva korisniku kartice posebnih goriva trgovac je dužan napraviti transakciju upita u stanje kako bi provjerio raspoloživu količinu goriva na računu korisnika. Nakon istakanja dozvoljene količine goriva trgovac koristeći karticu korisnika zadaje transakciju prodaje na točno istočenu količinu goriva. Ukoliko transakcija zadovolji sve formalne provjere i količina goriva za autorizaciju ne premašuje raspoloživu količinu na računu korisnika, transakcija biva odobrena. Kako bi se osigurala dvofaktorska autentikacija korisnika kartice, uz karticu goriva propisano je i predočenje osobnih dokumenata korisnika kartice te se je isti dužan potpisati na potvrdu o odobrenoj transakciji. Podaci o svim odobrenim i odbijenim transakcijama bilježe se u kartičnom sustavu Fine i na EFT POS uređaju te se na kraju svakog dana provodi poravnanje evidencija EFT POS uređaja s kartičnim sustavom Fine uspoređivanjem podataka o broju zabilježenih transakcija kao i o ukupnim količinama prodanog posebnog goriva. Tek se po provedenom postupku poravnavanja evidencija između EFT POS uređaja i kartičnog sustava u Fini transakcije smatraju konačnima i proknjiženima. U slučaju ustanovljenih razlika, posebice razlika između evidencija u blagajni distributera posebnog goriva i evidencija kartičnom sustavu, iste se rješavaju putem propisanih reklamacijskih postupaka koje može pokrenuti bilo koji od triju sudionika kartične sheme.

D. Izvještavanje nadzornih tijela

Podaci u sustavu nadzora potrošnje posebnih goriva omogućavaju praćenje potrošnje korisnika kartica, ali isto tako i prodavatelja goriva. Svi podaci o zabilježenim transakcijama se jednom dnevno iz transakcijske baze šalju u izvještajno-analitički sustav Carinske uprave za potrebe provođenja nadzora. Za potrebe provođenja izdavateljskih i stjecateljskih poslova, Fina je uspostavila izvještajni sustav koji omogućuje izdavateljima pregled podataka registriranih u sustavu.

V. REZULTATI PRIMJENE SUSTAVA

Učinci primjene sustava promatrani su samo na slučaju primjene u poljoprivrednoj proizvodnji radi dostupnosti odgovarajućih podataka. Naime, podaci na temelju kojih se dodjeljuju kvote za namjene u plovidbi, ribolovu i akvakulturi nisu javno dostupni. S druge strane, podaci o ukupno obrađenim poljoprivrednim površinama, što je prema [2] temeljni kriterij za određivanje kvote, dostupni su kroz [9]. Potrošnja posebnih goriva, odnosno, plinskog ulja za namjene u poljoprivredi čini većinu ukupne potrošnje, te je time najznačajnija za promatranje i analizu.

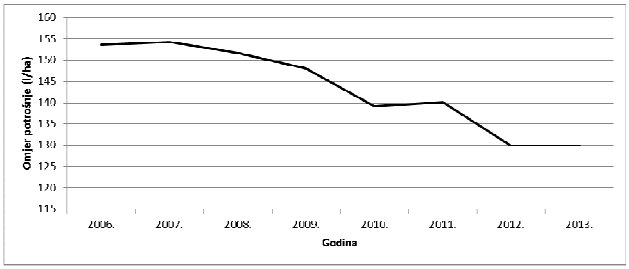
U [10], [11] i [12], u tablicama „3.3.6 Dizelsko gorivo" tih dokumenata, objavljeni su podaci o potrošnji dizel goriva, odnosno, plinskog ulja po pojedinim sektorima. Iskazana je potrošnja dizel goriva u milijunima litara za sektor poljoprivrede po godinama za razdoblje od 2006. do 2013. godine. Iz [9] uzeti su podaci o ukupnoj površini korištenog poljoprivrednog zemljišta za isto razdoblje i uspoređeni u Tablici 1 i Slici 2.

Iz podataka je vidljivo veliko smanjenje potrošnje dizel goriva po jedinici obrađene poljoprivredne površine 2010. godine te 2012. godine sa zadržavanjem gotovo jednake razine omjera potrošnje po jedinici poljoprivredne površine u 2013. godini u odnosu na prethodnu godinu. Navedene promjene u podacima, prema [2], koincidiraju s uvođenjem novog sustava nadzora potrošnje posebnih goriva u srpnju 2010. godine, odnosno, činjenicom da je 2011. godine kvota povećana za polovicu neiskorištene kvote iz 2010. godine te da je time 2012. godina prva godina u kojoj je dosljedno primjenjena kvota izračunata prema propisanim pravilima u [2].

Zbog navedenih utjecaja, iz detaljnih promatranja izuzete su 2010. i 2011. godina, kao godine izuzetaka nastalih polovičnom primjenom novog sustava i dodatnim povećanjem kvota.

Tablica 1 Korištena poljoprivredna površina i potrošnja plinskog ulja po godinama

	Korištena poljoprivredna površina u hektarima (ha)	Potrošnja plinskog ulja za namjene u poljoprivredi u milijunima litara (Ml)	Omjer Potrošnje plinskog ulja i Korištene poljoprivredne površine (l/ha)
2006.	1.230.183	189,0	153,64
2007.	1.201.756	185,5	154,36
2008.	1.289.091	195,6	151,73
2009.	1.299.582	192,4	148,05
2010.	1.333.835	185,7	139,22
2011.	1.326.083	185,8	140,11
2012.	1.330.973	173,0	129,98
2013.	1.301.985	169,1	129,88



Slika 2 Prikaz omjera potrošnji plavog dizela po jedinici poljoprivredne površine od 2006. do 2012. godine

Statistička analiza za radzoblje od 2006. do 2009. godine pokazuje da je godišnje prosječno potrošeno 151,94 litara dizel goriva po hektaru korištene poljoprivredne količine. Pearsonov koeficijent korelacije veličina potrošnje i površine poljoprivrednog zemljišta za razdoblje od 2006. do 2009. godine od 0,92 samo dosljedno pokazuje snažnu, propisima određenu, ovisnost tih veličina. Kako je prosjek omjera potrošnje dizelskog goriva po jedinici poljoprivredne površine za 2012. i 2013. godinu samo 129,92 litara dizel goriva po hektaru obrađenih poljoprivrednih površina, može se zaključiti da je 2012. i 2013. godine potrošnja dizelskih goriva smanjena za 14% u odnosu na prosjek godišnje potrošnje dizel goriva po jedinici površine prije uvođenja sustava, odnosno, u razdoblju od 2006. do 2009. godine.

Kako Pearsonov koeficijent nema previše smisla promatrati na skupu parova veličine 2, odnosno, samo za 2012. i 2013. godinu, nužno je skrenuti pažnju na pad vrijednosti standardne devijacije omjera potrošnje dizelskog goriva po jedinici poljoprivredne površine sa 2,82 za razdoblje od 2006. do 2009. godine na samo 0,07 za 2012. i 2013. godinu, odnosno, čak za dva reda veličine.

VI. ZAKLJUČAK

U ovom radu prezentirali smo način primjene i učinke sustava za nadzor potrošnje posebnih goriva. Prezentirani rezultati ukazuju na snažnu povezanost primjene sustava na smanjenje potrošnje posebnih goriva u poljoprivrednoj proizvodnji, te time i smanjenje upotrebe posebnih goriva mimo propisanih namjena. Vrijednost standardne devijacije omjera potrošnje dizelskog goriva po jedinici poljoprivredne površine za 2012. i 2013. godinu koja je za 4 reda veličine manja od promatrane veličine ukazuje da je razlika vjerojatno manja od statističke pogreške. Ukoliko podaci iz slijedećih godina pokažu ovakvu konzistentnost, svakako će se nametati zaključak da je primijenjeni sustav nadzor uklonio gotovo sve anomalije u korištenju plavog dizela u poljoprivredi. Ovakav sustav moguće je efikasno primijeniti i za nadzor bilo koje druge vrste robe ili usluga koje imaju smanjenu cijenu za krajnje korisnike ali samo za određene namjene. Kako autorima nije poznat sličan sustav nadzora potrošnje goriva s smanjenim trošarinama niti u EU niti bilo gdje drugdje u svijetu, već se isti većinom svode na markiranje goriva ili povrat iznosa trošarine prema plaćenim računima, svakako treba promovirati njegovu primjenu u

zemljama članicama i kandidatkinjama za pristup EU koje imaju zajedničku politiku trošarina na goriva za namjene u poljoprivredi.

Abstract - The number of people who are using social media websites is constantly growing. Customers increasingly expect banks to offer more services via social media platforms. Recent studies confirmed that customer retention is likely to increase at banks that offer a strong social media experience. This paper explores the maturity of social media use in banking service sector with particular focus on Facebook, Twitter, YouTube and LinkedIn. Empirical data have been collected mainly through visual inspection of social media accounts of major banks in Western Balkan Countries and the results have been compared and presented. Various types of indicators for measurement of social media activity have been used: number of fans, subscribers and followers, number of video views, number of posts in last 15 days, visibility of the social media channel on the official web page, social engagement and others. Based on these and other data we made quantitative comparison and qualitative analysis of the intensity of social media use in banking industry in the region of Western Balkan Countries.

I. INTRODUCTION

According to Digital Insights blog and its social media 2014 statistics, Facebook has 1.28 billion registered monthly active users, Twitter has 255 million, and LinkedIn has 187 million, while Youtube has 1 billion total users globally. Looking closely to this statistic an interesting question is placed in front of business practitioners: Where else can you find such a large number of potential buyers at one place and having the opportunity for instant direct communication with all of them? Businesses must understand the role of information technology for their marketing strategy and its impact on shaping the global marketplace in order to survive and compete. Today technology plays vital role in peoples everyday life activities and marketers need to reshape their marketing strategies for communication and interaction with their customers. The global financial crises and economic recession from 2008 affected firms' marketing strategies and budgets. Usually companies in a period of financial crises reduce their marketing and IT budgets. But marketing function plays key role during and after financial crises for companies to remain profitable and customer responsive. Scholars (Kirtiş and Karahan, 2011) have confirmed that for both big and small firms, social media marketing as strategy compared to traditional media help to advertise products and services during and after economic crises with lower cost.

In the last two decades marketing as academic discipline and marketing activities as business practices have been changed dramatically. The main driver for such a change in the domain of marketing management is the emergence of the internet and the era of web 2.0. Several important changes occurred in the domain of contemporary marketing activities: 1. broader access to marketing media – everyone who have access to internet can distribute content with low cost not only corporations with large marketing budgets (Tuten, 2008) 2. Power shift – empowered and intelligent customers versus weaker competitive position of corporations (Porter, 2001) (Urban, 2006) 3. Higher level of interaction – old fashioned one way of communication is changed to two way direct communication (Kim and Ko, 2012).

Answering the question what can be included under term social media is not easy task. Kaplan & Haenlein (2010) indicate that often there is confusion among managers and academic researchers regarding the meaning of social media. The main question appointed by the same authors is: How social media differ from Web 2.0 and User Generated Content. They explain that Web 2.0 is representation of ideological and technological foundation while User Generated Content can be seen as sum of all ways in which people use Social Media. On the other hand social media is defined by these authors as a group of Internet-based applications that build on the ideological and technological foundations of Web 2.0, and that allow the creation and exchange of User Generated Content (Kaplan & Haenlein, 2010). In their article Kaplan and Haenlein have classified social media in the following six categories: 1) blogs, 2) collaborative projects 3) social networking sites 4) content communities 5) virtual social worlds and 6) virtual game worlds.

Banking industry cannot stay aside just watching the enormous growth of social media activity. Banks like no other organizations rely on reputation. The positive brand

awareness and banking reputation is on stake. Since the global economic and financial crises client sensitivity regarding banking service reliability and trustworthiness has become even more important. Vemuri (2010) stresses the need for bridging the gap between banking and social media use. He advocates for stronger activity of banks on social media. Dissatisfied clients spread very fast bad news on the internet through number of tweets, retweets and viral videos with million views. These interactions create negative awareness and influence the way clients make decisions.

However a research study published by Teller Vision in 2013 showed that retail banks in USA, United Kingdom, Germany, France and Australia will spend considerably less comparing to other industries on social media marketing. This study confirms manifestation of vigilance behavior by banks when it comes to marketing through social media. Banks' caution regarding social media use is influenced also by result reported that only a quarter of 3000 quizzed consumers use social media to follow and keep up-to-date with certain companies. More than three quarters of consumers are predominantly on the various platforms to keep in touch with friends and family.

The results from Global Retail Banking Digital Marketing Report in 2013 reported that amount being spent by retail banks on social media is very small and as a final remark at the end of the report a notion is mentioned that social media use by banks has reached a "plateau". Hence we can say that banks are facing with a key challenge in the use of social media in terms of opportunities and threats. This challenging situation in social media use by banks was the main driver for the authors of this paper to delve more deeply into this problem. Second main driver for the research conducted in this paper was the lack of data about social media use by banking industry in the region of Western Balkan Countries. The authors expect to contribute to the research literature by covering this research gap.

II. RESEARCH METHODOLOGY

Large amount of data have been collected in order to achieve the research goal of the study related to the main research question: How much banks from Western Balkan countries are active in use of social media platforms? The region of western Balkan countries was chosen for this research because all countries have similar level of economic development and political environment (not EU members) which makes comparison between countries more reliable. Also most of the countries (Macedonia, Serbia, Kosovo, Bosnia and Herzegovina and Montenegro) in the past were belonging to one state and all have passed through more or less similar reforms in the banking sector. Hence, banks from six western Balkan countries were included in this research study: Macedonia, Kosovo, Serbia, Bosnia and Herzegovina, Montenegro and Albania.

Regarding the methodology the authors were following consistent procedure with several steps in the process of data collection. Firstly, a list was created with all licensed banks operating in the western Balkan. To compile the list authors have used official data from national banks of all countries in the region. At the beginning the total number of banks included in the list was 107 banks. Two banks, one from Serbia and one from Montenegro have been removed from the sample because they recently received the license and they still did not start to operate. Thus a list of 105 active banks was used to conduct the research. Also it is important to mention that only privately owned retail banks were included in the sample.

Secondly, four main social media platforms have been used to collect data about banks social media activity: Facebook, YouTube, Twitter and LinkedIn. These four platforms have been chosen as a result of checking the leading platforms by use in all countries from this region. We were using Alexa as web analytics tool and its rankings of top websites in each country from western Balkan region. According to Alexa (http://www.alexa.com/topsites/countries) four social media platforms Facebook, YouTube, Twitter and LinkedIn were always rated as top websites in front of all other social media platforms in all countries, except Kosovo and Montenegro for which there were no data by Alexa rankings. Also we were following the results from two industry reports. First was the Social Media Marketing Industry Report for 2014 ranking the same four platforms as most often used from marketers (Stelzner, 2014). The second report was the First Global Retail Banking Digital Marketing Report for 2013 who was also ranking these four platforms as most often used by banks in all regions in the world.

Thirdly we made visual inspection of all banks' official websites from the sample to determine social media visibility. If we could find on the official web page link to the social media platform we were using the link to navigate our search towards the respective platform and to collect data such as: number of Facebook fans, Twitter followers, YouTube subscribers etc. If there was no any link confirming presence on some of the four social media platforms, than we were checking existence of social media account by using the official name of the bank or their official brand abbreviation in a direct search on all four selected platforms. All these data have been collected in a period of one month somewhere from the middle of November to the middle of December in year 2014.

The research goals of the study were twofold: First, this study is mainly exploratory and descriptive in its nature with a research endeavor mainly focused to depict the situation with social media use in banking sector in one region, Western Balkan Region. Second the authors are trying to make comparison between the social media presence and activity in banking industry between the countries in order to identify interesting trends and substantial differences.

III. DATA ANALYSIS AND RESULTS

In the following section we present and analyze the collected data and discuss the results. Fig. 1 shows social media presence of banks from Western Balkan Countries measured by existence of official account on a particular platform.

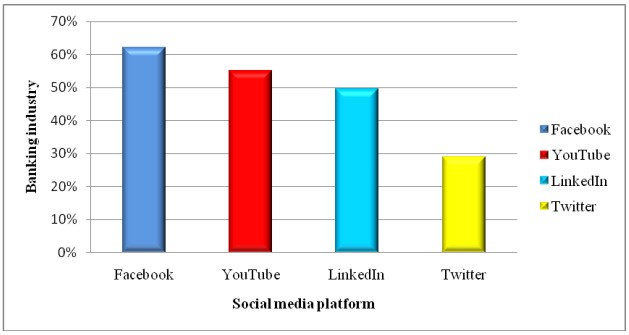

Figure 1. Social media platform presence by banks

The analysis of the results given in fig.1 shows that Facebook is the most often used platform by banks measured by existence of official bank fan page. Further are following YouTube, LinkedIn and at the end are the Twitter accounts. These results are consistent with both industry reports used in this study regarding the Facebook as most often used platform by retail banks. Slight difference exist when we compare the rest of the three platforms meaning that in the Western Balkan Countries banks are more present on YouTube comparing to Twitter and LinkedIn reported as more often used by retail banks globally.

In fig. 2 data are given about number of social media accounts, expressed as relative proportion to the number of banks in whole banking sector in a particular country. From the data on this figure we can notice that the presence of banks on certain social media platforms differs by country. Facebook is the platform most often used by banks from all countries except Macedonia. In Macedonia LinkedIn is the most often used social media platform based on number of official accounts. The second important trend easily noticeable is that YouTube and LinkdIn in all countries are more often used by banks than Twitter. But the presence of banks on YouTube and LinkedIn differs by country indicating that in Serbia, Kosovo and Montenegro, YouTube is more often used unlike in Albania, Bosnia and Herzegovina and Macedonia where LinkedIn is more often used.

Having this broad picture about banking industry presence on social media platforms in western Balkan countries, it is interesting to delve more deeply and to investigate social media activity on particular platforms beside only presence. First interesting social media metric used to compare social media activity of banking industry was number of Facebook fans, YouTube subscribers, Twitter and LinkedIn followers. In order to be able to compare the data from countries with different population and different potential for subscriptions to a particular platform we were using relative proportion of actual users to the total population of the country.

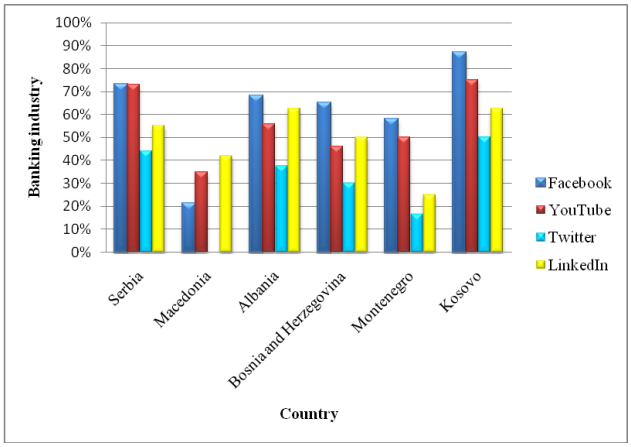

Figure 2. Social media platform presence by banks per country

Table 1 shows the percentile share of platform members in form of fans, subscribers or followers in relation to the total population of the country. The data from table 1 indicate that banks from all countries are most active on Facebook when we use Facebook fans as metric comparing to YouTube subscriptions, Twitter and LinkedIn followers. We also made visual inspection of Facebook timeline of all bank profiles for the whole region to determine the average time present on platform. The results indicate that until present moment on average banks have been present on Facebook for 1.9 years, on YouTube 1.3 years and on Twitter 0.9 years. For LinkedIn we could not determine when a profile was created and thus we have not included data for this social media platform. However data which show the length of time being on a certain social media platform are quite consistent with the number of active fans, subscribers or followers as a social media activity metric.

TABLE I. RELATIVE PROPORTION OF PLATFORM USERS TO THE TOTAL POPULATION OF THE COUNTRY

		Facebook fans	***YouTube subscribers***	***Twitter followers***	***LinkedIn followers***
1	Macedonia	2.34%	0.01%	0	0.28%
2	Serbia	9.06%	1.21%	0.4%	0.22%
3	Albania	5.50%	0.001%	0.011%	0.33%
4	Bosnia and Herzegovina	4.97%	0.004%	0.014%	0.13%
5	Montenegro	7.50%	0.007%	0.489%	0.06%
6	Kosovo	11.52%	0.019%	0.022%	0.25%

Second interesting remark can be derived by data comparison from table 1 and fig. 2, related to consistency in social media activity by country and platform. Namely, Kosovo and Serbia are the countries with the highest percentage of banks having official fan page on Facebook or official channel on YouTube. At the same time they are the two countries having largest number of Facebook fans and YouTube subscribers calculated as relative proportion to the total population of the country. On the other hand

Macedonian banking sector has the lowest number of official fun pages, measured as relative proportion to the total number of banks. Also Macedonia has the lowest average number of Facebook fans expressed relatively to the total population of the country. But this is not consistent trend for all social media platforms because data showed that although in some countries there are less official accounts on some platforms (for example YouTube, Twitter and LinkedIn) there are more subscriptions or followers. For example Montenegro banking sector has relatively lower number of Twitter accounts than Serbia but relatively more followers. Also Macedonian banking sector have lower number of YouTube official channels comparing to Albania and Bosnia and Herzegovina but relatively more subscribers. This indicates that we cannot derive straight correlation between presence on account on a particular platform and number of subscriptions for each country. The difference is a result of the various intensity with which the banks are using particular platforms in different countries. There is big disproportion in active use of social media platforms by particular banks in each country which adds value to the average scores per country.

We were also using social media visibility on the web page as metric to determine the level of platform visibility in banking sector. For this purpose we have manually inspected all bank web pages to check whether we could identify visible sign of the social platform on which the particular bank is active. The fig. 3 shows the data related to social media visibility.

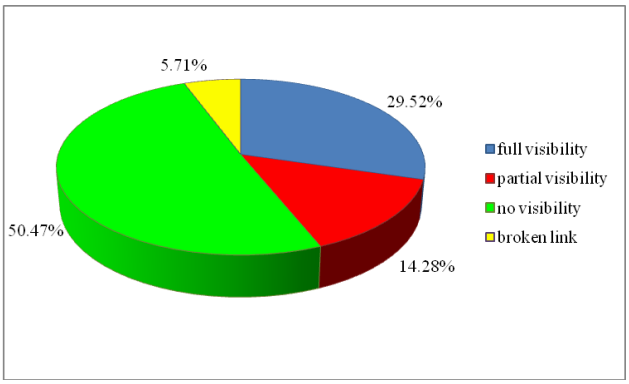

Figure 3. Social media visibility in the banking industry in the region of Western Balkan countries

To check the visibility of social media platforms on the web pages in banking industry we developed four categories: full visibility, partial visibility, no visibility and broken link. The first category full visibility means that the bank has visibly marked all social platforms on which is officially active on its own web page. The second category partial visibility means that the bank has visible links to some of the social media platforms but not to all. This means for example that the bank have official Facebook fun page but does not have visible link on its official web page which navigates the clients towards that particular platform. Third category no visibility means that the bank does not have any visible sign of any social media platform on its official web page. And the fourth category broken link represents situation when we could identify visible sign of some social media platform but the link was not navigating towards that social media platform.

If we analyze the data presented in fig.3 we could easily notice that 50.47% of the banks have no visibility at all of social media presence on its own official websites. Around 30% (or only 29.52%) of the banks have full visibility which is closely to only one third of the whole banking sector in the region of western Balkan countries. Even if we would add the numbers of partial visibility and broken link (which summed together are closely to 20%) to the number of full visibility we would come up with the number of 50% of the banks who have been involved in providing some visibility of its own social media platform on the official web page. It is also interesting to note that from 50% of the banks who did not have visibility on the web page half (or 25%) did not have presence on any social media platform. This is also important because one fourth (or 25%) of all banks from all countries from the western Balkan region did not have presence on any of the four social media platforms included in the research of this paper. If we compare the data by country we could easily notice that Kosovo and Serbia again are two countries leading in full social media visibility on the official banking web pages. Only small number, several banks from Albania and Bosnia and Herzegovina has been classified to the category broken link (18.75% or 11.55% of the total banks in the country).

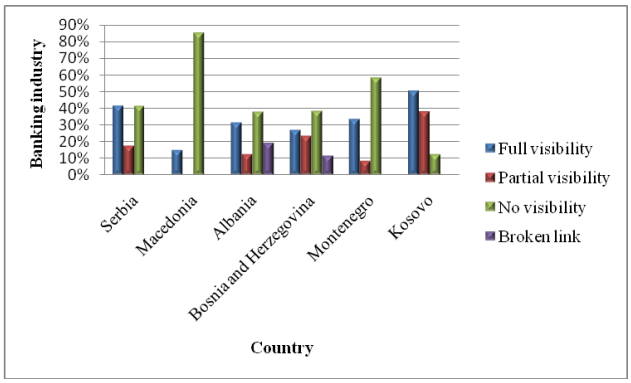

Figure 4. Social media visibility in banking industry per country

The data confirmed again that highest full visibility is present in Kosovo and Serbia, in the two countries who were scoring in the top also on the previous metrics presented in table 1 and figure 2. Macedonian banking industry was scoring very low on previous indicators of social media activity and again is at the very bottom regarding the social media visibility measurement.

In order to acquire deeper understanding of social media activity of banking industry in the region of our research interest, we also collected data for social engagement of

banks and their members on the social media platforms. For this purpose we were collecting data for:
1. Facebook – in form of Facebook posts, fans and bank comments in last 15 days;
2. YouTube – video uploads in last 3 months, total views and views of last video;
3. Twitter - number of total tweets, tweets and retweets in last 15 days;
4. LinkedIn – updates and comments in last 15 days. We have split the data in two general categories: 1) engagement of banks and 2) engagement of their social platform members. The table 2 presents the engagement of banks on four social media platforms with metrics as average number to the total number of banks in each country.

TABLE II. SOCIAL MEDIA ENGAGEMENT OF BANKS AS RELATIVE PROPORTION TO THE TOTAL NUMBER OF BANKS IN COUNTRY

		Facebook posts (last 15 days)	***YouTube video uploads (last 3 months)***	***Twitter total tweets***	***LinkedIn updates (last 15 days)***
1	Macedonia	1	0.14	0	0
2	Serbia	7.48	2.13	517	0.48
3	Albania	0.68	0.81	18.1	0.125
4	Bosnia and Herzegovina	4.8	4.03	53.62	0.14
5	Montenegro	3.3	0.5	118	0.16
6	Kosovo	5.87	3.75	64.25	0.625

Having the data for social engagement by banks we can easily notice again that two banking sectors from two countries Kosovo and Serbia are scoring again very high. This is again confirmation for the banking sector of these two countries as leading in using social media platforms for promoting own services. We can also confirm that Macedonian banking sector is again at the bottom of social media engagement comparing to banks from other countries in the region. Some metrics related to bank engagement (such as bank comments) have not been presented because they have been very low close to zero for all countries comparing to members comments.

TABLE III. SOCIAL ENGAGEMENT OF PLATFORM MEMBERS AS RELATIVE PROPORTION TO THE TOTAL NUMBER OF BANKS BY COUNTRY

		Facebook fans comments (last 15 days)	***Total YouTube video views***	***Retweets by followers***	***LinkedIn Comments (last 15 days)***
1	Macedonia	2	3898	0	0
2	Serbia	15	87933	4	0.03
3	Albania	0.625	2267	0	0
4	Bosnia and Herzegovina	63	13107	0.03	0
5	Montenegro	1.58	1992	0.58	0
6	Kosovo	33.5	29371	0	0

In table 3 data are presented for social media engagement by platform members. Interesting change for the first time appeared regarding the top two countries ranked by social media activity. Bosnia and Herzegovina appeared as most active on Facebook and YouTube regarding the platform members engagement measured by fans comments and total video views. Right behind Bosnia and Herzegovina are the two countries Kosovo and Serbia who were scoring very high in most of the metrics especially for these two platforms taking into account previously presented data.

We have also compared the data for social media activity of bank members of larger group operating under same brand in more than one country. We compared their social media metrics between banks within the group expecting to identify some common behavior regarding social media bank group policy. But we did not identify any consistency within the groups in different countries. This means that the banks which belongs to the same group and operate in different countries have presence on very different social platforms with diverse intensity. Hence they manifest different maturity in social media activity. This situation give us the knowledge that social media activity is highly decentralized between the banks within the same group and management of the group does not have social media strategy for the entire group.

In order to identify trends between certain social media metrics used in this paper we performed several bivariate Pearson correlations between social media metrics. The most significant correlation coefficients are presented bellow in the table 4.

TABLE IV. RESULTS FROM BIVARIATE CORRELATIONS

		Facebook fans	***Twitter followers***	***LinkedIn followers***	***YouTube subscriptions***
1	Total Assets	0.636**	0.415**	0.505**	0.269**
2	Time being on Facebook	0.365**	/	/	/
3	Time being on Twitter	/	0.548**	/	/
4	Time being on Youtube	/	/	0.056	/

** Correlation is significant at the level 0.01 level (2 - tailed)

* The data for total assets of banks are for year 2013 collected by publicly available financial reports from official bank web pages.

The results in table 4 shows that we have identified positive correlation between the sizes of banks measured as total assets and number of members of different social media platforms. This means that larger banks have more Facebook fans, Twitter followers, LinkedIn followers and YouTube subscriptions comparing to smaller banks. It is interesting to notice that smaller banks are not using more intensively the opportunity of social media in their competitive battle with larger banks taking into account

their smaller marketing budgets for promotion on traditional marketing media. When we analyze the data related to time having an official account on some social media platform and number of members in form of fans or followers we identified significant positive relationship for Facebook and Twitter but not for YouTube. This means that the banks that have been longer period present in the past on Facebook and Twitter have more fans and followers. This proposition was not confirmed for YouTube.

IV. RESEARCH LIMITATIONS

The research endeavor of the authors of this article was to depict the situation of social media use by banks in the region of Western Balkan Countries. Although this study has contributions, it has inherent limitations that warrant caution in interpretation of the results. First, the whole study was based on a data collected by desk research which means that data from primary sources such as surveys or interviews with banks officials were not included in the analysis. It would be interesting in future research to compare some field data with the results presented in this study. Second, the data have been collected in a single point in time which means that longitudinal trends in social media use cannot be derived from the study results. Third, subjective interpretation of the study results from the authors can be also strong limitation of the study.

V. CONCLUSION

The purpose of this research was to analyze and explore how banks from Western Balkan Countries are currently using social media for their marketing purposes, and to compare the results between the countries in order to derive some general conclusion for the whole banking sector in the region. Through the results that we have obtained from data manually collected by visual inspection of official websites and social media platforms social media marketing in banking sector in this region is still in emerging phase. The results confirmed that banks are not exploiting fully the potential of social media. The results showed that in countries with the highest participation in terms of presence on social media platforms, one-third of all banks did not have at all presence on any social medium. We also found that size of the market and the number of banks that constitute the banking sector does not play a role in boosting the social media activity of the banks. Maybe some other market characteristics play significant role in social media activity in banking industry which further needs to be investigated. In most of the rankings Serbia and Kosovo were scoring very high on social media activities and at the same time these two countries lay on the total opposite side on a continuum regarding market size. Another evidence of immature use of social media by banking industry can be found in the data showing social media visibility. More than 50% of the banks do not have any visible link for navigation towards the social media platforms, in around 5% of the cases the links were broken and in 15% of the cases not all media platforms on which the bank was active were included on the official webpage. The results were even worse when we inspected social engagement of banks and their social media members. We concluded that most of the banks are not continuously involved in communication with their clients with exception of only few of them. The results regarding the most often used platforms converged with other studies for other regions that most often used platforms by banks have been Facebook, YouTube, Twitter and LinkedIn. When we were inspecting social media visibility we could very rarely notice some other social media platform such as Google + or Instagram. We identify significant positive relationship between size of the bank and number of subscriptions to certain social media platform. This means that smaller banks do not outperform larger banks by increasing its' own population on the social media platforms. Although this is expected to a certain extent because larger banks normally would have larger number of clients, having more strong social media marketing strategy by smaller banks can help them to have influence on wider market space. Also the data showed positive relationship between time being present on a certain social media platform and number of subscriptions. This means that the banks that started earlier to be present on a particular social media platform have larger audience to influence. Taking into account the research limitations mentioned above we can conclude that maturity of social media marketing of banking sector from Western Balkan Countries is still on modest level.

Abstract - Demands on transmission systems increased due to the growing demand for services supported by the Internet. It has consequences in the continued development network in communication systems. This work is focused on the current state of Wavelength Division Multiplex (WDM) systems, on the recommendation of ITU for Coarse WDM (CWDM) and Dense WDM (DWDM) and on the possibilities of using different types of add/drop multiplexers (OADM) in optical transmission paths. In the present there exist many solutions of OADM and some of them are shown in this article. In the environment of optical systems with increasing amount of transmission information and power undesirable effects occur, such as nonlinear effects, but this subject is out of scope of this article.

I. INTRODUCTION

With the coming of optical fibers there were also new opportunities within transmission systems for short as well as long distances. In addition to the many benefits of new technology as for example increased transmission capacity, higher transmission speed, greater security etc. also new challenges that need to be solved come up. The main challenges include linear and nonlinear effects. Restrictions occasioned by linear effects are not examined in this work. Attention is primarily devoted to nonlinear phenomena and their effects in an optical fiber.

The work is focused also on introducing of current solutions of transmission systems which include dense wavelength division multiplexing (DWDM). For each approach standard that include some recommends is used. The same applies for DWDM, its way of working is formed by the International Telecommunication Unit (ITU). Specifically, there is the recommendation identified as - Recommendation ITU-T G.694.1. With the increasing amount of information there is an ambition to use a larger number of transmission channels, and this happens even when using DWDM technology in optical communication networks. In other words the traffic channels are narrower and they are proposed in greater numbers on the same size of bandwidth.

On the transmission path there is a large number of devices which are designed to receive, modify, amplify signals, etc. Devices receiving and working with optical signal also include optical add/drop multiplexers (OADM). This device has many similarities with optical cross connectors (OXC). Currently types of reconfigurable OADM (ROADM) are used but in early development fixed OADM (FOADM) was preferred.

II. ALL OPTICAL DWDM SYSTEMS

Wavelength division multiplexing (WDM) is presently the most innovated technology in optical fiber communications. In the past two decades, optical communications has totally changed the way we communicate. It is a revolution that has fundamentally transformed the core of telecommunications, its basic science, its enabling technology, and its industry. By this method, capacity can be increased by using more than one optical carrier (wavelength) on a single fiber. Therefore, adding a second transmitter and receiver to an optical fiber can double the bandwidth of that communications system. This method of increasing the capacity of an optical system has appeal for a variety of reasons. For transmission systems using a 1310 nm laser, a second laser at 1550 nm is usually added. The reason for choosing these wavelengths is that they lie in the "windows" or ranges of least attenuation. This allows the signal to travel a longer distance. Fig. 1 shows specification of wavelengths.

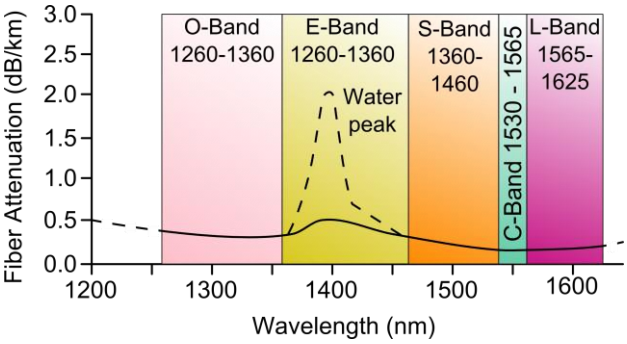

Figure 1. Graph of dependencies between fiber attenuation and wavelength for individuals bands.

To meet the rapid increase in the demand for multiterabit/s transmission capacities, 40 Gbit/s based dense wavelength division multiplexing (DWDM) is becoming the next generation in large-capacity systems. Expansion of WDM channels results in an increase in the complexity of optical network node [1].

The cost-difference between CWDM and DWDM is known to be large, favoring CWDM as the low-cost alternative. For channel counts beyond eight channels, DWDM may be a preferred technology because:

- Flexible upgrade: DWDM are more flexible and robust with respect to fiber types. DWDM

upgrade to 16 channels is viable on both G.652 and G.652.C fibers. This stems from the fact that DWDM always employs the low-loss region of the fiber, while 16 channel CWDM systems involves transmission in the 1300-1400 nm region, where attenuation is remarkable higher.

- Scalability: DWDM solutions allow upgrade number of channels, allowing a much higher total capacity on the fiber than a CWDM solution.
- Cost: CWDM still shows to be cost-efficient for 8 channel systems. However, for higher channel counts than 8, the higher attenuation in the fiber may prove DWDM to be a better alternative than CWDM.
- Long spans: DWDM employs the 1550 nm wavelength band which can be amplified using conventional optical amplifiers, Erbium Doped Fiber Amplifiers (EDFA's), enhancing transmission distance to hundreds of kilometers [2].

Dense wavelength division multiplexing (DWDM), a wavelength division multiplexing (WDM) technology, is characterized by narrower channel spacing than coarse WDM (CWDM), as defined in [ITU-T G.671]. In general, the transmitters employed in DWDM applications require a control mechanism to enable them to meet the application's frequency stability requirements, in contrast to CWDM transmitters, which are generally uncontrolled in this respect. DWDM uses frequency grid. It is a reference set of frequencies used to denote allowed nominal central frequencies that may be used for defining applications [3].

The frequency grid defined by ITU G.694.1 supports a variety of fixed channel spacing ranging from 12.5 GHz to 100 GHz and wider (integer multiples of 100 GHz) as well as a flexible grid. Uneven channel spacing using the fixed grids are also allowed. The current steps in channel spacing for the fixed grids have historically evolved by sub-dividing the initial 100 GHz grid [4, 5, 6].

Today, wavelength transport uses a 100 Gbit/s infrastructure, but with the introduction of super-channels and higher order modulation rates, 400 Gbit/s or even 1 Tbit/s transport will be realized. An IP or MPLS core network may require 100 Gbit/s links between locations, but for many applications finer bandwidth granularity can improve network efficiency. To that end, integrating OTN or multi-protocol label switching (MPLS) switching with the transport network to support sub-wavelength services is important.

Table I illustrates some nominal central frequencies within the C and L bands based on the 12.5 GHz minimum channel spacing anchored to the 193.1 THz reference. Table I also illustrates the 25, 50 and 100 GHz grid frequencies within the same region. The endpoints shown are illustrative, not normative. Fig. 2 shows basic scheme of DWDM transmission system [4, 7].

TABLE I. EXAMPLE OF NOMINAL CENTRAL FREQUENCIES OF THE DWDM GRID

Approximate nominal central wavelength (nm)	**Nominal central frequencies (THz) for spacing of:**			
	12.5 GHz	***25 GHz***	***50 GHz***	***100 GHz***

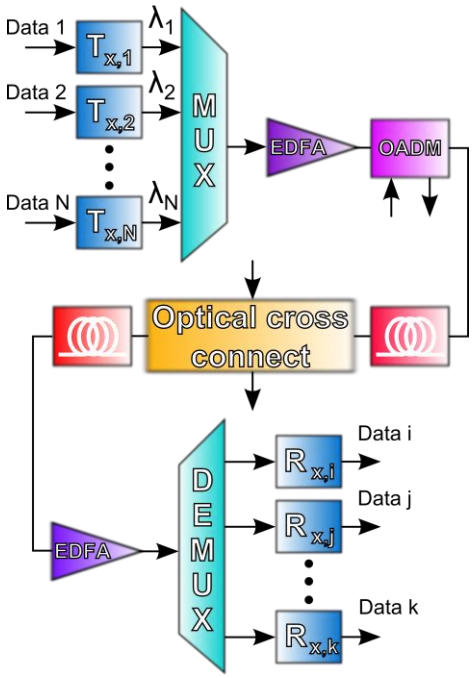

Figure 2. Model of optical transmission DWDM system using Optical Add/Drop Multiplexers.

All efforts are targeted at more efficient transmission. Future of optical transmissions is joined with reduction crosstalk among channels traffic, superior source of light, higher spectral efficiency, more efficient use of fiber spectrum, and corresponding scaling in WDM line-card capacity of WDM systems. Smarter ways to utilize optical capacity are critical since transmission costs have been decreasing slower than grooming and switching costs. Integrated transport and switching can improve the efficiency of the client network using techniques such as port virtualization and transit traffic reduction. Trends in transmission systems are showed in the Fig. 3.

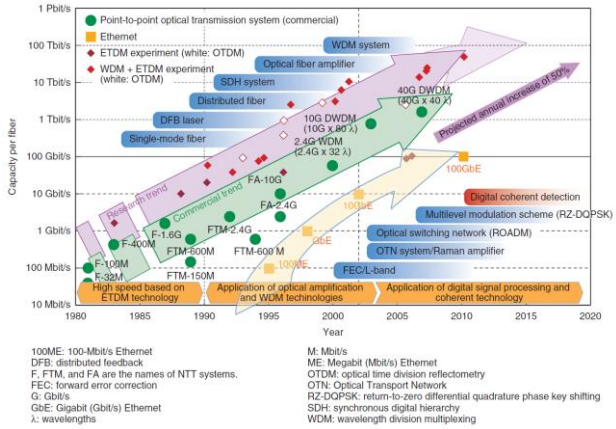

Figure 3. Trends in optical transport technologies [15].

Optical transport network capacity requirements continue to grow in order to meet worldwide IP traffic demands. Today's networks can provide 10 Tbit/s per link, and doubling or even tripling that capacity will be possible in the next several years. Technologies that include higher order modulation (e.g. 16-QAM) will increase spectral efficiency. They can be combined with Nyquist or OFDM super-channels to provide the necessary capacity. Various optical technologies, such as higher order modulation, coherent detection, soft-decision FEC, and super-channels will help transport networks provide the needed capacity for the near future. Long term, increasing a link's capacity can be supported by using wider bandwidth optical amplifiers or utilizing fibers with multiple cores and multiple propagation modes. These innovations are not yet mature, and significant development is still required. Maximizing network efficiency through smart bandwidth management can reduce required transmission capacity, resulting in lower cost and power consumption. Grooming can take the form of either OTN or MPLS switching with OTN preferred for private line applications and MPLS optimized for data applications. It is more efficient to integrate the transport and switching functions into a single platform, but low-cost optical interconnect will support separate transport and switching implementations. Joint optimization of the transport and client networks is important to maximize efficiency, and techniques such as port virtualization and transit traffic reduction can significantly reduce client network bandwidth requirements [8, 9].

III. Optical Add/Drop Multiplexer

Add/drop multiplexers are needed for wide-area and metro-area networks (similar to SONET ADMs) in which one or more channels need to be dropped or added, while preserving the integrity of other channels. The demultiplexer separates all channels, optical switches drop, add, or pass individual channels, and the multiplexer combines the entire signal back again [10].

Most multiwavelength-ring networks being deployed today employ fixed (or static) OADMs (FOADMs) because FOADM technology is quite mature today. However, reconfigurable OADMs (ROADMs) are more powerful because a network based on tunable ROADMs can easily adapt to fluctuating traffic demands.

A. Fixed Optical Add/Drop Multiplexers

Fixed OADMs are very often called also Configurable AODM (COADM). We can tell that their basic role is dropping and adding data signals on dedicated channels. FOADMs have allocated channels at non-dynamic nodes and enabled dropping and adding of single or multiple wavelength channels from DWDM. Configurable OADM allow the producer to customize the number of channels, specifications of filters, and power equalization. For dense channel plans with 50 GHz channel spacing, the FOADM typically covers an optical frequency interleaver. Most configurations have low loss and are temperature-insensitive. Fixed OADMs are less expensive than ROADMs, the efficiency of this architecture is dependent upon having a network with predictable and very stable traffic demand.

B. Reconfigurable Optical Add Drop Multiplexers

With approach a lot of video applications on the Internet is growing demands to the larger bandwidth. It is possible the link capacity increase by migration from lower speeds to 40 Gbit/s or up to 100 Gbit/s and using WDM technology. This is good result only for point-to-point communication but we need to change ever requirements for the bandwidth demand. The optical networks have to be able dynamically add, drop, and route channels at individual nodes. This type of management in optical networks is supported by ROADMs [11].

ROADM provides adaptivity in re-routing optical stream, avoiding defective connections, looks for the stability of the services, it can be configured remotely. They enable new wavelength channels to be installed by simply placing transponders at the end point. The rapid network reconfiguration provided by ROADMs could also become an enabler of dynamic network services, such as switched video for IPTV. For all of these reasons, ROADMs will continue to have a significant effect on the design of optical networks [12, 13].

Reconfigurable OADMs include three different types:

- Wavelength Blocking (WB).
- Planar Lightwave Circuit (PLC).
- Wavelength Selective Switch (WSS).

ROADMs are capable of enabling an advanced dynamic power/gain control for each channel and enable the remote management functionalities such as remote monitoring and remote configuration management. ROADMs not only can effectively increase the wavelength efficiency and network capacity of to day's optical network, but also are a promising technology for future high-bit-rate optical networks such as grid-less optical networks and all optical networks.

The most used type of ROADM is wavelength selective switch. This technology have become the established heart of the modern DWDM reconfigurable agile optical network. It serves as the optical component which is responsible for dynamically routing, blocking and attenuating all DWDM wavelengths within a network node. Therefore, the performance of this device is

generally the one of the dominant attributes which define the performance of the overall network system.

WSSs are more versatile, smaller, consume less power, and are less expensive than 2nd generation ROADMs. WSSs are typically designed to handle 40 incoming wavelengths on a fiber, and drop any combination of wavelengths out any of 8 ports (some systems can drop more). The WSS is an N-degree ROADM, which allows reconfiguration beyond typical 2-degree (usually east-west) configurations (WSS system can be used to interconnect rings or mesh points). This means that wavelengths can be routed from any node to any other node across multiple rings and networks [14].

IV. EXPERIMENTS

Experiments with OADM show basic properties of optical add/drop multiplexer in DWDM system. Fig. 4 shows block scheme of used system. Simple WSS-based ROADM architecture was used in this scheme.

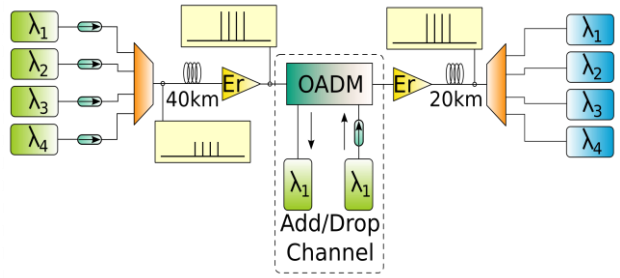

Figure 4. Block diagram of experimental system.

In this model was used four wavelengths (tx_1 = 193.35 THz, tx_2 = 193.45 THz, tx_3 = 193.55 THz, tx_4 = 193.65 THz). Fig. 4 shows spectrum transmitted signals. Wavelengths in the figure are before amplification.

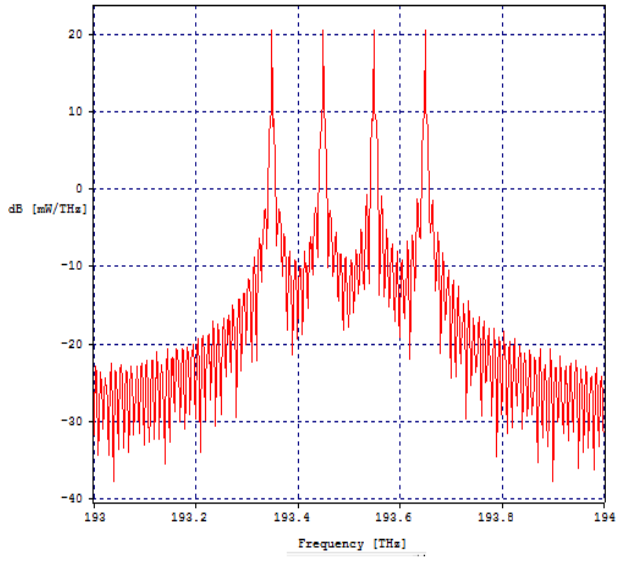

Figure 5. Spectrum of transmitted signals.

Fig. 5 shows signal after amplification. It is possible to see that levels of signals are more intensive.

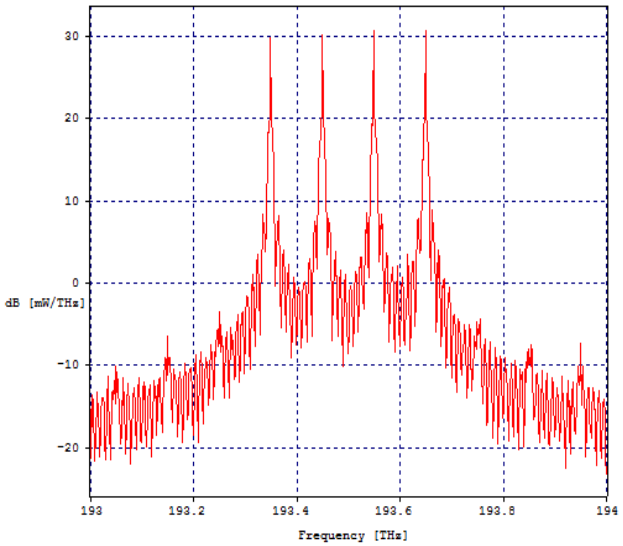

Figure 6. Spectrum of signals after amplification.

Bit Error Rate (BER) of signal with frequency 193.35 THz (dropped signal) is 7.67299×10^{-20}. This value is still on the value which can consider as sufficient for well recognized at the receiving end. Fig. 6. shows Eye diagram of dropped signal (193.35 THz). The signal was influenced by different attenuation effects on the 40 km transmission path.

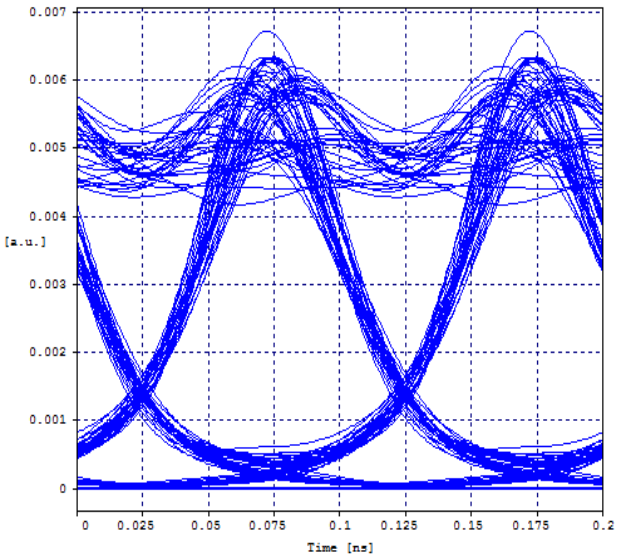

Figure 7. Eye diagram of dropped signal.

In the next step is frequency which had dropped, it is again used for transmitted another information. Eye diagram is almost ideal, after passing the signal through the OADM (Fig. 8.).

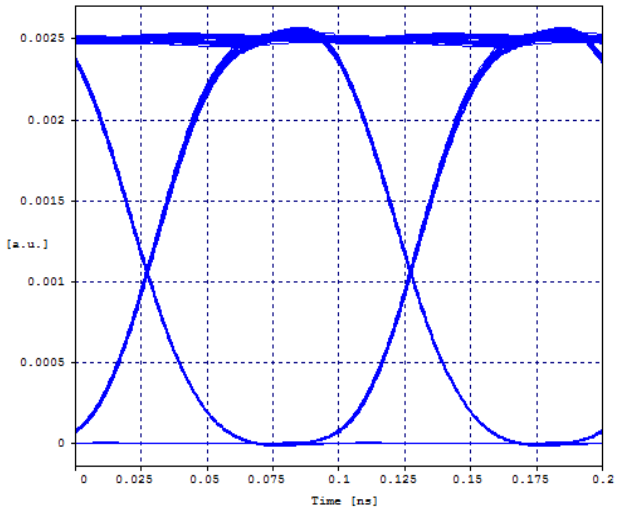

Figure 8. Eye diagram of inserted signal.

Signals on the received side are in the good condition and their BERs are at the border $1.10163x10^{-16}$(Fig. 9).

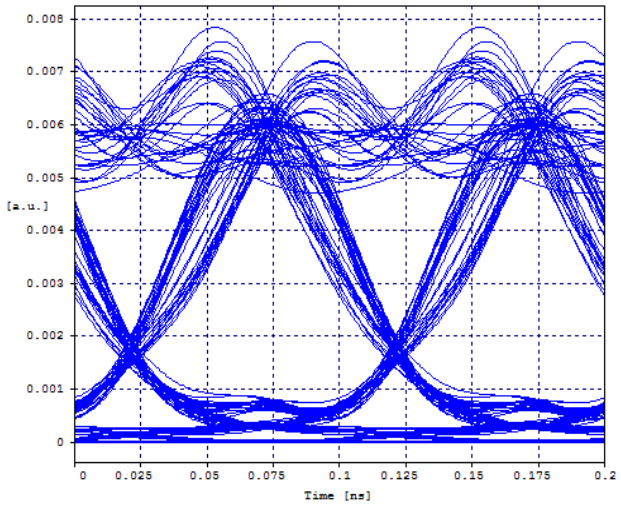

Figure 9. Eye diagram of received signal at the end transmittion path.

V. CONLUSION

Workplace Research of optoelectronic systems on Department of Electronics and Multimedia Communications at the Technical University in Kosice within the specialization is focused on the investigation of optical multiplexers and demultiplexers. This paper constitutes basic information about Optical Add/Drop Multiplexers. Initial experiments are designed to present behavior of transmission systems operating in accordance with the recommendations of ITU standards and manufacturers of optical devices. The measurements showed what effect does the distance on the transmitted signal and the fundamental property OADM, ergo withdrawal (attenuation) certain wavelength and wavelength addition to the transmission path. The experiment uses 100 GHz frequency grid spacing for different transmission channels in DWDM system. The quality of the transmitted signal is showed in the form of BER and eye diagram.

Korelacijska analiza dotoka u akumulacijske bazene

E. Sutlović, K. Zoričić, T. Modrić
Sveučilište u Splitu, Fakultet elektrotehnike, strojarstva i brodogradnje, Split, R. Hrvatska
Elis.Sutlovic@fesb.hr, Kristian.Zoricic@fesb.hr, Tonci.Modric@fesb.hr

Sažetak - Problem optimalnog korištenja akumulacijskih bazena je posebno složen, jer proizvodnja električne energije na jednom slivu posredno utječe na potrebnu proizvodnju iz ostalih elektrana u sustavu, na troškove pogona cjelokupnog elektroenergetskog sustava, na profit itd. Treba istovremeno promatrati više akumulacijskih bazena i niz korisnika. Osnovni ulazni podaci u svim simulacijskim i optimizacijskim proračunima, su prirodni dotoci u akumulacijske bazene. Međusobne veze u pojavi određenih dotoka značajno utječu na modeliranje dotoka u proračunima. U okviru korelacijske analize ustanovljava se postojanje veze između dva niza podataka, njen oblik, jačina i smjer. Na osnovu relevantnih hidroloških podataka mjerenih u nizu godina, napravljena je korelacijska analiza prirodnih dotoka u akumulacijske bazene na različitim riječnim slivovima. Korelacijska analiza dotoka zemljopisno bliskih riječnih slivova obuhvatila je izračun Pearsonovih koeficijenata korelacije i dijagrame rasprostiranja između dotoka u akumulacijske bazene na rijeci Cetini, Krki i Zrmanji. Korelacijska analiza zemljopisno udaljenih riječnih slivova obuhvatila je izračun Pearsonovih koeficijenata korelacije i dijagrama rasprostiranja između dotoka u akumulacijske bazene na rijeci Cetini i Kupi te Cetini i Dravi. Uočene su značajne razlike u prosječnoj jakosti veza u raznim primjerima.

I. UVOD

Optimiranje rada akumulacijskih bazena je izuzetno složen i važan zadatak za niz korisnika vode te za društvo u cjelini. U elektroenergetskim sustavima sa znatnim udjelom hidroenergije planiranje rada akumulacijskih bazena utječe na moguću proizvodnju svih nizvodnih hidroelektrana na slivu. Međutim, osim elektroprivrede, postoji i niz drugih korisnika akumulacijskih bazena i vodnih tokova. Cilj planiranja rada akumulacijskih bazena je naći „optimalan“ način korištenja raspoložive količine vode nastojeći pri tome zadovoljiti više korisnika i brojna ograničenja [1], [2].

Problem optimalnog korištenja akumulacijskih bazena za potrebe elektroprivrede je posebno složen, jer proizvodnja električne energije na jednom slivu posredno utječe na potrebnu proizvodnju iz ostalih elektrana u sustavu (i hidroelektrana i termoelektrana), na troškove pogona cjelokupnog elektroenergetskog sustava, na profit itd. Dakle, treba promatrati više akumulacija te uzeti u obzir sve nizvodne hidroelektrane (HE) koje se napajaju vodom iz uzvodnih akumulacijskih bazena.

Proces planiranja obično se dijeli na kratkoročno (do sedam dana), srednjoročno (nekoliko mjeseci do godinu dana) i dugoročno (godina dana i duže). Za rješavanje problema planiranja rada akumulacijskih bazena koriste se bilo različite simulacijske metode ili pak matematički optimizacijski proračuni koji definiraju funkciju cilja i pripadna ograničenja na različite načine. U svim tim analizama cjelokupni period promatranja se dijeli u manje, jedinične vremenske periode odnosno diskretne vremenske korake unutar kojih se različite varijable i ulazni parametri ne mijenjaju. Obično se za osnovni vremenski period kod srednjoročnog i dugoročnog planiranja rada akumulacijskih bazena uzima jedan tjedan ili jedan mjesec [1] - [5].

Osnovni ulazni podaci u svim simulacijskim i optimizacijskim proračunima su prirodni dotoci u akumulacijske bazene te nizvodni pritoci na određenim mjestima. Prirodni dotoci i pritoci na određenoj lokaciji mogu se predstaviti na više načina. Najjednostavniji način je koristeći zabilježeni povijesni niz mjeren u relevantnom broju godina, a složeniji i općenitiji je korištenjem različitih prilagođenih modela ulaznih podataka. Jednostavniji je deterministički model dotoka u kojem se svi dotoci (na svim lokacijama i u svim vremenskim periodima) tretiraju kao poznate veličine, ali daljnji optimizacijski postupak zahtijeva čitav niz proračuna sa različitim mogućim scenarijima. Stohastički pristup problemu optimiranje rada akumulacijskih bazena već kroz stohastički model dotoka nastoji ugraditi neizvjesnost budućih dotoka i stohastička obilježja problema [3] - [8].

Rezultat proračuna, bez obzira na korišteni model dotoka, daje režim ispuštanja voda u svakom jediničnom vremenskom periodu na ukupno „optimalan“ način. U pravilu simulacijski i optimizacijski proračuni pretpostavljaju da u cjelokupnom periodu promatranja, npr. godini dana, suma svih ispusta iz bazena odgovara sumi dotoka uz određene gubitke zbog isparavanja, procjeđivanja itd.

O kvaliteti ulaznih podataka za simulacijski ili optimizacijski proračun ovisi i kvaliteta cjelokupnog proračuna optimalnog planiranja. Dakle, optimalno planiranje i korištenje voda na nekom slivu temelji se na sustavnom višegodišnjem prikupljanju hidroloških podataka te njihovoj analizi i obradi [9]. Međutim, riječni slivovi, iako zahvaćaju vodu iz zasebnih područja, imaju nekad slične karakteristike o kojima treba voditi računa prilikom modeliranja za potrebe proizvodnje električne energije. Međusobne veze u pojavi određenih dotoka značajno utječu na modeliranje dotoka u proračunima i složenost proračuna. U okviru korelacijske analize

ustanovljava se postojanje veze između dva niza podataka, njen oblik, jačina i smjer ne ulazeći pri tome što je uzrok, a što posljedica.

Cilj rada je, na osnovu relevantnih hidroloških podataka mjerenih u nizu godina, napraviti korelacijsku analizu između prirodnih dotoka u akumulacijske bazene na različitim riječnim slivovima. Posebno će se tretirati zemljopisno bliski riječni slivovi od onih udaljenih. Istražit će se i statistički definirati korelacijske veze među dotocima u akumulacijske bazene grupirane u manje vremenske periode. Prema jakosti veze ćemo ocijeniti da li je opravdano zanemariti neke korelacijske veze u određenom tipu proračuna. Drugim riječima, kada tražimo optimalni režim korištenje akumulacijskih bazena za rad hidroelektrana i simuliramo npr. dotoke na rijeci Zrmanji, trebamo li uzeti u obzir simulirani dotok npr. na rijeci Cetini ili pak na rijeci Dravi? Da li je realno da dotok na Zrmanji bude blizu maksimalne vrijednosti, a istovremeno na Cetini ili Dravi blizu minimalnih vrijednosti i obrnuto? Koliko su jake te veze, i koliku grešku radimo, ako ih zanemarimo prilikom simulacije?

Korelacijska analiza zemljopisno bliskih riječnih slivova obuhvatila je izračun Pearsonovih koeficijenata korelacije i oblikovanje dijagrama rasprostiranja srednjih mjesečnih dotoka za dotoke u akumulacijske bazene na rijeci Cetini, Krki i Zrmanji. Također su računati Pearsonovi koeficijenti korelacije i dijagrami rasprostiranja za srednje tjedne dotoke na rijeci Cetini i Krki. Korelacijska analiza zemljopisno udaljenih riječnih slivova obuhvatila je izračun Pearsonovih koeficijenata korelacije i oblikovanje dijagrama rasprostiranja srednjih mjesečnih dotoka za dotoke u akumulacijske bazene na rijeci Cetini i Kupi te Cetini i Dravi. Uočene su značajne razlike u prosječnoj jakosti veza u raznim primjerima.

II. KORELACIJSKA ANALIZA

Istraživanjem i kvantificiranjem povezanosti među promatranim pojavama, odnosno varijablama, bavi se korelacijska analiza [10], [11]. Neka neki događaj ima dva obilježja x i y, gdje je x mjerena vrijednost jednog, a y mjerena vrijednost drugog obilježja. Nakon n mjerenja dobit ćemo skup od n parova (x_i,y_i), i=1,2, ..., n. Budući da je riječ o uređenim parovima, nakon n mjerenja rezultat ćemo moći predstaviti sa n točaka u koordinatnom sustavu. Skup tih točaka se zove dijagram rasprostiranja. Iz rasporeda točaka otkrivamo oblik, smjer i jakost veze između obilježja x i y:

- kod funkcionalne veze točke (x_i,y_i) leže na jednoj krivulji, a ako je ta krivulja pravac govorimo o linearnoj funkcionalnoj vezi;
- kad obilježja x i y nisu vezana funkcionalnom vezom, ali dijagram ipak pokazuje tendenciju izduživanja u jednom smjeru govorimo o stohastičkoj vezi među slučajnim varijablama x i y;
- ako točke (x_i,y_i) ne pokazuju tendenciju gomilanja u nekom smjeru, obilježja x i y su nepovezana.

Kod stroge funkcionalne veze (ili deterministčkog odnosa) za svaku vrijednost x se točno zna vrijednost varijable y. Kada su slučajne varijable x i y stohastički povezane, za jednu vrijednost od x dolazi više vrijednosti od y koje su raspoređene po nekom zakonu vjerojatnosti. Stoga se pri stohastičkoj vezi za određeni x može samo odrediti interval kojem se ta vrijednost nalazi i to uz izvjesnu vjerojatnost.

Jakost stohastičke veze mjeri se koeficijentom korelacije ρ. Koeficijent linearne korelacije osnovnog skupa (populacije), ili Pearsonov koeficijent definiramo kao

$$\rho = \frac{ko\,\mathrm{var}\,ijanca(x,y)}{\sqrt{\mathrm{var}\,ijanca(x)\cdot \mathrm{var}\,ijanca(y)}} = \frac{\sigma_{xy}}{\sqrt{\sigma_x^2\sigma_y^2}}. \qquad (1)$$

Vrijednost koeficijenta korelacije je $-1 \le \rho \le +1$. Za $\rho=\pm1$ govorimo o funkcionalnoj vez dviju varijablii, a za $\rho=0$ varijable su nezavisne. U ostalim slučajevima imamo stohastičku vezu među varijablama. Općenito labavijoj vezi odgovara manji $|\rho|$, a čvršćoj veći $|\rho|$.

Nepristranu procjenu koeficijenta korelacije ρ, označimo sa r. Tada je koeficijent linearne korelacije uzorka [11]

$$r = \frac{\sum_{i=1}^{n}(x_i-\bar{x})(y_i-\bar{y})}{\sqrt{\sum_{i=1}^{n}(x_i-\bar{x})^2\sum_{i=1}^{n}(y_i-\bar{y})^2}} = \frac{s_{xy}}{\sqrt{s_x^2 s_y^2}}. \qquad (2)$$

Nepristrana procjena kovarijanca varijabli x i y, s_{xy} je

$$s_{xy} = \frac{1}{n-1}\sum_{i=1}^{n}(x_i-\bar{x})(y_i-\bar{y}). \qquad (3)$$

Nepristrana procjena varijance varijable x, s_x^2 i nepristrana procjena varijance varijable y, s_y^2 su:

$$s_x^2 = \frac{1}{n-1}\sum_{i=1}^{n}(x_i-\bar{x})^2, \qquad (4)$$

$$s_y^2 = \frac{1}{n-1}\sum_{i=1}^{n}(y_i-\bar{y})^2. \qquad (5)$$

U primjeni se stupanj jakosti korelacije r obično definira na slijedeći način

$\lvert r \rvert$	**Jakost korelacije**
0	nema korelacije
0 - 0,5	slaba korelacija
0,5 - 0,8	srednje jaka korelacija
0,8 - 1	jaka korelacija
1	potpuna korelacija

Ponekad se umjesto koeficijenta korelacije r koristi koeficijent determinacije r^2 $(0 \le r^2 \le 1)$.

III. KORELACIJSKA ANALIZA DOTOKA U ZEMLJOPISNO BLISKE AKUMULACIJSKE BAZENE

A. Dostupni podaci

Analizu smo proveli koristeći podatke dotoka rijeka dalmatinskih slivova i to rijeke Cetine u akumulacijsko jezero Peruća, rijeke Krke u kompenzacijski bazen Brljan uz hidroelektranu Miljacka i rijeke Zrmanje u akumulacijsko jezero Štikada [12]. Na raspolaganju smo imali:

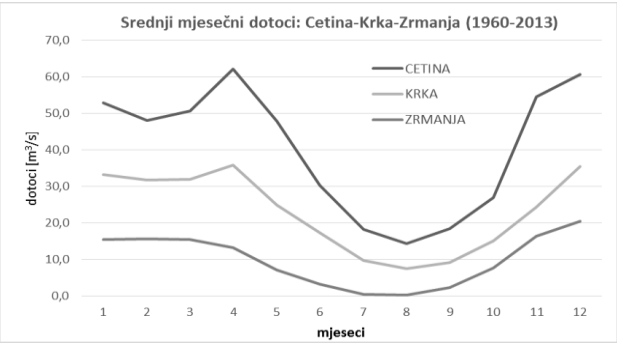
- srednje dnevne dotoke za rijeke Krku i Cetinu od 2000. do 2013. godine,
- srednje mjesečne dotoke za rijeku Krku i Zrmanju od 1950. do 1990. godine te od 1996. do 2013. godine,
- srednje mjesečne dotoke za rijeku Cetinu od 1960. do 1990. godine te od 1996. do 2013. godine.

Svi mjereni dotoci su prirodni dotoci u „gornje“ akumulacije na slivu (ili „sirovi“ podaci), odnosno nikakve uzvodne aktivnosti nemaju utjecaja na mjerene dotoke. Dotoci na pojedinom mjernom mjestu su uvijek mjereni na jednak način, kako bi se smanjila mogućnost greške u fazi prikupljanja podataka. Period od 1991. do 1995. je izostavljen iz analize obzirom da su neki podaci u ovom periodu rezultat estimacije, a ne sustavnog mjerenja kao i ostali.

B. Korelacijska analiza srednjih mjesečnih dotoka

Na slici 1 prikazani su srednji mjesečni dotoci na sva tri mjerna mjesta. Već se sa dijagrama nazire da se prirodni dotoci na ove tri rijeke dobro „prate“. Srednji mjesečni dotoci su za sva tri mjerna mjesta računati u istom periodu i to od 1960 do 1990 te od 1996. do 2013. godine kako bi bili usporedivi. U tom periodu srednja vrijednost dotoka u akumulacije je 39,7 m^3/s na rijeci Cetini, 23,1 m^3/s na rijeci Krki i 9,8 m^3/s na rijeci Zrmanji.

Nepristrana procjena Pearsonovog koeficijenta korelacije prema (2) za sve mjesece u godine izračunata je za dotoke na Cetini i Krki i Cetini i Zrmanji za period od 1960. do 1990. godine te od 1996. do 2013. godine, a za dotoke Krke i Zrmanje za period od 1950. do 1990. godine te od 1996. do 2013. Vrijednosti ovih koeficijenata po mjesecima te njihova srednja vrijednost dani su u tablici 1. Uočavaju se jake korelacijske veze u većini promatranih mjeseci.



Slika 1. Srednji mjesečni dotoci u akumulacije

TABLICA I. VRIJEDNOSTI PEARSONOVIH FAKTORA KORELACIJE ZA SREDNJE MJESEČNE DOTOKE ZEMLJOPISNO BLISKIH AKUMULACIJA

Mjeseci	CETINA-KRKA	CETINA-ZRMANJA	KRKA-ZRMANJA
I	0,8302	0,8739	0,8210
II	0,9120	0,8886	0,8191
III	0,8844	0,8221	0,8097
IV	0,8587	0,7349	0,7259
V	0,8766	0,6970	0,7076
VI	0,8412	0,8120	0,7898
VII	0,8309	0,5979	0,7381
VIII	0,8610	0,4747	0,5652
IX	0,7640	0,7260	0,6969
X	0,9433	0,9258	0,8253
XI	0,8699	0,8730	0,8054
XII	0,8892	0,8952	0,8551
r_sr god	0,8635	0,7768	0,7633

Kako bi bolje ilustrilali korelacijske veze među dotocima u akumulacijske bazene na slikama 2, 3 i 4 prikazani su dotoci u mjesecu listopadu za sva tri promatrana para. Na slikama 5, 6 i 7 prikazani su dijagrami raspršenja za iste korelacijske veze također u mjesecu listopadu. Na dijagramima su također prikazani automatski računati koeficijenti determinacije (r^2). Sva tri dijagrama raspršenja jasno pokazuju tendenciju izduživanja u jednom smjeru.

C. Korelacijska analiza srednjih tjednih dotoka

Obzirom da smo raspolagali srednjim dnevnim dotocima u uzvodne akumulacije na Cetini i Krki u istom neprekidnom periodu od 14 godina, iz srednjih dnevnih dotoka smo u prvom koraku izračunali srednje tjedne protoke, a potom izračunali nepristranu procjenu Pearsonovog faktora korelacije za ovaj uzorak prema (2). Dijagram srednjih tjednih dotoka, prikazan na slici 8, jako sliči dijagramu srednjih mjesečnih dotoka za Cetinu i Krku prikazanog na slici 1, ali uz finiju „diskretizaciju“. Osim toga, podaci srednjih mjesečnih dotoka su dobiveni iz znatno dužeg perioda promatranja od 49 godina.

Nepristrane procjena Pearsonovog koeficijenta korelacije za svaki tjedan, prikazane grafički na slici 9, se kreću od 0,6272 u 30. tjednu do 0,9847 u 2. tjednu, prosječno 0,8728. Dakle, i tjedni koeficijenti korelacije između ova dva riječna dotoka su izuzetno visoki. Prosječna vrijednost koeficijenta korelacije srednjih tjednih dotoka je približno jednaka prosječnoj vrijednost koeficijenta korelacije srednjih mjesečnih dotoka (0,8635) iz čega se da zaključit da izbor osnovnog perioda promatranja (tjedan ili mjesec) nema znatnijeg utjecaja na iznose koeficijenta korelacije. Ipak, zaključak treba uzeti s dozom opreza jer proračun nije rađen na istom broju godina, odnosno broj promatranih parova dotoka u proračunu koeficijenta korelacije srednjih mjesečnih dotoka je značajno veći nego u proračunu koeficijenta korelacije srednjih tjednih dotoka.

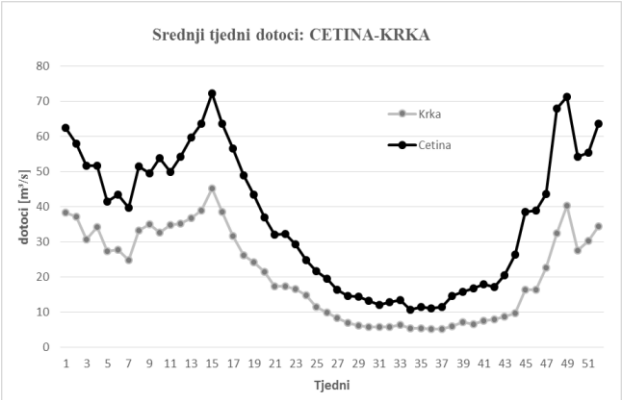
IV. KORELACIJSKA ANALIZA DOTOKA U ZEMLJOPISNO UDALJENE AKUMULACIJSKE BAZENE

A. Dostupni podaci

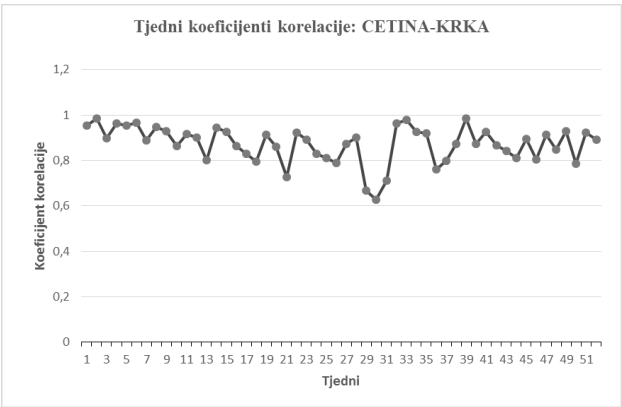
Uz podatke o dotocima na rijeci Cetini, Krki i Zrmanji za korelacijsku analizu dotoka u zemljopisno udaljene akumulacije koristili smo srednje mjesečne dotoke za rijeke Dravu i Kupu od 1950. do 2013. godine. Dok su dalmatinske rijeke Cetina, Krka i Zrmanja dio jadranskog sliva, rijeke Kupa i Drava su dio crnomorskog sliva.

Drava je rijeka kišno-ledenjačkog režima s malom vodnom količinom zimi i velikom krajem proljeća i početkom ljeta zahvaljujući velikoj akumulaciji vode u snijegu i ledu [12] i [13]. Dotoci u rijeku Dravu su mjereni na ulazu u RH, i nisu potpuno nezavisni obzirom na niz uzvodnih HE u Austriji i Sloveniji. Međutim, to su većinom protočne HE, s malim utjecajem na nizvodni režim.

Dotoci u rijeku Kupu mjereni su na zahvatu HE Gojak gdje se dotoci Zagorske Mrežnice i Ogulinske Dobre koriste za proizvodnju električne energije i ispuštaju u rijeku Kupu. Mjereni dotoci su potpuno nezavisni od uzvodnih aktivnosti na riječnom slivu.



Slika 8. Srednji tjedni dotoci u akumulacije na Cetini i Krki



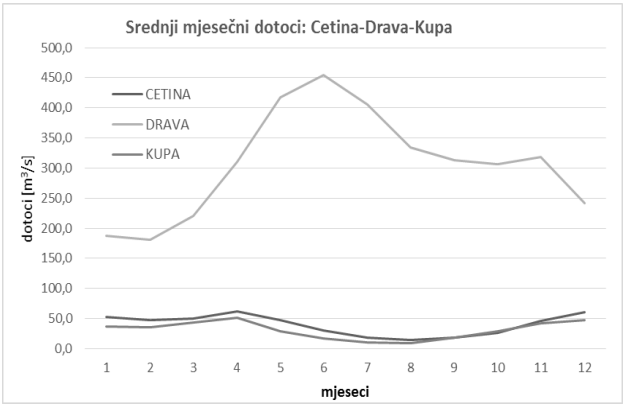
Slika 9. Nepristrana procjena koeficijenata korelacije tjednih dotoka rijeka Krke i Cetine

B. Korelacijska analiza srednjih mjesečnih dotoka

Napravljena je korelacijska analiza dotoka u rijeku Cetinu sa dotocima u rijeku Dravu i dotoka u rijeku Kupu. Iz analize je izostavljen period od 1950. do 1960 i 1991. do 1995. zbog nepotpunih podataka na rijeci Cetini.

Na slici 10 prikazani su srednji mjesečni dotoci na sva tri mjerna mjesta. Slika baš nije pregledna obzirom da je srednji godišnji dotok Drave u mjerenom periodu na promatranom mjernom mjestu (309,5 m^3/s) značajno veći od srednjih godišnjih dotoka Cetine (39,7 m^3/s) i Kupe (30,8 m^3/s) u istom periodu na promatranim mjernim mjestima, ali se ipak uočava da npr. Cetina i Drava imaju „suprotan“ režim.

Nepristrana procjena Pearsonovog koeficijenta korelacije prema (2) za sve mjesece u godine izračunata je za dotoke na Cetini i Dravi te Cetini i Kupi za period od 1960. do 1990. godine te od 1996. do 2013. godine, a za dotoke Drave i Kupe za period od 1950. do 1990. godine te od 1996. do 2013. Vrijednosti ovih koeficijenata te njihova srednja vrijednost dani su u tablici II. Korelacijske veze su slabe, naročito sa rijekom Dravom. Očito je da rijeka Drava pripada sasvim drugom režimu dotoka.

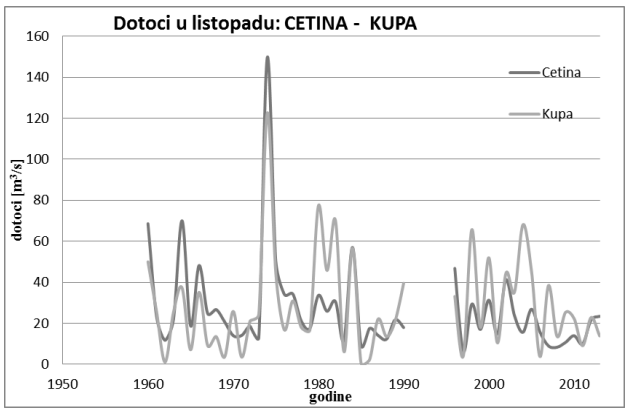


Slika 10. Srednji mjesečni dotoci u akumulacije na Cetina, Dravi i Kupi

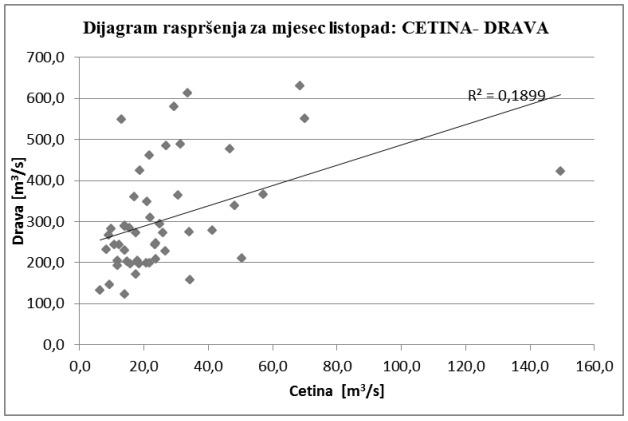
TABLICA II. VRIJEDNOSTI PEARSONOVIH FAKTORA KORELACIJE ZA SREDNJE MJESEČNE DOTOKE ZEMLJOPISNO UDALJENIH AKUMULACIJA

Mjeseci	CETINA-DRAVA	CETINA-KUPA	DRAVA-KUPA
I	0,4651	0,6079	0,5021
II	0,5345	0,6502	0,6167
III	0,6110	0,7527	0,5204
IV	0,4643	0,6921	0,4510
V	0,2267	0,5203	0,1793
VI	0,3603	0,4695	0,1313
VII	0,3688	0,2359	0,4821
VIII	0,0940	0,1873	0,2943
IX	0,1433	0,6255	0,3011
X	0,4358	0,7160	0,5255
XI	0,5610	0,4811	0,5181
XII	0,6519	0,7102	0,4037
r_sr god	0,4097	0,5541	0,4105

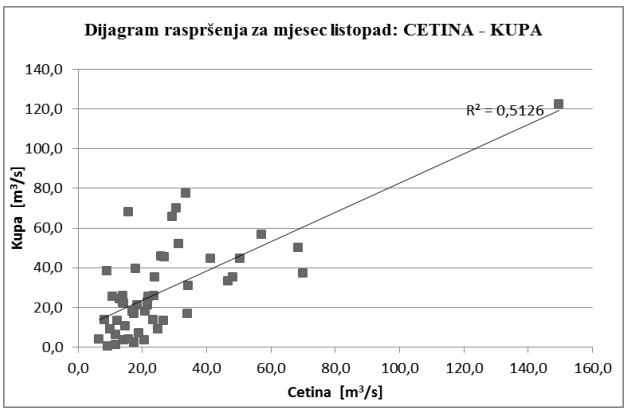
Prikaz srednjih mjesečnih dotoka u akumulacije na Cetini i Kupi u mjesecu listopadu za cijeli promatrani period prikazan je na slici 11. Iz ovog dijagrama se također vidi da dotoci na Cetini i Kupi nisu u značajnijoj korelaciji. Prikazi srednjih mjesečnih dotoka u akumulacije na Dravi, ne samo što nisu u korelaciji, već su i znatno veći od dotoka na Cetini i Kupi te nisu prikazivani takvi dijagrami. Na slikama 12, 13 i 14 prikazani su dijagrami raspršenja za sve tri korelacijske veze također u mjesecu listopadu. Uočavaju se bitno drukčiji oblici, manji faktori determinacije i veće raspršenje na ovim dijagramima nego na analognim dijagramima na slikama 5, 6 i 7.



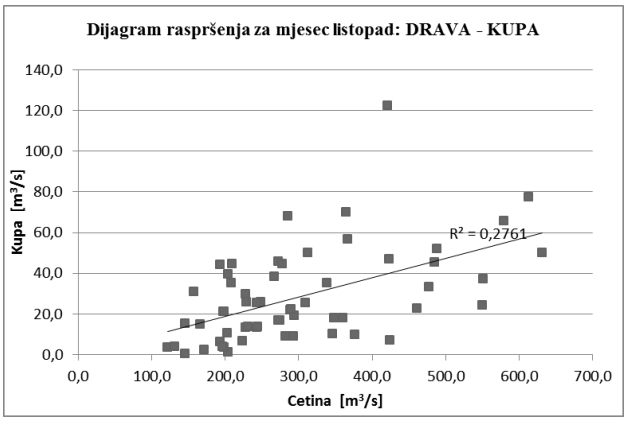
Slika 11. Srednji mjesečni dotoci u listopadu u akumulacije na Cetini i Kupi



Slika 12. Dijagram raspršenja srednjih mjesečnih dotoka u listopadu u akumulacije na Cetini i Dravi



Slika 13. Dijagram raspršenja srednjih mjesečnih dotoka u listopadu u akumulacije na Cetini i Kupi



Slika 14. Dijagram raspršenja srednjih mjesečnih dotoka u listopadu u akumulacije na Dravi i Kupi

V. ZAKLJUČAK

Napravili smo korelacijsku analizu između prirodnih dotoka posebno za geografski bliske, a posebno za geografski udaljene akumulacijske bazene, a sve na različitim riječnim slivovima. Izračunali smo jakost korelacijski veza u analiziranim slučajevima.

Dobiveni rezultati su u skladu sa očekivanjima. Pokazali smo da geografski bliski akumulacijski bazeni, iako imaju različita područja zahvaćanja oborinskih voda, imaju vrlo slične režime dotoka. S druge starne, geografski udaljeni bazeni se ponašaju različito.

Izračunate vrijednosti korelacijskih veza jasno ukazuju da prilikom modeliranja ili simuliranja dotoka u akumulacijske bazene treba vodit računa o korelacijskim vezama među njima. Prije izgradnje dobrog modela dotoka, treba ispitati korelacijske veze među dotocima na različitim bazenima. Ako su veze slabe, dotoke možemo modelirati nezavisno. Tamo gdje su korelacijske veze jake, nezavisno modeliranje dotoka nije realno.

PLC/SCADA systems in automation control design for individual quick freezing process in cooling tunnels

Goran Jagetić, Marko Habazin, Tomislav Špoljarić
University of Applied Sciences - Department of Electrical Engineering, Zagreb, Croatia
g.jagetic@gmail.com, mhabazin18@gmail.com, tomislav.spoljaric@tvz.hr

ABSTRACT - Individual quick freezing process is a complex cooling process that takes place in cooling tunnels and is used for dynamic thermal processing of certain type of goods. Type of goods and temperature of goods that needs to be achieved over specific time in cooling tunnel determine the complexity of cooling process. Complex cooling process is therefore divided into two types of regulation. Temperature regulation, the inferior type, is used for control of the cooling and defrosting parts of the system according to predefined room temperature. Superior time-cycle regulation is used to control various cycles of operation by defining its time frames. These cycles together form a period of time in which the cooling system is appropriately used for goods' freezing.

This paper describes further development in automation control design for complex cooling process in cooling tunnels. This design includes selection of appropriate control devices (temperature/pressure regulators, PLC device, HMI/SCADA), definition of LADDER program solution for dynamic time-cycle control, connection and configuration of HMI/SCADA system used for defining the number/duration of time cycles of cooling and defrosting operations and monitoring the system conditions.

I. INTRODUCTION

Simple cooling process [1] is thermal process used in refrigeration systems for maintaining room temperature via temperature regulator and at least one temperature probe. Temperature is achieved and maintained by correct switching of refrigeration system elements – compressor, electromagnetic valve, evaporator fans and condenser fans. This basic type of operation is not time-dependent and is most commonly used in small scale cooling systems with required temperature above 0°C.

When required room temperature needs to be maintained below 0°C, refrigeration system needs defrosting for evaporator section due to icing. This is done by switching the electrical heaters that need to be inserted into the evaporator section or, when electrical defrost is not available, by defrosting with hot gas. Defrosting element operation (heater or valve) is done separately from other refrigeration system elements (compressor, fans, etc.).

When defrost is needed, control design takes form of one cycle regulation [1] thus making it time dependent. A repeating cycle of operation consists of two periods of operation: refrigeration period and defrosting period. Refrigeration period is longer and in it refrigeration elements (compressor, condenser and evaporator fans) are switched according to room temperature probe/probes. Defrosting period is much shorter and in it defrosting elements (electrical heaters/hot gas valve) are switched according to evaporator temperature probe or by time (off-delayed timer function of a regulator). Fig. 1 shows simplified block diagram of a small scale refrigeration system operated by one-cycle regulation (refrigeration with defrost).

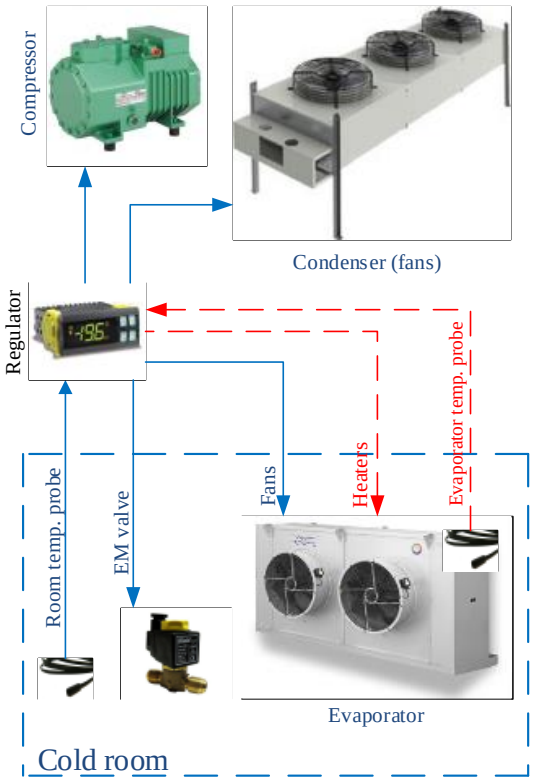

Figure 1. Block diagram of a simple cooling process

On a fig. 2 a time flow diagram of a simple cooling process is shown with one cycle control design (refrigeration with defrost period). A repeating time cycle duration is described with simple equation:

$$T_c = T_r + T_d, \qquad (1)$$

where T_r is a refrigeration period duration and T_d is a defrost period duration. When refrigeration process is active, temperature regulation according to room temperature probe is active. When defrost process is active, temperature regulation according to evaporator temperature probe is active.

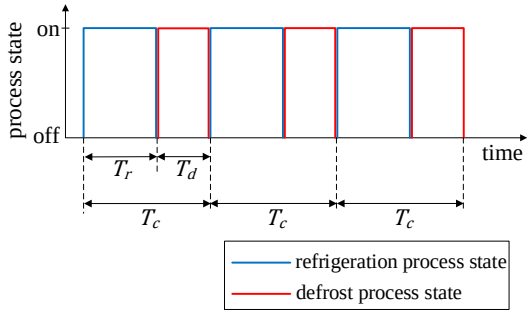

Figure 2. Time flow diagram of a simple cooling process

The complexity of a described control system may increase in larger cooling systems by adding also the pressure control in suction line (for sequential switching control of the compressors in a multiset) and discharge line (sequential switching control of condenser fans). Most of today's temperature regulators have a two cycle control, which also increases the complexity by defining durations of two different refrigeration periods, while defrost duration is the same in each cycle, but is also user defined. All these additions still make the cooling process simple.

II. Complex Cooling Process and Individual Quick Freezing

When defining complex cooling process, one needs to take into account that room temperature is not the main parameter. Room temperature is intermediary parameter for achieving the main parameter - temperature of goods that needs to be achieved over time. This type of processing certain type of goods requires specific definition of time cycles involved in process [3]. By specific definition it is assumed that each cycle has its duration defined by end user. It means that each operation period, whether it is refrigeration or defrost period, has also its duration defined in each of the cycles. A number of cycles is also defined by end user.

Because there are a lot of types of goods that can be cooled or frozen over time [5], control system design for one system needs to have a possibility for end user to define number of operating cycles and various durations of that cycles, thus making it possible for one system to process different type of goods. This type of design makes the system time-dependent, which requires more than one control device to maintain the process on a desired level of efficiency.

On fig. 3 a time flow diagram of one such complex cooling process is shown. This process consists of three refrigeration periods of different durations, and three defrost periods of same duration. Processing time is defined with T_p:

$$T_p = T_{r1} + T_{r2} + T_{r3} + 3 \cdot T_d, \qquad (2)$$

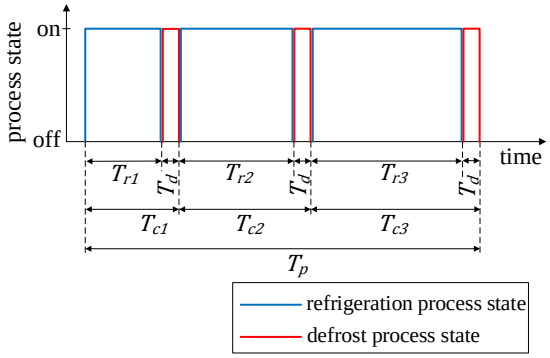

Figure 3. Time flow diagram of a three-cycle complex cooling process

Processing time is a duration of a whole process and it can be repeated. But in individual quick freezing it is a duration of a freezing process of goods, therefore it is not repeated until the next goods' exchange.

There is a possibility for defrost and refrigeration elements of a system to act at the same time for a brief moment when system goes from one state to another. That may be unwanted in larger systems from perspective of rational electric energy consumption and unwanted protective elements' switching states. In that case pause periods are introduced. Pause periods maintain the system inoperative for short period (about 5 to 10 seconds) in order the switching to be done properly.

With this in mind, processing time for n number of cycles can be generally described as:

$$T_p = \sum_{i=1}^{n} (T_{pr,i} + T_{r,i} + T_{pd,i} + T_{d,i}), \qquad (3)$$

where for i-th cycle terms are:

- $T_{r,i}$ – refrigeration period,
- $T_{d,i}$ – defrost period,
- $T_{pr,i}$ – pause period before refrigeration,
- $T_{pd,i}$ – pause period before defrost.

Complex cooling process may be implemented in control design of a small scale refrigeration system (temperature control only with switching of compressors and fans), as well as in larger scale refrigeration systems' control designs with pressure and temperature control. One such design is described in this paper. This proposed design is implemented to work with large scale refrigeration system in a freezing tunnel. Cooling process that takes place in a tunnel is also known as individual quick freezing.

Individual quick freezing is a refrigeration process of a complex nature that manages predefined

type of goods. Generally, the term or its abbreviation IQF relates to fast freezing process of solid foods such as various types of vegetables, meat, fish or fruit while trying to preserve virtually most of the properties of the parent foodstuffs. A great and fast reduction in room/tunnel temperature reduces rapidly the temperature of goods. This halts the activities of microorganisms that cause goods to deteriorate and generate toxic substances. Additionally, the enzymatic and biochemical reactions of the digestive enzymes which are found in all living tissues and whose activities continue even after death are also greatly reduced. In goods frozen with IQF process there is no clumping together and there aren't any pieces of grains. Goods remain individual separate pieces. Hence the term "individual" [6].

There are several types of individual quick freezing processes [4], and the one described in this paper is called individual quick freezing in air-blast freezing tunnels. The goods intended to be frozen are placed on trays. These trays are placed inside the tunnel, where freezing process takes place for a specified amount of time. Afterwards, the packages are removed and usually taken to cold rooms intended for storage.

III. Automation Control Design of a Freezing Tunnel

Devices used in IQF control design can be separated in two groups – devices used for time regulation and devices used for temperature/pressure regulation. Devices used for time regulation are PLC and SCADA/HMI devices, and for temperature and pressure regulation are used various types of specific microcontroller devices.

Freezing tunnel described in this paper has a carrying capacity of 30 tons of different types of fresh fish. Cooling system for that freezing tunnel has two screw type compressors, two evaporators (three fans each) and two condensers (three fans each). Compressor motors are operated by part winding start contactor combination, and all fans are operated by frequency converters. For time regulation Eaton's EASY® relay device Easy800 with additional analog I/O module and XV touch panel is chosen. For temperature/pressure regulation chosen devices are: Carel's pRACK® microcontroller device for compressor and condenser control and MPXpro® microcontroller device for evaporator, electromagnetic and thermoexpansion valve operation.

Compressor control operates according to suction pressure level, temperature and pressure of oil in compressor and cooling medium temperature. Condenser control operates according to discharge pressure level. Since the pRack device manages compressor, the only signal needed is digital input for start/stop. According to that signal and to several probes inside the compressor, the pRack device manages the switching of the compressor.

Evaporator control with MPXpro® operates according to inlet and outlet temperature of the evaporator during refrigeration period. In defrost period electric heaters are switched according to evaporator temperature probe. MPXpro® controller manages also the opening of electromagnetic valve and sequential opening of the thermoexpansion valve.

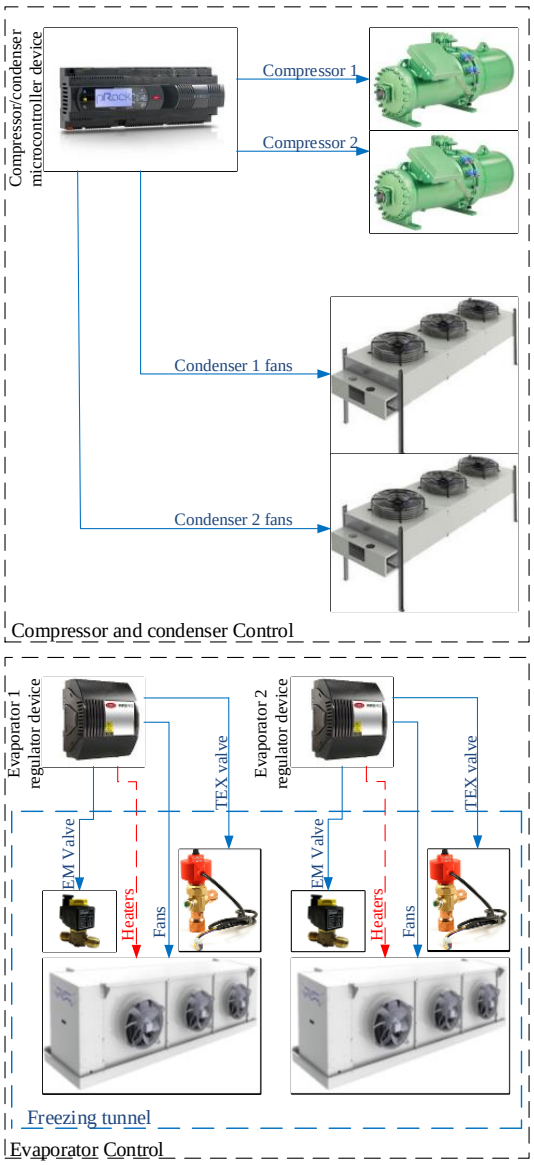

Figure 4. Simplified temperature/pressure control design for individual quick freezing process example

Time cycle control operates according to initial values of number of cycles and duration of cycles entered by end user. This provides desired variability in defining the parameters of processing time by end user. With this the process becomes dependable on goods' type and desired quality of freezing process.

When refrigeration period is active, every refrigeration element of the system works according to its regulator. Compressor is active if pressure

control demands switching on, and if protective devices are not in fault mode: if oil temperature and pressure are in defined limits, cooling medium temperature is also in defined limits and motor protective switch is not tripped. Condenser fans are switched on if discharge line pressure control demands activation and if protective devices are not are not in fault mode. In similar fashion, evaporator fans are operated by evaporator control device and its predefined temperature. All fans have a frequency converters for fine regulation of temperature and pressure.

In defrost period only electric heaters are switched on. This is done according to temperature probe in evaporator connected evaporator control device. In pause period all system components are switched off.

IV. PROGRAM SOLUTION WITH LADDER LOGIC

Complex cooling process is defined with variable number of cycles. Each cycle is defined with sequence pause-refrigeration-pause-defrost.

Minimum number of cycles in a process are three cycles and maximum number are seven cycles. Defrost and pause period are the same for all cycles and are user defined. Refrigeration period in each cycle is separately defined after selecting the number of cycles.

Before programming the system for a cooling purpose starts, it is necessary to make a list of variables. The list includes the physical and virtual I/O variables used later in the program and, and is shown in table 1.

TABLE I. LIST OF VARIABLES IN LADDER PROGRAM

Device	I/O signal	Name
EASY 822-DC-TCX (Main base)	I1	Local start/stop
	I2	Local/remote
	I3	Compressor 1 active
	I4	Comp. 1 motor protection fault
	I5	Comp. 1 oil protection fault
	I6	Evaporator 1 fan mot. prot. fault
	I7	Condenser 1 fan mot. prot. fault
	I8	Compressor 2 active
	I9	Comp. 2 motor protection fault
	I10	Comp. 2 oil protection fault
	I11	Evaporator 2 fan mot. prot. fault
	I12	Condenser 2 fan mot. prot. fault
	Q1	Refrigeration period activation
	Q2	Defrost period activation
	Q3	Pause period activation
	Q4	End of process
	QA1	Speed reference - evaporator fans
EASY 411-DC-ME (Analog module)	AI1	Evaporators' inlet temperature
	AI2	Evaporators' outlet temperature
	AI3	Suction line pressure
	AI4	Discharge line pressure
	AI5	Actual evaporator fan speed
	AI6	Actual condenser fan speed
	AO1	Speed reference - condenser fans
	AO2	(Optional for compressor speed ref.)

The code programming of the process is done in EASY Soft-Pro 6 software package [2]. It is used for communication setup, definition of variables and writing the code of the process. For the purpose of easier understanding, the code is sampled into several main sections.

Communication protocol known as easyNET® network (serial interface RS232) has been chosen for purpose of sending/receiving data between HMI interface (end user) and PLC device.

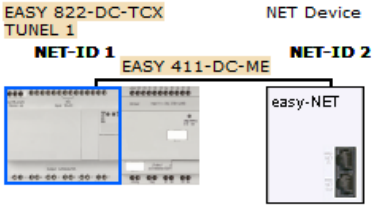

Figure 5. Hardware selection for freezing tunnel project design in easySOFT pro v6.9

First part of the circuit diagram includes getting a number of cycles from easyNET® and transferring it to a memory location in easy822 (block GT01). Comparator blocks CP01 and CP02 are used for checking whether the number of cycles is appropriately selected. If the check condition is fulfilled, a conditional marker M10 is set. This is shown on fig. 6. Based on the user input the program takes number of cycles from the SCADA.

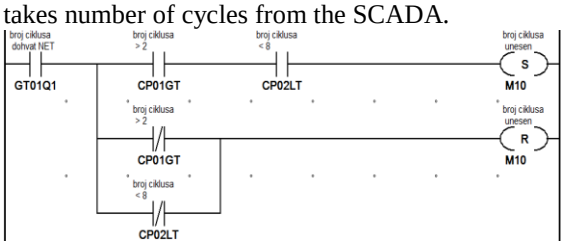

Figure 6. Program section 1 – acquirring a number of cycles

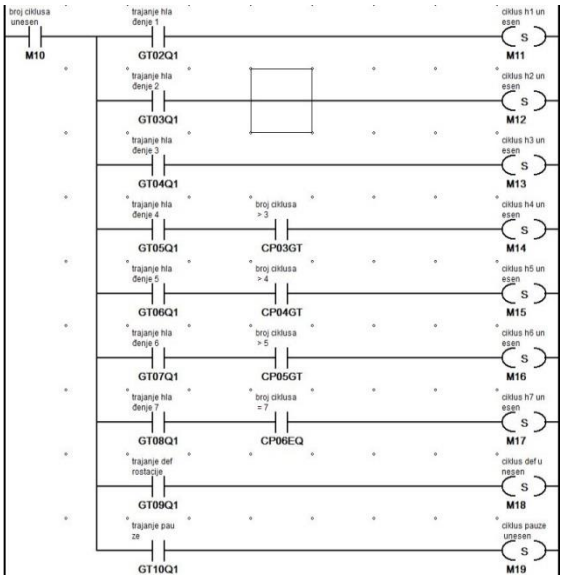

Figure 7. Program section 2 – acquirring a duration of cycles

On fig. 7 a data acquisition from SCADA (GT03-GT08 function blocks) concerning duration of refrigeration periods in each cycle, as well as fixed defrost and pause periods, is shown.

Digital input data acquisition is done by putting bit values to easyNET® network (blocks 4SN01 - 4SN10) according to digital input states (I03-I12), as shown on fig. 8.

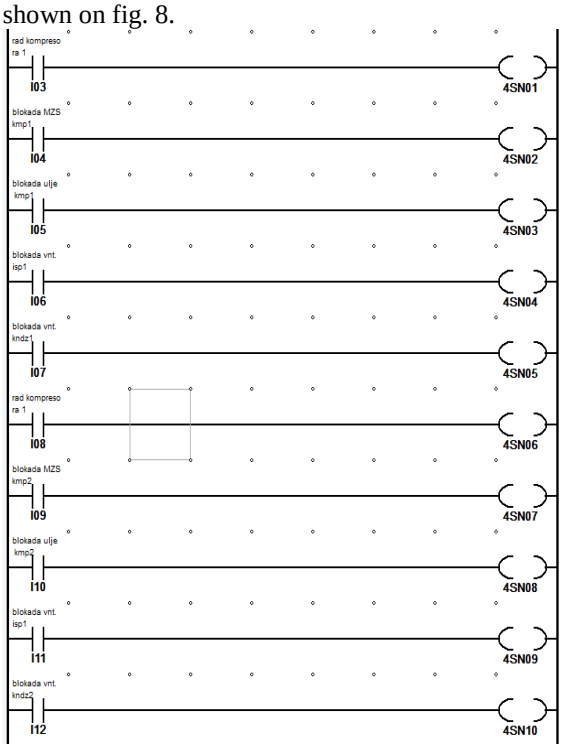

Figure 8. Program section 3 – digital input acquisition

Analog input data acquisition is done by 100ms sample flashing timer. Each time a timer contact makes/breaks, certain data is transferred via "put value to NET" block (PT01-PT06) from input to easyNET® memory location in form of variable MW (marker word with 16bit length), as shown on fig. 9.

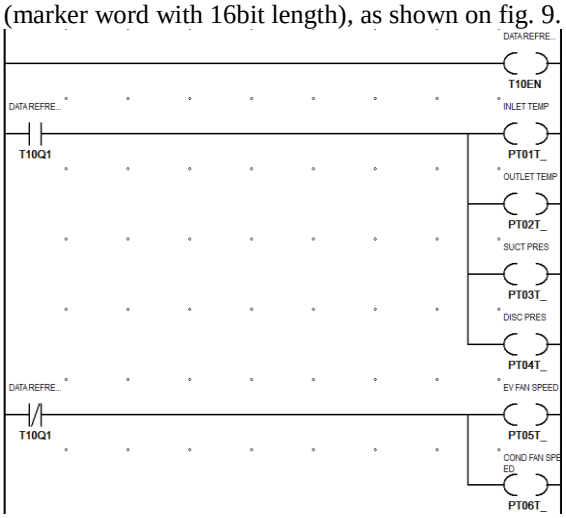

Figure 9. Program section 4 – analog input acquisition

In each cycle, data of different refrigeration period duration needs to be transferred. This is done by using data block which transfers data from memory location where GT block put the duration of refrigeration and transfers it to a memory location of a refrigeration timer.

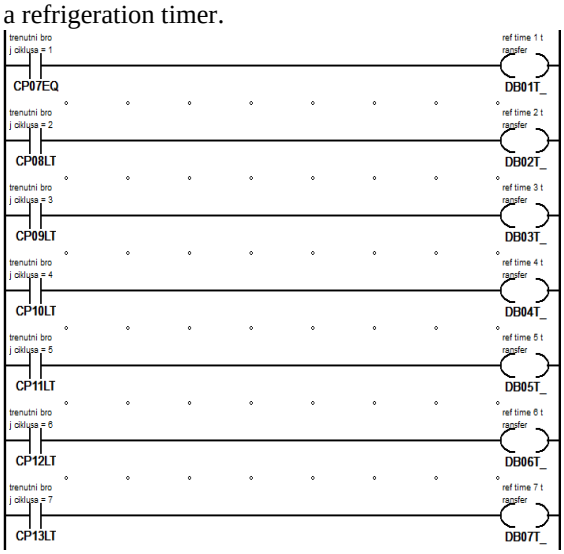

Figure 10. Program section 5 – refrigeration time transfer

User input on SCADA determines the start of the process (4RN01 contact). It is also possible to start the process manually from the electronic cabinet using the 0-1 switch on the door of the cabinet. Start is defined with rising edge marker M05 that is enabled on two additional conditions: refrigeration times for first three cycles have been set (M06) and defrost and pause periods have been set along with number of cycles (M07). Also, finishing the process depends on value in counter of cycles (C01) or local switch position (I01).

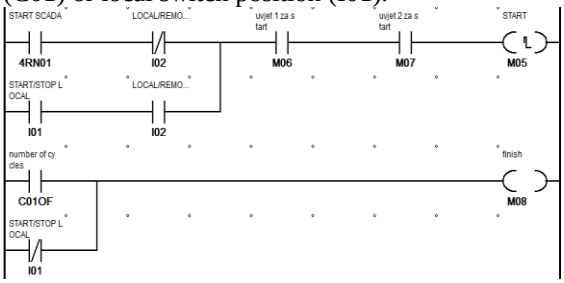

Figure 11. Program section 6 – conditions for starting and finishing of the process

Starting and repeating condition of the process is shown on fig. 12. Timer starts counting on a falling edge of a pulse given by starting (M05) or repeating cycle marker (M09). In this instance a counter C01 counts up.

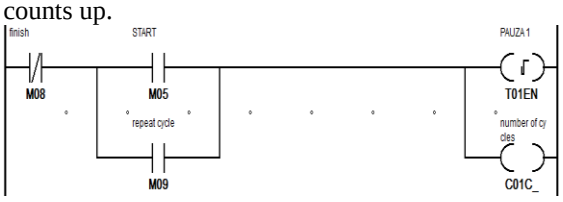

Figure 12. Program section 7 – starting the first timer of the process and repeating the cycle

When timer T01 is done with counting, similar process starts with refrigeration timer T02. This

process repeats with pause timer T03 and defrost timer T04. After T04 is done, a marker M09 for repeating the cycle is set and the process repeats in next cycle if a counter C01 contact allows it.

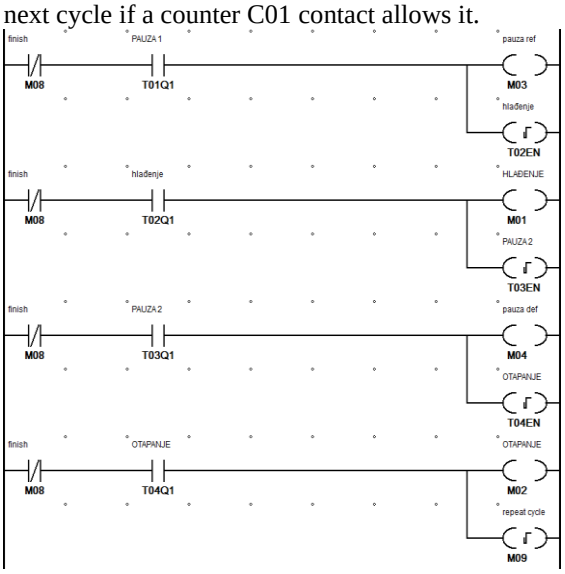

Figure 13. Program section 8 – pause, refrigeration and defrost timers counting

When the process is finished, a timer and counter are reset, as is shown on fig. 14.

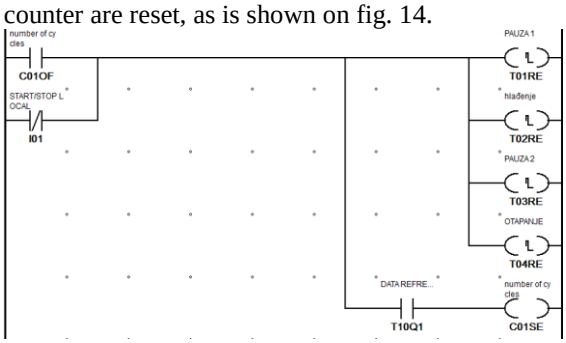

Figure 14. Program section 9 – reset of timers and counter upon completion of the process

V. HMI / SCADA System Connection

In this section, a RS232 serial connection between Easy822 PLC device and HMI device is observed. Other ways to ensure PLC-HMI connection include RS485 and Ethernet protocols. This cooling process is designed for general purpose and with minimum cost and primarily for that reason RS232 communication is chosen. Also, with this type of communication no additional converter modules are needed.

In this paper, proposed SCADA system is designed to work in a cooling system with three freezing tunnels. Control design with three PLC devices is selected to show the modular behavior of a proposed three tunnel control system. In this case each tunnel's control system is presented as one module of that design. Every tunnel is controlled by one EASY relay with additional analog module. Eaton's XV-152 touch panel is selected as a HMI device. Touch panel is connected with PLC devices through serial RS232 communication cable. This cable is used for connection of a panel and first PLC device. All three PLC devices are connected via Eaton's easyNET® network. A program for selected HMI device is made in Eaton's Galileo® software package. Described cooling system design with SCADA is shown on fig. 15.

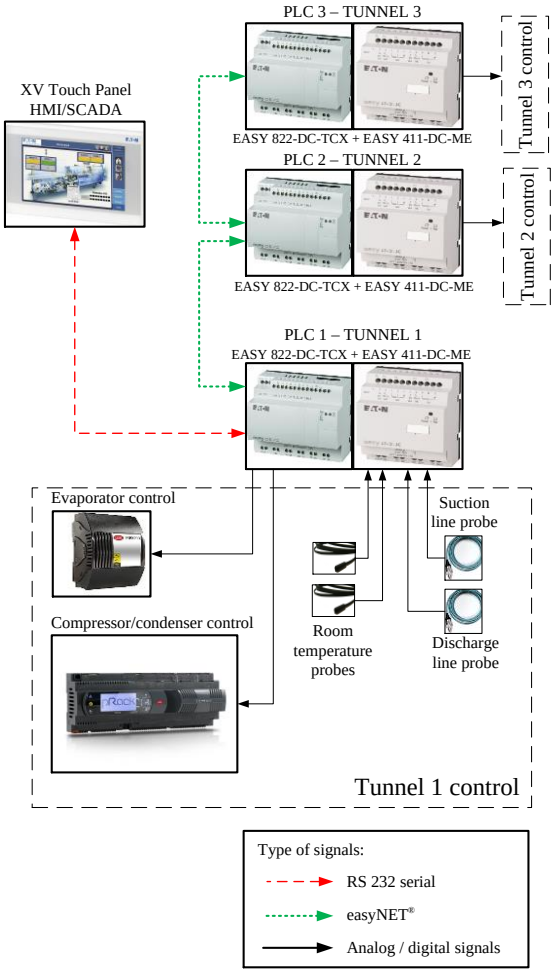

Figure 15. Observed cooling system design

Data used by SCADA system consists of input signals listed in table II and output signals listed in table III.

TABLE II. List of Input Signal Variables in SCADA

Device	Input signal	Name
XV-152 Touch panel	I1	Local start/stop
	I3	Compressor 1 active
	I4	Comp. 1 motor protection fault
	I5	Comp. 1 oil protection fault
	I6	Evaporator 1 fan mot. prot. fault
	I7	Condenser 1 fan mot. prot. fault
	I8	Compressor 2 active
	I9	Comp. 2 motor protection fault
	I10	Comp. 2 oil protection fault
	I11	Evaporator 2 fan mot. prot. fault
	I12	Condenser 2 fan mot. prot. fault
	AI1	Evaporators' inlet temperature
	AI2	Evaporators' outlet temperature
	AI3	Suction line pressure
	AI4	Discharge line pressure

TABLE III. LIST OF OUTPUT SIGNAL VARIABLES IN SCADA

Device	Output signal	Name
XV-152 Touch panel	Q1	Pause period activation
	Q2	Refrigeration period activation
	Q3	Defrost period activation
	Q4	End of process
	QA1	Speed reference - evaporator fans

Communication with easyNET® protocol manages up to 8 connected devices, and the last element of the network needs to be terminated with a bus termination resistor. Example of a wiring concept of such network is shown on fig. 16.

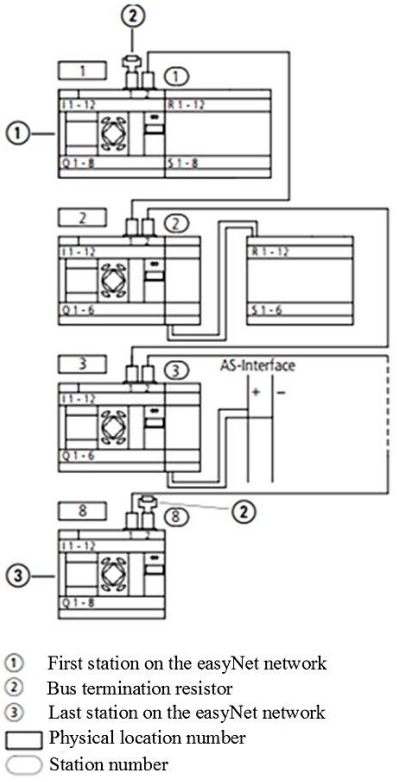

Figure 16. Wiring concept of an easyNET® network with up to 8 different Easy devices [4]

Two masks of SCADA design are shown. First mask is shown on fig. 17 and is used for process monitoring of the entire system. In this mask a selection of one of the tunnels is possible.

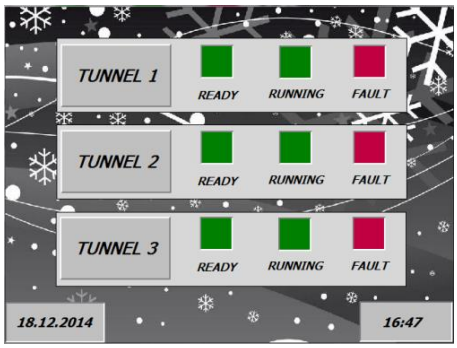

Figure 17. First mask of SCADA design

By selecting, end user can gain access to other masks used for monitoring and control each of the tunnels. One such mask (monitoring the tunnel 1) is shown on fig. 18.

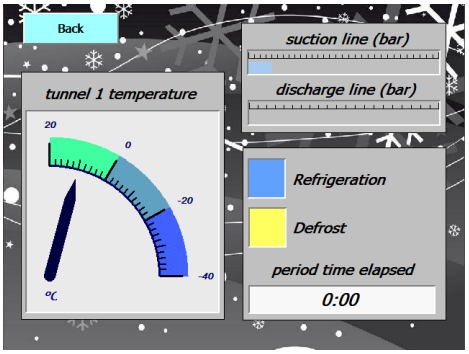

Figure 18. Monitoring mask of SCADA design for freezing tunnel 1

When connecting by easyNET® several Easy800 stations operated by the same LADDER diagram and one HMI device, a precaution needs to be taken when defining tags in SCADA. When linking a certain signal with its graphic representation on SCADA, e easyNET®'s station number from which the signal originates comes first. Then, the address of a signal is defined. In table IV several examples for signal tags from tunnel 1 are listed.

TABLE IV. EXAMPLES OF ADRESSING SIGNALS IN LADDER AND SCADA

Address name in LADDER diagram	Address name in Galileo (SCADA)
I1	NET1.I1
I3	NET1.I3
I4	NET1.I4
I12	NET1.I12
QA4 (MW95)	NET1.MW95

VI. CONCLUSION

Individual quick freezing is a complex cooling process that requires certain additions in cooling control design. Standard temperature/pressure regulators control all the refrigeration elements in a system. Due to dynamic nature of process over time additional regulation device is introduced. A PLC device controls the appropriate timing of each cycle in a process.

Possibility to define different cycles along with their number was introduced via SCADA system design running on a HMI device. Monitored values such as temperature, pressure and time of the current cycle are visible by SCADA. This gives the end user access to define the process itself, as well as visual control of the process that is currently running.

Finally, a three tunnel connection is introduced as an example to show the enhancement potentialities of modular design with several small PLC devices. Although one more complex PLC device could be selected and programmed for use

with three tunnels, this approach was selected due to its modular design and program simplicity: one simpler LADDER program can be downloaded in up to eight different smaller PLC devices and a network of tunnels can be easily set through this approach. According to requirements of a predefined three tunnel network a SCADA system was enhanced to work with three cooling tunnels simultaneously.

With correct selection of equipment a described type of automation control design for freezing tunnels can be accessible, used for general purpose and easy to maintain.

Sustav grijanja pogona za sušenje papira

Robert Bukvić, Goran Malčić i Danijel Maršić
Tehničko veleučilište u Zagrebu/Elektrotehnički odjel, Zagreb, Hrvatska
goran.malcic@tvz.hr

Sažetak - S obzirom da je u današnje vrijeme potražnja papira sve veća, proizvođači su prisiljeni postavljati sve više granice u smislu proizvodnje i poboljšanja kvalitete papira. Tako u papirnoj industriji veliku ulogu vodi sama izgradnja papirnog stroja koji je u potpunosti automatiziran pomoću programljivih logičkih kontrolera (eng. *Programmable Logic Controllers, PLC*). U radu je prikazan vrlo bitan segment papirnog stroja koji služi za sušenje papira prilikom proizvodnje. Prikazan je tehnološki proces i sustav automatizacije te nadzorno-upravljačko rješenje sustava.

I. UVOD

U današnjem svijetu papir igra veliku ulogu u našim životima zbog svakodnevnog korištenja bilo to za pisanje, tiskanje, čitanje, pakiranje, novčano plačanje, svakodnevnu higijenu i još mnoge druge svrhe. Zbog velike potražnje papira kroz povijest inženjeri su bili prisiljeni pronaći način kako da se ljudima omogući veća potrošnja papira. Izumom tiskarskog stroja započinje nova era moderne proizvodnje papira gdje prvi puta u povijesti francuz Luis Rober 1799. godine u proizvodnju uvodi prvi parni stroj pomoću kojega se mogla proizvoditi beskonačna papirna traka. Pravi napredak u masovnoj industrijskoj proizvodnji papira je započeo tek u prvoj polovici dvadesetoga stoljeća [1].

Ovaj rad se bazira na jednom od važnijih dijelova papirnog stroja u kojemu je prikazan sustav grijanja za dio pogona koji je zadužen za sušenje papira tzv. "Dryer section". Cilj rada je prikazati jedno od modernih rješenja sustava grijanja pogona za sušenje papira kompanije Voith koja je jedna od vodećih kompanija u papirnoj industriji. Pritom je prikazan pristup razvoju nadzorno-upravljačkih rješenja takvih sustava upotrebom programskog rješenja PCS7 kompanije Siemens.

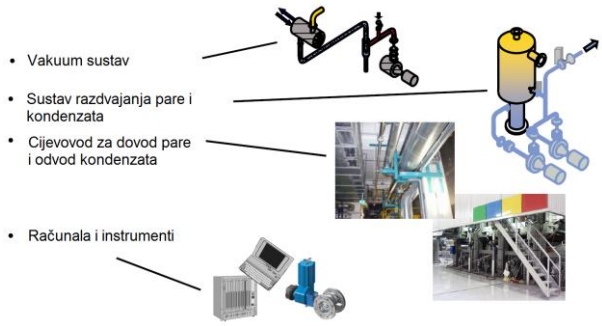
II. TEHNOLOŠKI PROCES SUSTAVA GRIJANJA POGONA ZA SUŠENJE PAPIRA

Sustav grijanja pogona za sušenje papira je vrlo bitan segment u papirnoj industriji jer ovisno o sustavu grijanja koji se koristi u postrojenju, može se doprinijeti maksimalnom učinku sušenja papira uz minimalnu potrošnju energije.

Svrha pogona za sušenje papira je povećati udio suhog sadržaja papirnog tkiva između 90 i 98% pomoću isparavanja. Sušenje papira je proces prijenosa toplinske mase kako bi toplina bila prenesena od izvora topline do papira po principu isparavanja vode. Ovisno o vrsti papirnog stroja odnosno vrsti papira primjenjuju se različiti prijenosi topline i načini sušenja papira.

Najčešći princip sušenja papira je pomoću pare i kondenzata na način da se vodena para kondenzira na unutarnjoj površini stijenke cilindara kroz koje prolazi papirno tkivo. Toplina se prenosi kroz papirno tkivo na način da se zagrijava isparavanjem vode. Stopa prijenosa topline iz pare do stijenki cilindara ovisi o brzini protoka kondenzata. Brzina protoka uglavnom ovisi o brzini papirne mašine, ali i o količini kondenzata kojeg cilindar može primiti te o promjeru samoga cilindra. Brzina papirnog stroja za vrijeme radnog procesa iznosi oko 1000 m/min.

Sustav grijanja pogona za sušenje papira u većini slučajeva nalazi se ispod postrojenja papirnog stroja te se sastoji od sustava za vakuum, sustava za razdvajanje pare i kondenzata, cjevovoda za dovod pare i odvod kondenzata te računala i instrumenata u polju koji služe za upravljanje kompletnim sustavom (sl.1.).



Slika 1. Osnovni segmenti sustava grijanja pogona za sušenje papira

Glavne značajke sustava za grijanje pogona za sušenje papira su:

- odvodnjavanje kondenzata iz cilindara za sušenje papira.
- opskrba parom cilindra za sušenje papira.
- utvrđivanje suhoće papira nakon pogon za sušenje.
- kontrola profila vlage u smjeru papirnog stroja.

Sustav grijanja podijeljen je prema toplinskim skupinama (eng. *Heating groups, HG*):

- kontrola profila vlage u smjeru papirnog stroja.
- HG 1 - 1. pred sušenje (eng. *1st pre-dryer*)
- HG 2 - 2. pred sušenje, glavna skupina (eng. *2nd pre-dryer, master group*)
- HG 3 - 3. završno sušenje (eng. *3rd after dryer*)
- HG 4 - 4. završno sušenje (eng. *4th after dryer*)

Sustav grijanja za pogon sušenja papira opremljen je sa jednim stupnjem kaskadnog sustava koji se nalazi u dijelu predsušenja i obuhvaća toplinsku skupinu 1, dok se

toplinska skupina 2 te toplinske skupine 3 i 4 koje se nalaze u završnom dijelu sušenja opskrbljuju direktno svježom parom koja pristiže iz kotlovnice.

Svrha kaskadnog sustava je iskoristiti akumuliranu paru dobivenu iz spremnika prve grupe i kondenzat koji je nastao prilikom gubitka pritiska te koji se korsiti u sljedećoj manje grijanoj toplinskoj skupini. Ovako nastala para se odvaja od kondenzata u pojedinačnim spremnicima tvz. separatorima te se dovodi do sljedeće toplinske skupine dok se kondenzat dostavlja u spremnik za pohranijvanje (eng. *Collecting tank*) preko razlike tlaka ili preko pumpe za kondenzat.

III. STRUKTURA SUSTAVA AUTOMATIZACIJE

Kompletna infrastruktura računalne mreže bazirana je na ethernet i profibus komunikaciji što je u većini slučajeva standardan način komunikacije u industrijskim postrojenjima (sl.2.).

Računalne stanice za upravljanje i nadgledanje sustava:

- WinCC serveri (eng. *WinCC Servers - Server 1, Redundant Server 2*)
- inženjerske stanice (eng. *Engineering Stations*)
- operatorske stanice (eng. *Operator stations - OS1, OS2, OS3, OS4*)
- OnQ serveri (eng. *OnQ PCs / OnV Monitoring / Profilmatic / Measurement Server*)

Računalne stanice za upravljanje i nadgledanje sustava međusobno su povezane preko mrežnog preklopnika trećeg sloja (eng. *Level 3 switch*) putem ethernet mrežne komunikacije brzine 100 Mbit/s kao i sa programirljivim logičkim kontrolerima koji se nalaze u mrežnoj strukturi. Ethernet mreža se pritom dijeli na:

- procesnu mrežu (eng. *Process Net*)
- terminalnu mrežu (eng. *Terminal Net*)

Terminalna mreža služi za komunikaciju između svih računalnih stanica te printera dok procesna mreža služi za komunikaciju inženjerskih stanica, WinCC servera te OnQ servera sa programirljivim logičkim kontrolerima putem komunikacijskog procesora CP 443-1. Daljnja komunikacija prema distribuiranim periferijama koje se nalaze u polju odvija se putem profibus računalne mreže preko PLC komunikacijskog procesora CP 443-5 [2].

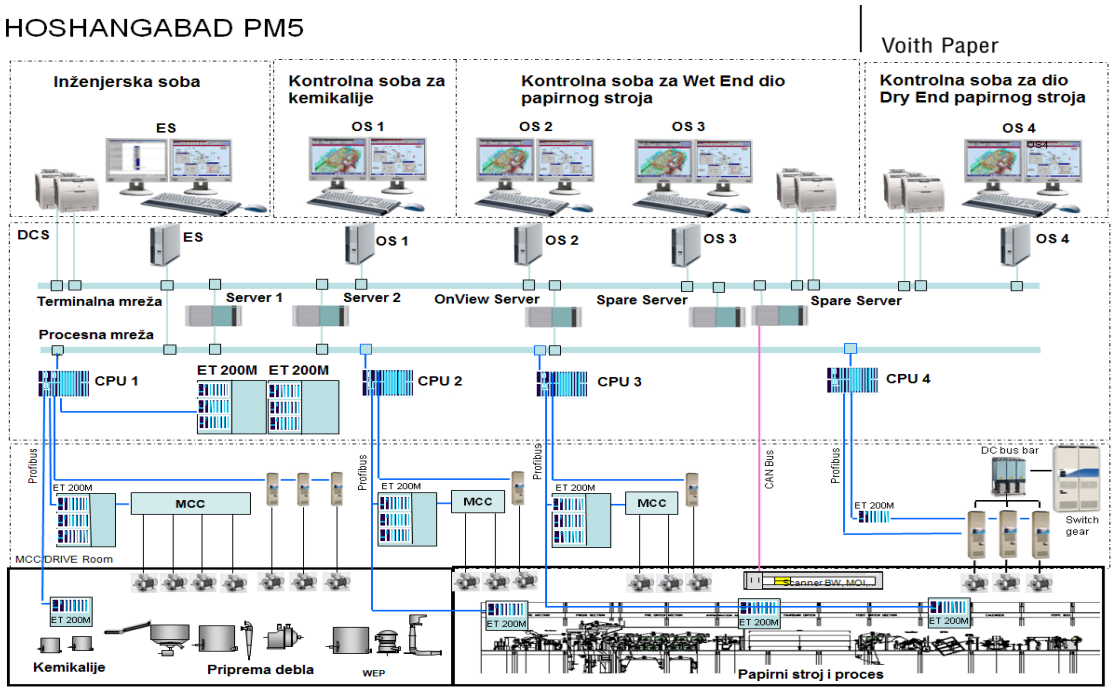
IV. PROGRAMSKO OKRUŽENJE PCS7

Kao programski alat za izradu sklopovske konfiguracije i programa za upravljanje procesom koristi se Siemensovo programsko okruženje PCS7, koji je uz Siemens Step 7 često korištišteni programski alat u industrijskim postrojenjima [3]. PCS7 je sustav centralnog inženjeringa gdje niz alata maksimalno pojednostavljuje te pruža bržu i kvalitetniju izradu projekata. Svi inženjerski alati su dio PCS7 programskog okruženja za izradu programskih aplikacija, konfiguriranje skolopvlja te komunikacijskih funkcija, a pozivaju se iz centralnog projektnog preglednika Simatic Manger (sl. 3.).

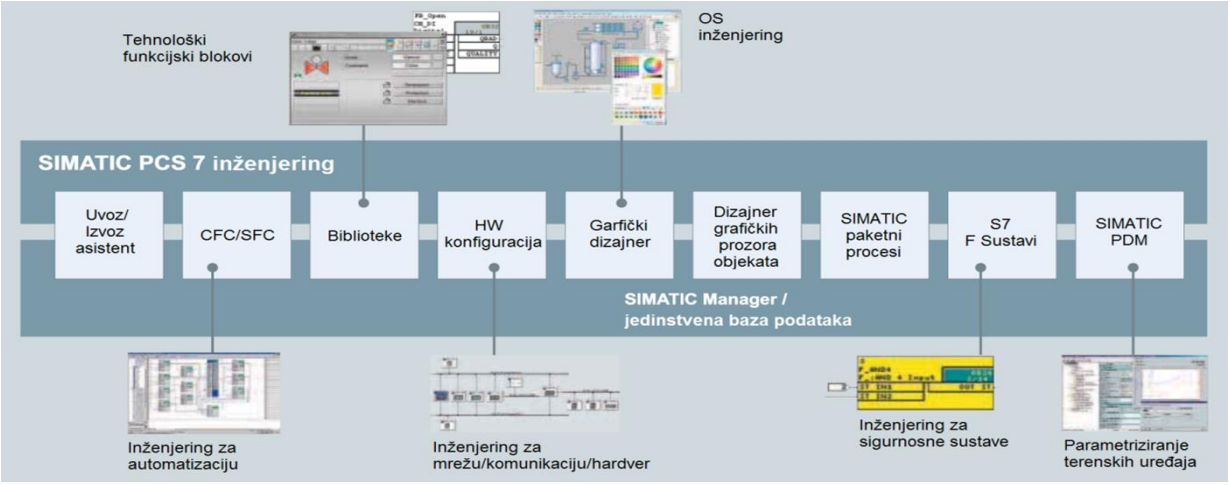
Programiranje PLC uređaja izvodi se prema zahtjevima krajnjeg korisnika te prema funkcijskom opisu procesa i funkcijskim planovima danima od izvođača projekta. PCS7 sadrži programske pakete koji se mogu programirati u tekstualnom ili grafičkom obliku kao što su:

- CFC (eng. *Continuous Function Chart*)
- SFC (eng. *Sequential Function Chart*)
- SCL (eng. *Structured Control Language*)

U ovom slučaju program se izvodi preko CFC grafičkog načina programiranja koji se inače koristi kao programski paket za dizajniranje biblioteka (eng. *Library*), automatizacijske logike, blokada (eng. *Interlocks*) i kontrolnih procesa.



Slika 2. Struktura računalne mreže sustava automatizacije



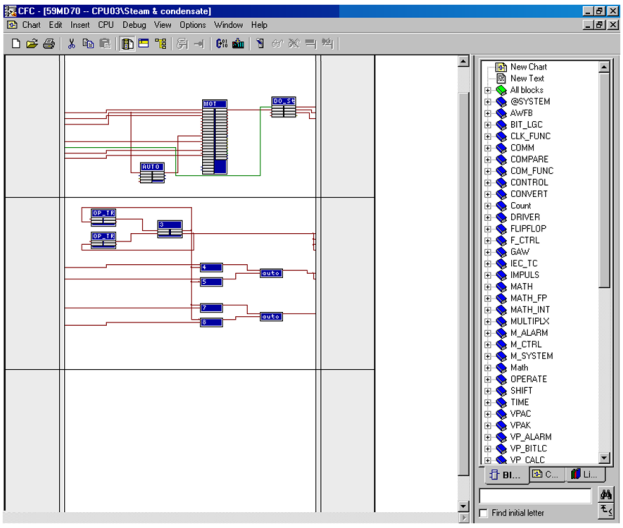
Slika 3. Struktura programskog okruženja PCS7

Program se kao što je već spomenuto izrađuje preko CFC grafičkog načina programiranja u CFC editoru. CFC petlja se može otvoriti i izraditi u bilo kojem od preglednika, ali radi bolje preglednosti postrojenja i programiranja korisiti se iz preglednika po postrojenju. Prije dodavanja CFC petlje na nivou CPU03 dodijeljuje se hijerahijska mapa sa nazivom sekcije papirnog stroja.

U CFC editoru koji je prikazan na sl. 4. sa desne strane nalazi se katalog sa bibliotekama koje sadrže:

- funkcije (eng. *Functions, FC*)
- funkcijske blokove (eng. *Functions blocks, FB*)

Funkcije i funkcijski blokovi ubacju se iz kataloga u CFC editor koji se sastoji od particije sa šest prozora za izrađivanje programa gdje svaki prozor sa lijeve i desne strane sadrži pregled ulaznih i izlaznih signala (sl. 4.).



Slika 4. Osnovni dijelovi CFC editora

Programsko rješenje je izrađeno na temelju službene dokumentacije tvrtke Voith koja sadrži:

- funkcije (eng. *Functions, FC*)
- funkcijski opis, FDS (eng. *Function description, FDS),*
- funkcijske planove, FUP (eng. *Function plan, FUP*),
- ulazno izlaznu listu signala, U/I lista (eng. *Input output list, I/O list*).

V. IZRADA UPRAVLJAČKOG PROGRAMA

Prije samog unošenja programa potrebno je odrediti u kojem ciklusu će se izvoditi pojedini dijelovi programa, definirati tablicu sa ulazno izlaznim signalima (eng. *Symbol table*) te izraditi predloške CFC petlji na temelju kojih se izrađuje upravljački program.

Ciklus za izvođenje programa odabran je prema funkciji koja se obavlja u procesu pa je tako za razmatrani sustav grijanja određeno periodičko izvođenje programa sa blokovima OB32 i OB33. Blokovi za periodičko izvođenje programa koriste se za izvođenje regulacijskih petlji, motora te prekida u realnom vremenu. U ovom slučaju CFC petlje koje sadrže motore, upravljačke ventile te grupno pokretanje postavljene su u ciklus OB33 koji vrši izvođenje programa u 500ms. CFC petlje koje vrše mjerenja u procesu postavljene su u duži ciklus OB32 koji vrši izvođenje programa u 1s. CFC petlje postavljene u ciklus OB33 postavljene su iz razloga jer dolazi do bržih promjena određenog događaja u procesu te zbog kraćeg perioda izvođenja omogućuje se brža reakcija. CFC petlje koje su postavljene u ciklusu OB32 služe samo za prikaz mjerenih vrijednosti iz procesa za što je dovoljan ciklus od 1 sekunde.

Nakon definiranog cilkusa za izvođenja programa potrebno je definirati ulazno izlaznu tablicu signala koja služi kao komunikacija između sklopovlja i programske podrške. U/I tablica signala pripremljena je od strane projektanata koji su zaduženi za detaljno planiranje sklopovlja, ali u praksi se često dogodi da dana dokumentacija ne odgovara u potpunosti softveru koji je potrebno izraditi pa je tablicu potrebno detaljno provjeriti i ispraviti ukoliko se ne podudara sa trenutnim stanjem. U/I tablicu signala potrebno je eksportirati (eng. *Export*) iz sustava Comos koji služi za detaljan inženjering. U/I tablica signala se eksportira kao excel datoteka te ista importira u PCS7 tablicu simbola koja se nalazi na nivou programa u PCS7 sučelju. Za importiranu U/I tablicu potrebno je provjeriti U/I adrese sa već konfiguriranom sklopovskom konfiguracijom te naziv svakog signala sa U/I listom signala.

Zbog opsežnosti programa u nastavku rada nisu detaljno opisane CFC petlja programa već je prikazan pristup izradi CFC predložaka koje je potrebno izraditi prije samog kodiranja na kojima se baziraju ostale CFC petlje. CFC predlošci su podijeljeni prema sljedećem:

- elektromotorima
- upravljačkim ventilima
- senzorima

Prije ubacivanja blokova definira se pozicija određenih blokova po prozorima CFC editora radi lakšeg pregleda programa. Prozori su definirani na sljedeći način:

- 1. prozor za blokove ulaznih signala
- 2. prozor za blokove izlaznih signala (osim u slučaju motora gdje se nalazi u 4. prozoru)
- 4. prozor za glavne funkcijske blokove VP_MOT, VP_PID, VP_MMON
- 5. prozor za blokove blokade i praćenja izlazne vrijednosti, te u slučaju motora za logiku za automatsko upravljanje.
- ostali prozori su za ostalu logiku po vlastitom izboru korisnika

Prilikom ubacivanja blokova potrebno je obratiti pozornost na raspored blokova koji se vidi u desnom uglu svakog bloka u zelenom kvadratiću gdje je prikazan ciklus i pozicija bloka. Pozicija bloka se definira prema rasporedu izvršavanja što je jako bitno prilikom izvođenja programa. Tako se blokovi ulaznih signala postavljaju na prvu poziciji, blokovi izlaznih signala na zadnju poziciju, a glavni funkcijski blokovi između ulaznih i izlaznih blokova u ovisnosti o redoslijedu ostalih blokova.

A. Elektromotor

Za izradu CFC petlje pumpe za kondenzat na spremniku kondenzata definiraju se blokove koji su potrebni za nadzor i upravljanje. Elektromotor ima ulogu pumpe koristi 2 ulazna i 1 izlazni signal za komunikaciju sa PLC uređajem. Potrebno je osigurati upravljanje i nadzor putem nadzornih zaslona te povezati logiku koja je zadužena za automatsko pokretanje pumpe. Za izradu CFC predloška za pumpe korišteni su standardni blokovi iz kataloga.

B. Upravljački ventil

Softverske izvedbe upravljačkih ventila baziraju se na istoj logici koja sadrži PID regulator koji reguliranu izlaznu vrijednost šalje na izlaz upravljačkog ventila. Upravljački ventil koji je upravljan preko PID regulatora koristi 1 ulazni i 1 izlazni signal dok u slučaju gdje PID upravlja sa dva upravljačka ventila koriste se 2 izlazna signala.

U slučaju da ulazna procesna vrijednost dosegne ili prekorači maksimalnu i minimalnu vrijednost, na nadzornom ekranu pojavljuje se alarm. Vrijednosti za alarm definiraju se na sljedećim ulazima bloka PID:

- LIM_HH za alarm visokog prioriteta PV Alarm High
- LIM_LH za alarm niskog prioriteta PV Warning High
- LIM_LL za alarm niskog prioriteta PV Warning Low
- LIM_LH za alarm visokog prioriteta PV Alarm Low

VI. ALGORITAM UPRAVLJANJA SUSTAVOM

Kako bi algoritam upravljanja sustavom ispravno radio potrebno je osigurati sljedeće uvjete:

- instrumentalni i radni zrak,
- paru,
- cilindri za sušenje u pripremi za pokretanje,
- otvoreni ručni ventili i ventili na pumpama,
- zatvoreni ventili za odvodnjavanje na separatorima,
- puštena voda za hlađenje za vakuum kondenzator,
- zadane vrijednosti upisane.

Nakon što su svi potrebni uvjeti osigurani može se krenuti sa pokretanjem sustava grijanja.

A. Dovod pare kroz glavnu dovodnu cijev

Osiguranu paru koja dolazi iz kotlovnice potrebno je propustiti do sustava za grijanje tj. do razdjelnika za paru (eng. *Steam Distributor*) putem dva upravljačka ventila PCV01 i PCV02 koji koriste tzv. Split range način kontrole pritiska. Zbog velikog promjera dovodne cijevi za paru koriste se dva upravljačka ventila od kojih je PCV02 premosni ventil (eng. *Bypass valve*) koji je ujedno manji od glavnog ventila PCV01 te je montiran na zaobilaznu cijev manjeg promjera. Zbog velike temperature i pritiska pare osigurano je sporije otvaranje ventila PCV02 te nakon što se on u potpunosti otvori, tek tada se u potpunosti otvoriti ventil PCV01 kako ne bi došlo do naglog porasta temperature u cijevima i hidraulučkog udara ukoliko je negdje prisutan kondenzat. Otvaranjem ventila PCV01 povećava se temperatura u cijevi, a time i pritisak kojega je potrebno smanjiti na 4.5 bara. Povećanjem temperature preko 100°C otvara se ventil TCV01 koji je upravljan preko PID regulatora koji tako propušta konenzat kako bi postepeno ohladio paru tj. smanjio pritisak.

B. Dovod pare kroz glavnu dovodnu cijev

Nakon što se dobio željeni pritisak od 4.5 bara kreće se sa modom Odzračivanje (eng. *Dearation*). Prije samog odzračivanja sustava svi regulatori i motori se postavljaju u automatski mod rada. Pritiskom na tipku AUTO na nadzornom ekranu šalje se signal na na sve blokove regulatora i motora, a pritiskom na tipku DEARATION sustav počinje sa odzračivanjem. Određeni PID regulatori postavljaju se u mod praćenja tj. upravljani ventili se u potpunosti otvaraju za vrijeme odzračivanja i pokreće se pumpa 59MD60 kako bi se odzračio vakuum sustav. Neposredno nakon pokretanja odzračivanja postepeno se počinje otvarati ventil glavnog ventila za paru kako ne bi došlo do hidrauličkog udara i oštećenja cilindara unutar toplinskih skupina.

C. Održavanje topline sustava

Nakon završetka odzračivanja sustav se postavlja u mod Održavanja topline za pred sušenje i završno sušenje (eng. *Keep warm*). Za vrijeme moda Održavanje topline prekida se mod praćenja PID regulatroa te počinje kontrola sa izlaznim vrijednostima regulatora pritiska i diferencijalnog pritiska. Putem upravljačkih ventila pritiska regulirano se propušta para u cilindre na pogonskoj strani stroja dok se sa diferencijalnim

upravljačkim ventilima pritiska odvodi kondenzat koji se nakuplja u cilindrima prema separatorima.

D. Radni mod sustava

Dolaskom papira do pogona za sušenje papira te pritiskom na tipku OPERATION prelazi se u radni mod (eng. *Operation*) gdje počinje proces sušenja papira. Prelaskom u ovaj mod počinje upravljanje sa zadanim radnim vrijednostima i faktorima koje su postavljene od strane procesnog inženjera putem nadzornog ekrana. Kako bi se izbjeglo ručno postavljanje moda operacije po dolasku papira predloženo je da se automatski osigura postavljanje sustava u mod operacije. Predložena ideja bila je da se osigura postavljanje foto ćelije na početku pogona za sušenje papira kako bi se po dolasku papira i prelasku preko foto ćelije dobio signal kojim bi se programski osiguralo automatsko postavljanje u radni mod. Ista logika vrijedi i za završno sušenje papira.

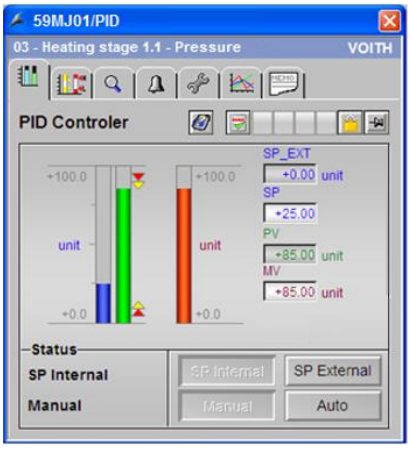
VII. IZRADA NADZORNOG PROGRAMA

Kako bi se omogućila komunikacija između operatera i procesa potrebno je izraditi nadzorni program za upravljanje procesom HMI (eng. *Human Machine Interface*) putem operaterskog računala (eng. *Operator Station*) ili panela na dodir (eng. *Touch Panel*). Nadzorni program za upravljanje procesom izrađuje se putem WinCC aplikacije (eng. *Windows Control Centre*) koja je sastavni dio Simatic programskog paketa. WinCC aplikacija služi za izradu nadzornih ekrana, procesnih alarma te komunikaciju između PLC uređaja i operativnog sustava koja je definirana tagovima. Sama aplikacija integrirana je u sučelju PCS7 te se projektima izrađenima u WinCC aplikaciji pristupa direktno preko PCS7 sučelja. Slike nadzornih ekrana izrađuju se u grafičkom dizajneru (eng. *Graphic Designer*) koji se nalazi u lijevom dijelu WinCC preglednika. U grafičkom dizajneru za sliku nadzornih ekrana dodjeljuju se elementi kojima se upravlja, procesne veličine (eng. *tags*) kojima se objekti povezuju sa PLC uređajem i alarmi za greške u procesu.

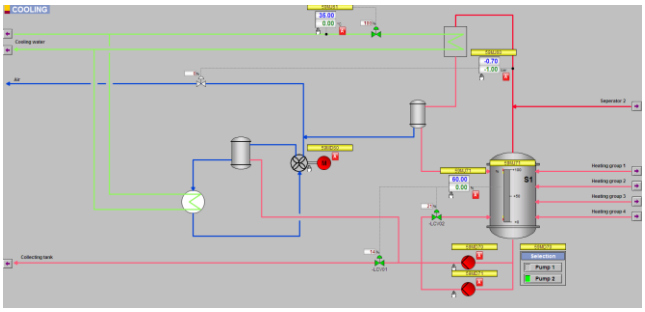
Elementi i alarmi koji se dodijeljuju na radnu površinu nalaze se u predlošku PCS7 Typicals iz kojeg se vrlo jednostavno dodjeljuju na radnu površinu nadzornog zaslona koji se izrađuje, po principu kopiraj i zalijepi (eng. *copy/paste*). Po završetku slike nadzornog ekrana elementi se povezuju sa procesnim veličinama kojima se potom prema potrebi dodjeljuju alarmi. Alarmi su podijeljeni po klasama prioriteta te se takvi pojavljuju na nadzornim ekranima u ovisnosti o greškama koje se javljaju iz procesa.

Klikom na pojedini element zaslona operateru se otvara pripadajući grafički prozor tog elementa. Slika 5. prikazuje jedan takav primjer grafičkog prozora elementa VP_PID koji služi za upravljanje i detaljan prikaz stanja PID regulatora.

Slika 6. okvirno prikazuje koncept nadzornog zaslona sustava za hlađenje pare i kondenzata sa svim pripadajućim grafičkim elementima. Zaslon omogućuje operateru upravljanje procesom u kojemu se hlađenjem pare plinovitog agregatnog stanja dobiva kondenzat u vakuum kondenzatoru.



Slika 5. Grafički prozor elementa VP_PID



Slika 6. Nadzorni zaslon sustav za hlađenje pare i kondenzata

VIII. EKSPLOATACIJSKE KARAKTERISTIKE

Kako različiti pritisci pare u cilindrima za sušenje uzrokuju različite temperature na površinama cilindra koje utječu na karakteristike sušenja papira, bitno je nadgledati temperaturu površine cilindara koja je definirana krivuljom zasićenja koja daje ovisnost temperature u odnosu na pritisak pare. Iz tog razloga potrebna je zasebna kontrola pritiska za svaku toplinsku skupinu.

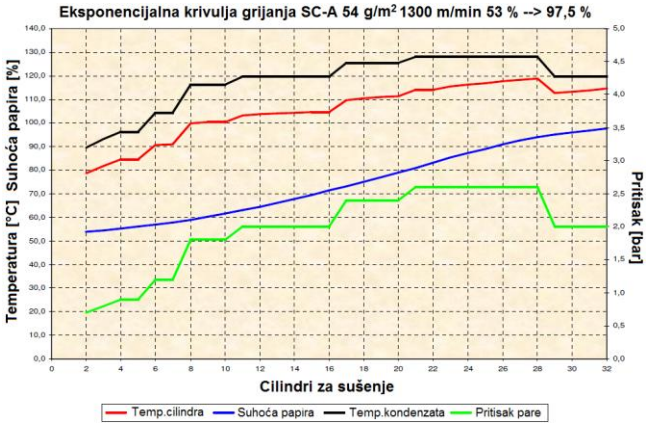
Odnos između pritiska pare, temperature kondenzata, temperature cilindara i završnog proizvoda procesa suhoće papira prikazan je eksponencijalnom krivuljom grijanja. Kako nije bilo moguće dobiti kompletnu dokumentaciju projekta, eksponecijalna krivulja iz koje se vide eksploatacijske karakteristike preuzeta je iz proizvodnje novinskog papira tvrtke SCA (Svenska Cellulosa Aktiebolaget) koja koristi isti sustav grijanja samo sa više cilindara koji su također podijeljeni po toplinskim skupinama.

Eksponecijalna krivulja prikazana je na sl. 7. te sadrži sljedeće eksploatacijske karakteristike:

- težina papira - 54 g/m^2
- brzina proizvodnje - 1300 m/min
- suhoća papira - 53 - 97,5 %
- temperatura cilindara - 79 - 119,5 °C
- temperatura kondenzata - 90 - 128 °C
- pritisak pare - 0,7 - 2,6 bara

Prikazana eksponecijalna karakteristika prikazuje sušenje papira težine 54 g/m^2 kroz cilindre za sušenje pri brzini proizvodnje od 1300 m/min. Plava krivulja suhoće papira prikazuje eksponecijalni rast od 53 % suhoće do

97,5 % prilikom prolaska papira kroz cilindre. Kako papir prolazi kroz cilindre i toplinske skupine tako se povećava pritisak pare (zelena krivulja), a time i temperatura cilindra (crvena krivulja) i konedenzata (crna krivulja). Na početku grafa se vidi kako su cilndri na početku u prvim toplinskim skupinama manje grijani te kako sadržaj papira primiče kraju, cilindri u zadnjim toplinskim skupinama se sve više griju što i rezultira suhoću papira.



Slika 7. Eksponencijalna krivulja grijanja

Ovakav princip sušenja papira se koristi da bi se dobila što bolja kvaliteta papira, izbjeglo oštećenje i pucanje papira te postepeno izvukla vlaga iz sadržaja papira. Iz tog razloga kao što je već spomenuto ranije svaka toplinska skupina ima zasebno upravljanje gdje svaki upravljački ventil ima zadanu vrijednost koja se povećava prelaskom i manje grijane toplinske skupine u veću.

IX. ZAKLJUČAK

Svakodnevna prisutnost papirnih proizvoda u današnjem svijetu označuje sastavni dio našeg kulturnog razvoja i vrlo bitan segment u modernom društvu. Današnja proizvodnja papira u svijetu iznosi otprilike oko 400 milijuna tona na godinu te predviđeni porast proizvodnje procjenjuje se na oko 500 milijuna tona do 2020. godine . Serija Hainan PM 2 tvrtke Voith je trenutno najveći papirni stroj na svijetu čija je širina 11,8 metara, a dugačak je 600 metara. Sadrži 87 cilindara za sušenje papira te proizvodi oko 4500 tona na dan .

Tehnologija koja se danas koristi kao sustav grijanja pogona za sušenje papira iznimno je bitan segment papirnog stroja. Sustav grijanja pogona za sušenje koji je prikazan u ovom radu osim minimalne vlažnosti papira od svega 2 do 5 % u konačnom proizvodu, omogućuje u potpunosti automatiziranu odvodnju kondenzata, smanjenu konzumaciju pare i smanjeni gubitak kondenzata. Nakon pokretanja sustava, sustav počinje sa automatskim režimom rada gdje je iz prakse poznato da operateri zaduženi za sustav grijanja imaju potrebu samo nadgledati proces grijanja za vrijeme proizvodnje.

Prikazan sustav grijanja je referenca za ostale sustave grijanja gdje će se sa velikom pouzdanošću u budućnosti primjenjivati u novim papirnim postrojenjima. Ovakav sustav grijanja ostavlja mjesta za nadogradnju u budućnosti gdje će se dolaskom novih tehnologija i istraživanjima unaprijediti postojeći sustav kako bi se smanjila vlažnost, potrošnja energije proizvodnje i troškovi.

Uređaj za testiranje baterijskih ćelija 18650

Alen Jakoplić, Danijel Maršić i Goran Malčić
Tehničko veleučilište u Zagrebu/Elektrotehnički odjel, Zagreb, Hrvatska
goran.malcic@tvz.hr

Sažetak – Prilikom izrade baterijski napajanih elektroničkih sklopova, uvjek se postavlja pitanje vremenskog ograničenja rada tako izvedenog sklopa. Kako bi dobili točne vrijednosti, za pojedine baterijske ćelije potrebno je izvršiti njihovo testiranje odnosno kontrolirano prazniti i mjeriti njihov napon i struju. Ako se želi saznati kapacitet ćelije potrebno je istu prvo napuniti, te onda prazniti određenom strujom i mjeriti vrijeme, a dobivene rezultate treba na odgovarajući način prikazati korisniku. U radu je prikazan razvoj prototipa uređaja za testiranje baterijskih ćelija pomoću Arduino sustava. Opisane su sve sastavne komponente uređaja i objašnjen je rad sklopa kao cjeline. Testiranje se provodi na baterijskim ćelijama normiranih brojem 18650 koje su danas jedne od najkorištenijih.

I. UVOD

Arduino je *open-source* platforma bazirana na sklopovlju i programskom paketu koji je fleksibilan i jednostavan za korištenje. Može se koristiti za razvijanje interaktivnih objekata očitanjem stanja raznih prekidača i senzora, te upravljanje raznim indikatorima, aktuatorima i ostalim fizičkim izlazima [1].

Li-Ion baterija pripada skupini punjivih baterija. Prednost ovakvih vrsta baterija je vrlo velika gustoća energije koja se može pohraniti u njima, triput veći nazivni napon od napona koji je u baterijama na bazi nikla (3,7 V prema 1,2 V), nema potrebe za periodičnim pražnjenjem odnosno može ih se puniti u bilo kojem stanju napunjenosti i dugi životni vijek koji može biti od 500 do 1000 ciklusa.

Slabost litij-ionskih baterija je što nisu pogodne za pražnjenje jakom strujom, mogu stariti i kad ih se ne koristi te se u određenim okolnostima mogu pretjerano zagrijati pa čak i eksplodirati. Vrlo su osjetljive na prepunjavanje kao i na pretjerano pražnjenje, zbog čega svaka komercijalna baterija ima elektroniku koja rješava takav problem [2].

Kada baterija u sebi sadrži više baterijskih ćelija spojenih u seriju kako bi se povećao izlazni napon potrebno je koristiti sve ćelije istoga kapaciteta kako bi se one istovremeno ispraznile i napunile. Ako jedna ćelija ima manji kapacitet od ostalih onda će se prije isprazniti i tako doći u opasno niske napone ili prije napuniti, te čak stvarati rizik od požara. Kako bi se to izbjeglo baterije se balansiraju ili nadziru. Nadziranje svake pojedine ćelije omogućuje prekid punjenja ili pražnjenja kada jedna od baterija dođe do kritičnog napona.

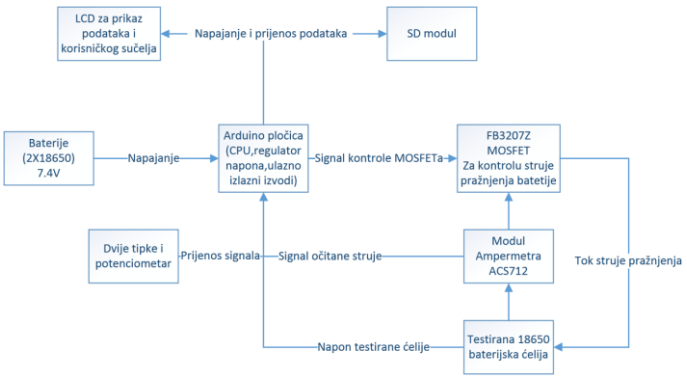
Rješenje tog problema je balansiranje. Postoji gornje i donje balansiranje. Gornje balansiranje je u širokoj uporabi radi veće pouzdanosti. Radi na principu da se na baterijske ćelije koje prve dođu do napona na kojem su pune spoji mali teret koji ih održava na tome naponu. Gornje balansirane baterije prazne se dok god jedna od ćelija ne dođe do napona na kojem se smatra praznom i onda pražnjenje mora prestati kako se ne bi oštetila ta ćelija. Ostale ćelije neće se isprazniti do kraja.

Donje balansiranje izvodi se samo jednom i nije potreba nikakva dodatna elektronika za nadzor baterija. Radi na principu da se sve ćelije isprazne na napon na kojemu se smatraju praznima, te onda sve zajedno pune i koriste. Pošto su spojene u seriju, kroz sve ćelije prolazi ista struja pa se sve pune na isti kapacitet u mAh. Pune se sve dok jedna od ćelija ne dođe do napona na kojemu se smatra punim.

Trenutno je najprodavanija baterijska ćelija oznake 18650 te joj cijena iz tog razloga neprestano pada. Prodaja elektroničkih sklopova s baterijskim napajanjem je također u porastu jer je tržište upravo preplavljeno takvim sklopovima (eng. gadgets). U ovom radu je opisan uređaj koji kontolira stvarne vrijednosti baterijskih ćelija 18650 koje nalazimo na tržištu.

II. IDEJNO RJEŠENJE UREĐAJA

Osnovni cilj je razviti uređaj za testiranje baterijskih ćelija oznake 18650 koji bi radio kao samostalan uređaj koji ne mora biti povezan s računalom ili napajanjem iz električne mreže. Uređaj za testiranje baterijskih ćelija 18650 potreban je kako bi se izmjerile energetske mogućnosti baterijskih ćelija odnosno utvrdio kapacitet ćelije, te padovi napona pod pojedinim opterećenjima. Potrebno je kontrolirano prazniti baterijske ćelije mjerenjem struje i napona ćelije te vremena koje je potrebno da se ona isprazni, te na kraju omogućiti prikaz i spremanje izmjerenih podataka. Centralni dio uređaja je ATmega mikrokontroler smješten na Arduino pločici (Sl.1.).



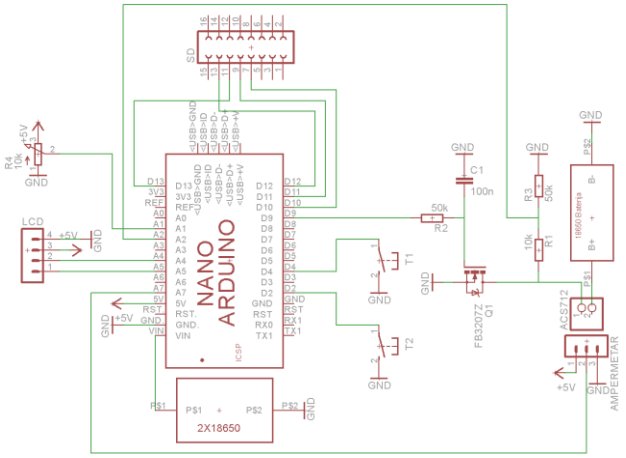
Slika 1. Idejna blok shema uređaja

Baterijske ćelije 18650 testiraju se mjerenjem njihovog kapaciteta u mAh ili Wh, mjerenjem maksimalne struje koju baterija može dati i mjerenjem pada napona na bateriji prilikom određenog opterećenja. Kada se sastavlja baterija načinjena od više ćelija potrebno je znati kapacitet svake pojedine ćelije kako bi se dobro rasporedila spremljena energija, te energetske mogućnosti ćelija kako bi se osiguralo da su prikladne za davanje željenog napona, struje ili snage. Nove ćelije obično dolaze s popisom parametara iz tvornice pa nije potrebno ponovno mjerenje, ali kod reciklaže starih baterija ili kod baterija s nepoznatim parametrima, novo mjerenje je iznimno bitno. Moguća je i provjera performansi baterija nakon nekog vremena korištenja (provjera pada kapaciteta).

Uređaj za testiranje 18650 ćelija radi na principu kontroliranoga pražnjenja baterija pomoću MOSFET (eng. *metal – oxide – semiconductor field effect transistor*) tranzistora na kojeg je montiran hladnjak kako bi se disipirala energija prethodno pohranjena u baterijama. Bateriju prvo treba napuniti na propisani napon kako bi se dobilo što točnije očitanje. Prije početka mjerenja potrebno je unijeti željenu struju pražnjenja. Struja pražnjena se određuje ovisno o budućoj uporabi baterije.

III. SKLOPOVSKO RJEŠENJE

Centralni dio cijeloga uređaja je *Arduino Nano* kompatibilna pločica na kojoj se nalazi ATmega mikrokontroler u kojem se izvodi program koji upravlja cijelim uređajem. Mikrokontroler ima mogućnost analogno digitalne i digitalno analogne pretvorbe koja je potreba kako bi uređaj radio. Na Arduino nano pločici nalazi se još utor za USB vezu koji se koristi za programiranje i prijenos podatke te čip koji omogućuje komunikaciju sa ATmega mikrokontrolerom putem USB sučelja.



Slika 2. Električna shema uređaja

A. *Kontrola izlazne struje baterije*

Izlazna struja baterije kontrolira se MOSFET tranzistorom tipa FB3207Z. S obzirom da je MOSFET naponom upravljani tranzistor kojemu vodljivost ovisi o naponu između nožica G i S u ovom se slučaju taj napon regulira mikrokontrolerom kako bi se MOSFET doveo u aktivno područje rada.

ATmega mikrokontroler analogni izlaz na svojim nožicama realizira signalom pulsno širinske modulacije (eng. *Pulse Width Modulation, PWM*). Kako bi se izlazni PWM signal mikrokontrolera mogao koristiti za upravljanje MOSFET tranzistorom potrebno ga je prvo izgladiti. To je realizirano nisko propusnim filtrom prvoga reda kojeg je potrebno podesiti na što nižu frekvenciju kako bi što bolje filtrirao izmjeničnu komponentu signala.

B. *Mjerenje struje baterije*

Kako bi mikrokontroler mogao aktivno regulirati struju baterije potrebno je mjeriti samu struju baterije. Mjerenje struje baterije izvedeno je modulom za mjerenje struje pomoću Hallovog efekta. Hallova sonda osjeti magnetsko polje čija jačina ovisi o struji koja teče kroz vodič. Ovaj modul za mjerenje struje koristi ACS712 ELCTR-20A čip koji je pogodan za rad s mikrokontrolerom. Maksimalni doseg čitanja struje je 20 A, te daje signal od 100 mV/A.

C. *Mjerenje napona baterije*

Mjerenje napona baterije izvedeno je uporabom samog ATmega mikrokontrolera. Analogni ulazi mikrokontrolera rade tako da mjere napon od 0 do 5V referenciran masom i napajanjem mikrokontrolera. Napon baterije mjeri se tako da se njena negativna strana spoji na masu, a pozitivna na analogni ulaz mikrokontrolera.

D. *Disipiranje snage baterije*

Baterija se tijekom mjerenja kapaciteta mora prazniti zbog čega je potrebno ugraditi hladnjak jer MOSFET tranzostor ne može disipirati dovoljno energije baterije pretvorene u toplinsku energiju. Kako bi se mogle testirati relativno velike struje i snage ugrađen je aktivni hladnjak koji pomoću ventilatora forsira strujanje zraka kroz sam hladnjak te time povećava njegovu disipaciju. Ventilator hladnjaka može se programski isključiti prilikom mjerenja manjih snaga kako mi se uštedjelo na energiji baterija uređaja.

E. *Korisničko sučelje i prikaz podataka*

Navigacija kroz korisničko sučelje realizirana je pomoću potenciometra i dvije tipke (jedna za odabir, a druga za povratak). Položajem potenciometra odabire se što prikazati na ekranu prilikom mjerenje, te se njime unose različiti parametri (mjerenja struja, napon i sl.). Prikaz korisničkog sučelja i podataka realiziran je pomoću 16x2 LCD modula koji ima LED pozadinsko osvjetljenje. LCD modul sa ATmega komunicira pomoću modula za I2C komunikaciju pa je broj nožica potreban za rad modula smanjen sa 8 na 4.

F. *Spremanje podataka testiranja*

Spremanje podataka za detaljniju analizu realizirano je uporabom SD Arduino modula.(eng. *Secure Digital*) koji omogućuje jednostavno povezivanje Arduino sustava sa SD karticom. Podaci testiranja spremanju se u *.csv* tip datoteke na SD karticu koje se nakon testiranja može spojiti sa računalom. Na taj način mogu se vidjeti podaci testiranja i generirati grafovi koji sadrže iznose mjerene struje i napona u vremenu te ostale podatke.

G. *Napajanje uređaja*

Napajanje uređaja realizirano je pomoću dvije baterije tipa 18650. Pritiskom na sklopku za uključivanje sustava one su spojene na 5 V regulator napona koji se nalazi na Arduino pločici te na ventilator hladnjaka ako je spojen. Regulator dalje napaja ostale komponente. Potrošnja uređaja je oko 50 mA bez ventilatora i 150 mA sa ventilatorom.

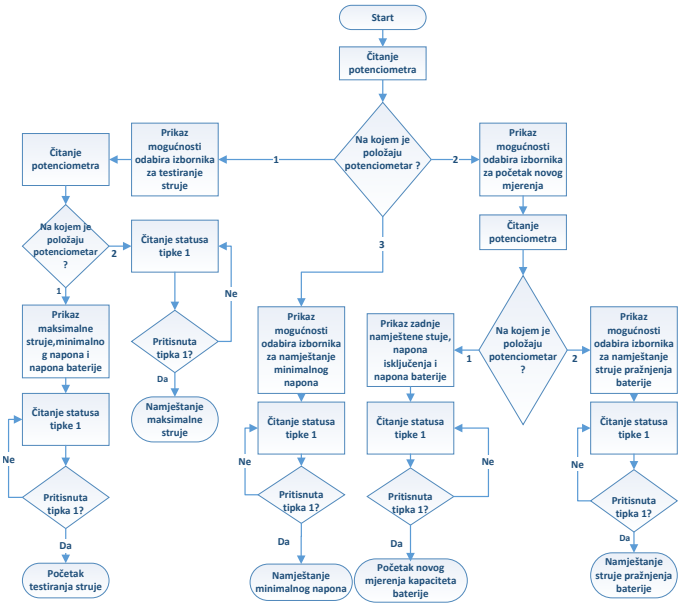
Dvije baterije 18650 koje napajaju uređaj spojene su u seriju tako da daju nazivni napon od 7,4V te imaju kapacitet od 2000 mAh. Uređaj je moguće napajati i preko 5V USB konektora koji se nalazi na Arduino pločici. Pritom treba pripaziti da napon bude točno 5V kako bi senzori mogli ispravno raditi.

IV. PROGRAMSKO RJEŠENJE

Programsko rješenje uređaja je izrađeno u Arduino aplikaciji. U ovom dijelu su ukratko opisane sve osnovne funkcije uređaja izvedene u programskom rješenju.

A. *Mjerenje kapaciteta baterije*

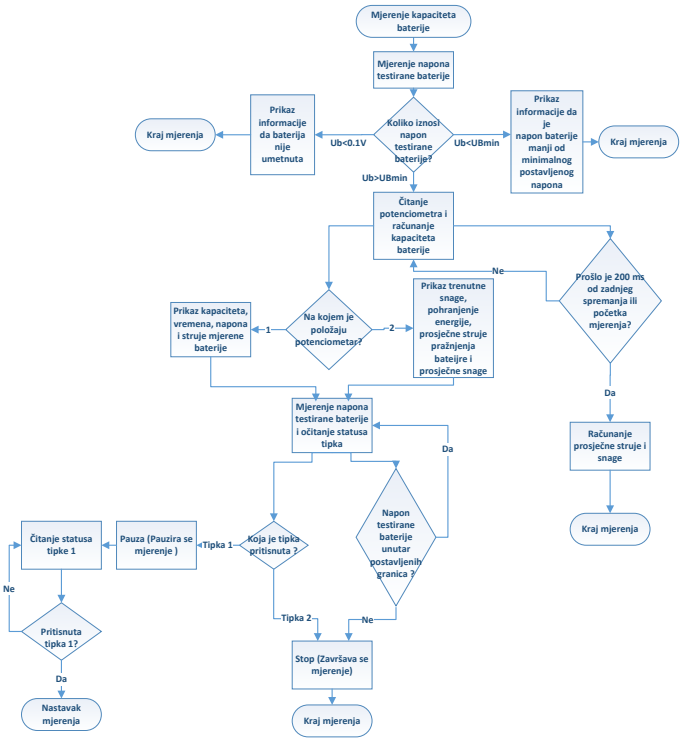
Prije početka mjerenja kapaciteta baterije potrebno je po potrebi namjestiti osnovne parametre kao što su struja kojom se baterija prazni odnosno napon do kojega se prazni. Pritiskom na tipku 1 u prikazu parametara postavljenih prvo se provjerava napon testirane baterije, te ako taj napon nije unutar postavljenih granica, mjerenje se odmah završava (Sl. 3.).



Slika 3. Dijagram toka potprograma korisničkog sučelja

Ako je napon unutar postavljenih granica tada počinje mjerenje te se svakih 200 milisekundi računa prosječna struja i snaga (Sl. 4.). Taj se iznos koristi za proračun kapaciteta baterije u mAh.

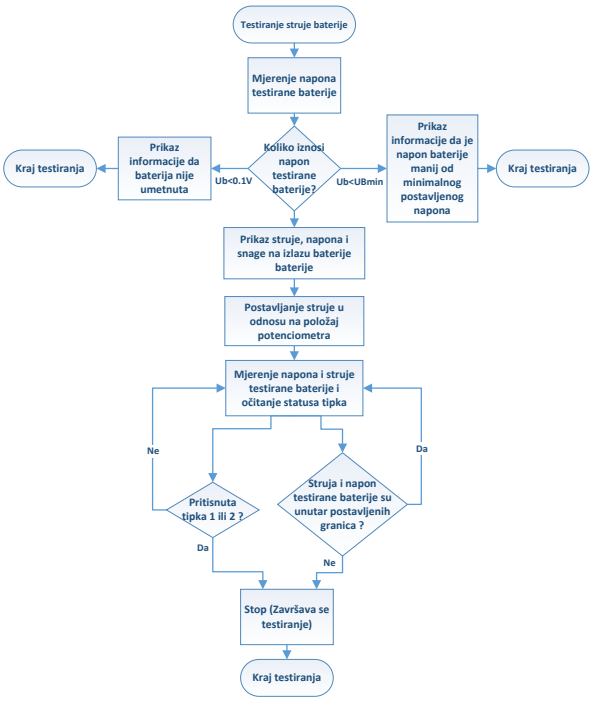
Mjerenje završava kada napon padne na postavljeni minimalni napon baterije. Svi izmjereni parametri se tijekom mjerenja spremaju na SD karticu.



Slika 4. Dijagram toka potprograma za mjerenje kapaciteta baterije

B. *Testiranje struja baterije*

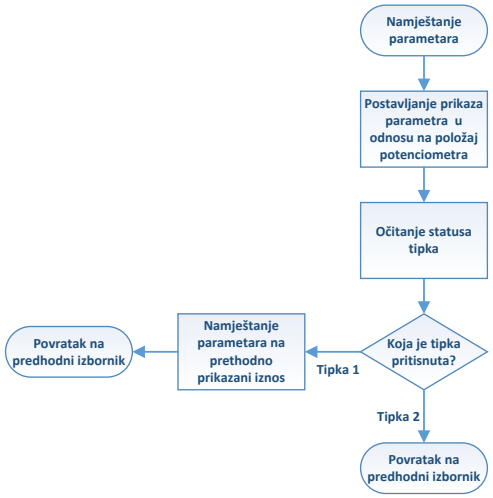
Prije samog početka testiranja struje baterije potrebno je po potrebi namjestiti maksimalnu struju pražnjenja i minimalni napon baterije za što je zadužen potprogram prikazan na Slici 3. Nakon toga se očitavaju napon i struja baterije te se ovisno o stanju baterije struja postavlja na željeni iznos. Ta se petlja vrti sve dok ručno ne prekinemo testiranje pritiskom na bilo koju tipku, dok napon ne padne ispod dozvoljenoga ili struja prijeđe postavljenu graničnu vrijednost (Sl. 5.).



Slika 5. Dijagram toka potprograma za testiranje struje baterije

C. *Namještanje i spremanje parametara*

Ako se neki parametar želi namjestiti korištenjem korisničkog sučelja prvo je potrebno doći do njegovoga prikaza u sučelju te pritisnuti tipku 1. Nakon ulaska u izbornik namještanja parametara čita se položaj potenciometra te u odnosu na njegov položaj ispisuje se iznos parametra na ekranu. Ako se pritisne tipka 1 parametar se postavlja na prikazanu vrijednost i prikaz se vraća na prethodni izbornik (Sl. 6). Ako se taj parametar sprema u EEPROM memoriju prvo ga je potrebno preračunati u vrijednost od 0 do 254 korištenjem funkcije "map()". Parametar se preračunava u vrijednost od 0 do 254 zato što je u EEPROM memoriju moguće spremiti samo broj unutar tih granica. Unutar EEPROM memorije moguće je spremiti i broj 255, ali on se koristi za provjeru je li išta spremljeno u memoriju. Ako se pritisne tipka 2, parametar ostaje na svojoj prethodnoj vrijednosti te se bez promjene parametara izvršava povratak na prethodni izbornik.



Slika 6. Dijagram toka potprograma za namještanje parametara

Prilikom svakog pokretanja očitava se EEPROM memorija. Ako u određenim mjestima u memoriji nije spremljen nikakav podatak tj. očitana vrijednost iznosi 255, taj podatak postavlja se na unaprijed određenu vrijednost (maksimalna struja baterije na 2,5 A i minimalni napon na 3 V). Ako je u očitanim mjestima u memoriji spremljen neki podatak isti se preračunava u spremljenu vrijednost.

D. *Mjerenje vremena*

Za mjerenje vremena u ovom rješenju korišten je sat (eng. *clock*) ATmega mikrokontrolera koji mjeri vrijeme otkada je mikrokontroler uključen. Kako bi se očitalo to vrijeme koristi se naredba "millis()". U programu nije ključno vrijeme proteklo od trenutka uključenja mikrokontrolera nego vrijeme proteklo od trenutka početka mjerenja. Prilikom početka mjerenja varijabla "previousMillis" izjednačuje se s trenutnim vremenom te se nadalje ona uspoređuje s tim trenutnim vremenom mikrokontrolera. Kada je njihova razlika jednaka odabranom intervalu (primjerice 1000 milisekundi kako bi se mjerila sekunda) izvršava se određena funkcija (kod mjerenja vremena sekunda se poveća za 1). Ova metoda mjerenja vremena ne koristi se samo za mjerenje vremena mjerenja kapaciteta baterije nego i za neke druge funkcije. Kada se prikazuju parametri mjerene baterije oni se ne prikazuju u realnome vremenu nego svakih 200 milisekundi koristeći ovu metodu mjerenja vremena. Pokazuju se svakih 200 milisekundi kako bi se izbjegla mutna slika radi prebrzih promjena brojeva.

V. EKSPLOATACIJSKE KARAKTERISTIKE UREĐAJA

A. *Testiranje struja baterije*

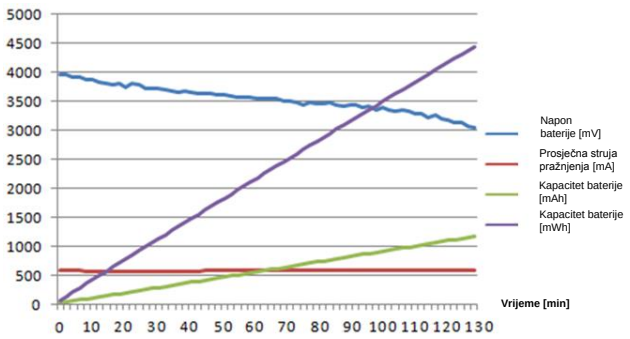
Uređajem se mogu testirati maksimalne izlazne struje 18650 baterijske ćelije te pad napona na određenoj struji. Potrebno je podesiti minimalni napon do kojega se želi opterećivati baterijska ćelija te maksimalna struja testiranja. Ovi parametri namještaju se kako se nehotice ne bi oštetila ćelija. Kada se pokrene mod rada "Test struje" potenciometrom je moguće regulirati izlaznu struju ćelije, a na ekranu mogu se pratiti njen iznos, napon i izlazna snaga baterijske ćelije. Usporedbom napona prije opterećenja određenom strujom i tijekom opterećenja određenom strujom može se ustvrditi pad napona na ćeliji uslijed opterećenja tom strujom.

B. *Donje balansiranje*

Ako se baterija želi donje balansirati potrebno je napon svih njenih ćelija spustiti na napon na kojemu se one smatranju praznima. Pomoću "Testa struje" ćelija moguće je kontrolirano prazniti baterijsku ćeliju. Ako se donja granica napona baterije postavi na napon na koji se namjerava balansirati baterija tada mod "Test struje" omogućuje spuštanje napona ćelije na taj napon budući da se struja automatski postavlja na nulu kada se dostigne taj napon. Kada baterija dostigne donji napon potrebno je malo pričekati da se napon na bateriji stabilizira, što obično znači da se i malo digne, te onda ponovno pustiti struju da se napon spusti. Taj postupak potrebno je ponavljati dok god se napon ne stabilizira na željenom naponu. Ako se struja postavi na veću od nule taj će se postupak automatski odvijati.

C. *Rezultati testiranja*

Na Sl. 7. je moguće vidjeti rezultate testiranja jedne baterijske ćelije oznake 18650 provedenog ovim uređajem. Korištena je mogućnost spremanja parametara ispitivanja na SD karticu kako bi se nakon testiranja generirao graf za pregled ispitivanja i očitanje rezultata. Uređaj je spremio podatak da je početni napon testiranje baterije bio 4176 mV. Dakle baterija je bila puna prije početka ispitivanja kako bi to i trebalo biti da bi se dobili što točniji rezultati.



Slika 7. Rezultati testiranja baterijske ćelije oznake 18650

Moguće je uočiti da je napon baterije u prve dvije minute pao na 4,0 V. Nakon toga napon je relativno konstantno padao do 120. minute nakon čega je počeo brže padati. Na 3,0 V prekinuto je mjerenje kao što je bilo podešeno u postavkama uređaju. Pritom je prosječna struja bila oko 550 mA, te da je kapacitet u mAh i mWh linearno rastao s vremenom kao što se i očekuje.

VI. ZAKLJUČAK

U radu je prikazan razvoj uređaja koji uspješno testira kapacitet i performanse baterijskih ćelija oznake 18650. Ćelije je moguće testirati pod raznim opterećenjima, na ekranu nadzirati parametre koji se testiraju, te nakon testiranja generirati graf kako bi se vidjelo ponašanje ćelije u vremenu.

Kontrola struje pražnjenja baterije izvedena je njenim mjerenjem i kontroliranim povećanjem vođenja MOSFET tranzistora dok ona ne dođe na željeni iznos. Cijelo to vrijeme mjeri se napon testirane ćelije kako on ne bi pao ispod minimalnog napona ćelije, te kako bi se vidjelo ponašanje napona u odnosu na struju.

Prilikom izrade uređaja do problema je došlo je kada je ponestalo memorije na ATmega mikrokontroleru. Program je trebalo što efikasnije napisati i broj funkcija se trebao smanjiti samo na osnovne potrebne za ispravan i koristan rad uređaja kako bi program stao na memoriju mikroprocesora.

Nedostaci uređaja su spremanje više različitih parametara u memoriju zbog nedostatka iste i mogućnost kalibriranja uređaja pomoću korisničkog sučelja. Nedostaju i neke funkcije uređaja kao što je testiranje kapaciteta baterije pražnjenjem konstantnom snagom. Rezolucija spremanja podataka na SD karticu je samo dvije minute radi nedostatka mogućnosti generiranja grafa s više parametara u Excelu zbog čega bi bilo praktičnije koristiti MATLAB. Uređaj je ograničen na testiranje samo baterijskih ćelija oznake 18650 jer samo one fizički stanu u uređaj, a i sve funkcije napravljene su s njima u vidu pa se tako ne mogu testirati struje pražnjenja veće od 15A i baterije čiji naponi ne iznose oko 4V.

Rezultati mjerena pokazuju ponašanje napona ćelije u vremenu tijekom konstantnoga opterećenja i na kraju mjerenja njen kapacitet u mAh i mWh. Uvidom u te podatke može se ustvrditi kako i za što koristiti tu ćeliju. Testiranjem struje vidi se pad napona ćelije pod određenim opterećenjem i je li ta ćelija pogodna za određeno opterećenje.

Sklopovska i programska rješenja iz ovoga rada mogu se koristiti za daljnji razvoj toga uređaja ili pak za promjenu primjene istoga. Može se dodati mikrokontroler s više memorije kako bi se dodale funkcije. Moguće je i dodavanje funkcije istovremenog testiranja većeg broja ćelija, te punjenje istih prije mjerenja kako bi očitanje bilo što točnije. Potrebno je korištenje nekih drugih aplikacija za generiranje grafova što bi omogućilo stvaranje grafova veće rezolucije radi detaljnije analize ćelije.

Abstract - This paper presents several layout optimizations in order to decrease both, internal power and area of digital standard cells. Since D flip flop (Dff) represents a large part of digital area, post-layout simulations have been performed on this cell designed with advanced design rules and lower widths. Results show that internal power of Dff is reduced by 20 % during rising and falling transitions of output Q. Moreover, the area of Dff is reduced by 20 % for similar clock to Q propagation delays. Indeed, a new process has been developed and I_{ON} current is improved by 15 % and 50 % for respectively NMOS and PMOS transistors which permits to reduce the width of MOSFETs.

Keywords – Low power, standard cells; D flip flop, design rules, drive current enhancement, strain silicon

I. INTRODUCTION

Nowadays, many applications based on microcontrollers require more processing speed and less dynamic and static consumption to increase battery life-time of mobile applications such as tablets, smartphones, and laptops. The most effective way to decrease consumption of digital CMOS Integrated Circuits (ICs) is to reduce the supply voltage V_{DD} and all capacitances contributors such as routing and MOSFETs intrinsic capacitances [1], [2]. Moreover, in order to reduce the cost by microcontroller, marketers and designers are very interested in decreasing the surface area filled by the digital logic of the circuit to improve their density of integration. The aim of this paper is to study the possibility to reduce both, internal power and area of standard cells by remaining on same technological node.

This work focuses on low voltage MOSFETs devices used in standard cells and manufactured in conventional e-NVM (embedded non-Volatile Memory) CMOS 80 nm process with compressive Shallow Trench Isolation (STI) oxide, gate oxide thickness of 2.1 nm, dual doped polysilicon gate, pocket implants, and compressive Contact Etch Stop Layer (CESL).

This paper is presented as fallow: section 2 will present several layout improvements which could be used in standard cells and section 3 will show internal power and area gains obtained on D flip flop (Dff) designed with new optimized design rules. Finally, last section will give some concluding remarks.

II. LAYOUT OPTIMIZATION STUDY

A. Hammer Head Removal

In order to decrease internal power and area in standard cells, the minimum width (W_{MIN}) of transistor have to be used as far as possible, especially when timing is not predominant. However, with conventional 80 nm design rules, designers have to insert an active Hammer Head (HH) in source and drain regions (S/D). This solution increases the length of the transistor by 28 % due to the distance gate to active, as shown in Fig. 1. Hense, minimal width is not currently used in standard cells as demonstrated on classical MCU digital circuit in Fig 2. 24 % of PMOS and 35 % of NMOS transistors are designed with a higher dimension in order to avoid an increase of the standard cells area with HH layout.

In this part, we are studying the possibility to remove HH while maintaining a high level of process robustness. For that, chain resistance of more than 12 000 contacts in series is measured on several devices designed with different active widths (W_{ACT}), as presented in Fig. 3.

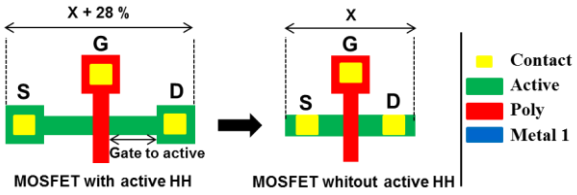

Fig. 1: Layout of MOSFETs with or without active hammer head

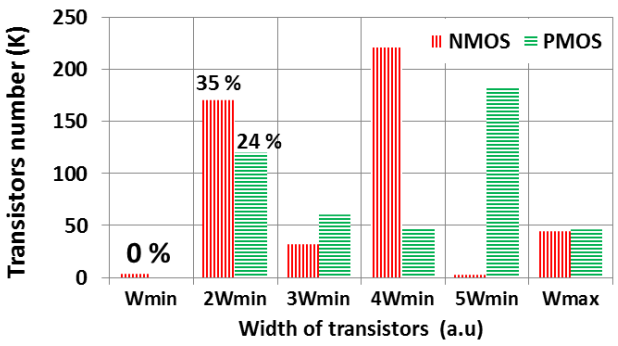

Fig. 2: MOSFETs distribution of classical digital circuit

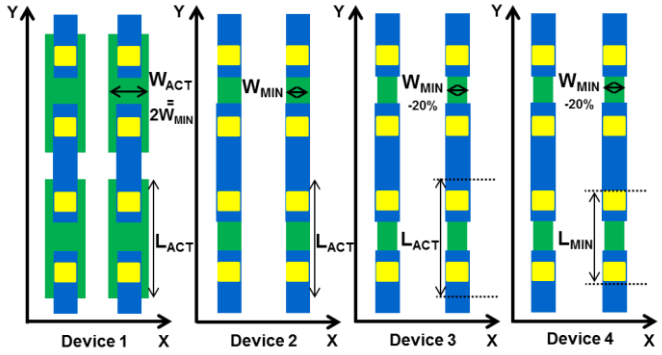

Fig. 3: Layouts of different contact chain resistances

In device 1, no HH is necessary to contact S/D regions because $W_{ACT} = 2W_{MIN.}$ However, HH has to be inserted in devices 2, 3 and 4 with lower $W_{ACT} = W_{MIN-20\%}$. Device 4 will be the most aggressive layout without contact enclosure in W and L directions. As depicted in Fig. 4, the contact resistance increases when W_{ACT} is reduced due to the increase of the active finger resistance. No effect of distance L_{ACT} is observed between device 3 and device 4 without any contact enclosure. As a consequence, the contact resistance is stable without outliers regardless of W_{ACT}. Moreover, a similar study was done with overlay matrix trials in W and L directions in order to prove the manufacturability.

In order to estimate the intrinsic change induced by the modifications, threshold voltage (V_T), saturation (I_{DSAT}), linear (I_{DLIN}) and drain leakage (I_{OFF}) currents have been measured. Poly HH is also removed (Fig. 5). I_{DSAT} currents of all devices are aligned, no change is observed between NMOS and PMOS with or without HH as shown in Fig. 6. I_{OFF} current is also plotted in Fig. 7 and remains unchanged.

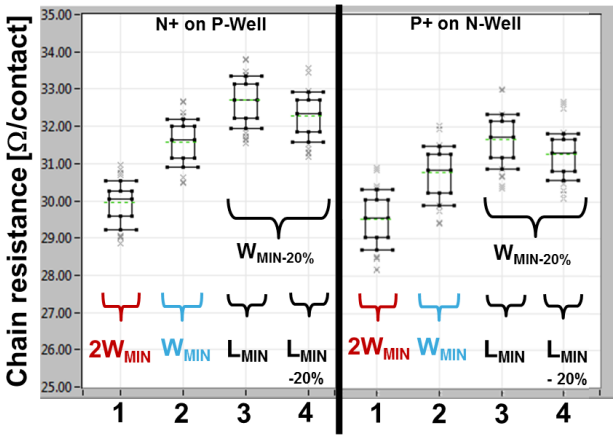

Fig. 4: Contact resistance of devices on N-well and P- well actives

Fig. 5: Layout of devices with or without active and poly HH

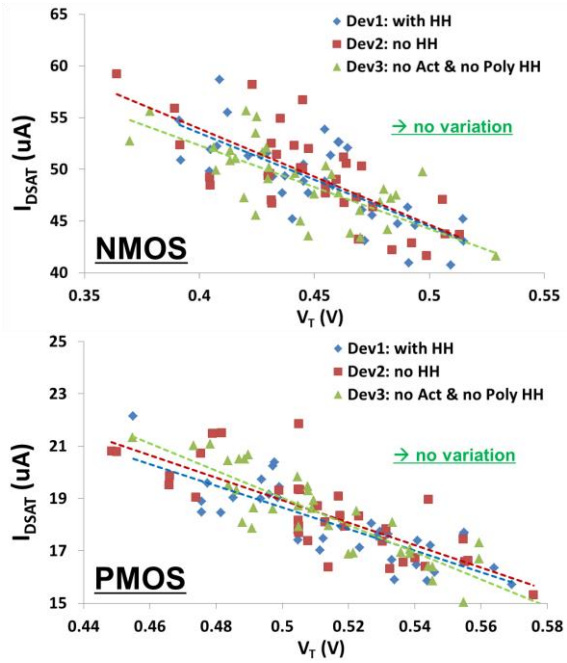

Fig. 6: $I_{DSAT}(V_T)$ for different layouts

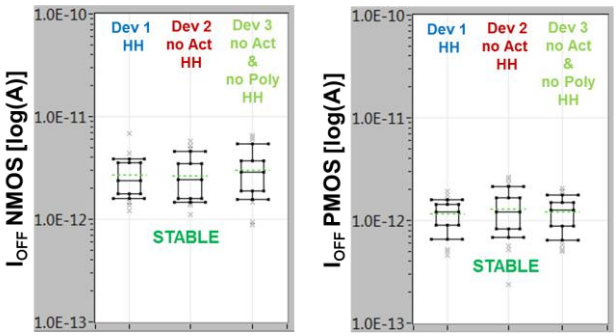

Fig. 7: Leakage currents (I_{OFF}) of NMOS (left) and PMOS (right)

Then, CMOS inverters Ring Oscillators (ROs) [4] are used to confirm the dynamic behavior of different layouts presented in Fig. 8. The clock frequency (F_{RO}) detailed in (1) is measured and compared between reference RO1 with HH and others ROs without HH. Where n is the number of CMOS inverters, I_{DYN} the dynamic current, V_{DD} the supply voltage and T_D the period of oscillation.

$$F_{RO} = \frac{1}{2.n.T_D} = \frac{I_{DYN}}{2.n.C_{LOAD}.V_{DD}} \qquad (1)$$

As observed in Fig. 9, ROs frequency is 5 to 7 % higher thanks to the reduction of S/D diffusion capacitances. Indeed, the load capacitance (C_{LOAD}) is essentially represented by the intrinsic MOSFETs capacitance (gate and diffusion). A slight reduction of these capacitances induces a decrease of C_{LOAD} and then an increase of the frequency. Finally, frequency is slightly decreased between RO2 and RO3 due to the increase of gate to contact capacitance. In conclusion, robustness and manufacturability of HH removal have been demonstrated. It confirms the ability to use minimal width in digital standard cells.

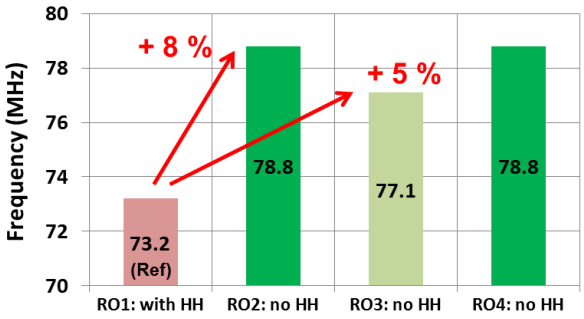

Fig. 9: Frequency gains regarding RO1

B. *Move Gate Contact over Active Area*

As previous analyse proven the ability to remove poly HH, gate contact could be directly placed over active area instead of over STI. To our knowledge, this innovative design approach has never been reported and manufactured yet. The reliability of this optimization has been demonstrated in a previous work and the main parameters of MOSFETs remain unchanged [5].

The layout with gate contact over active is presented in Fig. 10. It allows reducing significantly the height of the transistor and could be interesting in specific standard cells. I_{DSAT} versus V_T is plotted with gate contact over active and STI for typical W. no difference is observed for PMOS transistor in Fig. 11 while an insignificant reduction is observed for NMOS (- 1.5 %) in Fig. 12. It could be due to the tensile strain added on the channel during tungsten deposition. Indeed, it has been demonstrated that tensile strain in "out of plane" direction of the channel decreases the carriers mobility of NMOS and enhances the carriers mobility of PMOS [6], [7]. It means that compressive stress in the NMOS channel is more important when the gate contact is filled over active area instead of over STI. I_{OFF} current is also plotted in Fig. 13 and remains unchanged.

RO frequency has been measured and plotted in Fig. 14. All tested dies (30) on wafer are functional. As expected, the speed is slightly decreased by 1.4 % for $W = 2W_{MIN}$ and by 3.4 % for $W = W_{MIN}$, probably due to the NMOS mobility reduction.

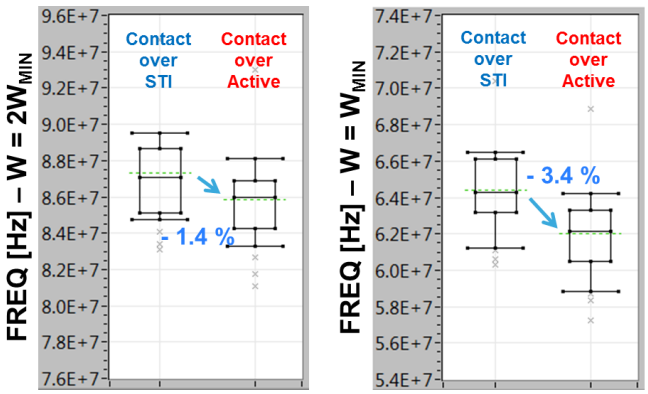

Fig. 14: ROs frequency with or without gate contact over active area

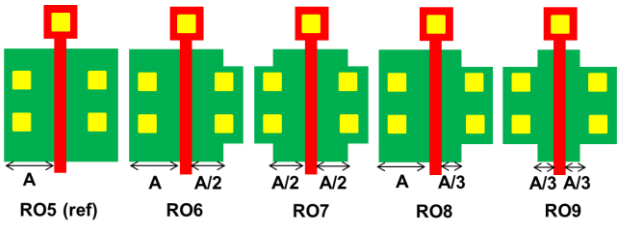

Fig. 15: MOSFETs layouts inside ROs for S/D capacitances reduction

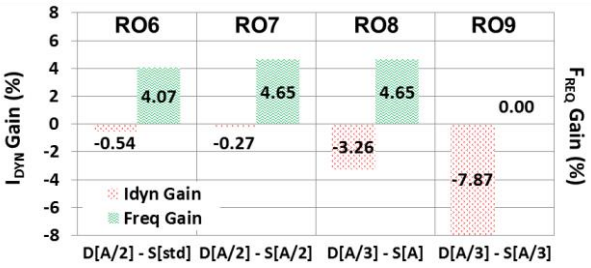

Fig. 16: Dynamic current and frequency gains regarding RO5

C. *Source/Drain Capacitances Reduction*

In order to decrease dynamic current, all capacitances contributors need to be scaled. When C_{LOAD} is mainly composed by intrinsic MOSFETs capacitance, a slight reduction of S/D capacitances allows decreasing dynamic current without impacting RO frequency. Therefore, different layouts are proposed in Fig. 15. The other benefit of this technique is to take advantage of mechanical stress coming from the STI to enhance the mobility of PMOS transistors [7]–[9]. Nevertheless, it will decrease the mobility of NMOS. As presented in Fig. 16, RO frequency is increased thanks to the reduction of diffusion capacitances. By moving active S/D distance from A to A/3, RO5 frequency is equivalent to RO1 while the dynamic current consumed is reduced by 8 % as show Fig. 16.

III. Internal Power and Area Gain

In a previous work, a new process has been developed in order to improve drive current (I_{ON}) of MOSFETs. I_{ON} is improved by 15 % and 50 % for respectively NMOS and PMOS transistors at same I_{OFF} [3]. We use 45° rotated substrate and very high tensile CESL (Contact Etch Stop Layer) to respectively enhance hole and electron mobility [6], [7]. In addition, EOT engineering has been performed and it resulted in using decoupled plasma nitridation process in order to improve MOSFETs performances through a reduced EOT and therefore a better gate electrostatic control without degrading gate leakages. With the use of different mobility boosters, active widths could be reduced in standard cells to decrease internal power and area without impacting the propagation delays.

Since, it represents 40 % of digital area in classical MCU circuit, a new D flip flop (Dff) contained 40 transistors is layouted with lower active widths and optimized design rules reminded in Fig. 17. Poly end-cap distance (E) and gate contact to active distance (S) are also reduced. Dff schematic is presented in Fig. 18. In a first trial, up to 20 % of area reduction is obtained as displayed in Fig. 19 with active and poly layers visible. It appears that routing wires (polysilicon/metal1) and gate contacts could be different between reference and new Dff.

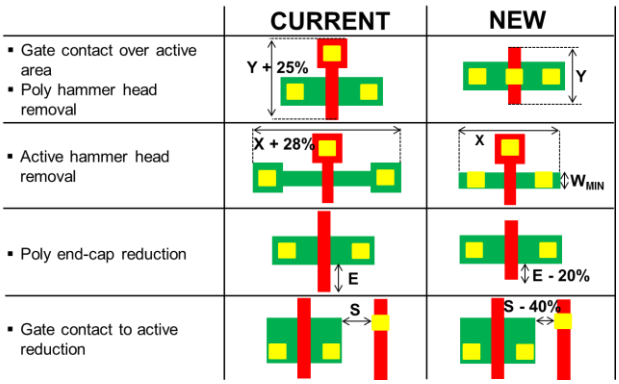

Fig. 17: Summary of optimized design rules

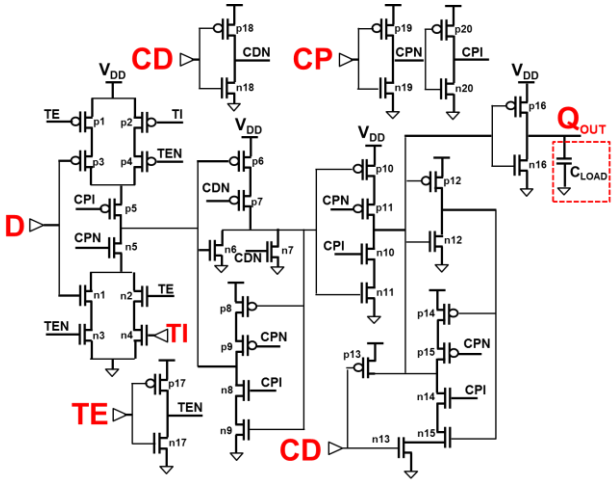

Fig. 18: Schematic of D flip flop

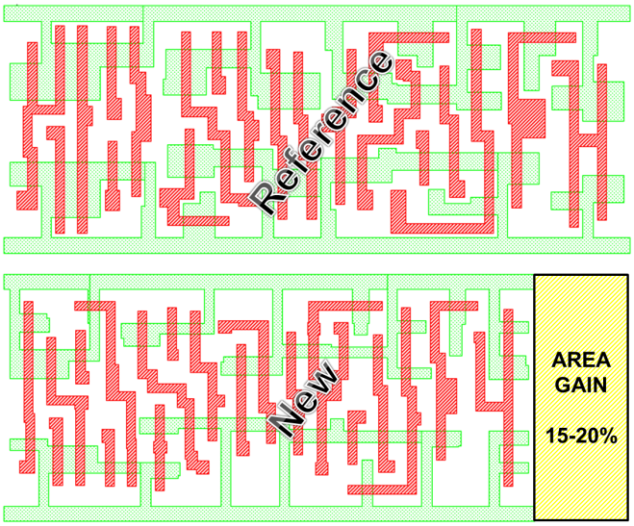

Fig. 19. Layout comparison between reference and new D flip flop

Spice post-layout simulations with RC parasitics have been performed on reference Dff with current model card and new Dff with new model card based on electrical values of new optimized process parameters (I_{DSAT}, I_{DLIN}, I_{OFF}, V_T). It appears that internal power of new Dff is reduced by almost 20 % during rising and falling edges of output Q as shown in Fig. 20. It is mainly due to the reduction of MOSFETs width by 40 % to 50 %. Moreover, clock to Q delay is reduced by 10 % for typical value of C_{LOAD} and by 5 % for maximum value of C_{LOAD} during falling edge. During rising edge, Clock to Q delay remains stable between current and new Dff (~-2%). The gains are presented in Fig. 23 and Fig. 24. These results show that propagation delays remain unchanged for all specified values of C_{LOAD} given by digital library. The propagation delay clock to Q is defined in digital library as the time interval between the input stimulus crossing the threshold of 40 % of V_{DD} for the rising signal and 60 % of V_{DD} for the falling signal. These times are reminded in displayed in Fig. 20. Internal power consumed during rising and falling transitions are calculated using (1) and (2)

$$E_{INT\_RISE} = V_{DD}.\int I_{VDD\_ALIM} - C_{load}.V_{DD}^2 \quad (1)$$

$$E_{INT\_FALL} = V_{DD}.\int I_{VDD\_ALIM} \quad (2)$$

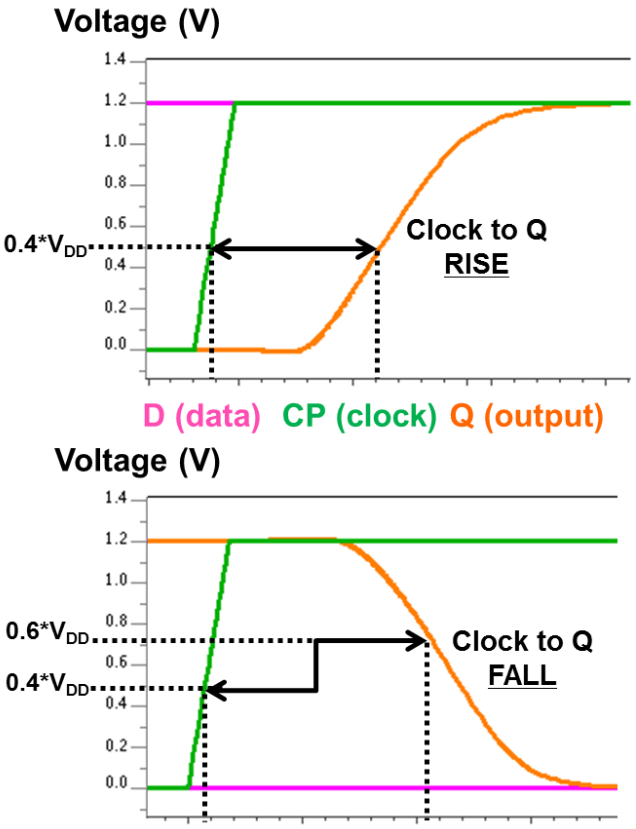

Fig. 20: Definition of clock to Q delays during rising and falling edges

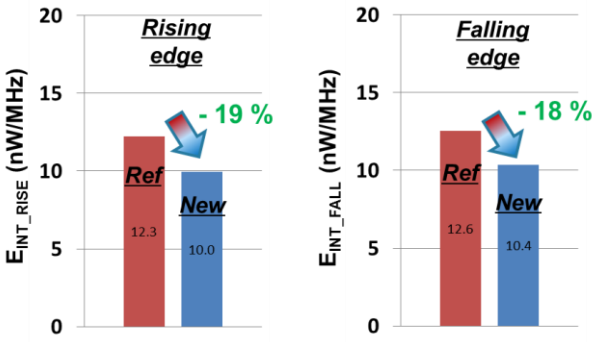

Fig. 21: Internal power gain between reference and new Dff

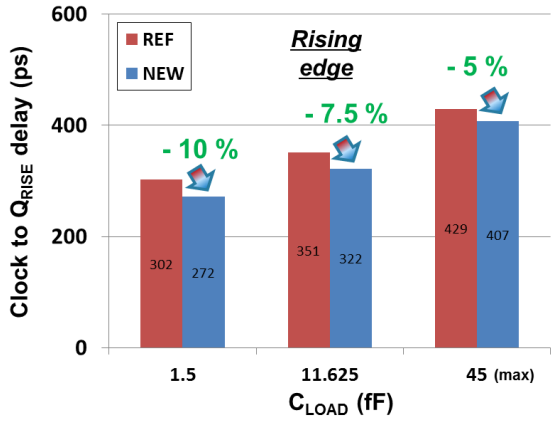

Fig. 22: Clock to Q gain during rising edge

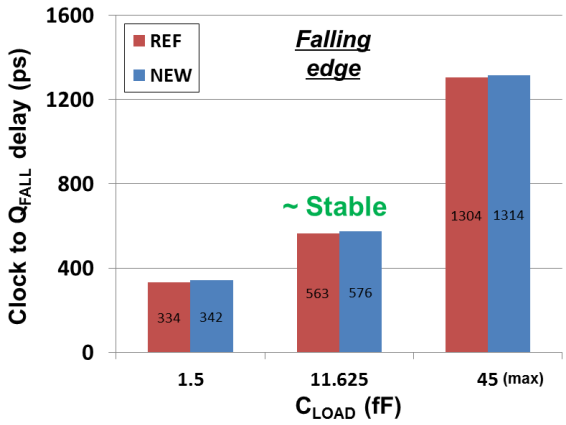

Fig. 23: Clock to Q gain during falling edge

Finally, Monte Carlo (MC) simulations have been performed in order to study the local mismatch variation between reference and new Dff. as observed in Fig. 24 and Fig. 25 for 1000 runs, the standard deviation of clock to Q delays is almost similar between reference and new Dff,. Insignificant increase (~2%) is observed during rising and falling transitions, probably due to lower transistor width. Indeed, the standard deviation of a threshold voltage ($\sigma\Delta V_T$) is inversely proportional to the transistor area [10].

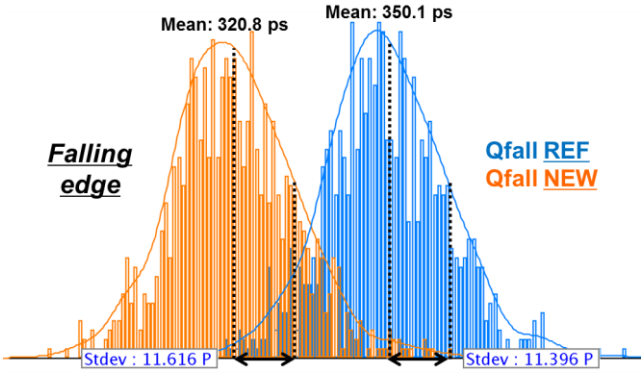

Fig. 24: Standard deviation of clock to Q during falling transition

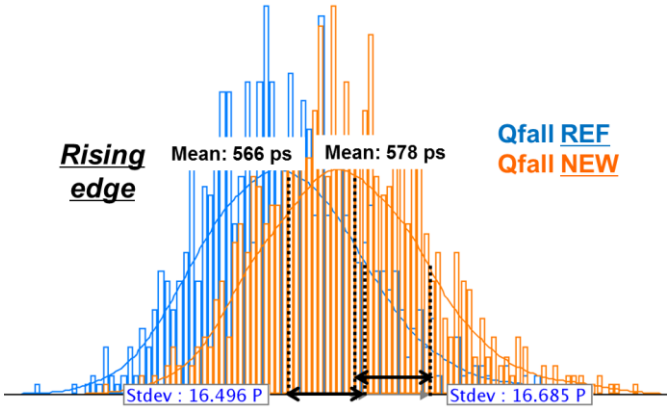

Fig. 25: Standard deviation of clock to Q delay during rising transition

IV. Conclusion

In conclusion, this work demonstrates the ability to reduce internal power of D flip flop designed in CMOS 80 nm e-NVM technology by 20 % without outliers. For that, active widths of transistor have been reduced by 40 % to 50 % and propagation delays remain unchanged thanks to the use of high mobility process features. Moreover, all layout optimizations performed on low-voltage MOSFETs used in digital standard cells were presented in this paper. For a first time, we proved the possibility to place gate contact over active area instead of STI area and remove hammer heads without any change in MOSFETs performances. All optimizations were embedded to design a new flip flop and up to 20 % in area reduction was obtained in a first trial.

Most importantly, the methodology presented in this paper could be reused with the most recent technologies in order to reduce internal power and area of digital standard cells.

Abstract - This paper presents a simple architecture for clock-fault detection in high-speed applications. The overall principle consists in converting a possible error of time to a logic voltage level. When a high voltage level is present at the output, a reliable clock is detected whereas a low voltage level implies a clock error. This detection system is intended for all System-on-Chip such as microcontrollers which use external clock from 4 MHz to 50 MHz. The proposed circuit is realized in CMOS 40 nm process technology. Simulation results prove the suitability of the structure and its integration on silicon is strongly considered by clock error detection in integrated circuits.

Keywords— Clock-fault detection, High-Speed Circuits, Clock error, Peak detector, Crystal oscillator

I. INTRODUCTION

Nowadays, microcontrollers and more generally System-on-Chip (SoC) are characterized by theirs high level of integration, and theirs very low power consumption. The increase of frequency in these chips is also a point to be noticed so as to drive high-speed applications. The clock is one of the predominant elements in a microcontroller. Indeed, it allows the processor to latch the data at the desired frequency and synchronize communication. So, a very well quality of the input clock is required in order not to impact the entire clock system distribution. A Phase-Locked Loop (PLL) is usually used to generate stable divided frequencies to synchronize signals in the core [1]. A clock default could have very bad effects on the overall performances of the microcontroller and that is why it is absolutely imperative to monitor the input clock.

Clock references for microcontrollers can be internal or external. A clock multiplexer tolerates a clock switching [2]. To avoid some potential clock errors, it exist some clock fault detection techniques to inform that the clock is not decent. Some of these techniques are mentioned in the literature for many field of application. Triple modular redundancy (TMR) [3] and N-tuple modular redundancy (NMR) [3][4] are commonly designed in fault tolerant computer systems. Considering the dimensions of integrated circuits, these architectures are too area-consuming. Most common techniques use the properties of some elementary components such as capacitor and MOS transistors to realize the clock detection [5][6]. The main advantages of this implementation are low area, low consumption and very easy integration.

The clock fault detection architecture presented here is based on the time-to-voltage converter as already employed [5][7]. The paper is organized as follows. Section II presents the general architecture of the system. The circuit implementation with its major features and some simulation results are described in section III and IV respectively. Conclusion is drawn in the last section.

II. ARCHITECTURE

Different ways allows providing clock in microcontrollers: Internal clock based on electrical phase-shift such as RC oscillators which can operate in a wide frequency range and external clock coming from mechanical resonant devices such as crystal and ceramic resonator. The external clock can be also originated from another chip. This paper is only focused on high-speed clocks from 4 MHz to 50 MHz. The simplified representation of the clock detection system is depicted in Fig. 1. It is composed of a multiplexer and the clock detector which is enabled with the bit EN_CKD.

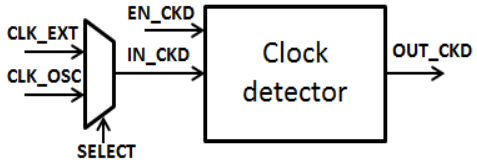

Fig. 1 Simplified representation of the clock detection system

The clock source is determined by programming the selection bit SELECT. The type of clock depends on the application. It is determined by a combination of features including power consumption, operating frequency, accuracy, cost and environmental requirements. The multiplexer enables choosing between an external clock CLK_EXT and the oscillator clock CLK_OSC. A flag OUT_CKD = '1' is generated when a clock faster than 4 MHz is present whereas OUT_CKD = '0' for the other cases of input signal. In an ideal world, the node IN_CKD is a perfect full swing square wave with 50 % duty cycle. In reality, the received clock can be damaged

for many reasons. Interferences, cross-talk, noise coupling, jitter noise, bad electrical connections on the external board or a design problem are the main causes of clock defaults. Few examples of received clocks are shown in Fig. 2. Other types of undesired clocks such as clock deletion in low and high half-cycle or in full period exist. In these cases, a recovery circuit is used in addition to the clock detector to reassemble the clock [8].

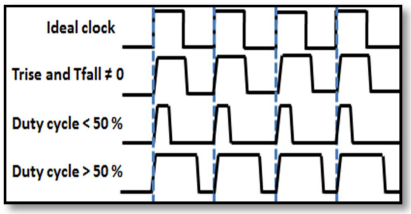

Fig. 2 Example of received clocks

So, the functionality of the clock detector is mandatory in order to inform the core that the input clock is defaulting. In the case where mechanical resonant oscillator with a good clock signal is snatched out of the board, the clock detector is able to detect it with no consequence on the clock distribution network.

III. Circuit Implementation

A. Block diagram of the proposed circuit

The circuit received an analog clock in input. Firstly, the signal is digitized to pull up to logic '1' or pull down to logic '0'. Then, the clock is filtered to delete the continuous current component in case of an input continuous voltage. A level detector is added to compare a charged value to a threshold voltage. Finally, a decision is done in function of the detection level result. So, the input analog clock is converted to voltage level equals to logic '1' when a clock is present, or logic '0' when there is no clock. The block diagram of the circuit is presented in Fig. 3.

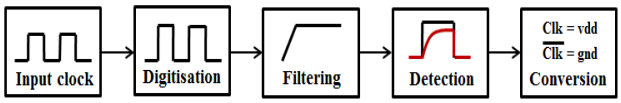

Fig. 3 Block diagram of the proposed circuit

B. Detection circuit

The complete detection circuit is made of elementary components with 12 transistors which form 3 buffers, 1 diode, 2 resistances and 2 capacitances. The circuit is composed of two basic analog functions including a high-pass filter CR and an envelope detector. The operating of the different functions for this detection circuit is explained in the following. The circuit is shown in Fig. 4.

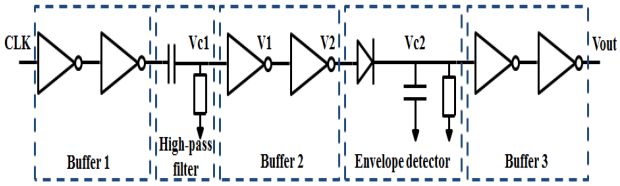

Fig. 4 Detection circuit

C. Envelope detector

The envelope detector circuit is usually used for amplitude demodulation. The circuit is composed of three passive components, a diode D, a resistance R, and a capacitance C. The circuit is represented in Fig. 5.

During the high half-cycle of the input signal, D is forward-biased and C quickly loads. When the low half-cycle occurs, D is reverse-biased and C slowly unloads in R. The time constant $\tau = RC$ must be quite high to ensure a slow unload of C through R between two high half-cycle. So, R and C values must be chosen to be functional on the whole frequency range. The circuit response to a 4 MHz square wave input with a rise time and a fall time equal to 100 ps is shown in Fig. 6.

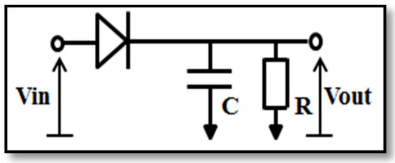

Fig. 5 Envelope detector circuit

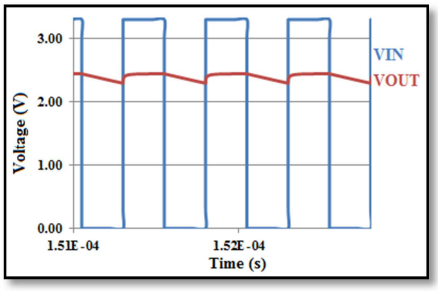

Fig. 6 Response of the envelope detector circuit

D. High-pass filter

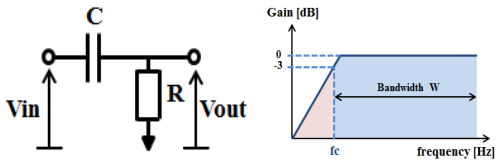

Fig. 7 High-pass filter with its frequency response

A 1st order passive high-pass filter composed of a series capacitance C and a resistance R tied to ground is used to block any DC input signal. In our case, it enables blocking input DC voltage upper to the threshold voltage of the diode present in the envelope detector circuit. At low frequencies, the capacitance acts as an open circuit because its reactance is very high. The filter blocks all input ac signals until the cut-off frequency f_c which is defined by R and C values (1).

$$f_c = \frac{1}{2\pi RC} \tag{1}$$

To be compliant with specifications, the cut-off frequency is fixed at a bit fewer than 4 MHz. The high-pass filter response with a 4 MHz and 48 MHz square wave input signal is shown in Fig. 8 and Fig. 9. The output waveform consists in two spikes, one positive on

rising edge and one negative on falling edge. The higher the input frequency will be the output signal will look like to the input signal because the capacitance has no time to be unloaded in the resistor.

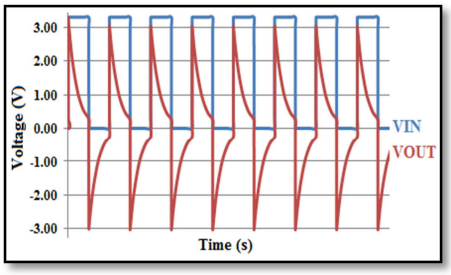

Fig. 8 CR response with 4 MHz square wave input

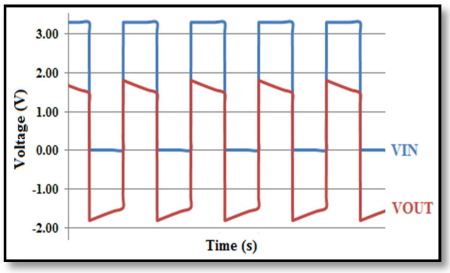

Fig. 9 CR response with 48 MHz square wave input

E. Clock buffering

Three buffers are present in the complete circuit of the clock detector as shown in Fig. 4. Each one has its own property. The first buffer is largely inserted to improve the input signal strength in case of damaged input clock. The aim is to be sure to pull up a high half-cycle to the power supply and to pull down a low half-cycle to the ground. The role of the second buffer is to amplify the output of the high-pass filter. Since the series capacitance cuts the DC current, the signal Vc1 must be amplified. As Vc1 can be a negative voltage, the threshold voltage of the second buffer is shifted by increasing the NMOS dimensions. Consequently, the threshold voltage is lower than Vdd/2 as shown in Fig. 10. In our case, a good trade-off is found at about Vdd/4. This value allows operating the circuit for all process cases and an input voltage range from 1.8 V to 3.6 V.

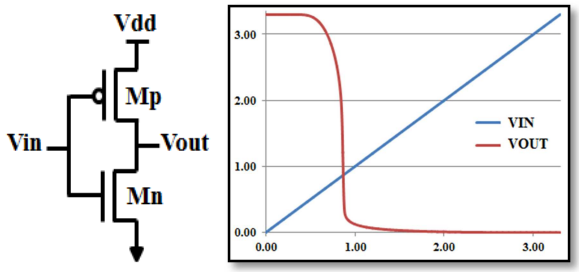

Fig. 10 CMOS inverter with its characteristics

The third buffer is placed after the envelope detector circuit. It allows ensuring a decent output level. It also provides an output signal intended for the core of the microcontroller in order to ensure the clock synchronization in the system or not.

IV. Simulation Results

The whole circuit is implemented in CMOS 40 nm process technology. All simulations are done with Eldo simulator. The voltage range is from 1.8 V to 3.6 V and three temperatures are tested. The process cases include slow, typical, and fast transistor models. The circuit is able to operate on the frequency range from 4 MHz to 50 MHz. The simulation results are shown below to demonstrate the good operating of the circuit in case of typical clock, with low and high half-cycle.

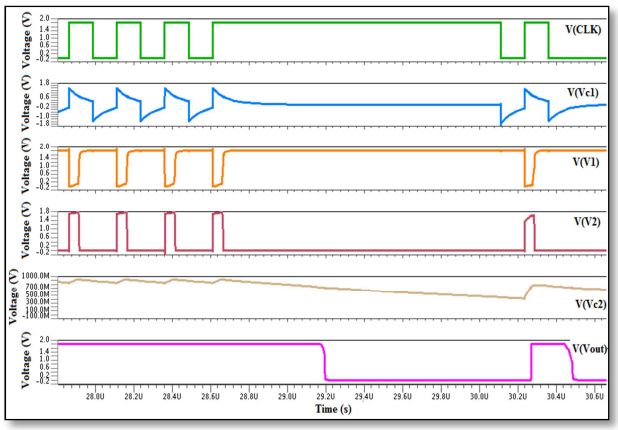

Fig. 11 Waveforms for a long high cycle with a 4MHz input clock at 1.8V in typical conditions

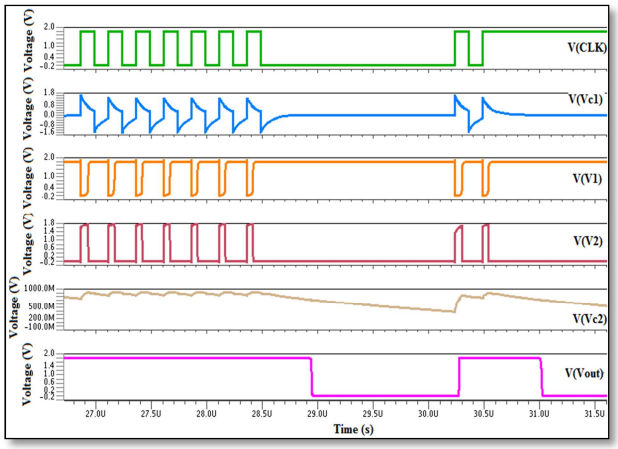

Fig. 12 Waveforms for a long low cycle with a 4MHz input clock at 1.8V in typical conditions

In both cases, when a long high cycle or a long low cycle occurs, V1 is pulled up to ‘1’. The node Vc2 slowly decreases and when the voltage is enough low, it reaches the threshold voltage of the following buffer. Then, the conversion is done. There is no clock anymore and Vout is equal to ‘0’.

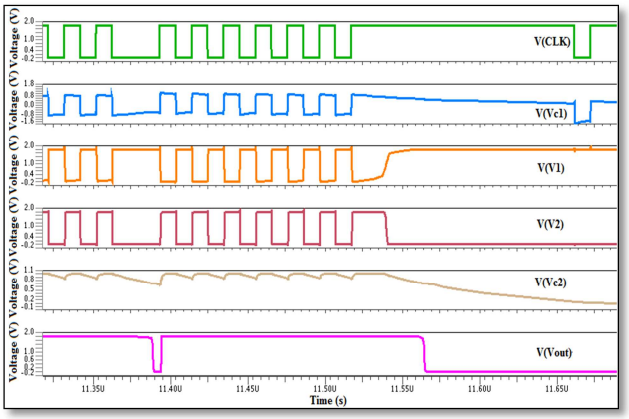

Fig. 13 Waveforms with a 48MHz input clock at 1.8V in typical conditions

The circuit is designed to address all types of mechanical resonator. The frequency range of these components for high frequency applications is about from 4 MHz to 48 MHz. So, the case with a 48 MHz input clock is shown in Fig. 13. The results seem similar to the previous result with a 4 MHz input clock. A long high state level is detected as a default by the circuit. If the clock is regenerated, then the output voltage switches its state to '1'.

The Fig. 14 shows the case where the input is very slow. The output reacts to a rising edge of the input. As the clock stays unchanged, Vc2 decreases and the output voltage goes back to '0'.

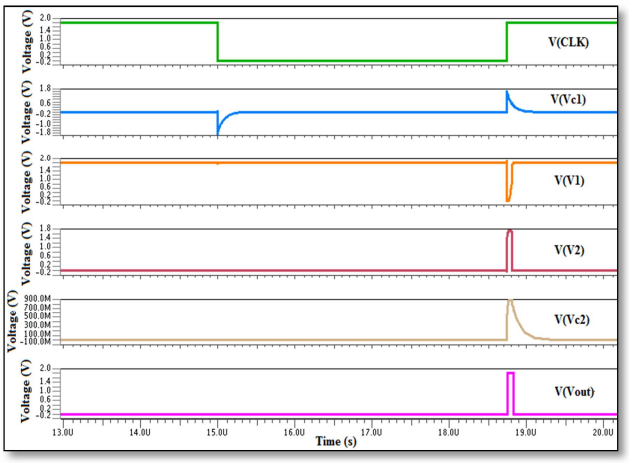

Fig. 14 Waveforms in case of slow input clock at 1.8V in typical conditions

All process cases have been simulated and the circuit operates quite well. The min and max DC consumption is written in the conclusion. The major limitation of this circuit is the presence of the diode which implies a voltage drop on Vc2. It would be a problem if the supply voltage is highly decreased. Nevertheless, the circuit offers a good trade-off between the consumption of area and the specifications.

V. Conclusion

In this paper, an analog circuit for clock detector has been introduced in 40 nm process CMOS technology. The principle is based on amplitude demodulation with an envelope detector circuit. Simulation results show the suitability of the circuit. An error of time is converted to a voltage level. The proposed circuit presents some advantages including very low area-consuming and very low power consumption in particular. It operates from 1.8 V to 3.3 V between -40 °C and 125 °C. The circuit is able to detect a clock default for the frequency range from 4 MHz to 50 MHz. The architecture covers the main clock defaults and can be associated with an integrated recovery circuit.

Table 1 Summary of the main clock detector performances

Supply voltage [V]	1.8		3.6	
Process	Slow		Fast	
Frequency range [MHz]	4	48	4	48
DC consumption @ -40°C [µA]	19.76	36.65	101.52	121.10
DC consumption @ 25°C [µA]	17.09	33.62	90.01	110.48
DC consumption @ 125°C [µA]	15.41	31.13	76.83	99.38

***Abstract*—Often one of the biggest practical challenges in parallel programming is choosing the right algorithm for a particular architecture, that is choosing the right architecture for a particular algorithm. In this paper, we discuss the differences between the behavior of one relatively simple algorithm, the reduction algorithm and somewhat more complex, the algorithm for matrix multiplication, throughout the execution of these algorithms on the unique architecture, Parallella board. In order to evaluate the performance of parallel implementation, some metrics such as speedup, have been measured through performing these algorithms both sequential and parallel. Furthermore, this analysis includes three different parallel implementations of both algorithms.**
All this has been done in order to determine exactly which type of algorithm is architecture of Parallella board designed for. The main conclusion of our experimental study is that for more complex algorithms Parallella board shows better results, because the majority of the time of total program execution time, when running simpler algorithms is spent on the communication, synchronization and other side effects that parallelization brings.

***Key words* —Parallella board, speedup, reduction, matrix multiplication**

I. INTRODUCTION

Often one of the biggest practical challenges in parallel programming is choosing the right algorithm for a particular architecture, that is choosing the right architecture for a particular algorithm. The main goal of this paper is to show how to program on Parallella board using STDCL program module as well as how to choose an appropriate algorithm for this purpose. This paper describes two types of algorithms: reduction algorithm and algorithm for matrix multiplication. The importance of the reduction algorithm is that it can serve as a replacement for the whole class of algorithms in which one scalar result has to be calculated over a range of values [1].

The implementation of the reduction algorithm on the Parallella board has been made in three different ways. The first implementation is a sequential implementation of this algorithm and it was made on the Parallella main ARM processor using C programming language. The second implementation presents a parallel implementation that is not optimized written in OpenCL. The third implementation represents optimization of the naïve approach used in the second implementation.

Besides the reduction algorithm, this paper gives both sequential and parallel implementation of the algorithm for matrix multiplication. The matrix multiplication algorithm is important because it is the core building block of Linear Algebra.

Both of the above mentioned algorithms were executed on Parallella board and in order to evaluate performance, their execution time was measured and compared.

II. USED ALGORITHMS

A reduction is a very simple operation that takes an array of data and reduces it down to a single element [1]. In this paper, reduction algorithm represents the implementation of simple algorithm in which single precision floating point elements are added to produce the scalar sum. The program is relatively trivial and consists of allocating memory for the data, initializing the array of data, summing the elements of the array and printing the result which is a floating point value.

Amdahl's law is used to find the maximum speedup to an overall system when only part of the system is improved [2].

$$\text{Speedup} = \frac{1}{S + \frac{1-S}{N}} \tag{1}$$

N—number of parallel processing elements
S—the fraction of sequential execution that is inherently sequential

Applying Amdahl's law to reduction algorithm, the following calculations have been made:

- Percentage of sequential code execution (S) = 44,3%
- Percentage of parallel code execution (1-S) = 55,7%
- Number of parallel processing elements (N) = 16

$$\text{Maximum speedup} = \frac{1}{0.443 + \frac{0.557}{16}} = 2.09 \tag{2}$$

The product C of two matrices A and B is defined as

$$C_{ik} = A_{ij} \times B_{jk} \tag{3}$$

where j is summed over for all possible values of i and k [3]. The dimensions of the matrices must satisfy

$$(n \times p)(p \times m) = (n \times m) \tag{4}$$

The algorithm for matrix multiplication consists of four parts. The first part is allocation of the storage for matrices that are being multiplied. Then, the matrices operands and result matrix are initialized. After initialization, the calculation is performed producing the result matrix. The last part of this algorithm is printing out the result matrix.

Applying Amdahl's law to the matrix multiplication algorithm, the following calculations have been made:

- Percentage of sequential code execution (S) = 2,1%
- Percentage of parallel code execution (1-S) = 97,9%
- Number of parallel processing elements (N) = 16

$$\text{Maximum speedup} = \frac{1}{0.021 + \frac{0.979}{16}} = 12.302 \quad (5)$$

III. ALGORITHMS PARALLELIZATION

The Parallella board consists of dual core ARM central processor and 16-core Epiphany coprocessor and represents a heterogeneous computer system [4]. When programming on Parallella board this unique architecture must be taken into account. Therefore, throughout writing a parallel implementation of both algorithms, reduction algorithm and matrix multiplication algorithm three basic requirements for code changes must be included. First, the code to execute on coprocessor must be written. This code is called Kernel code. The second change is referred to allocating memory that is shareable between the ARM host and the Epiphany coprocessor. Third change is coordination of activities on coprocessor. Allocating memory and activity coordination is placed in what is called Host code, because it is executed on Parallella's central processor, that is host processor. So, in conclusion, in order to run any algorithm in parallel on Parallella board the code must be divided in two parts. First one is Kernel code that will be executed on Parallella's Adapteva Epiphany 16-core coprocessor. Second one is the Host code. It is executed on Zynq dual-core host processor.

Below, it will be explained how to parallelize both reduction and matrix multiplication algorithm, that is how to write their Kernel and host Code.

A. Reduction algorithm—Naïve implementation

Kernel code represents the part of sequential code from chapter 2 in which the calculation is performed, modified and customized to perform in parallel. Kernel code has three arguments: number of elements of data vector, data vector and temporary array used to store the partial sums. The idea of the Kernel code is that the work of adding numbers is divided as evenly as possible to compute partial sums, simultaneously. The final result is calculated by adding up these partial sums.

Host code represents the part of sequential code from chapter 2 in which the allocation of the memory and vector initialization has been done, except that this time, memory that is shareable between the ARM host and the Epiphany co-processor is allocated. Also, in host code it must be ensured that the host memory is synchronized with the Epiphany device prior to its use by our kernel. After all this is done, the execution of Kernel code has been forked and block on the host until all of the co-processor operations are complete.

B. Reduction algorithm—First approach to optimization

First question when programing Parallella is not how one can organize the parallelism, but rather how the organization of the parallelism needs to be done, considering Parallella's architecture.

In naïve implementation when we defined the index range used to launch threads, we asked for n threads executed in local workgroups of 16 to match the number of cores on the Epiphany processor. In order to change this, there are some code modifications need to be made.

The code changes include "folding" loops into the kernel so that each of the coprocessor cores executes approximately 1/16th of the calculation within a single kernel. There is no guarantee that the balancing of work is fully equal, unless the total number of elements in the array is divisible by 16. However, a division of work is as close to even as much as it is possible for those numbers not divisible by 16.

C. Reduction algorithm—Second approach to optimization

With both naïve and first approach of reduction algorithm parallel implementation, there is a significant overhead to manage work items, because full array must be forwarded to each work unit every time. Therefore, the second approach to optimization introduces implementation in which local memory of cores is used instead of device-shareable memory is used.

D. Matrix multiplication algorithm—Naïve implementation

Similar to reduction algorithm, naïve implementation of matrix multiplication algorithm represents the part of sequential code from chapter 2 in which the calculation is performed, modified and customized to perform in parallel.

Kernel code has six arguments: matrices operands and result matrix, and their dimensions. The idea of the Kernel code is to simultaneously calculate the result matrix elements.

E. Matrix multiplication algorithm—First approach to optimization

To optimize matrix multiplication, we must assure that for every memory movement, we execute as many flops as possible. So, first approach to optimization matrix multiplication algorithm represents a code modification that calculates one row instead of one element of the result matrix simultaneously.

F. Matrix multiplication algorithm—Second approach to optimization

Each element of C (result matrix) in a row uses the same row of A, and the same columns of B (A and B are matrix operands). So, the second approach to optimization of matrix multiplication algorithm represents a code

modification in which matrix A rows and matrix B columns are copied into core's local memory. This prevents the overhead of pulling it from global memory for each computation of each element of the result matrix.

All implementations of both algorithms were executed on Parallella board. The results obtained during their execution are presented in chapter 4.

IV. MEASUREMENT AND RESULT PRESENTATION

Figure 1 shows comparison of the time of execution for four different implementations of the reduction algorithm described in chapter 3 (serial implementation, naïve parallelization, first approach, and second approach to optimization).

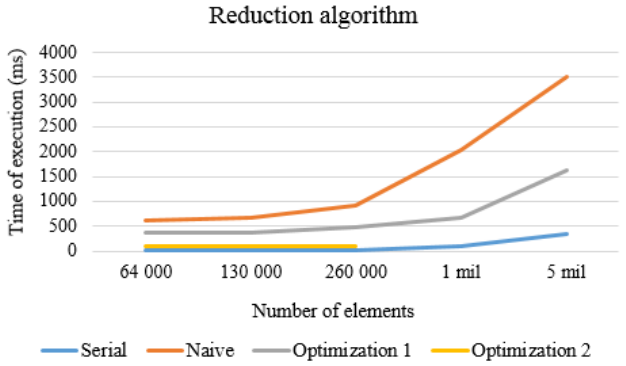

Fig. 1 Comparison of the relationship between the time of execution and number of elements in an array for four different implementations of reduction algorithm

Figure 2 shows the relationship between sequential and three different parallel implementations of reduction algorithm, that is, it shows how the time of execution is getting closer to sequential execution time with every optimization that has been made. It shows how with every optimization, parallel implementation achieves higher speedup comparing to the previous one, but is still slower than sequential implementation due to the large overhead.

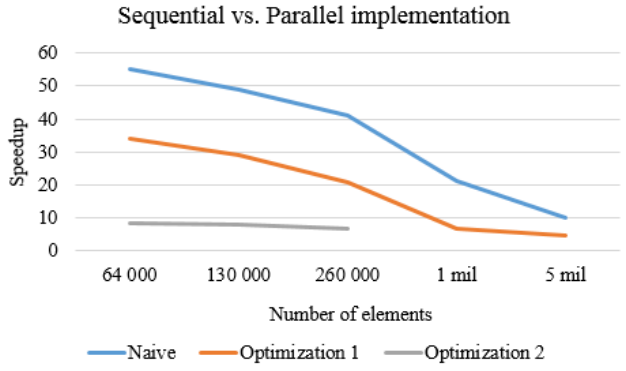

Fig. 2 Comparison of speedup achieved with three different parallel implementations of reduction algorithm using five different lengths of an input array

A. Reduction algorithm - Naïve implementation

Naïve parallel implementation of reduction algorithm is much slower than sequential implementation due to the huge overhead in establishing communication between the host processor and the Epiphany coprocessor. Numbers that will be added to the final sum need to be forwarded to each core of coprocessor. Regardless of the architecture, the goal is to employ as many processors as possible to work simultaneously. After cores have performed the addition, they return the results to the host, which performs the final summation of values stored in temporary variables. Load balancing is poor because all cores are waiting for the final result is placed in temporary variable in the host. As shown in Figure 1, tests were carried out for a different number of elements.

B. Reduction algorithm—First approach to optimization

As presented in Figure 1, this optimization of kernel achieved speedup compared to the naïve implementation, but is still slower than sequential implementation due to the communication overhead.

C. Reduction algorithm—Second approach to optimization

Unlike previous implementations of the algorithm, in this kernel there is less communication between coprocessor and host memory. Therefore, the performance of this implementation is better than other kernel implementations, but is still slower than sequential. This balance of work is better than the previous implementations because processors do not lose time to copy the elements that will not be used. Each core of Epiphany coprocessor has 32 KB of local memory, and float numbers occupy 4B, so the maximum number of float elements that can be stored in each core's local memory is approximately 8.000 elements [4]. In Parallela-16 board, this is a memory constraint, because only 130.000 elements can be stored in Parallela's local memory, and therefore additional speedup can not be achieved.

Figure 3 shows comparison of the time of execution for four different implementations of matrix multiplication algorithm described in chapter 3 (serial implementation, naïve parallelization, first approach, and second approach to optimization).

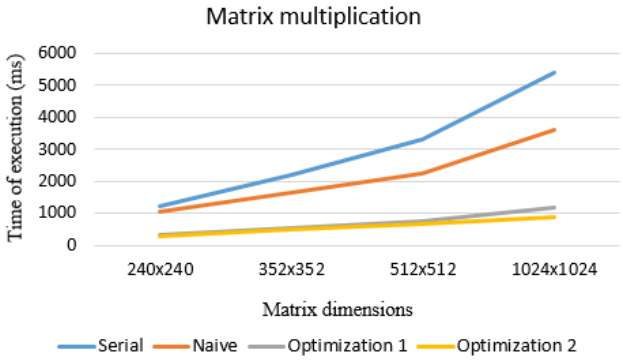

Fig. 3 Comparison of the relationship between the time of execution and matrix dimensions for four different implementations of matrix multiplication algorithm

Figure 4 shows the relationship between sequential and three different parallel implementations of matrix multiplication algorithm. It shows how with every

optimization, parallel implementation achieves higher speedup comparing to the previous one and to the sequential implementation.

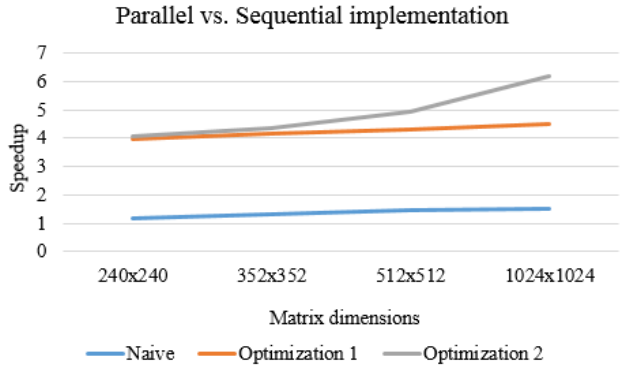

Fig. 4 Comparison of speedup achieved with three different parallel implementations of matrix multiplication algorithm using four different matrix dimensions

D. Matrix multiplication algorithm—Naïve implementation

Since the algorithm of matrix multiplication contains high level of parallelism, a naïve parallelization achieved small speedup in comparison to the sequential implementation. Each of the cores gets indexes of row and column that will be calculated, and after the calculation is performed, core stores the result in a temporary variable. As in the naïve implementation of reduction algorithm, there is a large overhead due to communication between host and coprocessor. This balance of work is not satisfactory because the individual working items are waiting for others to finish the work if the number of elements is not divisible by 16. Execution time and speedup are shown in the Figure 3.

E. Matrix multiplication algorithm—First approach to optimization

In this kernel optimization, a significant speedup is achieved in comparison to the naïve and sequential implementation of the matrix multiplication algorithm. Every Epiphany core calculates entire row of the matrix that is multiplied, not a single item as it was the case in naïve kernel function. A communication overhead is reduced due to the less communication between host and cores. Yet, every core still takes elements from global memory which is significantly slower than local memory.

F. Matrix multiplication algorithm—Second approach to optimization

Every working element row and column that will be calculated are stored in core's local memory. Since every core on Parallella board has 32 kB of local memory, and knowing the fact that floating point number takes 4B of memory, a maximum of 8,000 elements can be copied to the core's local memory [5]. As the data are closer to the processor, the time required for fetching data processing is shorter. This approach showed the best results for the matrix multiplication algorithm.

G. Comparison of results of reduction algorithm and matrix multiplication algorithm

For matrices of a size less than 32x32, using parallel matrix multiplication algorithms described in chapter 3, Parallella doesn't achieve any speedup in comparison to the sequential implementation, due to the large overhead. As the number of elements increases, so does the speedup, as expected. The limitation of Parallella 16 board is the size of the local memory. On newer versions of Parallela, local storage is higher as well as the number of processors, which allows larger speedup to be achieved.

If one compares the speedup and achieved execution time for reduction and matrix multiplication algorithms for the same number of elements, it can be seen that it is better to use Parallela board for matrix multiplication algorithm because the algorithm has a higher amount of parallelism that can be achieved, in comparison to the reduction algorithm.

In the study, we concluded that Parallella board consumes an average of 5.7 W. The maximum energy consumption reached was 6.1 W.

V. Conclusion

This paper presents a parallel implementation of two algorithms, reduction algorithm and matrix multiplication algorithm. The performance of these parallel implementation is evaluated through comparing speedup (time of execution).

Common feature, for both algorithms described in this paper, is that speedup which can be achieved is directly proportional to the total number of elements. As the number of elements increases, speedup increases.

However, parallel implementations of an algorithm for matrix multiplication significantly reduced the computing time both compared to an implementation on a single-core processor and compared to parallel implementation of reduction algorithm. Reduction algorithm showed no significant speedup compared to its sequential implementation due to additional costs of overhead.

Therefore, the main conclusion of our experimental study is that for more complex algorithms such as matrix multiplication algorithm Parallella board shows better results. (It is said that the algorithm for matrix multiplication is more complex than reduction algorithm because it contains a larger proportion of the code that is possible to parallelize.) The main reason for that is that majority of the time of total program execution time, when running simpler algorithms, such as reduction algorithm, is spent in the communication, synchronization and other side effects that parallelization brings.

A. Guidelines for future work

Additional speedup can be achieved using newer versions of Parallella board with Epiphany coprocessor that has 64 instead of 16. That speedup can be achieved because there are more work units available (64) to simultaneously carry

out mutually independent and demanding tasks such as matrix multiplication.

In addition, on newer version of Parallella board capacity of the local memory is larger. As the conclusion of this paper earlier presented total number of elements is directly proportional to speedup. And if there is additional memory, larger total number of elements can fit in local memory. Therefore, higher speedup can be achieved.

Another optimization that can be done to parallel implementations of two algorithms presented in this paper is loops unrolling.

E-mail: drazen.cika@rec-global.com

Abstract –The advent of the new Internet-of-Things (IoT) paradigm in last few years redefined the ways how the small embedded systems can enhance smart sensors and actuators to provide new possibilities in ubiquitously interconnected global world. Although there is a rising tendency in modern low-power embedded system design to provide some kind of IoT functionality out-of-the-box due to the availability of network-aware microcontrollers and system-on-chip (SoC) solutions, there is also a great need to upgrade legacy solutions to fit them into this new paradigm shift. In this article we describe a simple generic framework for upgrading legacy devices, which was built upon the state-of-the-art low cost and low power off-the-shelf hardware components, and open source software. The solution can be easily adapted for various types of smart sensors and actuators. We describe a common set of requirements for building such systems, design decisions reasoning, comparison and justification of HW/SW components choice, and sample demonstration of adaptation and upgrade of the chosen commercial equipment, a device for bubble production at children fun events and similar applications.

I. INTRODUCTION

The embedded devices based on microcontrollers have been in use for many years, and most devices today have some sort of intelligence in a form of software built in, at least in part of functionality. It could be concluded that all those devices were capable of communication with their environment in elegant and transparent manner, but this is not always the case. The devices designed and put into operation before the proliferation of low power microcontrollers and low cost wireless interfaces are very often isolated when it comes to the communication with external world. There may be various interfaces available for users or system maintenance, but those are often based on the wired infrastructure such as the legacy RS232 port, USB connection, Ethernet port and similar. It is not always an easy task to enable such devices to communicate with their environment over the Internet. Older devices which have not been designed based on the microcontroller or microprocessor could be completely cut out of the Internet of Things (IoT) future driven by most silicon vendors and technology adopters today [1].

At the lowest level of the system design for the typical IoT application in most cases there is a requirement for some computationally capable low power microcontroller. Usually requirement is also long autonomy from a single battery power supply, embedded network interface (wired or wireless, typically Ethernet, Wi-Fi, and Bluetooth), embedded communication protocol stack, persistent data storage, and some scalable real-time operating system (RTOS). Moreover, there is typically a need to provide access from a smart client device with rich user interface, such as tablets or smart phones. This is a typical scenario for upgrading legacy systems to provide Internet connectivity, remote monitoring, data logging, crowd sensing etc. [2].

In this article the possibility is explored to enable such legacy devices, even those originally containing no firmware and digital electronics, to exchange the information with their environment using the wireless communication and Internet. In other words, the attributes ‘smart’, and ‘networked’ are added to some low cost equipment possibly having only few simple functions.

II. MICROCONTROLLER PLATFORM

The STMicroelectronics© microcontroller (MCU) used on the development board chosen for this demonstration project belongs to the STMF32F4 family, which is based on the ARM Cortex M4 core. The STM32F4 Discovery evaluation board is shown in the Figure 1. It is used for this project because of the low cost, expandability and convenient form factor enabling easy design of the necessary carrier and expansion board with power supply and wireless and I/O interfaces. The carrier board custom designed for the purpose of this project, and populated with the STM32F4 Discovery and all interfaces is shown in the Figure 2.

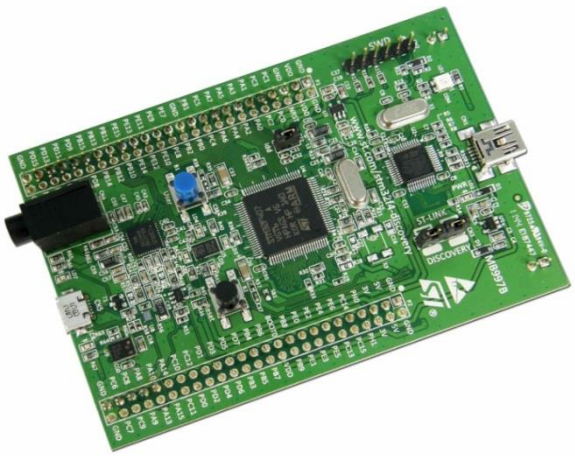

Figure 1. STM32F4 Discovery evaluation board

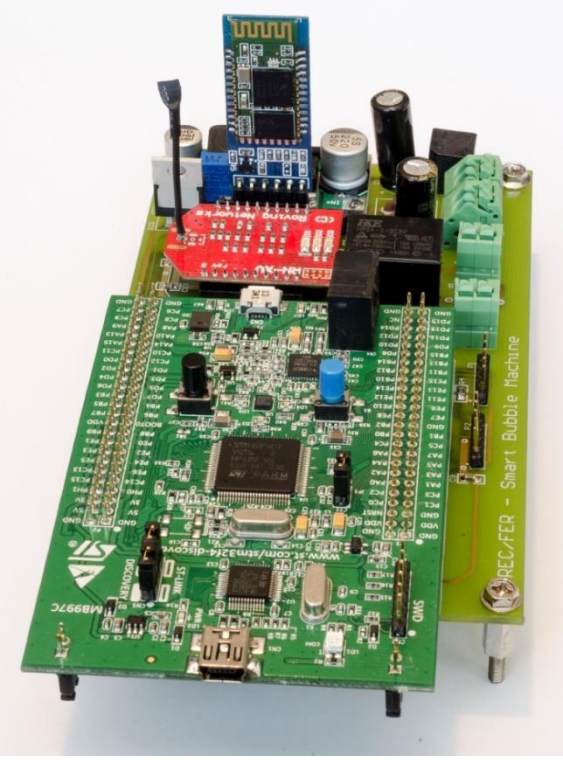

Figure 2. Carrier board with power supply and I/O interfaces

The specific DSP instructions and extensions available on Cortex M4 platform have not been used here, so that some other low power microcontroller core like the ARM Cortex M0 could also be used. Key factors for the platform selection are often device availability and support by the tool vendors, manufacturers and community. The STM32F4 platform is well supported and easily available on the market. It also has the Ethernet interface controller and more Flash and RAM resources than Cortex M0 based derivatives, which makes it more suitable for RTOS based applications with TCP/IP, web server functionality and other more resource demanding tasks.

The software (firmware) for the STM32F4 Discovery board is implemented using various peripheral and system core libraries. Functions for controlling and interaction with peripheral devices, such as GPIO pins, USART interface and I2C interface are written using the Standard Peripheral Drivers library supplied by the STMicroelectronics©, but any other functionally equivalent library could be used.

The example project device described in this article has two actuators for which the output control is implemented:

- AC motor relay is driven by the general purpose input / output (GPIO) pin which is configured as output
- DC motor speed is controlled using pulse width modulation (PWM), therefore appropriate timer channel had to be configured for PWM.

The Real-Time Clock (RTC) is the clock oscillator with support needed to keep track of the current time. Although RTCs are often used in personal computers, servers and embedded systems, they are also present in almost any electronic device that requires accurate time keeping. Use of the separate RTCs avoids the necessity for microprocessor or microcontroller to run all the time just in order to keep time, so the sleep mode of operation is possible if needed. RTC can be realized as external chip from the same or different manufacturer, or it could be available within the silicon of the main MCU, which is the case in this project. RTC on the STM32F4 series offers additional features like the calendar, the alarm, the periodic wakeup unit, tamper detection, and support for the time stamp and calibration applications. RTC uses external oscillator and Static RAM (SRAM) memory which are powered by Li-Ion battery connected to dedicated MCU pins. Configuration and initialization of RTC is done using the Standard Peripheral Library.

III. WIRELESS INTERFACES

Bluetooth is the wireless technology standard for exchanging data over short distances, usually between fixed and / or mobile devices. It is mainly used for peer to peer communication, but could also be useful for building personal area networks (PANs). It was originally conceived as a wireless alternative to the RS-232 data cables.

Bluetooth can connect several devices while overcoming their synchronization problems. There is large number of ready-made Bluetooth modules on the market, which simplifies the design of the device. One of the most popular modules is the HC-05 [3]. It offers serial (USART) interface for communication with MCU, and configuration is done using AT commands. The module itself is not suitable for direct soldering on the through-hole PCB, so the custom carrier board was designed for the project using only seven pins as an interface, as shown in the Figure 3.

Wi-Fi is a local area wireless technology that allows an electronic device to participate in computer networking using 2.4 GHz UHF and 5 GHz SHF ISM radio bands.

Wi-Fi devices can connect to a network resource such as the Internet via a wireless network access point. Such access point (or hotspot) has a range of about 20 meters indoors and a longer range outdoors. Hotspot coverage can comprise an area as small as a single room with walls that block radio waves, or as large as many square kilometers across multiple overlapping access points.

Wi-Fi has adopted various encryption technologies. The early encryption (WEP) proved to be easy to break. Higher quality protocols (WPA, WPA2) were added later. There are various pre-built Wi-Fi modules on the market, such as the WiFly from the company Roving Networks© shown in the Figure 4 and described in [4].

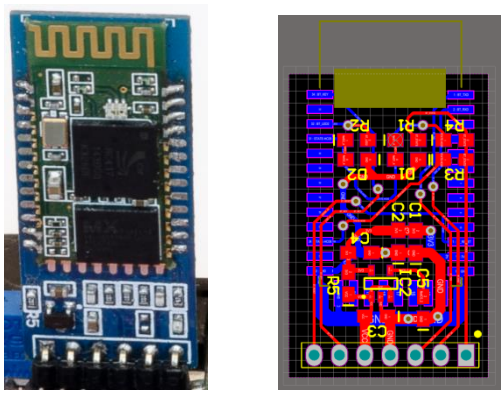

Figure 3. Bluetooth module with its custom carrier board

Figure 4. Wi-Fi module RN-XV WiFly by Roving Networks

Wi-Fi module is actually a small communication computer incorporating 802.11 b/g radio, 32 bit processor, TCP/IP stack, the real-time clock, crypto accelerator, power management unit and analog sensor interface. The module is pre-loaded with Roving firmware to simplify integration and minimize development time of the application. In the simplest configuration, the hardware only requires four connections (PWR, TX, RX and GND) to create a wireless data connection.

IV. DATA LOGGING AND FILE SYSTEM

Each field device with sensors and actuators can have requirement for data logging, so the storage space for larger amount of data might come handy. SD card functionality is implemented to fulfill such requirements, and the Secure Digital Input/Output (SDIO) Interface was chosen for this purpose and enabled using the Standard Peripheral Driver Library. The SD card connector had to be added to the custom designed carrier board, as it was not present on the basic evaluation board.

For handling and managing files the well-known and popular Chan's FatFs is used[5]. FatFs is generic FAT file system module for small embedded systems. It is written in compliance with the ANSI C standard, and is separated from the I/O layer. Since the FatFs module is a file system layer, it is completely separated from the physical devices, such as memory card, hard disk or any other type of storage device.

The low level device control module is not a part of FatFs module and is provided by implementer of the file system functionality.

V. REAL TIME OPERATING SYSTEM

When confronted with the requirements to handle several asynchronous communication tasks, while keeping the responsive user interface and handling measurement data from the sensors in the background, developers usually opt for the usage of some operating system to help partition tasks in manageable chunks of code. Also, the embedded devices often have real time response requirements, and specifically IoT devices have to behave economically and be able to go to sleep when there are no tasks to be executed left. The support of the Real Time Operating System is needed, or at least preferred.

Multitasking and the real time requirements are in the case of this application achieved by FreeRTOS [6]. FreeRTOS is the real-time operating system kernel for embedded devices. It is distributed under the GPL with an optional exception. FreeRTOS is designed to be small and simple. The kernel itself consists of only three or four C files. To make the kernel code readable, easy to port, and maintainable, the FreeRTOS is written almost entirely in C and there are only few assembly functions included where needed, mostly in the architecture-specific scheduler routines. The FreeRTOS provides functions for multiple threads, mutexes, semaphores, software timers, and other common RTOS objects. It also supports thread priorities.

The FreeRTOS based software structure of the demo application shown in this article can be seen in the Figure 5. Various colors mark tasks, interrupts, HW resources, global variables, or the RTOS objects such as semaphores or message queues. Data received over the USART is handled by interrupts in the background. Every byte is forwarded by the interrupt to corresponding message queue and then handled by the task responsible for the particular message queue content. The task checks the message queue one byte at the time and sends them to the parser function. The parser sets some control signals and semaphores, accordingly to the command parsed from the string received from the message queue.

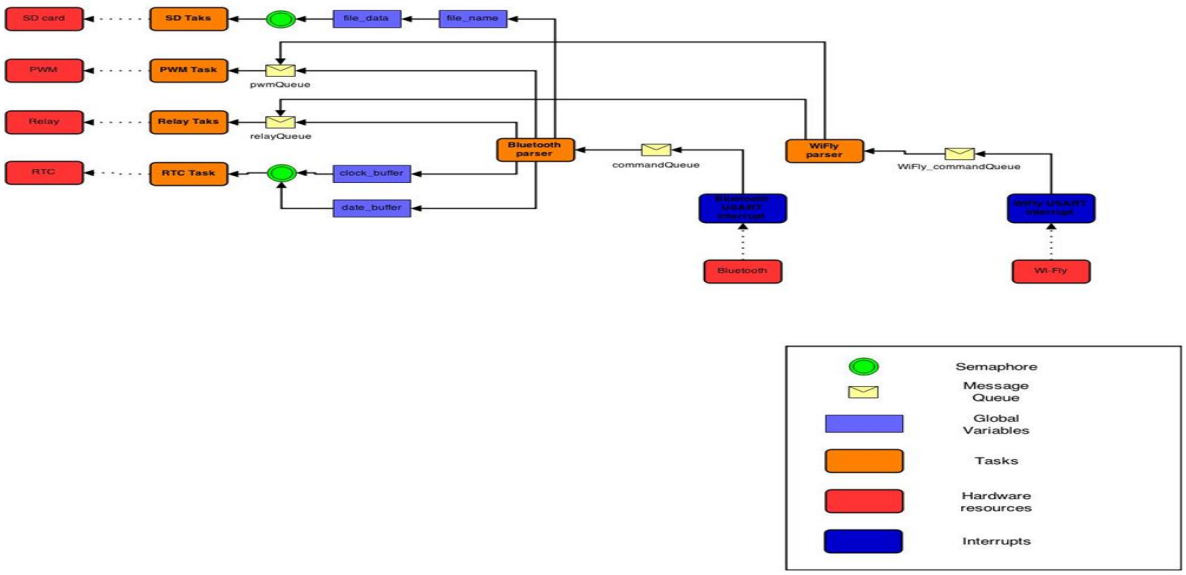

Figure 5. Firmware block diagram

VI. EXAMPLE PROJECT DESCRIPTION

The example project chosen for the demonstration purposes is called the Smart Bubble Machine. Its purpose is purely entertainment, and as its name suggest its main function is to produce bubbles. In its original form shown in the Figure 6 it is very simple device which basically can only be turned on or off, and when turned on it produces the soap bubbles in a constant stream until turned off.

The mechanics and electronics built initially into the machine by the manufacturer are simple: the transformer, some basic power supply, and AC and DC motors. Figure 7 shows the hardware components added to the bubble machine so that it could earn the 'Smart' attribute.

The basic principle of operation is very simple. The AC motor is connected directly to the 220 V AC mains power supply, and it was used to rotate the big blue perforated disc. After modification, this motor can be also started and stopped under software control using the on-board electromechanical relay. The transformer is used to transform 220 V AC to 12 V AC which is then fed to the full wave rectifier circuit. The resulting 12 V DC voltage was originally used only to continuously drive the DC motor (actually the PC CPU type ventilator) which blows air into the perforated disc, thus creating bubbles. Before exposure to the air stream, the plastic disc rotates through the liquid soap (detergent) filled into externally mounted reservoir.

After modification, the step down switching convertor module was added instead of simple basic rectifier supplying 5 V DC, and additional low drop out linear voltage stabilizer provides the 3,3 V DC voltage needed. All components needed for the project are placed on already mentioned carrier board shown also in the Figure 7. The PC type ventilator is now driven by the PWM output, so that fine control over the ventilator speed became possible and it was implemented in software. The remote control is now possible from the near distance and over the Internet using the tablet or Smartphone with custom Android application installed, or via the web based user interface from any web browser.

Figure 6. The exterior of the Bubble Machine

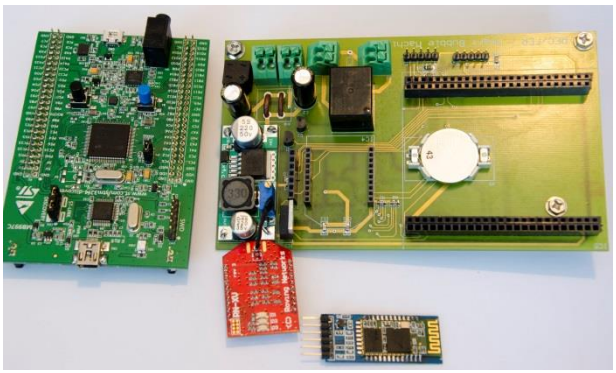

Figure 7. Components added to the Bubble Machine

VII. CONTROL SOFTWARE USER INTERFACE

The software control for the Smart Bubble on the remote side is implemented twice: as the Android application and as the Web application. Both applications enable users to monitor and control the device using simple graphical user interface, as shown in the Figure 8 and the Figure 9. Only parts of the screen are shown here due to the space constraints, and there are connection and help buttons in the bottom of the Android application screen, as well as the console terminal at the bottom of the web user interface screen.

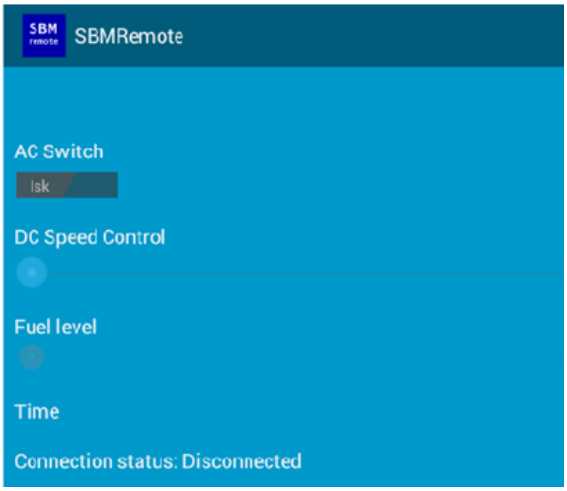

Figure 8. The Android application user interface

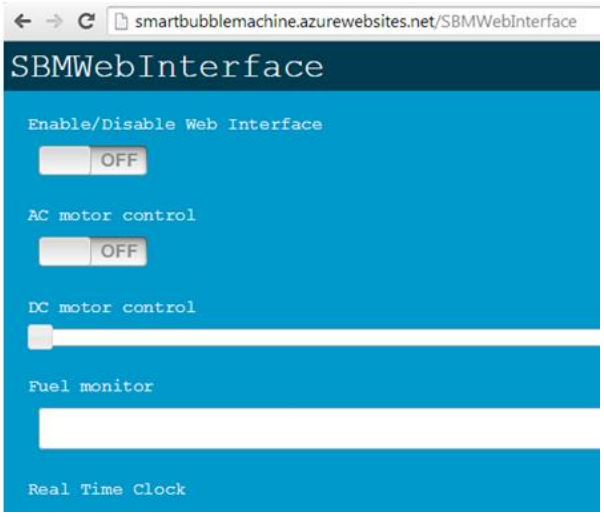

Figure 9. The Web application user interface

The Android application connects to the device using the Bluetooth interface, so that user can change additional parameters and configure device also for the web interface access. It resolves the situation in which the Wi-Fi access has to be configured for new network.

Additionally the Android application offers some debugging features, like the terminal for monitoring transmitted and received data. The terminal application and permission to change the device parameters such as Bluetooth or Wi-Fi connection passphrase are administrator privileged functions.

Parameters which can be changed are divided in three groups:

- Bluetooth connection parameters: Bluetooth module name and passphrase
- Wi-Fi module parameters: Network SSID, WEP encryption, WPA passphrase
- Real-time clock parameters: time and date

Web application is developed using the ASP.NET framework. Application runs on the Microsoft Azure web server, and interacts with the Smart Bubble device using the HTTP GET method. It also enables multiple users to control and exchange data with the device at the same time. This is done using the SignalR notification hubs and jQuery Ajax library. Application has console which is updated every time change is made by any user. Additionally it contains debugging messages which are useful in developing or upgrading the device firmware. Both applications can't be used at the same time, since the Android application is event driven, but device must periodically send http requests to refresh. Therefore the web interface can be disabled using the *Enable/Disable*control shown in the Figure 9.

Furthermore, Android application sends and receives data independently. For example, the real-time clock data is sent every second, while sensor data such as the fluid level sensor (not implemented jet) could be sent when the sensor readings are changed. The web application keeps the TCP connection open and sends data after device requests data, and posts sensor data and real-time clock data to the web application.

V. CONCLUSION

This project is demonstration of basic principles of microcontroller usage to control and monitor device remotely using the wireless connection, actuators such as AC or DC motors, and standard off-the-shelf client device such as the tablet or smart phone.

Possibility is added for the user to remotely turn simple legacy device or machine on and off, to regulate the speed of the ventilator thus influencing the bubble production rate, and it would be easy to program the machine to operate independently and log data during operation.

It is also shown how to implement and use some widely used technologies, such as the Bluetooth, the Wi-Fi, the SD card, the Flash file system, or the RTC. The Real Time Operating System (RTOS) has been applied successfully.

Using the resources and techniques described, any legacy machine can be controlled and monitored remotely from the close range or over the internet using two different wireless options, data from sensors can be collected and sent to the server, new machine configuration can be sent and information stored on the MCU or SD card, and the machine can connect itself to the Internet based on some predefined events.

Therefore, control and monitoring can be performed without being anywhere near the machine, and without usage of any proprietary technology or components.

All modules, voltage convertors, actuator drivers and microcontroller development board itself are mounted on the custom designed PCB, and some more custom boards have been designed where necessary, or feasible.

ACKNOWLEDGMENT

Project sponsored by Research and Engineering Center d.d., Zagreb. The authors would like to thank the RESEARCH AND ENGINEERING CENTER d.d. Zagreb company (REC) for the support and resources provided during this development. The device was displayed at the REC Global stand during 2015 Embedded World Exhibition in Nurnberg, Germany [7], where it was working flawlessly for three days.

Turning a smartphone into structured light 3D scanner

M. Lelas, T. Pribanić
Faculty of Electrical Engineering and Computing, Zagreb, Croatia
marko.lelas@fer.hr, tomislav.pribanic@fer.hr

Abstract: As they became a very power full hardware platform, available and attractive for a very high number of users, smartphones are receiving more and more attention recently, being an important commercial field but a popular research topic as well. In this paper, we present a method to create dense 3D models of small-scale objects. We facilitate the hardware already available on the smartphones thus turning them into practical 3D scanners without the need of additional hardware. Our algorithm is based on the weak structured light approach, using the capabilities of the HTC Evo 3D smartphone (flash, rear camera). The first reconstruction results are presented as well as the guidelines for the future work. Finally, an approach which should be able to turn every smartphone available on the market into a practical and easy to use 3D scanner is proposed.

I. INTRODUCTION

Generation of accurate 3D models has been a goal in computer vision for some time, resulting in the numerous approaches and methods for achieving flexible and accurate systems for 3D reconstruction. To name just a few of the most successful approaches, there are the active stereo – coded structured light [4], photometric stereo [7], and the passive stereo [5] systems. They all have in common that in each approach the trade-off between system complexity and reconstruction results must be made. In general, the more accurate and reliable the reconstruction results are, the more expensive and processing intensive the system becomes. Depending on the predictable field of the system application and the demand on the level of reconstruction accuracy that the application demands, one or the other approach is applied.

Mobile devices (smartphones and tablets) have strongly evolved in the last decade. This devices offer mobility combined with almost all the convenience that was previously available only with the personal computers (internet access, camera, multimedia, variety of applications…). As a result, new applications expanding the scope of the field in which mobile platforms have been utilized, are developed and the research field is now days very propulsive. The above mentioned was a strong motivation for our work, which has a final goal to provide the mean of turning popular smartphones into practical and easy to use 3D scanner, thus expanding the field of application of smartphones to the field of computer vision - 3D reconstruction. However, some platform-related limitations still remain and the most rigid hardware restriction, common to all mobile platforms, is still the power consumption limitation. In order to provide a long enough period of autonomous life of the device, applications must be power-efficient, which means that both processing and memory requirements of the application must be as low as possible.

This fact turned our research towards investigation of 3D reconstruction methods with lower processing requirements suitable for optimal utilization of the resources available on the smartphones thus leveraging the advantages of the targeted hardware platform. The proposed method is based on the weak structured light approach [1], which is relatively simple method in the means of computing and processing requirements. However, unlike in [1] we do not require an extra light source. We simply introduce smartphone flash for the similar purpose. The result is a novel method for dense 3D reconstruction of small-scale objects which is optimal in the means of efficient utilization of the resources available on the HTC Evo 3D smartphone [9].

This paper is structured as follows. Section 2 gives the insight in the computer vision methods which are in the grounds of our approach and the current state of the art in the field of 3D reconstruction on smartphones. In Section 3 our approach is described in more detail, current shortcomings and the possible improvements in the future work are pointed out. Also the results showing the efficiency of the proposed method are

shown. Section 4 concludes with a summary and an outlook on future work.

II. RELATED WORK

Field of 3D reconstruction on smartphones was all until recently relatively poorly investigated and therefore there are not many works which deal with this topic. Because of the emerging need for new applications and all the commercial potential which this area has, the situation is more and more changing. Klein and Murray [3] have presented the Parallel Tracking and Mapping (PTAM) system on a mobile phone which aims at enabling different augmented reality applications of the mobile phone. The goal to give the users the possibility to create and maintain the Augmented Reality (AR) content without the need for complex and expansive tools has also motivated authors in [2] to design an 3D reconstruction system on the smartphone based on the shape-from-silhouette approach. Won, Lee and Park [8] have presented the work where they implemented an active 3D shape aquisition method based on photometric stereo. They used a pair of smartphones which collaborated as the master and a slave where a slave was engaged to illuminate the scene (using the flash) from the appropriate viewing points while master recorded the images. In [6] authors have presented a complete on-device 3D reconstruction pipeline for mobile monocular hand-held devices, which generates dense 3D models. To make the tracking and mapping process more resilient to rapid motions and to estimate the metric scale of the captured scene, the on-device inertial sensors are utilized.

The base method for our work is the weak structured light approach which is in more detail explained in the following paragraph. The method is simple and not processing intensive. It also utilizes the resources available on most of the modern smartphones (camera, flash) and therefore it seems optimal for the application. A fact that a possibility to turn a smartphone into a practical weak structured light 3D scanner by utilizing the flash has not yet been recognized by a scientific research further motivated our work in this direction.

A. Weak Structured Light

This approach aims at constructing a simple 3D reconstruction system which requires minimal equipment and has low processing requirements but still yields a very good accuracy. The general principle consists of casting a moving shadow with a stick onto the scene, and estimating the three-dimensional shape of the scene from the sequence of images of the deformed shadow. The objective is to extract scene depth at every pixel in the image.

Figure 1: The Weak Structured Light setup [10].

The system setup consists of a point light source, a stick which is used to cast a shadow upon the scene and a camera and a processing system, as can be seen from the Figure 1.

IV. PROPOSED METHOD AND RESULTS

As it can be seen on the Figure 2, the experimental setup for the proposed method is very simple. It takes one L-shaped profile which is in our case made of two orthogonally placed plexiglass boards (otherwise used for the camera calibration), holder for the smartphone, a smartphone and a stick. There are some procedure modifications which make it possible to use just one plexiglass board as a horizontal plane at the cost of having to compute the accurate position of the light source.

The reconstruction process is performed through four main activities. Those activities are: image acquisition, shadow detection, triangulation and output model generation.

Figure 2: The experimental setup.

A. *Image acquisition*

The first step of the reconstruction process is acquisition of a video of the reconstructed scene. The smartphone is placed on the holder with the flash turned on. The video is acquired while the shadow is being casted on the scene by dragging the stick in front of the flash from one side to the other. Once the scene has been scanned with the shadow, the video acquisition is stopped. Then, the consequent frames are extracted from the video and used as an input for the shadow detection step.

B. *Shadow detection*

Shadow detection process is performed in the grey level colour space. The input images (frames extracted from the video) are scanned line by line, identifying the shadow edge pixel in each line. Assuming the ideal pinhole model of the light source, brightness distribution should be uniform throughout the whole image with a big drop in intensity only on the pixels covered by the shadow making the shadow detection process a trivial task. Due to the properties of the scene that is reconstructed and the deviation of the flash from the ideal pinhole light source model, shadow detection process is not trivial. Figure 3 presents one representative input frame and grey scale representation of the corresponding line (the line which is marked red in the input image represented by Figure 3). As it can be seen from the Figure, the pixel intensity distribution is not uniform. Therefore, the shadow is modelled by a parabolic function and the pixels in line which correlate the most with the model are identified as a "shadow pixels" (the pixels marked green in the Figure 3). Parabolic interpolation is than performed at these pixels to identify the shadow edge at sub pixel precision.

Shadow detection process is finished after all the frames of interest have been processed. The goal is to have all the pixels of the reconstructed scene identified as a part of the detected shadow, in one of the analysed frames, as this enables the dense reconstruction because every pixel detected as a shadow pixel on the reconstructed model results in reconstruction of the correspondent image 3D point at the output of the triangulation process.

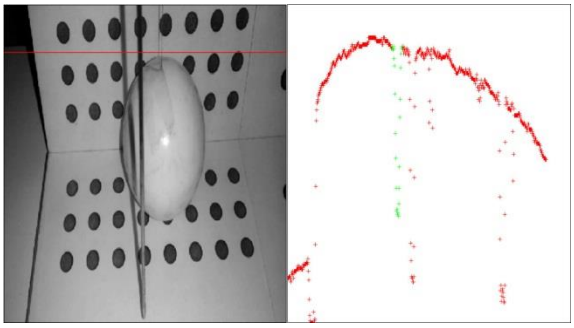

Figure 3: Shadow detection.

C. *Triangulation*

The 3D reconstruction is done by finding the intersection of the back projected line of the "shadow pixel" identified on the reconstructed object with the shadow plane. To identify the shadow plane, the pixels lying in the horizontal and vertical plane are identified. Those pixels are presented in the Figure 4 (green – vertical and blue-horizontal plane).

By fitting the identified pixels to a line, horizontal and vertical lines are reconstructed and the plane defined by those two lines is identified as a shadow plane. The "shadow pixels" which correspond to the reconstructed model (marked red in the Figure 4) are used to calculate the back projected lines to intersect with the calculated shadow plane. The points of the intersections are the 3D representations of the shadow pixels. The proposed method results in a dense 3D reconstruction as every shadow pixel yields a corresponding 3D point.

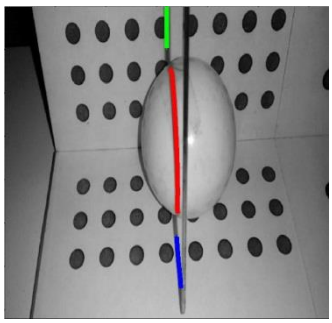

Figure 4: Shadow pixels and shadow plane.

D. Output model generation

The reconstructed 3D points generated by the triangulation process are used as an input to Delaunay triangulation. This way a mash is generated. Fitting the image texture to the mash, the final 3D representation of the reconstructed model is obtained. Figure 5 shows the result of the output generation process for the case of reconstruction of a white ball. As it can be seen a proposed method recovers successfully the circular ball shape. Moreover, the Figure 6 presents the reconstruction of a small angel figure. Even in this more demanding scenario with abrupt changes in depth, we have recovered a realistic 3D shape.

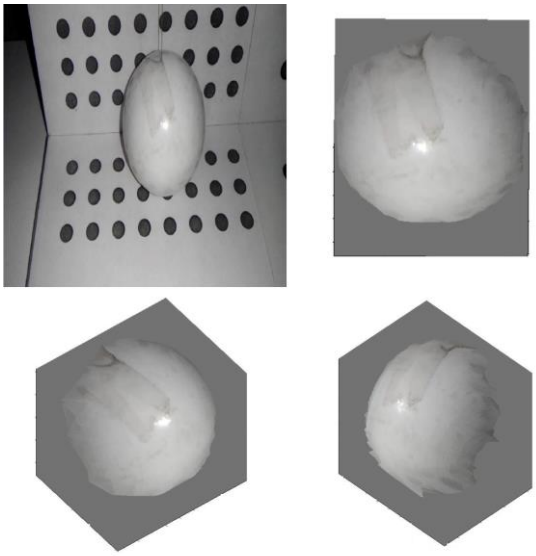

Figure 5: Results of the 3D reconstruction of the white ball. 2D view, front, left and right 3D view representation.

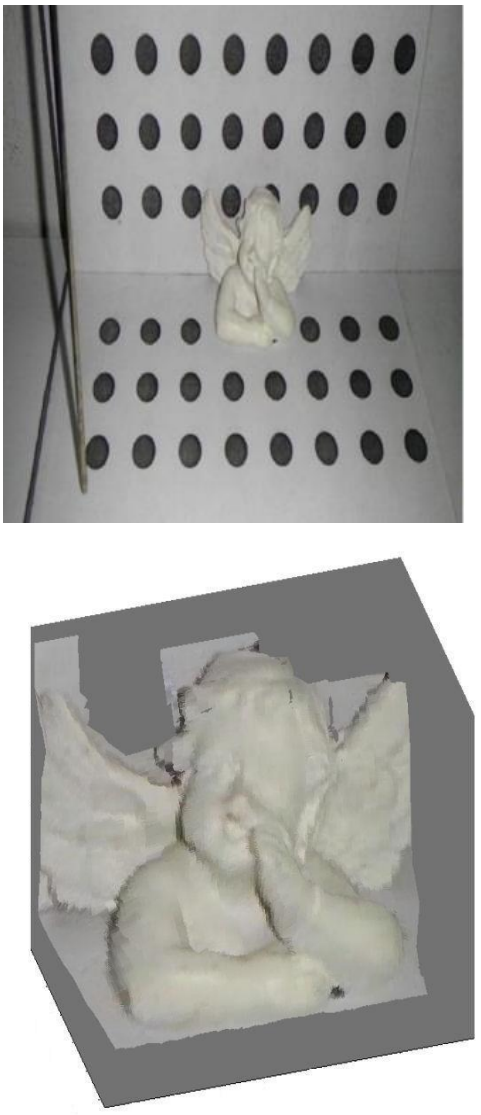

Figure 6: Results of the 3D reconstruction of the figure of angel.

V. SUMARY AND FUTURE WORK

We have shown that the ground idea of this work, turning the smartphone into a practical 3D (weak) structured light scanner using only the hardware available on the device (flesh, camera), is feasible. The presented results show that the system works well for reconstruction of the small-scale objects. The improvements in the shadow detection process, that would make it even more accurate and robust to the conditions of the environment, are in the scope of our future work.

In addition, some smartphones, like HTC Evo 3D, are equipped with two rear facing cameras, thus opening up the space for combining the aforementioned reconstruction approach with the passive stereo. In future work investigating that possibility is planned. There are also smartphones which are not equipped with the flash. For that scenario, we plan to develop practical laser add-on for the smartphone, which would project the laser line that could be used for scanning the scene and performing the 3D reconstruction using the laser line instead of the projected shadow.

antegrbic8@gmail.com

***Abstract*—The Hamiltonian completion problem is an NP-hard problem which consists of finding the smallest number of additional edges to make the graph Hamiltonian. This minimal number of extra edges is defined to be the Hamiltonian Completion Number (HCN). This is a well known problem but rarely analyzed in academic circles. We study the problem on random sparse graphs and compare results of determining HCN with different heuristic approaches. We developed a modification of the Ant colony optimization (ACO) and show that, while the standard ACO presents a better approach to this problem than observed Genetic and Immunological algorithms, the modified ACO provides the best results by far.**

I. Introduction

HAMILTONIAN completion problem (*HCP*) is a problem that has been addressed to a limited extent in scientific literature. It has applications in assigning frequencies to multiple transmitters in a geographic area [1] and in distributed computing (assigning processes to processors). Let $G = (V,E)$ be an undirected, non-weighted graph. The Hamiltonian completion problem consists of finding a minimal number of edges $d \in \mathbb{N}$ to add to graph G to make it Hamiltonian. This minimal number of extra edges is also denoted as Hamiltonian Completion Number (HCN). A Hamiltonian graph, also called a Hamilton graph, is a graph possessing a Hamiltonian cycle, a cycle which visits each vertex in the graph exactly once.

The problem was presented in 1970. by Boesch, Chen and McCugh and by Goodman and Hedetniemi independently. The problem is clearly NP-hard in general case (since its solution gives an answer to the NP-complete problem of determining whether a given graph has a Hamiltonian cycle [2]). For some special cases, like trees, cactus graphs and series-parallel [3], there are polynomial time and even linear time [4] algorithms. However, to our knowledge there have still not been found acceptable solutions, including approximate algorithms, in general cases. In 2012. David Gamarnik and Maxim Sviridenko [5] have computed an asymptotic solution to the HCP for random sparse graphs $G = (V,\frac{c}{n})$, where $c < 1$, $n = |V|$ is the number of edges in the graph and each edge is selected independently with probability $\frac{c}{n}$. We will use this class of graphs in our analysis.
This paper will present a detailed overview of different heuristic approaches to solving the HCP and introduce a novel approach, called Twins Ants Colony algorithm. The novel approach is presented in detail and tested thoroughly in comparison with standard approaches. Tests prove the Twins Ants Colony algorithm provides much better results than the observed standard algorithms.

The paper is organized as follows. In Section II, we explain the genetic and immunological algorithm approaches to the problem. Section III focuses on the Ant colony optimization approach, with a special accent on the original Twins ant colony optimization algorithm and its justification. Section IV describes the testing procedures and explains the results. Section V provides concluding remarks and directions for future work.

II. Genetic and immunological algorithm approach

Genetic and immunological algorithms are used widely in approaching NP-hard problems. These algorithms belong to the larger class of evolutionary algorithms (EA), which generate solutions to optimization problems using techniques inspired by natural phenomena. In this section, we give a short overview of basic genetic and immunological algorithm approaches as applied to the HCP.

A. Genetic algorithm

The solution representation is a permutation of vertices without the vertex 1, which we use as the first vertex by default. Setting one vertex at a fixed position simplifies the implementation of crossover operators. It is important to emphasize that this does not reduce the number of solutions, i.e. each solution is a cycle and the "first" position doesn't exist in a cycle, so fixing one vertex only prevents different rotations of the same cycle to appear as different solutions.
For the termination condition, we used a predefined number of generations so that the algorithm converges.
The algorithm begins with a randomly generated population, with the size of $numIndividuals$:

B. Genetic algorithm with a greedy operator

A possible improvement can be achieved with a greedy operator similar to those often used in solving the Traveling

Data: Randomly generated population of individuals
Result: Population from which we take the one with least edges added
while *(termination condition is not reached)* **do**
1) Give scores to individuals.
2) Select two best rated individuals and store them in $newPopulation$. Use the Roulette wheel selection to select $numIndividuals - 2$ and store them in $newPopulation$.
3) Use the crossover operator, as proposed in [6], to cross selected individuals.
4) Use inversion mutation to inverse individuals in $newPopulation$.
5) Possibility of mutation decreases in time.
6) Replace initial population with $newPopulation$. Repeat until the termination condition is reached.

end

Algorithm 1: Genetic algorithm with a crossover operator

salesman problem. The main idea is that edges appearing in both parents are more likely to be advantageous. Thus, the operator keeps the intersection of two parent cycles and sets it as the basis for their children, while the rest of the children edges are generated randomly. Unfortunately, this variant didn't provide a significant improvement and, for that reason, we have omitted it from further discussion and test results.

C. Immunological algorithm

The solution representation and the termination condition are similar to those already described in the genetic algorithm. The algorithm begins with a randomly generated population, with the size of d:

Data: Randomly generated population of size d
Result: Population from which we take the one with least edges added
while *(termination condition is not reached)* **do**
1) Clone every antibody k times (we now have $(k+1) \times d$ antibodies).
2) Each clone undergoes the process of hypermutation.
3) Count affinity of old antibodies and hypermutated clones. Build the new population out of d best individuals.

end

Algorithm 2: Immunological algorithm

As it will be shown later on, both of these algorithms have had difficulties finding optimal solutions in bigger graphs, i.e. graphs with a 100 vertices or more. There is a naturally imposed improvement which consists of not generating our initial population randomly, but in an educated fashion, e.g. using the Twins Ant Colony algorithm to create an initial population of solutions.

III. Ant Colony Optimization approach

A. Ant colony algorithm

Ant colony optimization is an algorithm inspired by natural behavior of ants. Ants, while searching for food, travel through a terrain (graph) spreading on different paths and leave traces of pheromones on the paths that prove successful or possibly lead to a source of food. After a while, they all "converge" to the same path. We can observe HCP accordingly and notice that since the solution is represented as a cycle, every vertex is a good enough starting point for ants. Thus, all ants start at vertex 1 and follow the algorithm:

Result: Cycle with the least HCN from all the ants who participated in the algorithm
while *(termination condition is not reached)* **do**
1) Every ant finds a path:
   while *(the path is not complete)* **do**
   a) Let $V = \{v_{i1}, ..., v_{in}\}$ be the set of all unvisited neighbors of the vertex v_i.
   b) If $V \neq \emptyset$, connect to a neighbor j with probability ${}^{c_j}/_{\sum_{k \in V} c_k}$, where c_k is the strength of pheromone scent on the edge (v_i, v_{ik}).
   c) If $V = \emptyset$, randomly choose a vertex from all unvisited vertices and connect.
   end
2) Compare results for all ants.
3) The best ant leaves its pheromones on all edges that it used and that exist in the graph.
4) Pheromones evaporate in the entire graph.

end

Algorithm 3: Ant colony optimization algorithm for HCP

B. Twins Ant colony optimization algorithm

A clear flaw of the ACO approach to this problem is that it relies heavily on randomness. Next algorithm, as a greedy modification of the standard ant colony algorithm, represents a novel approach to solving HCP for sparse graphs. The basic idea is that every ant comes with a twin ant which helps construct an optimal cycle by constructing the cycle a from a series of smaller paths. The first ant is greedy, he starts from the lowest degree vertex connects to vertices using the same probabilities as before. When he stops, the twin ant tries to "fill in" the path that his brother has created, making sure no new connected components have emerged. It can be shown that the twin ant indeed justifies the greedy approach.
In the following algorithm description, the word "team" is used to denote both ants (brothers) which are building one path:

Proposition. *The twin ant justifies the greediness of the algorithm.*

Proof. Let $G = (V, E)$ be an arbitrary graph and $x = (x_1, e_1 ..., x_n, e_n)$ an optimal cycle, where $\{x_1, ..., x_n\}$ are vertices and $\{e_1, ..., e_n\}$ edges in the cycle.

We define $E^{'} := E \cap \{e_1, ..., e_n\}$ and observe connected components $C_1, ..., C_m$ in graph $G' = (V, E')$. It is clear that

Result: Cycle with the least HCN from all the teams who participated in the algorithm

while *(termination condition is not reached)* **do**

1) Every team finds a path:
2) Start from a lowest degree vertex and make it the base.
   while *(the path is not complete)* **do**
   a) Let $V = \{v_{i1}, ..., v_{in}\}$ be the set of all unvisited neighbors of the current vertex i.
   b) If $V \neq \emptyset$, connect to a neighbor j with probability $c_j / \sum_{k \in V} c_k$, where c_k is the strength of pheromone scent on the edge (i, v_{ik}).
   c) If $V = \emptyset$, stop at current vertex i_1. The twin searches for more edges (as in step b), starting from the base.
   d) When the the twin stops at a vertex, let's call it i_2, add the path from i_1 to i_2 to the cycle under construction (a).
   e) The team jumps to an unvisited vertex with the lowest degree. This is done by adding a new, nonexisting edge to the cycle. This is the new base.
   end
3) Compare results for all teams.
4) The best team leaves its pheromones on all edges that it used and that exist in the graph.
5) Pheromones evaporate in the entire graph.

end

Algorithm 4: Twins Ant colony optimization for HCP

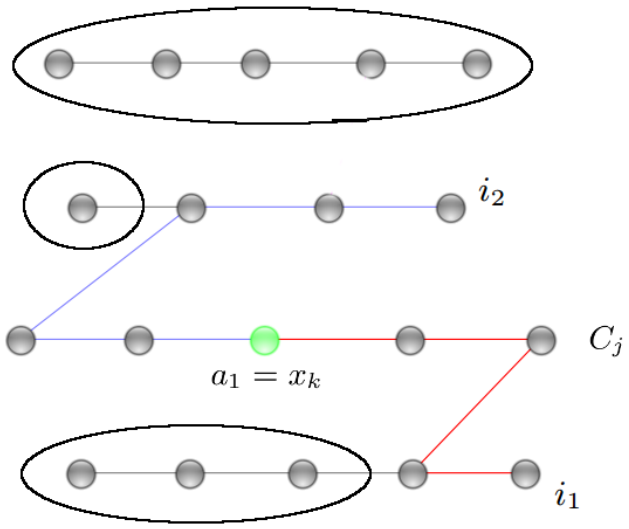

Fig. 1: One step in the Twins ant colony algorithm. There are four connected components from the modified graph $E^{'}$, where C_j is the third one, and each component is represented by one line. Grey edges present edges in $E^{'}$, red ones present edges passed by Ant 1 and blue edges present edges passed by the Twin. All of those edges exist in the original graph E. Ant 1 starts at $a_1 \in C_j$ and goes through red edges. The twin then starts at a_1 and goes through blue edges. After this step, the path from i_1 to i_2 (red and blue edges) will be added to the cycle a. We can see that after that, the entire component $C_j \subseteq a$ and there is the same number (4) of unconnected components (the current one and the 3 circled ones) as before the ants passed, in the graph $E^{'}$.

every component C_i is a linear graph. We will show that the algorithm can construct a cycle $a = (a_1, ..., a_n)$ for which $HCN(a) \leq HCN(x)$.

Let $a_1 = x_k$ be a vertex that belongs to $C_j = (x_{k-s}, ..., x_k, ..., x_{k+l})$ and we set $HCN(a) = 0$. Now Ant 1 can choose the vertices towards x_{k+l}: $x_{k+1}, ..., x_{k+l}$. If Ant 1 has unvisited neighbours left, it connects to the vertex x_{k_j} in component $C_{j_1} = (x_{k_{j_1}-s_{j_1}}, ..., x_{k_{j_1}}, ..., x_{k_{j_1}+l_{j_1}})$. At this point, the ant can choose vertices towards one end of the component, $x_{k_{j_1}-1}, ..., x_{k_{j_1}-s_{j_1}}$.

It is important to see that this has not increased the number of connected components N_c. Namely, the set of the vertices that we haven't included in a, $\{x_{k_{j_1}+1}, ..., x_{k_{j_1}+l_{j_1}}\} =: C'_{j_1}$, makes at most one connected component, which replaces C_{j_1}. Let us notice that this point is valid also in the case where $C_{j_1} = C_j$. In that case $x_{k_j} = x_{k-r}$, where $x_{k-r} \in \{x_{k-s}, ..., x_{k-1}\}$. Following the same procedure as above, the set of vertices not included in a will be $\{x_{k-r+1}, ..., x_{k-1}\} =: C'_j$, which makes at most one connected component, while replacing C_j.

Once again, if the ant can move forward, it connects to a vertex in another component and repeats the same procedure. When Ant 1 has no more unvisited neighbors to connect to, Ant 2 starts from the base x_k.

Ant 2 can now connect to $x_{k-1}, ..., x_{k-s}$. Doing this, we have included the entire component C_j to the path a. At this point, Ant 1 either can't connect to new vertices, or it connects to a vertex in another component and continues with the similar procedure as Ant 1.

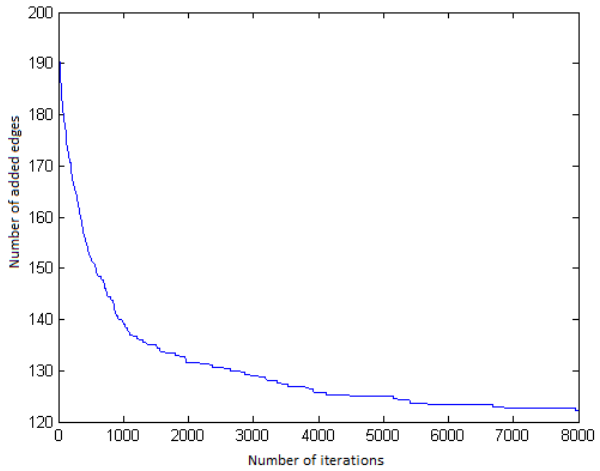
When Ant 2 stops, $C_j \subseteq a$, and $N_c \leq m$. Adding a new edge $e \notin E$, we connect to component C_i which increases $HCN(a)$, $HCN(a) = HCN(a) + 1$ and decreases N_c, $N_c = N_c - 1$. Analog to the last step, at the end of this one, we will have $C_i \subseteq a$, and $N_c \leq m - 1$.

Continuing the procedure inductively, in at most $m - 1$ steps, we will have $HCN(a) \leq m - 1$, $N_c = 1$ and $V \subseteq a$. Adding one more edge, we'll have created a Hamiltonian cycle with $HCN(a) \leq m$. But, $HCN(x) = |C_1, ..., C_m| = m$, so $HCN(a) \leq HCN(x)$.

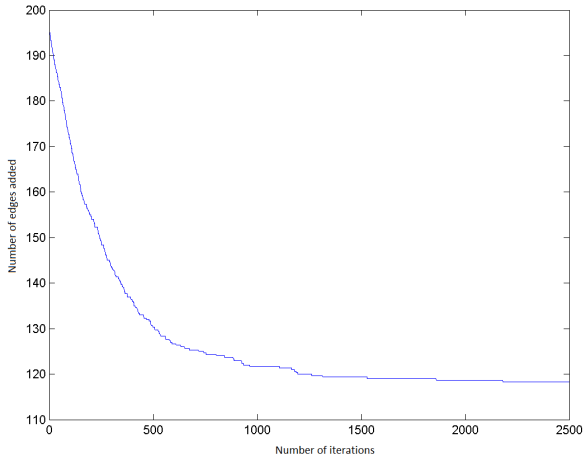
□

IV. Testing and Results

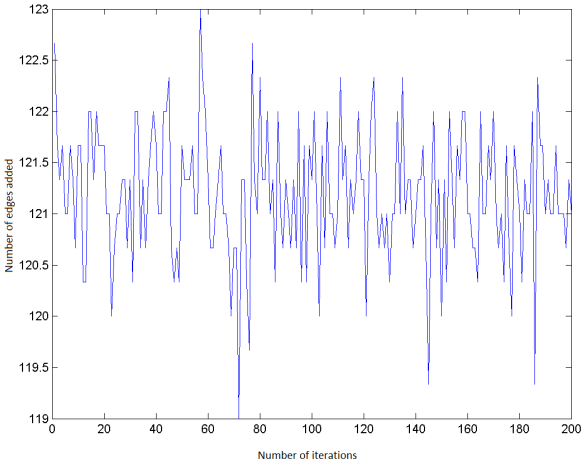
As we mentioned earlier - in our testing we have considered only graphs $G = (V, \frac{1}{n})$, where $\frac{1}{n}$ denotes the possibility that an edge will be included in a graph or not. We can see that this sort of graph is actually an Erdős-Rényi random model graph [7]. We have implemented all of our algorithms and GUI in MATLAB®. Graphs have been stored as incidence matrices. Also, we used compressed sparse format for storing graphs. We used operations for I/O with sparse matrices from



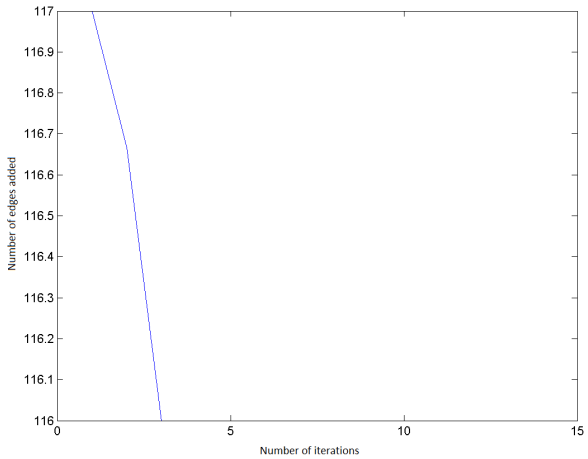
(a) Genetic algorithm, duration: 40.01 sec, best solution: 122.233



(b) Immunological algorithm, duration: 100.01 sec, best solution: 118.33



(c) Ant colony algorithm, duration: 24.14 sec, best solution: 118



(d) Twins Ant colony algorithm, duration: 1.17 sec, best solution: 116

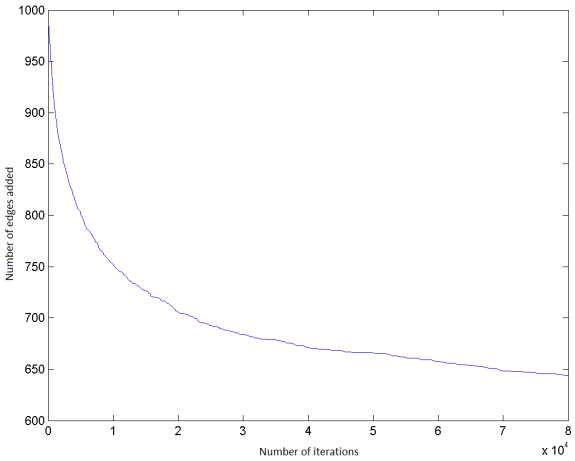
Fig. 2: The testing results for randomly generated graphs with 200 vertices

http://math.nist.gov/MatrixMarket/mmio/matlab/.

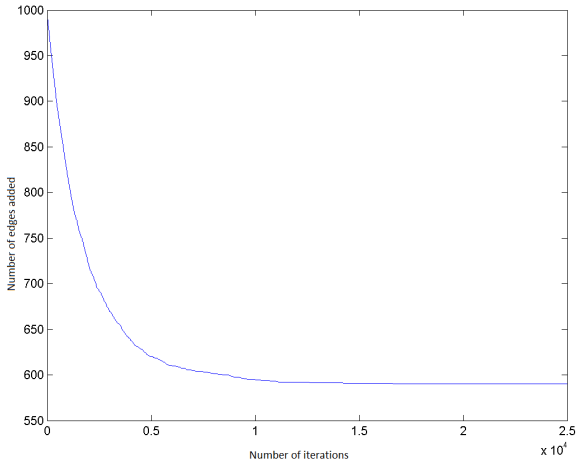
Algorithms have been tested on 30 instances of randomly generated graphs of order 200 (results on Figure 2) and on instances of order 1000 (results on Figure 3). Each testing has been repeated three times with the same parameters and each result represents the average of all three tested cases. Figure 4 shows the results of all 4 algorithms on 10 different graphs in a column-fashion. Obviously, the Twins Ant Colony algorithm achieves best results. The computer that was used for computation had a Intel©Core i5 2,3 GHz processor and 6GB RAM.

A. Some remarks on results and testing

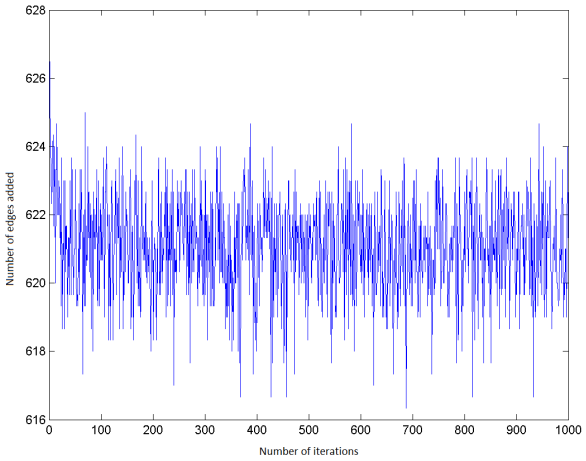
- The Genetic algorithm gave disappointing results, not converging for a fairly long time and not providing satisfying solutions as presented in Figure 2a and Figure 3a. Various experimenting with parameters and time vs. result analysis resulted in concluding the best elitism parameter is 8 (of 64).
- The Immunological algorithm seems to approach this problem significantly more successfully than the Genetic algorithm and provides fairly acceptable solutions, but is still not time feasible. Results can be seen on Figure 2b and Figure 3b.
- The Ant colony algorithm gives acceptable solutions when tested on smaller graphs compared to other algorithms (Figure 2c), but is not very successful in bigger graphs (Figure 3c). The obvious solution divergence is a result of the excessive randomness used in the algorithm, which we have discussed before.
- The Twins Ant colony algorithm provides best solutions in both smaller and bigger graphs (see Figure 2d and Figure 3d). Moreover, it proves to be the fastest out of the tested algorithms by far. As the testing was conducted on randomly generated graphs, we are unable to confirm the optimality of the Twins Ant colony algorithm solutions.



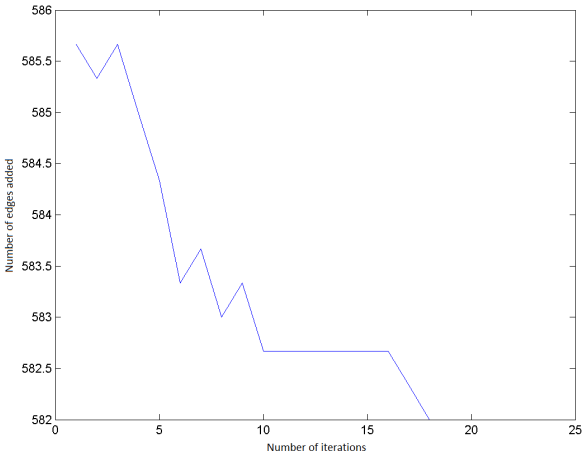
(a) Genetic algorithm, duration: 5136.6 sec, best solution: 664



(b) Immunological algorithm, duration: 3045.6 sec, best solution: 590



(c) Ant colony algorithm, duration: 2399.5 sec, best solution: 611



(d) Twins Ant colony algorithm, duration: 24.51 sec, best solution: 582

Fig. 3: The testing results for randomly generated graphs with 1000 vertices.

Nevertheless, as all other algorithms seem to converge to solutions with equal or greater Hamiltonian completion number, we can be optimistic about the nature of our solution.

V. Conclusion

Genetic algorithm proved to be too slow and imprecise for approaching this problem. Immunological algorithm has shown an improvement in terms of performance and considerable improvement in precision. Ant colony algorithm proved to be better than aforementioned algorithms but the real improvement is achieved in the Twins Ant colony algorithm. Adding the greedy component to the algorithm improves accuracy and reduces the time required to achieve convergence by narrowing the solution space. The twin ant ensures that an optimal solution persists in the solution space. It would be interesting to see how this approach could be applied to similar heuristics used in solving NP-hard problems.

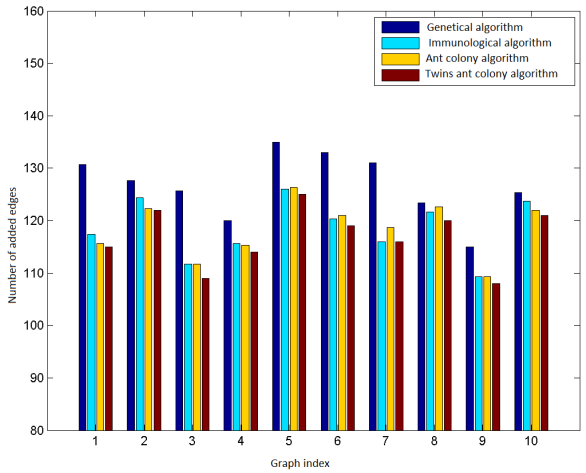


Fig. 4: Final solutions of algorithms when tested on 10 different graphs with 200 vertices. The x-axis is labeled ”Graph index” and y-axis is ”Number of added edges”. We can see that the best results are achieved with the algorithm.

Security of End User Wireless Networks in Zagreb Area

Jasmin Redžepagić*, Danijel Studen *, Vladimir Gavranić*, Alberto Teković**
* University College for Applied Computer Engineering
** VIPNet d.o.o.
danijel.studen@racunarstvo.hr

Abstract - Every network has its operator. The goal for this paper was to show how much configuration was performed by the operators after wireless networks were put in place. We have used a method called war driving to map out the locations and settings being broadcasted from the multitude of Wi-Fi devices in the Zagreb area. The main driver was to point out how much of the scanned devices are left at their factory settings and the security consequences that might follow should they remain as such.

A. Adoption and availability of Internet in Croatia

According to Eurostat, in data released for 2014, 69% of Croatian domestic population has logged on to the Internet during the past three months preceding the poll. European 28 country average is 78%, and Croatia is in the lower third of the table, according to the results [1].

Broadband penetration is also below European average. Only 68% of households have broadband Internet [2]. Although this is below average, broadband can be considered widespread when talking about urban areas. We base this assumption on relatively slow adoption of broadband in rural areas, which either have no access due to lack of infrastructure, or are unable to afford high speed Internet or any Internet connection at all.

For an average user, high speed Internet is readily available, at moderate cost.

B. Technologies used

Today almost all devices use some form of wireless communication technology. Technology most commonly used is Wi-Fi.

By itself, Wi-Fi [3] is trademark by Wi-Fi Alliance, and is used to denote equipment that is fully compliant with standard. Currently, it covers IEEE 802.11a, and IEEE 802.11b/g/n standards [4].

C. Encryption standards

In context of wireless security, we are dealing with three distinct encryption standards, all of them defined on 802.11 networks.

In order of protection provided, they are WEP, WPA and WPA2. Network can also be configured as unprotected, but this is strongly discouraged.

WEP is a protocol that is very easy to bypass. There are numerous very detailed documents explaining and showing step by step how to obtain the required password for the network intrusion [5]. This is a major problem because all exploits are well documented and no previous knowledge about how or why it works is needed. Given a set of tools and specific instructions it takes only a few minutes to circumvent WEP. Once the required password is successfully acquired, and connection to the network is established by obtaining an IP address, access to all the available resources in the network is possible. Given the combination of high success rate and public knowledge this is the most commonly used attack vector in the wireless networks area. The ISPs claim that they keep the devices operating on WEP for "backwards compatibility" but since WEP is considered obsolete[1], and all the devices available on the market today are capable of supporting higher grade encryption, this encryption method should not be used at all.

WPA is a standard designed to replace WEP on same hardware, or to be more precise, to enable old devices running WEP to be more secure. This was a major requirement, since there were a huge number of devices already on the market that had to be supported. Keys that are used are 128 bits, although it is possible to use 256bits keys they are not usually configured. WPA, sometimes also called TSN (Transition Security Network) uses RC4 standard for encryption.

WPA2 is a different beast and is currently the standard used in wireless encryption. It uses AES for encryption, a very strong algorithm enabling high security. Pre-shared key (PSK) configuration is the most common in both personal and enterprise users.

I. WHAT IS SECURITY?

As defined by Institute for Security and Open Methodology [6], Security is "a form of protection where a separation is created between the assets and the threat. This includes but is not limited to the elimination of either the asset or the threat. In order to be secure, the asset is removed from the threat or the threat is removed from the asset. "

Safety is defined as "A form of protection where the threat or its effects are controlled. In order to be safe, the controls must be in place to assure the threat itself or the

[1] WEP is officially retired since 2004 by Wi-Fi Alliance.

effects of the threat are minimized to an acceptable level by the asset owner or manager".

Using these definitions as guidelines, we decided to define that end-user networks are assets needing protection, and that a threat is any third party not explicitly authorized to use the network.

Threats can take many forms, we focused only on those coming from "outside" through wireless networks.

Looking from the security perspective networks can be separated into different groups.

Unsecure networks are those that have no configured encryption, and allow unsecure logon. Even from an average user standpoint they are least usable, since all the modern operating systems by default warn the user if he tries to connect to such a network. Leaving a network in such a state means that all information on the network is available, and all network shares are visible to any computer, unless configured otherwise.

Absolutely no wireless network should be left open unless we intend to provide open access to the network, but even then other ways of protecting the information on the network should be implemented.

Weak-security networks are currently the biggest problem if you look at them from a defense standpoint. In this context, our primary concern is with WEP enabled networks, since they use protocol that was proven unsecure a long time ago. Its insecurity is so deep that all sources dealing with wireless security recommend avoiding using WEP. Exploits and tools to crack and avoid WEP are available for years, and a dedicated attacker can crack and use a WEP protected network in a matter of minutes.

Networks that use WPA provide stronger security, since availability of dedicated cracking applications is limited [7, 8]. There are known ways to crack a WPA protected network, but they are extremely slow, and require advanced tools and knowledge outside of a casual hacker. WPA is mainly used by older equipment, and is hardware compatible with WEP devices. All new devices support both WPA and WPA2.

Strongest networks are those utilizing WPA2. Although there are rumors that WPA2 can be hacked, there are no known vulnerabilities that will provide entrance other than brute force types of attack, and even those are extremely complicated due to the nature of the algorithm.

II. EQUIPMENT USED

For the data capture process we used a Linux system running Kismet [9], a popular application for wireless network scanning.

System was installed on a laptop, configured on a mobile platform, a car that was deployed across the city of Zagreb.

For time and geo referencing we used an external GPS receiver connected to the laptop. Receiver was made by Garmin, and provided precise data on each scanned network.

External wireless card made by Alpha networks, model AWUS036NHR has been used. Card uses USB connection, and has an external antenna connector that was used to connect omnidirectional antenna with 8dBi gain. Antenna was placed inside the vehicle, next to the rear window, away from any source of interference. This has assured enough flexibility to emulate real life scenario of a user with a laptop trying to connect to a wireless network.

Kismet was run as a server, with visual interface running only to verify correct operation while (during) scanning.

Results are provided as an xml file. Kismet is capable of doing packet capture, and even running an active scan against a given network. However, for the purpose of this paper only passive methods of scanning have been used.

For a given network Kismet logged start of signal acquisition, end of signal acquisition, and data on signal power at min, max, and peak values. Location for each measurement was also logged.

From the packets captured, Kismet logs all the data it can extract - frequency of signal carrier, channel used, wireless standard used, and type and availability of security protocols used.

III. IDENTIFYING EQUIPMENT

Identifying network equipment used by a specific network is very simple with wireless devices, the same as all the rest of the network devices. Each device has a unique MAC (media access control) address. With a few clicks on the Internet it is possible to accurately find the model and manufacturer of any device given its MAC address. The easiest way is to scan through the MAC databases to check the vendor ID.

Once the device is sold to the ISP, the ISP pre-configures IP address on the device as well as the encryption method. With a little research, it is possible to identify the ISP using the pre-configured name. Sometimes the name itself is obvious as the ISP uses the name as a sort of free advertisement.

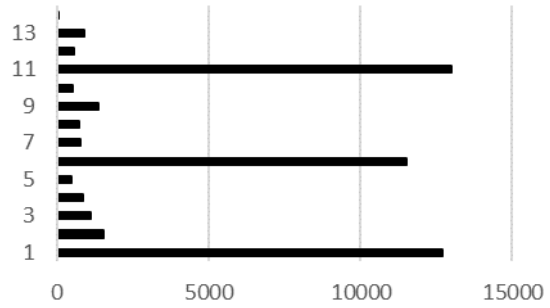

Figure 1. Distribution of Wi-Fi Channels used by channel number / number of networks using it

Once we have all the data, rest is simple. We can access the Internet and find default values for the username and password, which in turn gives us a good

probability of logging in to the network and taking it over and this is where wireless security comes into play.

From the end user standpoint, any wireless security mechanism can be seen as a way to authorize users to connect to the network itself and to ensure that communication is secured and not visible by third parties.

IV. ANALYZING DATA

Collected data has been stored in xml files, and evaluated offline, after the scan. All in all, we had around more than 700 GB of raw text data consisting of XML formatted files. Since XML is difficult to work with, we used a utility, GisKismet that is able to read Kismet formatted xml files, and transfer them to a much more usable SQL database. Data format that this particular utility uses is called SQLLite3, and is basically all in one SQL database that does not need a server, and can be used on multiple platforms. By running SQL queries, it is possible to analyze data, and even output data as distinct geo referenced points on a map, enabling us to visualize data.

For further data visualization through charts, Microsoft Excel has been used to prepare the data, and Google Earth being used to visualize georeferenced data.

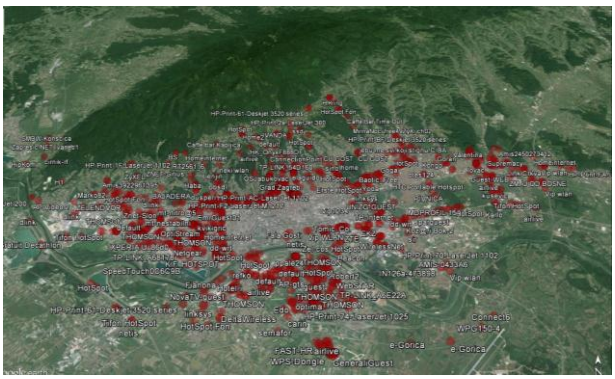

Figure 2 visualizing the data within Google Earth

Due to a huge number of individual data points, using Google Earth for this task is difficult, and extremely slow. Georeferenced data is on the other hand only needed for targeted attacks on a given network, but we logged it anyway, to ensure that all the data we collected can be verified, and to enable extraction of data subsets for latter analysis. But once the data is filtered, Google Earth visualization becomes invaluable tool in any analysis.

In total, 46332 individual networks, or network devices that identified themselves as individual networks have been scanned. It is possible that some of them are just parts of some larger network, and that by itself is another possible security problem.

Out of those networks, 1027 were configured as "cloaked". Cloaking is a security technique that hides SSID (service set identifier) from casual scanning, and can stop network from being visible on some devices. In reality, this poses almost no protection at all, since there are multiple ways that network information can be found [10]. It has to be noted that, after all, we managed to locate and note all those networks while in reality only managing to grab a few frames of useful data from any given network.

Table 1 depicts all the encryption methods used by individual networks. Each network can use more than one method of encryption, in order to accommodate different devices with different encryption capabilities.

TABLE I. ENCRYPTION TYPES

Encryption	Number	Percentage
None	1079	2,33%
WEP	7407	15,99%
WEP40	1	0,00%
WPA Migration Mode WEP104 WPA+TKIP	6	0,01%
WPA Migration Mode WEP104 WPA+TKIP WPA+PSK WPA+AES-CCM	1	0,00%
WPA Migration Mode WEP40 WPA+TKIP WPA+PSK	1	0,00%
WPA+AES-CCM	285	0,62%
WPA+PSK WPA+AES-CCM	12687	27,38%
WPA+TKIP	33	0,07%
WPA+TKIP WPA+AES-CCM	126	0,27%
WPA+TKIP WPA+PSK	9971	21,52%
WPA+TKIP WPA+PSK WPA+AES-CCM	14735	31,80%

Since network encryption is negotiated between the device and the network itself, we classified each network by its least secure network standard. In this context, WEP40 can be classified as "normal" WEP, as well as WEP104. WPA+AES-CCM denotes WPA2, since it uses most secure CCM standard, and AES encryption.

When broken down this means that most of the networks actually use two standards, WPA and WPA2, at the same time.

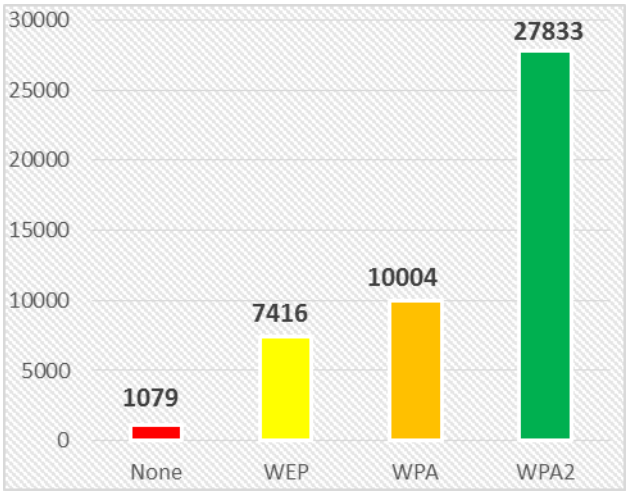

Figure 3 Distribution of network encryption based on our sample

As can be seen from the data collected, around 18% of networks use no encryption at all, or use WEP. We consider these networks as unsecure. Since these types of networks made relatively large percentage of our data sample, this points to a major problem. Users are configuring security settings that will serve only to deter casual hackers.

More than 50% of the networks use WPA2, which is good, but they are configured to allow both WPA and WPA2 connections. This means that device that connects to the network has to make sure to use stronger encryption algorithm.

One more important point to take into account are network names. All the ISPs in Croatia use similar ways of naming their networks, almost all of them using some kind of prefix, and appending a unique identifier to the name. Taking that into account, occurrences of large sets of similar names in the dataset point to default network names being used. All of this means that end users rarely change any settings on their equipment, even if it means using sometimes unusual and inconveniently complicated network names and passwords assigned by their operator.

V. ARE THE NETWORKS SECURE?

Most, if not all of the equipment we scanned during our data collection was sold and deployed by ISPs. Only devices that did not fit that description were printers, a couple of similar end user devices (Access points for extending coverage), and professional devices used in enterprise and similar networks. One notable mention is Eduroam network spanning University of Zagreb locations, open to all the students, and utilizing advanced data protection and traffic monitoring way beyond the scope of this paper. During the scan we also noticed a small number of point to point links, but their relatively small number (a couple of hundred) compared to the data sample enables us to ignore them as statistically insignificant.

VI. CONCLUSION

Most of the network equipment that was encountered during the scan was sold or leased from local telecom operators, as was concluded by network names and MAC addresses used. Network configuration follows similar pattern, newer network devices being configured with stronger encryption than the older one, probably due to large part of configuration being done from the operators' side, not involving end users.

A lot of networks still use weak encryption or no encryption at all, but the situation is improving as new equipment rolls out.

Equipment that uses Wi-Fi technology but comes preconfigured without any encryption poses a large problem for the security.

All this points out to a dire need for large scale campaign to educate end users on benefits and problems that new technology such as Wi-Fi has.

Another point is that right now operators more or less have all the control over end users network, since the cannot rely on users being in control of their own networks. This should be fixed by education, since users need to be able to at least recognize possible threats to their network and their data, and be able to take appropriate actions.

Learning from student thesis products: examples and experiences

M. Vučićević, S. Predanić, T. Horvat
University of applied sciences, Department of Electrical Engineering, Zagreb, Croatia
martina.vucicevic@tvz.hr; spredanic@tvz.hr; thorvat3@tvz.hr

Abstract - Products life cycle goes through several different development stages. One of the tasks set before engineers is to start from an idea and build it up all to the final product. This process is taught to students through seminars and graduation thesis. In education environment it is possible, and desirable, to divide the process so that students can easily acquire necessary knowledge and skills. Experiences at Department of Electrical Engineering of University of applied sciences proved that electrical and electronic products resulting of graduation thesis are also useful in the teaching process of current students, either by direct use in laboratory work or by student work on product enhancement. This paper will present student products and applications implemented in classroom, and their possible improvements.

I. INTRODUCTION

In the education process student learning is often divided between being a passive listener to new knowledge in ex-cathedra lectures, and a hands-on active work during various types of work like laboratory exercises or problem solving in the classroom. Most often the active work is preferred as students can remember just 10% of what they see, but more than 90% of what they do. So, at the University of applied sciences in Zagreb, several different approaches were taken on the problem of making an active classroom. From making special circuits and models for use in laboratory, to using professional software for simulating real electronic projects.

That approach to learning proved successful and is currently the way which most teachers take as the best one. But making models and examples is often time consuming tor the teachers, while at the same time it constrains student creativity. A different approach of giving the students the opportunity of making teaching materials proved as a better system in both engaging the students and giving them a feeling of pride and independence.

In this article a few examples of previous teaching models and examples will be described, and a few of student projects will be shown. A continuous evolve of the projects is possible due to knowledge sharing between student generations, with teacher as a mentor and a facilitator in giving access to knowledge rather than boring teaching from afar.

II. CURRENT MODELS

Current models and examples for teaching in which students are engaged in a continuous work can be summarized in two different categories:

- software elements in which a simulation or planning of a real system is made
- hardware elements in which students can engage themselves in a tactile work with the elements and the surroundings (additional tools like measuring equipment or just trying to "break" things).

Although the software systems have an advantage of being democratic, as each student can take the software home and install it for home usage (e.g. if they are more interested and involved), the end result sometimes feel empty due to its virtual nature. Such extensively used systems is Labcenter Proteus, which is often used in courses of digital electronics and microcontrollers. [1] This software allows the user in rapid prototyping and designing a circuit, in making firmware for such circuits and to simulate not only the student made system, but to simulate various tools which would normally take a lot of space and money. As Labcenter Proteus is often used in professional work, students get a lot of practical knowledge, with the only disadvantage of using a completely virtual system.

Hardware elements are much better in use, where students have a real circuit board, box, or some other part of equipment. Such elements are used extensively throughout the University of applied sciences in Zagreb, from Electrical engineering with special circuits for big motors, over the automation courses where simulators for industrial system were made [2], all to communication systems and digital circuits where special boards are made.

Figure 1 PLC's State Simulator

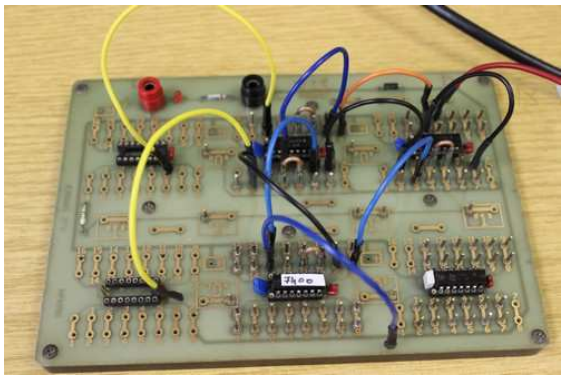

Figure 2 Circuit board used in the laboratory exercises

The option of seeing the systems, of understanding them, and using them in several possible ways, gives the students a much more realistic feel to expectations about their learning and knowledge level, and their future professional life.

Both of these approaches are starting to be even more combined in systems that use material tactile simulators and measuring computer software which allows fast and easy analysis of the given data. University of applied sciences uses National Instruments LabVIEW (as a software part) and MyDAQ (as a hardware acquisition system) as an easy-to-use integration system. Such models are then used in both ex-cathedra teaching [3], and as laboratory exercises and examples. But as mentioned earlier, making a good model is a tedious task which takes a lot of time and often requires teachers' expertise in the subject and their abilities to improvise and design simple but effective learning systems.

The idea which has taken off is to make teaching models as the necessary proof of independent work in showing the ability to solve engineering problems. Such work is expected for students' graduation thesis. By making models for future students in their thesis projects, students deepen their current knowledge while making the best possible product in the fear of being embarrassed in front of their peers and feeling proud when they do well. The projects often don't look as a polished product because it's in their intended nature to be changed, improved, and destroyed if necessary, for the better learning experience of future students.

Figure 3 Traffic light simulator

Figure 4 Model of a house, simulating heating and cooling

III. EXAMPLE OF A STUDENT PRODUCT

One of extensively changed and used student model is a model of an elevator. Started as a student graduation thesis, it is used for demonstration in several different academic areas:

- as an example for systems which use electric motor power to generate force
- as an example for digital electronics
- as an system which includes one programmable microcontroller, but also has an option of connecting other microcontrollers systems
- as a system which can be controlled through different physical simulators/controllers and through computer based (LabVIEW) simulators.

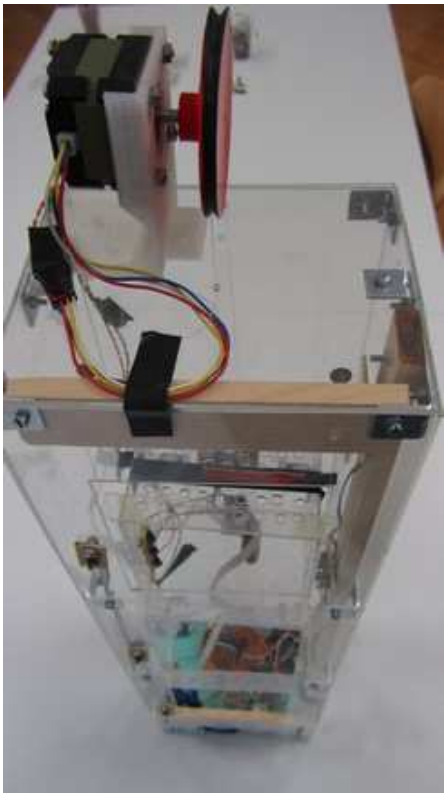

Figure 5 Elevator model

The elevator was conceived primarily as a programmable microcontroller tool, but its use widened after the student who prepared the system made it modular and easy to repair, change and improve. With student's thesis as a starting point, different simulations in LabVIEW and Proteus were made, also by students. Such simulations are then used in laboratory exercises, and are given as homework to students, in which they can change the software in the microcontroller and in some cases, completely change how the elevator works. This gives everyone a chance in the tactile part of learning, when they see the real product of their work. As elevator is a common thing in their lives, they can relate in how it should work and can propose improvements.

Proposed improvements are tested in simulations (if possible) and documented for the future use. In cases where the improvements are physical, an option to reverse the changes is necessary. During the use of the elevator, such reversing was seldom, as students have great ideas and are motivated in improving the system. Such examples are 3D printed motor bracket and the pulley which proved like a good change, while the students learned to use a 3D printer and the necessary software. Another example is the change in motors, where a DC motor was changed to a stepper motor for finer control of the elevator - this made an additional change in a simpler motor driver circuit. Due to such flux of this system, it doesn't looks like a finished product which is by itself an advantage as students are not afraid of working on it, even during the laboratory exercises.

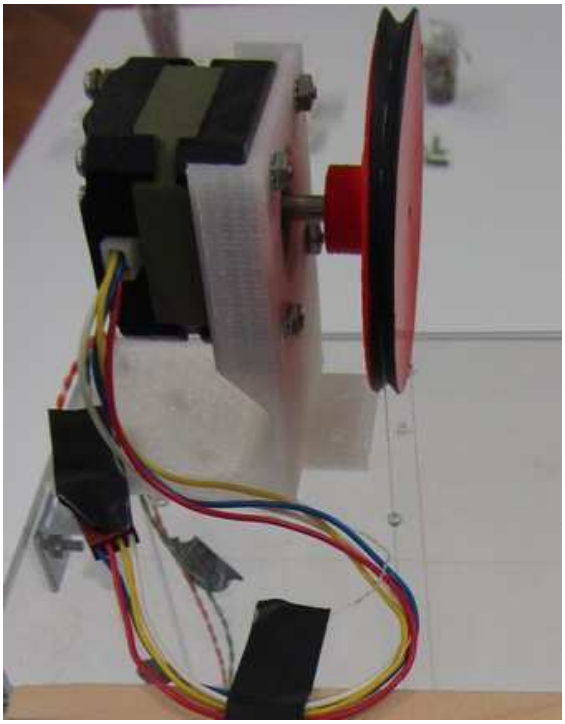

Figure 6 Parts of the elevator - printed on the 3D printer

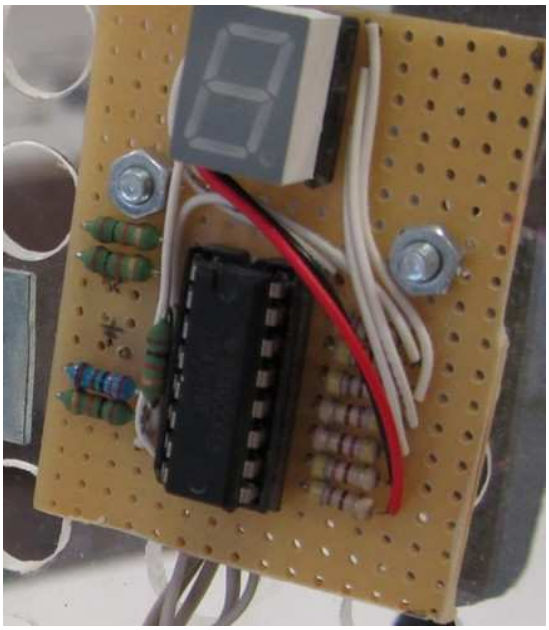

Figure 7 Parts of the elevator – 7 segment display

Some parts of the elevator are simple circuits normally thought separately from the connecting circuits. Usual way of learning about them was only on special circuit boards or on protoboards, but in the elevator these systems are integrated into one unity. Such an example is the use of a 7 segment display to show the floor on which the elevator is currently, which is controlled through a BCD decoder chip, which is in turn controlled by a microcontroller or a MyDAQ acquisition system. Such an arrangement is obvious for a professional, but sometimes students have problems with integrating simple systems into a complex system.

The elevator has an Arduino microcontroller for its primary control. Arduino is one of the most popular microcontroller systems for novices. In the elevator this microcontroller board can be reprogrammed and the programmer (student) can change the behaviour of the elevator logic. The program is first checked in Proteus simulation, to ensure that it is working correctly. The elevator is modular so a change in the electronic brain (the microcontroller) is easy, as most wires are already prepared for connection on other boards or systems (like MyDAQ).

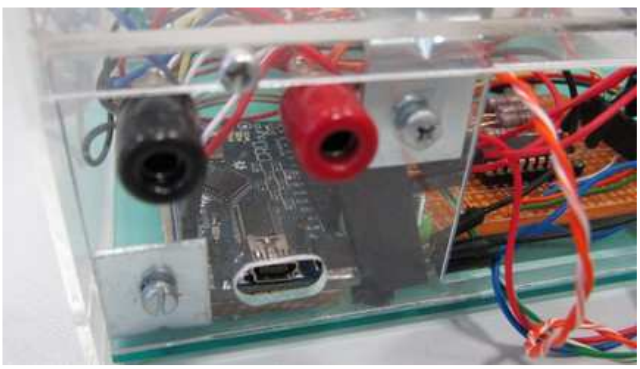

Figure 8 Parts of the elevator – Arduino board

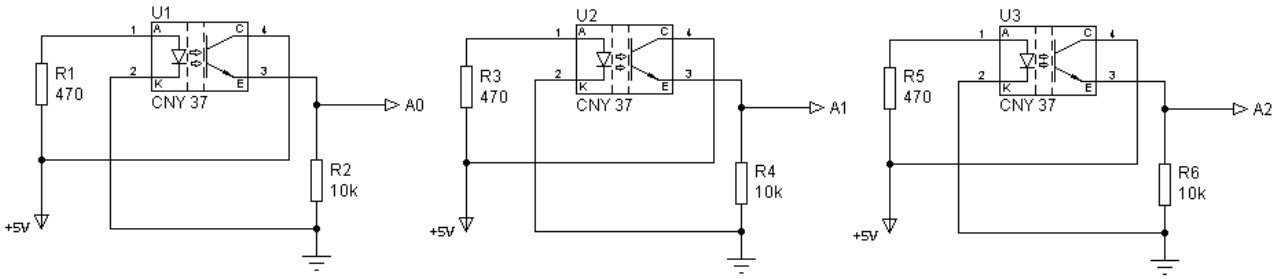

Figure 9 Schematic for elevator position detection using optocouplers

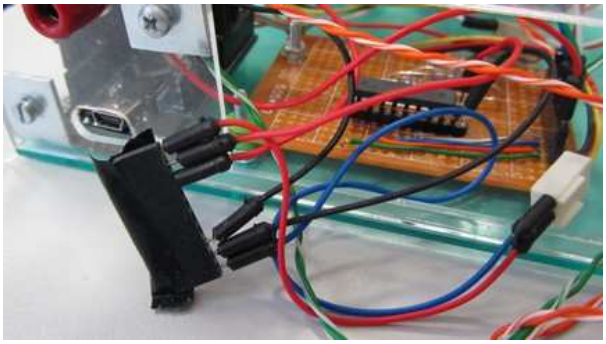

Figure 10 Parts of the elevator – ease of access for modular changes

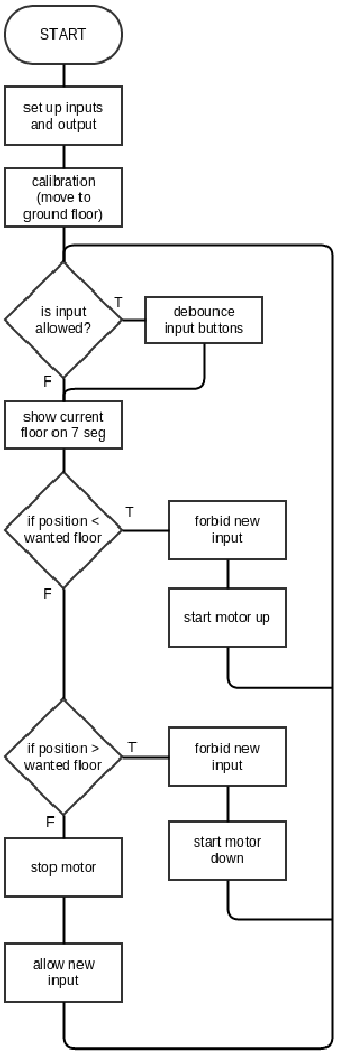

Figure 11Elevator model flowchart

IV. FUTURE MODELS

Previous models proved successful, and there are ideas for future models made as student thesis. As models with several different systems are more practical in multidisciplinary teaching, the future models will incorporate such ideas.

First interesting model is a model of a parking ramp, which is already used as a practical simulation in software. Such a system consists of several parts: the sensors for a car, sensors for the ramp, the motor, and a display for showing the number of parked cars. Parking ramp system covers most of the ideas used in elevator, but it can be made smaller and more practical for use by students. Due to its low complexity it can be made in several copies, so several students could work in parallel.

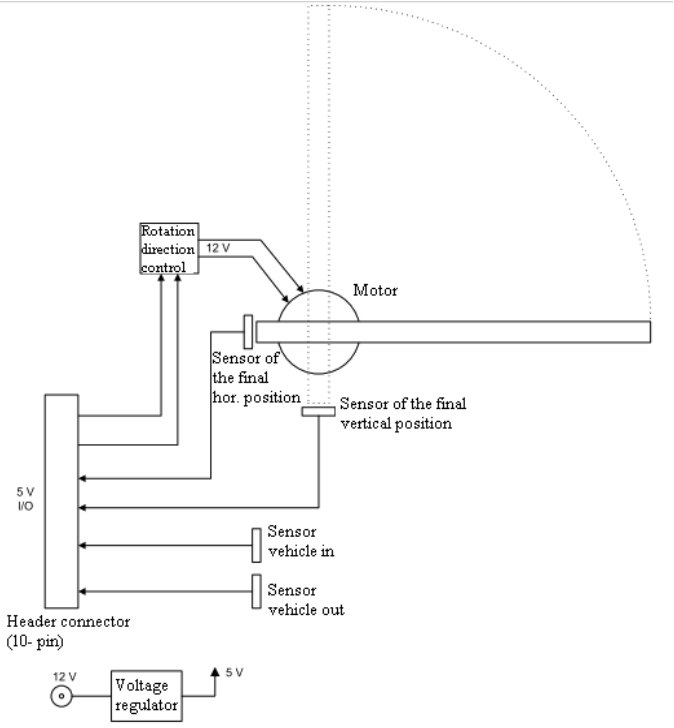

Figure 12 Basic schematic for the parking ramp model

Another interesting model is the use of different sensors with a microcontroller and which has an option to send data wireless. Using one of standard communication protocols, a portable sensor system can be used for different tasks. Although the sensory nodes are already easily obtained, a modular system should be used in teaching environment to prepare students for future IoT (Internet of Things). Currently available system are often very integrated, so modularity and a connection to a software like LabVIEW would help students in achieving higher understanding of sensory nodes. Modular also must give an option in changing the communication protocols: connecting to mobile phones via Bluetooth, to Wi-Fi networks via additional modules and to other possible communication protocols (like Xbee, nrf24 or even to 3G or 4G networks).

Some ideas come from students themselves, but they often take their models home as they grow attached to them. Their graduation thesis project becomes their pride and joy.

V. CONCLUSION

Models of different real systems are often used in teaching, and the problem of making a model is left to the teacher. At University of applied sciences Zagreb the making of a real life model is given as an opportunity to students, as their final thesis. Student work has to be checked by the mentor during the making of the model, but even a model which is badly put together helps in making the next version or gives clues in how to improve the original. This practice cannot be used in all courses as some are still reliant on the teachers' ability to imagine and to make an exemplary system, but many teachers are changing the paradigm of learning and are trying to show the students of what they are capable of, even with having low resources or technical options. This paper shows some examples of previous view on models (software and hardware), and gives an example of a different type of multipractic model (in this case, an elevator), which was made by a student.

Models made this way which are used in lectures and laboratory work are constantly improving due to student engagement, good documentation which is usable for knowledge sharing (it's made out of students final thesis) and due to new ideas which are coming from a pool of young perspective people, eager to leave their mark on their University.

Abstract - In this paper we describe a complex networks analysis of Wikipedia. We construct 10 different networks from Wikipedia entries (articles) related to the chosen domain. The goal of the experiment is to extract domain knowledge in terms of identifying entries that are centrally positioned and entries that are strongly related. We apply complex networks analysis on all acquired networks and examine the networks' structure. We employ centrality measures in order to find centrally positioned entries in the network. Furthermore we identify communities and find which entries are densely connected according to the network structure.

I. INTRODUCTION

Complex networks exhibit specific topological features, such as high clustering coefficients, small diameters, a power-law degree distribution, community structure, one or several giant components, hierarchical structures, etc. Two important classes of complex networks that can be further differentiated are small-world networks [1] with small distances and high clustering coefficients as main properties and scale-free networks [1] which can be characterized by a power-law degree distribution.

Wikipedia can be modelled as a complex network in a way that Wikipedia entries are nodes, and links between two nodes are established if there is a hyperlink between these two entries. Early attempts to quantify Wikipedia using complex networks analysis were focused only on network structure of linked Wikipedia entries. In [2] Zlatić et al. present an analysis of Wikipedias in several languages as complex networks. They show that many network characteristics (degree distributions, growth, topology, reciprocity, clustering, assortativity, path lengths and triad significance profiles) are common to Wikipedias in different languages and show the existence of a unique growth process. The same authors studied Wikipedia growth based on information exchange in [3]. In [4] an analysis of the statistical properties and growth of Wikipedia is presented. Pemble and Bingol [5] have constructed two complex networks out of English and German Wikipedia corpora and analyzed conceptual networks in different languages.

The other research direction is focused on content found on Wikipedia and analyses Wikipedia as a (domain) knowledge network. In Fang [6] they first extract a specific domain knowledge network from Wikipedia (specifically, four domain networks on mathematics, physics, biology, and chemistry) and then carry out statistical analysis on these four knowledge networks. Also, they show that MathWorld and Wikipedia Math share a similar internal structure. In [7] Masucci et al. extract the topology of the semantic space and measure the semantic flow between different Wikipedia entries. They further analyze a directed complex network of semantic flow. In [8] the results of semantic language networks analysis are presented in general.

Motivated by the second approach that studies Wikipedia as a knowledge network, we wanted to study how the network structure is related to domain knowledge. The goal of our experiment was to extract centrally positioned entries in the network and analyze how these entries are related to domain knowledge and are some more important than other. In the second part of the experiment the task was to extract entries that belong to the same community and check whether they are semantically related.

In our previous research, we have already analyzed Wikipedia as a complex network [9], but by constructing a network of syllables. Also, we examined the structure of Croatian language networks in [10,11,12]. In [12,13] we applied network measures for a keyword extraction task. In all our previous experiments we were focused solely on language structure and this is our first attempt to analyze semantic relations in a network.

In the second section we present key measures of complex networks involved in network structure analysis. In the third section we describe data sources and network construction principles. In the fourth section we present the results. Finally, the fifth section contains a conclusion and possible directions for future research.

II. NETWORK STRUCTURE ANALYSIS

In this section we review some of the most important network measures [14]. Every network has an N number of nodes and a K number of links. The degree

This work has been supported in part by the University of Rijeka under the project number 13.13.2.2.07.

of a node *i* is the number of links with which the node is connected, k_i. Considering the fact that we are working with directed networks, we must specify two types of degrees: the in-degree, k_i^{in}, corresponding to the number of incoming links and the out-degree, k_i^{out}, equal to the number of outgoing links for any particular node *i*. The average degree of the network is:

$$< k > = \frac{2K}{N}. \tag{1}$$

For the directed networks we omit multiplication by 2. In the further equations we assume that the network is directed and that the total possible number of links is equal to $N(N\text{-}1)$. For every two connected nodes *i* and *j*, the number of connections lying on the path between them is represented as d_{ij}, and so d_i is the average distance of a node *i* from all other nodes, and it is obtained by:

$$d_i = \frac{\sum_j d_{ij}}{N}. \tag{2}$$

For the next two measures, if a network contains more than one component, we consider the largest component. The average shortest path length between every two nodes in a network is:

$$L = \frac{1}{N(N-1)} \sum_{i \neq j} d_{ij}. \tag{3}$$

And the maximum distance results in the network diameter, *D*:

$$D = max_i d_i. \tag{4}$$

The clustering coefficient is a measure which defines the presence of connections between the nearest neighbours of a node. And so, c_i (the clustering coefficient) of a node is a fraction between the number of edges E_i that exist between that k_i and the total possible number:

$$c_i = \frac{2E_i}{k(k-1)}. \tag{5}$$

The average clustering coefficient of a network is defined as the average value of the clustering coefficients of all nodes in a network:

$$C = \frac{1}{N} \sum_i c_i. \tag{6}$$

Density of a network is a measure of network cohesion defined as the number of observed links divided by the number of total possible links:

$$d = \frac{K}{N(N-1)}. \tag{7}$$

Degree centrality of a node *i* is the degree of that node. It can be normalised by dividing it by the maximum possible degree $N-1$:

$$dc_i = \frac{k_i}{N-1}. \tag{8}$$

Betweenness centrality quantifies the number of times a node acts as a bridge along the shortest path between two other nodes. Let σ_{jk} be the number of shortest paths from node *j* to node *k* and let $\sigma_{jk}(i)$ be the number of those paths that pass through the node *i*. The normalised betweenness centrality of a node *i* is given by:

$$bc_i = \frac{\sum_{i \neq j \neq k} \frac{\sigma_{jk}(i)}{\sigma_{jk}}}{(N-1)(N-2)}. \tag{9}$$

Closeness centrality is defined as the inverse of farness, i.e. the sum of the shortest distances between a node and all other nodes. Let d_{ij} be the shortest path between nodes *i* and *j*. The normalised closeness centrality of a node *i* is given by:

$$cc_i = \frac{N-1}{\sum_{i \neq j} d_{ij}}. \tag{10}$$

Modularity measures the quality of the network partition in the communities. The modularity of a network partition is a scalar value between -1 and 1 that measures the density of links inside communities as compared to links between communities. Let e_{ij} be the fraction of edges in the network that connect vertices in group *i* to those in group *j*, and let $a_i = \sum_j e_{ij}$. Then the modularity can be calculated using following equation:

$$Q = \sum_{i=1}^{k} \left(e_{ii} - a_i^2 \right). \tag{11}$$

The degree assortativity coefficient measures the tendency of nodes in a network to connect to nodes similar to themselves. The coefficient lies between -1 and 1 and it is quantified via the Pearson correlation. Positive *r* values indicate a correlation between similar-degree nodes. Let q_k and q_j be the distribution of the degree of out-edges that do not connect to the other node in question, e_{jk} the joint probability distribution of q_k and q_j, and σ_q^2 the variance of the distribution. Then we can calculate the assortativity coefficient using the following equation:

$$r = \frac{\sum_{jk} jk(e_{jk} - q_j q_k)}{\sigma_q^2}. \tag{12}$$

On the meso-scale level complex networks analysis includes a community detection task [15]. Communities, in this sense, are groupings of densely interconnected nodes within a network. In other words,

nodes in a community have a greater amount of connections amongst each other than with other nodes in the network. Several algorithms are used for community detection such as hierarchical clustering, Girvan-Newman's algorithm, minimum-cut method, etc. One of the most efficient is the Louvain method [16], a greedy optimization method that optimizes the modularity of a network's partitions. The number of communities (*Nc*) represents the amount of such groupings found within a network.

III. NETWORK CONSTRUCTION

For the purpose of our experiment we collect entries from Wikipedia and construct networks related to the domain. Our intention was to construct two types of networks: level 2 networks and level 4 networks. We construct level 2 networks by starting with a chosen seed entry (e.g. "*Complex network*" or "*Data*"), storing all the hyperlinks to related entries from the seed entry's text (level 1) and proceeding to extract the hyperlinks from all the entry pages taken from the original entry (level 2). Analogously, we construct level 4 networks by taking the first 10 hyperlinks from a given entry page and proceeding to repeat the task three times, arriving at level 4. We limit the hyperlinks to the first 10 due to the computational complexity at the same time having in mind that the most general hyperlinks are usually at the beginning of the entry's text.

Therefore, the first task is the construction of a web scraping program which would extract hyperlinks from a Wikipedia entry's text. The hyperlinks are extracted using a Python package for HTML parsing called Beautiful Soup which parses the HTML structure of a given HTML document into a parse tree. By navigating the tree we locate the tag ID which corresponds to article content ("mw-content-text") and proceed to extract the hyperlinks which themselves are found within paragraph (<p>) tags and finally inside link (<a>) tags in that section of the page. Finally, each network is stored in an edge list in the following format: "entry title" \t "linked entry title". We had some difficulties with processing non-ASCII script and hyperlinks that weren't connected to other documents (citations, in-page references, etc.), but we managed to avoid those by checking the data during the extraction process.

In our directed network, each entry's title represents a node and it is connected to other entries hyperlinked in its text, again represented as network nodes. We construct a total of 10 domain networks for five chosen seed entries: "*Byte*", "*Complex network*", "*Computer science*", "*Data*" and "*Programming language*". The naming scheme includes the level of a specific network in its name (e.g. the level 2 network for "Byte" is BT2). Since we consider unweighted networks, we dismiss double links. This, along with the fact that some entries do not contain 10 hyperlinks resulted in our level 4 networks having less than 10^4 expected edges. We use Python and the NetworkX software package developed for the creation, manipulation, and study of the structure, dynamics, and functions of complex networks [17].

IV. RESULTS

In this section we present the results of our measuring described in section 2, such as average degree $\langle k \rangle$, average path distance L, diameter D, average clustering coefficient C, density d, modularity Q, number of communities (N_c) and degree assortativity coefficient r. We also present the most central nodes (according to the three centrality measures) and communities in networks detected by using the Luvain algorithm.

In Table I. we present estimated global network measures. There are certain differences between measures for level 2 and 4 which are evident upon closer inspection. For instance, level 4 networks have significantly larger average path lengths, diameters, assortativity coefficients, often a significantly larger number of detected communities and slightly larger average degrees. The modularity measure and density are comparable between the two, whilst level 2 networks show larger clustering coefficients.

For comparison with random networks, the table also includes two measures for equivalent random networks (Erdös-Renyi random graphs) – the average shortest path length ($L_{ER} = \ln N / \ln \langle k \rangle$) and the average clustering coefficient ($C_{ER} = \langle k \rangle / N$). The results show that the complex networks we have constructed have a significantly higher average clustering coefficient than their Erdös-Renyi random graph counterparts. This, in addition with a relatively small average shortest path length L led us to conclude that we are dealing with small-world networks as described by Watts and Strogatz [20]. For the purposes of this comparison we treat the networks as undirected.

Moreover, a distinctly high modularity coefficient Q (higher than 0.7 in all but one network, as visible in Table I.) shows a clear tendency towards community clustering of nodes present in the networks. We did not observe any strict rule governing community size across networks, although level 2 networks have an understandably smaller N_c which we contributed to the very construction principle as described in section 3.

Figure 1 and Figure 2 show the degree distribution plots for level 2 and level 4 networks corresponding to the "computer science" and "complex network" entries respectively. The observed difference between the level 2 and 4 networks is believed to be due to the method of network construction.

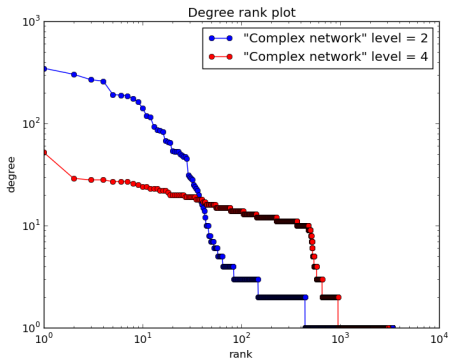

Figure 2 - Degree distribution for CN2 & CN4

TABLE I. GLOBAL NETWORK MEASURES CALCULATED FOR ALL 10 NETWORKS

Measure	"Byte"		"Complex network"		"Computer science"		"Data"		"Programming Language"	
Network	BT2	BT4	CN2	CN4	CS2	CS4	DT2	DT4	PL2	PL4
Number of nodes (N)	3945	3632	3405	3070	12881	3630	2297	3658	7467	3965
Number of edges (K)	5112	5611	4132	5008	18852	5851	2630	5531	13933	6215
Average degree ($<k>$)	1.296	1.545	1.214	1.631	1.464	1.612	1.145	1.512	1.145	1.612
Avg. shortest path (L)	3.693	6.834	3.198	9.218	3.417	6.277	3.086	6.369	3.127	6.277
Avg. shortest path (L_{ER})	8.693767	7.2662195	9.168408	6.791134	8.8088393	7.0022451	9.340827	7.4144377	10.763658	7.0776521
Diameter (D)	9	15	6	22	7	14	7	14	6	22
Average clustering coefficient (C)	0.06	0.021	0.043	0.024	0.074	0.019	0.043	0.019	0.082	0.021
Average clustering coefficient (C_{ER})	0.000657	0.0008508	0.0007131	0.0010625	0.0002273	0.0008882	0.000997	0.0008267	0.0003067	0.0008131
Density (d)	0.0003	0.00042	0.00035	0.00053	0.00011	0.00044	0.00049	0.00041	0.00025	0.0004
Modularity (Q)	0.778	0.776	0.794	0.763	0.725	0.771	0.828	0.779	0.594	0.78
Number of communities (N_c)	17	32	17	21	23	27	18	31	19	30
Degree assortativity coefficient (r)	-0.592	-0.048	-0.521	0.021	-0.491	-0.028	-0.561	-0.048	-0.468	-0.059

After the analysis on the global level, we analyse the networks on the local level in terms of centrality measures. Tables II. and III. show lists of top ten entries according to the three centrality measures for the two seed entries: "*Computer science*" and "*Programming language*". We analyse the degree centrality, betweenness centrality and closeness centrality. For the degree centrality we treated the network as undirected. For each centrality measure and domain there are two lists of entries, one for level 2 networks and another for level 4 networks. We noticed that the lists for level 2 networks consist of entries that are semantically related to the seed entries ("*Computer science*" or "*Programming language*") in a way that might be ascribed as belonging to a hierarchy. This is especially evident for the closeness centrality measure. For example, the list of top ten entries according to the closeness centrality for the seed entry "*Computer science*" contains other scientific domains (theoretical computer science, mathematics, artificial intelligence, physics, engineering) and for the seed entry "*Programming language*", list contains some prominent programming languages (C, Java, Perl, Python, C++).

TABLE II. TOP TEN ENTRIES IN THE „*COMPUTER SCIENCE*" NETWORKS (CS2, CS4) REGARDING THE THREE CENTRALITY MEASURES: DEGREE CENTRALITY, BETWEENNESS CENTRALITY AND CLOSENESS CENTRALITY

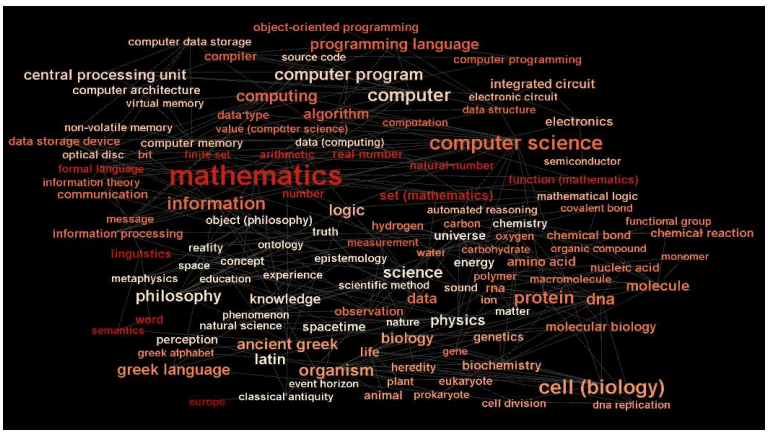

Figure 3 – Communities in the CS2 network

In the second part of the experiment we analyse communities in all 10 networks in order to explore which entries are grouped together. Figure 3 shows most significant entries from the CS2 network grouped into communities. Different communities are presented in different colours. For example, entries related to the mathematics domain (*mathematics*, *number*, *set*, *function*, *real number*, etc.) are in the red-coloured community; entries related to the computer science domain (*computing*, *algorithm*, *compiler*, etc.) are in the orange-coloured community; entries that are related to the biology domain (*cell*, *organism*, *gene*, etc.) are in the light-orange coloured community and entries that are related to the philosophy domain (*reality*, *concept*, *knowledge*, etc.) are in the white-coloured community. It can be observed that entries grouped into communities are more closely semantically related than entries from different communities. The results are similar for other networks; semantically related entries are grouped into communities much more than entries that are not semantically related.

V. CONCLUSION

In this paper we present our initial attempt to study Wikipedia as a complex network. We extract parts of Wikipedia related to 5 chosen seed entries. We construct 10 different networks using two different principles of construction. Then we analyse the global structure of all networks. We show that all networks have similar properties: a high average clustering coefficient in comparison to the random networks, small distances, low density and community structure. From these global measures we may conclude that all 10 networks extracted form Wikipedia are small-world networks. These results are in line with previous studies of Wikipedia as a complex network.

Furthermore, we explore semantic relations in the constructed networks. We use network centrality measures to extract entries in the networks that are significant according to the network structure. Three centrality measures are employed for this task: degree centrality, betweenness centrality and closeness centrality. It can be observed that for level 2 networks centrality measures obtain good results (especially closeness centrality). Among top ten entries according to the closeness centrality are entries that are semantically related to the domain. This can be useful for modelling taxonomy or domain ontology. Furthermore, semantically related entries are grouped into communities more often that entries that are not semantically related.

These findings can be partially explained as a consequence of network construction rules employed in this experiment. However, these preliminary results suggest that Wikipedia is well organised and its structure can be captured and explored by a complex networks approach. In future work we plan to extract a broader section of Wikipedia and explore its potential as a knowledge network. We will study the domain knowledge extraction possibilities and perform the evaluation of the results.

***Abstract*—In this paper we describe LaNCoA, Language Networks Construction and Analysis toolkit implemented in Python. The toolkit provides various procedures for network construction from the text: on the word-level (co-occurrence networks, syntactic networks, shuffled networks), and on the subword-level (syllable networks, grapheme networks). Furthermore, we implement functions for the language networks analysis on the global and local level. The toolkit is organized in several modules that enable various aspects of language analysis: analysis of global network measures for different co-occurrence window, comparison of networks based on original and shuffled texts, comparison of networks constructed on different language levels, etc. Text manipulation methods, like corpora cleaning, lemmatization and stopwords removal, are also implemented. For the basic network representation we use available NetworkX functions and methods. However, language network analysis is specific and it requires implementation of additional functions and methods. That was the main motivation for this research.**

I. Introduction

The study of graphs and networks plays an important role in various research domains. The advent of the computer age increased the interest in the large real-world networks that are studied as complex networks. These networks exhibit specific topological properties (high clustering coefficient, small diameter, community structure, one or several giant components, hierarchical structure, heavy tail degree distribution, etc.). Various classes of complex networks have been analyzed, such as for example: technological networks, biological network, information networks or social networks [31]. One possible class includes language networks as well.

Various construction rules may be applied in order to construct a network from the text. The usual way is to construct networks of word co-occurrences [14], [23], [24], [28], [35] or syntactic networks [1], [11]–[14], [21], [22]. There are also experiments with shuffled (randomized) networks [10], [18], [21], [28], [29]. Furthermore, syllables networks [4], phoneme networks [2] or semantic networks [9] can be constructed as well. Additionally all these networks can be constructed as undirected or directed, unweighted or weighted. In most cases the best way to represent the text is to chose directed and weighted variant of the network [24]. There are various software, tools and packages designed and developed for the task of complex networks analysis: Gephi [6], NodeXL [17], SNAP [3], Cytoscape [34], NetworkX package [16] for Python, igraph package [15] for C, Python and R. All these tools enable calculating standard global network measures (such as average clustering coefficient, average shortest path length, diameter, average degree, degree distribution, density, modularity, assortativity, etc.) and the local network measures (different centrality measures: degree, betwenness, closeness, eigenvector, etc.). Some of the tools (for example Gephi, NewtorkX, iGraph, SNAP) provide network analysis on the meso-scale level with implemented algorithms for community detection. Also there are some tools designed and focused only on one aspect of the network analysis, for example GraphCrunch [19] for graphlet analysis, GRAAL [30] for graph and network alignment or FANMOD [38] for motif analysis.

However, there is no software specialized for tasks of language network construction and analysis. Our main motivation was to implement a simple toolkit that provides various language network construction possibilities and suitable network analysis functions. Furthermore this toolkit can be used for various NLP applications, such as for example keyword extraction task [7], [8], [37] or text type classification [27].

The LaNCoA toolkit is focused mainly on the language networks construction task which includes various methods for the corpora manipulation (text preprocessing and cleaning, lemmatization, shuffling procedures and preparation for the language networks construction) and procedures for generation of various word-level and subword-level networks directly from the given corpora. The toolkit also enables complex network analysis in terms of calculating all important global and local network measures, network and text content analysis, and various plotting data possibilities. To some extent, the LaNCoA toolkit uses existing functions from the NetworkX Python package as a basic foundation for some more specific network construction and analysis tasks. Furthermore, there are some measures important for weighted and directed networks that are not implemented in the standard network-manipulation packages which are therefore implemented in the LaNCoA toolkit, such as the selectivity measure, network reciprocity, network entropy, inverse participation ratio, and link overlap measures.

The paper is structured as follows. In Section II we describe the language networks. In Section III we give a short overview of the complex networks analysis task. Then we present the LaNCoA toolkit in Section IV and we describe LaNCoA toolkit applications in Section V. We give a conclusion remarks

This work has been supported in part by the University of Rijeka under the project number 13.13.2.2.07.

in Section VI.

II. Complex Network Analysis Task

A complex network is modeled as a graph G. A graph $G = (V, E)$ consists of a collection of vertices, or vertex set, V and a collection of edges, or edge set, E. In the complex network approach vertices are called nodes and edges are called links. The study of networks can be classified in three levels: global (macro-scale) level, meso-scale level and local (micro-scale) level.

The study at the macro level attempts to understand the global structure of a network. At this level, relevant parameters are average degree, degree distribution, average path length, average clustering coefficient, density, modularity, assortativity, etc. An the meso-scale level the interaction between nodes at short distances are studied. This includes community detection or analysis of small subgraphs such as motifs or graphlets. At the micro level the study is focused on the behavior of single nodes. Identification of the important nodes in the network using different centrality measures or just deterring degree, strength, clustering coefficient or betweenness and other parameters of a single node. In [31] a detailed overview of all network measures and formulas is given.

III. Language Networks

Written, as well as spoken language can be modeled via complex networks where the lingual units (e.g. words) are represented by vertices and their linguistic interactions by links. Language networks are a powerful formalism to the quantitative study of language structure at various language sublevels. Complex network analysis provides mechanisms that can reveal new patterns in complex structure and can thus be applied to the study of patterns that occur in the natural languages. Thus, complex network analysis may contribute to a better understanding of the organization, structure and evolution of a language.

On the word-level, text can be represented as a complex network of linked words: each individual word is a node and interactions amongst words are links [14]. The interactions can be derived at different levels: structure, semantics, dependencies, etc. On the subword-level, syllable or grapheme networks can be constructed, where nodes can be represented by syllables or graphemes, while their dependencies (e.g. positions of syllables within words or graphemes within syllables) are links [4].

The properties of the co-occurrence networks are derived from the word order in texts [14], [23], [24], [28], [35]. Commonly they rise from the simple criterion such as co-occurrence of two words within a sentence, or text; or as co-occurrence of words within the given co-occurrence window. In the networks where the linkage is limited to the sentence borders during the construction, the sentence boundary can be considered as the window boundary too.

The syntactic networks are constructed using syntactic dependencies relations. Syntactic dependencies between words are formally expressed by dependency grammar (e.g. set of productions (rules) in a form of a grammar). The dependency grammar is used to present the syntactic relationships from sentence in a form of syntactic dependency tree. The properties of the syntactic networks are analyzed in [1], [11]–[14], [21], [22]. The results suggests that modelling human language using syntactic networks is important for language analysis because not all of the properties of the text structure are captured within co-occurrence networks.

For the purpose of better understanding of the language structure, one approach to address the questions of the word order in the language is to compare networks constructed from normal texts with the networks from randomized or shuffled texts [10], [18], [21], [28], [29]. Networks constructed from such shuffled texts are commonly regarded as shuffled networks.

Syllable and grapheme networks are important for studying structure of a language at the subword-level. In the syllable networks, nodes are represented by syllables and a link between two syllables can be established if they belong to the same word or if they are neighbors in the word. [4]. The same principle applies to the grapheme networks, where two graphemes are linked if they co-occurre as neighbors within a word or a syllable.

Figure 1 present different construction rules for stated language network types.

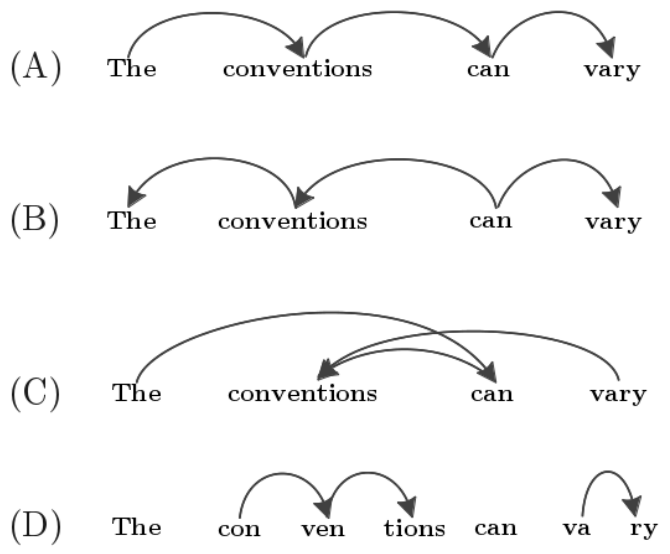

Fig. 1. Language networks construction rules presented on one toy-example sentence "The conventions can vary.": (A) Co-occurrence network, (B) Syntactic dependency network, (C) Shuffled network, (D) Syllable network

IV. The LaNCoA Toolkit Overview

LaNCoA is free and open source software licensed under the General Public License version 2. The source code of a working version is available for download from the official GitHub repository at https://github.com/domargan/LaNCoA.

All of the LaNCoA functionalities work for any of the languages written in any set of graphemes based on the letters of the classical Latin alphabet (Latin script). Only Latin script languages are supported (commonly used by about 70% of the world's population).

The LaNCoA toolkit is implemented in Python programming language. Python is an excellent tool for scanning and manipulating textual data and also provides various packages and libraries for scientific computations and data visualization. One of those is the popular NetworkX package, designed for exploration and analysis of complex networks and network algorithms. Our goal was to utilize basic NetworkX functions to develop extra procedures suitable for language network construction and analysis. We have also implemented functions for calculation of some non-standard general complex network measures. We have based our plotting procedures on proven quality matplotlib library for producing visualization figures.

Toolkit is divided into six modules that enable various aspects of language and text corpora analysis: i) corpora manipulation, ii) language networks generation, iii) single language network analysis, iv) multiplex language networks analysis, v) content analysis, and vi) data plotting. Modules are grouped into two main parts: network construction and network analysis. Modules provide procedures for tasks such as corpora cleaning, utilization of different network construction principles, analysis of global and local network properties, comparison of networks based on original and shuffled corpora, comparison of networks constructed on different language levels, etc. The generalized architectural structure of our toolkit is visualized and presented in Figure 2. In this section we describe each module's function individually.

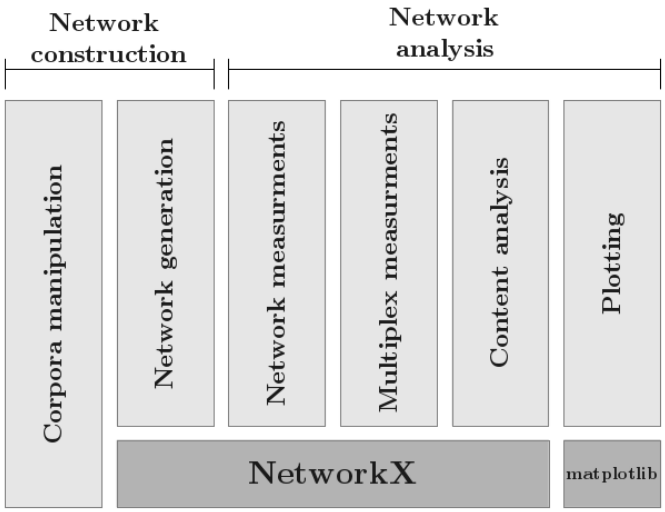

Fig. 2. LaNCoA architecture

A. Network Construction

Network construction part of our toolkit consists of two modules: the corpora manipulation module and the network generation module.

1) Corpora Manipulation Module: Corpora manipulation module can be used for several tasks with focus on various functions used to manipulate textual corpora. All of the tasks are optional and can be performed independently by the user's choice. Implemented LaNCoA functions are the following:

a) Corpus cleaning and Unicode normalization: It is important to have clean and high quality corpus before the process of the network generation, so the user can utilize LaNCoA to clean the corpus from the unwanted characters or data. LaNCoA also supports the usage of unclear and "dirty" textual data, but the noise-cleaning of the corpus is recommended, since it can greatly reduce the risks of badly constructed networks or network pollution. All UTF-8 characters which are not defined as letters or numbers of the classical Latin alphabet can be removed from the textual corpus. On the other hand, any set of those UTF-8 characters (or all of them) can be kept (preserved) in the text by users' choice. In addition, the NFKD unicode normalization [39], [40] of all Latin script letters can optionally be performed directly in the process of corpus cleaning. Compatibility decomposition replaces the code points of a base letter into a single precomposed letter. For example, unicode letters 'ć' or 'š' can be normalized into 'c' and 's' characters.

b) Removal of stopwords from a corpus: Stopwords are a list of the most common, short function words which do not carry strong semantic properties, but are needed for the syntax of language (pronouns, prepositions, conjunctions, abbreviations, interjections,...). Examples of stopwords are: 'is', 'but', 'and', 'which', 'on', 'any', 'some'. Stopwords from any language based on the Latin script can be removed by providing adequate text file containing the list of stopwords.

c) Lemmatization of a corpus: Lemmatization is the process by which single words are reconducted to their citational form. For instance the word 'networks' is converted into its standard form 'network'. Lemmatization, along with the morphological analysis, is the foundation of all the processes involved in language normalization. Lemmatization can be performed for any language based on the Latin script by providing adequate text file containing the list of all word form-lemma pairs, since the lemmatization in LaNCoA is based on the find-and-replace principle.

d) Text shuffling: Co-occurrence complex networks properties are derived from the word order in texts. Commonly, the shuffling procedure randomizes the words in the text, transforming the text into the meaningless form. Shuffling procedures destroy the sentence and text organization in a way that the standard word-order and syntax of the text is eradicated. As expected, the typical word collocations and phrases are completely lost, as well as the forms of the morphological structures and local structures of words' neighborhood. We implemented two different shuffling principles: shuffling on the sentence level and shuffling on the whole text level. The vocabulary size, word and sentence frequency distributions stay preserved in both shuffling procedures. Additionally, in the sentence level shuffling approach, the sentence structure of the text and the number of words per sentence are also preserved. In the text-level shuffling, the original text is randomized by shuffling the words and punctuation marks over the whole text. This approach also changes the number of words per sentence.

2) Network Generation Module: LaNCoA's network generation module can be used for the generation of complex language networks directly from corpora or from other language networks. It can be used for several independent tasks of building networks on word and subword-level Networks can be generated as weighted or unweighted, as well as directed or undirected. All generated networks can be saved for later

use in the standard edgelist file format. Implemented functions are the following:

a) Co-occurrence networks generation: The co-occurrence window m_n of size n is defined as a set of n subsequent words from a text. Within a window the links are established between the first word and $n-1$ subsequent words. Words are also linked according to the optional usage of specified delimiters (e.g. punctuation marks). In the networks where the linkage is limited to the sentence borders during the construction, the sentence boundary is then the window boundary too. In the networks without delimiters, words are linked within a given co-occurrence window regardless of being in different sentences. Standard approach is to limit the co-occurrence window size within the sentence delimiters, but a user may or may not specify any type of delimiters (any UTF-8 character). The weight of the link between two nodes is proportional to the overall co-occurrence frequencies of the corresponding words within a co-occurrence window. Co-occurrence networks can be generated directly from the raw text data that does not necessary conform to rules of grammar or orthography. Three steps in the network construction for a sentence of 6 words, with usage of the delimiters, for the co-occurrence window sizes $n = 2$ and $n = 6$ are shown in Figure 3.

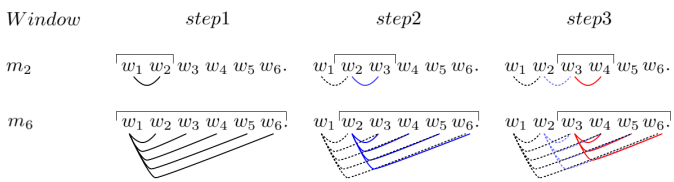

Fig. 3. An illustration of 3 steps in a network construction with a co-occurrence window m_n of sizes $n = 2$, and $n = 6$. $w_1 ... w_6$ are words within a sentence

b) Syntactic networks generation: The syntactic structure of language is captured through syntactic dependency relations between pair of words in a sentence: the head word the governor of relationship and the dependent word - the modifier. Syntactic dependencies between words are formally expressed by dependency grammar which is used to represent the syntactic relationships from sentence in a form of syntactic dependency tree. The sentences boundaries are preserved, since the syntactic dependency is inherent to the sentence. The weight of the link between two nodes is proportional to the overall frequencies of the corresponding words within a syntactic dependency tree. User must provide a corpus in a form of syntactic dependency treebank file written in the CoNLL-X format.

c) Syllable and grapheme networks generation: The syllable networks are constructed from the co-occurrence of syllables within words. Syllable list is obtained from the dictionary file already containing syllabified words. The weight of the link between two syllables is proportional to the overall frequencies of the corresponding syllables co-occurring within words from a text. Syllable networks can be generated directly from the raw text corpora. The structure of grapheme networks depends on a existing network of syllables. Two graphemes are linked if they co-occur as neighbours within a syllable. The weight of the link between two graphemes is proportional to the overall frequencies of the corresponding graphemes co-occurring within syllables from a syllable network.

d) Word-list subnetwork and word-ego subnetwork generation: Two types of word-level subnetworks can be generated from existing co-occurrence or syntactic networks: word-list network and word-ego network. Word-list network is a simple subnetwork based on a provided list of words. Specified nodes (words) and corresponding links between them are extracted from the original network. Word-ego network is a subnetwork of neighbors centered at one specified node (word) within a given radius. These subword-level networks can be generated to examine the networks of semantic importance, word's predecessors, successors, or entire word neighborhood of keywords within a given radius.

B. Network Analysis

Network analysis part of the LaNCoA toolkit consists of four modules: single network analysis module, multiplex network analysis module, content analysis module and data plotting module.

1) Single network analysis module: Single network properties can be analyzed on global and local scale. LaNCoA uses some calculation methods implemented in the NetworkX Python package. These include standard basic network features, for e.g., the average path length, diameter and radius, global and local clustering coefficient, network transitivity, and network density. In addition to NetworkX's procedures used for calculation of classic network properties, LaNCoA provides several other procedures for calculation of non-standard network measures, such as selectivity and inverse participation ratio (both available for directed and undirected networks), calculation of network entropy based on the degree, strength, selectivity and inverse participation distributions, and network reciprocity.

2) Multiplex network analysis module: LaNCoA provides some simple functions for analysis of multiplex networks. Multiplex network is network in layers, and with connections between layers; the interconnections between layers are only between a node and its counterpart in the other layer (the same node). This module enables overlap analysis of two different separated networks consisted of the same sets of nodes. Implemented functions, for example, enable calculation of the Jaccard distance of two different networks, as well as the total and total weighted link overlap measures.

3) Content analysis module: Content analysis implies the examination of the text corpora's content (e.g. role of the individual words) by using the complex network environment. This module provides several ways of text analysis by calculating simple network statistics, such as the top n words, syllables or graphemes with the largest number of different individual neighbors, calculation of the most frequent word-pair relations, the distance between given words in the network environment, or calculation of the centrality measures for all of the words within a corpus.

4) Data plotting module: LaNCoA provides functions for plotting of the network's data by utilizing the methods from the matplotlib Python library. Users can generate various 2D figures based on the calculated network measures. Such figures

include rank plots for the directed (in- and out-) or undirected degree, strength and selectivity distribution values of multiple networks on the same scale, as well as the degree, strength and selectivity histograms and scatter plots. It is also possible to generate the plots describing the dynamic growth of a network regarding the number of connected components, presenting the ratio of newly 'read' unique words (or syllables or graphemes) and the corresponding number of components in a given point of time in the process of co-occurrence network construction.

V. The LaNCoA Toolkit Applications

We have used the LaNCoA toolkit in several of our experiments where we have worked with the language networks.

In [24] we presented the results of our first experiment with the Croatian co-occurrence language networks. In this experiment we constructed 30 different co-occurrence networks, weighted and directed, from the corpus of literature, containing 10 books written in or translated into the Croatian language. We examined the change of network structure properties by systematically varying the co-occurrence window sizes, the corpus sizes and removing stopwords. We used the LaNCoA toolkit for all these network construction tasks.

In [5] we compared Croatian, English and Italian language networks based on the same five books. We performed lemmatized and non-lemmatized network construction with and without stopwords using the LaNCoA toolkit.

In another experiment [25] we addressed the problem of Croatian text complexity by constructing the linguistic co-occurrence networks form normal texts and shuffled text. In this experiment we have tested whether complex network measures can differentiate between normal and shuffled texts. We employed various methods from the LaNCoA toolkit for calculating the network measures and generating various plots in order to find the differences between two classes of networks. In [26] we extended this research by introducing additional shuffling procedure: the sentence-level shuffling procedure and by introducing a node selectivity as a new complex network measure. All shuffling procedures and network construction tasks were performed with the LaNCoA toolkit.

Furthermore, we used the LaNCoA toolkit for various experiments with the selectivity measure. In [36] we compared language networks from Croatian literature and blogs. In [7], [8], [37] we analysed the potential of the selectivity measure for the keyword extraction task. We also used the LaNCoA toolkit for the Croatian language networks construction for the purposes of the network motif analysis of Croatian literature performed in [33]. In [27] we used methods from the LaNCoA toolkit to generate 150 different weighted and directed networks and to calculate local and global network measures used in the task of text classification.

VI. Conclusion

In this paper we presented an overview of the LaNCoA toolkit for language networks construction and analysis. Currently, its basic functionalities rely on the corpora manipulation and language network construction methods implemented in the two separate modules. Another set of modules provide methods for the network analysis task. These modules employ some of the basic methods that already exists in the NetworkX package. However there is a set of functions for the network analysis not covered by the standard network-manipulation packages. Among them are certain functions that deals with the measures for the weighted and directed networks. These functions are of special interest for the language networks analysis and we implemented them in our toolkit.

The LaNCoA toolkit is in the early stage of development and there is still place for major improvements, especially in the network analysis tasks suited for the language networks. However, we managed to use this toolkit successfully in all of the language network experiments that we performed. For the future work, we plan to implement simple and robust user interface. In addition, we would like to develop some more specific language-oriented network analysis functions and also make improvements in the existing code whenever it is possible.

***Abstract* — This paper presents a comparative analysis of the two most commonly used parallel sorting algorithms: Bitonic Sort and Parallel Radix Sort. Many problems require efficient sorting of large amounts of data and that is why sorting has been, and still is, an important discussion topic in computer science. Traditionally, sorting algorithms are implemented on CPUs, but the performance of the CPU doesn't increase as steadily as until about 10 years ago. It has been proven that the complexity of comparison based sorting algorithms can be no lower than O(*nlogn*). The computing power of parallel devices is rapidly increasing, which indicates a new approach towards improving the efficiency of sorting. The benchmark in this paper will show whether or not any speedup can be gained from more compute power, and if so, can it outweigh and by how much, the overhead caused by a higher complexity of the sorting algorithm. This will be analyzed by comparing the performance of *OpenCL* kernels of the two mentioned parallel sorting algorithms with the sequential implementation of the Quick Sort algorithm. The hardware used for this experiment is an *AMD R9 270* GPU and an *Intel i5-4460* CPU.**

***Keywords* – Sorting algorithms, *OpenCL*, GPGPU**

I. Introduction

Sorting algorithms, nowadays, are a very common problem in computer science and a very often discussed topic mainly because the overall improvement of sequential sorting algorithms has stopped in the last few decades. By following the trend in overall computing, the most obvious answer lies in parallel computing, but is it really possible to divide the sorting process into individual independent pieces fit for parallel execution? After much work and effort that has been put into the development of such parallel versions of sorting algorithms, it has been proven that sorting really can be "divided and conquered", which resulted in the creation of a very large number of sorting algorithms that show the advantages of parallel processing. But how much speedup can there really be achieved ?

As mentioned before, the best sequential sorting algorithm today (without using special properties of the elements) has the complexity *O(nlogn)* [6]. Generally speaking, by using a parallel algorithm the *optimal* performance that can be achieved on *n* processors is [6]:

oc – Optimal Complexity
stc – Sequential Time Complexity
nop – Number of processors

$$oc = \frac{stc}{nop} = \frac{O(n\,logn)}{n} = O(log\,n) \qquad (1)$$

Equasion (1) does not take into account the overhead spent on communication between processors and this makes, generally, a *realistic O(logn)* parallel sorting algorithm hard to achieve. Nevertheless, any improvement made represents a step towards the goal: faster sorting.

Today, there are a lot of proposed algorithm models for parallel sorting, but the focus of this paper lies on the two most commonly used:

- Bitonic Sort
- Parallel Radix Sort

It is very hard to determine which algorithm is the best for which particular architecture taking into consideration the vast variety of parallel architectures and the fact that there is no theoretical model that can be applied to predict the performance of an algorithm on different architectures. This makes experimental studies, like this paper, more important for the behavior and performance evaluation of different sorting algorithms on different parallel machines.

The *AMD R9 270* has 20 compute units of which each has 64 ALUs. Each ALU can be considered a processing element in *OpenCL* terminology. [4] As a result there is a total of 1280 processing elements. It is important to split the work appropriately so that no processing element is idle while other processing elements do work. The GPU core works at a frequency of 975 *MHz* and the memory at a frequency of 5600 *MHz*. The single precision processing power of the card is about 2.3 *TFLOPs*. Since the card uses a 256-*bit* wide bus, this results in a maximum bandwidth of 179.2 *GB/s*. [1] Whether this bandwidth given the card's compute power will be a bottleneck in the sorting algorithms will depend on the algorithm's implementation and this will reviewed later in more detail.

The other important hardware component in the experiment is the *Intel i5-4460* CPU. It has four cores which work at a clock rate of 3.2 *GHz*. Each of the cores has 64 *KB* of L1 cache and 256 *KB* of L2 cache. On top of that there is a shared L3 cache of 6 *MB*. [2] Caching will play an important role in the sequential implementation of the sorting algorithm. As will be shown in the next section, Bitonic Sort's time complexity is $O(nlog^2n)$. Quick Sort has a time complexity of only *O(nlogn)*. Given that Bitonic Sort will be executed on 1280 more threads and that the clock rate ratio between the GPU and CPU is 9.75/32 = 0.304 a speedup of at most 1280*0.304/*logn* = 390/*logn* is expected where *n* is the number of elements sorted. Radix Sort's complexity, in the best case scenario, is *O(kn)* [7] and it is expected that it gives us the best performance.

The expected performance for each of the three algorithms is shown in *Figure 1* :

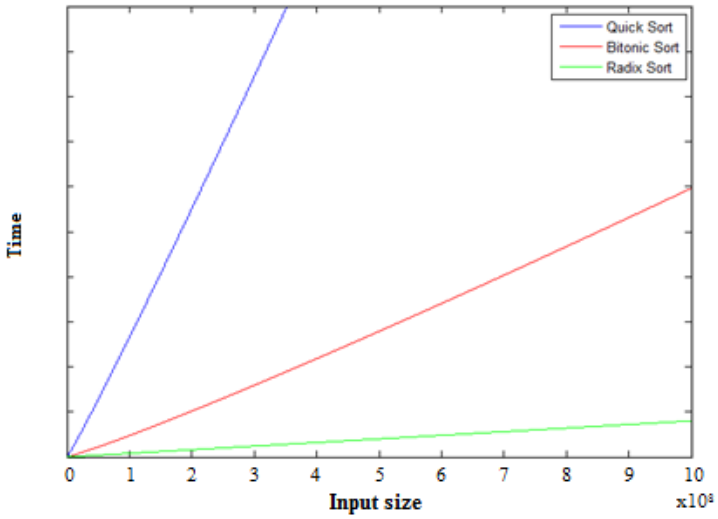

Fig. 1. Expected performance of the mentioned sorting algorithms

It should be repeated that this is only the ideal case that represents the maximum speed up. What can be achieved in practice is different.

II. Parallel Sorting Algorithms

In this section, the Bitonic Sort and Parallel Radix Sort algorithms will be described.

A. Bitonic Sort

Bitonic Sort is a well-suited algorithm for parallel architectures. It works by creating bitonic sub-sequences in the original array, starting with sequences of size 4 and continuously merging the sub-sequences to generate bigger bitonic sub-sequences. Finally, when the size of this sub-sequence is the size of the array, it means the entire array is a bitonic sequence. By repeated applications of the bitonic split, a bitonic sequence can be converted into a monotonic sequence and thus a sorted array is achieved. The time complexity of the Bitonic Sort algorithm is $O(nlog^2n)$.

Next, the algorithm is going to be described in more detail. For clarification, the term bitonic sequence must be well defined. A bitonic sequence is a sequence that monotonically increases (decreases), reaches a maximum (minimum), and then monotonically decreases (increases). A bitonic split is an operation on a bitonic sequence such that if $a_i > a_{i+n/2}$, the two elements are exchanged, $1 \leq i < n$. This will produce two bitonic sequences, A and B, with the property that all elements of A are lesser than any element in the sequence B. If the process would be repeated on both A and B, it would lead to four bitonic sequences such that each sequence would contain elements that are lesser than the elements in the next sequence. Repeating this process until *n/2* bitonic sequences are produced will result in a sorted array. It is clear that a bitonic sequence can be sorted in *O(logn)* steps where each step has *n* operations. This results in a complexity of *O(nlogn)* for sorting a bitonic sequence. [3]

Next up is the arbitrary sequence of numbers. Sorting an array of length 2^n is done in *n* stages. Every *i*-th stage has a total of *i* passes. Every pass does length/2 comparisons. Since the total number of passes is $O(log^2n)$ and each pass does *O(n)* comparisons, the total time complexity of the algorithm has to be $O(nlog^2n)$.

The first stage of the algorithm converts the unsorted array into segments of length 2. Every pair of adjacent segments forms a bitonic sequence. The next stage produces segments of length 4 and so on. In each pass elements at a distance of $2^{(Stage\ -\ PassOfStage)}$ are compared. The elements are exchanged depending on the sort direction for the particular block (the length of the block equals twice the distance). The first stage inverts the direction of sorting after every successive pair of elements. The second stage does this after two pairs of elements, the third after four pairs and so on. After n stages the whole array is a bitonic sequence.

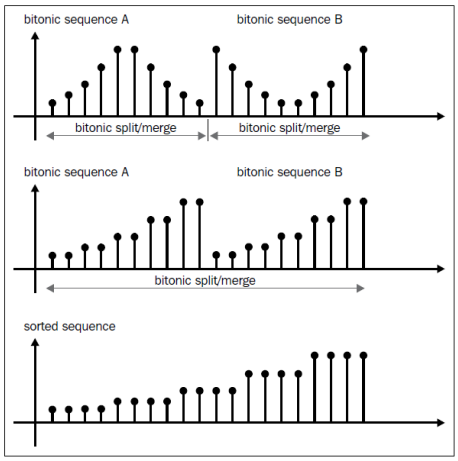
Now it's time to examine the OpenCL implementation of the Bitonic Sort algorithm. The variable *pairDistance* is the distance between the pair of elements that are being compared in each invocation of the kernel and the variable *threadId* is the thread identificator. A block is a group of consecutive elements in the array that are being compared. The variable *blockwidth* is the width of this block. Each processing element can compute the indices of the elements in the array that need to be compared. The index of the left element can be computed according to the following formula:

$$Leftid = (threadId \ \% \ pairDistance) + (threadId \ / \ pairDistance) * blockwidth \quad (1)$$

And the index of the right element can be computed as:

$$Rightid = Leftid + pairDistance \quad (2)$$

An illustrative example of how the whole process is executed and the Bitonic sort *OpenCL* kernel pseudo code are given in *Figure 2* and the code snippet below.



```
__kernel sort(__global *data, int stage i, int pass_of_stage j, int dir)
{
        /*using values of i, j, dir – get left_Id & right_Id*/
        left_child = data [left_Id]
        right_child = data [right_Id]
        compare(left_child, right_child)
        /*copy left & right child values to data with respect to dir*/
        data [left_child] = max(left_child, right_child)
        data [right_child] = min(left-child, right_child)
}
```

Fig. 2. Bitonic Sort execution example [4] & pseudo code

It can be concluded that over 90% of the code is parallelizable. The host processor only has to pass the stage number and the pass of the stage to the processing elements. This means that nearly all of the computing time is spent executing the parallelizable code which is implemented as the kernel function.

B. Radix Sort

Radix Sort treats keys as multi-digit numbers in which each digit is an integer with a value between 0 and m, where m is the radix. [4] Given this definition a 32-bit integer could be treated as a 4-digit number with $m = 2^{32/4} = 256$. Radix Sort sorts keys by splitting them into digits and sorting the digits one at a time, starting from the least significant digit. In each pass keys are distributed into buckets according to the digit currently being processed and then collected from the buckets. This is illustrated in the following example :

Suppose an array consists of the following input elements: 72, 32, 13, 84, 95, 42, 53, 61, 14 and 15 and the base (*radix*) is 10. During the first pass the keys will be distributed into bins as follows:

(61), (72, 32, 42), (53, 13), (84, 14), (95, 15)

The keys are collected and distributed again according to the second (and in this case most significant) digit :

(13, 14, 15), (32), (42), (53), (61), (72), (84), (95)

After collecting the keys again, a sorted array will be the end result.

In an *OpenCL* implementation, keys are broken into 8-*bit* digits and sorted one digit at a time, starting with the least significant digit. This is repeated four times to complete the sorting procedure (sorting of 32-*bit* integers). Each time the following three phases are executed to sort the appropriate digit for that phase:

1) Calculate the histogram of an unsorted array
2) Pre-scan the histogram bins
3) Rank and permute the keys to get a sorted array

A detailed description of each of the phases will be given in the next section.

In the first phase, the input array is divided into blocks of N * M elements. M is the radix (256 in this case) and N is the number of work-items in a block. Ideally, each thread of the GPU would be assigned a portion of the work that needs to be completed. With this in mind, the ideal number for N for the *AMD R9 270* is N = 64.

In the second phase, the histogram bins are pre-scanned. The pre-scan operation takes a binary associative operator $\oplus$ with identity I, and a vector of n elements.[8][9] There are B * N histograms where B is the number of blocks and N the number of work-items in a block. The bins are arranged so that the 0^{th} block bin comes first, and the $(B - 1)^{th}$ block bin last. Each block's histogram bins are arranged so that the 0^{th} work-item bin comes first, and the $(N - 1)^{th}$ work item bin comes last. After the pre-scanning is completed, the histograms are passed into the third and final phase.

In the third phase, each work-item permutes its allotted 256 elements by using its pre-scanned histogram bins.

The pseudo code for the *OpenCL* kernel is given below:

```
b ← no. of bits
A← Input Data
cmp ← 1
cnt0 ← contains zero's count
cnt1 ← contains one's count
One, Zero ← Bucket Arrays
Mask ← Temporary Array

for ( i = 0 to 2b – 1)
{
    for ( j = 0 to A.size)
    {
        if (A [j] && cmp)
            cnt1 ++
            One [cnt1] ← a[j]
        else
            cnt0 ++
            Mask [cnt0] ← j
     }
    for( j = cnt0 to A.size)
        Mask [j] ← A.size – cnt0 + j
    A ← shuffle(A, one, Mask)
    cmp ← left_shift(cmp)
}
result ← A
```

In conclusion, this algorithm is embarrassingly parallel, as each bin can be sorted independently. The only sequential part of the program would be the sorting by the least significant digit. In the ideal case, as the program progresses, more and more processors would get engaged in the sorting process.

III. Main Results

As already mentioned in the introductory section, the Quick sort algorithm has been executed on the *Intel i5-4460* CPU and the Bitonic and Radix sort algorithms have been executed on the *AMD R9 270* GPU. The execution times for various input sizes are presented in the *Figure 3* :

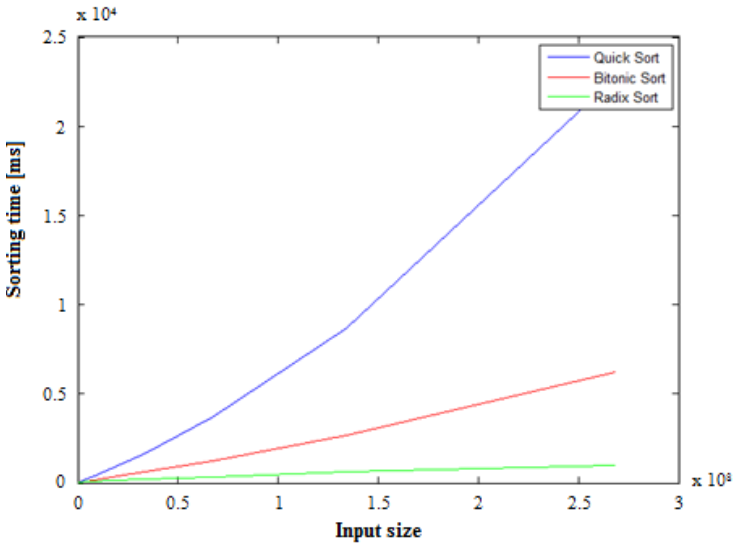


Fig. 3. Execution time results for the mentioned parallel sorting algorithms

As can be seen in the table and graph, the performance of the parallel sorting algorithm is much better than the performance of Quick sort for large input arrays. For small input arrays (up to a million elements), Quick sort performs better. The reason why this happens is because of the overhead introduced in the parallel algorithms. It takes time to split the work and distribute it to the processing elements. That overhead outweighs the gains gained from parallelization in small problems. This was expected since parallel algorithms are developed to handle large problems.

The Quick sort algorithm behaves as expected. The increase in computation time is super-linear starting from 1 million elements up. For smaller problem sizes the increase in computation time is sub-linear. This is caused by caching. As the problem size increases, a lower percentage of the data can be cached and thus it takes longer to fetch it for computation.

The same can be said about the Bitonic Sort algorithm. The difference here is that the increase in computation time becomes super-linear after a much larger problem size. The larger the problems size, the more insignificant does the overhead become. It should be noted that the speedup gained is much lower than the ideal speedup.

As already mentioned, caching reduces the sorting time when Quick sort on the CPU is executed. On the other hand, all data on the GPU is fetched from global memory. The latency of the global memory severely limits the speedup potential. The bandwidth is sufficient for all problems up to a billion elements. At that point it's the capacity of the global memory that limits further gains from parallel processing.

As expected, Radix Sort has an almost linear increase in computation time and is also the fastest among the three tested sorting algorithms. Local memory was used to increase performance. The reason why the computation time increase is only almost linear and not truly linear is the limited capacity of the local memory. There is only 64 KB of local memory available to each of the compute units. Another performance limit is imposed by the latency of the global memory. Local memory reduces that latency, but due its limited capacity data must be continuously transferred between the global memory and local memory if the problem size is too large.

IV. Conclusion and Future Work

The performance of Bitonic Sort and Parallel Radix Sort for the GPU using *OpenCL* has been analyzed and compared to the serial implementation of the Quick Sort algorithm. The conclusion is that speedup can be achieved by parallelizing sorting algorithms. The speedup depends on the number of elements that need to be sorted. As presented in the graph, the larger the array, the bigger the speedup. For arrays larger than 64 million elements Bitonic Sort performs more than three times better and Radix Sort more than ten times better than Quick Sort with some limitations that need to be taken into account. Nonetheless, there are many problems with these characteristics and the research of parallel sorting algorithms will be an important topic in the future.

Hardware is also an important factor in parallelization of the algorithms. The work must be split and distributed in a way that all processing elements receive an equal share of the work which can be a major problem in the implementation of sorting algorithms. Given the diversity of available hardware it is impossible to make a single best implementation since the best implementation is always slightly different for each hardware component. In the case of Parallel Radix Sort, it is important to split the array into blocks so that the element count divided by the radix is equal to the number of processing elements in a single compute unit of the GPU. Since the AMD R9 270 has 64 processing elements per compute unit, the element count in each block would ideally be M * 64 where M is the radix.

The biggest problem was the latency of the global memory. Bitonic sort can be further improved by making use of local memory. Radix Sort's limitation is the capacity of the local memory.

The capacity is only 64 KB and for arrays larger than 65536 elements, data needs to be swapped between the global and local memory which limits speedup. These are the biggest two problems which need to be solved in future work on this topic.

Mobile application for finding ATMs

Mario Lončar, Jasmin Abou Aldan, Marina Ivašić-Kos
Department of Informatics, University of Rijeka, Rijeka, Croatia
{mario.loncar, jasmin.abou.aldan, marinai}@uniri.hr

Abstract - This paper describes mobile application that gives Android users the ability to find ATMs quickly. Currently, the application offers locations of ATMs for various banks in Rijeka, Croatia. It also provides the possibility of finding the shortest path to the chosen ATM, as well as helpful tips where they can withdraw the money free of charge. The idea for this application was born after realizing that many people were wasting time looking for a place to withdraw money. This application saves time to inhabitants as well as to visitors of the city.

Keywords: mobile application, Android, geo-locations, maps, navigation.

I. INTRODUCTION

Many people waste their time looking for places where they can withdraw the money. Positions of the closest ATM are sometimes unknown to the inhabitants, especially when they are in the part of the city that do not visit often. Finding the ATM becomes even more demanding task for tourists in unfamiliar city. They want to spend as much time as possible having fun and sightseeing instead of wandering to get the money.

Touristic cities like Rijeka usually offer Wi-Fi hotspots at most frequently visited places so everyone can use internet connection. This opportunity can be used to download and use available applications on Google Play that facilitate the user to gather additional information about the destination. Below are applications that could be used for finding ATM together with their shortcomings.

AdriaGUIDE [13] Rijeka is a travel guide that provides most important information for the visitors, including ATM locator. However, after choosing a language on welcome screen, the application crashes so we could not see its functionality. Last update was on October 12, 2012.

Bankomati HR [14] offers ATM locations of all Croatian cities. On the other hand, it offers only eight banks and no navigation to chosen ATM. User interface looks out of date and there is no option for showing locations of all ATMs, instead you have to check each of them. On the bottom of the screen are ads that cannot be moved. Last update was on September 16, 2013.

Adria ATM [15] has intrusive ads on the top of action bar. When starting this application, map shows all ATMs of all banks on the list. If you want to check ATM locations of only one bank you have to uncheck banks on the list and then choose the bank you need which takes a lot of time. Application does not offer navigation, but only address of an ATM. It has implemented crowdsourcing, but crashes sometimes after adding a new ATM location. Last update was on August 2, 2013.

BankoMap [16] does not offer navigation nor banks to choose, every bank has the same default pin. It offers a small amount of ATMs. Last update was on October 12, 2010.

In order to help users finding an ATM quickly and easily, we developed Find My ATM application. It is a mobile application that offers ATM locations of all banks in Rijeka, useful advices on where the money can be withdrawn free of charge and shortest path to each ATM.

II. APPLICATION OVERVIEW

Find My ATM is mobile application developed for Android platform using Android Studio [3]. Android Studio has recently replaced Eclipse with Android Development Tools (ADT) and become the official Java integrated development environment (IDE) for developing Android applications.

It is based on Java IDE developed by JetBrains and available as an IntelliJ IDEA open source community edition [8]. The IntelliJ IDE enables fast coding by giving smart and relevant suggestions, code completion, on-the-fly code analysis, project navigation and reliable refactoring tools. It has better layout previewing and is much easier to use and user friendly than Eclipse.

The key components of the Find My ATM application are working with maps, determining the geo-location of the user and computing the shortest path to the selected ATM. Therefore, the Android package that includes map libraries was added to the Android software development kit (SDK).

A. Android mapping libraries

We have considered several mapping libraries available for Android applications [1]: Google Maps API [2], ArcGIS Runtime API [9], OSMDroid API [10] and MapsForge [11].

Google Maps Android API is the default mapView for Android, and uses the data from Google Maps. It allows presentation of maps as satellite, terrain, and hybrid as well as Street View. Vector-based tiles of Google map can be used in offline mode. Additionally, map tiles can be customized adding information and markers onto the map to indicate specific points for an application. Customized maps can be shown in online mode.

ArcGIS runtime API shows data in offline mode, by storing tiles in the TIFF, PNG or JPG storage format, or by using tile packages. Users can access high-quality geospatial data and explore raster data and aerial imagery through Image GeoServices. OSMDroid is also library of raster maps and provides using tiles for off-line access.

MapsForge is library for rendering OSM (Open Street Maps) data on the fly. It has a special optimized tile format, and good rendering performance. Nutiteq library is open source if it is used with OpenStreetMaps. It has many unique features like support for 3D, custom Map API's, offline routing and maps in any projection.

After testing different mapping APIs, we have chosen Google Maps API. The main reason was the familiarity of users to Google Map interface and functionalities since it is preinstalled on every Android device.

B. Set up of Google Maps in application

The Google Maps Android API uses OpenGL ES version 2 to render the map. If OpenGL ES version 2 is not installed, map will not appear. It is necessary to add the following in AndroidManifest.xml:

```
<uses-feature
        android:glEsVersion="0x00020000"
        android:required="true"/>
```

This notifies external services of the requirement. In particular, it has the effect of preventing Google Play Store from displaying your app on devices that does not support OpenGL ES version 2.

To use Google Maps in an application you need to create a valid Google Maps API key. The key can be used with any application that calls Google Maps API, and supports unlimited number of users. To obtain the key one should register to the Google APIs Console providing the application signature key given to application during development and the application package name. Then, a valid API key must be entered in AndroidManifest.xml file. Later it will be necessary to register application via its package in this Play Store console together with the SHA-1 fingerprint of signature key.

C. User interface

Android Studio offers advanced layout editor that allows you to drag-and-drop widgets into your layout and preview layout while editing the XML. In general, the XML vocabulary for declaring user interface elements closely follows the structure and naming of the classes and methods, where elements names correspond to class names and attribute names correspond to methods. This application has two XML layouts. First is for the main activity, which includes Google Maps fragment and *listview* for banks. Second XML layout is consisted of one *textview* that presents one row in *listview*.

An Android application typically has several activities. Each activity displays a user interface that allows the user to perform a specific task such as to select an item or view a map. To perform interactions between application components or different applications, an Intent should be used. Intent is abstract description of an operation to be performed. It is most often used for launching of activities.

Our application is launched by passing a method *startActivity*() to the system that opens a single screen with user interface showing all banks that have ATMs in Rijeka, Fig. 1. To define the list of all banks in Rijeka, data available on the website [12] was used. For locations of each ATM, geo-coordinates posted on the official documents of each of the banks were used.

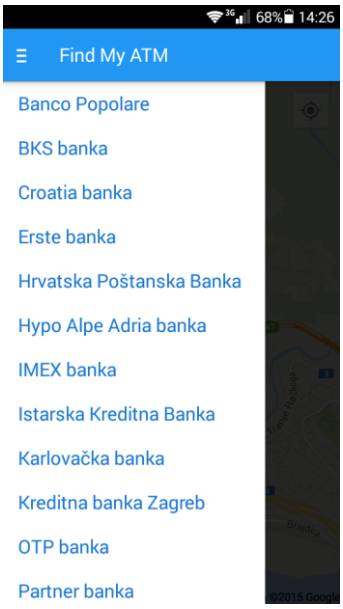

Figure 1. Navigation drawer displays available banks in Rijeka

Data about banks and their ATM coordinates and addresses is stored in JSON format database on Parse.com [6]. Parse.com offers backend services for the developers as well as SDK for a multitude of platforms. It allows accessing data through objects. When you create a new App in Parse, you can create a new class and then import data to that class. Imports can be from CSV, XLS, TXT and JSON files, or you can manually create a table in each class by defining the columns and types of the stored data. The important feature of Parse.com is the subsequent implementation of crowdsourcing. In that way, users can enter position and the address of new ATM on their own, as well as report possible wrong coordinates or address of an ATM. In order to use Parse classes and methods, a developer has to include Parse SDK files to Android Studio project within the folder libs. The following code directs *build.gradle* to look for appropriate libraries in the folder libs:

```
dependencies: {

   compile fileTree(dir: 'libs', include:
   ['*.jar'])

   }
```

To connect an application with Parse Core, in *onCreate*() method, a *Parse.initialize*() method is embedded that takes context, application ID and client key as parameters. If *ParseAnalytics*().*trackAppOpened*() and

ParseAnonymousUtils.logIn() methods are implemented in application, developer can keep track and get daily reports about usage of the application.

The main advantage of using Parese.com is that the developer does not have to think about the infrastructure, because the team responsible for Parse takes care of it. By using Parse, one can easily upgrade a database that is immediately available for use without entering the code of the application.

List of 20 banks is stored in Activity object in string array called banks_array:

```
mBankNames = getResources()
.getStringArray(com.mario.findmyatm.R.array.ba
nks_array);
```

To provide access to the data items that should be presented and to enable view for each item, an Adapter object is used. An Adapter object acts as a bridge between types of available displays of data defined in *AdapterView* object and the data that will be used for a selected view. In this application *ArrayAdapter* object is used and backed by an array of arbitrary *mBankNames* objects. The *ArrayAdapter* class expects that provided resource id reference a single *TextView* in the larger layout resource. When *TextView* is referenced, it is filled with each object in the *mBankNames* array.

```
    mDrawerList = (ListView) findViewById
(com.mario.findmyatm.R.id.left_drawer);

    mDrawerList.setAdapter(new ArrayAdapter
<String> (this,
com.mario.findmyatm.R.layout.drawer_list_item,
mBankNames));
```

D. Implementation and Customization of Google Maps

If the Internet connection is available, user can choose one bank among 20 of them on the list for which wants to see the ATM locations. In addition, an option that displays ATMs of all banks on the list is available too. To perform these operations the system uses the Intent that identifies and starts the appropriate service with method *SetUpMapIfNeeded*. The Intent can be also used to start an activity that is contained in a separate application or to communicate with a background service using method *bindService(Intent, ServiceConnection, int)*.

A method *SetUpMapIfNeeded*() sets up the map if the Google Play services APK is correctly installed and the map has not already been instantiated. If the map is not installed, a prompt for the user is shown to install/update the Google Play services APK on his device. A user can return to this fragment activity after following the prompt and correctly installing/updating/enabling the Google Play services. Since the fragment activity may not have been completely destroyed during this process, *onCreate*() method may not be called again so we should call this method in *onResume*() to guarantee that it will be called.

If the map is installed properly, data taken from Parse Core [7] is displayed at map in the form of pins (Fig. 2), each time the user selects a bank item in the list view.

Figure 2. Pins on the map present locations of ATM for a selected bank

The address and coordinates of an ATM on Parse Core look like this: *["Riva Boduli 1, 45.325389, 14.442115"]*. When user selects a bank, method that gets object identified with a given key on Parse is called. Method stores object from Parse to an *ArrayList*<String>. With foreach loop, the *ArrayList* is split by comma and its elements are stored in variables that are later used for drawing the pins on a map. The code snippet used to get data from Parse is as follows:

```
for (String s : myArray) {

    String[] s2 = s.split(",");
    String address = s2[0];
    Float lat = Float.parseFloat(s2[1]);
    Float lng = Float.parseFloat(s2[2]);
    LatLng coo = new LatLng(lat, lng);
}
```

Instead of standard Google Maps pins, we used custom pins, so that each bank uses specific pin as its logo (Fig. 2). Pins are 32 x 32 .png format images. After selecting a bank, action bar changes title with *setTitle*() method according to the bank we have chosen:

```
mTitle = title;
getSupportActionBar().setTitle(mTitle);
```

E. Implementation of Navigation Directions

To be able to provide information to the user about the closest ATM, the current location of the user should be determined.

One has to allow access to the location information in the settings in order to use My Location. Otherwise, an Alert, which leads to Location settings, will pop up as shown on the Fig. 3.

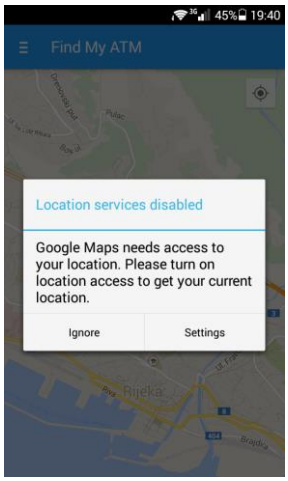

Figure 3. Location services alert

To check if Location access is enabled we have used the code snippet:

```
if(!locationManager.isProviderEnabled(Location
Manager.GPS_PROVIDER) &&
!locationManager.isProviderEnabled(LocationMan
ager.NETWORK_PROVIDER))
    //alert shows up
```

Also an Internet connection is required for using the application. If a user does not have Internet connection, an Alert which leads to Internet settings will appear (Fig. 4). We used methods from Connectivity Manager class to check whether Network Connection is available or not:

```
connectivity(){
    if(isNetworkAvailable()){
       //set up map
    }else{
       //alert shows up
    }
}
```

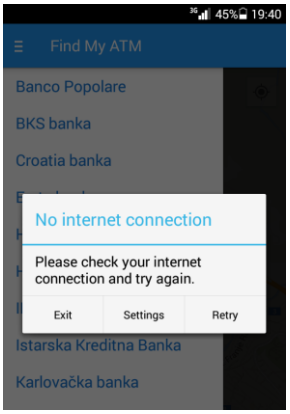

Figure 4. Connection alert

When the location information is enabled and network connection is available, the button with label My Location appears in the upper right corner and shows the location of the user (Fig. 5).

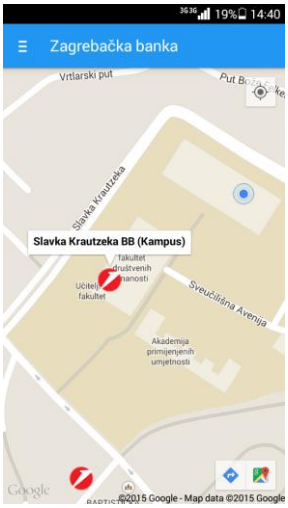

Figure 5. Location of the user is marked in the screen

Navigation options appear when one of the ATMs is selected. The navigation to a specific ATM depends on the chosen means of transport. All functions from Google Maps API are implemented so the user can select the navigated to a specific ATM by car or by public transport or on foot (Fig. 6). For the selected navigation type, several different routes are offered and time necessary to reach the selected ATM is calculated. In addition, voice control can be used to control Navigation.

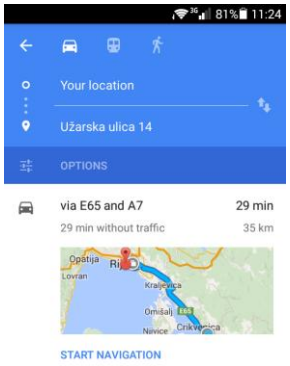

Figure 6. Navigation to the selected ATM

Furthermore, an application offers all sorts of information available for the selected ATM and advices on where you can withdraw your money free of charge (Fig. 7). Advices appear in a Dialog box that can display one, two or three buttons. Which button to implement depends on dialog's action. Method *setPositiveButton*() is used when you should accept and continue with the action. For canceling the action method *setNegativeButton*() is used. Method *setNeutralButton*() is used when the user may not want to proceed with the action, but does not necessarily want to cancel. It is possible to add only one of each button type to an

AlertDialog. To display information to the user in a dialog box we have used the *setMessage*() method.

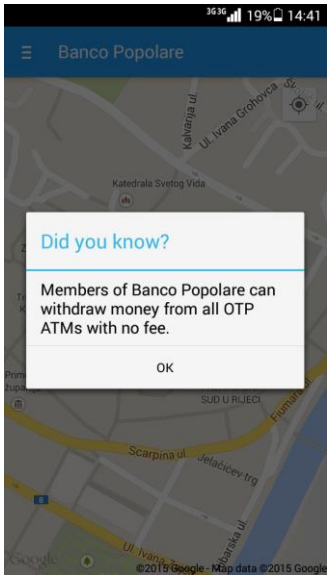

Figure 7. Tip about selected ATM

Find My ATM runs on android 4.0 or higher which covers 87% of Android devices [4]. Using lower Android API versions may affect in losing core feature set. Application requires multiple permissions defined in *AndroidManifest.xml* (Fig. 8).

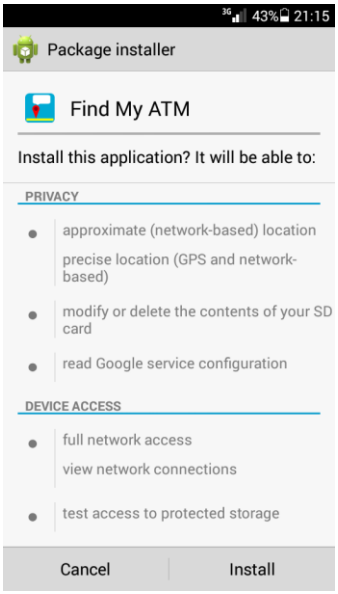

Figure 8. Permissions

We have used *Genymotion* [5] emulator for testing the application as well as physical devices. Genymotion is a fast third-party emulator that can be used instead of the default Android emulator that turned to be very slow even after installing Intel Hardware Accelerated Execution Manager.

III. CONCLUSION

We have developed the Android mobile application Find My ATM that enables finding of ATM locations quickly. The application also provides the possibility of finding the shortest path to the chosen ATM, as well as helpful tips where money can be withdrawn free of charge. The application is currently available only for various banks in Rijeka. However, an expansion on other Croatian cities is expected.

Inhabitants find this application very useful. Foreign tourists does not have an internet connection in Croatia, but major Croatian cities offer Wi-Fi hotspots on frequently visited places, so in future we will try to make an arrangement with tourist office for a free promotion of this application.

Currently, Find My ATM is in version 1.1.1 available for Android. It will be available for iOS users soon. In addition, voice search on Croatian language will be implemented so ATMs will be even easier to find. Parse.com offers an easy way to implement local data store, so we are planning to add this feature, as well as offline maps, in version 1.2. Other upgrading of the application will be made according to the user's needs and suggestions.
