Metodologija procjene kapaciteta RF spektra za potrebe implementacije mobilnih servisa u periodu do 2020. godine sa primjenom u BiH

Almedin Džebo, Amina Krivošić

Regulatorna agencija za komunikacije, Sarajevo, BiH

dzebo.almedin@gmail.com, amina.krivosic@gmail.com

Sažetak

Zahtjevi za brzi prenos velike količine podataka podrazumijevaju i povećanu potrebu za dodatnim resursima RF spektra uzimajući u obzir trendove korištenja različitih mreža, upotrebu superiornijih modulacionih postupaka, nove tehnologije, digitalnu agendu kao inicijativu u sklopu strategije razvoja Europa 2020 te niz drugih faktora. Za procjenu zahtjeva za frekvencijama, novi modeli moraju biti razvijeni i procijenjeni na način da omoguće prostornu i vremensku koralaciju između telekomunikacijskih usluga imajući u vidu uslove na tržištu i scenarije mrežne implementacije. U radu je prezentirana modifikovana verzija metodologije procjene kapaciteta spektra definirana ITU preporukama, prilagođena uslovima u Bosni i Hercegovini. Cilj je pokazati realne potrebe za RF resursima upotrebom parametara i pokazatelja rasta i razvoja mobilnih mreža koji korespondiraju sa realnim i konkretnim parametrima koji egzistiraju na tržištu telekomunikacija. Proračun potrebnog spektra za mobilne komunikacije bazira se na principima definiranja servisa, tržišnog kretanja i očekivanja te tehničkog i operativnog okvira za proračun.

Ključne riječi: procjena kapaciteta spektra, mobilni servisi, planiranje RF spektra, proširenje spektra za IMT, širina opsega

I. UVOD

Za realizaciju mobilnog servisa potrebni su odgovarajući radiofrekvencijski resursi. Obzirom da novi servisi zahtijevaju brzi prenos velike količine podataka, potreba za dodatnim resursima je u stalnom porastu. Stoga se ovaj ograničeni resurs mora efikasno planirati. Da bi se identificirao spektar na međunarodnom i evropskom nivou, a zatim namijenio i dodijelio na nacionalnom nivou, potrebno je nekoliko godina. Zbog toga je potrebno već sad započeti planiranje spektra za IMT za 2020. godinu.

Planiranje i alociranje RF opsega je pitanje o kojem se, zbog svoje važnosti, osim na tehničkom nivou raspravlja i na nivou političkih i drugih interesnih grupacija. Stoga je u strategiju razvoja pored realnih tehničko-eksploatacionih, involvirano i niz faktora koji su nastali kao produkt lobiranja i interesa kako proizvođača opreme tako i drugih grupacija zainteresovanih za porast korištenja RF spektra za ovu vrstu servisa.

Realna procjena potrebnih kapaciteta za razvoj mobilnih komunikacija vrši se na ekspertnom nivou uzimajući u obzir trendove korištenja različitih mreža (npr. nelicencnih RLAN sistema), novih tehnologija koje upotrebom superiornijih modulacionih postupaka na efikasniji način koriste spektar, potrebu za razvojem drugih servisa, odgovarajuće strategije prezentirane u EU dokumentu „Digital Agenda 2020“ i još mnogo faktora koji utiču na potrebu korisnika za mobilnošću.

U prošlosti, procjena zahtjeva za RF spektrom za razvoj bežičnih aplikacija odnosno servisa razmatrala se u okviru jednog sistema i jednog scenarija na tržištu. Pojavom konvergencije između mobilnih i fiksnih telekomunikacijskih i multi-mrežnih okruženja, kao i međupovezivanjem različitih komplementarnih pristupnih sistema nametnut je novi kompleksniji pristup problematici razvoja metodologije za procjenu potrebne količine spektra za mobilne komunikacije.

U okviru Međunarodne unije za telekomunikacije, ITU radna grupa JTG 5 koja je zadužena za pitanja koja su vezana za IMT (International Mobile Telecommunications), priprema prijedlog koji treba da dimenzioniše potrebe za novim frekvencijskim opsezima za implementaciju mobilnih komunikacijskih servisa. Prijedlog bi trebao da sadrži konkretne podatke o potrebnim resursima za period do 2020. godine sa specificiranim RF opsezima koji bi mogli da zadovolje buduće potrebe. Prijedlog će se razmatrati na Svjetskoj radio konferenciji WRC-15 (World Radio Conference) koja će se održati u Ženevi krajem 2015. godine i predstavlja jednu od najvažnijih kandidovanih tema konferencije. Ključni element za procjenu predstavlja izbor modela proračuna odnosno korištenje odgovarajuće metodologije. Metodologija procjene potrebnih kapaciteta propisana je ITU preporukama serije M u kojima su razmatrani različiti scenariji budućeg razvoja mobilnih mreža i servisa. Evolucija se odvija na način da se vrši stalno praćenje i poređenje rezultata dobijenih proračunom sa stvarnim saobraćajnim parametrima te se u skladu s tim vrši korekcija algoritma procjene.

Procjena potreba za spektrom razmatra se kroz ITU WP 5D za vrijeme pripreme za WRC-15. Agenda Item 1.1. nalaže razmatranje dodatne namjene za mobilne servise na primarnoj osnovi i identifikaciju dodatnih frekvencijskih opsega za Međunarodne mobilne telekomunikaje (IMT) i odgovarajuće regulatorne odredbe u cilju omogućavanja razvoja zemaljskih mobilnih

širokopojasnih aplikacija u skladu sa Rezolucijom 233 sa WRC-12.

Rezolucija 233 sa svjetske radio konferencije 2012. je pozvala na istraživanje i donošenje studija i prijedloga za buduće zahtjeve za spektrom i potencijalne opsege koji mogu biti kandidovani za IMT i druge zemaljske mobilne širokopojasne aplikacije [1].

II. PROŠIRENJE OPSEGA ZA MOBILNE MREŽE

Prema asocijaciji GSMA mogući opsezi koji će biti kandidovani na WRC-15 u okviru teme 1.1. su navedenim u slijedećoj tabeli:

Opis	Spektar	Korištenje	WRC-15
Opseg (<1GHz)	Dijelovi opsega 500-600MHz [470-694MHz]	TV PMSE	WRC-15 regionalna identifikacija za IMT korištenje Potrebna kooperacija sa radiodifuznom industrijom
	700MHz [694-790MHz]	TV PMSE	WRC-15 regionalna IMT identifikacija: Region 1 (AI 1.2)
Opseg (1GHz-3GHz)	Dijelovi opsega 1.4 GHz [1350-1525MHz]	D-Radio Fixed Link Scientific	WRC-15 globalna identifikacija za IMT korištenje Korištenje u naučne svrhe, samo u dijelovima opsegai u nekim dijelovima regiona
	2700-2900 MHz	Radar	WRC-15 globalna identifikacija za IMT korištenje
Opseg (3GHz-6GHz)	3.4-3.6 GHz	IMT (u nekim zemljama) Sat.	WRC-15 globalna identifikacija za IMT korištenje
	3.6-3.8 GHz	IMT Sat.	WRC-15 globalna identifikacija za IMT korištenje
	Dijelovi opsega 3.8-4.2 GHz	Sat.	WRC-15 globalna identifikacija za IMT korištenje
	Dijelovi opsega 4.4-4.99 GHz	Sat.	WRC-15 globalna identifikacija za IMT korištenje

Tabela 1. Potencijalni opsezi za mobilne komunikacije kandidovani za WRC-15

(izvor CPM-15: A Guide to WRC-15 Agenda Item 1.1)

Za harmonizaciju IMT na globalnom nivou, najveću mogućnost imaju slijedeći opsezi:

- Sub-700MHz UHF (470-694/698 MHz)
- L-Band (1350-1400 & 1427-1518 MHz)
- 2.7-2.9 GHz
- C-Band (3.4-3.8 GHz & 3.8-4.2 GHz)

Zahtjevi za spektrom za IMT-2000

Generalno problem procjene zahtijevane širine radio spektra sastoji se od slijedećih podproblema:

- Razvoj scenarija i određivanje vrijednosti ulaznih parametara
- Proračun zahtijevanog kapacitita sistema u skladu sa ponuđenim saobraćajem i zahtijevanim kvalitetom servisa
- Proračun potrebne širine radio spektra potrebnog da se obezbijedi zahtijevani kapacitet sistema

ITU - R Izvještaj M.2290 " Procjena budućih zahtjeva spektra za terestrijalni IMT" predstavlja prognozu rasta ukupnog iznosa mobilnog saobraćaja u svijetu do 2020. godine te modele potražnje za spektrom za IMT usluge bazirane na prognozi saobraćaja [2]. Ovi modeli su relativno sofisticirani i dijele saobraćaj na različita servisna okruženja (npr. urban, suburban, rural, home, office, public) i klase usluga (npr. streaming, interactive, background). Ovaj model trenutno predviđa da će biti potrebni IMT spektar između 1340 (niže tržišne postavke) i 1960 MHz (više tržišne postavke) za zadovoljenje potreba za uslugama do 2020. godine.

Imajući u vidu veće zahtjeve ukupni procijenjeni zahtjevi su oko 1800MHz. Poredeći sa već do sad identificiranih 1172MHz, trebaće još oko 500MHz dodatnog spektra.

III. METODOLOGIJA PROCJENE RF SPEKTRA ZA MOBILNE SERVISE

Preporuka ITU-R M.1390 - Metodologija za proračun potreba za spektrom za zemaljski IMT-2000 sadrži metodologiju proračuna zahtijevanog spektra procijenjenog za IMT-2000. Obezbjeđuje sistematski pristup koji uzima u obzir geografski uticaj, uticaj tržišta i saobraćaja, tehničke i sistemske aspektre i konsolidaciju rezultata zahtjevanog spektra. Metodologija je primjenjiva na radio prenosne tehnologije bazirane na komutaciji krugova i komutaciji paketa i može objediniti servise koji su okarakterizirani asimetričnim protokom saobraćaja. Metodologija je dovoljno fleksibilna da obezbijedi globalno sagledavanje potreba za spektrom ili jedinstvene zahtjeve regionalnih tržišta [3].

Osnovni cilj metodologije je odrediti individualne zahtjeve za spektrom za sve kombinacije specifičnih okruženja i usluga u datom geografskom području i kombiniranje seta individualnih zahtjeva za spektrom zajedno sa ukupnom terestrijalnom komponentom koja se procjenjuje podrazumijevajući odgovarajuće faktore kao što su konkurentske usluge na datom geografskom području. Pored toga uzeti su u obzir uticaj više operatora, i dijeljenje spektra.

Obzirom da procjena ne daje konkretne rezultate, metodologija prije svega uzima u obzir primarne faktore za potrebni spektar.

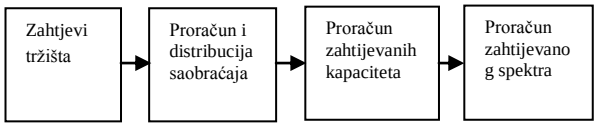
Ograničenja ove metodologije su što ona razmatra samo jedan tip mreže IMT-2000 bez mogućnosti razmatranja višestrukih mreža koje egzistiraju istovremeno. Također, M.1390 nije model mreža koje se sastoje od višestrukih tipova ćelija u istom geografskom području (kao što su makro ćelije i mikro ćelije za ukupno pokrivanje ili povećanje kapaciteta.

O metodologiji proračuna najviše odgovora je dato u okviru preporuke M.1768 koja je razvijena 2005 godine, a usvojena na Svjetskoj radio konferenciji WRC-07. Zbog ograničenja dotadašnjih metodologija i novih zahtjeva za spektrom na WRC-07 standardizirana je metoda ITU-R Recommendation M.1768, 2005 [4].

Nova verzija metodologije definisana preporukom ITU - R M.1768-1 (Metodologija proračuna potreba za spektrom za zemaljsku komponentu IMT) ima u vidu najnoviji napredak u IMT tehnologiji i razvoj IMT mreže: uvođenje dijeljenja spektra između makro i mikro ćelijskih slojeva (IMT-Advanced) i uvođenje novih parametara spektralne granulacije za IMT sisteme. Ažurirana metodologija sadrži zahtjeve za spektrom IMT u cjelini, a dijeli se između dvije pristupne radio tehnike (RATG-Radio Access Tehnic Group): RATG 1 : Pre - IMT sistem, IMT -2000 i njegova poboljšanja, RATG 2: IMT - Advanced. Metodologija procjene zahtjeva za spektrom slijedi tehnološki neutralan pristup i uzima u obzir tržište, tehnologije i razvoj informacija. [4]

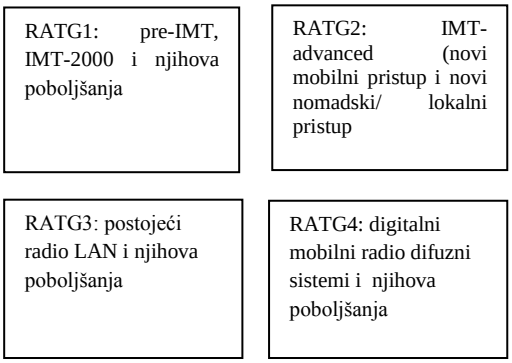
Dijagram toka metodologije

Opći dijagram toka metodologije iz Preporuke ITU-R M.1768-1 sastoji se od devet uzastopnih koraka koji su grupisani u četiri glavna bloka kao što je prikazano na slici 2. Metodologija počinje sa analizom podataka tržišta, prelazi na poračun i distribuciju saobraćaja, a zatim proračuna potrebnog kapaciteta, prije nego što se zaključi dijagram sa procjenom zahtijevanog spektra. Slika 2. prikazuje opći tok proračuna zahtijeva za spektrom.



Slika 2. Opći tok proračuna zahtijeva za spektrom

Definicije u metodologiji Preporuke ITU-R M.1768-1 radio pristupne tehnologije (prethodno tehnika) grupe (RATG) koriste definicije iz Izvještaja ITU-R M.2074 – Radio aspekti za zemaljsku komponentu IMT-2000, koji su sažeti u slici 3. Izvještaj ITU-R M.2074 također predstavlja opravdanje za korištenje RATG pristupa [5]. Treba napomenuti da metoda u Preporuci ITU-R M.1768-1 procjenjuje potražnju spektra samo za RATG 1 i 2, ali ne i RATG 3 (RLAN) i RATG 4. [4] Iako metoda uzima u obzir saobraćaj globalnih mobilnih telekomunikacije različitih mobilnih sistema kao što su IMT i RLAN, ipak zahtjevi spektra se računaju samo za IMT. Treba imati na umu da se ove metodologije mogu koristiti za procjenu ukupnih IMT zahtjeva za spektrom određene zemlje samo ako se sve trenutne vrijednosti ulaznih parametara zamjenjuju vrijednostima koje se primjenjuju na određene zemlje.



Slika 3. Radio pristupne tehnologije

U najnovijoj verziji preporuke ITU Rec M. 1768-1, objavljene u aprilu 2013. godine definiše se metodologija proračuna potrebnih količina RF spektra na način da se usvajaju novi trendovi koji vladaju na tržištu telekomunikacija, tehičko-tehnološki razvoj proizvoda i usluga te ostale promjene nastale u radio i servisnom okruženju. Komponenete metodologije su funkcionalno podijeljene u devet koraka i to:

1. Definisanje pojmova kategorije servisa (SC), servisnog okruženja (SE), radio okruženja (RE) i grupa pristupnih radio tehnologija (RATGs - Radio access technology groups);

2. Analiza prikupljenih podataka o tržištu koja je definisana u ITU izvještajima ITU-R M.2072 i ITU-R M.2243;

3. Izračunavanje potrebnog saobraćaja za određenu kategoriju servisa i okruženja;

4. Raspoređivanje saobraćaja na različite RATG-ove i radio okruženja unutar RATG-a;

5. Određivanje sposobnosti kapaciteta sistema da opsluži datu količinu saobraćaja;

6. Proračun potreba za spektrom za različite RATG1 i RATG2;

7. Usvajanje potrebnih podešavanja kao što su zaštitni opsezi, više operatora, primjena podešavanja uzimajući u obzir praktični razvoj mreže;

8. Proračun ukupnih potreba za RF spektrom;

9. U zadnjem koraku se raspoređuje odgovarajući resurs na odgovarajuće RATG-ove. [4]

Procjena potrebnog spektra proračunata je za RATG1 (pre-IMT, IMT-2000, i njihova poboljšanja) i RATG 2 (IMT-Advanced) za 2020. godinu. Kako za različite zemlje postoje razlike u procjeni i rastu podataka o mobilnim komunikacijama, tako su u okviru izvještaja ITU M.2290 date dvije ekstremne situacije. Naravno u nekim zemljama će doći do odstupanja i nacionalni

zahtjevi za spektrom mogu biti manji ili veći od predviđenih vrijednosti.

	Ukupni zahtjevi za spektrom za RATG 1	Ukupni zahtjevi za spektrom za RATG 2	Ukupni zahtjevi za spektrom za RATG 1 i 2
Situacija sa manjom gustinom korisnika	440 MHz	900 MHz	1340 MHz
Situacija sa većom gustinom korisnika	540 MHz	1420 MHz	1960 MHz

Tabela 4 - Ukupni zahtjevi za spektrom za oba RATG u 2020. godini prema izvještaju ITU-R M.2290-0

Ovaj izvještaj nudi rezultate istraživanja procjene zahtjeva za spektrom za zemaljski IMT [6].

Procijenjeni zahtjevi za spektrom se računaju pomoću metodologije definirane u Preporuci ITU-R M.1768-1 i odgovarajućih vrijednosti ulaznih parametara, uzimajući u obzir najnoviji napredak u tehnologijama i razvoj zemaljskih IMT mreža, kao i najnovija zbivanja na tržištima mobilnim telekomunikacija. Ukupni zahtjevi spektra za oba RATG 1 (tj pre-IMT, IMT-2000 i njegova poboljšanja) i RATG 2 (tj IMT-Advanced) u 2020. godini procjenjuju se pomoću dvije različite situacije kako bi se istakle razlike u tržištima i vremenske rasporede za rast mobilnih podataka u različitim zemljama. Procijenjeni ukupni zahtjevi spektra za RATGs 1 i 2 su 1340 MHz i 1960 MHz za postavke niže gustoće korisnika i postavke veće gustoće korisnika, respektivno.

Prema ITU modelu koji se zasniva na preporuci 1768-1 ukoliko se koristi poseban program za proračun spektra, ubacujući realne cifre dobije se da je potreba za spektrom puno manja nego ona proračunata ITU modelima. Tako se prema istraživanjima LS Telcom-a [7], EBU-a, ESOA došlo do rezulatata da su potrebe za spektrom 240 MHz u 2020. god.

IV. PRIMJENA U BIH

Procjena potrebnih RF kapaciteta za potrebe mobilnih mreža predstavlja veoma važan faktor u razvoju telekomunikacija koji treba da ponudi smjernice za budući razvoj tehnologije i usluga. U velikom procentu ovo je pitanje, kako je ranije prikazano u radu, determinisano zahtjevom tržišta odnosno odgovarajućim socio-ekonomskim faktorima koji preovladavaju u određenoj sredini. Zahtjev za proširenje kapaciteta mobilne mreže predstavlja stalni proces koji se postavlja pred telekom operatore. S druge strane operatori moraju planirati proširenja vodeći računa o stepenu iskorištenja trenutnih kapaciteta, troškovima uvođenja novih kapaciteta te napraviti procjenu koja će ponuditi izbalansirano rješenje koje će omogućiti kreiranje pozitivnog ambijenta za poslovanje kompanije. Obzirom da su frekvencijski resursi koje koristi mobilna mreža za pristup do krajnjeg korisnika veoma vrijedni planiranju mreže treba pristupiti studiozno i sa velikom pažnjom.

Primjena metodologije procjene predložene u ITU Rec.1786-1 u Bosni i Hercegovini se mora, zbog specifičnosti geopolitičke situacije u BiH, razmatrati sa više aspakata koji u određenoj mjeri odstupaju od principa tržišno orijentisane ekonomije čemu BiH teži. Zvanično definisanom strategijom razvoja telekomunikacija definisana su tri operatora mobilne telefonije što predstavlja administrativno ograničenje odnosno zabranu ulaska novih „ igrača“ na tržište telekomunikacija. Ova odrednica direktno utiče na razvoj konkurencije na tržištu te s tim u vezi i na razvoj novih proizvoda i usluga. „Atipično“ tržište mobilnih komunikacija u BiH se mora uzeti kao faktor koji nepovoljno utiče na razvoj, uvođenje i eksploataciju mobilnih mreža.

Sa aspekta iskorištenja RF spektra namijenjenog za potrebe mobilnih komunikacija, tradicionalno namijenjeni opsezi GSM-900 i DSC 1800 su podijeljeni između tri operatora. U novije vrijeme postoje zahtjevi za korištenje tehnologije koja na efikasniji način koristi navedene opsege tako da danas imamo korištenje LTE tehnologije u GSM 900 opsegu. Ovaj indikator pokazuje da su trenutni kapaciteti u dobroj mjeri iskorišteni. Što se tiče opsega koji su namijenjeni proširenju kapaciteta odnosno razvoju novih tehnologija u mobilnim mrežama, kao što su opsezi 700 MHz, 800 MHz, 2.6 GHz, administrativne pretpostavke za korištenje su ispunjeni ali ne postoje zahtjevi za komercijalno korištenje. LTE mreže egzistiraju u Bosni i Hercegovini samo u fazi testiranja. Ako se uzme u obzir da u regionu već egzistira LTE, može se odrediti odgovarajuće „kašnjenje“ za implemetacijom LTE mreža u BiH.

Preporuka ITU Rec.1786-1, koja je napravljenja za globalnu estimaciju potrebnih količina RF spektra, predstavlja dobru polaznu tačku za određivanje potrebnih količina RF spektra i u BiH. Analizom referentnih podataka datih u preporuci utvrđeno je da predimenzionisana vrijednost potrebnih resursa te da navedeni podaci ne korespondiraju sa realnim korištenjem ovih usluga (referenca LS Telcom). Ovdje se može lako doći do zaključka da je u izradi preporuke u velikoj mjeri učestvovala i industrija koja je jako zainteresirana za razvoj novih radiokomunikacijskih sistema.

U slučaju BiH, referentni podaci su uzeti iz zvaničnih podataka Agencije za statistiku BiH kao što su: broj korisnika mobilne telefonije, ukupan broj minuta u mobilnom saobraćaju, gustoća pretplatnika po km^2, pokrivenost signalom u zavisnosti od korištene tehnologije (2G, 3G, 4G) [8]. Analize pokazuju da najveći broj korisnika koristi veoma mali kapacitet prenosa manji od 16 kbit/s i to u 40 %. Multimedijalne sadržaje na brzinama do 144 kbit/s korsiti 30% korisnika, a ostatak korisnika se može svrstati u kategorije zahtijevnijih korisnika za srednjim i višim zahtjevom za kapacitetom prenosa podataka. Što se tiče mreža sa ćelijskim pokrivanjem u Bosni i Hercegovini, dominiraju makro i mikro ćelije ovisno o okruženju da li je urbano ili rualno. Hot spot mreže su realizovane u nokoliko gradskih središta, a piko ćelijie nisu zastupljene u značajnijem obimu.

V. ZAKLJUČAK

Količina potrebnog radiofrekvencijskog spektra u mobilnim komunikacijama važan je faktor prije svega zbog neprekidne potrebe za povećanjem mobilnog saobraćaja. Za procjenu zahtjeva za frekvencijama, novi modeli moraju biti razvijeni i primijenjeni na način da omogućavaju razmatranje prostornih i vremenskih korelacija između telekomunikacijskih usluga, uzimajući u obzir uslove na tržištu i scenarije mrežne implementacije. Metodologija predviđena ITU modelima analizira podatke tržišta, poračun i distribuciju saobraćaja, proračuna potrebnog kapaciteta da bi došla do procjene zahtijevanog spektra.

Uzimajući sve ranije navedeno u obzir možemo zaključiti da sadašnje korištenje RF spektra namijenjnog za mobilne komunikacije u BiH odgovara trenutnim i potrebama u bliskoj budućnosti (dvije godine). Trend povećanja obima saobraćaja proteklih godina je 5% u odnosu na predhodnu godinu. To znači da će za period do 2020. godine, u svakom sluačaju biti potrebno manje RF spektra nego što to predviđa ITU. Uzmemo li u obzir i povećanje obima saobraćaja koji se ostvaruje preko WiFi te korištenje manjih ćelija unutar makro ćelije kao metode povećanja efikasnosti RF spektra, proširenje na nove opsege će biti značajno manje od globalnih predviđanja.

Sažetak - Razvoj poslovnih procesa potrebnih za realizaciju i aktivaciju korisničkih usluga jedan je od osnovnih preduvjeta za uspješno korištenje usluga na području javne telekomunikacijske mreže. Kako se radi o velikom broju različitih i složenih poslovnih procesa vrlo je važna njihova precizna specifikacija i dokumentacija. Pri tome je vrlo bitno odabrati način i format prezentacije poslovnih procesa koji se uspješno može koristiti ne samo u specificiranju potrebnih promjena u sustavima za podršku potrebnim za upravljanje telekomunikacijskom mrežom, već i u svrhu dokumentiranja poslovnih procesa na način da se dokumentacija može koristiti u različite svrhe kao što je analiza poslovnih procesa ili razumijevanje poslovnih procesa od strane različitih sudionika kao što su IT stručnjaci ili eksperti iz poslovne domene. Vrlo je bitno da se dokumentacija može koristiti i u svrhu razvoja nove arhitekture sustava za podršku kao što je NGSSM (Next Generation Service and System Management).

U radu je prezentiran jedan od načina specificiranja i dokumentiranja poslovnih procesa za realizaciju telekomunikacijskih usluga koji omogućava primjenu specifikacija u različite svrhe.

Ključne riječi: poslovni procesi, sistemska operativna podrška, korisničke usluge, modeliranje, specifikacija

I. UVOD

Telekomunikacijsko tržište čini vrlo složeno i živo poslovno okruženje u sklopu kojeg je potrebno osigurati poslovne procese koji osiguravaju efikasnu realizaciju telekomunikacijskih usluga. Ovo nije nimalo jednostavno ostvariti jer uspješna realizacija usluga u tako složenom okruženju ovisi o mnogo čimbenika. Od osiguravanja potrebnih akcija za realizaciju usluge, preko koordinacije više poslovnih procesa za realizaciju složenih usluga pa do razmjene potrebnih podataka za konfiguraciju mrežnih elemenata i komunikaciju između sustava koji upravljaju telekomunikacijskom mrežom.

Da bi se osigurali efikasni poslovni procesi u tako složenom poslovnom okruženju jednu od ključnih usluga imaju specifikacije poslovnih procesa. Specifikacije koje se uspješno mogu koristiti u dizajniranju poslovnih procesa kako na području javne telekomunikacijske mreže, tako i u drugim poslovnim područjima, ne bi trebale imati samo jednostruku namjenu. Osim u svrhu specificiranja potrebnih promjena u sustavima za podršku koji djeluju u sklopu sustava za upravljanja telekomunikacijskom mrežom, specifikacije trebaju omogućiti i prikaz poslovnih procesa koji omogućava njihovu analizu te njihovo dokumentiranje koje se može koristiti u različite svrhe.

Jedno od vrlo bitnih svojstava specifikacija je i mogućnost njihovog korištenja u definiranju poslovnih procesa koje je potrebno podržati od strane novih arhitektura sustava za podršku. Način dizajna poslovnih procesa treba biti takav da se pojedini segmenti poslovnih procesa mogu uspješno preslikati u strukturu podržanu novom arhitekturom sustava.

U radu se razmatra i predlaže jedan od mogućih načina dizajniranja i dokumentiranja poslovnih procesa koji se koriste za implementaciju i aktivaciju usluga na području javne telekomunikacijske mreže.

II. PREDLOŽENI NAČIN SPECIFIKACIJE POSLOVNIH PROCESA

Da bi se uspješno modelirali poslovni procesi za realizaciju telekomunikacijskih usluga potrebno je definirati model poslovnih procesa kroz koji se uspješno mogu definirati svi elementi potrebni za specificiranje akcija koje je potrebno poduzeti u sklopu realizacije i aktivacije usluge. Osnovni preduvjet za modeliranje poslovnih procesa je korištenje grafičkog načina prikaza kao jednog od standardnog oblika prezentacije poslovnih procesa. U [2] su definirani osnovni elementi modela potrebni za modeliranje i specificiranje poslovnih procesa koji se koriste za implementaciju telekomunikacijskih usluga. Ti su elementi:

A. Početni i završni čvor

Ovi se elementi modela koriste za definiranje početka i kraja poslovnog procesa koji se modelira.

B. Ručni zadatak

Služi za definiranje akcija koje trebaju izvršiti akteri poslovnog procesa.

C. Odlazni i dolazni signal

Specificira se komunikacija između sustava koji sudjeluju u procesu realizacije telekomunikacijske usluge.

D. Podprocesi

Definiraju cjeline od kojih se sastoje poslovni procesi. Podprocese čine akcije koje se odnose na pojedinu uslugu

i potrebno ih je poduzimati u određenom dijelu poslovnog procesa.

E. Čvor odluke

Definira mjesto u poslovnom procesu kada je na temelju određenog kriterija potrebno odlučiti u kojem će se smjeru nastaviti tijek poslovnog procesa.

F. Čvor dijeljenja

Definira se mogućnost paralelnog odvijanja aktivnosti u poslovnom procesu.

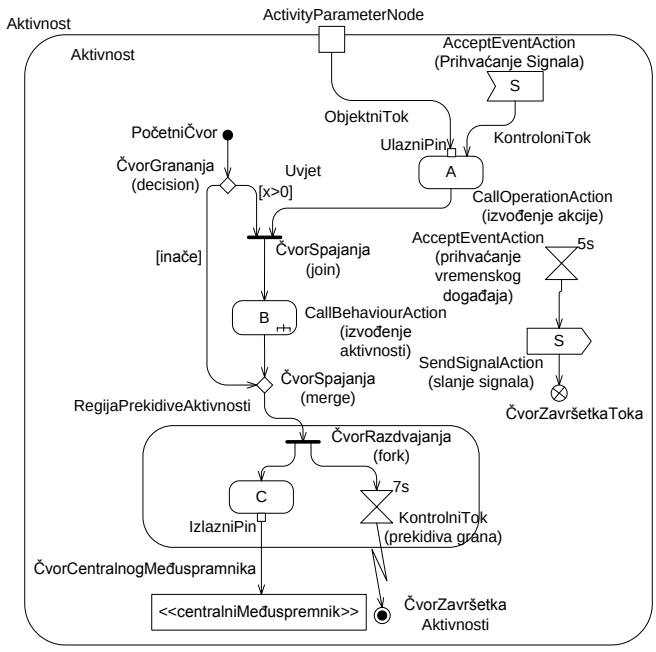
G. Vremenska kontrola

Definira zaustavljanje poslovnog procesa na određeno vrijeme.

H. Prekid procesa

Specificira se mogućnost prekida procesa na temelju definiranih kriterija kao što je tehnička nemogućnost realizacije usluge.

Na temelju definiranog modela poslovnog procesa bilo je potrebno odabrati alat za dizajniranje poslovnih procesa čija sintaksa podržava elemente modela. U [3] je predložen UML2 dijagram aktivnost čiji elementi odgovaraju elementima modela. Slika 1 prikazuje sintaksu UML2 dijagrama aktivnosti.



Slika 1: Sintaksa UML 2 dijagrama aktivnosti

UML (Unified Modeling Language) je standardizirani alat koji ima široku primjeru u grafičkom modeliranju softverskih rješenja. Alat koristi više različitih dijagrama koji modelirani sustav prikazuju iz različitih perspektiva. Dijagram aktivnosti definira dinamičko ponašanje sustava. To ga uz njegovu sintaksu čini vrlo korisnim alatom za dizajniranje poslovnih procesa i specificiranje potrebnih promjena u sustavima za operativnu podršku kojima se upravlja odvijanjem poslovnih procesa.

No, iako je odabrani dijagram aktivnosti alat kojim se poslovni procesi za realizaciju usluga u telekomunikacijskoj mreži mogu vrlo dobro dizajnirati njegovo korištenje samo po sebi nije dovoljno bez definiranog koncepta za modeliranje i specificiranje složenih poslovnih procesa. Naime, poslovni procesi postaju sve složeniji. Tu se ne radi samo o realizaciji jedne određene usluge, već se vrlo često radi o procesima kojima se istovremeno korisniku realizira više usluga. Tu su i procesi migracije usluga gdje se prilikom realizacije određene usluge pokreće i migracija postojećih usluge s jedna na drugu tehnologu. Na području telekomunikacija djeluje veći broj operatora te je potrebno osigurati sve veći broj različitih složenih poslovnih procesa koji upravljaju prelaskom korisnika između operatora.

S druge strane sustavi za operativnu podršku kojima se upravlja poslovnim procesima imaju svoju arhitekturu i to je potrebno uzimati u obzir prilikom specifikacije potrebnih promjena u sustavu. Zaista je veliki izazov modelirati poslovne procese i specificirati programsku podršku na način da su složeni poslovni procesi jasni sa stanovišta potrebnih akcija za realizaciju usluga s jedne strane i da jasno i precizno definiraju potrebne promjene u sustavima sistemske operativne podrške s druge strane.

Zato je bilo potrebno definirati koncept kojim se uspješno mogu modelirati složeni poslovni procesi i specificirati potrebne promjene u sustavima. Jedan od mogućih načina, koji se i predlaže u ovom radu, je korištenje scenarija i osnovnih podprocesa kojima se modeliraju poslovni procesi i dizajnira sistemska operativna podrška [5].

Svaki scenarij predstavlja poslovni proces koji se može pokrenuti prilikom realizacije ili korištenja telekomunikacijskih usluga. Složeni poslovni procesi na čije se modeliranje korištenjem koncepta scenarija želi naročito utjecati su na primjer migracija govorne usluge s PSTN (Public Switched Telephone Network) mreže na VoIP (Voice over Internet Protocol) i istovremeno uključenje pristupa Internetu i IPTV-a (Internet Protocol Television) ili istovremeno isključenje govornih i širokopojasnih usluga (pristup Interentu i IPTV) te portiranje numeracije i iznajmljivanje lokalne petlje (pretplatničke parice) drugom operatoru.

Scenarij se sastoji od osnovnih cjelina (podprocesa) kojima se definira skup akcija koje je potrebno odraditi u određenom periodu odvijanja poslovnog procesa. Primjer takvog podprocesa su konfiguracije na mrežnim elementima operatora koje je potrebno odraditi prije aktivnosti na području pristupne mreže ili aktivacije usluga kod korisnika. Podprocesi se, kao i osnovni procesi, modeliraju kroz dijagrame aktivnosti. U modeliranju podprocesa dalje se specificiraju akcije koje je potrebno odraditi u tom dijelu odvijanja poslovnog procesa.

Na ovakav se način postiže modeliranje poslovnih procesa kroz više razina složenosti. Prva razina definira scenarij i specificira osnovne cjeline (podprocese) od kojih se sastoji scenarij. Ovo je najniža razina složenosti i kroz nju se poslovni proces jasno modelira opisom osnovnih

cjelina od kojih se sastoji. Vrlo važan element modela su napomene koje se pridjeljuju svakoj cjelini i u kojima se opisuju osnovne aktivnosti koje je potrebno pokrenuti u sklopu cjeline. Ova razina modela vrlo je bitna u kontekstu analize E2E (s kraja na kraj) procesa kojeg operator treba provesti kako bi od korisnika preuzeo zahtjev, realizirao telekomunikacijsku uslugu i konačno naplatio svoje usluge.

Kroz ostale razine složenosti specificiraju se potrebne akcije za realizaciju telekomunikacijske usluge. Podprocesi kojima se modeliraju cjeline u sklopu scenarija mogu u sebi također sadržavati podprocese koje specificiraju proces kroz veću razinu složenosti. Na ovim razinama složenosti specificiraju se detalji potrebni za implementaciju potrebnih promjena u sustavima sistemske operativne podrške.

Ovakvim konceptom modeliranja poslovnih procesa za realizaciju telekomunikacijskih usluga postiže se jasno, strukturirano i precizno specificiranje potrebnih akcija u sklopu poslovnog procesa.

Drugi izazov je kako razvijeni model poslovnog procesa koristiti za specifikaciju potrebnih promjena u postojećoj arhitekturi sistemske operativne podrške, a da istovremeno model može poslužiti za definiranje poslovnih procesa koje je potrebno realizirati kroz novu arhitekturu sistemske operativne podrške.

Sami koncept scenarija i osnovnih cjelina od kojih se sastoji scenarij daje već dobru osnovu za rješenje ovog izazova. Scenarij opisuje procese na način da se definiraju osnovne akcije koje je potrebno poduzeti za realizaciju telekomunikacijske usluge bez obzira na arhitekturu sistemske programske podrške. I u ostalim razinama složenosti kojima se specificiraju detalji za implementaciju sistemske programske podrške elementi modela prvenstveno su usmjereni na ono što je potrebno realizirati, a ne kako. Način implementacije kroz postojeću arhitekturu sustava opisan je ili odvojeno od samog modela ili u sklopu modela, ali jasno odvojeno od ostalog opisa koji se prvenstveno odnosi na opis što je potrebno realizirati. Time se omogućava korištenje modela poslovnog procesa i za specifikaciju poslovnih procesa za realizaciju kroz drugu arhitekturu sistemske programske podrške ili barem definiranje osnovnih cjelina (podprocesa) i poslovnih pravila koje je potrebno osigurati kroz tu novu arhitekturu sustava.

III. PRIMJER SPECIFIKACIJE

Na slici 2 je prikazan primjer modeliranja scenarija. Model se odnosi na specificiranje poslovnih procesa kojima se upravlja kroz sustav za upravljanje tijekom poslova (workflow). Scenarij modelira složeni poslovni proces kojim se realizira migracija govorne usluge iz PSTN mreže u VoIP, portiranje (prijenos) numeracije u govornu mrežu drugog operatora te potrebna konfiguracija mrežnih elemenata kojom se omogućava prijenos govorne usluge preko ADSL pristupa iznajmljenog drugom operatoru. Ovo je vrlo složeni scenarij koji u sebi sadrži specifikaciju aktivnosti koje su potrebne za istovremenu realizaciju više usluga i više različitih procesa.

Poslovni proces se sastoji od više podprocesa koji definiraju cjeline unutar kojih je potrebno izvršiti određene aktivnosti u svrhu uspješnog odvijanja poslovnog procesa predstavljenog ovim scenarijem. Prva cjelina je ispitivanje tehničke mogućnosti u sklopu koje je potrebno ispitati postoje li potrebni mrežni kapaciteti za realizaciju usluga. Nakon toga se pokreću konfiguracije mrežnih elemenata potrebnih za realizaciju usluga i procesa. Kako se u ovom slučaju radi o poslovnom procesu koji se tiče i drugog operatora vrlo je bitno poštivati vremensku komponentu. Konfiguracije mrežnih elemenata koje imaju utjecaj na rad već postojećih funkcionalnosti potrebno je izvršiti u točno definirano vrijeme. To je vidljivo u napomeni kojom se opisuje podproces „Konfiguracija DSLAM-a“.

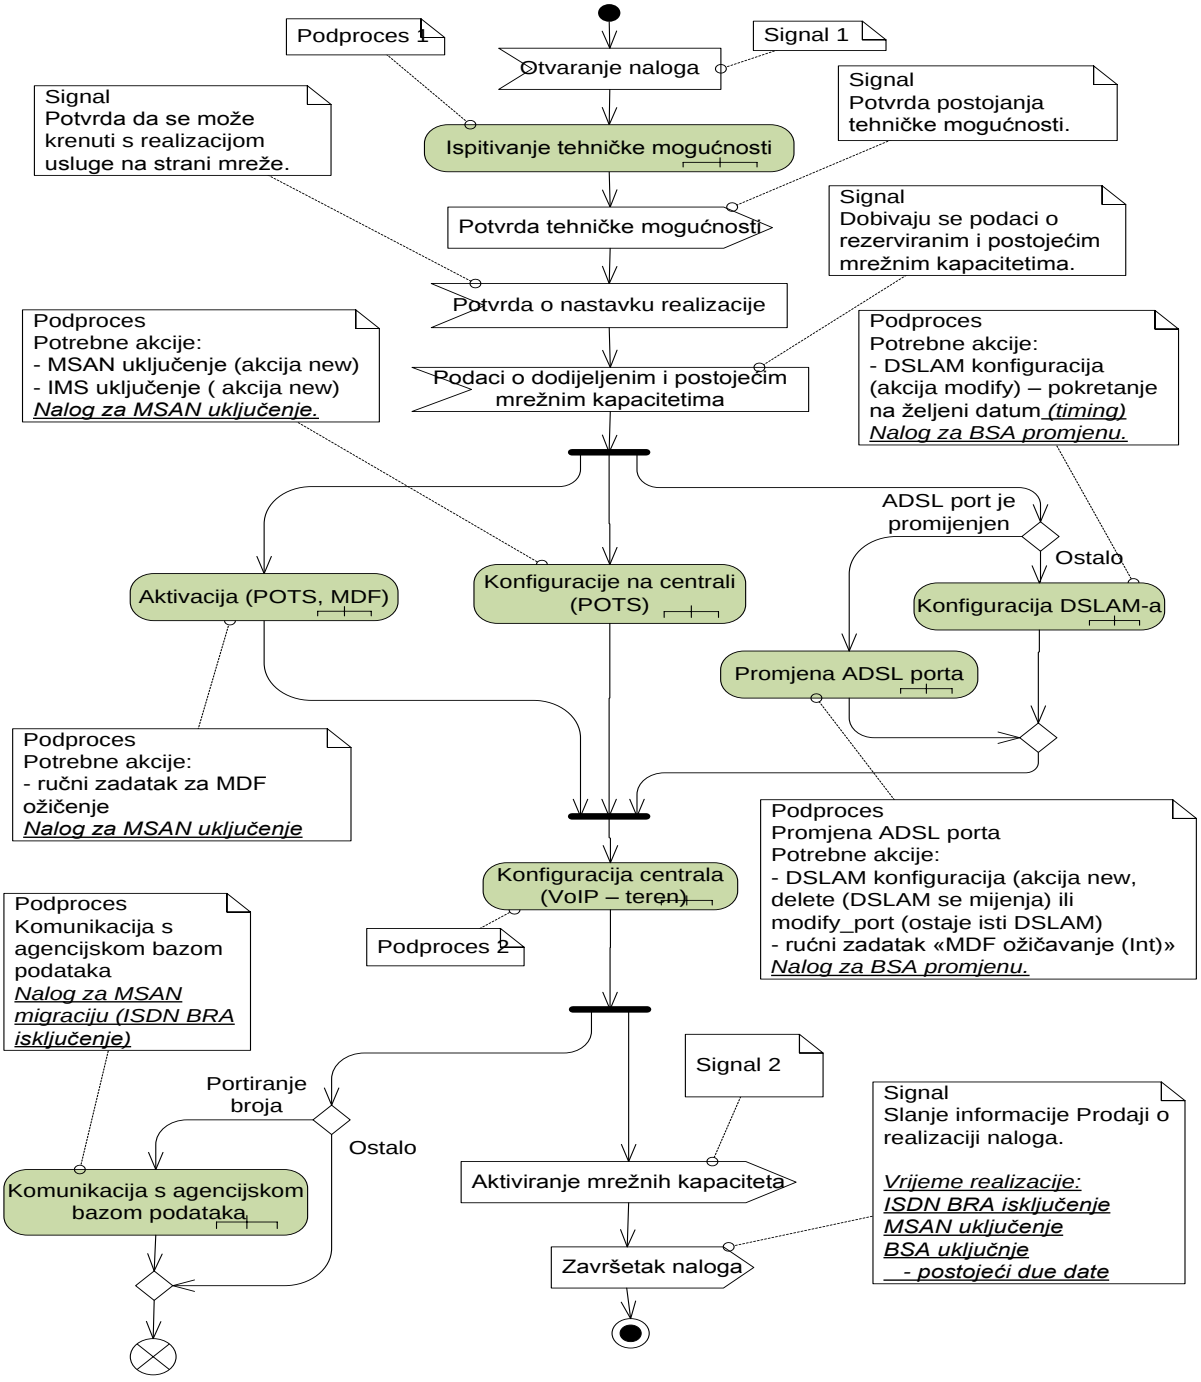
Nakon realizacije potrebnih konfiguracija mrežnih elemenata u definirano vrijeme može se pristupiti oslobađanju mrežnih elemenata koji više nisu potrebni nakon realizacije ovog scenarija, tj. složenog poslovnog procesa. To je definirano u podprocesu „Konfiguracija centrala (VoIP – teren)„. Ranijim pokretanjem ovog podprocesa dovelo bi se do prijevremenog prekida usluga što se svakako želi izbjeći.

Konačno, nakon provedenih aktivnosti pokreće se podproces kroz koji se obavještava baza podataka Agencije zadužene, između ostalog, i za definiranje odnosa između operatora da je portiranje brojeva između operatora izvršeno.

Model jasno opisuje osnovne cjeline i akcije koje je potrebno poduzeti, a i jasan je vremenski redoslijed i raspored akcija za uspješnu realizaciju složenog procesa. U modelu su specificirane i pojedinosti bitne za implementaciju poslovnog procesa kroz postojeću arhitekturu sistemske operativne podrške (označeno italic fontom). Te su pojedinosti jasno razgraničene od dijela modela kojim se modelira poslovni proces gledajući na aktivnosti u mreži potrebne za realizaciju usluge. Time se postiže mogućnost uspješnog korištenja modela za specificiranje potrebne sistemske podrške u postojećoj sistemskoj operativnoj podrški, a istovremeno i za modeliranje procesa koje je potrebno podržati kroz novu arhitekturu sustava buduće sistemske operativne podrške.

Na slici 3 prikazan je podproces kojim je opisana jedna od cjelina opisanog scenarija. Podprocesom se kroz dijagram aktivnosti opisuje dio procesa na način da se specificiraju potrebne promjene već do detalja potrebnih za implementaciju u sustavima za podršku. No, i na ovoj razini modela i dalje se zadržava princip da se specifikacije i opis elemenata modela odnose na potrebne aktivnosti u mreži, a ne i na postojeću arhitekturu sustava. Ukoliko je potrebno dodatno specificirati, recimo, neki od uvjeta kojima se kroz čvor odluke definira u koju granu će ići tijek poslovnog procesa to se radi uz dodatno specificiranje (na primjer tablica kroz koju se postojeći uvjet u modelu preslikava u uvjet koji u sebi sadrži tehničke detalje vezane uz arhitekturu i strukturu sustava). Naravno, postoje još i dodatni detalji koji se mogu specificirati u zasebnim dokumentima, a sami model ostaje „neopterećen“ detaljima vezanim uz postojeću strukturu i arhitekturu sustava.

Vrlo je bitno da model sadrži i podatke koje je potrebno razmjenjivati između sustava koji sudjeluju u upravljanju poslovnim procesima za realizaciju telekomunikacijske usluge te podatke potrebne za aktere koji sudjeluju u poslovnom procesu realizacije telekomunikacijske usluge.



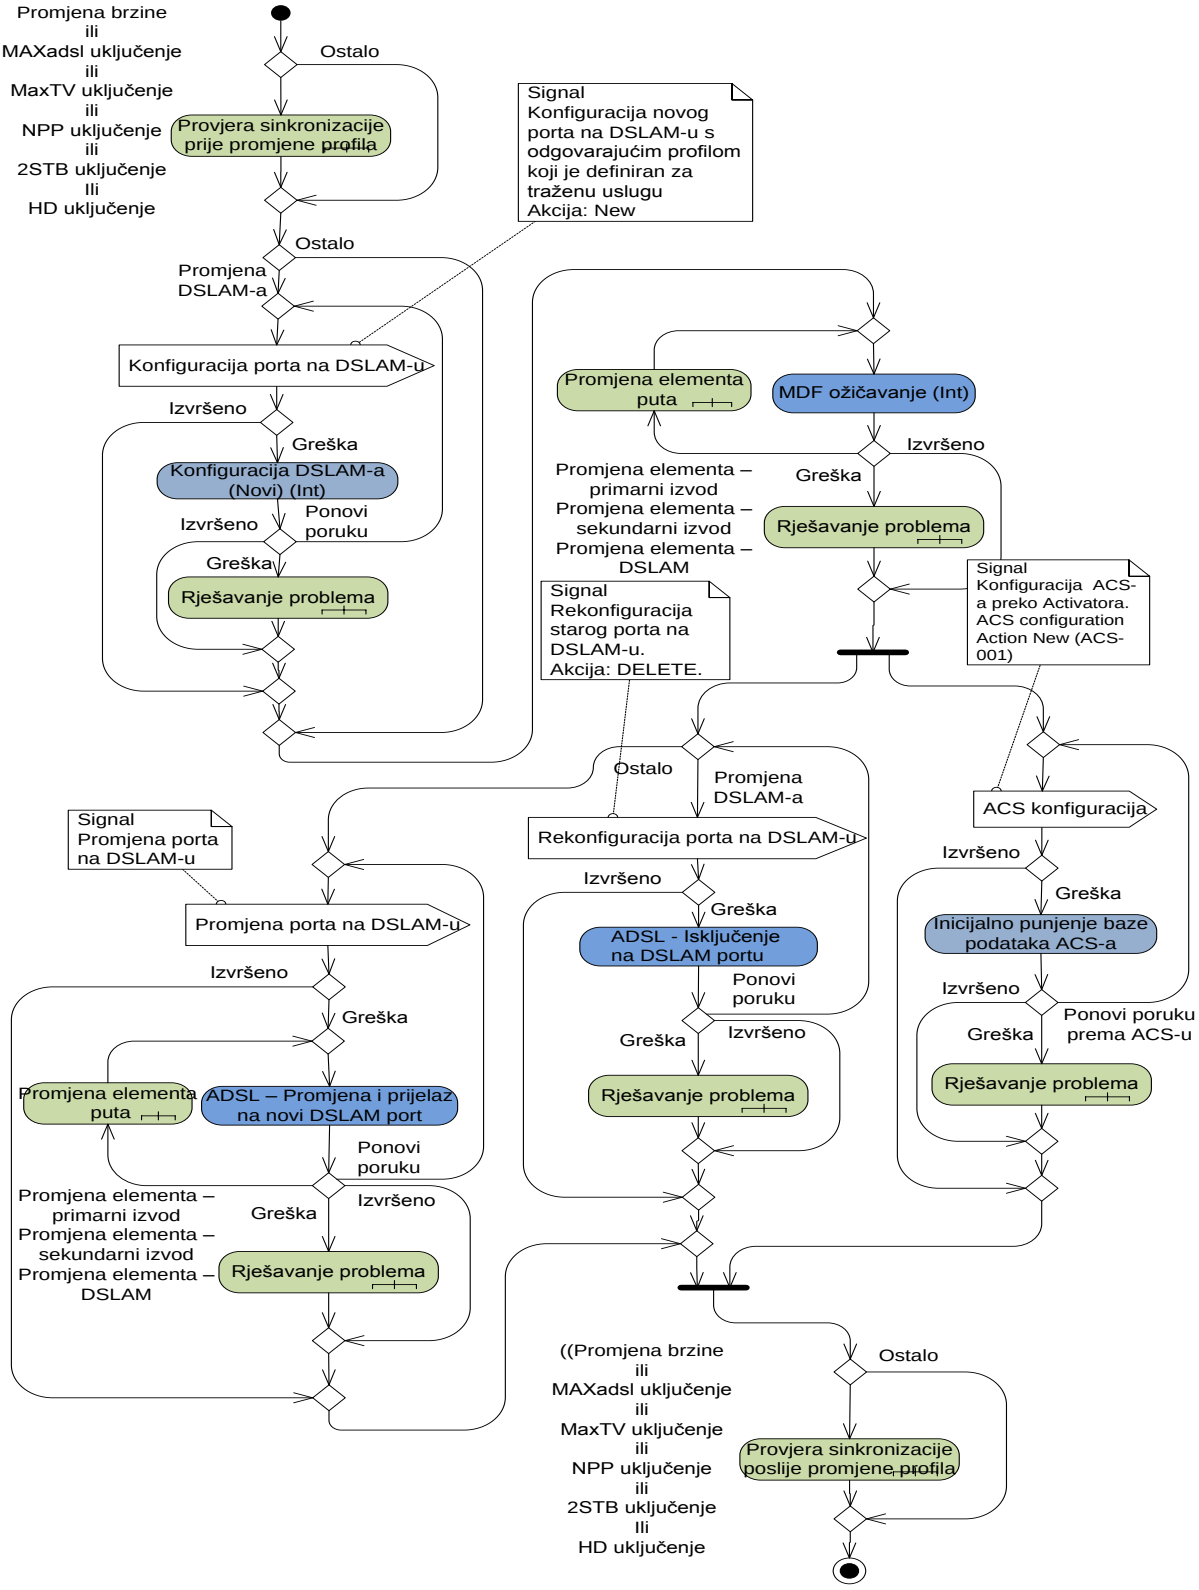
Signal 1 – Iniciranje otvaranje naloga na strani mreže
Tri naloga iz Donata (CRM sustav):- ISDN BRA isključenje (razlog «Migracija ISDN», produkt «Number portability»; MSAN uključenje (uključenje «Migracija ISDN»); BSA promjena
Kod scenarija: ISDN_TO_MSAN_BSA_CHANGE

Signal 2 – Aktiviranje mrežnih kapaciteta.
Koodinacija naloga prema DIS-u (sustav koji sadrži podatke o mrežnim kapacitetima): Prvot – ISDN BRA isključenje (akcija confirm); Drugo– MSAN uključenje (akcija confirm); Treće – BSA uključenje (akcija confirm)
Storniranje: Prvo – BSA uključenje (cancel); Drugo – MSAN uključenje (cancel); Treće – ISDN BRA isključenje (cancel)

Podproces 1 - Ispitivanje tehničke mogućnosti na strani mreže za ADSL i rezervacija potrebnih mrežnih kapaciteta
Koordinacija (čeka se na akciju PROCEED u prethodnom nalogu) prema DIS-u: Prvo – ISDN BRA isključenje (akcija start); Drugo - MSAN uključenje (akcija start); Treće – BSA change (akcija start)

Podproces 2- Konfiguracija IN centrale (akcija new; ako broj pripada PSTN numeraciji), PSTN centrale (ICS-8), IMS centrale (akcija UNLOCK); isključenje brojeva na ISDN BRA priključku (akcije disconnection numbering; ICS-8 add za broj koji migrira na VoIP; ICS-6 add za broj koji se portira drugom operatoru
Nalog za MSAN uključenje.

Slika 2: Scenarij složenog procesa



Slika 2: Podproces „Promjena ADSL porta“

IV. ZAKLJUČAK

Poslovni procesi koji se koriste na području telekomunikacijske mreže za realizaciju usluga vrlo su složeni što je rezultat vrlo složenog poslovnog okruženja. Da bi se uspješno upravljalo takvim procesima potrebna je upravljačka mreža kojom se osiguravaju potrebne aktivnosti za realizaciju usluge.

Ključnu uslugu u definiranju poslovnih procesa ima specifikacija. Specifikacija treba precizno definirati sve potrebne promjene u sustavima kako bi se osigurali potrebni poslovni procesi te jasno modelirati poslovne procese tako da se može jasno razaznati potrebni slijed aktivnosti u sklopu procesa. Koncept scenarija i prikaz scenarija kroz definirane cjeline kojima se opisuje određeni slijed aktivnosti kao dijela sveukupnog poslovnog procesa jedan je od načina kojim se pridonosi preciznosti i jasnoći specifikacije i modela poslovnog procesa. Na taj se način ne dolazi samo do uspješne specifikacije potrebnih promjena u postojećoj sistemskoj operativnoj podršci, već se model poslovnog procesa može uspješno koristiti i u definiranju i modeliranju poslovnih procesa koje je potrebno provesti kroz novu arhitekturu sistemske operativne podrške.

SERVICES

Semantic Approach to Accommodation & Booking Related Web Services

I. Pavković* and I. Štajduhar**
* Vienna University of Technology, Vienna, Austria
** Faculty of Engineering, Department of Computer Engineering, University of Rijeka, Croatia
ivan.pavkovic@student.tuwien.ac.at

Abstract - There are several types of information that tourists most often search for when planning a trip. Commonly, these are information about the location, travel, accommodation and nearby attractions. Almost all the knowledge that an average tourist needs already exists, but the current knowledge is highly decoupled and its aggregation is time consuming. Another problem with tourism-related Web services is that they do not correlate with each other. The information they share is often represented differently, is not connected and is sometimes even in contradiction. In this paper, we provide an overview of the differences in data representation between most popular Web tourist services, and introduce the *A&B* ontology that covers their data representation and enables the service discovery. Additionally, we propose a framework that is connected to the aforementioned Web services, translates the data to the *A&B* ontology, links the data and provides a single endpoint for multiple Web services.

I. INTRODUCTION

The rise in number of online accommodation and booking related Web services, provide the users huge amounts of data about different locations, accommodation, attractions, travel and similar information. In this paper we distinguish three different roles: (I) accommodation & booking related websites (Web service providers), (II) service providers (e.g. accommodation owners, attraction managers etc.) and (III) Clients.

A recent Google's travel study [1] discovered that 78% of the participants choose online sources for planning their travel activities. It is also worth noting that 85% of leisure travelers are undecided on a brand, when choosing their vacation packages. Moreover, the consultants of *Expedia*, one of the largest booking Web services, emphasised in their latest study [2] that travelers from UK and USA pay visits to 36.5 different travel websites in a 45 day period, prior to their booking. Additionally, there are several other problems regarding online travel services, e.g.:

- The data and knowledge provided by different service providers are decoupled, and its aggregation is time consuming.
- The data are redundant and inconsistent. Different services often provide the same data (e.g. one hotel is offered on multiple services), but they represent the same data differently.
- Web service providers are unable to distinguish themselves from one another, i.e. they are unable to clearly point out their pros and cons, which would help the clients choose their service.
- Accommodation provider's goal is to maximize the visibility of his objects, and possibly to offer them to as many booking-related Web service providers as possible. However, managing and updating data over a large number of various services is a tedious and repetitive task.

Accommodation-related Web services rarely share their data. Moreover, knowledge sharing rarely exists or is completely nonexistent. Therefore, the today's advanced Web 2.0 technologies and techniques, such as *Semantic Web*, service discovery and *Linked Open Data* (LOD) are rarely applied.

In this paper, we weigh the importance of *Semantic Web* technologies in tourism, travel and booking related Web-services domains. In knowledge management and *Semantic Web* research areas, ontologies are considered essential in order to describe various concepts and relationships between them [3]. Ontologies are formal specifications of a shared conceptualization of a domain [4]. They enable us to use shared vocabulary within a domain, thus standardizing the communication and solving the interoperability problem within a large heterogeneous network. These are, however, not of much use without the appropriate implementation within the domain. *Linked Data* is the usage of *Resource Description Framework (RDF)* and the *Hypertext Transfer Protocol (HTTP)*, for the purpose of publishing and connecting structured data on the Web, where different data sources point to each other.

García-Crespo et al. [3] state that tourism is a data rich domain, and depending on the purpose of the study, different approaches should be considered. This paper is organized as follows. In the following section, we compare the currently available ontologies in the tourism domain, and evaluate their applicability to our domain of accommodation and booking-related Web services. In section III, we analyse the data representation used by most popular services, describe the process and define a new universal ontology for tourism-related Web services. In section IV, we propose a system that is connected to

The work presented in this paper is partially supported by the University of Rijeka research grant 13.09.2.2.16.

TABLE I. ANALYSIS OF EXISTING TOURISM-RELATED ONTOLOGIES. THE COVERAGE OF RELEVANT TOURISM CONCEPTS AND THE APPLICABILITY TO ACCOMMODATION-RELATED WEB SERVICES SCORES WERE ESTIMATED.

Ontology	Main Concepts	Coverage of relevant tourism concepts [a]	Covered domains	Applicability to accommodation-related Web services [b]
E-Tourism	What, Where, When, Tourist	2	Activities, Locations, Accommodation, Weather	2
Harmonise	Events, Accommodation, Attractions, Gastronomy	3	Events, Gastronomy	3
QALL-ME	Country, Destination, Site, EventContent, Event, Transportation, Contact, CreditCard, Currency, Facility, Genre, Language, Location, Period, PersonOrganization, Price, Room	4	Events, Locations	3
Hontology	Accommodation, Facility, Room, Service/Staff, GuestType	4	Accommodation	4
ACCO	Accommodation Feature, BedDetails, Brand, DeliveryMethod, PriceSpecification, Warranty scope, Offering, Document…	2	Accommodation offers	2 (as extension only)
cDOTT	MeansOfTransport, Room, Accommodation, Attraction, FoodServiceOrganization, GeographicalRegion, Activity, Event, Booking, Reservation, Ticket, Voucher, CityPass, AttractionPass	5	Transport, Accommodation, Attractions, Locations, Calendar	4

a. range: from 1 (narrow) to 5 (broad)

b. range: from 1 (not applicable) to 5 (excellent applicability)

multiple accommodation-related Web services. Our system aggregates the data from multiple sources, translates the data, connects the data and represents it with our universal ontology, finally providing a single endpoint for multiple sources.

II. OVERVIEW OF THE EXISTING TOURISM-RELATED ONTOLOGIES

There are more than several ontologies that try to cover the aspects of e-Tourism and related areas. Many of the existing ontologies are specific to certain use-case or organization-specific scenarios. Some of the more popular ontologies, those more relevant to our domain of accommodation-related Web services, are described next. A brief analysis of the presented ontologies is summarised in Table I.

A. E-Tourism ontology

E-tourism ontology [5] was built upon the idea of further development of Web applications. It gives an answer to three questions: (I) What – What does a tourist see (activity); (II) Where – Where are the interesting places for a tourist to stay (location, accommodation); and (III) When – When can the tourist visit a particular place (timetable, weather). These three questions represent the basic concepts (classes), along with the forth concept, Tourist, where the tourist and his preferences are described. This ontology, however, covers a rather small domain, does not use standardised taxonomy, does not cover concepts widely used in tourism-related applications today (e.g. reviews, calendar), and does not recognize Web service providers, nor the concept of a service provider.

B. Harmonise ontology

Harmonise ontology [6] was derived from the EU project *Harmonise*, which was aimed at data-interchange standardisation. Because various tourist organisations use different data formats, the purpose of *Harmonise* was to exchange information without needing to change the data scheme. Several organisations participated in its development, e.g. *WTO (World Tourism Organisation)*, *eCTRL (e-Commerce and Tourism Research Laboratory)*, and several national tourist boards. It is represented with *RDF*, and covers events (conferences, performances and sports), accommodation (hotels and guest houses, disregarding private holiday apartments and camp sites), attractions and gastronomy domains. The project was, however, discontinued and the ontology is no longer available online for free use.

C. QALL-ME ontology

QALL-ME [7] is yet another EU-funded project that led to the development of a domain-specific ontology for multilingual and multimodal question answering in the tourism domain. It has seventeen classes: Country, Destination, Site (accommodation, gastro, attraction, and infrastructure), EventContent, Event, Transportation, Contact, CreditCard, Currency, Facility, Genre, Language, Location, Period, PersonOrganization, Price and Room. *QALL-ME* ontology covers a wide area that can be reused for the domain of accommodation-related Web services. On the other hand, it has a narrow definition of Accommodation (Bed and Breakfast, Campsite, Chalet, Cottage, Hostel, Hotel, Resort), Rooms (CinemaRoom, ConferenceRoom, Guestroom, RestaurantRoom), and the Facilities are not even defined (e.g. Pool, Air Conditioner). Understandably, taking into

account its initial purpose, the concept of a Web service provider does not exist.

D. Hontology

Hontology [8] is a multilingual ontology for the accommodation sector. It was built on concepts similar to *QALL-ME* ontology, and brought in alignment with structured content on *DBpedia.org* and *Schema.org*. *Hontology* was initially created, considering a scenario of applications, processing reviews about accommodation present in modern Web services. Its main concepts are Accommodation, Facility, Room, Service/Staff and GuestType. Unlike *QALL-ME* ontology, *Hontology* utilizes expanded concepts, e.g. Accommodation (IceHotel, CapsuleHotel, etc.), Facility (HeatingSystem, Parking, Wi-FiZone, etc.) and Rooms (SingleRoom, DoubleRoom, StudioApartment, etc.). The concept of a service provider and a Web service provider, however, do not exist. Moreover, a calendar implementation does not exist, also.

E. ACCO Accommodation Ontology

ACCO Accommodation Ontology serves as an extension to *GoodRelations* ontology [9, 10]. *GoodRelations* ontology is a lightweight ontology for annotating offerings and other aspects of e-commerce on the Web. It is the only *Web Ontology Language* (OWL) ontology, officially supported both by Google and Yahoo. *ACCO Accommodation Ontology* [11] is a Web vocabulary for hotels, vacation homes, camping sites, and other e-commerce accommodation offers. It mostly focuses on creating price features. For accommodation-related Web-services domain it can only serve as an extension, used for achieving better search-engine visibility.

F. cDOTT ontology

cDOTT ontology [12] integrates modularised ontologies such as *W3C Time* and *W3C Geo*, that center around their core domain ontology for the tourism sector. The motivation for the creation of such approach is that the process of developing and maintaining a single tourism ontology that covers the whole tourism market, including geographical, temporal, and user-related information, would be very tedious. This approach leads to a loose coupling of ontologies, while retaining flexibility and extensibility. Its core ontology covers a broad range of tourist concepts, also covering the temporal context which can be applied for reservation calendar purposes. It also distinguishes service providers for attractions, but not for accommodation service providers or Web service providers.

G. Summary of the existing, tourism-related, ontologies

Prantner et al. [13] suggest that the current state of domain ontologies is quite limited and unsatisfactory, due to the specific targeting to various different organisations, sectors and applications.

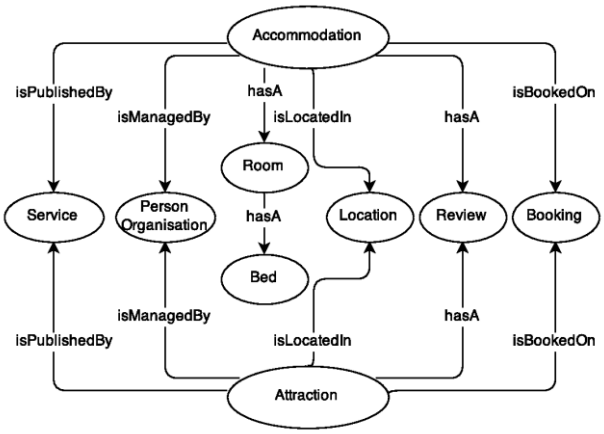

Figure 1. *A&B* ontology schema – basic concepts and data properties.

Summing it all up, most of the ontologies lack standardisation, agreed upon by multiple parties, and only a few offer a broad coverage of relevant tourism concepts. Moreover, none of the aforementioned ontologies offers a machine-accessible semantics, describing a network structure that could be applied to accommodation-related Web services. According to Ding et al. [14], this causes problems and affects content providers, intermediaries and content users.

III. ACCOMMODATION AND BOOKING (A&B) ONTOLOGY

The *A&B* ontology was developed, based on the *Ontology Development 101* method, proposed by Noy and McGuinness [15]. Our idea was to build an ontology that covers a wide range of accommodation and booking related Web services:

- Booking Web services – e.g. *Booking.com*, *Expedia.com* and *AirBnB.com*
- Hospitality exchange Web services – e.g. *Couchsurfing.com* and *BeWelcome.com*
- Accommodation swapping Web services – e.g. *HomeExchange.com* and *HomeForSwap.com*
- Travel-related Web services for reviews – e.g. *TripAdvisor.com*

During the ontology development, we focused our interests on three key roles in accommodation-related Web-services domain:

1. Accommodation & Booking Web service provider – Web services that provide certain data
2. Service provider – providers of real-world services, such as accommodation owners, hotel management, owners and managers of attractions
3. Clients – users of a Web service

We constructed a tourism-related *OWL* ontology. *OWL* is a vocabulary extension of *RDF*, and it consists of

classes (concepts within a domain), class-hierarchy (taxonomy of concepts), properties and property values, relations between classes (inheritance, disjointness, and equivalence), restrictions (cardinalities) and individuals.

In section II, we identified the similarities applicable to accommodation-related Web services with two existent ontologies, *Hontology* [8] and *cDOTT* [12], which were partially reused in our ontology. Semantic snippets, such as *Schema.org* and *Microformats.org* were also under consideration.

A. Main concepts

We defined the following main concepts in the *A&B* ontology, within the domain of accommodation-related Web services: Location, Attraction, Review, Room, Bed, PersonOrganization, Booking and Service. We describe the concepts and differences in concepts that differentiate our ontology, next.

Accommodation

The concept of accommodation is common to all tourism ontologies. We took a specific approach in order to define its subclasses and data properties. For defining subclasses (types of accommodation), we examined the data from various booking-related Web services (e.g. *AirBnB.com*, *Booking.com*, *Flipkey.com*), *Schema.org* and *DBpedia.org*. The overview of the accommodation types found is presented in Table II.

We added a broad range of accommodation types to our ontology. We chose the concepts that are more specific, e.g.:

- Watermill and Windmill on *FlipKey.com*, over Mill on *VRBO.com*
- Camper/Mobile Home and Camper/Van on *FlipKey.com* over a Camper/RV on *AirBnB.com*

Finally, the concept of accommodation has over fifty defined accommodation type subclasses.

In order to define data properties, we used a similar approach, where we compared the data representation over various Web services. There are over two hundred different data properties. Due to page limit, they are not described in detail in this paper. Regardless, the method we used can be roughly described using the following principles:

- If there were conflicts on data properties between different services, e.g. property Shower had a Boolean (has shower/does not have shower) value on one service, and an integer value on another service (has two showers), we used the version supported by more Web services;
- If a certain property was defined as string value (description) on one service, and as a Boolean value on another, we kept them both, since they semantically provide different meanings.

Service

In the *A&B* ontology, a specific accommodation or attraction is managed by a certain person or organisation, and that refers to a service provider role. Certain accommodation or attraction is, however, published by a certain service, where we refer to the role of a Web service provider, e.g. *Apartment in Vienna* is managed by *Jane*, and is published on *AirBnB.com*. Therefore, the primary purpose of the service concept is to identify the Web service, an instance belongs to.

Another purpose of the service concept is to resemble the *Universal Description, Discovery and Integration (UDDI)* [16] mechanism with Web services. *UDDI* is a standard by which Web services broadcast themselves on the Internet, as a mechanism to register and locate different services, in order to enable service composition.

TABLE II. OVERVIEW OF ACCOMMODATION TYPES ON POPULAR WEB SERVICES, SCHEMA.ORG AND DBPEDIA.ORG

URL	**Supported accommodation types**
AirBnB.com	Apartment, House, Bed&Breakfast, Loft, Cabin, Villa, Castle, Dorm, Treehouse, Boat, Plane, Camper/RV, Igloo, Lighthouse, Yurt, Tipi, Cave, Island, Chalet, Earth House, Hut, Train, Tent, Other
Booking.com	Apartment, Bed&Breakfast, Country House, Guesthouse, Homestay, Farm Stay, Lodge, Vacation Home, Villa, Chalet, Hotel, Motel, Inn, Capsule Hotel, Condo Hotel, Resort, Resort Village, Campground, Luxury Tent, Riad, Ryokan, Love Hotel, Boat
FlipKey.com	Apartment, Bed&Breakfast, Barn, Beach Hut, Boathouse, Bungalow, Camper/Mobile Home, Camper/Van, Castle, Cave House, Chalet, Chateau, Condo, Converted Chapel, Cottage, Farmhouse, Finka, Fort, Gite, Guesthouse, Hotel Apartment, House, Houseboat, Lighthouse, Lodge, Log Cabin, Manor House, Narrowboat, Penthouse, Riad, Shepherd's Hut, Ski Chalet, Studio, Tented Camp, Tipi, Tower, Townhouse, Treehouse, Trullo, Villa, Watermill, Windmill, Yacht, Yurt
HouseTrip.com	Apartment, Boat, Castle, House, Studio
VRBO.com	Apartment, Barn, Boat, Bungalow, Cabin, Castle, Chalet, Chateau/Countryhouse, Condo, Estate, Farmhouse, Hotel, House, Houseboat, Lodge, Mill, Studio, Tower, Townhome, Villa, Yacht
Wimdu.com	Holiday Home, Apartment, Private Room, Chalet Or Cabin, Castle, Farmhouse, Treehouse, Boat, Car
Schema.org	Bed&Breakfast, Hostel, Hotel, Motel, Lodging Business, Residence
DBpedia.org	Beach Hut, Gîte, Tourist Home, Sleep Box, Camping Coach, Hotel, Motel, Safari Lodge, Houseboat, Hospitality Service, Holiday Cottage, Vacation Rental, Lodging, Villa, Home Exchange, Coaching Inn, Homestay, Wilderness Hut, Mountain Huts, Resorts, Hostels, Campsites, Bed And Breakfasts, Vacation Rental, Villas

There are several different approaches to service discovery with semantic technologies [17,18,19]. Ours, however, can be seen as a *KISS* (keep it simple, stupid) approach within our small domain: every web service provider marks accommodation or attractions of his own. This approach assumes information sharing between different services.

The final purpose of the service concept is to serve as a policy negotiator between different Web services. As such, a Web service publishes terms, under which it shares internal data. E.g., a certain Web service allows reuse of its own accommodation units to another service, under the condition of taking a commission of three percent. Additionally, from a service provider's perspective, the accommodation manager can state the conditions under which he will allow publishing the information on his or hers accommodation unit on other Web services (e.g. apartment owner allows reuse on another Web services that take a commission lower than ten percent, and whose payment is upon the guest's arrival).

Booking

Booking concept defines a temporal aspect in the *A&B* ontology, i.e. covering the time-related aspects in domain of accommodation-related Web services. This concept is usable both for Accommodation and Attraction classes. For Accommodation, its purpose is to be used as a reservation calendar. With the assumption of knowledge sharing between Web services, this concept also eliminates the need of changing the availability periods on all Web services, i.e. a Web service can access the unavailable periods from other services and form a real-time availability calendar. For several attraction types, it is used to represent the booked periods, e.g. a masseur that is already booked on a certain date and time or specifying the time and date properties for a needed car-rental service. In order to define the Booking concept, we used the same approach as in the *cDOTT* ontology [12]. We integrated the *W3C Time* ontology, in order to model temporal concepts. *W3C Time* ontology is used for describing the temporal content of Web pages and the temporal properties of Web services.

Other concepts

The Attraction concept is used to describe attraction and nearby places in a certain location. It was modelled in alignment to *Schema.org*' CivilStructure, Landform, LandmarkHistoricalBuildings, LocalBusiness, TouristAttraction schemas and hListing on *Microformats.org*.

Bed is a basic capacity unit for a certain accommodation type. The Bed concept is used to broaden the range of Web services that can use the *A&B* ontology, e.g. the accommodation listing on *Couchsurfing.com* has a shared room that has a couch bed.

The PersonOrganization concept is used to define the owners or managers of a certain accommodation or attraction. It was modelled in alignment to *FOAF* ontology [20], *Schema.org* Person and Organization schemas and hCard on *Microformats.org*.

The Location concept, used to describe a certain location, has the following subclasses: Place, Region and Country. These subclasses are interlinked: a region can be located in a country and a country can be located in a region. However, due to the complexity of geolocations, this concept was not completely elaborated and will probably be remodelled and integrated with an external ontology.

Finally, the Review concept, used to evaluate a location or a service, was modelled in alignment to *Schema.org* Review and AggregateRating schema and hReview on *Microformats.org*.

IV. FUTURE WORK

In the future, we are planning to develop a framework that implements and comprises of all the aspects of the *A&B* ontology. We propose the following simplified framework's architecture:

- Knowledge aggregator – the component whose task is to aggregate the data from multiple accommodation-related Web services. The data is accessed with usage of various APIs, data dumps, provided *SPARQL* endpoints [21] or data extraction techniques. This component can be seen as a knowledge aggregation mashup composition of various Web services.
- Translator & Connector – the component that translates the aggregated data to the *A&B* ontology. After the translation, the component searches for similarities between individuals. In cases of high similarities that have the same data, the individuals are connected as Linked Data.
- Frontend – a Web frontend that enables users to query different Web services, enables service providers to add their properties and define policies for sharing, enables Web services to use SPARQL endpoints of this framework and enables them adding their SPARQL endpoints to the framework.

The benefits of this approach were discussed in previous sections of this paper.

V. CONCLUSION

In this paper, we study the currently available tourism-related ontologies and analyse their applicability to the domain of accommodation and booking-related Web services. Furthermore, we introduce the *A&B* ontology, an ontology aimed to cover the domain of accommodation and booking-related web services. The ontology was built in alignment to data represented on the most popular booking-related web services, *W3C Time* ontology and semantic snippets such as *Schema.org* and *Microformats.org*.

Furthermore, we proposed a framework that fully utilizes the benefits of the *A&B* ontology: one that connects to various accommodation-related web services, translates the data to the *A&B* ontology, connects it and provides a single endpoint, both for users and for other Web services. This approach solves several current problems related to accommodation and booking-related Web services, such as data dispersion and inconsistency, limited visibility of individuals and undistinguished Web services.

Voice over Wi-Fi

D. Bilajbegovic
Ericsson Nikola Tesla d.d., Zagreb, Croatia
damir.bilajbegovic@ericsson.com

Abstract – Voice over Wi-Fi, also known as Wi-Fi Calling, is a new service introduced by mobile operators just few months ago. Voice over Wi-Fi enables establishing "ordinary", Circuit Switch like, calls via Wi-Fi network. Unlike Over The Top Voice over IP calls which establish calls via any type of IP network, Voice over Wi-Fi enables seamless integration to existing telecommunication core offering same look and feel as well as same security level but without any intervention made by customer. This paper describes Voice over Wi-Fi integration in operator's core network, show reusing of the existing security solutions and influence of this feature on the Mobile Operator behavior. As this feature is new and very interesting so it is going to be very interesting to see how operators are going to adopt this feature as well as what technology changes it will push.

I. INTRODUCTION

Traditionally Mobile Network Operators made their brand and revenue by offering Circuit Switch voice services to their customers. And for the years this was the main service and main source of income. But with the rapid development of IP data communication, this position of undisputed provider of voice communication services is threatened with by the new Over The Top (OTT) service providers.

Voice over IP services was first introduced for personal computers. They offered a free alternative for long distance calls and solution for free text communication (chatting) compared to SMS texting. The most known and still the synonym for such solutions was Skype.

With Smartphones development and advanced mobile data infrastructure, Voice over IP services was offered to the customer via his phone. These services were now offered to the customers "all the time" making them available not only via traditionally mobile networks but also via these new OTT platforms. In parallel to development of traditional Mobile networks, Wi-Fi networks started to the widely available, not only at customer home and office but also on various free public hot spots.

Customer had for the first time alternative solution for establishing voice calls. They could use:

- Traditional CS mobile network to establish and receive voice calls
- OTT solutions for establishing and receiving voice calls via Mobile packet network or Wi-Fi network, for just a fraction of the price

Traditional MNO are now facing the situation where they are providing only "data pipe" for the OTT operators, and even worse, they are not any more the exclusive "data pipe" provider for specific customer.

II. USER PERSPECTIVE

With the fact that the Mobile network operators are threatened to be neglected and left to invest a lot of money in network infrastructure while their revenues are shrinking, Voice over Wi-Fi solution appeared as one of the services that could change the market back in the MNO favor.

Voice over Wi-Fi enables establishing Voice over IP calls via Wi-Fi network. At first this looks like something that already exists but the difference is in the way how this solution is implemented compared to the OTT solutions.

Voice over Wi-Fi was introduced with presentation of Apple iOS 8 platform in September 2014. The iOS 8 based phones iPhone 6 and 6 Plus offered Wi-Fi Calling service natively supported [5]. Also iPhone 5s could be upgraded to support Wi-Fi calling. At the same time Samsung offered the same feature in their flagship models of smartphones.

Figure 1. Voice over Wi-Fi configuration on mobile phone

Customer with such phone has only to enable Wi-Fi Calling feature in the phone setting and this is all the interaction that customer needs to do [7]. Example of this configuration is showed in the Figure 1. Unlike OTT applications, it does not need to install any application, configure it, configure its user profile, nor link or maintain separate phonebook. Their look and feel is the same as with normal phone calls.

Native build in support for Wi-Fi Calling (as it is often referred by smartphone manufactures) is important for quick adoption and fast market penetration for this service.

III. TECHNICAL IMPLEMENTATION

In the core of mobile network operator a lot of changes needed to be introduced and modified to support Voice over Wi-Fi. MNO needs to introduce the IP Multimedia Subsystem (IMS) with all the modifications to the MNO network. Beside implementation nodes, MNO must also modify the MNO Operating and Support System (OSS) and Business Support System (BSS). This could be a problem as the implementation could be costly from financial and man power usage point of view.

Basic foundation for simpler Voice over Wi-Fi introduction is that Mobile Network Operator already has IMS or Voice over LTE (VoLTE) implemented in its network. Support VoLTE is big benefit for easier Voice over Wi-Fi introduction. MNO that already have VoLTE needs only to modify Packet Data Network Gateway (PDN) or/and introduce evolved Packet Data Gateway (ePDG) in their network to support the customers connected via Non-3GPP network (Figure 2). Additional modifications (configurations) need to be implemented on Policy and Charging Rules Function (PCRF) node and on the Authentication, Authorization and Accounting (AAA) Node to support Wi-Fi users.

In the traditional mobile network defined by 3GPP standards Packet Data Network Gateway (PDN Gateway) need to be upgraded to support User Equipment (UE) access via Trusted Non 3GPP IP Access network [1]. Trusted Non 3GPP IP access networks are typically Wi-Fi networks whose Access Points are maintained by the same MNO and which has already implemented solution for authentication and authorization of such users. These users attach to the PDN Gateway and via IMS register themselves in MNO network.

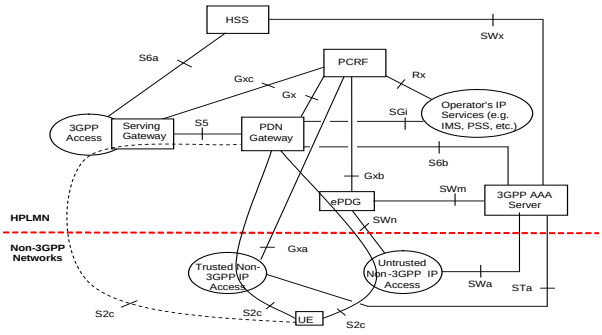

Figure 2. Voice over Wi-Fi configuration on mobile phone

For the users that are attached via Untrusted Non 3GPP IP Access networks, additionally evolved Packet Data Gateway (ePDG) node needs to be added to the network which enables establishing trusted connection between UE and PDN. ePDG perform authentication and authorization of the user and will create IP sec tunnel between ePDG and UE and GPRS Tunneling Protocol (GTP) Default tunnel between ePDG and PDN Gateway.

These users are typically connected via home, office or public free Wi-Fi network and represent majority of the typical Wi-Fi users and MNO does not have power to influence on the UE Access Point.

When performing Authentication and Authorization, the system uses UE already available security information stored in the UE SIM module and in the AAA/HSS server. What makes Voice over Wi-Fi really different from OTT solutions is the message exchange that is showed on Figure 3. Traditional OTT solutions will have only first two steps of message exchange. Voice over Wi-Fi solution, in step 3-8, uses the existing information about the UE (3), reuses it also during authentication procedure (4) and enforces it via already deployed network elements (5-8). Unlike the OTT solutions, MNO and UE do not need any additional security mechanism nor have any weak spots during initial configuration of the application (i.e. initial authentication and authorization of user). For the details please refer to the [3].

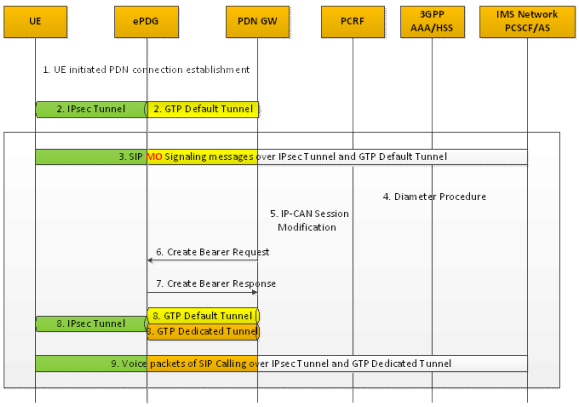

Figure 3. Voice over Wi-Fi SIP/IMS messagess exchange

After the user has been attached to the MNO network, UE starts usual IMS registration procedure. After successful registration, depending on the network configuration, UE can call or be called via Wi-Fi network or 2G, 3G or LTE network. When UE moves out of the Wi-Fi coverage, user will still be available via 2G, 3G and/or LTE network. If the user has already established Voice over Wi-Fi call, when loosing Wi-Fi coverage call can be handed over to the LTE (Voice over LTE call) and vice versa. Currently there isn't defined solution for the Wi-Fi call to be handed over from Wi-Fi to 2G / 3G network. As Voice over Wi-Fi is just introduced we could expect that the standardization of 2G/3G handover to Voice over Wi-Fi (and vice versa) is going to be the next step in standardization process and we will see it in following year or so.

The IMS itself needs only to be configured for additional type of users. As IMS is designed as access network independent system, adding support for Wi-Fi users is easy task. It might seem to be a complicated process to implement Voice over Wi-Fi but implementation is often done by simple software upgrade of existing nodes with some additional configuration. The most important and often time consuming task of every MNO - integration with OSS and BSS tools is minimal or non-existing. So MNO that wants to introduce Voice over Wi-Fi needs first to implement LTE network and then with easy modification of current network enable support for Voice over Wi-Fi.

IV. INFULANCE ON THE CUSTOMER AND MNO BEHAVIOUR

With implementation Voice over Wi-Fi solution, both customer and MNO are facing different behavior patterns.

MNO are now extending their network cover beyond their physical network infrastructure. It is as just as the MNO has turned up millions of base stations in just one day. MNO signal coverage can be now extended to the places where their mobile signal is very bad or it is not reachable at all. Typically in the city they are house basements, which are dig in the ground and the MNO signal is very weak. At the same time home Wi-Fi signal is typically stronger as it is only few meters above typical house basement. In the rural hilly areas, there are often some gaps where few houses are covered with weak or without MNO signal but if there is Wi-Fi access point, signal strength problem is solved.

These locations are typical for the places where MNO has network coverage. For instance T-mobile USA is with this feature providing higher network coverage, compensating lower 2G/3G/LTE network coverage compared to other Tier 1 operators in USA.

On the other hand, UE can access from the locations that are "roaming locations". When user is traveling abroad, income based roaming calls is split between home MNO and visiting (roaming) MNO. By offering Voice over Wi-Fi, MNO can reduce the price of such "roaming" calls and at the same time keep all the income based on such calls. Some MNO, like T-Mobile USA, priced these roaming calls the same was as it is local call, while other like France Telecom are treating this calls as ordinary roaming calls.

From the user perspective, Voice over Wi-Fi solution enabled "higher network signal" (MNO network coverage) and enabled lower roaming costs while not spending time in mobile phone configuration, maintaining different users profiles and different phone books. When the user is using Voice over Wi-Fi, it is going to be indicated by the icon and it will be only note that the customer is using Voice over Wi-Fi. User experience should be the same as it is traditional CS call.

Regarding availability of the smartphone devices, all the mayor phone manufactures implemented this feature in their flagship models and as the time of writing there are more than 30 models supporting Voice over Wi-Fi.

V. CONCLUSION

Introducing Voice over Wi-Fi enables MNO to extend their network coverage, increased availability of their services and extended potential number of customers.

Compared to the OTT operators, Voice over Wi-Fi enabled MNO to have the same or better network coverage and the same or better availability of their services. With "One Click" configuration procedure and uniform look and feel user experience MNO are in advantage position over the OTT operators.

From the standardization point of view, it is also going to be interesting to see how the 2G/3G handover to Voice over Wi-Fi (and vice versa) is going to be standardized as well as the policy of MNO how to handover the calls.

As Voice over Wi-Fi is launched just half a year ago it is going to be interesting to observe implementation of this solution at MNO network as well as the MNO price and marketing strategy for the customers.

An Example of Real Time QoE IPTV Service Estimator

N. Goran*, M. Hadžialić **
* BH Telecom JSC, Sarajevo, Bosnia and Herzegovina
** University of Sarajevo, Faculty of Electrical Engineering, Bosnia and Herzegovina
nermin.goran@bhtelecom.ba; mesud.hadzialic@etf.unsa.ba;

Abstract - this paper will consider an estimator which includes mathematical modelling of physical channel parameters as information carrier and the weakest links in the telecommunication chain of information transfer. It will also identify necessary physical layer parameters which influence the quality of multimedia service delivery or QoE (Quality of Experience). With the modelling of the above mentioned parameters, the relation between degradations will be defined which appear in the channel between the user and the central telecommunication equipment with domination of one media used for information transfer with certain error probability. Degradations in a physical channel can be noticed by observing the change in values of channel transfer function or the appearance of increased noise. Estimation of QoE IPTV (Internet Protocol Television) service is especially necessary during delivery of real time service. In that case the mentioned degradations may appear in any moment and cause a packet loss.

***Keywords* — Access network; Quality of Service; Quality of Experience; Quality of Physical Layer; Channel estimation;**

I. INTRODUCTION

Evaluation of video signal quality using different objective and/or subjective methods at application layer of OSI/ISO model has been tested in the point of presence of the tested signal or one of its components. During IPTV (Internet Protocol Television) service delivering there is no information about original signal on user's side; therefore QoE/QoS estimation in real time is a big challenge. If so, there are at least two possible scenarios. There can be feedback from users about service, such as crowdsourcing etc., which is used to warn network components about decrease of video signal quality as some authors researched in [1-5]. The second scenario is usage of available QoS indicators for quality estimation without necessary evaluation on the user's side as some authors researched in [6-10]. In the first case without already defined procedures that the user is expected to fulfil so the service provider can get a clear image of an upcoming problem, it cannot be unambiguously defined why or in what amount the service degradation occurred in particular time. It is also important to mention that this type of testing would take a lot of customer's time. In the second case estimator needs to be put between the user and service provider in order to give information about level of quality being delivered to the user. This refers to correlation between user subjective estimations and appearance of QoS (Quality of Service) indicator degradations in parts of telecommunication network. Thus, there are two benefits. First of all to get objective video signal testing, since video signal is estimated on the basis of objective measure parameters. Then to find the part of network which causes problem in distribution of IPTV service. Telecommunication network consists of three logical parts: service, core and access. Each of them has specific parameters that can be measured and used for estimating error number that appears during IPTV service delivery. At the same time, communication inside telecommunication network is carried out via protocols in accordance with OSI reference model. During a service delivery, MPEG-2 packets are transferred through OSI layers and certain parts of the packets e.g. the information from header can be used to ensure QoS. As we know, there is a huge number of transformations in message formed by OSI layer rules. The message passes through physical and data layer to network layer and so on. It is obvious that degradations in physical layer are propagated to user who uses and estimates the service by own subjective measure. This paper will consider influence of information carrier in access network as well as the weakest link in information carrier chain. Using estimation of the mentioned parameters, it is possible to find the relation between appearances of degradations on location user-telecommunication network with domination of one media for information transfer with a certain error probability. The problem is especially expressed during service delivery in real time with the possibility of appearance of the mentioned degradations which can cause packet loss and additionally complicate the estimation. The paper will also present the frame for mathematical modelling of transfer information loss through OSI reference model.

II. FRAME MODEL

Frame model begins at the service part of telecommunication network in the place where service is obtained by TV station. In that point, it is possible to define starting level of service quality using simple methods, due to having original signal characteristics necessary for distribution towards the user. Therefore, by

testing the parameters such as PSNR in particular frames of video signal or degradation caused by resolution decrease, different artefacts in video or blurring, system can enhance the quality of IPTV service. When service is prepared and code scheme chosen, the service is sent into network of numerous switches and routers. Degradation of network parameters can occur in any of them, such as packet losses in video signal, delays or delay variations. These parameters make errors that occur in core network and have a great influence on IPTV service i.e. they make video frame degradations or complete frame loss. The mentioned parameters are related to network layer of OSI/ISO reference model and they are often considered by a large number of authors who deal with this topic. After video packets are distributed to access node such as DSLAM (Digital Subscriber Line Access Multiplexer), they are supposed to be delivered to end user's LAN (Local Area Network) over a physical media. Thus, at the end point it is necessary to transfer video signal to user over physical channel with specific information capacity which can be obtained on that channel using different modulation and code techniques. For this purpose, different media and technologies are used. If QoE values are considered in real time, higher or lower QoE violation can occur with impairment of QoS parameters of network and/or application layer in OSI/ISO referent model. As it was mentioned in introduction, a great number of authors have researched the relation between proposed QoS parameters and QoE of the user of delivered service. However, in the case of consideration of physical telecommunication channel, which can be time varying, it can be concluded that a problem can appear as well as disappear in different times. In access network domain e.g. relation between access network and network of network operator, this is related to appearance of stationary and non-stationary noise. Therefore, it is necessary to observe QoS/QoE relation in real time e.g. in time of service delivery and its consummation.

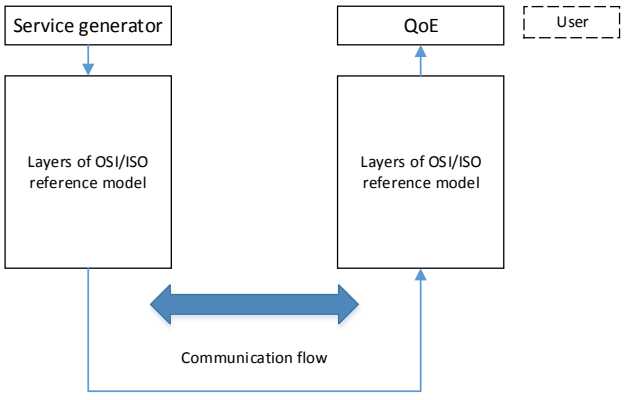

Figure 1. Communication flow of IPTV service

Fig. 1 depicts an example of communication flow between service provider and user during service delivery.

According to OSI/ISO reference model, communication flow passes through every layer which adds header in message of the previous layer. At the top is user's QoE which besides of numerous subjective parameters depends on QoS indicators. It's possible, due to the different manipulative data, that are provided by specific protocols, using monitoring (decoding) of these data, to have insight into how negative changes in lower layer influence data in higher layer of OSI/ISO reference model. This relation between different OSI layers of QoS indicators can be used for ME depicted in the Fig.2.

Considering the Fig.2, a connection can be found

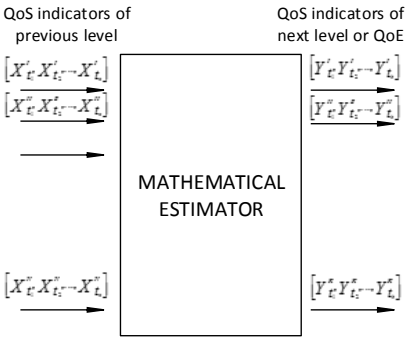

Figure 2. Example of mathematical estimator

between QoS indicators of the previous and the next OSI layers. For example, if we consider three vectors of input parameters, like delay X^D, jitter X^J or packet loss X^P and estimate output vectors that represent QoS indicators of next OSI layer or even QoE, we can find correlation between them. Considering that communication chain, for example, negative appearances in physical OSI layer will be propagated through data link layer, network layer and so on. On other hand, QoE is a perceived and subjective measure of services delivered through numerous telecommunication links. Appearance of impairment, perceived by user, in video services is a reflex of error appearances in any OSI/ISO layers. Monitoring QoS indicators can help to find link between parameters to forecast value of QoE in every telecommunication part, during exchange of information between different layers. As we can conclude, there are so many parameters and it is necessary to identify the essential one that is valuable for determination of QoS/QoE correlation and consequently QoE level.

III. MATHEMATICAL OBSERVATIONS

Observing the Fig. 2, it can also be noticed, there are time realizations of indicators in the previous OSI/ISO layer that cause incidental realizations in the next OSI/ISO layer. If vectors Ys represent vectors of time series parameters of interest for estimating incidents in the next layer of OSI/ISO model and Xs represent time series of incidental parameters, we can write the next equation:

$$Y^I{}_t = \sum_{K=1}^{N} \sum_{n=1}^{p} A_n X^K{}_{(t-p)} + E_t \qquad (1)$$

In equation (1), $X^{K}_{(t-p)}$ and Y^{I}_{t} represent different vectors of a particular time series while E vector represents stochastic variables. Those vectors represent only one realization of random process in specific time monitoring. Some kind of estimation of these particular processes has to be done to show the amount of influence of every observed variable on the processes in the next OSI level. To determine what has happened here we need to examine the nature of processes i.e. if particular time series are stationary or non-stationary or even ergodic. Also correlation between different X series i.e. series in the same layer should be examined. We can use consideration of autocorrelation and partial autocorrelation function for forecasting process nature and examination of next layer parameters. For the sake of simplicity, we have considered only one physical parameter i.e. noise margin parameter labelled as X. If process depends on its own previous values and its fluctuations, the next equation can be written as:

$$X_t = \sum_{j=1}^{p} \varphi_j X_{t-j} + \mathrm{e}_t - \sum_{i=1}^{q} \theta_i e_{t-i} \tag{2}$$

This equation represents known autoregressive moving average model. If there are some increasing or decreasing values of variable X, then the next equation can be defined as:

$$\varphi(\mathrm{L})\nabla^d X_t = \theta(\mathrm{L})\,\mathrm{e}_t \tag{3}$$

Equation (3) represents the same model including trends i.e. ARIMA model. Operator ∇^d signifies difference between operator order d, $\varphi(\mathrm{L})$ and $\theta(\mathrm{L})$ characteristic polynomial order L and e process of white noise. ARIMA model defines if process is stationary or non-stationary essentially. For analyzing the process behavior and its influence on QoS indicators of next layer, we have to determine time autocorrelation function of variable X obtained from equation (2) and (3) as well as ensemble autocorrelation function. These functions are defined by next two equations:

$$R_{tt} = \frac{\sum_{t=k+1}^{n} (X_t - \bar{X}) \bullet (X_{t-k} - \bar{X})}{\sum_{t=1}^{n} (X_t - \bar{X})^2} \tag{4}$$

$$R_{xx} = \frac{\sum_{x=s+1}^{n} (X_x - \bar{X}) \bullet (X_{x-s} - \bar{X})}{\sum_{x=1}^{n} (X_x - \bar{X})^2} \tag{5}$$

Considering equations (4) and (5) we can identify the nature of process of particular time series and it can be used for error propagation estimation through layers. We need to notice, if E(X) and Et(X) from equations (4) and (5) have the same values, the process is ergodic.

IV. Test Environments

In order to validate above mentioned model, we have chosen an experimental method in which SDTV (Standard-definition Television) IP service is delivered via MPEG-2 transport stream, UDP transport protocol, IP network protocol, ATM and ADSL2+ data link and physical layers. We have used noise margin [11] as parameter of physical layer and code violation CV and number of corrected errors as parameter of data layer, respectively. Packet loss was chosen as QoS indicator and we have correlated it with modified IQX hypothesis. We have used correlation between these losses and QoE for examination of video loss and compered our results and the results obtained by IQX hypothesis [7]. Physical channel was under the influence of stationary and non-stationary noises that cause negative effects in different OSI layers.

V. Results

Overview of a part of the results obtained from test environment is given in the Table I and Table II. Parameter X determines average changeability of noise margin that caused the appearance of frame loss; ΔX represents noise margin difference between different time intervals; FEC determines the number of corrected bits at the same time; E(X), Et(X), Var(X), Rxx, Rtt are expected values, variance and autocorrelation functions of ensemble and time, respectively. We have considered packet loss like QoS indicator because it can be correlated, based on IQX hypothesis, with QoE perceived by user. Mentioned parameters have been monitored in the same time intervals.

TABLE I: Measured parameters of Physical Layer in DSL environment

T(s)	X	ΔX	Et (X)	Var (X)	E (X)	Rxx	Rtt
t1	14	-0,1	10,93	4,38	10,36	-4,61	0,88
t2	14,1	0,1	10,91	4,79	10,36	-3,8	0,78
t3	14	0	10,83	4,79	10,36	-3,74	0,63
t4	14	0	10,93	4,64	10,36	-4,06	0,48
t5	14	0	10,89	4,91	10,36	-3,6	0,33
t6	14	2,4	10,77	5,14	10,36	-2,24	0,18
t7	11,6	-0,7	10,51	3,26	10,36	-5,98	0,09
t8	12,3	4,4	10,63	3,47	10,36	-1,5	-0,02
t9	7,9	0	9,94	3,83	10,36	-0,82	-0,03
t10	7,9	0	9,93	3,98	10,36	-0,75	-0,05
t11	7,9	0,1	9,93	3,91	10,36	-0,71	-0,06

After t5 there is appearance of non-stationary noise that caused negative effects in data and network layers. These effects produced video packet loss in IPTV service and consequently they disturbed a proper level of QoE. The

coefficients of autocorrelation function Rtt are shown in table I and the presence of non-stationary noise can be noticed especially in three correlation coefficients of Rtt.

TABLE II: MEASURED PARAMETERS OF DATA LINK LAYER, NETWORK LAYER AND QOE

T(s)	Frame loss	FEC	Packet loss	ARIMA	Mod QoE	IQX QoE
t1	0	0	0	14,01	4,07	4,07
t2	0	27	0	13,7	4,07	4,07
t3	0	0	0	13,18	4,07	4,07
t4	0	0	0	12,21	4,07	4,07
t5	0	0	0	10,68	1,90	1,06
t6	84	20165	28,70%	9,46	4,02	1,06
t7	1	927	0,30%	8,43	4,07	1,06
t8	0	222	0	7,87	4,07	1,06
t9	0	272	0	7,86	4,07	1,06
t10	0	0	0	7,85	4,07	1,06
t11	0	43	0	7,85	4,07	1,06

At the same time ARIMA model (eq. 3) forecasts values of variable X. Appearance of non-stationary noise has caused loss of the frames and consequently packet loss.

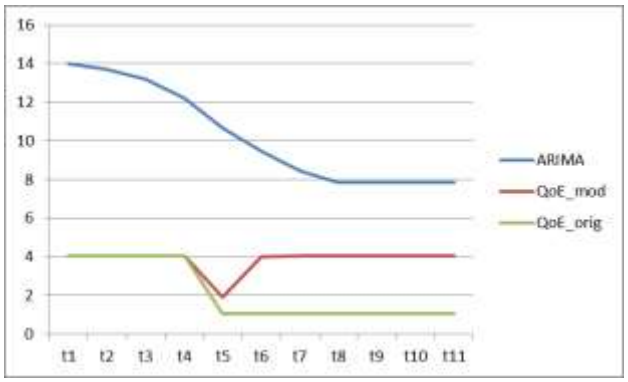

Figure 3. Model results

We have also calculated originate IQX QoE hypothesis [7] and modified one given in [11]. It can be noticed in Fig. 3, upper line defines ARIMA trends calculated by (3) and tracks changes of variable X caused by non-stationary noise while lower lines define values of originate and modified QoE. If we consider originate IQX hypothesis (QoE_orig), after appearance of packet loss, there is a fall of QoE level which lasts for all considered time. In contrary, that time dependency between QoS indicators (noise margin in this case) and QoE level is considered in our model. Although QoE_mod fall is noticed at the same time interval, in t8 interval after non-stationary noise disappears, we have a proper level of QoE again. Consequently, it cannot precisely define QoE level, because of time varying channel and its randomness i.e. without considering physical layer parameters.

VI. CONCLUSION

In this paper, the mathematical modelling of an estimator has been given. Also we have shown what the estimator needs to have for proper forecasting of QoS indicator time series which represents one realization of random process. This consideration refers to time and using the estimator QoE can be valued in a particular time interval. In the case of SLA (Service Level Agreement) offered by network provider, implementing this kind of solution can give the insight into how much of the service consumed time a customer had a proper level of QoE. Also, it can be used for feedback that helps system to repair itself without user intervention. For future work we plan to use more parameters in every OSI layer and find causality between them.

SAŽETAK: Transportna infrastruktura je važan segment u sektoru transporta i po svom značaju predstavlja glavnu podlogu za održivi razvoj zemlje. Kreiranje ekonomske politike neizostavno podrazumijeva kreiranje i razvoj transportne politike, odnosno razvoj infrastrukture. Poseban značaj pridjeljuje se kvalitetnijem usmjeravanju prometnih tokova, smanjenju broja prometnih nesreća i bržoj reakciji kada se one ipak dogode te kreiranju novih usluga primjenom informacijsko komunikacijskih tehnologija.

Integracija tehnologija iz područja mobilnih telefonskih mreža (GSM, 3G, HSDPA) s prometnom tehnikom omogućuje povećanu kvalitetu prometnih usluga i širi spektar njihovih funkcionalnosti. To je naročito primjetno u području informiranja putnika, pružanja turističkih usluga, akcija u slučaju prometnih nesreća te novih usluga iz područja inteligentne logistike te naplate prometnih usluga javnog gradskog prijevoza.

Potreba za sve većom pokretljivošću u suvremenim urbanim sredinama, kao i funkcioniranje gradskog prometa u sve složenijim uvjetima rezultirala je potrebom za uvođenjem naprednih prometnih usluga baziranih na informacijsko komunikacijskim tehnologijama i M2M komunikaciji. Među značajnije M2M aplikacije u prometnom kontekstu ubrajaju se domene umreženih vozila i unapređenje usluga javnog gradskog prijevoza.

U radu je opisana usluga spajanja vozila javnog gradskog prometa na širokopojasnu mrežu u svrhu naplate usluge javnog gradskog prijevoza u urbanim sredinama. Osnovna ideja uvođenja navedene usluge je uvesti dodatni kanal prodaje karata korištenjem mobilnih uređaja te na njima pripadajućih naprednih tehnologija za NFC i QR kôdove.

KLJUČNE RIJEČI

1. Javni prijevoz, 2.Naplata usluga, 3. Mobilne komunikacijske tehnologije, 4. NFC, 5. QR

I. UVOD

Potreba za sve većom pokretljivošću u suvremenim urbanim sredinama, kao i funkcioniranje gradskog prometa u sve složenijim uvjetima rezultirala je potrebom za uvođenjem naprednih prometnih usluga baziranih na informacijsko komunikacijskim tehnologijama i M2M komunikaciji. Očigledna ograničenja klasičnog pristupa razvoju prometnog sustava, u skladu s načelima znanstveno utemeljene politike gospodarenja i održivog razvoja, potakla su zahtjeve za novim usklađenim rješenjima u cestovnim i drugim granama prometa te njihovim sučeljima (lukama, kolodvorima itd.). Naplata usluga javnog gradskog prijevoza u urbanim sredinama se smatra jednim od značajnih prometnih problema s obzirom da troškovi za nenaplaćene usluge utječu kako na operativne tako i na administrativne troškove

Prema dosadašnjim istraživanjima [3] oko 60% usluga javnog gradskog prijevoza uspije se naplatiti, što znači da oko 40 posto korisnika ne plaća voznu kartu. Istraživanje o uslugama tvrtke Gradski prijevoz putnika d.o.o. u gradu Osijeku 2012, koju je izradila tvrtka Audeo [4] pokazuje da čak 60% korisnika smatra kako je cijena vozne karte previsoka. Uzme li se u obzir da se u Gradu Zagrebu preveze godišnje oko 300.000.000 putnika [2], može se zaključiti da prijevoznici javnog gradskog i prigradskog prijevoza trpe velike gubitke.

U ovom radu opisano je rješenje Smart Transport Sustav koje služi za naplatu usluga javnog prijevoza korištenjem mobilnih komunikacijskih tehnologija te platformi za mobilna plaćanja. Osnovna karakteristika ovog modela je da putnik plaća samo prijeđeni put, što uslugu čini atraktivnom za krajnje korisnike. U naletu novih tehnologija koje se koriste za plaćanje i sve većoj popularizaciji platformi za mobilna

plaćanja, Smart Transport je nova usluga koja predstavlja savršen spoj mogućnosti telekom operatera i potreba prijevoznika i krajnjih korisnika.

II. ZNAČAJ MOBILNIH KOMUNIKACIJSKIH TEHNOLOGIJA U JAVNOM PRIJEVOZU

Prosječna komercijalna brzinu vozila javnog prijevoza u gradovima u regiji iznosi do 20 km/h To znači da se na temelju iskustava može zaključiti kako bi uvođenje naprednih sustava upravljanja javnim prijevozom otvorio mnogo prostora za poboljšanja i povećanje zadovoljstva korisnika. Treba posebno istaći da primjena i implementacija inovativnih informacijsko-komunikacijskih sustava omogućuje povećanje protočnosti i ubrzanje javnoga i privatnoga prometa u gradu, a u konačnici se postiže i rasterećenje prometnica u gradu te na prilazima gradu.

Upravo mobilne komunikacijske tehnologije te širokopojasna rješenja igraju ključnu ulogu pri implementaciji naprednih usluga. Samim time mobilne komunikacijske tehnologije postaje sve važniji u transportnoj industriji budući da kompanijama u ovoj branši omogućava da posluju uspješnije, povećava sigurnost putnika i podržava zaštitu okoliša [1]. Ovako osmišljena inteligentna transportna rješenja otvaraju nova zanimljiva ICT tržišta velikih potencijala.

Povezivanje vozila javnog gradskog i prigradskog prijevoz na širokopojasnu mrežu može imati svrhu uvođenja dodatnog kanala prodaje i kontrole karata u javnom prijevozu. Integracija takvog sustava sa sustavom za satelitsko praćenje vozila omogućit će prijevoznim operaterima pristup širokom rasponu informacija o poziciji, brzini i smjeru kretanja autobusa, vremenu zaustavljanja, prijeđenoj kilometraži, vremenu polaska i odlaska s određenih lokacija, itd. Svi navedeni podaci mogu poslužiti pri uspostavi modela naplate usluge „plati koliko koristiš“ (eng. PAYG – Pay As You GO) [6].

Inovativna rješenja ovakvog tipa su temelj stvaranja novih usluga za planiranje kretanja gradom, pa i putovanja na međugradskim rutama. Budući da im sustav omogućuje mobilni širokopojasni pristup Internetu korisnici mogu jednostavno dobiti uvid u informacije o lokaciji vozila. Putnici tako štede vrijeme i imaju mogućnost kupnje karata na način koji im najviše odgovara. Operaterima javnoga prijevoza pak širokopojasni pristup omogućuje implementaciju aplikacija koje će podržati razvoj njihovoga poslovanja.

III. SMART TRANSPORT SUSTAV

Prema određenim procjenama i pokazateljima, smatra se da se samo oko 40% usluga javnog gradskog prijevoza uspije naplatiti. Prema tome može se zaključiti da prijevoznici javnog gradskog i prigradskog prijevoza trpe velike gubitke.

Osnovna ideja uvođenja Smart Transport sustava je uvesti dodatni kanal prodaje karata korištenjem mobilnih uređaja te na njima pripadajućih naprednih tehnologija za NFC i QR generatora. Primjenom Smart Transport sustava se želi postići sljedeće:

- Povećati broj novih putnika koji će nakon uvođenja usluge koristiti javni gradski prijevoz – u ovom kontekstu, radi se o putnicima koji su do sada koristili osobne automobile ili druge modove prijevoza te putnici koji imaju kraće rute za vožnju te im se nije isplatilo plaćati punu cijenu karte
- Povećati broj platiša – mnogi putnici koriste javni gradski prijevoz no ne plaćaju ga. Ovom uslugom bi stimulirali putnike da plaćaju prijevoz s obzirom da će na način koji je opisan tehničkim rješenjem imati mogućnost plaćanja po PAYG modelu.
- Unaprijediti sigurnost usluge mobilnog plaćanja putne karte, na način da se eliminiraju svi sigurnosni propusti koje su imali slični, ranije korišteni (i uglavnom odbačeni), sustavi.

Rješenje podrazumijeva da putnik plati samo onaj dio puta koliko se vozio u autobusu/tramvaju ili nekom drugom vozilu (eng. PAYG model – Pay As You Go). Treba naglasiti da se ovim rješenjem razmatra javni prijevoz, no uslugu je moguće modificirati i za druge oblike prijevoza (npr. taxi uslugu). Plaćanje, tj. računanje cijene, može biti definirano na temelju prijeđene kilometraže, vremena vožnje ili broja stanica između ulaska putnika u vozilo i izlaska putnika iz vozila. U ovom projektu cijena će se računati prema broju prijeđenih stanica.

IV. ARHITEKTURA I FUNKCIONALNOSTI SUSTAVA

Arhitekturalno gledano, sustav se sastoji od uređaja u vozilu (OBU) i Smart Transport aplikacije (STA) na platformi za mobilno plaćanje. Također, potrebna je i

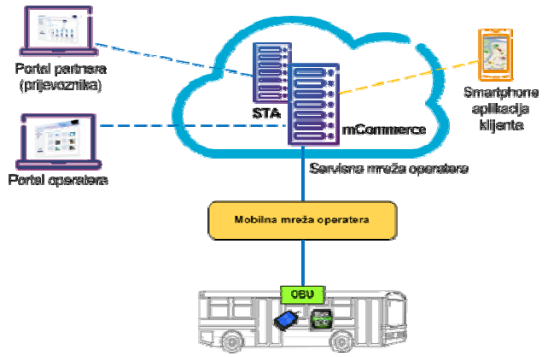
klijentska aplikacija na pametnom uređaju korisnika usluge.
U proces plaćanja uključene su slijedeće platforme telekom operatera i tehnološke cjeline:

- On-board unit (OBU) na vozilu, sa pripadajućim senzorima
- mCommerce platforma za mobilna plaćanja
- Smart Transport aplikacija
- Smartphone aplikacija sa NFC ili QR-kôd funkcionalnosti (za putnika i za kontrolora)

Smart Transport rješenje obuhvaća centralnu Smart Transport aplikaciju (STA) na platformi za mobilna plaćanja, te aplikaciju za pametne telefone putem koje se inicira plaćanje "putne karte" putem NFC kanala i QR kôda, i aplikaciju kojom se vrši kontrola karata u vozilu. Platforma za mobilno plaćanje poput mCommerce platforme u servisnoj mreži mobilnog operatera koristit će se kao platforma za plaćanje, na koju će se integrirati Smart Transport Aplikacija.

Koncept cijelog rješenja temelji se na komunikaciji u stvarnom vremenu između jedinice u vozilu (on-board unit) i centralne Smart Transport aplikacije povezane s mCommerce sustavom [5]. Infrastruktura treba biti osigurana od strane telekom operatera, a istovrememo telekom operater igra i važnu ulogu u cijelom procesu – operater pruža podršku za autentikaciju krajnjeg korisnika. Autorizacija svake transakcije vrši se na centralnom mCommerce sustavu (unutar mreže mobilnog operatera). Dakle, mCommerce platforma u mreži mobilnog operatera uz pripadajuće elemente mreže mobilnog operatera omogućava vrhunsku sigurnost svih transakcija, te nosi ulogu i centralne AAA platforme.

Dva su osnovna modela rješenja, ovisno o tehnologiji koju krajnji korisnik koristi prilikom ulaska u vozilo / izlaska iz vozila – rješenje bazirano na NFC tehnologiji i rješenje koje se koristi QR-kôd tehnologijom. Bez obzira koristi li se za identifikaciju i autentikaciju korisnika NFC ili QR-kôd, sam prometni model podataka („*call flow*“) je isti u oba slučaja. OBU na sebi ima integriran i NFC čitač i QR-kôd čitač, a koja će se tehnologija koristiti – ovisi o mogućnostima mobilnog uređaja korisnika. U ovom modelu svi podaci vezani uz transakciju prenose se do centralne aplikacije (STA) zaštićenim kanalom, preko OBU-a. Moguće je implementirati i alternativni QR model, koji ima drugačiji tok podataka (preko mobilnog uređaja korisnika).



Slika 1: Smart Transport aplikacija (NFC) – pregled sustava

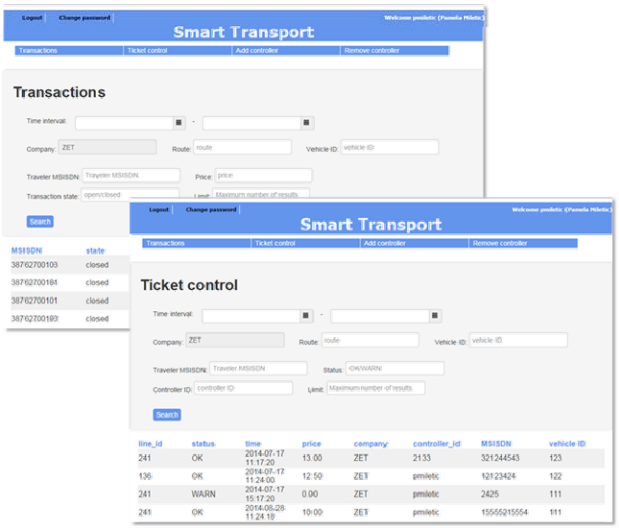
V. VALIDACIJA KONCEPTA

Validacija samog koncepta napravljena je razvojem i testiranjem ovog sustava u laboratorijskom okruženju, te testiranjem istog u stvarnim prometnim uvjetima. Komunikacija OBU i centralne aplikacije izvedena je putem GPRS/HSPA komunikacijskih kanala mobilnog operatera.

Smart Transport aplikacija pokrenuta je na Tomcat poslužitelju i direktno povezana sigurnim IP kanalom (VPN tunel) sa mCommerce platfromom u mreži mobilnog operatera. Backend STA aplikacije komunicira s jedne strane s mCommerce sustavom a s druge strane s jedinicama u vozilima (OBU). Komunikacija s OBU je zaštićena na više razina, kako bi sigurnost komunikacije i samih transakcija zadovoljila standarde tražene na tržištu.

Jedinica u vozilu (On Board Unit – OBU) je prilagođena smještanju u vozilo, te su sve postavke vezane uz napajanje, komunikaciju, sigurnost i izdržljivost uzeti u obzir i zadovoljeni prilikom dizajniranja iste. OBU prema krajnjem korisniku ima izložene NFC i QR ulazne kanale, a prema centralnoj aplikaciji je povezana ranije opisanim načinom. Fizički je u vozilu smještena odmah na ulaznim/izlaznim vratima.

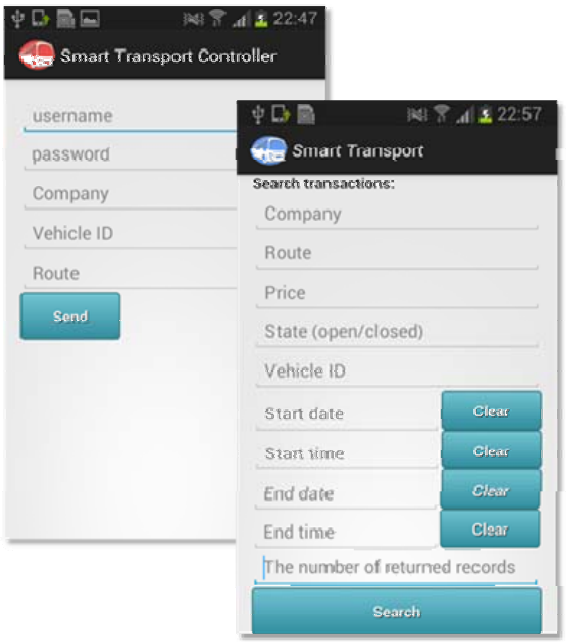
Sama centralna STA aplikacija u svom frotendu nudi sučelje za upravljanje jedinicama u vozilima, upravljanje samom uslugom, te administracijsko-reporting sučelje. Na slici ispod vidi se nekoliko ekrana sa GUI-ja centralne aplikacije.



Slika 2: Smart Transport aplikacija GUI – primjer sučelja

Smartphone aplikacija za korisnika realizirana je na Android platformi za Smartphone uređaje. Aplikacija omogućava krajnjem korisniku korištenje usluge putem NFC ili QR tehnologije (ovisno o mobilnom aparatu), te istovremeno i pregled svih svojih transakcija direktno na Smartphone aplikaciji mobilnog uređaja. Posebno je razvijena smartphone Aplikacija i za Kontrolora, koja koristi iste tehnologije, a prilagođena je kontroli karata u vozilu.

Na slijedećoj slici pokazani su primjeri grafičkog sučelja testne smartphone aplikacije za korisnika i aplikacije za kontrolora.



Slika 3: STA Smartphone App. – primjeri sučelja

VI. ZAKLJUČAK

Sveprisutnost pokretnih mreža, niske cijene sklopovlja za bežičnu komunikaciju i dostupnost uređaja sa podrškom za umrežavanje stvorilo je uvjete za razvoj kako platformi za M2M komunikaciju, tako i specifičnih usluga i aplikacija zasnovanih na M2M komunikaciji.
Uslugom spajanja vozila javnog gradskog prijevoza s mobilnom širokopojasnom mrežom putem modula za mobilni širokopojasni pristup visokih brzina te postavljanjem senzora na vozila, unapređuje se usluga elektroničke naplate karata i satelitskog praćenja autobusa a operaterima se omogućuje i pristup širokom rasponu informacija o poziciji, brzini i smjeru kretanja autobusa, vremenu zaustavljanja, prijeđenoj kilometraži, vremenu polaska i odlaska s određenih lokacija, te uvjetima u okolini (emisija CO, CO2, O2, temperatura i vlaga…) itd.

Abstract - Advances in the new mobile networks are steadily increasing the demand on network resources, and new standards must ensure that the networks are managed effectively in order to ensure that users of the network remain satisfied with their Quality of Service (QoS) and Quality of Experience (QoE). The simulations opportunities represent a chance to reduce the digital divide and to ensure the new 5G networks with minimum cost of time and financials. The simulation of teletraffic models allows the modeling of resource management issues, admission of system users with different parameters.

I. INTRODUCTION

Mobile networks constantly evolve. In the 1980s, when wireless technology began to go mainstream, the 1G analog networks supported the bulky, brick-like mobile phones from that era. The 90s saw the introduction of 2G digital networks, when Code Division Multiple Access moved mobile phones beyond voice transmission into data and text messaging. Around 2001, third generation devices appeared, first in Japan, offering the high-speed data transfer and Internet connection used in the earliest smartphones. The first 4G LTE and WiMAX networks appeared in 2011 [1,7]. Given the natural decade-long development cycle, fifth generation (*5G*) networks are due around 2020.

Simulations represent a good opportunity to reduce the digital divide and to ensure the new 5G networks. Many universities and researchers are currently involved in simulation modeling to provide better results. This paper presents an analysis and development of the teletraffic models used in three of the Bulgarian universities: University of Ruse, College of Telecommunications and Post in Sofia and Southwest University of Blagoevgrad.

The implementation of simulation program is made with .NET. The teletraffic models with geometrical and Pareto arrival distributions, which are versatile, possessing a pseudo-memoryless property which makes the solution of many GE-type queuing systems and networks analytically tractable. The new communication systems are interested in the modeling and performance evaluation of single communication links, but in the modeling of more devices in the whole network. Typically, the performance of the whole network containing many links working in parallel and interfering with each other is of primary interest.

This type of simulation allows the modeling of resource management issues, admission of system users with different priority, interaction and network loading by several types of traffic sources, etc. The aim of such modeling is network capacity evaluation and probabilities of failure.

II. TRENDS OF 5G MOBILE NETWORKS

The trends of 5G mobile access is to be built upon new radio access technologies, evolving 4G, LTE, HSPA, GSM and WiFi. The new requirements are widely varying. The services, devices, number of clients are in super wide variety.

The new communication needs of a massive deployment of various devices, such as with low complexity parameters to more advanced parameters. The industrial and medicine devices must be lifesaving. The variety of services must be with very low latency and probability of blocking.

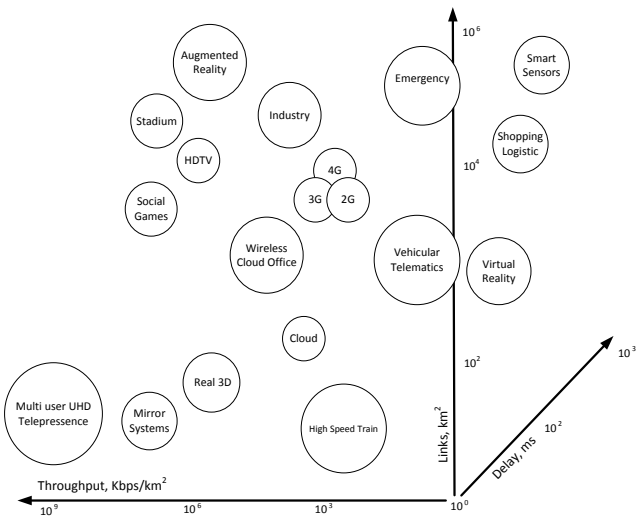

Figure 1. Services of 5G mobile network

The services must be amazingly fast in very dense crowds of users [8]. The fast connections is a key factor for success of development of so important services as health and security sectors, fire brigade, high speed trains and cars (Fig.1). The services are:

- Shopping logistic;
- Vehicular telematics;
- Virtual reality;
- Emergency;
- Stadium, crowd of people;
- Wireless cloud offices;
- High speed trains;
- Multiuser UHD telepresence;
- HDTV;
- Mirror Systems;
- Social games;
- 2G, 3G and 4G services;
- Smart sensors.

The Quality of Experience requires fully connected users not only for static users. The expectation of connectivity is no matter where or how one is moving [8]. Highly mobile devices, e. g. trains and cars, are communicating machines for this scenario, but also sensors related to widely varying applications, e.g. moving components in industries, plants, other vehicles.

III. SCENARIOS FOR TELETRAFFIC MODELS FOR 5G MOBILE NETWORKS

The heavy traffic models must be simulated, because the various expectations must be fulfilled on very high level. Some scenarios could be described:

- ***Emergency communications***; ***traffic efficiency*** and ***safety*** must be with the highest priority of all services and scenarios. When occurs an event as an accident, the devices and the network must be able to switch to "emergency mode", with the highest priority, and the battery life must be surviving for a long time.
- ***Teleprotection*** in smart grid network will ensure the people with very important messages, which will be sent between substations for prevention of some kind of accident (for example as car crash).
- ***Blind spots*** are the next scenario. The wireless systems have to provide ubiquitous coverage in rural and heaving shadowed areas. The real time remote computing for mobile terminals must ensure the connection.
- ***Virtual reality office*** is the communication point with the necessary of high data rates. The telepresence and communication between the offices of one company must work without problems. Applications with high data rates must be with high security.
- ***Shopping mall***, ***traffic jam***, ***concerts***, ***stadium*** or ***open festivals*** are places with very high density of users and devices. The expectations are for huge amount of aggregated data traffic about up to 900 Gb/km^2. The users inside the stadium or concert will generate high quality videos or could transmit outside the HD movies. The density of users in the shopping mall is high, but the access of broadband communications must be fulfilled.

The necessity of transmitting a huge amounts of data in very short times, very fast connections and priorities of different services is exact description of arrivals and departures of different clients in described scenarios in 5G. It could be described with Geometrical and Pareto distributions with heavy load. The high data rates, the demand and availability of bandwidth is raising at a much faster rate [2,3,5]. The emergency communication must have very low probability of blocking and high reliability. Therefore, the priorities in the model are dynamic.

The teletraffic delay system with two parallel inputs with Geometrical and Pareto distribution, and one service output with Geometrical distribution, with finite capacity N was applied with the scenarios of 5G networks (Fig.2).

The GE is of the form:

$$F(t) = P(W \le t) = 1 - \tau e^{-\sigma t}, \quad t \ge 0, \\ \text{where} \quad \tau = 2/(C^2 + 1) \quad \text{and} \quad \sigma = \tau v, \tag{1}$$

where W is a mixed-time random variable of the inter event – time, C^2 is the squared coefficient of variation of W [4].

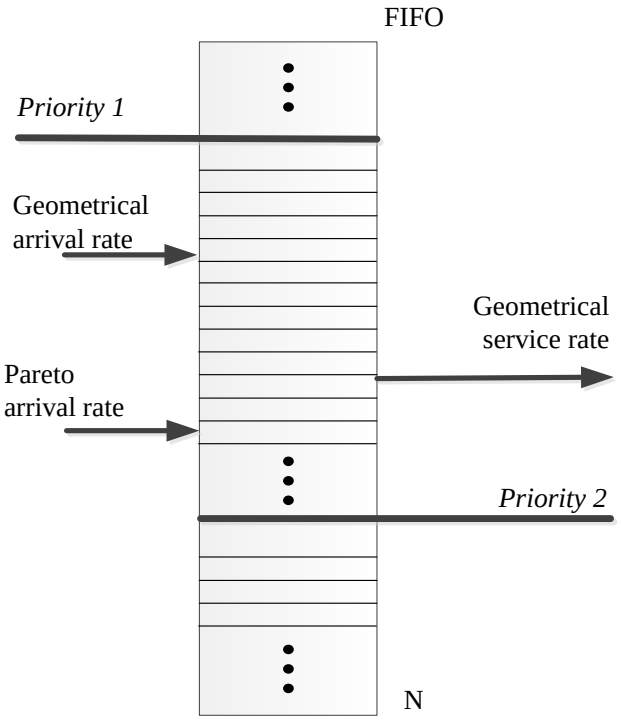

Figure 2. Teletraffic system for 5G mobile network

For $C^2<1$, the GE distribution model cannot be physically interpreted as a stochastic model.

For $C^2>1$, the GE model is a mixed-time probability distribution and can be interpreted as bulk time distribution with underlying counting process equivalent to compound Poisson process with parameter $2\nu/(C^2+1)$ and geometrically distributed bulk size with mean $(C^2+1)/2$ and squared coefficient of variation $(C^2-1)/(C^2+1)$.

The approximate universal closed form expression for GE for blocking probabilities π_i, i=1,2,…R, can be determined by using GE-type probabilistic arguments and is described by (2):

$$\pi_i = \sum_{\upsilon=0}^{N_1} \delta_i(\upsilon)(1-\sigma_i)^{[N_i-\upsilon]^+} P(\upsilon), \qquad (2)$$

where $\delta_i(\upsilon) = \delta_i$, if $\upsilon = 0$ or otherwise, $\sigma_i = (C_{ai}^2+1)/2$, $\delta_i = r_i / (r_i(1 - \sigma_i) + \sigma_i)$, and $r_i = (C_{si}^2+1)/2$.

The queuing system has for each class i (i=1,2,…,R, $R>1$) the arrival rate $1/\lambda_i, C_{si}^2$ and the service rate $1/\mu_i, C_{si}^2$.

The blocking probability is π_i that an arrival of class I will find in the system at the full capacity [7].

The blocking probability is determined by arrival sequence, independently by the rule of service FCFS (*First Come First Serve*), LCFS (*Last Come First Serve*) or HOL (*Head of Line*) static users.

IV. Simulation of Teletraffic Models for 5G Mobile Networks

The program for Simulation of Rare events in teletraffic systems with single queue is made with the .NET Framework, because it is the way that programming will be done on a Microsoft machine from now. And not just on a Microsoft machine. The ADO.NET is used for creating web site, and for manipulating databases. This framework create applications for mobile phones and PDA's with .NET, this is one of the main reasons for using it.

The .NET Framework is a whole lot of Classes (called Namespaces) and the technology to get those Classes to work [6]. The main component is called the Common Language Runtime. With .NET, more than 15 different programming languages can use the Common Language Runtime. One of these languages is, of course Visual Basic .NET. Another is C#.

The simulation of the three main types of queuing systems is made of the AMD Athlon(tm) II X2 250 Processor 3.00 GHz and 3 GB RAM, running 32-bits operation system is Windows 7 Professional.

First simulations are made with M/M/1/N queuing sytems with the .Net tools, because it was necessary to compare analytical and simulation results, to prove and validate the new results. The simulation of the queuing system is made for different number of observations n. The increasing of arrival rate leads to insignificant increasing of blocking events. We choose arrival and service rate, to receive appropriate result. First simulations were made with the disciplines of service. The amount of rare events in system with disciplines of service: LIFO and FIFO are with insignificant difference.

TABLE I. Teletraffic system with N=60

Service rate	n	Arrival rate 1	Arrival rate 2	Dynamic priority 1 and 2		Blocking events
0.5	100000	0.5	Pareto	30	30	4
	30000	Pareto	0.5	30	30	1
	50000		0.5	30	30	1
	10000	0.2	Pareto	50	40	2
	10000	0.4		30	60	2
0.48	10000	0.3	Pareto	30	60	3
0.44	10000	0.2	Pareto	40	60	2
	10000	0.25		60	60	3
0.4	10000	0.2	Pareto	50	40	2
	30000			50	40	4
	50000			50	40	5
	10000			60	50	1
	10000			40	60	5

The priorities in the modeled system are dynamic; the service rates of GE are with values 0.2, 0.3, 0.4, 0.44, 0.48 and 0.5. The number of examples are 10 000, 30 000, 50 000 and 100 000. The GE service rate is with values from 0.2 to 0.5. Table 1 shows simulation results with N=60 places for service in the system, the relative error is 10%, the received blocking events. The results of teletraffic system with N=90 are described in Table 2.

TABLE II. Teletraffic system with N=90

Service rate	n	Arrival rate 1	Arrival rate 2	Dynamic priority 1 and 2		Blocking events
0.5	100000	Pareto	0.35	60	60	5
	10000		0.35	50	60	1
	50000		0.35	60	60	2
	10000		0.35	40	90	3
	30000		0.35	40	90	4
	50000		0.35	40	90	4
	100000		0.35	40	90	5
	10000		0,35	80	60	1
0.4	10000	Pareto	0.1	90	70	5
0.4	30000	Pareto	0.1	90	70	2
0.4	10000	0.5	Pareto	50	80	6
0.3	30000	0.4	Pareto	45	45	3
0.3	50000			45	45	4
0.3	10000			45	45	1
0.2	10000	Pareto	0.1	90	70	1

Service rate	n	Arrival rate 1	Arrival rate 2	Dynamic priority 1 and 2		Blocking events
0.2			0.1	90	40	1
0.2		0.4	Pareto	45	45	1

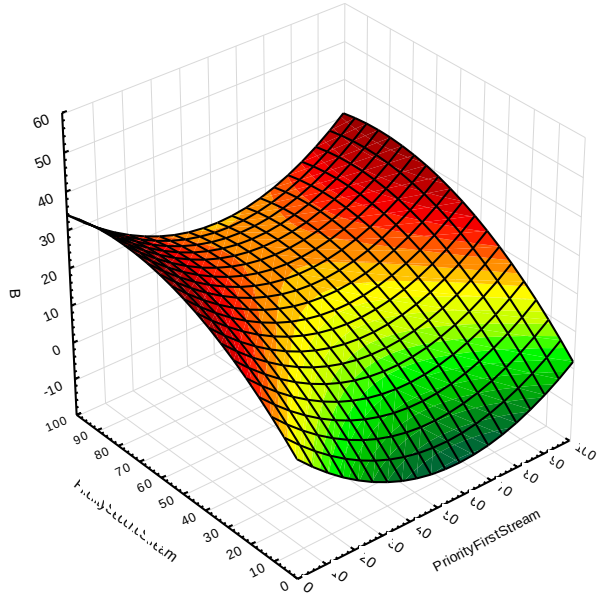

Figure 3. The relationship between dynamic prorities and blocking events B

On Fig. 3 and Fig.4 are shown the dependences between system parameters as first and second priorities, arrival and service rates and blocking events *B*.

The simulation experiments show that the blocking events in the system decrease with the length of the queues and increase if the dynamic priorities are increasing.

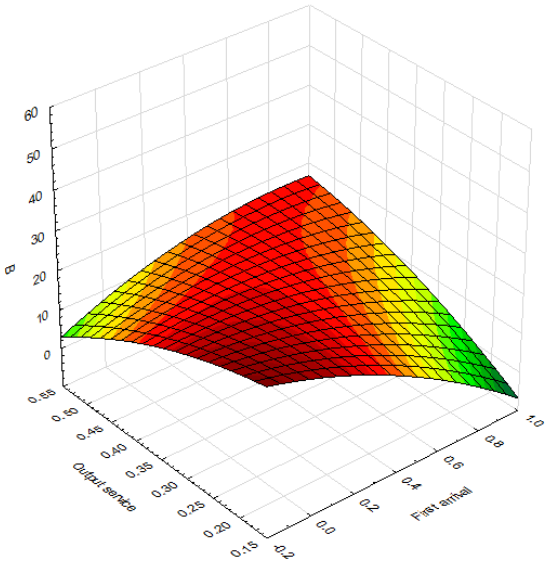

Figure 4. The relationship between arrival rate and service rate and blocking events

The potential users of the simulation product and software could be working groups in the area of the next generation mobile networks.

V. CONLUSION

In this paper we have reviewed, presented, validated and discussed the scenarios for teletraffic models for 5G mobile networks. Secondly, this paper presents an implementation of teletraffic models developed in .NET for estimation of blocking events.

The simulation results are received for queuing system with Geometrical and Pareto arrivals with two dynamic priorities, the service rate is implemented with Geometrical distribution. The service is organized with FIFO and a finite buffer size *N*.

The simulation results show that the blocking events in the system decrease with the length of the queues and increase if the dynamic priorities are increasing.

The future work is the study for the blocking probability with RESTART method for with *c* servers and finite capacity *N*.

Abstract - We analyze an error-detecting code with a fixed length redundancy, based on quasigroups. We obtain experimental results for the probability of undetected errors when quasigroups of different order are used for coding and conclude how the probability of undetected errors depends on the order of the quasigroup used for coding and the parameter of the code.

I. INTRODUCTION

In [1] we have defined a model of error detecting code based on quasigroups. An important parameter for every error-detecting code is the probability of undetected errors. In this paper we will analyze this probability for our error-detecting code.

In Section II are given the basic mathematical definitions needed for the code, while in Section III is given the definition of our error-detecting linear code. In Section IV are given the probabilities of undetected errors when for coding are used quasigroups of order four, order eight and order sixteen for different lengths of the input block. These probabilities are obtained using simulation process, which is also explained in this section. Also, in this section we analyze how the probability of undetected errors depends on the length of the input block and the parameter of the code for all three quasigroups used for coding. Finally, in Section V we analyze how the order of the quasigroups used for coding affects on the probability of undetected errors. At the end, in Section VI are given the conclusions of the paper.

II. MATHEMATICAL PRELIMINARIES

Since the considered model of error-detecting codes is based on linear quasigroups, in this section we will give a definition of this algebraic structure.

Definition 1: Quasigroup is algebraic structure $(Q,*)$ such that

$$(\forall\, u, v\in Q)(\exists!\, x, y\in Q)(x*u=v \wedge u*y=v) \qquad (1)$$

Definition 2: The quasigroup $(Q,*)$ of order 2^q is linear if there are non-singular binary matrices A and B of order $q\times q$ and a binary matrix C of order $1\times q$, such that

$$(\forall u, v\in Q)\ x*y=z \Leftrightarrow \boldsymbol{z}=\boldsymbol{x}A+\boldsymbol{y}B+C \qquad (2)$$

where $\boldsymbol{x}$, $\boldsymbol{y}$ and $\boldsymbol{z}$ are binary representations of x, y and z as vectors of order $1\times q$ and + is a binary addition.

In what follows when we say that $(Q,*)$ is a quasigroups of order 2^q, then we take $Q=\{0, 1, 2,\ldots, 2^q-1\}$.

Due to the Definition 2, linear quasigroups instead to be presented with the quasigroup operation * can be presented with a binary matrices A, B and C. We will do so in the future in this paper.

III. THE DEFINITION OF THE QUASIGROUP ERROR-DETECTING LINEAR CODE

The model of error-detecting linear code based on linear quasigroups is defined in a following way: Let $(Q,*)$ be a linear quasigroup and let k be a number such that $1\le k\le n-1$. Each input block $a_0a_1\ldots a_{n-1}$, where all $a_i\in Q$, is extended into a block $a_0a_1\ldots a_{n-1}d_0d_1\ldots d_k$. The redundant characters are defined as follows:

$$d_i=a_i*a_{i+1}*a_{i+2}*\ldots*a_{i+n-2},\ \ i=0, 1, \ldots, k \qquad (3)$$

where all operations in indexes are modulo n. The coded block $a_0a_1\ldots a_{n-1}d_0d_1\ldots d_k$, turned into binary form, is transmitted through the binary symmetric channel.

Restriction $k\ge 1$ ensures that all information characters $a_0, a_1,\ldots, a_{n-1}$ are controlled by at least one redundant character. The second constraint ($k\le n-1$) ensures that there will be no two identically defined redundant characters.

As we can see from the definition of the model, this code always adds fixed number of redundant characters, regardless of the length of the input block. More precisely, for a given k, this model always adds $k+1$ redundant characters on the input block.

Since, there are noises in the channel, some of the characters may not be correctly transmitted. In order to check whether the received block is correct, the receiver checks whether equations (3) are satisfied for the received block. If there is some i for which the equation (3) is not satisfied, the receiver concludes that there are errors in transmission and it asks the sender to send the block once again. But, since the redundant characters are transmitted through the binary symmetric channel, it is possible that they are incorrectly transmitted, too. This can result with a situation in which (3) is satisfied for all $i\in\{0,1,\ldots,k\}$, although some of the information characters $a_0, a_1,\ldots, a_{n-1}$ are incorrectly transmitted. This means that it is possible to have undetected errors in transmission. For this reason

it is important to obtain the probability of undetected errors. From the definition of the model, it is obvious that besides from the bit-error p, it depends on the length of the input block n, the parameter k, but also it depends on the order of the quasigroup used for coding.

IV. The Probability Of Undetected Errors

In this section we will briefly explain the process of simulation (subsection *A*). Using this process, we will obtain experimental results for the probability of undetected errors when for coding are used quasigroups of order four (subsection *B*), order eight (subsection *C*) and order sixteen (subsection *D*). For each of these cases, we will consider two choices of the parameter k in the error-detecting model defined with (3): one in which the redundancy is twelve bits and the other in which the redundancy is sixteen bits (i.e. fifteen bits for quasigroup of order eight). For each of these cases, the probability of undetected errors is obtained for length of the input block from k+1 to 20. Additionally, we obtain the probability of undetected errors for input blocks of length 64 and some other block lengths, which we will need in Section V. These probabilities are obtained for probability of bit-error p in the binary symmetric channel from 0.01 to 0.5 with step 0.01.

A. The simulation process

In this subsection we will give short description on the process of simulation. The probability of undetected errors for a block with length n, transmitted through a binary symmetric channel with probability of bit-error p is obtained in the following way:

First we generate an input message of length s which is the largest integer smaller than 1000000 which is devisable with n. The generated message is over the alphabet Q. Then, this message is separated into blocks with length n and each block is coded separately. After that, this coded message, which contains all the coded blocks, is turned into binary form. We generate the noise in the binary symmetric channel, which is a binary string with length equal to the length of the coded input message turned into binary form. The noise string is generated such that the probability of occurrence of one in this string is p. The positions in the noise string to which there is one are the positions on the coded input message in a binary form that are incorrectly transmitted. The output message is calculated with simply adding the coded input message in binary form and the noise string per modulo 2. Now, for every incorrectly transmitted block we check if equations (3) are satisfied. If the equation is not satisfied for some i, the error in transmission is detected. But, if all equations are satisfied, the error will not be detected. We count the number of incorrectly transmitted blocks in which the error is not detected. The probability of undetected errors is calculated by simply dividing this number with the total number of blocks in the input message.

B. The probability of undetected errors when linear quasigroup of order 4 is used for coding

For coding is used the linear quasigroup of order four represented with the following binary matrices:

$$A=\begin{bmatrix}1 & 0\\ 1 & 1\end{bmatrix},\ B=\begin{bmatrix}1 & 1\\ 0 & 1\end{bmatrix} \text{ and } C=\begin{bmatrix}0 & 0\end{bmatrix}.$$

Using the simulation process described in subsection *A*, we obtained the probability of undetected errors for different values of the block length n when for coding is used the above linear quasigroup of order 4. The maximums of this probability are given in Table I.

In the first column of Table I is given the length of the input block, in the second column are given maximums of the probability of undetected errors when k=5, and in the third column are given maximums of the probability of undetected errors when k=7. In the last column is given the quotient of the maximums of the probability of undetected errors in the case when k=5 and k=7.

Recall that the number of redundant characters is k+1. This means that when k=5, there are 6 redundant characters, while when k=7, there are 8 redundant characters. Since when a quasigroup of order 4 is used for coding, every character is represented with two bits in a binary form, follows that when k=5 there are 12 redundant bits, while when k=7 there are 16 redundant bits.

TABLE I. MAXIMUMS OF THE PROBABILITY OF UNDETECTED ERRORS WHEN FOR CODING IS USED QUASIGROUP OF ORDER 4

120	0.155000	0.141400	1.0961810

The empty fields in Table I are due to the constraint $k \le n-1$, which implies $n \ge k+1$. For this reason when $k=7$, block length n must be greater that or equal to eight.

As we can see from Table I, for a given k, when the block length n increases, the probability of undetected errors increases, too. This is expected result. Namely, when block length n increases, the number of characters that these k redundant characters need to control increases, thus increasing the chance that some incorrectly transmitted character will pass unnoticed. For this reason, from the aspect of the probability of undetected errors it is better to divide the messages in to blocks with as small as possible lengths.

From Table I can be seen that for small values of the block length n the probability of undetected errors in the case $k=7$ is much smaller than the probability of undetected errors in the case $k=5$. But, as the block length n increases, the quotient decreases and for larger values of the block length n, the two considered cases have almost equal probabilities of undetected errors. This means that for smaller values of the block length n it is better to use larger values of the parameter k, but as block length increases it loses the advantage since the probability of undetected errors is not so smaller any more, but computations are more complicated and larger value of k adds more redundant characters.

C. *The probability of undetected errors when linear quasigroup of order 8 is used for coding*

In this case for coding is used the linear quasigroup of order eight represented with the following matrices:

$$A=\begin{bmatrix}1 & 0 & 1\\ 0 & 1 & 1\\ 1 & 1 & 1\end{bmatrix},\ B=\begin{bmatrix}0 & 1 & 1\\ 1 & 1 & 1\\ 1 & 0 & 1\end{bmatrix} \text{ and } C=\begin{bmatrix}0 & 0 & 0\end{bmatrix}$$

The values for the parameter k for which we obtained the probability of undetected errors are chosen in the following way. When quasigroup of order 8 is used for coding, binary representation of each character contains three bits. For this reason, in order to have 12 bits redundancy, which is 4 characters of the quasigroup, the parameter k must be 3. Since 16 is not divisible by 3, it is impossible to have 16 bits redundancy when quasigroup of order 8 is used for coding. The nearest natural number to 16 which is divisible by 3 is 15. In order the redundancy to be 15 bits, which is 5 characters from the used quasigroup, k must be 4.

The maximums of the probability of undetected errors when the above quasigroup of order 8 is used for coding in the cases when $k=3$ and $k=4$ are given in Table II.

As in the case when quasigroup of order 4 is used for coding, for a given k, when block length n increases, the probability of undetected errors increases, too. Also, for small values of the block length n the probability of undetected errors in the case $k=4$ is smaller than the probability of undetected errors in the case $k=3$. But, as the block length n increases, the quotient decreases and for larger values of the block length n, the two considered cases have almost equal probabilities of undetected errors, which can be seen from Table II.

TABLE II. MAXIMUMS OF THE PROBABILITY OF UNDETECTED ERRORS WHEN FOR CODING IS USED QUASIGROUP OF ORDER 8

D. *The probability of undetected errors when linear quasigroup of order 16 is used for coding*

In this case we used the quasigroup of order sixteen represented with the following binary matrices:

$$A=\begin{bmatrix}0 & 1 & 1 & 1\\ 1 & 0 & 1 & 1\\ 1 & 1 & 0 & 1\\ 1 & 1 & 1 & 1\end{bmatrix},\ B=\begin{bmatrix}1 & 0 & 1 & 1\\ 1 & 1 & 0 & 1\\ 1 & 1 & 1 & 1\\ 0 & 1 & 1 & 1\end{bmatrix} \text{ and } C=\begin{bmatrix}0 & 0 & 0 & 0\end{bmatrix}$$

The maximums of the probability of undetected errors when this quasigroup of order 16 is used for coding are given in Table III. We consider two cases: $k=2$ (given in the second column) and $k=3$ (given in the third column). In the last column is given their quotient. When quasigroup of order 16 is used for coding, binary representation of each character contains four bits. Therefore, when $k=2$, there are 3 redundant characters, i.e. 12 bits, while when $k=3$, there are 4 redundant characters, i.e. 16 bits.

As can be seen from Table III, the probability of undetected errors has exact the same properties explained in the case when quasigroups of order 4 and order 8 are used for coding. For this reason in all three cases are valid conclusions explained in Subsection *B* of this section.

TABLE III. MAXIMUMS OF THE PROBABILITY OF UNDETECTED ERRORS WHEN FOR CODING IS USED QUASIGROUP OF ORDER 16

V. IMPACT OF THE QUASIGROUP ORDER ON THE PROBABILITY OF UNDETECTED ERRORS

It is reasonable to compare the probabilities of undetected errors when lengths of the input blocks expressed in bits are equal and the numbers of redundant bits are also equal. For this reason we will separately analyze the two cases of the redundancy length: 12 redundant bits (Subsection *A*) and 16 redundant bits (Subsection *B*). In both of them we will compare the probability of undetected errors for input blocks with equal lengths expressed in bits, when for coding is used quasigroup of order 4, order 8 and order 16. Comparison is made using Table IV - Table VII in which the block length n is expressed in bits.

A. Twelve Bits Redundancy

In the first column of Table IV is given the block length in bits, in the second column is given the maximum of the probability of undetected errors when for coding is used quasigroup of order 4 (k=5), while in the third column is given the maximum when for coding is used quasigroup of order 8 (k=3). In the last column is given the quotient of these two probabilities.

TABLE IV. MAXIMUMS OF THE PROBABILITY OF UNDETECTED ERRORS WHEN REDUNDANCY IS 12 BITS AND FOR CODING ARE USED QUASIGROUPS OF ORDER 4 AND ORDER 8 AND THEIR QUOTIENT. BLOCK LENGTH IS EXPRESSED IN BITS

n	order 4	order 8	(order 4)/(order 8)

132	0.12488	0.05336	2.34025487
144	0.12929	0.05668	2.28031051
156	0.13190	0.05885	2.24134237
168	0.13190	0.06280	2.10036624
180	0.13383	0.06645	2.01401053
192	0.13844	0.06664	2.07744598
204	0.14138	0.06970	2.02847920
216	0.14500	0.07167	2.02325487
228	0.14990	0.06587	2.27580856
240	0.15500	0.06773	2.28838695

In the first column of Table V is given the block length in bits, in the second column is given the maximum of the probability of undetected errors when for coding is used quasigroup of order 8 (k=3), while in the third column is given the maximum when for coding is used quasigroup of order 16 (k=2). In the last column is given the quotient of these two probabilities.

The data for the probabilities of undetected errors in Table IV and Table V are extracted from Table I - Table III by selecting appropriate k and calculating the block length expressed in characters from the appropriate quasigroup. In order to obtain the block length expressed in characters from the quasigroup of order 4, order 8 and order 16, the block length n expressed in bits should be divided by 2, 3 and 4, respectively.

As we can see from Table IV and Table V, using quasigroup of higher order provides smaller probabilities of undetected errors. For smaller values of the block length n, the reduction of the probability of undetected errors is larger. For larger values of the block length n, the probability of undetected errors is a little bit more than twice smaller when quasigroup of order 8 is used than when quasigroup of order 4 is used. Also, for larger values of the block length n quasigroup of order 16 gives approximately twice smaller probability of undetected errors than the quasigroup of order 8. From Table IV and Table V can be obtained the result how many times the quasigroup of order 16 gives smaller probability of undetected errors than the quasigroup of order 4. Namely, it can be easily verified that if for a given block length n, the quasigroup of order 8 gives t_1 times smaller probability of undetected errors than the quasigroup of order 4 and for the same n, the quasigroup of order 16 gives t_2 times smaller probability of undetected errors than the quasigroup of order 8, than for that n, the quasigroup of order 16 gives t_1t_2 times smaller probability of undetected errors than the quasigroup of order 4.

TABLE V. MAXIMUMS OF THE PROBABILITY OF UNDETECTED ERRORS WHEN REDUNDANCY IS 12 BITS AND FOR CODING ARE USED QUASIGROUPS OF ORDER 8 AND ORDER 16 AND THEIR QUOTIENT. BLOCK LENGTH IS EXPRESSED IN BITS

For illustration of the reduction of the probability of undetected errors for all values of the bit-error p in the binary symmetric channel and the shape of this function (as function of the bit-error p) in Fig. 1 are given probabilities of undetected errors for smaller block length, while in Fig. 2 are given probabilities of undetected errors for larger block length for all three used quasigroups.

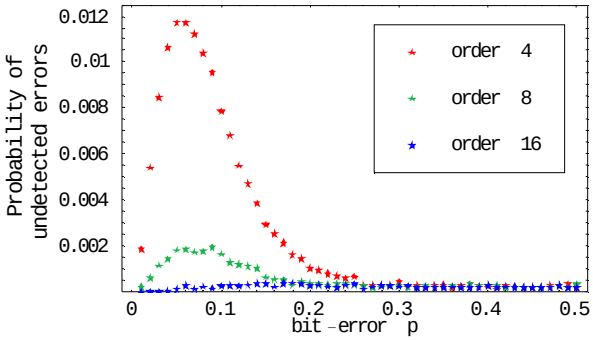

Figure 1. The probability of undetected errors when block length is 24 bits and redundancy is 12 bits.

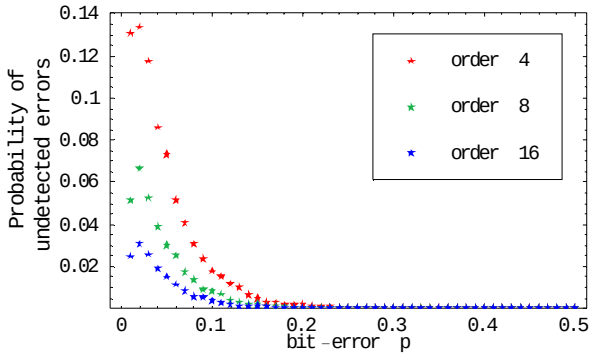

Figure 2. The probability of undetected errors when block length is 180 bits and redundancy is 12 bits.

B. *Sixteen Bits Redundancy*

In Table VI are given the maximums of the probabilities of undetected errors when the quasigroup of order 4 (k=7) and the quasigroup of order 8 (k=4) are used for coding, while in Table VII are given the maximums of the probabilities of undetected errors when the quasigroup of order 8 (k=4) and the quasigroup of order 16 (k=3) are used for coding. The values for these two tables are obtained from Table I – Table III in a same manner as described for Table IV and Table V.

From Table VI and Table VII we see that the same conclusions that we made in the case when there are 12 redundant bits are valid in this case, too.

For illustration in Fig. 3 are given probabilities of undetected errors for smaller block length, while in Fig. 4 are given probabilities of undetected errors for larger block length for all three used quasigroups.

TABLE VI. MAXIMUMS OF THE PROBABILITY OF UNDETECTED ERRORS WHEN REDUNDANCY IS 16 BITS (I.E. 15 BITS FOR THE QUASIGROUP OF ORDER 8) AND FOR CODING ARE USED QUASIGROUPS OF ORDER 4 AND ORDER 8 AND THEIR QUOTIENT. BLOCK LENGTH IS EXPRESSED IN BITS

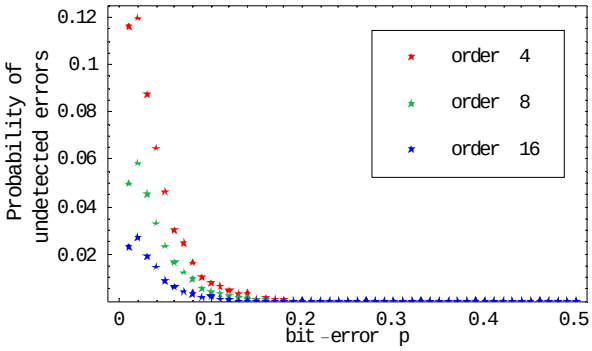

Figure 4. The probability of undetected errors when block length is 192 bits and redundancy is 16 bits.

From Fig.3 and Fig. 4 can be seen the proportion of the functions of the probability of undetected errors for one smaller and one larger input block. We give one figure with smaller and one with larger block length since in the above analyses we concluded that in these two cases the proportion of the probabilities are different.

VI. CONCLUSION

Using simulation we analyze a model of error-detecting linear code based on quasigroups. We considered the cases when linear quasigroups of order 4, order 8 and order 16 are used for coding. For each of these cases are analyzed two cases for the parameter *k* of the error-detecting model: one which gives 12 redundant bits and the second which gives 16 redundant bits when quasigroup of order 4 and order 16 is used, i.e. 15 redundant bits when quasigroup of order 8 is used.

From obtained results we conclude that for a given quasigroup and parameter *k*, when block length *n* increases, the probability of undetected errors increases, too. Also, for small values of the block length *n*, the larger value of the parameter *k* gives smaller probability of undetected errors. But, as the block length *n* increases larger *k* loses the advantage since for larger values of the block length *n* the two considered cases for the parameter *k* have almost equal probabilities of undetected errors. From this we conclude that for smaller values of the block length *n* it is better to use larger value of the parameter *k* (more redundant characters), but for larger values of the block length *n* it is better to use smaller values of the parameter *k* since probability of undetected errors is not so larger any more, but computations are simpler and are added less redundant characters. Overall, from the aspect of the probability of undetected errors it is best to divide the messages in to as small as possible blocks and in the same time to choose larger values for the parameter *k*. These conclusions are valid for all considered orders of the quasigroup used for coding.

Also, we conclude that the multiplication of the order of the quasigroup used for coding by two results with approximately twice smaller probability of undetected errors for larger values of the block length *n*. For smaller values of the block length, using quasigroup of higher order for coding results with larger reduction of the probability of undetected errors.

Due to the simple linear construction of the quasigroups, the codes that we defined and analyzed in this paper are suitable for use in light-weight hardware devices.

An integrated remotely controlled oceanographic measuring station

Kalinić, H.; Jelavić, D.; Ivanković D.; Bašić, J.; Muslim, S.; Marasović, S; Dadić, V.

Institute of Oceanography and Fisheries, Croatia

hrvoje.kalinic@izor.hr

Abstract – In this paper describes an oceanographic measuring station as a part of automated system for oceanographic measurement with remote control and data visualization. Oceanographic measuring station consists of operator's computer and a number of different measuring devices that produce data continuously. Each device has its own software interface that allows user interaction with the data. Such interface suffice when operator work with only few measuring devices and when the type (manufacturer) of a measuring device is not frequently changing, but it becomes cumbersome as more and more various devices became available for oceanographic data acquisition. In our setup the operator's computer is replaced by embedded computer dedicated to serve as a middle layer between sensor and database server with whom the operator communicates. The embedded Linux box run a set of daemons which acquire and archive data and transfer it to database, and a daemon that supervise the device and the entire process. A part of the acquired data is publicly available through visualization on Institute's website (www.izor.hr). The dynamic visualization of the data is done in javascript.

I. INTRODUCTION

The Mediterranean is one of the busiest seas in the world in terms of traffic. Even if it covers only 0.7% of the total sea surface in the world, it hosts 30% of the overall international maritime traffic. In order to monitor it and measure the rate of change and human influence on such important oceanographic system many information from both simulations and in-situ data acquisition is required.

In oceanography a vast amount of information is produced by many oceanographic sensors that measure physical[1], biological[2], chemical[3] parameters which are scattered across the shore, on the sea surface or in the sea. The type of data acquired by various oceanographic sensors ranges from meteorological data like air temperature, pressure, wind speed, insolation, humidity, rain accumulation (rain rate), ultraviolet radiation etc. to oceanographic data like sea temperature, conductivity (a proxy for salinity), chlorophyll, scattered matter, CDOM, sea current velocity, wave size, depth (measured with pressure) of the water etc. [4,5]

An important and interesting kind of oceanographic data acquisition happens when multiple informations are acquired from various sensors at various locations (or depths). This necessary leads to large amount of data, provided by the large amount of various sensors. Managing multiple data sources easily becomes cumbersome. Thus, an automated system for ocanographic research was a long term goal of many ocenographers [6,7]. Remote control of these systems are preferable, as they can be sparsely distributed over a large area or might need a frequent sampling at the specific area. Moreover, centralization of this access would contribute for easier data integration, research and could allow sensors to interact to one another and to adapt to environmental changes.

II. PROBLEM DESCRIPTION

As large amount of sensors produce data continuously the need for a more systematic approach for data load and storage becomes necessary. Many measuring devices come with heterogeneous proprietary client based software which makes them suitable for on-situ operations, but less suitable for automated, remote or even centralized control. In a typical setup, measuring device is connected to an operator's personal computer via serial data interface using RS232, RS485 or sometimes even RS422. This, as a consequence, puts the requirement for the operator to be within in a close range of the sensor in order to access and manipulate data. The close range of is defined by the RS232 standard that states the maximum capacitive load of 2 500pF. Although low-capacitance cables can be used for serial connection and thus allow larger distance, for an ordinary cable, this means that at the most a few tens of meters of cable should be used for a reliable serial connection. Therefore, for a longer distance, other standards are better suited.

In oceanography, often a satellite communication is used to transfer data to a distant location. However, this is an expensive form of communication. Luckily, the Croatian side of Adriatic is largely covered by the signal from commercial mobile operator due to the largely indented coast. Thus, we aim to exploit this advantage and use a general packet radio service (GPRS) for data transfer.

The measuring devices come have vendor specific communications protocols. This is usually solved with a dedicated user applications provided by the manufacturer, and is quite suitable for manual data acquisition. However, in order to automate the process, an automated method is preferred. Moreover, for a centralized data access all the sensor data needs to be stored in a uniform way.

All of this can be done with a single device that (i) translate the data from the sensor and store it in a file and (ii) uses GPRS to transfer it to a file server. For the first part the communication with each vendor specific device needs to be solved, and in the second case it is preferable to reduce power consumption by switching the GPRS

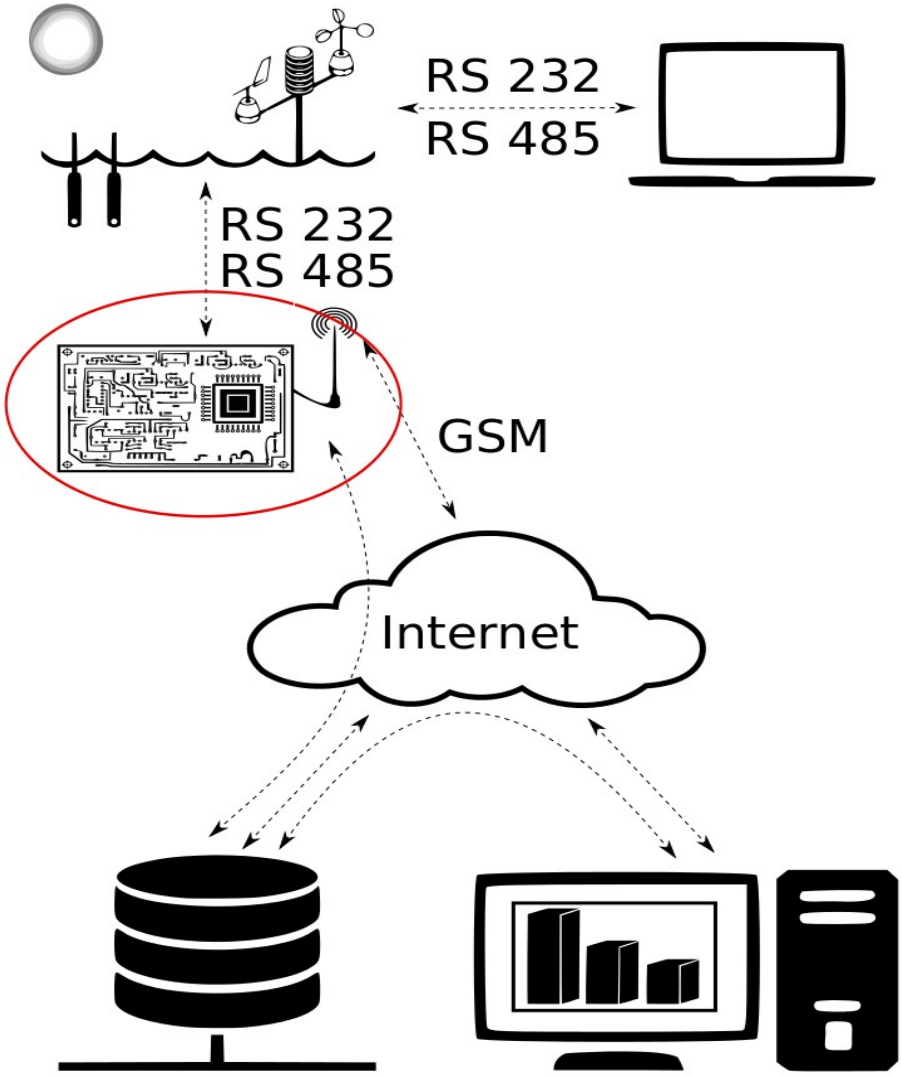

Figure 1. A schematic overview of an automated system for oceanographic measurement with remote control and data visualization. The first row depicts a typical setup where measuring device is connected to a computer (via RS232) through which the operator access and manipulate the data. This setup is replaced with the embedded computer and the database server with whom the operator communicate. The embedded computer is marked in red.

module on and off depending on the amount of acquired data. As addition, a watch-dog or a supervisor that contributes to larger reliability of the system is desirable. Finally, once the data is available on the server, it should be visualized for a data inspection or dissemination.

Both the classical approach and the proposed solution to the data acquisition are described in the schematic overview given in Figure 1. In the top of the Figure 1, a typical setup where measuring device is connected to a computer through which the operator access and manipulate the data. This setup is replaced with the embedded computer and the database server with whom the operator communicate.

Notice how the proposed architecture allows automated near real-time oceanographic data acquisition and does not require operator presence on the site to control the device or visualize the data. In the next section we will describe the embedded computer in more details

III. PROPOSED SOLUTION

Our proposed solution extends the idea of a measuring system by replacing the local personal computer of the measuring station with the embedded computer. In this way, the embedded computer can be utilized as the middle layer between the sensor and a server that stores the data. In this setup the data is transferred via Internet to a file server using FTP protocol. The data is then transferred to a database which permanently stores the data and metadata (e.g. the measuring system configuration). Once the data is in the database the operator can access and manipulate the data, or even change the configuration of the measuring system from remote location.

In order to automate this process a set of specially designed applications which run as a daemons on a Linux [8] embedded computer are initialized to gather the data from a device and to write the data to a file which is later transferred to the database server. Although all daemons that gather the data communicate with the device via serial data (RS232, RS422 or RS485) interface, each daemon is device specific and can be considered as a wrappers which unify the interface for a second stage of the process, which is file transfer. We will refer to such a program as data acquisition program and it its functionality can broadly be described with steps depicted in flow diagram shown in Figure 2. Naturally, the program is enclosed with opening of the serial port, sensor wake-up and reset of the watch-dog counter and it repeats for each cycle of the sensor data acquisition.

The gathering of the data is done in cycles where in each cycle each sensor produce a number of measurements that are stored in separate temporary files. Once the measurement cycle is complete the temporary files are marked as new, and ready for sending. Thus, the files are compressed and sent to folder named "2send" which acts as a pipe. Each of these files are appended to a file in the archive folder which is compressed once a day. If there is an Internet connection available, the files are sent, otherwise they are appended to a sensor specific file, which is scheduled to be sent once the connection is restored. The "archive" folder is acting like a large circular buffer, and any data from this folder can be sent to server upon request. The process is depicted in the chart given by Figure 3, and most of the depicted operations happen in the daemon called file manager.

In particular, file manager operates on the newest files once the sensor data acquisition finishes its cycle and crates a new file from a temporary file. In most basic implementation file manager operates with FTP protocol, and apart form sending or scheduling files for a later transfer, the file manager can respond to a request form the server, and resend the files form the archive if they are

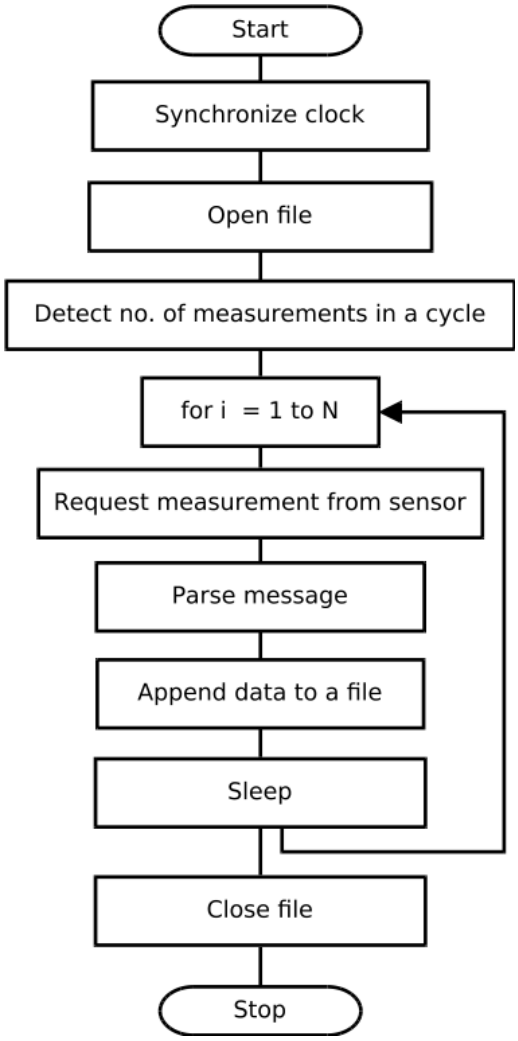

Figure 2. Flow diagram for data acquisition

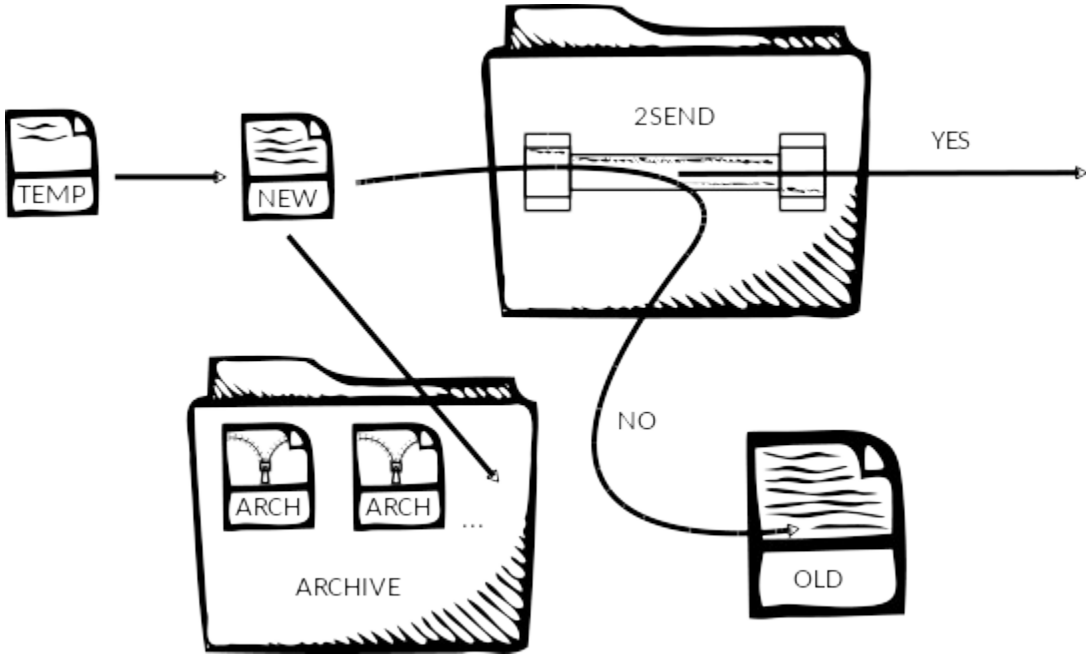

Figure 3. Process file procedure within the file management daemon

corrupted, inconsistent or missing. An overview of a file manager implementation is given by the following pseudo-code:

```
read configuration
reset watch-dog counter
download new configuration files (if any)
process files
sleep
```

As can be noticed form the pseudo-code, apart form data management, a file manager is used to download configuration download as well. The configuration files downloaded by the file manager can be used to set-up file manager, as well as the sensor or the data acquisition process, or some other part of the system. The notification that the configuration files are downloaded file server receives through standard process file procedure, i.e. the configuration file (once loaded) copies to the "2send" folder. In this way, the server will receive the station configuration once the network is available. If the station configuration is as the server requested it to be, it will stop sending the configuration files.

The daemons are supervised by a separate program – the supervisor – that assures that no data is lost due to the temporary power failure, unresponsive devices or programs, broken processes, etc. Thus, both data acquisition daemon and the file manager daemon are expected to report their proper functionality, or face restart. In addition to basic functionality of the watchdog (if timer is not reset, reset the daemon) the supervisor also inspects the overall health of the system and logs the information in a separate file. This file can be sent to the server as any other file. Similarly, the configuration file that describes which part of the system are monitored can be downloaded from a file server using the file manager as well.

The final part of the system is on the server side, where received data has been unpacked and passed to database. Database input is done through external table, which apart from data input, also validates the data, (if necessary, depending on the sensor type) calculate the mean value and in case of error or inconsistency send warnings.

IV. System performance

The embedded device we are using as the Linux box has a 192 Mhz RISC CPU and 32 MB SDRAM with up to four RS232 ports. In the experimental setup the larger number of measuring devices than the number of RS232 ports can be attached if a ETH to RS232 conversion or a multiplexer is used. Each device have multiple sensors and sometimes measure 20 or more parameters.

The system was tested in near real time data acquisition, where measuring cycle of devices was reduced to one minute with data transmission cycle reduced to a minute as well. The number of generated files depend on the number of the attached devices, and the size of each file depends on the number of sensors within each devices, or more precisely, on the number monitored parameters. Naturally, if the transmission cycle is not the same as the measuring cycle the size of the file will depend on that parameter as well.

Each manufacturer equips the measuring device with different sensors and various additional parameters can be retrieved from it. Typical parameters are: temperature humidity, pressure, conductivity, wind, waves, oxygen concentration, rain or hail intensity or duration etc. Some parameters can be measured outside or inside, some (as pressure or temperature) are measured for both sea and air, and some are measured on different depths, while some or vector values whose velocity and direction are reported as independent paremeters.

Consider a typical setup the number of monitored parameters easily surpass few dozens since 4 measuring devices can be attached to the embedded Linux box. If the system is operating in near real time data acquisition each device each minute create a file between 100B and 1kB in size, which for one day totals to 1440 files or 5760 files from all four devices. The size of the archived files, after compression, typically ranges between 13 and 300 kB per device.

V. Acquired data visualization

For data visualization we used pure JavaScript charting library - Highcharts. Along with numerous chart types and data manipulation techniques, Highcharts supports many functionalities that increases interactivity, such as: tooltip labeling, zooming, exporting and printing images. It also supports multiple axes if you want to compare variables that are not the same scale - for example air temperature versus Humidity. This Web page uses JSON (lightweight data-interchange format) adapted to read raw data fetched from the database and to draw these values into the chart. This method of formatting data allow us to load JSON file externally and draw dynamic charts that are automatically updated each minute.

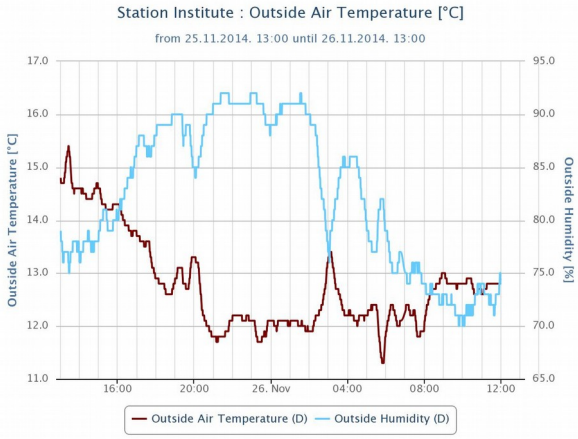

Figure 4. 24h graph for air temperature and humidity

It can be defined one or two measuring parameters to display on chart. Visualization procedure also enables to define date and time (rounded to the minute) depending on the last value that should be shown on a chart, and timespan (defined in hours) preceding that time. If these two variables are not user defined, procedure draws

measured data of the last 24 hours. Data density is rounded by the minute and is displayed in line chart. An example of such chart from the webpage is given in Figure 4. With Highcharts other visualization form sensors are possible, as well, such as an example showing a wind rose graph in Figure 5.

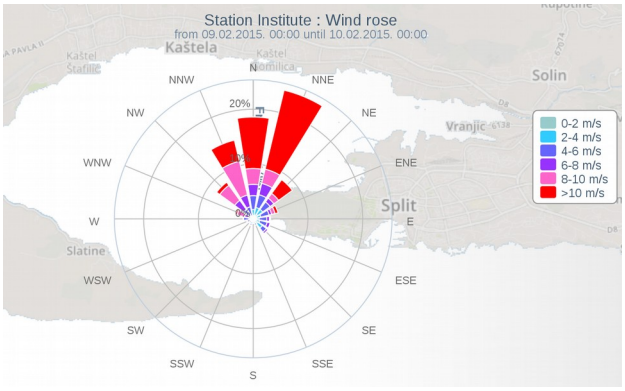

Figure 5. A wind rose form the station at the shore near Institute

VI. Conclusion

The proposed solution extends the idea of a measuring system by replacing the local personal computer of the measuring station with the embedded computer. On the embedded computer three daemons operate: (i) data gathering daemon – which is device specific and responsible for communication with the device, (ii) file manager daemon – which is is responsible for unified communication with the server, and (iii) the supervisor that assures the first two daemons work correctly and inspects the overall health of the system.

The proposed architecture allows automated near real-time oceanographic data acquisition and does not require operator presence on the site to control the device or visualize the data. The system is already functional and part of the acquired data is publicly available through Institute's website (www.izor.hr). The dynamic visualization of the data is done with Highchart visualization engine and visualization engine developed by Institute.

Role of Performance Measurements in Process of Migration to IP Mobile Backhaul in 3G Networks

D. Ilišević * and N. B. Ćurguz*
* Telekomunikacije RS a.d., Banja Luka, Bosnia and Herzegovina
dijana.ilisevic@mtel.ba, natasa.banovic-curguz@mtel.ba

Abstract - New 3G and Long Term Evolution (LTE) mobile network has again made mobile backhaul a key area, especially regarding current network, and considering LTE growing traffic requirements. Network planning is undergoing major changes in terms of the technologies and methodologies. Smooth evolution to LTE networks will enable transformation from circuit-switched (CS) to all-IP architecture and ultimately to network function virtualization (NFV) to facilitate ICT transformation. This paper presents use of performance measurements to improve quality in process of migration to IP mobile backhaul in 3G networks (LTE license is not available in B&H).

I. INTRODUCTION

Demand for mobile backhaul (MBH) capacity continues to rise as consumers using more data and video services with their mobile handsets. The constant increase in data traffic is also forcing Mobile Service Providers (MSP) to invest in their infrastructure capacity in all segments of the networks, from the core to the access and transport. Ensuring multiple network technologies increases operational and engineering complexity, reinforcing the need for new ways to evaluate quality.

While transitioning to an IP infrastructure help MSPs address their current bandwidth demands; it does introduces some new level of management complexity that can impact service quality and often leads to strong OPEX increase. At the same time, as the scope and nature of mobile services continue to evolve (from 2G Base Transceiver Station (BTS) to 3G+ NodeB (NodeB is a term used in UMTS equivalent to the BTS) , 4G LTE and now LTE Advance), efficient utilization of MBH in migration process requires using a mix of pseudowire, native and hybrid deployments, and each require separate end-to-end management.

II. IP MOBILE BACKHAUL

After the deployment of HSPA (High Speed Packet Access), the volume of mobile packet data traffic has exploded to the point where it has exceeded circuit-switched traffic. Furthermore, with the deployment of LTE and 4G mobile systems, it is expected to increase even more [1]. To cope with the changed traffic composition, operators need to migrate their legacy Time Division Multiplexing (TDM) networks to packet-switched backhaul networks capable of supporting high volumes of packet traffic (while maintaining low OPEX).

Mobile backhaul refers to the network between base station sites and network controller/ gateway sites for all generations of mobile technologies (Base Station Controller – BSC in 2G networks and Radio Network Controller-RNC in 3G networks). As MSPs are moving to all – IP (Internet Protocol) mobile world, transport network are undergoing a dramatic migration to support a large bandwidth data and video services. At the core of the mobile network transformation is the migration from voice-based technologies TDM to multimedia communications based on the IP standards. This migration reflects the fact that consumers are moving from voice-centric services to more data-intensive and mobile services such as real-time video streaming. MSPs that utilize IP and the related SIP (Session Initiation Protocol) standards can deliver mobile data services at a higher quality and lower cost.

Current network transformation involves much more than replacing TDM-based equipment with IP-based equipment. Transformation is a holistic process that typically happens in phases, depending on the unique business plans that a MSP is facing. Analysis of the different migration options shows that there is no unique solution or single migration path that fits all types of backhaul networks. Irrespective of the level of Ethernet support, the migration path involves an intermediate step of a TDM/ATM/Packet hybrid backhaul. The hybrid nature of the mobile backhaul will depend upon using interface between the BTS/NodeB and BSC/RNC. Hybrid approaches of tomorrow will reverse the hierarchy by carrying TDM traffic encapsulated over packet based transport. Existence of 2G/3G/4G over a common wireless access network besides new traffic demands gives us a lot of challenges, usually to support equipment configuration of different generation [2]. Main goal is to fulfill the inexpensive and rapid deployment of the following:

- Convergence of 2G/3G/4G over a common mobile backhaul (provide comprehensive support for current 2G and 3G traffic, and provide an easy migration path to LTE).
- Scalable solutions (sufficient E1 capacity and allocate enough Ethernet capacity to fulfill current and future traffic growth).

- QoS ensured through traffic classification, policing (rate limiting), scheduling to queues and shaping of egress traffic to a specific line rate.
- Synchronization (ensure backhaul nodes capable of effectively interworking between TDM, SyncE and Precision Time Protocol)

To satisfy such escalating and changing demands, MSPs need to be able to deploy and expand the new systems more easily, and also have the means to monitor and optimize system performance automatically. Therefore, such demands give a lot of pressure to transport part of network to make them to become self – tuning especially in 2G/3G/4G networks. New Radio Access Network (RAN) architecture such as HSPA, HSPA+ and LTE has led to an increasing demand for backhaul capacity. BTS and NodeB interfaces A_{bis} and I_{ub} could be realized as shown in Table I.

TABLE I. A_{BIS} AND I_{UB} INTERFACES

2G	Interface	3G	Interface
A_{bis}	FE/GE L2	I_{ub}	FE/GE L2
A_{bis}	FE / GE L3	I_{ub}	FE / GE L3
A_{bis}	E1	I_{ub}	E1

Regarding possible scenarios, it is imperative to choose best solution of interfaces, layers (L2 or L3) to ensure network capacity demands regarding investments, legacy and traffic growth and following possible advantages and disadvantages of L2/ L3 networking.

Network planning is undergoing major changes in terms of the technologies and methodologies. As MSP industry becomes increasingly competitive, planning become ever more important. To ensure LTE ready IP MBH is possible even in 3G networks. In process of modernization of 2G/3G network new RAN equipment has to be swapped and new deployments are LTE ready. With new advanced transport modules it is possible to BTS/NodeB will be directly connected to optical or electrical FE interface on site using WMPT module (ALL IP sites). It should be L3 networking and optical/ electrical FE port on WMPT is used for co-transmission for 2G and 3G base station as given in Figure 1. WMPT (WCDMA Main Processing and Transmission Unit) board is an IP gateway for GTMU boards (GSM Transmission& Timing&Managament Unit) and WMPT acts as a router.

There are four options for VLAN usage:

- 2G and 3G use only one VLAN: 2G/3G service, signaling and NodeB O&M will be in same VLAN.
- 2G and 3G use separate VLAN: 2G is one VLAN and 3G is in another.
- 2G and 3G use separate VLAN: 2G and 3G uses one VLAN for service, other VLAN for 3G O&M (recommend this option).
- 2G and 3G use three VLANs: 2G and 3G use separate VLAN. NodeB O&M is assigned third VLAN.

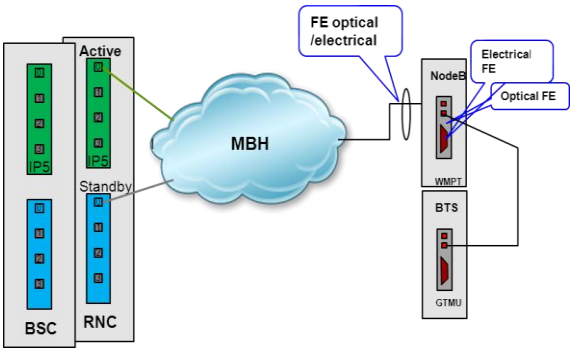

Figure1. ALL IP 2G/3G sites.

Use of L3 is proposed, and basically is questioning what level IP (LTE) MBH is mature [3]. Understanding L3 advantages requires understanding additional transport capabilities to build up LTE ready MBH. This approach allows MSPs to make a strategy to support future LTE network and easy to predict future capacity requirements. Deployment of LTE MBH also assume besides transition from TDM to IP but also reviewing the network topology. In case of microwave MBH, this assume move from 1+1 to 1+0 and ring topology as enabling more capacity and availability (reducing Capex and Opex).

III. PERFORMANCE MEASURMENTS – IMPROVING NETWORK QUALITY

Process of standard telco metrics were initially designed to measure part of network and with new customer oriented approach misses the point. Key Performance Indicator (KPI) is a new standard to provide service oriented approach in performance measurements. KPI measurements provide monitoring the entire End-to-End (E2E) mobile infrastructure from packet or circuit switched core elements to radio access network nodes, and detailed visibility to the underlying transport entities along the entire path of service delivery.

This allows MSPs to achieve numerous efficiencies in operating and engineering their networks and also standardize their performance management needs. Migration process in MBH shown in Figure 2 is followed by total transformation of mobile industry and business model.

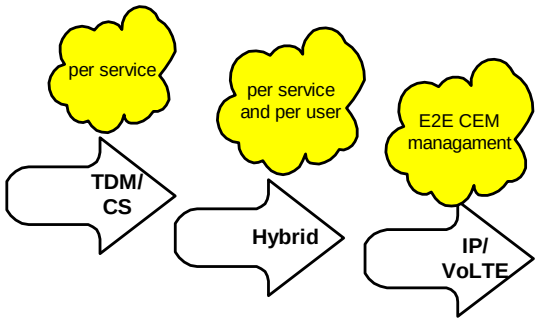

Figure 2. Migration process in MSPs approach.

New LTE networks is data oriented technology and enables proactive operation and moves focus on improving E2E customer experience through core, radio, and IP planning and optimization The circuit-switched (CS) and future VoLTE network will coexist for a long time and coordination between the two is crucial for seamless Customer Experience Management (CEM) and whole mobile network evolution.

Mobile network performance measurements per service may not be the best approach for systematic troubleshooting when degradations are detected on customer experience. The real challenge comes in diagnostic network problem that impact customer experience. These problems may be specific to a particular cell, device, core network element or application. Relevant KPIs shall be able to set alarming thresholds for different services. Furthermore, it is important to be able to detect relevant node/nodes and improve service delivery and loss of income – customer churn. Introducing performance measurements in MSP`s organization shows how to improve whole network efficiency including network design, network deployment, dynamic scaling, service and capacity forecast, and troubleshooting [4],[5]. New mobile network deployments are unprecedented in its complexity and represent a great challenge to MSPs and telco business transformation. Transformation process is very complex and covers cultural, engineering and business transformation [6]. The main goal is to move from just engineering point of view to customer oriented approach in process of maintaining the strength in core business while unlocking other areas like data analytics, music distribution and payment channels.

IV. MEASURMENTS RESULTS IN MTEL NETWORK

In this paper, a part of real Mtel mobile 2G/3G radio access network is analyzed after modernization of network elements in access and transport network (replacement of all existing 2G and 3G base stations by new LTE ready SingleRAN stations) and transport network (replacement of all existing TDM equipment with hybrid or IP equipment). For LTE ready backhaul solution L3 is recommended, and Mtel has viewed as more flexible to optimization and supports easier additions and changes (VLAN option 3 is used).

Rise of new application and services, together with competitive market has led to complex scenario in which quality of service plays a major role. When new IP MBH is introduced, MSPs require complete coverage from a quality perspective, but at the same time the operators is very sensitive to CEM impacts. KPI oriented approach has taken center stage as the performance platform offers significant advantages over traditional network monitoring systems and troubleshooting tools. A key challenge in this migration process has been how to ensure high quality for both voice and data services. Synchronization hybrid scheme, consisting of SyncE, PTP and TDM components, is needed to address synchronization requirements in a practical deployment scenario.

The general concept of performance indicators is that network elements and probes, which are used as service resource instances, are placed at certain nodes of the network infrastructure to pick up performance-related data, e.g. cumulative counters of protocol events. In constant time intervals or in near real time this performance-related data is transferred to higher level service assurance and performance management systems. Figure 3 shows the performance management process of the M2000. It includes the following procedures: performance measurement setting, performance data import, performance data display, performance data synchronization, and performance data northbound export.

There are different kinds of input for a KPI formula: cumulative counter values, constant values, timer values seem to be the most important ones. Also KPI values that have been already computed are often seen in new KPI formulas. In this paper, all chosen KPIs use standard counters and formulas in accordance to 3GPP and vendor recommendation [7], [8]. They are given in the equations (1), (2), (3), (4), (5), (6), (7) and (8). All of them are computed, measured and defined with its relevant counters, using network management software iManager M2000, Huawei [7].

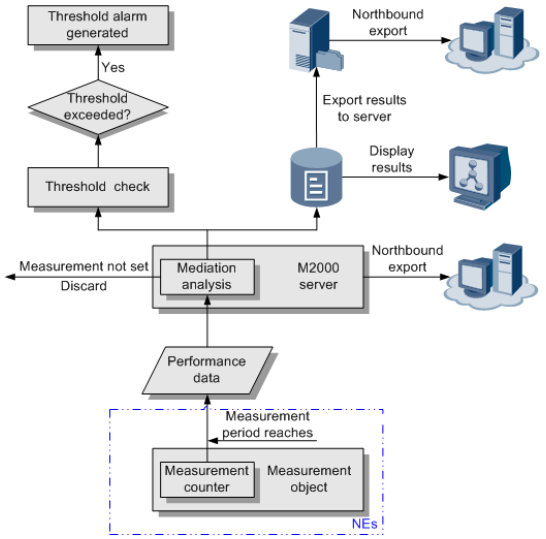

Figure 3. Performance management process, [7].

RRCSRservice = *([RRCSuccConn[Stab]/[RRCAttConn[Stab])*{100}* (1)

AMR RAB SR =*VS.RAB.SuccEstab.AMR]/ [VS.RAB.AttEstab.AMR]*{100}* (2)

PS RAB Setup SR = *([VS.RAB.SuccEstabPS.Conv]+ [VS.RAB.SuccEstabPS.Str]+[VS.RAB.SuccEstabPS.Inter]+[VS.RAB.SuccEstabPS.Bkg])/([VS.RAB.AttEstabPS.Conv]+[VS.RAB.AttEstabPS.Str]+[VS.RAB.AttEstabPS.Inter]+ [VS.RAB.AttEstabPS.Bkg])*{100}* (3)

AMR Call Drop Ratio =*VS.RAB.Loss.CS.AMR]/ ([VS.RAB.Loss.CS.AMR] +[VS.RAB.Loss.CS.Norm.AMR])*{100}* (4)

PS Service Drop Ratio= *([VS.RAB.Loss.PS.RF]+ [VS.RAB.Loss.PS.Abnorm])/([VS.RAB.Loss.PS.RF]+ [VS.RAB.Loss.PS.Abnorm]+[VS.RAB.Loss.PS.Norm])*{100}* (5)

Soft Handover SR (Cell)= *([SHO.SuccRLAddUESide]+ [SHO.SuccRLDelUESide])/([SHO.AttRLAddUESide]+ [SHO.AttRLDelUESide])*{100}* (6)

CS Inter-RAT Handover SR (WCDMA to GSM)(Cell)=IRATHO.SuccOutCS]/[IRATHO.AttOutCS]*{100} (7)

PS Inter-RAT Handover SR (WCDMA to GPRS)(Cell)= *[IRATHO.SuccOutPSUTRAN]/ [IRATHO.AttOutPSUTRAN]*{100}* (8)

In Tables II and III are given measurement results (KPIs) for

- call completion - *RRC Setup Success Rate*, *AMR RAB Setup Success Rate* and *PS RAB Setup Success Rate*,
- retainability - *AMR Call Drop Ratio* and *PS Service Drop Ratio,* and
- mobility management – *Soft Handover Success Rate*, *CS Inter RAT Handover Success Rate* and *PS Inter RAT Handover Success Rate* [8], [9].

KPI`s target values are defined in accordance to Communications Regulatory Agency BH [10]. Recommendations values for KPIs can be changed depending on the local network and its environment, growth and customer requirements.

Implementation of mobile backhaul using IP based solution provides results under expected thresholds. We used highly efficient Performance Management tool - iManager M2000, Huawei. We have analyzed average values of chosen KPIs for six sites with different number of cells (1, 2 or 3) in Banja Luka region, after network modernization in comparison to referent KPI target value. The measurements have been made in busy hours for 40 samples. Sites are chosen with MBH realized with different transmission mediums (microwave and fiber).

Table II shows that call completion KPIs, for all sites after swap of NEs, are better than 98%.

TABLE II KPIS FOR CALL COMPLETION

U Cell	RRC SR service (%)	AMR RAB SR (%)	PS RAB SR (%)
KPI target	**98%**	**98%**	**98%**
Site1_Cell1	99.57	100.00	100.00
Site2_Cell1	99.88	100.00	100.00
Site3_Cell1	99.79	100.00	100.00

Through every mobile network upgrades or changes, MSP aim to increase capacities and improve network performance to attract more subscribers and reduce subscriber churn through increased customer satisfaction, at the lowest possible cost. To achieve these goals, MSPs must carefully evaluate the capacity and performance capabilities of the products they are considering for deployment. As new hardware, firmware, or services are introduced, they should be carefully evaluated for performance and it must be verified that they do not negatively impact the performance of existing network services.

Measurments values in Table II and III shows that even in 3G MBH it is possible to start transitioning to an IP infrastructure, and minimize difficulty in future process of migration to IP MBH and make current operations more efficient (scalable solution that provide capacity management in large traffic dynamics).

V. CONCSLUSION

Results given in this article shows that migration to all IP transport ensure that KPI`s of existed services are under expected thresholds values and also using this approach is promising for future development of mobile networks (migration to all IP transport networks). Using KPIs validation is proven way to ensure quality improvements and provide quality monitoring for every element in mobile network and increase overall quality of network. This IP transport evolution in MBH for 3G networks ensure connecting future and present generation of mobile networks.

Smooth evolution to LTE networks will enable transformation from circuit-switched (CS) to all-IP architecture and ultimately to network function virtualization (NFV) to facilitate ICT transformation. This is very important task for customer oriented approach that every MSP trying to accomplished.

Abstract - **Planning, building and optimization process of radio access networks is a complex dynamical activity, which requires a lot of planning effort and time. The final goal is to build a radio network, which consists of minimum infrastructural components, and offers the best coverage and service quality. In order to consider all the possibilities of GSM signal coverage during planning time, and before the installation of equipment on certain location, it is very important to do software simulation of the GSM signal coverage of the observed area. Consequently, it is important to use an optimal predictive model which, using the appropriate digital maps, will offer the most realistic picture of the future radio access network. Taking this into account, subsequent optimization process and re-analysis would be reduced to a minimum.**

In this paper, comparative analysis of the software prediction GSM coverage area signal with the results obtained by measurements after the implementation of planned radio infrastructure at the proposed base station, will be presented. In order to assess the credibility of the software predicted GSM signal coverage area, measurements of GSM signal in urban area were performed. Final results were verified using statistical nonparametric chi square test. Further, the software prediction relation in regard to the measurement signal after the implementation of system is defined, and potential causes are treated.

Keywords—GSM, prediction, measurements, Chi-square test.

I. INTRODUCTION

One of the primary objectives of any mobile services provider is well planned radio-access network, which is essential in minimizing additional costs. Access network is a key part of any network in a sense of providing appropriate availability and quality of service to the end user. Therefore, mobile signal coverage, number of potential users, and traffic demands represent major input parameters in planning of all wireless networks. On the other hand, the optimization of mobile networks can be observed as a process of improving overall quality in network, that can be perceived by end-user [1]. By doing this, operators enable an efficient using of network resources.

Further, the regular functioning of one radio access network greatly depends of initial assumptions and software simulation which predict future coverage of the area with mobile network signal. The important step during this process represents the selection of appropriate prediction model which, using convenient digital maps, have to be capable to give, as much as possible, the realistic idea of future radio network coverage area.

In this paper, the results of conducted drive-test measurement of GSM signal for urban network case, are presented, with the ultimate goal of checking credibility and correctness of coverage area of this signal predicted using appropriate software. Further, comparative analysis of the values of GSM signal levels obtained by these procedures, e.g. checking and behavior of software prediction in regard to measurements. This analysis is conducted using nonparametric statistical chi-square mapping, which treats the level of reliance on the certain hypothesis acceptance or rejection. Lastly, results and potential causes for such results are interpreted.

II. PRACTICAL ANALYSIS OF GSM SIGNAL COVERAGE

Below, the analysis of GSM signal coverage for the certain area will be described. The final goal is to evaluate precision of software prediction of GSM signal coverage for urban area, without using objects elevation maps. Firstly, the selected cell with all parameters will be described, then the software prediction and drive test measurements will be conducted in the planed cell coverage area. Adjustable features of the “real" base station and base station software created are identical.

A. Selecting the base station and area to be analyzed

When choosing base station, it was primarily important to select an urban area, to prove efficiency of prediction model. Due to urbanity demand, the area of city Sarajevo was chosen. Also, it was necessary to take into account some limitations of GPS device, and limitations of software for GSM signal level measuring. Because of need for four satellites to be visible, it wasn’t favorably to consider the town center area of Sarajevo. The limitations of measuring tool are possibility of limitating the measurements on one carrier frequency, so it was necessary to choose BCCH channel frequency of the base station with a minimum number of adjacent cells with the same BCCH channel frequency. During analysis, base station Merkur, cell number one was considered, located in Otoka, Sarajevo, with frequency 1800 MHz.

The reason why the 1800 MHz cell was chosen is because various characteristics of spreading radio wave on different frequencies. Because of less attenuation of signal on lower frequencies, GSM 900 signal will at any point will be better than GSM 1800 (in case of cells co-located on one site). On the other side, to unload GSM 900 cell, a part of overalll capacity should take over GSM 1800 cell, and that is done using hierarchical structure of cells (HCS content).

B. Base station coverage prediction

In order to predict signal coverage for 1800 MHz cell (MERKUR18), TEMS software tool was used [3]. In this tool, all the data are loaded in form of layers. For this coverage prediction, a few layers were used:

- Georeferenced orthophoto map of the area.
- Database with data for all base stations for chosen mobile service provider.
- Elevation map, with relief data for chosen area, not including information about area type (urban, suburban, rural).
- Roads and vegetations information.

For GSM signal coverage prediction Ericsson 9999 propagation model is used [3], because other models need map of objects in order to analyze coverage, which was not available at the time of research. Prediction model tuning was not conducted.

In Figure 1 prediction of composite GSM signal coverage for chosen cell is shown (Best Server-composite), using selected layers and overall base station's EIRP.

For predicting cell coverage, 2000 meters is taken as cell radius, with cell in the center of the area, for getting a clearer overview of area with smaller signal levels, and therefore better analysis and comparation with results obtained by measurements.

C. Base station signal level measurements results

Analysis of base station coverage is done using Nemo Outdoor and Nemo Analyze software tools [6]. Measurements which can be conducted when analyzing GSM signal area coverage are divided into three categories:

- IDLE mode measurements. Idle mode means that GSM signal is measured without connection establishment, and this type of measuring is used to determine GSM signal coverage level of certain area.
- Measurements during connection establishment.
- Measurements with connection established (DEDICATED mode). Dedicated mode is used for determining the quality of signal, handover procedure success rate and determining continuity of established call (measuring with connection established-connected mode).

Measuring of signal level in idle mode are conducted for this paper for the reason in dedicated mode connection on radio link is established and functions „Power Control" and „Discontinuous Transmission" on link are activated. This functions, in order to keep level of network interference low and to extend battery lifetime, limit emitted power of base station and mobile phone to minimum needed value [2]. For this reason, level of signal in dedicated mode is 5 to 10 dBm lower than real level of signal, measured in idle mode.

Measuring signal levels in the coverage area of cell MERKUR18 are conducted in idle mode. These results are compared with signal power levels results obtained by prediction. On the cell coverage area three measurements of signal level are conducted, in order to average the results, and observe variations of signal level in different periods of time.

One of the results is shown on Figure 2. Observing the conducted measurements, it can be concluded that signal levels measured through different time periods slightly differ, and it is consider normal taking multipath fading into account.

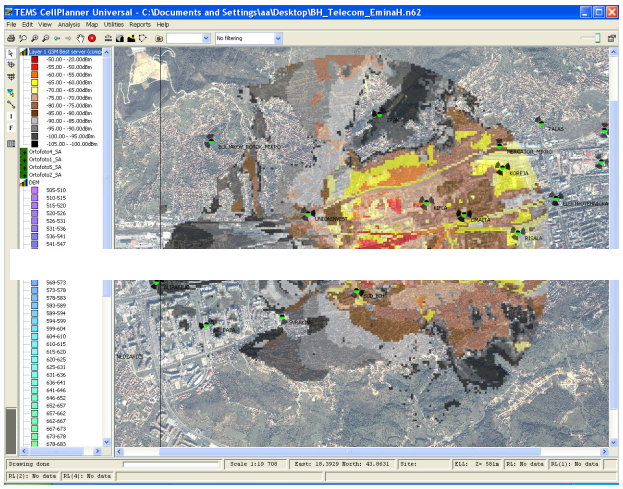

Figure 1. Coverage prediction map (composite) for chosen GSM cell

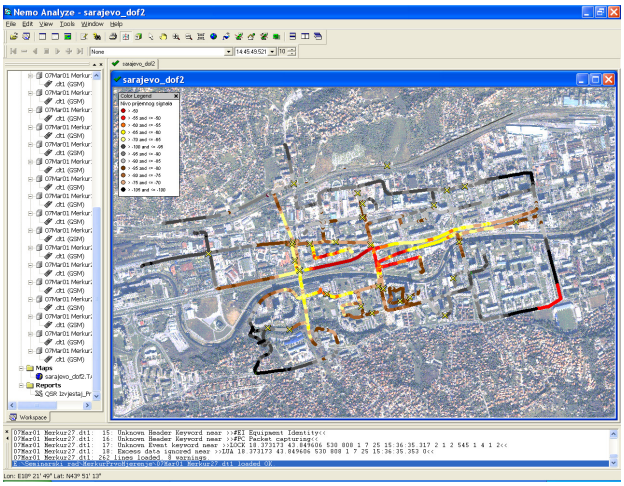

Figure 2. Measurement results showing GSM signal strength for chosen cell (first reading)

Figure 3 represents GSM signal strength as a function of distance from base stations antenna, values were taken from measuring files. In Figure 4, the same diagram is shown, while approximated diagrams for path loss and slow fading are added.

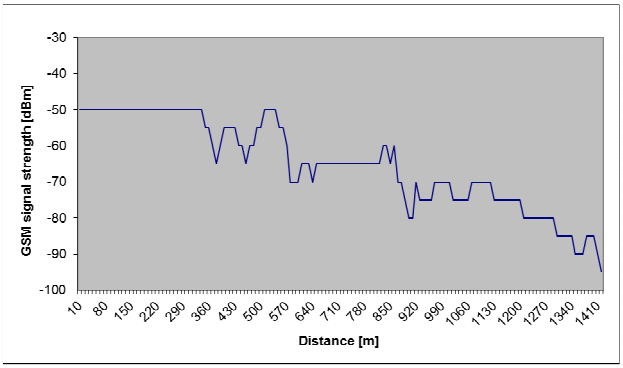

Figure 3. GSM signal strength as a function of distance (based on measurements results)

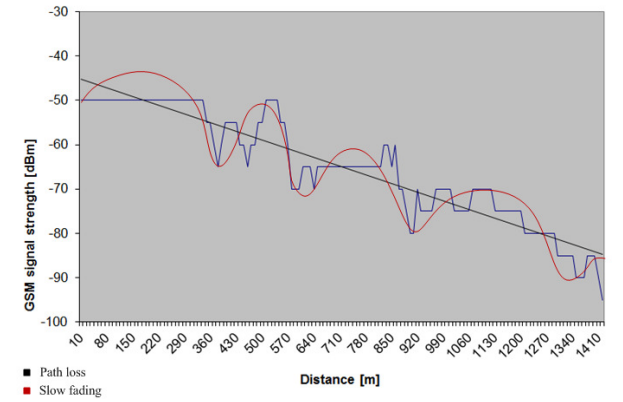

Figure 4. Path loss and slow fading shown using measurement results

III. STATISTICAL SIGNIFICANCE TEST

After obtaining the results of an area GSM signal coverage level, and representing the results in format suitable for further analysis, it is necessary to determine the relationship between the values of GSM signal strength obtained by both procedures, and to assess credibility of predicted GSM signal coverage using software tool propagation model. In order to do that, it is necessary to conduct certain statistical significance test, which will statistically compare values obtained by both procedures. Any statistical significance test which is correctly performed, has conclusions about confidence grade with which certain hypothesis could be accepted or rejected. In this paper, χ^2 test is chosen.

Nonparametric χ^2 statistical test is statistical significance test for the tabelar analysis with two variables. Typically, hypothesis being tested with χ^2 distribution is: whether or not are to different samples different enough in some characteristics or aspects of their behavior, to conclude that these samples' population of origin are also different or not different, in certain features or aspects of their behavior.

Nonparametric χ^2 test is rough estimation of credibility; it accepts weaker, less accurate data as input, unlike parametric tests (e.g. t-tests and variance analysis), so it has lower status among other statistical tests. However, it's limitations are it's power, because χ^2 distribution is tolerant of input data accuracy, so it can be applied to wide research area.

χ^2 test is usually used to test statistical significance of the results presented in tables with two variables. Interpretation of tables with two variables is a part of χ^2 test results interpretation, so the analysis will be conducted using tabular analysis with two variables [4].

A. *Conducting the χ^2 test*

As we mention before, χ^2 is nonparametric test. It does not require that the sampled data are more ore less arranged by normal distribution (like t-test do), although it is based on assumption that variable is normally distributed in the population from which samples were taken.

Requirements of the χ^2 test are as follows:

- The sample should be taken randomly from the population.
- The data should be presented as frequency of occurrence (not a percentage).
- Measured variables should be independent.
- The observed frequencies of occurrence should not be too low.

In this work, it will be assumed that the values that we collected from GSM signal coverage correspond to practically measured values.

In carrying out χ^2 test is necessary to provide sufficient number of samples that will be used for testing. In order to achieve reliable results, we will take the number of samples in the amount of 1.000.

TABLE I. GATHERED RESULTS FOR PREDICTION AND MEASUREMENTS

GSM signal strength of the sample	Result obtained by prediction	Result obtained by measurements
-105<x<-100	30	99
-100<x<-95	25	181
-95<x<-90	33	147
-90<x<-85	68	142
-85<x<-80	119	64
-80<x<-75	155	60
-75<x<-70	106	70
-70<x<-65	117	56
-65<x<-60	222	43
-60<x<-55	41	33
-55<x<-50	48	52
-50<x	36	53

TABLE II. PARAMETER VALUES BEFORE AND AFTER CORRECTION

GSM signal strength of the sample	χ^2 value	χ^2 value after correction
-105<x<-100	158,70	1,375
-100<x<-95	973,44	0,090
-95<x<-90	393,81	4,266
-90<x<-85	80,53	0,007
-85<x<-80	25,42	0,690
-80<x<-75	58,22	3,368
-75<x<-70	12,22	2,647
-70<x<-65	31,80	2,173
-65<x<-60	144,32	0,734
-60<x<-55	1,56	0,923
-55<x<-50	0,33	0,285
-50<x	8,02	1,422

These samples were taken randomly based on their coordinates (longitude and latitude). For every sample obtained by prediction, the sample with same coordinates obtained by measurements is taken for comparison purposes.

Measured signal strength value will be collected, then the points with the same coordinates will be found on the GSM signal prediction coverage map, and value of the signal strength in these points will be collected, too. For each range of values of the GSM signal strength, for measured and predicted values is necessary to provide the sum of samples with a given signal strength and record it for further analysis.

Furthermore, it is necessary to determine the desired error tolerance. We will assume error probability Pe=0,05. For further analysis is also necessary to know the number of degrees of freedom ν. This number is defined as:

$$\nu = (r-1)(c-1) \tag{1}$$

where r is the number of rows in the table with data to be analyzed, and c is the number of columns in the same table.

After sampling, it is necessary to ”measure” the difference between the pairs of observed and expected frequencies of occurrence. Observed values in this case are values obtained by measuring the GSM signal strength, and expected values are values obtained by software prediction tool. Further, it is necessary to calculate the difference between the observed and expected frequencies of occurrence for each column (for each range of values of the signal strength), square the difference, and finally divide the resulting number by expected frequency of occurrence.

The resulting value is called χ^2 value for given signal strength values range in our case.

$$\chi^2 = \frac{(O-E)^2}{E} \tag{2}$$

Where :

χ^2– constant by which the accuracy of assumptions is evaluated;

O – measured value;

E – predicted value.

After collected data, values shown in Table I, χ^2 values shown in Table II are calculated. Summing the values from Table II we get the overall $\chi 2$ value, which in our case is 1.888,37.

The resulting number should be compared with the values in the table of upper critical values of χ^2 distribution with ν degrees of freedom. For Pe=0,05, ν=11, critical value of χ^2 distribution is 19,675. The tested value is obviously much higher than the critical value χ^2 distribution, indicating that the initial hypothesis is incorrect.

B. Correction of the results

Since the results obtained by measurements deviate significantly from the results obtained by the software prediction, we started the analysis of the results obtained, in order to establish a correlation between these two procedures.

Given that there is no real possibility of correction practical measurements (intervention on the antenna system, base station, which refers to the modification of azimuth, tilt and height of the antenna), the only to affect the correlation of these values is to correct prediction software parameters.

Corrections made to the parameters of the base station (antenna system) used during software prediction, were reflected in the modifications to the azimuth, tilt, and height of the antenna system.

So, after a detailed analysis and comparison of prediction and measurement results, it was found that the optimal alignment of these results is obtained using the parameters given in Table III.

Base station’s antenna system radiated power (EIRP) has not been modified after the correction (base station’s combiner type remained the same - Gc, and output power of the base station cabinet 2206). The result after correction made using above parameters is shown in Figure 5.

TABLE III. BASE STATION PARAMETERS BEFORE AND AFTER CORRECTION

Value type	Antena height	Azimuth	Downtilt
Before correction	23m	75°	3°
After correction	22m	80°	2°

TABLE IV. GATHERED RESULTS FOR PREDICTION AND MEASUREMENTS AFTER CORRECTION

GSM signal strength of the sample after correction	Result obtained by prediction	Result obtained by measurements
-105<x<-100	88	99
-100<x<-95	177	181
-95<x<-90	124	147
-90<x<-85	141	142
-85<x<-80	71	64
-80<x<-75	76	60
-75<x<-70	85	70
-70<x<-65	46	56
-65<x<-60	49	43
-60<x<-55	39	33
-55<x<-50	56	52
-50<x	45	53

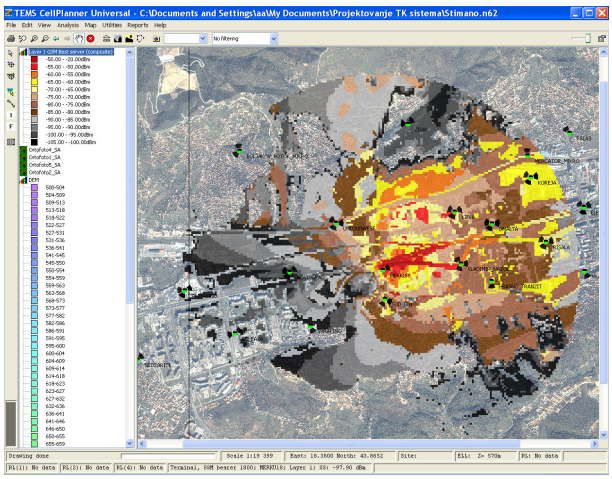

Figure 5. Coverage prediction map after correction

After correction of the overall sum of the number of samples, the values for the $\chi 2$ parameter are presented in Table IV.

By summing above values a corrected $\chi 2$ value 17.98 is obtained.

The resulting number should be compared with the values in the table with the upper critical values of $\chi 2$ listed. For values of Pe = 0.05, ν = 11, critical value of $\chi 2$ distribution is 19.675. The test value is in this case less than the critical value of $\chi 2$ distribution, indicating that the initial hypothesis is true.

IV. CONCLUSION

The basic step in the development of each mobile radio network is good planning. Today different software tools are used to plan coverage of the radio network. After software coverage planning, and commissioning a certain transmitter, it is necessary to control the inspect signal strength value, in the way of measuring the GSM signal strength. During this process, conclusion that the measured value more or less deviate from the values obtained by prediction is often. The reasons are different, and one of the key reasons is a lack of quality elevation terrain maps, that prediction model uses to predict the signal strength.

In order to test the accuracy of prediction using the appropriate model intended for urban and suburban areas, applied to an urban area, measuring the signal strength in the service zone for cell MERKUR18 is performed. Values obtained by measurements and prediction were compared by nonparametric $\chi 2$ test. Results of this test indicated the large deviations of the measured values compared to the values obtained by prediction. From the values that were used during analysis it can be concluded that measured values deviations from predicted values are higher in the weaker signal strength samples, and lower for areas with good signal coverage area. Areas with higher quality signal are areas near the antenna system, i.e. areas where there is line of sight to the base station (without objects, and therefore the reflection). From this we can conclude that the main reason for the poor results the lack of high-quality maps, more precisely, the lack of folders to the present elevations, as the terrain, and objects (folders with facilities were not available for analysis). Another potential reason could be used predictive model, however, as all the prerequisites for the correct operation of the model are not provided used, valid comparison of the different models wasn't done, and it could be an objective of future researches.

In order to perform the correlation of the measurement results and prediction software results, only the possible corrections for this case were done: corrections of parameters of the antenna system. Thus, after a number of changes optimal parameters were identified, and by applying the $\chi 2$ test on the obtained results it was found that these results were very well correlated.

Abstract - Software Defined Networking (SDN) is a networking approach based on a centralized control plane architecture with standardised interfaces between control and data planes. SDN enables fast configuration and reconfiguration of the network to enhance resource utilization and service performances. This new approach enables a more dynamic and flexible network, which may adapt to user needs and application requirements. To this end, systemized solutions must be implemented in network software, aiming to provide secure network services that meet the required service performance levels. In this paper, we review this new approach to networking from an architectural point of view, and identify and discuss some critical quality issues that require new developments in software technologies. These issues we discuss along with use case scenarios. Here in this paper we aim to identify challenges for further evolution of software technologies in addressing problems of network evolution. Our view is based on the need for strong integration of network and software technologies, and therefore we establish the main focus of the paper on discussing SDN demands on software technologies. The main contribution is in categorization of open research problems and presenting ideas and opening new opportunities for future research.

I. INTRODUCTION

Software Defined Networking (SDN) is a paradigm that is related to idea of offering the network resources to end users as a service (NaaS) over an open Application Programming Interface (API). In this paradigm, from the network operator perspective, the key differential element is to replace industrial standard Command Line Interface (CLI) for managing directly network devices with an open interface, which can be used to programmatically perform device management. Today, we have two protocols NETCONF [1], proposed by IETF, which provides mechanisms to install, manipulate, and delete the configuration of network devices, and Open Flow[2], proposed by ONF, as communications interface between the control and forwarding layers of an Software Defined Network (SDN) architecture. Introduction of open protocols enables faster evolution and interoperability among equipment of different vendors. Thus, leads to an idea of separating switching hardware and control logic as is presented in Fig. 1.

In OSI layer two and layer three implementations of the modern transmission networks there is a plethora of control protocols allowing for autonomous switching and routing of Internet traffic. Autonomous control is achieved by their distributed communication relying on continuous tracking of surrounding network topology. Thus significant processing power of network equipment is spent on spreading common topology view among these network nodes (according to some research studies more then 30%). Also, transmission overhead and link utilization may represent also significant issue. With the continuous trend of network scale, creating larger transmission chains, this current autonomous control approach becomes more and more inefficient and leading to unacceptable performances and convergence time exceeding conventional constraints. As network grows, more and more centralized approaches to network management are needed. The main problems identified are with **responsiveness**, **reliability** and **scalability**. A solution that is getting more and more attention nowadays is introduction of aforementioned layering approach with centralization of control logic. The aim of separating control logic from the switching logic into two distinct network planes is to decouple the forwarding and device operating functions from the network control logic. This new approach increases the efficiency in handling a dynamic network, and provides better adaptation to changing traffic patterns.

The idea of fully integrated network solution with separation of control logic into separate layer from pure hardware switching layer without logic, just based on dynamically changing data table, is far away from realization. Although, it looks simple it requires significant virtualization of network management activities and procedures that are not so simple in the current state of the art. Therefore, an endeavor has to be invested into simplification of existing network management operations providing backward compatible, easy to scale and performance wise solutions.

The aim of this paper is to introduce into concepts of Software Defined Networking and explore and discuss open research problems on SDN software technology. For this purposes we survey work on SDN software technologies and on concrete use cases we identify and explain main open research problems in that area. Finally, main contributions of the paper are in introducing new ideas on future research that is to be considered in developing of SDN software technologies.

II. SDN ARCHITECTURE

The basic key elements of SDN are separation of network control logic from network hardware operation and simplification of network device logic. This enables automatization of network management processes and logic above the control layer, centralization of network control logic, and openness of network resources through open standards and to end users.

Figure 1 captures the overall SDN architecture, which consists of three planes (layers): data plane, control plane and application plane. The data plane comprises the forwarding devices. At the control plane, the logic is implemented in a software platform termed SDN controller (SDNC). The SDNC's interface towards Data Plane is realized through the southbound API (*Application Platform Interface*) [3], see Fig 1. The SDNC platform contains a logical representation of the underlying network resources, and several control functions that implement operations and functions for the network. The capabilities built into the network control plane are exposed to the application plane through the Northbound API that is SDNC's interface for communication between Application and Network Control Plane. The applications, located in the application plane, leverage the northbound interface to implement higher layer service logic.

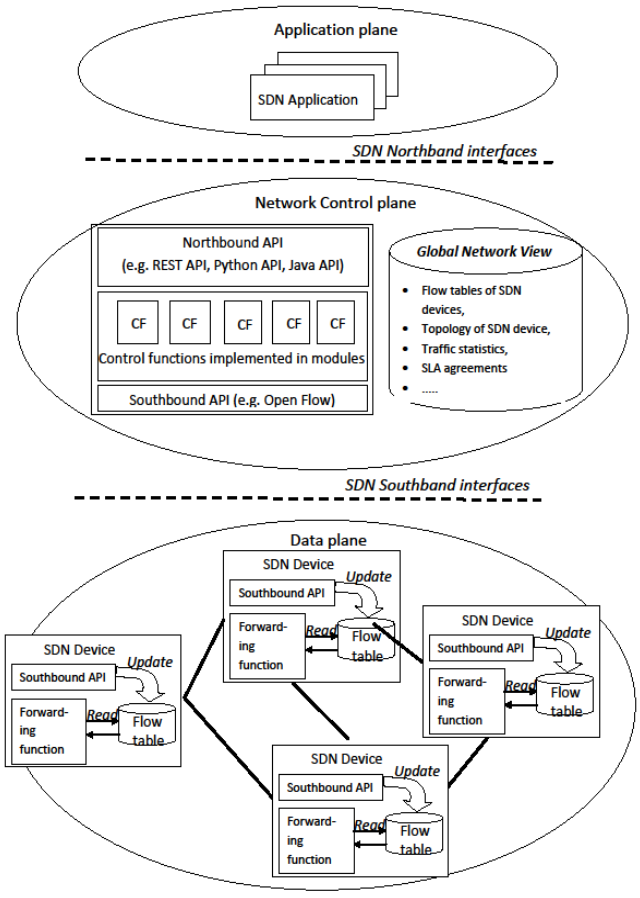

Figure 1. Overview of Software Defined Network Architecture

A. SDN Northbound Interfaces

The SDN northbound interfaces, as is defined in [3], specifies the functions exposed by the SDN control plane, for programming of SDN applications and services and it is implemented as an Application Programing Interface (API). There can be various implementations for the northbound API, depending on the network control plane and the requirements of the network services built on top of it. Figure 1 shows some possibilities for such implementations (e.g. REST, Java, etc.). These implementations fall under three main categories:

- Controller APIs that use a general purpose language (e.g. Java, C, Python).
- APIs based on web services (e.g. REST).
- APIs based on Domain Specific Languages (DSL).

The first category contains the most common and used APIs. They allow the developer to write new service modules integrated in the controller platform (Figure 1). The variety of languages depends on the implementation language of the controller platform. Some examples of controllers are: NOX in C++, POX in Python, Floodlight, ONOS and OpenDaylight in [4], [5], [6], [7], [8]. The northbound APIs in this category lead to tight coupling of the services (control functions) with the controller platform.

The second category of APIs is based on web services. Some controllers offer a REST API through which applications can get information about the state of the network, and send control messages to the switches. This type of APIs emphasizes simplicity and modularity: the network services may be programmed in any language as long as they comply with the REST interface. They are well suited for integration with external platforms, using service oriented architectures. The main disadvantage is that it may be difficult to expose the full set of capabilities of the control plane as REST APIs. While the control plane and the southbound interface are generally event-driven (network generated events), it is harder to implement an event driven REST API thus to preserve the same programming model towards the SDN applications. There are efforts in the open source community to provide event notifications through the northbound interface [6], although this is challenging. The RESTCONF protocol [9] tries to establish a standardized method for exposing the control plane resources (e.g. devices, flows, etc.) to the SDN applications using an event-driven paradigm (including event notifications and remote procedure calls).

The third category of APIs is based on domain specific languages. Their main purpose is to ease the task of expressing network policies by using high level abstractions. Examples of research work in this area are Netcore, Frenetic, and Pyretic [10], [11]. A network control plane that exposes such an API, takes as input a policy describing the expected network behavior, and compiles the policy into low level rules (e.g. Open Flow entries) that are installed in the forwarding devices. This programming model makes application development easier by moving the complexity from the applications to

the control plane policy compiler. The policy compiler ensures that the behavior enforced in the data plane is correct and does not lead to inconsistent traffic treatment (due to possible conflicting policies).

One of the challenges regarding the definition of northbound APIs is choosing the correct level of abstraction for the network resources exposed through the APIs. If the abstractions are very low level, then the application development becomes increasingly complex. On the other hand, high level abstractions make development easier but they may become less powerful (i.e. decrease visibility and control over the resources).

B. Southbound Interface

The southbound interface defines the communication between the network control plane and the data plane (Figure 1). The OpenFlow (OF) protocol has been standardized in 2009 and it is currently the most used protocol implemented on the SDN southbound interface. OF is based on abstraction of forwarding logic using flow tables. Inside a forwarding device, the forwarding function is performed based on the OF entries in one or several flow tables (Figure 1). An OF entry is a *match* and *action* tuple. The *match* part defines the headers to match against the packets arriving at the forwarding device, while the *action* part defines the actions to apply to the matching packets. In its first version, OF had limited capabilities, covering mostly Ethernet, IP, and transport headers [2]. In later versions several features have been defined, making OF more versatile:

- Pipe-line processing of packets using multiple flow tables. This mechanism enables applying a series of actions for a packet.
- Tunneling support using Multi-Protocol Label Switching (MPLS)[12] and Provider Backbone Bridge (PBB) [13].
- Support for IPv6.

Several other extensions have been defined for the OF protocol in order to support circuit switched and optical networks. While OF enables controlling the forwarding behavior in the data plane and collecting statistics about the network, it does not make it possible to configure the devices. Examples of protocols that enable configuration and management of devices are NETCONF, SNMP, and OF-Config [1] [14] [15]. These protocols enable for example configuration of operating parameters of the devices, such as queues, ports, etc.

III. USE CASE SCENARIOS

Two exemplary case scenarios are chosen here to illustrate the advantages provided by SDN in managing current network services and infrastructures.

1. Network Slicing / Virtualization

A network infrastructure under the supervision of an SDN controller (SDNC) can be "shared" by multiple users without mutual knowledge or impact, creating de-facto "virtual networks". This is a likely solution for "multitenant" operations where network infrastructure resources can be dynamically allocated and modified among the different tenants via the centralized and programmatically control of the SDNC. While this type of network "slicing" can be achieved by the physical separation and control of ports and queues in the forwarding devices, a more scalable and flexible solution can be achieved if the SDNC becomes the manager for tag-based (overlay) conventional virtual networks, i.e. by managing VLAN (Ethernet) tags or MPLS labels.

2. Data Center & Virtual Infrastructure

This is very much exploited currently in different commercial solutions targeting Datacenter (DC) networks, where computer resources virtualization has become the de-facto standard mechanism to maximize the utilization of equipment and distributing its cost. DC network topologies are based on massive tree structures of servers rooted by common switches in share physical collocated racks (i.e. TORs: Top of the Rack switches). TORS are as well interconnected in tree architecture towards gateways connecting to external networks. While traditionally "leaf" nodes in these tree topologies were mere hardware servers, in today virtualized environments they are virtual machines (VMs), instantiated when and where needed by virtualization hypervisors. These VMs, in order to enable connectivity within the virtualized network are linked via virtual switches, which can be controlled by an external SDNC. This enables to create overlay networks, as the ones mentioned previously, within the DC to represent different tenants (customers) or applications. DC network management challenges, such as dynamic traffic migration (i.e. when copying or migrating a VM from one physical server to another) or inclusion-deletion to-from different virtual (overlay) networks within the DC, become extraordinarily simplified when based on a centralized-programmatic SDNC operation, rather than a manual configuration-reconfiguration from a human (fail-prone) manager.

IV. SOFTWARE TECHNOLOGIES

The introduction of network virtualization enabled further development and flexibility of networking in cloud environments. However, SDN aims to centralize network control, thus it aims to *softwarify* network engineering theory into network services offered to its users leading to easier and more efficient network management. However, numerous problems exists and still more work has to be done to define network engineering theory that would be ready for network softwarisation.

Here we aim to introduce some of the problems and open areas for research but we are not aiming to review all the state of the art in this field.

V. OPEN PROBLEMS

Movement to the new SDN paradigm, aiming to *softwerize* the network, is full of challenges. There is a growing body of research in that direction. Some well established top journals have devoted a special issue to SDN. There have been three HotSDN conferences with

Identify applicable sponsor/s here. If no sponsors, delete this text box.

continuously increasing number of papers submitted. A new conference started on Software Defined 5G Networks. Workshops are addressing particular topics in SDN such is for example Workshop on Architectures and programming paradigms for emerging 5G Networks. Numerous papers have already been written and published and number is continuously increasing. One of the biggest concerns is how can software technologies help in this migration and where we need their help. Main challenges with network virtualization are addressed per each identified use case scenario in [16]. Here in this paper we aim to identify challenges for further evolution of software technologies in addressing problems of network evolution. We survey problems addressed by numerous authors on SDN software technologies and discuss them here in several categories. Also, important to note is that we are not aiming to review all the existing literature on challenges and provided solutions. Here we just describe open problems and occasionally provide reference for better illustration of problem.

First problem that we address here is the consistency problem between the logical representation of the network resources at the network control plane, and the physical resources in data plane. This consistency problem is associated with liveness properties. This problem is twofold. If we strive to keep consistency then we will sacrifice responsiveness and vice versa. A consistent network model at the control plane requires that well defined synchronization procedures are executed frequently in order to update the network control logical model with information from the data plane. This leads to increased resource consumption at the SDNC side and introduces delays on the control channel, thus decreases the overall responsiveness at the control plane. On the other hand, optimizations may improve responsiveness but may also introduce uncoordinated behavior that in the case of large network complexities, is leading to a non-reliable system, with routing loops and black holes. Optimizations as shortcuts are not welcome solution in such complex systems. System scaling is limited with distributed relationship between logical and physical resources and maintaining their mutual relationship is not trivial [17]. Software technology research aims to identify set of representative relations, that are easy to manage and maintain, investigate specific trade-offs that are dependent on controller implementations and to find alternative mechanisms on delays or reliability. Consistency effect is evaluated from different perspectives and vast amount of software technologies has been proposed to address this problem and still this is a hot research area widely involving computer science and complex network theory.

To achieve high scalability, flexibility and availability it is identified as mandatory to implement redundancy at control plane. In [18] experimenting with different topologies it is identified that one controller location is often sufficient to responsiveness requirements but not for fault tolerance requirements. Some researchers has come with statement that the only possible way to secure highly available but reliable platform is to introduce redundancy and distribution of control logic. However, in that scenario we introduce completely new branch of problems dealing with synchronization and concurrency issues while handling concurrent policy updates [19]. Here we face with full complexity of programming network control function with high reliability and availability demands while capable for executing numerous concurrent processes for variety of different users. Majority of knowledge in this domain has already been collected within industry such is for example Ericsson knowledge base developed in more than 40 years of evolution of AXE based telephone exchange that in its *AXE 810* version that implements control logic as standalone node that is central in next generation networks for handling control (signaling) of end user traffic in resource network layer. This switch is central to many core network implementations of Next Generation Networks (see 3GPP standards) and is reliable, robust and easy to scale solution. However, most of the solutions are not implemented to be used at runtime as is required in new network evolution phase (5G networks). The synchronization and concurrency issues are big concern of these networks. As communication is a central element of these networks and aiming to *softwarify* network engineering theory we may need to control harmonies execution of numerous industries specific hardware related policies and numerous interacting industry standards. This is actually one of the biggest concerns of further network evolution. For that reason we may need new abstractions for structured communication - centered programming and to specify and implement program communication safe software. One promising example is behavioural type theory that introduces new behaviuoral types for describing interactions involving multiple peers and that abstracts these interactions as a global scenario [20], [21]. Message exchange among concurrently running multiple peers are verified at global level thus enabling independent certification of each party's local implementation if it is in correspondence to global behaviour. Based on that theory a lot of interesting approaches has been presented at workshop on *Programming Language Approaches to Communication and Concurrency cEntric Systems (PLACES)*. One good example is Scribble programming language [22] that allows certification of global protocol interaction and projection onto local protocol implementation. Except the tools for editing, verifying and projecting, there is work in progress of development of numerous libraries that allow its integration with some general purpose languages such are java or python.

In centrally controlled network architecture that is continuously growing, its management becomes extremely complex and security vulnerabilities becomes more complex and error prone. Data integrity and confidentiality for information exchange in a network with dynamic policies require innovation in the area of cryptographic algorithms or authentication certificates. Some cyber security controls, that would be implemented as part of software tehnology for next generation systems

such as access control, network isolation or monitoring are areas under investigation.

Another problem is with central management of global network view. This task requires huge amount of network data to be effectively stored into database, restored and up to date. Problem of storing of huge amount of data as well as effective information capturing from this big data volumes is a huge issue. One approach is usage of hierarchy abstraction. In [23] proposal is to use hierarchical policies that show positive performance results.

Expression of configuration protocols such as Open Flow and Netconf is limited. A numerous studies question their flexibility to different configuration needs, and their expression abilities in relation to the performance requirements [24]. Here we have tight interaction between telecommunication and computer science profession in defining right abstractions that would provide expressive protocol and its implementation language for efficient, reliable but secure communication between abstract network notation and physical resources. There is continuous work in progress in standardization of these protocols and its implementations as well as identification of new avenues for further evolution in configuration protocols and languages.

Modeling abstractions, software organization at control but also at device level may have significant influence of service performance offered by SDN network. This is especially interesting to observe in relation to system potential to scale. For example, an earlier study show that splitting of architecture in Mobile Switching Centre has significantly degrade service performances and scaling abilities, [25]. Software modelling methods have to be revised with software dynamics in mind. A software engineering modeling tool that aims to model how software application with intensive dynamic scaling requirements has to be distributed in respect optimized resourse costs has been proposed by [26]. An object oriented programming approach implementing type system aiming to optimize resource usage costs by governing software distribution within multicore systems has been proposed in [27].

Architectures that rely on open standards and open source code community benefit in terms of progressive development and prototyping. Moreover, an integrated view that is maintained among various industries through open community turns out with positive interoperability characteristics. However, there are numerous drawbacks. Open community is good choice for simple prototyping solutions without strict and formal rules, based on easy and general purpose languages. But, in case of complex system there are numerous studies that proved that human factor should not be neglected. For example, programming language *Erlang* contains some interesting concepts that are developed assuming unreliable software. The right balance between advanced software technologies that human should consume while developing software and software technologies that accepts not perfect world has to be achieved. One way to deal with this issue is to develop certification technology for software packages that are to be deployed into complex network that would be based on using built in typecheckers.

The way how system evolves very much influence its further ability to scale, further develop, maintain required reliability levels, etc. Learing from existing complex systems that evolved over decades may bring some fruitful knowledge. Identification of software behaviour and identification of autonomous modeling techniques that could be easily implemented into network or development environemnt may be used to introduce discipline in SDN network in open source environment.

VI. CONLUSION

Software Defined Networks have been developed and invented as new paradigm in telecommunication world but it is highly based on computer science theories. Numerous efforts that were invested within computer science field developing theories in formal languages and verification tools have finally show their full practical benefit. Developing complex software systems such a modern telecommunication networks become extremely challenging task. Add hoc shortcutting engineering solutions is not desirable any more but we should strive on systematized solutions. The best known systematization technology is governed by sound formalisms that are implemented within technology that humans use to engineer complex systems. In the SDN world the need for systematization of existing network and traffic engineering knowledge is evident. And this is still not enough; we need this systemized knowledge packed in nice formal packages that will be simple and easy to integrate in complex system that we develop and use. For this future step there is need for diverse skills and competences, a huge experience and practice base of engineering existing networks, theoretical sense for knowledge systematization and representation in meaningful way and again engineering knowledge to apply systematized solutions in practice. Moreover, expertise from different knowledge domains are identified as needed. Just to mention a few, network and traffic engineers, reliability engineers, computer scientist, mathematicians, and complex network theoreticians. Software technologies just have to be developed for new networking paradigm used for developing complex software systems and lot of efforts has to be invested prior final solution. Here in this paper we survey key SDN problems, demonstrate details on real use case examples and based on that we identify main categories of existing research in SDN software technology. Furthermore, we open some new avenues by introducing some ideas for future research in SDN software technology.

Abstract – Software Defect Prediction (SDP) empirical studies are highly biased with the quality of data and widely suffer from limited generalizations. The main reasons are the lack of data and its systematic data collection procedures. Our research aims at producing the first systematically defined data collection procedure for SDP datasets that are obtained by linking separate development repositories. This paper is the first step to achieving that objective, performing an exploratory study. We review the existing literature on approaches and tools used in the collection of SDP datasets, derive a detailed collection procedure and test it in this exploratory study. We quantify the bias that may be caused by the issues we identified and we review 35 tools for software product metrics collection. The most critical issues are many-to-many relation between bug-file links, duplicated bug-file links and the issue of untraceable bugs. Our research provides more detailed, experience based data collection procedure, crucial for further development of SDP body of knowledge. Furthermore, our findings enabled us to develop the automatic data collection tool.

I. INTRODUCTION

The research community is in need of a systematically defined data collection procedure for Software Defect Prediction (SDP) studies. In order to achieve this goal, we need to be aware of all the issues that could lead to data bias. Data collection from freely available open source projects is becoming increasingly popular, so we decided to reveal as many issues that are present in their development repositories.

A great number of empirical studies tried to indentify the best approach to SDP and most of them are collected in several systematic review [1,2,3,4]. However, there is still work to be done on reproducibility of empirical studies based on datasets retrieved from development repositories [5]. Detailed and replicable data collection procedures have to accompany the datasets in order to achieve greater generalization of SDP studies [1]. Furthermore, it is known that SDP repositories often suffer from data quality issues like: outliers, missing values, redundant or irrelevant attributes and instances, overlapping classes, contradictory samples, data shifting, imbalance of classes or replicability [6], [7]. Thus, we need to start systematically build a knowledge base on reusable research datasets. In this paper, we want to stress on role of human introduced bias in data collection procedure because it is developers who make entries into development repositories. We also recognize the importance of reusable tools for automated data collection that could play significant role in systematically building of uniformly obtained datasets. Freely available reusable tools, that have open source software with clearly defined data collection mechanism implemented, could form a base for wider discussion of data collection issues and its relations to bias. It is important that all research in the area of SDP collects the data according to a standardized procedure in order to perform repeatable and verifiable case studies that will benefit the body of knowledge. Thus, we aim to develop a rigorous systematic data collection plan that could be reused by other researchers. We also plan to quantify the main sources of bias. That kind of information would improve comparability between studies and generalization ability. Building a detailed data collection procedure and addressing all the possible issues is the first and crucial step in that process. Moreover, we believe the procedure should also be explained clearly enough to be applicable in industrial research as well as in academic that most often rely on open source software [8].

The paper is structured according to the guidelines given by Runeson and Höst [9] and Kitchenham et al. [10]. Section II puts our research into context and presents the related work. Section III explains in detail experimental planning where we organized the objective of our research into several research questions, presented the subject of the experiment and the means to perform it, defined the tasks that are going to be executed and methods how to do it, described the experiment design and prepared the analyzes and validation procedures that will enable us to answer the research questions. Section IV describes the execution of experiment. Finally, we present the results and answers to each research question in Section V and conclude the paper in Section VII.

II. BACKGROUND AND RELATED WORK

The importance of building a verifiable, repeatable and accurate data collection plan was recognized and put into several steps by Basili and Weiss [11]. Our research goal is to create most often used type of SDP datasets

using such a data collection plan. We analyzed all the 36 papers that were selected for final analysis in [1] because those were the ones that contained description of data collection procedure. However, we identified there is a lack of systematic unified mechanism in that area. There is a number of SDP studies that contain a section describing their data collection. However, there are no guidelines for reporting the crucial details of data collection process. Hence, it is not not performed systematically and one could not compare and quantify bias introduced with the data collection process.

Nevertheless, there were some attempts in that direction. A very good example of planned validation procedure can be found in [12]. They analyzed possible threats to validity, prepared and performed a manual check of a subset of potentially flawed data and evaluated the soundness and completeness of their data collection procedure. A detailed plan of analysis that should confirm the appropriateness of a novel approach for the data collection procedure in the phase of linking bugs to changes is present in [13]. They prepared a sort of benchmarking data set, manually collected and validated using observer triangulation. They named it "*the ground truth*" and used it to compare their novel approach to the traditional one in terms of precision, recall and F-measure evaluation metrics. We believe this approach should be used more often when introducing novel concepts because with the use of statistical tests of significance it could accelerate the diversification of true improvements. Confirmation to our statements comes from research presented in [14] that used the same "ground truth" data set and in [12] that even improved and enlarged such a data set. One commonly identified issue is the *bug linking* issue when collecting the data from two separated repositories of bugs and source code changes is addresed in [15]. The paper [16] identified the bug-feature bias and commit feature bias in defect datasets.

To the best of our knowledge, this is the first research intended to find all other issues present in the data collection procedure that could lead to biased software defect prediction datasets. We want to identify all the critical information that may be useful in comparison of different studies. It is important to be systematic because otherwise we could unintentionally include a source of bias and not be able to evaluate its impact. In our study we used students to manually collect the datasets and we draw conclusions from their data collection process. The similar approach is mentioned as in [16] but no systematic approach for the analysis of manually collected datasets is proposed. In this paper we conduct a systematic experiment which aims to identify all the traps in data collection process that lead to bias. In the remainder of the paper we refer to them as **issues**.

III. EXPERIMENTAL PLANNING

A. Research Goal

Our research goal is to create a systematic data collection procedure for SDP data sets that will enable us to develop automated data collection tool. To achieve this goal, we follow the process of data collection procedure development presented in Figure 1. This paper presents the first step of that process. Its purpose is to reveal and quantify all the issues that stand in the way of creating the data collection procedure, and to find the appropriate software metrics tool.

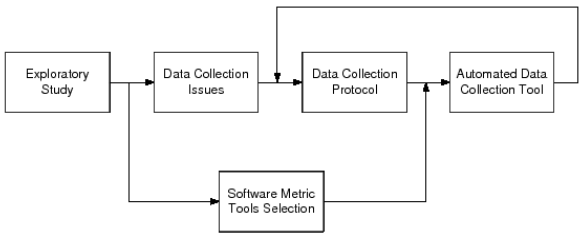

Figure 1. Research plan

B. Research Questions

Our research goal is divided into two research questions that will guide our exploratory study:

RQ1. Which issues affect the data collection procedure and how could they be overcome?

RQ2. Which software metrics tools are best suited for automatic collection?

Giving answer to **RQ1** is the primary purpose of this study. We hope to acquire as much experience and insight into the issues of data collection process as possible. Answering **RQ2** will help us develop an automated data collection tool. There is a number of software metrics (SM) tools present on the Internet and in related work so we need to review them and implement the ones that satisfy certain criteria.

C. Experimental Subjects

The participants that conduct the data collection are 12 students of the Faculty of Engineering at the University of Rijeka, Croatia, enlisted in the course of Software Engineering Management, obligatory in the first year of graduate Computer Science study program. This is an appropriate course because it teaches the students the importance of proper and accurate data in the decision making processes in the evolution of a large and complex software product. The participants had no previous experience with SM tools, little experience with bug repository use and mixed experience with source code management repositories. That is why they were all introduced to the concepts of these repositories in preparation exercises and seminars. Meanwhile, we omitted the fact that this is an exploratory study and that the observer triangulation is used.

D. Experimetnal Material

The main experimental material are: software development repositories, SM tools, and data collection forms. There are two **development repositories** crucial to the SDP data collection: the bug tracking (BT) repository and the source code management (SCM) repository. The Eclipse open source community is the most often used subject in SDP data collection so we used its largest projects in our experiment: JDT, PDE, Platform, BIRT and Mylyn. We use the term large projects for those that contain houndreds or thousands of

source code files and have been developed through at least a decade of evolution. The Eclipse community uses Bugzilla as its BT and GIT as its SCM repository. Bugzilla is a Web-based general-purpose bug tracker that allows developers to keep track of both defects that cause loss of functionality and requirements' requests. GIT is a distributed version control and source code management system with complete history and full version tracking capabilities. The **SM tools** are required in the second phase of our experiment for calculation of various product metrics. Further details are given in section IV-A. We use five **data collection forms** in the data collection procedure. Each form is prepared and explained in details for each of the tasks demanded from the participants to solve:

Form 1 is designed to collect the pieces of information from the BT repository: Bug ID, Product, Version, Summary (Full), Priority, Assignee, Number of Comments, Opened, Changed.

Form 2 is designed to document the bug-commit linking output: Bug ID, Found (yes/no), Commit ID.

Form 3 is designed to collect the pieces of information related to the linked files from the SCM repository: File path, Bug ID, Insertion, Deletion

Form 4 is designed to collect all the metrics obtained by SM tools both before and after the bug fix: File path, Product Metrics (m_1, m_2, ..., m_n).

Form 5 is designed as the final dataset form that containes all the metrics and the number of bugs for each file: File path, Metrics (m_1, m_2, ..., m_n), Number of bugs, Release.

E. Tasks and Methods

We need to perform several **tasks** to answer our research questions:

1. Examine the appropriateness of SM tools for our data collection procedure
2. Execute the data collection procedure manually and automatically
3. Analyze the collected data and examine the sources of bias

The first task gives us the answer to the **RQ2**. It needs to be done prior to data collection because it is an investigation of its own and the results are implemented in the second task. The manual execution of the data collection reduces initial researcher bias and gives insights into the issues that need to be addressed. Making the data collection precess automatic could reveal some additional issues. Furthermore, the manual and automatic data collection provide us with valuable data for evaluation of the issues and for answering the **RQ1**. In order to conduct all of these tasks, we use the following **methods**:

1. **Seminars** for reviewing the SM tools
2. **Written Instructions with Examples** for each step of the data collection procedure
3. **Data analysis and validation methods** of the results obtained during the experiment

The participants are given a preselected subset of the SM tools for reviewing and they are involved in the execution of data collection procedure. The authors of this paper perform the literature and Internet survey to locate all the SM tools, form a list of the most representative range of product metrics, find the candidate tools for further examination through seminars, plan the data collect procedure, prepare the written instructions and examples for each step of the data collection procedure, and determine the data analysis and validation techniques that we explain in more details in the following section.

F. Experimental Design

The manual collection is executed to identify all the issues present in our data collection process. The task scheduling is performed so that it allows a validation of the performance of different SM tools and the data itself early enough to enable timely corrective action on data collection procedure. Since participants could be the source of bias as well, we assign each project and each tool to more than one participant, i.e. following the principle of observer triangulation [13]. The participants are given personalized tasks in 4 exercises with 52 steps and explained by 21 screen-shot figures. The data collection procedure is divided into several phases. Each phase, along with its issues is presented in Figure 2. We describe them in more details and give a proposition how to solve them in the remainder of this subsection.

SM Tool Selection: The initial phase is to select the SM tools for collection of software metrics that represent the independent variables in SDP. Since we decided to analyze Eclipse projects and collect the most often used software metrics, the tool needs to be able to analyze large projects written in java and give reports for calculated software product metrics on file or class level of granularity.

Issue 1.1 The SM tools requirements are:

1. **Availability of tool** - for in-use testing
2. **Programming language** – java
3. **Level of granularity** – file / class level
4. **Software metrics** – product metrics
5. **Usability - input** – capable for large projects
6. **Usability - output** – *csv*, *html* or *xml* reports

Project Selection: The initial phase also needs to select the open source project that will be the source of SDP data set. The issues that affect this initial phase are:

Issue 2.1 The project needs to be present both in the BT and in the SCM repository

Issue 2.2 The project's releases from BT must be present as release tags in SCM repository

The presented issues are rather self-explanatory. We need to be able to access the source code, the bugs and the corresponding releases in both repositories. We evaluate these issues by choosing a great number of projects from the chosen Eclipse community, and analyze which projects contain release designations in both repositrories.

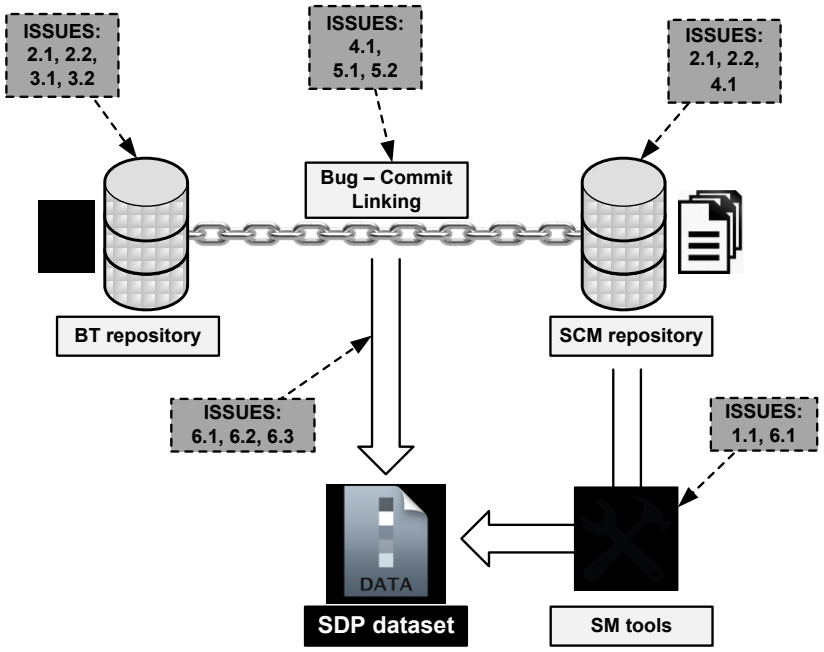

Figure 2. The impact of identified issues on each data collection phase

Bug Repository Collection: The first data collection phase is to find defects from the Bugzilla repository and collect all the valuable pieces of information.

Issue 3.1 The bug must be relevant to SDP
Issue 3.2 The bug should be solved

BT repositories typically store bugs and enhancements. Furhteremore, bugs may relate to minor typographical errors. The bugs relevant to SDP are the ones that represent a loss of functionality which is indicated by severity level above trivial. Since we need to linking the bug to source code, the bugs need to be solved in order to be present in the commits from the SCM repository. A BT tabular report, as presented in **From 1**, for all releases of each project is required with following parameters:

- Bug Status: resolved, verified and closed
- Bug Resolution: fixed
- Bug Severity: blocker, critical, major, normal and minor

This way we bypass all the unconfirmed, invalid or duplicated defects, defects that are not solved or that could not be solved and requirement requests.

We evaluate the impact of these issues by comparing the number of bugs that satisfy our parameters to the number of bugs that satisfy opposite parameters (Bug Status: unconfirmed, new, assigned and reopened; Bug resolition: invalid, wontfix, duplicate, worksforme, moved and not_eclipse; Bug severity: enhancement, and trivial).

SCM Repository Collection: The second data collection phase is to find the SCM repository for the chosen project in GIT. We need stable releases of the project for future analysis of software metrics. If issues 2.1 and 2.2 are both satisfied, there remains only one issue, related mostly to large projects and we evaluate it by counting the number of such projects.

Issue 4.1 The project may be divided into several sub-repositories within the foundation's top level GIT repository

Bug - Commit Linking: The most important data collection phase is to link the BT and SCM repositories because it yields the number of defects per software module. Every source code change is stored within commits and each commit has the developers description of the change within a message. The linking is done by searching the Bug ID in the commit message. We use **Form 2** to record successful linking.

Issue 5.1 The Bug ID number may be a part of larger block of characters
Issue 5.2 The Bug ID may be present in more than one commit

The issue of varying length of the Bug ID presents an obstacle to automatic data collection. It is important to search for the exact match of the Bug ID. We evaluate its impact by calculating the percentage of the Bug IDs we can link with the simple search and the strict search we mentioned. The second issue is because of the nature of complex bugs that require a lot of change, possibly in different subrepositories, and because of the loose development rules in the community. We evaluate it by comparing the number of linked commits and the number of bugs.

Source Code Analysis: This phase consists of calculating the product metrics of all the source code files in each release of the chosen project. The SM tools are used for that purpose. All the product metrics obtained by these tools are collected in **Form 4**.

SDP Dataset Generation: The final phase of our data collection procedure is to construct the final SDP dataset in the **Form 5**, combining the output of the previous two phases.

Issue 6.1 The file identifier needs to be unique for the *Source Code Analysis* and the *Bug - Commit Linking*
Issue 6.2 File – Bug cardinality is many-to-many
Issue 6.3 Single file can be changed in multiple commits that are linked to one bug

The unique identifier of any file present in one release is its *File Path*. In order to cope with issue 6.1, the file path was extracted from commits in the same way it was extracted in the output of SM tools. Neglecting this issue would make it very difficult to connect the previous two phases. Due to issue 6.2 and 6.3, we count the number of distinct *File Path* and *Bug ID* (FB) ordered pairs in **Form 3**. To evaluate the potential impact of issue 6.2, we compare the number of FB pairs with the number of linked files and bugs. The impact of issue 6.3 will be evaluated through the number of FB duplicates.

IV. RESULTS

The literature and Internet survey found 35 SM tools (12 from [8] and additional 23 from the Internet search) and we analyzed them all. The tools were compared against demands presented in subsection III-F. In the first stage, we analyzed the tool descriptions. In the second stage, we anylzed the remaining tools more thoroughly in usage on a sample project through participants' seminars. In the third stage, we tested the tools in large scale manual data collection. 19 tools passed the first review stage, 5 tools passed the second and only 2 remained in the end. Here is a full list of tools we analyzed: iPLASMA, inFusion, inCode, CodeCover, JavaNCSS, ckjm, Understand, Borland Together, CodeSonar Static Analysis Tool, CodePRO Analytix, Metrics 1.3.8, Moose, JavaMetrics, Testwell CMT ++ (CMTJava), JDepend, Dependency Finder, JarAnalizer, CCCC, Source Code Metrics, Classycle, Sonar, Resource Standard Metrics, Jhawk, Jtest, SonarGraph, PMD, JDiff, CodeCount, LocMetrics, CodeAnalyzer, JMT, Jmetric, ES2, Xradar, Essential Metrics. Table 1 presents 7 categories of disqualifying factors we applied and the number of tools reject due to each of them.

The tools that were tested in use are: CodePRO Analytix, Metrics 1.3.8, Source Code Metrics, Jhawk and LocMetrics. Metrics 1.3.8. required projects to be built and Source Code Metrics required the restart of NetBeans for each following analysis. A great number of analyses dictated to exclude these two tools. We did not manage to automate the Code PRO Analytix and since it was incapable of analyzing whole project releases it was discarted as well. The LOC Metrics[1] proved to be a fast tool offering a sample of 10 simple product metrics and the JHawk[2] enriched the set of metrics with additional 40. The complete set of software product metrics provided by these two tools is wider than in any other related study.

TABLE I. SM TOOLS REVIEW - ISSUE 1.1

Requirement	*Important characteristics*	*Rejection rate*
1	Availability of tool	5
2	Programming language - java	0
3	Level of granularity - files	7
4	Software metrics - product - too few metrics	4 4
5	Usability - large input	3
6	Usability - output reports	1
7	Other - older version of another Other - not a tool, a platform Other - trial version too limited	2 2 2

The evaluation of data collection issues is presented in tables 2, 3, 4, 5 and 6. Table 2 reveals that not all of the Eclipse projects are present in the GIT repository. We analyzed 85 different Eclipse projects from BT repository. We found 76 of them in SCM repository, indicating that the issue 2.1 is rarely present. Furtheremore, for 51 projects we managed to find release tags in SCM that correspond to release numbers from BT. It shows the naming convention of releases are not always consistent and that issue 2.2 could impact greater number of projects. Finally, we found that 37 projects are distributed in more than one sub-repository, showing that it is important to be aware of issue 4.1. Table 3 presents the importance of choosing the appropriate parameters while searching for bugs in the BT repository. We compare the number of bugs collected by Our parameters (subsection III-F-Bug repository collection) and by other parameters. We can expect a completely different SDP dataset if we do not limit the *Bug Resolution* to fixed only. On the other hand, bugs with incomplete data (expected by **Form 1**) are rare and could cause insignificant bias. The inclusion of bugs of opposite severity may cause from 10% - 15% bias in the number of bugs. For the Mylyn project, the bias rises to 45%. Table 4 demonstrates the need for a precise search criterion for establishing the bug - commit links. A great number of incorrectly linked bugs may occur if we simply search for the Bug ID as a series of digits (Simple Search) and not defining its surrounding characters (Strict search). The bias in the linking rate from 7% - 40% proves issue 5.1 to be very important. Table 5 reveals that a single bug ID may be linked to more than one commit and that it is highly important to be aware of issue 5.2. Table 6 reveals that the number of FB pairs is much greater than the number of files that were linked to bugs, proving that the majority of bugs is located in a smaller part of the software. We also notice that the number of linked files can be both greater (PDE, BIRT, Mylyn) or lower (JDT, Platform) than the number of linked bugs, proving that issue 6.2 needs to be taken into account. The number of FB pair duplicates is presented in table 7. We performed additional manual root cause analysis of a subset of FB duplicates. We discovered that some FB pairs even occurred more than twice and their cause was:

TABLE II. EVALUATION - ISSUES 2.1, 2.2 AND 4.1

Demand	*Important characteristics*	*Acceptance rate*
-	Total projects analyzed	85
1	Present in BR and SCM repository	76
2	Corresponding release tags	51
3	>1 SCM subrepository	37

TABLE III. EVALUATION - ISSUES 3.1, AND 3.2

Bug requirement	**Number of bugs per project**				
	JDT	***PDE***	***Platform***	***BIRT***	***Mylyn***
Our paramaters	20353	7318	38511	13071	3492
Opposite severity	2875	895	4604	1243	1581
Opposite status	0	0	0	0	0
Opposite resolution	16488	3570	32582	3059	1909
Incomplete bug data	64	26	108	7	1

TABLE IV. EVALUATION - ISSUE 5.1

Linking Technique	**Linking rate per project**				
	JDT	***PDE***	***Platform***	***BIRT***	***Mylyn***
Bugs:	18696	6822	34641	8101	2739
Simple Search:	80.5%	65.8%	80.7%	59.8%	52.3%
Strict Search:	72.0%	58.6%	71.2%	18.9%	16.1%

• There are both a bug test and a bug fix reported for the same FB pair

• There are 2 bug fixing commits reported in the SCM for the same FB pair

• There had been reported one or two temporary bug fixes before the final bug fix was reported

• There are both a bug fix and a revert bug fix reported for the same FB pair

All the reasons we found show us that only the final bug fixing commit should be regarded as relevant

V. THREATS TO VALIDITY

There are two major threats to validity to our experiment: the specificity of data (only several largest Eclipse projects written in java stored in Bugzilla and GIT) and the possibility of human error from the participants. However, observer triangulation and the partial automation of the process reduced this the human error influence and most recent experiments showed the procedure can be also successfully used for other projects from other foundations, like Mozilla or Apache. In contrast to usual data collection procedures, we welcomed the differences in collected data from different participants because those were indicators of issues we need to address.

VI. CONLUSION

The goal of this exploratory research was to identify as many issues that may cause bias in the SDP data collection procedure. Our survey of related research and other sources in this area available on the Internet resulted in a preliminary data collection protocol. That protocol, along with detailed descriptions was given to 12 participants of our experiment and they were assigned 5 major Eclipse projects. Their output data was then analyzed and validated through a number of metrics and manual inspections.

TABLE V. EVALUATION - ISSUE 5.2

Number of	**Multiple bug-commit links per project**				
	JDT	***PDE***	***Platform***	***BIRT***	***Mylyn***
Bugs linked:	13468	3995	24663	1532	441
Commits linked:	17667	7573	29669	2127	3002

TABLE VI. EVALUATION - ISSUE 6.2

Number of	**Multiple file-bug links per project**				
	JDT	***PDE***	***Platform***	***BIRT***	***Mylyn***
Bugs linked:	13468	3995	24663	1532	441
Files linked:	12080	6629	15084	4273	975
Bug-file links:	25476	16595	23784	6663	1258

TABLE VII. EVALUATION - ISSUE 6.3

Number of	**Duplicated file-bug links per project**				
	JDT	***PDE***	***Platform***	***BIRT***	***Mylyn***
FB duplicates:	768	1233	903	4	0

As an answer to our **RQ1,** we identified and quantified several important issues that may become a significant source of bias in the SDP dataset. The collection starts with the choice of proper open source projects that contain their data in the BT and the SCM repositories. Some larger projects contain several SCM subrepositories. Relevant bugs are the resolved, verified and closed ones with the resolution fixed and severity level above trivial because SDP requires only those that caused a loss in functionality. Linking between bugs and commits must be done in a carefully defined strict manner because otherwise we might obtain bias in linking rate. Multiple links between bugs and commits (i.e. files) and duplicated file-bug links can be expected. We also answered our **RQ2**. After we thoroughly analyzed 35 SM tools, we identified *LOC Metrics* and *JHawk* as the most appropriate for our automatic data collection tool [17]. These two SM tools provide us with a respectable subset of 50 product metrics and are suitable for automating the data collection process.

Finally we find evidence that human error is widely present in development repositories. Allthough the Bug ID is a unique identifier of a software defect, it cannot be always linked to the commit that made it fixed. Therefore, a certain number of bugs remains untraceable and becomes an issue in the phase of determining the non-fault-prone files as well as the fault-prone ones. However, there are indications that some versions suffer a lot less from this problem and a more detailed analysis is intended for our future work.

ACKNOWLEDGMENT

The work presented in this paper is supported by the University of Rijeka research grant Grant 13.09.2.2.16.

Trendovi u izgradnji podatkovnih centara u Hrvatskoj

Marko Galac*, Davorin Valenčić **
* Combis d.o.o./Sektor mrežne infrastrukture i povezivanja, Zagreb, Hrvatska
** Veleučilište Velika Gorica/Velika Gorica, Hrvatska
Marko.galac@combis.hr , davorin_valencic@yahoo.com

Sažetak – Izgradnja standardnih podatkovnih centra (engl. Data Center), gdje smatramo podatkovne centre u fiksnim objektima postala je na nekim način standard današnjeg vremena. U posljednjih nekoliko godina pojavljuje se trend izgradnje mobilnih ili modularnih podatkovnih centara. To su podatkovni centri (najčešće u kontejnerskoj izvedbi) gdje korisnik u jednoj „kutiji“ dobije kompletan podatkovni centar s ugrađenim svim potrebnim sustavima . Upravo iz razloga što je podatkovni centar malih dimenzija, vrijeme planiranja i izgradnje je svedeno na minimum te postoji mogućnost preseljenja na novu lokaciju kroz period eksploatacije. Uz sve ove prednosti, ovaj tip podatkovnih centara u potpunosti teži smjeru „zelene“ tehnološke infrastrukture. U ovom članku su prikazani trendovi u izgradnji podatkovnih centara, s osvrtom na trenutno stanje u Hrvatskoj..

I. UVOD

Računala u današnjim vremenima više nisu nešto što je dobro imati i koristiti, već su postala potreba. Aplikacije i korisnički programi koje koriste gotovo sve organizacije za vođenje svog poslovanja ili pružanje usluga korisnicima, svakim danom su sve zahtjevniji po pitanju računalnih resursa najviše u smislu procesorske snage i memorije. Također pojavljuje se potreba za maksimalnom mogućom dostupnosti računala, odnosno računalnog sustava, kako ne bi došlo do narušavanja produktivnosti organizacije. Nedostupnost računalnog sustava, ne samo kod profitabilnih organizacija, može uzrokovati velike gubitke. Primjerice nedostupnost sustava neke od službi za pomoć unesrećenima u nekoj od situacija može uzrokovati velike materijalne a i ljudske gubitke. Kod profitabilnih organizacija, poput banaka, pružatelja Internet servisa, telekom operatera gubitci se mjere u velikim svotama novca. Sukladno gore navedenim rizicima većina organizacija odlučuje investirati u dodatne mehanizme koji štite njihove računalne sustave od rušenja odnosno nedostupnosti istih.

Jedan od mehanizama za osiguranje i podizanje razine dostupnosti sustava je izgradnja podatkovnog centra. Podatkovni centar je prostor sa kontroliranim parametrima u koje se smještaju računalni sustavi, sustavi za pohranu podataka i ostala ključna komunikacijska oprema. Prostor podatkovnog centra u objedinjuje nekoliko sustava kako bi se postiglo optimalno i u potpunosti kontrolirano okruženje za rad računalnih sustava. Neke organizacije zbog svojih potreba, investiraju u izgradnju redundantnog podatkovnog centra, što je zapravo najčešće replikacija primarnog podatkovnog centra smještena na nekoj drugoj lokaciji.

U posljednje vrijeme pored izgradnje klasičnih podatkovnih centara, koji se izgrađuju u postojećim prostorima ili se grade zasebni objekti za podatkovni centar, sve veću primjenu nalaze mobilni i modularni podatkovni centri koji su svoju primjenu do sada nalazili najčešće u vojnim organizacijama ili u organizacijama za upravljanje u kriznim uvjetima.

A. *Prednosti novih trendova*

Prednost pristupa izgradnje modularnih i/ili mobilnih podatkovnih centara je prvenstveno rok za izgradnje. Kod dosada, standardnog pristupa, izgradnji, potrebno je ishođenje velike količine dokumentacije za što je u često bilo potrebno više vremena no što je potrebno za samu izgradnju podatkovnog centra.

Pored kratkog roka izgradnje, predefinirana i unaprijed standardizirana rješenja modularnih/mobilnih podatkovnih centara omogućuju organizaciji kvalitetno planiranje, financiranje i izračun povrata investicije takvog projekta.

II. POJAM PODATKOVNOG CENTRA

Pod pojmom podatkovni centar (engl. Data center), kako je već u uvodu spomenuto smatramo posebno izgrađen objekt ili posebno uređenu prostoriju unutar objekta koja je namijenjena za smještaj ključnih računalnih sustava, uređaja za pohranu podataka (eng. storage) te ključne komunikacijske opreme, poput preklopnika, usmjerivača (eng. router) te sličnih uređaja. Unutar podatkovnog centra oprema se smješta u za to posebno dizajnirane ormare (eng. rack), i to prema ranije definiranom rasporedu kako bi se osigurao dovoljan kapacitet hlađenja i napajanja električnom energijom. Za postizanje visokog nivoa dostupnosti podatkovnog centra sustavi hlađenja i napajanja , kao jedni od ključnih komponenata, izvode se u redundantnoj opciji kako bi se osigurao kontinuitet rada u slučaju kvara ili redovitog servisa jednog od sustava.

Podatkovni centar možemo podijeliti na nekoliko osnovnih elemenata [1]:

- Izvori napajanja;
- Sustavi hlađenja;

Ovaj rad je podržan od Veleučilišta Velika Gorica, Velika Gorica, Hrvatska i tvrtke Combis d.o.o., Zagreb, Hrvatska.

- Komunikacijska instalacija (komunikacijski kabeli);
- Zaštita prostora (sustavi automatskog gašenja, sustavi vatrodojave, sustavi tehničke zaštite, sigurne sobe – IT kavezi);
- Sustav nadzora.

Svaki od ovih sustava dodatno možemo dodatno podijeliti na vrste i tipove.

A. Povijest podatkovnih centara

Podatkovni centri počeli su se razvijati još u rano doba računalne industrije. Tadašnja računala (mainframe) bila su velikih dimenzija te je za njihov smještaj bilo potrebno osigurati zasebne prostorije. Paralelno sa time računala su zahtijevala posebne uvjete za rad, poput rashladnih sustava i velike količine električne energije. Povezivanje tadašnjih računalnih komponenti zahtijevalo je velike količine kabela. Zbog takvih zahtjeva pojavila se potreba za razvijem metoda organizacije smještaja računalnih komponenti unutar tog posebno namijenjenog prostora. Tada se počinju dizajnirati postolja za smještaj računalnih komponenti, prethodnica današnjih serverskih ormara, dizajnirani su podignuti podovi, danas poznati kao tehnički pod, kako bi se omogućilo polaganje kabela ispod razine poda te su razvijani posebni sustavi napajanja i hlađenja koji su mogli zadovoljiti zahtjeve tadašnjih računala [2].

Kroz godine računala su se počela razvijati, postajala su dostupnija te je upotreba postaja sve raširenija, posebno u većim organizacijama koje su ih koristile za svoje poslovanje. Razvojem novih tehnologija računalni sustavi postajali su sve složeniji i sve veći, te su i organizacije počele pridavati sve veći značaj kontroliranoj okolini u kojima ti sustavi rade.

Osamdesetih i devedesetih godina u primjeni se sve više pojavljuju klijent-poslužitelj arhitektura. Poslužitelji polako zamjenjuju stara računala u tim prostorima. Tada se počinje koristiti pojam podatkovni centar, za posebno namijenjen prostor sa zadovoljavajućom infrastrukturom u kojoj je smještena oprema za centraliziranu obradu i pohranu podataka [2].

Devedesetih godina počinje ubrzan razvoj informatičkih tehnologija, raste potreba za brzim pristupom podatcima te pristupu Internetu. Organizacije koriste računalne sustave za upravljanje poslovanjem, pružanje usluga svojim korisnicima. Sve to zahtjeva stabilan računalni sustav jer on postaje veoma važna komponenta koja osigurava sigurno poslovanje organizacija. S obzirom da uređenje takvih prostora i investicija u snažne računalne sustave zahtjeva znatnu financijski izdatak, manje organizacije nisu bile u mogućnosti izgraditi vlastite podatkovne centre, i tada se pojavljuje se pojam kolokacija (engl. collocation), što podrazumijeva najam prostora u podatkovnom centru. Kolokacijom smatramo najam određenog dijela prostora u podatkovnom centru za smještaj korisničke opreme (serverski ormari u koje se potom smješta oprema) ili čak najam prostora unutar serverskog ormara za smještaj jednog ili više servera korisnika. U današnje vrijeme veće organizacije grade podatkovne centre koji isključivo imaju takvu namjenu. U Hrvatskoj postoji nekoliko takvih podatkovnih centara a neki od primjera su HT-Hrvatski Telekom DC Selska, podatkovni centar Križ - Data Cross u Jastrebarskom pored Zagreba te Altus IT.

B. Standardi i klasifikacija podatkovnih centara

Jedan od najčešće korištenih standarda za podatkovne centre je standard TIA-942 kojim su specificirani osnovni zahtjevi u dizanju podatkovnih centara. Standard je donesen od strane TIA – *Telecommunications Industry Association*. TIA organizacija akreditirana je od strane američkog nacionalnog instituta za standarde (eng. *ANSI - American National Standards Institute*) za razvoj standarda koji se temelje na industrijskim standardima, a za široku paletu informacijskih i komunikacijskih tehnologija (ICT tehnologija). Uvođenjem standarda za dizajn i izgradnju podatkovnih centara uvelike je olakšan posao projektantima koji su prije standardizacije nailazili na probleme poput nekompatibilnosti opreme zbog različitih pristupa ili zahtjeva pojedinih investitora.

Sam standard definira ključne elemente podatkovnog centra:

- kvalitativne detalje prostora i dizajn objekta/prostora,
- kabelsku (komunikacijsku) infrastrukturu,
- energiju (sustave napajanja i sustave hlađenja) i
- utjecaj na okoliš.

Paralelno sa TIA-942 standardima podatkovni centri klasificiraju se i prema Tier klasifikaciji, a zavisno o arhitekturi izvedbe i dostupnosti podatkovnog centra. Uptime Institute definirao je Tier Classification System kako bi konstantno mogao kvalificirati podatkovne centre u smislu instaliranih performansi pojedinih sustava, odnosno infrastrukture, kao i njihovu dostupnost [3].

Osim spomenute Tier certifikacije, Uptime Institut dodjeljuje i takozvani certifikat operativne održivosti čiji je cilj upravljanje, poslovanje i održavanje podatkovnog centra a nije temeljen na njegovom dizajnu sustava. Operativna održivost utvrđuje ponašanja i rizike izvan sustava Tier klasifikacije (I, II, III, IV) koji utječu na dugoročnu učinkovitost podatkovnog centra. U pojednostavljenom smislu to je poveznica između upravljanja i Tier funkcionalnosti infrastrukture podatkovnog centra. Tri glavna elementa certifikacije operativne održivosti su [3]:

- Upravljanje i operacije (npr. prisutnost osoblja na lokaciji, kadrovska osposobljenost, programi održavanja);
- Karakteristike izgradnje (npr. dodatni sustav neprekidnog napajanja - UPS);
- Lokacija podatkovnog centra (npr. opasnost od poplave, transportni koridori);

Certifikacija operativne održivosti izdaje se u tri razine [3]:

- Gold – iskorišten potpun potencijal za neprekidan rad infrastrukture ili su čak i pojačani pojedini dijelovi infrastrukture;
- Silver – postoje mogućnosti za poboljšanje da bi se postigao puni potencijal instalirane infrastrukture;
- Bronze – postoje značajne mogućnosti za poboljšanje da bi se postigao puni potencijal instalirane infrastrukture.

Samim time certifikat operativne održivosti postaje dodatak na Tier klasifikaciju podatkovnog centra.

C. Tier klasifikacija

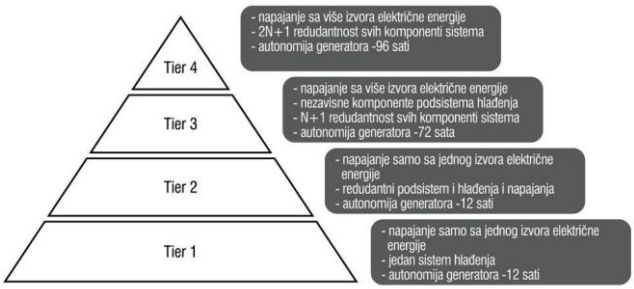
Tier klasifikacija je standardizirana metodologija koja određuje dostupnost (engl. availability) podatkovnog centra, a ujedno omogućuje investitoru da na temelju nje izrađuje proračune povrata investicije te performansi podatkovnog centra. Postoje dvije metodologije standardizacije koje se koriste, a to su [3]:

- Tier certifikacija izvedbene dokumentacije i
- Tier certifikacija izgrađenog podatkovnog centra.

Može doći do pitanja zašto postoje dvije standardizacijske forme po kojima se vrši certifikacija, ako se podatkovni centar gradi sukladno izvedbenoj dokumentaciji. Odgovor je veoma jednostavan i praktičan. Prilikom izrade izvedbene dokumentacije nemamo uvid u sve potencijalne izazove s kojima se možemo sresti na lokaciji izgradnje podatkovnog centra. Ukoliko se pojavi potreba zbog nekog ranije nepoznatog izazova, potrebno je izvršiti preinake na sustavima prilikom izgradnje i tada nastaje odstupanje od izvedbene dokumentacije i procjena na temelju izvedbene dokumentacije više nije vjerodostojna.

Tier certifikacija koja se odnosi topologiju infrastrukture podatkovnog centra podijeljena je u četiri razine, odnosno četiri nivoa dostupnosti [3]:

- Tier 1 – dostupnost iznosi 99,671% na godišnjoj razini, odnosno do maksimalno 28,8 sati godišnje neraspoloživosti, i ne postoji redundancija sustava.
- Tier 2 – dostupnost iznosi 99.741% na godišnjoj razini, odnosno do maksimalno 22 sata godišnje neraspoloživosti, a redundancija sustava je N+1.
- Tier 3 – dostupnost iznosi 99,982% na godišnjoj razini, odnosno do maksimalno 1,6 sati godišnje neraspoloživosti, a redundancija sustava je N+1 ili N+2.
- Tier 4 – dostupnost iznosi 99,995% na godišnjoj razini, odnosno sustav ne smije biti neraspoloživ duže od 0,4 sata godišnje, a redundancija sustava je 2N+1; 2N+2, …



Slika 1. Tier klasifikacija [9]

Pojmom redundancije (engl. redundancy) sustava smatramo sustave koji se instaliraju pored tj. paralelno sa primarnim sustavom a u cilju osiguranja dostupnosti tog sustava kao dijela infrastrukture podatkovnog centra. Postoji nekoliko modela redundancije od koji se u podatkovnim centrima koriste najčešće modeli [3]:

- 2N – redundantni model koji osigurava da svaka komponenta sustava ima rezervu (engl. backup) kako bi se postigao efekt što manje vjerojatnosti pada sustava, odnosno nema SPoF (engl. no single point of failure) točke.
- Need+1 odnosno koncept redundancije gdje je kapacitet konfiguriran da uključuje kapacitet koji se koristi, ali da postoji i rezervni koji se uključuje u slučaju pada primarnog kapaciteta.
- Need+2 odnosno koncept redundancije gdje je kapacitet konfiguriran da uključuje kapacitet koji se koristi, ali da postoje 2 rezervna koji se uključujuća u slučaju pada primarnog kapaciteta ili se treći uključuje u slučaju pada prva dva

U praksi se još mogu pronaći konfiguracije sustava koje se izvode kombinacijom nekih od gore navedenih modela.

III. OSNOVNI ELEMENTI PODATKOVNOG CENTRA

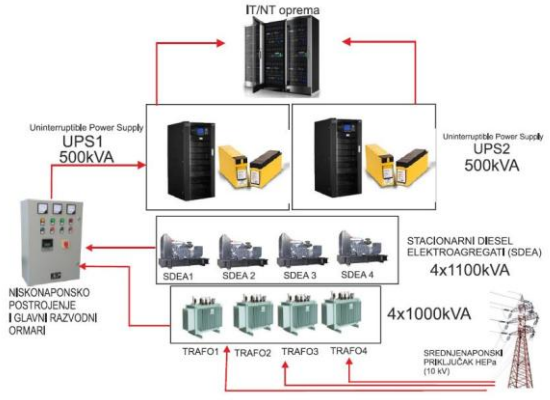
A. Sustavi napajanja

Sustav napajanja jedan je od najkritičnijih elemenata podatkovnog centra. Ispad sustava napajanja trenutačno uzrokuje prekid rada svih sustava podatkovnog centra što ima za posljedicu nedostupnost podataka, korisničkih servisa te samim time uzrokuje velike gubite u financijskom smislu. Kako bi se izbjegao takav scenarij sustavi napajanja se izvode na način da se osigura primarni i sekundarni izvor napajanja.

Primarni izvori napajanja su sustavi napajanja preko javne energetske mreže. Sukladno Tier standardima za Tier 3 i Tier 4 klasifikaciju potrebno je osigurati minimalno dva neovisna izvora napajanja sa javne energetske mreže. Primarni izvor napajanja sastoji se od srednje naponskog priključka, transformatorskog postrojenja, nisko naponskog postrojenja te glavnog razvodnog ormara u kojem se spajaju primarni i sekundarni izvori napajanja te se iz istog izvodi energetski razvod unutar podatkovnog centra.

Sekundarni izvori napajanja su sustavi napajanja neovisni o javnoj energetskoj mreži i služe kao izvori napajanja u slučaju pada odnosno nedostupnosti primarnog izvora napajanja. U sekundarne izvore napajanja svrstavamo diesel elektro agregate te potencijalno neke od alternativnih izvora napajanja. Neprekidni izvori napajanja (engl. uninterruptable power supply - UPS) također mogu biti uvršteni u sekundarne izvore napajanja iako u pravilu oni služe kao premosnica prilikom ispada primarnog izvora napajanja do uključenja sekundarnog izvora napajanja i tu imaju ključnu ulogu. U pojednostavljenoj verziji procesa, prilikom ispada primarnog izvora napajanja, sustav dojavljuje nadzornom sustavu alarm koji potom uključuje diesel eletro agregate kojima je potrebno neko određeno vrijeme da bi se sinkronizirali i pustili napajanje u energetsku mrežu podatkovnog centra. Upravu u tom trenutku neprekidno napajanje ima ključnu funkciju da premosti taj period tj. da oprema radi na izvoru napajanja iz uređaja za neprekidno napajanje. Kada se sinkroniziraju agregati i puste napajanje u mrežu, neprekidno napajanje prima signal da se pojavio izvor napajanja na njegovom ulazu i vraća se u čekanje i puni baterije za eventualni novi ispad.

Snaga diesel elektro agregata i sustava neprekidnog napajanje definira se sukladno maksimalnom očekivanom kapacitetu podatkovnog centra. Jedan od najčešćih pristupa u izgradnji podatkovnog centra da se izgradnja ovih sustava radi u dvije faze, gdje se u prvoj fazi instalira potreban kapacitet koji će biti instaliran u nekom skorijem periodu, a druga faza se pokreće kada je kapacitet ugrađen u prvoj fazi na 75 – 80 % iskorištenosti. U Tier klasifikaciji definirano je i vrijeme autonomije rada na sekundarnom izvoru napajanja. Prema Tier standardima spremnici goriva za agregate moraju imati spremnike goriva za minimalno 12 sati rada pod punim opterećenjem.



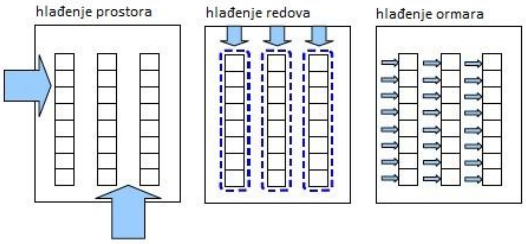
Slika 2. Blok shema sustava napajanja podatkovnog centra [7]

B. *Sustavi hlađenja*

Sustavi hlađenja podatkovnog centra također su jedan kritičnih dijelova infrastrukture podatkovnog centra. Namjena im je održavanje optimalnih uvjeta za rad računalne i komunikacijske opreme unutar podatkovnog centa. Optimalni uvjeti za rad opreme su između 16º C i 24ºC te relativne vlažnosti zraka između 40% i 55 %. U slučaju ispada sustava hlađenja dolazi do brzog porasta temperature u prostoru gdje je smještena oprema te postoji opasnost od pregrijavanja opreme i samim time kvara na istoj. Drugi parametar koji može uzrokovati kvarove na opremi je relativna vlažnost zraka, jer u slučaju prevelike vlažnosti zraka pojavljuje se kondenzat koji može uzrokovati kratki spoj na opremi, a u slučaju preniske vlažnosti zraka moguća je pojava statičkog elektriciteta koji također može uništiti ili značajno oštetiti opremu [2]. Svi ti potencijalni rizici moraju biti svedeni na najmanju moguću mjeru, pa se sukladno tome pridaje velika pažnja sustavima hlađenja. Kako bi bili sigurni da će sustav hlađenja biti dostupan u svakome trenutku, preporuka je da se spoje na način da imaju napajanje sa primanog i sekundarnog izvora napajanja. Naravno da redundancija ovog sustava nije opcija nego nešto je obavezno.

Sustave hlađenja možemo pojednostavnjeno podijeliti na vanjske i unutarnje jedinice , a međusobno spojene čine jedan sustav. Vanjske jedinice su najčešće veliki hladnjaci (engl. chiller), što su uređaji koji služe za hlađenje rashladnog medija koji se potom šalje kroz sustav cijevi u unutarnje jedinice koje hlade zrak u prostoru. Rashladni medij može biti voda, glikol ili plin, najčešće freon.

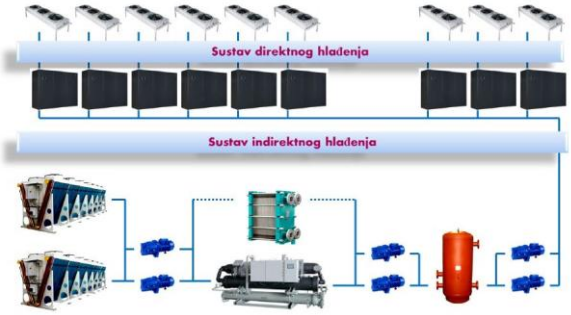
Unutrašnje hlađenje podatkovnog centra može se izvesti na nekoliko načina. U praksi najčešći pristupi u izvedbi su hlađenje prostora (eng. room based cooling), hlađenje između redova ormara u kojima je smještena oprema (eng. row based cooling) ili hlađenje pojedinog ormara (eng. rack based cooling)



Slika 3. Načini hlađenja prostora podatkovnog centra [4]

Unutarnje jedinice također mogu biti izvedene u nekoliko oblika, a najčešće su to CRAC sustav ili InLine/InRow sustav. CRAC sustav upuhuje hladan zrak direktno u prostor ili u prostor ispod tehničkog poda u podatkovnom centru, te na taj način stvara tlačnu komoru i hladan zrak izlazi ispred ormara u kojima je smještena oprema kroz izstrujne ploče u podu. InLine/InRow izvodi se na način da se klima jedinice smještaju između ormara u kojima je oprema te hladan zrak ispuhuju ispred same opreme. Kod ovog sustava postoji nekoliko opcija načina ispuhivanja hladnog zraka prema opremi ali generalno princip rada je isti.

Za postizanje veće efikasnost rada sustava oprema se zatvara u takozvane hladne zone, čime se smanjuje volumen prostora koji je potrebno hladiti.



Slika 4. Blok shema sustava hlađenja podatkovnog centra [7]

C. *Komunikacijska infrastruktura*

Komunikacijska infrastruktura obuhvaća sve potrebne bakrene i svjetlovodne kabele koji su potrebni za komunikaciju između opreme, senzora, mjerača ili drugih elemenata unutar podatkovnog centra. Kabelsku infrastrukturu možemo podijeliti na pristupne komunikacijske sustave te sustave vertikalnog i horizontalnog kabliranja.

Pristupna kabelska infrastruktura obuhvaća, najčešće mono modne svjetlovodne kabele, koji se koriste za povezivanje podatkovnog centra sa udaljenom lokacijom korisnika, redundantnim podatkovnim centrom (DR site[1]) ili za pristup Internetu. Za povezivanje udaljenih lokacija najčešće se koristi dark fiber, odnosno iznajmljena ili vlastita svjetlovodna veza koja se koristi isključivo za promet podataka. Za povezivanje na Internet infrastrukturu podatkovni centar se spaja na mrežu pružatelja usluge ili direktno na neko od čvorišta u Europi.

Sustavi vertikalnog i horizontalnog kabliranja obuhvaćaju lokanu pasivnu komunikacijsku infrastrukturu koja je namijenjena komunikaciji unutar podatkovnog centra, komunikaciji između ormara (međuveze) i povezivanje korisničkih računala. Za ovaj sustav najčešće se koriste više modna optička vlakna OM3 ili OM4 karakteristika, te bakreni kabeli (UTP ili STP) kategorije 6A ili 7.

OM3 i OM4 karakteristika svjetlovodnih kabela je standardom definirana karakteristika svjetlovodnog kabela a odnosi se na brzinu prijenosa podataka i propusnost (eng. bandwith). Konkretno za OM3 brzina prijenosa je do 10 Gbps na udaljenosti do 600 m. Za povezivanje komunikacijskih ormara (vertikalno kabliranje) i horizontalno kabliranje koriste se kabeli kategorije 6A ili kategorije 7. Brzina prijenosa je do 10 Gbps propusnost 500 MHz za Cat.6A, 600MHz za Cat.7. Kategorija 8 za sada je u povojima a omogućavati će brzine 40 Gbps. Identična stvar je i sa bakrenim kabelima gdje su standardom definirane kategorije koje određuju brzinu prijenosa i propusnost kabela [9].

D. *Zaštita prostora*

Zaštita prostora obuhvaća sustave zaštite od pojave požara, neautoriziranog pristupa podatkovnom centru. Ugrađuju se sustavi vatrodojave, sustavi gašenja požara te sustav tehničke zaštite koji obuhvaća video nadzor i kontrolu pristupa.

Sustavi vatrodojave pomoću senzora otkrivaju prisutnost čestica gorenja u zraku ili rade na principu prepoznavanja dima. Centralna jedinica sustava vatrodojave spaja se na centralnu jedinicu sustava gašenja te se obično spaja i na centralu koja automatizirano šalje obavijest o požaru lokalnoj vatrogasnoj postaji i odgovornoj osobi podatkovnog centra. U slučaju pojave požara , vatrodojavna centrala aktivira sustav gašenja, isključuje napajanje podatkovnog centra te šalje obavijest o požaru nadležnim službama i/ili osobama.

Sustav gašenja požara u podatkovnom centru aktivira se na osnovi dojave vatrodojavne centrale ili ručnog uključivanja sustava. Sustav gašenja izvodi se plinom , kako bi šteta nakon gašenja bila što manja te da ne bi došlo do ugroze osoba koji su se eventualno zatekle u prostoru za vrijeme požara , odnosno da oprema koja nije bila zahvaćena požarom ne bi bila oštećena djelovanjem medija za gašenje. U tu svrhu koriste se plinovi FM200 ili Novec 1230.

Sustav tehničke zaštite služi za nadzor prostora i perimetra podatkovnog centra te kontrolu ulaska i izlaska iz prostora. Sustav se sastoji od video kamera koje se raspoređuju sukladno definiranim standardima te čitača magnetskih kartica, otiska prsta ili slične metode prepoznavanja identiteta osobe.

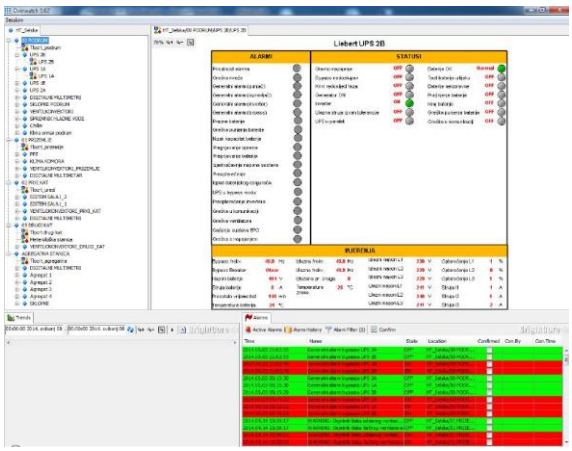
Sustavi zaštite prostora spajaju se na centralni nadzorni sustav objekta ili samog podatkovnog centra kako bi korisnik imao u svakom trenutku dostupnu informaciju o događajima u podatkovnom centru.

E. *Centralni nadzorni sustav*

Centralni nadzorni sustav, CNUS[2], omogućava kontrolu, prikupljanje informacija o radu svih ugrađenih sustava i njihovih elemenata, analizu podataka te udaljeno upravljanje. Daljinsko upravljanje ima značajnu ulogu u upravljanju DR podatkovnim centrima ili u slučaju pružatelja komunikacijskih usluga, upravljanje PoP čvorištima. .Implementacijom centralnog nadzornog sustava na temelju prikupljenih podataka i detaljne analize moguće je ostvariti znatne uštede u pogledu preventivnog tj. redovnog održavanja podatkovnog centra. Pored ušteda centralni nadzorni sustavi mogu preprogramiranom logikom izvršiti određene procese, poput gašenja određenih sustava ili automatskog podešavanja parametara na sustavima kako bi se izbjegao prekid u radu.

[1] DR Site - *Disaster recovery site* – podatkovni centar u kojem je smještena oprema na koju se repliciraju podatci iz primarnog podatkovnog centra. Najčešće se grade po principu zrcala, dakle identični kao primarni podatkovni centar.

[2] CNUS- Centralizirani nadzorni i upravljački sustavi



Slika 5. SNUPI - Sustav nadzora i upravljanja procesima infrastrukture tehnoloških prostora [7]

IV. TRENDOVI U IZGRADNJI PODATKOVNIH CENTARA

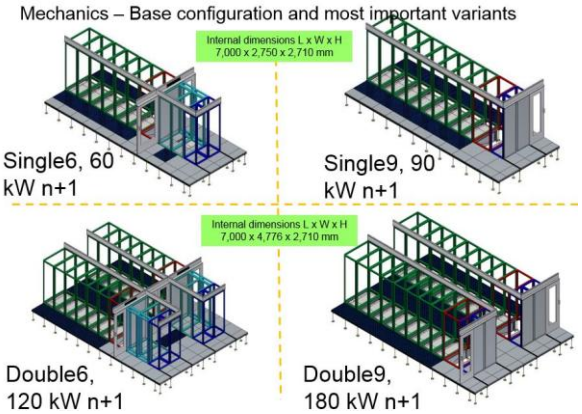
Izgradnja standardnih podatkovnih centra, gdje smatramo podatkovne centre u fiksnim objektima postala je na nekim način standard današnjeg vremena. U posljednjih nekoliko godina pojavio se trend izgradnje mobilnih ili modularnih podatkovnih centara. To su podatkovni centri, najčešće, u kontejnerskoj izvedbi standardnih dimenzija, gdje korisnik u jednoj „kutiji" dobije kompletan podatkovni centar sa ugrađenim svim sustavima. Dodatno je potrebno osigurati eventualno vanjsku rashladnu jedinicu i priključak napajanja koji su također dostupni u kontejnerskoj izvedbi. Jasno je da zbog zadanih dimenzija, podatkovni centar ne može imati kapacitet poput standardnog podatkovnog centra pa se stoga koristi metoda modula, koji se potom spajaju u jednu cjelinu kako bi se postigao potreban kapacitet. Ova izvedba podatkovnih centara posebno je zanimljiva organizacijama koje nisu izgradile podatkovni centar u vlastitim prostorima te postoji mogućnost da će kroz period eksploatacije doći do potrebe preseljenja podatkovnog centra na neku novu lokaciju Upravo iz razloga što je podatkovni centar sam za sebe ili su moduli standardnih dimenzija, preseljenje cijelog sustava ne predstavlja problem.

Ovakvim pristupom planiranja, izračuna povrata investicije i ostalih parametara investitor može detaljno isplanirati buduće korake vezane za proširenje kapaciteta sukladno potrebama. Neki od vodećih svjetskih kompanija za pružanje Internet usluga ili komunikacijskih usluga počele su koristiti ovakav pristup izgradnji svojih podatkovnih centara.

Iako i Hrvatskoj postoje tvrtke koje nude takva rješenja, investitori nisu još prepoznali prednosti novih trendova . Za primjer, možemo uzeti jednu od učestalih situacija gdje investitor, recimo tijelo javne uprave, investira u podatkovni centar, u prostoru koji nije u vlasništvu javne uprave već ima najam na određeni broj godina. Investicijom od nekoliko milijuna, javna uprava postaje ovisna o toj lokaciji bez obzira koliko troškovi najma porasli u određenom periodu. Upravo u takvim situacijama, organizacije pristupom izgradnje mobilnog ili modularnog podatkovnog centra štite svoju investiciju kroz cijeli period eksploatacije i samim time ostvaruju velike uštede.

Hrvatske tvrtke svoja rješenja plasiraju na vanjsko tržište gdje svojim korisnicima isporučuju visoko sofisticirana rješenja.

U Hrvatskoj i užoj regiji prepoznata je prednost MDC[3] rješenja koja na nivou jednog ili nekoliko spojenih serverskih ili komunikacijskih ormara osiguravaju sve zahtjeve željenog Tier standarda. MDC rješenja također su modularnog i mobilnog tipa. Ovakav tip rješenja najčešću primjenu nalazi u financijskim organizacijama koje svoje podatke štite najvišim stupnjem. Najviši stupanj zaštite osigurava neometan rad opreme unutar MDC-a sukladno normi vatrootpornosti F90, otpornosti od prodora vlage te svih ostalih parametara zaštite koji su usklađeni s EN normama.



Slika 6. Primjer standardiziranog modularnog rješenja za podatkovni centar [7]

[3] MDC-Micro Data Center – Sustav koji omogućava sve uvjete koje zadovoljava klasični podatkovni centar ali na nivou jednog ili više serverskih/komunikacijskih ormara

Tabela 1 Usporedba podatkovnih centara u Hrvatskoj

U gornjoj tabeli možemo vidjeti usporedbu izgrađenih podatkovnih centara u Republici Hrvatskoj, na temelju javno dostupnih podataka. Svi navedeni podatkovni centri izgrađeni kao podatkovni centri za kalkulaciju, dakle za najam korisnicima. Podatkovne centre tvrtki koje su gradile podatkovne centre za vlastite potrebe nisu uzete za usporedbu jer je većina podataka koje uspoređujemo poslovna tajna ili je potrebna posebna suglasnost istih da se ti podatci javno objavljuju. Iz usporedbe možemo vidjeti da su se investitori prilikom izgradnje podatkovnih centara vodili standardom te je usporedba veoma jednostavna i razumljiva. Također se može vidjeti da se kroz godine mijenjaju trendovi u pojedinim sustavima, posebno u ovom našem slučaju, na sustavu gašenja. FM 200 zamijenio je Novec , koji je ekološki prihvatljiviji. Na sustavima hlađenja, svi navedeni, zadržali su se na CRAC sustavu hlađenja sa zatvaranjem u hladnu zonu, kako bi što više smanjili trošak energije i održavanja sustava hlađenja.

Kako je ranije spomenuto vidljiv i je i pristup izgradnje u fazama, sukladno popunjavanju kapaciteta. Data Cross i T Com završili su prvu fazu izgradnje, napravljena je priprema za drugu fazu koja će biti pokrenuta čim kapaciteti prve faze budu gotovo iskorišteni [5]. Altus IT je imao nešto drugačiji pristup, možda iz razloga što je izgradnja u fazama jedan od novijih trendova, ta je odmah instalirao svu planiranu snagu, odnosno kapacitete [6].

VI. ZAKLJUČAK

Kako bi mogli lakše prikazati kolika je u stvarnosti korisnost i isplativost ulaganja u izgradnju podatkovnih centara, pokazuje studija koju je napravio Ponemon Institut, pod pokroviteljstvom Emerson Network Power. Neplanirani ispadi podatkovnog centra su skupi, a troškovi zastoja su u porastu, navodi se u studiji. Prosječna cijena po minuti neplaniranog zastoja je sada 7900 $, što je 41 % posto više od cijene iz 2010. godine koja je bila 5600 $ po minuti [1]. Iznosi koji su dobiveni nisu nikako mali, te se brzom analizom može doći do zaključka kako investicija u podatkovni centar je veoma isplativa a i povratak investicije je, u odnosu na druge projekte, veoma kratak.

	Unajmljeni podatkovni centar	Vlastiti podatkovni centar
Početni troškovi	+	-
Troškovi održavanja	+	-
Fleksibilnost nadogradnje	-	+
Nadzor prometa	-	+
Sigurnost	-	+

Tabela 2 . Usporedba izgradnje podatkovnog centra i kolokacije [2]

Iz ove usporedbe može se do odgovora da li investirati u vlastiti podatkovni centar ili koristiti uslugu kolokacije. Svaka organizacija bi trebala napraviti detaljnu analizu svojih potreba i zahtjeva za dostupnosti te na temelju toga donijeti konačnu odluku [2]. Ukoliko se radi o organizaciji sa manjim kapacitetom računalnog sustava, izgradnja vlastitog podatkovnog centra vjerojatno neće biti isplativa jer će povrat investicije biti veoma dug. Kako bi skratili taj rok, organizacije smanjuju investiciju na štetu dostupnosti sustava, pa u konačnici dobiju za uloženi novac nešto što neće ispuniti njihova očekivanja u smislu dostupnosti i pouzdanosti. Podatkovni centi koji su namjenski građeni za kolokacije uvijek su bolji odabir u takvim situacijama iz razloga što su građeni sukladno najvišim standardima i garantiraju određen nivo dostupnosti, te korisnik nema potrebu vršenja redovnih održavanja sustava i usklađivanja sa zakonskim normama.

Velike organizacije, posebno one koje djeluju na globalnom tržištu najvjerojatnije će za ishod analize imati rezultat da je investicija u izgradnju vlastitog podatkovnog centra isplativija te će shodno tome pokrenuti projekt izgradnje podatkovnog centra.

Abstract – Biomedical research, such as analyses of antiproliferative properties of certain compounds designed to target various human cancer cells, often requires extensive preclinical evaluation to obtain conclusive evidence. The first step in biological evaluation is typically very rigorous in comparing different compounds' concentrations on a number of target cells *in vitro*. Therefore, the experiments yield a set of data that needs to be properly documented, classified, stored and analyzed. This paper presents the Data Storage and Analysis System designed to make that process simpler, faster and less prone to human errors. The importance of such research and its implications lead to high sensitivity to bias. Our system minimizes the chance for human error in the process of data transfer by making the process as automatic as possible and allowing the posterior validation of data by the lead researchers. The analysis most often requires both numerical calculations, such as the IC_{50} value, and graphical visualization of compounds' performances. The system offers to researchers a simple interface for simultaneous comparison of results by choosing the appropriate combination of a compound, target cells and date of experiments.

Keywords: data storage, data analysis, visualization

I. INTRODUCTION

Antiproliferative evaluation of novel potential or existing anticancer compounds is a standard part of preclinical evaluation of great chemical and pharmacological importance. Those compounds that posses the ability to target specific signalling pathways, *i.e.* in cancer could be used in combined treatment approaches to improve cytotoxicity of drugs and clinical response of patients.

Extensive *in vitro* experiments need to be performed to achieve conclusive first evidence in such studies. For example, a study performed by Gazivoda, Kraljević et al. [1] tested 23 different compounds for antiproliferative activities on 7 cell lines (5 tumour cell lines and 2 human fibroblasts) at various micromolar concentrations. The results showed that five compounds exhibited antiproliferative effects and the one with the strongest concentration-dependent effect was chosen for further biological evaluation. The authors compared its effect with a commercial kinase inhibitor used as standard treatment of Philadelphia positive leukaemia. The new compound presented by the authors, exhibited promising results as it achieved greater antiproliferative effects *in vitro*. Indeed, *in vitro* evaluation of biological data coupled to bioinformatics analyses represents the 'golden standard' in the modern drug development process.

Having in mind a high number of potential compounds' combinations and tested concentrations, as well as requirement to perform the tests on diverse target cells, the amount of data may increase rapidly [2]. The need for a systematic data storage and analysis approach is evident [3] and this paper presents a system designed precisely for that purpose. The system's database is structured to allow multiple users – researchers to upload the data obtained in a standard form by any microplate absorbance reader. The process is made as automatic as possible to avoid human errors, which are typically the dominant reason of data bias. The researchers are required to fill the date related to compounds' names, tested concentrations and names of employed cell lines. The entering of data into the system is a two-step process with the first step based on initial values 'Day zero' and 'Blank' and the second step on final results template load. Since these steps might be slightly prone to human error, the researcher administrator is given the privilege to check and correct the entered data. The system also allows the researcher to automatically calculate the most important parameters like: Values for controls (untreated cells), percentage of growth cells (PG) treated with certain compounds at various concentrations and inhibitory concentration 50 (IC_{50}) and to visualize the concentration-response curves for each tested compound and cell lines. In this paper we present *data **S**torage and **A**nalysis for conducting **B**iotechnological **E**xperiments **S**ystem*, SABES. The SABES system was developed by students within the Software Engineering and Information Processing (SEIP) Lab, at the University of Rijeka [4], where we have had the experience of working on other ICT platforms like data collection tool for software defect prediction [5] and ambient assisted living environment [6]. The SABES system accelerates and improves the experimental workflow in early evaluation of potential drugs or biologically active compounds *in vitro*. In particular, it allows comparison of any compound's effect on any cell type *in vitro* by ensuring a simple and systematic storage within the system.

The structure of the paper is as follows: Section II presents the purpose of SABES system and gives a detailed design in five subsections; Section III presents the conclusion and future work intentions.

II. SABES SYSTEM

The usual workflow of *in vitro* experiments is presented in Fig 1. *Groups* of *Experimenters* are formed based on common research interest in research projects and one experimenter may be a part of more than one group. A group is analyzing the growth of a certain number of *Cells* when interacting with certain *Compounds*. In each experiment, the compound effect is analyzed in several levels of *Concentration*. The experimenter may perform a number of experiments using microplate absorbance reader that produces a standardized output table in .xls format for each experiment (*Experiment Table)*. There is one experiment table at the beginning of the experiment and it is called *Day* zero and the experimental end-point table that we refer to as the *Measurement*. Both experiment tables include *Blind Test* values and *Control value* only in the Measurement file. The blind test values refer to absorbance values of test reagents used for assessment of cell growth and the control value stays for untreated cells. These values are important for proper analysis of measurement results. Finally, besides the experimenters, we also distinguish the Role of researchers that perform these analyses. They can view, modify and combine data from several experiments.

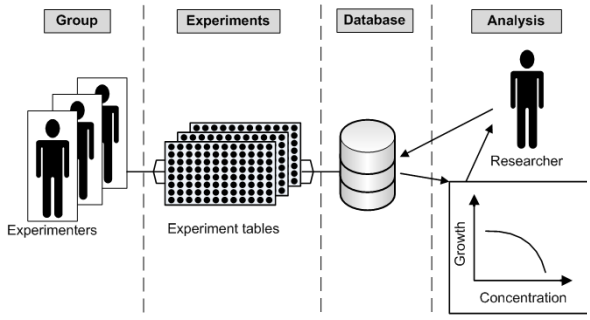

Figure 1. SABES Experiment

Here presented experiment storage and analyses is time-consuming and in particular, major problems are encountered when a need arises for localization of raw data - experimental files upon a certain length of time, or when finding only those files related to effects of the same compound or its behaviour for the same target cells, or even when a need is to additionally compare and group results from various experiments. Furthermore, the experiments may be run by students where unintentional mistakes occur at a higher rate in transfer or analysis of raw data. The previous modality of work included a manual copy-paste activity of raw data into semi-formatted Excel sheets prepared for data analyses. That is why the first task of SABES system was to provide for a controlled import of raw experimental data in a user friendly fashion and less prone to errors. With the SABES system, all the data is stored in a single database, and the user is guided through the data import process, without the need to be an expert in the field. Stored data are easily accessible through the interface. Furthermore, the system allows the supervision of main researchers or mentors and the possibility of additional manual checking of errors. The second task we achieved with the SABES system is comparison of previously performed experiments by the following filters: (1) the person who made the experiments, (2) by tested compound, or by (3) type of cells. The user may choose the data, make a graphical plot, calculate IC_{50} values, and even analyze mean values for a certain experimental point and standard deviations on a graph. In the following section we present the system architecture and technologies employed for its implementation where a detailed explanation of its most important parts is described.

A. Structure

The SABES data storage and analysis system is implemented using standard web development technology tools PHP, MySQL and jQuery. PHP is a server-side scripting language that is used for web development for a long time. Thus, it is supported both in Windows and Linux OS. It contains built-in modules for accessing many of the most popular database servers, making it easy-to-implement. One of the main advantages of PHP is its ability to run the scripts directly on a server, without previous compiling. The system's data storage functionality needs to support large amounts of raw data and that is why we used a relational database designed in MySQL, the most widely used open-source relational database management system. AJAX (Asynchronous JavaScript And XML) is a group of techniques used on the client-side, which allows the development of fast dynamic web applications because it sends and retrieves data asynchronously (in the backend). The jQuery framework is a cross-platform library designed to simplify the client-side scripting. We used it to simplify the implementation of AJAX queries, *i.e.* to achieve the asynchronous communication with server-side, which makes the application resemble to a desktop application from the user perspective [7]. The SABES system architecture is presented in Fig 2. The technologies we used removed the web browser incompatibility so the system can be run in any browser without any design adjustments.

B. Database

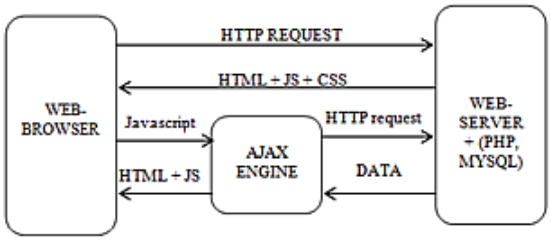

Figure 2. SABES system architecture

The database has two functions in the SABES system, the administrative function of assigning roles to the users and the data storage function. The Entity-Relationship (ER) diagram of the database is presented in Fig 3. Authentication of users is done based on the data from table User. It consists of the username, password and the

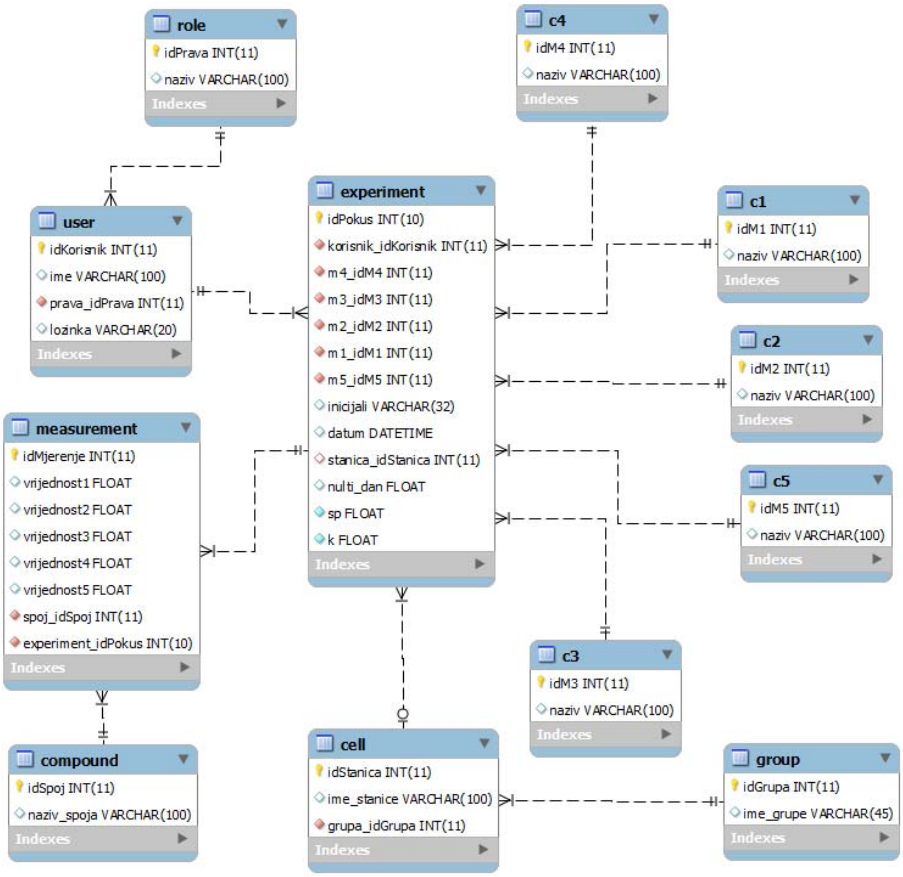

Figure 3. SABES system database

role assigned to each user by the administrators. The Role table divides the users into two groups: experimenter and researcher, as presented in Fig 1.

Experimenters are the users that conduct experiments, import the data into the system and can view and edit only their own data. Researchers have the administrative role and they can import, view and edit any data stored within the system.

The data import is done through the *Experiment table* obtained at the output of the device for cellular growth measurement, so it has the major influence on database structure. General pieces of information are stored within the table named Experiment, the most important table that consists of information about the experimenter, date of experiment, target cell (and indirectly about the group that conducted the experiment through table Group), the day zero, the blind test and the control value for an experiment. The measurement values obtained from the *experiment table* are stored within table Measurement. One *experiment table* can contain measurements for up to 4 compounds on 1 target cell. Each compound, stored within table Compound, has its own row in table Measurement. Each compound can be applied in up to 5 different concentrations. Thus, each compound concentration is stored in adequate tables (c1, c2, c3, c4, c5). Since the compound concentrations usually have recurring values, we avoided duplicated entries by separating them into such, additional tables. The mere form of *experiment table* does not allow the entry of more than 4 measurements and that limitation was not needed in the database design. The integrity of the data obtained for each research project (named *Group* in Fig 1) is achieved with table Group. One group can analyze more than one target cells. If more groups decide to analyze the same target cell, they should name it differently. In that way, no unintentional overlap of research between different groups will occur. Furthermore, the presented ER diagram supports both demands given by researchers-users:

- View the experiment results for a single Cell from a defined Group
- View the experiment results for all Cells tested with one Compound

C. Data Import

The user interface contains the data import form, presented in Fig 4. The *experiment table* obtained as output of an experiment is structured in a standardized xls format, which allowed us to create an automatic data import module. It is designed to make the automatic data import process less prone to human error than the previously accustomed manual process. Thus, it guides the user through the process by several steps. It is also designed to be easily understandable and usable by experimenters that are not experts in this field. The only restriction is not to change the default structure of the *experiment table*.

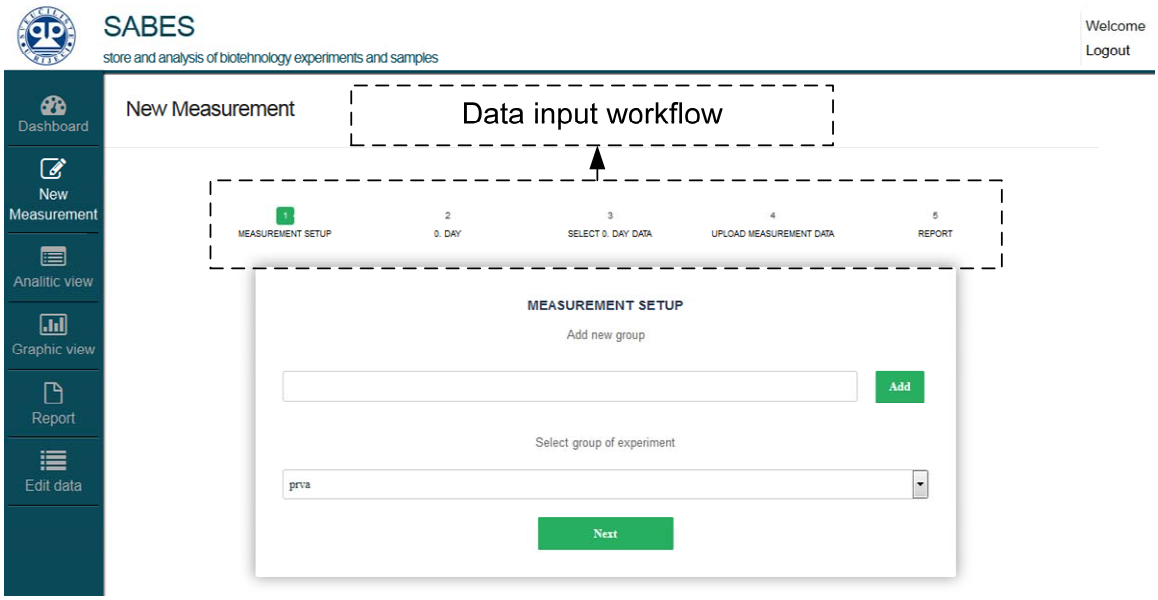

Figure 4. SABES system

The data import process initiates with the selection of the *Group*. The system offers the user to select from all the previously entered Group names. If the Group is a new one, the user is given the option to enter its name for the first time. The second step is to browse the location of the two *experiment tables* in xls format that are stored locally on the computer. The first *experiment table* that the user imports should contain the 0^{th} *day* values. The *experiment table* is then sent to server for processing. The relevant data are then structured and returned to the user for examination. The user then needs to select the column that represents the 0^{th} *day* values for the cell that is currently under examination. The second *experiment table* for import is the one that contains the *measurement* values. All the data are then stored in the database and the user is presented with the data import status. If there was an error in data import process, the user is informed that he should repeat the process. The complete data import sequence diagram is presented in Fig 5. Its steps are:

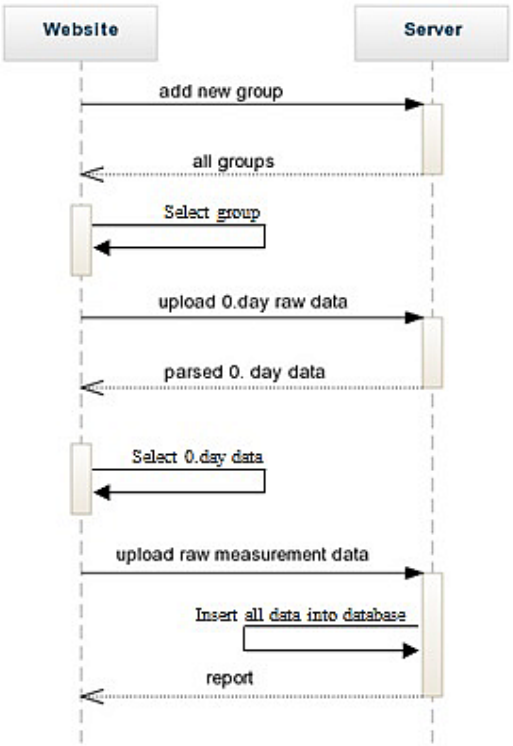

Figure 5. Data import sequence diagram

1. Selecting an existing *Group* or entering the name of a new one
2. Browse the *experiment table* with 0^{th} *day* values
3. Select the column of the *cell* under examination
4. Browse the *experiment table* with *measurement* values
5. Report the user of the data import success

D. Data Analysis

The SABES system automatically performs data analysis of imported data. Measures that are important for data analysis are maximum, minumum, mean and standard deviation values for each *Compound-Cell-Concentration* (*CCC*) combination and the IC_{50} value. The *CCC* combination represents a set of values that analyze the impact of the same *Concentration* of a *Compound* on a certain *Cell*. One *experiment table* contains four values for one *CCC* combination and their mean value and standard deviation for further analysis and visualisation must be calculated. The IC_{50} value represents the most important calculation within the experiment. It represents the *half-maximal inhibitory concentration*, *i.e.* the level of *Compound Concentration* that achieves 50% inhibition of the maximum cellular growth for the analyzed *Cell*.

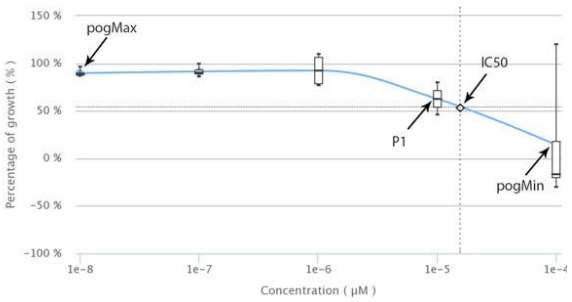

Figure 6. Određivanje intervala za izračun IC_{50}

The estimation of the IC_{50} value is done with linear approximation between two neighbouring levels of concentration that inhibit the cellular growth above and beyond 50%, as presented in Fig 6. The maximum percentage of cellular growth for one *Compound-Cell* combination is presented with the *pogMax* value and the mimum percentage is presented with the *pogMin* value. The 50% cellular growth (pog50) is then obtained by formula (1):

$$pog50 = pogMax - 0.5 \cdot (pogMax - pogMin) \quad (1)$$

The pog50 value is then used to find the two neighbouring values of concentrations that are used in the experiment and stored in the database using the general expression (2):

$$\dots pog_{n-1} < pog_n < pog_{50} < pog_{n+1} < pog_{n+2} \dots \quad (2)$$

The values of pog_n and pog_{n+1} are the two neighbouring values we are looking for. For the example given in Fig 6, the pogMin value is the pog_{n+1} value. The IC_{50} value is then calculated using a standard linear equation between two points given by Equation (3):

$$y = y_a + (x - x_a)\frac{y_b - y_a}{x_b - x_a} \quad (3)$$

where y_a is the pog_n value, y_b is the pog_{n+1} value, x_a is the *Compound concentration* for pog_n value and x_b is the *Compound concentration* for pog_{n+1} value. IC_{50} value is equal to x, when pog50 is inserted as y in (3).

E. Data Selection and Visualisation

The SABES system also offers the graphic view after analyzing the imported data. There are two possible ways to select the data for analysis:

6. Filter the data by *Group* and by *Cell*
7. Filter the data by *Compound*

The graphical user interface of the graphic view window is presented in Fig 7. Filtering the data by *Group* and by *Cell* can be done using the filter elements above the cellular growth graph and filtering the data by *Compound* can be done using the filter elements of the left side of the graph. Sequence diagram of filtering the data by *Group* and by *Cell* is presented in Fig 8. The *Group*

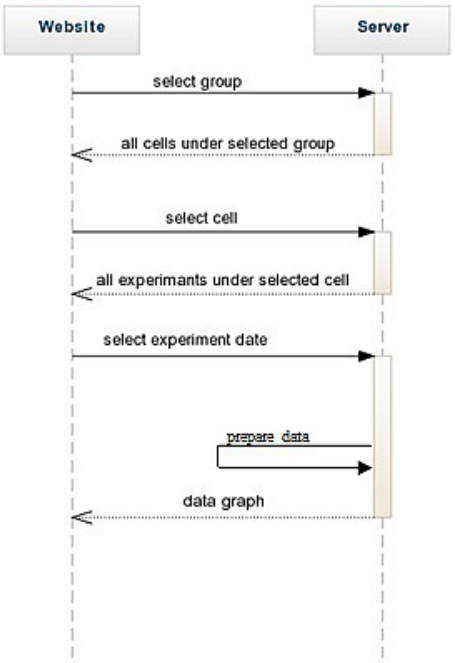

Figure 7. Data selection sequence diagram - filter by *Group* and *Cell*

filter offers a drop-down menu that is automatically filled with all the *Group* names within the database. The server then returns only the names of *Cells* that were analyzed by the chosen *Group*. After selecting the name of *Cell*, the server gives a list of all the experiments that were conducted for selected *Group* and *Cell*. The user then selects the experiment he wants to analyze and the graph is plotted in the cellular growth graph area, as presented in Fig 6. Each graph generated with the SABES system exhibits the effect of four different *Compounds* used in several levels of concentration with a target *Cell*. The x-axis of the graph represents the levels of concentration and the y-axis of the graph represents the percentage of cellular growth. Filtering the data by *Compound* is simpler and hence we omit its sequence diagram. The data filtering starts with the selection of the *Compound* and then the server returns the names of all *Cells* that were analyzed with it in *Cell* filter. The number of *Cells* that will be plotted on the same graph is arbitrary and left to user's decision.

There are two curve plotting styles implemented in the SABES system. The first one is based on plotting a continuous "*spline*" curve that is calculated based on mean values for a certain *CCC* combination. This is the standard presentation style of presented *in vitro* experiments. The other style is based on drawing of a box & whisker plot. The box represents the inter-quartile range, the whiskers represent the complete range of data, and the middle line presents the median. As we mentioned earlier, each experiment contains at least four measurements for the same *CCC* combination and these values are the basis for the box & whisker plot. If the data are filtered by *Compound*, then we can have a large number of experiments that have the same *CCC* combinations and the box & whisker plot is done for all of them. This style is optional and it can be omitted from the graph.

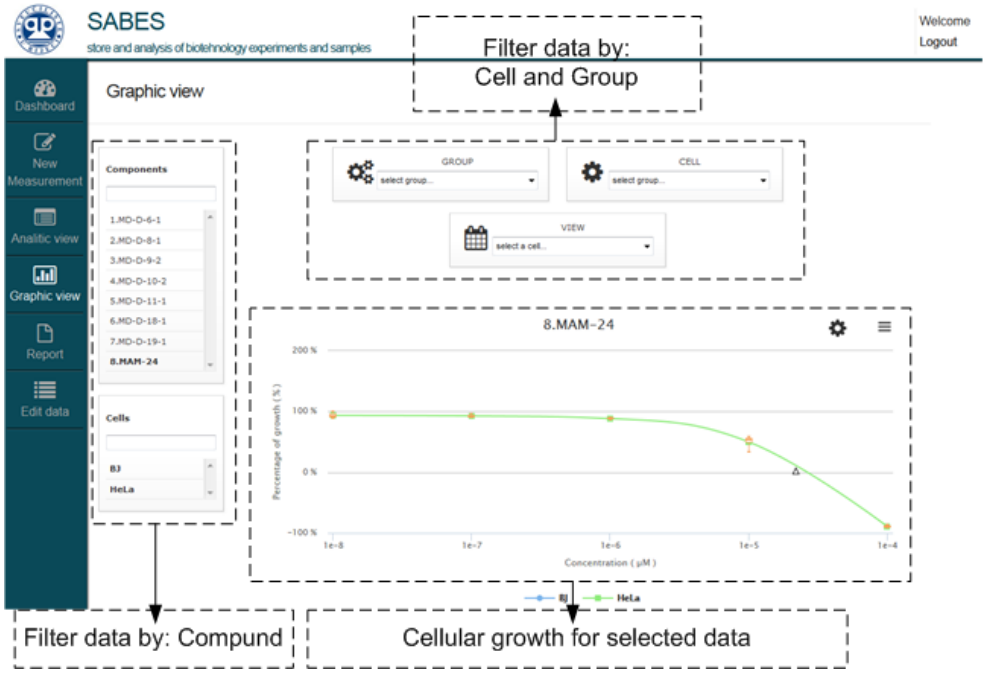

Figure 8. Graphic view for filtering and plotting the experiment data

III. CONLUSION AND FUTURE WORK

One of the biggest obstacles in advancements of any scientific field is limited data storage and analysis capacities. Although, there are vast technologies ready for data generation that are very well supported with powerful and relatively cheap processing equipment for data analysis, there is still a large area of intervention in smaller, specialized domains, *i.e.* biological experimental research where automatization and optimisation of processes might be designed in line with customers/users' needs. Importantly, scientists should understand deeply the phenomena under investigation on large number of data samples to generate generalising theories. And here the key obstacles remain data analysis, data presentation and systematization. This gap might be filled through interdisciplinary collaboration among researches from natural science and computer science. Their interaction indeed, may be of vital importance for future evolution in both disciplines. This paper presents an endeavour in that direction. Here we present a simple IT based solution to error prone process of manual data collection, data aggregation and data analysis. We focused on issues how to simplify the data storage, data aggregation and data analysis process and remove as much as possible human bias from datasets in analysis by taking care of an easy to use approach through the IT system called SABES system that is jointly developed by students and researchers from the University of Rijeka.

One of the major concerns of data management systems today is in their ability to deal with large data sets. Structured data collection process simplifies data accumulation. Data aggregation and analysis rules and policies that may be developed per each individual research experiment may be fault prone and computational intensive task. Future work should consider development of new technologies and programming abstractions that would be able to cope with these issues. We started to create a data management platform for scientific research purposes and future work will be on future evolution of SABES system by integrating more data structures, developing an environment for collaborative and interdisciplinary research as well as extending its abilities to support big data.

ACKNOWLEDGMENT

The work presented in this paper is supported by the University of Rijeka, Croatia research grants (numbers 13.09.2.2.16 and 511-21).

***Sažetak* - Korištenje javnih usluga u oblaku (eng. cloud) od strane masovnih pružatelja usluga za smještaj poslovnih podataka i sustava još je uvijek prilično kontroverzna tema. Razlog tome su neutemeljeni strahovi u pogledu sigurnosti, nedostatak povjerenja u pružatelje usluga, njihovu mogućnost brzih promjena na sustavima, fleksibilnost i na kraju cijena.**

Usluge u oblaku vrlo su ovisne o mrežnim elementima u rješenju te se obično sastoje od virtualiziranih otoka u klasičnom mrežnom okruženju. Iako SDN (eng. Software Defined Network) još nije došao u pravom smislu do okruženja u oblacima, te ne postoji javno dostupna industrijska standardizacija, trenutno dostupne tehnologije omogućavaju dizajn i izgradnju dovoljno pouzdanih, fleksibilnih, a opet robusnih sustava za automatizaciju i mreže i korisničku kontrolu mrežnih postavki.

***Ključne riječi - cloud*, mreža, virtualizacija, automatizacija, portali, korisničko iskustvo**

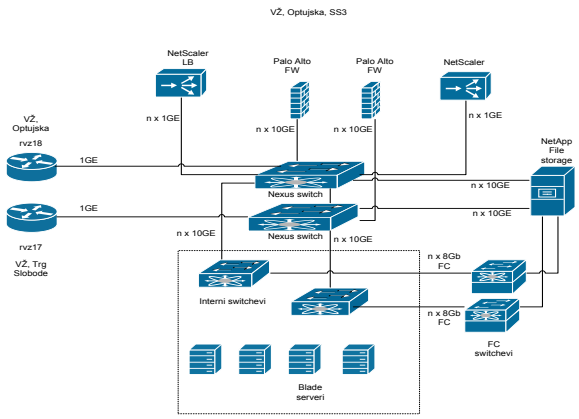
I. UVOD

Prema standardu NIST (National Institute for Standards and Technology), da bi se rješenje moglo smatrati *javnom uslugom u oblaku* (u daljnjem tekstu *Cloud*), ono nužno mora podržavati sljedećih 5 karakteristika:

- Samouslužnost,
- Širokopojasnu mrežu,
- Lokacijsku neovisnost,
- Elastične resurse,
- Mjerljive usluge.

Podatkovni centri i infrastruktura koja podržava *Cloud* sa sistemske strane prilično je kompleksna, kao što se može vidjeti na slici 1 (primjer za uslugu Virtualno Računalo u HT Cloud-u).

Mreže operatora i pružatelja *Cloud* usluga sastoje se od velikog broja specifičnih uređaja. Da bi se pokrenula nova usluga često je izazov pronalaženje prostora za prihvat ovih uređaja, održavanje postaje sve teže, velika složenost takvih okruženja, povećanje troškova energije, kapitalnih ulaganja, nalaženje vještina potrebnih za dizajn na tržištu rada zatim integracija i upravljanje svime time postaju gotovo nemogući. Štoviše, rješenja bazirana na vlastitim fizičkim resursima vrlo brzo dolaze do kraja isplativosti održavanja te zahtijevaju puno od osoba koje ih implementiraju. Što je još gore, životni vijek usluga postaje sve kraći, kako se tehnologija i inovacije ubrzavaju. Virtualizacija funkcije mreže ima za cilj rješavanje tih problema iskorištavanjem standardne IT tehnologije virtualizacije za konsolidaciju mnogo vrsta mrežne opreme. Ovaj rad se temelji na projektu koji je trebao dokazati da je virtualizacija mreže primjenjiva za bilo koju funkciju unutar fiksne i mobilne mrežne infrastrukture.



Slika 1. Arhitektura rješenja

Cilj

Cilj je uspostaviti potpunu automatizaciju mreže te omogućiti korisniku potpunu kontrolu nad mrežnim postavkama koje se odnose na korisnikove *Cloud* sustave a koji uključuju virtualne poslužitelje, virtualna računala, kolokacijske poslužitelje i lokalna korisnička računala spojena brzom vezom (*ClearPath* platforma).

Mrežni pristup trebao bi biti transparentan te bi korisnik morao moći mijenjati način mrežnog pristupa neovisno o *Cloud* usluzi koju koristi. Mijenjanje mrežnih postavki mora unutar *Cloud*-a biti moguće preko samouslužnih portala:

- Uspostava automatske aktivacije mrežnih elemenata:
  - *Nexus* komutatora na koje je spojen javni oblak,
  - *Palo Alto* vatrozid,
- Uspostava automatske aktivacije *ClearPath* platforme radi njezine integracije s uslugom virtualnih poslužitelja i kolokacijskom uslugom.

- Uspostava korisničkih portala koji će omogućiti korisniku upravljanje mrežnim resursima unutar njegovog zakupljenog prostora na javnom oblaku:
    - vatrozid između korisnikovih mreža,
    - balansiranje opterećenja korisnikovih usluga,
    - kontrola adresne translacije prema javnoj mreži za sve korisnikove privatne adrese,
    - uspostavu dinamičke translacije za korisnikove resurse unutar oblaka prema Internetu,
- Sve aktivacije unutar *Cloud* platforme moraju se izvršiti orkestracijom.

Ključ pojednostavljenju usluga, a time i smanjenju operativnih troškova i mogućnosti povećanja usluga je u apstrakciji usluga odnosno apstrakciji kompleksnosti usluga, aktiviranja i orkestracije.

Primjerice, ako izaberemo virtualni poslužitelj kojem povećavamo resurse (primjerice procesorsku snagu), na klasičan način prvo ćemo izabrati akciju, potom s liste virtualni poslužitelj na kojem vršimo promjenu. Pristup koji smo izabrali i koji se pokazao vrlo uspješnim jest da okrenemo uloge i da prvo izaberemo subjekt, a potom na subjektu vidimo listu akcija koje je moguće provesti nad odabranim subjektom u tom trenutku, te izaberemo odgovarajuću akciju. Dakle, subjekt – predikat pristup.

U konstelaciji samouslužnih portala i cilja da portali moraju pružiti maksimum informacija i pristup do željene informacije/produkta s minimalnim brojem korisničkih odabira dizajnirali smo samouslužne portale na bazi *dodataka* (u daljnjem tekstu *widget*).

Widgeti se dijele na:

- Informativne - bazirane na *live-tile* ili graf funkcionalnostima,
- Entitete – odnosno subjekte.

Informativni *widgeti* prikazuju informacije koje administratoru ili korisniku sustava (osobi koja kupuje, bilo tvrtki ili pojedincu) pruža informacije koje najčešće imaju potrebu pratiti.

Izgled ekrana (kontrolne ploče) administratora VPS portala sa svim relevantnim podacima, prikazan je na slici 2.

Entiteti su revolucionirali portale, grafička sučelja i korisničko iskustvo te način na koji su usluge prezentirane krajnjem korisniku. Ta apstrakcija obuhvaća razdvajanje aplikacija i podataka od fizičkih ograničenja, dok istovremeno pruža mogućnost upravljanja i zaštite.

U nastavku ćemo obraditi pristup *Cloud* uslugama kroz apstrakciju aplikativnim entitetima, te apstrakciju kompleksnosti mrežnih usluga kroz kontekst SDN-a, odnosno tehničku izvedbu koja treba simulirati SDN.

II. HT *CLOUD* SAMOUSLUŽNI PORTALI

HT *Cloud* infrastrukturni portali sastoje se od:

- VPS – Virtualnih privatnih poslužitelja (eng. Virtual Private Server) modula,
- VDi – Virtualnih radnih površina (eng. Virtual desktop) modula,
- Hex – Hosted exchange modula,
- SSO – Single Sign On modula.

Cloud samouslužni portali prošli su nekoliko stupnjeva evolucije da bi konačno došli do vrhunskog izgleda i stanja. Dizajnirani su za najbolje moguće korisničko iskustvo (eng. user-experience) i funkcionalnost.

Započeli smo dizajniranjem *klasičnih* portala – s listama, stranicama, velikim zaglavljem i podnožjem, listama i stranicama za unos korisničkih podataka, stranicama za prikaz izvještaja i slično.

Kada smo analizirali web stranice na osnovu predikata i subjekta, došli smo do toga da klasične web stranice funkcioniraju na osnovu izbora akcije (predikata) iz liste, te potom izbora subjekta na kojem će se izvršiti odabrana akcija. U HT *Cloud* portalima smo te postavke okrenuli.

Entiteti su *widgeti* koji predstavljaju apstrakciju neke usluge. U kontekstu VPS-a, virtualni poslužitelji su entiteti i prikazani su na slikama 3 i 4.

Svaki entitet zna koje sve akcije se na njemu mogu provesti. Entitet ima sve potrebne parametre, informacije i naredbe koje ga definiraju i koje su neophodne za upravljanje funkcionalnošću. Akcije postavljaju entitet u promijenjeno stanje u nekom vremenu i okruženju.

Možemo ići tako daleko i reći da su portali u ovom kontekstu samo spremnici za entitete i služe im za stvaranje novih entiteta i pokretanje drugih naredbi koje su iznad entiteta.

Tako dizajnirani portali, *widgeti* i entiteti su inherentno pripremljeni za responzivan web – da se prezentiraju na tabletima ili pametnim telefonima.

Svaka akcija koje ne može biti direktno izvršena klikom na entitet podiže *lightbox* (JS modal dialog), koji je također responzivan.

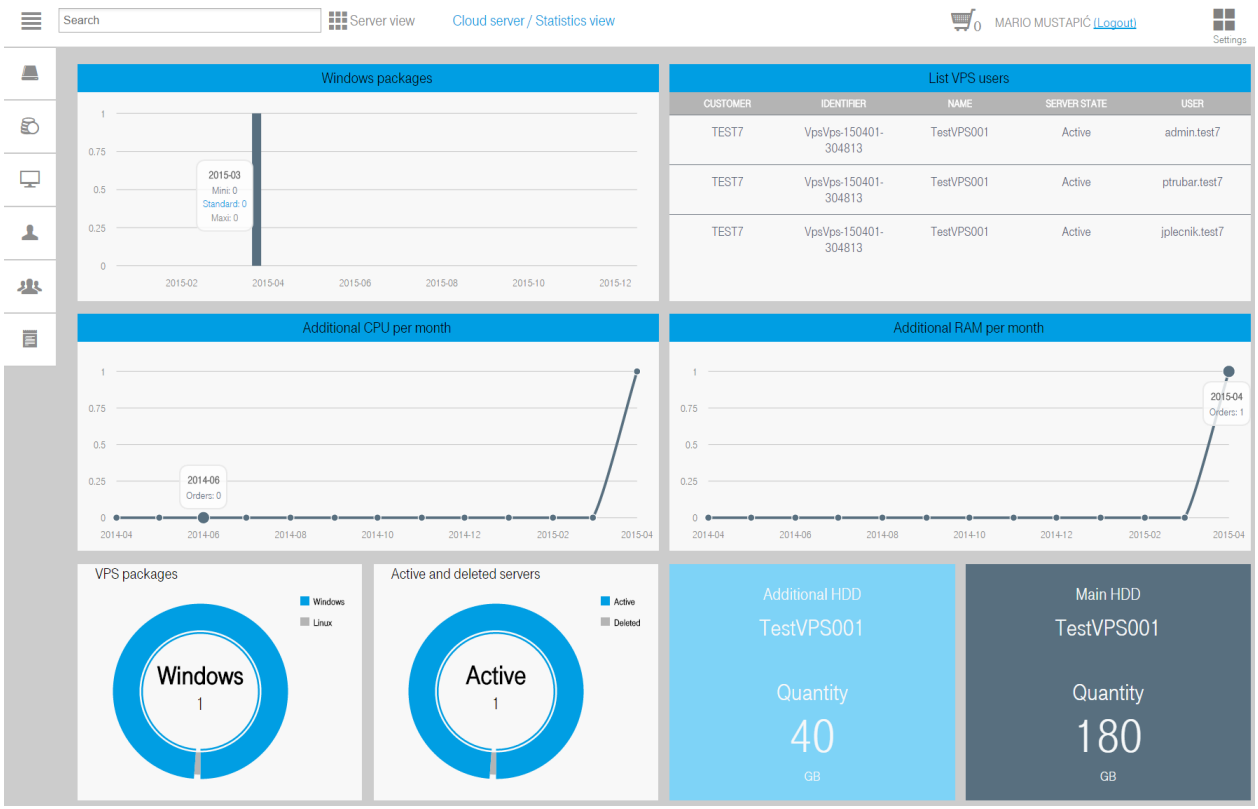
III. IMPLEMENTIRANO RJEŠENJE

Korisnik se spaja isključivo na Portale putem kojih definira i izvršava postavke na mrežnom nivou za sustave u svom vlasništvu.

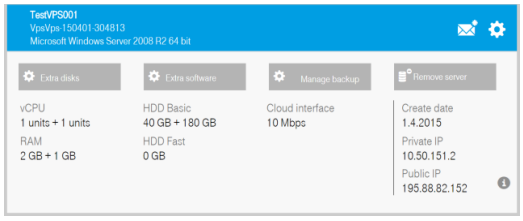
Portali korisničke akcije izvršavaju isključivo pozivanjem metoda na orkestratoru koji zatim iste izvršava na infrastrukturi. Sve postavke se spremaju u zasebnu bazu podataka kojoj pristupa *NetProv* portal.

Za potrebe ove usluge dodatno se konfigurira sljedeće:

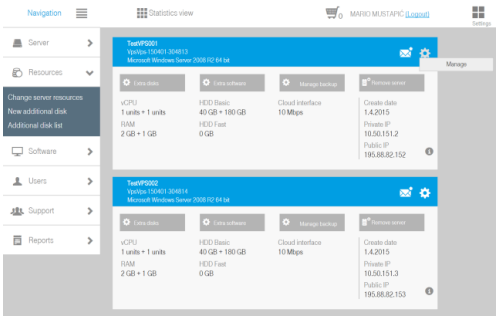
- Na PE uređajima rvz17 i rvz18 dodaje se nova logička veza i podmreža u VRF-u *CLOUD*_SME (podmreža ne smije biti iz 10.0.0.0/8). Preporuka je bar /28 podmreža kako bi ostalo dovoljno IP adresa za HSRP između rvz17 i rvz18 te IP adrese koje će služiti za NAT/PAT potrebe na PAN VATROZID.



Slika 2 – Kontrolna ploča



Slika 2: Entiteti (Widget-i)



Slika 3: Entiteti opcije

- VLAN se konfigurira na *Nexus* komutatoru te pušta prema konektorima na koje je spojen PAN VATROZID
- Na PAN VATROZID-u se konfigurira novi virtualni usmjeritelj radi odjeljivanja *Cloud* pristupa od postojećeg Internet pristupa i nova IP adresa na podmreži prema PE.
- Na PAN VATROZID-u se dodaje NAT konfiguracija prema *Netscaler*-u (koristi se postojeća mreža PAN – Netscaler). IP adresa za pristup u VDI se upisuje na DNS poslužitelj.
- Na PAN VATROZID-u i *Netscaler*-u se dodaju odgovarajuća usmjerenja prema korisničkim podmrežama (radi povratnog prometa).
- Na PAN VATROZID-u se dodatno konfigurira NAT od strane virtualnih radnih površina prema korisničkim podmrežama. Za potrebe NAT-a na PAN VATROZID-u se stoga koristi jedna ili više adresa iz pristupnog podmreža. Virtualne radne površine mogu komunicirati s lokalnim poslužiteljem kod korisnika pri čemu vezu uvijek pokreće virtualna radna površina.
- Na PAN VATROZID-u treba postaviti odgovarajuće per AD user ACL koje pojedinom korisniku dopuštaju pristup samo njegovom LAN segmentu.
- Na PAN VATROZID treba podesiti *rate-limit in/out* prometa s *Cloud* infrastrukture prema korisničkim lokacijama (ograničenje je suma brzina svih lokacija)
- Za kolokacijsku mrežnu aktivaciju dodatno je potrebno na PAN-u konfigurirati ACL koji dopušta nekom korisniku *Cloud* računala pristup samo do njegovog kolokacijskog podmreža.

- Za pristup *Cloud* računala do virtualnih poslužitelja na PAN-u treba podesiti NAT prema podmrežama virtualnih poslužitelja, usmjeravanje prema podmrežama virtualnih poslužitelja i odgovarajući ACL.

Ciljano mrežno sučelje je prikazano na slici 5

Samouslužni portali koji entitetima podržavaju implementirano upravljanje ciljanim mrežnim sustavom prikazani su na slici 6.

IV. ZAKLJUČAK

Virtualizacija mrežnih funkcija već se događa pa za nekoliko godina možemo očekivati da će telekomunikacijska industrija izgledati vrlo slično IT industriji. Tu će biti široki spektar poslovnih modela koji više odgovaraju modelima softverske industrije. Složenost okruženja na apstraktnom nivou će biti daleko manja, a nivo samostalne kontrole će biti drastično veći. Kao što je navedeno u ovom dokumentu, virtualizacija mrežnih funkcija će donijeti mnoge prednosti za mrežne operatore te njihove partnere i klijente, istovremeno pružajući priliku za stvaranje novih vrsta eko-sustava (uz tradicionalne modele nabave na temelju povlaštenih cijena sa strateškim partnerima) koji će poticati i podržavati brze inovacija sa smanjenim troškovima i smanjenim rizicima. U ovome radu opisanim pristupom postigla se razina željene konfiguracije i apstrakcije virtualiziranih elemenata uz podržavanje svih traženih karakteristika i marketinških zahtjeva.

Data Storage and Synchronization in Private Cloud

D. Hodanić, N.Vrkić and M. Tomić
University of Rijeka, Faculty of Engineering, Department of Computer Engineering, Rijeka, Croatia
{dhodanic, nvrkic, mtomic}@riteh.hr

Abstract - Usage of cloud systems for data storage has many advantages over the traditional approaches. It is already widely used and its popularity is still fast-growing. The systems must be implemented and maintained in a way that not only satisfies the performance and resource availability requirements, but also fully addresses the questions of security, privacy and data ownership. However, concerns related to those questions very often lead to considerations of a private cloud implementation.

In this paper, we explore a private cloud implementation suitable for small to medium businesses. We introduce main types of cloud computing as basic service models and analyze private cloud systems features. Advantages and disadvantages in comparison to public cloud services are considered. Implementation of private cloud solutions in a lab environment allowed us to examine the ease of the setup and maintenance as well as the usability of the chosen solutions and their applicability for the target user group.

I. INTRODUCTION

Cloud technologies have infiltrated society in many aspects. Our culture is currently built around mobile devices, social media, cloud platforms, intelligent systems and many more. There is a lot of personal and business information that has to be stored. Cloud storage and synchronization are highly popular for personal use. In contrast, organizations are still cautious with moving their businesses into the cloud. Privacy and security are the main concerns when considering cloud solutions. Most of the popular cloud services offer public cloud service model. Public cloud platforms opened the cloud concept to personal users. There is no doubt that these systems earned their popularity, but for some user groups more private solutions are potentially a more viable and acceptable option.

Although cloud platforms extended possibilities in terms of storage and synchronization for organizations, they also produced some uncertainties. With enterprises and cloud services, trust issues were bound to come up. Trust is depicted as a complex factor formed of control over assets, data ownership, failure prevention and security. Khan et al. showed in [1] that building trust in cloud services comes with time, good performances, security, more client control and transparency. Therefore, private clouds found their way into many organizations and application areas where trust is of great concern. For instance, Doelitzscher et al. in [2] presented a case for building a private cloud for collaboration and e-learning services in HFU University. Architecture and software aspects were analyzed in detail, with conclusions about private cloud benefits at the university and its IT department. A more general comparison of several cloud computing platforms has been given in [3] to provide better understanding and useful details for choosing the best cloud solution given a specific case. The authors focused on private and hybrid clouds, namely OpenNebula and Nimbus and considered OpenNebula solution to be suitable for building a highly scalable cloud computing environment. In [4], the Eucalyptus was considered in details. Eucalyptus is an open source private and hybrid cloud software representative, suitable for the use in enterprises. It is compatible with Amazon Web Services (AWS) cloud interface, allowing interaction between a private and a public cloud. Atefi et al. presented in [5] the use of open source private cloud for digital forensics. Seafile was chosen due to its advanced features for preserving privacy, file syncing, and collaboration. In a prototype research from Mościcki et al. [6], a private cloud solution for internal use by the CERN employees has been analyzed in depth, as an alternative to the public cloud services. The authors chose ownCloud as a viable platform for an open source private cloud solution for file sharing and synchronization on a very large scale. OwnCloud competitors, such as Pydio, Seafile, SparkleShare and Syncany were discarded because of feature incompleteness, usability issues or failing to support necessary file formats. They found that only ownCloud satisfied most of their demands for building an open source cloud solution which can compare well to commercial solutions.

Private cloud systems are highly adjustable to user's needs and offer great flexibility in terms of the number of active users and feature implementations. There are several solutions, but also many different concepts for custom usage within organizations. In this paper, we explore how private cloud solutions may benefit small to medium businesses (SMB). A deployment of an open source private cloud system with software solutions such as ownCloud, provides business users with internal control of privacy and sole data ownership. We also consider questions of security, scalability and cost.

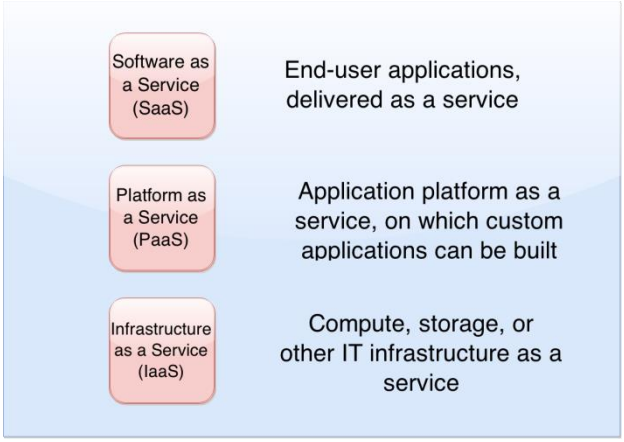

Figure 1. Basic cloud computing service models

II. CLOUD COMPUTING CONCEPTS AND CLOUD STORAGE MODELS

A. *Definition of the cloud*

There is more than one definition of cloud computing, but most of them have a similar meaning – using computer resources on demand. This is a model for delivering information technology services where resources are retrieved from the Internet using web-based tools. Applications can communicate with servers where all data and software packages are stored. Cloud computing model allows access to information as long as a client's device has access to the web. Companies may find that the cloud computing allows them to reduce the cost of information management, since they are not required to use their own infrastructure, but instead lease it from service providers [7].

B. *Cloud service models*

There are three basic cloud computing service models: Infrastructure as a Service (IaaS), Platform as a Service (PaaS) and Software as a Service (SaaS), as shown in Fig. 1.

Infrastructure as a Service (IaaS) is a service model where cloud computing service providers share their storage, network, and other computing resources with their clients. Clients are able to run their own software. A user does not operate or control fundamental physical infrastructure of a cloud but has control over operating systems, storage, deployed applications, and possibly limited control of selected networking components. Service providers give their users access to multiple virtual server instances, so different users access the same infrastructure at the same time. They have flexible access, meaning they can reach the infrastructure from any location and any device that has a network connection. With regards to security problems, many IaaS providers offer a private cloud environment for cloud hosting [8].

Platform as a Service (PaaS) is a service model similar to IaaS but it provides an additional level of functionality. It is a model for running applications without the need to maintain the hardware and the software infrastructure at organizations. PaaS service providers allow customers to deploy, run or develop applications on their cloud infrastructure. A user does not manage nor control the underlying cloud infrastructure (including network, servers, operating systems), nor storage, but has control over the deployed applications and possibly over configuration settings for the application-hosting environment. PaaS offers software developers several advantages including cost savings, reduced technical maintenance and increased mobility. Costs for purchasing servers, other hardware or required software licenses are reduced or eliminated [8] [9].

Software as a Service (SaaS) cloud model operates on a virtualized and a pay-per-use billing model. In this model, software applications are rented to contracted customers by SaaS service providers. The applications are accessible from various client devices through a client interface, such as a web browser. The client does not operate nor control the fundamental cloud infrastructure including servers, storage, network, operating systems, nor individual application features, with the possible exception of application configuration settings, as specified by the service provider. Applications on providers cloud infrastructure are always up-to-date, pre-installed and configured. This reduces the time spent for installation and configuration of software on local machines. It also allows SMBs to use a software that would otherwise be too costly due to a high licensing fees. Maintenance costs are reduced as well, as the SaaS provider owns the environment and the cost is split among all customers using that solution [8] [9].

C. *Cloud deployment models*

A public cloud is a model that provides users access to the cloud over the Internet, using client interfaces, such as common web browsers. It is typically based on a pay-per-use model. This helps cloud clients to better match their IT expenditure at an operational level by decreasing its capital expenditure on IT infrastructure. Public clouds are less secure than other cloud models because they place an additional burden of ensuring all applications and data accessed on the public cloud are protected from malicious attacks [8]. Security is a very challenging problem in the public cloud model. Service providers are responsible not only for storing data, but also for securing it. Moreover, many organizations and private users are sharing the same resources [7], which means the provider must also implement isolation between different customers.

A private cloud is set up for organization's internal use. Service provider is no longer a third party associate, but the organization itself. There are several variations in a private cloud setup. Software components are always run privately. However, hardware modules may be owned by the organization, but also hosted elsewhere. A private cloud approach provides more control over the data ownership and privacy. However, it also implies the organization's own responsibility for setting up both the infrastructure and a software environment, as well as security measures implementation and, later on, the maintenance of each system component. Fig. 2

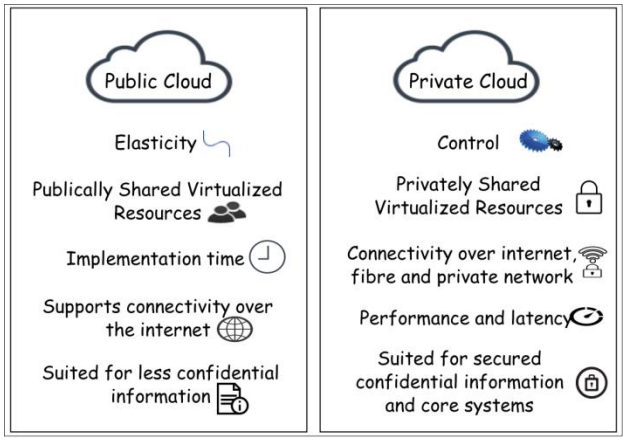

Figure 2. Differences between private and public cloud solutions

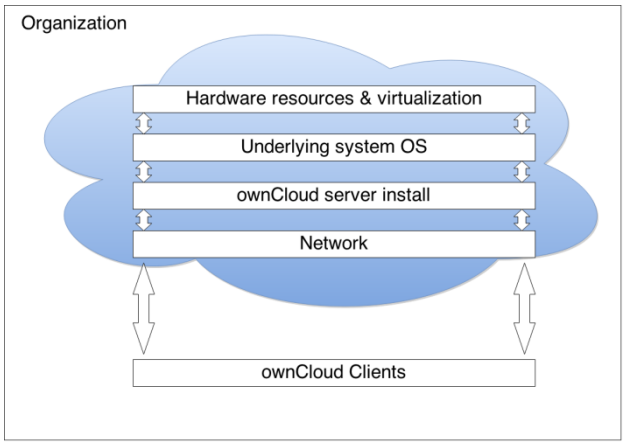

Figure 3. OwnCloud architecture components in an organization

summarizes advantages and disadvantages of private and public cloud solutions.

A hybrid cloud model combines benefits of both private and public cloud. It is composed of two or more different cloud infrastructures that are bound together [9].

III. PRIVATE CLOUD

A private cloud may be set up in-house or hosted with a third party service provider. Typically, a private cloud is owned by the organization itself. Organizations may benefit from a private cloud in many ways. When internal infrastructure is used, organization is the sole owner of its data and the only entity having access to it. This reduces or eliminates several potential public cloud service problems, such as sharing platform with other users, possible unauthorized access to the data, changes of providers privacy policy, unexpected service outages, data content restrictions, dependence on a third party organization, control over the equipment and flexibility in a form of cloud bursting.

On the other hand, disadvantages of the private cloud model also have to be taken into consideration. Since an organization is running the entire cloud platform, planning and preparation is essential. Initial investment in hardware and software sometimes proves to be a serious obstacle, although, using existing hardware resources with several equipment upgrades, implementation of virtualization techniques and open source software, may significantly reduce the initial cost. After the infrastructure is set up, an organization needs to deploy a private cloud system, implement security measures and enable seamless remote access. The cloud also needs to be maintained and monitored for security and performance. This requires skilled personnel whom not all organizations can afford.

Some authors suggest private clouds can obtain some of the public cloud benefits by merging into a hybrid cloud approach [10].

IV. IMPLEMENTATION, SECURITY AND FEATURES OF A PRIVATE CLOUD SOLUTION

A. *Demo environment*

In this section we explore setup and security aspects of a full-featured open source system for a private cloud implementation. Demo environment was built using virtualized servers on own infrastructure. As an underlying OS, a Linux server distribution was chosen. OwnCloud server was installed on top of the virtualized server. In a typical organization, the cloud would only be connected to the organization's internal network. To gain access to the cloud, remote clients would first need to access organization's LAN, usually by means of a VPN connection. Then, they would be able to access the cloud in the same manner as if they were physically present at the organization's premises. Fig. 3 illustrates components of a private cloud setup in an organization using ownCloud.

Lab setting allowed us to explore the system in a real everyday use-case scenario. Testing was done on a smaller scale environment, but interpretation of results is applicable to larger deployments. OwnCloud was chosen as a cloud solution, being the most popular open source solution for SMBs at the moment.

B. *OwnCloud implementation and security*

Currently, ownCloud supports Linux and Windows servers as a system base. Installation of server-side ownCloud is supported in different scenarios. In a lab environment, we used Linux packages as a preferred installation method. One of the most important system configuration steps is to implement basic security measures. Using the Secure sockets layer (SSL) and the Transport layer security (TLS) for protected access is highly recommended. SSL/TLS provide both data confidentiality and integrity for TCP/IP transmissions. Client-server communication using TLS protocol should be safe from many security attacks. End-to-end authentication and data confidentiality are provided by cryptographic algorithms in SSL/TLS. It provides a one way authentication, as the servers identity is already known to the client, whereas the client rests

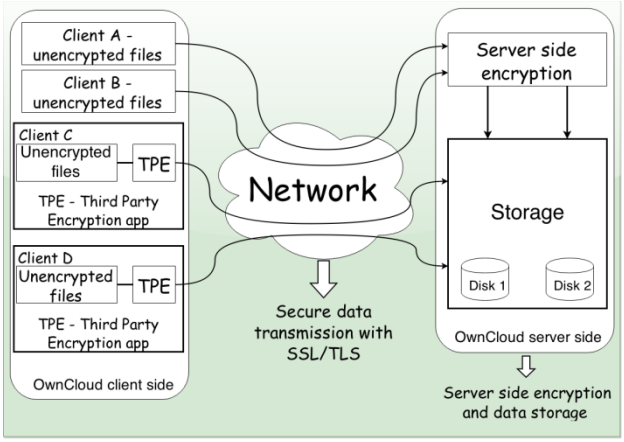

Figure 4. File encryption in a private cloud system

unauthenticated. Two endpoints using TLS connection can be certain that communication is indeed between those two devices, without the presence of a third party [11].

Another strongly advised feature is usage of the ownCloud provided Encryption app for the server-side encryption. In this case, after client data arrives over a secure SSL/TLS connection to the server side, the Encryption app executes automatic creation of a 4096-bit private and public key pair for each user. Private keys are encrypted using users login credentials with AES 256 algorithm [12]. Using the keys, the data is encrypted and protected from theft. In case of lost user credentials, administrator may access protected data to recover information. This encryption model is claimed in [12] to be highly secure and optimized to perform well with a larger amount of data, large file sizes and a great number of users. OwnCloud administrators have full control over the encryption keys. Using this encryption model, stored files should be protected from unauthorized access.

If absolute confidentiality is required, client-side encryption must be implemented. The client side encryption refers to encryption of data on a client's own device, before sending it through a secure connection towards the server. This way, the data never leaves a user's device unencrypted and not even an administrator can gain access to it. Although neither of ownCloud editions offer a client-side encryption, it can be implemented using a third party software, such as Credeon. Fig. 4 shows the aforementioned file encryption scenarios.

C. *OwnCloud client and features*

OwnCloud offers data access, synchronization and data sharing across devices, everything in a controlled environment. Its architecture is extensible and works with any storage [13]. Synchronizing ownCloud with various devices is reinforced with client applications. Desktop clients are supported for multiple operating systems: Windows, Mac, different Linux distributions and versions, as well as Android and iOS for mobile clients. When stored in the ownCloud, user's files, folders, contacts, calendars and images are accessible from PCs, laptops, smartphones and other mobile devices at any given time or location. From a user's point of view, only a network connection is needed for data synchronization among devices. Previously synchronized data on desktop devices are accessible without a network connection, since the data are also stored locally. OwnCloud web server acts as a main repository of users data. When a client connects to the server, a system automatically updates two lists of data: the list of data that has remained unchanged, and the list of data that has changed since the last synchronization. In this manner, a client is able to download and send only a list of files that have been changed. This speeds up the process of scanning and analyzing which files need to be updated. Storing and synchronizing is different with mobile devices, as their limited memory is not well-suited for keeping gigabytes of data. Consequently, mobile clients require network connection for data access.

D. *OwnCloud scalability*

Both ownCloud editions, the ownCloud Community and the ownCloud Enterprise, were designed to accommodate whole range of application areas [13], and for that they needed a scalable architecture. Scalability issues were analyzed in detail in [14]. SMBs that invest in a dedicated infrastructure for ownCloud should have no need to implement anything beyond the simple ownCloud setup. However, in case that ownCloud is accommodated on an existing infrastructure or an organization grows significantly, a performance or storage bottlenecks could occur.

A standard approach to building a scalable solution is to have separate servers for each of the private cloud service tiers, such as database, data storage or application tiers. As this setup is unnecessarily complex and too costly for SMBs, a more adequate solution would be to use a model with collapsed tiers. In a consolidated configuration, shown in Fig. 5, a single computing node can be used to host a web server, the ownCloud software, a storage server and a MySQL server. Having two or more such computing nodes behind a load balancer enables the clients' requests to be served by each of the nodes in a round-robin manner. OwnCloud allows scale-out of each component to be performed while running, thus providing continuous service - keeping the data accessible and applications uninterrupted.

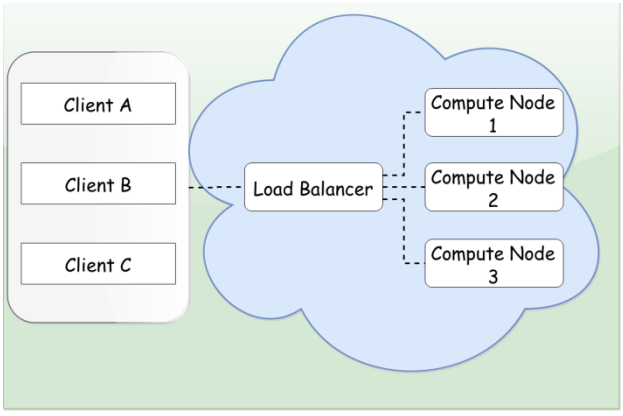

Figure 5. OwnCloud scalable deployment model

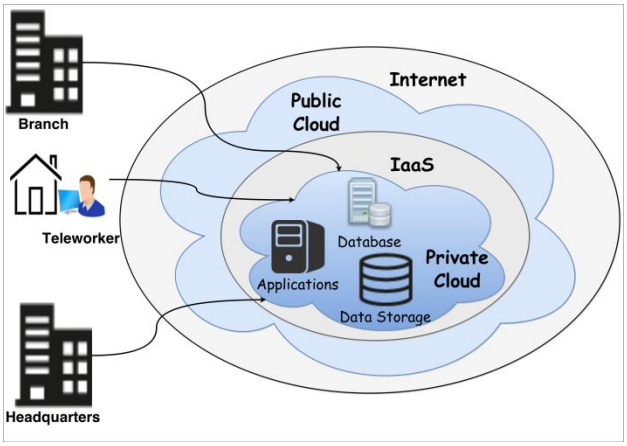

Figure 6. Hybrid approach to ownCloud deployment

E. OwnCloud in a cloud

By now, we only discussed deployment of ownCloud on a private infrastructure, i.e. within the organization. Another option could be a hybrid approach, in which the infrastructure is provided by an outer cloud service provider [1]. In this configuration, a private cloud system is hosted in a public cloud using leased infrastructure. The approach could be very interesting for businesses looking to minimize initial infrastructure investment and, later on, maintenance costs. Although the infrastructure is leased, with careful cloud implementation, data security should not be significantly impacted. Some organizations may be reluctant to invest in their own infrastructure and this approach might be a compromise which would allow them to have enough benefits of private clouds to alleviate concerns they might have with public cloud systems.

Another advantage of a hybrid cloud is flexibility in terms of changing capacity. With a pay-per-use model, an organization can momentarily scale-up or scale-down as necessary, something that is not always possible, especially in the case of SMBs, with own infrastructure. Therefore, a hybrid cloud in some cases may be a better option and a more cost efficient solution, easier and quicker to deploy than a private cloud, but also more secure than public cloud. Running ownCloud on an external infrastructure is shown in Fig. 6.

V. CONCLUSION

Public cloud services are very popular, however, organizations are still cautious with moving their businesses into the cloud. In case of trust or data security being a serious concern, we suggest using private cloud solutions. A private cloud approach eliminates the trust issue. It preserves data ownership and can improve both privacy and security. The solution we explored is scalable and is suitable not only for SMBs but also for larger deployments. For organizations which do not have enough resources to invest into their own infrastructure or to maintain it, we suggest a hybrid cloud solutions. In this case, a private cloud is hosted on a public cloud infrastructure, making a tradeoff between security and privacy on one side and cost on the other. It allows even SMBs with very limited resources to leverage benefits of the private cloud solutions.

Testing in the Private Cloud

Tomislav Pavić, Ivan Vrbovčan, Marija Šoša Anić
Hrvatski Telekom d.d., Zagreb, Croatia
tomislav.pavic@t.ht.hr, ivan.vrbovcan@t.ht.hr, marija.sosaanic@t.ht.hr

Abstract - Due to a requirement for increasing the development speed of new telecom services and enhancing functionalities of existing ones, telecom providers are trying shorten and automate creation of testing environments. Using cloud infrastructure installed on its own premises for that purpose opens myriad of new possibilities and gives an opportunity to improve traditional development process.

In this paper we will provide an overview of our approach for creating testing environments in the private cloud using open source solutions that works on top of the OpenStack cloud infrastructure. The overview will include description of the approach related to the existing development process, high level architecture and requirements for successful implementation of the presented approach.

I. INTRODUCTION

Due to a requirement for increasing the development speed of new telecom services and enhancing functionalities of existing ones, telecom providers are trying shorten and automate creation of testing environments. Using cloud infrastructure installed on its own premises for that purpose opens myriad of new possibilities and gives an opportunity to improve traditional development process.

In this paper we will show the possibilities of improving the process of application development and deployment through the automation of creation and administering of testing environments which required a great amount of time and effort from our IT staff. In this approach we are using an open source private cloud O/S (OpenStack) enhanced with technologies for automation (Chef) and run-time control (Cloudify) – see Figure 1. These tools make it possible to automate the process of creating the environment for testing purposed and thus minimizing the need for manual work.

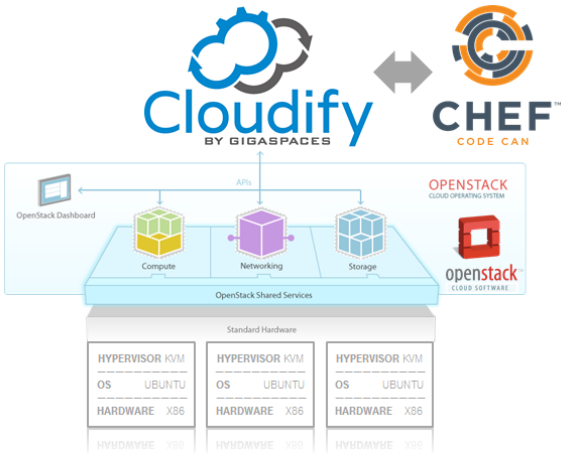

Figure 1: Components and how they Work Together [10]

Hrvatski Telekom (HT) started to evaluate open-source cloud computing solutions starting in 2011 [1]. As result of this effort OpenStack (http://www.openstack.org/) was chosen as the most viable solution for creation open-source cloud infrastructure commonly known as an Infrastructure as a Service (IaaS). OpenStack project has been started with high expectations to run large cloud installation. It is characterized by rapid development and fast growing level of community support. High level of modularity and robustness is suitable for vendor customizations and development of value-added features. Recent releases offer many new features such as distributed scheduler for deploying VMs, strong image management service, unified identity management system, IPv6 and VPN support. List of recent improvements include major improvements to OpenStack's networking, orchestration, and metering systems in addition to many features that support software development and big data analysis. Common cloud operations are performed via a web-based OpenStack Dashboard user interface. OpenStack has many important players on its side and became one of the leaders in cloud computing arena.

Having selected open-source solution for IaaS we have recognized that we need capable tool for application installation and configuration. Based on findings from joint venture project with FER we selected Chef for that purpose [4]. Chef (https://www.chef.io/) is a systems and cloud infrastructure automation framework which can be used for easy deployment servers and applications to any physical, virtual or cloud location with no matter the size

of the infrastructure. It relies on abstract definitions known as cookbooks and recipes. Cookbooks are used to describe how a specific part of infrastructure should be built and managed declaratively. Applying these definitions we are able to fully automate our infrastructure (not only cloud based). Rich repository (cookbooks, recipes, versions, attributes, resources, providers, libraries, and templates), roles, data bags, environments and configuration files simplified development of custom tailored recipes and can be used for complex production environments.

Third component in our tool-box is Cloudify (http://getcloudify.org/) which is an open-source cloud computing Platform as a Service (PaaS) solution by GigaSpaces Technologies. It can be integrated with Chef so the services lifecycle can be simplified by using Chef to take care of keeping service configurations up-to-date with current specifications as defined by roles and cookbooks. This approach isolates the application completely from the underlying cloud runtime. Cloudify recipes provide the execution plans for installing, starting, orchestrating and monitoring an application stack including actions to ensure self-healing and horizontal scalability.

II. SOLUTION TEST AND ACCEPTANCE PROCESS

Existing Solution Test and Acceptance Process (see Figure 2) as part of development process in HT is based on ITIL V3 [5-9].

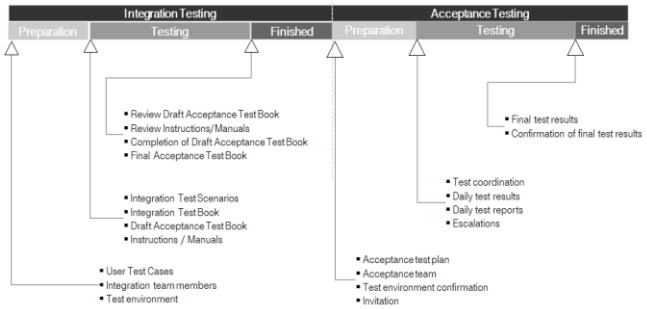

Figure 2: Solution test and acceptance process [3]

Solution Test and Acceptance Process is designed to ensure quality control of IT systems. The main objective is to ensure interoperability of systems through the activities of analyzing and documenting detected errors ensuring correct behavior of software systems prior to going live. The goal of the process is to improve resolution of problems raised from the testing process with the test time reduced as much as possible. This can be done by improving the allocation of tasks and improving utilization of used resources (both physical and human).

Test management as is defined in ITIL Service Transition stage [7] includes the planning, control and reporting of activities. Prior any testing activity detailed planning of required test resources should be done which includes prioritizing and scheduling what is to be tested and when. During the testing activities any incident, problem, errors, non-conformance, risk and any other issue should be properly managed so that incoming known errors and their documentation can be timely processed. Monitoring progress and collecting feedback from validation and test activities are essential to reduce errors that may end up into production. Other activities include capturing configuration baseline, collection of test metrics, analysis and reporting.

Test management should be able to identify activities that can impose delays. These issues needs to be proactively managed through the activities of mitigating risks and implementing changes identified during testing activities.

Clearly this process is huge time and resource consumer and HT internal analysis [3] prove that. Another finding stated that automation of Solution Test and Acceptance Process in HT is currently on very low level and for integration testing totally missing. That was the main driver for pilot implementation of testing in the private cloud.

III. PILOT IMPLEMENTATION

To create and administer pilot environment we used the following Open Source tools – see Figure 3:

- OpenStack Havana: for private cloud infrastructure installation based on four physical servers
- Chef Server 11.0.8: to automate O/S configuration (which is installed manually) and installation/configuration databases and other applications
- Cloudify 2.7.0: PaaS as a tool for run-time control and deployment

This pilot is based on real world applications that are used in T-HT:

- Donat: internally developed client/server CRM application based on Oracle and Microsoft technologies
- Citrus: web application based on Postgresql, Apache, Ruby on the Rails and Memcached used as application inventory

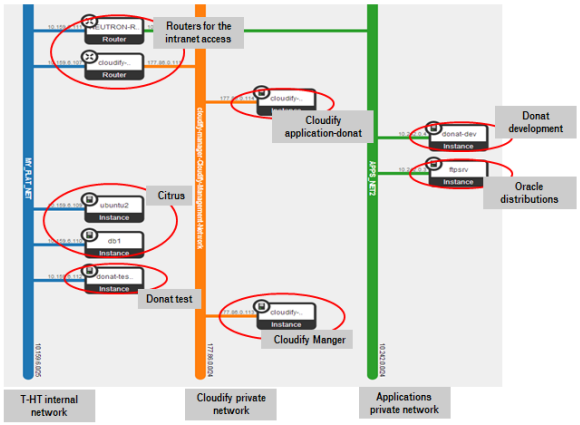

Figure 3: Pilot Environment

Deployment process is defined as follows – see Figure 4:

1. Connect to the OpenStack cloud from the Cloudify Management virtual machine (VM). This initial connection ensures OpenStack cloud is operable and accessible.
2. Create one or more application VMs on OpenStack. Number of VMs depends on initial requirements of application workload.
3. Get IPs addresses of application VMs. This IPs are used by Chef and Cloudify Management for further activities that need to be done on these VMs and for needs for maintain possible dependences of created VMs (e.g. for establishing communication between application and database servers).
4. Install Cloudify client on application VM which is responsible for communication with Cloudify Management and execution of local tasks
5. Install Chef client on application VM which is responsible for communication with Chef server.
6. Register Chef client to Chef server and ensure secure communication
7. Provide Chef recipes to the Chef client to be installed on local VM
8. Install and configure required software on application VM

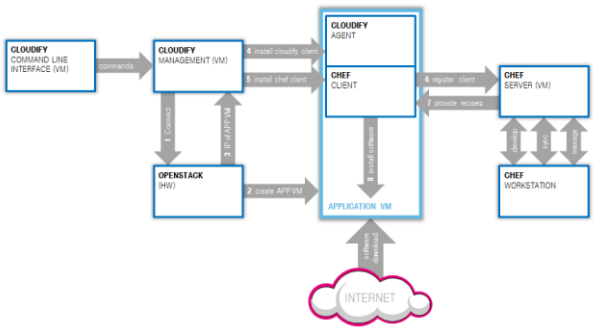

Figure 4: Deployment process [10]

Based on existing Chef recipe for the Oracle Database 11g Enterprise Edition it was easy to install Oracle database and later on to create Cloudify recipe based on that service:

```
service {
  extend "../../../services/oracle"
}
application {
  name="donat"
  service {
    name = "oracle"
  }
}
```

As can be seen from this example an application recipe describes the application name, the services it requires and their interdependencies – see Figure 5. A service is defined as set of service instances in form of cluster from which an application tier is created (e.g. web cluster of service instances). In this context it is important to distinguish between a service and a service instance. A service is defined as a cluster which is made from at least one service instance. Every service instance always resides on one host (typically this is an VM created exclusively for that service instance), whereas a service is the collection of all service instances and in case that thre is more than one service instances than obviously it would span multiple machines. It is important to understand that each service is installed, managed, and monitored by a service recipe.

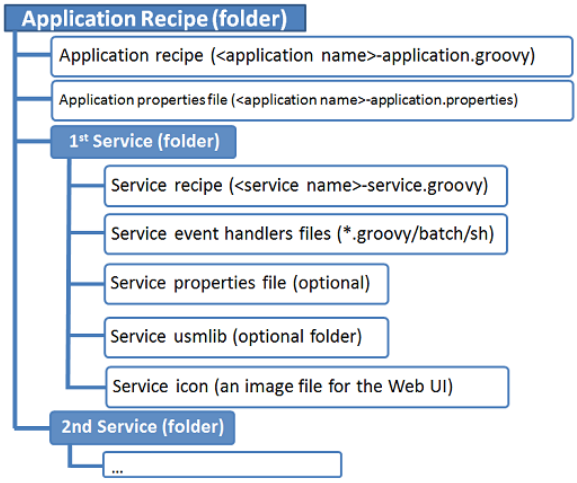

Figure 5: Application's recipe folder structure [11]

IV. CONCLUSION

In this work we have presented high level solution concept for testing in the private cloud. Based on this approach initial pilot implementation on simplified scenario was done to prove validity of proposed models and concepts. After successfully finished pilot we have identified following positive aspects of this approach:

- Easy to install OpenStack using appropriate Chef Cookbooks (in this Pilot we have used Rackspace Private Cloud cookbooks)

- Common cloud operations are performed via web-based OpenStack Dashboard user interface
- Easy to deploy servers and applications using Chef to any physical or cloud location
- Cloudify recipes provide the execution plans for installing, starting, orchestrating and monitoring an application stack
- Easy to use and modify existing recipes (Chef and/or Cloudify) - no matter the size of the infrastructure

Besides these positive aspects still careful planning is required because conversion of legacy systems can be difficult especially if there is no existing recipe (Chef and/or Cloudify) for the specified application.

Although, pilot was successfully finished more work on automation and orchestration has to be done, and it remains for the future phases.

zeljko.bozinovic@bhtelecom.ba, nasuf.hadziahmetovic@bhtelecom.ba

Abstract - There are many access technologies which it is possible to realize new and reconstruct the existing access networks. The goal is to find those technologies that will best meet the quality parameters, use of existing resources and provide support to current and future services. In considering this problem there are many criteria to be taken into account. In consideration we started from the hypothesis that technology can change the status of optimality when changing bandwidth and density of users. Possible optimization methods do not provide a universal approach to this problem. In this paper, the methodology used, which also takes into account the quality criteria and criterion optimal utilization of existing network resources. As a result, this paper offers a new algorithm and optimization methods suitable for the optimization of both fixed and mobile access networks. Also, the algorithm and optimization methods perform optimal technology choice with corresponding topology at the given conditions. The results confirm the initial hypothesis.

I. INTRODUCTION

Construction of new and reconstruction of existing access networks expressed the problem of choosing the optimal solution. The optimal solution depends on the parameters of quality, quantity of resources needed and the total cost. There are many different methods and software packages used for optimization and planning [1], [3] and [4]. Unfortunately, most of these methods of optimization are not universally usable and provide a solution taking into account only one criteria. Even the methods that are set as a universal do not include all segments that are necessary for quality optimization. The reason for this is the desire to be applied in the broader spectrum of possible optimization process. On the other hand, the most commonly treated problems of the new networks without taking into account the possibilities of exploiting the resources of existing access networks.

It was observed that the increase in bandwidth and user density in access networks, could cause the initially less optimal solution becomes the best solution and vice versa [2]. This hypothesis, which is partly proved in the paper [2], because we considered only a passive part of the access network, we have taken as a starting hypothesis in this paper.

To prove our initial hypothesis, we developed a new algorithm and optimization method for techno-economically optimal selection of access technologies. The algorithm takes into account the quality parameters that are eliminatory for selection of optimal solution. He also compares the needs of the considered solution for resources and available resources of the existing access network. The algorithm allows an optimization of wired, wireless and mobile access technologies and their combinations. With minor adjustments it can be used also for the other areas of optimization.

By applying the algorithm to the technologies analyzed in the paper [2], we received confirmation of the initial hypothesis. The reason for using technology from the work [2] the possibility of utilization of part of the previously obtained results. On the other hand, we have shown that the change of solutions optimality is influenced by the increase in bandwidth, user density, and the relationship between prices of active equipment and fiber optics.

II. DEVELOPMENT OF MATHEMATICAL MODEL AND ALGORITHM

A. *Initial assumptions*

For mathematical modeling of a passive part of the network we used the mathematical model and the initial assumptions elaborated in the work [2].

In addition to the initial assumptions given in [2], we introduced the following assumptions, no impairment of generality:

- We will observe only technologies that have been considered in the paper [2], for the use of the obtained results and the possibility of mutual validation.
- Mobile technologies currently is not be taken into consideration;
- We will ignore the parameters of quality, because the choice of parameters can vary from case to case;
- The impact of resource utilization of the existing access network is mathematically modeled, but it will not be considered due to variations from case to case;
- Instead of the actual price, we will use the normalized prices. They are obtained by dividing the required amount of resources with the lowest necessary amount of resources;
- Passive network components are included into the price of required active elements of technology under consideration. Exceptions are optical cables.

B. Mathematical model

By studying the optimization method, which is used to optimize the access networks, we noticed that they generally use one optimization criterion or parameter for ranking solutions. By studying the access networks, it is clear that the optimization problem is significantly more complex, and that cannot be reduced to a single parameter or criterion.

Optimization problem is reduced to finding a balanced relationship between quality, cost and constructed network resources. As a solution imposed by the combined methods of optimization of all these parameters simultaneously.

In our case, the length and number of optical fibers, and the amount of passive and active network elements directly dependent on bandwidth and users density [2]. Also, the amount of resources and their arrangement depend on the parameters of the quality required. While the quality parameters are stricter it is generally necessary needed higher amount of passive and active equipment, regardless of the applied solutions. If it is not possible to reach some of the set quality parameters it is necessary to improve observed solution. This means more passive and/or active elements, and therefore more expensive solution. The entire procedure must be repeated for all considered bandwidths.

Required passive and active resources, are necessary to compare with the available resources of the existing access network. If resources are sufficient then the additional cost solutions are zero. If the available resources are insufficient then the additional cost are given by equation (1).

$$C_{ij}^{add} = C_{ij}^{as} + C_{ij}^{ds} \tag{1}$$

where is:

C_{ij}^{add} – additional price of the i-th solution and the j-th bandwidth,

C_{ij}^{as} – additional price of the aggregation segment of the i-th solution and j-th bandwidth,

C_{ij}^{ds} – additional price of the distribution segment of the i-th solution and j-th bandwidth.

In equation (1) are:

$$C_{ij}^{as} = \left(L_{ij}^{as} - L_{av}^{as}\right) \cdot C^{\frac{as}{1m}} \tag{2}$$

$$C_{ij}^{as} = \left(L_{ij}^{ds} - L_{av}^{ds}\right) \cdot C^{\frac{ds}{1m}} + C_{ij}^{add\ bs} \tag{3}$$

where are:

L_{ij}^{as} – the required length of the aggregation segment of the i-th solution and j-th bandwidth,

L_{av}^{as} – available length of the aggregation segment of the existing network,

$C^{\frac{as}{1m}}$ – price of the aggregation segment per 1m length,

L_{ij}^{ds} – the required length of the distribution segment of the i-th solution and j-th bandwidth,

L_{av}^{ds} – Available length of the distribution segment of the existing network,

$C^{\frac{ds}{1m}}$ – price of the distribution segment per 1m length,

$C_{ij}^{add\ bs}$ – price missing resources for the base station of the i-th solution and j-th bandwidth, which do not include active equipment base station.

The total normalized price for i-th solution is given by equation (4).

$$C_i^{nor} = \sum_{j=1}^{m} \left(C_{ij}^{nor\ opt} + C_{ij}^{nor\ eq} + C_{ij}^{nor\ add} + C_{ij}^{nor\ bs}\right) \tag{4}$$

In equation (4) are:

$$C_{ij}^{nor\ opt} = \frac{L_{ij}^{opt}}{L_{j\,\min}^{opt}} = \frac{L_{ij}^{as} + L_{ij}^{ds}}{L_{j\,\min}^{opt}} \tag{5}$$

$$C_{ij}^{nor\ eq} = \frac{C_{ij}^{eq}}{C_{j\,\min}^{eq}} \tag{6}$$

$$C_{ij}^{nor\ add} = \frac{C_{ij}^{add}}{C_{j\,\min}^{add}} \tag{7}$$

$$C_{ij}^{nor\ bs} = \frac{C_{ij}^{bs}}{C_{j\,\min}^{bs}} \tag{8}$$

In equation (4), (5), (6), (7) and (8) are:

C_i^{nor} – normalized total price of the i-th solution for all considered bandwidths simultaneously,

$C_{ij}^{nor\,opt}$ – normalized price required optical fibers of the i-th solution and the j-th bandwidth,

L_{ij}^{opt} – the total length of optical fibers of the i-th solution and the j-th bandwidth,

$L_{j\,\min}^{opt}$ – the minimum required length of optical fibers for the j-th bandwidth,

$C_{ij}^{nor\,eq}$ – normalized price of the necessary active equipment of the i-th solution and the j-th bandwidth,

C_{ij}^{eq} – price of necessary active equipment of the i-th solution and the j-th bandwidth,

$C_{j\,\min}^{eq}$ – the minimum price of the necessary active equipment of the j-th bandwidth,

$C_{ij}^{nor\,add}$ – normalized additional price of the i-th solution and the j-th bandwidth,

$C_{j\,\min}^{add}$ – minimal additional price for the j-th bandwidth,

$C_{ij}^{nor\,bs}$ – normalized price of the active base stations equipment of the i-th solution and the j-th bandwidth,

C_{ij}^{bs} – the price of the active base stations equipment of the i-th solution and the j-th bandwidth,

$C_{j\,\min}^{bs}$ – the minimum price of the active base stations equipment for the j-th bandwidth,

m – number of the bandwidths under consideration.

When the algorithm does not evaluate mobile access technologies then $C_{ij}^{bs} = 0$, and $C_{ij}^{nor\,bs} = 0$, in (4).

Selection of techno-economic optimal solution is made from the (9).

$$C_{\min} = C_1^{nor} \;\; for\; i = 1\; and$$
$$C_{\min} = C_i^{nor} \;\; if \;\; C_i^{nor} < C_{\min} \;\; for\; 1 < i < n \qquad (9)$$

Where is:

$C_{\min}$ – the minimum price of the considered solutions for all considered bandwidths simultaneously.

Often it is not possible to compare the prices of network elements due to differences in technology, or in a case when we do not know the unit prices of these elements. This is most often case with active equipment. In this case for the purpose of price comparisons we introduce a_{kj} parameter in the following way:

$$L_{ij}^{opt} \cdot C^{opt} + N_{ij}^{eq} \cdot C_i^{eq} = L_{kj}^{opt} \cdot C^{opt} + a_{kj} \cdot N_{kj}^{eq} \cdot C_{\min}^{eq} \qquad (10)$$

If we adopt:

$$C_i^{eq} = C_{\min}^{eq} \qquad (11)$$

Then from equations (10) and (11) follows:

$$a_{kj} = \frac{C^{opt} \cdot \left(L_{ij}^{opt} - L_{kj}^{opt}\right)}{N_{kj}^{eq} \cdot C_{\min}^{eq}} + \frac{N_{ij}^{eq}}{N_{kj}^{eq}} \qquad (12)$$

In equations (10), (11) and (12) are:

C^{opt} – price of the optical fibers independent of technology,

N_{ij}^{eq} – the amount of active equipment of the i-th solution and j-th bandwidth,

C_i^{eq} - the price of the active equipment of the i-th solution,

$C_{\min}^{eq}$ - the minimum unit price of active equipment,

a_{kj} - regulator equipment costs of the k-th solution and the j-th bandwidth.

From equation (10) we notice that the parameter a_{kj} indicates how much the cost of equipment can be higher / lower than the minimum costs of active equipment, if equation (11) is satisfied.

If it is $a_{kj} > 0$, then it is possible to realize the price of the active equipment in real conditions. In that case total price of k-th solution can be more preferable than total price of i-th solution. In the case where $0 < a_{kj} < 1$ the price of the k-th solution should be a_{kj} times less than the minimum cost $C_{\min}^{eq}$. If it is $a_{kj} = 1$ than the price of k-th solutions active equpment is equal to the minimum price of active equpment. When is $a_{kj} > 1$ price of k-th solutions active equipment can be a_{kj} times larger than the minimum costs of active equipment.

In the case where $a_{kj} \le 0$ price is in undefined area. When $a_{kj} = 0$, equipment have not got a value. When $a_{kj} < 0$ the price of the equipment must have negative value. We conclude that for a given $C_{\min}^{eq}$, with $a_{kj} \le 0$ there is not exist the k-th solution which satisfy equation (10) in real conditions.

When we have to determine the parameter a_{kj} then it is determined for all solutions and all bandwidths. By adding parameters a_{kj} for all bandwidths, we get the summary parameter a_k for k-th solution according to the equation (13).

$$a_k = \sum_{j=1}^{m} a_{kj} \qquad (13)$$

In this case, the optimal solution is determined using the expression (14).

$$C_{\min} = a_1 \;\; for\; i = 1\; and$$
$$C_{\min} = a_k \;\; if \;\; a_k > C_{\min} \;\; for\; 1 < k < m \qquad (14)$$

C. *The optimization algorithm*

Based on the mathematical model and the above considerations in part B, we formed the optimization algorithm, which is shown in shorter form at Figure 1.

The algorithm begins by defining the available resources of existing access network, coverage area, user's density, bandwidths, quality parameters and characteristics of access technologies.

As a first step, we examine whether we consider radio technology. If we consider wire technology, then we determine the number and total length of required optical fibers and the number of active elements, as a function of bandwidth and users density. If we are considering a radio technology then we determine the number and type of

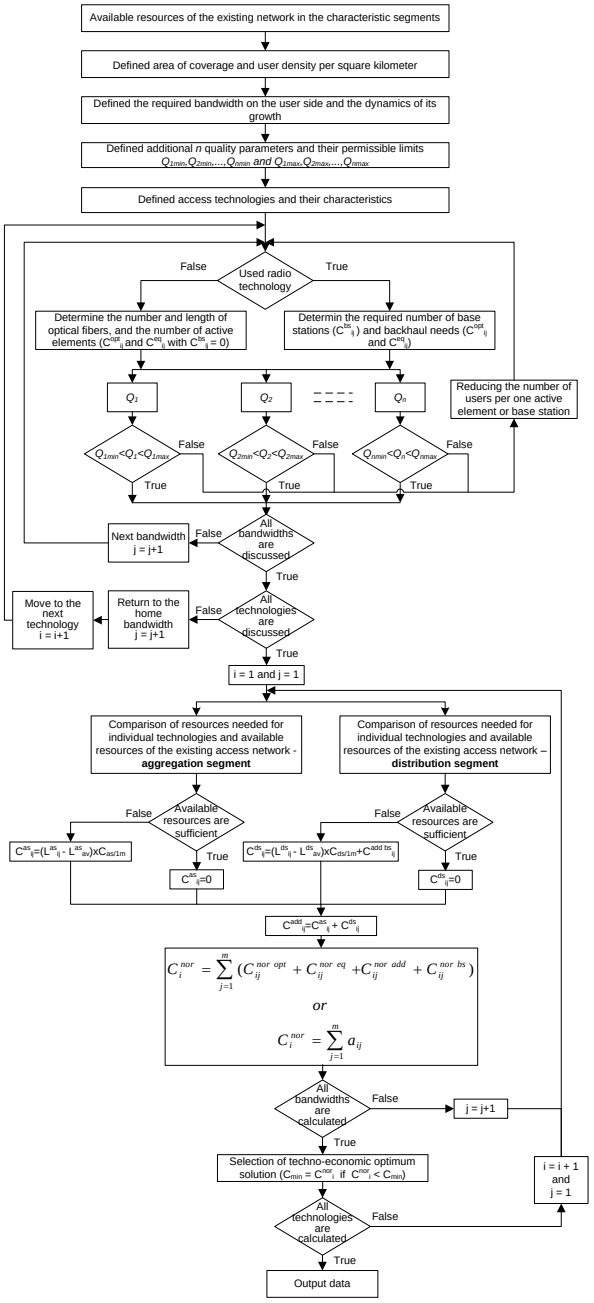

Figure 1. The optimization algorithm for wired, wireless and mobile access networks

base stations. Also, we determine the required amount of active equipment, and the number and length of optical fibers to connect base stations to the rest of the network. These calculations are made on the basis of mathematical model given in [2]. Based on the initial assumptions, mathematical model for radio technology was not observed in this paper.

After determining the necessary resources for the analyzed solution we perform its comparison with the quality parameters. If any of the parameters is not within the allowed limits we reduce the number of users per one active element or a base station. The process is repeated until the obtained solution does not satisfy the defined quality parameters within the permitted limits. This procedure is repeated for all considered bandwidths. If the preliminary proceedings conducted for all bandwidths, the same procedure is repeated for the next technology.

When the procedure is finalized for all technologies, the required resources of individual solutions are compared with the available resources of the existing access network. The aim of this comparison is the maximum utilization of existing resources while reducing the cost of a new product. When the available resources are sufficient then the extra cost are zero. Otherwise, they are calculated according to equations (1), (2) and (3).

All prices are normalized in equations (5), (6), (7) and (8). In this way, prices may not be expressed in monetary units, and they can be combined among themselves for the various elements of the network.

If the elements of technological solutions differ, and we do not know the real price, our solution to this problem is the introduction of a parameter a_{kj}. The parameter a_{kj} is determined by the equation (12). Normalized price for i-th solution we calculate according to equation (13). In this case the solution with the minimum cost is determined using the equation (14).

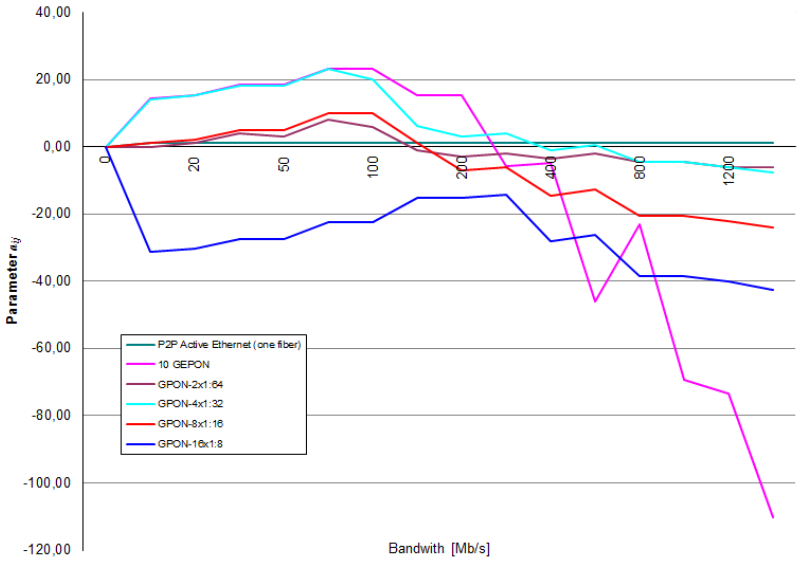
If the total normalized price is calculate according to equation (4), then the solution with the minimum cost determined using the equation (9).

One solution, or more of them, which possess a minimum price presents an optimal solution for the given initial conditions observed access network.

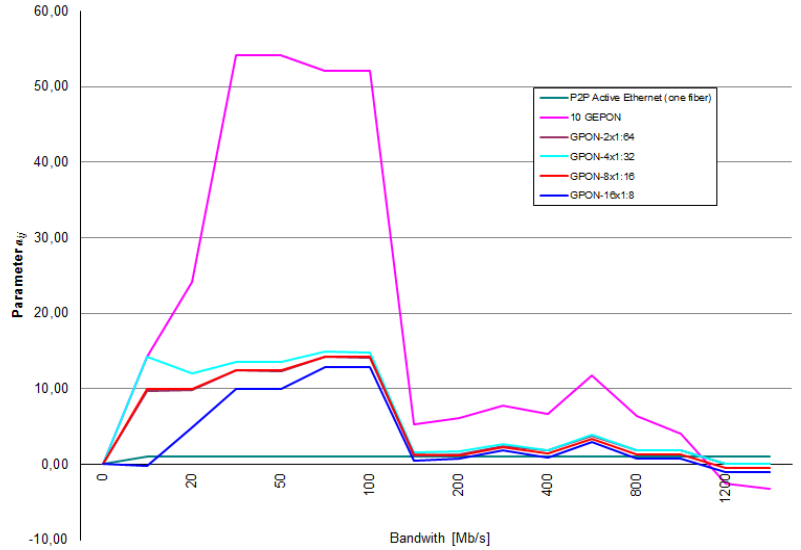
III. RESULTS

Taking into account the previously adopted assumptions and using the developed mathematical model and algorithm, we obtained results that confirm our initial hypothesis. They also verify the results that were previously obtained in the work [2]. At Figure 2 a) and b) are presents the results of behavioral parameters depending on the changes in bandwidth, the users density of 10 and 100 users / km2, respectively. The same calculations are made and the users density of 1000, 10 000 and 100 000 users / km2. For this users density are obtained almost identical parameter relates, such as shown in Figure 2. b). The difference is mainly related to the equalization parameters for GPON solutions, and its increase by 10 GEPON solution in relation to the other. As expected, the solution with active Ethernet has a constant value for all bandwidths, due to the assumption of a minimum price of its active equipment.

On Figure 3. Are presented the results of behavioral parameter a_k in dependence of users density, when $C^{opt}/C^{eq}_{\min}$ = 1/10. When $C^{opt}/C^{eq}_{\min}$ has got a values 1/100, 1/1000 and 1/10 000, behavior of the parameter a_k is similar to the behavior of parameter a_{kj}.



a)



b)

Figure 2. a) and b) The behavior of the parameter a_{ij}, with respect to the change of bandwith, for users density of a) 10 users/km^2 and b) 100 users/ km^2

Solution for active Ethernet in this case is constantly for all user densities.

IV. DISCUSSION

At lower user density results show that changes solutions benefits caused by changing bandwidth much more pronounced than at higher user densities. Also, in Figure 3. we can see that at different user's densities completely different solutions become the most appropriate for the application. Through that we have argued the initial hypothesis.

When users density reaches a certain value of the convenience use is stabilizing and the difference in the benefits of individual solutions becomes approximately constant. The lower limit users density at which stabilize the relationship between the benefits for the use of individual solutions is reduced to a lower value of relationships $C^{opt}/C^{eq}_{\min}$.

On Figure 3. It is visible that for the small user densities up to 100 users / km2, the most suitable solution is GPON 4x1: 32. For higher users density the most suitable solution is 10 GEPON. With the reduced relations $C^{opt}/C^{eq}_{\min}$ gradually on all user densities suitable solution becomes 10 GEPON.

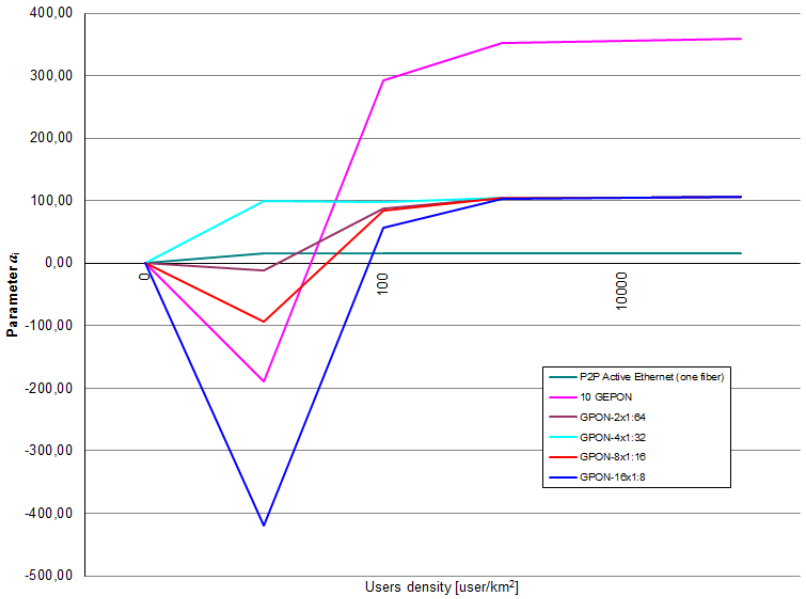


Figure 3. The behavior of the parameter a_i, with respect to the change of users density and $C^{opt} / C^{eq}_{\min} = 10$

Considering the behavior of the parameter a_k depending on user density and relations $C^{opt} / C^{eq}_{\min}$ we notice that he does not give specific values of prices of individual solutions. He gives limits in which individual solutions can be most favorable. If the actual cost of the active equipment meet this limit it becomes the most suitable solution. If the actual cost of the active equipment does not meet the limits given by the parameter a_k then solutions with this active equipment will not be the best solution.

In this way we do not get the final but conditionally optimal solution. The algorithm and implemented method finds the final optimal solution in the case of recognition of real price of active and passive equipment.

The subject of further research by this method would be the development of mathematical models for wireless and mobile access technologies. Continued research will entail adequate quality parameters. New research will also include other access technologies, which were not the subject of this study.

The above research will not affect the generality of the results obtained in this paper.

V. CONCLUSION

The initial hypothesis is confirmed, and at the same time are verified the results obtained in the paper [2]. Achieved contribution of this paper is a new method in the process of optimizing access networks, formed mathematical model, and a new algorithm that describes each step of the new method.

The method and algorithm are applicable for all access technologies. With minor adjustments they can be applied in other optimization processes. For a new needs it is necessary to adjust some parts of the mathematical model. The most part of the mathematical model is universally accepted and can be used for other optimization tasks.

***Abstract*— This paper demonstrates the design, implementation and the evaluation of a new open source tool for estimating end-to-end packet loss between a source and a destination node over the lossy Internet. Different from the most of the proposed tools in the literature that uses either TCP or UDP, and may require long time to accurately predict the packet loss rate, the proposed tool utilizes both features of the TCP and UDP, thus making it able for accurately predicting the packet loss of a communication link within a short probing time, which makes it appropriate for real-time multimedia applications. Our performance evaluation shows the effectiveness of the proposed tool even in relatively short probing time.**

Keywords—Network probing, active probing, packet loss estimation and prediction, multimedia applications

I. INTRODUCTION

Internet packet loss is considered one major factor that greatly affects the quality of many Internet applications such real-time multimedia services including audio and video streaming, VoIP, video conferencing, etc. [1]. These applications are becoming very essential in our daily life and users are continuously demanding better performance. The main problem that the Internet is not originally designed to transport real-time Internet traffic. As such, different mechanisms have been used to improve the transmission quality of these applications [2]. Some examples of these techniques are the use of joint source and channel coding for determining the optimal source/channel encoding scheme for a given network packet loss, such that the expected received video or audio quality is maximized. Another approach is to dynamically change the multimedia encoding rates and qualities such that a low encoding rate with a low media quality is used when the network is congested, where high packet loss is encountered, while higher rate with higher quality is used for less congested networks [3]. However, all these proposed algorithms and techniques rely on estimating the network packet loss, so the appropriate action can be taken. Moreover, predicting the packet loss rate helps in network management and routing the Internet traffic to less congested links [4]. Furthermore, many of the proposed QoS routing algorithms rely on estimating the packet loss rate for different routes and communication links [5, 6].

Packet loss estimation can be performed using passive or active methods [7]. In passive methods, the behavior of the ongoing TCP sent packets and their re-transmitted packets are observed and an estimation for the end-to-end packet loss is obtained, these methods can be useful for monitoring the network and evaluating the QoS of different transmission links, which is very valuable for Internet Service Providers (ISPs) [8] who try to direct the traffic to the less congested links. These methods assume the existence of a TCP traffic between a source and a destination node, which may not be available in case these two nodes are exchanging real-time multimedia contents that normally use UDP traffic. The other probing technique samples the network by sending probing packets between the source and the destination nodes, the sent packets can be an ICMP, TCP or UDP packets. In the literature, there are many tools proposed to predict and measure the network packet loss. In what follows, a brief description of the most closely related work in the literature is provided. Authors in [9] designed a tool named *tulip* that utilizes the ICMP protocol in sending ICMP echo packets to a destination node, and by exploiting the ICMP features such as the timestamps and IP identifier counters, return remote timing and ordering information, the path packet loss can be estimated. However, ICMP-based tools have two main problems as reported in [10] that reduce their accuracy and practicality. Authors in [10] proposed a TCP-based networking measurement tool called *Sting*. Sting analyzes the TCP stream to predict packet loss in both directions between the receiver and the transmitter nodes. However, due to the TCP protocol operation nature and features such as: three way handshaking, packets re-transmission in case of packet loss, packets acknowledgment in case of packet reception, etc.; it will require significant time to estimate the packet loss. In addition, TCP packets have large packet header size, which increases the transmission overhead and delay. As such, TCP- based techniques may not be timely efficient for real-time multimedia applications that require a quick method to estimate the link packet loss.

The rest of the paper is organized as follows: Section II discusses the tool design, its features, and implementation. Section III describes the test-bed setup used in the experimental evaluation. Section IV provides performance evaluation of the tool. Finally, Section V concludes the paper and suggests future works.

II. TOOL DESIGN AND IMPLEMENTATION

In this section, a detailed description of the tool design implementation and architecture is provided. Further, the tool operation and how it can estimate network packet loss is demonstrated and supported by some examples.

A. NetProb design and operation probing modes

As shown in Figure 1, the tool is composed of two main components; the transmitter and the receiver. Suppose the network packet loss of the one way path between two computers over the Internet is to be estimated. Then, the transmitter component should run on the first computer while the receiver component should run on the second computer. Each one is composed of two different modules, TCP and UDP modules. The transmitter component operates as a TCP and UDP sender, while the other component operates as a TCP and UDP receiver. The TCP sender role is to establish the connection through the handshaking process shown in Figure 2. The handshaking packet will notify the receiver of the probing settings that will be used by the transmitter, mainly, the *Notification Period (NP), the Probing Window (PW), and the Probing Sleeping Period (PSP)* defined later, After the TCP receiver receives the handshaking packet, it will accept this connection by sending an acknowledgment signal to the transmitter, then the UDP sender at the transmitter starts probing UDP packets according to the probing settings configured at the transmitter. These settings include the NP, PW, PSP, and also the size of the probing packets. The NP defines the time period that the receiver will wait to receive the probed packets sent by the transmitter. At the end of this period, the receiver will estimate the packet loss and send it to the transmitter. In fact, the receiver is able to estimate the packet loss since the transmitter during the handshake stage sent how many UDP packets will be transmitted during this probing period. The number of packets sent during a probing period is defined as the PW. After the transmitter sends the UDP packets as defined in PW, it sleeps for a period of time defined as the Probing Sleeping Period. The PSP is simply the time duration in which the transmitter will sleep and stop from probing packets, after this time elapses, the probing period ends and the transmitter will record the reported packet loss sent by the receiver during the probing period, and then repeat the probing process again (i.e. sends a TCP handshaking packet and then start sending UDP packets). Notice that varying the PSP is inversely proportional with the probing rate, which is defined as the number of probed packets during the probing period. Consequently, increasing the PSP while fixing the PW will reduce the probing rate and vice versa. For example, if PW was set to 5, and the receiver only receives 4 packets during NP, then it will report 20% packet loss estimation for this probing period.

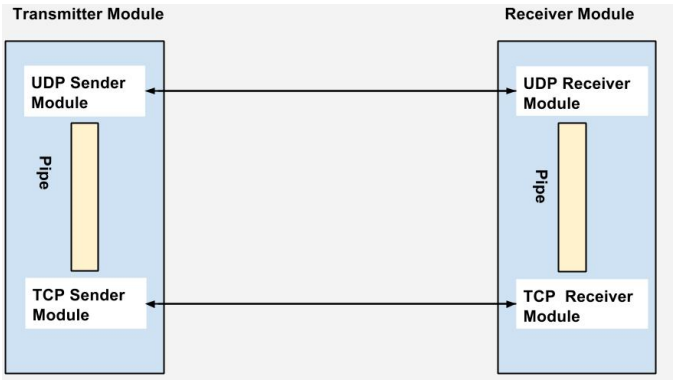

Figure 1: The NetProb software architecture

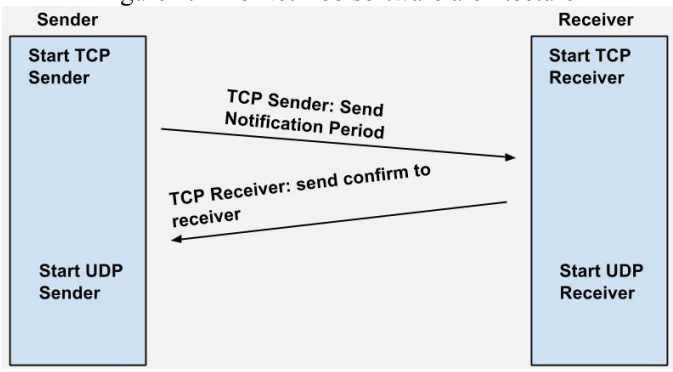

Figure 2: NetProb Handshaking steps

Figure 3 depicts the steps after the transmitter and receiver initialized the connection through the handshaking process, through which NP, and PW were both set to 5. After that, the transmitter starts sending the UDP probing packets to the receiver (Step 1), then it sleeps for 5 seconds (PSP = 5), while the receiver node waits for a period of NP seconds (5 in this example), it counts the number of received UDP packets, estimates the packet loss, and sends its estimation to the transmitter using a reliable TCP connection (Step 2). The transmitter then saves the received packet loss ratio, and also calculates the overall average loss ratio for the all probed packets (Step 3). Notice that this value will be the same as the one received by the receiver for the first probing period, but after that, it will be the average of the subsequent estimated packet loss for each probing period. Then the sender will start a new probing period after the PSP (5 seconds in this example) finishes (Step 4). Once this step is finished, the NetProb finishes one probing period, and restart another period by issuing a new handshaking packet to the receiver node. Notice that this combination of both TCP and UDP assures synchronization between the transmitter and the receiver.

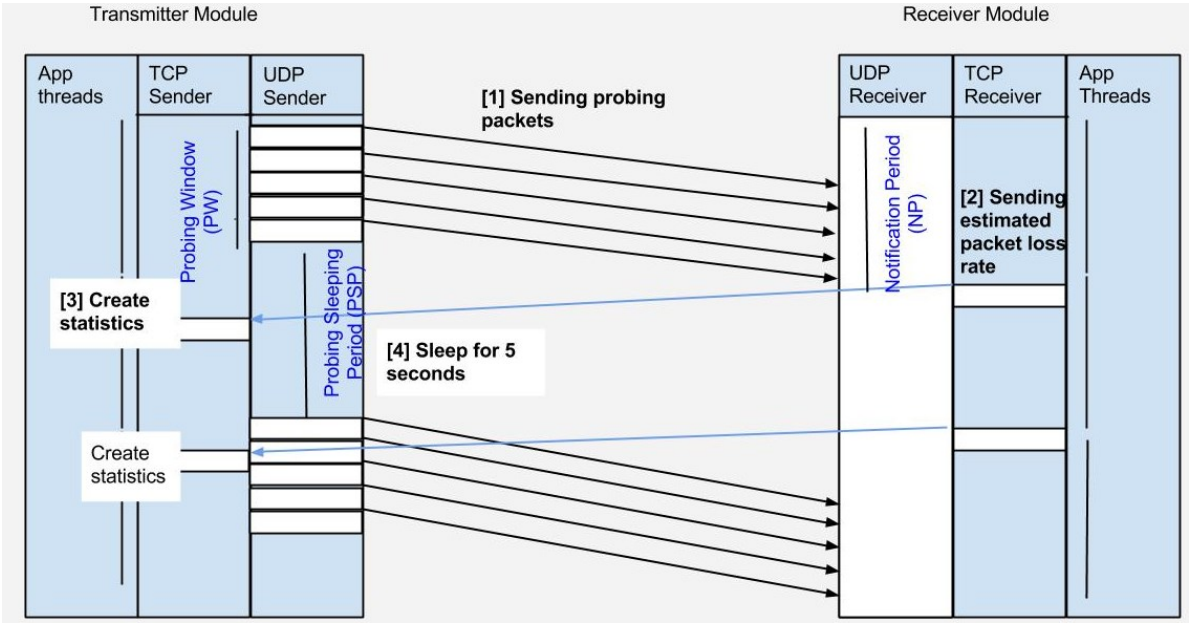

Figure 3: NetProb operation steps for one probing period

B. *Probing modes*

NetProb is designed to operate in two different modes; the first one is the fixed probing mode, in which the same probing settings are used for all probing periods. The other mode allows NetProb to probes packets non-uniformly; hence packet probing can follow certain statistical distribution. In this mode, NetProb changes its parameters on each probing period. So it can have different number of probing packets, probing packet size, and different sleeping periods between probing rounds. Figure 4 shows an example of non-uniform probing, as shown in the figure, the tool is configured to use a PW of 5 packets, and PSP of 3 seconds on the first probing period, while the values are changed in the second probing period to 4 packets, 6 seconds for the PW, and PSP, respectively.

C. *NetProb implementation*

NetProb is built using Python under Microsoft Windows Operating system. It provides the user with simple GUI, which was built using the Tkinter library [11]. The tool has three main threads, the main application thread, which initiates the tool and also starts the other two threads; the TCP and the UDP threads, these two threads open a TCP, UDP sockets, respectively between the sending and the receiving nodes. Notice also since the receiving node has to report the estimated packet loss for each probing period to the sending node, a reliable connection using TCP is used for this purpose, as such, the receiving nodes has to establish another TCP socket with the transmitting node. Further, since the program utilizes both TCP and UDP sockets, Inter-Process Communication (IPC) is performed by using pipes as shown in Figure 1.

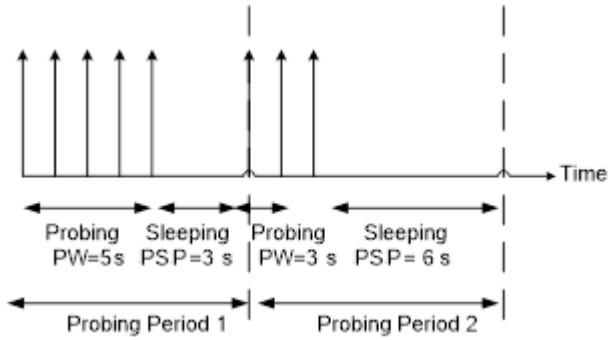

Figure 4: NetProb non-uniform probing mode

III. TEST-BED SETUP

In order to verify the tool performance and accuracy in predicting packet loss, a test-bed shown in Figure 5 is built. As depicted in the figure, the test-bed consists of two computers (laptop 1 and laptop 2), both running Microsoft Windows 7 operating system, the two computers are connected together through a direct Ethernet cable. However, in order to emulate the Internet behavior in a controlled way, the Microsoft Network Emulator Toolkit NEWT [12] is installed at one of the two computers; laptop 1 in this figure. The emulator is capable of emulating different characteristics of the Internet such as packet loss and transmission delay using different statistical models. More details about the emulator settings are provided in the following subsection.

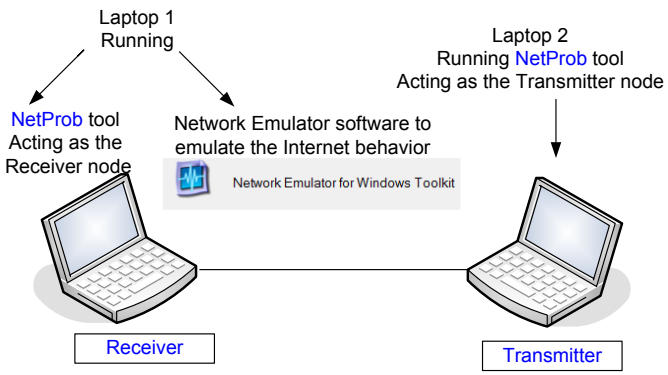

Figure 5: Test-bed setup

A. *Network emulator settings*

The emulator is used to emulate the Internet packet loss in a controlled way. In this paper, the Gilbert Eliot (GE) packet loss model is used to emulate packet loss [13]. As shown in Figure 6, this model uses two state Markov chains to describe the lossy characteristic of the Internet. It characterizes the network into two states: a Good state (**G**), which represents a less congested network situation with probability of packet loss equals to (1 - K), which has small values, while the other Bad state (**B**) represents a highly congested link with high probability of packet loss equals to (1 - H). Further, the network changes its status from Good to Bad and vice versa with a transition probabilities P and R, respectively. All these probabilistic parameters of the GE model determine the average packet loss rate.

Finally, the emulator can provide a background traffic emulation with certain transmission rate, we used the Pareto On/Off probabilistic model [14] with a shape factor, packet size, traffic rate, burst-time, idle- time equals to 1.5, 500 Bytes, 1Mbps, 1 second, 1 second , respectively.

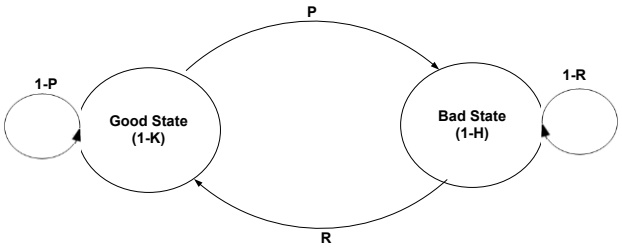

Figure 6: Gilbert Eliot packet loss model

B. *NetProb settings*

The tool provides the user with many various parameters that determine the probing behavior such as: probing packet size, number of probed packets in the probing window, idle probing time or the sleeping period, the notification period, and finally and the total probing time. In the following experiments, we tried different values of the above parameters. The Probing Accuracy (PA) is used in estimating the network packet loss accuracy which is calculated using Equation (1):

$$PA = (1- abs (L_{avg}- L_{est}) / L_{avg}) * 100\% \qquad (1),$$

where L_{avg} is the average packet loss set by the NEWT emulator, which can be controlled using the GE loss model parameters, and L_{est} is the estimated packet loss predicted by the NetProb tool.

IV. PEFORMANCE EVLAUATION

Several experiments have been conducted to verify the tool operation and it's capability in predicting the packet loss of the end-to-end path between a source and a destination node. In the conducted experiments, we varied the parameters of GE loss model to obtain various packet loss rates. Table I shows one of these experiments where the following parameters have been used to setup an average packet loss of 10% on the GE model (1 - K = 0.01, 1- H = 0.1, P = 0.99, and R = 0.01). The NetProb tool has been configured to use a probing packet size of 500 bytes, the NP, and the PSP are both set to 1 second, the PW was set to 5 packets. Notice that the optimal choice of these parameters is still one of our ongoing research works. As depicted in Tables I, II, III, and IV, the NetProb estimation accuracy was very high even for short probing times and for various average packet losses (5%, 10%, 15%, and 20%) which proves the effectiveness of the tool in packet loss estimation within a short operation time.

Table I: Probing accuracy when the average packet loss approximately equals to 5% under various probing durations. GE model settings are (1 - K = 0.01, 1 – H = 0.05, P = 0.99, and R = 0.01)

Probing time (s)	L_{avg}	L_{est}	PA (%)
100	4.85	5.14	94.0
120	5.20	5.78	88.8
140	5.24	5.76	90.1
160	4.95	5.34	92.1
180	4.95	5.19	95.19
200	4.96	5.07	97.7

Table II: Probing accuracy when the average packet loss approximately equals to 10% under various probing durations. GE model settings are (1-K =0.01, 1-H=0.1, P= 0.99, and R= 0.01)

Probing time (s)	L_{avg}	L_{est}	PA (%)
100	9.5	9.6	98.9
120	9.7	10.8	88.6
140	9.8	10.48	93.1
160	9.5	9.5	100
180	9.64	10.55	91.0
200	9.75	10.5	92.30

Table III: Probing accuracy when the average packet loss approximately equals to 15% under various probing durations. GE model settings are (1 - K = 0.01, 1- H = 0.15, P = 0.99 , and R = 0.01)

Probing time (s)	L_{avg}	L_{est}	PA (%)
100	14.9	13.6	91.3
120	15.0	16.16	92.3
140	14.7	15.5	94.5
160	14.6	15.5	93.8
180	14.5	13.66	93.8
200	14.79	14.77	99.9

Table IV: Probing accuracy when the average packet loss approximately equals to 20% under various probing durations. GE model settings are (1 - K = 0.01, 1 – H = 0.2, P = 0.99, and R = 0.01)

Probing time (s)	L_{avg}	L_{est}	PA (%)
100	18.8	19.0	98.9
120	19.95	20.0	99.74
140	20.1	22.5	88.1
160	20.05	22.5	87.5
180	19.97	21.56	92.0
200	19.78	20.9	94.3

V. CONCLUSION AND FUTURE WORK

In this paper, a network probing tool based on the TCP and UDP protocols has been proposed, where TCP is used only for connection control while UDP traffic is used for packet loss estimation. The tool showed accurate and fast estimation for the network packet loss, which makes it a good choice for estimating packet loss for real-time multimedia applications. As a future work, we are currently working on studying the optimal settings of the tool parameters such as the probing rate, the probing packet size, the probing period duration, etc., that give the best estimation accuracy with minimum probing overhead. We are also working on making the tool capable of estimating other network parameters such as the end-to-end delay and the bandwidth. Finally, we are looking forward receiving feedback from the research community after using the tool, which will be taken into consideration for further developments and improvements.

Abstract— **Migration of customers from PSTN to IMS network brings challenges in replacing the existing services with equal services on the IMS network. Emergency service centers are special types of customers that require high availability of the service and fast responses to potential failures. Differences in technology require different approaches for handling same requirements. This paper describes the method for detection of failures on emergency service centers in IMS network that we have implemented in our network. The method is based on charging events for the detection of alternative call routing cases in the situations of unavailability. In the paper we describe the motivation for such approach and analyze the results and types of failures we encountered. In addition, the paper provides wider aspects of the implementation of the emergency service centers in IMS network.**

Keywords: emergency call handling; IMS; failure detection; PSTN migration;

I. INTRODUCTION

Migration of customers from PSTN (Public Switched Telephone Network) to IMS (IP Multimedia Subsystem) network brings challenges in replacing the existing services with equal services on the IMS network. Emergency service and emergency service centers are one of the most delicate services and customers to migrate. Apart from the most important requirement of keeping the service availability and minimizing the risk of outages during migration, emergency service centers are treated as very important customers and often special solutions are designed for them. In this paper we are describing the solutions for migration of emergency service centers that we have developed in IMS network with the focus on the improvements in failure detection and the analysis of the results. IMS network standardization bodies have recognized the need for special handling of emergency sessions and have dedicated technical specifications [1] addressing this subject. Implementation of emergency call handling architecture on open-source project Open IMS is described in [2] with the focus on providing a test bed for verification of technical specifications. An overview of challenges in implementation of emergency call handing in production IMS network is given in [3]. As we can see from the papers, there are several topics that should be addressed when implementing and migrating emergency call centers from PSTN to IMS network. While localization of customers, selection of nearest PSAP (Public Service Answering Point) and recognition and prioritization of emergency calls are handled by the IMS network, mechanisms for alternative routing of calls in case of unavailability is unlike to PSTN not supposed to be handled by the IMS network thus it should be handled differently e.g. on application server (AS) using call forwarding service.

In this paper we are describing the configurations of two types of emergency call centers that are migrated to IMS: emergency centers with local PBX (Private Branch Exchange) connected over ISDN BRA and emergency centers with local analogue PBX where PBX functionality is provided by the network. On each type of access different causes of failure can happen resulting in service unavailability which triggers alternative call routing that is registered in charging events. These charging events can be used as triggers for alarming the network operations center which can then take necessary steps to determine and eliminate the cause of failure. Specific to emergency call centers is that they are used primarily to receive calls therefore it is much harder for them to detect the faulty line i.e. it is the caller who first encounters the faulty line. For this reason alternative call routing and network detected failure play very important role in emergency call handling.

The paper is organized as follows. Section II describes the principles of configurations of emergency call centers on IMS and the idea of the failure detection mechanisms. Section III describes the architecture of the failure detection mechanisms. Section IV analyzes the results and provides the insight in the types of encountered failures, conducted analysis and ideas for improvements. Section V summarizes the conclusions of this paper.

II. EMERGENCY CALL CENTER IN IMS

IMS network is a telecommunication network that is part of a layered architecture and unlike to PSTN doesn't have dedicated last mile connection but relies on IP connectivity which is expected to be provided by lower layers. Multi layered approach brings more elements in consideration when it comes to possible failure points and it also brings split responsibility for failure detection and remedy. In this chapter we are describing configurations of emergency centers in our network and possible types of failures.

A. Types of emergency call centers

Figure 1 shows ISDN PBX connected to PSTN network. This is a typical configuration of medium sized emergency call center in Croatia. Up to four ISDN links from operator's telephone exchange are installed at customer's premises. Each of the links is terminated in one ISDN network termination (NT) equipment. The emergency call center connects its own PBX to the NTs. Usually a recording device is also placed in between the PBX and the ISDN NT. Typically regular phones connected to the PBX are used for receiving and placing calls.

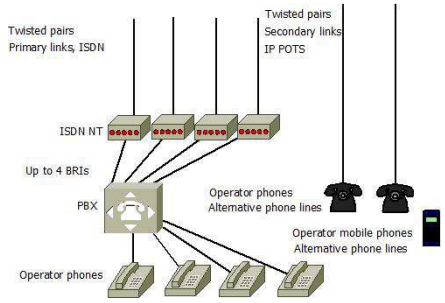

Figure 1 Emergency call center in PSTN with ISDN BRA PBX

On the right side of the figure alternative lines for receiving emergency calls are shown. In some emergency call centers alternative lines are placed at the same location as primary lines i.e. they serve only as backup lines when primary lines are not working. In other emergency call centers, alternative lines are actually primary lines of another emergency call center i.e. in case of failure another emergency center beside its own traffic handles also the traffic of the center which is in failure.

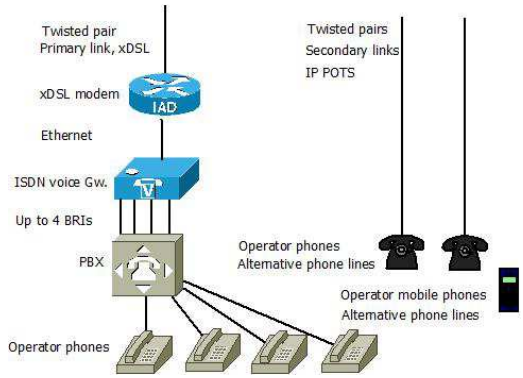

Figure 2 Emergency call center in IMS with ISDN BRA PBX

Figure 2 shows the same emergency call center migrated to IMS network. The difference on the customer premises is that the ISDN NTs are replaced with the xDSL modem and ISDN voice gateway (GW). The xDSL modem is connected to the operator's network over a single twisted pair cable meaning that all other lines used for ISDN connection became obsolete after the migration. The role of the xDSL modem is to provide the IP connection to the ISDN voice GW which then provides the ISDN BRI interfaces to the customer's PBX and the SIP user agent functionality for registration and communication with the IMS network. ISDN GW is the main element at customer's premises where operator's configuration and customization for proper functioning of the service is configured.

Another type of emergency service center is shown on Figure 3. Customer uses the analogue PBX which is connected over analogue lines (POTS lines) to operator's telephone exchange and has several phones connected to it. The operator's telephone exchange provides the functionality of serial distribution of incoming calls to analogue lines.

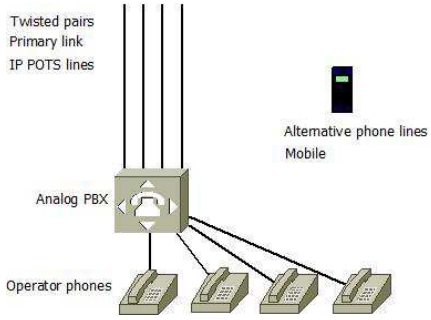

Figure 3 Emergency call center with analogue PBX

In this scenario when migrating the emergency call center form PSTN to IMS nothing changes on the last mile for the customer. Nevertheless, from the network point of view the differences are huge. The entire service logic has to be emulated by the IMS network. In IMS network the serial distribution of incoming calls and other call features are provided by the application server (AS). The emulation of POTS interface is provided by the multi-service access node (MSAN) which is a node located in operator's access network that acts as a SIP user agent towards the IMS network.

Besides the just described configurations, there are some special call features required from emergency call centers and that need to be developed especially for their purpose i.e. such features are not provided to regular customers. Example of such features is the type of call transfer which is used by the 112 center in Croatia where the transferred emergency call from 112 center to another emergency center is actually a new call which carries the identity presentation of the original caller. Requirements of this kind are handled by special configurations on the AS, ISDN GW and on session border controller (SBC). SBC as the first node in the access to the IMS network handles also the requirements for the prioritization of calls.

To be able to efficiently handle these specifics, in our implementation, we have introduced emergency subdomain in which we have separated all emergency call centers from regular IMS users. Using a subdomain as a differentiator of emergency call centers a special call handling and many dedicated features to emergency call centers can be applied. One of such features that we implemented is triggering alarms in case when a call arrives to an emergency call center which is for some reasons not reachable. The architecture of such

mechanisms and benefits of implementation are explained in next chapters.

B. *Failures and possibilities for failure detection*

High availability is crucial when designing a call handling solution for emergency call centers. Obviously, failures cannot be completely avoided therefore it is important to detect them as soon as possible. By failure we are referring to any circumstance that is preventing the emergency call center to receive or place calls. Usually it can be caused by faulty equipment, wrong configuration of equipment or connectivity problems.

In PSTN network failure detection on the line or in the communication with the PBX is much easier than it is in the IMS network. This is especially the case on the ISDN where such features are more evolved end it is easier to monitor the lines. If we compare the installation of the emergency call center with ISDN BRA PBX in IMS network to the installation in the PSTN network we see the higher risk of failure that is introduced with additional equipment and lower number of physical lines (twisted pairs) at customer premises. This doesn't refer only to faulty or misconfigured equipment, but also to human factor on the site which can result in accidental disconnections and/or wrong connections between elements. Additionally, instead of dedicated telephony equipment (ISDN NT), we are placing the multipurpose equipment (xDSL modem). The ISDN NT equipment follows more rigorous standards for stability, protocol adherence and quality of implemented maintenance functions. That, in turn, results with better fault detection system.

In the case of analogue PBX configuration compared to the ISDN BRA PBX configuration advantages in failure detection are in the fact that there is no new and additional equipment at customer premises and that SIP user agent is placed on the MSAN node which is located in central office. Since MSAN node is part of operator's network equipment, placed in operator premises and serves many customers it is integrated into operator's real-time monitoring system. This brings much higher probabilities for faster fault repair. Unfortunately, real-time monitoring of xDSL modems and ISDN GWs is not very practical because of their very large number in the network and the fact that a lot of customers switch them off on purpose, e.g. out of working hours for preventing electricity consumption.

In IMS network failures can be detected based on SIP response codes which are generated as responses to SIP requests for sessions, registration, re-registration etc. Failures can be detected on network side or by the SIP user agent. When the SIP user agent receives the error response code on registration or on session initiation attempt or it doesn't receive the response at all, it usually tries to reattempt to register over the alternative SIP proxy which it has been configured in it. On the other side the IMS network can only detect if the SIP user agent is registered and if the registered user agent properly responds to SIP requests. There's no way the network can force or ping an unregistered user agent to register. That is because SIP registration is the mechanism for associating the user agent with its location and unregistered user agents remain unavailable to the network. Since SIP registration is periodical activity, possible failure situation is when the network sees the registered user agent which is in fact unavailable due to network conditions and cannot respond to SIP requests. In such cases the user agent is not aware of session requests or any problems with the network until it attempts to re-register. Such and other unavailability cases have to be handled by the network in the way to provide the routing to an alternative emergency destination, since the primary is not reachable. In our case, we are doing the alternative routing on the IMS application server which triggers the call forwarding service on not reachable user agent. Such functionality should be only operator administered since is vital for proper functioning of the emergency service. It is important to note that such call forwarding for emergency call centers should be free of charge therefore special charging logic for such scenarios should be developed.

III. FAILURE DETECTION SYSTEM ARCHITECTURE

The architecture of the failure detection system is shown on Figure 4. The figure shows the IMS network with the application server (AS) which is providing the services to the emergency call centers. In our network we are using two types of AS which are handling the emergency call centers. The type of AS is determined by the type of access (MSAN or xDSL) to which the emergency call center is connected. Nevertheless, the alarming logic is the same for both types of AS. Each AS is connected to the charging mediation function which analyzes offline charging records and sends the alarm events to the network monitoring system.

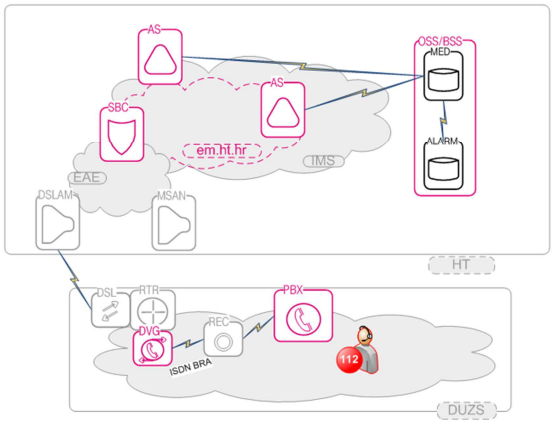

Figure 4 Architecture of the alarming system

The charging mediation logic is implemented in the way to detect a forwarded call of the IMS users which are in the emergency domain i.e. the emergency call centers. During each call the AS sends charging account records [4] to the charging system which is performing real-time analysis of such records. Such records, among other, contain information about the called domain, indication that the call has been forwarded, type of call forwarding service and the reason for forwarding the call. Alarm is triggered when the forwarded call from emergency call center is finished.

IMS as a network can only detect failures of this type based on SIP response error codes which are generated by the involved network elements. Other ways for detecting such failures would be to monitor SIP signaling and filter desired SIP response codes, or to trigger alarms directly from the AS. Since we are interested only in particular SIP response error codes and only for particular IMS users and call scenarios, we found it more practical to implement the alarm generation logic on the charging system. Generally, unavailability of user equipment will be more frequent when the IMS network will serve also mobile devices in VoLTE scenario, meaning that unlike with fixed terminals for mobile terminals is a normal behavior that it is switched off or located in the area with no network coverage.

IV. Analysis of results

After the implementation of the described alarming system we have performed initial analysis of the alarms occurred over the period of two months. The goals were to find issues which are causing the alarms and to establish a solid fault repair procedure which will be triggered when an alarm occurs. First results showed a lot more alarms that are occurring than expected. Such amount of alarms required to search for alarm occurrence patterns and to perform alarm filtering to eliminate alarms which were not caused by unavailability of endpoints.

Correlation between alarms and all calls placed towards specific emergency call center showed two types of alarm occurrence: (*i*) periodic, where alarms are occurring between successful calls and (*ii*) continuous, where alarms are occurring on each call attempt. Continuous are most problematic from the emergency call center perspective but are also most easy to detect and to find the problem and a solution it is just matter of reaction time and problem type. On the other hand, periodic failures are most difficult to detect, and often it is most difficult to find the cause of the problem. It is in those cases where our failure detection system brings more value. Detecting a periodic failure from emergency call center is difficult because its primary role is to receive calls. Our emergency call handling configuration provides alternative routing in cases of unavailability of one emergency center. That means that the user always reaches another emergency call center (or even the same emergency call center but over the alternative line) if the primary is not reachable so it is not experiencing service outage and doesn't notice that there is a reason to report a problem. This brings us to the conclusion that such types of failures should be detected by the network and with dedicated failure detection logic.

Simulation of alarms in test environment showed that the MSAN generates busy response code in some cases of failure on its POTS line e.g. short circuit, contact of the line with ground etc. For this reason we have configured the application logic to forward the calls from the analogue PBX on the alternative mobile device even in the busy case. This situation in the alarm analysis introduced a lot of confusion since there was no way to distinguish the failure from the regular busy case ad such alarms had to be discarded.

Analysis of the remaining alarms showed that most commonly following types of failures are:

- Wrong connections of PBX and ISDN GW. ISDN GW is equipped with four BRI interfaces may not all be configured. How many ports are configured depends on the installed capacity, usually it is just two. In such cases it can happen that the user for some reasons disconnects the PBX from the right port on the ISDN GW and connects it to the port that is not configured resulting in reduced capacity (two instead of four ISDN channels). This type of misconfiguration cannot be easily detected by the user himself.
- Wrong configuration on the ISDN GW resulting in reduced capacity.
- Unregistered SIP user agent(s) on the ISDN GW.
- Defects on the BRI link between the ISDN GW and the PBX resulting in instabilities of the link meaning that the link is irregularly up or down.

Some of these failures would have been difficult to detect without the implemented alarming system. Additionally, during the analysis of endpoint configurations some other misconfigurations have been detected like the one on the ISDN GW which resulted in the inability of making outgoing calls. Repairing detected failures resulted in lower number of alarms.

V. Conclusions

In this paper, we have described the configurations of emergency call centers in IMS network which are based on analogue PBX and ISDN BRA access points, the implementation of the failure detection system based on charging events and provided the analysis of alarms generated by this system. Implemented alarming system proved to be useful for detecting failures that would otherwise be very difficult to notice. Most of the detected failures showed that there was a problem on the end point which resulted in repairing action of the endpoint configuration meaning the ISDN GW or the customer PBX. Further work on the subject is to check each endpoint which is generating occasional alarms and to apply alarm filtering for the busy case. In this way we will reduce the number of alarms and be able to setup a real-time reaction procedure in the case when an alarm occurs. Additional improvements in the alarm logic could be to detect the occurrence of the subsequent successful call for alarm seizure or classification. ISDN PRA emergency center access points were not described in this paper because at the moment they are not implemented in our network, but the alarming logic also for these types of access points remains the same.

Analysis also showed that there is a need for alternative routing of emergency calls in cases of unavailability of endpoints and that it increases the general reliability of the emergency call handling.

Abstract - **Incremental relaying has been recently introduced to overcome the problem with the restricted resources utilization associated with fixed relaying schemes in a pre-determined manner. Only when the direct path is not usable, the incremental relaying exploits the feedback from the destination to inform the relay about the necessity to send the source signal. In this paper, the performance analysis in terms of the bit error rate (BER) of the decode-and-forward (DF) incremental relaying over mixed fading channels is provided. The effects of the Co-channel interference near the destination and the relay caused respectively by the multiple L and N interferers are presented. Numerical results are provided to prove the solidity of our assumptions and compare the results of the system with and without the effects of the interference at the relay.**

Keywords: ***Incremental relaying, cooperative diversity, decode-and-forward, interference, bit error rate (BER), signal to noise ratio (SNR), signal to interference ratio (SIR), maximal ratio combiner (MRC).***

I. INTRODUCTION

The deployment of the cooperative diversity has been considered due to its appealing attributes in term of extending the battery life of the communication devices, extending the coverage area and the spatial diversity gain at the destination [1-3]. Cooperative wireless networks are implemented by placing the intermediate nodes between the sending node (the source) and the receiving node (the destination) in an attempt to enhance the reception of the source signal at the destination.

Incremental relaying came into play to mitigate for the deficiencies of the fixed schemes by saving the channel resources in which the relay will get involved only when the direct path is not usable [4].

Performance analysis of relay systems with interference at the relay was presented in [5]. Closed-form expressions for outage probability and BER in relay-based cooperative diversity systems over different fading channels with the presence of multiple interferers near the destination were introduced in [6-7].

In this paper, we discuss the decode-and-forward incremental relaying cooperative diversity by introducing an intermediate single relay and multiple L and N interferers located near the destination and relay, respectively, which will affect the performance of the system in response to the Co-channel interference over mixed fading channels between the source-destination and the source-relay-destination paths.

This paper is further presented as follows; Section II provides the system model. Section III provides the performance analysis and derived tight closed form formula of bit error rate. Results and discussion are presented in section IV. Finally we concluded this paper in section V.

II. SYSTEM MODEL

In Fig. 1, the channel coefficient between the source and the destination is assumed to follow the Rayleigh distribution whereas the Channels coefficients between the source-relay and the relay-destination are assumed to follow the Nakagami-m distribution. The relay will participate with the source in transmitting its signal to the destination upon the reception of the destination's negative feedback that request the relay to send the source signal within the second time slot. The relay then will decode the source signal, re-encode it and then send it to the destination.

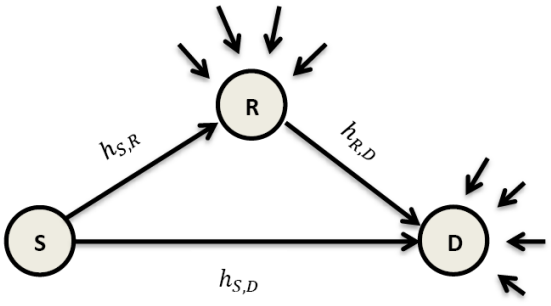

Fig. 1 Cooperative Diversity Network with Multiple Interferers L and N Located near the Destination and the Relay, respectively.

The noise at the destination is assumed to be Additive White Gaussian Noise with a unity variance N_o. Beside that, near the destination and the relay, the channels from the L and N interferers respectively that cause a Co-channel interference

are assumed to be a sum of identically, independently and exponentially distributed Rayleigh random variables which consequently will degrade the overall performance of the system. All the nodes in the system are equipped with one single antenna and Time Division Multiple Access (TDMA) is used as the multiple access technique, it is worth to mention that Frequency Division Multiple Access (FDMA) can be used too.

Within the first time slot, the destination will receive a signal directly from the source and based on the quality of this signal, the destination will decide whether or not the relay should participate in the transmission. From instance, if the direct transmission was successful and the destination can properly process the source signal from the direct transmission, then a positive feedback from the destination will be sent to both the relay and the source respectively informing them about the successfulness of the direct transmission and requesting the source to send a new signal within the second time slot. Otherwise, if the destination failed to receive the source signal or the direct path was in outage, then the relay will be requested to resend the source signal within the second time slot which by then will be combined with the source signal at the destination using the MRC.

The received signals at both the relay and the destination within the first time slot are:

$$y_{S,D}(t_1) = h_{S,D}\sqrt{E_s}\, x(t_1) + n_1(t_1) + I(t_1) \quad (1)$$

$$y_{S,R}(t_1) = h_{S,R}\sqrt{E_s}\, x(t_1) + n_2(t_1) + I(t_1) \quad (2)$$

where $x(t)$ is the symbol signal with a normalized energy. $n_1(t_1)$ and $n_2(t_1)$ are the AWGN noise terms at the destination and E_s is the signal energy. The interference effects at the destination and the relay within the first time slot are represented by $I(t_1)$.

If the relay participates in the transmission within the second time slot, then the received signal at the destination from the relay is denoted as:

$$y_{R,D}(t_2) = h_{R,D}\sqrt{E_s}x_r(t_2) + n_3(t_2) + I(t_2) \quad (3)$$

where $x_r(t_2)$ is the regenerate signal at the relay within the second time slot . $I(t_2)$ is the interference effects near the destination within the second time slot.

The destination will assess the usability of the direct link by comparing the signal to noise ratio of the direct path against $\gamma_o$which is the minimal threshold for which the destination can receive the source signal merely depending on the direct path without the help of the relay.

In the interference environment, in most of the communication systems, rather than working on the SNR at the destination a transgression is made to merely work on the signal to interference ratio SIR since the noise effects near the destination is not comparable to that of the Co-channel effects and since the interference limited environment is a common practice in the literature.

In the following section, we will derive the building blocks in deriving the performance metrics, namely the probability density function (PDF) and the cumulative distribution function (CDF) of both the SIR at the relay from the source link and the SIR at the destination from both the relay and source respectively.

III. PERFORMANCE ANALYSIS

To derive one of the performance metrics, namely the BER, of the incremental relaying scheme, both the PDF and the CDF of the SIR at the destination from the source (direct path) and the relay need to be derived. Incorporating the effect of the Co-channel interference near the destination, it is a common practice in the literature to work merely in an interference limited environment due to the fact that the noise effects at the destination and the relay are not as severe as the effects of the interferers.

A. Probability Density Function of SIR's $\boldsymbol{\eta_{S,D}}$, $\boldsymbol{\eta_{R,D}}$ and $\boldsymbol{\eta_{S,R}}$

Given that the SNR of the direct path $\gamma_{S,D}$ follows the exponential distribution and the fading channels from the interferers to the destination ($\gamma_b = \sum_1^L \gamma_k$) is assumed to be a sum of identically, independently and exponentially distributed random variables. The PDF of the SIR ($\boldsymbol{\eta_{S,D}}$) at the destination from the source path is given as follows [6]:

$$f_{\eta_{S,D}}(\eta_{S,D}) = \frac{\varsigma_{S,D}}{(\lambda_{S,D}+\eta_{S,D})^{L+1}} \quad (4)$$

where $\lambda_{S,D} = \frac{\overline{\gamma_{S,D}}}{\overline{\gamma_d}}$, $\varsigma_{S,D} = L(\lambda_{S,D})^L$, $\overline{\gamma_d} = \frac{\mathcal{E}}{N_o}E({\alpha_k}^2)$ is the average SNR of each independent interfering channel, and $\gamma_b = \frac{\mathcal{E}}{N_o}\sum_{k=1}^{L}{\alpha_k}^2 = \sum_{k=1}^{L}\gamma_k$ where γ_k is the instantaneous SNR from the $k-th$ interfering channel and L is the number of interfering channels near the destination. $\gamma_k's$ are mutually and statistically independent .

The PDF of the SIR $\boldsymbol{(\eta_{R,D})}$ at the destination from the relay path is given as follows**:**

$$f_{\eta_{R,D}}(\eta_{R,D}) = \frac{\zeta_{R,D}{\eta_{R,D}}^{m-1}}{(\eta_{R,D}+\lambda_{R,D})^{L+m}} \quad (5)$$

where $\lambda_{R,D} = \frac{\overline{\gamma_{R,D}}}{m\overline{\gamma_d}}$, $\zeta_{R,D} = \frac{(L+m-1)!}{m^L\Gamma(m)(L-1)!}(m\,\lambda_{R,D})^L$

Following the same approach used in [6] to derive (4) and (5), the PDF of the SIR $\boldsymbol{(\eta_{S,R})}$ at the relay from the source is given as follows**:**

$$f_{\eta_{S,R}}(\eta_{S,R}) = \frac{\zeta_{S,R}{\eta_{S,R}}^{m-1}}{(\eta_{S,R}+\lambda_{S,R})^{N+m}} \quad (6)$$

where $\lambda_{S,R} = \frac{\overline{\gamma_{S,R}}}{m\overline{\gamma_r}}$, $\zeta_{S,R} = \frac{(N+m-1)!}{m^N\Gamma(m)(N-1)!}(m\,\lambda_{S,R})^N$

B. The Cumulative Distribution Function of SIR's $\boldsymbol{\eta_{S,D}}$, $\boldsymbol{\eta_{R,D}}$, and $\boldsymbol{\eta_{S,R}}$

The CDF of the SIR $\boldsymbol{(\eta_{S,D})}$ at the destination from the source path is given as follows [6]:

$$F_{\eta_{S,D}}(\eta_{S,D}) = \left[\frac{(\lambda_{S,D}+\eta_{S,D})^L - {\lambda_{S,D}}^L}{(\lambda_{S,D}+\eta_{S,D})^L}\right] \quad (7)$$

The CDF of the SIR $(\boldsymbol{\eta_{R,D}})$ at the destination from the relay path is given as follows [6]:

$$F_{\eta_{R,D}}(\eta_{R,D}) = \frac{\zeta_{R,D}{\eta_{R,D}}^m}{m(\lambda_{R,D})^{L+m}}\ {}_2F_1\left(L+m, m; m+1; -\frac{\eta_{R,D}}{\lambda_{R,D}}\right) \quad (8)$$

where ${}_2F_1(a,b;c;d)$ is the Gauss Hyper-geometric function [10].

Following the same approach used in [6] to derive (7) and (8), The CDF of $\boldsymbol{\eta_{S,R}}$ at the relay from the source path is given as follows:

$$F_{\eta_{S,R}}(\eta_{S,R}) = \frac{\zeta_{S,R}{\eta_{S,R}}^m}{m(\lambda_{S,R})^{N+m}}\ {}_2F_1\left(N+m, m; m+1; -\frac{\eta_{S,R}}{\lambda_{S,R}}\right) \quad (9)$$

C. Bit Error Rate Analysis

The incremental relaying average unconditional bit error rate is expressed as:

$$p_e = \Pr(\eta_{S,D} \le \gamma_o) \times P_{div}(e) + \left(1 - \Pr(\eta_{S,D} \le \gamma_o)\right) \times P_{direct}(e) \quad (10)$$

where the first term characterizes the case when the relay helps the destination in the transmission and the second term is the case without the help of the relay and this is emphasized by the complement of $\Pr(\eta_{S,D} \le \gamma_o)$ in the second term. $P_{div}(e)$ is the average probability that an error occurs in the combined diversity transmission from the source and the relay to the destination by the MRC where as $P_{direct}(e)$ is the probability of error at the destination given that the destination decides that the relay should not forward the source signal, in such a case the destination depends only on the direct transmission.

The conditional probability of error takes the form $\alpha\, Q\left(\sqrt{\beta\eta_{S,D}}\right)$ with α and β represent the constellation parameters. For BPSK, α and β are 1 and 2 respectively, for M-PSK, $\alpha = 1$ and $\beta = 2\sin\left(\frac{\pi}{M}\right)^2$, for M-QAM, $\alpha = 4$ and $\beta = \frac{3}{(M-1)}$, $Q(x) = \frac{1}{\sqrt{2\pi}}\int_x^\infty e^{\left(-\frac{y^2}{2}\right)}dy$ is the Gaussian Q-function [8].

The approximated expression of $P_{direct}(e)$ was derived in [6] which is given as:

$$P_{direct}(e) \approx \alpha\rho \sum_{i=1}^{2} A_i \left\{ e^{-\gamma_o a_i \beta} \sum_{k=1}^{L} \frac{(k-1)!(-a_i\beta)^{L-k}}{(L)!(\gamma_o+\lambda_{S,D})^k} - \frac{(-a_i\beta)^L}{(L)!} e^{a_i\beta\lambda_{S,D}} E_i\left[-a_i\beta(\gamma_o+\lambda_{S,D})\right] \right\} \quad (11)$$

where $E_i[x]$ is the Exponential Integral function [10, (8.211.1)].

When the relay helps in relaying the source signal, the MRC at the destination will combine the two signals and the probability of error $P_{div}(e)$ is expressed as [6]:

$$P_{div}(e) = p_{SR}(e)p_x(e) + (1 - p_{SR}(e))p_{com}(e) \quad (12)$$

where $p_{SR}(e)$ characterizes the probability of error at the relay and $p_x(e)$ is the probability of error at the destination given that the relay decoded unsuccessfully and is bounded by 0.5 as stated in [11] and [12]. The term that represents the error probability at the destination given that the relay decode correctly is $p_{com}(e)$.

$p_{SR}(e)$ can be expressed as:

$$p_{SR}(e) = \alpha \int_0^\infty f_{\eta_{S,R}}(\eta_{S,R})\, Q\left(\sqrt{\beta\eta_{S,R}}\right) d\eta_{S,R} \quad (13)$$

using the Prony's approximation of the Q-function, $p_{SR}(e)$ can be expressed as:

$$p_{SR}(e) \approx \frac{\alpha\zeta_{S,R}}{\sqrt{2\pi}\Gamma(N+m)(\lambda_{S,R})^{N+m}}\left(\frac{2}{\beta}\right)^m \times G_{3,2}^{1,3}\left(\frac{2}{\beta\lambda_{S,R}}\middle|\begin{matrix}1-N-m, 1-m, \frac{1}{2}-m \\ 0, -m\end{matrix}\right) \quad (14)$$

where $G_{p,q}^{m,n}\left(x\middle|\begin{matrix}a_1,\ldots,a_n \\ b_1,\ldots,b_q\end{matrix}\right)$ is the Meijer's G-function [10,(9.3)].

For the second event, if the relay decoded the source signal correctly, then the spatial diversity will be obtained once the destination combines the received signals from both the source and the relay and this is emphasized by the complement of $p_{SR}(e)$ which is $(1 - p_{SR}(e))$ confirming the success of the decoding process at the relay, in this case, the error probability $p_{com}(e)$ will be expressed as [6]:

$$p_{com}(e) \approx \alpha \int_0^\infty f_{\eta_{R,D}}(\eta_{R,D}|\eta_{S,D} \le \gamma_O)\, Q\left(\sqrt{\beta\eta_{R,D}}\right) d\eta_{R,D} \approx \frac{\alpha\zeta_{R,D}}{\sqrt{2\pi}\Gamma(L+m)(\lambda_{R,D})^{L+m}}\left(\frac{2}{\beta}\right)^m \times G_{3,2}^{1,3}\left(\frac{2}{\beta\lambda_{R,D}}\middle|\begin{matrix}1-L-m, 1-m, \frac{1}{2}-m \\ 0, -m\end{matrix}\right) \quad (15)$$

To get the overall expression of the BER substitute (15), (14), (12) and (11) into (10).

IV. NUMERICAL RESULTS

In this section we analyze the performance of the decode-and-forward incremental relaying system over mixed fading channel encompassing the effects of the interference near the destination and the relay. The effect of changing Nakagami-m order and the threshold value γ_o on the system behavior is investigated too.

As can be seen from Fig. 2, the impact of the interference at the destination is much greater than that near the relay. For example, a system with (L=1, N=5) outperforms a system with (L=3, N=1) when the BER is 10^{-1} by about 3dB. and that explains the degradation on the system performance of the interference at the destination compared with the interference near the relay.

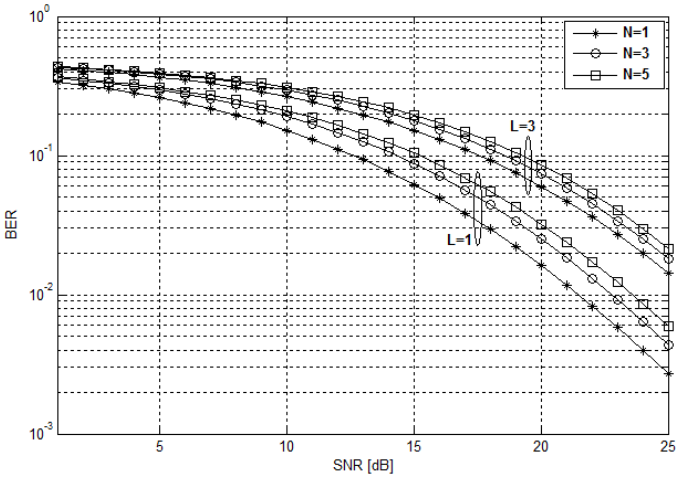

Fig. 2 Bit Error rate fir BPSK modulation with Different number of interferers at the destination (L=1,3), Different number of interferers at the relay (N=1,2,3), (m=1) and (γ_o= $\overline{\gamma_r}$=$\overline{\gamma_d}$=10 dB).

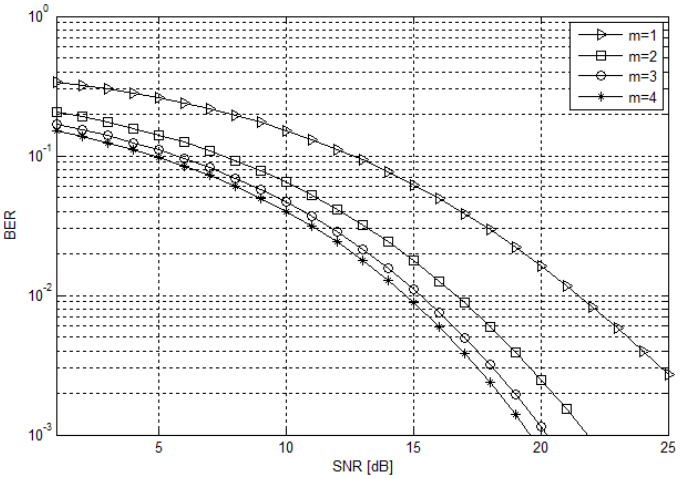

Fig. 3 Bit Error Rate for BPSK modulation with Different values of the nakagami order (m=1,2,3,5), (L=N=1) and (γ_o= $\overline{\gamma_r}$=$\overline{\gamma_d}$=10 dB).

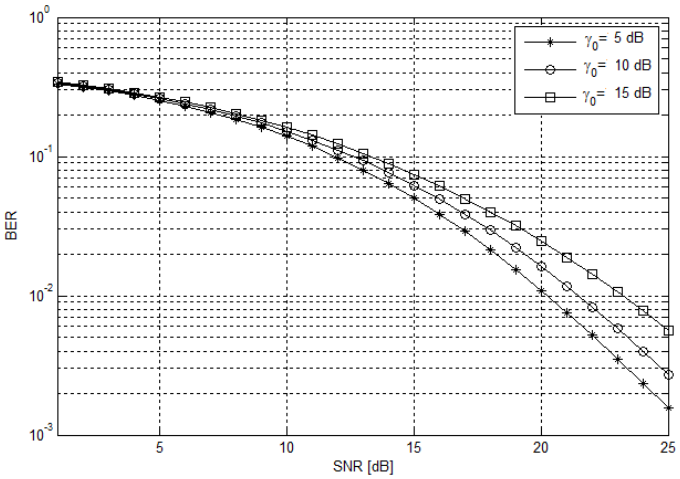

Fig. 4 Bit error rate for BPSK modulation for different values of (γ_o=5,10,15 dB), (L=N=1), (m=1) and ($\overline{\gamma_r}$=$\overline{\gamma_d}$=10 dB).

As depicted in Fg. 3, as the nakagami order increases, then system performance will be enhanced in response to that. For instance, at a BER of 10^{-2}, the system with (m=4) outperforms the system with (m=1) by about 7dB. which reflects the impact of increasing the Nakgami order m on the system performance.

The degree of degradation of the system performance when changing γ_o, $\overline{\gamma_r}$ and $\overline{\gamma_d}$ will vary. For instance, Fig. 4 represents the effects on the system when changing γ_o and it's apparent that when we increase γ_o, then the system will be degraded and as an example on that, given that the BER is 10^{-2}, then the system with γ_o=5 dB outperforms the system with γ_o=15 dB by 4 dB.

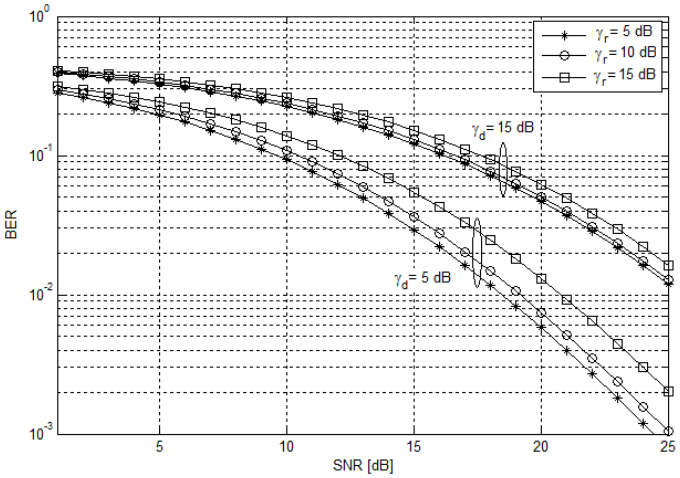

Fig. 5 Bit error rate for BPSK modulation for different values of (γ_o=5,10,15 dB), (L=N=1), (m=1) and ($\overline{\gamma_r}$=$\overline{\gamma_d}$=10 dB).

Likewise, if we increase $\overline{\gamma_d}$ then the system performance will be degraded consequently and this has more impact on the system than increase $\overline{\gamma_r}$. In other words, the increment of $\overline{\gamma_r}$ is incomparble to that of $\overline{\gamma_d}$ and this is obvious as depuicted in fig.5. For instance, given that the BER is 10^{-2}, then for a system with ($\overline{\gamma_d}$=15 dB, $\overline{\gamma_r}$ = 5 dB) to have the same performance as that with ($\overline{\gamma_d}$=5 dB, $\overline{\gamma_r}$ = 15 dB) then an increment of SNR of about 5 dB is required in order to acheive the same behavior.

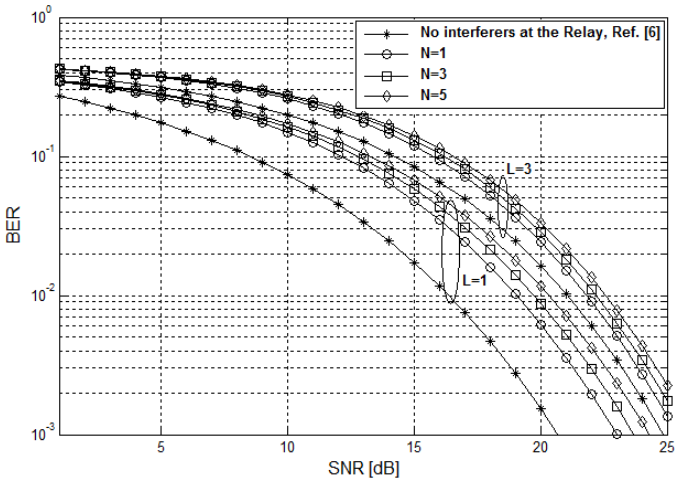

Fig. 6 BER comparison with and without the presence of the interference at the relay where (L=1,3), (N=1,3,5), (γ_o= $\overline{\gamma_r}$=$\overline{\gamma_d}$=10 dB) and (m=3).

In order to see the impact of the interference at the relay and measure the results on the system performance compared with the case where there is no interference at the relay, Fig. 6

depicts that comparison and shows that the impact of the presence of the interference at the relay is considerably has less degradation on the BER performance of the system compared to the presence of the interference at the relay. As a consolidation for that, the difference between a system that have (L=1, N=5) and that with (L=3) is only 1 dB when the BER is 10^{-2}. Another comparison is depicted in Fig. 7 that consolidates the results of Fig. 6 and shows the case if we increase the SNR from each interferer near the relay and compare it with the interference near the destination. Apparently, the required increment on the SNR for a system with (L=1, $\overline{\gamma_r}$=17 dB) to behave exactly the same as that with (L=4) is around 3 dB when the BER is 10^{-2} which is incomaparble to the required increment of the SNR if we compare the two systems with (L=1) and (L=4), which is around 8 dB.

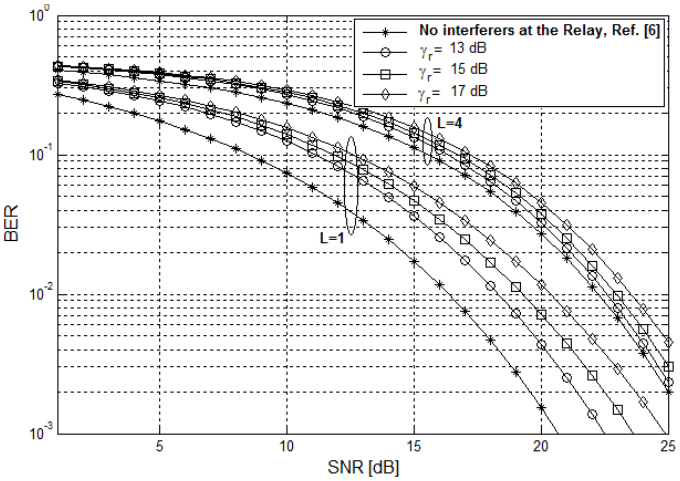

Fig. 7 BER comparison with and without the presence of the interferrence at the relay where (L=1,4), (N=1), (γ_o=$\overline{\gamma_d}$=10 dB) ($\overline{\gamma_r}$=13,15,17 dB) and (m=3).

V. CONCLUSION

This paper discusses and analyzes the performance of the decode-and-forward incremental relaying with the presence of multiple interferers near the destination and the relay. The incremental relaying systems achieve the spatial diversity at the destination and utilize the channel resources. Numerical results show that the improvement on the BER of a decode-and-forward incremental relaying over mixed fading channels can be achieved by increasing the Nakagami order m and will be drastically degraded if we increase the interferers at the destination L, γ_o and $\overline{\gamma_d}$ which have more impact on the system as if we increase the interferers at the relay N and $\overline{\gamma_r}$. Numerical results also compare the system behavior with and without the presence of the interference at the relay and shows that the interference at the relay have a relatively less impact on the system performance compared to that near the destination.

Abstract - **Incremental relaying was firstly introduced in order to accommodate for the restriction associated with the fixed relaying schemes by using the intermediate relays only when they are needed by using a feedback from the destination to determine whether or not to use the relay which depends mainly on the usability of the direct path between the source and the relay. When the relay receives this negative feedback from the destination then it will send the signal to the destination within the second time slot which by then will be combined with the source signal using MRC, and by this, the system resources will be utilized efficiently. This paper provide the performance analysis of a decode-and-forward incremental relaying cooperative relaying over Rayleigh and Nakagami-m mixed fading channels with the presence of multiple interferers L and N near the destination and the relay respectively, which in turn will degrade the overall system performance and also compares the system performance with and without the presence of the interferers near the relay. Numerical results are provided to validate our assumptions.**

Keywords: ***Incremental relaying, cooperative diversity, decode-and-forward, interference, outage probability (OP), signal to noise ratio (SNR), signal to interference ratio (SIR), maximal ratio combiner (MRC).***

I. INTRODUCTION

The appealing advantages of using cooperative diversity make it the promising solution for the deployment of the future wireless communication systems. Cooperative diversity is implemented by the introduction of the multiple relaying nodes between the source and the destination in order to prolong the battery life, extend the coverage area and achieve the spatial diversity at the destination [1]. In fixed relaying schemes, the destination will combine the two received signals from both the source and the relay by the MRC.

Aside from the advantages of implementing the fixed cooperative diversity schemes in terms of its implementation simplicity and the spatial diversity gain at the destination, they don't utilize the channel resources efficiently since the relay forwards the source signal regardless of the channel conditions. Since most of the time the direct path is usable which makes the utilization of the relay path a waste of resources.

Performance analysis in terms of symbol error probability (SEP) and outage probability (OP) for the amplify-and-forward (AF) and decode-and-forward (DF) relaying over Rayleigh and Nakagami-m fading channels have been thoroughly analyzed and discussed [2-3].

Incremental relaying was firstly introduced to overcome these restrictions by using the assistance of the relay node only when needed [4] by the virtue of using a feedback channel from the destination to both the source and the relay informing them about the quality assessment of the direct transmission which also will inform the relay to participate in forwarding the source signal in an opportunistic manner. The destination will combine the two received signals from both the source and the relay using MRC as stated in [5].

Performance analysis of relay systems with interference at the relay was presented in [6]. Closed-form expressions for outage probability and BER in relay-based cooperative diversity systems over different fading channels with the presence of multiple interferers near the destination were introduced in [7-8].

In this paper, we discuss the decode-and-forward incremental relaying cooperative diversity by introducing an intermediate single relay and multiple L and N interferers located near the destination and the relay, respectively, which will affect the performance of the system in response to the Co-channel interference over mixed fading channels between the source-destination and the source-relay-destination paths and compares the result and effect of the interference presence near the relay to that near the destination.

This paper is further presented as follows; Section II provides the system model. Section III provides the performance analysis and derived tight closed form formula of outage probability. Results and discussion are presented in section IV. We concluded this paper in section V.

II. SYSTEM MODEL

In Fig. 1, the channel coefficient between the source and the destination is assumed to follow the Rayleigh distribution whereas the Channels coefficients between the source-relay

and the relay-destination are assumed to follow the Nakagami-m distribution. The relay will participate with the source in transmitting its signal to the destination upon the reception of the destination's negative feedback that request the relay to send the source signal within the second time slot. The relay then will decode the source signal, re-encode it and then send it to the destination. The noise at the destination is assumed to be Additive White Gaussian Noise with a unity variance N_o. Beside that, near the destination and relay, the channels from the L and N interferers respectively that cause a Co-channel interference are assumed to be a sum of identically and independently distributed Rayleigh random variables which consequently will degrade the overall performance of the system. All the nodes in the system are equipped with one single antenna and Time Division Multiple Access (TDMA) is used as the multiple access technique, it is worth to mention that Frequency Division Multiple Access (FDMA) can be used too.

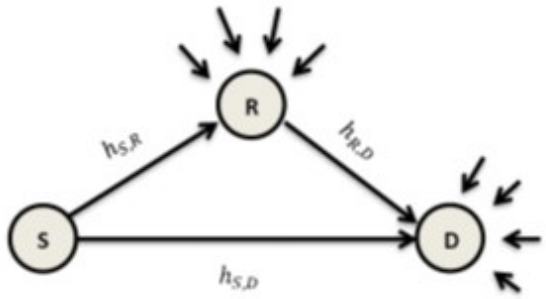

Fig. 1 Cooperative Diversity Network with Multiple Interferers L and N Located near the Destination and the Relay, respectively.

Within the first time slot, the destination will receive a signal directly from the source and based on the quality of this signal, the destination will decide whether or not the relay should participate in the transmission. From instance, if the direct transmission was successful and the destination can properly process the source signal from the direct transmission, then a positive feedback from the destination will be sent to both the relay and the source respectively informing them about the successfulness of the direct transmission and requesting the source to send a new signal within the second time slot. Otherwise, if the destination failed to receive the source signal or the direct path was in outage, then the relay will be requested to resend the source signal within the second time slot which by then will be combined with the source signal at the destination using the MRC.

The received signals at both the relay and the destination within the first time slot are:

$$y_{S,D}(t_1) = h_{S,D}\sqrt{E_s}\, x(t_1) + n_1(t_1) + I(t_1) \quad (1)$$

$$y_{S,R}(t_1) = h_{S,R}\sqrt{E_s}\, x(t_1) + n_2(t_1) + I(t_1) \quad (2)$$

where $x(t)$ is the symbol signal with a normalized energy. $n_1(t_1)$ and $n_2(t_1)$ are the AWGN noise terms at the destination and E_s is the signal energy. The interference effects at the destination and the relay within the first time slot are represented by $I(t_1)$.

If the relay participates in the transmission within the second time slot, then the received signal at the destination from the relay is denoted as:

$$y_{R,D}(t_2) = h_{R,D}\sqrt{E_s}x_r(t_2) + n_3(t_2) + I(t_2) \quad (3)$$

where $x_r(t_2)$ is the regenerate signal at the relay within the second time slot . $I(t_2)$ is the interference effects near the destination within the second time slot.

The destination will assess the usability of the direct link by comparing the signal to noise ratio of the direct path against $\gamma_o$which is the minimal threshold for which the destination can receive the source signal merely depending on the direct path without the help of the relay.

In the interference environment, in most of the communication systems, rather than working on the SNR at the destination a transgression is made to merely work on the signal to interference ratio SIR since the noise effects near the destination is not comparable to that of the Co-channel effects and since the interference limited environment is a common practice in the literature.

In the following section, we will derive the building blocks in deriving the performance metrics, namely the probability density function (PDF) and the cumulative distribution function (CDF) of both the SIR at the relay from the source link and the SIR at the destination from both the relay and source respectively.

III. PERFORMANCE ANALYSIS

The derivation of the outage probability necessitates is to derive the PDF and the CDF of the SIR at the destination. And since the interference is higher than the noise near the destination and its impact is more severe than the noise effects, based on this assumption, a transgression is made to merely work on the SIR at the destination.

A. Probability Density Function of SIR's $\boldsymbol{\eta_{S,D}}$, $\boldsymbol{\eta_{R,D}}$ *and* $\boldsymbol{\eta_{S,R}}$

Given that the SNR of the direct path $\gamma_{S,D}$ follows the exponential distribution and the fading channels from the interferers to the destination ($\gamma_b = \sum_1^L \gamma_k$) is assumed to be a sum of identically, independently and exponentially distributed random variables, the PDF of the SIR ($\boldsymbol{\eta_{S,D}}$) at the destination from the source path is given as follows [7]:

$$f_{\eta_{S,D}}(\eta_{S,D}) = \frac{\varsigma_{S,D}}{(\lambda_{S,D}+\eta_{S,D})^{L+1}} \quad (4)$$

where $\lambda_{S,D} = \frac{\overline{\gamma_{S,D}}}{\overline{\gamma_d}}$, $\varsigma_{S,D} = L(\lambda_{S,D})^L$, $\overline{\gamma_d} = \frac{\varepsilon}{N_o}E({\alpha_k}^2)$ is the average SNR of each independent interfering channel near the destination, and $\gamma_b = \frac{\varepsilon}{N_o}\sum_{k=1}^{L}{\alpha_k}^2 = \sum_{k=1}^{L}\gamma_k$ where γ_k is the instantaneous SNR from the $k-th$ interfering channel and L is the number of interfering channels near the destination. $\gamma_k's$ are mutually and statistically independent .

The PDF of the SIR $(\boldsymbol{\eta_{R,D}})$ at the destination from the relay path is given as follows [7]**:**

$$f_{\eta_{R,D}}(\eta_{R,D}) = \frac{\zeta_{R,D}\ {\eta_{R,D}}^{m-1}}{(\eta_{R,D}+\lambda_{R,D})^{L+m}} \quad (5)$$

where $\lambda_{R,D} = \frac{\overline{\gamma_{R,D}}}{m\overline{\gamma_d}}$, $\zeta_{R,D} = \frac{(L+m-1)!}{m^L\Gamma(m)(L-1)!}(m\,\lambda_{R,D})^L$

Following the same approach used in deriving (5), the PDF of the SIR $(\boldsymbol{\eta_{S,R}})$ at the relay from the source is given as follows [7]**:**

$$f_{\eta_{S,R}}(\eta_{S,R}) = \frac{\zeta_{S,R}\ {\eta_{S,R}}^{m-1}}{(\eta_{S,R}+\lambda_{S,R})^{L+m}} \quad (6)$$

where $\lambda_{S,R} = \frac{\overline{\gamma_{S,R}}}{m\overline{\gamma_r}}$, $\zeta_{S,R} = \frac{(N+m-1)!}{m^N\Gamma(m)(N-1)!}(m\,\lambda_{S,R})^N$, $\overline{\gamma_r} = \frac{\varepsilon}{N_o}E({\alpha_k}^2)$ is the average SNR of each independent interfering channel near the relay, and $\gamma_b = \frac{\varepsilon}{N_o}\sum_{k=1}^{L}{\alpha_k}^2 = \sum_{k=1}^{L}\gamma_k$ where γ_k is the instantaneous SNR from the $k-th$ interfering channel and N is the number of interfering channels near the destination. $\gamma_k's$ are mutually and statistically independent.

B. The Cumulative Distribution Function of SIR's $\boldsymbol{\eta_{S,D}}$, $\boldsymbol{\eta_{R,D}}$, and $\boldsymbol{\eta_{S,R}}$

The CDF of the SIR $(\boldsymbol{\eta_{S,D}})$ at the destination from the source path is given as follows [7]:

$$F_{\eta_{S,D}}(\eta_{S,D}) = \left[\frac{(\lambda_{S,D}+\eta_{S,D})^L-{\lambda_{S,D}}^L}{(\lambda_{S,D}+\eta_{S,D})^L}\right] \quad (7)$$

The CDF of the SIR $(\boldsymbol{\eta_{R,D}})$ at the destination from the relay path is given as follows [7]:

$$F_{\eta_{R,D}}(\eta_{R,D}) = \frac{\zeta_{R,D}{\eta_{R,D}}^m}{m(\lambda_{R,D})^{L+m}}\ {}_2F_1\left(L+m, m; m+1; -\frac{\eta_{R,D}}{\lambda_{R,D}}\right) \quad (8)$$

where ${}_2F_1(a,b;c;d)$ is the Gauss Hyper-geometric function [9].

The CDF of $\eta_{S,R}$ at the relay from the source path is given as follows:

$$F_{\eta_{S,R}}(\eta_{S,R}) = \frac{\zeta_{S,R}{\eta_{S,R}}^m}{m(\lambda_{S,R})^{N+m}}\ {}_2F_1\left(N+m, m; m+1; -\frac{\eta_{S,R}}{\lambda_{S,R}}\right) \quad (9)$$

Proof:

The CDF of $\eta_{S,R}$ is found by integrating the PDF of $\eta_{S,R}$ as follows [10]:

$$F_{\eta_{S,R}}(\eta_{S,R}) = \zeta_{S,R}\int_0^{\eta_{S,R}} f_{\eta_{S,R}}(y)dy \quad (10)$$

Solving the integral in (10) using [9,(3.381.1)], the compact form of the CDF of $\eta_{S,R}$ will be as in (9).

C. Outage Probability Analysis

In the incremental relaying system, if the direct path is in outage, then the destination will request the relay to assist in relaying the source signal in attempt to mitigate for the fading severity in the direct path. Still there is a probability that the overall combined signal by the MRC at the destination will be in outage. (i.e, the SNR of the combined signals from the source and the relay within the second time slot by the MRC will fall below a pre-specified threshold γ_o).

Formulating all possible scenarios of the system outage probability, p_{out} is given as [7]:

$$p_{out} = \Pr(\eta_{S,D} \le \gamma_o) \times P_r[\min(\gamma_{S,R}, \eta_{S,D} + \eta_{R,D} \le \gamma_O | \eta_{S,D} \le \gamma_o)]$$

$$p_{out} = P_r(\eta_{S,D} \le \gamma_o)\left[1 - P_r(\eta_{S,D} + \eta_{R,D} > \gamma_o | \eta_{S,D} \le \gamma_o)\right] \times P_r(\gamma_{S,R} > \gamma_o | \eta_{S,D} \le \gamma_o)$$

$$p_{out} = P_r(\eta_{S,D} \le \gamma_o) \times \left[1 - \frac{P_r(\eta_{S,D}\le\gamma_o) - P_r(\eta_{S,D}+\eta_{R,D}\le\gamma_o)}{P_r(\eta_{S,D}\le\gamma_o)} P_r(\gamma_{S,R} > \gamma_o)\right] \quad (11)$$

where the first argument within the min(•|•) operator in the above expression represents the outage at the relay and the second one represents the outage at the destination .

Further simplifications on the above expression yields [7]:

$$p_{out} = \Pr(\gamma_{S,R} \le \gamma_o)\Pr(\eta_{S,D} \le \gamma_o) + \Pr(\gamma_{S,R} > \gamma_o)\Pr(\eta_{S,D} + \eta_{R,D} \le \gamma_o) \quad (12)$$

When using the MRC, the value of $\eta_{R,D}$ will be much higher compared with $\eta_{S,D}$ since we used the relay path in the first place to compensate for the deficiency of the direct transmission. And hence, we can rely on the SIR at the destination from the relay path and totally ignore the SNR from the direct path to get the approximated outage probability expression as in (13).

IV. NUMERICAL RESULTS

Fig. 2 compares the impacts of increasing the number of interferes near the destination and the relay, namely the effects of L and N respectively, on the system performance, apparently as the number of interferers near the destination increases, the system performance will be degraded and affected drastically compared with increasing N near the relay. As depicted from the figure, in order for a system with two interferers near the destination to have the same performance as that with only one interferer, then an increment of around 4 dB on the SNR is required in order to achieve the same performance when the outage probability is 0.5. This case is incomparable with the number of interferers at the relay which is accommodated by a slight increment on the SNR.

$$p_{out} \approx \frac{\zeta_{S,R}{\gamma_o}^m}{m(\lambda_{S,R})^{N+m}}\left[\frac{(\lambda_{S,D}+\gamma_o)^L-\lambda_{S,D}{}^L}{(\lambda_{S,D}+\gamma_o)^L}\right] {}_2F_1\left(N+m,m;1+m;-\frac{\gamma_o}{\lambda_{S,R}}\right)+\frac{\zeta_{R,D}{\gamma_o}^m}{m(\lambda_{R,D})^{L+m}}\left[1-\frac{\zeta_{S,R}{\gamma_o}^m}{m(\lambda_{S,R})^{N+m}}\ {}_2F_1\left(N+m,m;1+m;-\frac{\gamma_o}{\lambda_{S,R}}\right)\right]\ {}_2F_1\left(L+m,m;1+m;-\frac{\gamma_o}{\lambda_{R,D}}\right) \quad (13)$$

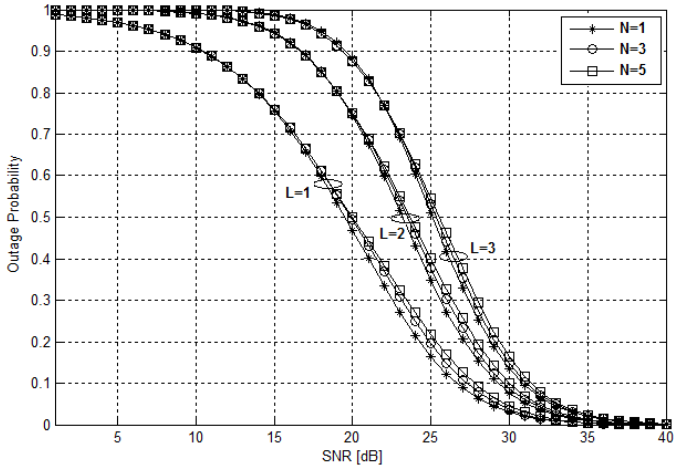

Fig. 2 Outage Probability for different number of interferers (L=1, 2,3), (N=1,3,5), (m=2) and (γ_o= $\overline{\gamma_r}$=$\overline{\gamma_d}$=10 dB).

Fig. 3 compares the effects of increasing γ_o along with the number of interferers near the relay. From the figure, it is obvious that increasing N near the relay is incomparable to the increment of γ_o and have a slight impact on the system. For instance, for a system with (γ_o=10 dB) to have the same performance as that with (γ_o=15 dB) then an increment of (SNR=5 dB) is required in order to achieve the same performance when the outage probability is 0.5 while only a fraction of an SNR is required for a system with (N=5) to have the same performance as that with (N=1).

Elaborating on the enhancement parameters on the system performance, Fig. 4 depicts the enhancement on the system when we increase the Nakagami order m. As can be seen from the figure, the impact of increasing m will take effect after SNR=22 dB. For example, a system with (m=1) will have the same performance as that with (m=5) after increasing the SNR of about 3 dB when the outage probability is 0.2. This increment will be greater if we have more interferers near the destination and less if we have only one interferer near the destination.

In comparing the effect of the interferers near the relay and the destination, Fig. 5 elaborates on this and depicts the results on the system performance if we increase $\overline{\gamma_d}$ and $\overline{\gamma_r}$ respectively. For example, a fraction of SNR is required for a system with ($\overline{\gamma_r}$=5 dB) to have the same performance of a system with ($\overline{\gamma_r}$=15 dB) if we have (L=N=1) which is incomparable with the required increment for a system with ($\overline{\gamma_d}$=5 dB) to have the same performance as that with ($\overline{\gamma_d}$=15 dB) which is apparently around 8 dB SNR when the outage probability is 0.4.

As a result, the degradation on the system performance is apparent if we increase γ_o, $\overline{\gamma_d}$, $\overline{\gamma_r}$, L and N. But at the same time the severity of increasing these parameters will vary depending on the parameters themselves. As explained in this section, increasing L, γ_o, $\overline{\gamma_d}$ will have more impact on the system performance unlike the case if we increase N and $\overline{\gamma_r}$. Finally, increasing m will improve the system performance and this enhancement will take effect after certain SNR, namely, when the SNR is beyond 22 dB.

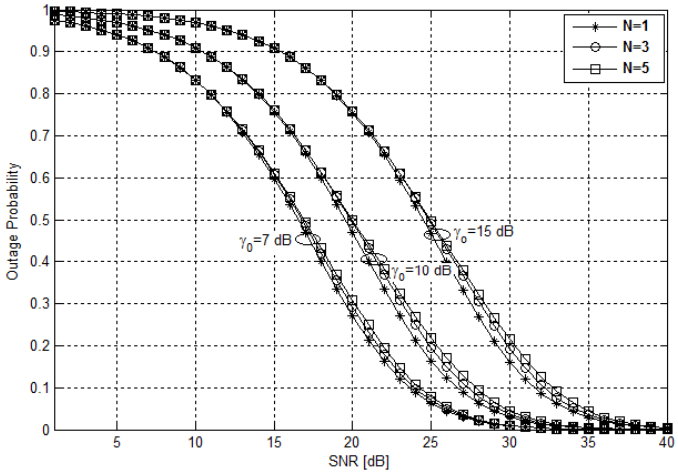

Fig. 3 Outage Probabilty for Different vlause of (N=1,3,5), (γ_o=7, 10,15 dB), (L=1), (m=2) and ($\overline{\gamma_r}$=$\overline{\gamma_d}$=10 dB).

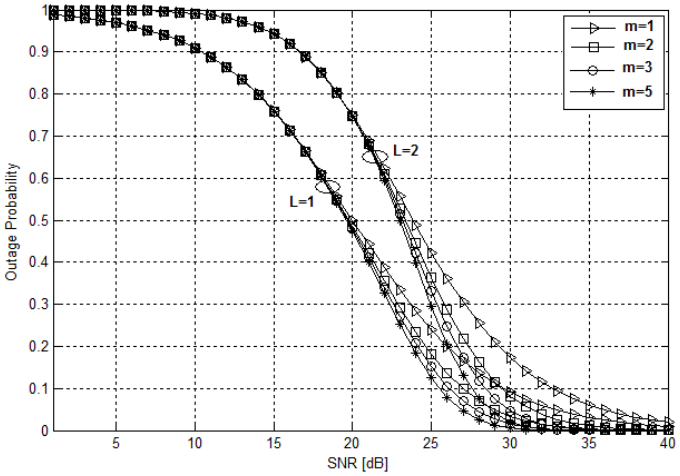

Fig. 4 Outage Probability for Different values of (m=1,2,3,5), (L=1,2), (N=2) and (γ_o= $\overline{\gamma_r}$=$\overline{\gamma_d}$=10 dB).

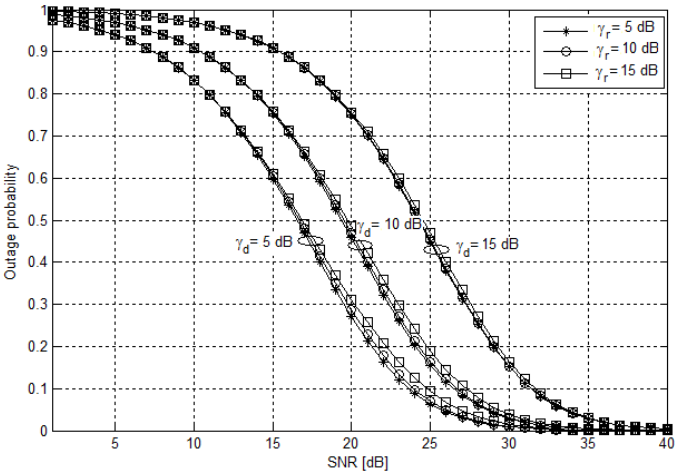

Fig. 5 Outage Probability for Different vlaues of ($\overline{\gamma_d}$=5, 10, 15 dB), ($\overline{\gamma_r}$=5, 10,15 dB), (L=N=1) and (γ_o=10 dB)

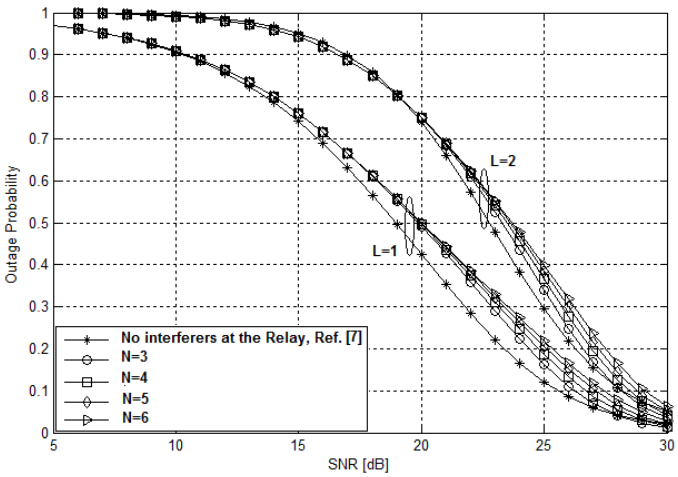

Fig. 6 Outage Probability Comparison representing the performance of two systems with and without the interference at the relay when ($\overline{\gamma_d} = \overline{\gamma_r} = \gamma_o$ =10 dB), (L=1, 2), (m=4) and different values of (N=3,4,5 and 6).

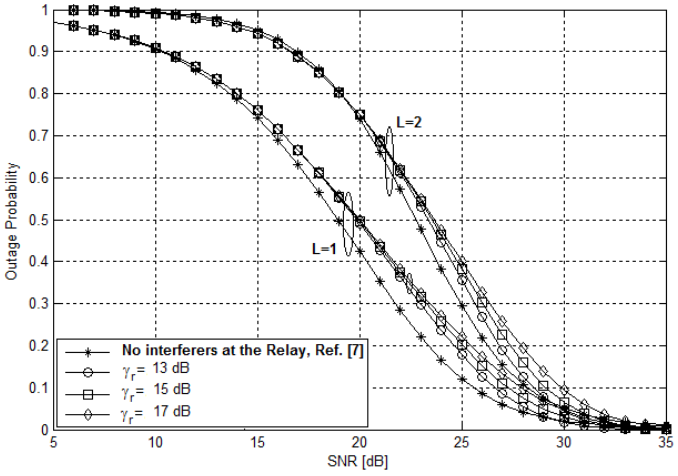

Fig. 7 Outage Probability Comparison representing the performance of two systems with and without the interference at the relay when ($\overline{\gamma_d} = \gamma_o$ =10 dB), ($\overline{\gamma_r}$= 13,15.17 dB,)(L=1, 2), (m=4) and (N=2).

As a comparison between the performance of the system with and without the interference at the relay, Figure 6 presents the impact of the interference at the relay on the outage probability which is apparently a minor degradation compared with the impact of the interferers at the destination. For example, when we consider an outage probability of 0.2, then of a system with five interferers near the relay (N=5) to have the same performance as that without interferes near the relay and (L=1) then a SNR of about 3 dB is needed which emphasizes the fact that the severity of the interference at the destination has much more impact on the system performance compared with that of the interference at the relay.

Elaborating on the comparison between the two cases with and without interference at the relay, Fig. 7 shows the effects on the system performance when we vary the SNR of each interfering signals and compare them with the case where we don't have interferers at the relay. For instance, impact of the presence of the interferers near the destination has more severity than increasing the individual SNR of the interferers near the relay. As an example on that, the required SNR for a system without interferers near the destination to have the same performance as that with 2 interferers at the relay and ($\overline{\gamma_r}$ =17 dB) is about 3 dB which is incomparable to that required by a system with two interferers at the destination and no interferes at the relay.

V. CONCLUSION

The adaptive cooperative diversity draws a considerable attention from the researchers since they exploit the channel resources efficiently as opposed to the fixed relaying schemes which do so inefficiently. This work discusses the performance namely, the Outage Probability of the Decode-and-Forward incremental relaying system with the presence of the multiple L and N interferers near the destination and relay respectively over Rayleigh and Nakagami-m mixed fading channels which indicates that as the Nakagami-m order increased and the number of the interferers and the value of γ_o decreased a considerable enhancement in the overall performance of the system will be achieved. Numerical results showed that the effects of the interference near destination are more severe than that near the relay.

Abstract – **In this paper, two user Cooperation systems based on differential chaos shift keying (DCSK) with orthogonal sub-channel in the broadcast phase and cooperative phase using Walsh code sequence is proposed. Single relay of decode and forward (DF) type is investigated according to the conventional cooperation protocol. Outage probability is derived and verified by simulation. Independent three paths Rayleigh and Nakagami-m fading channels are considered. Numerical results show an enhancement of the system performance for the Nakagami-m fading channel over the Rayleigh fading channel. Monte Carlo simulation shows a high agreement with the numerical results.**

Keywords: ***Outage probability, differential chaos shift keying (DCSK), multipath Rayleigh fading channel, multipath Nakagami-m fading channel, cooperative communication system.***

I. INTRODUCTION

Due to the characteristic of the chaotic signal such as security in transmission, resistance of jamming, and low power consumption, its use in communication systems gabbed a great attention. A Number of chaos-based communication schemes have been proposed and analyzed. Such schemes included Chaos Shift keying (CSK) [1], Chaos-Based DS-CDMA , Differential Chaos Shift keying (DCSK) [2]-[4], and Frequency-Modulated DCSK (FM-DCSK) [5], [6].

In DCSK and frequency-modulated (FM)-DCSK, there are no need to have a knowledge of the channel estimation or the code acquisition and synchronization, so many ultra-wideband systems based on them have been proposed lately [7]-[9].

The performance of any system in a wireless network is affected by the fading and intersymbol interference (ISI), which appears in the multipath propagation environment. Diversity technique, by which many replicas of the same signal are transmitted over independent channels, can be used to mitigate the effect of signal fading.

Multiple-antenna diversity technique is one of the most attractive techniques that can be easily used and combined with other diversity techniques. However, due to the variation of the carrier, it has been difficult to use multiple antenna diversity on a DCSK based system. Moreover, in wireless sensor networks (WSN) multiple-antenna diversity cannot be used because of the size and the cost of the sensors. Thus, a new spatial diversity technique is needed [10], [11]. User cooperation diversity is a good substitute to the multiple antenna diversity [12].

In this paper, a cooperative system consisting of two-users based on DCSK over a Nakagami-m fading channel is proposed. The performance of the system has been studied in terms of the outage probability.

The rest of this paper is organized as follows. Section II presents the principle of the two-user cooperative system based on DCSK and the outage probability of the proposed system. Performance evaluation and simulation results are presented in Section III. Finally we conclude our paper in section IV.

II. SYSTEM MODEL

A. DSCK

In DCSK system, the carrier is a chaotic signal generated using one of the chaotic mapping methods like Cubic and Logistic mapping method, while the modulator is a differential shift keying.

In Binary DCSK systems, the symbol duration is divided into two halves; in the first one, a reference copy of the chaotic signal is transmitted, while in the second half, the digital transmitted information will be repeated if it was '1', or reserved if the digital information was '0'.

Two orthogonal basis functions, $g_1(t)$ and $g_2(t)$ are used to represent the modulated signal as follows:

$$s(t) = s_{m1}g_1(t) + s_{m2}g_2(t)$$
$$(s_{11}\ s_{12}) = \left(\sqrt{E_b}\ \ 0\right)$$
$$(s_{21}\ s_{22}) = \left(0\ \ \sqrt{E_b}\right) \quad (1)$$

where $s(t)$ is the modulated signal and E_b is the bit energy.

The orthogonal basis functions $g_1(t)$ and $g_2(t)$ are represented as:

$$g_1(t) = \begin{cases} +c(t), & 0 \le t < \frac{T}{2} \\ +c\left(t - \frac{T}{2}\right), & \frac{T}{2} \le t < T \end{cases} \quad (2)$$

$$g_2(t) = \begin{cases} +c(t), & 0 \le t < \frac{T}{2} \\ -c\left(t - \frac{T}{2}\right), & \frac{T}{2} \le t < T \end{cases} \quad (3)$$

where T is the bit duration and $c(t)$ is the chaotic signal.

At the receiver side, using suboptimum Autocorrelation receiver (AcR), and depending on the received signal, $r(t)$, an observation signal will be given by:

$$z = \int_{T/2}^{T} r(t) r\left(t - \frac{T}{2}\right) dt \quad (4)$$

B. Two-User Cooperation Model

Consider a cellular system with two mobiles communicating with a base station. The links between the users in such a system are assumed to be independent as well as the links between users and base station. The channel state stays the same during the cooperative period. In other words, frequency selective fading channel is used. The investigated system uses conventional cooperation protocol, single relay of the type DF, and half-duplex transmission.

Fig.1 below shows the transceiver model of the proposed system.

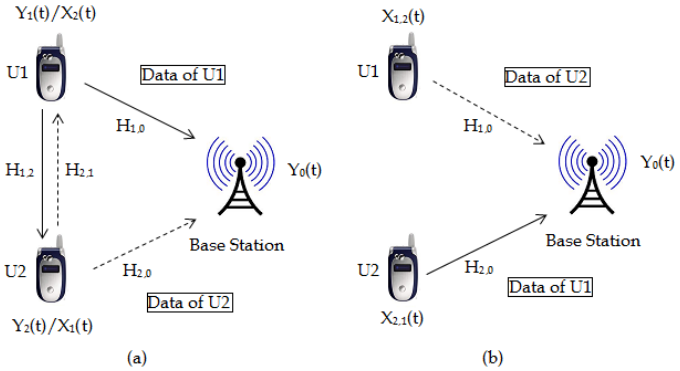

Fig.1 Cooperative transmission scheme (a) Odd period (b) Even period.

As can be seen from the figure, the received signal at the base station, user 1 and user 2 are, $Y_0(t)$, $Y_1(t)$ and $Y_2(t)$ respectively, which can be expressed as in (5) and (6).

where $X_i(t)$, $i = 1,2$ is the transmitted signal from users and $Z_i(t)$, $i = 1,2$ is the white Gaussian noise with zero mean and power spectral density $N_i/2$. $H_{i,j}(t)$ is the multipath channel linear time-invariant impulse response given by $H_{i,j}(t) = \sum_{l=1}^{L} \alpha_l \delta(t - \tau_l)$, where L is the number of multipath components, the attenuation and delay of the l^{th} path is α_l and τ_l, respectively. In the even period, user one will use $Y_1(t)$ to reconstruct the data of user two and transmit it to the base station. Using $Y_2(t)$, user two will do the same.

C. Outage Probability Performance

The outage probability is defined as the probability that the instantaneous SNR (γ_b) falls below a predetermined ratio (γ_{th}).

$$P_{out} = P_r(\gamma_b < \gamma_{th}) \quad (7)$$

Equivalently, it is the Cumulative Distribution Function evaluated at γ_{th}:

$$P_{out} = F_\gamma(\gamma_{th}) = \int_0^{\gamma_{th}} f_\gamma(\gamma) d\gamma \quad (8)$$

In this section, outage probability is derived for a DF cooperative relaying system over Rayleigh and Nakagami-m multipath fading channels.

An error free relay of the type Decode and Forward (DF) is used in order to derive the outage probability of the DCSK-CC, as well as the use of conventional cooperative protocol that is divided into two phases; the first half is called the 'broadcast phase' and the second is called 'cooperation phase'. Denote f as the global spread spectrum factor. During modulation, and since the proposed system has only two users, we force the length of each carrier segment, $\beta = f/4$ to make sure that the global spread-spectrum factor kept constant.

During the 'broadcast phase', each user transmits his own data, which is received and detected by the base station (BS) and the other user. For example the signal transmitted by user 1 is $X_1(t)$, user 2 will receive these data according to:

$$Y_2(t) = H_{1,2}(t) \otimes X_1(t) + Z_2(t) \quad (9)$$

which will be used by user 2 to make a hard decision to estimate $b^{(1)}$ of user 1.

1. Rayleigh Fading Channel:

Using the PDF for the Rayleigh multipath fading channel, the outage probability is given by (10).

where, $\beta_1 = \frac{1}{\overline{\gamma_1}(\overline{\gamma_1} - \overline{\gamma_3})}, \beta_2 = \frac{\overline{\gamma_3}}{(\overline{\gamma_1} - \overline{\gamma_3})^2}, \beta_3 = \frac{\overline{\gamma_1}\,\overline{\gamma_3}}{(\overline{\gamma_1} - \overline{\gamma_3})}$

Let $A_1 = \frac{{\beta_1}^2}{6}$, $A_2 = \beta_1\beta_2$, $A_3 = {\beta_2}^2 + 2\beta_1\beta_2\beta_3$, $A_4 = 2{\beta_2}^2\beta_3 + 2\beta_1\beta_2{\beta_3}^2$, $A_5 = {\beta_2}^2$, then P_{out} is given by (11).

2. Nakagami-m Fading Channel:

The PDF of γ_b is the convolution of the PDF's of the multipath channels. Hence,

$$f(\gamma_b) = f(\gamma_1) \otimes f(\gamma_2) \otimes \ldots \otimes f(\gamma_L) \quad (12)$$

where $\gamma_b = \left(\frac{E_b}{N_o}\right) \sum_{l=1}^{L} {\alpha_l}^2$, assuming α_l is an independent and identically-distributed (i.i.d) Nakagami-m random variable, and the PDF of γ_l, $f(\gamma_l)$, will have a gamma distribution that is given by:

$$f(\gamma_l) = \frac{{m_l}^{m_l} {\gamma_l}^{m_l - 1}}{\Gamma(m_l) \overline{\gamma_l}^{m_l}} \exp\left(-\frac{m_l \gamma_l}{\overline{\gamma_l}}\right)$$

where $\gamma_l = \frac{E_b}{N_o} {\alpha_l}^2$, $\overline{\gamma_l} = \left(\frac{E_b}{N_o}\right) E\{{\alpha_l}^2\}$.

For simplicity, assuming L=3, the PDF of γ_b is given by (13).

where $a_l = \frac{{m_l}^{m_l}}{\Gamma(m_l) \overline{\gamma_l}^{m_l}}$ and $b_l = \frac{m_l}{\overline{\gamma_l}}$.

On the other hand, at the base station, the total signal to noise ratio (SNR) is given by $\gamma_b^{BS} = {\gamma_b}^{odd} + {\gamma_b}^{even}$, therefore, $f(\gamma_b^{BS})$ is obtained using:

$$f(\gamma_b^{BS}) = f({\gamma_b}^{odd}) \otimes f({\gamma_b}^{even}) \tag{14}$$

The PDF of γ_b^{BS} is given by (15).

where $c = {a_1}^2 a_3 B(m_1, m_3) B(m_1 + m_3, m_1)$.

Substituting equation (15) in (8), the outage probability is given by (16).

Using the series representation of the confluent hypergeometric function ${}_1F_1(b, a, \beta\gamma)$

$${}_1F_1(b, a, \beta\gamma) = \sum_{n=0}^{\infty} \frac{b^{(n)}(\beta x)^n}{a^{(n)} n!} \tag{17}$$

where $a^{(n)}$ and $b^{(n)}$ is the rising factorial given by:

$$x^{(n)} = \frac{\Gamma(x+n)}{\Gamma(x)} \tag{18}$$

Let $c = \frac{\left(a_1{}^2 a_3 B(m_1,m_3) B(m_1+m_3,m_1)\right)^2 \Gamma(2m_1+m_3)^2}{\Gamma(4m_1+2m_3)}$, the outage probability is given by:

$$P_{out} = c \sum_{n=0}^{\infty} \frac{b^{(n)} \beta^n}{a^{(n)} n!} {b_1}^{-(n+a)} \gamma(n + a, b_1 \gamma_{th}) \tag{19}$$

where $\gamma(.,.)$ is the upper incomplete gamma function.

III. Results And Discussions

Fig.2 shows a significant match between the two carves of the system outage probability over Rayleigh and Nakagami-m fading channels with m=1. Fig. 3 shows A comparison between the exact expressions of the outage probability and the simulated results for the DCSK-CC system over Rayleigh fading channel for different values of γ_{th}. As demonstrated, the simulation results match with the exact results.

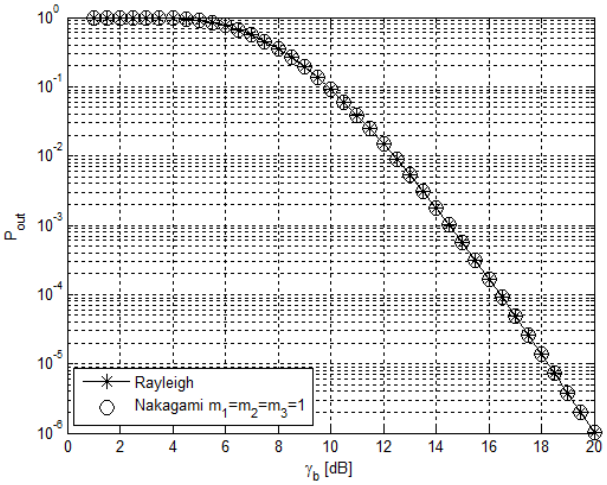

Fig .2 Outage probability for the DCSK-CC system over Rayleigh and Nakagami-m fading channel with m=1 .

$$odd\ period \begin{cases} Y_1(t) = H_{2,1}(t) \otimes X_2(t) + Z_1(t) \\ Y_2(t) = H_{1,2}(t) \otimes X_1(t) + Z_2(t) \\ {Y_0}^{odd}(t) = H_{1,0}(t) \otimes X_1(t) + H_{2,0}(t) \otimes X_2(t) + {Z_0}^{odd}(t) \end{cases} \tag{5}$$

$$even\ period \quad {Y_0}^{even}(t) = H_{1,0}(t) \otimes X_{1,2}(t) + H_{2,0}(t) \otimes X_{2,1}(t) + {Z_0}^{even}(t) \tag{6}$$

$$P_{out} = \int_0^{\gamma_{th}} \left(\left(\frac{1}{6} {\beta_1}^2 {\gamma_b}^3 - \beta_1 \beta_2 {\gamma_b}^2 + {\beta_2}^2 \gamma_b + 2\beta_1 \beta_2 \beta_3 \gamma_b - 2{\beta_2}^2 \beta_3 - 2\beta_1 \beta_2 {\beta_3}^2 \right) \exp\left(\frac{-\gamma_b}{\overline{\gamma_1}}\right) + \left({\beta_2}^2 \gamma_b + 2{\beta_2}^2 \beta_3 + 2\beta_1 \beta_2 {\beta_3}^2 \right) \exp\left(\frac{-\gamma_b}{\overline{\gamma_3}}\right) \right) d\gamma_b \tag{10}$$

$$P_{out} = \left\{ \left[\left(-A_1 \overline{\gamma_1} {\gamma_{th}}^3\right) + \left(\left(-3A_1 {\overline{\gamma_1}}^2 - A_2 \overline{\gamma_1}\right) {\gamma_{th}}^2 \right) + \left(\left(\left(-6A_1 {\overline{\gamma_1}}^3\right) + \left(-2A_2 {\overline{\gamma_1}}^2\right) + \left(A_3 \overline{\gamma_1}\right) \right) \gamma_{th} \right) \right] \left(\exp\left(\frac{-\gamma_{th}}{\overline{\gamma_1}}\right) \right) \right\} + \left\{ \left(-6A_1 {\overline{\gamma_1}}^4 - 2A_2 {\overline{\gamma_1}}^3 + A_3 {\overline{\gamma_1}}^2 - A_4 \overline{\gamma_1}\right) \left(exp\left(\frac{-\gamma_{th}}{\overline{\gamma_1}}\right) - 1 \right) \right\} + \left\{ -A_5 \overline{\gamma_3} \gamma_{th} exp\left(\frac{-\gamma_{th}}{\overline{\gamma_3}}\right) \right\} + \left\{ \left(-A_5 {\overline{\gamma_3}}^2 + A_4 \overline{\gamma_3}\right) \left(exp\left(\frac{-\gamma_{th}}{\overline{\gamma_3}}\right) - 1 \right) \right\} \tag{11}$$

$$f(\gamma_b) = {a_1}^2 a_3 B(m_1, m_3) B(m_1 + m_3, m_1) \exp(-b_1 \gamma_b) {\gamma_b}^{2m_1+m_3-1} \, {}_1F_1(m_3, 2m_1 + m_3, (b_2 - b_3)\gamma_b) \tag{13}$$

$$f({\gamma_b}^{BS}) = \frac{c^2 \Gamma^2(2m_1+m_3)}{\Gamma(4m_1+2m_3)} \exp(-b_1 \gamma_b) {\gamma_b}^{4m_1+2m_3-1} \, {}_1F_1(2m_3, 4m_1 + 2m_3, (b_2 - b_3)\gamma_b) \tag{15}$$

$$P_{out} = \int_0^{\gamma_{th}} \frac{\left(a_1{}^2 a_3 B(m_1,m_3) B(m_1+m_3,m_1)\right)^2 \Gamma(2m_1+m_3)^2}{\Gamma(4m_1+2m_3)} e^{(-b1\gamma)} \gamma^{a-1} \, {}_1F_1(b, a, \beta\gamma) dx \tag{16}$$

Fig. 4 shows a comparison between numerical and simulated results of the outage probability for different values of the fading parameter m. Obviously, there is an agreement between numerical and simulation results. It can be seen from the figure that the performance of the system is enhanced with the increase of value of m.

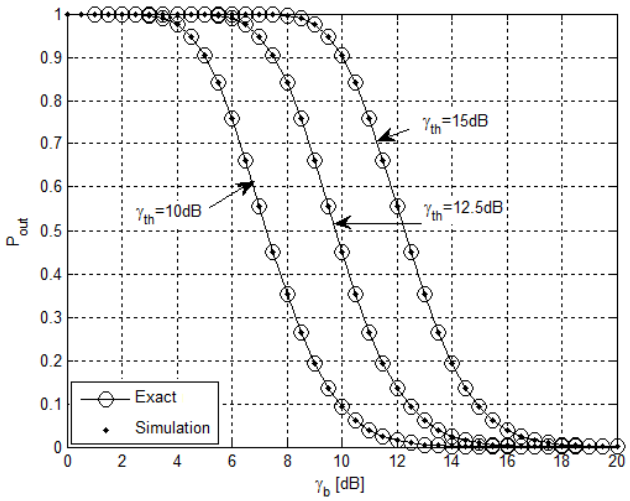

Fig.3 Outage probability of DCSK-CC system over Rayleigh fading channel at different values of γ_{th}.

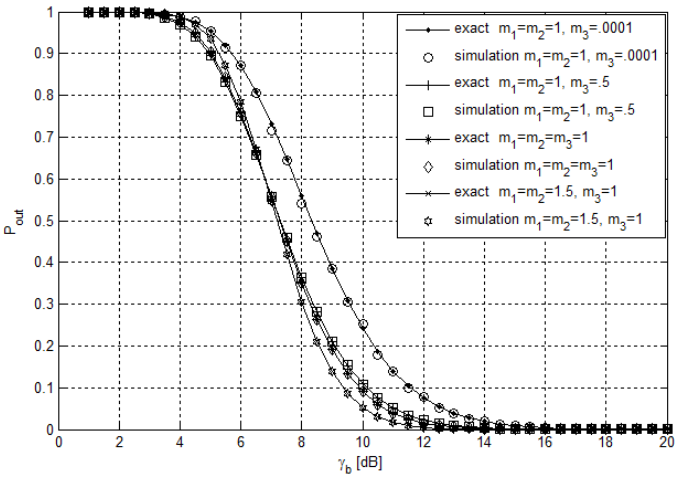

Fig.4 Outage probability of DCSK-CC system over Nakagami-m fading channel with different values of the fading parameter m , at fixed γ_{th}.

IV. CONCLUSION

In this paper, a two-user Cooperative system based on DCSK modulation over Rayleigh and Nakagami-m fading channels have been proposed. A discussion on the performance behavior of the system is provided by evaluating its performance in terms of outage probability. Closed form expression of this metric has been derived. The higher values of the fading parameter (m) provide better performance as expected. Simulation results using Monte Carlo method show a high agreement with the numerical results of outage probability.

Abstract - **In this paper, the performance of the outage probability (OP) for cognitive dual-hop relay networks with amplify-and-forward (AF) relay under spectrum sharing constraints on primary user (PU) over independent and identically distributed (i.i.d.) Nakagami-m fading channels is investigated. An exact closed-form expression for the OP of the proposed system is derived under the peak interference power (I_p) at the primary user. The impact of the PU location on the OP performance is studied also.**

Keywords: **Nakagami-m fading, cognitive relay network, dual hop, cognitive radio, amplify-and-forward relaying, outage probability.**

I. INTRODUCTION

One of the most important topics that have been recently considered in the research areas is the Cooperative Diversity (CD), which makes a virtual antenna arrays among the cooperative nodes to combat the multipath effects and to extend the coverage area of the network [1]. In our wireless communication evolution the need for spectrum bands becomes more and more and it considers a big challenge in all applications either in Ad-hoc networks or in wireless local area networks (WLANs).

Cognitive Radio (CR) which was proposed in 1998 by Joseph Mitola is a promising technology to solve the spectrum shortage and to utilize the underutilized spectrum, where in CR we define two users, the first one is the primary user (PU) which have a licensed spectrum access and have the priority for transmission and the second one is the secondary user (SU) which have unlicensed spectrum access. The SU can access the channel if the PU does not use it, but suddenly if the PU decides to transmit its own data, the SU shall stop its transmission; this access strategy of spectrum sharing is called overlay strategy [2-4]. In the underlay strategy, the spectrum is accessible to the SU under an interference constraint at the PU receiver. Therefore, the SU is allowed to access the channel as long as its transmit power is below a certain threshold [5].

OP is one of the important performance metrics of wireless networks. For the outage probability definition; some authors defined it as the probability that the symbol error probability (SEP) exceeds a maximum tolerable level [6, 7], some authors defined it as the probability that the instantaneous signal-to-noise ratio (SNR) at the destination goes below a predefined threshold [8].

The OP for cognitive decode-and-forward (DF) relay networks has been derived in [9, 10]. In [11] the authors derived the OP of cognitive dual-hop relay networks with AF relay over Rayleigh fading channels under spectrum sharing constraints on a PU. Since the Nakagami-m distribution gives the best fit for land-mobile [12] and indoor mobile [13] multipath propagation, closed form expression for cognitive dual-hop relay networks with AF relay under spectrum sharing constraints on PU over i.i.d. Nakagami-m fading channels is derived in this paper. The improvement for the transmission using AF relaying over the conventional transmission (without relays) in cognitive radio networks (CRNs) is depicted, and the impact of the PU location on the OP performance is studied also.

This paper is further presented as follows; Section II provides the system and channel models, as well as the structure of the CRN components. Section III provides the performance analysis and derived expression of outage probability. Results and discussion are presented in section IV. We concluded this paper in section V.

II. SYSTEM AND CHANNEL MODELS

Consider a dual-hop cooperative spectrum sharing system as shown in Fig.1, where (S) is the SU source node, (D) is the SU destination node, (R) is the AF SU relay, and (P) is the PU receiver. Furthermore, we suppose that the direct link between nodes (S) and (D) is not available due to the severe shadowing and path loss. All nodes are provided with a single antenna and operate in a half-duplex mode.

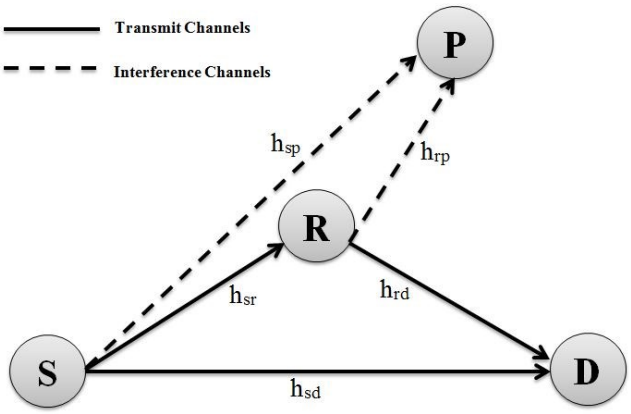

Fig.1: Dual-hop Cognitive relay network

Due to the interference power constraints, both the SU source and the SU relay should satisfy the two following relations respectively:

$$P_s \left| h_{sp} \right|^2 \le I_p \tag{1}$$

$$P_r \left| h_{rp} \right|^2 \le I_p \tag{2}$$

where P_s and P_r are the transmit power at the SU source and at the SU relay, respectively, I_p is the maximum allowable interference power on the PU receiver, and h_{sp} and h_{rp} are the channel coefficients links of S→P and R→P respectively.

In the 1st-hop transmission, the SU source transmits its signal to the relay under a transmit power constraint as mentioned before. Thus; the maximum transmit power at (S) can be expressed as:

$$P_s = \frac{I_p}{\left| h_{sp} \right|^2} \tag{3}$$

The received signal at (R) can be written also as:

$$y_r = \sqrt{P_s}\, x\, h_{sr} + n_r \tag{4}$$

where x is the transmitted information symbol, h_{sr} is the channel coefficient of the link S→R, and n_r is the additive white Gaussian noise (AWGN) at (R), having the power of N_o. In the second-hop transmission, the relay amplifies the received signal from (S) and forwards it to the destination in its new form given by:

$$\begin{aligned} y_D &= G\, h_{rd}\, y_r + n_D \\ &= \sqrt{P_s}\, x\, G\, h_{rd}\, h_{sr} + G h_{rd}\, n_r + n_D \end{aligned} \tag{5}$$

where h_{rd} is the channel coefficient of the link R→D, and n_D is the additive white Gaussian noise (AWGN) at (D), having the power of N_o, and G is the relay gain. Our choice of the relay gain will take into account the relay noise and assume channel state information (CSI)-assisted. So we can express the relay gain as:

$$G^2 = \frac{P_r}{P_s \left| h_{sr} \right|^2 + N_o} = \frac{\bar{\gamma} \left| h_{sp} \right|^2}{\left| h_{rp} \right|^2 \left(\bar{\gamma} \left| h_{sr} \right|^2 + \left| h_{sp} \right|^2 \right)} \tag{6}$$

where $P_r = I_p / \left| h_{rp} \right|^2$ is the transmit power at (R), and $\bar{\gamma} = I_p / N_o$.

We assume that the fading channels are i.i.d. flat Nakagami-m channels, and the channel power gains $X \in \{ \left| h_{sp} \right|^2, \left| h_{sr} \right|^2, \left| h_{rp} \right|^2, \left| h_{rd} \right|^2 \}$ have a gamma distribution, with means power Ω_{sp}, Ω_{sr}, Ω_{rp}, and Ω_{rd}, respectively. Thus the cumulative distribution function (CDF) of each one of these power gains can be expressed as:

$$F_X(x) = 1 - \frac{\Gamma(m_X, \lambda_X x)}{\Gamma(m_X)} \tag{7}$$

and the probability density function (PDF) as:

$$f_X(x) = \frac{{\lambda_X}^{m_X}}{\Gamma(m_X)} x^{m_X - 1} e^{-\lambda_X x} \tag{8}$$

where $m_X \in \{m_{sp}, m_{sr}, m_{rp}, m_{rd}\}$ represents the corresponding fading severity parameter m, $\lambda_X = m_X / \Omega_X$, and $\Gamma(.,.)$ is the incomplete gamma function given by [14, (8.350.2)].

III. PERFORMANCE ANALYSIS

To start our analysis for this cognitive relay network, we have to determine the instantaneous end-to-end signal-to-noise-ratios (SNRs) for each hop:

$$\gamma_1 = \frac{P_s \left| h_{sr} \right|^2}{N_o} = \frac{\bar{\gamma} \left| h_{sr} \right|^2}{\left| h_{sp} \right|^2} \tag{9}$$

$$\gamma_2 = \frac{P_r \left| h_{rd} \right|^2}{N_o} = \frac{\bar{\gamma} \left| h_{rd} \right|^2}{\left| h_{rp} \right|^2} \tag{10}$$

where γ_1 and γ_2 are the instantaneous end-to-end SNRs for the 1st-hop and the 2nd-hop, respectively. Thus; the instantaneous end-to-end SNR at (D) can be expressed as [15],

$$\gamma_{e-e} = \frac{\gamma_1 \gamma_2}{\gamma_1 + \gamma_2 + 1} \tag{11}$$

The last equation may be expressed in a more mathematically tractable form. To achieve that; a tight upper-bound approximation was suggested in [16] using γ_D instead of γ_{e-e}, where γ_D is expressed as:

$$\gamma_D = \min(\gamma_1, \gamma_2) \tag{12}$$

Since γ_D is the minimum of two random variables, we need to find the CDF for the SNR of each hop and then apply the following equation to find the CDF for γ_D:

$$F_{\gamma_D}(\gamma) = 1 - \left(1 - F_{\gamma_1}(\gamma)\right)\left(1 - F_{\gamma_2}(\gamma)\right) \tag{13}$$

Theorem 1: The CDF of γ_1 is given by:

$$F_{\gamma_1}(\gamma) = 1 - \Upsilon_{sp,sr}(\gamma) \tag{14}$$

where $\Upsilon_{sp,sr}(\gamma)$ is given as in (15).

$$\Upsilon_{sp,sr}(\gamma) = \frac{(\lambda_{sp}\bar{\gamma})^{m_{sp}}(\lambda_{sr}\gamma)^{m_{sr}}}{m_{sp}\,(\lambda_{sp}\bar{\gamma}+\lambda_{sr}\gamma)^{m_{sp}+m_{sr}}} \cdot \frac{1}{B(m_{sp},m_{sr})} \cdot {}_2F_1\left(1, m_{sp}+m_{sr}; m_{sp}+1; \frac{\lambda_{sp}\bar{\gamma}}{\lambda_{sp}\bar{\gamma}+\lambda_{sr}\gamma}\right) \quad (15)$$

$$\Upsilon_{rp,rd}(\gamma) = \frac{(\lambda_{rp}\bar{\gamma})^{m_{rp}}(\lambda_{rd}\gamma)^{m_{rd}}}{m_{rp}\,(\lambda_{rp}\bar{\gamma}+\lambda_{rd}\gamma)^{m_{rp}+m_{rd}}} \cdot \frac{1}{B(m_{rp},m_{rd})} \cdot {}_2F_1\left(1, m_{rp}+m_{rd}; m_{rp}+1; \frac{\lambda_{rp}\bar{\gamma}}{\lambda_{rp}\bar{\gamma}+\lambda_{rd}\gamma}\right) \quad (17)$$

where $B(.,.)$ is the Beta function given by [14, (8.384.1)], and ${}_2F_1(.,.;.;.)$ is the Gauss hypergeometric function given by [14, (9.100)].

***Proof*:** The proof is given in Appendix A.

Theorem 2: The CDF of γ_2 is given by:

$$F_{\gamma_2}(\gamma) = 1 - \Upsilon_{rp,rd}(\gamma) \quad (16)$$

where $\Upsilon_{rp,rd}(\gamma)$ is given as in (17).

***Proof*:** The proof is given in Appendix B.

Substituting (14) and (16) into (13) the CDF of γ_D is:

$$F_{\gamma_D}(\gamma) = 1 - \Upsilon_{sp,sr}(\gamma)\,\Upsilon_{rp,rd}(\gamma) \quad (18)$$

Substitute γ_{th} into (18) the P_{out} will be as:

$$P_{out} = \Pr(\gamma_D \le \gamma_{th}) = 1 - \Upsilon_{sp,sr}(\gamma_{th})\,\Upsilon_{rp,rd}(\gamma_{th}) \quad (19)$$

IV. Results and Discussion

In this section, numerical results are given to validate our analysis, where the outage threshold is defined to be 1 dB. We consider the co-linear topology for all nodes in our system, where the distance between the SU source (S) and the SU destination (D) is normalized to be one. As a result the (S) and (D) are located at coordinates (0,0) and (1,0), respectively. The SU relay (R) location is designed to be at the middle distance between (S) and (D) with a coordinates (0.5,0).

The path loss of each channel follows an exponential decay model; which means that the channel mean power between any two nodes is modeled as $\Omega_X = d^{-\alpha}$, where α is the path loss exponent and it can be set to four in the free-space propagation with non-line-of-sight model.

Fig.2 depicts the OP performance of cognitive spectrum sharing system for two different transmission scenarios including the AF relaying (no direct link), and the direct transmission. Hence, the OP of the direct spectrum sharing scenario is given as:

$$P_{out}{}^{direct\ transmission} = 1 - \Upsilon_{sp,sd}(\gamma_{th}) \quad (20)$$

As can be seen from Fig.2, the first scenario of transmission using AF relaying outperforms that of direct transmission, and more than 5 dB gain can be obtained using the AF relaying transmission compared to the conventional one. One note to be mentioned too is that the PU is at the coordinate (0.6,0.6) and the severity parameter is two for channels.

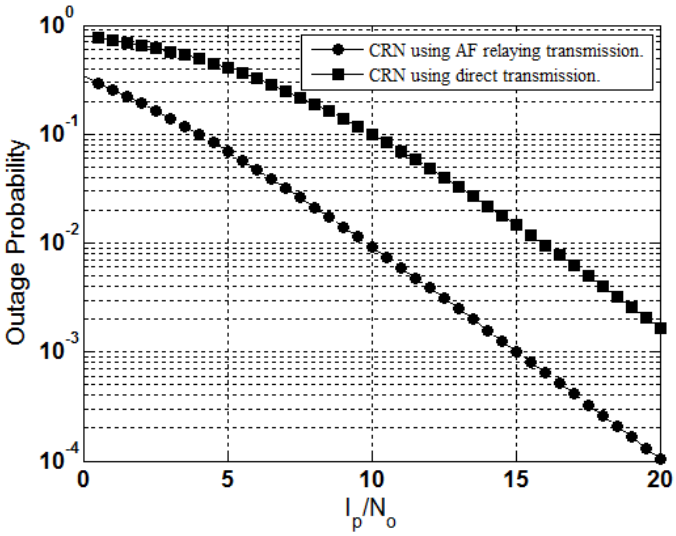

Fig. 2 OP of cognitive network using AF relaying transmission and direct transmission.

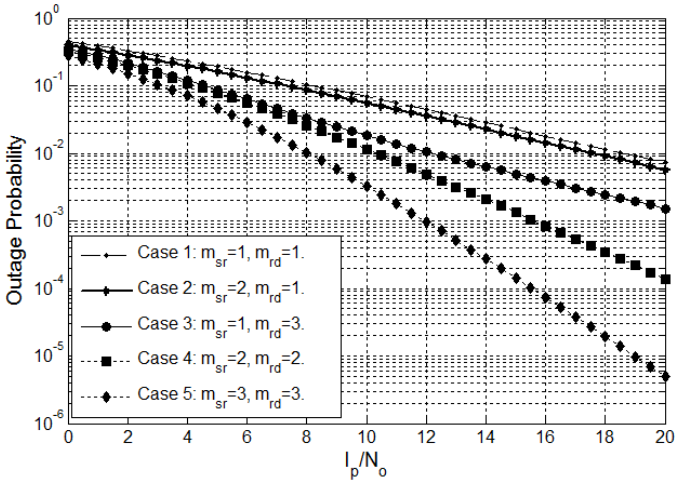

Fig. 3 OP of cognitive relay network (varying the severity parameters of the channels).

Fig.3 shows the impact of fading severity of the secondary network links on the outage performance where the PU location is at (0.6,0.6) coordinates and the fading severity parameters for the interference links are (m_{sp}=m_{rp}=1). The figure shows five cases with different fading severity parameters; Case 1: the two hops have the same severity parameters (m_{sr}=m_{rd}=1); which represents the Rayleigh case, Case 2: the first hop is less severe than the second hop (m_{sr}=2, m_{rd}=1), Case 3: the second hop is less severe than the first hop (m_{sr}=1, m_{rd}=3), Case 4: the two hops have the same severity

parameters (m_{sr}=m_{rd}=2), and Case 5: the two hops have the same severity parameters (m_{sr}=m_{rd}=3). The first thing to be noted here is that our results conform the results in [11] which describes the Rayleigh fading channels and it is considered the worst outage performance case in all cases. The results show that the outage performance depends on the minimum fading severity parameter of the two hops and the best outage performance case is case 5; since the two hop have the same severity parameters which equal three.

The outage performance for different locations of the PU is depicted in Fig.4. It is obvious that the best performance can be achieved for the case when the PU at coordinate (0.8,0.8), in which the minimum interference power of the PU is satisfied. From the figure, the outage probability will decrease as the PU moves away from the secondary network.

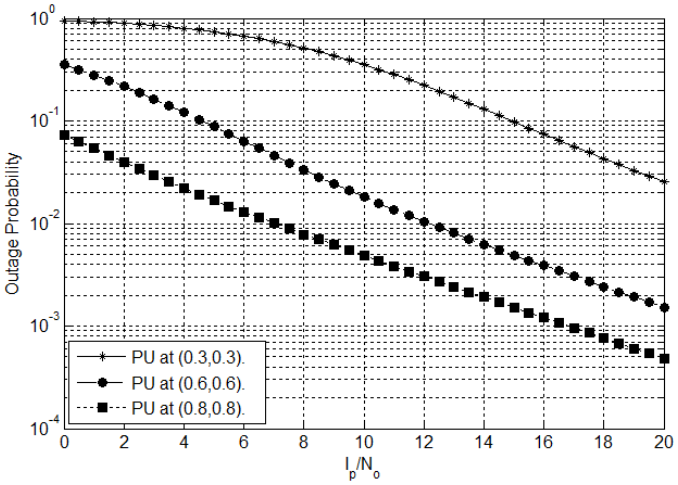

Fig. 4 OP of cognitive relay network (varying the PU location, and m_{sp}=m_{rp}= m_{sr}=1, m_{rd}=3).

V. CONCLUSION

In this paper, considering a spectrum sharing scenario, the outage probability of an underlay cognitive AF relay network over i.i.d. Nakagami-m fading channels under interference power constraiants on the PU has been investigated. From the results we see that the cognitive AF relaying transmission outperforms the conventional direct transmission, and the outage performance depends on the minimum fading severity among the two hops. Furthermore, the impact of the PU location has been studied and it is shown that the PU location plays a main role in the outage perfmorance; as the PU moves away from the secondary network, the outage probability decreases. As a result, these findings are very important for the wireless networks design.

APPENDIX A

For notational simplicity, let us denote the following terms: $X_1 = |h_{sr}|^2$ and $Y_1 = |h_{sp}|^2$.

In order to find the CDF of the SNR for the 1st-hop, $F_{\gamma_1}(\gamma)$, we need to rewrite γ_1 as:

$$\gamma_1 = \frac{\bar{\gamma}|h_{sr}|^2}{|h_{sp}|^2} = \bar{\gamma}\frac{X_1}{Y_1} \quad (A.1)$$

So we can express $F_{\gamma_1}(\gamma)$ as:

$$F_{\gamma_1}(\gamma) = \int_0^\infty F_{X_1}\left(\frac{\gamma y}{\bar{\gamma}}\right) f_{Y_1}(y)dy \quad (A.2)$$

Then,

$$F_{\gamma_1}(\gamma) = \int_0^\infty \left[1 - \frac{\Gamma\left(m_{sr}, \frac{\lambda_{sr}\gamma y}{\bar{\gamma}}\right)}{\Gamma(m_{sr})}\right]\left[\frac{\lambda_{sp}{}^{m_{sp}}}{\Gamma(m_{sp})} y^{m_{sp}-1} e^{-\lambda_{sp} y}\right] dy \quad (A.3)$$

and for simplictiy we can write the above integral as:

$$F_{\gamma_1}(\gamma) = I_1 - I_2 \quad (A.4)$$

where

$$I_1 = \int_0^\infty \left[\frac{\lambda_{sp}{}^{m_{sp}}}{\Gamma(m_{sp})} y^{m_{sp}-1} e^{-\lambda_{sp} y}\right] dy \quad (A.5)$$

and

$$I_2 = \int_0^\infty \left[\frac{\Gamma\left(m_{sr}, \frac{\lambda_{sr}\gamma y}{\bar{\gamma}}\right)}{\Gamma(m_{sr})}\right]\left[\frac{\lambda_{sp}{}^{m_{sp}}}{\Gamma(m_{sp})} y^{m_{sp}-1} e^{-\lambda_{sp} y}\right] dy \quad (A.6)$$

$I_1 = 1$ using (A.7) below,

$$\int_0^\infty y^{\mathrm{n}} e^{-\mathrm{a}y} dy = \frac{\Gamma(n+1)}{a^{n+1}} ; n > -1 , a > 0 \quad (A.7)$$

using [14, (6.455.1)] we can express I_2 as:

$$I_2 = \frac{(\lambda_{sp}\bar{\gamma})^{m_{sp}}(\lambda_{sr}\gamma)^{m_{sr}}}{m_{sp}\,(\lambda_{sp}\bar{\gamma}+\lambda_{sr}\gamma)^{m_{sp}+m_{sr}}} \cdot \frac{1}{B(m_{sp},m_{sr})} \cdot {}_2F_1\left(1, m_{sp}+m_{sr}; m_{sp}+1; \frac{\lambda_{sp}\bar{\gamma}}{\lambda_{sp}\bar{\gamma}+\lambda_{sr}\gamma}\right) \quad (A.8)$$

where $B(.,.)$ is the Beta function given by [14, (8.384.1)], and ${}_2F_1(.,.;.;.)$ is the Gauss hypergeometric function given by [14, (9.100)]. By substituting I_1 and I_2 in (A.4) we get $F_{\gamma_1}(\gamma)$ as:

$$F_{\gamma_1}(\gamma) = 1 - \Upsilon_{sp,sr}(\gamma) \quad (A.9)$$

where

$$\Upsilon_{sp,sr}(\gamma) = \frac{(\lambda_{sp}\bar{\gamma})^{m_{sp}}(\lambda_{sr}\gamma)^{m_{sr}}}{m_{sp}\,(\lambda_{sp}\bar{\gamma}+\lambda_{sr}\gamma)^{m_{sp}+m_{sr}}} \cdot \frac{1}{B(m_{sp},m_{sr})} \cdot {}_2F_1\left(1, m_{sp}+m_{sr}; m_{sp}+1; \frac{\lambda_{sp}\bar{\gamma}}{\lambda_{sp}\bar{\gamma}+\lambda_{sr}\gamma}\right) \quad (A.10)$$

APPENDIX B

For notational simplicity, let us denote the following terms: $X_2 = |h_{rd}|^2$ and $Y_2 = |h_{rp}|^2$.

In order to find the CDF of the SNR for the 2nd-hop, $F_{\gamma_2}(\gamma)$, we need to rewrite the γ_2 as:

$$\gamma_2 = \frac{\bar{\gamma}\,|h_{rd}|^2}{|h_{rp}|^2} = \bar{\gamma}\frac{X_2}{Y_2} \quad \text{(B.1)}$$

So; we can express $F_{\gamma_2}(\gamma)$ as:

$$F_{\gamma_2}(\gamma) = \int_0^{\infty} F_{X_2}\left(\frac{\gamma y}{\bar{\gamma}}\right) f_{Y_2}(y)\,dy \quad \text{(B.2)}$$

using the same procedure in Appendix A, we get the CDF of the SNR for the 2nd-hop as:

$$F_{\gamma_2}(\gamma) = 1 - \Upsilon_{rp,rd}(\gamma) \quad \text{(B.3)}$$

where

$$\Upsilon_{rp,rd}(\gamma) = \frac{(\lambda_{rp}\bar{\gamma})^{m_{rp}}(\lambda_{rd}\gamma)^{m_{rd}}}{m_{rp}\,(\lambda_{rp}\bar{\gamma}+\lambda_{rd}\gamma)^{m_{rp}+m_{rd}}} \cdot \frac{1}{B(m_{rp},m_{rd})} \cdot {}_2F_1\left(1, m_{rp}+m_{rd}; m_{rp}+1; \frac{\lambda_{rp}\bar{\gamma}}{\lambda_{rp}\bar{\gamma}+\lambda_{rd}\gamma}\right) \quad \text{(B.4)}$$

Abstract - **In this paper, the outage performance is investigated for cognitive dual-hop relay networks with amplify-and-forward (AF) relay and selection combining (SC) receiver at the destination under spectrum sharing constraints on primary user (PU) over independent and identically distributed (i.i.d.) Nakagami-m fading channels. We derive an exact closed-form expression for the outage probability (OP) of the considered system under the peak interference power I_p at the primary user, and the impact of the PU location on the OP performance is studied also. Moreover; the effects fading severity for the two hops on the OP is investigated also for this cognitive relay network (CRN).**

Keywords: **Nakagami-m fading, cognitive relay network, dual hop, cognitive radio, amplify-and-forward relaying, selection diversity, outage probability.**

I. INTRODUCTION

Recent measurements have shown that most of the allocated spectrum is under-utilized and the new wireless services need more spectrum bands. To improve inefficient use of allocated spectrum, the concept of Cognitive Radio (CR) has been introduced. CR is one of the important technologies for wireless applications that has considered as a spectrum opportunistic technology. The main goal of CR is to exploit licensed bands without a license, where the unlicensed user (Secondary User) can use the spectrum band of the licensed user (Primary User) when the primary user is idle [1-3].

One of the important issues in CR is the sensing accuracy which refers to the precision in detecting the presence of the primary user[4]. Therefore; there are many solutions are existed to deal with this issue such as cooperative spectrum sensing where multiple secondary users cooperate together to improve the sensing accuracy and it takes smaller time to check the presence of the primary user resulting both decreasing in the sensing time period and increasing in the transmission time period for secondary user[5,6].

The spectrum is accessible to the SU the underlay strategy under an interference constraint at the PU receiver. Therefore, the SU is allowed to access the channel as long as its transmit power is below a certain threshold [7]. For the outage probability definition, some authors defined it as the probability that the symbol error probability (SEP) exceeds a maximum tolerable level [8, 9], some authors defined it as the probability that the instantaneous signal-to-noise ratio (SNR) at the destination goes below a predefined threshold [10].

The OP for cognitive decode-and-forward (DF) relay networks has been derived in [11, 12]. In [13] the authors derived the OP of cognitive dual-hop relay networks with AF relay over Rayleigh fading channels under spectrum sharing constraints on a PU. In [14] an exact OP of cognitive dual-hop relay networks wth AF relay and selection combining receiver at the destination over Rayleigh fading channels has been derived. While in [15] closed-form lower-bounds and asymptotic expressions for the outage probability of dual hop cognitive relay network with a single AF relay has been derived using different strategies to determine the transmit power of the SU source using the power series for the lower incomplete gamma function.

Comparing AF with DF relay, AF requires much less delay as the relay node operates time slot by time slot and it requires much less computing power as no decoding operation, and since the Nakagami-m distribution gives the best fit for land-mobile and indoor-mobile [16] multipath propagation; exact closed form expression for the outage probabilitiy of cognitive relay network with AF relay and selection diversity under spectrum sharing constraints on PU over i.i.d. Nakagami-m fading channels is derived in this paper. The impact of the of the PU location on the outage probability will be studied by varying the location of the PU with respect to the SU network and the effects of the fading severity for the two hops on the outage probability will be investigated also for this CRN.

The main difference in opportunistic relay selection between CR networks and non-CR networks that is in CR networks due to the channel gain of the link from the secondary user source to the primary user the individual SNR

of each path contains the same random variable, which is not easy for analysis. So we will deal with a problem of multiple statistically dependent random variables.

This paper is further presented as follows; Section II provides the system and channel models, as well as the structure of the CRN components. Section III describes the analysis framework for evaluating the outage probability. Numerical results and discussion are presented in section IV. We concluded this paper in section V.

II. SYSTEM AND CHANNEL MODELS

Consider a dual-hop cooperative spectrum sharing system as shown in Fig.1, it is shown that the communication between the SU source (S) and the SU destination (D) may be satisfied using two paths; the first path is by using the direct conventional transmission and the second one is by using the AF relay link. For the direct link, the transmission takes palce in one phase where the SU source (S) transmits its signal to the SU destination (D) under a transmit power constraint I_p with a transmit power

$$P_s = \frac{I_p}{|h_{sp}|^2} \tag{1}$$

where h_{sp} is the channel coefficient of the link S→P. The transmission using the AF relay takes place in two phases. In phase I, the SU source transmits its signal to the relay under a transmit power I_p constraint with a transmit power $P_s = I_p / |h_{sp}|^2$. In phase II, the relay amplifies the received signal from (S) and forwards it to the destination, and the signal is transmitted with a transmit power of $P_r = I_p / |h_{rp}|^2$, where h_{rp} is the channel coefficient of the link R→P.

Both signals from the relaying path and from the direct path are combined together at the destination using a SC receiver to choose the best path for transmission. All nodes in our system are provided with a single antenna and operate in a half-duplex mode . Moreovere, we assume the channel state information (CSI)-assisted case.

We assume that the fading channels are i.i.d. flat Nakagami-m channels, and the channel power gains $X \in \{ |h_{sp}|^2, |h_{sr}|^2, |h_{rp}|^2, |h_{rd}|^2, |h_{sd}|^2 \}$ have a gamma distribution, with means power Ω_{sp}, Ω_{sr}, Ω_{rp}, Ω_{rd}, and Ω_{sd}, respectively. Thus the cumulative distribution function (CDF) of each one of these power gains can be expressed as:

$$F_X(x) = 1 - \frac{\Gamma(m_X, \lambda_X x)}{\Gamma(m_X)} \tag{2}$$

and the probability density function (PDF) as

$$f_X(x) = \frac{{\lambda_X}^{m_X}}{\Gamma(m_X)} x^{m_X - 1} e^{-\lambda_X x} \tag{3}$$

where $m_X \in \{m_{sp}, m_{sr}, m_{rp}, m_{rd}, m_{sd}\}$ represents the corresponding fading severity parameter m, $\lambda_X = m_X / \Omega_X$, and $\Gamma(.,.)$ is the incomplete gamma function given by [17, (8.350.2)].

III. PERFORMANCE ANALYSIS

In order to find the outage probability performance, we have to determine the instantaneous end-to-end signal-to-noise-ratios (SNRs) received at the destination (D) from the two paths. The isnataneous SNR at (D) reffering to the direct link transmission can be expressed as

$$\gamma_{direct} = \frac{P_s |h_{sd}|^2}{N_o} = \frac{\bar{\gamma} |h_{sd}|^2}{|h_{sp}|^2} \tag{4}$$

where $\bar{\gamma} = I_p / N_o$. The instantaneous SNR at (D) referring to

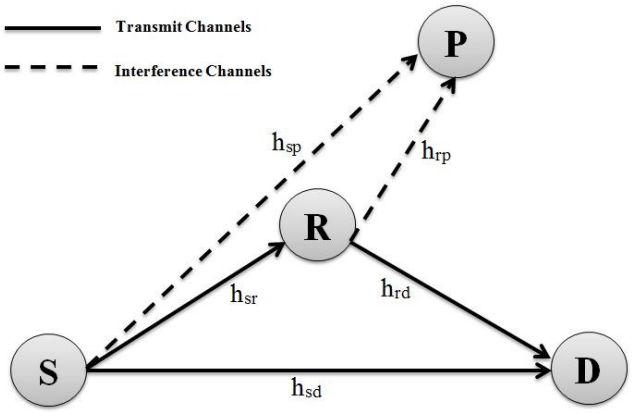

Fig.1: System Model for cognitive AF relay network with a selection combining receiver.

the AF relaying link transmission can be expressed as [18]:

$$\gamma_{relay} = \frac{\gamma_1 \gamma_2}{\gamma_1 + \gamma_2 + 1} \tag{5}$$

where γ_1 and γ_2 are the instantaneous end-to-end SNRs for the 1st-hop and the 2nd-hop, respectively, given by:

$$\gamma_1 = \frac{P_s |h_{sr}|^2}{N_o} = \frac{\bar{\gamma} |h_{sr}|^2}{|h_{sp}|^2} \tag{6}$$

$$\gamma_2 = \frac{P_r |h_{rd}|^2}{N_o} = \frac{\bar{\gamma} |h_{rd}|^2}{|h_{rp}|^2} \tag{7}$$

Thus; we can rewrite γ_{relay} as follows:

$$\gamma_{relay} = \frac{\frac{\bar{\gamma} |h_{sr}|^2}{|h_{sp}|^2} \frac{\bar{\gamma} |h_{rd}|^2}{|h_{rp}|^2}}{\frac{\bar{\gamma} |h_{sr}|^2}{|h_{sp}|^2} + \frac{\bar{\gamma} |h_{rd}|^2}{|h_{rp}|^2} + 1} \tag{8}$$

It can be seen from (4) and (8) that γ_{direct} and γ_{relay} are statistically dependent due to the presence of the common random variable h_{sp} which makes the performance analysis not easy to find. (8) may be expressed in a more mathematically tractable form, to achieve that; a tight upper-

bound approximation was suggested in [16]. Thus; we will use γ_t isntead of γ_{relay}, where γ_t is expressed as:

$$\gamma_t = min\ (\gamma_1, \gamma_2) \tag{9}$$

Since we have the SC receiver at the destination that chooses the best path for transmission; we may express γ_{SC} as

$$\gamma_{SC} = max\ (\gamma_{direct}, \gamma_t) \tag{10}$$

where γ_{SC} is the instantaneous SNR at the destination using a SC receiver.

Due to the presence of the common random variable h_{sp}, we will apply the conditional statistics on the channel coefficient of the link S→P, and it is important to note that the remaining random variables, $\{|h_{sr}|^2, |h_{rp}|^2, |h_{rd}|^2, |h_{sd}|^2\}$, are independent. Since γ_{SC} is the maximum of two random variables, we need to find the CDF conditioned on h_{sp} for the SNR of each path and to apply the following equation

$$F_{\gamma_{SC}}(\gamma/Y) = F_{\gamma_{direct}}(\gamma/Y)\, F_{\gamma_t}(\gamma/Y) \tag{11}$$

where $Y = |h_{sp}|^2$.

Theorem 1: The CDF of the SNR for the direct path conditioned on *Y* is given by:

$$F_{\gamma_{direct}}(\gamma/Y) = 1 - \frac{\Gamma\left(m_{sd}, \frac{\lambda_{sd}\gamma}{\bar{\gamma}}y\right)}{\Gamma(m_{sd})} \tag{12}$$

Proof: The proof is given in Appendix A.

Theorem 2: The CDF of the SNR for the AF-relaying path conditioned on *Y* is given by

$$F_{\gamma_t}(\gamma/Y) = 1 - \Upsilon_{rp,rd}(\gamma)\frac{\Gamma\left(m_{sr}, \frac{\lambda_{sr}\gamma}{\bar{\gamma}}y\right)}{\Gamma(m_{sr})} \tag{13}$$

where $\Upsilon_{uv,ij}(\gamma)$ is a function of γ and it is given by:

$$\Upsilon_{uv,ij}(\gamma) = \frac{(\lambda_{uv}\bar{\gamma})^{m_{uv}}(\lambda_{ij}\gamma)^{m_{ij}}}{m_{uv}\left(\lambda_{uv}\bar{\gamma} + \lambda_{ij}\gamma\right)^{m_{uv}+m_{ij}}} \cdot \frac{1}{B(m_{uv}, m_{ij})} \cdot {}_2F_1\left(1, m_{uv} + m_{ij}; m_{uv}+1; \frac{\lambda_{uv}\bar{\gamma}}{\lambda_{uv}\bar{\gamma} + \lambda_{ij}\gamma}\right) \tag{14}$$

where $B(.,.)$ is the Beta function given by [17, (8.384.1)] and ${}_2F_1(.,.;.;.)$ is the Gauss hypergeometric function given by [14, (9.100)].

Proof: The proof is given in Appendix B.

Using theorems 1 and 2 and after some mathematical manipulations, $F_{\gamma_{SC}}(\gamma/Y)$ can be written as follows,

$$F_{\gamma_{SC}}(\gamma/Y) = 1 - \Upsilon_{rp,rd}(\gamma)\frac{\Gamma\left(m_{sr}, \frac{\lambda_{sr}\gamma}{\bar{\gamma}}y\right)}{\Gamma(m_{sr})} - \frac{\Gamma\left(m_{sd}, \frac{\lambda_{sd}\gamma}{\bar{\gamma}}y\right)}{\Gamma(m_{sd})} + \Upsilon_{rp,rd}(\gamma)\frac{\Gamma\left(m_{sr}, \frac{\lambda_{sr}\gamma}{\bar{\gamma}}y\right)}{\Gamma(m_{sr})}\frac{\Gamma\left(m_{sr}, \frac{\lambda_{sd}\gamma}{\bar{\gamma}}y\right)}{\Gamma(m_{sd})} \tag{15}$$

Since the OP is the probability that the instatneous SNR at (D) goes below a predefined threshold, γ_{th}, we can find the OP as :

$$\mathrm{OP} = \Pr(\gamma_{SC} \le \gamma_{th}) = \int_0^\infty F_{\gamma_{SC}}(\gamma_{th}/Y) f_Y(y)dy \tag{16}$$

Substituting (15) into (16) and using [17, (6.455.1)], [17, (8.352.4)], and the multinomial theorem we can express the OP of underlay CRN with a single AF relay plus direct link over i.i.d. Nakagami-m fading channels using a SC receiver as:

$$OP = 1 - \Upsilon_{rp,rd}(\gamma_{th})\Upsilon_{sp,sr}(\gamma_{th}) - \Upsilon_{sp,sd}(\gamma_{th}) + \frac{{\lambda_{sp}}^{m_{sp}}\ \Upsilon_{rp,rd}(\gamma_{th})}{\Gamma(m_{sp})} \sum_{l,w,m_{sd},\lambda_{sd}}^{*} \sum_{t,u,m_{sr},\lambda_{sr}}^{*} \left(\frac{\gamma_{th}}{\bar{\gamma}}\right)^{S_1+S_2} \frac{\Gamma(S_1+S_2+m_{sp})}{[\lambda_{sp} + \frac{\gamma_{th}}{\bar{\gamma}}(\lambda_{sd}+\lambda_{sr})]^{S_1+S_2+m_{sp}}} \tag{17}$$

where

$$\sum_{l,w,m_X,\lambda_X}^{*} = \sum_{l_1 \dots l_{m_X}}^{*} \frac{1}{l_1! \dots l_{m_X}!} \prod_{w=0}^{m_X-1} \left(\frac{{\lambda_X}^w}{w!}\right)^{l_{w+1}} \tag{18}$$

$$S_1 = \sum_{j=0}^{m_{sd}-1} j\ l_{j+1} \tag{19}$$

$$S_2 = \sum_{j=0}^{m_{sr}-1} j\ t_{j+1} \tag{20}$$

IV. Numerical Results and Discussion

In this section, we show the numerical results to validate our analysis. We consider a co-linear topology for All nodes in our cognitive relay network model, where the distance between the SU source (S) and the SU destination (D) is normalized to be one, and the SU relay (R) is located at the middle distance between (S) and (D). Therefore, the coordinates for (S), (D), and (R) are (0,0), (1,0), and (0.5,0), respectively.

The outage threshold is defined to be 1 dB and the path loss of each channel follows an exponential decay model with an exponent can be set to four in the free-space propagation with non-line-of-sight model. The OP performance for different transmission scenarios of cognitive spectrum sharing including the conventional transmission (without relays), transmission via AF relaying, and cooperative transmission with selection combining are compared in this section. The

impact of fading severity of the secondary network links on the OP is evaluated for a fixed location of the PU. Finally, we evaluate the impact of the PU location on the OP by taking different locations for the PU receiver.

Fig.2 compares the outage performance for three different transmission scenarios of cognitive spectrum sharing network including the direct transmission, AF relaying transmission, and cooperative transmission with SC receiver. As can be seen from the figure that the cooperative spectrum sharing transmission with SC outperforms the two other transmission scenarios since the diversity order increased to two. More than 5 dB gain can be obtained using the AF relaying transmission compared to the conventional one. The PU is at the coordinate (0.6,0.6).

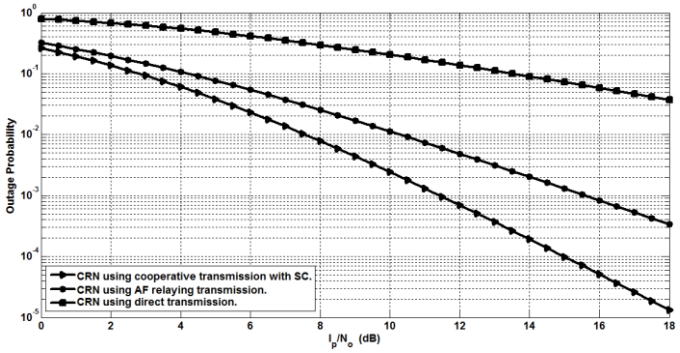

Fig.2: OP of cognitive network using direct transmission, AF relaying transmission, and cooperative transmission with SC (m_{sp}= m_{sr}= m_{rd}=2, m_{rp}= m_{sd}=1).

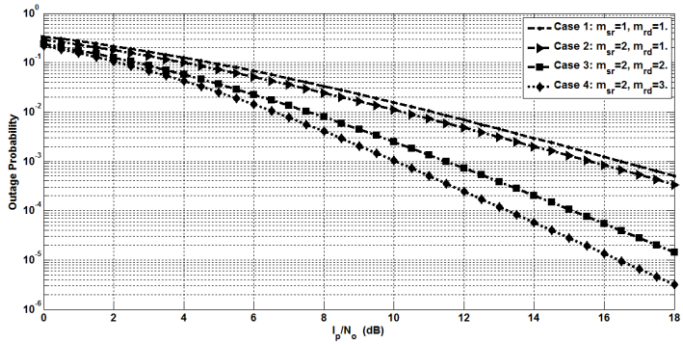

Fig.3: OP of cognitive relay network (varying the severity parameters of the channels).

Fig.3 shows the impact of fading severity of the secondary network links on the outage performance where the PU location is at (0.6,0.6) coordinates and the fading severity parameters for the interference links are (m_{sp}=m_{rp}=1) and the fading severity between (S) and (D) is (m_{sd}=1). The figure shows four cases with different fading severity parameters; Case 1: the two hops have the same severity parameters (m_{sr}=m_{rd}=1); which represents the Rayleigh case, Case 2: the first hop is less severe than the second hop (m_{sr}=2, m_{rd}=1), Case 3: the two hops have the same severity parameters (m_{sr}=m_{rd}=2), and Case 4: the second hop is less severe than the first hop (m_{sr}=2, m_{rd}=3). The first thing to be noted here that our results conform the results in [14] which describe the Rayleigh fading channels and it is considered the worst outage performance case in all cases. The results show that the outage performance depends on the minimum fading severity parameter of the two hops and the best outage performance case is case 4; since the two hops have the same severity parameters which equal two.

The outage probabilities for different locations of the PU is depicted in Fig.4. The best performance can be achieved for the case when the PU at coordinate (0.8,0.8), in which the minimum interference power of the PU is satisfied. So, the outage probability will decrease as the PU moves away from the secondary network.

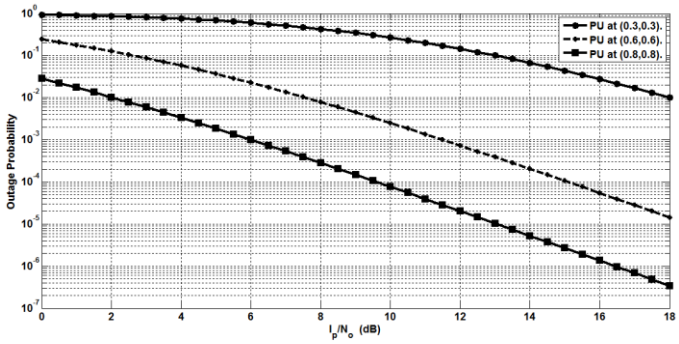

Fig.4: OP of cognitive relay network (varying the PU location, and m_{sp}=m_{rp}= m_{sd}=1, m_{sr}= m_{rd}=2).

V. CONCLUSION

In this paper, we have derived exact closed-form expression for the outage probability of cognitive AF relay network over i.i.d. Nakagami-m fading channels under interference power constraints on the PU. Many important issues for wireless network design have concluded. The first one; the cooperative spectrum sharing transmission outperforms the conventional direct transmission and the transmission using AF relaying since the the diversity order increased by two. Moreover, we have shown that the outage performance depends on the minimum fading severity among the two hops of the relaying link. Finally, the effect of the PU location on the network performance has been studied and it is shown that varying the location of the PU faraway from the SU network improves the outage performance.

APPENDIX A

For notational simplicity, let us denote the following terms: $X_0 = |h_{sd}|^2$ and $Y = |h_{sp}|^2$. In order to find the CDF of the instantaneous SNR for the direct path conditioned on h_{sp}, $F_{\gamma_{direct}}(\gamma/Y)$, we need to rewrite γ_{direct} as

$$\gamma_{direct} = \frac{\bar{\gamma}\,|h_{sd}|^2}{|h_{sp}|^2} = \bar{\gamma}\frac{X_0}{Y} \qquad (A.1)$$

Therefore; we can express $F_{\gamma_{direct}}(\gamma/Y)$ as follows,

$$F_{\gamma_{direct}}(\gamma/Y) = \Pr\left(\frac{X_0}{Y} \le \frac{\gamma}{\bar{\gamma}}\right) = F_{X_0}\left(\frac{\gamma}{\bar{\gamma}}y\right) \qquad (A.2)$$

After the substitution in the Nakgamai-m CDF , we can get

$$F_{\gamma_{direct}}(\gamma/Y) = 1 - \frac{\Gamma\left(m_{sd}, \frac{\lambda_{sd}\gamma}{\bar{\gamma}} y\right)}{\Gamma(m_{sd})} \quad (A.3)$$

APPENDIX B

In order to find the CDF of the instantaneous SNR for relaying path conditioned on h_{sp}, $F_{\gamma_t}(\gamma/Y)$, we need to find the CDFs for both hops conditioned on h_{sp} . For notational simplicity, let us denote the following terms: $X_1 = |h_{sr}|^2$ and $X_2 = \frac{\bar{\gamma}|h_{rd}|^2}{|h_{rp}|^2}$.

We can rewrite the instantaneous SNR for the 1st-hop as follows,

$$\gamma_1 = \frac{\bar{\gamma}|h_{sr}|^2}{|h_{sp}|^2} = \bar{\gamma}\frac{X_1}{Y} \quad (B.1)$$

Therefore; we can express the CDF for the 1st hop conditioned on h_{sp}, $F_{\gamma_1}(\gamma/Y)$, as follows,

$$F_{\gamma_1}(\gamma/Y) = F_{X_1}\left(\frac{\gamma}{\bar{\gamma}} y\right) = 1 - \frac{\Gamma\left(m_{sr}, \frac{\lambda_{sr}\gamma}{\bar{\gamma}} y\right)}{\Gamma(m_{sr})} \quad (B.2)$$

We will do the same analysis as in $F_{\gamma_1}(\gamma/Y)$ to find CDF of the SNR for the 2nd-hop conditioned on h_{sp} , $F_{\gamma_2}(\gamma/Y)$, then; the instantaneous SNR for the 2nd-hop, γ_2, does not depend on Y and using the notation that we supposed before, we can rewrite γ_2 as

$$\gamma_2 = \frac{\bar{\gamma}|h_{rd}|^2}{|h_{rp}|^2} = X_2 \quad (B.3)$$

Therefore;

$$F_{\gamma_2}(\gamma/Y) = F_{\gamma_2}(\gamma) = \int_0^{\infty}\int_0^{\frac{\gamma y}{\bar{\gamma}}} f_{|h_{rd}|^2}(x) f_{|h_{rp}|^2}(y) dy \quad (B.4)$$

After some manipulations and using [17, Eq.(6.455.1)], we can express $F_{\gamma_2}(\gamma/Y)$ as

$$F_{\gamma_2}(\gamma/Y) = 1 - \Upsilon_{rp,rd}(\gamma) \quad (B.5)$$

where $\Upsilon_{uv,ij}(\gamma)$ is a function of γ and it is given by:

$$\Upsilon_{uv,ij}(\gamma) = \frac{(\lambda_{uv}\bar{\gamma})^{m_{uv}}(\lambda_{ij}\gamma)^{m_{ij}}}{m_{uv}\left(\lambda_{uv}\bar{\gamma} + \lambda_{ij}\gamma\right)^{m_{uv}+m_{ij}}} \cdot \frac{1}{B(m_{uv}, m_{ij})} \cdot {}_2F_1\left(1, m_{uv} + m_{ij}; m_{uv}+1; \frac{\lambda_{uv}\bar{\gamma}}{\lambda_{uv}\bar{\gamma} + \lambda_{ij}\gamma}\right) \quad (B.6)$$

where $B(.,.)$ is the Beta function given by [17, (8.384.1)] and ${}_2F_1(.,.;.;.)$ is the Gauss hypergeometric function given by [17, (9.100)]. Then; $F_{\gamma_t}(\gamma/Y)$ can be expressed as

$$F_{\gamma_t}(\gamma/Y) = 1 - \Upsilon_{rp,rd}(\gamma)\frac{\Gamma\left(m_{sr}, \frac{\lambda_{sr}\gamma}{\bar{\gamma}} y\right)}{\Gamma(m_{sr})} \quad (B.7)$$

goran.dimic@fer.hr

Abstract - Energy efficiency in these days is as it should be, a part of every scientific research, especially in electronic communications in which it holds a notably significant role. When it comes to electronic communications, what matters is that the network is efficient not only for environmental reasons but for economical, as well. In telecommunication network, control of all the network aspects is crucial, because an inadequate control could easily end up with energy's over-usage. This paper presents a simulation of basic energy network components, which is a part of the project "Information and Communication Technology for Generic and Energy-efficient Communication Solutions with Application in e-/m- Health" (ICTGEN). The growing importance of ICT in everyday life such as the one of communication devices surrounding us, has lead us to bigger impact in using ICT equipment globally.

I. INTRODUCTION

Energy and its role in today every part of living is indisputable. This is the reason why energy efficiency is very important in all aspects of life. It is especially applied in research and development of new technologies with the main purpose being energy efficiency. Developing technologies influence global awareness of climatic changes. The ICT (Information and Communication Technology) is not exception. In the past, development of telecommunication networks has two main components: performance of system and profitability. As energy costs contribute significantly to the operational expenditures of telecommunication network operators, energy consumption has become a vital economic interest of network operators today. Thus, increasing performance and increasing profitability of system are inseparable with energy efficiency.

The traffic volume is predicted to grow at tremendous rates during the next few years. In addition, data centers are becoming increasingly important for the provisioning of telecommunication services, and there is a huge and increasing demand for using mobile services and applications. Thus, the very important question is what are the methods of optimization energy resources in telecommunication networks?

I. METHODOLOGY

Importance of ICT in daily living and number of communication devices that surround us is increasing. Consequently, this led to a significant increase of energy consumption of ICT equipment in total share of global energy consumption, which then led to important question of increasing energy efficiency of communication equipment and networks, mainly as increasing number of Internet users led to increasing number of smart devices based on wireless technology (such as smartphones, tablets, entertainment devices, medical devices, wireless sensors in smart houses and similar network equipment and devices). These days, in data centers energy consumption is one of main expenses; this is the reason for telecommunication companies to invest in research of energy efficient elements of network infrastructure. Until now, optimization of energy efficiency was focused to a dynamic control on hardware level (voltage controlling, clock speed and cooling methods). New methods are focused towards optimization of algorithm for controlling load of communication network. Here, energy saving is achieved in a way that we temporarily turn off network units which are not in use at a moment. In that way, it is possible to save energy in numbers that we cannot reach optimizing devices on hardware level. Furthermore, reduction of total energy from electricity power network are not only advantage of optimizing energy efficiency of end networked devices and sensor networks, but also increasing autonomy of battery powered devices. This has a positive influence on reliability, durability and long-term applicability for this kind of devices. In networks for environment parameter tracking that are used in smart home environment energy efficiency and optimization have a special focus.

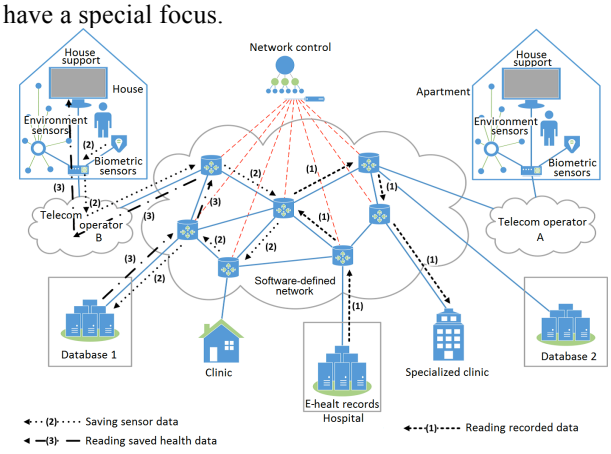

Figure 1 ICT network for application in e-/m- Health

Subject of active research in that field covers architecture development of Wireless Sensor Network (WSN) with very low power consumption specialized for environment parameter tracking in smart environment, which has to

allow maximal autonomy for network elements without constant power supply, also it has to allow high level of interoperability with other devices in communication network. Challenge for designing architecture and implementing algorithm for controlling energy efficiency is to synchronize multiple tasks, like a need for very low power consumption of network elements with need of a few years autonomy, interoperability within communication standards (like ZigBee, Wi-Fi and Bluetooth), implementation of complex algorithms for controlling energy efficiency of computer components. This is the reason why there is no standard for architecture of wireless area network for that purpose.
On second figure is shown a part of network and example of routing data. On figure 2 we can see that transfer of audio data and video data is achieved in two ways, because audio data must have the fastest route and video data must have sufficient bandwidth.

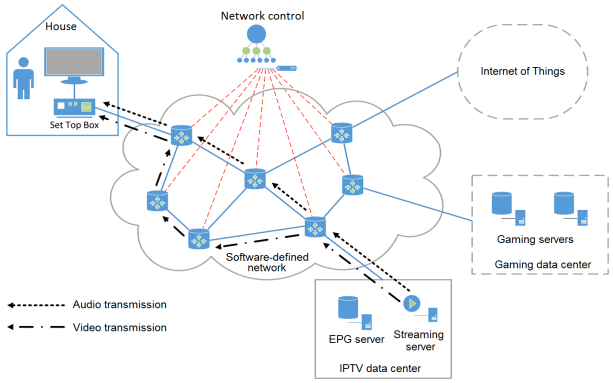

Figure 2 Routing of data

II. SIMULATION

The goal of ICTGEN project is to develop telecommunication network with end purpose in e-/m-health. Data which will be transferred in this network will be different in a purpose and in a requirements for network such as, medical records, video, home environment data collected via wireless sensor network etc. This information has a wide amount of data and can be very small from a few bites such as sensor data, to a few giga bites such as Magnetic Resonance Imaging (MRI). As requirements on network are big, energy efficiency can be successful by using elements of network where their usability is at maximum. As example, this work presents a simulation of wireless sensor network based on devices with ZigBee protocol (Fig. 3). With this, we ensure that network will have bigger autonomy of sensors and end devices with battery power supply. On the other hand, if video data or speech have to be exchanged with wireless network, WLAN devices based on 802.11 protocol will be used. These two networks are simulated and presented.

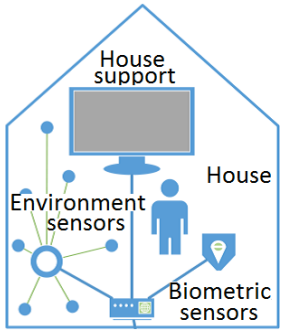

Figure 3 Wireless network in home environment

A. *WIRELESS SENSOR NETWORK BASED ON ZigBee DEVICES*

The OPNET ZigBee model uses four process models:

- ZigBee MAC model implements a model of the IEEE 802.15.4 MAC protocol.
- ZigBee Application model which represents a low fidelity version of the ZigBee Application Layer as specified in the ZigBee Specification. The process model initiates network joins and formations, generates and receives traffic and generates different simulation reports.
- ZigBee Carrier Sense Multiple Access/Collision Avoidance (CSMA/CA) model which implements the media access protocol of the MAC layer.
- ZigBee Network model which implements the ZigBee Network Layer as specified in the ZigBee specification. This model is responsible for routing traffic, process network join, formation requests and generating beacons.

Global MAC throughput is the total data traffic in bits/sec successfully received and forwarded to the higher layer by the 802.15.4 MAC in all the nodes of the WSN. Fig. 5 shows the global throughput for our ZigBee network. Network consists of one coordinator, four routers and eight end devices (Fig. 4)

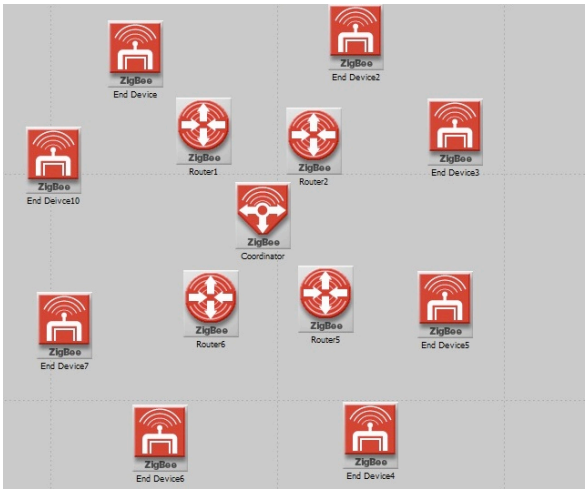

Figure 4 Topology of ZigBee network

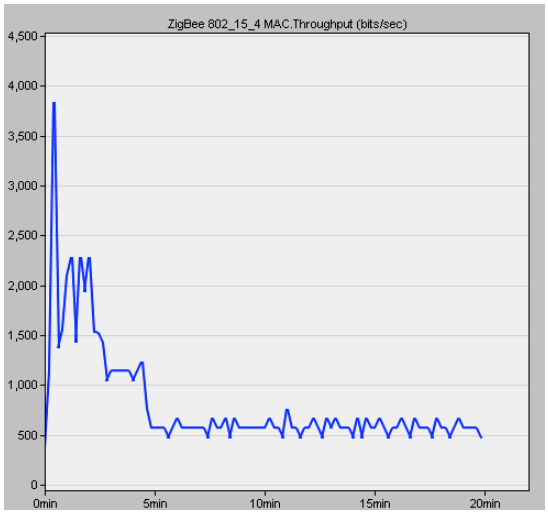

Figure 5 Global throughput for ZigBee network

B. *WLAN*

The field of wireless local area networks (WLANs) is being widely studied and used in various emerging research domains such as mobile and pervasive computing, where WLANs provide high-speed wireless connection and support accessing information from anywhere and anytime. WLANs support a wide range of applications, which may include simple applications such as web browsing etc. and the other ones, for instance, video streaming and video conferencing. IEEE 802.11 is a vital standard for wireless LAN, which adopts the standard 802 logical link control (LLC) protocol that is further divided into two sub layers: physical layer (PHY) and medium access control (MAC) layer. This configuration provides optimized functionality for wireless communication. The physical characteristics of 802.11a and 802.11g are identical – both are based on OFDM and support data rate of 54 Mbps. However they differ in operating frequency spectrum– 802.11a operates on 5 GHz band, while 802.11g on 2.4 GHz. 802.11bis based on DSSS and operates at 2.4 GHz band with transmission rate from 1 to 11 Mbps. 802.11a has significant advantage due to the wide range spectrum of 5 GHz, having more number of independent channels. Both 802.11b and 802.11g are compatible with each other as both operates on 2.4 GHz spectrum, but this may cause degradation in system performance as 2.4 GHz is a small band spectrum with a lesser number of independent channels.

In this simulation we are using 802.11g protocol for video streaming purpose.

On fig. 7 is shown received and sent traffic from one router (node_3) to another (node_2) and on fig. 8 is shown global throughput in WLAN.

Our network will be used in different ways, such are video, medical findings and data transmission, even the ones tracking surroundings of patients inside of their homes, or in the hospital. Energy efficiency comes from wise choosing of the right technology for the right use. In prior pictures (Fig. 5 and 8) we can see simulation results, such as the ones that come from differences in throughput when using ZigBee and WLAN. ZigBee is used for transmitting data from the sensor, and WLAN for video transmission. However, dual use of both together in some moments is unnecessary and uneconomical too, since while doing that we waste electricity and reduce the autonomy of our battery powered devices. Suggested solution is to shut down machines whenever it is necessary, depending upon their purpose. It can be done with software-defined networks and devices. By doing that a significant amount of energy might be saved.

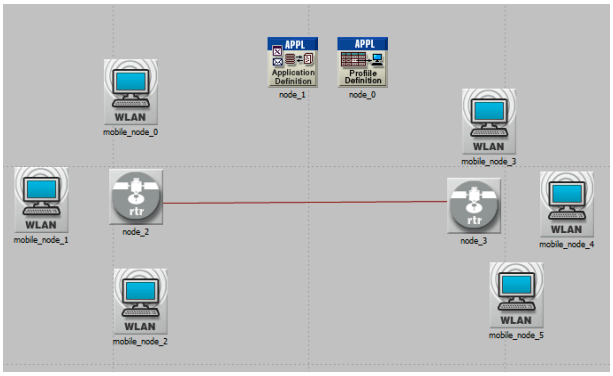

Figure 6 WLAN network

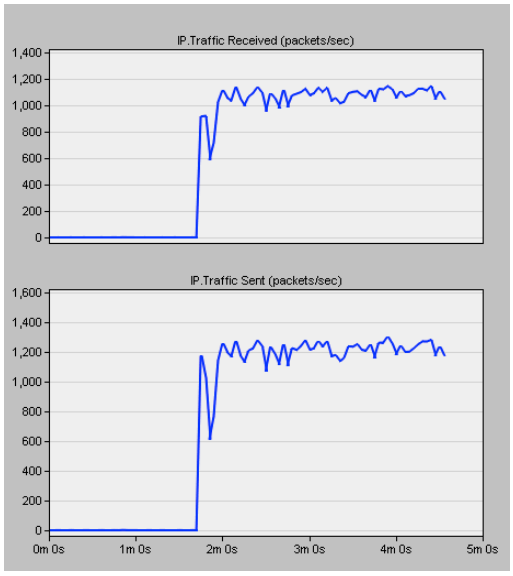

Figure 7 Traffic sent

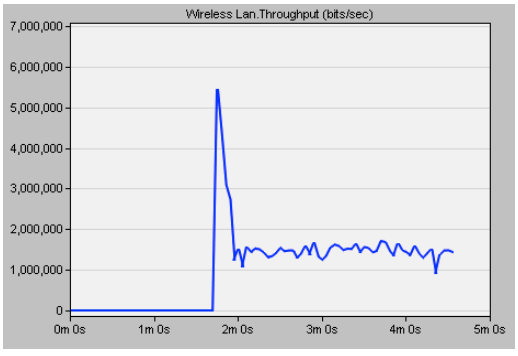

Figure 8. Global throughput of WLAN

III. FURTHER WORK

In order to properly estimate energy efficiency, the simulation of the full network is needed. Also, all protocols have to be performed in one simulation.
Also, for wireless part it would be very useful to implement some wireless devices which are battery powered, in which way we will have entirely system requirement on battery supply for that kind of devices.

IV. CONLUSION

In this paper the wireless part of telecommunication network with application in e-/m. health (optimized to be energy-efficient) is presented. Two parts of wireless network are presented and simulated, one based on ZigBee devices and other on WLAN. This network has multiple kinds of devices and protocols, because it has to transfer different kinds of information. Requirements for transferring information depend of information itself. MRI for example has few gigabytes so if we need to send or receive that kind of information wirelessly we will use WLAN. ZigBee devices, on the other hand, will be used for transferring information from sensors.

V. ACKNOWLEDGEMENT

The research leading to these results has received funding from the project "Information and communication technology for generic and energy-efficient communication solutions with application in e-/m-health (ICTGEN)" co-financed by the European Union from the European Regional Development Fund.

Environmental Sustainability of Information and Communication Technologies for Advanced Metering and Home Area Networks

Vedad Mujan and Slavisa Aleksic
Vienna University of Technology/Institute of Telecommunications, Vienna, Austria
slavisa.aleksic@tuwien.ac.at

Abstract - The challenges imposed on the current electric power grid have led to the need of an improved and smarter electric power grid, i.e., the smart grid. The smart grid will enable not only a bidirectional transfer of electricity, but also a two-way data exchange between various systems essential for a correct operation of the advanced metering infrastructure (AMI) and home area network (HAN) applications. The realization of the smart grid will require the deployment of additional information and communication technology (ICT) equipment in various domains. This will unavoidably lead to an increase in electricity consumption. In order to obtain a meaningful environmental sustainability analysis, additional to the operation phase, various other ICT equipment life cycle stages, i.e., raw material extraction and processing, manufacturing and assembly, recycling and disposal, as well as transportation, have to be included in the assessment as well. In this paper, we present an exergy-based life cycle assessment (E-LCA) of ICT equipment for smart grids involved in AMI and HAN applications. Based on a model developed for the city of Vienna, it is shown that the cumulative embodied and operational exergy consumption distribution and their development significantly differ for the AMI and the AMI/HAN scenario.

I. INTRODUCTION

The current electric power grid does not fulfill the requirements of the 21st century [1]. An improved and smarter electric power grid, i.e., the smart grid, promises a reduction of greenhouse gas (GHG) emissions, introduction of huge amounts of renewable energy sources, and improvement of methods associated with current electric power production, delivery, and consumption [2]. Such benefits and features of the smart grid will heavily rely on a bidirectional information exchange between various systems, accompanied by a massive deployment of information and communication technologies (ICTs) in its different domains. The overall smart grid can be divided into seven domains according to the National Institute of Standards and Technology (NIST) smart grid conceptual reference model, namely into: 1. bulk power generation, 2. transmission, 3. distribution, 4. customer, 5. operations, 6. markets, and 7. service provider [2]. The customer and distribution domains of the smart grid are those that are expected to be equipped with the largest number of additional ICT equipment [3], such as smart meters, power line communication (PLC) modems, and data concentrators. This ICT equipment is required for various smart grid applications, making the customer and distribution domain more pronounced than the others. Additionally, user devices (UDs) like smartphones, tablets, notebooks, digital subscriber line (DSL) modems, and home energy management systems (HEMSs) are seen as an important part of the customer domain [2,4]. These devices will provide users with real-time information on their actual electricity consumption, and are essential for various management and control applications. Based on these considerations, we focus our research on the advanced metering infrastructure (AMI) and home area network (HAN) applications for smart grids. AMI includes the entire network infrastructure as well as the ICT equipment between customer smart meters and the meter data management system (MDMS) located in the data and control center (DCC) [4]. Some examples of AMI equipment are smart meters, PLC modems, data concentrators, base stations, switches, and routers. The HAN defines the network required to link various consumer appliances and systems with the HEMS, in order to achieve efficient management and control functions [4].

In this paper, we apply a holistic modeling method to assess the environmental sustainability of ICT equipment required for the AMI and HAN smart grid applications. While many studies analyze only the energy consumption of ICT equipment during its use (i.e., operational energy consumption), many other life cycle stages are not considered, such as raw material extraction and processing, manufacturing and assembly, recycling and disposal, as well as the transportation of various materials and components. To obtain a more meaningful environmental sustainability analysis of ICT equipment, the evaluation of these other life cycle stages has to be included in the assessment as well [5]. The *exergy-based life cycle assessment* (E-LCA) provides means for such an analysis, and takes the entire lifetime of ICT equipment into consideration, i.e., from cradle to grave. It represents a sound approach for the environmental sustainability analysis of ICT equipment, based on its life cycle exergy consumption. The obtained total exergy consumption of a component or a system serves as a measure for the attained environmental sustainability. The main benefit of an exergy analysis in comparison to an energy analysis is the fact that different forms of energy can be directly

compared with each other, which is related to its utilization of the second law of thermodynamics, not considered in an energy analysis. Moreover, the application of E-LCA for the environmental sustainability analysis of ICT equipment does not take as much time as a LCA, and leads to more meaningful and unambiguous results [6]. The E-LCA is therefore used here as the environmental sustainability indicator of choice for the assessment and evaluation of ICT equipment required for a proper operation of the AMI and HAN applications. The assessment based on the E-LCA framework confirms the assumption that the customer and distribution domains are indeed the most exergy consuming ones (considering the AMI and HAN smart grid applications), i.e., those domains are closely linked to environmental sustainability issues.

The paper is structured as follows. Section II provides basic insights into exergy and the E-LCA approach for ICTs. In Section III, the description of the overall model developed for the environmental sustainability analysis of the AMI and HAN applications is outlined. Moreover, basic assumptions are provided. Section IV presents and discusses the obtained results. Finally, a summary and conclusions are provided in Section V.

II. EXERGY-BASED LIFE CYCLE ASSESSMENT (E-LCA) OF ICT EQUIPMENT

E-LCA provides a very useful framework for the environmental sustainability assessment of ICTs. This has been recognized by many researchers, and there are already a few studies which utilize the exergy concept for the evaluation of the environmental sustainability of ICTs [5-9]. The quantity *exergy* itself relies on the first and second law of thermodynamics. It is defined as the maximum amount of useful work that can be attained from a system when brought into thermodynamic equilibrium with its reference environment [10,11]. Put more simply, it can be understood as the quantity of energy that can be converted into useful work, i.e., the portion of energy available to be consumed [12]. The major difference which distinguishes exergy from energy is the fact that it is never conserved due to irreversibilities (i.e., internal inefficiencies) attributed to most real processes [13]. The energy balance of a process states that the difference between input and output energy equals zero, i.e., $En_{in} - En_{out} = 0$ [13]. This means that the total amount of energy is conserved. According to the exergy balance, on the other hand, the difference between input and output exergy is greater than zero, i.e., $Ex_{in} - Ex_{out} > 0$, indicating a decrease in the quality of energy (i.e., exergy) of a process [11,13]. Based on that, more insights into the efficiency of diverse processes are provided. The exergy balance is, moreover, proportional to entropy generation ΔS, weighted by the temperature T_0 of the exergy reference environment:

$$Ex_{loss} = Ex_{in} - Ex_{out} = \Delta S T_0. \quad (1)$$

Relation (1) is also known as the law of exergy loss [13], and states that the difference between the exergy at the input and the output of a system corresponds to entropy creation, i.e., irreversibilities. The total exergy loss of a system is obtained by estimating and summing up the exergy losses of its subsystems or components, i.e., $Ex_{loss,system} = \sum Ex_{loss,component}$. The E-LCA considers the same life cycle phases just like a life cycle assessment (LCA) framework, but leads to a simple and unambiguous outcome (i.e., an exergy consumption value) that can be used for easy and more meaningful ICT equipment environmental sustainability assessment purposes. Moreover, it is not that time consuming and difficult to derive in contrast to a LCA [6]. Figure 1 depicts graphically the different exergy consumption life cycle stages of ICT equipment that are considered [5]. The exergy consumption of ICT equipment in each of these life cycle stages are estimated and analyzed using the E-LCA framework. As exergy cannot be conserved, it is assumed that the overall exergy losses accumulated during the ICT equipment lifetime correspond to their cumulative exergy consumption [13]. Therefore, the evaluation of various ICT equipment involved in AMI and HAN applications is based on their exergy consumption, which, on the other hand, serves as a measure for the attained environmental sustainability. Additionally, a distinction is made between *embodied exergy consumption* (EEC), i.e., the exergy consumed during raw material extraction and processing, manufacturing and assembly, recycling and disposal, as well as transportation, and *operational exergy consumption* (OEC), i.e., the exergy consumed during operation (including cooling if present). This will allow us to compare these two different exergy consumption categories with each other, and to indicate the most exergy consumption related one. Based on that, more information about category groups of ICT equipment with significant improvement potential is provided, i.e., the ICT equipment most strongly related to environmental sustainability issues.

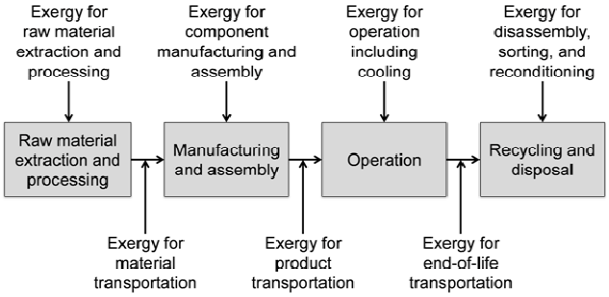

Figure 1. Life cycle exergy consumption stages of ICT equipment

III. DESCRIPTION OF THE MODEL

In this section, we present the overall smart grid model developed for the assessment of the AMI and HAN applications. Additionally, main assumptions required for the E-LCA of ICT equipment are provided. The considered overall smart grid model is composed of submodels for the home area network/building area network (HAN/BAN), neighborhood area network (NAN), radio access network (RAN), core network (CN), and the data and control center (DCC). A case study for the city of Vienna has been developed, with the aim to assess the EEC and OEC over a time period from 2020 to 2040 (i.e., operational duration of 20 years). Our assumption is that by the year 2020, the city of Vienna

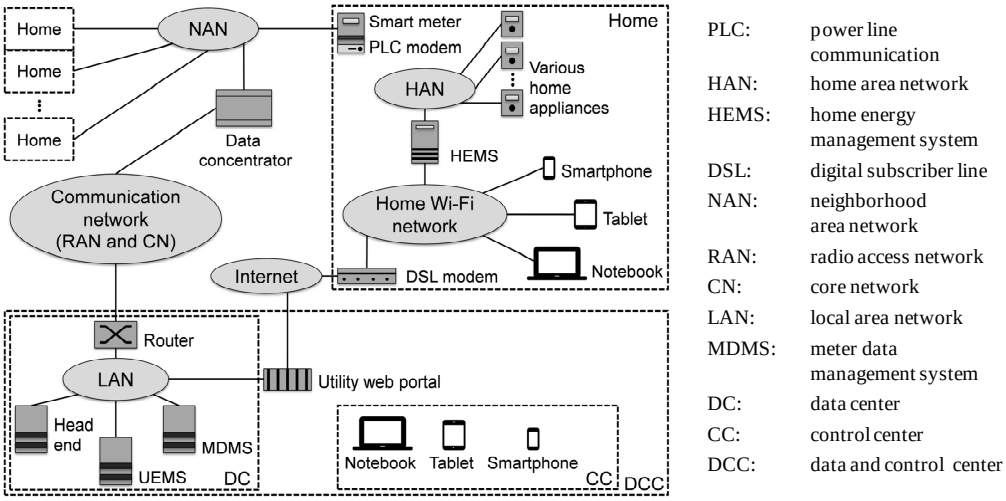

Figure 2. Overall smart grid model for the advanced metering infrastructure (AMI) and home area network (HAN) applications

will be equipped with appropriate smart metering, data processing and forwarding equipment (i.e., smart meters, PLC modems, and data concentrators), required for a correct operation of the AMI application [14]. The equipment needed for an appropriate functioning of the HAN application (e.g., smartphones, tablets, notebooks, DSL modems, and personal computer (PC) towers) is already in existence and widely utilized for various other purposes in almost every (if not every) household. These devices may as well be utilized for a multitude of different home energy management applications in connection with the smart grid concept. The PC tower, for example, may provide the functionality of a HEMS. For that purpose, adequate software programs would be required. Smartphones, tablets, and notebooks could be equipped with suitable mobile applications and software programs as well, enabling users to visualize their electricity consumption. This would, moreover, lead to an increased energy consumption awareness, and enable a greater involvement of consumers in the smart grid concept. The approach of dividing the overall smart grid model in different submodels will give us the opportunity to point out the most exergy consumption related ICT equipment, and with that the most dominant smart grid domains. Based on that, the domains that are closely related to environmental sustainability issues can be indicated.

A. *Overall Model*

The overall smart grid model is schematically depicted in Figure 2. The HAN/BAN equipment includes smart meters and PLC modems, as well as user devices (UDs) like smartphones, tablets, notebooks, DSL modems, and HEMSs required for a proper utilization of the HAN application. NAN equipment includes additionally to those of the HAN/BAN also data concentrators, required for data collection, processing, and forwarding purposes, and represents a very essential component of the smart grid. RAN equipment includes Global System for Mobile Communications (GSM) and Universal Mobile Telecommunications System (UMTS) equipment, i.e., base transceiver station (BTS), base station controller (BSC), Node B, and radio network controller (RNC) racks. The CN comprises serving General Packet Radio Service (GPRS) support node (SGSN) and gateway GPRS support node (GGSN) racks, as well as core switches. Copper and optical fiber cables, required to link RAN and CN equipment, are included in the model as well. Such a holistic approach allows us to obtain more meaningful conclusions on the environmental sustainability of ICTs associated with the AMI and HAN applications.

B. *Model for AMI and HANs*

The AMI represents the basic infrastructure of the future smart grid. It includes, e.g., smart meters, PLC modems, data concentrators, communication network equipment, and DCC equipment (see Figure 2). It is assumed that the data measured by smart meters are delivered to the data concentrator by means of the PLC technology. Moreover, the average number of smart meters (i.e., households) that can be supported by a data concentrator is assumed to be equal to 150. The forwarding of data for further evaluation and processing purposes from the data concentrator to the DCC is accomplished by means of cellular mobile communication systems, i.e., GSM and UMTS,. AMI is expected to bring a huge number of advantages with it, like increased reliability and energy efficiency, as well as a thorough insight into the condition of the entire smart grid. This will provide the staff at the DCC with advanced management and monitoring opportunities, and enable important remote control functions essential in the course of unusual or unexpected events [4].

The HAN considered here can be seen as an enhancement of the AMI. It extends the smart grid idea into the home, and enables important home energy management functions. It is used to link various consumer appliances with the HEMS by means of PLC or, e.g., the low-rate wireless personal area network (LR-WPAN) communication technology ZigBee. User devices such as smartphones, tablets, notebooks, DSL modems, and HEMSs are interconnected by means of the home Wi-Fi network and provide users with real-time electricity consumption information. This enables the users to see where and when their electricity consumption is at its peak, providing a way to cut down electricity bills. The

link between the HEMS and the utility energy management system (UEMS) is achieved by means of the Internet and the utility web portal [4], as depicted in Figure 2).

C. Assumptions and Scenarios

Information on the number of households in Vienna, their expected development, as well as the average number of persons per household is obtained from Statistics Austria. An operational duration of 20 years is assumed, i.e., a time period from 2020 to 2040, with the aim to gain more insight into the development of the lifetime exergy consumption of ICTs associated with the AMI and HAN smart grid applications. Based on that, the number of households in Vienna is expected to increase from 927,905 in 2020 to 1,027,846 in 2040 [15]. This corresponds to a yearly average household increase of 4,997.05 households. The average number of persons per household during this time period is assumed to be equal to 2. The total traveled distance of extracted and processed raw materials to their manufacturing and assembly location in Shenzhen, Guangdong in China is assumed to be equal to 5,000 km. From there, the final products are transported over Shanghai, China and Hamburg, Germany to the location where they will be deployed, namely to Vienna, Austria. The total traveled distance of these products was estimated to be equal to 22,403 km. For the end-of-life transportation, a recycling plant in Berlin, Germany is assumed. The total traveled distance of damaged or used up ICT equipment to this location was estimated to be equal to 675 km. The provided distances between the different ICT equipment life cycle stages (i.e., raw material extraction and processing, manufacturing and assembly, operation, recycling and disposal) were estimated by means of the Google Maps route planner. Moreover, various transportation modes (i.e., truck, rail, and ship) between these different locations are considered. Table I provides additionally some further ICT equipment assumptions required for the E-LCA case study, e.g., lifetime assumptions, EEC, and OEC of various devices. The OEC values listed in Table I were calculated based on the respective lifetime of the considered device. Material/component composition of smart meters, PLC modems, data concentrators, and HEMSs, required for the E-LCA, was in part based on analytical analyses, as well as information obtained from [16], [17], [18], and [5], respectively. Exergy consumption data of RAN and CN equipment (including copper and optical fiber cables), as well as that of routers and switches (i.e., rack/edge, aggregation, and core switches), was obtained from [7-9]. The lifetime of BTS and BSC racks is assumed to be equal to 7 and 8 years, respectively; that of Node B and RNC racks to 8 and 9 years, in that order. The lifetime of both the SGSN and GGSN racks is assumed to be equal to 10 years. The lifetime of routers, switches, and DSL modems is assumed to be 3 years. Data on technology and ICT equipment penetration was based on the information obtained from Statistics Austria and on the forecasts provided in [9].

It should be mentioned that the EEC of ICT equipment is, moreover, weighted by a usage factor (UF), accounting for the time it is used for the AMI and HAN applications. Smartphones, tablets, and notebooks will be used for other purposes most of the time (e.g., telephony, various internet services, mobile and video games). They will be used for home energy management applications for only about one hour daily (i.e., uptime of 4.17%). For that reason, their EEC is much smaller than that of smart meters, PLC modems, and data concentrators (see Table I). The same holds for the RAN and CN equipment, i.e., this equipment will be used for only a few minutes daily for the AMI application. The uptime of HEMSs and DSL modems, on the other hand, is assumed to be equal to 95% (i.e., 22.8 hours), however, with an average load of 50%. Based on these assumptions, the cumulative EEC and OEC of ICT equipment is investigated over the defined time period of 20 years for the AMI application alone (AMI scenario), and then in combination with the HAN application (AMI/HAN scenario). Moreover, the most exergy consuming ICT equipment in the case of these two scenarios is indicated. Based on that, the most dominant exergy consumption related (i.e., environmentally pronounced) smart grid domains are provided.

TABLE I. MAIN ASSUMPTIONS FOR THE E-LCA CASE STUDY

Device	***Lifetime [years]***	***EEC [MJ]***	***OEC [MJ]***
Smart meter	15	1,511.31	709.56
PLC modem	10	1,528.21	378.43
Data concentrator	7	2,849.66	529.80
HEMS	4	6,664.83	15,878.37
Smartphone	2	59.9	0.54
Tablet	2	62.13	1.17
Notebook	3	85.53	9.89

IV. RESULTS AND DISCUSSION

This section presents the results obtained from the E-LCA applied to ICTs involved in AMI and HAN applications. In the AMI scenario, only ICT equipment required for a correct operation of the AMI application is included in the assessment of the exergy consumption (i.e., environmental sustainability). The AMI/HAN scenario considers additionally UDs, i.e., smartphones, tablets, notebooks, DSL modems, and HEMSs, required for various home energy management applications. These devices are essential for a proper utilization of the HAN application.

Figure 3 depicts the distribution and the development of the cumulative EEC and OEC of ICTs for the AMI scenario over the defined period of 20 years. It is evident that the cumulative EEC dominates over the entire operational duration. The cumulative EEC and OEC values at the end of the operational duration of 20 years were estimated to be equal to 6.14 petajoules (PJ) and 2.127 PJ, respectively. This corresponds to 74.27% and 25.73% of the overall cumulative exergy consumption. Smart meters, PLC modems, and data concentrators, termed advanced metering, processing, and forwarding (AMPF) equipment in the scope of this paper, represent the ICT equipment category with the strongest contribution to the depicted cumulative EEC development. The large increase of the cumulative EEC between 2030

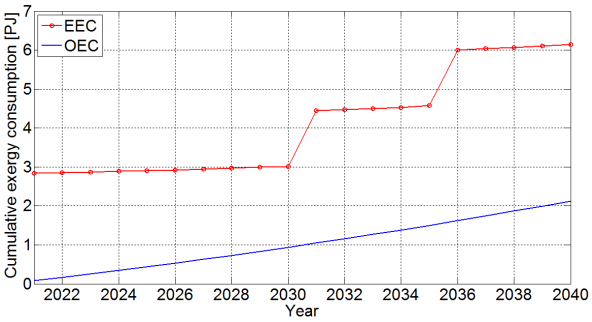

Figure 3. AMI scenario: distribution and development of the cumulative embodied exergy consumption (EEC) and the cumulative operational exergy consumption (OEC) of the overall smart grid model considering the AMI smart grid application

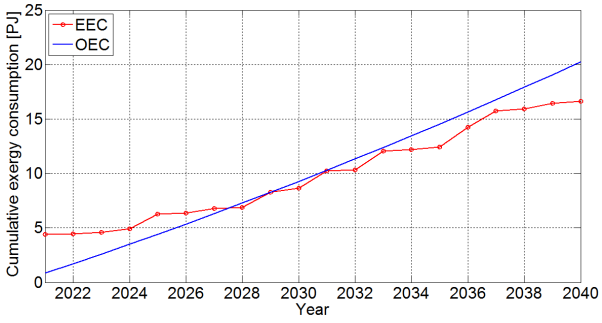

Figure 4. AMI/HAN scenario: distribution and development of the cumulative embodied exergy consumption (EEC) and the cumulative operational exergy consumption (OEC) of the overall smart grid model considering the AMI and HAN smart grid applications

TABLE II. AMI SCENARIO: CUMULATIVE EEC AND OEC DISTRIBUTION AMONG ICT EQUIPMENT CATEGORIES

ICT equipment category	***Cumulative EEC [%]***	***Cumulative OEC [%]***
AMPF	99.10	78.54
RAN	0.04	0.87
CN	0.01	0.41
DCC	0.86	20.19

and 2031, as well as between 2035 and 2036 arises due to the replacement of a huge number of PLC modems and smart meters, respectively, i.e., those that have been installed at customer locations in the year 2020. Table II provides additionally the breakdown of the cumulative EEC and OEC among the different ICT equipment categories of the overall smart grid model for the AMI scenario, obtained at the end of the operational duration of 20 years. As can be seen, the AMPF equipment contributes the most to the overall cumulative exergy consumption (i.e., EEC and OEC). Even though the number of ICT equipment deployed in the DCC is very much less than that of the AMPF equipment, their contribution to the cumulative OEC of about 20% is comparatively high. This is because the power consumption of the AMPF equipment is much lower than that of the ICT equipment utilized at the DCC. The share of the DCC equipment to the cumulative EEC is less than 1%, and therefore almost negligible. The share of the other ICT equipment categories (i.e., RAN and CN) to the cumulative EEC and OEC is very low compared to the AMPF and DCC equipment. Such a low contribution of RAN and CN equipment to the overall cumulative exergy consumption comes from the fact that it is utilized for the AMI application for only few minutes daily. These results clearly indicate the large importance of the customer and distribution domains of the smart grid (i.e., domains encompassing a large number of smart meters, PLC modems, and data concentrators), as well as the DCC because of their relatively high OEC. The cumulative EEC of ICT equipment was determined to be the largest contributor to the overall cumulative exergy consumption, during the entire operational duration, in the case of the AMI application. The AMPF equipment was ascertained to be the most dominant ICT equipment. The cumulative OEC is comparatively low, considering the large amount of AMPF equipment deployed in the customer and distribution domains, whereas the cumulative OEC of the DCC equipment contributes considerably to the overall cumulative OEC.

Figure 4 visualizes the distribution and the development of the cumulative EEC and OEC of ICTs for the AMI/HAN scenario. All assumptions made for the AMI scenario were left equal. However, the AMI/HAN scenario includes in the assessment of the cumulative exergy consumption besides the ICT equipment of the AMI scenario also UDs, namely smartphones, tablets, notebooks, DSL modems, and HEMSs. The quite different cumulative EEC and OEC distribution and development for the AMI/HAN scenario compared to the AMI scenario is clearly evident from Figure 4. It can be seen that the cumulative OEC becomes the most dominant exergy consumption category after approximately 7.5 years (i.e., between the year 2027 and 2028). The cumulative EEC and OEC for the AMI/HAN scenario were estimated to be equal to 16.628 PJ and 20.249 PJ at the end of the operational duration of 20 years, respectively. This corresponds to 45.09% and 54.91% of the overall cumulative exergy consumption. In Table III, the distribution of the cumulative EEC and OEC consumption among the different ICT equipment categories of the overall smart grid model for the AMI/HAN scenario, obtained at the end of the operational duration of 20 years, is provided. It is evident that the cumulative OEC becomes the major contributor to the overall exergy consumption, with the UDs being the most exergy consumption related ICT equipment category. The most dominant (i.e., exergy consumption related) component of the UDs was determined to be the HEMS. This is because the uptime of most other UDs (i.e., smartphones, tablets,

TABLE III. AMI/HAN SCENARIO: CUMULATIVE EEC AND OEC DISTRIBUTION AMONG ICT EQUIPMENT CATEGORIES

ICT equipment category	***Cumulative EEC [%]***	***Cumulative OEC [%]***
UDs	63.07	89.49
AMPF	36.59	8.25
RAN	0.01	0.09
CN	0.00	0.04
DCC	0.32	2.12

and notebooks) was assumed to be only about one hour daily. The uptime of the HEMS, however, was assumed to be equal to 95% (i.e., 22.8 hours). This fact makes the HEMS the most important (i.e., environmentally relevant) UD. Furthermore, it represents with 95.86% the strongest contributor to the cumulative OEC of all other UDs.

V. Summary and Conclusions

In this paper, we analyzed the environmental sustainability of ICT equipment involved in advanced metering (AMI) and home area network (HAN) smart grid applications. For that purpose, we applied an exergy-based life cycle assessment (E-LCA) framework. The assessment was based on a smart grid model developed for the city of Vienna. The cumulative embodied exergy consumption (EEC) and operational exergy consumption (OEC) of ICT equipment deployed in the various submodels of the overall smart grid model have been estimated and analyzed. The obtained exergy consumption of ICT equipment served as a measure for the attained environmental sustainability. We defined two scenarios, namely the AMI and the AMI/HAN scenario, and estimated the cumulative EEC and OEC for both of them. We proved that the customer and distribution domains are indeed the most exergy consumption related domains of the smart grid, and consequently, the most environmentally important domains considering the AMI and HAN smart grid applications.

The cumulative EEC was determined to be the most dominant exergy consumption related category over the entire operational duration of 20 years in the case of the AMI scenario. This result justifies and clarifies the importance of a holistic assessment approach, as it takes the entire ICT equipment life cycle exergy consumption into account and not just the exergy consumption during operation. The advanced metering, processing, and forwarding (AMPF) equipment, namely smart meters, PLC modems, and data concentrators was, moreover, ascertained to be the ICT equipment category with the strongest contribution to the overall cumulative exergy consumption (i.e., EEC and OEC). The cumulative OEC was determined to be the less exergy consumption related category over the defined operational duration in the case of the AMI scenario, and with that the category associated with lower environmental effects. The cumulative OEC of the DCC equipment was estimated to contribute by about 20% to the overall cumulative OEC, which is a comparatively high percentage considering the moderate number of ICT equipment deployed in the DCC. It can be concluded that in the case of the AMI scenario, the cumulative EEC of AMPF equipment strongly relates to environmental sustainability issues, i.e., it has the strongest potential to negatively impact the environment.

In the case of the AMI/HAN scenario, the cumulative OEC was determined to be the leading exergy consumption related category after about 7.5 years of operation. The strongest contribution to the overall exergy consumption is attributed to home energy management systems (HEMSs). Such a result arises due to a large number of deployed HEMSs and their respective high uptime of 95%, leading to a cumulative OEC share of 95.86% compared with all other UDs. The fact that HEMSs contribute the most to the overall cumulative OEC is, however, relaxed by the fact that their main purpose is the energy efficient management of consumers' electricity consumption. The energy consumption savings related to the use of HEMSs are believed to be larger than their own power consumption, leading to an indirect improvement of the environmental sustainability.

Abstract - The paper discusses the possibilities and aspects of continuous, remote monitoring system of non-ionizing electromagnetic radiation using certain networks for measuring and storage of measurement results. First are stated the motives for the usage and installation of such networks and preliminary activities necessary for the proper design of systems, as well. Further, the system architecture and methodology of such measurements are described, where defined requirements are placed in front of the remote monitoring station. Control of measurements is achieved from a remote distance via GSM, GPRS or other telecommunication services. Such systems allow full control of remote monitoring stations, as well as continuous recording of all measurement results. Measurement results from all monitoring stations are collected in control centre, where a comprehensive analysis of all measurement data can be done and published on certain website afterwards.

I. INTRODUCTION

Mobile telephony is nowadays a commonplace worldwide spread communication technology, which still increasingly spreads by new base stations continuous installations. Over 1.4 million of GSM/UMTS base stations exist in the world nowadays [1] and a new generation of 4G systems of these devices is already introduced and installed in some countries. Installation and operation of several wireless network bands in the last decade such as GSM, GPRS, UMTS, TETRA and Wi-Fi systems, increased public concern about exposure to radiation emitted from these sources, [1, 2]. Together with the traditional, well-established broadband systems (FM and UHF-VHF television, radar systems, etc.) this requires continuous care to inform the general public about levels of their exposure to non-ionizing radiation. More or less all human population is exposed to electromagnetic radiation. One of several reasons for the general public's fear is media announced and unconfirmed "scientific" studies, which cause feelings of uncertainty and perception of unknown and undiscovered possibility damage. Other factors are subtle care and a sense of control or expertise lack in the process of determining the location of new base stations or transmitters of any kind [1]. The so-called "ad hoc" measurements are the first step to estimate the level of electromagnetic field radiation. However, such measurements are carried out in a specific, fixed-time interval (1-2 hours) at certain date and under the certain circumstances, [2]. More appropriate and more acceptable way of estimating electromagnetic radiation levels to the general public represents 24 hours continuous measurements of electric field strength. This allows recording of the current situation on the field and continuous comparison of measured values with the reference levels of radiation prescribed by the relevant organizations, such as ICNIRP (International Commission for Non-Ionizing Radiation Protection) or the local authority organizations. Therefore, the network for continuous monitoring and recording of electromagnetic radiation levels in non-ionizing radiation band may represent the best solution to this problem. Another important reason for the installation of such networks is a possible way of measurement results presentation on certain "website" domain, which could be available to general public [2]. Monitoring networks are useful tool and help reducing the public's concern about potential hazard effects and impacts of non-ionizing radiation on human health. For this purpose, such networks across Europe and Africa (Italy, Greece, Spain, Portugal, UK, Malta and Egypt) are set and implemented, so far. These networks require overcoming of many challenges in terms of hardware certification, network control, daily maintenance, etc. [1, 2]. Therefore, there is a need for development of such networks in Balkan countries and that need is a result of widespread public fears about hazard effects and unknown consequences on human health caused by exposure to electromagnetic radiation. Such networks would have multiple targets and aims [1]:

- to inform the general public about current scientific researches;
- to inform the general public about radiation exposure levels and percentage of measured levels compared to them;
- to activate the procedure for additional measurements if they are higher than reference levels;
- to activate the procedure for reducing the reference levels, if needed;
- to reduce social tensions generated by the fear of radio communication networks installation.

Having all this on mind, we can freely conclude about necessity of development and implementation of such systems in Balkan countries in the nearer future.

II. PRELIMINARY ACTIVITIES

Before designing and installing such a complex network, it is necessary to carry out preliminary activities that will provide optimal selection of measurement points within the meaning of the most objective presentation of the current situation in the monitored area, from the electromagnetic radiation point of view. In order the quality selection of measuring points to be achievable, it is necessary to have all the information in the form of a database about: a) the schedule and location of all electromagnetic radiation sources at observed area with their full technical characteristics; b) terrain configuration with all associated buildings and structures, etc. Thanks to different modern radio-waves prediction propagation software, it is possible to predict the signal levels for each point in the observed area. More information is given in [3]. Many of these software are modular and open for adaptation to specific problems that can serve certain types of radio systems. The quality of all modern methods for radio-planning system largely depends on the quality of the information database available to the designer. Considering that, a great attention to the databases must be devoted. Therefore, it is necessary to provide or make several type of information for quality databases such as:

- A number of observed area scanned maps the (i.e. in the scale of 1:25,000, 1:50,000, 1:100,000, the territory of the major cities' wider surrounding in the scale of 1:150,000, 1:50,000 and 1:5000, etc.);
- A number of base station locations and technical characteristics of all radio transmitters;
- The types of used antenna systems;
- Digital base of terrain heights with 50×50m horizontal resolution;
- Digital database of vegetation on the earth's surface for the entire territory, if possible;
- Vector base of streets for major cities;
- Database of digitized satellite pictures.

Comprehensive analysis is carried out to eliminate a huge number of potential measurement points and in accordance to certain criteria (i.e. the intersection method) real shortlist for future measurement points is made. Then, these measurement points are verified by means of mobile measuring systems (spectrum analyzers). Afterwards, a remote-controlled measuring stations (RMS) in each verified measurement point is installed.

III. ARHITECTURE OF MONITORING SYSTEM AND METHODOLOGY OF WORK

The concept of the system should be based on the principle of ensuring the independence of performed measurements, so the general public can be sure that the results presented on a certain domain are not under the influence of various interest groups such as: Telecommunication operators, political parties, Government authorities, etc., [1, 4-7]. Therefore, the monitoring network should be funded with public money in total, without any sponsorship by the operator or other non-institutional subjects. Also, it would be decentralized so the local administration could have absolute control in their administrative areas. The network would be composed of several remote measurement stations (RMS), several local control units (CU) and one central unit, [1]. Each RMS must have communication with the local CU via public wireless communication networks such as GSM, GPRS or UMTS. This connection allows the installation of RMS in every area covered by the mobile operators' signals. CU control RMS units and save the measured data to be hosted on the "website", afterwards. Any interested party can access to stored results via Internet, [1, 2, 7]. Data from all local CU are collected in the central unit. Similar implementations are presented on Figure 1. [1] and Figure 2. [2].

A. Remote measuring stations

Measuring equipment or remote measurement stations (RMS), must be a completely autonomous units able to, [2, 7]:

- operate continuously, 24 hours a day;
- measure electromagnetic radiation in the frequency range that covers all or most of the sources that contribute to the overall radiation exposure;
- save the measurement results in internal memory and transmit them to control unit via wireless interface;
- be powered from the low voltage network of 220V or more often from the preferred solar panels;
- be completely remote-controlled, with no need for human presence;
- solve any kind of abnormal or unusual operations (such as self-diagnosis, overheating, loss of power, a supply failure, etc.) and report that to the control units (CU).

In order to meet all of these requirements in full, RMS should include broadband isotropic three-axis electric field sensor, the module with the necessary electronics, GSM/GPRS/UMTS modem which is used for communication with the relevant local control centre (the downlink is used for remote configuration, programming and polling, while the uplink is used for reporting the measurements and other information such as alarms) as well as temperature and humidity sensors, [2, 7]. All these should be calibrated prior to installation in the network and every 6-12 months thereafter. In order to obtain more relevant data, measurements should be performed within a wide and a narrow range of frequencies. Broadband RMS would record electric field strength and/or power density in the frequency range 100 kHz - 3GHz, in which the majority of the radiation sources would be included.

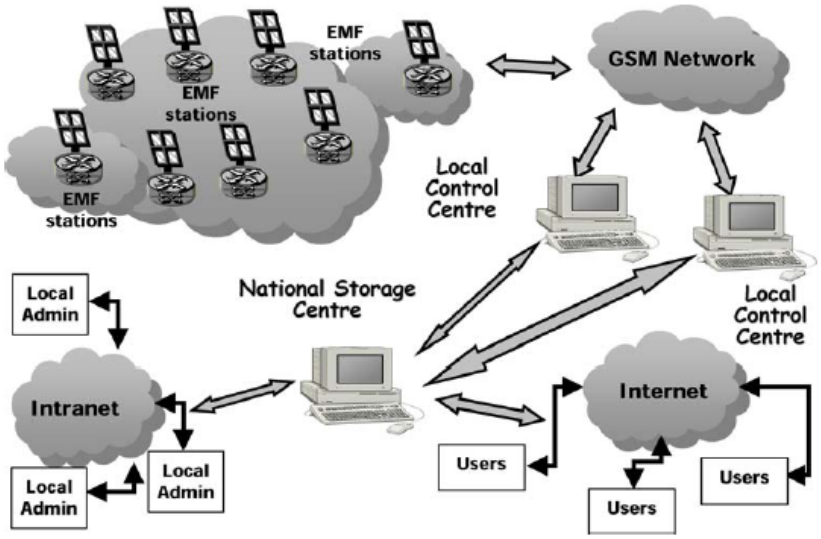

Figure 1. Architecture of monitoring system, National Storage Centre implemented

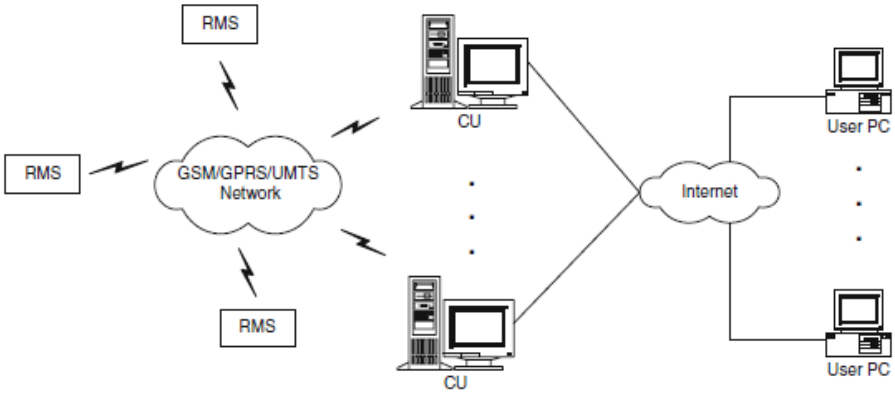

Figure 2. Architecture of monitoring system, local implementation

Figure 3. Examples of monitoring stations: EE4070-WB RMS station at Koskinou, Rhodes (left) and MCE-410 RMS station at Heraklion, Crete (right)

Other observed frequency ranges would be i.e. 880-960 MHz (GSM/UMTS 900 band), 1880-2100 MHz (DCS 1800 plus UMTS band), 2600 MHz (LTE - Long-term Evolution or 4G band) [8], etc. For frequencies above 100 kHz certain requirements must be met in order to avoid exceeding of electric field strength reference levels.

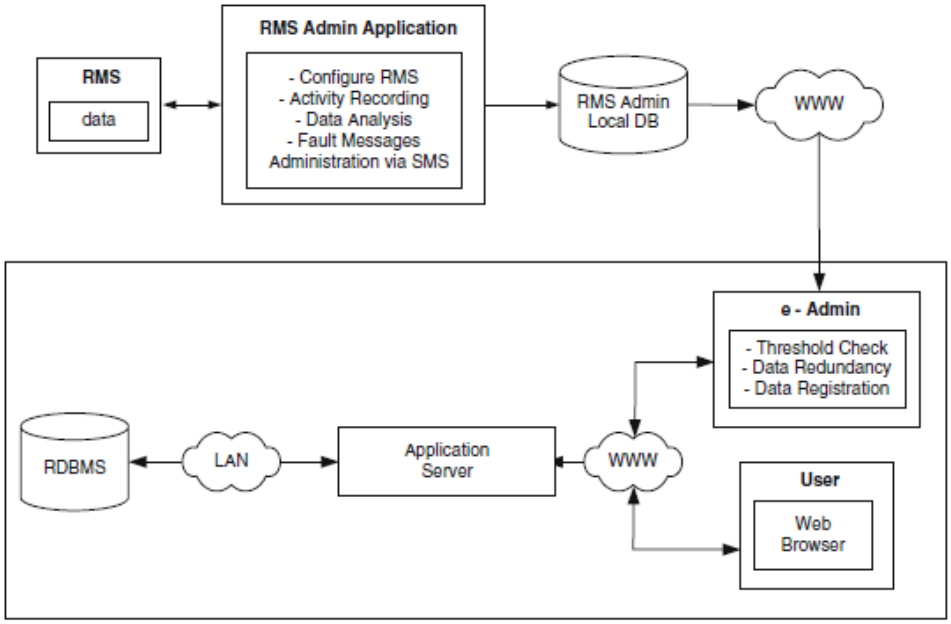

Figure 4. Software architecture

According to [9], the coefficient of total exposure to electric fields from multiple sources can be obtained by the following formula:

$$\sum_{i>1MHz}^{300GHz}\left(\frac{E_i}{E_{L,i}}\right)^2 \le 1 \qquad (1)$$

where E_i is measured intensity of electric field at frequency i, $E_{L,i}$ is the reference level of electric field given in Table I, according to ICNIRP standard. The relation (1) must be satisfied for all values measured by remote measuring stations.

TABLE I. ELECTRIC FIELD STRENGTH REFERENCE LEVELS FOR GENERAL POPULATION EXPOSURE, ICNIRP

Frequency f (MHz)	Electric Field (V/m)
0.15–1.0	87
1.0–10.0	$87/f^{1/2}$
10–400	28
400–2000	$1.375\,f^{1/2}$
2000–300000	61

Nowadays, there are wide range of measuring devices from different manufacturers, which could be used as a RMS [6, 7]. These devices are completely autonomous and can be remotely controlled via GSM/GPRS protocol, [2]. Examples of remote monitoring stations are presented on Figure 3. However, there are some restrictions on this type of equipment. The broadband measurement cannot determine the contribution of inndividual frequency bands or equivalent radiation sources. Additionally, measuring in only one point actually represents the situation of the measuring the whole band and that would require a very rigorous criteria for the selection of that point. Therefore, there are multiple criteria for the selection of the measurement sites (points). High population concentration is among the most important criteria. The special features of each location must be chosen to cover places of special interests, to include the presence of buildings of particular interest for the local community (e.g., schools, homes, hospitals and public places including zones like gardens, parks, shops, etc.) and to include the existence of antennas in the close vicinity of the measuring sites, as well [2, 3, 7]. One of proposals for measuring site selection criteria can include public opinions where the representatives of the population can decide where the measuring stations will be placed in their town or part of the city [1, 2]. To overcome these limitations, it would be necessary, in every area, to perform additional "ad hoc" measurements periodically, with different mobile equipment, every 6 to 12 months. These measurements would not be replaced by continuous measurement but would only amend them. The effect of that action would be twofold, [2]. First, by using a spectrum analyzer or a highly selective radiation meter a separation between the radiation sources would be achieved. Above all, a verification of continuous measurement accuracy would be possible by simple results comparing of these two methodologies. The time interval between these measurements can vary and it is limited by the need of human presence in the observed area.

B. Control units

The control unit would be a computer server equipped with a wireless modem and software applications which can interact with different types of monitoring stations. This software is necessary for, [2]:

- control and configuration of the RMS;

- collection of data from RMS via wireless network;
- saving and storing data on a hard drive;
- data processing and presentation of it via certain website, Figure 2.

The software architecture that could allow all of the above is shown in Figure 4. Usually, manufacturers of RMS provide software application for control units and data collection. With this application, a system administrator would have the ability to change the measurement points and measuring station communication parameters. The software application of CU would collect the measured value from measuring stations and save them in the local database (such as MS SQL Server or MySQL), [2]. In this way, a complete history of measurements for a certain administrative area would be stored in the local control unit database. In addition, there would be a web server (such as MS IIS or Apache) that could host the website in order to print the measured values and export it to text format, [1, 2]. For collection, consolidation and data presentation from all control units a web-based application should be developed and that application would be hosted on the central server. This application should collect data from all local databases, process them, filter and display them to the final user in an appropriate form. Examples of such applications are RDBMS which is is a Relational Data Base Main Server (built on MS SQL server) and "e - Admin" which is a web-based network administrative tool (developed in Java), [2].

C. *Central unit*

It would also be a computer equipped with a wireless modem which would be located in the national storage centre. It would have a software application for:

- collecting the processed data at the regional level by CU via wireless network
- storing data on the hard disk
- processing of data collected at the national level and presentation of it via the corresponding website, Figure 1.

D. *A website presentation*

The website could contain both static and dynamic pages and aim at presenting the measurement results for all the monitored sites. It could also provide information concerning the non-ionizing electromagnetic radiation exposure limits. Through the website, the visitors could view graphs of the measured values for custom date/time interval selection. Furthermore, a comparison of the measured values with reference levels could be presented. A feedback form would be also available to the public for them to express questions or comments to the system administrators.

IV. CONCLUSION

A proposed and described system for remote monitoring and recording of non-ionizing radiation is based on the usage of modern technological solutions and available systems. Automation of this system is achieved using computer-based units and their networks and remote communication is achieved using available mobile services. Web-based application allows permanent access to all measured data from any place. Automated measurement and monitoring of the whole system or network can be carried out remotely using GSM, GPRS or other telecommunication connections. The system provides the full ability to program or set and define the parameters for each monitoring station and to monitor and save all the measurement results in 3D form in an automated, remote-controlled and continuous way. The control centre collects measurement results from all monitoring stations and performs a complete analysis of all measured data and stores them for a long period of time. Such a system for monitoring and recording of non-ionizing radiation parameters would have a very useful social role. Direct communication with a large number of populations would provide full information to the general public, in terms of exposure to non-ionizing radiation and build a long-term confidence in such monitoring systems. Periodic analysis of monitoring system measurement results by additional measurement with different spectrum measuring equipment, could establish the trust even more. The network could easily be expanded in order to gain the full coverage of the observed territory. That way, the entire population, government, mobile operators and other interested parties would have a direct, continuous information about the levels of non-ionizing radiation, which would be one of the contributors preventing a possible harmful radiation on human health side-effects. At the end, the installation of the monitoring network would have, as final objective, the creation of a "national map" describing the real situation and highlighting the possible "over-radiated" territories.

Energetic Self-regulation of eWALL System

Ž. Martinović, D. Budić, D. Šimunić
Faculty of Electrical Engineering and Computing / Department of Wireless Communications
Unska 3, 10000 Zagreb, Croatia
E-mail: zeljko.martinovic@fer.hr, dora.budic@fer.hr, dina.simunic@fer.hr

In the last few years, there has been intensive research in the field of human motion and environment energy harvesting. That kind of energy harvesting used for power supply self-regulation in eWALL system (e WALL for Active Long Living) would contribute to increased energy efficiency of the system. The paper will represent possible methods and ways of energy harvesting in eWALL system. Statistical evaluation of the harvested energy will be given. The paper will also consider other, possible undeveloped ways of energy harvesting in terms of the practical implementation of the system. These methods and statistical estimates may relate to eWALL system, but also to other systems such as e.g. smart homes. Energy accumulation can be achieved from user motion, differences in ambient temperature, vibrations, radio frequency radiation and other technologies that are available to eWALL users.

I. INTRODUCTION

eWALL (*e Wall for Active Long Living*) is a system of intelligent services that will be possible to set up in any corner of our home or health institution, which aims to facilitate and extend active life expectancy of people with special needs. eWALL system is shown in Fig.1. Independent living is becoming a major challenge in terms of the population of the third age, which directly affects:

1. Family and friends;
2. An easier life with diseases;
3. Care providers;
4. EU health system;
5. Insurance companies

eWALL prototype is a result of partnership work on EU FP7 project after first year of research and development. The prototype is a result of integration and optimization work package led by the Faculty of Electrical Engineering and Computing, University of Zagreb. In Fig. 2 is shown the eWALL prototype integration environment

The prototype consist of a central *Gigabyte Brix* unit with the Ubuntu operation system and ELO "42" touch screen. Sensor network, which aims to harvest and send information about user in defined *Couch* database, consists of:

1. Environmental sensors (gases, light, humidity, temperature)
2. Portable sensors, based on *Arduino Lilypad* development tools, with built-in accelerometer.
3. Pressure sensor designed for the control of the user in bed.
4. Sensors for visual monitoring of the user's face based on *Kinect* solutions.
5. Sensors for motion control

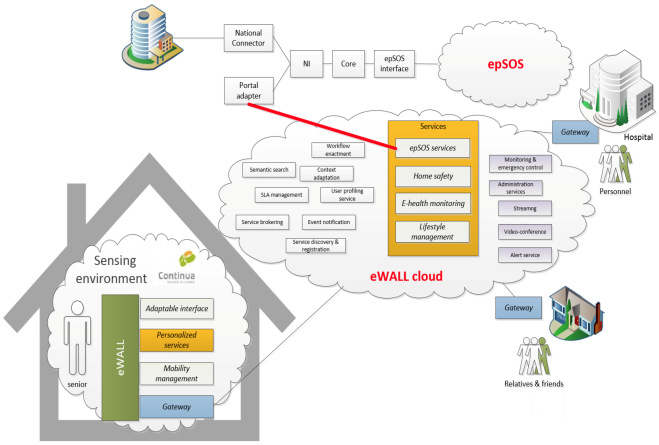

Figure 1. eWALL System

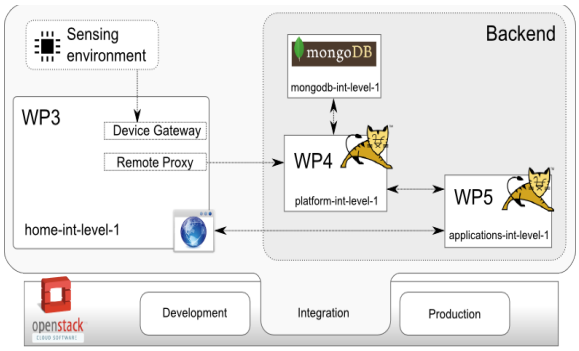

Figure 2. M12 Integration eWALL prototype environment

Besides the mentioned sensor network, prototype also consists of platform, application solutions for monitoring users and their activities. In the next period, the development of advanced versions of prototype will lead to an increase and diversity of sensors in order to give better user supervision and ensure timely response to negative scenarios. In accordance with development of prototype, one of the issues is system

power and energy self-regulation. Increase in energy efficiency of the system would greatly facilitate the use of the system, especially as seen from the user side. Regarding to this, we give an overview of possible user self-regulatory methods and statistical evaluation of possible energy harvesting methods.

II. OVERVIEW OF METHODS FOR ENERGY HARVESTING

Energy harvesting from user environment or user movement has, in recent years, become one of the most promising scientific research areas. The main goal of energy harvesting is to provide power to devices that consume small amounts of energy (mW). Energy harvesting models applicable to eWALL can be divided by energy source, represented by table 1. and Fig. 3.

TABLE 1. ENERGY SOURCES IN eWALL ENVIRONMENT

1. Kinetic energy from user motion;
2. Temperature difference between user and environment;
3. Environment vibrations (sound);
4. Radio frequency energy;
5. External source (sun, rain, snow, wind);

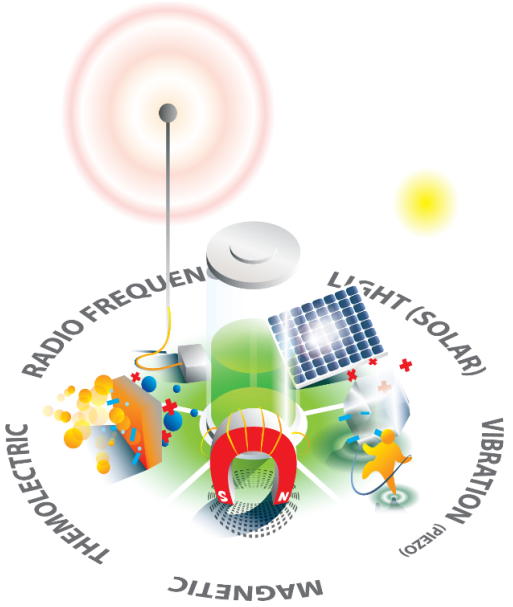

Figure 3. Energy sources in environment

There are two basic groups of sensitive materials that are used for the design and construction of micro mechanic sensor films (MEMS). These films are made of ZnO (*zinc - oxide*) and PZT (*lead zirconium titanate*) materials. The sensitivity to detect changes in the charge of ZnO films is much lower than in PZT. Because of that, ZnO is more commonly used then PZT materials for MEMS film. The sensitivity of such accelerometers was initially researched from year 2003 [6] when the defined sensitivity was from 0.1 to 7.6 pC/g.

Harvesting of kinetic energy from the movement of users is one of the initial motivations for scientists in this field. Statistic evaluation of energy harvesting from hand movement [4] provides 1.21 μW at one motion. The accelerometer is usually attached to the wrist. All movements of the arms, which have the force acting on the mass below 0.015 g are ignored. In further research, energy is harvested by placing accelerometers on the ankle, elbow and hip. The values obtained are in the range μW. Besides the systems with one degree of freedom, systems [5] that were taking into account the orientation of the force were also used. Results have not shown significantly increased amount of harvested energy.

The harvested energy, as we have previously mentioned, may be substituted for battery power in portable devices. One of these systems is the one [7], which provides charging a mobile device via walking. The problems are setting the device properly to harvest energy in running shoes or proper placement of sensitive polymer materials. For energy storage we used lithium batteries. During one hour, 4 steps per second generated 0.05 J energy, that is power about 13 μW. Therefore, to ensure the mobile phone power supply of 2 W, it is necessary to make millions of steps. The resulting power is controlled with DC-DC circuit whose efficiency is about 65 %.

Studies [11] have shown that it is possible to harvest 20 μW of power on the basis of difference in body temperature and the room temperature at 22 degrees. The required size of the film in this case is 9 cm^2. It was also found that film with 0.5 cm^2 can during run at 11.3 km/h harvest 3.7 μW. That provides 2.2 μW per cm^2 or 7.4 μW per cm^3 of film. The energy generated by thermal difference is harvested by the thermoelectric generator, which is set to a specific part of the body.

eWALL prototype consists of few hard disks that are used for processing and storage of data. It is known that in starting phase, hard disk consumes an average of 1.9 W, in idle phase 6.2 W and in operating phase 8 W of power. Energy can be harvested from the static stress and pressure during the operating phase of a disc. For the purpose of energy harvesting, energy harvester is designed [8]. Designed harvester consists of thin pressure and vibration sensitive film that is added to the flex cable of the hard disk. Research has shown that from the rotation of the hard disk, about 0.55 W of power can be harvested, 58% of it, or 0.32 W comes from hard disk vibrations. The remaining amount is harvested from the kinetic motion of the central engine torque.

To harvest energy, vibrations can combine with solar panels [3]. Solar panels have been set up along the road. Energy gain was based on the use of a double solar technology. The use of piezoelectric system has been introduced which uses car vibrations to power each solar collector. The vibrations were giving a sine wave with amplitude of 10 V. With voltage amplifier, voltage would go up to 20 V. That voltage would then

be converted by bridge to DC voltage from 17 V that can charge the battery.

One of the sources of energy is the radio frequency radiation. Initial studies were based on RFID technology. With designed RF - DC converter at distances of less than 10 m with the signals less than 50mV, the conversion efficiency reached 60%. Maximum theoretical standardized RF power harvested [17] on the frequency 900 MHz is 7 mW, and at 2.4 GHz is 1 mW for a distance of 40 m without obstacles. Research [18] shows that depending on input power of RF radiation (70 W/cm2 – 30 W/cm2) it is possible to harvest between 420 µW and 8 µW.

III. EWALL HUBS FOR ENERGY HARVESTING

Figure 4. eWALL energy hubs

Energy harvesting hubs represented with Fig. 4 and Table 2. would be set in eWALL environment to supply energy to low consumption sensors that have limited time use.

TABLE 2. EWALL ENERGY HARVESTING HUBS

1. Slippers (walking around the house)
2. Sneakers/Shoes (walking out of the house, running)
3. Termogenerator on the apron (kitchen)
4. Kitchen floor
5. Kitchen scale
6. Window hubs
7. Exercise bike
8. eWALL system hard disk
9. Pressure sensors in the bed
10. Modem
11. Washing machine
12. Dishwasher
13. Electric/wall plug

Those hubs can be expended by any element in the users' home that has power source, which can be utilized. That energy can power sensors with low power consumption such as: pressure sensors (bed), sensors to detect a gas leak, motion sensors, sensors for measuring temperature, sensors for measuring medical data (oxygen saturation, blood pressure, etc.). Energy harvesting is, according to many studies, particularly suitable for e-health sensors that have low energy consumption and are used in limited period of time. eWALL system is based precisely on the e-health sensors.

IV. ESTIMATION OF HARVESTED ENERGY

One of the most common and most easily applicable methods for energy harvesting is the installation of a piezo electric film in slippers or sneakers/shoes. According to the available measurements, 60 steps charge capacitor to the level of 21 V. According to equation (1) 92.5 µJ per one step is harvested.

$$E = \frac{1}{2} x V^2 x C \quad (1)$$

Users of the eWALL system will be stimulated with series of applications and reminders to physical activity. If we assume that the user will make between 5000 m and 10000 steps a day, we get the possible daily amount of harvested energy in the range between 7.7 mW and 0.016 W. On a monthly basis we are talking about the range between 0.23 W to 0.46 W.

If the user runs or workouts, the number of steps per second is on average 3 or 4. Assuming that the user runs in the countryside or on a bicycle for exercise 2 km a day, then we are talking about harvesting 0.65 µW daily, on a monthly basis, about 13 µW. One of the central devices in eWALL system will be *Xbox Kinect* device. It will be used, among other things, for exercise through interactive content. According to above-mentioned study, from one movement 1 µW can be harvested.

If user, every week, makes 100 movements in front of Kinetic device, on a monthly basis we are talking about the harvested 0.4 mW. eWALL should enable users to monitor their sleep quality. It can be done by monitoring users' motion in bed. That same motion can provide energy harvesting.

If we, according to Fig. 4., place 5 pressure sensors with DC-DC circuits in bed stand, we can use force to achieve power self-regulation in bed. For work purposes, bed sensor is needed, in the worst case, to ensure 1.25 mW of power. Assuming that the voltage generated by the force stored in the capacitor is 0.3 V per pressure, it is possible to provide a power of 0.75 mW and save 60% energy.

One of the more common sources for energy harvesting is vibration. Vibrations in the user's home can be caused by the washing machine, clothes dryer, hard drive, wind hitting the windows of the observed object, etc. Within the eWALL system, at least one hard disk will be used for data processing, and also one more for user data storage. Using energy harvesters, we can save up to 9 % of the energy in the operating/quiet mode.

Regarding to that, there is an extremely large number of devices for energy harvesting from vibrations, which are based on an electromagnetic, electrostatic, piezoelectric, and magnetostrictive mode. The electrostatic capacitive energy harvester [2] is a mechanical micro inverter with high sensitivity to vibration. The design of the inverter is reduced to designing four-layered capacity. Testing confirmed that the vibrations of 67 Hz, with large enough load resistance, could generate 175 W of power. For comparison, an asphalt leveling roller has the vibration of 67 Hz. Source of vibration was a vibrator. A device used in the assessment of vibration can simulate various types of intensity and vibrational forces. Power estimation is given by (2).

$$P = \frac{Q^2}{2\,x\,Cmin}\,x\,f \qquad (2)$$

Expression (2) shows us the way of calculating the resulting power. Q is the charge on the sensitive film, Cmin is minimum defined capacity of the unit, and f is vibration frequency. If we define the vibration as displacement of the object relative to the equilibrium axis, it is possible [12] to harvest 30 μW per millimeter displacement. Electrostatic energy harvested from the vibrations that is based on the setting up of static marble lines along the sensitive film, can harvest, from the displacement of 1.2 mm, around 0.18μW [13]. From the vibrations in limited periods of time, few hundred μW can be harvested.

One of the indirect ways of self-regulation is the optimization of sensor measurement methods, for example, energy regulation of CO2 [1] sensor by optimizing sampling. Battery consumption is proportional to sample size in any space. Reducing power consumption by reducing the size of samples, and at the same time preserving the quality of output sensor data is the way they can be self-regulated. In Table 3 summary of energy harvesting estimation is given.

TABLE 3. ESTIMATION OF HARVESTED ENERGY

Method	Energy harvested
Walking (per step)	92.5 μJ
Running (per km)	0,32 μW
Hand move (per movement)	1 μW
Body move (per pressure)	0,75mW
Vibration (per 1 mm displacement)	30 μW
RF (per bream)	2 - 4 μW

Possibility of energy harvesting by small samples exists also in radio frequency (RF) radiation. Previous studies have been conducted on different RF technologies (*WI-FI, Bluetooth, RFID*, etc.). Key characteristics in terms of RF energy harvesting are receiving antenna sensitivity, RF-DC converter and the generated output voltage. The utilization amount of reflected RF beams mainly depends on conversion factor of RF-DC converter. Research has shown [19] that it is possible to achieve an output voltage of 1.5V at the strength of the reflected beam from 1mW (-10dBm). The generated power would be the equivalent of 2-4 μW. The relatively low conversion factor of RF-DC converter, researchers are trying to annul by different methods. The last of them is designing RC-DC converter using metamaterials. For conversion, array of 7 antennas has been used and resulting efficiency was close to solar panel efficiency, which is 37%. If the mentioned converter becomes scientifically established (which would harvest 0.37mW on 1mW signal strength), it would be possible to power devices that consume significantly more energy.

V. CONCLUSION

The paper describes some of the existing methods of energy harvesting and possibility to apply them for the purpose of eWALL system power self-regulation. Statistics for possible energy harvesting has been shown. In developing energy harvesters, biggest shift is made with piezo electric harvesting methods. The research focus is on RF harvesting methods but also on external energy sources. Latest harvesting methods such as rainfall energy over the roof of the house built by a sensitive film shows us that awareness of recycling energy is growing unstoppably. Mentioned methods could harvest energy and directly power sensors or could be stored in batteries. This work will serve to further research and designing energy harvesters for the purposes of eWALL system and also as an overview of existing methods on a practical system such as eWALL.

Investigation of electromagnetic compatibility of high frequency polymer-welding machines

Lyuben Iliev, Ivaylo Stoyanov, Teodor Iliev, Elena Ivanova
University of Ruse, Department of Electrical and Electronic Engineering, Ruse, Bulgaria
lailiev@uni-ruse.bg

Abstract - The article presents the results of a measurement of the electromagnetic disturbances of a High Frequency (HF) plastic welding machine and their analysis. These types of machines are used in food processing, medical field, plastic or other dielectric material welding or heating. Because they operate with high power high frequency electromagnetic fields, they emit electromagnetic disturbances with high amplitudes up to several GHz. For these reasons, these machines are strictly regulated by standards for electromagnetic compatibility.

I. INTRODUCTION

High frequency (HF) welding is the joining of material by supplying HF energy in the form of an electromagnetic field (27.12 MHz) and pressure to the material surfaces to be joined. A high-power high frequency generator produces the energy which is guided through a transmission line to the electrodes of the machine. The machine basically acts as a capacitor with high dielectric losses in the dielectric material used (Fig. 1). The electrical energy causes the molecules within the material to start moving, which generates heat that causes the material to soften and thereby fuse together. No external heat is applied, it is instead generated within the material. After cooling the welded surface under maintained pressure, the material is fused and a weld has been created. The weld seam can be at least as strong as the surrounding material – or even stronger.

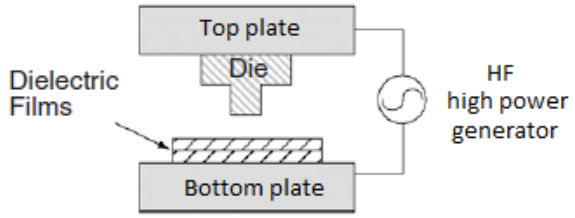

Figure 1 Diagram of the welding machine

Four important factors that affect the final weld result are pressure, welding effect, welding time and cooling time. These parameters can be adjusted and combined in different ways to achieve the optimal welding result for a specific material.

The material most commonly used with HF welding is PVC (polyvinyl chloride), sometimes called vinyl and PU (Polyurethane). The material can be thick or thin, reinforced or coated. It can also be plain, colored or patterned [1]. A photo of the tested welding machines can be seen on (Fig. 2).

Figure 2 Tested Welding machine series E

A. *EMC issues with HF welding machines*

The power of the HF welding machines can vary from less than 1 kW up to 20 kW or more. The frequency of the magnetic field is around 27.12 MHz. This means that high-power high frequency electromagnetic disturbances are produced during the working cycle of the machine. The harmonics of the generated frequency can reach up to several GHz with very high amplitudes. These disturbances might create many problems with electrical equipment operating near the machines, disturbances in the communication devices and can even have harmful effects on humans. For these reasons, such machines are subject to regulation according to a standard for electromagnetic compatibility - EN 55011:2010 [2]. The machines are intended to operate in industrial sites, that is why the standard has higher limits for the disturbances than in the domestic or urban areas.

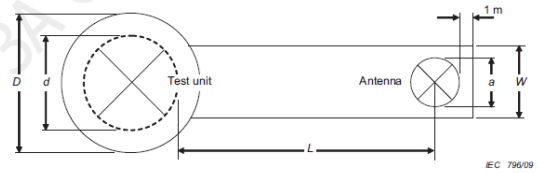
Electromagnetic compatibility ensures that the electrical devices can operate in a given surroundings without disturbing other devices or being disturbed.

The HF dielectric welding machines are usually heavy (several hundred kilograms or up to several tons). For this reasons they are not usually tested in laboratory conditions, but on the operation sites in normal conditions. The machine contains electronic components, it is a finished appliance intended for end user. According to the Guide for the EMC Directive 2004/108/EC it is classified as an apparatus [3]. It is intended for

incorporation into given fixed industrial installation. The directive provides set of requirements for these machines. According to the document the state of the art engineering practices should be applied for the machine manufacturing and also they should be documented and presented to the user and the authorities when required. Also if the machine creates disturbances which lead to improper operation or failure of other devices, then the manufacturer must take actions in order to fix the problems.

B. Standard EN 55011:2010

The title of the standard EN 55011:2010 is "Industrial, scientific and medical equipment - Radio-frequency disturbance characteristics - Limits and methods of measurement." In the Annex A of the standard it can be seen that the HF welding machine is classified as Group 2 "ISM RF equipment in which radio-frequency energy in the frequency range 9 kHz to 400 GHz." In the detailed description, plastic welding machines can be found.
The standard also defines the requirements about the test site an how the measurement must be held. Fig. 3 shows the distance requirements.



$D = (d + 2)$ m, where d is the maximum test unit dimension
$W = (a + 1)$ m, where a is the maximum test unit dimension
$L = 10$ m

Figure 3. Minimum size of the test area

The distance between the antenna and the test unit is defined to be 10m. There must be no other objects between the antenna and the measured machine. Also all other objects that might reflect the electromagnetic field must be removed from the room where the measurement takes place.
Table I shows the limits for the measurement results which are defined for 30 m distance from the test device and 10 m.

TABLE I LIMIT LINES FOR RADIATION MEASUREMENTS

Frequency range MHz	Limits for a measuring distance of D in m			
	On a test site D = 30 m from the equipment		On a test site D = 10 m from the equipment	
	Electric field	Magnetic field	Electric field	Magnetic field
	Quasi-peak dB(µV/m)	Quasi-peak dB(µA/m)	Quasi-peak dB(µV/m)	Quasi-peak dB(µA/m)
0,15 – 0,49	-	33,5	-	57,5
0,49 – 1,705	-	23,5	-	47,5
1,705 – 2,194	-	28,5	-	52,5
2,194 – 3,95	-	23,5	-	43,5
3,95 – 20	-	8,5	-	18,5
20 – 30	-	-1,5	-	8,5
30 – 47	58	-	68	-
47 – 53,91	40	-	50	-
53,91 – 54,56	40	-	50	-
54,56 – 68	40	-	50	-
68 – 80,872	53	-	63	-
80,872 – 81,848	68	-	78	-
81,848 – 87	53	-	63	-
87 – 134,786	50	-	60	-
134,786 – 136,414	60	-	70	-
136,414 – 156	50	-	60	-
156 – 174	64	-	74	-
174 – 188,7	40	-	50	-
188,7 – 190,979	50	-	60	-
190,979 – 230	40	-	50	-
230 – 400	50	-	60	-
400 – 470	53	-	63	-
470 – 1 000	50	-	60	-

At the transition frequency, the more stringent limit shall apply.
NOTE On a test site, class A equipment can be measured at a distance of 10 m or 30 m.

A quasi-peak detector should be used for the measurement in order to identify not only the peaks, but also the duration of the disturbances.

II. MEASUREMENT

A. Antenna

The antenna which is used for the measurement is log-periodic type with the following specifications:

- Freq.Range: 30-1000MHz
- Gain: -10~6.5dBi Typ..
- VSWR: 2.5:1 typ. (10.0:1 typ. @ 30MHz)
- Power Handling: 300W
- Connector: N-Female
- Material: Al
- Size: 1720mm(L) x 1450mm(H)

The antenna is shown on Fig. 4

Figure 4 Log-periodic antenna 30-1000 MHz

B. Spectrum analyzer

The spectrum analyzer used is a Hameg HM5014-2 with the following specifications (Fig 5):

- Frequency Range : 0.15 MHz…1.050GHz
- Frequency Resolution: 1kHz (6½ digit in readout)
- Resolution Bandwidths (RBW) @ 6dB: 1 MHz, 120 kHz and 9 kHz
- Video Bandwidth (VBW): 4kHz
- Sweep Time (automatic selection): 40 ms, 320 ms,1 s*)
- Measurement Range: -100dBm…+10dBm []

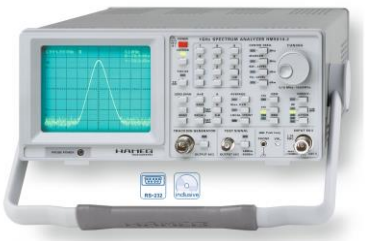


Figure 5 Hameg HM5014-2 spectrum analyzer

C. Software

The software used to record the measurement results is AS100E and is provided by Hameg. All the measurement components with their specifications can be set up in the software and all the values are calculated automatically and then the measurement is displayed graphically.

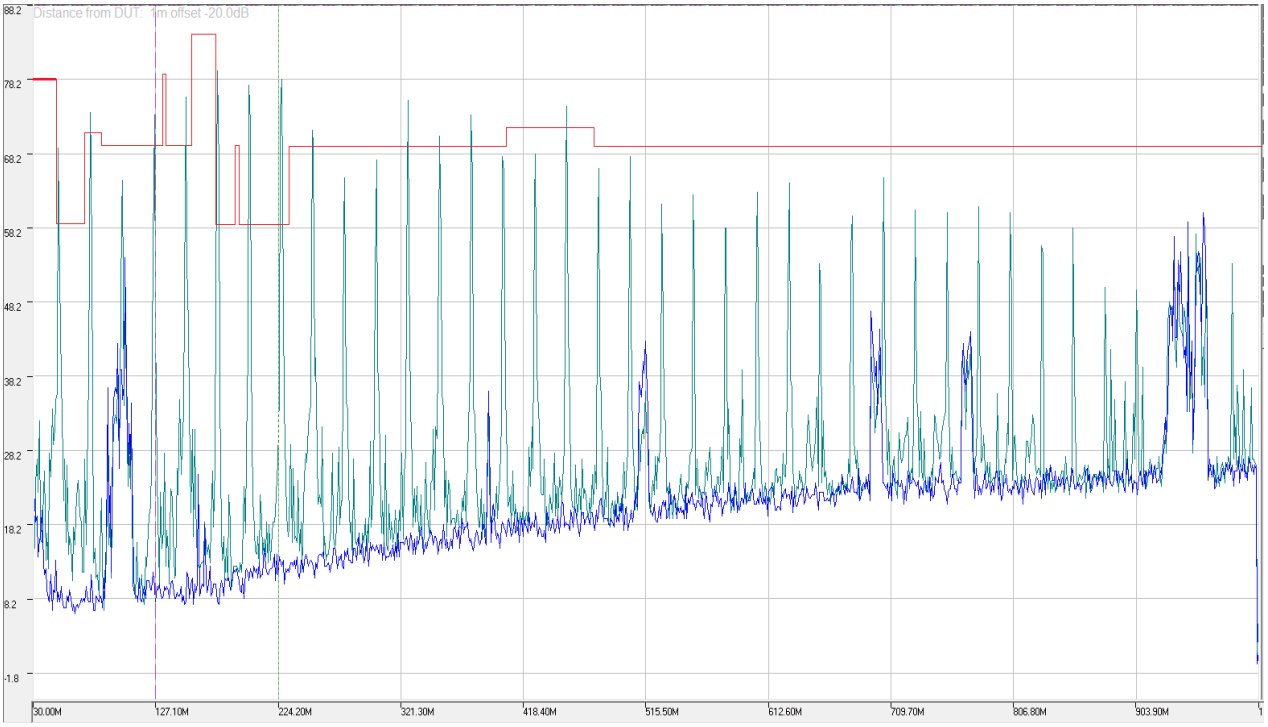

Figure 7 Measurement results for welding machine E200

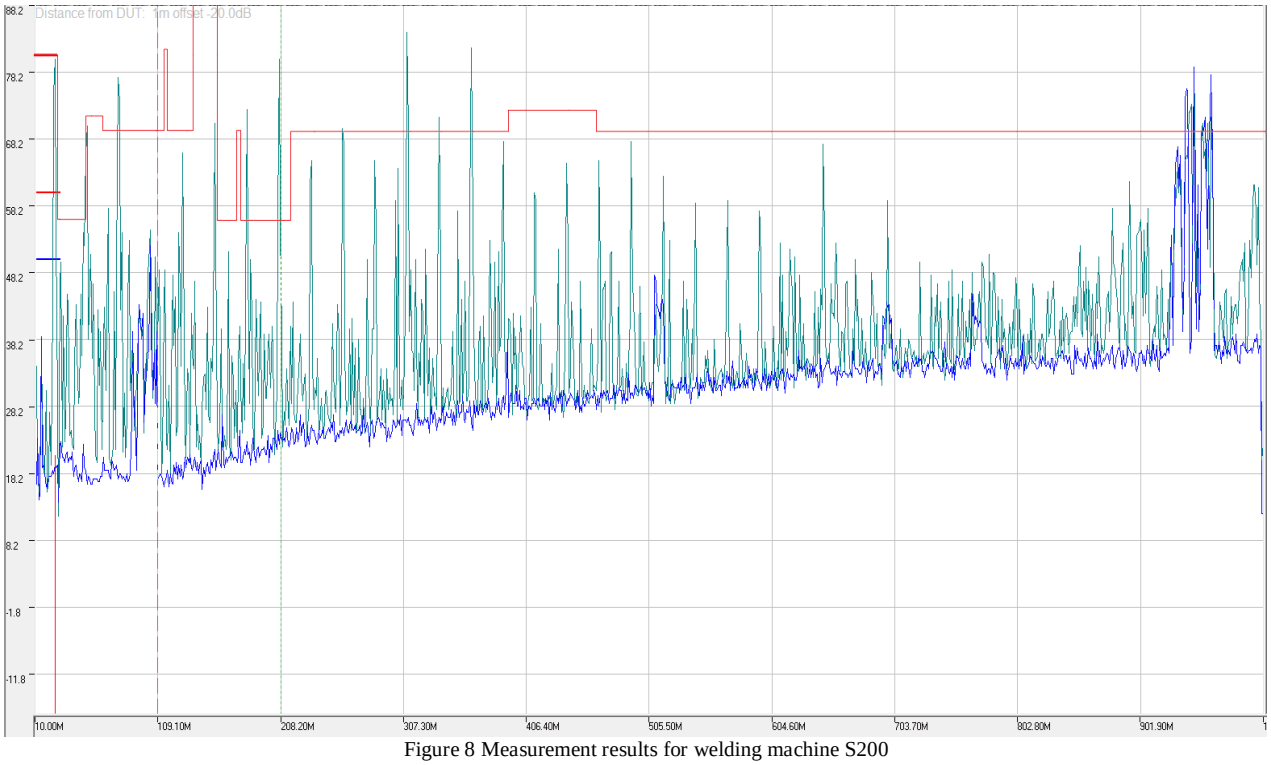

Figure 8 Measurement results for welding machine S200

D. Measurement set up

The measurement set up can be seen on fig. 6

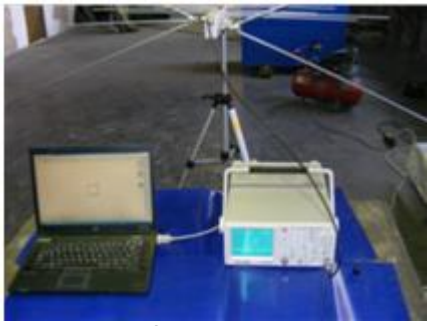

Figure 6 Measurement set up

Because of the smaller space of the testing site, the measurement was made at 3 m distance between the antenna and the machine. 10 dB are subtracted from the results in order to be comparable to 10 m distance, as in the standard. The measurements from 10 m are more correct than the ones held from 3 m, because of the near filed interactions in lower frequencies. The measurement data was recorded on a laptop PC with the special software installed. A 20 dB internal attenuator was used in order to protect the spectrum analyzer from the high energy electromagnetic pulses.

One welding cycle of the machine has a duration of about 15 seconds and then the machine stops. A 15 seconds sweep measurement from 10 MHz to 1 GHz was set up in the software in order to measure the whole welding cycle.

E. Measurement results

Two different machines were tested. Both must operate at 27,12 MHz. The first one, model E200, has a output power of 6kW and the other, model S200, has 9 kW output power.

Two measurements are made for every machine. First with machine turned off, in order to record the ambient electromagnetic field and the second the measurement of the machine in operational cycle. The actual value is obtained as a difference between the ambient and the operational electromagnetic field.

Fig. 7 Shows the measurement results for E200 machine.

The results show that the first harmonic is at 25 MHz and its value is 69 dBµV/m. The other harmonics can clearly be seen and they are repeated every 25 MHz.

From the measurements can be concluded that the disturbances from the machine E200 are at the edge of the compliance limit lines according to the standard EN 55011:2010. The machine disturbs nearby FM receivers, but no other harmful effects on other devices is detected.

Fig. 8 shows the measurement results for welding machine S200.

The results show that the first harmonic is at 26 MHz and its value is 60 dBµV/m. The harmonics repeating every 26 MHz can also be clearly seen on the graphic. The machine S200 is also very close to the limit lines but still under them. It also disturbs FM receivers nearby.

III. CONLUSION

The results of the measurements show that the disturbances from both plastic welding machines are very close to the limit lines specified by the standard for industrial equipment EN 55011:2010. A proper redesign of the machines will provide better results . Some of the suggestions are better geometric construction of the transmission line, shielding of the components and cables, better filtering of the supply voltage and communication wires.

***Abstract*— Significant part of the total energy consumption in distribution and core optical networks is contributed by the energy consumption of Internet Protocol (IP) routers. In this paper, an energy efficiency analysis has been performed for the case of real metro-optical network of a medium size city. Two real metro-optical network configurations, mores specifically dark fiber and the dense wavelength division multiplexing (DWDM) have been analyzed in terms of the energy efficiency. Obtained results provide insight into daily variations of routers' energy efficiency expressed in watts (W) per Mb/s of transferred traffic. In addition, cons and pros for selection of analyzed network configurations in real metro-optical implementations have been presented from the point of energy efficiency.**

Keywords*— optical, router, metro, network, energy-efficiency, dark fiber, WDM, green

I. INTRODUCTION

In this paper, energy-efficiency analyses for the real metro-optical network that is a part of e-Split project network infrastructure will be presented. The e-Split is a joint project of Croatian Academic and Research Network (CARNet) and the City of Split, Croatia. In the frame of this project, optical infrastructure based on a dark fiber has been developed. The dark fiber is a privately operated optical fiber infrastructure that is run directly by its owner, rather than by purchasing bandwidth or leasing line capacity. It is called "dark" because it is not in use until owner activates network resources [1].

Metro optical infrastructure connects CARNet member institutions in Split to the CARNet core network. Current implementation of given network infrastructure is based on dark fiber without implementation of WDM technology. WDM is a technology which multiplexes several optical carrier signals into a single fiber by using different wavelengths of light. This enables bidirectional communications over one fiber, as well as multiplication of capacity. Two most used WDM technologies are CWDM (Coarse Wavelength-Division Multiplexing) and DWDM (Dense Wavelength-Division Multiplexing). Basic CWDM characteristics are: used at distances below 50 km, without need to use optical amplifiers, up to 18 wavelengths in single fiber, 45 Gbps per single fiber, 2.5 Gbps per wavelength, less expensive than the DWDM systems.

Essential DWDM characteristics are: up to 240 wavelengths in single fiber, 32 C-band wavelengths are used in practice, 2.4 Tbps per single fiber, 10 Gbps per wavelength, at greater distance optical amplifiers are needed, more expensive then the CWDM. DWDM system (Figure 1) sends signals from several sources over a single fiber, based on signals multiplexing at the sending end and demultiplexing at the receiving end. Multiplexing is done by a multiplexer through taking optical wavelengths from multiple fibers and combining them into one light beam. At the receiving end demultiplexer has to separate out the components of the light so that they can be detected by separating the received beam into its wavelength components and coupling them to individual fibers.

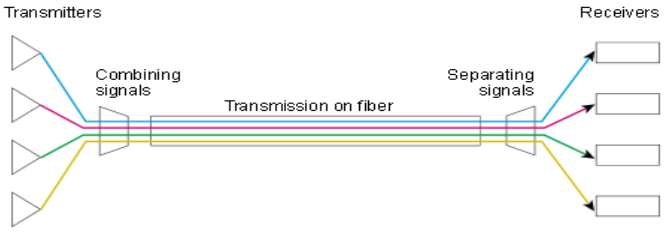

Figure 1: DWDM functional schema

In a unidirectional system, there is a multiplexer at the sending end and a demultiplexer at the receiving end. Two systems would be required at each end for bidirectional communication, and two separate fibers are needed. In case of bidirectional DWDM, multiplexer/demultiplexer must be at each end of the link because of the fact that single fiber is used for communication. Different wavelengths have to be used for full-duplex communication [2].

In the implemented real metro-optical network, ends of the optical fibers are closed with small form-factor pluggable (SFP) interfaces. The SFPs are popular industry format interface jointly developed and supported by many network component vendors. In the analyzed network, implemented SFP technology supports single wavelength transmission over single mode optical fiber.

Although expandable slots of the analyzed network equipment support WDM line cards, this technology is not used due to current user's needs which don't require WDM. However, constant increase of the network traffic transferred over implemented and analyzed metro-optical network, might demand upgrade to some of the WDM technologies in a near future. Besides operator increase in capital expenditures (CAPEX) due to implementation of additional optical elements such as multiplexers and demultiplexers, amplifiers and transceivers, upgrade to the WDM technology will also raise the operational expenditures (OPEX). This is because additional optical elements with router WDM line cards increase overall network energy consumption. This in turn increases overall operator OPEX. For that reason, differences in the energy efficiency among those two metro-optical network implementations based on single wavelength SFP and WDM technology are analyzed in the paper.

Research activates on this subject are supported by the EU project: Establish Pan-European Information Space to Enhance Security of Citizens - FP7 Grant Agreement No: 607078.

The rest of the paper is organized as follows: related work focused on improving energy efficiency of metro-optical networks is presented in Section 2. Physical and logical topology including architecture and active equipment of the analyzed network are introduced in Section 3. Section 4 shows results of real traffic patterns detected during seven days period. Power efficiency of network architecture based on dark fiber and DWDM technology has been discussed in Sections 5 and 6, respectively. Comparison of power efficiency among the dark fiber and DWDM technologies implemented in analyzed network are given in Section 7. Finally, some concluding remarks are given in Section 8.

II. RELATED WORK

Considering continuous increase for bandwidth in the core networks and overall Internet, satisfying power demands will be a fundamental challenge in the next generation networks (NGN). Authors in [3] present methods of potential savings achievable through power-aware network design and routing. Energy consumption model of large-scale optical network is discussed in [4]. It is shown that telecoms can improve energy efficiency of the network by changing hardware characteristics of active network equipment.

In addition, it is known that routers chassis and line cards consume significantly higher amount of energy in core networks. Different fill levels of the chassis results with different energy consumption. Higher fill level will result with more energy-efficient network. Even an empty chassis with no line cards consumes a large amount of energy. Therefore, a chassis with higher fill level has lower energy consumption per transferred bit [5].

Backbone networks transport large aggregated amount of traffic. Three different network architectures based on the WDM technology are compared in terms of power consumption in [6]. Methods for minimizing energy consumption in the WDM based transport architectures are presented in [7]. Particular realizations of static optical core networks are compared with the dynamic packet switched architecture based on the WDM in [8]. Survey of the most relevant research efforts considering backbone networks power consumption reduction is given in [9].

Considering all these facts, in this paper we perform energy consumption analyses of two network architectures, which, according to our knowledge haven't been previously analyzed. First network is static and fully operational real optical network maintained by the CARNet, and second is assumed dynamic optical network based on the xWDM technology. This network architecture might be used as future metro-optical network of e-Split project, and such network is widely implemented in large-scale interconnections, like interconnections inside large cities.

III. NETWORK ARCHITECTURE

A. Backbone optical ring

At the physical layer of analyzed network (Figure 2), there is the dark fiber cable with 192 fibers forming backbone optical ring which connects five network nodes (A-E)

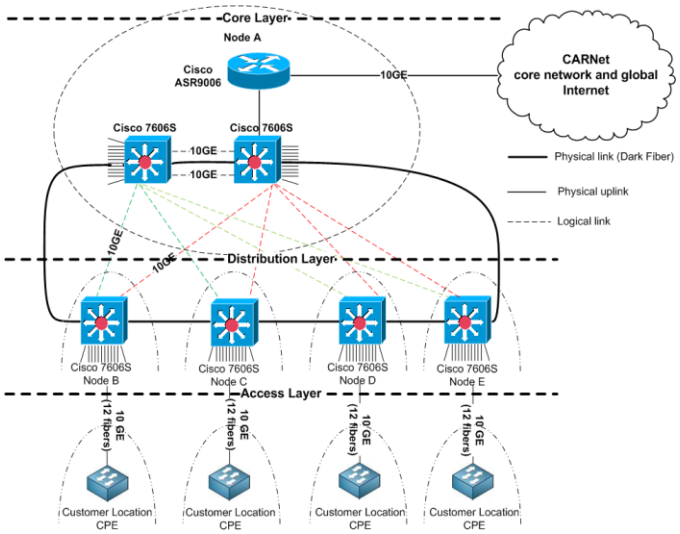

Figure 2: Analyzed network topology with dark fiber and SFPs

allocated inside one medium size city. Figure 2 illustrates logical and physical topology of the analyzed network based on the optical ring. The 24 fibers in the dark fiber cable are used for ensuring redundant logical connection to a main CARNet node (Node A). The dark fiber as point-to-point network architecture is chosen at the physical layer in order to satisfy requirements such as: simplicity, scalability and robustness.

Every customer location is connected in the same way (Figure 2): one optical cable with 12-fibers connects the end site of the costumer to the closest shaft. From that shaft, two fibers are used to connect end site to nearest node through the backbone ring. Two fibers are patched in the shaft as redundancy in case that fiber cut occurs. The remaining eight fibers are reserved for future use in the case when more connections will be needed. Each end site is connected to the geographically closest node (Figure 2).

Implemented architecture allows simple bandwidth increase through activation of new interfaces (line cards) at the end of the dark fiber optical links. This can be performed without coordination of carrier service provider, while full monitoring of all network devices by the owner of the network will remain. Passive network equipment at every end site includes: rack, optical patch panel, power socket extension, cable ducts, shelf for active network equipment.

B. Active network equipment

Main network node for connecting all other CARNet's nodes of the e-Split network to the CARNet backbone network is Node A (Figure 2). Main Node A is composed of two Cisco 7606 routers working in failover mode. All other nodes of the e-Split network have one Cisco 7606 router logical connection with the main Node A via redundant 10 Gbps links (Figure 2). Each node aggregates geographically closest end sites and each end site has access (L3) switch (such as Cisco 3560).

Cisco ASR9000 router is used in node A for interconnection with distribution layer as well as providing interconnection with main node in Zagreb (Figures 2 and 4). Node A is connected with a main node of the CARNet

network in Zagreb city with the 10 Gbps uplink. Node in Zagreb provides access to the global Internet for all CARNet's users. Technical characteristics of the core and distribution network equipment in terms of central processing unit (CPU) types and random access memory (RAM) are shown in Table 1.

Cisco ASR9000 router components are shown in Table 2. Main part of Cisco ASR9000 router is A9K-RSP-4G Route Switch Processor comprising the following components: bidirectional nonblocking fabric, 40-GB hard drive, switch fabric, High-performance dual-core CPU, 4GB RAM and 1GB flash memory. It supports high 1/10/100-Gbps port throughputs. The A9K-MOD80-TR is modular line card, that is optimized for fast packet transport and requires modular port adapters to customize each slot. The A9K-24X10GE-TR is 24-Port 10 Gigabit Ethernet Line Card designed for various Cisco ASR platforms. It provides up to 10 Gbps of throughput per single port. Finally, the A9K-4T-L is modular 10-Gigabit Small Form-Factor Pluggable (XFP)-based line card. Short reach (SR), intermediate reach (IR), long reach (LR), CWDM, DWDM, and 10/100/1000BASE-T interfaces are supported.
Distribution layer includes Cisco 7606-S router with components shown in Table 3. The WS-X6708-10GE is 8-port Ethernet 10GBase-X module with 1 GB of RAM designed for various Cisco platforms. The WS-X6748-SFP is model of gigabit Ethernet SFP interface module. Router has two of these modules and one Route Switch Processor 720. Firewall module is stateful inspection firewall with application and protocol inspection engines. It provides up to 5.5 Gbps of throughput, 100,000 new connections per second, one million concurrent connections or 256,000 NATs (network address translations) and up to 80,000 ACL (access control list) entries. Up to four firewall services modules (FWSM) can be installed in a single chassis, providing scalability of up to 20 Gbps per chassis.

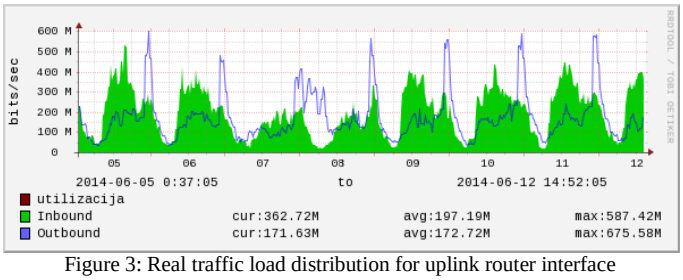

Figure 3: Real traffic load distribution for uplink router interface

IV. REAL TRAFFIC PATTERNS

For analyzed network, real inbound and outbound traffic patterns between end sites and the global Internet will be presented. One of the Cisco 7606-S routers aggregates all end sites (Figure 2) and provides connectivity to the CARNet backbone through Cisco ASR9000 router. Traffic data were obtained on uplink of this router which is link to the Cisco ASR9000 router (Figure 2). The other Cisco 7606-S router serves as backup (works in failover mode). Distribution of the real traffic load detected on the router for uplink interface is presented in Figure 3. Traffic loads presented in Figure 3 are the snapshot obtained from network traffic monitoring system. Data were taken in the interval from June 5 to June 12, 2014. Monitoring system is based on open-source Zenoss software that collects constantly (24/7) real-time data of network traffic.

It can be noticed that traffic pattern has typical day/night pattern, which is consequence of different user's activity during day and night. End locations reaches around 1.4 Gbps at maximum in 7 days period. Around 590 Mbps is maximal inbound and around 680 Mbps is maximal outbound traffic.

V. POWER EFFICIENCY OF CORE AND DISTRIBUTION LAYERS BASED ON DARK FIBER

In order to estimate power consumption of active network equipment in the distribution and core layer, online Cisco tool known as "Cisco Power Calculator" [10] were used. Application enables users to calculate the power supply requirements for a specific configuration of network element. Firstly, power consumption of distribution and core layer of the active network equipment presented in Figure 2, which uses dark fiber and SFPs (without WDM technology) are estimated. Then, power efficiency for network presented in Figure 4, with interface modules that supports DWDM technology is simulated. The data presented in Table 4 shows: output current/power and system's heat dissipation for the Cisco 7606-S router with elements supporting dark fiber (without DWDM line cards), having configuration presented in Table 2. The same parameters for CiscoASR9000 having configuration presented in Table 3, with elements supporting dark fiber (without DWDM links) are shown in Table 5.

In order to calculate power efficiency, traffic loads from distribution and core layers of the e-Split network infrastructure were selected. In addition, typical power consumption values characteristic for network operation at standard operating temperature (20° C) for each router configuration presented in Tables 4 and 5 were used. Traffic loads data were taken in typical periods of one working day (Wed, June 11 2014.) and one weekend day (Sun, June 8

2014.). Inbound and outbound traffic loads were taken at the uplink interfaces of distribution router CISCO7606-S in node A, which aggregates all customer end sites, and core router ASR9006 in Node A, which provides interconnection with main node in Zagreb. Power efficiency was calculated for each traffic direction (inbound and outbound). Traffic load and power efficiency for distribution layer devices (CISCO7606-S router) at working day and weekend are shown in Table 6.

Typical traffic load and power efficiency for core layer devices (ASR9006 router) at working day and weekend are presented in Table 7. Both tables show distinctions in the inbound and outbound traffic loads during different periods of the day and week, what influences on device power efficiency. From Tables 6 and 7 can be noticed that power efficiency for inbound traffic is always larger then efficiency for outbound traffic, due to higher traffic in inbound direction caused by larger user exploitation of services form Internet.

VI. POWER EFFICIENCY OF CORE AND DISTRIBUTION LAYERS BASED ON DWDM TECHNOLOGY

In addition to the power consumption analyses of network based on dark fiber technology with the SFPs, power consumption and heat dissipation analyses for network which enables data transfer over DWDM technology has been

performed. The proposed architecture for given network based on DWDM technology is shown in Figure 4. Results obtained from Cisco power calculator in terms of heat dissipation and power consumption are presented in Tables 8 and 9. Table 8 presents obtained results for the Cisco 7606-S router. Furthermore, power consumption and heat dissipation data for Cisco ASR9000 assuming hardware configuration which includes interfaces supporting the DWDM technology are presented in Table 9.

Also, for Cisco 7606-S and Cisco ASR9000 router, both having DWDM hardware components, power efficiency comparison with a real traffic load is given in Tables 10 and 11, respectively. Tables 10 and 11 show power efficiency for bidirectional traffic, which is represented as sum of inbound and outbound traffic. Due to performed analyses on the same network, it is possible to perform direct comparison among obtained results.

VII. RESULTS COMPARISON

In the analyses, traffic load data in characteristic periods of a day (Table 6, 7 and 10, 11) are selected. It may be seen in Figure 3 that the maximum traffic loads occur around 00:00, and the minimum traffic loads occur around 08:00 AM. Bidirectional traffic load in specific timestamps and estimated power consumption are used for calculation of the power efficiency values [W/Mbps] for each network configuration (dark fiber and DWDM).

It shown in [11] that significant daily variation of traffic load has impact on instantaneous power consumption of network devices. However, our initial assumption is that typical power consumption of network device is constant in the regular network operation. This is the case when device is not loaded with a large amount of traffic, and when the value of memory and CPU utilization does not vary significantly in time. This is exact situation in our test case, since analyzed network is over capacitated for the purpose of accepting future traffic loads increase during period of next 10 years.

It can be clearly seen from Tables 6, 7 and 10, 11 that power efficiency is inversely proportional to the traffic load.

TABLE 10: CISCO7606-S POWER EFFICIENCY COMPARISON

Time (Wednesday, June 11)	Power efficiency (bidirectional dark fiber SFP interface) [W/Mbps]	Power efficiency (bidirectional DWDM interface) [W/Mbps]
00:00	1975/665.69 (2.97)	2201/665.69 (3,31)
08:00	1975/304.94 (6.48)	2201/304.94 (7.22)

16:00	1975/477.37 (4.14)	2201/477.37 (4.61)
20:00	1975/545.51 (3.62)	2201/545.51 (4.03)

Table 11: CISCOASR9000 POWER EFFICIENCY COMPARISON

Time (Wednesday, June 11)	Power efficiency (bidirectional dark fiber SFP interface) [W/Mbps]	Power efficiency (bidirectional DWDM interface) [W/Mbps]
00:00	1550/682.5 (2.27)	1860/682.5 (2.73)
08:00	1550/375.72 (4.13)	1860/375.72 (4.95)
12:00	1550/607.63 (2.55)	1860/607.63 (3.06)
16:00	1550/508.62 (3.05)	1860/508.62 (3.66)
20:00	1550/558.61 (2.77)	1860/558.61 (3.33)

For the higher values of the traffic load, power efficiency in W/Mbps is lower. This means that for the same consumed power, larger amount of data can be transferred.

In addition, values of power efficiency in core and distribution network based on dark fiber and DWDM technology are compared. Firstly, Cisco 7606 router in the distribution layer is analyzed. Its uplink towards the core layer has maximum traffic load around midnight. Its estimated total output power consumption with SFP line cards is 1,975 W, and the estimated total output power consumption with line card that supports DWDM is 2,201 W. Figure 5 presents data power efficiency curve interpolated for whole day.

Furthermore, Cisco ASR9006 router in the core layer was analyzed. Traffic transferred over its uplink towards the main node in Zagreb has the same shape as traffic pattern of the router in the distribution layer (maximum traffic load around midnight). It's estimated total power consumption when dark fiber and DWDM is implemented equals to 1,550 W and 1,860 W, respectively. Considering this, data power efficiency in characteristic times of the day is calculated and interpolated for whole day. Obtained results are shown in Figure 6.

Finally, we give power efficiency comparison for each device on working day and weekend (Sunday), in case of optical network based on dark fiber technology. Power efficiency comparison for Cisco 7606 and ASR 9006 on working day and weekend is shown in Figure 7 and 8, respectively. Larger differences between power efficiency on working and weekend day is consequence of significant difference in amount of traffic during this days Also, in comparison with DWDM configuration, Figures 5 and 6 shows that SFP implementation contributes to the reduction of power consumption. This is due to lower power consumption of SFP hardware components. Hence, SFP implementation is more favorable for networks with low CPU utilization and lower amounts of traffic. Based on results presented in Figures 7 and 8, it can be noticed that independently of implemented technology (SFP or DWDM), power efficiency of devices is better for working day, meaning that higher amount of traffic can be transferred for the same amount of consumed power.

Additionally, calculation of power consumption for a given network infrastructure based on dark fiber with SFPs (without

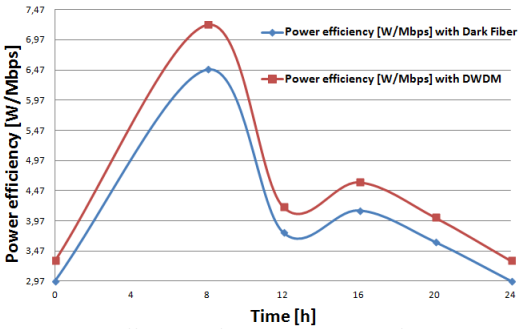

Figure 5: Power efficiency of Cisco 7606 in dark fiber and DWDM Optical networks

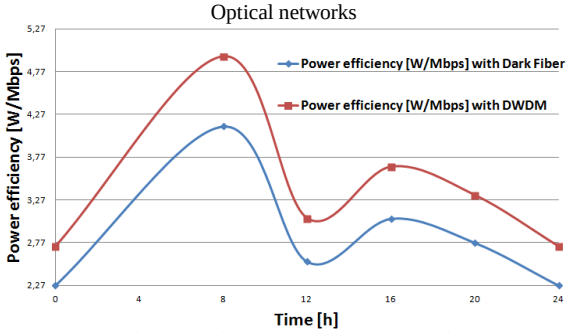

Figure 6: Power efficiency of Cisco ASR 9006 in dark fiber and DWDM optical networks

DWDM) is performed. As presented in Figure 2, network has five nodes with six Cisco 7606 routers and one ASR 9006. Each 7606 router consumes power of 1,975 W, while ASR 9006 typically consumes 1,550 W, what gives total instantaneous power consumption equal to the 13,400 W for routers in core and distribution layer of analyzed metro-optical network.

In case of the same metro-optical network with five nodes working with DWDM hardware, optical network architecture must contain ten additional 10 Gbps transponders (Figure 4) that typically consume 68.5 W each [12]. Total estimated power consumption in this case would be 14,085 W. This represents increase in power consumption of network core and distribution layer for more than 60 MWh yearly, what further gives favor on practical implementation of dark fiber.

VIII. CONCLUSION

In this paper, energy consumption analyses of the real metro-optical network based on prominent technologies such as the dark fiber and DWDM are presented. Analyses is performed for real traffic patterns, according to which, power efficiency of distribution and core level network equipment was estimated. It is shown that daily variation of traffic pattern influence on power efficiency (W/Mbps) of network devices, since higher amount of traffic can be transferred for the same amount of power consumption. Additionally, obtained results show that metro optical-networks of a small and medium size cities, based on dark fiber consumes less overall energy when compared with equal network based on the DWDM technology. Hence, dark fiber in terms of energy-efficiency is optimal solution for metro-optical networks of small and medium cities having low amount of data traffic and low

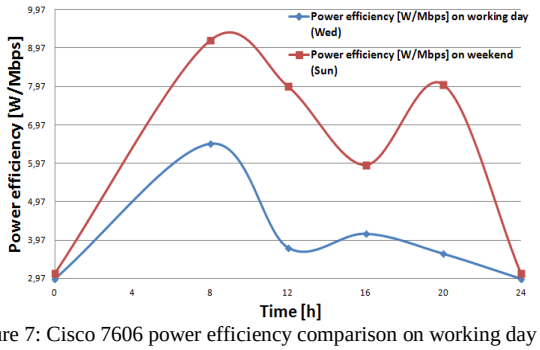

Figure 7: Cisco 7606 power efficiency comparison on working day and weekend

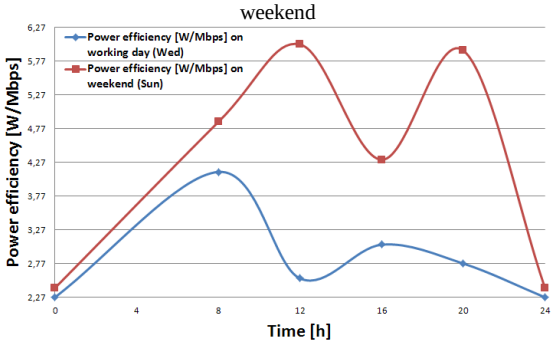

Figure 8: Cisco ASR 9006 power efficiency comparison on work day and weekend

network equipment CPU utilization. However, in case of large metro-optical networks where huge bandwidth demands must be satisfied, DWDM as technology has to be considered, regardless of lower energy-efficiency. Our future research activities will be focused on energy-efficiency analyses of optical amplifiers in metro-optical networks.

Doprinos informacijsko-komunikacijskih tehnologija smanjenju emisije CO_2

Mirza Berković i Amel Kosovac

Fakultet za saobraćaj i komunikacije, Sarajevo, BiH
mirza.berkovic@gmail.com; amelkosovac@gmail.com

Sažetak – Cilj rada je analiza modela procjene doprinosa ICT-a na smanjenje CO_2 emisija i sistema procjene. Problem istraživanja je baziran na činjenici da ne postoji generički model mjerenja doprinosa ICT-a na smanjenje CO_2 emisija. U radu se definiše model strukture sistema procjene doprinosa te analiziraju funkcije sistema procjene uključenih komponenti ICT-a u skladu s opisanom svrhom. Pri čemu na funkcionisanje modela procjene utječu brojni faktori okoline, koji se dijele na unutrašnje i vanjske faktore okoline. Svrha definisanja modela i upravljanja doprinosom je reducirati vjerovatnoću pojave negativnih efekata i kontrolirati njihove posljedice kako bi se ostvarili pozitivni ciljevi projekta. Sistem procjene smanjenja CO_2 emisija primjenom ICT-a je dinamički sistem, što znači da tokom vremena dolazi do promjena čiji su uzroci procesi koji se odvijaju u elementima sistema, a njihovo djelovanje prenosi internom strukturom sistema. Ocjena CO_2 efikasnosti ICT sistemi i procjena mjera za smanjenje CO_2 otiska kritično zavise od prikupljenih podataka obzirom na veliki elemenata koji su duboko povezani sa socijalno-ekonomskim razvojem i akvizicijom podataka, pri čemu je vrlo teško izvršiti interpolaciju budućih scenarija. U radu je također korištena AHP metoda za višekriterijsko odlučivanje pri donošenju odluke o selekciji i izboru ICT servisa na postavljene kriterije za rješavanje problema smanjenja CO_2 emisija.

I UVOD

Generalna hipoteza istraživanja glasi da procjena ključnih doprinosi informaciono-komunikacionih tehnologija (ICT-a) na smanjenje CO_2 emisija predstavlja mjerljiv postupak u okviru napora uspješne kvantifikacije i ocjene utjecaja ICT-a, a u funkciji smanjenja karbonski emisija. Radi se o resursu velikog potencijala za povećanje energetske efikasnosti i ublažavanje prisutnih klimatskih promjena. Načini na koji ICT tehnologija utječe na smanjenje emisije CO_2 mogu biti iznenađujući, a rezultati značajni.

Da bi mogućnosti ICT-a, na nekom području, bile optimalno iskorištene neophodno je da postoji jasan matematički model procjene doprinosa istih na smanjenja karbonski emisija. Kompleksnost procesa definisanja matematičkog modela proizilazi iz činjenice nedovoljne rasvjetljenosti prirode utjecaja ICT-a na smanjenje emisija, odnosno činjenica da veze između ICT i životne sredine mogu biti direktne i indirektne (→ , ↳), pozitivne i negativne (+,-), jednosmjerne i dvosmjerne (⇄), itd. Upravo zbog toga je i glavni problem i izazov istraživanja da se definiše konkretan model procjene doprinosa ICT-a na smanjenje CO_2 emisija koji će omogućiti da se ovi utjecaji kvantifikuju, prate i kontrolišu te da se na osnovu istih efikasno i svrsishodno projektuju novi sistemi. Činjenica je da do sada nije provedeno istraživanje koje bi dalo prije svega jasnu empirijsku vezu između primjene ICT-a i smanjenja CO_2 emisija, prepoznalo najrizičnije faktore te dalo odgovor na pitanje kako iste uspješno mjeriti. Drugim riječima, razvoj generičkog modela za procjenu efekata postaje nužan uslov, za dalju dinamiku ulaganja u ICT tehnologije sa svrhom ublažavanja klimatskih promjena. Osnovu istraživanja u radu, predstavlja identifikacija, analiza i procjena ključnih matematičkih varijabli utjecaja ICT-a na smanjenje CO_2 emisija te analiza, odnosno analiza iz ugla ICT proizvoda, projekata i organizacija a u funkciji dizajniranja modela procjene. Podršku procesu dalju i različita tijela koja su udružili napore u pronalaženju adekvatne, ali prije svega standardizovane procedure za procjenu (kvantifikaciju, praćenje i izvještavanje) emisija štetnih polutanata za koje je odgovoran sektor ICT-a [1]. Proces matematičke formalizacije doprinosa ICT-a u osnovi se temelji na vrednovanju emisija pokretanja bita (informacija) umjesto pokretanja atoma (materije) referentnog sistema, što je bit procesa dematerijalizacije. Telekomunikacijski sistem, kao sistem za upravljivu distribuciju bita, nudi ključnu alternativu i pametnu nadgradnju različitih sistema sa značajno manjim nivoima emisije. Osnovni izazov leži o dualnoj prirodi ovog odnosa jer ICT-a sa jedne strane doprinosi smanjenju negativnih ekoloških utjecaja (kroz povećanje efikasnosti sistema, supstituciju prijevoza, itd), ali sa druge strane i sam sektor ICT-a je generator negativnih ekoloških utjecaja, prije svega emisija CO_2 [1].

Procjena ICT-a na smanjenja CO_2 emisija veoma je kompleksan proces i zahtjeva definisanje velikog broja varijabli. Sa jedne strane ovdje se radi o istraživanju dva fenomena, jednog tehničkog karaktera, koji ima jasno definisane i mjerljive varijable, a sa druge strane imamo prirodne fenome utjecaja koji imaju i određeni broj nezavisnih varijabli. Nezavisne varijable koje je veoma teško mjeriti, uključuju i subjektivni utjecaj koji se ne smije zanemariti, ali se ne može ni strogo uzročno determinirati i opisati. Istražuje se utjecaj upotrebe ICT-a kroz životni ciklus na smanjenje emisija CO_2 izvora i pri tome se definira kao pozitivan ako je dobivena vrijednost veća od vrijednosti utjecaja ICT-a, troškovi su manji ili jednaki.

U cilju definisanja modela mjerenja utjecaja, neophodno je izvršiti sistematizaciju utjecaja ICT-a na CO_2 emisije, odnosno sistematizovati pravce primjene ICT-a i sve relevantne faktore koji utječu na efekte primjene ICT-a.

II ZNAČAJ INFORMACIONO - KOMUNIKACIONIH TEHNOLOGIJA ZA SMANJENJE KARBONSKIH EMISIJA

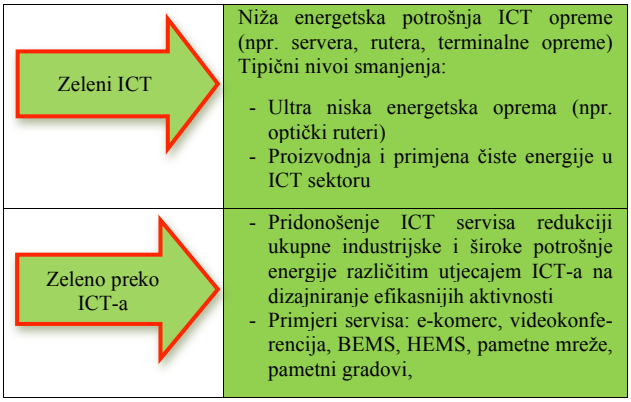
Donošenjem ispravnih odluka o načinima proizvodnje, kupnje i primjene proizvoda ICT-a imamo sposobnost osigurati goleme ekološke koristi. To može obuhvatati štednju energije kroz nadziranje i upravljanje njenom upotrebom,

stvaranje efikasnijih transportnih sistema te smanjivanje potreba za putovanjima primjenom video servisa i drugih oblika elektronskih transakcija. U tom kontekstu ICT tehnologije treba posmatrati s tri aspekta: društvenog i ekološkog utjecaja proizvodnje ICT proizvoda i kako se može smanjiti negativan utjecaj; utjecaja korištenja ICT-a proizvoda na održivi razvoj, posebno njegovu ulogu u proizvodnji energije i klimatskim promjenama i načina na koji se ICT proizvodi mogu primijeniti za poboljšanje životnih uslova. Prema [2], ICT se sastoji od hardvera, softvera, mreža i medija za prikupljanje, pohranjivanje, procesiranje, prenošenje i prezentaciju informacija (glasovnih, podatkovnih, tekstualnih i slikovnih), kao i od srodnih usluga. ICT se, prema istom izvoru, može podijeliti na informacijsku i komunikacijsku infrastrukturu (ICI) i na informacjisku tehnologiju (IT). ICI se odnosi na hardver i softver za prikupljanje, pohranjivanje, procesuiranje, prenošenje i prezentaciju informacija, a IT na telekomunikacijske sisteme i mreže, te na servise koji se njima koriste. Prema [6] definirana je djelatnost ICT sektora: ICT sektor obuhvata proizvodnju opreme i usluga za prikupljanje, prijenos te prikaz podataka i informacija elektronskim putem. ICT sektor su aktivnosti koje spadaju u uniju skupova aktivnosti informacijske tehnologije i telekomunikacija. Aktivnosti koje se nalaze u sektoru informiranja, a koje nisu u presjeku skupova s aktivnostima IT sektora i telekomunikacija, ne ubrajaju se u ICT sektor. Prema [2] postoje dvije ICT sektorske kategorije unutar kojih imamo specifične oblasti (TABLICA 1).

TABLICA 1. KATEGORIZACIJA ICT SEKTORSKE INDUSTRIJE

ICT industrija	OECD broj kategorije	Kategorije
Industrija ICT proizvodnje i trgovine	2610	Proizvodnja elektronskih komponenti i ploča
	2620	Proizvodnja računara i periferne oprem.
	2630	Proizvodnja komunikacijske opreme
	2640	Proizvodnja potrošačke elektronike
	2680	Proizvodnja magnetnih i optičkih medij
	4651	Veleprodaja kompjutera, periferne opreme i softvera
	4652	Veleprodaja elektronske i tk. opreme
Industrija ICT servisa	5820	Objavljivanje softvera
	6110	Bežične telekomunikacijske aktivnosti
	6120	Žičane telekomunikacijske aktivnosti
	6130	Satelitske telekomunikacijske aktivnosti
	6190	Ostale telekomunikacijske aktivnosti
	6201	Aktivnosti računarskog programiranja
	6202	Računarsko savjetovanje i upravljanje računarskom opremom
	6209	Aktivnosti IT-a i računarskih servisa
	6311	Obrada podataka, hosting i vezani servisi
	6312	Web portal
	9511	Popravak računarske i periferne opreme
	9512	Popravak komunikacijske opreme

Pri korištenju ICT-a, postaje sve značajnije razmatranje i procjenjivanje, ne samo mjerljivih i direktnih ekoloških utjecaja ICT sektora, nego i redukcijskih ekoloških koristi koje primjenom ICT-a možemo imati u smanjenju CO_2 emisija. U tom kontekstu, saradnja i optimizacija putem više ekonomskih sektora je značajna prilika. Termin „zeleno“ se danas često koristi za sistematično objašnjenje efekata primjene ICT-a. „Zeleno preko ICT-a“ se odnosi na dekarbonizaciju drugih sektora implementacijom ICT rješenja, dok „Zeleni ICT“ ukazuje na smanjenje karbonskog intenziteta samog ICT sektora (slika 1.). Efekti smanjenja CO_2 emisija putem „Zeleno preko ICT-a“ prema istraživanjima iz [4] mogu biti ekvivalentni sniženju od pet i više puta karbonskih emisija samog ICT sektora, uz pretpostavku da su ICT potencijali aktivno korišteni.



Sl. 1. Konceptualne razlike između “Zeleni ICT” i “Zeleno preko ICT-a”

III IDENTIFIKACIJA POZITIVNIH I NEGATIVNIH EFEKATA PRIMJENE ICT-a

ICT-a ima i pozitivne i negativne mjerljive efekte na okoliš (Sl. 2.) Negativan efekat je moguće izračunati pomoću mjerljivog ekološkog opterećenja uzrokovanog ICT uređajima i opremom, kao na primjer vrijednost potrošnje energije, prirodnih resursa i količina stvorenog ICT otpada.

Procesno stanje pozitivnog utjecaja, ICT usluge mogu napraviti kroz energetski efikasniji stil života i način poslovanja, jer npr. omogućavaju dematerijalizaciju, odnosno prijenos informacije umjesto fizičkih objekata, reduciraju kretanja ljudi i efikasniji transporta roba. U cilju balansiranog razvoja sa ekološkog stanovišta, neophodno je pristupiti i minimiziranju negativnih faktore ICT te maksimizirati pozitivne efekata. Iz tog razloga, i pozitivni i negativni ekološki efekti ICT trebaju biti kvantificirani, te ako je moguće, izvršiti procjenu u širem kontekstu.

Početni način kvantifikacije ova dva efekta je predložen od strane brojnih organizacija. Tako npr. prema [5] metodologija za procjenu ekoloških utjecaja ICT-a, razmatra utjecaje:

- ICT proizvoda, mreža, i servisa,
- ICT projekta,
- primjene ICT-a u poslovnim organizacijama,
- primjene ICT-a u gradovima (uključuje i druga administrativna područja koja mogu biti pokrivena sa procjenom ekoloških utjecaja u gradovima),
- primjene ICT-a na razini država.

Vrlo je važno na osnovu prethodnog da procjena utjecaja ICT-a nužno uključuje definiciju granica procjene, pri čemu srednje vrijednosti rezultata procjena ne bi smjeli značajno varirati ovisno o izboru granica. U svim slučajevima, definisane granice procjene trebaju biti adekvatno dokumentirane.

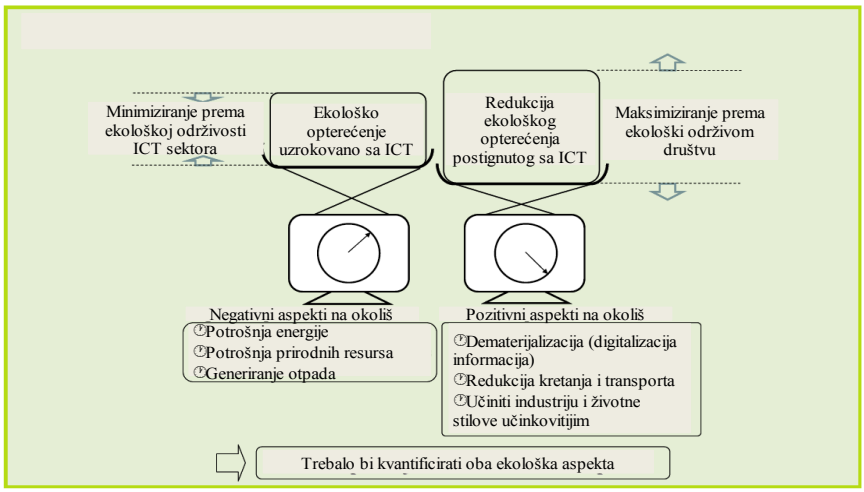
Dakle sistemski posmatrano ICT sektor ima dvostruku prirodu s obzirom na CO_2 emisije, odnosno postoje dva reda efekata s obzirom na ekološke utjecaje ICT-a:

- Efekti prvog reda (ili ekološko opterećenje ICT-a): utjecaji kreirani putem fizičkog postojanja ICT-a i uključenih procesa npr. CO_2 emisije, e-otpad, upotreba opasnih i rijetkih materija, ne-obnovljivih resursa, koji zajedno predstavljaju ekološko opterećenje vezano za ICT proizvode, mreže i usluge u toku njihovog životnog ciklusa. Dakle direktni utjecaji se odnose na utjecaje koje proizvođači i krajnji proizvodi industrije ICT-

a zajedno sa korisnicima tih proizvoda imaju na životnu sredinu. Glavni nosilac ovih utjecaja je ICT tehnologija.

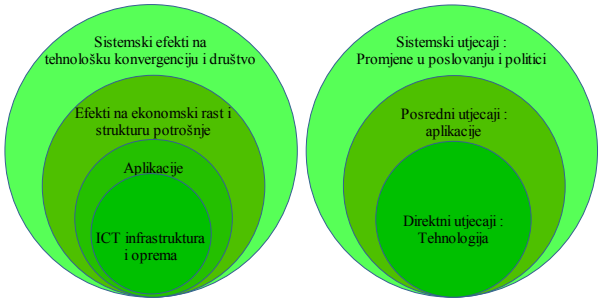
- Efekti drugog reda (ili redukcija ekološkog opterećenja): utjecaji i mogućnosti stvorene primjenom ICT-a. Ovo uključuje redukciju efekata ekološkog opterećenja koji mogu biti ili stvarni ili potencijalni, npr. substitucija putovanja, optimizacija saobraćaja, promjena radnog okruženja, upotreba ekoloških kontrolnih sistema, upotrebe e-poslovanja, e-vlada, itd.. Važno je spomenuti "Indirektne efekte" koji predstavlja mogućnost redukcije emisije stakleničkih plinova i to u pet velikih područja: dematerijalizacija, pametni motorni sistemi, logistika i transport, zgrade i pametne mreže. Indirektni utjecaji odnose se na rješenja ICT-a koje se koriste u ekonomskim i društvenim aktivnostima, a koje smanjuju utjecaj tih aktivnosti na životnu sredinu. U osnovi ovog utjecaja je činjenica da ICT učestvuju u proizvodnji i potrošnji većine proizvoda. Iako je ovaj utjecaj u osnovi pozitivan, jer omogućava racionalnije korištenje resursa, njegovu procjenu treba sprovoditi oprezno. Razlog je što često sistemi bazirani na ICT podrazumijevaju veću potrošnju energije (iako manju potrošnju radne snage) u odnosu na konven-cionalne (neautomatizovane) sisteme.

Pozitivni i negativni utjecaji ICT-a shematski opisuju sadržaj ekoloških utjecaja ICT-a na okoliš (Sl. 2.). Efekti prvog reda su direktno vezani za negativne efekte ICT-a na okoliš, a efekti drugog reda su poistovjećeni s pozitivnim efektom ICT-a. Za sve ove efekte, ključni indikatori ekoloških performansi trebaju biti korišteni.

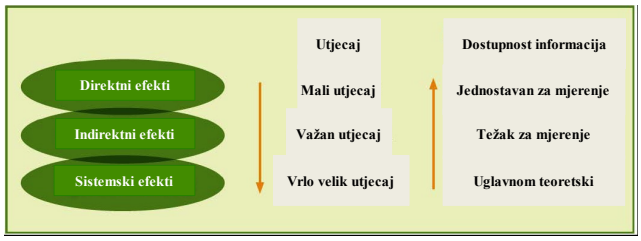


Slika 2. Pozitivni i negativni utjecaji ICT-a

Pored gornja dva tipa utjecaja ICT na životnu sredinu primjetno je postojanje i sistemskih utjecaja" (Sl. 3). Sistemski utjecaji ili efekti trećeg reda se odnose na faktore koji nisu tehnološki već organizacioni i upravljački. Glavni utjecaj ICT u ovom kontekstu je u širenju informacija koji će uticati da proizvođači i korisnici svoje ponašanje promjene u pravcu boljeg odnosa prema životnoj sredini. Međutim, i u ovom domenu treba biti oprezan pri procjeni utjecaja. Promjene na mikro nivou često ne rezultuju proporcionalnim koristima na makro nivou. Veća energetska efikasnost nekog proizvoda (npr. automobila) može smanjiti potrošnju energije za pojedinačnog korisnika, ali istovremeno zbog dostupnosti za širi krug potrošača, do-vesti do veće ukupne potrošnje na nivou regiona ili države [5].



Definisana su tri pravca djelovanja ICT-a na ekonomske procese: optimizacija (primjena različitih rješenja za povećanje energetske efikasnosti, na primjer u automobilskoj industriji); dematerijalizacija i supstitucija (za-mjena procesa i proizvoda digitalnim formama - telekonferencija umjesto sastanaka uživo); podsticaj (ICT mogu povećati potražnju za određenim proizvodima) i degrada-cija (ICT rješenja mogu otežati procese upravljanja otpadom).



Slika 3. Tri tipa utjecaja ICT na životnu sredinu

Nekoliko kategorija procjena ekoloških utjecaja može se izvršiti na polju ICT (tablica 2.). Kategorije su vezane za široko ciljani okvir procjene utjecaja. Spomenute kategorije mogu biti poboljšane i dalje razvijane.

TABLICA 2. KATEGORIJE PROCJENE EKOLOŠKIH UTJECAJA

1.	potencijal otopljavanja ili emisija stakleničkih plinova	6.	stvaranje fotohemijskog ozona,
2.	potrošnja energije	7.	acidifikacije zraka
3.	crpljenje resursa	8.	eutrophikacija vode
4.	iscrpljenje ozona	9.	emisije otrovne pare
5.	emisije otrovnih supstanci	10.	stvaranje opasnog otpada

Većina analiziranih metodologija se fokusira na energetsku potrošnju i emisije stakleničkih plinova. Selekcija je izvršena u kontekstu dva ključa područja: maksimalna proizvodnja nafte i klimatske promjene usljed ljudskih aktivnosti.

Korištenje ICT-a rješenja može pridonijeti također, potrebi nešto više materijala, više komponenti, manje energije i manje otpada. Redukcija ekološkog opterećenja može potjecati od utjecaja ICT na dematerijalizaciju temeljenu na zamjeni visoko karbonskih proizvoda i aktivnosti sa ICT mogućnostima nižih karbonskim alternativama (TABLICA 3), ovo uključuje:

TABLICA 3. ICT ALTERNATIVE

1.	online mediji	4.	e – trgovinu
2.	e – ticketing	5.	e – papir
3.	videokonferencije	6.	telerad ili drugi servisi

Efikasnost dematerijalizacije u smanjenju CO_2 emisija zavisi o behaviorističkim promjenama i dostupnosti infrastrukture. U tom kontekstu, moguće je imati efekat povratnog djelovanja (povećanom upotrebom opreme ICT-a). Treba uočiti da nagomilavanje efekata velikog broja ljudi koji koriste ICT, pravi složeniju procjenu ICT utjecaja u srednjeročnom roku. Primjetno je da analizirane mogućnosti redukcije emisije, u drugim sektorima putem upotrebe ICT-a, ima značajne povratne efekte. Upotreba ICT-a može povećati efikasnost potrošnje energije, može povećati učinkovitost i smanjenu proizvodnju i potrošnju resursa, te smanjiti kretanje ljudi i roba. Tablica 4. prikazuje listu kategorija pri čemu metrike redukcije ekološkog opterećenja se razlikuju po kategorijama ekoloških utjecaja. Spomenute vrste kategorizacija utjecaja mogu biti procijenjene na različitim poljima ICT-a:

- utjecaj ICT proizvoda,
- utjecaj ICT mreža,
- utjecaj ICT usluga.

Za proizvode, mreže i usluge funkcionalne jedinice mogu biti drugačije analizirane: na primjer, vrijeme tokom kojeg jedan korisnik telefonira, broj poslanih e-mail-ova, količina podataka prenesena preko mreže, vrijeme tokom kojeg jedan korisnik koristi videokonferencijski servis itd. Procjena utjecaja ICT proizvoda, mreža, i usluga zahtijeva definiciju granica, pri čemu granice trebaju biti dokumentirane. Procjena može biti ograničena na jedan dio životnog ciklusa komponente ili servisa ili pokriti ukupan životni ciklus, uključujući, naprimjer, ekstrakciju sirovina, proizvodnju komponenti, skladištenje, transport i distribucija, upotrebu, recikliranje i upravljanje otpadom. Za utjecaje proizvoda, mreža i usluga, odgovornost za utjecaje je raširena preko cijelog nabavnog lanca. Vremensko ograničenje je sintetičko, u smislu da postoji nagomilavanja procesa procjenjivanja utjecaja tokom dužeg vremena i prostora. Procjenjivanje može varirati tokom vremena ovisno o variranju samih procesa.

Za utjecaje proizvoda, mreža i usluga, također je potrebno izvršiti procjene životnog ciklusa (LCA) npr. Primjenom ISO 14040 standarda koji opisuje principe i radni okvir za LCA i ISO 14044 koji specificira zahtjeve i pruža smjernice za LCA uključujući: definiciju cilja i opsega LCA, fazu analize životnog ciklusa inventara (LCI), fazu procjene utjecaja životnog ciklusa (LCIA), fazu interpretacije životnog ciklusa, izvještavanje i kritičan pregled LCA, ograničenja LCA, odnos između LCA faza, i uslova za upotrebu izabranih vrijednosti i alternativnih elemenata. ICT proizvodi, mreže i usluge svojim razvojem pružaju mogućnosti za:

- poboljšanje energetske efikasnosti,
- redukciju u potrošnji energije,
- redukciju u emisijama kroz cjeli životni ciklus proizvoda i opreme,
- održivost materijala i eliminiranje opasnih materijala (uključujući način pakiranja),
- spajanje nižih utjecaja pojedinih komponenti (multifunkcionalni proizvodi).

ICT proizvodi, mreže i usluge mogle bi imati značajne mogućnosti ublažavanja CO_2 emisija korištenjem istih u projektima smanjenja velikih GHG emisija drugih sektora:

- industrija: motori i industrijska procesna automatizacija,
- uslužnu djelatnost: veća efikasnost,
- transport: logistika, privatni prijevoz, efikasna vozila, saobraćajni tok, pametna rasvjeta,
- zgrade: pametne zgrade, redukcija prostora i energije,
- energija i toplina: pametna mreža, efikasna proizvodnja struje, nadgledanje i kontrola potrošnje energije, kombinirano nadgledanje i upravljanje potrošnjom topline i energije.

Na polju ICT-a, postoji naročito zanimanje za uspoređivanje situacije s ICT servisom sa njegovim temeljnim baznim scenarijem. Uspoređivanje ekološkog utjecaja dvo-satnog sastanka putujući zrakoplovom između dva grada s ekološkim utjcajem koje ima dvo-satni sastanak ostvaren putem videokonferencijskog servisa. Usporedba utjecaja između dvije situacije implicira procjenu ekoloških utjecaja u drugim sektorima i potrebu integriranja rezultata.

Procjene utjecaja na organizacijskom nivou zahtijevaju definisanje granica tretirane organizacije, pri čemu granice trebaju biti dokumentirane u različitim vremenskim okvirima razmatranja, osim ako je drugačije naznačeno, pri čemu je vremenski okvir od jedne godine obično optimalno rješenje. Ovaj tip procjene može biti izvršen retroaktivno nakon proteklog izabranog vremenskog okvira. Izabrani podaci korišteni za izvođenje procjene trebaju biti dokumentirani i raspoloživi za verifikaciju, pri čemu trebaju biti korišteni oni podaci koji imaju najbolju raspoloživu kvalitetu. Ovaj tip procjene može biti verificiran od treće strane nakon završetka procjene.

Procjena utjecaja ICT na projektnom nivou se sastoji od procjene jednog ili nekoliko tipova ekoloških utjecaja povezanih s lansiranjem projekta ciljajući na reduciranje ovih utjecaja, npr. emisije stakleničkih plinova. Potvrđivanje procjena utjecaja se sastoji od procjene utjecaja projekta prije samog početka do datuma kada je procjena izvršena. Jedan od ciljeva ove vrste procjene je predvidjeti potencijalne utjecaje projekta, identificirati aktivnosti unutar projekta odakle dolaze glavni utjecaji i odlučivanju kako smanjiti neželjene utjecaje a povećati željene utjecaje. Potvrdna procjene utjecaja leži u procjeni utjecaja projekta, ili dijela projekta, koji je završio na datum kada je procjena izvršena. To može izvršiti treća strana. Selektovani podaci korišteni za izvođenje procjene trebaju biti dokumentirani i raspoloživi za ovjeru, pri čemu podaci najbolje raspoložive kvalitete trebaju biti izabrani.

Utjecaji ICT-a na nivou grada ili drugom administrativnom nivou mogu imati važnu ulogu u razvoju zelenog prostora. Naprimjer, pametne zgrade i pametne mreže mogu stvoriti veću energetsku efikasnost. Inteligentni transportni sistemi uključujući električna vozila, luke i aerodromsku infrastrukturu čine transport više energetski efikasnim. Multimedijski konferencijski sistemi i

telerad mogu smanjiti obim putovanja i njegov karbonski otisak. ICT može također imati važnu ulogu u dizajniranju energetski efikasne javne infrastrukture. Procjena utjecaja ICT-a u gradu ili bilo kojoj drugoj administrativnom nivou zahtijeva definiciju granice grada ili neke druge administrativne razina pri čemu granice trebaju biti dokumentirane. Procjena utjecaja ICT-a na nivou pojedinačne zemlje ili grupe zemalja, ili regija unutar zemlje, ili nekom drugom administrativnom nivou, zahtjeva definiciju regionalne, državne, međunarodne ili neke druge razine administrativne granice pri čemu granice trebaju biti dokumentirane. Izabrani podaci korišteni za izvođenje procjene trebaju biti dokumentirani i raspoloživi za provjeru. Podaci najbolje raspoložive kvalitete trebaju biti izabrani. Različiti vremenski okviri mogu biti razmotreni, okvir od jedne godine je optimalno rješenje.

TABLICA 4. EFEKTI ICT-a

Kategorija	Efekti
Potrošnja materijala	Kod smanjenja materijalne potrošnje ekološka opterećenja vezana za proizvodnju i upotrebu kao i otpad mogu se značajno reducirati.
Potrošnja energije /upotreba energije	Uz povećanje učinkovitosti snage i utroška energije uz smanjenje potrošnje, ekološka opterećenja vezana za proizvodnju i prijenos energije, itd., mogu biti redukovana.
Kretanje ljudi	Kod reduciranja kretanja ljudi, ekološko opterećenje transporta može se reducirati.
Transport materijala	Kod reduciranja transporta materijala, ekološko opterećenje transporta može se reducirati.
Poboljšanje efikasnosti ureda	Kod efikasnog korištenja uredskog prostora, potrošnja struje za rasvjetu, klimatizaciju, itd., može biti redukovana, a time i okolinsko opterećenje.
Skladištenje robe	Kod smanjenja robnog skladišnog prostora, potrošnja struje za rasvjetu, klimatizaciju, itd. može biti redukovana, a time i ekološko opterećenje.
Bolja radna efikasnost	Kod povećanja efikasnosti rada, ekološko opterećenje može se redukovati
Otpad	Kod smanjenja otpadnih emisija, ekološka opterećenost zahtijevana za ekološko očuvanje kao i za odlagalište smeća može se reducirati.

TABLICA 5. OČEKIVANE EMISIONE REDUKCIJE ILI RAST PUTEM ICT-A U IZABRANIM PODRUČJIMA

Područja redukcije CO_2	Predviđeni utjecaji (primjeri)
Zgrade	Manje prostore za skladišta, npr. trgovine na malo zamijenjene sa online kupovinom. Veća energetska efikasnost sa naprednim rashladnim i toplotnim sistemima.
Industrijska proizvodnja	Proizvodnja nekoliko proizvoda i roba putem dematerijalizacije. Niža energetska potrošnja po jedinici proizvoda kroz korištenja ICT-opremeljenih mašina kao što su pametni motori.
Otpad	Manje GHG emisije putem zamjenjivanja kompakt - diskova s muzike putem Interneta.
Sistemi distribucije energije	Smanjene gubitaka snage putem preciziranog zahtjeva i procjenjivanja opskrbe primjenom ICT-a. Manja upotreba fosilnih goriva i povećan udio obnovljive energije omogućeno upotrebom pametnih mreža.
Transport	Manje korištenje vozila zbog teleprisustva i videokonferenciskih sistema Veća efikasnost goriva vozila kroz ubrzanu vožnju predpostavljenu smanjenjem prometnih gužvi. Veća efikasnost goriva korištenjem ICT-a pametnih transportnih sistema, na primjer, autobuski informacijski sistemi i realna vremenska navigacija.
Ostalo	Više slobodnog vremena za ljude, koje može biti potrošeno za povećanje GHG emisija drugih aktivnosti (efekat povratne sprege).

III PROBLEMI PROCJENE UTJECAJA ICT-A NA SMANJENJE KARBONSKIH EMISIJA

Većina analizirane literatura objavljene nakon 2000. godine o utjecaju ICT-a na okolinu i klimatska promjene fokusira se na podizanje svijesti o različitim ICT uslugama sa pozitivnim kratkoročnim ekološkim efektima, ali bez mogućnosti da se potpuno uhvati u koštac sa multi-slojevitim utjecajima koje ICT rješenja imaju na okoliš. Razumijevanje interakcije između emisija i ICT usluga je ograničeno sa nekoliko značajnih poteškoćama.

Pojedina ICT rješenja su raspoređena kao dio višestrukih i među-povezanih procesa. Naprimjer, korisnici pametnih telefona koriste nekoliko usluga istovremeno (skidanja muzike, web-pretraživanje i navigacijske usluge). Ovaj aspekt višestruke upotrebe djeluje kao ograničenje obračunavanju specifične i direktne emisije ICT servisa. Korištenje ICT ima širok i dubok utjecaj na ekonomiju i društvo. Kao utjecaj ICT usluga ne samo da uključuje ekološke već i društvene probleme, pri čemu su karakteristike ICT efekata obično prevladavajuće i transformirajuće. One ne uključuju samo efekte prvog reda koji mogu biti zahvaćeni u kraćem vremenskom razdoblju, već također i efekte drugog reda za duže razdoblje.

ICT usluge uključuju upotrebu više scenarija. Ukupan utjecaj ICT usluga je praćen sa aspekta korisničkog ponašanja, a promjene mogu biti iznenadne odnosno teške za predviđanje i procjenjivanje. Početna istraživanja su pokušala pokriti složenu dinamiku procesa u pokušaju procjene potencijala ICT usluga u redukciji CO_2. Međutim, konkretniji i napredni pristupi su razvijeni samo za pojedinačni ICT servis s minimalnim scenarijem inputa, kao npr. servis mašina-mašina i aplikacije mjerenja.

Ne samo da postoje kompleksnosti procjene ICT usluga ograničenih okvira i već također brojne manjkavosti i nisko povjerenje u ICT-vezanu statistiku. ICT statistika je obično prikupljana za šira geografska područja, kao što je nivo državne ili kontinentalni nivo, fokusirajući se na proizvodnju ICT opreme ili korištenje ICT servisa brojnih korisnika. Zbog toga, ponekad je vrlo izazovno razvrstati ICT utjecaje na raspoloživu ICT statistiku. Iz sadašnjeg ugla posmatranja, najviše dosadašnjih analiza i izvještaja budućih projekcija smanjenja CO_2 emisija je uzeto sa pretpostavkom procjenjenog povećanja penetracije servisa te u smislu poboljšane efikasnosti postignute sa ICT tehnologijama. Obrnuto, historijske analize, koje bi mogle sugerirati koliko su se CO_2 emisije reducirale sa primjenom ICT servisima, još uvijek nisu sprovedene. Većina izvještaja kombinuje top down i bottom up pristup u razvijanju modela i budućih scenarija kako bi savladali ograničenje raspoložive statistike. Osim toga, proces kvantifikacije unosi rizik preklapanja utjecaja kod primjene ICT servisa u procjeni potencijala akumulirane CO_2 redukcije unutar određene geografske granice.

IV MATEMATIČKA FORMALIZACIJA EFEKATA UTJECAJA ICT NA SMANJENJE KARBONSKIH EMISIJA

Na osnovu teorije vidimo da ICT može imati i pozitivan (+) i negativan (-) utjecaj na životnu sredinu, a ključni izazov je da se sagleda i ocjeni krajnji bilans [x+(-y)=z] utjecaja.

Redukcija energetskepotrošnje	=	Efekat redukcije energetske potrošnje primjenom ICT-a	-	Energetska potrošnja kroz primjenu ICT-a

Rezultat komparativne analize između referentnog proizvodnog sistema i ICT sistema mogu se dobiti izračunom razlike u ekološkog utjecaja između referentnog proizvodnog sistema i sistema ICT -a. Razliku možemo nazvati sekundarni efekat, a obrazac glasi:

$$EI_{razlika,i} = EI_{referentni,i} - EI_{ICTservis,i}$$

gdje su:

EI = okolišni utjecaj,
i = i-ta komparativna kategorija,
$EI_{razlika,i}$ *= i-ti sekundarni efekat,*
$EI_{razlika,i}$ *= i-ti EI referentnog proizvodnog sistema,*
$EI_{ICTservis,i}$ *= i-ti EI sistema ICT-a.*

Sumiranjem ukupne $EI_{razlike,i}$ dobivamo $EI_{razliku}$ ili sekundarni efekat sistema ICT-a pokrivanog referentnog sistema. Jednačina ispod prikazuje formulu za izračun sekundarnog efekta.

$$Ukupno\ EI_{razlika} = \sum EI_{razlike,i}$$

Pozitivni rezultat (ukupno $EI_{razlika}$ je pozitivno) indicira pozitivan utjecaj na okoliš a negativna vrijednost (ukupno $EI_{razlika}$ je negativno) predstavlja negativan utjecaj. Pozitivni sekundarni efekti indiciraju redukciju okolišnog opterećenja uslijed uvođenja ICT sistema. Negativni sekundarni efekti indiciraju suprotno. Broj elemenata usporedbi ovisi o diskreciji praktičara a struktura podataka smije varirati između LCA. Podjela na direktne, posredne i systemske utjecaje predstavlja potreban, ali ne i dovoljan okvir za djelovanje u pravcu ostvarenja koristi od ICT i smanjenja negativnih utjecaja tehnologija.

V PREDLOŽENI RADNI OKVIR PROCJENE CO_2 EMISIJA

U nastavku su opisani neki od mogućih ciljeva i kriterija razvijenog višekriterijskog modela odlučivanja o procjeni doprinosa ICT alternativa (servisa i opreme). Analizirajući ICT servise i faktore koji utječu na realizaciju usluga sljedeći ciljevi i kriteriji su prepoznati kao najznačajniji na osnovnoj razini procjene. Radni okvir procjene obuhvata ocjenjivane ciljeve i kriterije procjene.

A) Ciljevi procjene

Prema prethodnoj analizi i tački 2.3.1. identificirana su tri cilja procjene: proizvod, organizacija i projekat. Međutim prema tački 2.3.5. definisana su još dva cilja procjene: gradovi i države.

a) Proizvod

Proizvod se definiše kao bilo koja roba ili servis (ISO 14040). Međutim, prema ITU-T, sa značajnom stručnošću u oblasti telekomunikacijama, "mreže" i "usluge" su identificirane kao dodatne ciljeve procjena. Prema ITU-T definiciji, "proizvod" obuhvata sve robe, mreže i usluge.

b) Organizacija

Organizacija (REF ISO 14064-1) se definira kao kompanija, korporacija, preduzeće, tijelo ili institucija, ili njihove kombinacije, javne ili privatne, koje imaju svoju funkcije ili uprave.

c) Projekat

Projekat je referenciran na GHG projekat koji je definiran ISO 14064-2 standardom kao aktivnost ili aktivnosti sposobne da mijenjaju uslove utvrđene u baznom scenariju koji uzrokuje smanjenje emisija ili poboljšanja uklanjanja GHG-a. Na temelju ove definicije, ITU-T je definirao "ICT projekat" kao GHG projekat korištenja ICT proizvoda, mreža i usluga, u cilju smanjenja CO_2 emisija ili poboljšanja uklanjanje GHG i / ili stakleнički projekat korištenja ICT proizvoda, mreže i usluga, s ciljem uštede energije i energetske efikasnosti.

d) Grad i država

Prema (REF ITU-T L.1440 i L.1450), neophodno je osigurati relevantne metodologije za procjenu utjecaja korištenja ICT proizvoda, mreža i usluga u gradovima ili zemljama, istražujući načine na koji ICT može pomoći u uštedi potrošnje energije i energetske efikasnosti.

B) Kriteriji procjenjivanja

Prethodnom analizom standarda i smjernica, različitih razvojnih organizacija za standardizaciju, identificirani su sljedeći kriterije procjene:

- Inventar: vrsta inventara razvijena za različite GHG izvore i kanale u cilju proračuna ukupne emisije.
- Karbonski otisak: definiše se kao ukupna suma GHG emisija i GHG uklanjanja tokom faza životnog ciklusa proizvoda (izražava se kao neto utjecaj globalnog zatopljenja u CO_2). U definiciji, karbonski otisak se temelji na procjeni životnog ciklusa.
- Procjena životnog vijeka (LCA): Metodologija procjene ulaza, izlaza i potencijalnih utjecaj na okoliš sistema proizvoda tokom cijelog njegovog životnog ciklusa. Procjena životnog ciklusa primjenjena na određeni proizvod obuhvata robu, mreže ili usluge. Ona se bavi svim fazama života proizvoda od ekstrakcije sirovina, obrade materijale, prijevoza u svim fazama, proizvodnje, korištenja, popravake i održavanja te odlaganja ili recikliranja. Prema životnom ciklusu, inventar je sastavljen od svih relevantnih energetskih i materijalnih inputa i izlaza.
- Proračun ICT mogućnosti: proračun za pozitivne utjecaje omogućene primjenom ICT-a i negativne utjecaje uzrokovane korištenjem ICT-a.
- Eko-dizajn proizvoda: zahtjevi i postupci za integraciju ekoloških aspekata u procese dizajna i razvoja proizvoda, uključujući kombinaciju proizvoda, materijala i komponenti.
- Označavanje prema evaluaciji: ovo pokriva sve zahtjeve koji ukazuju na ekološke aspekte proizvoda. Znak zaštite okoliša može poprimiti oblik izjave, simbola, grafičke oznake na proizvodu.
- Provjera i verifikacija: proces s kojim se GHG tvrdnje može ocijenjivati prema usvojenim valjanostima i provjerenim kriterijima.

Svrha upravljanja inventarom procjenom smanjenja emisija je smanjiti vjerovatnoću pojave rizika netačnih procjena i kontrolirati njihove posljedice kako bi se ostvarili ciljevi projekta. Ciljevi projekta su izgradnja sistema procjene i efikasnog ulaganja u ICT tehologije. Funkcija sistema upravljanja inventarom procjenom definirana je opisanom svrhom. Na funkcioniranje sistema procjene utječu razni faktori okoline, koji se dijele na:

- **faktore unutrašnje okoline**: ICT inventar, proces proizvodnje elemenata inventara,
- **faktore vanjske okoline**: legislativni, makroekonomski i sociološki, kvaliteta tima za procjenu, dokumentiranost prethodnih projekata, procedure i upute sektora, i sl.

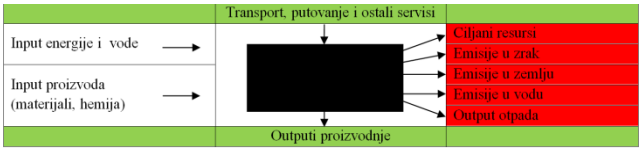
Elementi sistema upravljanja procjenom su:

1. identifikacija utjecaja sektora,
2. identifikacija granice i statističkih podataka,
3. analiza i razvoj dva scenarija za komparaciju,
4. procjena smanjenja CO_2 emisija i rizika,
5. projektovanje smanjenja CO_2 emisije do ciljne godine (kontrola procjene),
6. određivanje ukupnog neto efekta.

Preporuka je da podaci, bez obzira na korišteni model, treba da budu tačni, konzistentni, uporedljivi, jasni, sveobuhvatni, učestalo obnavljani, precizni i raspoloživi.

VI MODELIRANJE PONAŠANJA SISTEMA PROCJENE KARBONSKIH EMISIJA

Sistem upravljanja procjenom smanjenja CO_2 emisija primjenom ICT-a je dinamički sistem, što znači da kod njega tokom vremena dolazi do promjena čiji su uzroci procesi koji se odvijaju u elementima sistema, a njihovo se djelovanje prenosi internom strukturom sistema. Upravljati procjenom sa svrhom ostvarenja ciljeva projekta podrazumijeva provođenje procesa i aktivnosti tokom čitavog životnog ciklusa projekta. Jedinični proces tipično predstavlja opremu gdje je ICT proizvod proizveden, kancelariju ili trgovinu – ili izravnu aktivnost elementa gdje je servis proizveden. Jedinični proces može također biti vozilo ili " pokretna oprema " koja transportira ICT proizvode. Bilo koji jedinični proces može biti modelovan. Generički jedinični procesni model uključuje nekoliko ulaza i izlaza i može biti upućen na LCI modela opreme ili kraće model oprema. U mnogim slučajevima, rukovanje opremom nije samo ciljano na sistem proizvodnje sa LCA već također na druge proizvodne sisteme. Svi drugi ulazi i izlazi su definirani kao tokovi proizvodnje. Svaki input goriva i proizvoda, kao i svaki output otpatka, može uključiti transport koji je zatim dio input/output podataka povezanih na jedinicu procesa.



Slika 4. Inputi i outputi utjecaja ICT-a na životnu sredinu

Za razumijevanje ponašanja ili funkcioniranja sistema upravljanja procjenom, projekat procjene doprinosa ICT-a smanjenju CO_2 emisija moguće je analizirati kroz elemente dijagrama toka: priprema i planiranje projekta procjene u funkciji smanjenja CO_2 emisija. Na slici ispod je za fazu životnog ciklusa projekta procjene prikazan dijagram toka procesa upravljanja procjenom emisija. Pojedini proces ukratko je i verbalno opisan kako bi bilo jasno o kojem elementu sistema upravljanja procjenom se radi te koji se proces odvija unutar pojedinog elementa, u određenoj fazi životnog ciklusa projekta. Za grafički prikaz funkcioniranja sistema uobičajen je sistemski dijagram pod nazivom funkciogram, jer on omogućava izradu dinamičkog modela terminskog ponašanja nekog sistema.

VII MODELI ODLUČIVANJA U SISTEMU PROCJENE DOPRINOSA - MODEL DONOŠENJA ODLUKE O SELEKCIJI I IZBORU ICT SERVISA

U nastavku slijedi model za donošenje odluke o selekciji i izboru ICT servisa na postavljene kriterije za rješavanje problema smanjenja CO_2 emisija. Korišten je program Expert Chioce za AHP višekriterijsko odlučivanje.

A) Opis problema odlučivanja

Donesena je odluka o smanjenju CO_2 emisija primjenom ICT-a na određenom području. Na raspolaganju stoje brojni ICT servisi čije pozitivne i negativne utjecaje na nivo CO_2 emisija nemamo. U literaturi se nalaze brojni kriteriji ali je njihov odnos vrlo kompleksan i dvosmislen, zbog toga se javlja dilema koji ICT servis izabrati za najefikasnije ostvarenje postavljenog cilja.

B) Kriteriji za odabir

Za procjenu smanjenja CO_2 emisija izabrani su servisi koji su najpovoljniji u odnosu na slijedećih šest kriterija:

K1. - mogućnost identifikacije inventara emisija,
K2. - veličina ukupnog karbonskog otiska servisa,
K3. - procjena životnog ciklusa opreme,
K4. - mogućnosti procjene doprinosa ICT-a
K5. - nivo eko-dizajna proizvoda i ICT opreme,
K6. - mogućnosti validacije i verifikacije.
i dva pod kriterija:
K31. -nivo tehnološke zrelosti servisa,
K32. -% prihvačenost servisa od strane korisnika,

Dekompozicija problema - Za rješavanje konkretnog problema definisana je struktura prikazana u tabeli ispod. Glavni cilj je odabrati ICT servis sa visokim pozitivnim efektima na smanjenje CO_2 emisija i sa niskim negativnim efektima. Na nižoj hijerarhijskoj razini odlučivanja nalazi se šest kriterija odabira i dvapodkriterija, a na najnižoj razini su alternative – 19 raspoloživih servisa.

Nakon provedenog istraživanja, odabira relevantnih kriterija i definiranja modela višekriterijskog odlučivanja, podaci su obrađeni u programskom paketu Expert Choise 2000, a cilj je bio definisanje hijararhijskog stabla te odabir alternativa, koje bi prema istraživanjima bile najbolje opcije za smanjenje CO_2 emisija. Vrijednost kriterija i pod-kriterija nije prikazana zbog nekonzistentnih podataka dobivenih provedenom anketom. Nakon definisanja raspona potencijala utjecaja neophodno je izvršiti rangiranje potencijala utjecaja pojedinih servisa ICT-a na smanjenje CO_2 emisija.

TABLICA 6. RASPONI POTENCIJALA UTJECAJA

Opseg utjecaja (u skladu sa Indeksom spremnosti e-okruženja – EERI	**Raspon: -5 do + 5**
Visoko štetni negativni efekti	= -5
Srednje visoko štetni negativni efekti	= -4
Srednji štetni negativni efekti	= -3
Srednje niski štetni negativni efekti	= -2
Niski štetni negativni efekti	= -1
Ograničeni ili nepostojeći efekti	= 0
Niski pozitivni efekti	= 1
Srednje niski pozitivni efekti	= 2
Srednji pozitivni efekti	= 3
Srednje visoki pozitivni efekti	= 4
Visoki pozitivni efekti	= 5

TABLICA 7. SELEKTOVANI ICT SERVISI

Alternative	ICT servisi (po kriteriju smanjenja CO_2 emisija)
A1.	Navigacija u realnom vremenu
A2.	Autobuski informacioni sistem
A3.	E-logistika
A4.	Teleprisustvo i videokonferencije
A5.	Pametni rad
A6.	Sistem upravljanje energijom
A7.	Pametne mreže
A8.	E-zdravstvo
A9.	E-učenje
A10.	E-trgovina
A11.	E-vlada
A12.	E-civilni servisi
A13.	Digitalni sadržaj
A14.	Pametni motori u industrijskim procesima

Od odabranih 19 servisa, rangiranjem potencijala u odnosu na efekte drugog reda u BAU sistemima, odnosno na temelju vrijednosti kriterija smanjenja emisija, izdvojeno je 14 ICT servisa prikazanih u Tablici 7.

VIII Model donošenja odluke o području primjene alternativa ICT servisa

Područja primjene alternativa ICT servisa u funkciji cilja su vrednovana na osnovu dostupnih podataka sa visokom frekvencijom učestalosti servisa u području i kriterijem smanjenja emisija BAU sistema. Ključni indikatori koji su vrednovani prikazani su u tablici 8.

TABLICA 8. OBRASCI PRORAČUNA SMANJENJA ENERGETSKE POTROŠNJE

Ciljna područja ICT servisa	Kriteriji energetske redukcije
Potrošnja sredstava (papir, CD, DVD, itd)	Potrošnja energije za proizvodnju jedne jedinice proizvoda × umanjena veličina
Potrošnja energije/energetska potrošnja (gorivo, struja itd.)	Potrošnja energije po količini goriva × smanjena potrošnja goriva
Kretanje ljudi (automobilom, autobusima, itd.)	Potrošnja energije po količini goriva × smanjena potrošnja goriva
Kretanje roba (kargo itd)	Potrošnja energije po količini goriva × smanjena potrošnja goriva
Poboljšana efikasnost uredskog prostora	Potrošnja energije po površini ureda × smanjen iznos
Skladištenje roba (skladišni prostor, itd.)	Potrošnja energije po skladišnom prostoru × smanjen iznos
Poboljšana radna efikasnost	Potrošnja energije po površini (m^2) x površina korištena po osobi (m^2) x poboljšana radna efikasnost
Otpad (papir, industrijski otpad)	Potrošnja energije po količini otpada × umanjena količina

Rezultati softverske analize prikazani su su Tablici 9.

TABLICA 9. REZULTATI PROCJENE ALTERNATIVA PO SEKTORIMA

Područja smanjenja emisija	ICT alter	Potencijalno zahvaćeni sektori ICT alternativama		
		Transport	Gradnja	Industrija
Transport	A1.	Redukovana potrošnja goriva	Nije primjenjiv	Nije primjenjiv
Transport	A2.	Redukovana potrošnja goriva	Nije primjenjiv	Nije primjenjiv
Transport	A3.	Redukovana potrošnja goriva	Nije primjenjiv	Nije primjenjiv
Transport	A4.	Redukovana potrošnja goriva	Nije primjenjiv	Nije primjenjiv
Transport	A5.	Redukovana potrošnja goriva	Redukcija energetske potrošnje	Nije primjenjiv
Pametna gradnja	A6.	Nije primjenjiv	Redukcija potrošnje ener.	Nije primjenjiv
Pametna gradnja	A7.	Nije primjenjiv	Redukcija potrošnje ener.	Redukcija potrošnje ener.
Trgovina/ usluge	A8.	Redukcija potrošnje goriva	Redukcija potrošnje ener.	Nije primjenjiv
Trgovina/ usluge	A9.	Redukcija potrošnje goriva	Redukcija potrošnje ener.	Nije primjenjiv
Trgovina/ usluge	A10.	Redukcija potrošnje goriva	Redukcija potrošnje ener.	Redukcija potrošnje ener.
Trgovina/ usluge	A11.	Redukcija potrošnje goriva	Redukcija potrošnje ener.	Nije primjenjiv
Trgovina/ usluge	A12.	Redukcija potrošnje goriva	Nije primjenjiv	Nije primjenjiv
Trgovina/ usluge	A13.	Nije primjenjiv	Nije primjenjiv	Redukcija potrošnje ener.
Proizvodnja	A14.	Nije primjenjiv	Nije primjenjiv	Redukcija potrošnje ener.
Razine utjecaja		Visoki efekti	Negativni efekti	Ograničeni efekti

VI Zaključak

Rezultati istraživanja procjene doprinosa ICT-a na smanjenje CO_2 emisije pokazuju da dosadašnja metodologija procjene, kao skup parametara ili vrijednosti izvedenih na osnovu pozitivnih efekata, djelomično opisuje procesna stanje, te ne uključuje sistemske utjecaje koji prevazilaze domet same vrijednosti parametara karbonskog utjecaja. Analiza je pokazala da osim nepostojanja skupa relevantnih indikatora, dodatni problem kreira nedostatak modela prikupljanja podataka. Indikatori predloženi u literaturi mogu biti samo inicijalni indikatori procjene utjecaja. Za obuhvatniji i detaljniji pristup ovoj problematici neophodna su šira istraživanja i dostupnost terenskih podataka. Složenost procedura procjene i zahtijevani nivo informacione osnove čine da je posvećenost redovnoj ocjeni ekoloških utjecaja još uvijek samo dio pojedinačnih projekata. Kao i u svakom naučnom radu, u okvirima vremenskih i prostornih ograničenja, i ovdje se otvorilo niz dodatnih pitanja koje bi trebalo dalje obrađivati, kao što je vrednovanje i rangiranje efekata, odabir metode procjene efekata te definiranje modela prikupljanja podataka. Razvoj modela procjene doprinosa ICT-a na smanjenje CO_2 emisija nedvojbeno predstavlja ključni faktor uspješnog mjerenja pozitivnih doprinosa tehnologije. Bitno je naglasiti da kao što sistem nije numerički zbir elemenata i podsistema već njihov funkcionalni zbir [f(a,b,c)> >f(a)+f(b)+f(c)], tako i ovaj model nije samo numerički zbir parametara ICT komponenti i informacija nego uključuje i kompleksne relacije sa ostalim kompo-nentama i okolinom.

TELECOM INFRASTRUCTURE

A Low Energy Computer Infrastructure for Radio VOIP Supported Communication and SDR APRS in Education and Disaster Relief Situations

Kemal Hajdarevic*, Samim Konjicija**
*,** Faculty of Electrical Engineering, University of Sarajevo,
Sarajevo, Bosnia and Herzegovina
*khajdarevic@etf.unsa.ba, **skonjicija@etf.unsa.ba

Abstract – In long duration emergency and large scale disaster situations, information on asset position, information of current and information history of weather conditions, and communication are crucial for every rescue operation. Picture and voice are crucial so that affected population can make important decisions and take actions. Available technology offers affordable (low cost) and robust infrastructure solutions in disaster relief situations supported by radio amateur communication. In this paper we presented three types of services for which same hardware in essence can be used. First service is for GPS location mapping, second one is for VOIP communication, and third one is to provide real time video capturing. GPS location mapping was performed by using APRS-IS SDR, VOIP communication is performed via radio-svxlink-Internet using Echolink (svxlink which is linux compatible version) software, and for video capturing was used using Motion software. All above stated services is possible to install on low energy microcomputer such as Raspberry Pi which can be powered with 5 V battery or with mobile phone power adapter.

I. INTRODUCTION

In any emergency situation information on asset position, field and weather conditions, and communication are crucial for every rescue operation. We are all aware that these information are available to narrow specialized units such as military and rescue forces. These specialized units in critical situations might be overwhelmed with search & rescue activities and numerous requests for saving lives, assets, it is most likely that they will not be able to promptly give information such as specific person location, field and weather conditions, or to communicate with all affected individuals. Thus for our intention for documenting our findings is to propose solutions which can provide useful visual information, support alternative communication channels, and location mapping with support of radio amateur communications and radio amateur operators (hams).

II. RATIONALE FOR RADIO AMATEUR FREQUENCY SPECTRUM AND APPLICATIONS USAGE

Our intention is to propose compact housing for small microcomputer and other components which needs Internet connection able to communicate versatile type (video, voice, and data) of communication. Innovations in radio communications has great history and in last two decades radio spectrum became available to broader usage and in use by large part of global population through a usage of WIFI networks. While WIFI spectrum (2.4 and 5 GHz) as radio communication became available to broader usage this is just small part of radio spectrum which is available for testing and research activities. Because of its broad usage, sometimes researchers can find mentioned spectrum overwhelmed with traffic that different users can produce in the same time on WIFI networks. From the past, and lessons learned we may conclude that radio spectrum allocated for radio amateur spectrum could be used when all other means of traditional communication fails. Services that radio amateurs or Hams provide in every day and especially in critical situations [1] is crucial for critical infrastructure which is important for:

"health, safety, security or economic well-being of citizens or the effective functioning of governments" stated by [1].

This is because they provide information and technical support with communication services usually over HF radio spectrum and other services such as services that we presented in this paper: APRS-IS [2], Echolink / Svxlink [3], in cases of emergency when other means of communications does not work.

A. Rationale for position tracking using APRS-IS

Automatic Packet Reporting System (APRS) is real time radio amateur service able to transmit position reports, weather reports, and messages between users which are processed and visualized. Position reports supported by APRS or more precisely APRS-Internet Service (APRS-IS) use GPS data. One of Internet places which visualize APRS data is aprs.fi web site which updates data in real time as they are sent over Internet via nodes which are able to communicate in the same time with Internet and radio amateur nodes and networks. Because APRS position data are logged and visualized in real time APRS-IS can be used to support community in cases of emergencies [4, 5, and 6].

Using APRS-IS it is possible to achieve multiple goals [7]:

"Accurate position information about mobile & fixed stations. Tracking a mobile station. Monitoring of 'radio to radio digital text messages' on an Internet browser. Non-ham family members of a ham can track him/her and read

messages. Monitoring of real-time weather information originated from ham radio weather stations like Wind Speed, Wind Direction, Temperature, Barometric Pressure, Humidity, Rainfall etc. are available on this map with just the click of a button. Plotting of objects on the map. For example an accident site, crash site, intimation about a traffic jam for route planning, fire site, flood, cyclone, land-slide, road blockage etc. Allows important information to be exchanged without human intervention"

To use radio frequency (RF) and APRS-IS and VOIP Svxlink for testing and educational purposes, individuals and organizations have to have radio license within national associations. Each licensed radio amateur must have assigned call sign number to participate in APRS-IS. One of reasons for experimenting with APRS-IS is trend of new ham licensees issued in United States [8] and ARRL [9]. For the interest growth of RF usage, there could be reasons such as restructuring, new frequency band plan [8], [9], but available and low cost technology play important role as well. In this paper we presented low cost and available technology for sustainable APRS exploitation and infrastructure scalable for future developments. All mentioned could be reasons that trend shown in Figure 1, will be followed in other parts of globe.

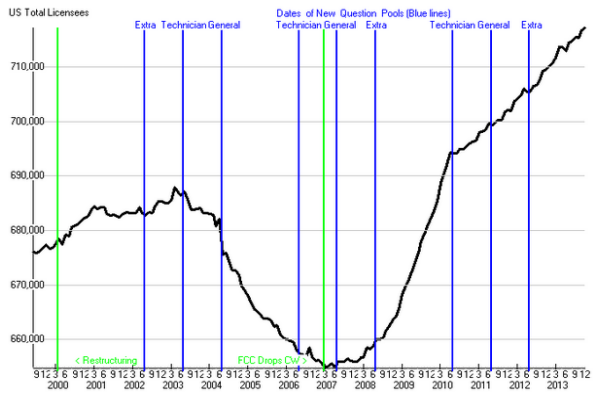

Figure 1. Steady and constant growth of new ham licensees in the US [8], [9]

Inventor of APRS is Bob Bruninga [10] in 1980's, and this system in that time was called Connectionless Emergency Traffic System (CETS) and was developed for National Disaster Medical System [11]. In the 1990's there were no available geographical maps like today's google maps, and maps have to be drawn manually. These maps were able to support smaller geographical areas compared with today's available mapping mechanisms which can span whole world. Today's technology allows usage of APRS-IS to transfer locally collected data, or local data collection point via TCP/IP using UDP, TCP, or HTTP directly to APRS-IS, or indirectly via RF and APRS Internet gateways [12] which is our choice since it eliminates need of operational GSM / GPRS or other network that would support TCP/IP communication between collection point and IGates [13]. An IGate [13] is a gateway APRS station. The IGate's task is to allow packets to cross from the local RF network to the APRS-IS as it is shown in Figure 2 where we presented our test bed infrastructure. APRS-IS is used as infrastructure to map location using commercially available radio APRS-IS is technology which brings different technological and open source advances at one place such as Linux operating system and applications which supports APRS-IS, TCP/IP infrastructure, low cost microcomputer hardware. One of indicators of how APRS-IS is used, can be seen at the aprs.fi web site. Referenced web APRS site is home for different information such as sensor readings, weather station reports. Different sensors can be used to collect data which might be crucial for early warnings on flood, fire, mudslides, and other potential nature disasters. These sensors can deliver information directly to Internet or as backup option via hamnet [14,15] network for rising alarms allowing proactive actions by those potentially affected and to rescuers. In recent years low cost and energy efficient microcomputer devices such as Raspberry Pi (RPi) [16] microcomputer became available which are suitable for education purposes [17, 18, 19, 20] which we used in our project to establish infrastructure for APRS reporting. Together with RPi it is possible to use software (in our case open source software) called software defined radio (SDR). The SDR Forum, in collaboration with the Institute of Electrical and Electronic Engineers (IEEE) P1900.1 group defined SDR as:

"Radio in which some or all of the physical layer functions are software defined" [21]

Today there are numerous commercial SDR solutions (hardware and software) with prices in thousands of dollars. Together with SDR open source solutions such as pymultimonaprs [22] it is possible to use low cost hardware to capture analogue and digital signals and use them to process captured signals on microcomputers such as RPi and build low cost SDR solutions which can be used for APRS-IS infrastructure. Core hardware component for this solution is RTL2382U [23] chipset which is used as DVB-T tuner for reception digital signals. Functionality of this chipset to capture radio frequency range from 22 to 1100 MHz [24] this chipset functionality which can be found in USB DVB-T dongles was discovered by Antti Palosaari and other researchers [25].

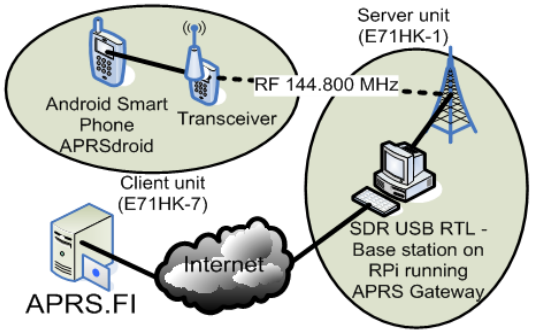

Figure 2. Infrastructure for APRS-IS

This type of infrastructure shown in Figure 2. allows location mapping and updates on APRS web site over Internet as other Internet services with difference that remote transceivers can reach transceiver base station from up to tens of kilometers (or more) when other infrastructure is not available.

B. Rationale for establishing VOIP communication using Echolink – Svxlink nodes

We saw potential of VOIP communication using open source svxlink [26] (variant of Echolink [27] software

built for linux distributions) software, in disaster relief operations. This software allows radio communication even if radio amateur does not have radio transceiver, to learn and educate other interested individuals and organizations, to test, research and to build infrastructure for other project and for potential disaster situations where radio communication was used [28] and can be used. Well educated individuals in alternative communication can play crucial role in any post disaster situation.

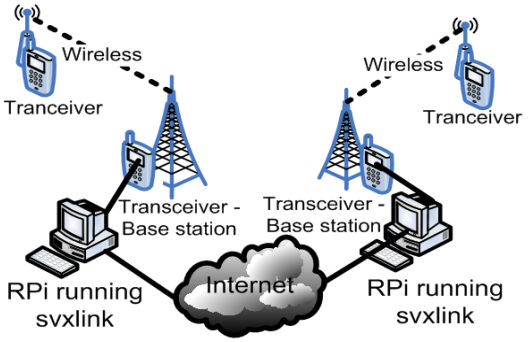

Figure 3. Infrastructure for APRS

C. *Rationale for establishing Motion video server*

Motion is open source surveillance video capturing software [29] able to capture video from one or more video cameras. Video can be monitored in real time, or pictures can be created in cases of detected motion. This is well documented software used on RPi microcomputers with RPi HD, and generic web cameras. Motion software has web based configuration management user interface and by accessing different ports to RPi with installed Motion it is possible to access live streaming or manage Motion software. Here motion is used to capture movement in near proximity of VOIP and GPS node that will visualize area around node for which we now exact GPS location.

D. *Expected goals and outcomes from establishing APRS, Echolink and Motion using on Raspberry Pi*

First goal was to use lessons learned, to build and document study case and to propagate practical and hands-on knowledge for education purposes first to student at University of Sarajevo, Bosnia and Herzegovina than to other local and other country universities.

Secon goal was to promote idea of using and providing infrastructure such as hamnet and svxlink VOIP as open source and free to use technologies in emergency situations.

Third goal was to build initial infrastructure with two svlxlink VOIP and iGate nodes located at two sites in Sarajevo city valley. This two svlxlink VOIP iGates would be able to accept local connections and transfer data to APRS-IS (Internet). This would open possibility for test and research activities. With established infrastructure, it is possible to measure usage and frequency of pymultimonaprs [22] application usage by users. Other test and research activities are possible such as different antenna design and usage of different frequencies.

E. *Design of experiment issues and scenario description*

As a practical part of this paper, our aim was to carry out performance measurements of number connections changing input radio frequencies. According to the theory design of experiment (DOE) [30] we deliberately change variables such as hardware components (transceivers), smart phones, antennas, configuration options for communication with svxlink [3], pymultimonaprs [22] and aprsdroid [31], Motion [32] applications.

III. Required Software and Hardware Components

For this project, different low cost versatile hardware and open source software components are needed. While software is open source hardware is needed but for which budget is less than 170 Euros, if Internet connection exist with appropriate access device.

A. *Hardware components*

In order to setup fully functional svxlink, APRS, and video capturing node there is need for hardware components plus cables, connectors stated below:

1. Microcomputer, Raspberry Pi B with following hardware specifications [16]:
   - Processor (CPU): ARM1176JZF-S (700 MHz)
   - Memory (RAM): 512 MB
   - Graphic processor (GPU): Broadcom VideoCore IV
   - System-on-Chip (SoC): Broadcom BCM2835
   - Communication: 1 × Ethernet 10/100 Mbps, 2 × USB, Audio-Out,
   - HDMI
2. Power: Micro-USB, ca. 300…700 mA
3. SD memory card minimum 2GB, and minimum class6, supported SD cards can be found on this link [33].
4. USB RTL DVB-T dongle
5. PMR or radio amateur transceiver such as Baofeng UV-5RE, 1 / 5 W, output [34].
6. USB hub with external power supply
7. USB Web camera or RPi HD camera
8. Smartphone with suitable Android OS

For initial system setup it is good to have USB Keyboard, monitor and HDMI / VGA convertor if needed because Raspberry Pi has only HDMI connector and not a VGA connector that most monitors are equipped with.

B. *Software components*

Five software components are needed for installing local APRS infrastructure are available on referenced web sites Raspbian Debian (Wheezy) distribution [34], pymultimonaprs [22], svxlink [3], Motion [32], and aprsdroid [31].

C. *Budget estimation*

As stated above budget for hardware is less than 170 Euros and software is open source solution, and hardware is only expense of this project.

TABLE 1. HARDWARE COMPONENTS PRICE LIST

Hardware component	**Price in Euros**
Raspberry Pi model B	32,50
HDMI / VGA converter	20
SD memory card	8
Baofeng transceiver	30
USB DVB-T dongle with RTL 2832U chipset	40
USB hub wit power supply	20
WEB camera	10
Cables an connectors	5
TOTAL	**165,50**

IV. INTERNET, PHYSICAL CONNECTIONS, AND RADIO INTERFACES

Prerequisites for establishment pymultimonaprs, and svxlink node are to have Internet connection.

A. *Internet connection*

There is no need for special port forwarding on firewall for pymultimonaprs [22] to operate and send GPS and other APRS data to APRS-IS. On the other hand Svxlink requires that router or firewall allow inbound and outbound UDP to ports 5198 and 5199, and outbound TCP to port 5200. Router has to be configured to "forward" UDP ports 5198 and 5199 to the Raspberry Pi on which svxlink is running [34]. For Motion software to be able to provide online capturing there is need to enable to port forwarding for port 8081 which is default port for Motion video broadcasting. There is no hardware requirements other then web camera has to be connected to RPi via powered USB hub.

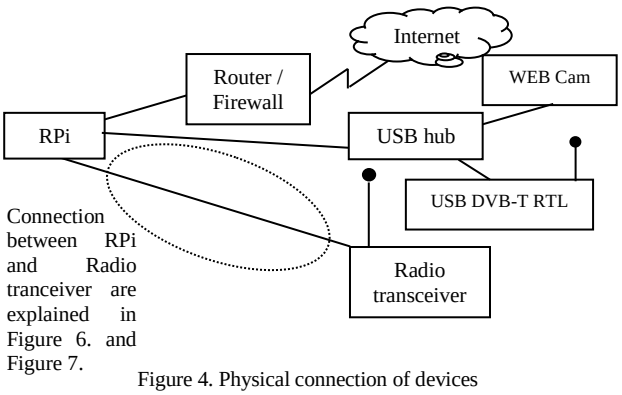

Figure 4. Physical connection of devices

Above-mentioned hardware has to be physically connected so that RPi is connected to router or firewall directly through UTP cable or via WIFI to switch or other communication device as it is shown in figure below.

B. *Physical connections for APRS*

SDR DVB-T RTL receiver which has task to receive GPS data over radio to be cone connecter to RPi via USB hub.

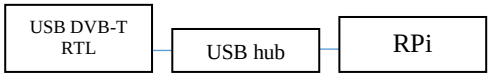

Figure 5. Block scheme of server side

C. *Audio physical connections for Svxlink*

RPi and radio transceiver have to be connected through audio cables, appropriate connectors, and using electronic components specified in Figure 7.

Kenwood, Wouxun, Baofeng [34] transceivers have same headset pin outs, and in Figure 6. is shown our connection scheme setting for mentioned types of devices.

In Figure 7. is shown scheme for Yaesu or Baofeng transceivers (jumper selection) for which sources [36, 37] were used as reference points. Idea for testing below described two options is to prove feasibility of using first and cheaper option for which only two condensers, cables and connectors were used.

D. *Phisical audio connection using VOX transceiver functionality*

For this option, transceiver has to be configured to use VOX option which is functionality to initiate transmission once it is recognized that sound (voice) is coming to microphone what simulates push to talk (PTT) button.

For this particular implementation voice is coming from USB sound card what has to be recognized as request for transmission. For this particular implementation only two condenser of 5 µF where used and appropriate audio connectors and conductors.

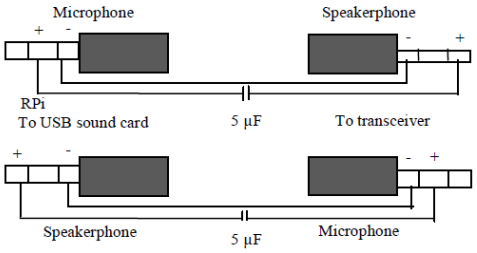

Figure 6. Physical connection of headset pin outs

E. *Phisical audio connection using USB/serial cable*

For this option, transceiver has to be used with USB conversion cable into serial cable which is used to capture voice and simulate PTT button via CNY17 photocoupler with appropriate audio transformers, connectors and conductors which is built based on [36, 37] options for Yaesu and Baofeng transceivers. Implementation is performed so that manual jumpers (JP) exists which can be used to choose different transceiver option (Yaesu or Baofeng) selection.

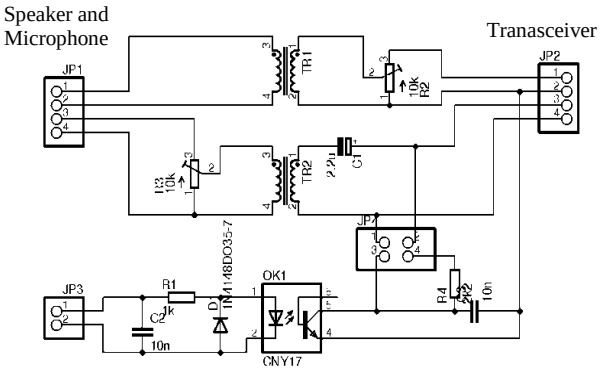

Figure 7. Physical connection of headset pinouts with USB / serial cable

V. BRIEF SETUP AND OPERATION INSTRUCTIONS

In order to operate pymultimonaprs [21], svxlink [3], Motion [32], node with Rasbian operating system it is important to install, configure and run it as defined in manual web pages referenced below.

A. *Setup instructions*

Installation image of operating system on RPi is described on web site [36]. For initial Raspbian Debian (Wheezy) implementation on RPi it is advisable to use Win32 Disk Imager [40] to install Raspbian Debian (Wheezy) operating system into SD card from PC which has SD card drive. To prepare Raspbian Debian (Wheezy) distribution for pymultimonaprs [21], svxlink [3], and Motion [32] installation and to install pymultimonaprs it is advisable use these installation procedures: for pymultimonaprs [41, 42], for svxlink [43], and Motion [44].

B. *Operation instructions*

After successful installation of pymultimonaprs, application can be started by executing command pymultimonaprs, or it can be configured to be started after each reboot by configuring /etc/rc.local file.

To start svxlink as a daemon command svxlink –daemon shall be executed and to start it at console is possible by typing command svxlink.

To start Motion application as daemon command `service motion start` shall be executed.

VI. APRS, MOTION, SVXLINK DATA AVAILABILITY AND OPERATION RESULTS

To enable APRS update information changes (received / transmitted packets, load, and possible other statistics and information) which are updated on web site www.aprs.fi in real time as it is shown in Figure 8. And Figure 9. This APRS online view can be used as a dashboard for monitoring activities for specific node or group of nodes and to monitor their available telemetry readings.

Figure 8. APRS shows two iGate nodes in Sarajevo valley

In Figure 9. are shown tracking results from aprsdroid application sent from smartphone via transceiver to APRS IGate.

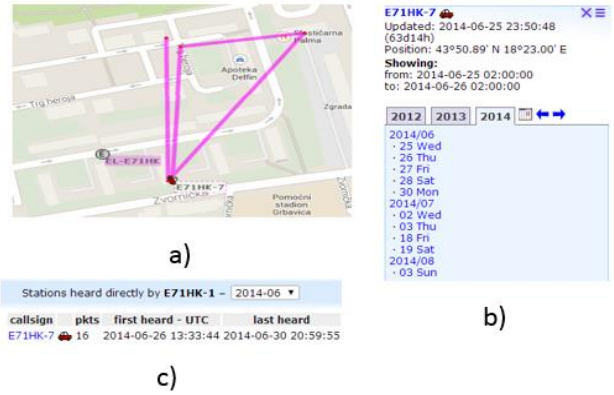

Figure 9. APRS information for E71HK (call sign of the first author of this paper) and neighboring stations

It is possible to APRS activities such as distance for specific date, using aprs.fi web site as it is shown in Figure 10.

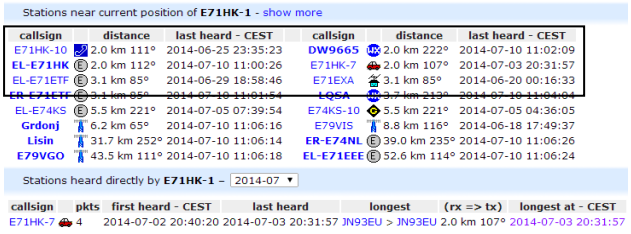

Figure 10. APRS information for E71HK and neighboring stations

It is possible to monitor traffic load on svxlink node in Erlangs for different period of time such as daily, weekly, monthly, and annually as it is shown in Figure 11. ER-E71ETF svxlink node which is node located at the Faculty of Electrical Engineering, University of Sarajevo. This node works as local repeater.

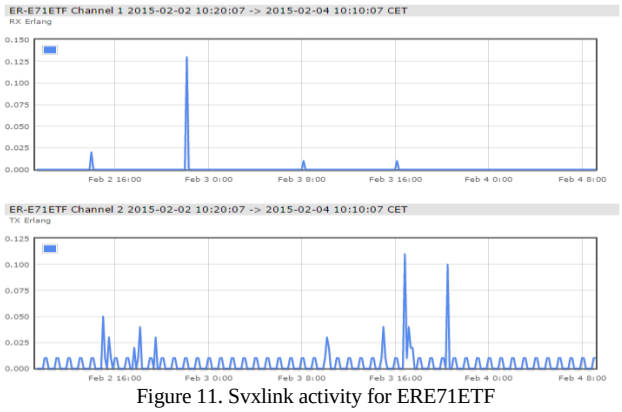

Figure 11. Svxlink activity for ERE71ETF

VII. CONCLUSIONS

From the preliminary results we may conclude that goals are reached because low cost infrastructure for education purposes and for disaster relief situations is built. This infrastructure is able to carry VOIP, reports APRS data and broadcast video with support of Internet or hamnet using low energy consumption hardware such as RPi. It is clear by APRS reports that number of radio amateurs were connected to already established svxlink (Echolink) nodes and initial awareness in local community

is reached by involving new radio amateur licensees (30 new radio amateur licenses for students of University of Sarajevo were issued during education process and during process of writing this paper), and involving other educational institutions to participate in radio amateur activities supported by University such as initial building hamnet infrastructure which is another project in progress and new svxlink nodes across Bosnia and Herzegovina what can be monitored in real time over aprs.fi web site.

Evaluation of Software Defined Radio Systems for Smart Home Environments

I. Vitas, D. Šimunić, P. Knežević

Faculty of Electrical Engineering and Computing, University of Zagreb, Zagreb, Croatia
igor.vitas@fer.hr

Abstract – Software Defined Radio systems are predicted to be radio access networks of next generation in all kind of wireless communications systems. Their use is not limited to radio front end that is first chosen for system operation. They can be upgraded by time as system needs changes or evolves which gives them radio front end flexibility never seen before in radio systems. Smart home environments such as eWALL system and other uses numerous of wireless technologies to control lot of appliances in them or to monitor specific health state of the people living there etc. Therefore, lot of wireless technologies have been developed solely for that purpose, leaders among them are ZigBee and Z-Wave technologies which are today standard for wireless home automation systems that are energy efficient and secure. Software Defined Radio is certainly very useful for future mobile communication systems. In this work Software Defined Radio system will be evaluated with a purpose of introducing local radio networks that are used in smart home environments based of Software Defined Radios. Benefits and shortcomings of using Software Defined Radio in this systems will be shown and evaluated.

Keywords **–** Software Defined Radio, smart home environments, local area networks, ambient assisted living, smart living, ubiquitous computing

1. INTRODUCTION

Software Defined Radio (SDR) is enabling technology for future wireless communication systems. Software Defined Radios are used today primary for research purposes but devices that will have the same or similar functionalities as Software Defined Radios will be used for future wireless communication systems. Re-configurability and re-programmability are key aspect of this kind of wireless communication systems. All technical systems that are made to be reconfigurable and reprogrammable are showing good perspective in future high-tech systems, such as Field Programmable Gate Array (FPGA) devices that are also key components of modern Software Defined Radio architecture.

Ambient assisted living (AAL) is one the focuses of modern European community as trends in last years show increase in population that is aged over 65 years. In year 2035 there will be 1/3 of the people that are older than 65 years and 1/9 of people that are older than 85 years.

Ambient assisted living is a wide term because it implies many research fields such as:

- Smart home environments
- Ambient intelligence
- Context aware computing
- Multi agent systems
- Robotics
- Internet of Things
- Wireless Sensor Networks
- Artifical Intelligence
- Human to Computer Interaction

As it is related to many research areas Ambient assisted living is also related to social economic trends in European countries. European union is community of different member states but its laws and economic practices in field of healthcare can still vary from state to state. There is a same challenge in development of AAL system both on technological and socio-economic level. This trend can also be seen in field of assisted living for elderly people. For example elderly people from Sweden often go to elderly residence in the south of Spain where residence for elderly people is cheaper and weather is warm. There is more than 5000 nursing homes in Spain and they are mostly private owned. For people who are staying in Sweden when they are in elderly age there are senior housing facilities which can be adapted to senior wishes regarding domotics, health care support and Ambient assisted living in general. Denmark is known for do-it-yourself retirement community because there groups of friends or like-minded people develop their own villages or apartments for living at elderly age. In every country pension schemes are different in amount of money that seniors receive per month as well in amount in healthcare support and other benefits in general for seniors that can be state financed. Technological trends in Ambient assisted living must conform to newest trends from medicine, economy, law and psychology. Developing of Ambient assisted living system that will be useful, affordable and admissible in all the EU is therefore complex task [1]. eWALL is Ambient assisted living system that is being developed by consortium financed by EU FP-7 research program. Architecture of eWALL system is shown on Figure 1.

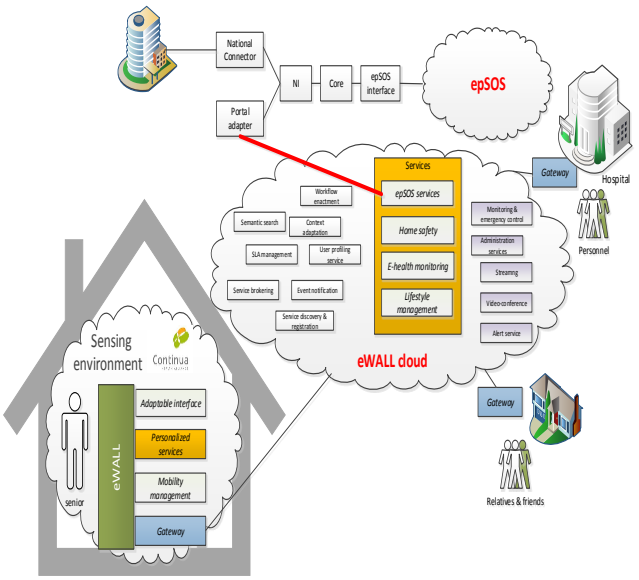

Figure 1 Architecture of eWALL - ICT system for AAL living.

Continua Health Alliance [2] announced that lifestyle management can address 60-80% of all cases, that happen to senior citizens, of unpredictable cases in the wellness and pre-illness conditions. It is obvious that the costs for the seniors and the National Departments of Health thus can be significantly reduced with introduction of AAL systems to environments in which elderly people spent most of their time. Large number of researchers and initiatives are trying to cope with the task of introducing AAL systems to everyday life of elderly people.

2. SENSOR TO GATEWAY WIRELESS CONNECTION IN SMART HOME/AAL ENVIRONMENT

Sensors are very important for AAL systems because they are producing low level metadata that is used later in AAL system for smart and intelligent reasoning. Metadata that is coming from these sensors need to be measured and transmitted safely to central gateway in AAL or smart home environment. Hardware and system level connection between sensors in smart home or AAL environment to central home gateway is given in Figure 2 and Figure 3.

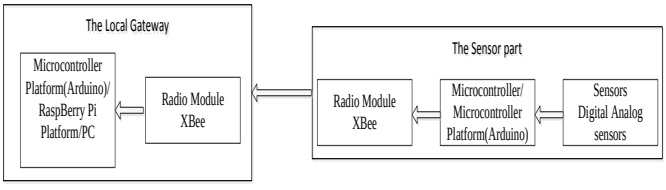

Figure 2 Possible hardware setup of sensor to gateway connection in smart home or AAL environment.

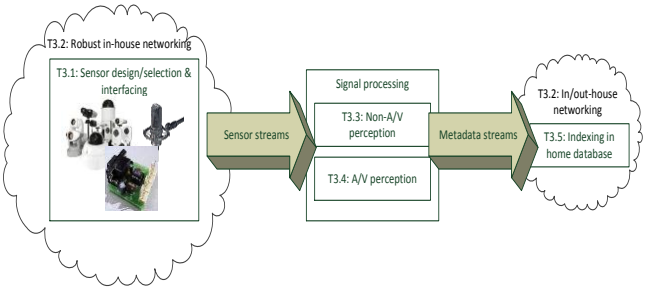

Figure 3 Sensors to gateway connection in smart home or AAL environment from system level perspective.

Connection between sensors, actuators and home gateway [3] can be done on wireless or wired way. Wireless connectivity offers freedom of nodes positioning all around the smart home/AAL space of interest but can be problematical when wireless connected sensor or actuator is on the edge that wireless signal can reach. Nevertheless this method of connecting sensors or actuators in this kind of environments is more usual than wired connections. Power Line Communications are becoming more and more represented for networking of various devices in smart home as well as in AAL environments. This market is rapidly growing because technology, primary chipsets, that enables this kind of communication are becoming more accessible and affordable. Most notable alliance of companies in field of Power Line Communications is Home Plug Alliance and CSEP – consortium for SEP2 interoperability. Vision of Home Plug Alliance connected home is shown on Figure 4.

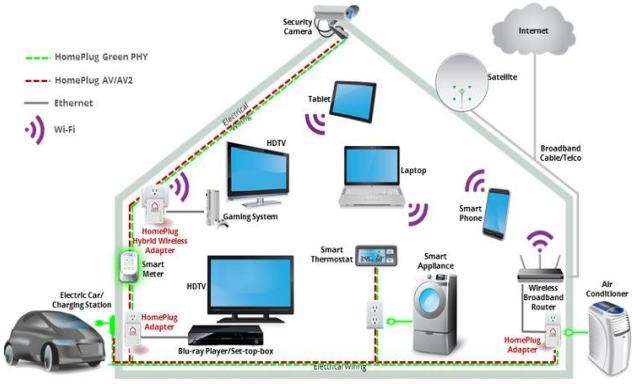

Figure 4 Home Plug Alliance vision of connected home environment.

Home Plug Alliance is committed to providing standards and set of guidelines for devices that are used for Power Line Communications. Home Plug Alliance defines Home Plug AV standard that is used to deliver an energy efficient and cost effective networking with optimized throughput for applications such as devices automation/control in smart home environment, security monitoring, energy management, device automation and all other machine to machine communications that are tolerant to communication latency. Most important standards regarding this leading Power Line Communication group are IEEE 1901 and IEEE 1905.1 standards. IEEE 1901 standard describes PHY and MAC specifications for power communication devices

across the entire spectrum of In-Home, Transport and Smart Grid applications. IEEE 1905.1 standard describes how to make benefit from using wide adopted standards including Wi-Fi (IEEE 802.11), Ethernet (IEEE 802.3), HomePlug AV (IEEE 1901) and MoCA (coaxial cables) in a software abstraction layer. With this standard it is shown how combination of wireless and wired networks can be beneficial for high performance in house networking. IEEE 1905.1 basically combines performance and reliability of wired networks with the flexibility of wireless for mobile devices. Data rates that can be offered by todays Power Line Communication devices can go up to 1 Gbps. This data rate is sufficient to support modern multimedia services in whole smart living/AAL space of interest.

CSEP, consortium for SEP2 interoperability is very interesting because it combines both wireless standards such as ZigBee, WiFi, Bluetooth and Home Plug Alliance to make devices that will conform to IEEE 2030.5 standard. This standard defines applications that enables home energy management via wired and wireless devices that support IP.

Wireless connection is still the most used way of connecting sensors and actuators in smart home/AAL environments.
Most used wireless protocols for connection with sensors and actuators are:

- Bluetooth
- WiFi
- Z-wave
- ZigBee

Some technologies such as Bluetooth Low Energy and ZigBee have found special place in smart home/ambient assisted living environments because they are part of Continua Health Alliance. Continua Health Alliance is an international non-profit organization with mission to offer end-to-end, plug-and-play connectivity of devices and services for personal healthcare. ZigBee Alliance in document [4] defines ZigBee profile for wireless networks that are used to implement wireless communication in healthcare systems. Uses cases for ZigBee networks that are dedicated for healthcare applications are divided into next categories:

1. Disease management (DM)
    - Non-critical patient monitoring (episodic)
    - Non-critical patient monitoring (continuous)
    - Patient alarm monitoring (low acuity)
    - Drug administration (e.g. insulin pumps)
2. Personal Fitness Monitoring (PFM)
    - Monitoring / tracking fitness level
    - Personalized fitness schedule
3. Personal Wellness Monitoring (PWM)
    - Activity monitoring
    - Safety Monitoring
    - Living independently

It can be seen that this applications domain suits perfectly to case studies in smart home and ambient assisted living environments that are defined by Continua Alliance.

Table 1 ZigBee, Bluetooth and Bluetooth LE technology comparison.

	ZigBee RF4CE	Bluetooth	Bluetooth LE
Network architecture	Multiple Star + mesh	Point-to-point + Pico net	Point-to-point + Pico net
# Devices supported in network	Virtually unlimited	7-16	Virtually unlimited
Frequency band	2.4 GHz	2.4 GHz	2.4 GHz
Mac/PHY specification	IEEE 802.15.4	IEEE 802.15.1	IEEE 802.15.1
Latency	<5 ms	100 ms	<10ms
Battery life	+15 years	Days	Weeks
Data rate	250 Kbit/sec	1-3 Mbit/sec	1Mbit/sec
RF Range	+50 m indoor	10 m	10 m
Security	128 bit AES	128 bit AES	128 bit AES

3. SOFTWARE DEFINED RADIO ARCHITECTURE AND ITS POSSIBLE APPLICATIONS IN SMART HOME/AAL ENVIRONMENT

Software Defined Radio is wide term that can describe various reconfigurable radio systems. Software Defined Radio system is often associated with term cognitive radio that is just one, but most widespread, field of research around Software Defined Radio architecture and its applications. Software Defined Radio concept was introduced in 1999 by Joseph Mitola [5]. In this work Joseph Mitola explained the vision about reconfigurable and software components in radio front end communication chain. Goal was to make framework for reconfigurable wireless architecture so one radio device can work within multiple wireless communication systems. Most used Software Defined Radio system today is Universal Software Radio Peripheral (USRP) system firstly build by company Ettus Research which was then acquired by National Instrument. System design of USRP Software Defined Radio system is given on Figure 5.

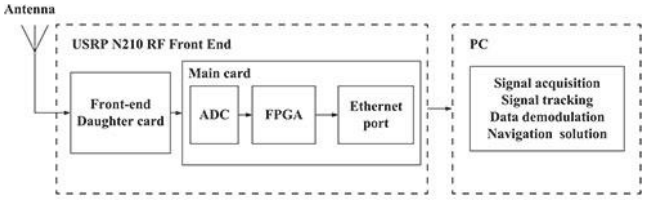

Figure 5 Architecture of NI USRP Software Defined Radio system.

One o of the key characteristics of USRP platform is radio frequency signal down and up conversion before ADC/DAC converters and Field Programmable Gate Array (FPGA) platform behind converters in radio front end chain. Field Programmable Gate Array (FPGA) platform is used for down converting sampled digital IF signal to digital baseband signal. After digital down conversion the signal is passed through digital filters and then sent to PC via USB 2.0 connection for further data demodulation. Similar thing is happening in transmit direction with difference of performing digital up conversion to digital IF signal instead of down conversion.

Front-end Daughter cards of USRP platform are used for implementation of radio front end circuits from antenna to the digital part of SDR system. The cards are offered in wide radio frequency bands from 10 MHz to 6 GHz so they can be

used for emulation of almost any radio frequency wireless communication system that is used today. There are numerous of projects conducted by university research groups and technological companies in which SDR USRP platform is used for emulation of modern high end wireless base station systems such as LTE, GSM, IEEE 802.11, IEEE 802.15.4. etc. All projects are implementing base stations using USRP platform in combination with PC. It is shown that all the issues that arise in this kind of wireless communication system implementation can be solved by modifying hardware or the software part of the system. Most of the systems are programmed using GNU Radio framework for USRP Software Defined Radio programming. One device can theoretically be used for implementation of different radio communication protocols with just change of the software. There are also applications of Software Defined Radio systems that are used for purposes such as radio astronomy [6].

Architectures of smart home environments, especially ambient assisted living environments rely on complex ontologies that define ambient assisted living environment architecture from data models point of view [7]. Ontologies aim to add semantics, i.e. meaning, to information to allow for reasoning over the data to derive further knowledge. Further reasoning in smart home environment can be implemented on a central home computer [8] and can also include ontologies for deployed sensor networks. In the past few years there has been work in order to define ontologies for sensors and sensor networks. As a result a number of ontologies have been defined that serve different purposes, applications and domains. Ontology that is developed by W3C consortium for sensor networks can be seen in Figure 6. This field of research is especially important for addressing future Internet of Things systems that will deliver a lot of data from different sensor sources in near future.

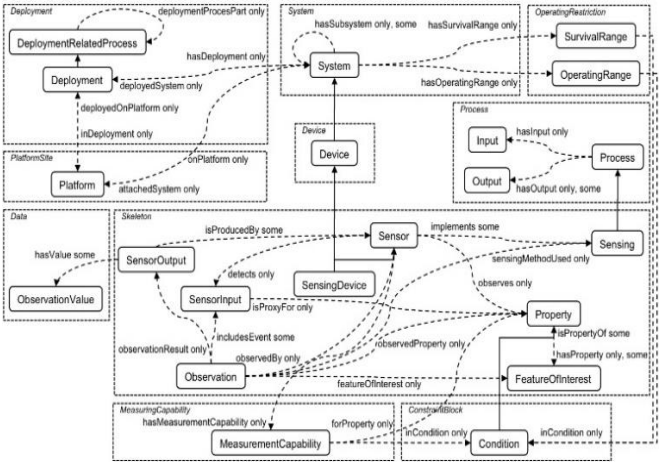

Figure 6 Ontology of W3C semantic sensor network.

Software Defined Radio can be used as a wireless hub in smart home/ambient assisted living environments to support unification of wireless links used in environment of that kind through one device. One Software Defined Radio system device can be used to control various wireless controlled domotic systems as well as other wireless multimedia systems that are used in environment. Wireless controlled domotic systems are usually not working full time so their reduced duty cycle is ideal for using one Software Defined Radio system device to control lot of wireless devices that can be supporting different wireless protocols on different frequencies made by different electronic equipment manufacturers.

4. CONCLUSION

In this work concept of smart home environments and ambient assisted living environments was presented through various methods and technologies that are used for wireless and wired connectivity in them. This connectivity is used for different purposes from controlling of home automation systems to streaming of multimedia data to user devices such as smartphones or tablets. Key aspects of current standards and technologies in this field is shown and concept of Software Defined Radio system as a general purpose wireless hub for controlling all wireless related device in smart home/ambient assisted living environment is given. In future work concept of controlling devices that utilize different wireless communication protocols with one Software Defined Radio will be implemented using National Instruments USRP radio platform.

Smartwatch as a Remote Server Monitoring Device: Implementation and Interaction Design

Armando Vega and Sandi Ljubic
University of Rijeka, Faculty of Engineering, Rijeka, Croatia
armando.vega@riteh.hr, sandi.ljubic@riteh.hr

Abstract - Present day computer ecosystem offers advanced connectivity of numerous devices, systems and services, providing the basis for the Internet of Things paradigm implementation. What most people perceive of its structure often lacks acknowledgement of the smallest parts of it, albeit as of recently the most used ones, namely smartphones and smartwatches. Being recognized as a prominent member of the wearable/ubiquitous computing family, smartwatches have been gaining in popularity proving themselves valuable in various contexts, ranging from providing fitness applications and general health monitoring, to always-on assistive technology for people with special needs. This paper focuses on an alternative approach to using smartwatches, considering them monitoring tools for system and network administrators able to provide fast and readily available information on various network equipment and services. For this purpose a proof-of-concept application suite was built, used to provide the status of important services on a remote Linux-based server, as well as the status of the server system itself. We show how smartwatches can offer different, and some unique, previously considered impractical ways to convey information. Supporting HCI aspects are specifically discussed, with respect to the Pebble smartwatch basic I/O capabilities limited to four hardware buttons and 1.26" monochromatic display.

I. INTRODUCTION

Recent advances in miniaturization and diminishing costs in battery, processor, sensor, and communication technologies are now enabling smartwatches to move from the specialist market to the mainstream [1]. Most of known smartwatch design efforts have seen them built by companies as wearable companions to their customary products, namely various smartphones and tablets. This made them dependent on existing same-manufacturer equipment, and usually limited in capabilities to conform to their counterparts. The smartwatch products sported custom OEM operating systems, proprietary interconnection interfaces and development processes tailored to a particular device or a specific generation of devices. The challenges of such vertically integrated design needed to be overcome for the smartwatch application development ecosystem to strive.

The Pebble watch, developed in 2012 as a result of one of the most successful campaigns in the history of crowd funding at the time, can be considered the first fully independent smartwatch [1]. It is very much still a device with a custom tailored operating system, however, it provides the developers with an easy to use SDK and open application programming interfaces, thus enabling easy integration and communication with most popular mobile operating systems running on present day smartphones and tablets.

Regarding the practical advantages of a device that is worn directly on the skin, various different approaches to interaction with target applications can be considered. Most current day applications are implemented leveraging the various built-in sensors, which provide information about user's movement and position in space. A plethora of existing mHealth applications provide general health and fitness monitoring and advisement, as well as remote tracking of said information, by making use of the paired devices' connectivity capabilities.

Such a device itself does not come without limitations, observed mostly in the relatively modest computing capabilities and a small screen size, as well as a seemingly small number of ways to interact with it. This provides both developers and researchers with certain challenges when it comes to design of applications for the platform, that need to be met with general usability guidelines in mind. Considering the device and its current application ecosystem, we decided to apply ourselves to research the possibilities of interaction, extending it by using sensor data in addition to buttons for input, and haptic feedback in addition to using the display for visual representation of information.

II. RELATED WORK AND MOTIVATION

Considering the focus of our work, related research efforts from the smartwatch domain can be divided into two main categories: (i) smartwatch application context of use, and (ii) interaction design for smartwatch devices. While context of use studies usually highlight the utility of particular smartwatch application in a given surroundings, HCI-oriented research specifically investigates ways of interacting with such a small wrist-worn device.

Smartwatches usually play a role of Bluetooth-tethered peripheral interfaces for smartphone devices, supporting common tasks such as message and phone call notifications checking [2]. As their onboard computational power, networking, and displays become more enhanced, game-based entertainment starts to be popular in this small form factor domain as well. Moreover, most modern smartwatch devices come with integrated motion sensors (e.g. accelerometer and magnetometer), which enables

physical activity recognition through analysis and classification of wrist movement patterns [3][4]. Accordingly, there exists an emerging trend in providing advanced smartwatch applications for fitness tracking and general health monitoring. Android Wear [5], Google's Android-based platform designed for smartwatches and other wearables, involves features such as step counting and heart rate monitoring, as well as GPS-based tracking of walking/running/cycling distance and speed. Smartwatches are also recognized as valuable tools within always-on assistive technology, since they can provide help for elderly people (e.g. in fall detection scenarios) and for users with special needs (e.g. people with visual impairments [6]). Additionally, implementations for general navigation within geo-map-oriented applications [7] and turn-by-turn traffic-based navigation are also available. Indeed, since the introduction of the first watch running a full operating system [8], smartwatch devices and related applications are being constantly improved, demonstrating usefulness in various contexts of use.

When it comes to the HCI aspects of smartwatches, we can straightforwardly claim that the form factor restricts both input and output capabilities. The predominant input methods in this domain still rely on physical buttons and touchscreens (where available). Since watches lack the surface area needed for numerous hardware switches, traditional keypad concept is upfront abandoned, thus making designs with just a few physical buttons a preferred option. However, as is the case with smartphones, text entry can be successfully performed using smartwatches, either by making use of touchscreen-based soft keyboards with specific character layouts [9], or by utilizing advanced skin-based and around-device interaction techniques [10]. Touchscreen displays are incorporated in today brands' flagship products (e.g. Samsung Gear S with a curved screen; Motorola Moto 360 with a circle-shaped display), with *tap*, *long press*, and *swipe* being the main interaction modalities for usual tasks such as pointing, selecting, and scrolling. Nevertheless, handling such small displays (less than 2") using direct touch imposes an interaction burden which can be attributed to the well known fat finger problem. Sensor-based interaction represents an additional benefit in smartwatch usage, since 3D mid-air gestures can be used, beside activity recognition, for application interface control as well. Various interaction sets can be derived in order to digitally augment commonly used gestures, as shown in the *Office Smartwatch* application [11], wherein knock, lock, and return gestures are implemented and afterwards used for controlling the office environment. Smartwatch input control, however, can be further empowered by using the watch face itself as a multi-degree-of-freedom mechanical interface. Although such a product cannot be found in the market, a proof of concept smartwatch that supports continuous 2D panning and twist, as well as binary tilt and click is already provided [12]. Finally, contemporary smartwatch devices have voice recognition enabled, thus providing the possibility to control various services with voice commands. Android Wear platform supports making voice memos and reminders, using voice web search, as well as voice control of navigation and multimedia streaming. From the output capabilities standpoint, smartwatches usually rely only on display technology (for presenting visual information), and acoustic/vibrotactile feedback (for invoking notifications).

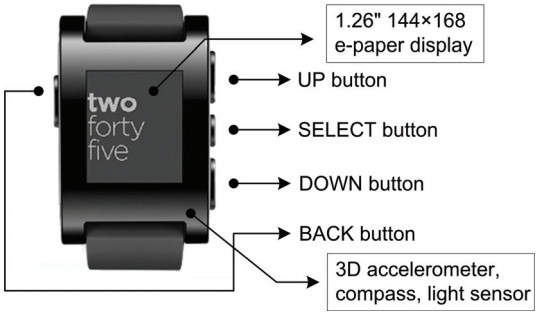

Figure 1. The front face of the Pebble smartwatch used in our proof-of-concept solution

Our proof-of-concept application suite contributes to an ubiquitous computing ecosystem by providing computer network administrators a wearable monitoring tool in a form of a dedicated smartwatch application. To the best of our knowledge, there exists no reported work regarding this specific context of smartwach usage. In addition, we show how good interaction design, involving multimodal operations and feedback control, can overcome rather limited I/O capabilities of the used smartwatch device. Namely, our application, intended to be run on the non-touchscreen-enabled Pebble smartwatch (Fig. 1), can be controlled with built-in hardware buttons, as well as with wrist movements only – using tilt and shake gestures. Incoming notifications are also presented in a multimodal way: along with visual information on the smartwatch display, various vibrating patterns are used as context-specific feedback. Consequently, the proposed design allows both touch-based and touchless interaction, as well as application handling without the explicit need for visual attention.

III. Application Suite Implementation

The design and implementation of the TOSS (*Timely Overview of Server Status*) application suite is divided into several parts (as shown in Fig. 2), consisting of the: (i) backend server-side application, (ii) Android-based intermediary service, and (iii) the Pebble smartwatch frontend application itself. A parallel can easily be drawn with the classic MVC (*Model-View-Controller*) software architectural pattern [13], as the respective design conforms to the exact pattern in all of its elements.

The server-side application, conforming to the *Model* part of the architectural pattern, manages the collection and provision of data for the suite. The intermediary Android-based service, related to the *Controller* part of the architectural pattern, in turn takes the data provided by the *Model* (the server-side application), reformats it according to the needs of the *View*, and leverages push-style communication to deliver data to the *View*. Finally, the Pebble smartwatch application, reflecting the *View* part of the architectural pattern, provides the user interface which conveys the information provided by the *Controller* part of the suite (the Android-based intermediary service).

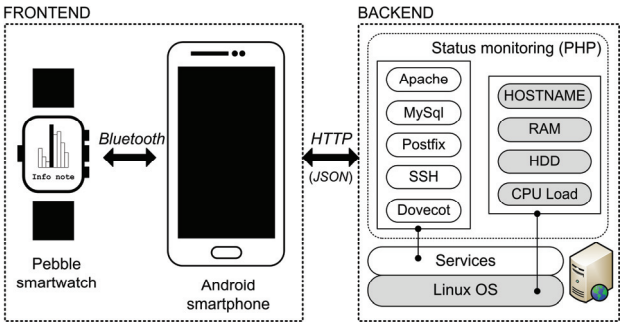

Figure 2. TOSS application suite design schematic

As each of the aforementioned elements required a completely different implementation approach, the design and implementation details of every system component will be further discussed separately.

A. Server-side monitoring application

The server-side monitoring application is implemented using an existing HTTP serving application (e.g. Apache HTTP Server) that supports execution of the PHP server-side scripting language. The application itself is written using PHP, and is built as a modular entity capable of dynamically loading supplementary modules which in turn provide additional data to the system. Each module is responsible for a single data point. The data retrieval part of a single module can have different means of getting the required data. However, all modules make use of a common interface for communication with the central data collection component. Provided data format is based on key-value pairs, consisting of the data identifier (e.g. mail service process name, system property name) and the data pertaining to the mentioned feature (e.g. service or system property status).

For the purposes of our proof-of-concept application suite, the server-side modules have been built to provide data on the different properties of a server running a GNU/Linux operating system and services most commonly found in the corresponding environment. As such, they are not in and of themselves portable to other platforms, as they leverage standard GNU/Linux interfaces for acquiring system and process information. However, since data collection modules can have different means of implementation, new modules can be built that would interact with other operating systems and platforms. Table I presents the list of available server-side modules, including a short description of the data they provide.

TABLE I. AVAILABLE SERVER-SIDE MODULES PROVIDED IN THE APPLICATION SUITE

Module name	Description (data provided)
mod_apache	Running status of the Apache HTTP Server service
mod_disk_usage	Disk usage percentages for all currently mounted volumes
mod_dovecot	Running status of the Dovecot MDA (*Mail Delivery Agent*)
mod_hostname	Configured hostname of the serving machine
mod_mysql	Running status of the MySQL database server
mod_postfix	Running status of the Postfix MTA (*Mail Transfer Agent*)
mod_ram_usage	Amounts of total and used system RAM
mod_ssh	Running status of the OpenSSH secure remote access server
mod_system_load	Load averages of the system's CPU for the last 1 minute, last 5 minutes and the last 15 minutes

```
{   "apache":"OK",
    "disk_usage":
    {   "rootfs":"6%",
    "/dev/root":"6%",
    "devtmpfs":"0%",
    "tmpfs":"0%"
    },
    "dovecot":"OK",
    "hostname":"isis",
    "mysql":"OK",
    "postfix":"OK",
    "ram_usage":
    {   "Used":"248",
    "Total":"989",
    },
    "ssh":"OK",
    "system_load":
    {   "1min":"0.00",
    "5min":"0.01",
    "15min":"0.05",
    }
}
```

Figure 3. Example of server-side generated JSON formatted data

The central server-side application, encompassing all the built-in modules, is itself completely platform independent, requiring only a PHP-interpreting capable HTTP server application. The collected data is provided to the client over a HTTP or ideally over a secured HTTPS connection, depending on the server configuration. Data transfer utilizes a JSON (*JavaScript Object Notation*) formatted text (Fig. 3) – the format supported in commonly used programming languages which usually provide readily available JSON parsing functions.

B. Android intermediary service

The intermediary service for the Android mobile operating system, used to collect the server-side generated information and push it to the Pebble smartwatch application, is implemented following a recommended approach by making use of the *SyncAdapter* framework [14]. As opposed to a simple *Activity* or *Service* application component, a *SyncAdapter* is handled in a special way on an Android operating system. This framework is specifically designed for tasks scheduled to repetitively run at specified time intervals. It provides, among other things, automated network status checking – that pauses execution until a network connection becomes available, and automated queuing of different (concurrently scheduled) sync adapters – which in turn provides improved battery performance. Moreover, *SyncAdapter* nicely incorporates into the standard Android accounts manager, enabling easy access to out-of-schedule manual invocation, as well as disabling/enabling its function altogether. The pluggable architecture of the framework allows for easy execution of callable components, thus providing us a possibility to easily implement the needed communication procedures. The officially provided PebbleKit Android Java library was

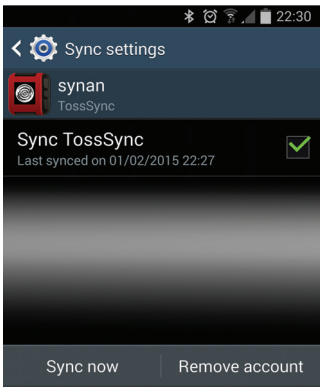

Figure 4. *SyncAdapter* component integrated into the Android OS

used for establishing Bluetooth communication with the Pebble smartwatch.

The Android intermediary service which incorporates our sync adapter, called *TossSync* (Fig. 4), is configured to synchronize with the server-side application at a specified time interval. Given the nature of system administration work, in our pilot testing sessions we found the most reasonable time interval (for such a fast response requiring purpose) to be 1 minute. Such a short interval of recurring data retrieval should provide a system administrator with a timely information that can quickly be responded to. Once new data is received on the Android smartphone, the JSON format is parsed and converted into a simpler key-value format counterpart appropriate for the Pebble communications API. Key-value pairs are then pushed over Bluetooth to the Pebble smartwatch OS, which in turn delivers the data to the target application. The Android component of the suite stores the latest received information from the server, and invokes the data push to the Pebble smartwatch only when some status change has been detected. The idea behind this is to improve battery performance on both the Android device and the smartwatch.

C. *Pebble smartwatch application*

The application running on the Pebble smartwatch, named *PebbleToss*, is used to convey information to the user wearing it by visual and haptic feedback. The application was implemented using the C programming language, leveraging the officially provided Pebble SDK for gathering available sensor information, button press handling and establishing Bluetooth communication with the Android intermediary service running on the paired smartphone.

Given the embedded nature of the smartwatch device, there were a few challenges that needed to be overcome during both the design and implementation phases of development. One notable characteristic is the previously mentioned small 1.26" screen, providing a viewable area of only 144×168 pixels with 1-bit black and white graphics. This constraint was especially important during the design phase, as it provided hard limits on the ways of conveying the needed information. Another challenge came in the form of computing capabilities, as the smartwatch provides only 128KB of RAM, of which only 24KB is available to applications, the rest being used for the function of the operating system itself. It was therefore important to make the application as efficient as possible with regards to memory usage.

The application's user interface consists of several parts, notably the main application window (MW) and the service status window (SSW), example snapshots of which can be seen in Fig. 5. Each window was specially designed given what it would be used for, combining both graphics and text to provide the needed information.

The main window can visually be separated into four sections, split horizontally. The topmost section displays the name of the server that is currently being monitored, taken as the defined hostname provided in the server-side generated data. The following section is the only part that doesn't depend on the data provided from the outside, as it displays the current day of the week, date and time. As seen on the example snapshots in Fig. 5, the part of this section displaying time has inverted colors with regards to the rest of the screen (white text on a black background), as it is considered most used and should easily be distinguished from the rest of the information given only a quick glance. The subsequent display section shows status of server system memory (RAM) usage, as well as used file system space (HDD). It combines graphics and text, providing graphical representation of the ratio of used and available resources. The information is shown using bar charts, with identifiers on each side of the chart specifying to what each bar corresponds to. This provides easily understandable and universal feedback that does not depend on the actual units used in each of the server properties. Finally, the bottommost section of the main window displays the system CPU load information, using the standard format of showing the load average for the past 1 minute, past 5 minutes and the past 15 minutes.

The service status window is used to display current status information on selected system services. This

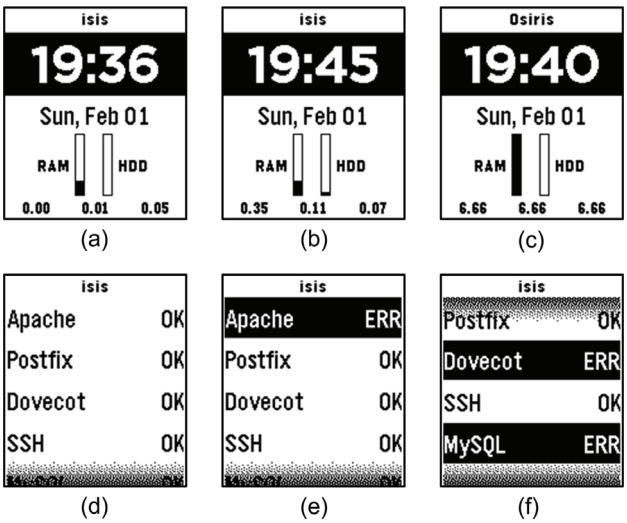

Figure 5. Smartwatch application snapshots. (a) MW (no vibrating alert): RAM and HDD are OK, system load is recently decreasing (5%→1%→0%); (b) MW (no vibrating alert): RAM and HDD are OK, system load is recently increasing (7%→11%→35%); (c) MW (vibrating alert - RAM pattern): Out-of-memory issue, system load is recently stagnating at 6.66%; (d) SSW (no vibrating alert): all services are OK; (e) SSW (vibrating alert - Apache pattern): www issue; (f) SSW (vibrating alert - Dovecot pattern followed by the MySQL pattern): email issue and database issue.

window is visually separated into two sections. The topmost section contains the name of the server that is currently being monitored, corresponding to the topmost section of the main window, providing UI consistency. The second section contains a scrollable list of selected system services and their last known status. As can be seen in Fig. 5, a service that has a status considered without problems shows the corresponding "OK" message, while services with reported problems have their status shown as "ERR" and are additionally highlighted (inverting the colors of the text and the background) providing easier discernment.

IV. INTERACTION DESIGN

In the smartwatch application development process, we put a special emphasis on simplifying both the user interface and related interaction, by taking advantage of Nielsen's usability heuristics [15]. Specifically, our goal was to provide simple and natural dialogue ("less is more" concept), consistent screen design, comprehensible metaphors (both icons and text abbreviations), and continuous feedback. Furthermore, we opted for multimodal interaction, thus giving the users possibility to handle the application in a way that serves given context of use the most. Following requirements for interaction design were settled:

- a quick and simple switch between the system status window and services status window
- one press forced-update invocation
- direct scrolling of services status window content
- different vibration patterns for different server-side notifications
- alarm timeouts (no forced deactivation)
- ability to perform basic application actions with and without pressing buttons on the smartwatch

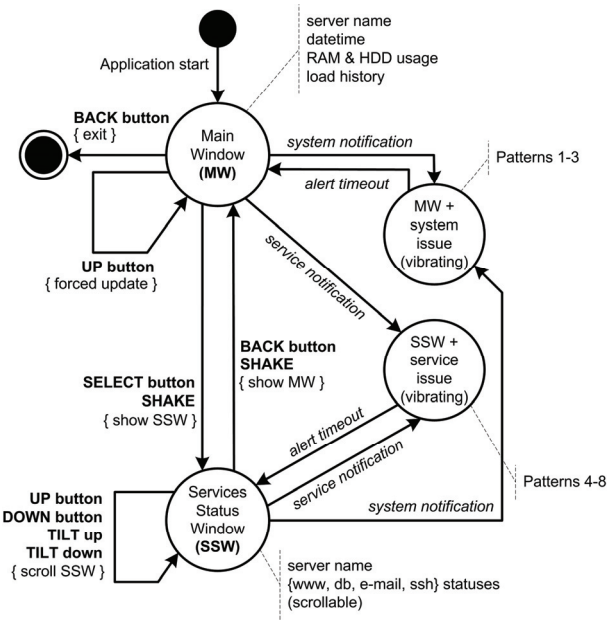

Figure 6. State diagram of interaction design used in our prototype

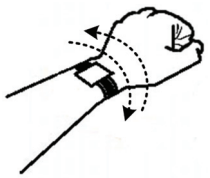

Figure 7. Touchless interaction: invoking tilt actions (for scrolling) and shake gesture (for windows switching) using wrist movements only

Fig. 6 presents the final version of interaction design incorporated in our solution, in a simple state diagram form. State transitions are either user-driven (representing user's explicit actions) or system-driven (automatically fired by server-side notifications).

To facilitate a quick and simple switching between two display screens (MW and SSW), SELECT and BACK buttons are chosen, making this basic window navigation consistent with other smartwatch applications (with respect to going down/up in the window hierarchy stack by pressing SELECT/BACK). The same action is additionally enabled by a SHAKE gesture, consisted of double tilt up/down wrist movements. While SHAKE gesture is thus used for windows toggling, tilting the smartwatch device in a single direction results with TILT UP or TILT DOWN – actions dedicated to scrolling activity within SSW display (Fig. 7). Scrolling can be concurrently achieved using UP and DOWN physical buttons. Within TILT and SHAKE gestures implementation, we defined a *neutral position zone* – an angle-based offset wherein the smartwatch is assumed to be motionless. By doing so we were able to filter out involuntary wrist rotations, i.e. to augment the disambiguation between spontaneous and deliberate movements (cf. [16]).

Although data synchronization with the server is set to be frequent (1 min interval), we nevertheless provided an update-on-demand possibility. Pressing the UP button when MW is displayed will immediately check for possible system/services status changes. Since forced update will likely be used on rare occasions, button press in this context does not have its tilt-based counterpart. All other interface actions allow for multimodality, providing the base for concurrent use of both touch-based and touchless interaction (Table II). Consequently, user is able to interact with the application even if her/his hand (not wearing the smartwatch) is busy.

TABLE II. INTERACTION MODALITIES AND ASSOCIATED INTERFACE ACTIONS

Interface action	Touch-based interaction	Touchless interaction
Show SSW	SELECT button press	SHAKE gesture
Show MW	BACK button press	SHAKE gesture
Scroll up SSW	UP button press	TILT UP gesture
Scroll down SSW	DOWN button press	TILT DOWN gesture
Forced data update	UP button press	-
Alert (de)activation	-	-

One of the main interaction aspects of our smartwatch application is providing feedback on particular system/service notification. When status change is detected, a sequence of interface actions is accordingly performed: (i) bringing front the related window (MW/SSW), (ii) updating GUI elements (string values and/or bar charts), and, if necessary, (iii) starting a notification alert with a particular vibration pattern. In general, a vibration pattern is represented by a sequence of vibration and stillness intervals with previously defined time length. We devised altogether eight vibration patterns: three for system notifications, and five for service notifications. For example, *low-disk-space* issue is notified by 8-seconds long continuous vibration. *Out-of-memory* problem is represented by 8 consecutive short vibrations (0.5s) separated with 0.5s stillness intervals (i.e. "beeping" for 8 seconds). Vibration pattern dedicated to the *high-CPU-load* starts with 4s "beeping", and is followed by 4s continuous vibration. On the other hand, all service notification patterns are constructed using Morse codes, reflecting only the first letters of service names (e.g. A for an Apache error, M for a MySQL error, and so on). We used a 1s base interval for coding dots, dashes, and silences. Initial testing in the development phase showed vibration patterns to be sufficiently diversified and suitable for easy recognition in eyes-free scenarios. By using vibration feedback alongside standard visual display, interaction design was empowered with multimodality on the output side. As a final result, the prototype application allows not only touch-based and touchless interaction, but full "blind-handling" as well.

V. Conclusion And Future Work

In the presented application suite prototype implementation, the Pebble smartwatch is used as a client interface for remote server monitoring. Owing to the smartwatch continual connection to the skin and standard mount location (wrist), target users can be provided with essential information in a timely fashion, irrespective of the current context of use (e.g. while driving, at a meeting, in a cinema). We have demonstrated that with a careful interaction design it is possible to overcome rather limited I/O capabilities of the used device. Namely, standard interaction modalities such as button presses and visual feedback are augmented by making use of the device's motion sensors and vibration motor. Hereby simple mid-air gestures (tilts and shake) were designed and initially tested for a suitable touchless interaction. Different vibration patterns are dedicated to the respective server issues, enabling the user to both disambiguate and comprehend the receiving notifications even without looking at the smartwatch display.

For future work, we plan to carry out formal usability testing of the proposed application. Specifically, we want to evaluate the intuitiveness of our interaction design, as well as get a more detailed insight into the efficiency, learnability, and users' satisfaction attributes. Finally, required physical efforts (wrist rotations) and mental efforts (disambiguating vibration patterns) have to be tackled in order to get a better understanding of ease-of-use constraints.

{oliver.jukic | ivan.hedi | ivan.speh}@vsmti.hr

Abstract - Main goal of research in this paper is to improve city infrastructure resilience capacity as well as management process of water supply network. Namely, water supply network is located over the wide city area, typically managed by company established for that purpose owned by city government. Water supply network is very important part of the city infrastructure. Hence, it is necessary to ensure high-quality and reliable water supply network management process. Our research is focused on mapping of telecommunications network management principles into water supply network management. Complete network view is graphically and geographically oriented using GPS based network elements coordinates. Real-time network control and management is based on network inventory management system which is presented in our previous work. Data from the real network are included in network management process using telemetry techniques and will enhance network management process. Finally, network model and relevant real-time data are integrated into the complete system that will cover all city infrastructure, acting as infrastructure data interchange portal usable especially in the case of disasters such as flooding, earthquakes, volcanos, etc. Indirectly, citizens will communicate with this platform through different users or services using telecommunications infrastructure.

I. INTRODUCTION

A. Water supply network

Every water supply network is located over the wide city area, typically managed by company established for that purpose owned by city government. Water supply network is very important part of the city infrastructure. In network theory, there are four general classes of networks: technological networks, social networks, information networks and biological networks. The division into classes is a useful one, since networks in the same class are often treated using similar techniques, ideas and algorithms [1]. Both telecommunication and water supply network belong to the class of technological networks. In water supply network almost all network elements are invisible, located in the ground. In most cases, network elements are not accessible through any communication infrastructure, and they are "software-free" elements. Hence, there is no possibility to implement self-detection or auto-discovery features. Hence, it is rather important to implement and maintain network configuration database. Water supply network operators usually have "database" as a collection of different type documents describing network, even in the electronic form. However, that is not enough for maintenance and management activities. There is very strong need for information system for network configuration management, which we call "inventory" management (in water supply network we use term "network inventory" for all elements building water supply network). As a first step in our research we have focused on related work and developing of our own water supply inventory management system [2].

B. Inventory management system architecture

Inventory management system architecture is shown on figure 1.

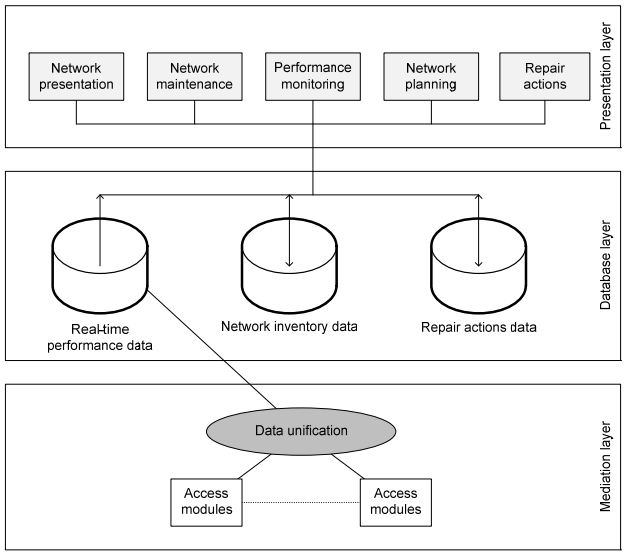

Figure 1. Inventory management system architecture

The system was developed and launched during the project "Knowledge-based water supply management" sponsored by company "Komrad d.o.o.", Slatina. System core is located at database layer. There are three main databases: network inventory database, repairing action database and real-time performance database. Central database in the context of network inventory system is network inventory database. It can be assumed as configuration database. Since there are no auto-discovery or self-detection features in a "software-free" network,

network inventory data must be imported into the database through graphical network presentation interface. Data collection process includes consolidation of all possible sources within the company, such as: network schemas, network descriptions, project plans, repairing logs, internal human knowledge, informal notes etc. Generally, there are two types of network elements: basic elements, such as valves or pipes, that cannot be divided into the smaller parts; compound elements, such as manhole, are compound of number of basic elements. GPS coordinates are a very important part of network inventory data model, since they allow network presentation on any GPS supporting platform [2]. Main functions of mediation layer are:

- data collection from water-supply network
- unification of all data formats
- aggregation of collected data on low level, preparing it for storage in real-time performance data warehouse

All data are collected by specific applications called access modules. Every access module uses specific techniques and performs specific actions in order to obtain data from the water-supply network. For instance, data can be collected through any kind of communication protocol (usually using GPRS for data transport), from existing databases or industrial measurement solutions [6]. Topology for collecting real-time data is shown on figure 2.

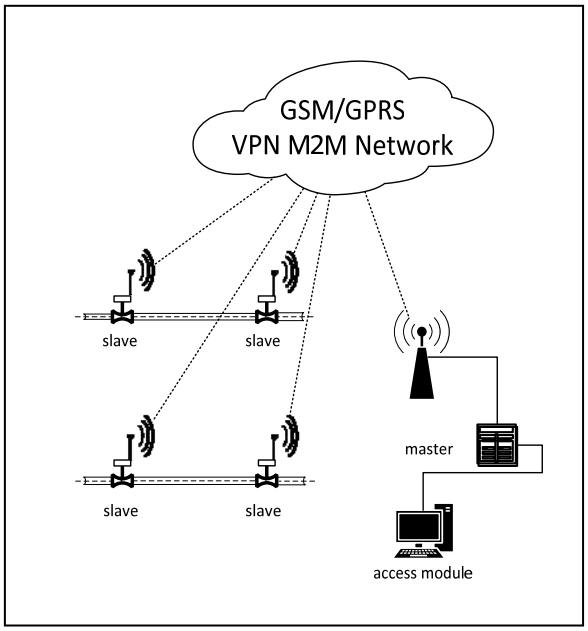

Figure 2. Topology of communication for collecting real-time data

Network presentation GUI is web interface located on the top of database layer. At presentation layer there is performance monitoring module. This is graphical interface which is connected to real-time performance data database and reading last measurement value for each node which consists of slave flow measuring module and serves as "performance cockpit". Basis for this graphical interface is Network inventory data presentation on GPS supporting platform (Figure 3.).

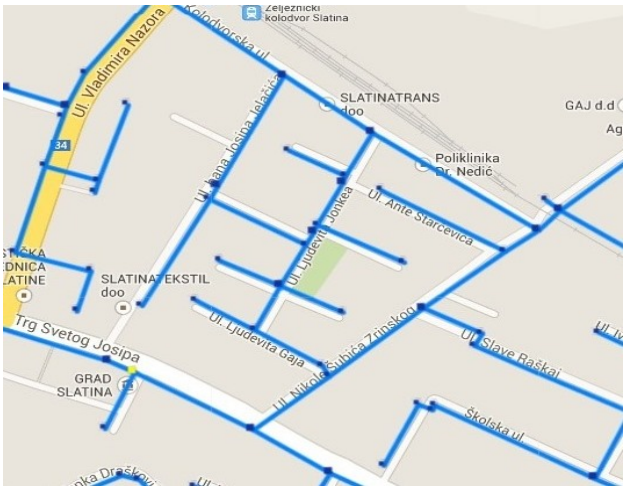

Figure 3. Network inventory data presentation on GPS supporting platform

C. *Related work*

Vienna Waterwork's approach to network maintenance and rehabilitation is described in [3]. Network information system of Vienna Waterwork is briefly presented. System is primarily used to provide assistance platform for planning process. For predicting pipe failures the proportional hazards model (PHM) is used.

GIS-based water supply information system for an urban area is described in [4]. The basic aim of that water supply information system is to serve as a decision support tool for Waterwork's management by helping maintain records of leaks and repairs.

Both systems are focused on inventory management, but currently without GPS coordinates. Real-time data integration is also not considered.

In [5] system using telemetry for obtaining real-time data from water-supply network is described. However, all data are propagated to SCADA application; inventory management is not considered.

All facts mentioned above have encouraged us to continue research and development activities leading to the integration of real-time collected data with network inventory system based on GPS coordinates.

II. PLATFORM TO IMPROVE CITY INFRASTRUCTURE RESILIENCE CAPACITY

A. *Water supply area*

In the water-supply network covered by our inventory management system, water is pumped into the two so-called zones: Low zone covers city area. There is clean water tank above the city - unused water from distribution network is pumped to this clean water tank. If necessary (for instance, if pumps are out of order, or capacity provided is less then capacity needed), water from tank is distributed by gravity to the city. High zone covers neighboring municipalities, with couple of alternative drinking water sources with limited capacity.
Both high and low zone have its own distribution network and also its "access" network where customers are

connected to the network. All data about network inventory are handled by information system described in previous section, providing real-time data collection, therefore enabling not only inventory data collection, storage and visualization, but also real-time network management.

B. Water supply network general architecture

The general water flow in the architectural system shown in Figure 4 is defined as follows:

1. Water is extracted from the sources under the earth. Physical and chemical processing is done.

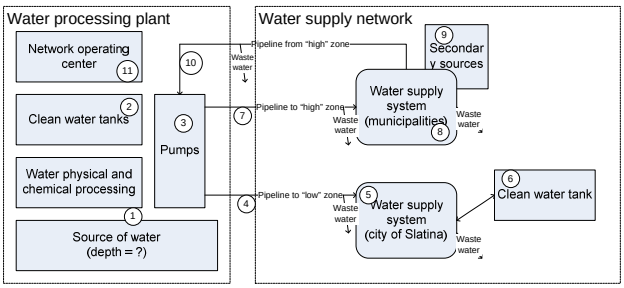

Figure 4. Water supply network general architecture

2. Water is stored into the clean water tanks (3 tanks).
3. Pumps are pumping clean water from the tanks in 2 directions called "Low" and "High" zone. "High" zone is actually city while "Low" zone are municipalities around. Actually, this is the point where water-flow enters the water distribution network.
4. Main pipeline to "high" zone is couple of kilometers length. There is the possibility to waste larger amount of water in short time period, because of huge diameter.
5. Water is distributed all over the city. Unused water is pumped to clean water tank located above the city.
6. If necessary (for instance, if pumps are out of order, or capacity provided is less then capacity needed), water from tank is distributed by gravity to the city.
7. Main pipeline to "low" zone is linking number of municipalities. There is the possibility to waste larger amount of water there, because of huge diameter also.
8. Every municipality has its own distribution network.
9. There are several small secondary sources of water located in municipalities. This water is injected in the general pipeline.
10. Pipeline for "low" zone forms a loop returning water to the water processing plant.
11. Whole process is monitored by Network operating center.

C. Network operating center

The network operating center is located at the "Water processing plant". Company is always guaranteeing personnel in these premises.

The General network operating center architecture is shown in Figure 5.

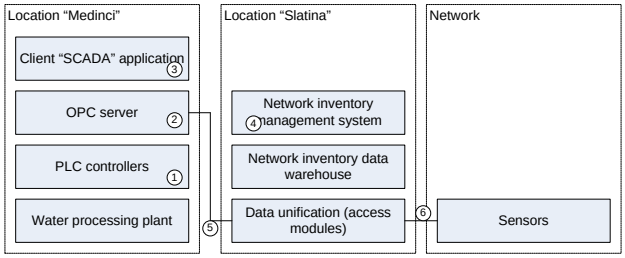

Figure 5. General architecture of network operating center

The network monitoring system includes:

1. Number of PLC controllers collect data from the plant. These data are mostly related to water processing, but there are number of parameters related to water distribution. For instance:
   - Pressure of water flow toward the "Low" or "High" zone
   - Flow of water stream toward the "Low" or "High" zone
   - Current amount of water in clean water tanks
   - Current pump status
   - Current pump power
2. Data from OPC controllers are stored in OPC (Ole for Process Control) server. Data are obtainable by any OPC client (standardized access).
3. The SCADA application, actually it is "RSView", OPC client. There are number of graphical presentations of water processing with integrated real-time data measured by PLC controllers.
4. Network inventory management system is located in the City of Slatina (web application with MSSQL server database).
5. Data from OPC server can be integrated in Inventory management system also, allowing tracking of important KPIs
6. Data from sensors located in network are integrated into Inventory management system also.

D. Central IT platform

Generally Central IT platform is used to collect whole relevant data from different sources such as water supply network operating center, electricity network operating center, gas transmission network operating center, telecommunication network operating center, citizens, 112 service and so on in emergency situation like flooding or some other type of disaster and triggers some relevant actions such as crisis emergency alerting, crisis management actions etc. Currently in test phase we collect relevant data which are connected to distribution of clean water which is very important when flood occur. Next phase of this research is to include all other relevant source and get complete central IT platform to improve city infrastructure resilience capacity.

One potential scenario of using that platform is when floods occur. This platform will be used (not exclusively) by (see Figure 6.): first responders such as police officers, firefighters, emergency medical technicians (EMT), infrastructure operators (water supply, electricity, gas transmission and telecommunications network operators),

general population, city council and its services, service #112, local electronic media, other services, NGOs, etc.

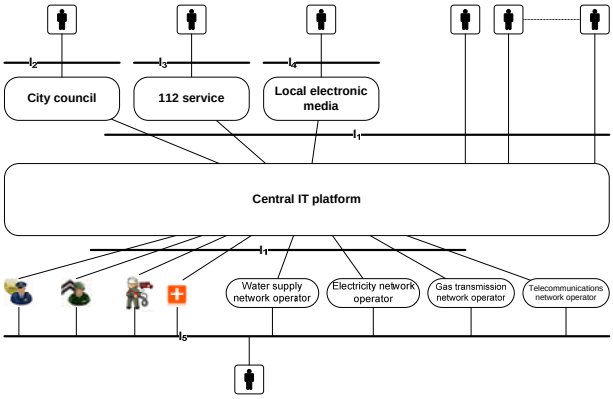

Figure 6. Central IT platform participants (logically)

Users from 1-5 will approach platform in both directions through a platform front-end (**I1**). Term "both directions" means they will be able to trigger some actions, or to receive guidelines, triggers, data etc. from platform. Some data are collected in permanent regime, while other are collected on demand (when something is "triggered" from the environment). Citizens will approach platform directly (**I1**) or indirectly. It is expected that more citizens from urban area will approach platform directly. Citizens from rural area probably will use another channels to send/obtain relevant information related to current disaster situation. Indirectly, citizens will communicate with platform through different users/services using telecommunications infrastructure: by contacting (phone, SMS, e-mail,...) to city council (**I2**), by contacting (phone, SMS, e-mail,...) to service #112 (**I3**), by contacting (phone, SMS, e-mail,...) to local electronic media and by receiving information from media (**I4**), by contacting (phone, SMS, e-mail,...) first responders and/or infrastructure operators directly (**I5**). One possible scenario when floods occur are shown on Figure 7.

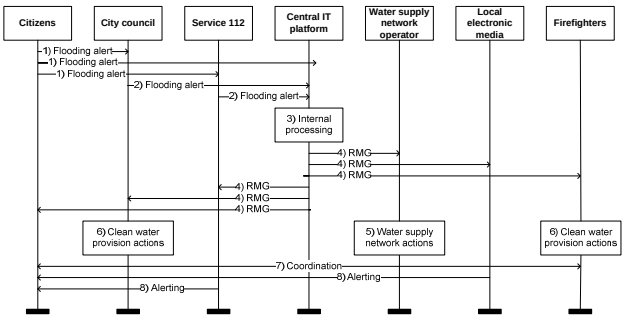

Figure 7. Flooding scenario

The workflow acts as follows: flooding alert is sent from citizens via different channels to city council, Service 112 or Central IT platform. Flooding alert is received and forwarded from the city council and Service 112 to the Central IT platform. Central IT platform performs internal processing, based on data collected on permanent regime, data from other sources, internal algorithms, rules etc. Resilience management guidelines (RMG) are launched and delivered/published to all platform users. For instance, Citizens can approach RMG by web or mobile application. According to RMG received, Water Supply Network Company will perform specific actions on water supply distribution network. For instance: detect areas where clean water distribution is disrupted increase/decrease pump power, switch on/off specific valves in order to cause re-routing of water-flow, fill up clean water tanks, generate specific alerts to citizens and other. At the same time, city council and firefighters will organize clean water provisioning to the areas where water clearance is disturbed. Actions mentioned above are coordinated. Local electronic media will inform citizens about current situation (e.g. special news). Service #112 will generate some public alerts (e.g. public city alarm – siren).

E. Legislation at the area of emergency management

System of protection and rescue of citizens, material and other goods in catastrophes and big accidents, way of controlling, handling and coordinating, tasks and constitutions of bodies for administration, way of alarming and informing in activities of protection and rescue in Republic of Croatia is regulated by the Law on Protection and Rescue. In catastrophes and big accidents district head (city council), mayor and district prefect directly command operative forces of protection and rescue of units from local and regional government. Each person has right to complete and timely information about all threats from the beginning of catastrophes and possibilities, ways, measures and activities of protection and rescue and if they notice threat from beginning of accident, big accident or catastrophes or its beginning, it is their duty to inform Service 112 without any delay, using the most convenient way and the fastest way of information transfer [7]. According to the Law on Critical Infrastructures, national critical infrastructures are systems, networks and objects of national importance whose disruption of functioning or disruption of goods or services supply can have serious consequences on national security, health and lives of people, possessions and environment security and economic stability and undisrupted functioning of government (water supply network, telecommunication network, electricity supply network etc.) [8]. By–law about standard operative procedures regulates the way of common action of operative forces (standard operative procedure) and Service 112, procedure for transfer of all available information connected to the emergency situation, accident or catastrophe after receiving information through number 112, procedure of processing and forwarding received information to operative forces and other participants of protection and rescue using most suitable and the fastest way of information transfer. So, there are some possibilities to implement Central IT platform to Service 112.

III. CONCLUSION

In this paper we have presented information system which is used to improve city infrastructure resilience capacity and it is based on inventory management system in water-supply network. Based on existing experience in telecommunications management area, we have compared basic aspects of management in water-supply and telecommunication networks. Encouraged by the results, we have developed inventory management system for water-supply network. Some of system components are still subject of research efforts; it will be subject of future work and will be presented in future papers. Main goal of research in this paper is to improve city infrastructure resilience capacity as well as management process of water supply network. Namely, water supply network is located over the wide city area, typically managed by company established for that purpose owned by city government. Water supply network is very important part of the city infrastructure. Hence, it is necessary to ensure high-quality and reliable water supply network management process. Our research is focused on mapping of telecommunications network management principles into water supply network management. Complete network view is graphically and geographically oriented using GPS based network elements coordinates. Real-time network control and management is based on network inventory management system which is presented in our previous work. Data from the real network are included in network management process using telemetry techniques and will enhance network management process. Finally, network model and relevant real-time data are integrated into the complete system that will cover all city infrastructure, acting as infrastructure data interchange portal usable especially in the case of disasters such as flooding, earthquakes, volcanos, etc. Indirectly, citizens will communicate with this platform through different users or services using telecommunications infrastructure.

Elektronička komunikacijska infrastruktura u zgradama

Dr.sc. Justina Bajt
Hrvatski Telekom d.d.
Zagreb, Republika Hrvatska
justina.bajt@t.ht.hr

Sažetak - Europska unija puno pažnje u svojim propisima poklanja razvoju elektroničkih mreža velikih brzina. Prema hrvatskim propisima o gradnji zgrada, svaka zgrada mora imati primjerenu elektroničku komunikacijsku infrastrukturu (EKI), koju mora izgraditi investitor prilikom gradnje zgrade, odnosno kasnije (su)vlasnici zgrade. Međutim, brzi razvoj elektroničkih komunikacija i povećanje broja korisnika elektroničkih komunikacijskih usluga u stambenim i poslovnim zgradama zahtijeva da, radi pružanja usluga svome korisniku, operator mora postaviti dodatnu EKI u zgradu. Postavljanje dodatne EKI zahtjeva uređenje odnosa između (su)vlasnika zgrade i operatora po pitanju ulaganja u EKI u zgradama i vlasništva na EKI. Budući da propisi iz područja elektroničkih komunikacija i gradnje ne uređuju u potpunosti ovo područje, pravna rješenja za investiranje u dodatnu EKI traže se u okviru općih propisa. S obzirom na značaj EKI u zgradama za budući razvoj elektroničkih komunikacija, zaključujemo da je ovo područje podnormirano i da je pravnom uređenju EKI u zgradama potrebno posvetiti posebnu pažnju u propisima o gradnji i elektroničkim komunikacijama. Bez omogućavanja operatorima nesmetanog pristupa infrastrukturi u poslovnim i stambenim zgadama radi pristupa do krajnjeg korisnika usluga, nije moguće očekivati značajan napredak u pružanju usluga korisnicima.

I. UVOD

Države članice Europske unije (EU) prihvaćanjem Digitalne agende za Europu (DAE) preuzele su obvezu omogućiti osnovni širokopojasni pristup svim Europljanima do 2013. i osigurati da do 2020. svi Europljani imaju pristup internetskim brzinama većim od 30 Mbit/s te da najmanje 50 % kućanstava u EU bude pretplaćeno na internetske veze brzine iznad 100 Mbit/s. Slijedom postavki DAE, kao sveobuhvatnog plana Europske komisije za poticanje gospodarskog rasta kroz stvaranje konkurentnije i digitalno modernije Europe, Europski parlament i Vijeće donijeli su Direktivu 2014/61/EU o mjerama za smanjenje troškova postavljanja elektroničkih komunikacijskih mreža velikih brzina (SL L 155/11, 23.5.2014.). Na europskoj razini time se osigurava stabilan pravni okvir radi stimuliranja ulaganja u otvorenu i konkurentnu brzu internetsku infrastrukturu i pripadajuće usluge.

Cilj je Direktive 2014/61/EU olakšati i potaknuti uvođenje elektroničkih komunikacijskih mreža (dalje u tekstu: EKM) velike brzine promičući zajedničko korištenje postojeće fizičke infrastrukture i omogućavajući učinkovitije postavljanje nove fizičke infrastrukture[1] kako bi trošak uvođenja takvih mjera bio što niži (čl. 1. Direktive). Direktiva polazi od toga da bi smanjenje troškova postavljanja EKM-a doprinijelo ostvarivanju digitalizacije javnog sektora šireći učinak digitalne financijske poluge na sve sektore gospodarstva uz smanjenje troškova za javnu upravu i pružanje učinkovitijih usluga građanima. Ostvarivanje ciljeva DAE i time ostvarenja općeg interesa države, njezinih građana i gospodarskih subjekata, zahtijeva da uvođenje EKM-a bude čim bliže lokaciji krajnjih korisnika uz istodobno potpuno poštovanje načela proporcionalnosti u pogledu ograničenja prava vlasništva vlasnika zemljišta i zgrada te vlasnika EKI.

Radi smanjenja troškova postavljanja širokopojasnih mreža na cijelom području EU, države članice trebaju stvoriti nacionalni pravni okvir za:

- Učinkovito planiranje i koordiniranje aktivnosti gradnje fizičke infrastrukture, uključujući i fizičku infrastrukturu unutar zgrada te smanjenje administrativnih tereta.
- Omogućavanje pružateljima usluga javnih komunikacijskih mreža pristupa fizičkoj infrastrukturi, uključujući i infrastrukturu unutar zgrada.
- Učinkovito dijeljenje fizičke infrastrukture u koju je, osim EKI uključena i infrastruktura drugih sektora javnih usluga (struja, plin, nafta, odvodnja otpadnih voda, topla voda te voda osim vode za ljudsku potrošnju), a koja je pogodna za postavljanje telekomunikacijskih kabela.

Države članice moraju do 1. siječnja 2016. godine donijeti i objaviti zakone i druge propise potrebne za

[1] Direktiva 2014/61/EU u čl. 2. definira „fizičku infrastrukturu" kao element mreže koji je namijenjen za smještanje drugih elemenata mreže, a da pritom i sam ne postane aktivni element mreže, poput cijevi, stupova, vodova, kontrolnih soba, zdenaca, ormarića, zgrada ili ulaza u zgrade, antenskih instalacija, tornjeva i stupova namijenjenih za pružanje javnih usluga (elektroničke komunikacije, struja, plin, nafta, odvodnja otpadnih voda, topla voda i voda). Međutim kabeli, uključujući svjetlovodne niti koje se ne koriste, kao i elementi mreže koji se koriste za opskrbu vodom namijenjenom za ljudsku potrošnju, nisu fizička infrastruktura u smislu te Direktive.

usklađivanje s tom Direktivom i o tome obavijestiti Europsku komisiju.

II. TEMELJNI ZAHTJEVI DIREKTIVE 2014/61/EU KOJE DRŽAVE ČLANICE MORAJU PRENIJETI U NACIONALNO ZAKONODAVSTVO

U cilju smanjenja troškova i olakšavanja uvođenja EKM-a velike brzine do samih krajnjih korisnika i istodobnog osiguravanja tehnološke neutralnosti, RH mora uskladiti svoje propise sa sljedećim temeljnim zahtjevima Direktive 2014/61/EU koji se odnose na fizičku infrastrukturu u zgradama i pristup toj infrastrukturi:

- Sve novoizgrađene zgrade na lokaciji krajnjeg korisnika usluga, uključujući njihove elemente u zajedničkom vlasništvu, a za koje su zahtjevi za građevinske dozvole podneseni nakon 31. prosinca 2016., moraju biti opremljene fizičkom infrastrukturom, tj. EKI-em unutar zgrade prilagođenom EKM-u velike brzine sve do zaključnih točaka mreže, a sve novoizgrađene višestambene zgrade i pristupnom točkom. Ista se obveza primjenjuje i u slučaju opsežnih radova na obnovi zgrade za koje su zahtjevi za građevinske dozvole podneseni nakon 31. prosinca 2016.
- Ako je zgrada već opremljena EKM-om velike brzine, svakom pružatelju usluga javnih komunikacijskih mreža koji ima aktivnog pretplatnika u zgradi pristup EKM-u zgrade mora biti osiguran pod transparentnim, razmjernim i nediskriminirajućim uvjetima.
- Svaki pružatelj usluge javne komunikacijske mreže ima pravo o svom trošku uvesti svoj EKM do pristupne točke.[2]
- Svaki pružatelj usluge javne komunikacijske mreže ima pravo pristupiti bilo kojoj postojećoj fizičkoj infrastrukturi unutar zgrade (EKI, cijevima za struju, plin, otpadne vode, toplu vodu) radi postavljanja EKM-a ako je udvostručavanje tehnički neizvedivo ili ekonomski neučinkovito.
- Gdje ne postoji ni pasivna ni aktivna infrastruktura prilagođena vezi velike brzine unutar prostorija krajnjih korisnika, niti alternativa za davanje na korištenje EKM-a pretplatniku, svaki pružatelj usluga javnih komunikacijskih mreža treba imati pravo dovesti svoju mrežu do privatnog prostora na vlastiti trošak, ponovno upotrebljavajući, ako je to moguće, postojeću fizičku infrastrukturu unutar zgrade (EKI te cijevi za struju, plin, odvodnju otpadnih voda, toplu vodu), pod uvjetom da utjecaj na privatno vlasništvo bude sveden na najmanju moguću mjeru.
- Svaki pružatelj usluga javne komunikacijske mreže ima pravo završiti svoju mrežu u prostorijama pretplatnika, uz suglasnost pretplatnika, pod uvjetom da se pritom na najmanju moguću mjeru svede utjecaj na privatnu imovinu trećih osoba.
- Svaki nositelj prava koje ga ovlašćuje koristiti pristupnu točku i fizičku infrastrukturu unutar zgrade, mora udovoljiti svim razumnim zahtjevima za pristup podnesenima od strane pružatelja usluga javne komunikacijske mreže pod pravičnim i nediskriminirajućim uvjetima.
- Pravo vlasništva vlasnika pristupne točke ili fizičke infrastrukture unutar zgrade ne smije biti dovedeno u pitanje u slučaju kada nositelj prava koje ovlašćuje na korištenje te fizičke infrastrukture ili pristupne točke, nije njihov vlasnik.
- Ne smije biti dovedeno u pitanje ni pravo vlasništva bilo kojih trećih osoba, kao što su vlasnici zemljišta i vlasnici zgrada, a države članice mogu utvrditi pravila o primjerenoj financijskoj naknadi osobama koje trpe štetu zbog izvršavanja navedenih prava.

Direktiva prepoznaje da ugradnja malih cijevi EKI-a tijekom izgradnje zgrade ograničeno utječe na povećanje troškova, dok naknadno opremanje zgrada cijevima EKI-a može biti značajan udio u trošku postavljanja EKM-a velike brzine. Stoga, od država članica zahtijeva se da sve nove zgrade ili zgrade koje je potrebno opsežno obnoviti[3] trebaju biti opremljene fizičkom infrastrukturom koja bi omogućila povezivanje krajnjih korisnika s EKM-om velike brzine. Također bi takve zgrade trebale biti opremljene pristupnom točkom putem koje bi pružatelj mogao pristupiti EKI-u i EKM-u unutar zgrade (dalje u tekstu za EKI i EKM zajedno koristi se skraćenica: EKMI). Ulagači u zgrade trebali bi ugraditi prazne cijevi od svakog stana do pristupne točke koja se nalazi u zgradi ili izvan nje da bi se omogućilo svakom operatoru javnih komunikacijskih mreža pristup do njegovih korisnika usluga u zgradi.

Budući da postojanje EKM-a velike brzine u zgradi bitno utječe na njezinu vrijednost, radi informiranja potencijalnih kupaca i stanara države članice trebale bi uvesti dobrovoljnu oznaku „pripremljeno za širokopojasni pristup" za zgrade opremljene takvom infrastrukturom i pristupnom točkom. Države članice mogu propisati i određena izuzeća od primjene te obveze, ali ta izuzeća moraju biti odgovarajuće obrazložena.

III. POSTOJEĆE HRVATSKO PRAVNO UREĐENJE ELEKTRONIČKE KOMUNIKACIJSKE INFRASTRUKTURE U ZGRADAMA

Na EKMI-i u poslovnim i stambenim zgradama odnose se sljedeći hrvatski zakoni i podzakonski propisi:

- Zakon o elektroničkim komunikacija (ZEK)[4] te podzakonski propisi doneseni na temelju ZEK-a:

[2] Pristupna točka je fizička točka koja se nalazi unutar ili izvan zgrade te koja je dostupna operatorima javnih komunikacijskih mreža, pri čemu je omogućena veza s infrastrukturom unutar zgrade prilagođenom EKM-u velike brzine.

[3] Opsežni radovi na obnovi prema definiciji iz čl. 2. Direktive znače izgradnju ili građevinske radove na lokaciji krajnjeg korisnika koji obuhvaćaju strukturne izmjene cijele fizičke infrastrukture unutar zgrade ili njezina značajnog dijela i za koje je potrebna građevinska dozvola.

[4] NN 73/08, 90/11, 133/12, 80/13 i 71/14

Pravilnik o tehničkim uvjetima za elektroničku komunikacijsku mrežu poslovnih i stambenih zgrada;[5] Pravilnik o načinu i uvjetima pristupa i zajedničkog korištenja EKI i druge povezane;[6] Pravilnik o svjetlovodnim distribucijskim mrežama (dalje u tekstu: SDM);[7]

- Zakon o vlasništvu i drugim stvarnim pravima (dalje u tekstu: ZV);[8]
- Zakon o gradnji[9] i Pravilnik o jednostavnim građevinama i radovima.[10]

ZEK uređuje dvije situacije gradnje, odnosno postavljanja EKMI-a u zgradama ovisno o tome postavlja li se takva infrastruktura i mreža u zgradi koja se tek gradi (novoj zgradi) ili u već izgrađenim zgradama koje nemaju odgovarajući EKMI (stare zgrade).

A. EKMI u novim zgradama

Investitor nove zgrade dužan je izgraditi EKMI u skladu s Pravilnikom o tehničkim uvjetima za elektroničku komunikacijsku mrežu poslovnih i stambenih zgrada, a EKMI mora biti obuhvaćen projektom zgrade. EKMI zgrade mora omogućiti svim (su)vlasnicima zgrade slobodan izbor operatora, a svim operatorima pristup zgradi uz ravnopravne i nediskriminirajuće uvjete (čl. 24. st. 5. ZEK-a). Iz navedene odredbe proizlaze obveze investitora gradnje zgrade (poslovne, stambene, poslovno-stambene), koje on ima tijekom gradnje, sve dok zgrada ne dobije uporabnu dozvolu. Koji je to minimum EKMI i povezane opreme potreban za namjenu zgrade određeno je glavnim projektom zgrade (dio koji se naziva elektrotehnički projekt), a u skladu sa standardima određenim Pravilnikom, koji moraju biti sukladni normama i tehničkim specifikacijama na koje upućuju obvezujuće zakonske odredbe čl. 24. st. 1., 2. i 3. ZEK-a. Budući da ZEK u čl. 3. utvrđuje da je „elektronička komunikacijska infrastruktura, ... gradnja, održavanje, razvoj i korištenje elektroničkih komunikacijski mreža i elektroničke komunikacijske infrastrukture i povezane opreme … od interesa za Republiku Hrvatsku," izgradnja EKMI u zgradama nije samo privatni interes investitora zgrade, nego je također interes RH, a koji se izražava kroz propisivanje minimalnih standarda EKMI-i određenih vrsta zgrada. Također, strateškim dokumentima RH zacrtan je razvoj širokopojasnih usluga i omogućavanje nesmetanog pristupa svakog građanina i pravnih osoba takvim uslugama, a nužni preduvjet tome je adekvatna EKMI u poslovnim i stambenim zgradama.

Koliki je značaj zakonodavac dao gradnji i korištenju EKMI-i zgrada govore i kaznene odredbe čl. 120. ZEK-a kojima su propisane novčane kazne za prekršaj[11] koji počini pravna osoba, odgovorna osoba u pravnoj osobi i fizička osobe koja ne poštuje odredbe čl. 24. st. 5. ZEK-a. Ako investitor zgrade ne izgradi EKMI primjerenu namjeni zgrade koja omogućava svim vlasnicima zgrade slobodan izbor operatora, a svim operatorima pristup zgradi uz ravnopravne i nediskriminirajuće uvjete, tada investitor čini prekršaj za koji može platiti novčanu kaznu navedenu u čl. 120. ZEK-a.

Dakle, sve zgrade koje su projektirane i izgrađene nakon stupanja toga Pravilnika na snagu 2009. godine, moraju imati svjetlovodni EKMI primjeren namjeni zgrade, a operatori mogu postaviti svoj EKMI samo za potrebe svojega korisnika ako im EKMI zgrade ne omogućava kvalitetno pružanje usluga.

B. EKMI u postojećim zgradama

U ranije izgrađenim zgradama vrlo često ne postoji EKI koji omogućava korištenje naprednih elektroničkih komunikacijskih usluga putem EKM-a velike brzine. Kada se u postojeću zgradu koja ima zastarijeli ili nedostatan EKMI, naknadno postavlja nova infrastruktura potrebna za pružanje novih usluga, primjenjuju se odredbe ZEK-a i ZV-a te Pravilnika o tehničkim uvjetima za elektroničku komunikacijsku mrežu poslovnih i stambenih zgrada. ZEK propisuje da vlasnici izgrađene poslovne ili stambene zgrade moraju omogućiti pristup svim operatorima u svrhu postavljanja, održavanja i razvoja EKMI-a, a izgrađen EKMI mora omogućiti svim vlasnicima zgrade slobodan izbor operatora, a svim operatorima pristup zgradi uz ravnopravne i nediskriminirajuće uvjete. Iz navedenog slijedi da su (su)vlasnici ranije izgrađenih zgrada, u kojima već postoji određen EKMI koji je sastavni dio zgrade i u suvlasništvu je svih (su)vlasnika zgrade, dužni omogućiti svim operatorima pristup toj zgradi, odnosno zajedničkim prostorima u/na/ispod zgrade, a u svrhu postavljanja, održavanja i razvoja EKMI-a (čl. 24. st. 6. ZEK-a).

Ako je u starim zgradama potrebno rekonstruirati, odnosno nadograditi postojeći EKMI zgrade ili postaviti tzv. prijenosni medij u premosnom sustavu, smatramo da je moguće primijeniti sljedeća pravila. Ako se rekonstruira postojeći EKMI zgrade tako da novi EKMI zamijeni dotadašnji EKMI zgrade, tada novi EKMI postaje konstruktivni, tj. neodvojivi dio zgrade. Međutim, ako se pored postojećeg postavlja dodatni EKMI zgrade, takav EKMI može biti odvojen od zgrade i predmet vlasništva pojedinog etažnog vlasnika, odnosno korisnika poslovnog ili stambenog prostora ili operatora elektroničkih komunikacija.

Vlasnici etažnih dijelova zgrade, odnosno korisnici poslovnih prostora (zakupci) i/ili korisnici stanova mogu imati svoj privatni EKM unutar zgrade. Takav EKM i za njega odgovarajući EKI može izgraditi o svome trošku svaki suvlasnik na čijem je suvlasničkom dijelu uspostavljeno vlasništvo određenog posebnog dijela nekretnine (etažni vlasnik) u skladu s odredbama čl. 82. st. 1. ZV-a. Dakle, suvlasnik ne mora za postavljanje takvog EKMI-a tražiti odobrenje od ostalih suvlasnika, nego može u skladu s građevinskim propisima, o svome trošku napraviti prepravke i zadiranje u zajedničke dijelove nekretnine vezano za postavljanje navedenih instalacija i to mu ne može zabraniti niti jedan od suvlasnika. Slijedom navedenog, suvlasnik (etažni

[5] NN 155/09
[6] NN 136/11, 44/12, 75/2013
[7] NN 57/14
[8] NN 91/96, 68/98, 137/99, 22/00, 73/00, 114/01, 79/06, 141/06, 146/08, 38/09, 153/09, 143/12 i 152/14
[9] NN 153/13
[10] NN 79/14
[11] U čl. 120. ZEK-a propisana je novčana kazna za pravnu osobu u iznosu od 50.000,00 do 500.000,00 kuna; za odgovornu osobu u pravnoj osobi u iznosu od 5.000,00 do 50.000,00 kuna; za fizičku osobu u iznosu od 2.000,00 do 20.000,00 kuna.

vlasnik) mogao bi postaviti EKMI za potrebe korisnika njegovog etažnog dijela.

Osim navedenog, dodatni EKMI u zgradi mogu postaviti i operatori elektroničkih komunikacija u skladu s odredbom čl. 14. st. 2. Pravilnika. Navedeno znači da u slučaju primjene različitih tehnologija EKMI-a (bakrene parice, koaksijalni kabeli, svjetlovodi), svaki operator ima pravo doći do svoga korisnika kroz zajedničke prostore u zgradi, postavljajući svoje kabele u zasebne nadžbukne kanalice ili zaštitne cijevi te da mu to (su)vlasnici zgrade (većina ili pojedinačno) ne smiju zabraniti. Dužnost vlasnika da omoguće pristup zgradi s pravnog aspekta ne znači da operator može slobodno, bez ikakvih pitanja i privola ući u tuđu nekretninu i raditi što ga je volja da bi postavio, održavao i razvijao EKMI. Pristup zgradi podrazumijeva pridržavanje određenih općih propisa o vlasništvu i drugim stvarnim pravima, kao i odredaba ZEK-a i Pravilnika.

C. Zakon o vlasništvu i drugim stvarnim pravima

ZV u čl. 82. st. 1. uređuje odnose među suvlasnicima u slučajevima kada bilo koji od suvlasnika želi napraviti nekakve promjene na zajedničkim dijelovima nekretnine, a koje se odnose na postavljanje vodova za svjetlo, plin, energiju, vodu, telefon i slične uređaje, radijske i televizijske antene, odnosno elektroničke komunikacije. ZV izričito određuje pravilo da suvlasnik na čijem je suvlasničkom dijelu uspostavljeno vlasništvo određenog posebnog dijela nekretnine (etažni vlasnik) ima ovlaštenje, ne tražeći za to odobrenje od ostalih suvlasnika, u skladu s građevinskim propisima, o svome trošku izvršiti prepravke i zadiranje u zajedničke dijelove nekretnine vezano za postavljanje navedenih instalacija i to mu ne može zabraniti niti jedan od suvlasnika. Dakle, suvlasnik ne mora za gradnju, odnosno postavljanje dodatnog EKI-a tražiti odobrenje od ostalih suvlasnika, nego može u skladu s građevinskim propisima, o svome trošku izvršiti prepravke i zadiranje u zajedničke dijelove nekretnine vezano za postavljanje navedenih instalacija i to mu ne može zabraniti niti jedan od suvlasnika. Dodatni EKI prema čl. 82. st. 1. ZV-a ne mora suvlasnik sam napraviti, nego to umjesto njega može napraviti operator koji mu pruža elektroničke komunikacijske usluge. Tako postavljen EKI u zgradi prema odredbi čl. 14. st. 2. Pravilnika o EKM poslovnih i stambenih zgrada smatra se dodatnim kabliranjem u zgradi (tzv. postavljanjem „prijenosnog medija u premosni sustav“) jer operator ima barem jednog korisnika u toj zgradi. Operator mora svoje nadžbukne kanalice i kabele postaviti tako da budu u skladu s građevinskim propisima i što manje narušavaju izgled zgrade, te da omogući i drugim operatorima postavljanje njihovih nadžbuknih kanalica. Predstavnik suvlasnika mora svakom operatoru koji ima najmanje jednog korisnika u zgradi dati izjavu, odnosno suglasnost kojom se omogućuje: postavljanje nadžbuknih kanalica ili zaštitnih cijevi i kabela u zgradi, te svakodobni pristup radi njihovog održavanja i korištenja. U slučaju prestanka pružanja elektroničkih komunikacijskih usluga u zgradi operator koji je napravio dodatno kabliranje, dužan je u roku 2 mjeseca po prestanku ugovora o isporuci elektroničke komunikacijske usluge: ukloniti dodatno kabliranje, dovesti dio EKMI-a zgrade u prvobitno stanje, sanirati sva pritom nastala oštećenja u zgradi. Ako operator ne učini navedeno, dodatno postavljene instalacije (dodatno kabliranje) postaju vlasništvo (su)vlasnika zgrade u skladu s odredbom čl. 14. st. 2. navedenog Pravilnika[1].

D. Pravilnik o tehničkim uvjetima za elektroničku komunikacijsku mrežu poslovnih i stambenih zgrada

Pravilnikom je utvrđen minimum EKMI-a koji bi investitori morali zadovoljiti prilikom gradnje poslovnih i stambenih zgrada. Taj minimum EKMI-a zgrade morao bi biti obuhvaćen glavnim projektom zgrade te bi slijedom toga taj EKMI, u skladu s općim propisima o gradnji, bio konstruktivni dio zgrade koji je od nje pravno neodvojiv. Iz općih propisa o gradnji i odredaba ZV-a o originarnom stjecanju vlasništva građenjem proizlazi da bi taj EKMI, kao konstruktivni dio zgrade, nužno pravno bio u suvlasništvu (su)vlasnika zgrade.

Investitor može glavnim projektom zgrade predvidjeti vrlo složen i skup EKMI koja udovoljava najvišim standardima za EKMI određene vrste zgrade. U tom slučaju investitor bi trebao u skladu s glavnim projektom i sagraditi takav EKMI koji također postaje sastavni, tj. pravno neodvojivi dio zgrade. Međutim, iz Pravilnika nije jasno može li investitor u glavnom projektu imati projektiran EKMI koji udovoljava minimalnim standardima propisanim Pravilnikom, a u izvedbi projekta napraviti EKMI koji udovoljava višim standardima. Smatramo da Pravilnik daje dovoljno mogućnosti da se već prilikom gradnje zgrade pored projektiranog EKMI-a izgradi i dodatni EKMI-i (čl. 14. st. 2.). Takav EKMI-i ne mora biti konstruktivni dio zgrade i slijedom toga može imati zasebnu pravnu sudbinu. Nadalje, mišljenja smo da za onaj dio EKMI-a koji investitor može postaviti preko određenog minimuma za određenu vrstu zgrade koju gradi tj. dodatni EKM i/ili EKI koji gradi, odnosno postavlja o svome trošku ili trošku nekog drugog subjekta (zakupca, ortaka, operatora, pojedinog etažnog vlasnika stambenog ili poslovnog prostora) kao tzv. „privatnu mrežu“, ne bi smjelo postojati ograničenje vlasništva na tom EKM-u i/ili EKI-u kako je određeno čl. 14. st. 2. i 3. Pravilnika. Takav EKM i/ili EKI mogli bi biti premosni sustav[12] u skladu s čl. 14. st. 2. Pravilnika koji je u vlasništvu operatora sve dok on pruža elektroničke komunikacijske usluge barem jednom svome korisniku u zgradi, a nakon toga operator mora ukloniti EKMI iz zgrade ili na valjanom pravnom temelju prenijeti EKMI u vlasništvo (su)vlasnika zgrade. Niti ZEK, a niti Pravilnik ne određuju da je premosni sustav u zgradi, predmet zajedničkog korištenja infrastrukture od strane drugih operatora tj. da operator koji je vlasnik EKMI-a u zgradi mora omogućiti korištenje svojeg EKMI-a i drugim operatorima.

Nadalje, iz odredbe čl. 14. st. 3. Pravilnika proizlazi da investitor u EKM-i i/ili EKI i/ili pristupnu kabelsku kanalizaciju zgrade može biti i operator elektroničkih komunikacija. Ako operator investira u gradnju kabliranja zgrade, odnosno EKMI-a zgrade i/ili pristupne kabelske kanalizacije zgrade, pitanje je tko postaje vlasnik EKMI-a i/ili pristupne kabelske kanalizacije. Smatramo da bez

[12] Premosni EKMI u zgradama s više korisnika poslovnih i/ili stambenih prostora definiran je čl. 6. st. 2. t. b. Pravilnika kao: „dio EKMI-a zgrade za potrebe samo određenog korisnika prostora u zgradi izveden premoštenjem zajedničkog EKMI-a“.

obzira što Pravilnik ne uređuje tko postaje vlasnik EKMI-a zgrade, operator ne bi mogao steći vlasništvo na onom dijelu EKMI-a koji je prema glavnom projektu zgrade neophodni minimum primjeren namjerni zgrade i time sastavni dio zgrade. Dakle, operator kao investitor gradnje EKMI-a i pristupne kabelske kanalizacije, mogao bi postati vlasnik samo onog dijela EKMI-a i pristupne kabelske kanalizacije koji prelazi okvire zadane glavnim projektom zgrade. Međutim, tada bi operator kao investitor EKMI-a i pristupne kabelske kanalizacije i (su)vlasnici zgrade svoje odnose morali međusobno urediti odgovarajućim pravnim poslom.

E. Preporuke Hrvatske agencije za mrežne djelatnosti

Hrvatska regulatorna agencija za mrežne djelatnosti (HAKOM) u suradnji s KUSRH – Koordinacijom udruga stanara RH, objavila je 2014. godine na svojim web stranicama brošuru „Svjetlovod dolazi u zgradu…“. Brošura je namijenjena (su)vlasnicima, predstavnicima (su)vlasnik i upraviteljima zgrada i odnosi se na svjetlovodne distribucijske mreže (SDM) te s njima povezane kućne instalacije. HAKOM posebno naglašava da se objavom brošure ne preferira svjetlovodna tehnologija u odnosu na neke druge tehnologije na koje se ne odnose propisi o SDM-u. Dakle, brošura HAKOM-a ne odnosi se na elektroničke komunikacijske instalacije u zgradama koje se sastoje od bakrenih i/ili koaksijalnih kabela, kabela za antenske prihvate, antenskih prihvata. Brošura se ne odnosi niti na one svjetlovodne instalacije u zgradi čiji je model postavljanja u zgradi uvjetovan tzv. zatvorenim modelom svjetlovodne mreže koja je postavljena do ulaza u zgradu ili u blizini zgrade. Naime, mreže koje su građene po modelu zatvorenih (krutih) svjetlovodnih mreža koji se primjenjivao prije stupanja na snagu Pravilnik o SDM-u, trebaju se po tom modelu završiti do stana, odnosno poslovnog prostora korisnika.

F. Temeljne postavke hrvatskih propisa o elektroničkoj komunikacijskoj infrastrukturi i mreži u zgradama

Iz gore navedene analize hrvatskih propisa o EKMI u zgradama koje proizlaze sljedeće temeljne postavke:

- EKI u zgradama može biti sastavni, konstruktivni dio zgrade i tada je u vlasništvu vlasnika, odnosno suvlasnika zgrade. Međutim neki dijelovi EKI-a kao što su npr. nadžbukne kanalice i kabeli u njima mogu biti u vlasništvu operatora elektroničkih komunikacija koji su ih postavili u zgradu radi pružanja usluga svojim korisnicima.
- U skladu s propisima o gradnji, za svaku rekonstrukciju, nadogradnju ili zamjenu postojećih, u pravilu, dotrajalih ili neadekvatnih bakrenih telekomunikacijskih instalacija u zgradi koje su postavljene u zgradu prilikom njezine gradnje i obuhvaćene su projektnom dokumentacijom zgrade, (su)vlasnici zgrade, kao investitori tih radova moraju dobiti izmjenu, odnosno dopunu građevinske dozvole zgrade u dijelu koji se odnosi na elektroenergetske i elektroničke komunikacijske instalacije zgrade (dio glavnog projekta zgrade pod nazivom „elektroprojekt“), tj. novu građevinsku dozvolu zgrade te se nakon njezine pravomoćnosti može početi graditi EKI. Takve nove instalacije konstruktivni su dio zgrade i, u skladu s propisima o vlasništvu i gradnji, vlasništvo su (su)vlasnika zgrade.
- Postavljanje dodatnog EKI-a u zgradi, bez zadiranja u postojeći EKI (ispravne i/ili dotrajalne ili neadekvatne instalacije), ne zahtijeva ishođenje građevinske dozvole zgrade (izmijene glavnog projekta zgrade u dijelu koji se odnosi na elektroenergetske i elektroničke komunikacijske instalacije zgrade).
- Pravilnik o tehničkim uvjetima za EKM poslovnih i stambenih zgrada, koji je na temelju ZEK-a donio HAKOM, detaljno uređuje tehničke uvjete gradnje, odnosno postavljanja EKMI-a u zgradama (novim i postojećim), kao i obveze (su)vlasnika zgrada i operatora koji pružaju elektroničke komunikacijske usluge korisnicima u zgradama. Projektanti zgrada, investitori gradnje poslovnih i stambenih zgrada i (su)vlasnici tih zgrada dužni su u procesu planiranja, projektiranja, gradnje, rekonstrukcije, dogradnje, uporabe i održavanja EKMI-a poslovnih i stambenih zgrada postupati u skladu s Pravilnikom [2].

IV. PRIMJENA RAZLIČITIH TEHNOLOGIJA GRADNJE, ODNOSNO POSTAVLJANJA EKMI-A U ZGRADAMA

Raniji propisi EU-a te najnovija Direktiva 2014/61/EU o mjerama za smanjenje troškova postavljanja EKM-a velikih brzina omogućavaju primjenu različitih tehnologija gradnje, odnosno postavljanja EKMI-a u zgradama (bakrene parice, koaksijalni i svjetlovodni kabeli) te slijedom toga ne diskriminiraju niti jednu od navedenih tehnologija u odnosu na druge tehnologije. I hrvatski propisi omogućavaju primjeni različitih tehnologija gradnje, odnosno postavljanja EKMI-a u zgradama, premda su dosadašnje aktivnosti HAKOM-a pretežito bile usmjerene na razvoj EKM-a po otvorenom modelu SDM-a. HAKOM je pravilnicima uredio da u zgradama koje nemaju izgrađen EKMI zgrade te pristupnu točku, operator koji je vlasnik SDM-a mora svoju mrežu završiti u zgradi i to do svakog stana, odnosno poslovnog prostora, tj. postaviti sve horizontalne i vertikalne instalacije u zajedničkim prostorima zgrade i to po otvorenom modelu postavljanja takvih mreža.

Radi pružanja novih usluga telekom operatori uvode pristupne svjetlovodne i koaksijalnih mreže kao NGA mreže (mreže nove generacije). NGA omogućavaju korisnicima brzine pristupa iznad 30 Mbit/s (a neke od njih omogućuju i pristup brzinama većim od 100Mbit/s). Takve pristupne mreže zahtijevaju uvođenje iste takve tehnologije i u zgrade, kako bi novi medij došao do krajnjeg korisnika. U RH postoji više operatora koji grade/postavljaju nove pristupne mreže i koji biraju tehnologiju postavljanja EKMI-a u skladu sa svojim poslovnim odlukama. Svaka od navedenih tehnologija ima svoje tehnološke posebnosti u smislu postavljanja u zgrade. Prema europskim i hrvatskim propisima niti jedna ne smije biti diskriminirana, odnosno stavljena u

privilegirani položaj u odnosu na druge tehnologije. Stoga u zgradama može biti istodobno primijenjeno više vrsta tehnologija (bakrene parice, koaksijalni kabeli, svjetlovodni kabeli/niti) ovisno o tome koju tehnologiju koriste pojedini operatori koji moraju udovoljiti zahtjevima svojih korisnika usluga. Budući da različite tehnologije postavljanja EKMI-a u zgrade imaju svoje posebne tehničko-tehnološke zahtjeve, ne mogu se kabeli različitih vrsta postavljati u istu nadžbuknu kanalicu ili zaštitnu cijev, nego je u pravilu potrebno za svaku vrstu kabela postaviti zasebne kanalice ili zaštitne cijevi.

Bakrena parična infrastruktura desetljećima je bila jedina infrastruktura koja se nalazi u zgradama i koja je bila prvenstveno prilagođena pružanju govorne usluge. Ta infrastruktura, u pravilu, obuhvaćena je projektom same zgrade te je stoga, sukladno hrvatskim propisima o gradnji i o vlasništvu, sastavni dio zgrada i u vlasništvu je (su)vlasnika zgrade. U RH bakrene parice i danas su najrašireniija infrastruktura koja je dostupna gotovo do svakog kućanstva/korisnika (cca. 1,6 mil.), a u većini stambenih zgrada to je jedina EKI. Nove usluge, koje se u pravilu pružaju u različitim paketima (širokopojasne usluge koje uključuju pristup internetu, usluge distribucije televizijskog signala), zahtijevaju znatno veće brzine prijenosa od onih koje su bile potrebne isključivo za prijenos telefonskog signala, odnosno govorne usluge. Stoga, da bi operatori mogli pružiti kvalitetne usluge svojim korisnicima, ZEK i ZV omogućavaju im postavljanje potrebnih instalacija do svakog njihovog korisnika.

Koaksijalni kabel je prijenosni medij „kabelske televizije“ koji korisnicima omogućuje korištenje svih multimedijskih usluga kao što su HD/3D televizijski programi, korištenje najbržeg interneta te usluga fiksne telefonije koji su sastavni dio modernih širokopojasnih mreža. Koaksijalni kabel danas je vrlo raširen prijenosni medij jer ima vrlo dobre prijenosne karakteristike i nisku cijenu. Najčešće se koristi kao završni prijenosni medij u sustavima kabelske televizije i privatnim kućanstvima povezivanjem satelitskih i zemaljskih antena s televizijskim prijemnicima i računala. Također, koristi se kao medij za analogni i digitalni prijenos podataka i različitih vrsta sadržaja. Koaksijalni kabeli su prijenosni medij u HFC mrežama (Hybrid Fiber Coax).

Svjetlovod je prijenosni medij sastavljen od više vrlo tankih svjetlovodnih niti načinjenih od stakla ili plastike koje provode svjetlosni signal te se omogućuje 100 puta veće brzine u usporedbi sa sadašnjim bakrenim mrežama (primjenom ADSL-a). Svjetlovodne mreže omogućuju izuzetno visoku kvalitetu prijenosa podataka na velike udaljenosti, gotovo bez slabljenja signala i sa znatno manjom potrebnom energijom te su neosjetljive na elektromagnetske smetnje. Na području RH postoje dva osnovna tipa svjetlovodnih pristupnih mreža: mreže koje su postavljene prije stupanja na snagu Pravilnika o SDM-u, te mreže koje se postavlja prema Pravilniku o SDM-u. Funkcionalna pravila za svjetlovodne mreže koje se postavljaju prema Pravilniku o SDM-u, opisana su u HAKOM-ovoj brošuri. Mreže koje su postavljene prije stupanja na snagu Pravilnika o SDM-u, tzv. kruti P2MP (točka-više točaka) model trebaju se završiti u zgradama po starom krutom modelu jer se ne može promijeniti konfiguracija izgrađene pristupne mreže od centralnih lokacija do zgrada korisnika te se u skladu s time moraju postaviti i kućne instalacije (EKMI zgrade). Model izgradnje kućne instalacije (premoštenja-vertikala) na postojećoj FTTH mreži, podrazumijeva izradu kućne instalacije do ispred svakog stana, odnosno ugradnju i vertikalnih i horizontalnih kanalica u zgradi, ugradnju glavnog razvodnog ormara i etažnih razvodnih ormara, ugradnju splitera, povlačenje instalacijskih kabela u vertikalama te priključnih kabela do ispred svakog stana. Izgradnja opisane kućne instalacije zahtjeva zasebni premosni sustav (sustav kanalica i glavnog razvodnog ormara), koji nije pogodan za smještaj drugih tehnoloških rješenja (druge vrste kabela).

V. ZAKLJUČAK

Prema odredbama ZEK-a, Pravilnika o EKM u poslovnim i stambenim zgradama i ZV-a moguće je, osim EKMI koji je sastavni i neodvojivi dio zgrade, imati i EKMI koji je „privatna mreža“ određenog korisnika usluga kao premosni sustav u vlasništvu operatora koji pruža usluge u toj zgradi. Dakle, „privatne mreže“ korisnika prostora, odnosno operatora mogu biti u vlasništvu osoba različitih od (su)vlasnika zgrade. Iz Pravilnika nije potpuno jasno koji dijelovi EKM-a i/ili EKI-a su obvezatni dijelovi infrastrukture zgrade, tj. moraju biti dio glavnog projekta zgrade te su kao sastavni dio zgrade vlasništvo (su)vlasnika zgrade, a koji se dijelovi EKM-a i/ili EKI-a mogu naknadno postaviti i biti kao „privatna mreža“, odnosno premosni u vlasništvu drugih subjekata na temelju nekog stvarnopravnog ili obveznopravnog odnosa.

Radi smanjenja troškova za postavljanje EKM-a velike brzine u zgradama Direktiva 2014/61/EU omogućava korištenje i drugih vrsta fizičke infrastrukture u zgradi, a što nije uređeno hrvatskim propisima. Stoga bi trebalo mijenjati, odnosno donijeti odgovarajuće propise kojima bi se hrvatske propise uskladilo s navedenom Direktivom tako da se omogući korištenje EKI i druge fizičke infrastrukture u zgradama, uz poštivanje načela neutralnosti tehnologije i nesmetanog pristupa operatorima do korisnika usluga.

ALGORITHMS & PROTOCOLS

Integrating Extreme Programming with Software Engineering Education

Jason Jen-Yen Chen* and Mike Mu-Zhe Wu*
* National Central University, Jhong-Li, Taiwan
jasonjychen@gmail.com

Abstract - This paper presents an 11-step "myAgile" method that integrates the extreme programming (XP) with existing university courses, attempting to build a modern software engineering education. Compared with XP, "myAgile" covers more phases, such as requirement engineering, detailed design, and reverse engineering. There were 288 students in 4 universities in Taiwan who participated in this effort. The students rigorously applied the method to develop, and to maintain, an object-oriented Grade System project in Java. The results showed that, objectively, the students produced maintainable software, which was clearly shown in another maintenance project by a different team at a distant time after the development. And, subjectively, students reported high job satisfaction that is so desperately needed in this profession.

I. INTRODUCTION

The extreme programming (XP) [1] is really a powerful agile method, which has been applauded by software engineers around the world, especially after the announcement of the agile manifesto [2] in 2001. Its 12 XP practices [3] bring us very useful engineering techniques. Note that software development involves both engineering and management aspects. The most widely-used agile method SCRUM [4], on the contrary, provides good management techniques. Because this work focuses on software engineering, rather than software management, SCRUM will not be further discussed here.

On light of this trend, we see an urgent need to integrate XP with existing courses, such as Object-oriented Analysis, Data Structure, Algorithm, Java Programming, Software Engineering, Software Testing, Software Engineering Environment, and further, to build a modern software engineering education. The endeavor brings about an 11-step XP-based "myAgile" method, which seems to be a simple and elegant way to do it.

This paper reports this "myAgile" method and its recent usage experience in Taiwan. The paper is organized as follows. First, the steps of the XP-based "myAgile" method are described. Next, a Grade System project is depicted. The students rigorously applied the method to develop the project. Then, a project questionnaire is used to collect students' feedback. Last but not least, a maintenance project highlighted this method.

II. "MYAGILE" METHOD

" myAgile" stresses face-to-face communication, which is of paramount importance in any agile method. All the steps of "myAgile" are thus conducted in "pair programming". That is, two developers sit side by side, one being the driver, while the other the reviewer. And they can switch role at any time. This ensures that very intense inter-human communication occurs in every single step of software development in order to obtain the highest possible software quality.

The 11 steps of the "myAgile" method are depicted below in Sections A to K. The input and output of every single step is described through detailed examples. Note that steps 5, 6, 9, and 10 are the original XP steps. Steps 0, 1, 2, and 3 are adopted from Software Engineering, especially Object-oriented method. And steps 4, 7, and 8 are specially designed by author Professor Chen. Overall, this method covers 3 phases of software process: 1) requirement engineering (steps 0, 1, 2), 2) architectural design (steps 3, 4, 5, 6), and 3) detailed design (steps 7, 8, 9, 10).

A. Step 0: Exploring Requirements

This step gathers the features (user stories) of the system by a pair of two customers. Since this step will be conducted in the customer site, rather than in the development site, it is omitted from the student project that will be reported in this paper.

B. Step 1: Scenarios

aUIpromptID or quit
The user wants to quit
aUIshowFinishMsg

Figure 1. (a) A simple scenario

aUIpromptID or quit
The user inputs ID
aUIshowWelcomeMsg

aUIpromptCommand:
1)show grade 2)show rank 3)update weights 4)exit
The user wants to exit

aUIpromptID or quit
The user wants to quit
aUIshowFinishMsg

Figure 1. (b) A complex scenario that extends the simple scenario

For each user story, an "on-site customer" and a developer sit side by side, jointly develop various scenarios - from simplest case gradually extending to complex cases in a step-wise refinement manner. For the

user story “manage grade systems”, Fig.1 (a) shows a simple scenario, while Fig. 1 (b) shows a complex one, which extends the simple one. In Fig. 1 (a), “aUI” is an object of the UI class. And, “promptID” and “showFinishMsg” are two public methods in the UI class. Note the boldfaces in Fig. 1 (b) shows that they originally come from Fig. 1 (a). If the developers are quite familiar with this, the step-wise refinement can be relaxed, meaning that the number of scenarios, as well as the development effort, can be reduced.

C. Step 2: Acceptance Test Cases and User Manual

For each scenario, add the exact data (expected system output data and user input data) to it. By doing so, a scenario turns into a testable acceptance test case. After all the cases are done, they are summarized to obtain a simple user manual that quickly gives users a feel of what the software is all about. Fig. 2 shows the acceptance test case related to the scenario in Fig. 1 (a). In Fig. 2, the system outputs “Enter ID or Q (Quit)?” and the user inputs “Q” to quit (note that “$” in “$Q” denotes it is a user input). After that, the system outputs “Finished” meaning that the system is finished.

```
aUIshows : Enter ID or Q (Quit) ?  $ Q
aUIshows : Finished
```

Figure 2. An acceptance test case

D. Step 3: CRC Session

For each acceptance test case, the on-site customer and 4 developers (2 pairs), totally 5 people, sit around a table to conduct a class-responsibility-collaborator (CRC) session [5] that traces a case to extract objects’ names and object interactions’ names. The objects’ names can easily deduce their class names, while object interactions names become public method names (responsibilities) for the class. Also, collaborator classes are identified during the trace. A class name along with its public method names make up a class interface. And the system architecture is composed of all these class interfaces. This really is an agile way to do Object-oriented analysis. Last but not least, don’t forget to add a class header on top of each and every class interface for documentation purpose. Fig.3 shows an example of class interface with class name C1 and two method interfaces, namely, a constructor C1 and another method m1 with two parameters p1 and p1 and a return class C2. Of course, there is a class header on top of it to document it.

```
/*-----------------------------
    Here is the class header
-----------------------------*/
public class C1 {
        publicC1 ();
        public C2  m1 (p1, p2);
} //end class C1
```

Figure 3. A class interface C1

E. Step 4: Reverse Engineering Tool

The Java class interfaces can be automatically processed by a reverse engineering tool to get graphical documents, such as UML class diagram [6]. Currently, the tool eUML2 [7] is used for the project. The developers really do not need to spend time anymore to draw the diagrams and further to verify them. It is guaranteed that the diagrams are consistent with the source code. What a relief!

This step is much more important for maintenance projects than for from-scratch projects. In this case, the maintenance engineers should first get a hard copy of the class diagram by using the tool. Then, carefully use pencil and eraser to modify the diagram and to trace the modified diagram against acceptance test cases through pair programming (1 pair) - or group review (2 pairs) if a case is a bit complicated. After the modification is done, modify the class interfaces and class headers next. This maintenance process has been field verified by the maintenance project in the Central University, as described in ”the maintenance” section later in this paper.

F. Step 5: Dispatching and Scheduling

After step 3 CRC session, the class interfaces are available and are posted on the white board in the software company. Each class interface is “picked-up” by a pair of developers based on the pair’s experience and preference. To be exact, this is not dispatching work. Instead, it is picking-up work. About scheduling, a pair themselves decides the number of days they need to finish a class, again, based on their experience plus a time allowance. Like XP, we use whiteboard to record and control the dispatching and the scheduling of programming tasks.

G. Step 6: Unit Test Code

Every public method (called a unit in XP) in a class interface needs to develop a number of test cases. And, each case is a combination of input parameter values of the method. For example, if a method “m1” has two input parameters, each with 2 values. Then, there are (2 times 2) 4 cases to test for that unit. Incidentally, it is normal as well as healthy to test quite a few cases for a unit. For example, if the first parameter has 5 values and the second 8, then there would have been (5 times 8) 40 cases to test. Next, develop JUnit [8] test code for each test case. Briefly, what test code does is to assert equality of: 1) hand-calculated expected result and 2) the actual result by executing the method. Fig. 4 illustrates the test cases and the simplified JUnit test code for method “m1”.

```
m1 test cases
test case 1: p1 with value1   p2 with value1
test case 2: p1 with value1   p2 with value2
test case 3: p1 with value2   p2 with value1
test case 4: p1 with value2   p2 with value2

public m1Test1 () {
  1. construct an object of C1 called obj1
  2. hand-calculate expectedResult of executing m1(value1, value1)
  3. actualResult = obj1.m1(value1, value1)
  4. assertEqual (expectedResult, actualResult)
public m1Test2 () { ……}
public m1Test3 () {…….}
public m1Test4() {…….}
```

Figure 4. An illustration of unit test code

H. Step 7: Data Structure Design

In object-oriented programming (OOP), presumably the public methods of a class work on the common data structure of that class. Furthermore, the data and the methods are subtly inter-related. That is, if a data structure is rather abstract, then the algorithms will be relatively simple. On the contrary, if low-level concrete data structures, such as arrays, are used, then the algorithms will get complicated. In this case, the source code will get longer, more complex, and thus more difficult to maintain.

We use a graphical document called "design sketch" to record the data structure along with a simple set of input data. The design sketch helps the developer to figure out how to get the output data from the input data, thus help develop build the problem solving thinking. It is required in this method to use as high-level data structures as possible, such as those in the Java collection framework (JCF).

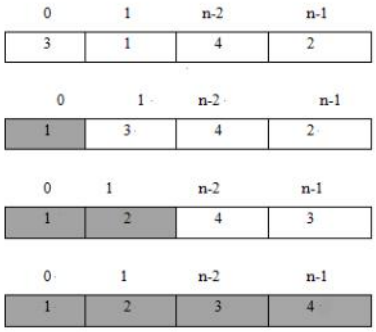

Figure 5. A design sketch of SORT [9]

For illustration purposes, however, we use a low-level data structure "array" here. Fig. 5 (reproduced from [9]) shows a design sketch with an array data structure, along with the input data "3, 1, 4, 2". And the task is to sort "3, 1, 4, 2" to "1, 2, 3, 4" . Note that the task is to sort n data. But, the design sketch intentionally shows only 4 data. The rationale behind this is to simplify problem solving thinking and pseudo-code tracing that follows next.

The sketch shows that we select the minimal number or "min" (1), from a list "3, 1, 4, 2" and swap "min" with the leftmost number (3). Next, we do the same to a smaller list without the leftmost number, that is "3, 4, 2". Repeat this until the list has been reduced to only two numbers in it, that is "4, 3". Amazingly, we now have a sorted list "1, 2, 3, 4". Notice that the array index 0, n-2, n-1 in the sketch will help the developer a lot in the algorithm design next. For example, how many iterations are needed? This question is easy to answer with the help of the sketch. The sketch in Fig. 5 clearly shows that the first iteration works on the list starting at index 0, and that the last at index n-2 (see the lists in white background). This gives us the idea of designing a loop from 0 to n-2, as shown in the pseudo-code in Fig. 6 (b).

When it comes to Java Programming, we use the Java data structure classes of the Java collection framework (JCF) [10] such as ArrayList, LinkedList, TreeMap, TreeSet, HashMap, HashSet, and PriorityQueue. Notably, the methods of these classes are all equipped with Big O time estimate. This enables development teams to get worst time estimates for all the methods they developed, which is so desperately needed by the customer!."

I. Step 8: Algorithm Design

Following the previous step, we write down the problem solving thinking in the natural language text called "pseudo-code". This usually takes several rounds from a very abstract level down to the algorithm level. Fig. 6 (a) shows a high-level abstract pseudo-code of SORT, while Fig. 6 (b) shows its low-level pseudo-code that is the algorithm. As just mentioned, the loop indexes specified in Fig. 6 (b) such as 0 and n-2 can be traced all the way back to the design sketch in Fig. 5!

```
1.select minfrom initial list,
  and then swap it with the leftmost number.
2.select min from smaller list (without the leftmost number),
  and then swap it with the leftmost number
3. repeat (2) until the smaller list contains only two numbers
```

Figure 6. (a) A high-level pseudo-code of SORT

```
fori from 0 upton-2
    1.min points to leftmost number of array[i..n-1] (that is i)
    2select min from array[i..n-1] (that is smaller list)
        forj fromi+1 upton-1
            if the number at j is less than that at min, let it be min end if
        end for
    3.swap the number at min with the leftmost number (that is array[i])
end for
```

Figure 6. (b) A low-level pseudo-code of SORT

One word about functional decomposition seems worthy of mentioning here. Each public method usually contains a big chunk of functionality, which should be decomposed into smaller, simpler lower-level private methods. This is actually the technique of structured programming (SP) [11]. SP says that, by using the 3 structured constructs of: 1) sequence, 2) selection, and 3) repetition, go to-less method can be constructed. Such a method has only one entry and one exit with subroutine calls in it. In reading such methods, there is thus no jumping around with undisciplined go to statements. Therefore, each method can be understood as one independent conceptual unit. If needed, you can read the details of a subroutine, which is another conceptual unit in its own right that can also be separately read and understood. Ideally, at the end, a subroutine should be less than 10 source lines, which makes code very readable, and thus highly maintainable.

One subtle thing about pseudo-code writing is that, for non-English speaking students, it is not easy at all to write pseudo-code in simple, correct English. Our solution to this problem is a technique called "Chinese sentence with English terms". That is, the students embedded English terms, which later are likely to become class names, object names, methods names, and so on, inside Chinese sentences. Students thus only need to develop right English terms, they no longer have to worry about English writing. This technique really helped the students.

One last thing about this step is that once the pseudo-code is done, the students need to manually trace it against a simple set of input data. With the abstraction provided by pseudo-code, the tracing would not be as difficult as tracing source code. And, if tracing is done in a "slow but firm" manner, all bugs will go away, even before coding starts! Nevertheless, it surely takes a lot of practice and quality-consciousness to do it right."

J. Step 9: Coding

Coding becomes an easy job in the "myAgile" method. All you need to do is just follow the logic of pseudo-code, and add Java source code beneath it.

K. Step 10: Unit Testing and Acceptance Testing

Unit testing refers to running the test code of a unit to test the source code of the unit. In XP, unit testing is equivalent to integration testing as will be explained next. The reason for this is that we continuously (one unit at a time) unit-test and integrate the units into the system in a bottom-up manner, thus making the low-level units naturally integrated with the unit currently being tested. This is called "continuous integration" [12], which turned out to be a powerful feature of XP.

When all the units of a user story (feature) are integrated, the on-site customer manually tests the user story against the acceptance test cases. That is, the on-site customer reads the test cases one by one and manually run the system accordingly. This is the acceptance testing of XP. The Software Testing course is thus integrated into this method. All the 11-steps of "myAgile" have been covered. Next, we will compare XP with "myAgile".

L. Comparing XP with myAgile

Compared with XP, "myAgile" shows 3 merits:

- Requirement engineering

  Trying to be as light-weighted as possible, XP pays little attention to requirement documentation. This certainly hurts acceptance testing, which needs to execute acceptance test cases to make sure that the system features can be accepted. To remedy that, " myAgile" requires on-site customer to develop scenarios from simple ones to complex ones in a step-wise refinement manner. Further, with exact data being added to the scenarios, they gradually evolve to become acceptance test cases. And, all these documents are in electronic file. All these measures greatly facilitate the evolution of requirement documents. Requirements change so rapidly that they need to be well documented and managed.

- Detailed design

  XP does not cover detailed design of classes at all. XP relies on qualified developers to design good classes. This is not enough! Instead, "myAgile" uses design sketch and pseudo-code to design data structure and then algorithm in a step-by-step way. By doing so, multiple abstraction levels of software can be constructed, which facilitates maintainers to quickly move from one abstraction level to another during maintenance process. Incidentally, this approach naturally integrates two required computer science courses, namely, "Data Structure" and "Algorithm", into this method.

- Reverse engineering

  One drawback about traditional software engineering is that design charts are usually inconsistent with the ever-changing source code. This leads to great difficulties in maintenance. Thanks to reverse engineering tools, we now have solution for it. You don't need to hand-draw design charts in the first place. Whenever you need to read design charts, just get them automatically by using a reverse engineering tool. Furthermore, it is guaranteed that the design is consistent with the code all the time. Next, we will describe the Grade System project.

III. THE PROJECT

We have designed a Grade System project for the students to apply the "myAgile" method. The reason why we chose this project is that a developer had to be very familiar with the problem domain, and this project indeed works on the domain that students are most familiar with.

This Grade System allows a user (student) to get his or her total grade and rank. Total grade is based on the weights, which can be updated. Rank denotes the order of the total grade of a student in the whole class.

Input file: The scores of all the students in a class. For example:

962001044 Lin, John 87 86 98 88 87

962001051 Lee, Wen 81 98 84 90 93

Note that the data field names for the above are:

ID name lab1 lab2 lab3 midTerm finalExam

The user menu to input command looks like this:

Input command 1) G (show Grade)
2) R (show Rank)
3) W (update Weight)
4) Q (Quit)

The students were given a 15-page project document [13] that includes:

- Scenarios (4 normal ones plus 2 exceptional ones)
- Simplified input file for tracing (two lines only)
- Acceptance test cases
- CRC design
- Architecture design in class interface, along with detailed design in design sketch and pseudo-code
- Real input file (about 60 lines)
- XP practices used in the project

As just mentioned, we gave the students 6 scenarios along with 6 acceptance test cases. And we ask them to add 2 more cases. We did CRC session for the students so that all of them work on the same architectural design, which is composed of 4 classes, namely, "Main", "UI", "GradeSystems", and "Grades". The data structure used in class "GradeSystems" is Java "LinkedList". The pseudo-codes of all the methods are given to students. And, an exemplary JUnit test code of a method is given too. Also, a simplified input file with just two lines (see the input file above) is provided for students to trace the algorithms. One-line input file cannot do it because executing a loop requires two lines at least. Of course, a real input file with about 60 lines is provided later for acceptance testing.

Regarding the development process, the students are required to use pair programming to develop this system in Java. With regard to the software engineering environment, the students must use:

- Eclipse [14] to develop easy-to-read Java source code, including header and pseudo-code
- JUnit to develop Java unit test code
- eUML2 to automatically generate UML class diagrams

Every method should not exceed 10 source lines. If too long, break it down into low-level private method. Every public method is required to have Big-O worst time estimate. At the end, turn in 3 documents:

- User manual & Acceptance test case in .doc file
- Source code in .java file
- Unit test code in .java file

The project grading will be based on readability of the documents just mentioned. And, a questionnaire will be distributed to collect students' feedback about using the "myAgile" method. Currently, we are particularly interested in how "Pair programming" and "Continuous integration" two important XP practices were going in this project.

The project has been successfully conducted in 4 universities in Taiwan, namely, Central University, Tsing-Hua University, Tam-kang University, and Taichung University of Education. The project duration varies from one university to another. In Central University, first, it is a one-month development project, followed by about one month "unlearn" period during which the students were told to forget about the project, and then it is a one-week maintenance project that maintains a project developed by other classmates. Next, we will describe the project questionnaire and its results.

IV. QUESTIONNAIRE

The questionnaire merely collects students' feedback about the method through the project. Category A question checks how well the students understand every single step of the method. Category B checks how well they use two XP techniques: Pair Programming [15] and Continuous Integration. And, Category C asks the students what impresses them most, and how their teams overcome communication problems, especially with foreign students in the team.

The project was conducted in 2013 in 4 universities in Taiwan. For administrative reasons, only 2 universities joined in 2014. There were totally 288 students who participated in it. All the students are new to "myAgile". The result of the questionnaires is summarized in Tables 1 and 2. As mentioned before, step 0 was omitted. Table 1 shows that Step 4 "reverse engineering tool" is the step that most students do not understand, regardless of university, with low scores 21, 73, and so on. This may result from the lack of free academic license of the tool. About the two focused XP techniques (Pair Programming and Continuous Integration), the students of Central University understand them better than those in other universities. Perhaps this is due to the teaching effort by Professor Chen at Central University.

TABLE I. THE PERCENTAGE OF STUDENTS WHO UNDERSTAND STEPS 1 THROUGH 10

	Step	**1**	**2**	**3**	**4**	**5**	**6**	**7**	**8**	**9**	**10**
2013	TsingHwa U.	95	98	48	21	68	77	98	98	97	90
	Central U.	98	100	81	73	90	96	90	83	100	98
	TamKang U.	87	67	42	22	60	56	76	71	69	73
	Taichung U.	100	96	71	31	43	78	84	63	80	86
2014	TsingHwa U.	100	95	65	40	90	75	90	90	100	70
	Central U.	100	96	89	79	89	96	96	92	94	96

TABLE II. THE PERCENTAGE OF STUDENTS WHO UNDERSTAND THE TWO XP PRACTICES

	XP practice	Pair programming	Continuous integration
2013	TsingHwa U.	76	63
	Central U.	90	85
	TamKang U.	67	62
	Taichung U.	75	69
2014	TsingHwa U.	77	70
	Central U.	83	78

Regarding the communication problems in a team, as quoted by a foreign student in Tsing-Hwa University who is from Central America, "There is no communication problem in our team at all!" It is a relief to know that language is not really a big problem, as long as everyone in the team is capable of speaking simple English.

V. THE MAINTENANCE

As said earlier, the project was conducted in 4 universities in Taiwan. Among them, the Central University finished the development project earlier than others, around mid-term exam. Therefore, Prof. Chen decided to conduct another maintenance project just before final exam.

The idea is that there are so many quality attributes, such as efficiency, usability, reliability, or maintainability. The authors strongly feel that maintainability is the most important one. The reason for this is that under the assumption of agile culture, the world is changing rather than static - and changing fast. With this, software

absolutely should be highly maintainable to cope with it. Further, with good maintainability, other quality attributes can be improved. For example, if usability is not good enough, then the user interface part should be maintained to fix this. Here, maintainability comes in. Therefore, the authors decided to run another maintenance project to examine the maintainability of the developed software.

The maintenance project is conducted as below. Right after the students finished the development project around mid-term exam, they were asked not to read, talk, or think about the project. This is the "unlearn" period trying to erase all the human memories about the project. This simulates the real world situation that a maintenance project usually comes many years after the original development project. Until two weeks before the final exam, Professor Chen randomly assigns each project to another different team to start the maintenance project.

The maintenance task mainly adds a user command "M (modify grade)" to the project. The maintenance team needs to read all the documents to get a full understanding of the architecture of the project. With the help of headers and reverse engineering tool, this can be quickly done. Then, the pair has to carefully modify the document (including source code) in a top-down manner. Along the way, they will use the original test code (some might need maintenance too) to assist continuous integration of the new system.

On the final exam day, the students stood up in front of the entire class to report their maintenance experience. And, the result was astonishing! Many pairs reported that they at first expected to finish the job in a week. But, it turned out that they finished it in one night! Because all the projects follow the same "myAgile" method to develop, it thus is easy for maintainers to read all the documents. They enjoyed the maintenance very much! There was a sense of high job satisfaction in the classroom that day. What a feeling! The authors sincerely hope that this passion can help the students through the inevitable tough times in their careers ahead.

Further, this is the first time for most students to read other people's code. They showed appreciation of other people's work. That is, they learned from others. This can lay foundation of the "respect" value of the agile culture.

VI. CONCLUDING REMARKS

The agile method, especially the engineering aspect provided by extreme programming (XP), has brought about a profound change to the software engineering profession, making it more enjoyable and more quality-conscious. The XP-based "myAgile" method integrates XP with existing courses to build a modern software engineering education. There are totally 11 steps in this method. Compared with XP, "myAgile" shows 3 merits:

- Requirement engineering

  It requires on-site customer to develop scenarios from simple cases to complex cases in a step-wise refinement manner.

- Detailed design

  It uses design sketch and pseudo-code to design data structure and then algorithm in a step-by-step way.

- Reverse engineering

  Design charts are automatically obtained, and guaranteed to be consistent with code all time.

A Grade System project is designed for students to practice the method in 4 universities in Taiwan. The post-project questionnaire showed that the students understood most steps, except for step 4 "reverse engineering tool", probably due to the lack of academic license. Also, it showed two focused XP practices, "pair programming" and "continuous integration", were well-understood by most students. In Central University, another maintenance project was conducted, which revealed that the developed Grade Systems were highly maintainable. Amazingly, some students showed high job satisfaction, which is so rare, yet so desperately needed, for software engineering profession.

***Abstract*- Building a complex load balancing mechanism requires good knowledge of network and networking metrics, all parts of computer systems that participate in the service, and especially sensors and sensor metrics that are providing important inputs to the mechanism algorithm. It is essential to identify potential sensors that can be used together with their specific metrics, and to understand on what degree those sensors and metrics can and may influence decisions of load balancing algorithms. The analysis of potential candidates, expected, and observed data that those sensors are returning together with their correlations with final decisions will be presented in this paper. To have the right data, and to understand the crucial correlations is essential in building a new advanced load balancing algorithm that can proactively influence load balancing decisions or reactively change decision in handling critical situations.**

I. INTRODUCTION

As discussed in previously published work [1] the intention is to define a new load balancing algorithm that will have better insight of shared resources, not only based on ingress (input) and egress (output) network traffic. Instead it will have much thorough overview of the entire computer system that is serving clients in order to avoid unwanted non-optimal balancing decisions leading to undesired outages. The load balancing decisions will be made in centralized software module called CLBDM (Centralized Load Balancing Decision Module), external to hardware load balancers, which will collect complete set of data, run load balancing algorithm, and feed the load balancers with balancing decisions.

Beside the CLBDM, there is also need to install agents on all servers in system, which will collect raw data from sensors, adjust them based on certain specifics of the local system, and send data to CLBDM.

In this case load balancers are barely routing the network traffic, not making any decisions.

It was also discussed in [1] that some of possible sensors beyond network traffic might be CPU usage and memory. The novel approach of this paper is to identify most indicative sensors together with their placement and identification of the expected numerical results of the sensors and their relevance or impact in building load-balancing decisions.

After identification of possible sensors a number of simulations were done in lab, which showed that there are correlations between sensors and final results. Moreover, impact factors of all discussed sensors were identified, quantified and built in the final load-balancing algorithm.

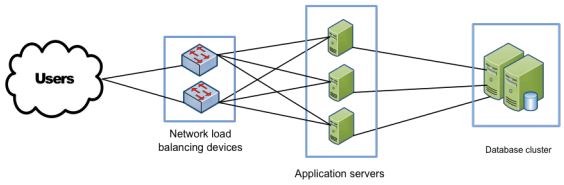

Figure 1: Schematics of typical high-availability computer system with hardware load balancers.

Computer system on which the tests were run is shown on Figure 1., and it is considered to be one of the most common setups that can be found nowadays.

II. DEFINITION OF SENSORS

The obvious starting point in identifying parts of computer system that can provide valuable information for load-balancing decisions was to observe statistics from network side of the system. As discussed in [1][2] it was already proven that data collected from network sensors, although exclusively used by other algorithms, could not be the only source of information for the advanced load-balancing system.

Beyond networking, sensors like CPU usage, memory usage, disk subsystem utilization, and number of concurrent users were considered.

All sensors will work on 5 seconds averages, to remove possible spikes, and not to overload the system with too much sensor reading activities.

Networking

Network sensors are obvious choice for all load-balancing algorithms, but should be used together with other sensors to overcome possible unwanted load-balancing decisions.

Beyond usual data that can be collected about the ingress and egress traffic load, other type of sensors can also be used.

The choice of sensors depends of the role of monitored server in computer system. For example front facing web/application servers are having one set of important sensors, while on the backend database servers completely different sensors and values will trigger our load-balancing decisions.

Another good candidate for sensor is the network latency. For example, if latency is detected by the software agent residing on web server on it's connection toward the database server, it might indicate issues on the database server(s) if the networking issues are eliminated.

All data that is produced by the agent and reported to the CLBDM must be adjusted to common set of values.

CPU usage

One of the most indicative sensors is CPU usage gathered from all components of the system. Values received from this sensor can clearly indicate the unwanted situations. One of the toughest decisions is to set triggering levels in configuration. It was observed that depending of the CPU type and installed operating system this value can differ, and at certain combination 90% CPU usage is acceptable, but 92% becomes an issue. On other systems this value can be at 95%. It is even more difficult to detect an issue where there are more cores in the CPU (and that is usual today), and received data even more depends on the operating system that is reporting it. So those data should also be adjusted to common set of values.

Memory

Memory sensor is somewhat similar to CPU usage sensor, and it also heavily depends on the operating system in use. Some operating systems (like Linux) cache parts of storage in memory, and it reports almost always that the memory is completely used, while the actual usage is different. Sensor should be aware of the real memory usage by having the knowledge of the host operating system and the way how it reports real memory consumption.

Disks

Sensors that observe disk status are also relevant and important for best load-balancing decisions, especially on database servers. There are many values that can indicate overload on the server, like the unusual traffic patterns, high disk usage and increased latency in disk responses. All of this can indicate many different situations, for example that disk subsystem is really overloaded or that disk system has imminent failure approaching. This sensor should be written in such a way that these possibilities are identified and observed. It also depends on the type of database setup if load-balancer can do anything to mitigate situation when disk subsystem becomes overloaded.

Number of http requests

One of the good indicators that something has gone wrong is unexpected rise of the http requests. This sensor might also be considered as one of the networking sensors, but it was isolated because it is better to pull this information from web server than from a networking subsystem where http requests can be aggregated (some network accelerators aggregate multiple http request to a single one to offload traffic from web servers). While the number of http request on the web server might still be aggregated, for the sake of sessions they must be uniquely identifiable – and counted for.

Number of users and sessions

One of the most observed sensors is a number of users and sessions. In ideally balanced system this number should be equal across all front facing web/application servers. Although it might not be a sensor on which to base decisions, it is important input for CLBDM to track current status of users and servers.

III. Adjusting Sensor Values on Agent Modules

As discussed before there is a need to make adjustments on agent (sensor) side in order to provide more unified data to CLBDM. It was generally decided that all sensors indicating utilization will be adjusted to fit range of values from 0 to 100 for a 5 second averages.

One of the most difficult sensors to adjust is a CPU usage sensor. In practice, it depends on the underlying operating system, number of processors and cores installed in the server.

Since most of modern applications and modern operating systems are handling multiprocessor and multicore environments well, it was decided that the overall CPU utilization will be calculated as aggregated usage of all cores divided by the number of cores to get the uniform numbers.

The aggregated number that have just been computed in this way will be then adjusted by the local agent, aware of the local operating system and caveats of its CPU reporting and handling typical values. Their values are adjusted in a way that ranges from 0 to 69 indicate normal operation, from 70 to 89 indicate intensive CPU operation and above 90 indicate overloaded processor.

Figure 2. shows how the typical values are adjusted by the agent.

Adjustment is calculated by the relatively simple formula that takes as one of the inputs a coefficient of CPU saturation (C_{cs}) that has been measured in lab, and then it is adjusted for sending to CLBDM. Here is the equation used:

$$U_c = \frac{U_r C_a}{C_{cs}} \qquad (1)$$

In this equation, C_a is a coefficient for adjustment, in this case we have decided that it is fixed to 90% to match previously decided scale. The C_{cs} is coefficient that depends on operating system and processor types. U_r is utilization as it is read from the system. It was observed in lab and the values are shown in Figure 3.

OS	CPU#	Cores	Per core utilization	Aggregated utilization	Adjusted value
Windows Server 2008	1	1	60	60.00	58.06
	1	4	38/26/33/41	34.50	33.39
	2	4	77/78/77/68 78/56/66/65	70.62	68.34
Linux 3.12	1	1	60	60.00	54.55
	1	4	38/26/33/41	34.50	31.36
	2	4	77/78/77/68 78/56/66/65	70.62	64.20
Windows Server 2012 R2	1	1	60	60.00	56.25
	1	4	38/26/33/41	34.50	32.34
	2	4	77/78/77/68 78/56/66/65	70.62	66.20

Figure 2: Adjusted values for some typical CPU setups and readings.

OS	CPU Saturation level
Windows Server 2008	93%
Linux Kernel 3.12	99%
Windows Server 2012 R2	96%

Figure 3: Values for CPU saturation for listed operating systems.

Beside the adjustment of CPU Usage values, it is also important to get correct information about real memory usage, since some of modern operating systems use the rest of the free memory as a dynamic cache, so the reported free memory might seem to be consumed, while in fact it is still available. The AM (Agent Module) needs to calculate exact amount of consumed memory and report to CLBDM in a percentage of total memory. Partial memory listing from a Linux based web server in Figure 4 shows that of 1.8 Mbytes of memory, only about 0.2 Mbytes is free, while in fact only about 1 Mbytes is consumed by the system and applications, and the 0.6 Mbytes is consumed by cache.

```
MemTotal:        1737364 kB
MemFree:          214568 kB
Buffers:          312484 kB
Cached:           653208 kB
SwapCached:         2444 kB
Active:          1041344 kB
Inactive:         354548 kB
Active(anon):     359332 kB
Inactive(anon):    70944 kB
Active(file):     682012 kB
Inactive(file):   283604 kB
Unevictable:           0 kB
Mlocked:               0 kB
```

Figure 4: Part of memory listing from a Linux based web server

When it's time to calculate the free memory for Linux systems, it is correct to sum consumed memory and deduct sum from the total available memory, than to blindly believe in number that system reports as a free memory. Free memory can be calculated with following formula:

$$M_{free} = M_{max} - (M_{sys} + M_{cache} + \cdots + M_{user}) \qquad (2)$$

From the disk subsystem it is possible to get a number of information about the current status, like the number of read/write operations, average read/write times, number of IOPS (I/O Operations), etc. Figure 5 shows a typical report from the Linux kernel.

Figure 5: Part of disk subsystem report from a Linux based web server

It is a little bit more difficult to adjust this type of raw data to fit need of CLBDM, but it is possible if data are tracked through the time. One of the important information here is the number of IO operations, bolded and underlined in each row. This number shows the number of operations in last second. As discussed in [4] the number of maximum IOPS for single hard disk depends on several factors (block size, disk type, …), but generally following values can be found in Figure 6.

Disk Type	Max IOPS
HDD SATA, 3 Gbit/s, 7200 RPM	≈150
HDD SAS, 6 Gbit/s, 15000 RPM	≈350
SSD SATA, 3 Gbit/s	≈1770

Figure 6: Maximum number of I/O operations on typical drives

There is additional difficulty if the drives are in the RAID array, or if the server is attached to external storage, then the number of maximum IOPS must be carefully calculated and fed into the Agent Module. For final normalization before reporting to CLBDM, following equation is used:

$$U_d = \frac{n_r}{n_{max}} * 100 \qquad (3)$$

where n_r is number of actual IOPS, and the n_{max} is a estimated maximum of IOPS for the attached disk subsystem.

IV. Results from Simulations

After identification of potential sensors, their normalization in the Agent Modules, a number of simulations were conducted in lab to prove correlations between sensors and the real status of the system.

The lab was setup as a virtual copy of the typical computer system setup as shown in Figure 1. Additional resources were added to play the role of the users (external to this system), and additional tools were used to simulate overloaded web/application servers. All simulated problems were conducted on one of the application servers, while others were not affected. Figure 7 shows the type, and number of simulations conducted.

Simulation type	Test ID	Seq. number
CPU overload, >99%	C1	1 – 200
Network overload, >99%	N1	201 – 400
Disk overload, >99%	D1	401 – 600
Combined, CPU + DISK	CD	601 – 800
Combined, all	CA	801 - 1000

Figure 7: Type of simulations conducted together with seq. numbers

Figure 8 shows the result of conducted tests and correlations with identified sensors.

	Simulations conducted				
Sensors observed	C1	N1	D1	CD	CA
Network traffic	0.18	99.9	0.27	4.3	97.7
Network latency	98.8	97.8	0.02	88.5	98.4
CPU usage	100.0	67.3	58.8	88.3	100.0
Memory usage	48.4	99.4	73.4	99.2	97.4
Disk usage	38.1	42.1	100.0	95.3	99.3
Number of http req.	0.0	99.9	0.2	0.0	34.3
Number of users and sessions	0.0	99.9	0.0	0.0	42.1

Figure 8: Correlation table for identified sensors and conducted lab simulations

The correlation table shown in Figure 8 shows correlations in percentage, meaning that 100% has perfect correlation between the sensors and the conducted tests, while the number close to 0 shows that there is no direct correlation detected for that sensor/test pair. Correlations were calculated by increasing overload factors during tests and observing results in sensor values.

First conducted test is the CPU overload test (C1) and its impact on the sensors on the web server. Test was repeated 200 times. To simulate high CPU usage command line tool called `stress` was used, and for reading of the results a number of tools like `vmstat`, `mpstat` and `htop`. All command were invoked from scripts to easily handle repeating the test, and saving results in the file after each of iteration, together with average results. It was observed that during all iterations the results were repeating, so the averages taken were almost exact with a single iteration.

CPU overload test has shown that it has high impact on the CPU sensor, and Network latency sensor. It has medium impact on the Memory usage and Disk usage sensor, while it has no impact on other sensors. The results were inline with expectations, and it shows that it has high correlation between impact on the system and sensors.

All other tests were conducted in similar manner, and the results showed correlations between certain sensors and the impact on the system. Some test showed results that were more fluctuating between the iterations, but the fluctuations observed were about +- 10%, what was accepted as satisfactory and the averages were used.

VI. Related work

Load balancing in cloud and virtual environments is becoming increasingly important in recent years, and the number of authors working on the similar models is growing up [3].

Nuaimi et al. [5] presented a performance survey of several load balancing algorithms in cloud computing. Another study on dynamic load-balancing techniques was conducted by Randles, Lamb, and Taleb-Bendiab [7].

Kuhn and Sesum-Cavic in [6] proposed their solution called SILBA (Self Initiative Load Balancing Agents) which exchanges pluggable algorithms to select the best algorithm for a certain problem and condition.

Bhadani and Chaudhary [8] proposed solution similar in concept with [1], offering a central decision module called Central Load Balancing Policy for Virtual Machines (CLBVM) to balance the load evenly in a distributed VM/cloud computing environment and migrates particular VM to lightly loaded server if its performance is affected by other VMs.

T-Y et al.[9] proposed a method to find an algorithm to minimize the data duplication and redundancy. The algorithm proposed is called INS (Index Name Server) and it integrates de-duplication and access point selection

optimization. There are many parameters involved in the process of calculating the optimum selection point. Its feeble points are: No forecasting algorithm to identify the future behavior of the nodes and it is complex in terms of implementation.

Xiaona Ren et al.[10] considers the unique features of long-connectivity applications, which are increasingly popular nowadays in cloud computing. An improved algorithm is proposed based on the weighted least connection algorithm. In the new algorithm, load and processing power are quantified, and single exponential smoothing forecasting mechanism is added.

While a number of authors are conducting similar research, there are no papers that are directly related to novel approach presented in this paper.

VII. CONCLUSION

In this paper, basics of advanced centralized load balancing approach were shown. In order to get better overview of the entire computer system that is serving services to end-users, it is imperative to understand exactly key performance indicators from the entire system, before making load-balancing decisions.

Following that, a number of key sensors were identified, and for some of them it was shown how the values were adjusted before importing them in the CLBDM, because of the differences between operating systems and how they handle information about key performance indicators. With this additional information CLBDM will have better overview of the entire system, and by using it's own internal algorithms feed load-balancing decisions to the balancers. While the algorithms are beyond scope of this paper it is intended to have the ability to store multiple algorithms as CLBDM sub-modules and to choose most appropriate load-balancing algorithm on the CLBDM on case-by-case basis.

To check expected correlations between identified sensors and key performance issues in the system, exactly 1000 simulations were conducted in the lab environment, divided in five different simulation types. The results were shown in the figures, together with the correlations between sensors and simulations. The results from simulations confirmed that by observing a number of sensors across the system it is easy to identify a number of performance issues across the system, and to influence load-balancing decisions in accordance with received results. It also shows that observing only networking sensors cannot detect the impact that conducted tests made on the system.

All of these prove that this approach has capability to detect difficulties that were hard to detect before, and to influence load-balancing decisions through specialized centralized module that has more thorough overview of the entire system serving services to the end users.

Design of the BCJR Decoding Algorithm with Reduced Space Complexity

Dejan Spasov

Abstract - Given an *M*-state (recursive) convolutional encoder, we show that, in theory, computing the forward alpha probabilities of the BCJR decoding algorithm can be done with 2*M* memory elements. Building on this idea we propose new design with reduced space complexity for the original BCJR algorithm. Initial experiments with rate-1/2 1025-bit-long Turbo Codes show possibility for compressing the size of memory for the alpha probabilities for about 97%.

I. INTRODUCTION

Given a length-*n* convolutional code with *M* states, the goal of the Bahl-Cocke-Jelinek-Raviv (BCJR) decoding algorithm is to provide Maximum A Posteriori (MAP) probability estimate L_i for each information bit y_i in the received sequence [1]. For a long time this algorithm has been considered of no practical importance due to its higher computational complexity compared to the Viterbi algorithm. However, the widespread popularity of Turbo codes sparked research interest on the decoder as well [2] - [4]. Many variations of the decoder have been proposed in attempt to lower the space or time complexities. One line of research that originated from [2], divided the trellis diagram in equally sized windows and then the BCJR algorithm is run within each window independently [2], [5]. Another popular algorithm that achieves memory reduction is the M-BCJR algorithm, in which certain states in the trellis diagram are considered dead an set to 0, thus reducing the memory requirement [6]-[8].

In this paper we addresses the issue of memory reduction in unoptimized BCJR algorithm. In Section II we start with the assumption that all forward alpha probabilities have to be stored and propose model with space requirements that do not depend on the code length *n*, but only on the number of encoder states *M*. Reduced space complexity comes at the cost of increased time complexity; thus, additional (but parallelizable) computations must be performed in the backward stage of the algorithm. In Section III we propose practically realizable BCJR decoder with reduced memory. However, due to the finite precision of computer arithmetic, this decoder cannot achieve the complexity of the theoretical model. In Section IV we use parallel concatenated Turbo Codes with RSC encoders to perform simulations with our modifications to the BCJR algorithm. We have observed memory reduction for 97% the forward α probabilities at the expense of acceptable 0.1 dB loss of the error correction capability of the Turbo system.

II. THEORETICAL FOUNDATIONS

In binary case, the Maximum A Posteriori (MAP) probability estimate at the time *i*, L_i, is given as logarithm of the ratio of two probability functions, i.e. when the observed bit is 1 and when the observed bit is 0 [9], [10]

$$L_i = \log \frac{\Pr\{y_i = 1 \mid observation\}}{\Pr\{y_i = 0 \mid observation\}} \qquad (1)$$

It is common that convolutional decoders are envisioned as to be moving through a trellis diagram and storing the necessary information in the vertices of the trellis. *Trellis diagram* is labelled *n*-partite graph, in which every path represents a valid codeword (fig. 1). Vertices of the *n* disjoint sets in the trellis represent all possible 2^l states of the encoder.

In this environment, the BCJR algorithm is envisioned as two stage process. In the first stage, known as *the forward α recursion*, the algorithm is moving through the trellis in left to right fashion and with each state *s* at the time *i* it associates probability function $\alpha_i(s)$ that is recurrently computed from its predecessors $\alpha_{i-1}(s')$ and the branch information $\gamma_i(s, s')$. In the second stage, known as the *backward β recursion*, the algorithm recurrently computes additional probability function $\beta_i(s)$ using different initial conditions and similar equations. Then, at the time *i* it combines $\beta_i(s)$

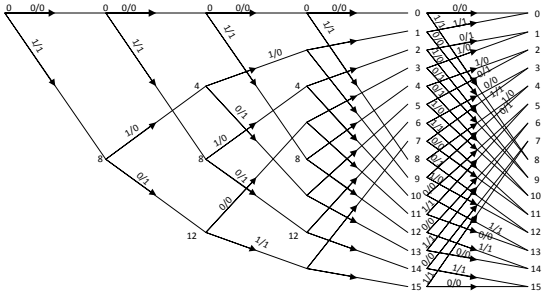

Figure 1. Trellis diagram of a 16-state convolutional code

with pre-stored $\alpha_i(s)$ and outputs (1).

The computation of the forward α probabilities starts from the initial conditions at the time i=0

$$\begin{cases} \alpha_0(s)=1 & s=0 \\ \alpha_0(s)=0 & s\neq 0 \end{cases} \tag{2}$$

and following the edges of the trellis with non-zero branch probabilities $\gamma_i(s,s')$, the decoder, at each iteration stores all $\alpha_i(s)$ and computes $\alpha_{i+1}(s)$, according to

$$\alpha_{i+1}(s')=\sum_s \alpha_i(s)\gamma_i(s,s'),\ c\ . \tag{3}$$

The computation of the backward β probabilities starts from the initial conditions at the time i=N

$$\beta_0(s)=1/N \quad \forall s \tag{4}$$

and following the edges with non-zero branch probabilities $\gamma_i(s,s')$, the decoder at each time i computes $\beta_i(s)$, according to

$$\beta_i(s')=\sum_s \beta_{i-1}(s)\gamma_i(s,s'),\ s'\in\{0,..,M-1\}\ . \tag{5}$$

During the backward stage our goal is to recompute $\alpha_{i+1}(s)$ from $\alpha_i(s)$ thus to eliminate the need to store all $\alpha_i(s)$ in memory. We will consider (3) as system of M linear equations with M unknowns, i.e $\alpha_i(s)$. Solving this system will give us the values $\alpha_i(s)$.

Let assume that with the forward recursion we have arrived at the time i=N-1 and we have computed all $\alpha_{n-1}(s)$. Next, we compute L_{n-1} and in parallel with the β recursion, we recompute all $\alpha_{n-2}(s)$ from $\alpha_{n-1}(s)$. We compute L_{n-2} and repeat this for all information bits.

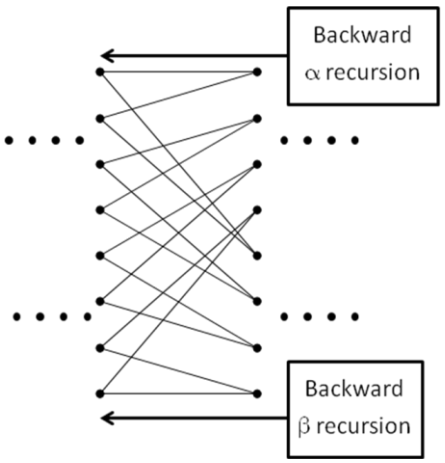

Figure 2. Backward computation of the $\alpha_i(s)$ probabilities

Thus with the forward recursion we only need to find all $\alpha_{n-1}(s)$, without storing any intermediary $\alpha_i(s)$. Then, during the backward computational stage we include additional processor (fig. 2) that backward-recursively computes $\alpha_i(s)$ from $\alpha_{i+1}(s)$.

We should note that this description of the BCJR algorithm can be applied on arbitrary block code.

A. BCJR Decoding of Convolutional Codes

In theory, any algorithm that solves system of linear equations can be used in the backward stage to solve (3). However, this approach may impose quadratic slowdown in the backward stage. Convolutional codes have certain regularity that helps in solving (3) faster. Convolutional codes over an alphabet of q elements have regular trellises that are made of M/q subgraphs known as butterflies. Thus, in the case of convolutional codes, (3) can be split into M/q independent systems of linear equations with q unknowns.

Example of a butterfly with corresponding channel and state probabilities for a convolutional code over binary alphabet is given on figure 3. The system of linear equations that corresponds to the butterfly is given with

$$\begin{aligned} \alpha_{i+1}(u)&=\alpha_i(x)\gamma_i(x,u)+\alpha_i(y)\gamma_i(y,u) \\ \alpha_{i+1}(v)&=\alpha_i(x)\gamma_i(x,v)+\alpha_i(y)\gamma_i(y,v) \end{aligned}\ . \tag{6}$$

Solving (6) for the unknowns $\alpha_i(x)$ and $\alpha_i(y)$, we obtain the expression that has to be computed in the backward decoding stage. Due to the symmetry in computations we use

$$\alpha_i(x)=\frac{\alpha_{i+1}(u)\gamma_i(y,v)-\alpha_{i+1}(v)\gamma_i(y,u)}{\gamma_i(x,u)\gamma_i(y,v)-\gamma_i(x,v)\gamma_i(y,u)}\ . \tag{7}$$

state x at the time i.

III. Design of the Decoder

In theory, forward α and backward α computation can be designed with memory size of just 2M. However, the finite precision of computer arithmetic introduces two types of errors that can deviate the decoder from the ideal behavior.

The first type of errors are *the round-off* errors. These errors occur during the many exponential computations of

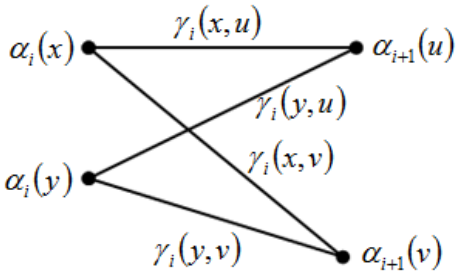

Figure 3. Binary butterfly of a convolutional code with corresponding metrics

the branch metrics $\gamma_i(s,s')$ in the forward and the backward stage. Round-off errors can cumulatively become so large that they will make the decoder catastrophic. To avoid this from happening, at this point of research, we use higher precision arithmetic – the IEEE's 754 double precision format. In addition we periodically store all $\alpha_i(s)$ at regular time intervals that are multiple of a constant T. Then we employ backward α computations between two successive storage points $\alpha_{iT}(s)$ and $\alpha_{(i+1)T}(s)$ (fig. 4).

The second type of errors are *the cancellation errors*. For example, in a butterfly it may happen that $\alpha_i(y) >> \alpha_i(x)$. Thus after the round-off stage, (6) will become

$$\begin{aligned}\alpha_{i+1}(u) &= \alpha_i(y)\gamma_i(y,u)\\ \alpha_{i+1}(v) &= \alpha_i(y)\gamma_i(y,v)\end{aligned}. \qquad (8)$$

We see that the value of $\alpha_i(x)$ is lost during the forward recursion. In the case of the BCJR algorithm we do not recover from these errors because they do not affect the performance.

In addition, it may happen $\alpha_i(x)$ to become negative. In this situation we can set $\alpha_i(x)$ to zero or we can take absolute value of (7).

The last issue that we have to resolve is the periodic normalization [5]. During the forward α computations, periodic normalization $\alpha_i(s)/t_{\alpha,i}$ is introduced in order to avoid overflow. However, during the backward α computation this normalization may create underflow. Hence we need to perform *denormalization*, i.e. to multiply $\alpha_i(s)$ with appropriate coefficients $t_{\alpha,i}$. Using the original normalization coefficients $t_{\alpha,i}$, would require to keep them all in memory. To avoid this we use normalization coefficients $t_{\beta,i}$, from the backward β recursion in the denormalization stage of the backward α recursion. Thus we eliminate the need to store the original normalization coefficients $t_{\alpha,i}$.

Next we give pseudo code for the backward α algorithm:

```
for each information bit i=n-1 downto 0
  if (i mod T == 0)
     restore α_i(s) from memory
  else
     for each state s<M
        using (5) compute α_i(s)
        α_i(s) = t_β,i * α_i(s) //denormalization
```

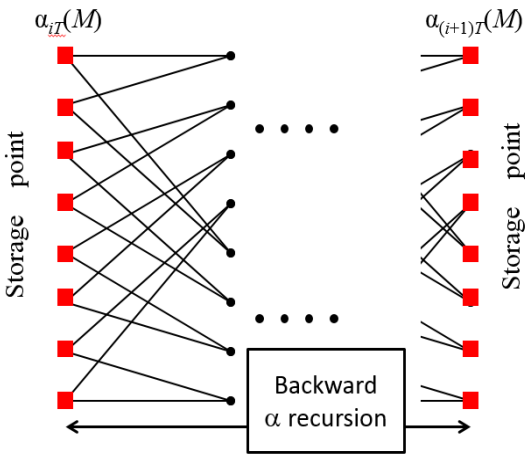

Figure 4. Periodical storage points in a real MAP decoder

IV. Practical Results

In testing our designs we have used parallel concatenated Turbo Codes (fig. 5). To be more precise we use rate-1/2 16-state 1025-bit long Turbo code over Gaussian channel. In addition, we use IEEE's 754 double precision format to store state and branch metrics, although we are fully aware that this format will not be very useful in implementing this algorithm on a chip.

The comparison between our algorithm and the traditional BCJR algorithm is given on figure 5. We can notice performance degradation when going from the regular BCJR decoder to the BCJR decoder with reduced memory size. For this simulation, we have chosen that the periodical storage points to be at distance $T = 35$ information bits. At this distance we clearly have observed performance loss of about 0.1 dB. However, careful research is needed in finding the largest possible acceptable T. We should note that at some point performance degradation becomes unacceptable. For example, we have noticed that this is clearly happening around $T = 50$. From the figure it can be concluded that for $T = 35$ performance loss is about 0.1 dB at BER around 10^{-5} – 10^{-6}. In our simulations round-off errors were dominant with the BCJR algorithm, the number of cancellation errors per frame was always less than 20 in a matrix of size 1025×16=16400 32-bit words.

V. Conclusion

We have demonstrated a possibility to achieve considerable memory reduction for the BCJR algorithm. We believe that this reduction technique is powerful enough so that other memory optimization techniques may become unnecessary. Moreover, with proper parallelization (like initiating the alpha and beta computations at the same time) we can build a decoder with space and time complexities that will come closer to the complexity of the Viterbi algorithm. This will open new horizons for the convolutional codes, like using

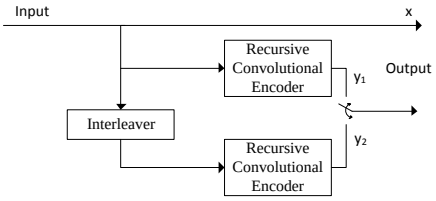

Figure 5. Binary butterfly of a convolutional code with corresponding metrics

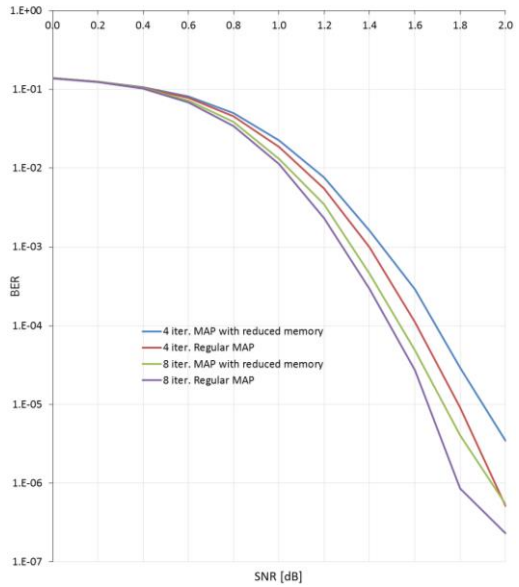

Figure 6. Performance comparison between MAP and reduced-memory MAP with periodical storage points at distance T=35

longer codewords or using convolutional encoders with 32 or even 64 states. On the hardware side, the benefit of memory saving is also important, because it will provide space reduction, less power consumption and increased decoding speed.

Popular and frequently implemented variant of the BCJR decoder is the Log-MAP algorithm. A question that naturally arises is if this reduction can be applied to the Log-MAP algorithm. While Log-MAP is often considered as MAX-Log-MAP with a correction term that is added to (7), in its nature, this algorithm is the BCJR algorithm with fixed-point arithmetic for the exponentiations. Thus in the case of the Log-MAP algorithm any memory reduction technique will increase the round-off errors, thus decreasing the interval *T* between two storage points (fig. 4).

Abstract – In this work we deal with the Achilles' heel of wireless sensor networks – energy efficient operation. By a combined MAC/physical layer attack on the issues contributing to energy overhead, we demonstrate the possibility of reducing the overall power consumption in a relatively straight-forward way without severe alteration of common communication protocols. Results of simulations of networks using the proposed scheme are shown, partially validating the crucial ideas behind it.

I. INTRODUCTION

The advent of large-scale wireless sensor networks (WSN) [1], [2] is well-nigh. This has been brought on by a simple fact gaining precedence as time goes on - with limited resources, it is not as important to amass more, but as to utilize the ones in possession as best as possible. Through constant automatized monitoring and administration of a given system, be it of agricultural, traffic or other kind, its performance can be significantly improved with tremendous savings in terms of needed resources. Moreover, the automatized administration is far less prone to miscalculation and error than human monitoring, thereby reducing the necessary manpower. Until recently, the monitoring and administration of a wide range of systems was infeasible due to a lack of affordable and energy-efficient sensing and controlling devices. At present, a number of formidable standards is at disposition, most notably the ZigBee platform. Hence, the rapid growth in application of large-scale WSNs is underway.

However, there is a number of open problems associated with large-scale networks, the crucial one being the lack of reliable, tested algorithms and protocols for network management, both from the traffic and energy-saving perspective. Though a large number of communication protocols and power-saving schemes have been devised that, in specific scenarios, outperform the standard ones found in e.g. WLAN, it seems there is no general consensus on the cornerstones of any wireless network design – network topology, shortest-path metrics, modulations, radio channel models, radiated power control, collision control etc. The reason for this dischord is the following. A „wireless sensor network“ (WSN) is an umbrella term referring to a large number of ad-hoc sensor networks, each designed with a specific purpose in mind and to be deployed in a specific enviroment. These range from battlefield monitoring, agricultural monitoring [3], patient monitoring in hospital enviroments etc. Hence, the requirements dictated by the application lead to radically different networks in terms of size, topology, data rates and, ultimately, energy consumption.

The aforementioned issues make obvious the fact that, if there is any progress to be made in the direction of a consistent scheme for sensor network optimization, efforts should be focused on the development of fairly general algorithms and schemes which could be applicable to a wide range of scenarios.

In this paper we propose several energy-saving strategies and a heuristic algorithm of MAC control, which could satisfy this requirement of generality. It is based on the combined probabilistic and quasi-deterministic administering of the network, both at the medium-access-control (MAC) and the physical (RF power) layer.

The paper is organized as follows. In section II, we define a general wireless sensor network and its constituents, along with the relevant parameters, reviewing the key problems in the reduction of power consumption. Then, we propose a scheme for mitigating these issues, in the form of general guidelines for power levels and data transmission speed. This is followed by a description of a power-saving algorithm based on the probabilistic relaxation of the stringent default settings of the 802.15.4 MAC protocol. We conclude that section with results of simulations carried out on networks operating according to the scheme proposed in the previous section. In addition, we discuss the potential drawbacks of the proposed scheme. We conclude the paper delineating further improvements which will be adressed in future work.

II. THE PROBLEM

A. *Definitions and initial assumptions*

A general wireless sensor network consists of a given number of nodes – devices collecting data generated by its adjunct array of sensors into a buffer, and transmitting it further. Each node represents a sensing „unit cell“ covering a given region of the enviroment to be monitored. In general, a node can have an arbitrary arrangenemt of heterogeneous sensors, each generating data at different rates. Here we shall not restrict ourselves

to a specific node architecture, or consider the impact of specific sensor arrangement in detail, but rather consider a node to be simply characterized by its data output. In other words, a node is a stochastic data source. We consider the network as centralized, i.e. there is a central node towards which all the data generated by sensing nodes is transmitted and is responsible both for data aggregation and network administration (e.g. a ZigBee network). This restriction excludes gossip-type networks, i.e. networks where the data generated by a node is disseminated towards all the nodes in the network.

Now, the sensors may be „sampling" a given dynamic physical variable at a constant rate, or the sampling may be event-triggered. As most commonly monitored processes obey the Poisson distribution, we may consider the total data output of a node in a given period of time to behave as a Poisson process [4]. This may aid in the estimation of characteristic transmission periods and the amount of data generated. In addition to being a data source, a node functions as a relay passing down data received from its neighbors to the destination node.

Seen from the perspective of energy consumption, the most significant process in a wireless sensor network is the radio transmission [2], contributing to between 50 to 70 % of the total energy overhead. Though largely dependent on the hardware node architecture, type of modulation and coding used, from manufacturer data sheets and on-site measurements it can be approximately evaluated that the act of transmission can consume anywhere from 10 to 200 mW, whereas sensing consumes approximately one to two orders of magnitude less. The CPU overhead, on the other hand, is comparable to the sensing consumption. In addition, in order for a network composed of sensing nodes to function reliably, one must ensure a stable data flow, i.e. avoid congestion.Then it can be seen that, in essence, one can swat two flies with one blow – ensuring a low data packet collision rate reduces the number of retransmissions, leading to a considerably lower power consumption. This is done by modifying a network's MAC layer. This is the direction a great number of authors take in mitigating the issue of energy efficiency, e.g. [5], [6], and is the direction we follow. However, we put greater emphasis on the interrelation between the MAC and the physical layer, as will be discussed in what follows.

Before we delve into the specifics of our consumption reduction strategies, we would like to address a commonly overlooked aspect of general wireless networks, not just sensor networks; its neglect leading to incorrect assumptions and, consequently, dubious MAC and routing algorithms. As is well known from mobile networks practice, the signal power in a wireless network fluctuates wildly, both in space and time due to strong coupling of a node's receiving/transmitting antenna to its enviroment. Obstacles, moving or stationary, irregular terrain and interefering signals from other sources all contribute to this predicament, rendering the network problem heavily stochastic. Unfortunately, a number of authors overly simplify the real-life scenario by various incorrect assumptions on the shape and size of a cell, neglecting potential link asymmetry and the influence of the terrain on fading. An excellent overview and rebuttal of these „myths" is given by Kotz *et al.* [7]. We base our work on the conclusions brought forth there in order to avoid typical pitfalls and enhance the generality of our approach.

B. Strategies, guidelines

As mentioned in the previous subsection, and thoroughly discussed in Kotz *et al.*, a realistic scenario in which a wireless sensor network operates is too complex to lend itself to simple models. Radio channels are prone to large variation in signal-to-noise ratio, and the mobility of obstacles and even nodes complicates analysis further. Though there are some radio channel models, extrapolated from a set of exhaustive measurements, which *may* give a more accurate picture of an actual scenario [8], they have not been tested extensively, and cannot be considered reliable. Sublimating the above discussion into a single conclusion, we state the first „ansatz":

In general, there is no reliable deterministic or quasi-deterministic metric applicable to the characterization of link quality between two nodes of a wireless sensor network. At best, a quasi-deterministic model may supplement a purely probabilistic metric.

In simple terms, how well a node transmits or receives data cannot be predicted by simple physical models, but can be quantified only by direct measurement based on reception acknowledgement. For example, one cannot predict if a data packet will be received by a node using the inverse-square power law, due to the large dynamics of the interfering signals. On the other hand, a node can request an explicit acknowledgement of reception from the destination node. On the basis of the ratio of successfully sent and dropped packets, a node can „deduce" whether it should increase the transmitting power or not, thus controlling the likelihood of successful transmission. Moreover, as shown by Blagojevic *et al.* [9], this line of thinking can be pushed even further to avoid explicit reception acknowledgement, which may actually degrade the performance of a WSN. Instead, a *probabilistic reception acknowledgement* may be used instead, where a node does not need to receive reception acknowledgements every time it sends a packet. It may ask for an acknowledgement sporadically, and based on the both the calculated reception ratio and its rate of change, decide which packets in the buffer should be sent/resent.

We build our approach upon this probabilistic reception acknowledgement paradigm. However, before we present the exact scheme, we would like to comment on general guidelines concerning the appropriate transmitted power and data rates leading to energy savings.

As most architectures suitable for implementation of WSNs grant the possibility of tuning the radiated power and varying the data rates, as well as of switching the nodes into various power-saving modes [1], it is paramount to use these degrees of freedom fully. The first rule of thumb applies to the radiated power. Specifically, whenever possible, a node should transmit the largest power possible, thus increasing the probability of reception; of course, provided it does not drown out the

signals from neighboring nodes. Therefore, when the package drop ratio, defined as

$$\eta = \frac{N_{dropped}}{N_{sent}} \quad , \tag{1}$$

increases above 0.4, the node should fire at maximum available power. For a ZigBee node, taken as an example, it is specified as 20 dBm. Otherwise, the power should be kept at approximately $0.7P_{\max}$ to reduce interference in neighboring cells; $P_{\max}$ is the largest power. As far as the transmission data rate is concerned, a larger data rate leads to a shorter transmission, thereby lowering the collision probability P_{col}. Another important observation is that if the node is in sleep-mode, as is the case when the sensor detection or innovation rates are low, the start-up time may be considerable once it goes back online. During this time no power is used for transmission, and hence one should be careful not to switch the node between the sleep and active state too often, especially when it generates a significant amount of data in consecutive frames. When this is the case, it is preferable to keep the node in the active state.

If these very general guidelines are adhered to, the power reduction factor with respect to the „out-of-the-box“ can be as high as 2. This has been confirmed empirically by network simulations carried out in OPNET.

C. A network algorithm

At this point we present the power-saving algorithm which partially mitigates the problem of long-term energy efficiency. Though there are plenty routing algorithms which use more complex score in choosing which nodes should be used as relays [10], [11], including , e.g., the effects of node power supply levels, interference etc., we opt to leave out such details, though they could be incorporated into our algorithm; this we leave for future work. In the present investigation, we assume a standard AODV routing algorithm as used in, e.g. ZigBee networks.

The algorithm presupposes the following statements to be true. Firstly, the nodes are static, with well-defined positions, as measured by the central node during the initial network setup. Each node knows its own position as well as of all the other nodes. If a node is added to the network, the central node calculates its position and passes it to all the other nodes. The communication is partitioned into time-frames, i.e. periods during which nodes can transmit and receive data, in turn partitioned into subintervals; a node picks an arbitrary subinterval and attempts to communicate. Secondly, during the initial setup, each node sends packets to its neighbors during a number of time-frames, requesting an acknowledgement reception. If the acknowledgement from the receiving node is not received within the next time-frame, the transmission is considered as failed. At the end of this “testing” period, each node has a cost table with packet reception ratios (transmission probabilities) for every node it can reach. Then, the network can start communicating according to routing tables built by the central node. During each round (time-frame), a sending node can update its cost table based on reception (or the lack of) acknowledgements. However, a more prudent strategy is to perform this every few rounds. In more detail, in general a WSN will not alter dramatically during several rounds of communication. Of course, fast-moving objects and short-burst noise sources may debilitate its functioning, but in most environments where such networks are deployed, this is not the case, or a relatively small proportion of nodes is affected. Therefore, cost tables may be updated once in a few rounds, which decreases the data overhead since a receiving node needs not send an acknowledgement in each one. This corresponds to a coarser “sampling” of the network statistics. It is possible if the statistics a node keeps does not change considerably in between two “sampling points”. In addition, it relaxes the condition of obligatory reception, necessitating retransmission until the packet is successfully delivered. Unfortunately, the implication is that there is no more guarantee of data delivery. However, most WSN networks do not transmit data which *must* be delivered. If a packet is not delivered, a newly generated one will replace it in the buffer. If this is the case, a simple strategy, ensuring that an “important” packet is delivered is to include a priority flag into the data packet – if a node receives a packet with the priority flag indicating an “important” packet, it should drop any other connection and relay the packet further. This will result in the interruption of a significant number of connections, which will need to be reestablished, increasing the energy overhead due to the increased number of new connection requests; this issue is the topic of ongoing research.

Now, as the cost table is updated, a node can assign a higher or lower transmission power depending on the probability of reception of the receiving node and its change between two transmissions. For example, if the probability of reception does not change significantly between two transmissions, while remaining above a certain threshold, the sending mode can lower the transmission power. Then, if the in probability reception does not drop below the threshold, it may maintain the chosen transmission power. This amounts to a dynamical adaptive power tuning scheme which can considerably decrease the overall power consumption.

As for the routing protocol itself, we assume the standard ad-hoc on-demand distance vectors algorithm (AODV) adopted in the ZigBee standard [12].

Essentially, the proposed algorithm blends the relaxation of the local-route cost calculation and package delivery with the AODV routing algorithm, adding the adaptive power tuning to form a flexible, simple and effective approach to power management.

To investigate the effect of the proposed acknowledgement relaxation, we compared the end-to-end delivery ratio of a network operating under the standard 802.15.4 protocol, and the same physical network operating under our proposed MAC algorithm. We have observed a 6 % degradation in the delivery ratio in the

latter case. This figure seems reasonable since a) the network dynamics is low (i.e. the generated data does not change abruptly over time periods on the order of tens of frames), b) the node RF power is, on average, increased with respect to the standard, out-of-the box network, and c) transmission times are shorter.

III. CONCLUSION

In this paper, we have argued that a probabilistic viewpoint should pervade any wireless sensor network design. The energy-saving algorithm presented is based on the relaxation of the explicit acknowledgement request, and entails an adaptive power tuning scheme, allowing one to control the power consumption in a simple way. Preliminary simulations have shown that the the reduction in power consumption with respect to a standard AODV-based network can be up to a factor of 2.6.

However, there remain open questions concerning the applicability of the algorithm to large-scale networks (having nodes on the order of tens of thousands and more), as well as the possible gains by partitioning the network into subnets, as is done, for example, when using the S-MAC protocol.

IV. ACKNOWLEDGEMENT

The research leading to these results has received funding from the project "Information and communication technology for generic and energy-efficient communication solutions with application in e-/m-health (ICTGEN)" co-financed by the European Union from the European Regional Development Fund.

Abstract-**Wireless sensor networks consist of large number of sensor nodes that have an ability to interact with the surrounding environment. The importance of finding the suitable protocol to estimate the trajectory for any moving target in a certain environment is a case of study for researchers. In this paper, new and accurate protocol for target tracking with minimum energy consumption is proposed. The proposed approach uses the static cluster and dynamic cluster head mechanism (SCDCH) to collect data from the active nodes, and then forwards it to the cluster head (CH), which in turn will send the collected data to the base station, without changing cluster border during the network's lifetime. Simulation results show that the proposed protocol has higher accuracy and save more energy compared with static clustering protocols which in turn increases the network lifetime.**

Keywords: ***Dynamic source routing (DSR), energy efficient, localization, static cluster and dynamic cluster head mechanism (SCDCH), target tracking.***

I. INTRODUCTION

Wireless sensor network (WSN) is an emerging technology which has a wide range of applications; included infrastructure protection, industrial sensing and diagnostics, battle-field and environmental monitoring, building's micro-climate controls system, biological and nuclear attack detection, context–aware computing (i.e., intelligent home and responsive environment) [1].

WSN inherits most of the features from the traditional networks. However, the unique nature of such networks adds more constraints that need to be addressed such as power consumption [2]. WSNs have several challenges such as restricted sensing and communication range as well as limited battery Capacity [3]. These limitations introduce many issues such as coverage, connectivity, network lifetime, scheduling and data aggregation. In order to prolong the WSN lifetime, energy conservation measures must be considered, scheduling and data aggregation are among the commonly used methods [4].

The energy source of a node is generally considered non-rechargeable. Using energy as a vital resource in WSNs, several MAC protocols have already been proposed to achieve higher energy efficiency during long idle period of the sensors. In WSN, an energy efficient MAC protocol is required for obtaining higher energy efficiency in difficult operating conditions, where node and link failures are common [5]. The MAC protocol manages radio transmissions and receptions on a shared wireless medium. Therefore, MAC has a high effect on network performance and energy consumption. To save the energy of the network, the total number of sensor nodes sending data is to be reduced thereby decreasing the transmission of the redundant data [6].

In [7], an energy-efficient based algorithm has been proposed, in which sensors around the target could control tracking the target statues, according to the target's direction and speed, extend sensors life and reduce the number of working sensors for target tracking system. In addition, a distributed boundary coverage algorithm has been evolved.

An approach based on dynamic sensor collaboration (DSC) for the information-driven has been proposed [8] to determine computation and communication cost using dynamic optimization information utility, by which the sensor network collaboration participants are determined.

A cluster-based distributed tracking scheme (CBDTS) has been discussed in [9]. The extended approach has been introduced by Zhao et al by adding ability to track multiple targets. Moreover, binary sensor network in [10] has tried tracking a moving object and ignoring the object direction, whether it's moving toward or away from the sensor.

The LEACH protocol has been discussed in [11]. This protocol is a remarkable scheme for immovable senor nodes. It joins the based routing of energy-efficient cluster ideas with the selected cluster head of each ones, enables saving communication resources by efficient signal processing distribution.

The rest of paper is organized as follows: Section II presents the proposed algorithm for the target tracking algorithm. Section III contains the simulation results. Finally Section IV concludes the paper.

II. PROPOSED ALOGARITHM

Energy consumption in WSN within the process of target tracking and data collection is the most critical factor. A new and accurate protocol for target tracking with minimum energy consumption and long nodes' life-time is designed in this paper. In the proposed approach, we consider that immovable homogenous nodes are distributed randomly in the field.

The network in cluster-based methods is divided into clusters. Each cluster includes member sensor nodes and a cluster head (CH). The CH is responsible for gathering data from its cluster's members and calculates the present target location and reports it to sink. The energy of the nodes is limited while the sink energy is assumed to be unlimited.

The proposed algorithm assumes that the nodes with the highest energy level in each zone at each interval time will be selected as CH according to LEACH algorithm. When the selections of CH are done, CH broadcasts control packet to its neighbor nodes, which reply with node ID and location of these nodes to the CH.

The sensors that find the target in its vicinity will promote one of them as a leader and transmit distance message to it. After that and by the evaluation of the received messages, the localization will be performed by leader. When the participants are apart, the Dynamic Source Routing (DSR) will be used for multi-hop communication.

The proposed approach uses the Static Cluster and Dynamic Cluster Head mechanism (SCDCH) to collect data from each member in the network, and then send it to the CH. Newton-Gaussian algorithm is used to calculate trajectory in addition to exact estimation method (Trilateration Algorithm). The comparison results demonstrated in the simulation section with the Static Clustering with Static Cluster Head Protocol and the proposed one using MATLAB software proves the enhancements of our proposed Protocol.

A. Network Topology

A network of M nodes is described as an M-vertex undirected graph S = (R = {1 …*M*}), every position *r* of each vertices *j* is defined by set of coordinates r_j = (x_j and y_j respective). A length $d_{j,i}$ between two vertices *j, I* ∈ R is referred to as G, which is the edges matrix. The network topology is translated by a three row matrix, where the positions of nodes are repositioned in columns as shown in Table 1.

Table 1: Topology Matrix

ID	1	2	3	.....	M
$X_{intercept}$	x_1	x_2	x_3	.....	x_M
$Y_{intercept}$	y_1	y_2	y_3	.....	y_M

According to simulation, all nodes will be reachable and fully connected based on multi hoped communication. The range of radio for the nodes should be configured optimally because that the connectivity is based on the radio range. To print out the topology network, the network matrix should be created and the radio range should be known. The network's layout includes vertices and edges between them. If the Euclidean spaces $d_{j,i}$ between the nodes *i, j* are smaller than the communication radius *R* of the considered nodes, the edges or line between the nodes can be printed, and since the wireless links are bidirectional and symmetric so $d_{i,j}=d_{j,i}$.

B. Routing Mechanism

By using the links comparison base, the routing data in (WSN) will be realized. It can compare the adopted links between the sender and the receiver in respect of links quality, the residual energy of nodes pairs or the length. Notwithstanding, the route for data delivery has been selected depending on the path with smallest investigated value. A MATLAB implementation of Dijkstra algorithm is used to discover the optional route between two nodes in the graph data structure. By using grshortpath function, the Dijkstra's algorithm is applied as in grTheory MATLAB toolbox.

The grshortpath function establishes a G matrix of neighbors, the source i and the destination j are the input arguments for the matrix. A dsp matrix with the shortest path between all node pairs in the network will be returned. Also, it returns vector with the shortest path between nodes *i, j*. The G matrix must have an exact form of the correct grShortPath algorithm processing. It contains three columns, where the first two columns contain all the nodes in the network that are neighbors of each other and the third column contains the Euclidean distance in meters between them. The G matrix can be created during the network layout printing as shown in Table II. As what mentioned before, the link lengths between all node pairs are compared with the uniform radio range R. If the condition $d_{i,j}$ <R is accomplished, the link will be assumed.

The G matrix created with these conditions since all required parameters such as IDs of two neighbors and their distance d must be known. Also, the condition of lengths is accomplished .The context of the G matrix is visualized in Table 2**.** G matrix is illustrated in Table 3**.**

Table 2: Pseudo code of layout visualization and E matrix definition.

Algorithm: G=createNbrTable
1: row = 1; *2: for all node pairs* *3: x = abs (x_i - x_j);* *4: y = abs (y_i _yj);* *5: dist = sqrt (x^2 + y^2);* *6: if $dist_{i,j}$< R;* *7: plot ([x_i , x_j],[y_i , yj]); % draw edge* *8: E(row,1) = ID_i;* *9: E(row,2) = ID_j ;* *10: E(row,3) = $dist_{i,j}$;* *11: row++;*

In case of using residual energy or link quality for establishing the route instead of the distance between nodes, we can replace the contained information in the third column of E matrix by the required information. Accordingly, the path between two nodes will be chosen as a path of high quality or with maximum energy.

Table 3: G matrix

ID_i	ID_j	$dist_{i,j}$
1	2	15.65
1	3	9.21
1	8	21.54
2	1	15.65
2	8	11.12
…	…	…

Fig. 1 shows the layout of the network which displays the links between all node pairs in the proposed protocol, a link is assumed when the length of the link between any two nodes is less than or equal to the communication range (R=80m). We deploy 80 nodes randomly in the land scape.

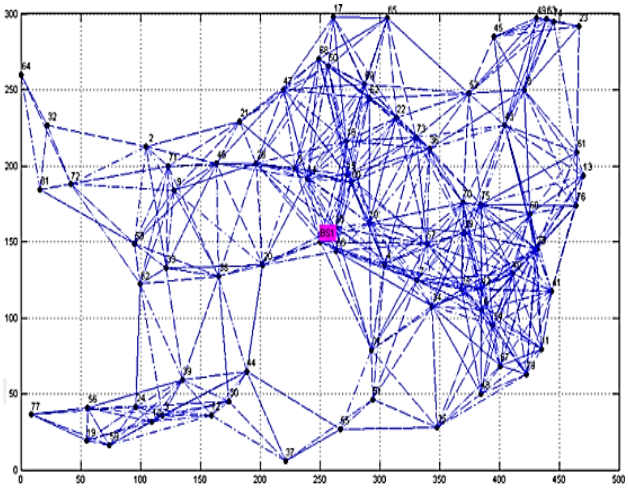

Fig. 1: Network layout with shortest path estimated by the grShortPath function.

C. Energy Model

We notice that, the energy model used in our simulation is the same one used in [12]. In this model, the energy of the sent (ET_x) and the received (ER_x) packets in the network can be described as in the following two equations:

$$E_{Tx}(k,d) = E_{elec} + E_{amp} * d^{a} \quad (1)$$

$$E_{Rx}(k) = E_{elec} \quad (2)$$

Free space model is considered in the short distance, a=2. In the simulation, the electric energy (E_{elec}) is assumed to be 50 nJ/bit and the amplifier energy (E_{amp}) is equal to 10 pJ/bit/m^2. Fig. 2 shows the sensor radio energy model main components.

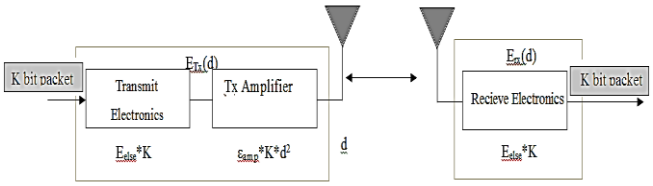

Fig.2: sensor radio energy model [13].

III. RESULTS AND DISCUSSION

In our simulation environment, the landscape has 400 nodes including CHs according to the number of zones. CHs and other nodes are randomly distributed between (x = 0, y = 0) and (x = 500, y=300) with sink at location (250,150). Each node will be initiated with 0.02j. (45-70) meters will be considered the range of communication among all nodes, sensing range is Rs=30 meters.

Target trajectory is selected randomly. Tracking period is set to 1 sec and simulation time is 3600 seconds (60 minutes), the free space model is considered in the short distance a=2 since sending distance between nodes in the cluster-based (CB) architecture that is used in the proposed protocol is assumed to be short. Fig. 3 shows the environment nodes distribution algorithm for 400 nodes.

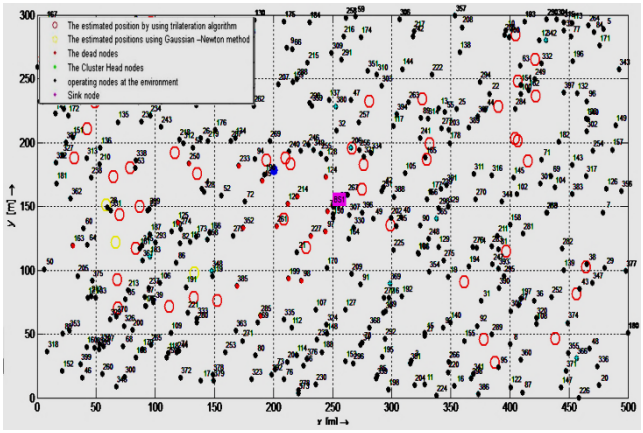

Fig. 3: Environment nodes distribution algorithm for 400 nodes

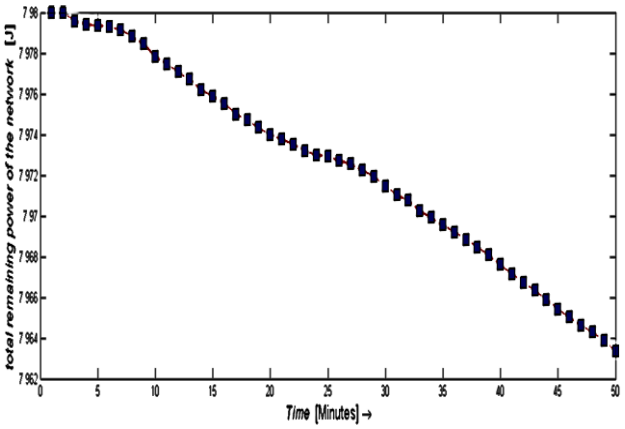

Fig. 4: The energy of the whole network for 400 node environment

Fig. 4 shows the total remaining power of the whole network as a function of simulation time for 400 node environment. From the figure, we observe that the remaining energy is decreased as a function of time. The remaining energy available for whole network at t=50 minutes is equal to7.964 J.

Fig.5 shows the number of dead nodes during the simulation time for 400 nodes. From the figure, it is clear that

after 50 minutes of the simulation, the number of dead nodes reaches 8 nodes for the simulated approach.

The proposed protocol is simulated using MATLAB and compared with well-known protocols, the static clustering approach [7] and the direct communication protocol, with the same simulation conditions. The comparison metrics are; the number of dead nodes, the estimated trajectory of the target, and network life time. The proposed approach shows higher accuracy, more energy saving, larger overall nodes lifetime. The remaining power at any node is inversely proportional to the number of processing messages that sent by this node. The remaining power of the network nodes is increased with the increase of nodes numbers.

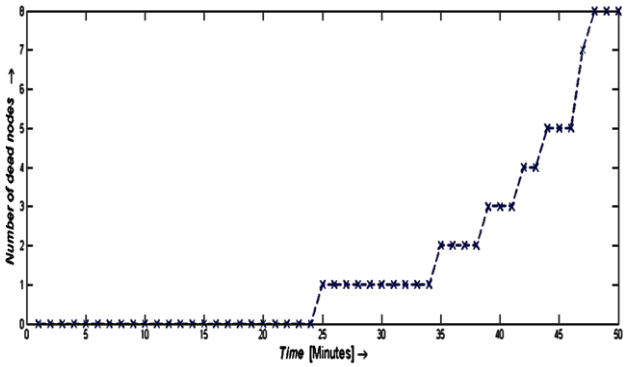

Fig.5: The number of dead nodes during the simulation time for 400 nodes

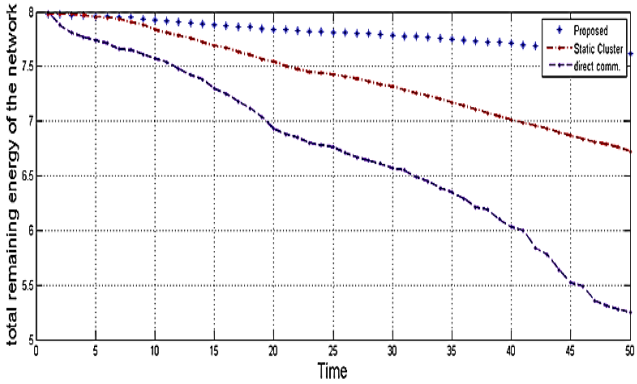

Fig.6: comparison between the total remaining energy for proposed dynamic Cluster Head protocol, the Static Cluster Head Protocol, and Direct communication protocol respectively

Table 4: Number of dead nodes for one round of simulation

Protocol	Number of dead nodes for one round of simulation
Proposed Protocol	17
Static Clustering Protocol	61
Direct Communication Protocol	120

Comparing the number of dead nodes for one round of simulation, Table 4, the proposed protocol has 17 dead nodes for one round of simulation, 61 dead nodes for the Static Clustering protocol, and 120 dead nodes for the direct communication protocol. We can conclude that the proposed protocol achieves significant reduction in energy consumption compared to the Static Cluster and direct communication protocols under the same conditions.

For the seek of comparing the network life time, Fig. 6 shows the total remaining energy of the network as a function of time. From the figure, one can see that the remaining energy within one simulation round is equal to 7.7 J, 6.70 J and 5.4 J for the proposed protocol, static CHs and the direct transmitting respectively. In addition to reducing energy dissipation, LEACH successfully distributes energy-usage among the nodes in the network such that the nodes die randomly and at essentially the same rate.

IV. CONCLUSION

In this paper, a new and accurate protocol for target tracking with minimum energy consumption and long life time nodes is designed. The proposed approach uses the static cluster and dynamic cluster head mechanism (SCDCH) to collect data from each member of the network and then send it to the cluster head (CH). The proposed protocol is simulated using MATLAB and compared with well-known protocols showing very good results in terms of the total remaining energy and number of dead nodes. The estimation error between correct and calculated trajectory using the proposed approach will be discussed and compared with recent published ones as an expansion work to this paper.

New Efficient On-Demand Multicast Routing Protocol over Mobile Ad hoc Networks

Khalid A. Darabkh and Ola A. Alsukour
The University of Jordan/Computer Engineering Department, Amman, 11942, Jordan
Emails: k.darabkeh@ju.edu.jo and ola.saqour@gmail.com

Abstract— **Due to its simplicity, efficiency, and robustness to mobility, the On-Demand Multicast Routing Protocol (ODMRP) become a standout amongst the most broadly utilized multicast routing protocols in Mobile Ad hoc networks (MANETs). Essentially, the robustness of this protocol is achieved via periodic route refreshing. However, the robustness of ODMRP comes at the expense of incurring a high control overhead to the network. In this paper, a protocol, as an improvement to ODMRP, is proposed where the refresh interval is basically adapted based on the Source Moving Speed (SMS) and number of disconnections reported by multicast members, namely, Improved ODMRP with Slow Start Join Query Refreshment (IODMRP-SSJQR). Since the majority of nodes in MANET rely on batteries, thus the main contribution of this research is to limit the amount of control information that is passed between nodes (i.e., reducing the control overhead over that in ODMRP).**

Index Terms — **On-demand multicast routing protocols, join query refreshment, source moving speed**

I. Introduction

Mobile Ad hoc networks (MANETs) are becoming increasingly popular and going to be an integral part of the future generation of mobile services [1-6]. A MANET is a vigorously reconfigurable wireless network wherein the mobility of nodes results in speedy and eccentric changes in the network topology [7-8]. Each node functions not only as a network host for transmitting and receiving data, but also as a network router for relaying packets to other nodes [9-12]. As the nodes move randomly and make frequent topology changes in MANETs, power resources, bandwidth, and processing abilities become critical [13]. To cope with the frequent changes in topology, multicast algorithms are always in need of improvements [14-15]. Multicast routing can basically be divided into four main procedures which include forwarding mesh creation, links breakage detection, local recovery, as well as join query refreshment [16].

One of the most important mesh-based multicast routing protocols is the On-Demand Multicast Routing Protocol (ODMRP) [16-17]. In this protocol, group membership and multicast routes are established and updated by the source on demand. When a multicast source has packets to send, but no route to the multicast group is available, it broadcasts a *JoinQuery* control packet to the entire network. In point of fact, this *JoinQuery* control packet is periodically broadcasted (i.e., every 3 seconds) to refresh the membership information and update routes. When an intermediate node receives the *JoinQuery* control packet, it stores the upstream node ID and reboradcasts that packet. When the *JoinQuery* packet reaches a multicast receiver, it creates and broadcasts a *JoinReply* control packet to its neighbors. When a node receives a *JoinReply*, it checks if it is situated on the path to the source and thus is a part of the forwarding mesh and broadcasts its *JoinReply* packet. In this way, every *JoinReply* control packet is relayed back to the source using the reverse path traversed by the *JoinQuery* control packet.

Notwithstanding the simplicity, efficiency, and robustness of ODMRP to mobility, it has some impediments. The static Join Query Refresh Interval Time (JQRIT) introduced in this protocol has a crucial role in its robustness via retaining redundant routes. Thus, the JQRIT is of a most extreme imperativeness to the performance of ODMRP. Such refresh interval cannot be chosen arbitrary since it has a terrible impact on the network performance. In ODMRP, the preferred value of this parameter is 3 seconds. This is justified by the need of achieving the highest possible packet delivery ratio. Unfortunately, one important dimension has been neglected which is the control overhead incurred to the network. In fact, the robustness is achieved at the cost of increasing the control overhead. In this article, we propose a protocol called Improved ODMRP with Slow Start Join Query Refreshment (IODMRP-SSJQR). This protocol follow the same forwarding mesh construction procedure employed in ODMRP. It is good to mention that there is no local recovery proposed in ODMRP. However, our proposed protocol proposes not only a new algorithm for local recovery, but also a new dynamic algorithm for join query refreshment that considers the source moving speed (SMS) and number of disconnections received from multicast receivers in its calculations.

The remainder of the paper is organized as follows: The proposed protocol is elucidated in Section II. Section III details the simulation environment. Experimental results along with observations and necessary discussions are presented in Section IV. The paper is summarized in Section V.

II. Proposed Protocol

In our local recovery algorithm, we aimed at reducing the refresh requests flooding by taking advantage of the fact that adjacent nodes have a higher probability to be detached simultaneously from the network within a short time. We employ a flooding aggregation technique and create a special control packet named as *DelegateRefreshRequest* packet. We inserted a new field inside *DelegateRefreshRequest* control packet called *HopCount*. Any node that receives the *DelegateRefreshRequest* packet creates an entry inside a local maintained table called *RefreshRequestTable* and stores the *HopCount* for a specific period (i.e., a minimum join query refresh interval time, 3 seconds). Thereafter, the node increases the *HopCount* field by one and rebroadcasts an updated *DelegateRefreshRequest* packet. When a node fails in local recovery and intends to generate *DelegateRefreshRequest* packet, it uses the *RefreshRequestTable* to detect if any neighboring node (*HopCount* is up to two) does generate a *DelegateRefreshRequest* packet recently. If a neighboring node does, the disconnected node refrains from sending a new *DelegateRefreshRequest* packet. Using this technique makes the suppression more efficient and representative for a group of disconnected neighboring nodes from the forwarding mesh, which will save the network recourses and enhance the overall network performance.

In our SSJQR proposed algorithm, we divided the source node moving speed into two ranges: low mobility speed (i.e., 1 - 30 mps) and high mobility speed (i.e., 31 - 50 mps). This division of the source node moving ranges was constructed based on the number of disconnections obtained through our simulation experiments while simulating the ODMRP. When the source node moves in a low mobility speed, the source node starts broadcasting *JoinQuery* control packet with a minimum refresh interval time (MinJQRIT, 3 secs) and exponentially increases the refresh interval time until two-thirds of the maximum refresh interval time (MaxJQRIT, 30 secs) unless no *DelegateRefreshRequests* are received. If a refreshment time exceeds the two-thirds of the maximum refresh interval with *DelegateRefreshRequests* absence, the increase of the JQRIT becomes linearly increasing by one-third of the previous JQRIT. The selection of the refreshment time behavior before and after the two-thirds of the maximum refresh interval was designed based on experiments to make the refresh interval increase properly with time. However, under source high mobility conditions, the JQRIT decreases proportionately to the difference between the previous and current source node speeds. Whenever the source node receives a *DelegateRefreshRequest* control packet, it decreases the JQRIT to the half of the current defined one (i.e., flight size). Figure 1 explains the whole adaptation of SSJQR algorithm.

III. Simulation Environment

In our simulation experiments, we assume that the network consists of 100 wireless nodes which were randomly distributed over a 1200 m x 800 m area. Addtionally, there is one multicast group, source, and 20 multicast receivers. As employed in [17], no packet or channel error model is considered in our simulations. The mobility model used is our simulations is *Random Waypoint* model where nodes in the simulation area select a certain destination and move towards it at a random speed that is uniformly chosen between the specified minimum speed (i.e., 1 mps) and selected maximum speed (i.e., 50 mps). Moving directions of each node were also chosen randomly and when nodes reached the simulation terrain boundary, they bounced back and continued to move. To demonstrate the effectiveness of our proposed protocol, we simulated it using The QualNet communications simulation platform (QualNet 7.1) on a PC with an Intel Core (TM) i7 CPU working at 2.4 GHz with a 2 MB cache and 8 GB RAM. Data points presented in the simulation results were calculated by taking the average of 20 simulation runs to eliminate the effect of any anomalous individual result.

IV. Results and discussions

Figure 2 shows the number of control packets generated by ODMRP and IODMRP-SSJQR against different node speeds. It is clearly seen that the ODMRP induces nearly 35000 control packets, more than the two times dose of the other protocol. This can be justified as the ODMRP induces significantly more *JoinQuery* wide flooding packets regardless of the mobility condition to maintain a robust forwarding mesh structure and exhibit better reliability. It is good to point out that this huge number of control packets, generated by ODMRP, has a severe impact on the network in term of bandwidth and node battery. However, for efficient results interpretations, Table 1 is included. As shown in table 1, the IODMRP-SSJQR cause an increase in the number of control packets as the network mobility speed increases, which is quite logical and convincing. In fact, this is in view of involving the source node speed factor in its adaptation.

TABLE I. The Number of Control Packets with Different Node Speeds

Maximum Node Speed (m/s)	IODMRP-SSJQR	ODMRP
10	7629	34475
20	8242	34752
30	8692	34927
40	10079	34944
50	11022	35097

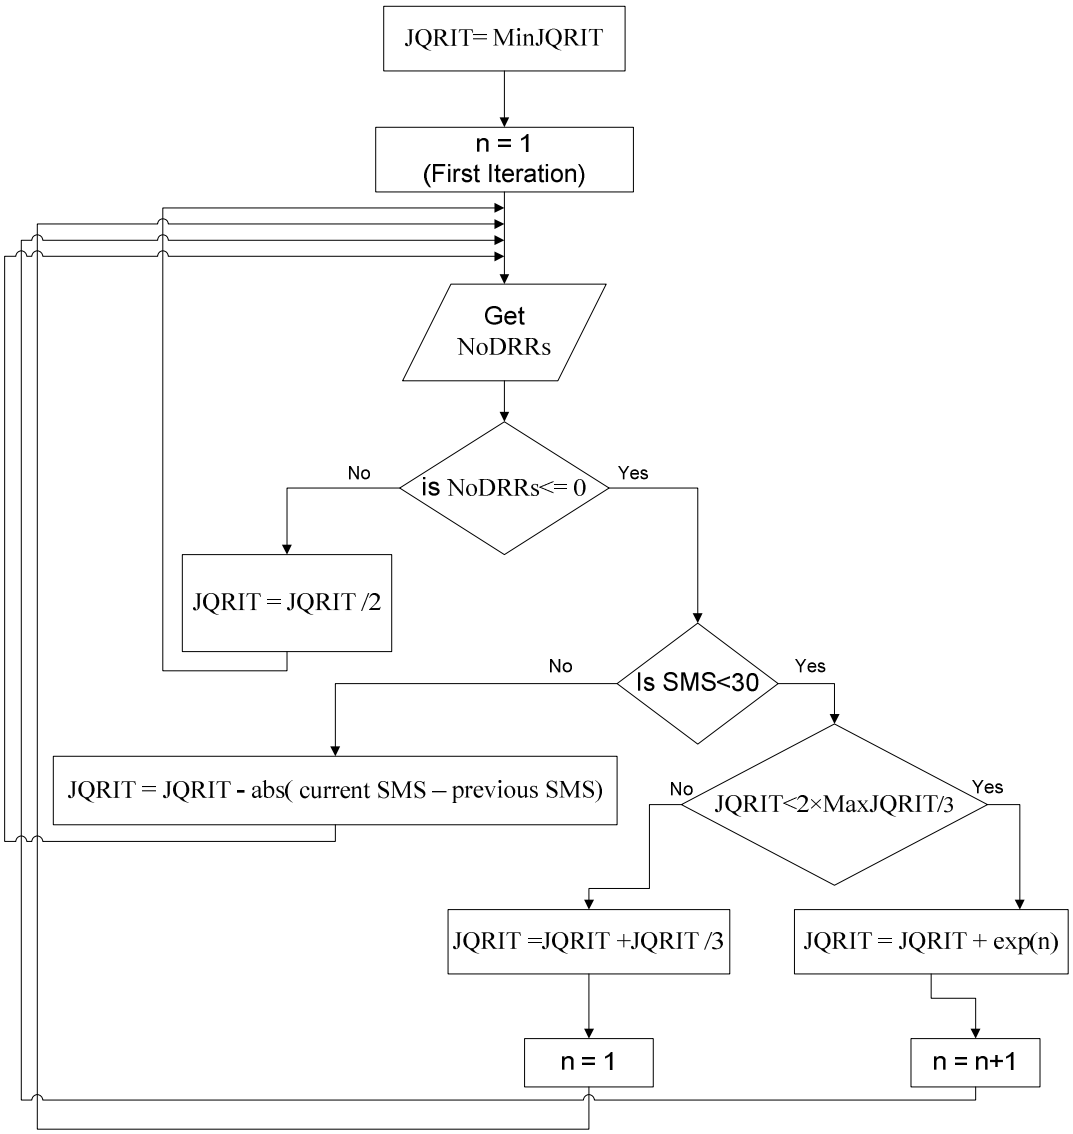

Figure 1. Flow diagram of SSJQR algorithm (where NoDRRs parameter refers to the number of *DelegateRefreshRequests*).

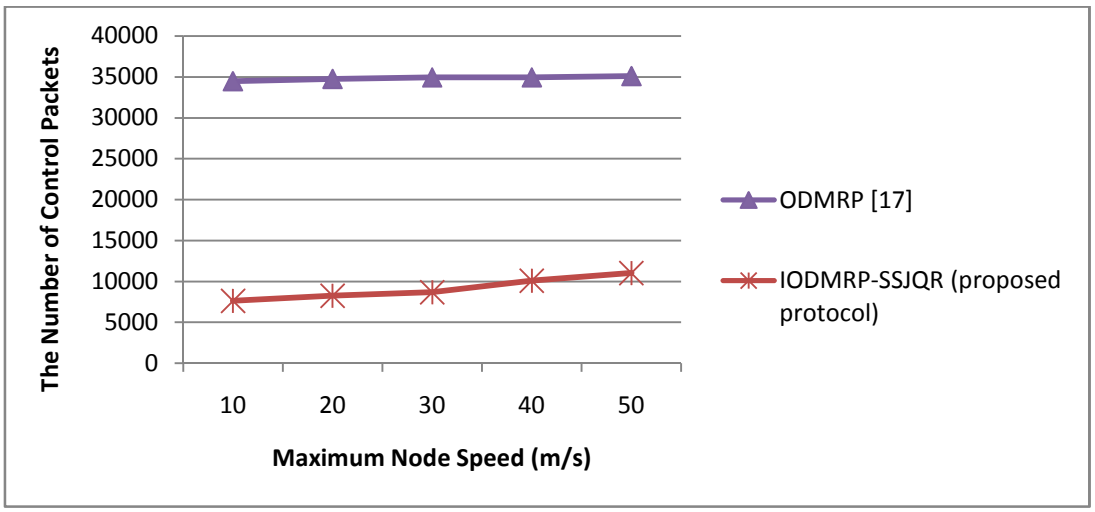

Figure 2. The number of control packets with different node speeds.

V. CONCLUSION

In this article, a new on-demand multicast routing protocol has been proposed as an improvement to ODMRP in Mobile Ad hoc networks, that is, IODMRP-SSJQR. In this protocol, two new algorithms have been proposed which include local recovery and dynamic join query refreshment interval time. Interestingly, the join query refreshment interval time is selected based on the SMS and number of disconnections reported by multicast members. The performance of this proposed protocol has been examined thoroughly utilizing the number of control packets metric. Many simulation experiments have been conducted using QualNet 7.1 and eventually concluded that our proposed protocol achieves an extraordinary improvement over ODMRP with respect to control overhead.

Abstract - In order to perform a simulative evaluation of the Hierarchical Mobile IPv6 protocol (HMIPv6) OMNeT++ simulation environment was used. OMNeT++ simulation package – INET framework and xMIPv6 was enhanced with an extension for HMIPv6, which includes Neighbor Discovery protocol, IPv6 router and the implementation of a Mobility Anchor Point (MAP). The simulation model was implemented as defined in RFC 5380 Hierarchical Mobile IPv6 – HMIPv6 Mobility Management. Enhancements are recognized in terms of an upgraded Router advertisement (RA) packet with option data about the MAP. We used dynamic MAP discovery, based on MAP option propagation in Router Advertisements from the MAP to the Mobile Node through certain (configured) router interfaces, within the routers in a network.

I. INTRODUCTION

The increase of mobile users, emergence of different radio access technologies and the increasing importance of IP services over wireless as well as wired networks, raises a number of new challenges. Delay sensitive applications, such as VoIP, have to guarantee IP service continuation during handover. In that sense Mobile IP (MIP) and Mobile IPv6 (MIPv6) were proposed to provide application-transparent IP-based mobility support.

Mobile IP is designed for mobility management of IP networks, but may result with high latency, packet loss and signaling overhead during handoff. Therefore, efficient handover implementation requires advanced mobile mechanisms that enhance Mobile IP, as well as adequate QoS support suited to real-time applications.

Hierarchical Mobile IPv6 (HMIPv6) is proposed to improve the performance of MIPv6, on signaling load and potentially reduce long handover latencies. In order to perform a simulative evaluation of the Hierarchical Mobile IPv6 protocol (HMIPv6) we used the OMNeT++ simulation environment and its communication networks simulation package INET Framework.

With the objective to implement a HMIPv6 simulation model for OMNeT++ 4.x, enhancements to the INET framework were needed, since the Extensible MIPv6 (xMIPv6) simulation model only provides mechanisms for the implementation of various MIPv6 protocol extensions.

We enhanced the INET Framework simulation model with an extended RA packet containing a MAP option, and upgraded the INET framework with dynamic MAP discovery. With this enhancement a valid HMIPv6 simulation model for OMNeT 4.x was established, for further simulation enhancements, in terms of simulation accuracy and validation tests.

II. THEORETICAL BACKROUND

Hierarchical mobility management for Mobile IPv6 is designed to reduce the amount of signaling between the Mobile Node, its Correspondent Nodes, and its Home Agent. HMIPv6 introduces a new entity called the Mobility Anchor Point (MAP), which acts as a local Home Agent (HA) for Mobile Node, to limit the amount of Mobile IPV6 signaling outside the local domain, and improve the performance of Mobile IPv6 in terms of handover speed [1]. When a Mobile Node performs handover between two access routers within the same MAP domain, it will send a BU (Binding Update) only to the MAP, not to its HA [2].

HMIPv6 protocol was developed to separate micro-mobility and macro-mobility, in regard to this RFC 5380 introduces extensions to Mobile IPv6 and IPv6 Neighbour Discovery to allow for local mobility handling. HMIPv6, as an extension of Mobile IP for micro-mobility management, involves three phases:

- MAP Discovery,
- MAP Registration,
- Packet Forwarding.

A. *MAP discovery*

The process of MAP Discovery continues as the Mobile Node moves from one subnet to the next. Every time the Mobile Node detects movement, it will also detect whether it is still in the same MAP domain. The Router Advertisement used to detect movement will also inform the mobile node, through Neighbor Discovery and the MAP option, whether it is still in the same MAP domain. The mobile node will always need to know the original sender of any received packets to determine if route optimization is required [1].

For a HMIPv6-aware implementation the Mobile Node will first register with a MAP by sending it a BU containing its Home Address and on-link address (LCoA). The Home Address used in the BU is the RCoA.

The MAP must store this information in its Binding Cache to be able to forward packets to their final destination when received from the different correspondent nodes or HAs. As the Mobile Node roams within a MAP domain, it will continue to receive the same MAP option included in Router advertisements from its AR. If a change in the advertised MAP's address is received, the Mobile Node must act on the change by sending Binding Updates to its HA and Correspondent nodes (CN) [1].

MAP Discovery is based on propagating the MAP option in Router Advertisements from the MAP to the Mobile Node through configured router interfaces within the routers. Router Advertisements are used for MAP Discovery by introducing a new option.

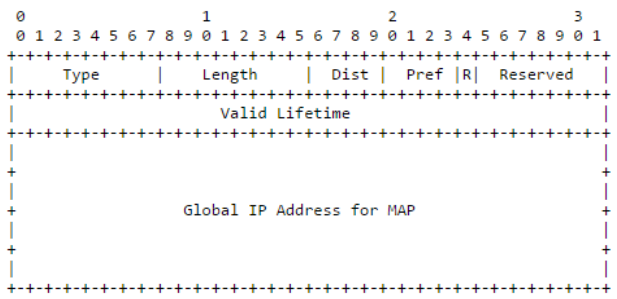

Figure 1. Neighbour Discovery Extension: The MAP Option [1]

The access router is required to send the MAP option (Figure 1. in its Router Advertisements, which are send while informing about its link presence within the IPv6 Neighbor Discovery protocol. The Router Advertisement message format has an ICMP header and message structure, like Figure 2. shows.

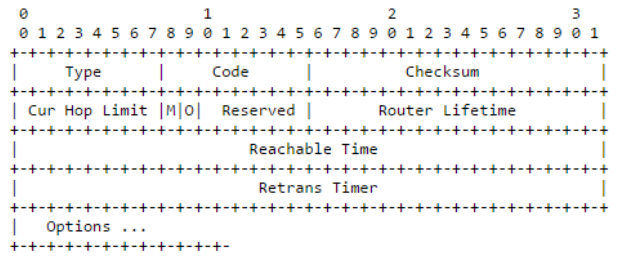

Figure 2. Router Advertisement Message Format [3]

Router Advertisements contain prefixes that are used for determining whether another address share the same link (on-link determination).

The MAP option must be available to all access routers (ARs), to be able to advertise it. The HMIPv6 specification introduces two different methods that access routers can be triggered to advertise a MAP option (MAP discovery):

- Static Configuration – Network operator manually configures all the ARs to send the MAP option, or
- Dynamic MAP discovery – Based on propagating the MAP option in Router Advertisements from the MAP to the Mobile Node through certain (configured) router interfaces within the routers.

We chose the implementation of dynamic MAP discovery.

B. MAP registration

Once the MAP has been discovered and selected, the next phase is MAP registration. MN needs to configure an RCoA on the MAP link, using the prefix advertised in the MAP option, and create a binding between the RCoA and LCoA at the MAP. The MN has to send an LBU message to the newly discovered MAP. The LBU message format is shown in Figure 3.

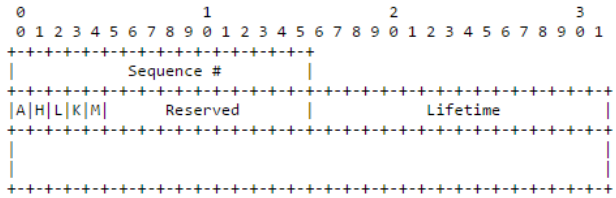

Figure 3. Local Binding Update [1]

A new flag is added: the M flag, which indicates MAP registration. When a Mobile Node registers with the MAP, the M and A flags must be set to distinguish this registration from a BU being sent to the HA or a correspondent node. If flag M is set to 1 it indicates a MAP registration.

The MN uses RCoA as the source IP address in all its packets, but tunnels them to the MAP using LCoA as the source IP address for the tunnel. In the next phase the MAP forwards packets towards the HA and CN's.

C. Packet forwarding

Following a successful registration with the MAP, a bi-directional tunnel between the Mobile Node and the MAP is established. All packets sent by the Mobile Node are tunneled to the MAP, which acts like a HA. The BAck message outer header contains the Mobile Node's LCoA in the source address field and the MAP's address in the destination address field for all outgoing packets. The inner header contains the Mobile Node's RCoA in the source address field and the peer's address in the destination address field.

For incoming packets the tunnel has to check the addresses with the changed source and destination address fields. MAP establishes a binding cache entry for RCoA, which enables packet forwarding of incoming packets to LCoA. For contrary direction a binding entry between the destination address of the tunnel and the interior package is established, to ensure internal packet forwarding to the HA and the CN's.

III. SIMULATION MODEL

To perform a simulative evaluation of the Hierarchical Mobile IPv6 protocol (HMIPv6) OMNeT++ simulation environment was used. OMNeT++ is an extensible, modular, component-based C++ simulation library and framework, primarily for building network simulators [4].

OMNeT++ requires the INET Framework, which is an open-source communication networks simulation package for the OMNeT++ simulation environment. The INET Framework contains models for several wired and wireless networking protocols, including UDP, TCP, SCTP, IP, IPv6, Ethernet, PPP, 802.11, MPLS, OSPF, and many others [5].

Since the earlier released Extensible MIPv6 (xMIPv6) simulation model [6], [7] does not scale well to new developments in the INET framework, enhancements to the INET framework were needed, to enable the implementation of HMIPv6 in the latest versions of OMNeT++ 4.x and INET Framework.

Authors [7] released IPv6SuiteWithINET simulation model to the OMNeT++ community with the base MIPv6 implementation in OMNeT++ 3.2, and assured that HMIPv6 protocol has been implemented, but needed to undergo validation tests, to be released in the coming months.

The available xMIPv6 simulation material was used as a base for our INET simulation model with HMIPv6 extension, which was implemented in accordance to RFC 5380 Hierarchical Mobile IPv6 – HMIPv6 Mobility Management. Several upgrades and modifications to the INET Framework simulation model were needed to create a working simulation model for HMIPv6, using thereby the latest RFC specification, and latest versions of OMNeT++ 4.x and INET Framework.

IV. SIMULATION RESULTS

The process of MAP discovery is needed to inform Mobile Nodes about the presence of the MAP and the distance of the MAP from the Mobile Node, and it continues as the Mobile Node moves from one subnet to the next. Every time the Mobile Node detects movement, it will also detect whether it is still in the same MAP domain.

The INET Framework simulation model was enhanced in a way that the RA packet contains a MAP option (Figure 4. which includes the MAP's global IP address, valid lifetime field which indicates the validity of the MAP's address and consequently the time for which the RCoA is valid, and other information like the distance vector from the MAP to the current access router (measured in hops, but need not be interpreted as the number of hops between MAP and the Mobile Node. Distance is set to 1 if the MAP is on the same link as the Mobile Node), the preference for this particular MAP (decimal value of 15 indicates the highest availability).

We upgraded the INET framework with an implementation of dynamic MAP discovery. In our simulation model the MAP_1 node was configured to act like a MAP on two network interfaces – Firstly as a MAP to the Internet (Internet Gateway node), whose network prefix is used for RCoA calculation, and secondly as a MAP toward to the Mobile Node which visits the MAP domain to forward packets, i.e. bi-directional tunneling, which enables sending of RA packets with MAP option, to routers in the downstream network.

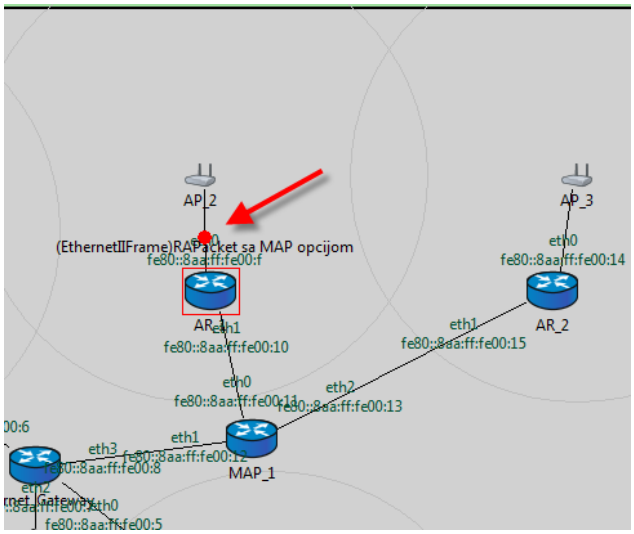

Figure 4. Router Advertisement packet with additional MAP option

Figure 5. shows the sequence diagram for the RA packet with MAP option in the HMIPv6 simulation model. AR_1 and AR_2 Router6 modules receive RA packets with MAP option from the MAP. Router6 modules were enhanced and configured to carry MAP options through interfaces connected with WLAN access points (AP_2 and AP_3), previously increasing Distance field for 1.

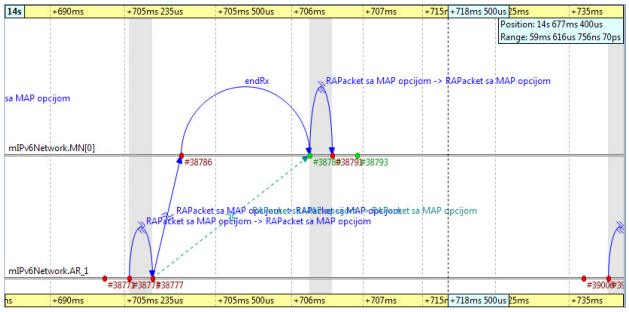

Figure 5. MAP option sequence diagram

At the end of the MAP discovery phase, the HMIPv6-aware Mobile Node MN[0] receives the Router Advertisement with MAP option, obtains the MAP IP address, obtains the Distance field of the MAP form current access router, and verfies if the lifetime is equal zero for the current MAP (a valid lifetime of zero indicates a MAP failure). If it is non-zero then MN[0] has to select a MAP with higher preferences. We enhanced the MN[0] WirelessHost6 module to process RA packets with MAP option.

Once the MN[0] has discovered and chosen MAP_1, it configures RCoA address, using the network prefix, advertised in the MAP option, and creates a binding between RCoA and LCoA at the MAP, assuming MN[0] has already configured a valid LCoA. Our INET framework simulation model was enhanced in the way that MN[0] sends the LBU packet to the newly discovered MAP (Figure 6.

The source IP address is a valid LCoA address, while RCoA is the Home Address in the LBU message. MAP_1

performs DAD (Duplicate Address Detection) procedure for the RCoA and sends BAck, which is identical to the MIPv6 BAck packet.

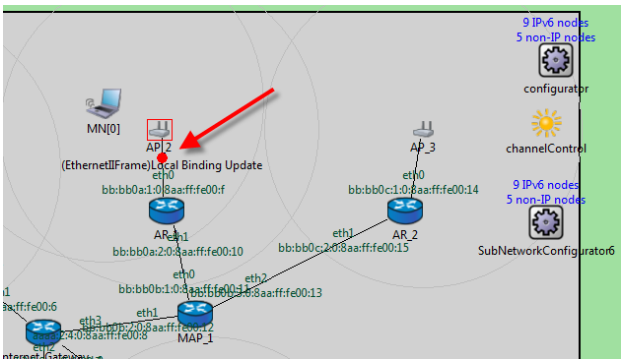

Figure 6. MN[0] sends LBU to discovered MAP

If BAck does not contain type 2 router header with the RCoA, MN[0] will reject BAck, previously controlling the error code in BAck, to check if a new RCoA should be calculated and a new LBU message send. Figure 7. shows the LBU message sequence diagram.

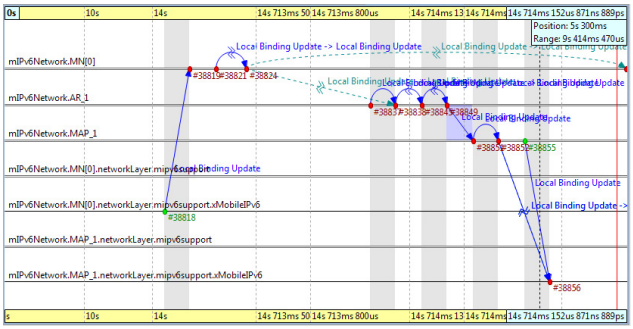

Figure 7. LBU sequence diagram

If a successful binding with the MAP cannot be done, MN[0] will approach the basic MIPv6 and send BU message to the Home Agent (HA) using LCoA as CoA address. If the binding with the MAP, MN[0] will use its RCoA as CoA with Home Agents and Correspondent Nodes. MN[0] has to wait for the BAck, before sending BU messages to Home Agents, or introducing the Return Routability procedure with Correspondent Nodes.

It should be noted that when binding the RCoA with the HA and Correspondent Nodes, the binding lifetime must not be larger, than the Mobile Node's binding lifetime with the MAP, which is received in the Binding Acknowledgement.

Following a successful registration with the MAP, a bi-directional tunnel between the Mobile Node and the MAP is established. All packets sent by the Mobile Node are tunneled to the MAP, which acts like a Home Agent. The BAck message outer header contains the Mobile Node's LCoA in the source address field and the MAP's address in the destination address field for all outgoing packets. The inner header contains the Mobile Node's RCoA in the source address field and the peer's address in the destination address field.

For incoming packets the tunnel has to check the addresses with the changed source and destination address fields. MAP establishes a binding cache entry for RCoA, which enables packet forwarding of incoming packets to LCoA. For contrary direction a binding entry between the destination address of the tunnel and the interior package is established, to ensure internal packet forwarding to the HA and the CN's.

The structure of the simulation model was defined in the NED (Network Description) language, and the enhancement implies a new module, i.e. SubNetworkConfigurator6 (Figure 8. needed to configure an IPv6 subnet in OMNeT++ 4.x. SubNetworkConfigurator6 module configures subnet prefixes for MAP_1, AR_1 and AR_2.

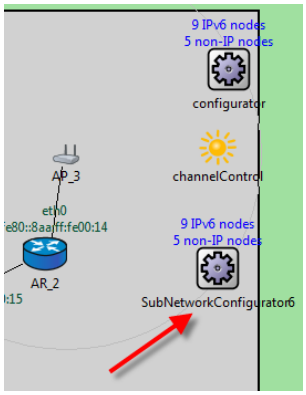

Figure 8. SubNetworkConfigurator6 module

The following table contains all files used in the simulation model, including their role description.

TABLE 1 INET FRAMEWORK FILES ENHANCED WITH HMIPV6 EXTENSION

File	Description
\inet\examples\mobileipv6\ HMIPv6Network.ned	Network topology definition in NED language
\inet\examples\mobileipv6\ omnetpp.ini	Configuration folder for simulation mode control
\inet\src\networklayer\autorouting \ipv6\ SubNetworkConfigurator6.cc	Configures IPv6 adressess and routing tables for hierarhy network topology
\inet\src\networklayer\icmpv6\ IPv6NeighbourDiscovery.cc	Implements Neighbor Discovery protocol for IPv6 (RFC 2461)
\inet\src\networklayer\icmpv6\ IPv6NDMessage_m.cc	HA information, HA Prefix information, MAP Option, etc.
\inet\src\networklayer\xmipv6\ xMIPv6.cc	Implements RFC 3775 Mobility Support for IPv6
\inet\src\nodes\ipv6\ Router6.ned	IPv6 router NED module

V. CONLUSION

We implemented an INET simulation model with HMIPv6 extension in accordance to RFC 5380 Hierarchical Mobile IPv6 – HMIPv6 Mobility Management. In that sense we enhanced the INET Framework simulation model with an extended RA packet containing a MAP option. Further we upgraded the INET framework with an implementation of dynamic MAP discovery. We made it possible for our simulation Mobile Node MN[0] to send the LBU packet to the newly discovered MAP.

Since a valid HMIPv6 simulation model for OMNeT 4.x has been established, further simulation enhancements are enabled in terms of simulation accuracy and validation tests. Further work will be directed to the development of an extended resource management scheme, which takes into account the QoS requirements of handover, such as packet delay, jitter and loss guarantees, and reduces the overall handover latency.

NEW METHODS & SOLUTIONS

Matrix inversion in the design of active queue management mechanisms

Pawel Mrozowski and Andrzej Chydzinski
Faculty of Automatic Control, Electronics and Computer Science, Silesian University of Technology, Gliwice, Poland
andrzej.chydzinski@polsl.pl

***Abstract*—A router exploiting the active queue management can drop arriving packets even if its buffer is not full. This is meant to notify the TCP senders to reduce their sending rates. One type of the active queue management is based on dropping arriving packets with probability that is a function of the queue size observed upon packet arrival. Although the queuing models of algorithms of this type have been developed, they present some numerical difficulties that have to be overcome in order to be practically usable, e.g. they require inverting large matrices. In this paper we compare several inversion methods with respect to their applicability in the parameterization of the dropping mechanism of the active queue management. In addition to their implementations on a CPU, we also check their performance when implemented on a graphics processor unit.**

***Index Terms*—active queue management, Internet routers, dropping function, numerical calculations, matrix inversion, graphics processor unit**

I. Introduction

The idea of the active queue management (AQM) in Internet routers is that arriving packets can sometimes be dropped even if the router's buffer is not full (see e.g. [1], [2], [3], [4], [5], [6]). This action is supposed to notify the TCP senders to reduce their sending rates, before the actual congestion happens at the bottleneck link. It has several positive effects discussed in the literature. Two the most important benefits are reduction of queue sizes and queueing delays as well as reduction of the effect of global synchronization of TCP flows.

An important type of the active queue management is based on dropping the arriving packets with probability that is a non-decreasing function of the queue size observed upon packet arrival. In the well-known RED (Random Early Detection) algorithm, [1], this function is linear. It can have other forms as well, e.g. exponential or doubly linear.

The queuing models of such algorithms have been solved in [7], [8], [9], using transform techniques[1]. In particular, the formulas for the most important performance characteristics, including the average queue size and the overall packet drop ratio, were provided. These formulas, however, present some numerical difficulties that have to be overcome in order to be practically usable. Especially demanding, but also the most practically useful, are the models which are able to mimic the self-similar structure of the network traffic. Their usefulness is connected with the fact that since the famous paper by Leland et. al., [12], we have known that network traffic posses some sophisticated statistical characteristics (e.g. self similarity), which have to be taken into account in models of queues in routers. Otherwise, all the obtained performance characteristics are optimistically underestimated. On the other hand, the models mimicking self-similarity are computationally very demanding. In particular, they require inverting huge matrices.

Detailed formulas will be provided in the next section, but just to get a picture of these demands, consider a link of capacity 1Gb/s and the average packet size on this link of 1000 bytes. The commonly used rule of thumb for dimensioning the routers buffers (e.g. [13]) is the bandwidth-delay product for 100ms or 200ms of buffering delay. Therefore, in our example we obtain the buffer for 12500 packets. On the other hand, a fine mimicking of the self-similar properties of the traffic may require matrices of sizes as big as 56×56 (see e.g. [14]). Therefore, as follows from formulas (1), (2) and (3) of Section II, we have to invert a matrix with $(56 \times 12501)^2 \approx 49 \times 10^9$ elements. Assuming a floating-point number format that occupies 8 bytes, the memory requirement for such matrix would be almost 4 tera bytes. Inverting matrices of this size is not trivial.

In practice the problem is a bit smaller due to the following two factors. Firstly, a more rough parameterization of the traffic can be used, for instance with 5×5 matrices (see e.g. [10], [15]), or even 3×3 (see e.g. [16]). Secondly, the application of the active queue management allows for a significant reduction of the buffer sizes. Therefore, instead of 12500, the buffer for 1000-2000 would be large enough. All off these lead to matrices with hundreds of milion elements, which still may take a lot of time to invert, when approached in a standard way.

Therefore, in this paper we compare several inversion methods with respect to their applicability in the parameterization of the dropping mechanisms in the active queue management. We try to speed up the computations in two ways: by using various algorithms for matrix inversion and multiplication and by implementing them on a GPU and CPU with multiple cores. Apparently, for a two-hundred-million-element matrix these operations can reduce the computation time by at least three orders of magnitude.

The rest of the paper is organized as follows. In Section II, the active queue management model and the most important formulas are presented. In Section III, the inversion algorithms are recalled. Then, in Section IV, the modifications and imple-

[1]For other queueing models solved in this way see e.g. [10], [11].

mentations on GPUs and multiple core CPUs are discussed. Section V presents the results of the tests performed using eleven different implementations of the inversion algorithms. In Section VI remarks concluding the paper are presented.

II. Queuing model

We deal with a single-server queue whose arrival process is the Markov-modulated Poisson process parameterized by the intensity matrix of the modulating chain, Q, of size $m \times m$, and the vector of corresponding intensities of Poisson arrivals, $[\lambda_1, \ldots, \lambda_m]$. Let $\Lambda = diag[\lambda_1, \ldots, \lambda_m]$.

The service time is of general type, described by a distribution function $F(t)$. The total number of packets present in the system is limited by the buffer size, b. Packets arriving when the buffer is full are dropped and lost.

Moreover, any arriving packet can be dropped with probability $d(n)$, where n denotes the queue length at the time of arrival of this packet. (This is the active queue management mechanism). Therefore, the dropping probability is a function of the queue length. The finite buffer means that there is $d(n) = 1$ for $n \geq b$.

Let I denote the unit matrix of size $m \times m$, $\mathbf{0}$ denote an $m \times m$ matrix of zeros, $\mathbf{1}$ denote the column vector of 1's, and δ_{ij} is 1 if $i = j$ and 0 otherwise. In [9] we proved that the Laplace transform of the queue length distribution at time t has the following form:

$$\phi(s,l) = G^{-1}(s)R(s,l), \qquad 0 \leq l \leq b, \tag{1}$$

with

$$G(s) = [G_{ij}(s)]_{i=0\ldots b, j=0\ldots,b}\,, \tag{2}$$

and

$$G_{ij}(s) = \begin{cases} A_{i,j-i+1}(s), & \text{if } 1 \leq i \leq b-2, i < j \leq b-1, \\ A_{i,1}(s) - I, & \text{if } i = j, 1 \leq i \leq b-1, \\ A_{i,0}(s), & \text{if } i = j+1, \\ U_0(s) - I, & \text{if } i = 0, j = 0, \\ V_0(s), & \text{if } i = 0, j = 1, \\ -I, & \text{if } i = b, j = b, \\ \mathbf{0}, & \text{otherwise,} \end{cases} \tag{3}$$

where

$$R(s,l) = [R_0(s,l), \ldots, R_b(s,l)]^T\,, \tag{4}$$

$$R_i(s,l) = \begin{cases} -\delta_{0l} z(s), & \text{if } i = 0, \\ -r_i(s,l), & \text{if } 1 \leq i \leq b, \end{cases}$$

$$A_{n,k}(s) = [a_{n,k,i,j}(s)]_{i,j}\,, \qquad 1 \leq i,j \leq m,$$

$$a_{n,k,i,j}(s) = \int_0^\infty e^{-st} H_{n,k,i,j}(t) dF(t),$$

$$U_n(s) = \left[\frac{(\lambda_i - Q_{ii})p_{ij} + d(n)\Lambda_{ij}}{s + \lambda_i - Q_{ii}}\right]_{i,j}, \qquad 1 \leq i,j \leq m, \tag{5}$$

$$p_{ij} = \begin{cases} 0 & \text{if } i = j, \\ \frac{Q_{ij}}{\lambda_i - Q_{ii}} & \text{if } i \neq j, \end{cases}$$

$$V_n(s) = \left[\frac{(1 - d(n))\Lambda_{ij}}{s + \lambda_i - Q_{ii}}\right]_{i,j}, \qquad 1 \leq i,j \leq m, \tag{6}$$

$$z(s) = \left[\frac{1}{s + \lambda_1 - Q_{11}}, \ \ldots\ , \frac{1}{s + \lambda_m - Q_{mm}}\right]^T, \tag{7}$$

$$r_n(s,l) = \begin{cases} \mathbf{0} \cdot \mathbf{1}, & \text{if } l < n, \\ \overline{D}_{n,l-n}(s) \cdot \mathbf{1}, & \text{if } n \leq l \leq b, \end{cases} \tag{8}$$

$$\overline{D}_{n,k}(s) = [d_{n,k,i,j}(s)]_{i,j}\,, \qquad 1 \leq i,j \leq m, \tag{9}$$

$$d_{n,k,i,j}(s) = \int_0^\infty e^{-st} H_{n,k,i,j}(t)(1 - F(t))dt,$$

and $H_{n,k,i,j}(u)$ denoting the counting function of the arrival process filtered by the dropping mechanism.

One of the main challenges when using formula (1) in practice is inversion of matrix $G(s)$. As $A_{i,j}(s)$, $U_0(s)$, $V_0(s)$, I and $\mathbf{0}$ are square matrices of size $m \times m$, from (2) and (3) it follows that matrix $G(s)$ is of size $(b+1)m \times (b+1)m$. Therefore, as discussed in Introduction, it can be huge even if the buffer size is moderate.

III. Inversion algorithms

In this section we recall briefly a few chosen inversion methods. To allow calculations for large matrices, the researchers try to reduce the computational complexity $O(\omega)$ by decreasing ω bound, [17], [18], [19]. Other ideas exploit more computing power, by using distributed programming and parallel programming. The latter approach focuses often on cheap computing power of general-purpose graphics processing units (GP-GPUs, see e.g. [20], [21]). Finally, there is a research direction on inverting sparse matrices, but this is beyond the scope of this paper - the matrices are not sparse herein.

A. Gaussian elimination

Gaussian elimination is the most popular method for finding the inverse of a square matrix. The time complexity of Gaussian elimination is $O(n^3)$. In order to calculate A^{-1}, the following elementary operations on matrix rows must be done.

1. For each row $k = 1, \ldots, n$ calculate:
   $a_{k,j}^{k+1} = \frac{a_{k,j}^k}{a_{k,k}^k}$ for $j = 1, \ldots, n$ and $a_{k,k} \neq 1$.
2. If $a_{k,k} = 1$ then:
   $a_{i,j}^{k+1} = a_{i,j}^k - a_{i,k}^k a_{k,j}^{k+1}$ for $i, j = 1, \ldots, n$ and $i \neq k$.
3. Extract inverted matrix:
   $[A|I] = \left[I|A^{-1}\right]$.

B. LU decomposition

The method was invented by A. Turing and it exploits the factorization of matrix A:

$$A = LU, \tag{10}$$

where L is a lower triangular matrix, while U is an upper triangular matrix. Two most popular decomposition algorithms are by Doolittle and Crout. The first one gives the unit lower triangular matrix, the second gives the unit upper triangular matrix.

1) LU factorization - Doolittle: The algorithm is derived from matrix multiplication:

$$a_{i,j} = \sum_{k=1}^{n} l_{i,k} \cdot u_{k,j}.$$

As L and U are triangular, we consider two cases. For $i \leq j$ we have:

$$u_{i,j} = a_{i,j} - \sum_{k=1}^{i-1} l_{i,k} \cdot u_{k,j}. \tag{11}$$

For $i > j$:

$$l_{i,j} = \frac{1}{u_{j,j}} \left(a_{i,j} - \sum_{k=1}^{j-1} l_{i,k} \cdot u_{k,j} \right). \tag{12}$$

The steps of the algorithm are:

1. Create matrices L, U and fill them with zeros, the diagonal in L fill with ones.
2. For $i = 1, 2, \ldots, j$ calculate $u_{i,j}$ using (11).
3. For $i = j+1, j+2, \ldots, n$ calculate $l_{i,j}$ using (12).

Finally, obtaining A^{-1} is done by forward or backward substitution on the columns of identity matrix.

The LU method is easy to implement and is relatively fast. It is also worth mentioning that there are modifications of the LU decomposition, aiming at error minimization, called "partial pivoting". More on this subject can be found in [22], [23].

C. QR decomposition

This factorization of the matrix is done as follows

$$A = QR, \tag{13}$$

where Q is orthogonal, while R is upper triangular. There are at least three different QR decomposition methods: Gram-Schmidt (orthogonalization), Givens rotations and Householder reflections, [24].

The algorithm consists of the following steps.

1. QR decomposition of A.
2. Inversion of the upper triangular factor R.
3. Multiplication according to the formula:

$$A^{-1} = R^{-1} Q^T. \tag{14}$$

D. Strassen method

Although the original paper [25] was devoted to matrix multiplication in time $O(n^{2.807})$, the author showed also that the algorithm breaks down the inversion of matrices into several multiplication operations and that the problem has in fact the same time computational complexity. To apply this method, we have to divide A into four submatrices of size $k = n/2$:

$$A = \begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix}. \tag{15}$$

The inverted matrix has a form of block matrix:

$$A^{-1} = \begin{bmatrix} c_{11} & c_{12} \\ c_{21} & c_{22} \end{bmatrix} \tag{16}$$

$$= \begin{bmatrix} a_{11}^{-1} + a_{11}^{-1} \cdot a_{12} \cdot S^{-1} \cdot a_{21} \cdot a_{11}^{-1} & -a_{11}^{-1} \cdot a_{12} \cdot S^{-1} \\ -S^{-1} \cdot a_{21} \cdot a_{11}^{-1} & S^{-1} \end{bmatrix} \tag{17}$$

where $S = a_{22} - a_{21} \cdot a_{11}^{-1} \cdot a_{12}$ is called Schur complement of a_{11} in matrix A. To speedup multiplications, temporary matrices are denoted by R_i, where $i = 1, \ldots, 7$. We have:

$$\begin{array}{ll} 1: R_1 = a_{11}^{-1}, & 2: R_2 = a_{21} \cdot R_1, \\ 3: R_3 = R_1 \cdot a_{12}, & 4: R_4 = a_{21} \cdot R_3, \\ 5: R_5 = R_4 - a_{22}, & 6: R_6 = R_5^{-1}, \\ 7: c_{12} = R_3 \cdot R_6, & 8: c_{21} = R_6 \cdot R_2, \\ 9: R_7 = R_3 \cdot c_{21}, & 10: c_{11} = R_1 - R_7, \\ 11: c_{22} = -R_6. & \end{array}$$

Finally we must rebuild the inverted matrix according to formula 16.

IV. Modifications

A. CPU parallelization

Analyzing the algorithm described in the previous subsection, we can see that some of its steps can be parallelized, since there are no internal dependencies between them. In particular, the operations can be divided into seven groups, I-VII, which are performed consecutively, while operations inside each group can be done in parallel way:

$$\begin{array}{ll} I: 1; & II: 2, 3; \\ III: 4; & IV: 5; \\ V: 6; & VI: 7, 11, 8; \\ VII: 9, 10. & \end{array}$$

B. Modified multiplication

In the Strassen method, the crucial role is played by multiplication operation, which influences severely the overall method complexity. Therefore we will discuss now multiplication methods, their improvements and GPU implementations.

1) Classic multiplication: If A is a $N \times M$ matrix and B is a $M \times P$ matrix, then matrix product AB is a matrix composed of the following elements:

$$(AB)_{ij} = \sum_{k=1}^{M} A_{ik} B_{kj} \quad for \;\; 1 \leq i \leq N \;\; and \;\; 1 \leq j \leq P. \tag{18}$$

The naive implementation of this formula may have the form:

```
1. For i = 1 to N
2.         For j = 1 to P
3.                 For k = 1 to M
4.                   AB(i,j) = AB(i,j) + A(i,k)B(k,j)
```

Surprisingly, the following minor modification of the code:

```
1. For i = 1 to N
2.         For k = 1 to M
3.                 For j = 1 to P
4.                   AB(i,j) = AB(i,j) + A(i,k)B(k,j)
```

may result in even 10 times shorter computations time. This is due the fact that compilers can optimize the latter code by creating temporary variable where the values $A[i][k]$ are

stored. The last nested loop requires fewer lookups into the arrays.

The classic implementation is available on GPUs. Namely, it is offered by function $cublasDgemm$ Level-3 Basic Linear Algebra Subprograms from [26], which was used in our experiments.

2) Strassen multiplication: In order to multiply two matrices A and B by the means of Strassen method, we use following decomposition of A and B into four sub-matrices. The multiplication is carried out by recursive partitioning into smaller blocks in the following way:

$$AB = \begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix} \begin{bmatrix} b_{11} & b_{12} \\ b_{21} & b_{22} \end{bmatrix}. \tag{19}$$

Firstly, we compute:

$$\begin{aligned} 1 : M_1 &= (a_{11} + a_{22})(b_{11} + a_{22}), \\ 2 : M_2 &= (a_{21} + a_{22}) b_{11}, \\ 3 : M_3 &= a_{11}(b_{12} - b_{22}), \\ 4 : M_4 &= a_{22}(b_{21} - b_{11}), \\ 5 : M_5 &= (a_{11} + a_{12}) b_{22}, \\ 6 : M_6 &= (a_{21} + a_{11})(b_{11} + a_{12}), \\ 7 : M_7 &= (a_{12} + a_{22})(b_{21} + a_{22}). \end{aligned}$$

Then we obtain:

$$AB = \begin{bmatrix} c_{11} & c_{12} \\ c_{21} & c_{22} \end{bmatrix},$$

where

$$\begin{aligned} c_{11} &= M_1 + M_4 - M_5 + M_7, \\ c_{12} &= M_3 + M_5, \\ c_{21} &= M_2 + M_4, \\ c_{22} &= M_1 - M_2 + M_3 + M_6. \end{aligned}$$

3) Coppersmith-Winograd multiplication: The algorithm described in [17] is the one with the lowest time complexity in this paper, which is $O(n^{2.376})$. There are numerous modifications in the literature, resulting in slightly better performance than the original version, [18], [19].

In the algorithm, matrices A and B are divided into four sub-matrices the size of $k = n/2$, as in (19). Then, the following temporary matrices are calculated:

$$\begin{aligned} &1 : S_1 = a_{21} + a_{22}, && 2 : S_2 = S_1 - a_{11}, \\ &3 : S_3 = a_{11} - a_{21}, && 4 : S_4 = a_{12} - S_2, \\ &5 : T_1 = b_{12} - b_{11}, && 6 : T_2 = b_{22} - T_1, \\ &7 : T_3 = b_{22} - b_{12}, && 8 : T_{43} = b_{21} - T_2, \\ &9 : P_1 = a_{11} \cdot b_{11}, && 10 : P_2 = a_{12} \cdot b_{21}, \\ &11 : P_3 = S_1 \cdot T_1, && 12 : P_4 = S_2 \cdot T_2, \\ &13 : P_5 = S_3 \cdot T_3, && 14 : P_6 = S_4 \cdot T_4, \\ &15 : P_7 = a_{22} \cdot T_4, && 16 : U_1 = P_1 + P_2, \\ &17 : U_2 = P_1 + P_4, && 18 : U_3 = U_2 + P_5, \\ &19 : U_4 = U_3 + P_7, && 20 : U_5 = U_3 + P_3, \\ &21 : U_6 = U_2 + P_3, && 22 : U_7 = U_6 + P_6. \end{aligned}$$

Finally, we obtain:

$$\begin{aligned} &23 : c_{11} = U_1, && 24 : c_{12} = U_7, \\ &25 : c_{21} = U_4, && 26 : c_{22} = U_5. \end{aligned}$$

The algorithm requires 7 multiplications and 15 additions/substractions.

C. GPU parallelization

The idea behind GPU parallelization lies within the parallel execution of the code using multiple threads. The main difference between CPUs and GPUs is that the latter has a lot more ALUs (arithmetic logic units) performing computations. The structure of a program for GPU consists of one kernel at a time divided into blocks which use independent groups of ALUs. Each block is comprised of threads. The threads within a block typically work together to compute a value and they share the same area of memory.

The main question is how to parallelize the code. The answer is not simple and depends on the algorithm itself. Good candidates are simple, naive algorithms, which perform many independent operations. In our calculations we benefited from large speedup of the following simple algorithms rewritten into CUDA (Compute Unified Device Architecture) [27] kernels: matrix addition, matrix subtraction, matrix multiplication. It is also possible to extend the idea of basic kernels by combining operations, e.g. multiplication with addition, etc.

Currently, a lot of research is carried out to answer the following questions (see e.g. [28]): How many threads per block should be used? How many blocks per grid should be used? The answers are not discussed herein, but they can potentially give a significant performance boost.

As always, there are some drawbacks. The first one is the amount of memory available for a GPU. Today, the most powerful graphical accelerators have 24GB of memory (12GB per GPU). As argued in Introduction, problems can sometimes be much bigger than that. One of the possible solutions is data partitioning. The second problem is that not all GPUs perform well with double-precision values (that is why the most of comparisons in the literature are done on single-precision numbers). In practice, we need to use high-precision numbers quite often. Another problem is relatively high cost (milliseconds) of transferring the data between host and device. Finally, it has to be mentioned that the GPU performs at top speed only when it is busy. Single or occasional jobs scheduled on a GPU take, very often, more time on the GPU, than CPU. The vendors try to overcome this problem by means of following technologies/frameworks like CrystalGPU [30], Grophecy [31] or virtualization, e.g. Pegasus project [32].

V. Test results

We compared the performance of the described above algorithms and their modifications using matrices up to 225 million of elements. Namely, the performance of the following eleven implementations were compared:

- Gaussian elimination on one CPU core,
- LU decomposition on one CPU core,
- QR decomposition on one CPU core,
- LU decomposition on CUDA,
- LU decomposition on 12 CPU cores,
- QR decomposition on 12 CPU cores,
- Strassen method with classic multiplication on 12 CPU cores,

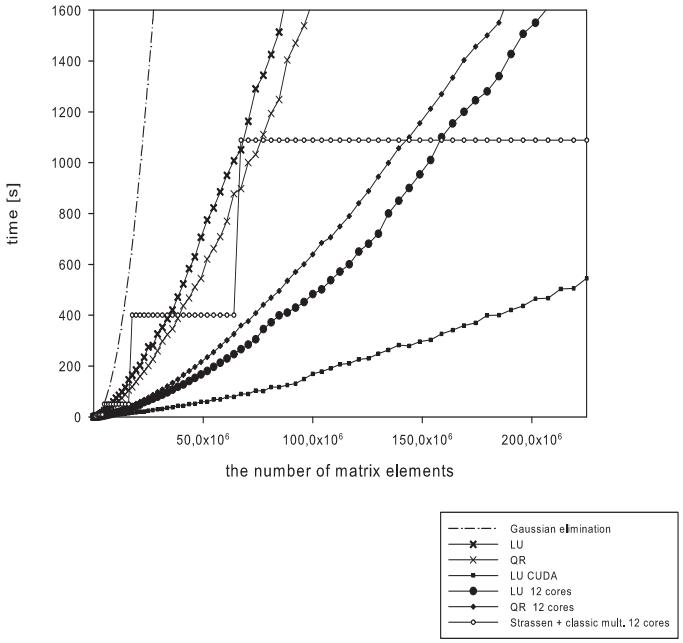

Fig. 1. Inversion time – comparison of various methods.

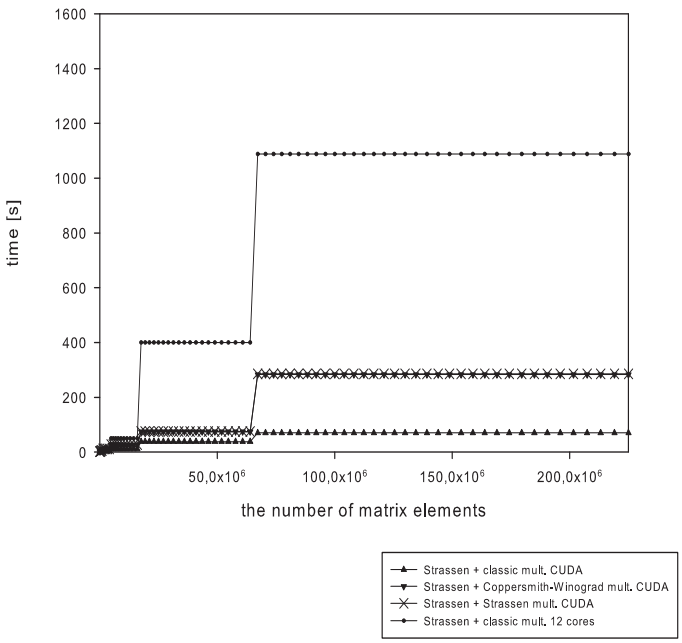

Fig. 2. Inversion time – Strassen method variants.

- Strassen method with classic multiplication on CUDA,
- Strassen method with Coppersmith-Winograd multiplication on CUDA,
- Strassen method with Strassen multiplication on CUDA,
- Gaussian elimination on CUDA.

The implementations were done in Java mostly by authors. As for the LU and QR algorithms, their single-core versions from the library JAMA were used, whilst the multi-core versions – from the library Ojalgo. The Gaussian elimination from the library Apache was exploited.

In the experiments, the inversion times for dense matrices of type (2), (3) in function of their number of elements were checked. For experimental purposes, we used several different workstations and different types of the GPU. The results shown herein were obtained on the workstation with two CPUs of Intel Xeon E5-2630 v2 type, 2.6GHz, 6 cores each, and the GPU of Nvidia Quadro 4000 type, with 3GB of memory and double-precision numbers.

The results are presented in Figs. 1, 2 and 3. In particular, in Fig. 1, the inversion times for various methods and large matrices are depicted. In Fig. 2, the inversion times for different implementations of Strassen method are shown. In Fig. 3, the inversion times for smaller matrices are presented.

As we can see, the Strassen method was the fastest among those we tested. Its version with classic multiplication implemented on CUDA provided the shortest computation time of 70 seconds for a matrix with 225×10^6 elements (see Fig. 2). Surprisingly, the Strassen method with Coppersmith-Winograd multiplication performed a bit worse. Most likely, it requires even larger matrices to fully benefit from its theoretical $O(n^{2.376})$ complexity.

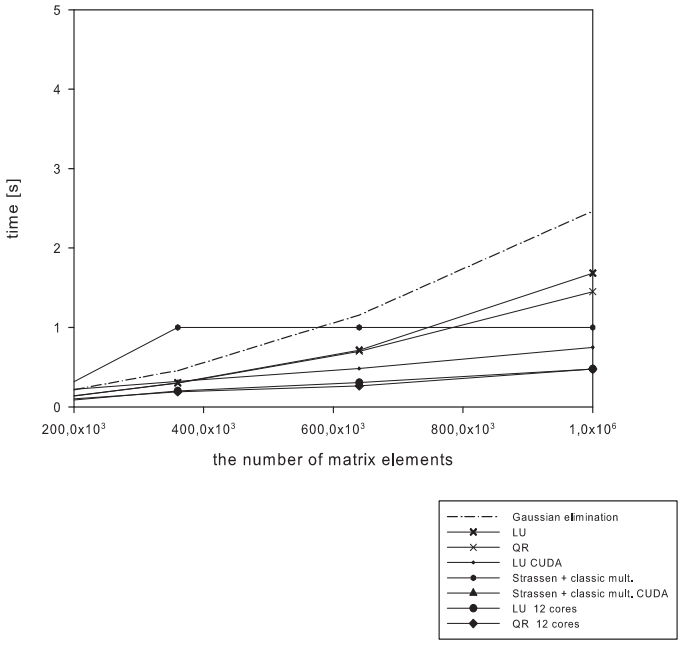

Fig. 3. Inversion time – moderate number of elements.

From Fig. 2 it follows also that exploiting the GPU is very beneficial and outperforms the multicore implementation.

The main disadvantage of the Strassen method is that the matrix size must be the power of 2. Otherwise the matrix must be padded with zeros (see [29]) and put in the left upper corner.

This explains the constant values on Strassen's method plots. This also increases the sizes of matrices to multiply, add and subtract. In the worst case scenario, we perform computations on matrices with almost doubled size we need.

As expected, the slowest method was the Gaussian elimination. The largest matrix we were able to compute using Gaussian elimination consisted of 169 million elements and it took more than 15 hours to finish computations.

For matrices of moderate sizes (up to 10^6 elements), other than Strassen methods can be recommended, e.g. the parallel version of QR algorithm (see Fig. 3). It is also worth underlining the strange behavior of GPU for moderate matrices. As wee can see, the computation time may decrease slightly between $4 \cdot 10^5$ elements and 10^6 elements when CUDA is used. This is the well-known anomaly related to "warm-up" period of the GPU and host-device memory transfer penalty.

The Java programming language turned out to be mature and efficient environment with good libraries for linear algebra. It offers a fully portable environment so we are not restricted by certain operation system and/or CPU architecture. The libraries that enabled us to use CUDA technology within Java are somewhat limited. In our opinion they do not use the full potential of CUDA technology, but they are easy to use and can be used in short time by the developers to speed up calculations. More on Java and GPU applicability to solve numerical problems can be found in [33].

VI. Conclusions

We compared several matrix inversion methods and their implementations for multi-core CPUs and GPUs with respect to their applicability in the design of dropping mechanisms of the active queue management. We demonstrated that the computation time can be reduced by at least three orders of magnitude when a properly chosen algorithm is used and implemented on a GPU. Of course, there is no need to equip the router with a GPU, because all the necessary calculations can be carried out by an external workstation, while the resulting dropping function can be uploaded to the router as a simple configuration file.

Abstract - Fiber optic communication has been developed and studied significantly for several decades. Firstly, there were problems related to fiber attenuation and a choice of some suitable materials. Nowadays there is a great demand on increasing data rate and bandwidth. Despite some persisting optical fiber's weaknesses, this technology seems to be a leading one in today's telecommunication systems. The cost of this technology is perhaps one of the most limiting factors. This problem could be possibly solved by substituting and surrounding of the existing network topologies with WDM systems. Not a massive production of WDM devices makes WDM systems still quite expensive. Besides of optical sources, fibers and optical amplifiers there is the main WDM component called a multiplexor or demultiplexer respectively. This paper will provide a basic overview of some Arrayed Waveguide Grating (AWG) based demultiplexers. AWG demultiplexer is a passive WDM element which is able to combine and separate a broadband high frequency optical signal over large distances.

I. INTRODUCTION

Growing demands on increasing data bit rate and bandwidth have inspired and motivated researchers to come up with new telecommunication concepts. Wavelength Division Multiplexing (WDM) systems have made a great revolution in communication technology. The first WDM prototype came up in 1970. Laboratory realization of the first real WDM architecture was presented 8 years later. WDM architecture is a generalization of orthogonal OFDM transmission system. As any other conventional communication system, a basic WDM link consists of a transmitter, a modulation element a multiplexor/demultiplexer, an amplifier (usually in between MUX and DEMUX), a demodulation circuit and a receiver. There have been a few main moments in history which made WDM systems happened. In 1960 there was a first laser invented [1]. Six years later Kao and Hockham worked with a concept of a dielectric optical fiber – a potential medium for data transmission [2]. The achievement of low-loss fiber (~20dB/km) was introduced in 1970 [3]. Later on, in 1978 the first a low-loss single mode fiber was introduced. Its attenuation was only about 0,2 dB/km which was a big step forward. In the same year the first EDFA (Erbium-doped Fiber Amplifier) was developed [4]. Finally the first commercially used WDM system was available in 1995. All mentioned developments were accomplished by gradual improving of a few fundamental WDM components like laser diodes and many kinds of single mode fibers. First high speed single channel transmission link was realized at 1300 nm wavelength (SMF transmission). This is the region of the lowest chromatic dispersion and attenuation. Fiber attenuation has the lowest value around 1550 nm wavelength. It's basically a material characteristic and cannot be shifted and influenced (for Si optical fibers). In order to maximize the transmission length and a data bit rate there was a high effort to produce an optical fiber with a low chromatic dispersion in different wavelength regions. Chromatic dispersion consists of material and waveguide (a fiber property) dispersion which makes this parameter partly tunable. There were lots of attempts to design an optical fiber with so called shifted (zero – level) chromatic dispersion. This was successfully achieved by introducing of DSF (Dispersion Shifted Fiber) around 1990. It didn't take a long time facing some new challenges with the invention of WDM systems. More channels (carriers) and longer geographical distances were asking for higher input power level at the transmitter end. Fairly new kinds of problems – nonlinear effects – showed up which had not been taken under the scope before. Despite the fact that there had been some work made on fiber nonlinearities, one of nonlinear effects – FWM (Four Wave Mixing) – started causing serious difficulties in terms of data bit rate in WDM systems. FWM effect appears when mixing neighboring signals are matching in phase. This was happening as a consequence of WDM operation closely to zero chromatic dispersion level (~1550 nm) and seriously limited WDM transmission length. This problem led to the development of new SMFs. This new fibers are called NZ – DSFs (Nonzero – DSFs) which allow a certain amount of a chromatic dispersion [5]. NZ – DSFs were a reasonable compromise between negative (linear and nonlinear) effects and reach in WDM systems. In fact de/multiplexer is a fundamental WDM element which combines and separates particular wavelengths carrying the actual information. It turns out that waveguide based de/multiplexors (so called AWG DE/MUX, from now only AWG demultiplexers) provide the best WDM performance. Nowadays, there are several AWG concepts challenging themselves. There are several kinds of grating multiplexers based like arrayed waveguide gratings, concave gratings as well as their various modifications [6]. There is a high demand to develop a device which would be able to carry as many channels as possible with satisfactory low crosstalk, high transmission, small physical proportions and low manufacturing costs.

II. PRINCIPLE OF ARRAYED WAVEGUIDE GRATING DEMULTIPLEXER

The principle of AWG demultiplexer in based on a Mach – Zehnder interferometer (MZI). AWG demultiplexer consists of two multi – port couplers interconnected by a waveguide array. An optical signal propagating through waveguide array is gradually shifted in phase (in a specific phase value). This device has a few practical implementations like reconfigurable AWG routers and switches [7].

A. AWG demultiplexer

Contrary to MZI, the AWG demultiplexer experiences lower losses, cheaper manufacturing and higher optical compatibility with circuits. Both couplers and waveguide array are integrated on the same substrate. A substrate is usually made of silicon and waveguide array require some additional substances ($GeSiO_2$, SiO_2 – Ta_2O_5). AWG demultiplexer is specifically designed for particular channel spacing defined for ITU CWDM, DWDM standards [8]. Temperature fluctuations also have considerable impact on this device that's why the temperature management has to be carefully controlled. An input signal in figure (Figure 1.) is getting through so called FPR1 (Free Propagation Region) and propagates towards the waveguide array.

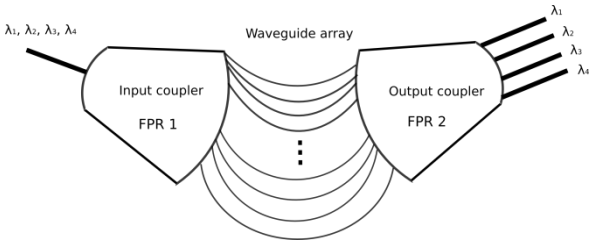

Figure 1. A basic scheme of Arrayed Waveguide Grating (AWG) demultiplexer with its two free propagation regions (FPRx).

This signal is coupled into the each waveguide from the waveguide array [9]. A physical length of each particular waveguide gets longer in a specific value ΔL from a previous one. It turns out that the particular waveguide phase shift will be different at so called grating circle of second FPR2 as shown in figure (Figure 2.).

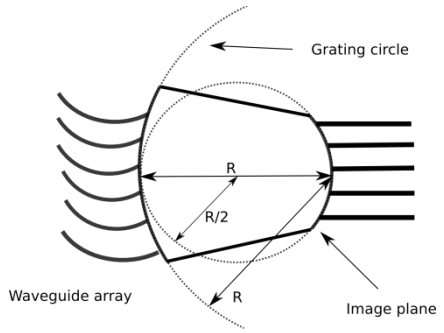

Figure 2. AWG demultiplexer's FPR2 with its image and grating circle.

B. Design of AWG demultiplexer

In order to achieve constructive interference at the image plane as shown in figure (Figure 2.), the FPR2 has to be specifically designed. Transparent grating is placed along grating circle. From the wave theory of light it turns out that every slit serves as a secondary source of light. Thanks to the phase mismatch (caused by ΔL) among waveguides in waveguide array there will be light diffraction happening. This is observed on image plane of FPR2. Optical signal has ultra-broad bandwidth in comparison to high-frequency links and particular informational channels are represented by certain carrier frequencies (wavelengths). The actual components of optical signal (λ_1, λ_2, λ_2…) are diffracted at grating circle, then travelling along FPR2 and finally spatially separated at image plane of FPR2 (Figure 2.). That's why constructive interference is desired in order to spatially isolate particular frequency components (channels) of the optical signal. This can be accomplished by following of the Rowland circle architecture applied for FPRs [10].

C. Free Propagation Region (FPR) Rowland geometry

Optical signal (light) passes through two FPRs of AWG demultiplexer and gets convergent. Diffraction gratings are located along grating circles (of both FPRs) and provide optical signal spatial separation. So called Rowland geometry satisfies the condition of constructive interference. Constructive interference occurs when various optical signal components from waveguide array are matching in phase at the certain spatial points of the FPR2 image plane. Optical fibers are then joined at these particular points [10]. The actual Rowland geometry looks like shown in figure (Figure 3.).

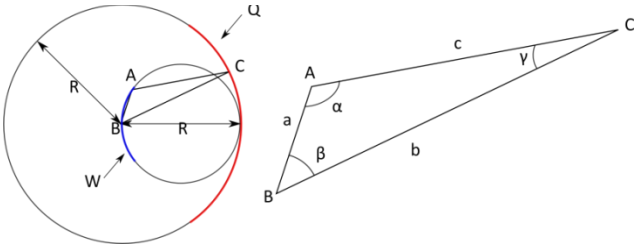

Figure 3. Free Propagation Region (FPR) of AWG demultiplexer – Rowland spatial geometry.

A fundamental condition for constructive interference is that a total phase shift has to be $n2\pi$ (n – integer). That is why it is very important to find a condition which will satisfy this requirement. In other words there is a need to know a distance c of triangle shown in figure (Figure 3.). This distance is needed to calculate a phase shift in FPRs for a particular wavelength. A total phase shift for FPR $\Delta\Phi_2$ can be expressed as shown in the following equation

$$\Delta\Phi_2 = \frac{2\pi}{\lambda} c\,, \tag{1}$$

where λ refers to an actual wavelength component. It is possible to calculate a c parameter from cosine formula

$$c = a^2 + b^2 - 2ab\cos(\gamma) \tag{2}$$

It is obvious that parameter $b=R$ as shown in figure (Figure 3.). On the other hand a parameter a can be evaluated from figure (Figure 4.).

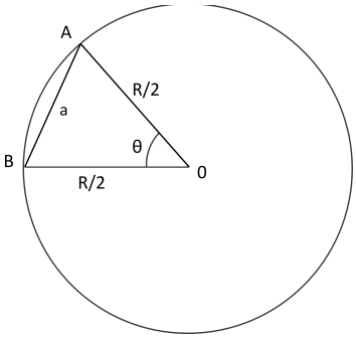

Figure 4. Parameter *a* calculation.

Parameter *a* equals to a length |AB| as it can be seen in both figures (Figure 3.), (Figure 4.).

$$a = R\sin\frac{\vartheta}{2} \tag{3}$$

Furthermore, a parameter *c* can be evaluated by using cosine formula from equation (2) and substituting *a* from (3).

$$c^2 = R^2\sin^2\left(\frac{\theta}{2}\right) + R^2 - R\sin\left(\frac{\theta}{2}\right)R\cos(\gamma) \tag{4}$$

$$c = R\sqrt{\left(1+\sin^2\left(\frac{\theta}{2}\right) - 2\sin\left(\frac{\theta}{2}\right)\cos(\gamma)\right)} \tag{5}$$

A final form for a total phase shift within a FPR can be expressed as following

$$\Delta\Phi_2 = \frac{2\pi}{\lambda}R\sqrt{\left(1+\sin^2\left(\frac{\theta}{2}\right) - 2\sin\left(\frac{\theta}{2}\right)\cos(\gamma)\right)} \tag{6}$$

D. A total phase shift of AWG demultiplexer

In order to work out a total phase shift for AWG demultiplexer it's important to consider a phase shift of the actual waveguide array $\Delta\Phi_1$ [11]. Particular waveguide's lengths differ from each other in a specific value ΔL

$$\Delta L = m\frac{\lambda_c}{n_{eff}}, \tag{7}$$

where *m* is an order of the actual waveguide, λ_c refers to a central demultiplexer wavelength and n_{eff} is an effective refractive index. It turns out that gradual ΔL increasing will cause a various phase difference $\Delta\Phi_1$

$$\Delta\Phi_1 = \beta\Delta L = 2\pi\Delta L\frac{n_{eff}}{\lambda}, \tag{8}$$

where β is a propagation constant. An optical signal is propagating through FPRs and waveguide array. As it has been already mentioned, it's needed to make sure that a total phase shift equals to multiple of 2π (9) as shown in figure (Figure 5.).

$$\Delta\Phi_1 + 2\Delta\Phi_2 = 2\pi \tag{9}$$

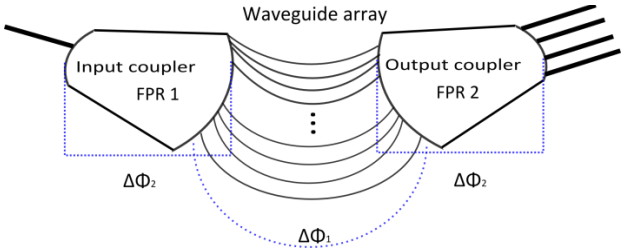

Figure 5. A total AWG demultiplexor's phase shift.

Considering previously mentioned equations, it's possible to define a final condition for AWG demultiplexer phase shift as shown in a following

$$2\pi\Delta L\frac{n_{eff}}{\lambda} + \frac{4\pi}{\lambda}R\sqrt{\left(1+\sin^2\left(\frac{\theta}{2}\right) - 2\sin\left(\frac{\theta}{2}\right)\cos(\gamma)\right)} = n2\pi \tag{10}$$

E. Planar Concave Gratings

PCG (Planar Concave Grating) demultiplexer is one of the competitive technologies besides AWG. In past, there were some technological problems to manufacture a PCG demultiplexer, which made it less popular. A recent progress in material research and more precise manufacturing technologies made PCG components usable in WDM systems. PCG demultiplexer has basically the same function as any other demultiplexer – to separate frequency components. There are two main differences in comparison to AWG systems [12]. PCG demultiplexer has only one FPR and its construction is constrained by Rowland geometry as shown in figure (Figure. 6). Contrary to AWG demultiplexer, an AWG doesn't have any waveguide array. An optical signal is separated on blazed nontransparent gratings.

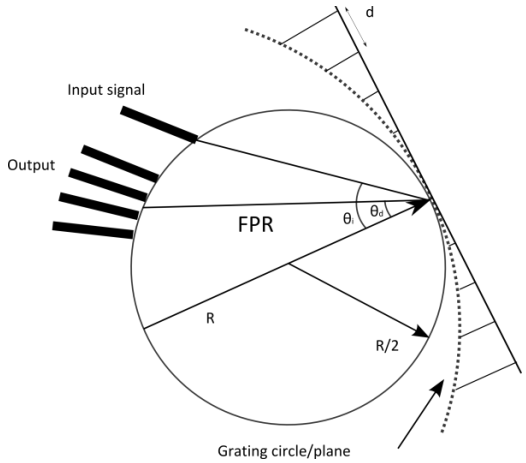

Figure 6. Planar Concave Grating demultiplexer.

A concave grating has several functions. It reflects and focuses light as shown in figure (Figure. 6) as well as separates different light components (diffraction of light). PCG devices have also satisfy grating formula

$$d\left(\sin\theta_i + \sin\theta_d\right) = m\frac{\lambda}{n_{eff}}, \tag{11}$$

where θ_i and θ_d are angles on the Rowland circle as shown in figure (Figure 6.). Parameter m refers to diffraction order and d is so called grating period [13].

F. *Hybrid demultiplexers*

In order to use an optical signal spectrum as efficiently as possible, there is one more interesting concept for WDM demultiplexer. Sometimes it's also called 2D demultiplexor because it combines AWG demultiplexor with a concave grating demultiplexer [15].

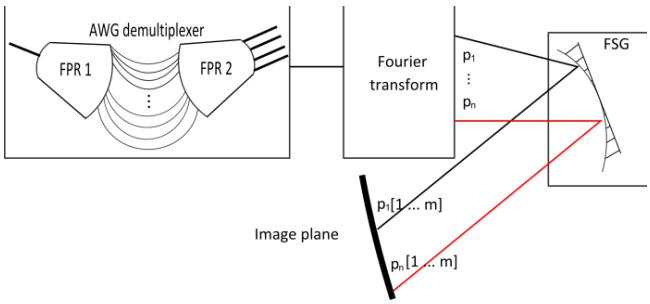

Figure 7. 2D hybrid AWG – Free Space Grating demultiplexer.

An optical signal is coming through the AWG demultiplexor which separates wavelengths along a vertical line (1D separating). Every AWG demultiplexer is capable to distinguish a finite number of diffraction orders *p*. Each filtrated channel has its bandwidth. It is 0.8nm for a DWDM standard which is about 100GHz of bandwidth. Such a range is still quite wide. There have been many experiments made lately to investigate the possibilities of using narrower bands [16]. These bands should satisfactory serve as fully reliable transmission channels for WDM systems in future. There are still problems with crosstalk's and proper detection and separation of particular channels. However this technology seems to be promising. The second part of such a demultiplexer is made of so called FSG (Free Space Grating). This component will divide each particular diffraction order p_i to the finite number of channels m_i. New channel focusing plane (perpendicular to the AWG demultiplexer output line) happens to appear. Finally, there is 2D matrix coming up as shown in figure (Figure 7.).

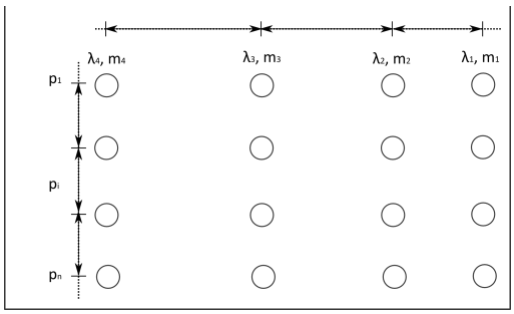

Figure 8. 2D hybrid demultiplexer's channel matrix.

The finite number of satisfactory filtrated channels (as well as channel spacing) is then specified and given by an actual AWG demultiplexor, laser's bandwidth and FSG demultiplexor.

III. Experiments And Results

We will picture a basic DWDM link with AWG demultiplexor as a fundamental element in this section. We decided to use a 16 channel ultra – dense DWDM (channel spacing 0.25 nm) system with EDFA amplifier on 200 km transmission link as shown in figure (Figure 9.).

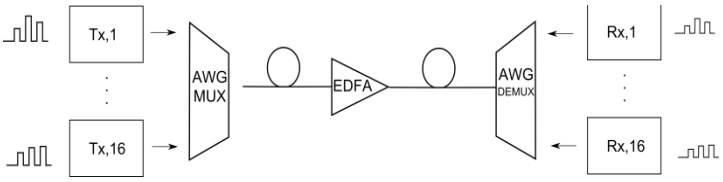

Figure 9. 16 channel DWDM transmission link with EDFA amplifier.

The most important WDM link's evaluative and qualitative indicator is BER as a function of Q – factor. There are several comparisons displayed in figure (Figure 10.)

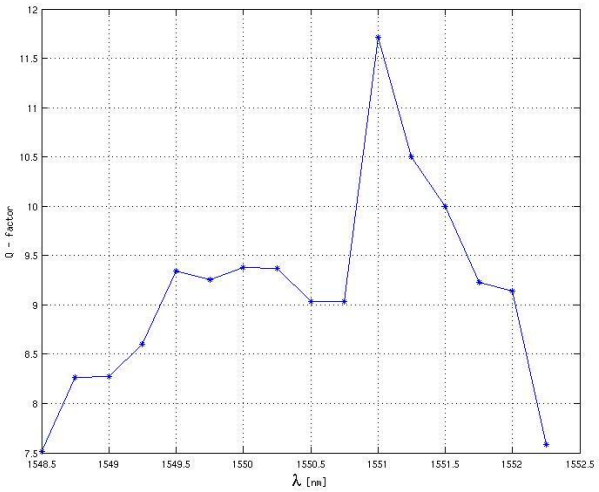

Figure 10. Q – factor as a function of wavelength

Figure (Figure 10.) shows the dependence of Q - factor as a function of a particular wavelength. The second chart (Figure 11.) refers to the BER evaluation as a function of wavelength.

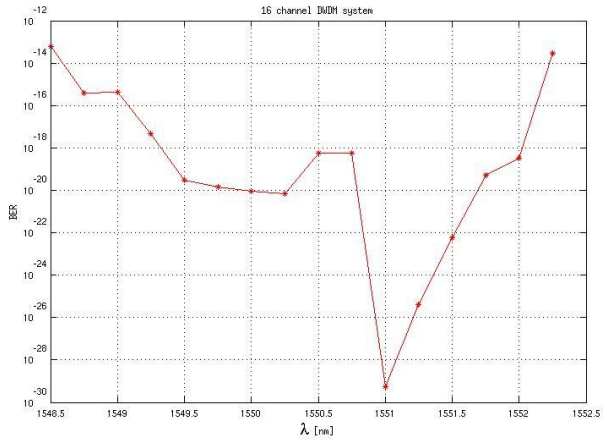

Figure 11. BER for particular channels as a function of wavelength.

The comparison in the figure (Figure 12.) shows an ideal BER curve as a function of Q – factor with simulated values (red color).

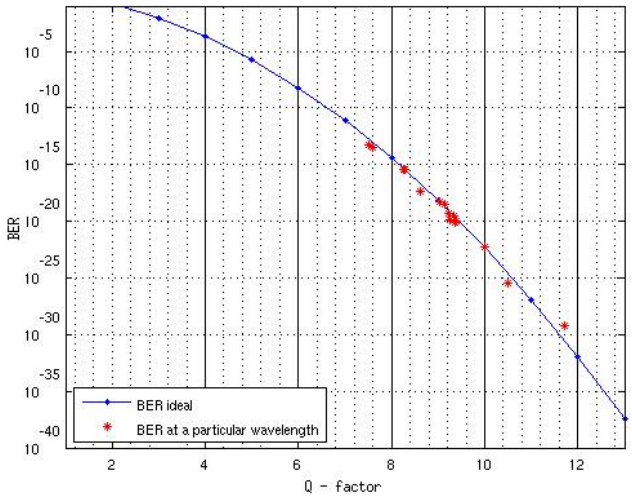

Figure 12. Comparison of BER and Q – factor for an ideal and experimentally simulated values.

IV. CONLUSION

We provided a fundamental WDM demultiplexors overview in this paper. As the most commonly used demultiplexor nowadays is AWG demultiplexor. However, there are some other options available. Hybrid demultiplexor seems to be the most promising future technology. Our simulations have pointed out at the ultra – dense DWD link with 16 channels in the experimental section. Chosen channel spacing was picked to investigate possibilities of using some alternative WDM setup in between two standardized regions for DWDM systems. Results show that these alternative spacing seems to be also appropriate for use in real operation.

***Abstract*— This paper proposes an improved version of early video frame discarding policy that adopts a threshold at the buffers of network elements to control the ingoing video traffic. This improvement is performed through taking the dependencies between video types into consideration to make decision whether to accept or discard any stream of video frame packets. Besides, two thresholds are employed to maintain the buffers of network elements. Furthermore, any frames where their decoding possibilities at the receiver side are almost negligible are prevented from being queued at the buffers of network elements. However, our proposed policy is evaluated in terms of the rate of non-decodable frames and peak signal-to-noise ratio (PSNR). Our proposed policy behaves very well and achieves a remarkable enhancement over the conventional early video frame discarding policy.**

***Index Terms*— Video discarding policies; video traffic; group of pictures; rate of non-decodable frames**

I. INTRODUCTION

In recent years, there has been a tremendous increase in demand for video streaming over wired and wireless networks [1-3]. Applications of digital video streaming include learning via distance [4], video teleconferencing [5], interactive digital TV [6], remote diagnosis/surgery, distance/remote sensing, and process monitoring [7]. Moving Picture Experts Group (MPEG) is one type of video compression techniques that was formed by ISO [8]. New advanced video coding (AVC) schemes appear like MPEG-4 AVC (H.264) that is used for compressing streaming media (audio or video) and distinguished over previous schemes (e.g., MPEG or MPEG-2) as of being capable of affording a lower data rate with comparable picture quality or a comparable data rate with considerably higher picture quality [9].

The compressed MPEG video data has three video frames: I-, P-, and B-frames whereas their repeated pattern is called the Group of Pictures (GOPs) [10, 11]. I-frame is considered an independent and reference frame as of being decoded at the receiver side independently of other P- and B-frames. P-frame is also considered a reference frame bearing in mind that in the decoding process, it depends only on the previous I- or P-frames. B-frames are ordinarily decoded based on the former or posterior I- or P-frames. Additionally, it is decoded using the interpolation of the former and posterior I- or P-frames. In light of previous discussions concerning video frames, it is good to stress on the fact that losing I-frames is more disadvantageous than losing P-frames though both are considered reference frames [12]. In other words, discarding the initial I-frame leads to having all subsequent frames of the same GOP useless. Analogously, losing P-frames may have severe consequences on the subsequent P- and B-frames. On the contrary, losing B-frames may not have any impact of the succeeding frames. Due to carrying the frame header information, losing the head-of frame packet is as worse as losing the whole frame [13].

In this paper, we propose a powerful video frame discarding policy called eclectic early frame discarding-with dependency (EEFD-wD). This policy is considered a novel extension to early frame discarding-without dependency (EFD-woD) policy proposed in [14]. Complete details about our proposed policy and EFD-woD policy will be provided shortly. However, our policy is evaluated based on the following performance metrics: the rate of non-decodable frames and peak signal-to-noise ratio (PSNR). Our proposed policy not only outperforms EFD-woD policy, but also achieves an extraordinary improvement.

This paper is organized as follows. The following section provides details about related work. Section III illustrates our proposed discarding polices. The simulation environment, results, and discussions are discussed in Section IV. Section V concludes our paper.

II. RELATED WORK

There are works in the literature focused on efficient message or email files discarding for TCP/IP-based transmissions utilizing discrete-time [15-16] and continuous-time [17-23] queuing systems. Additionally, there is a work proposed in [24] which predominantly involves two partial frame discarding policies for UDP-based transmissions including frame dependencies and is based on partial frame discarding policy proposed in [14] in which the frame dependencies were excluded.

It is leading light that the most relevant continuous-time-based work to our proposed discarding policies is [14] in which early frame discarding without dependency (EFD-woD) policy has been extensively evaluated in terms of frameput and average buffer contents considering the case where video frames are inputs to the buffers of network elements. The network and buffer model used in this policy is based on M/M/1/N system model in which *M*, 1, and *N* refer to the memoryless property, number of servers used, and number of customers that can be accommodated, respectively. The first *M* refers to the situation where packets that belong to a certain video frame arrive according to a Poisson process with arrival rate λ while the second *M* refers to case where packets at the

head of the buffer are served according to a Poisson process with a service rate μ (the service time follows exponential distribution). The system load (utilization factor) is expressed as ρ (i.e., $\rho=\lambda/\mu$). The length of a frame (in terms of packets) is assumed to be geometrically distributed where a packet belongs to the same frame with probability p, which is equal to $(1-q)$, and is discarded with the same probability. The first packet of a frame is called as a head-of-frame packet and arrives with probability q. In EFD-woD policy, a packet is queued with respect to a threshold K $(0 \le K \le N)$ that is employed to maintain the buffer occupancy level. In different words, once the buffer occupancy reaches at or above that threshold, no packets of a new frame are accepted. On the contrary, the subsequent packets, which belong to a frame has been partially accepted, are accepted.

III. Proposed Video Discarding Policy

Eclectic early frame discarding-with dependency policy (EEFD-wD) policy is basically based on EFD-woD policy proposed in [14]. Unlike EFD-woD policy, the EEFD-wD policy takes the dependencies between video types into consideration to make decision whether to accept or discard any stream of packets. This is accomplished by preventing the frames where the probability to be decoded at the receiver side is too low, as of losing their reference frames, from being buffered and served. Dissimilar to EFD-woD policy, the EEFD-wD policy employs two thresholds, K_L and K_H to maintain the buffer occupancy. Besides, the buffer records the frame type for each arriving packet. Interestingly, if packets belong to B-frame arrive at buffer occupancy lower than or equal K_L, then these packets will be unconditionally accepted. Once the buffer occupancy rises above K_L and stays below or reaches K_H, then arriving packets that belong to partially accepted B-frame will be accepted with probability (1-P_d). It is worth noting that a head-of-B-frame packet will not be accepted during this time interval. Furthermore, arriving B-frame packets at buffer occupancy lies above K_H will be completely rejected. The dropping function of B-frame packets is proposed as:

$$P_d = \begin{cases} 0, & buffer\ occupancy \le K_L \\ e^{\frac{\gamma(buffer\ occupancy - K_H)}{(buffer\ occupancy - K_L)}}, & K_L < buffer\ occupancy \le K_H \\ 1, & buffer\ occupancy > K_H \end{cases} \quad (1)$$

where γ is the exponential factor. The idea of proposing the exponential function shown above is to satisfy the shape shown in Fig. 1. As seen from this figure, the probability of accepting subsequent B-frame packets (i.e., partially accepted B-frame) is high as long as the buffer occupancy stays closer to K_L. Once the buffer occupancy gets higher and higher (i.e., comes closer to K_H) and for the sake of giving other reference frames the opportunity to get totally queued, the probability of buffering successive B-frame packets gets lower and lower.

Due to their importance, the way we deal with P- or I-frames is different. In other words, after conducting many experiments seeking for optimality, we propose that the I- and P-frame packets are accepted at any buffer occupancy level, whether the arrivals represent a head-of-frame packet or packets belong to already accepted frame. Furthermore, if I- and P-frame packets arrive when the buffer occupancy is at or above K_L where the empty space left is not enough, then eclectic mode will be incorporated. In this mode, which represents preventive expedient, a massive buffer search for B-frame packets will occur in which those packets that have the least average waiting time and their count suits or complies with the number of arriving I- or P-frame packets are selected to be substituted with reference frame packets. When there are no possible ways to accept these packets, either by not finding enough B-frame packets or originally not having B-frame packets, the arrivals will be discarded. Consequently, the subsequent packets of that frame will be also rejected. Not only to this extent, but also the rest frames of the current GOP will be disposed of. As an efficient reaction to this situation (i.e., best buffering management), the EEFD-wD policy will eject those buffered packets of that impaired frame, knowing that this frame will not be decoded at the receiver side. Actually, this is also applied for impaired B-frames.

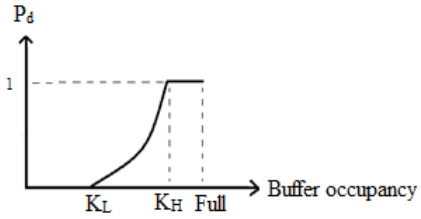

Fig. 1. Drop function of EEFD-wD policy.

IV. Simulation Results and Discussions

This section demonstrates the setup made for simulating our proposed discarding policy along with its obtained results. Subsection *A* discusses the simulation environment. Subsection *B* illustrates the performance metrics used. Finally, the results and discussions are presented in Subsection *C*.

A. Simulation environment

Many experiments were conducted to simulate our proposed discarding policy using Matlab 2010R on a Windows 7 and PC with an Intel Quad Core CPU working at 2.3 GHz with a 2MB cache and 2 GB RAM. These experiments are repeated 100 times and require 15 days to end. However, several benchmark raw videos are used in simulations which include *mobile_sif_mono*, *paris_cif*, *hall_monitor_cif*, *bridge_close_cif*, and *garden_sif* and are available in [25]. The obtained results considering all aforementioned raw videos were relatively similar. Hence, we consider in our simulation results the raw video (*paris_cif*) that has duration of 35.52 seconds. Fast forward MPEG encoder is used to compress the adopted raw video and then encode the generated H.264 video file to eventually extract the I-, P-, and B-frames, which are 1066 frames, utilizing a picturing rate of 30fps. In our proposed policies, the existence of B frames is very helpful. Thus, the GOP pattern used is IBP.

Video frames have different sizes compared to each other. I- frames are the largest frames while P-frames are larger than B-frames [26]. These frames must be fragmented into small packets before they are transmitted to meet the maximum transmission unit constraints. Typically, the mean frame sizes of I-, P-, and B-frames are chosen based on the bit rate used.

To have different load utilizations, we make the service rate stick to 3 (packets/sec) and arrival rate range from 2.5 to 20 (packets/sec). These values can be adjusted to keep the values of load utilization factors. The buffer is assumed to accommodate up to 20 packets as employed in [14]. As a summary of performing many experiments, seeking for those values of K_L, K_H, and γ that maximize the performance of our proposed discarding policy, the chosen values are $N/2$, $1.6xK_L$, $(K_H \geq 0.75\,N)$, 0.1, respectively.

B. Performance Metrics

To assess the performance of our proposed discarding policy, two performance metrics are used which include the rate of non-decodable frames and PSNR. The rate of non-decodable frames represents the ratio of accumulative number of frames that are served but will not be decoded at the receiver side to the number of total frames. The PSNR is one of the best objective ways and widely used to measure the quality of videos. PSNR is measured on a logarithmic scale based on the mean squared error (MSE) between the original video and an impaired one. Higher PSNR values usually refer to lower video impairments [27-28]. It can be found as follows [27]:

$$PSNR = 10\log_{10}\frac{(2^n-1)}{MSE} \qquad (2)$$

$$MSE = \frac{1}{H*W*T}\sum_{t=1}^{T}\sum_{h=1}^{H}\sum_{w=1}^{W}[f(t,h,w)-\tilde{f}(t,h,w)]^2 \qquad (3)$$

where H and W are the horizontal and vertical dimension in pixels of the video frame, respectively. T is the number of frames in the video, n is the number of bits per pixel while f and $\tilde{f}$ are the original and impaired video frames, respectively.

C. Results

Fig. 2 depicts the results of the rate of non decodable frames versus arrival rate for a buffer size of 20. The GOP length and pattern used are IBP and 15, receptively. Additionally, the bit rate used is 200kbps which implies that the mean frame sizes for I-, P-, and B-frames are 20, 3, and 1 packets, respectively. However, the negative effect of increasing the arrival rate on all policies is clearly observed. Unlike the EEFD-wD, the EFD-woD policy achieves higher rates of non-decodable frames. This is expected since frame acceptance is based on only buffer availability. To clearly distinguish between EEFD-wD and EFD-woD policies, they have been subplotted separately.

Fig. 3 delineates the PSNR versus arrival rate considering a buffer size of 20. The parameters related to GOP and bit rate are the same as previously mentioned. Obviously, the improvement of PSNR values as a result of employing EEFD-wD policy is extremely impressive. As a matter of fact, the policy that achieves lower rates of non-decodable frames should have higher values of PSNR. Genuinely, increasing the buffer size will improve the PSNR results for all policies. However, the decrease in PSNR values as the traffic load increases is also noticed for all policies.

V. CONCLUSIONS

This paper proposes an efficient video frame discarding policy (EEFD-wD) to control and maintain the buffers of wired/wireless hops under heavy loads of video stream. the proposed policy is based on EFD-woD policy proposed in [14] in which major amendments are made, out of which incorporating the dependencies existing among video frames, operating two buffer thresholds, and preventing any frames where their decoding possibilities at the receiver side are almost negligible from being queued at the buffers of network elements. In EEFD-wD policy and as soon as the buffer occupancy gets located between buffer thresholds, B-frame packets are accepted according to an exponential function which helps to limit the maximum number of B-frame packets that could exist in the buffer without degrading the overall video quality. Under unexpected video traffic and on account of accepting reference frames (I- or P-frames), those buffered B-frames are obliged to expel. The performance metrics used to evaluate the proposed discarding policies include the rate of non-decodable frames and PSNR. The effectiveness of our results is verified by comparing with EFD policy.

Mobile node localization using infrared angle of arrival sensor

D. Frantal, D. Arbula
Faculty of Engineering Rijeka, Computer science department, Rijeka, Croatia
dfrantal@riteh.hr, damir.arbula@riteh.hr,

Abstract - This paper presents mobile node localization algorithm for environments in which GPS or other positioning systems are not applicable or available. Existing localization systems are using propagation characteristics such as attenuation or speed of radio or ultrasound signals or timings of controlled laser radiation to estimate node azimuth and/or distance to nodes with known position (anchor nodes). Presented algorithm is using azimuth estimation based on measured angle of incidence of controlled infrared radiation from anchor nodes. Angle of arrival estimation and localization algorithms are implemented on low cost, small footprint and low power wireless nodes based on 8-bit microcontroller. Experimental evaluation results are promising and with further sensor optimization can guarantee high precision of estimated locations.

I. INTRODUCTION

Solution to mobile node localization problem in environments where general purpose localization methods are unavailable is presented in this paper. Method is implemented on low cost and low power wireless sensor network nodes [1]. Each node consists of microcontroller, radio module, and angle of arrival sensor prototype (Figure 1).

Node with unknown location receives true coordinates of limited set of nodes with known position (anchor nodes). Subsequently, using angle of arrival sensor it measures angle of incidence of infrared radiation emitted by anchor nodes and estimates their azimuths. With the data obtained from at least 3 anchor nodes, mobile node is able to calculate its position.

Existing solutions are based on radio interference measurements and require more expensive hardware with three [2] or two [3] antennas. There are also solutions that use rotating lasers [4] but they come with significant setup overhead.

A. Platform

Wireless sensor node platform used is commercially available under name JeeNode. This low cost platform consists of an 8-bit AVR RISC Atmel ATmega328P microcontroller, RFM12B radio module and 4 input/output ports. Communication with PC is possible through serial UART port. Each of 4 available ports provides digital and analog input/output, power lines, interrupt line and ground. The whole platform has small footprint and low power usage.

The work presented in this paper is supported by the University of Rijeka research grant Grant 13.09.2.2.16.

II. HARDWARE

A. Angle of arrival sensor

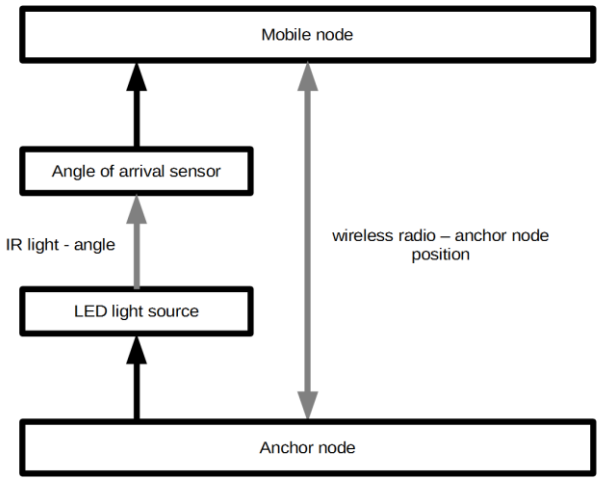

Figure 1. Conceptual scheme

Angle of arrival (AoA) sensor consists of 12 infrared phototransistors (Figure 4) [5] evenly distributed along the circular rim of the sensor. Infrared radiation is chosen to minimize expected interferences with visible light.

Each phototransistor emitter is connected to multiplexer input and with resistor in series to ground. Voltage is fed to phototransistor collector. Multiplexer channel selection is controlled by dedicated slave microcontroller and this way each voltage drop can be measured using 10 bit A/D converter on microcontroller's analog input (Figure 2).

B. IR radiation source

IR radiation source consists of 15 evenly circularly distributed infrared LE diodes [6] that can be switched on and off by microcontroller. LEDs are triggered (for short duration) by microcontroller digital output pin (DOP) that is connected to MOSFET because digital output pin can only provide 40 mA of current which is not enough for powering all LEDs. LEDs are connected directly to battery power source that provides 5 V (Figure 3).

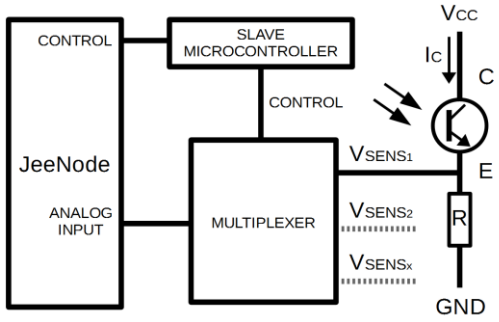

Figure 2. Phototransistor circuit collector current I_C (max 0.31 mA) is dependent on IR radiation intensity, V_{SENS} (max. 3.1 V) is voltage detected by microcontroller, pin is connected to multiplexer input.

III. NODE LOCALIZATION

A. Localization method

In the current setup, mobile node is the node with unknown position, likewise nodes with known coordinates or anchor nodes are stationary [7]. Anchor nodes are equipped with omnidirectional IR radiation source and mobile node is equipped with IR AoA sensor. If the mobile node is in the communication and AoA sensor range of at least 3 anchor nodes, then it is able to localize itself. In this paper only 2D localization is considered.

B. Localization procedure

Based on the stated assumptions, procedure for node localization is as follows:

1. Mobile node broadcasts request for nearby node IDs. All nearby anchor nodes in range send their ID with different delay (ID based) to mobile node.
2. Mobile node measures ambient IR radiation, that is, IR radiation in the environment with all anchor nodes having their IR diodes turned off.
3. Mobile node sends request to the first (by ID) nearby anchor node in range for position and IR radiation.
4. Anchor node switches its IR LEDs on, transmits location and lights on confirmation.
5. Mobile node using AoA sensor measures IR radiation intensity from different directions. To be able to calculate intensity that originates from anchor node IR LED, ambient IR radiation that was measured in step 1 is subtracted from values obtained in this step.
6. Mobile node estimates azimuth of the anchor node using measured intensity values (from each phototransistor, thus in each direction) of its IR radiation and sends confirmation that the location is received and angle of light arrival is measured. Estimated azimuth and anchor location are stored in memory.

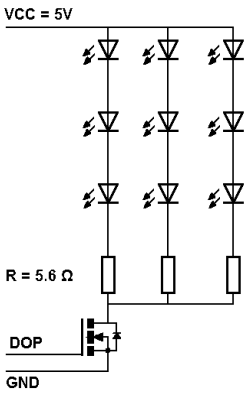

Figure 3. Radiation source scheme, total current drawn from voltage source by LEDs is 565 mA.

7. Localized node turns off LED light and transmits light off confirmation
8. After light off confirmation is received the steps 2. through 7. are repeated for each anchor node in the range.
9. After all anchors in the range have sent their locations and all azimuths are estimated mobile node selects three anchors with minimum geometric dilution of precision (GDOP). Localization precision depends on the relative locations of anchor nodes and this selection is mandatory to select most appropriate anchors triplet.
10. Location is estimated using selected anchors.

C. Azimuth estimation

Azimuth of the anchor node is estimated using measured voltage on each photodetector. Photodetectors on sensor are distributed evenly in order to cover fields which cover equal azimuth of circle. (Figure 4)

Radiation intensity is represented by voltage drop on a resistor in series with photodetector (phototransistor) and equals a numerical value.

Two phototransistors with maximum measured intensity are selected and their values V_1 and V_2 are used in estimation using the following expression

$$\beta = \frac{V_1 \times \alpha_1 + V_2 \times \alpha_2}{V_1 + V_2} \quad (1)$$

In which β is the angle of arrival, α_1 orientation of the phototransistor with highest voltage and α_2 orientation of the phototransistor with second highest voltage value.

D. Location estimation

Location estimation method is based on assumption that there are three anchor nodes in range (q_1, q_2, q_3) with known position (x_j, y_j) and unlocalized node p with unknown position and orientation (x, y, θ) (Figure 5) [8].

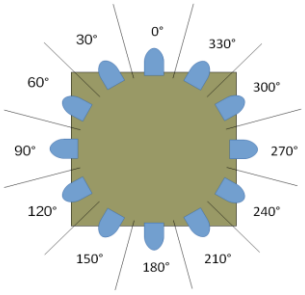

Figure 4. AOA sensor distribution of fields for sensor with 12 photodetectors

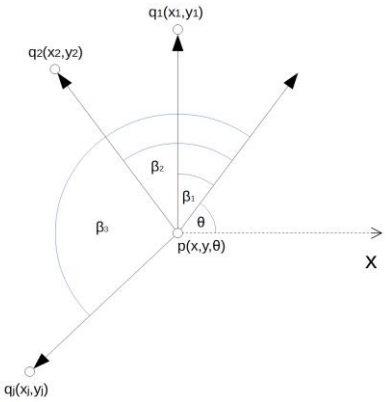

Figure 5. Nodes in 2D environment, q_1 q_2 and q_3 are selected anchors with known position and p is node with unknown position and orientation.

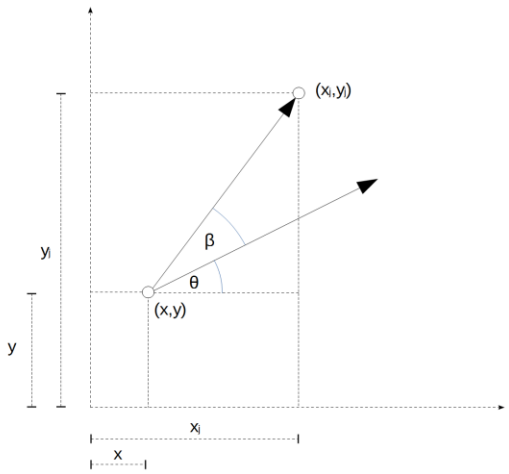

Figure 6. Nodes relation

$$q_j = \left[x_j + y_j\right], j = 1,2,3 \tag{2}$$

$$p = \left[x, y, \theta\right] \tag{3}$$

Anchor j azimuth β_j can be expressed using:

$$\tan\left(\theta + \beta_j\right) = \frac{y_j - y}{x_j - x}, j = 1,2,3 \tag{4}$$

where (x_j, y_j) represent j-th anchor node location, (x, y) mobile node location, θ mobile node orientation, and β is the angle between mobile node and anchor node as shown on Figure 6.

Equation (4) can be written as:

$$(x_j - x)\tan\left(\theta + \beta_j\right) = y_j - y, j = 1,2,3 \tag{5}$$

and by using trigonometric addition equations (5) it can be transformed to:

$$\frac{\tan\theta + \tan\beta_j}{1 - \tan\theta\tan\beta_j}\left(x_j - x\right) = y_j - y, j = 1,2,3 \tag{6}$$

$$\left(\tan\theta + \tan\beta_j\right)\left(x_j - x\right) = \left(y_j - y\right)\left(1 - \tan\theta\tan\beta_j\right) \tag{7}$$

After (7) multiplication and grouping:

$$\begin{aligned}&\tan\beta_j\left(x + y\tan\theta\right) - \left(y - x\tan\theta\right) - \\ &- \left(x_j + y_j\tan\beta_j\right)\tan\theta = x_j\tan\beta_j - y_j\end{aligned} \tag{8}$$

To simplify (8) can be multiplied with $\cos\beta_j$:

$$\begin{aligned}&\sin\beta_j\left(x + y\tan\theta\right) - \cos\beta_j\left(y - x\tan\theta\right) - \\ &- \left(x_j\cos\beta_j + y_j\sin\beta_j\right)\tan\theta = \\ &= x_j\sin\beta_j - y_j\cos\beta_j\end{aligned} \tag{9}$$

One can introduce following auxiliary variables:

$$\begin{aligned}u_1 &= x + y\tan\theta \\ u_2 &= y - x\tan\theta \\ u_3 &= \tan\theta\end{aligned} \tag{10}$$

So we can write (10) as:

$$\begin{aligned}&\left(\sin\beta_j\right)u_1 - \left(\cos\beta_j\right)u_2 - \left(x_j\cos\beta_j + y_j\sin\beta_j\right)u_3 = \\ &= x_j\sin\beta_j - y_j\cos\beta_j\end{aligned} \tag{11}$$

Equation (11) can be used for three nodes with known location to get three linear equations with three unknown variables in matrices:

$$A = \begin{bmatrix}\sin\beta_1 & -\cos\beta_1 & -x_1\cos\beta_1 & -y_1\sin\beta_1 \\ \sin\beta_2 & -\cos\beta_2 & -x_2\cos\beta_2 & -y_2\sin\beta_2 \\ \sin\beta_3 & -\cos\beta_3 & -x_3\cos\beta_3 & -y_3\sin\beta_3\end{bmatrix} \tag{12}$$

$$b = \begin{bmatrix}-x_1\cos\beta_1 & -y_1\sin\beta_1 \\ -x_2\cos\beta_2 & -y_2\sin\beta_2 \\ -x_3\cos\beta_3 & -y_3\sin\beta_3\end{bmatrix} \tag{13}$$

$$U = \begin{bmatrix}u_1 \\ u_2 \\ u_3\end{bmatrix} \tag{14}$$

Then we can write:

$$AU = b \tag{15}$$

$$U = \begin{bmatrix} u_1 \\ u_2 \\ u_3 \end{bmatrix} = \left(A^T - A\right)^{-1} A^T b \qquad (16)$$

From (10) one can substitute:

$$\begin{bmatrix} x \\ y \\ \theta \end{bmatrix} = \begin{bmatrix} \frac{u_1 - u_3 u_2}{1 + u_3^2} \\ \frac{u_2 - u_1 u_3}{1 + u_3^2} \\ \tan^{-1} u_3 \end{bmatrix} \qquad (17)$$

IV. EXPERIMENTS

Experiments were carried out to evaluate performance and precision of the angle of arrival sensor and mobile node location estimation.

A. Azimuth estimation accuracy

Accuracy was measured in three different luminance conditions with different light sources:

- Complete darkness (0 lux)
- Incandescent light bulb (90 lux)
- Sunlight (1280 lux)

TABLE I. MEASURMENTS IN DARKNESS

Luminance:	0 lux
Distance between LED light source - sensor	**Angle measurement root mean squared error**
180 cm (edge of detection range):	30°
90 cm (half range distance)	3.58°
2.5 cm (source and sensor touching)	7.15°

The data in Table I. represents angle measurement root mean squared error at different distances between the source and the sensor. Distances that were used are:

- Edge of IR detection range – when angular movement of light source can be barely detected by sensor
- Half range distance
- Source and sensor touching – source IR LED and sensor photodetector are touching

Figure 7 shows measured angle deviations from real angle values in range from 76° to 105° in complete darkness for 90 cm distance (half range) from light source to sensor.

Figure 7. Estimated azimuth deviation from real values in darkness

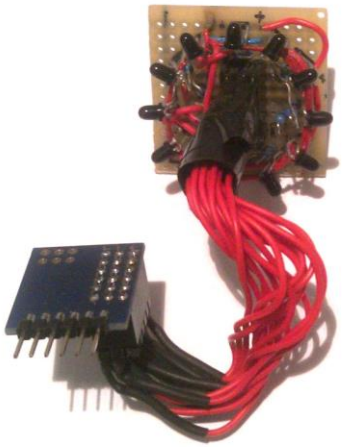

Figure 8. AoA sensor prototype

The best results were observed in complete darkness because there are no infrared components in light to interfere with the sensor operation and best accuracy is observed at half range distance. It is important to notice that observed results can be greatly improved by developing AoA sensor with smaller tolerances than prototype version (Figure 8) and by employing better filtering of surrounding noise (IR remote controllers, pulsating lights…)

B. Location estimation

Location estimation was carried using 3 anchor nodes at fixed coordinates (100,120; 10,100; 50, 20) and mobile node at different locations in range. True and estimated locations of the mobile node are presented in Table II.

TABLE II. LOCATION ESTIMATION RESULTS

True position x, y[cm]	Estimated position x, y [cm]	Deviation x, y [±cm]	Error distance [cm]
0,0	3,6	+3,+6	6,71
50,50	44,56	-6,+6	8,49
80,80	74,82	+4,+2	6,32
100,0	95,-8	-5,-8	9,43
0,120	-6,131	-6,+11	12,53
50,100	42,98	-8,-2	8,25
100,50	86,47	-14,-3	14,32
Error distance root mean square:			9,83

Position estimation is quite satisfactory if we take into account sensor price and still prototype development phase.

V. CONCLUSION

Although current platform and methods for azimuth and location estimation are still under development these initial results are very encouraging. Location estimation precision is high enough to be used for example in indoor mobile robot localization or assets tracking.

Future work includes integrated circuit development with both AoA sensor and IR LEDs using surface mount technology. Benefits would be twofold: precisely positioned phototransistors would allow better azimuth estimation accuracy and it would make platform more compact. As further optimizations each photodetector could be calibrated in order to compensate for systematic errors caused by imprecise phototransistors placements.

Another improvement could be more sophisticated algorithm for azimuth estimation that takes in account more than two phototransistors. Also, AoA range can be increased by driving IR LEDs with higher current for shorter period of time.

A Profile- and Community-Driven Book Recommender System

I. Petrović, P. Perković and I. Štajduhar
University of Rijeka, Faculty of Engineering, Department of Computer Engineering, Rijeka, Croatia
iva.petrovic5@gmail.com

Abstract - Book lovers often struggle to find something new to read. The choice of possible books to read can be overwhelming and confusing, making this subjective decision-making process quite difficult. Searching the Internet we often stumble upon opinions and book ratings of people who are strangers to us. We do not know what their favorite categories, authors, publishers and taste in books are, nor whether we should trust them. As a possible solution to the above mentioned problems, we present *Pickbooks* - a Web application that is partly a social network and partly a book database. It integrates the social aspects of today's popular social networks into a book recommender system, and not the other way around. It features book recommendation based on previously read books or personal preferences. It allows users to message and follow people they like, see their updates, reviews and get recommendations from them, and vice versa. The users are encouraged to rate a book they have read before, as those ratings affect the global lists of top rated and currently popular books. There are other features which are in the works and will allow us to further improve the presented application and attract more audience.

I. INTRODUCTION

Many book fans often find themselves in a situation where they do not know what to read next. Recommender systems are there to help them in these situations. Consider, for example, the *Internet Movie Database* (IMDb) website (http://www.imdb.com/). It is, most certainly, today's most popular movie database website. What if we could create something similar to that, but for book recommendations, i.e. a website that would incorporate those features and adapt them to books? Motivated and inspired by this idea, *Pickbooks* emerged.

A lot of websites give their users lists of top rated books, but that is no guarantee the users will like them. The main reason for this is the user's possible (and quite probable) disagreement with the interests and tastes of that author's list. One viable solution to this problem is to develop a recommender system embedded with some social network characteristics, enabling us to connect people with mutual interests. Broadening this vision of the recommender system by using these features provides the potential to bring books closer to the user.

In short, *Pickbooks* is a Web application, which fuses a book database, a social network and a book recommender system, into one product, available to users free of charge. Imagine binding a *Twitter*-like application (https://twitter.com/) [1] with a book recommender system, and you would understand the proposed idea.

The paper is structured in the following way. In the following section several popular and comparable related recommender systems are presented and the advantages of the proposed system over its direct competitor, *Goodreads*, are described. In section III, several important approaches to recommender systems are explained, introducing additionally some of the more popular consumer services as their respective representatives. The details concerning the proposed application and its' recommender system are outlined in section IV. In section V, final remarks are given together with an insight into the more probable future development plans for *Pickbooks*.

II. RELATED WORK

Browsing the Internet, one can find a lot of different types of recommender systems. Some of the most popular recommender systems, comparable to *Pickbooks* in several ways, are:

- *Last.fm* (http://www.last.fm/) is a music website that uses a recommender system called *Audioscrobbler*. Its goal is to create a detailed user profile based on the user's musical tastes. In this case, the profile is based on recording details of the tracks the user listens to.
- *Netflix* (*https://www.netflix.com/*) provides users with the ability to stream online videos on demand. Today, *Netflix* uses one of the best available recommendation algorithms. An extensive personalized video-recommendation system is based on ratings and reviews by its users.
- *Foursquare* (https://foursquare.com/) is a local search, recommendation system that learns what you like and leads you to places you love. Their recommendation system records places visited by the user, the things they like (reported to the application), and other users, whose advice they trust.

The recommendation system introduced in this paper is very similar to the recommender systems mentioned above. All three systems create a detailed profile based on a user's tastes. In the case of *Pickbooks*, this applies to book tastes, e.g. what book categories the user likes to

The work presented in this paper is partially supported by the University of Rijeka research grant 13.09.2.2.16.

read or what authors he or she prefers. Just like *Netflix*, the introduced recommender system is based on user's book ratings.

Pickbooks uses the best features of the most famous recommender system algorithms, combining them into one system that strives to give its users best book recommendations. What is new in this recommendation system? The goal is not only to collect data about users. It is also to provide users with the opportunity to give recommendations to their friends.

The main competitor of *Pickbooks* is *Goodreads* (*http://www.goodreads.com/*). It uses a recommendation algorithm to analyze which books people might like, based on books they have enjoyed in the past and books that people with similar tastes have liked. In order to get a book recommendation from this system, the user has to assign a rating to 20 books, at least.

For the authors of this paper, contemplating this from the perspective of *Goodreads* users, it was a big disadvantage. Sometimes rating books can be exhausting, especially if one hasn't read the books recently and cannot remember which 20 books to rate. It would be better to enable users to get a book recommendation immediately after registering. The proposed recommender system gives a book recommendation at the exact same moment the user starts searching for books or authors. Users are also given a list of top rated and trending books.

As was already pointed out, the idea was not only to create a recommender system, but also to interweave it with social network aspects. *Goodreads* implements a similar idea, i.e. it also enables their users to find friends with similar interests and to engage in conversations with them. *Pickbooks* also consists of a friend recommendation algorithm that monitors users' activities, what books they have read and how they have rated them, and based on that information it recommends cliques of users sharing the same interests. Another factor for the algorithm are the users' lists of friends. Using a user's list of friends, friends of his or hers friends are recommended. Most of social networks work on that principle, e.g. *Facebook* (https://www.facebook.com/) [2].

There are some features *Goodreads* is missing, which are implemented in *Pickbooks*:

- Generic representation of the system's data flow;
- Book recommendation when searching for book/author (e.g. based on book information the user is searching for, the system recommends similar books from the same category or books from the same author);
- Friend recommendations based on same interests or on mutual friends;
- Search for friends based on their name, e-mail address, city they come from or mutual friends;
- Easy way to recommend books to friends;
- Posting statuses about the books the user read/likes;
- Recommendation of top rated books from all categories.

III. RECOMMENDER SYSTEM

According to [3], recommender systems represent a powerful method for enabling users to filter through large information and product spaces, and, thus, pose an important part of the information and e-commerce ecosystem. The goal of a recommender system is to generate meaningful recommendations to a collection of users, for items or products that might interest them. There are several popular approaches to creating a recommendation algorithm: collaborative filtering, content-based filtering and a hybrid approach. They are described next.

A. *Collaborative filtering*

Collaborative filtering (CF) is a popular recommendation algorithm that bases its predictions and recommendations on the ratings or behavior of other users in the system. This type of approach collects and analyses a large amount of information on users' behavior, activities and personal preferences, and thus predicts what the users will like, based on their similarities to other users using the same service. The key advantage is that it does not rely on machine analyzable content and, as a result, it can generate recommendations without requiring an understanding of the item being recommended [4,5].

CF operates on the assumption that people will like similar things, which they liked in the past, and so can be slow to adapt at sudden changes in user preferences and other related information. The quality of recommendations are solely based on how much information a user has shared with the system, thus more information means better recommendations. Often, the algorithms operate on a user database that counts millions of entries and, as such, needs a large amount of computational power to calculate recommendations [6].

Last.fm, *Facebook*, *MySpace*, *LinkedIn* (https://www.linkedin.com/) and other social network services use collaborative filtering to recommend music, new friends, social connections, etc.

B. *Content-based filtering*

The second popular approach to creating a recommendation system is content-based filtering (CBF). In CBF, all items have a description and all users have a profile of their preferences (user history, ratings, personal information, etc.). The algorithm then matches the keywords from these two sources and generates a list of recommendations. The algorithm sorts and recommends items, based on their weight of importance.

One of the key challenges with this type of approach is concerned with enabling the system to use collected data from one source and apply the filtering to other content sources. For example, if a user likes a book category by the name of "Romance", it would be useful to be able to recommend movies, videos and news articles that contain that exact keyword [6].

CBF filtering techniques suffer from problems like limited content analysis, overspecialization and new users. Limited content analysis refers to the problem when a set of attributes, attached to every item in the collection, is rather small. No suitable suggestions can exist if the analyzed content does not contain enough information to differentiate items the user likes from items the user does not like. Overspecialization occurs when the system judges individual items based on a limited number of indicators. This results in the system recommending items that are either too alike to what the user has seen in the past or items that are content-identical to other recommendations shown at the same time. New users present a problem, because the recommendation algorithm has yet to receive profile information from the user to be able to create a recommendation based on criteria [7].

Examples of services that use this approach are: *Pandora Radio* (http://www.pandora.com/), *IMDB*, *8Tracks* (http://8tracks.com/), *Foursquare*, etc.

C. *Hybrid recommender system*

Hybrid recommender system (HRS), as the name clearly suggests, is a hybrid of the two aforementioned approaches to recommendation algorithms [8]. In recent history, researchers speculated that this kind of approach, combining collaborative and content-based filtering, may yield better and more accurate results, at least in some cases. Using the hybrid method, problems inherent to pure implementations (CF, CBF), like cold start and sparsity, can be overcome [9,10].

Netflix is one of the most popular services, which combines both collaborative and content-based filtering for recommending movies. Table I depicts the links between several popular Web services and their respective recommender system types.

IV. APPLICATION DESCRIPTION

Pickbooks is a Web application that allows people to discover new books, and share their thoughts about the ones they have already read. The application is powered by our own recommendation algorithm, which uses the hybrid approach for generating recommendations. Book recommendations are generated by leveraging user's personal preferences and connections with their friends. Previous searches, book ratings, the same book category and author preference with friends and friends of friends, book popularity - all are taken into account when learning about a user's reading preferences and habits.

TABLE I. RECOMMENDER SYSTEM TYPE USED BY A PARTICULAR WEB SERVICE

Web service name	CF	CBF	HRS
Last.fm	X		
Netflix			X
8Tracks		X	
IMDB		X	
Facebook	X		
Foursquare		X	
Pandora Radio		X	
MySpace	X		
LinkedIn	X		

Upon arriving on the landing page (Fig. 1), before starting using our recommender application, it is mandatory to give some information about oneself. The registration process requires the user to choose a unique username, password and enter an email address for further authentication. After a successful registration, the user is immediately able to search through the system's database, connect with his or her friends, meet other book lovers, rate his or her favorite books, keep a list of what to read next, etc. The system's topology is illustrated in Fig. 2. A more thorough analysis of its architecture is described next.

Our system can be roughly divided into five main parts:

- Home page,
- Profile page,
- Library,
- Friends, and
- Chat.

Home page (Fig. 3) is the main page of our Web application, where users are encouraged to search for recommendations for top rated and currently popular

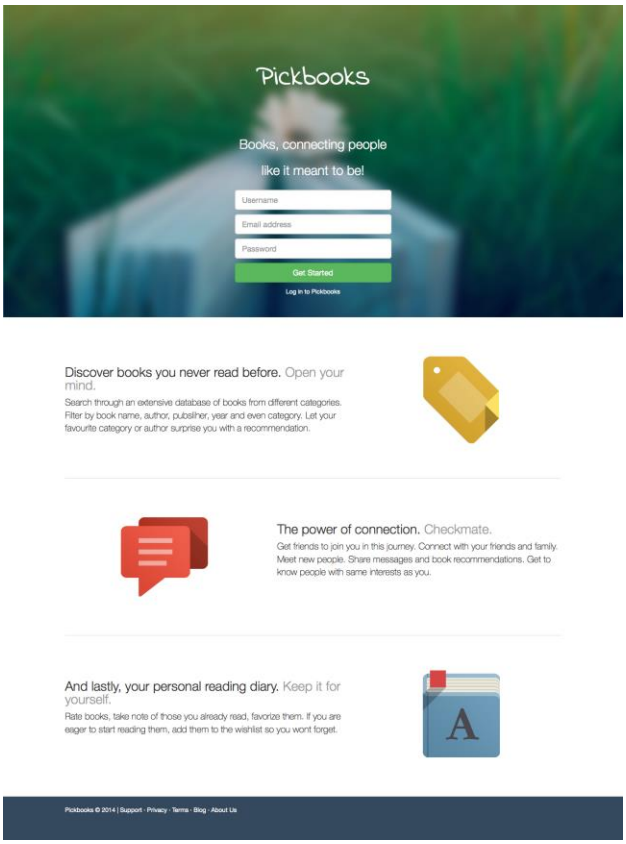

Figure 1. Landing page

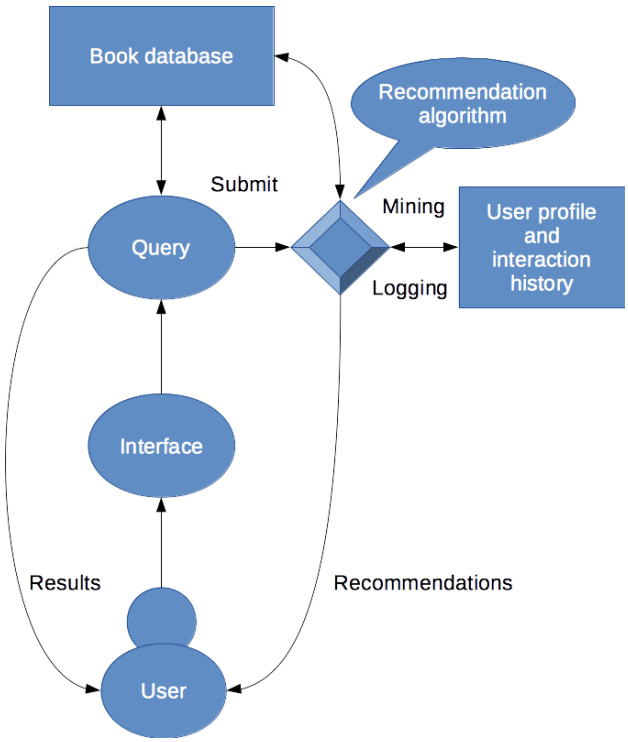

Figure 2. Generic representation of the system's data flow

books, among other things. An important part of this page is the news feed. There, users can find out who added them as a friend, and see what books their friends liked recently. Additionally, users are also able to share their opinions on interesting books they read with their friends through the option of posting statuses. They can also search for other users, sharing the same interests, or friends of friends, add them as their friends or send them messages. Home page combines basic recommendations and social network aspects, and puts them together in one place.

The profile page contains the public profile of the user. A user profile is personally curated by the owner, and contains the user's personal information (profile picture, full name, location, gender, biography and website), books he or she has read, his or her favorite books, books they would like to read next and personal statuses. Additionally, a list of people who are being followed by the user, and a list of people following the same user, are also available. All of the mentioned information can be explicitly hidden from the public, if the user chooses so, and can be adjusted using the security options.

Library page (Fig. 4) basically displays a book database. Searching for new books can sometimes be really exhausting. Our system enables filtering books by their name, author, publisher, publication year or category. To help the user even more in deciding what to read, the system provides a short book description, so he or she can have a quick look at the book content. Whilst reading the short description and basic information about a book, the user is also given a list of books from the same author and/or category.

Additionally, the user can recommend books to his or her friends. They will receive a notification about the recommendation shortly after it has been sent. Most of the book fans have their favorite authors, and want to read all of his or her books. Often they do not know which books they have read, and which they have not read yet. That is why it is useful to have a list containing all the books one has read. Our system allows the creation of lists like that one, and even more. The user is able to make his own wish list, a list of favorite books (once read), and even rate them.

The next part is the friends page. As it was already stated, our idea was to entwine a recommender system with a social network. Therefore, this approach required the introduction of a user's friends. This page allows the user to search for friends, or to find people sharing the same interests. There is an option to search and filter friends by name, email, location or mutual friends. Also, there is a generated list of people the user may know. When users find their friends, they can start following them, gaining the ability to receive information about their activities in the news feed on their home page.

The chat hub is the last main part of the Web application. On this page, the user can exchange messages in real time with his or hers friends, anytime he or she wants. If they are offline in that exact moment, that poses no real problem. They will receive a message when they come back online.

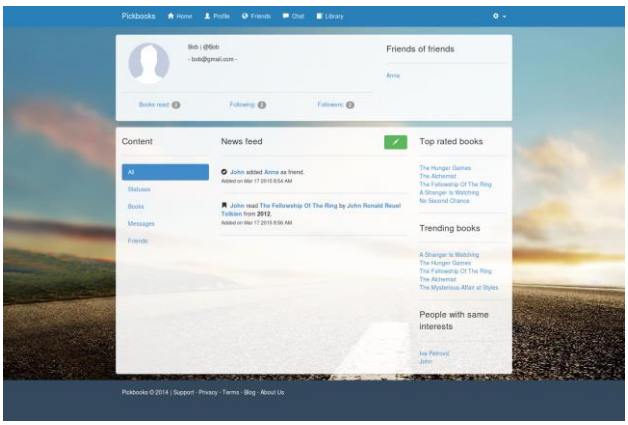

Figure 3. Home page

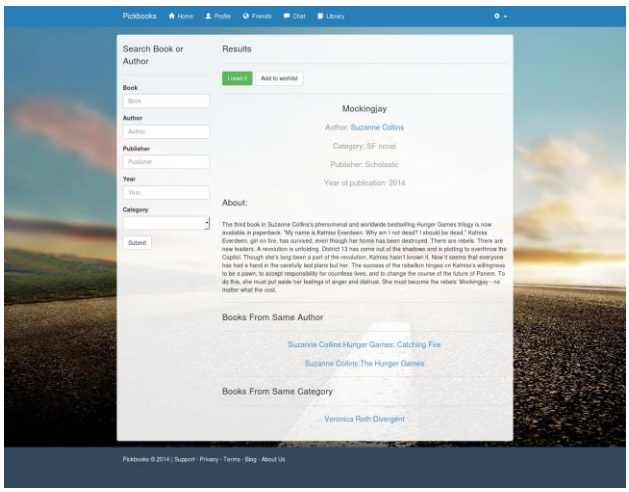

Figure 4. Library page

Pickbooks was developed using only free and open source Web technologies. For the frontend design, we used Bootstrap framework [11] and other custom HTML (Hypertext Markup Language), CSS (Cascade Style Sheet) and JS (JavaScript) scripts. The system's backend consists of both PHP (PHP Hypertext Preprocessor) and MySQL scripts, working together to enable users to interact with the application.

V. CONCLUSION AND FUTURE WORK

In this paper, a Web application for book lovers is presented to discover books and connect with friends. Although the expectations were met and the application has successfully evolved through development, there is still some work that needs to be done.

The idea for this application arose from the disappointment, evoked by the lack of good internet services regarding books. We found that Amazon's *Goodreads* has the biggest market share and that there are no other significant competitors in the market. This is the main reason this application was developed, thus fulfilling our vision regarding the approach to this kind of social experience and making it a reality.

We have a few features in store to improve the overall experience of *Pickbooks*, which will be added at a later date:

- Book lists: Every user will be able to create personal book compilations, like top lists, for every kind of occasion. The lists can then be shared with the public, for others to see, or just with friends. We believe this will allow users to find themselves a focused group of recommendations, created exclusively by other users, ones that will be very hard to reproduce by the algorithms or otherwise.
- Community driven database expansion: We will enable users to submit proposals for adding books to the library. They will be able to provide information about books and their authors. After the submission of data, administrators will confirm or reject books based on information authenticity.
- Administration page: In future we are going to develop an administration page where administrators will have the ability to confirm or reject user's book submissions. Also, another very important role of administrators will be to moderate the activity of the overall community, like deleting inappropriate content.
- Mood centric recommendations: A user's search for a book by categories can result in recommendations that don't necessarily suit his or her mood. We would like to extend our recommendation system, by adding an option of recommending books based on user's mood. This feature will be accessible only on demand. Getting book feedback from other users and analyzing keywords will allow us to get an estimate of a book's psychological effect.
- Online book purchases from retail stores: We would like to offer our users a quick and easy way to find a book and buy it online from different retail stores, available immediately.
- Further security and user privacy improvements: We know that user's personal information are indeed personal, therefore we would like to further improve security and privacy aspects of *Pickbooks*, giving users more control over these settings.
- As always, we strive to improve the accuracy and authenticity of book recommendations. We will take a look at our recommendation algorithms, see where we can improve, and try to fine-tune those areas.

***Abstract*—Choosing the DSL LARIS (LAnguage for Railway Interlocking Specifications) to develop control software for distributed railway interlocking systems can give us a lot of advantage over the general purpose languages, that have been proven in the industry over a long time. We present an extension of the LARIS language with session types to model the communication between railway entities. Our approach improves the safety and reliability of the system and also reduces the verification time by enabling the verification of deadlocks and livelocks of these systems. We evaluate the feasibility of our approach on a case study in railway interlocking.**

I. Introduction

Formal and automated verification of code correctness is a key component in the development of safety critical systems. Applying this principle in the software development of geographic railway interlocking systems (which must be concurrent and distributed) is more challenging, from several points of view. First, it is very difficult to specify global constraints in such systems. Secondly, assuming that these previously mentioned constrains are specified, it would be very challenging to verify them, because of the abstract and incomplete nature of the software specification.

Analyzing the current industrial practices, along with the state of the art programming languages and tools to develop distributed railway interlocking software, we concluded the following: Without a way to routinely and reliably build concurrent and distributed systems, following some correct-by-construction principles, the technical progress of these systems will draw to a close. Furthermore the price of such systems considering the development and maintenance costs, remains high. On the other hand, trying to follow the functional development principle [1], [2] and to explore the state space of such a system, it seems to be also generally impossible [2]. The verification leads approximately always to state explosion, therefore a new methodology to verify interlocking software correctness is highly welcome.

We have analyzed several geographic interlocking languages and methods [3], [4], and we concluded to choose LARIS [3] for our research. LARIS is a textual typed language for specifying geographic interlocking control systems.

The goal of our research is to extend the LARIS in order to enable a larger number of system requirements specification and formal verification on global level without compromising the current development process.

We propose the adoption of a new state of the art global specification principle named Session types in LARIS in order to enable static verification of global properties in the source code. This approach is in correlation with previous theoretical research results [5],[6].

The goal of this paper is to extend LARIS in order to ensure the correctness of its source codes against a local protocol specifications. These local protocol specifications are projected from a global protocol specifications developed in "Scribble" which is a "Session typed" protocol specification language [7].

Our contribution is twofold:

- We integrated Scribble into LARIS to enable the session typed protocols specification and verification
- We translated the "Scribble" local protocol specifications according to [5], into some weakest-preconditions and strongest-postconditions plus some static verification rules which can be statically verified with existing tools such as: [8], [9], [10], [11], [12], [13].

The rest of this paper is organized as follows: Sec. 2 introduces the DLS LARIS including the related terminologies and principles of railway interlocking systems, and the basic concept of "Session Types". Sec. 3 presents our LARIS source code verification principles to enforce specification of a local protocol. Sec. 4 illustrates our approach by modelling and verifying a combined scenario of route verification in the domain of the geographical railway interlocking systems; Finally, Sec. 5 draws the conclusion and presents the future works.

II. LARIS and Session types

A. Railway control

The management of a railway system consists of the following three essential layers: logistic,interlocking and infrastructure layer as in Figure 1. The control instructions for the railway yard has to be formulated at the logistic level. Next, it has to be guaranteed that the execution of control instructions does not lead to collisions and derailments. This is realized by means of an interlocking layer, which is the most important layer from safety perspective. This layer is located between the infrastructure and logistic level, and serves as a local solution for a specific railway yard, whereby the logic could be designed to cope with the peculiarities of the railway yard in a way to force the embodiment of safety principles and basic rules, according to which a train moves through a railway yard. On the top these, control instructions have to be passed on to the infrastructure elements like signals, points, tracks

etc.,These elements must change their state according to the received control instruction.

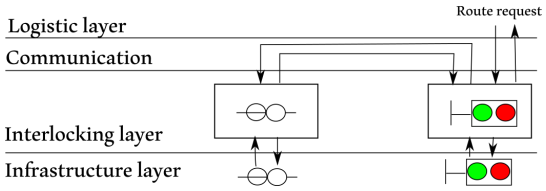

Fig. 1: Illustration of inter-object communication

B. LARIS

LARIS is a textual domain specific language for specifying geographical interlocking software. This language is a textual representation of the EURIS (EUropean Railway Interlocking Specification), a graphical specification language for railway interlocking systems. EURIS was inspired by the Prozes Ablauf Plane[2] being used at Siemens and it was used to specify the control of several railway yards. Hence, EURIS is a well-tested language, it became clear that it was appropriate for its intended use.

LARIS has an object-oriented architecture, consisting of a collection of generic components, representing the elements of the infrastructure such as signals and points. The components, which collectively make up the interlocking logic, communicate with each other by means of data-structures called telegrams. The components can also communicate with the logistic and infrastructure layers. These two layers can be considered the environment of the interlocking control system.

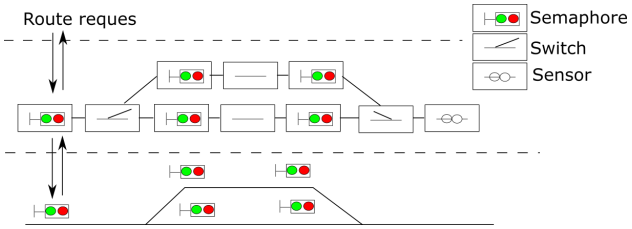

Fig. 2: Illustration of the layered interlocking architecture

The main advantage of LARIS over a functional specification method, is the possibility to reuse the previously defined components. The central part of this approach is the behavior specification of the components, which consists of handling incoming telegrams. When all types of components have been specified in full detail, the specification of a particular railway yard is constructed by simply connecting its separate building blocks in the appropriate manner (like in Figure 2).

Like in EURIS, LARIS uses LSC (Logic and Sequence Chart) for component specification. A typical LARIS LSC is given in [Listing 1.].

Listing 1 : LARIS LSC Example

```
1  LSC name(Ea,Eb:Component;Pa,Pb:Port;ID:Int) =
2    vars  V1,B2,V3:Bool;
3
4    initial skip
5
6    mes Pa?A06(RL:Int) =
7      RL:=RL+TSL;
8      if  TSU
9        then PER:=false;
10       else TRL:=true;
11     Eb |> Pb!A06(RL);
```

Explaining Listing 1, the LSC keyword is followed by a unique name and a list of initialization parameters. These parameters are given by the rail yard developer, who uses the static specification language of LARIS to specify these parameters at the LSC instantiation.

The message listening statement [Listing 1 Line 6] starts with the ”mes” keyword followed by a port identifier (in our case Pa) separated by a question mark from the telegram identifier(in our case A06) and a list of variables. From a semantic point of view, this can be interpreted as follows: if we receive a telegram A06 from the interface Pa and A06 contains the following variables, then the telegram must be processed with the following lines of code (see example [Listing 1 Lines 6:11]). The second statement is the message transmission [Listing 1 Line 11]. In this line of code the message A06 is sent out on the interface Pb to the component Eb, and subsequently the component Eb must have a definition to handle the message properly. A more detailed explanation can be found in [3]. The first advantage of LARIS over EURIS is that is well specified [3]. Another advantage is that of being a typed language: every variable used in LARIS has a certain type, so all the methods and operations must fulfill this type discipline.

C. Session types

In spite of its many benefits, as mentioned above, LARIS also has its disadvantages. Though it is true that the components can be reused anytime, there are times when these systems can have some serious safety or liveness issues. The source of these issues have been identified as lack of global specifications. To avoid this problem we suggest ”Scribble” a global protocol specification language. Scribble has a theoretical foundation, based on the π -calculus and Session Types, to ensure that protocols described using the language are sound, and do not suffer from deadlocks or livelocks.

Session types are a type formalism used to model structured communication-based programming for distributed systems [14]. In particular, binary session types, describe the communication between exactly two participants in such scenarios [15]. Duality is a fundamental notion of session types, as it describes compatible behaviors between communicating parties. When session types are added to a standard communication channel, it must statically enforce that client-server communication proceeds according to a previously defined choreography. The

object and benefits of this encoding are mainly in expressiveness and re-usability in larger system settings.

III. Verification principles

The central idea of session types is to parameterize a channel with some type that represents a protocol, which the type system then enforces [16]. In LARIS, there is no mechanism to encode a protocol. We may enforce a protocol using some special interface constraints, named local protocol type constraints. For the generation of local protocol type constraints, we decided to use the Scribble multiparty protocol specification language. Scribble is a platform-independent description language for the specification of asynchronous, multiparty message passing protocols [17], [18], [19]. Scribble may be used to specify protocols from both the global (neutral) and the local perspective of a particular participant (abstract as a role); at heart, the Scribble language is an engineering incarnation of the notation for global and local types in formal MPST (multiparty session types) systems and their correctness conditions [27]. The Scribble Conversation API provides the local communication operations the possibility to implement the endpoint programs for each role natively in various mainstream languages. The current version of Scribble supports Java [7] and Python [20] Conversation APIs [27].

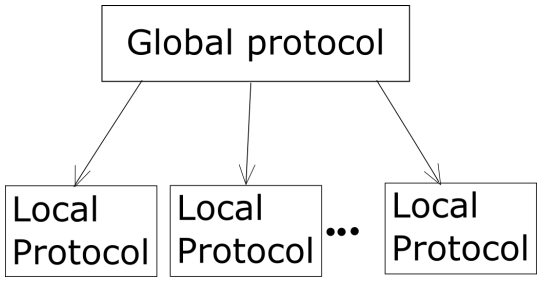

Fig. 3: Local protocol projection

Our development work-flow starts from the explicit specification of the global protocols in Scribble, similarly to existing informal approaches, such as sequence diagrams and communication diagrams. We modified Scribble in a way that it enables the specification of telegrams.

Intuitively, a choreography is well-typed, provided that shared channels are used and processes play roles according to the local protocols [Table II], and session channels are used according to global session protocols [Table I].

global G ::=	$A->B:\langle U\rangle;G$	(communication)
	$A->B:\{l_i:G_i\}_{i\in I}$	(branching)
	end	end
	t	(call)
U::=	S — G@A	
S::=	bool — int — string — ..	

TABLE I: Local protocol specification

Therefore, after the specification of the global protocols, the next step in the Scribble framework (Figure 3) is the projection of local protocols, for each role, from the global protocols. Having this specification, we must enforce it as a type discipline in LARIS, in order to be able to verify the specification correctness.

Local T ::=	$K!\langle U\rangle;T$	send
	$K?\langle U\rangle;T$	receive
	$K\oplus\{l_i:T_i\}_{i\in I}$	selection
	$K\&\{l_i:T_i\}_{i\in I}$	branching
	$\mu t.T\|t\|end$	end

TABLE II: Local protocol specification

To enforce this discipline, we introduce a new interface type constraint, named session type interface, which enables the identification of the roles in order to be able to verify the type discipline correctness.

One of the most challenging parts of this work, was to find an appropriate verification method to check the local protocol specification. We intend to verify only the safety aspects of this specification. In order to enable the safety verification of these aspects in LARIS, some well known formalisms (like: model checking, deductive verification (Hoare Logic, Separation Logic, etc.) etc.) must be adopted or a new formalism must be invented. We were inspired by the work of T.F.Melham [21], Aaron Turon and Mitchell Wand [22] and Peter OHearn and Tony Hoare [23] to transform π -calculus in a specification language with pre- and post-conditions. Intuitively, this transformation must be a one-to-one projection mechanism from the local protocol specification (from the Table [II]) into a specification method in LARIS, otherwise the correctness of the verification can not be assumed. We have identified some translation principles, which enable the total translation of the protocol specification into static verification rules, consisting of existential verification rules plus static specifications in form of Hoare logic pre- and post-condition. A Hoare Triple is of the form $\{P\}\ S\ \{Q\}$, where P is the precondition, Q is the post-condition, and S is the statement(s) that implement the function. These pre- and post-conditions could be verified subsequently to prove the type discipline correctness.

In the next section, we present the transformation.

π -calculus	Static specifications
$K!\langle U\rangle;T$	$\dfrac{x\in\mathbb{N}}{\{K!\langle U\rangle(x)\wedge Q\}K!\langle U\rangle\{K!\langle U\rangle(x+1)\wedge Q\}}$
$K?\langle U\rangle;T$	$\exists mesK?U();mesK?U()\equiv K?\langle U\rangle$
$K\oplus\{l_i:T_i\}_{i\in I}$	$\forall l_i:T_i;mesK?l_i()\equiv K?\langle l_i\rangle$
$K\&\{l_i:T_i\}_{i\in I}$	$\dfrac{\{l_i:T_i\}_{i\in I};\{x_i\in\mathbb{N}\}_{i\in I}}{\{K!\langle l_i\rangle(x_i)\wedge Q\}K!\langle l_i\rangle\{K!\langle l_i\rangle(x_i+1)\wedge Q\}}$

TABLE III: Local protocol translation rules

The specification of the ”receive” statement from [Table II]($K?\langle U\rangle;T$) is translated into this ”*mes* K?U() =” LARIS specification [Table III. In order to enable the static verification of this property, it is necessary to replace K with the

corresponding network interface from the protocol interface specification.

The ”branching” specification from the [Table II] can be reduced to a set of ”receive” specifications [Table III], because of the LARIS asynchronous message listening mechanism. Therefore, the verification consists of an iterative check of these listening statements. The ”end” keyword from the Table II plays no role in our definition because the persistent nature of the channel.

The remaining specifications translation from Table III needs a more sophisticated approach. Because of the asynchronous handling of the messages in LARIS, we can split a local specification into a list of ”receive” operations Table II followed by a list of operations of type ”send” Table II and ”selection” Table II. Our first goal is to avoid the unintended message transmission, the second, to ensure that the intended message transmissions are triggered once and only once, and third to ensure the message transmission order. The message transmission operations can be modeled with integer variables according to [21], therefore this specification can be partially translated into pairs of preconditions and post-conditions on these integer variables.

Let us consider the model of a message transmission an integer variable incrementation. Having this model, we can substitute the transmission operations with the corresponding models. An undefined message transmission on this interface is considered an error. The pre- and post-conditions of the message handler consists of assuming that the initial value of the model is zero and ensuring that the final state of the value is one. The order of the messages is ensured by the following assertion: Considering two messages m_i and m_j, and considering the model of m_i and m_j, $mod(m_i)$ and $mod(m_j)$ then:

$(K!\langle m_i\rangle;T).....(K!\langle m_j\rangle;T) \Longrightarrow m_i \geq m_j$

For the verification of the ”branching” statement from Table II we assume that all the variables, which model a message transmission, are zero. We must ensure the sum of these models will always be one. Although, in case of a protocol invocation, the problem seems to become more complicated, but actually it is simple and can be solved by replacing the sub-protocol body in the protocol.

IV. An Example

In this section we study the applicability of session types in industrial environments such as the Geographical Railway Interlocking Systems development. From the fundamental point of view, we demonstrate the correctness of our work using subsection III. We also illustrate the use of session types with an application, a subproblem from a route allocation problem.

According to Banci [2], [24] if a typical railway interlocking system receives a route request, the answer to this request has to go through a series of checks:

1) a route can not be locked if a track section element is occupied;
2) a route is available if no part of the route is already locked;
3) if the route is available it will be locked;
4) locking a route implies that all its track elements become locked;

Verification requirements from the previous mentioned steps, can be triggered also by the logical layer to verify the state of route elements, in order to prevent the triggering of an impossible route allocation. To prove our verification theory, we have chosen the implementation of the second item from the previous list. The verification process starts by sending a route verification request from the logistic layer to the interlocking layer. This request must be sent to one of the route end elements which must be a light signal. Depending on the light signal internal state, two scenarios are possible: In the first scenario the signal will answer with a fail message to the logical layer. In the second scenario the request must be delegated toward to the next route element in order to verify its state. This element must be the left or the right neighbor of the light signal.

```
1  module ro.ubbcluj.irg.RouteVerification;
2
3  type <telegram> "Telegrams.xts" from
4    "A06" as Route;
5  type <telegram> "Telegrams.xts" from
6    "A11" as Ok;
7  type <telegram> "Telegrams.xts" from
8    "A16" as SegmentError;
9
10 global protocol RouteVerification
11 (role LogisticLayer,role Semaphore,
12   role LeftElement,role RightElement ) {
13
14   verify(Route)
15     from LogisticLayer to Semaphore;
16
17   choice at Semaphore {
18     do RouteElementVerification(
19       Semaphore as SourceElement,
20       LeftElement as DestinationElement);
21   } or {
22     do RouteElementVerification(
23       Semaphore as SourceElement,
24       RightElement as DestinationElement);
25   } or {}
26
27   choice at Semaphore {
28     free(Ok) from Semaphore to LogisticLayer;
29   } or {
30     allocated(SegmentError)
31       from Semaphore to LogisticLayer;
32   }
33 }
```

Listing 2 : Scribble: Global route verification protocol

We consider the previous specification as a requirement. Before starting the development of a railway interlocking software requirement, it is recommended to clearly identify the involved railway elements, the role what each element plays and to specify a consistent communication protocol. These are done by specifying the choreography of communication between the railway track elements in order to have a proper communication mechanism to address the involved track elements without communication deadlock or live-lock. In our case these specifications are done in Scribble protocol

specification language Listing 2, 3.

As can be seen in Listing 2 the specification starts with the module specification. In the next step the necessary telegrams are imported (the telegrams are globally specified package types used by LARIS to transmit data). The roles are enumerated in the global protocol header. The "LeftElement" role means the element located before the semaphore in a railway yard, and the "RightElement" the element located after the semaphore in a railway yard.

The global protocol specification starts with a request transmission from the logistic layer to a semaphore. In order to answer the request, the semaphore must decide if the elements are allocated or not. Therefore the semaphore checks its internal state, and according to them it sends an answer to the logistic layer, or sends another request to its left or right neighbor according to the received route, as parameter from the logical layer, to check the neighbor's state. The neighbor must behave in the same way as the semaphore did, it must check its internal state and according to them must answer with an allocated message to the semaphore or must transmit the message forward until the package reaches the end node. Depending on its internal state, the end node must **send** an allocated or a **free** message. The messages must be propagated back to the semaphore, in order to enable the semaphore to answer the logistic layer with an appropriate response.

```
1  module ro.ubbcluj.irg.RouteElementVerification;
2
3  type <telegram> "Telegrams.xts" from
4    "A23" as Route;
5  type <telegram> "Telegrams.xts" from
6    "A24" as Free;

13   verify(Route)
14     from SourceElement to DestinationElement;
15
16   choice at DestinationElement{
17     free(Free)
18     from DestinationElement to SourceElement;
19   } or {
20     allocated(Error)
21     from DestinationElement to SourceElement;
22   }
23 }
```

Listing 3 : Scribble: Global element verification protocol

Having the protocol specification from Listing 2 and 3, we can start the semaphore implementation. Our extension of Laris enables the verification of the local protocol of the components. We followed the same principle as in [25],[26], and we have connected the protocol specification with LARIS with a new type of interface. The syntax of the specification can be found in Listing 5.

Hereafter, a short presentation of the syntax will be given. The syntax of the interface consists of a new expression "implement role" followed by a list of interfaces. Each interface definition has the following form: the global protocol name followed by a role identifier, which enables the identification of the local protocol [Listing 5 Lines 3:9], followed by a list of role associations, where each role is associated with the corresponding interface and component.

```
1  module ro.ubbcluj.irg
2    .RouteVerification_Semaphore_Ext;
3  type <telegram> "Telegrams.xts" from
4    "A06" as Route;
5  type <telegram> "Telegrams.xts" from
6    "A11" as Ok;
7  type <telegram> "Telegrams.xts" from
8    "A16" as SegmentError;
9  type <telegram> "Telegrams.xts" from
10   "A23" as REV_Route;
11 type <telegram> "Telegrams.xts" from
12   "A24" as REV_Free;
13 type <telegram> "Telegrams.xts" from
14   "A25" as REV_Error;
15
16 local protocol RouteVerification
17 (role LogisticLayer,
18   role LeftElement,role RightElement ) {
19
20   verify(Route) to Semaphore;
21
22   choice at Semaphore {
23     REV_verify(REV_Route) to LeftElement;
24
25     choice at LeftElement{
26       REV_free(REV_Free) from LeftElement;
27     } or {
28       REV_allocated(REV_Error) from LeftElement;
29     }
30
31   } or {
32     REV_verify(REV_Route)to RightElement;
33
34     choice at RightElement{
35       REV_free(REV_Free) from RightElement;
36     } or {
37       REV_allocated(REV_Error) from RightElement;
38     }
39   } or {}
40
41   choice at Semaphore {
42     free(Ok) to LogisticLayer;
43   } or {
44     allocated(SegmentError)
45       to LogisticLayer;
46   }
47 }
```

Listing 4 : Scribble: Local route verification protocol

The rest of the code remains unchanged. We removed some aspects (like the enumeration definitions or the "DestinationElement" role definition and implementation) from the code Listing 5, to make it compact and understandable.

In the remaining part of this section the verification process will be illustrated.

Having the local protocol discipline on our source code Listing 5, we must check if the discipline is respected or not.

The "receive" and "selection" properties from Table II are easy to check. This can be done simply by iterating over the AST (abstract syntax tree) of the LARIS language.

```
LSC Semaphore(EA,EB:Component;
        Pa,Pb:Port;TSL:Int)
implement role RouteVerifcation.Semaphore(
 LogisticLayer=[Log,log],leftElement=[EA,Pa],
 rightElement=[EB,Pb]),
RouteElementVerification.SourceElement(
  DestinationElement=[EA,Pa]),
RouteElementVerification.SourceElement(
  DestinationElement=[Eb,Pb]) =

  initial skip;

  mes log? A06 (RL:Bool[16]) =
    if STATE == ALLOCATED
      then Log |> log ! A16(self,ALLOCATED)
      else
        if RL[0]== true
          then EA |> Pa! A22(RL:Bool[16],1)
          else EB |> Pb! A22(RL:Bool[16],1);

  mes Pa? A24 (RL:Bool[16],size:Int,pos:Int) =
   Log |> Log ! A11();

  mes Pa? A25 (item:Id,state:State,RL:Bool[16],
    size:int,pos:int) =

    Log |> Log ! A16(item,state);

  mes Pb? A24 (RL:Bool[16],size:Int,pos:Int) =
    Log |> log ! A11();

  mes Pb? A25 (item:Id,state:State,RL:Bool[16],
    size:Int,pos:Int) =

    Log |> log ! A16(item,state);
```

Listing 5 : LARIS semaphore partial implementation

```
assume (var1 == 0 && var2 == 0
    && var3 == 0 && var4 ==0)
ensure (var1 + var2 + var3 + var3 == 1)
if STATE == ALLOCATED
      then
        var1++;
      else
        if RL[0]== true
          then var2++
          else var3++;
```

Listing 6 : LARIS send out verification model

To prove the ”send” and ”branching” property, we will apply the modeling and verification principle from the previous section. We have chosen to demonstrate the local protocol correctness from Listing 4. According to this specification, the message handler ”mes log? A06 (RL:Bool[16]) =” from Listing 5 must emit one of the following telegrams: A11 on the ”log” interface, A16 on the ”log” interface, A22 on the ”Pa” interface or A22 on the ”Pb” interface. These messages must be sent out once and only once. Following the modeling and verification rules from the previous chapter we replace ”Log | > log! A11” with ”var1++”,”Log | > log! A16” with ”var2++”, ”EA | > Pa! A22” with ”var3++” and ”EB | > Pb! A22” with ”var4++”. According to our specification we assume that each variable is zero and we ensure that the sum of these values will be one. The last step is straightforward, because there are a lot of static program verifiers [8], [9], [10], [11], [12], [13], which are able to prove the correctness of such a code with regards to the formal specification. This proves the soundness of our theory and its applicability in the practice.

V. Conclusion

In this paper we demonstrated that session types can be combined and used with a domain specific programming language like LARIS. Our work was inspired by the ”Scribble protocol language” combined with Java and Python [27],[28],[17], and also by T. F. Melham [21], Aaron Turon and Mitchell Wand [22] and Tony Hoare and Peter O’Hearn [23] works to translate the π -calculus into Hoare logic or Separation Logic specifications. Promising results have been reported in adopting session types in other programming languages, like Haskell [25],C# [29] and recently the Chorlang [30], but their approach is based on embedding session types into the programming language. We observed that combining ”Scribble” with LARIS can provide a lot of benefits in the verification and validation of a geographically distributed interlocking system. A major benefit of this combination is the local verification of global protocols. We modeled the message sending with an integer in order to enable the verification of the local protocol in LARIS. We encoded the local protocol specification into static verification rules, in addition with specifications in form of pre- and post-conditions to enable the verification of the generated model in order to ensure the safety properties correctness of this typing discipline. We validated our method on a railway interlocking problem implementation in Scribble and LARIS.

We consider that extending the protocol language ”Scribble” with a specification language like in [28] and [5] can open currently unexpected opportunities in the local verification of global properties. We expect that this specification and verification approach allows the framing of newly emerging issues in the world of communication centered programming and micro services, into the mainstream domains of type theories and systems.

Monitoring Cerebral Processing of Gustatory Stimulation and Perception Using Emotiv Epoc

Guruprasad Madhale Jadav, Miroslav Vrankić and Saša Vlahinić
Tehnički Fakultet Sveučilište u Rijeci, Rijeka, Croatia
jguruprasad@uniri.hr

Abstract - The affective and cognitive states of the user can be effectively monitored by electroencephalography (EEG). The human taste stimulation and perception produces changes in the EEG signals of the brain at several subdivisions of insula, orbitofrontal cortex and anterior cingulate cortex. In this work we propose a method which can be used to monitor these signals elicited by taste stimulation and perception using a simple gaming EEG device. Emotion elicited by taste recall is stronger than stimulus elicited emotion will be re-established but with a gaming EEG device. The results are presented for a number of subjects and obtained using the research edition of the gaming EEG headset.

I. INTRODUCTION

Neuro mechanism for taste preferences plays a very vital role in our lives. The gustatory stimulation and perception has not been the field in which extensive research has taken place, and the early results are disputed [1].

The acidic and alkaline forming effects of food and liquids that we ingest in our body can disrupt the pH level of some fluids in our body, and our oral fluid is one of them [2]. Our oral hygiene largely depends on the pH of the oral fluid, which directly gets affected by the food or liquids we chew or drink, also the effect of change in pH is clearly sensed by the gustatory organ which in turn causes change in EEG signals, these signals can be recorded at different frontal and temporal locations at several subdivisions of insula, orbitofrontal cortex and anterior cingulate cortex [1].

The research edition of the Emotiv's gaming EEG headset also called as Epoc headset is a consumer brain-computer interface device, which communicates with the computing environment wirelessly. This headset observes temporal pattern of the EEG signals produced by the human brain. A simple to setup device like this can be used to assign control tasks to a particular taste perception by monitoring the changes in Event Related Potentials (ERP). The Emotiv's Epoc headset does not need an experimental laboratory setup where pre and post experimental difficulties like electrode placement and rinsing of subjects hair to remove electrode gel becomes mandatory. It needs minimal adjustment of electrodes and uses cotton felt pads which are to be pre soaked in saline solution to make good contact with the scalp (Bobrov et al., 2011; Stytsenko et al., 2011). The EEG activity for the affective and cognitive states of the user elicited by taste stimulation and perception respectively can be observed at the electrode locations AF3, AF4, F3, F4, F7, F8, FC5, FC6, T7 and T8 according to 10-20 system of electrode placement [3].

The stimulus related EEG can be monitored without the need of active attention of the subject where as taste perception needs active cognitive attention of the subject. In this work we show that taste stimulus elicited EEG signals can be observed at the channel locations AF3, AF4, F3, F4, F7, F8, FC5, FC6, T7 and T8 for Emotiv's Epoc headset, by using time-frequency representation for stimuli of different pH values. We try to determine if emotion elicited by taste recall is stronger than stimulus elicited emotion. We also tried to evaluate if there is a clear difference in the frequency pattern for stimuli of different pH levels. Frequency pattern of taste recall of the stimuli will be re-evaluated to see if it is stronger than the actual stimuli [4]. We will also observe the taste perception of acidic and alkaline pH stimuli's in comparison with each other, to see if there is a difference in frequency pattern and if it is distinguishable.

II. MATERIALS AND EXPERIMENTS

A. Participants

5 right handed subjects between age 20 and 30 participated in the experiment. All the participants who were chosen did not have any past neurological and psychiatric disease. They were instructed not to eat or drink anything except water 3 hours prior to the experiment. The Inter Stimulus Interval (ISI) was a brief (1 hour), and the subject rinsed his/her mouth with water after every stimulus presentation. The cognitive secession was conducted separately after a 24 hour time interval.

B. Device specifications

The EEG headset consists of 14 gold plated contact sensors, which make contact with the detachable electrode tips. These electrode tips have foam which is soaked in saline solution and sits on the scalp adapting to the scalp topology such as shape of the scalp and hairs because of its cushioning effect, the saline solution acts as a good conductive medium for small voltage fluctuations giving an efficient contact area. These electrodes are aligned in

TABLE I. GUSTORY STIMULI USED FOR AFFECTIVE EXPERIMENT

Serial no.	***Stimuli***	***State***	***pH***
1	Citric acid	liquid	2
2	Sodium bicarbonate	liquid	9

10-20 electrode placement technique pre attached to the headset with arms fixed to point the electrode at the locations: AF3, F3, F7, FC5, T7, P7, O1, O2, P8, T8, FC6, F8, F4, AF4, Common Mode Sense (CMS) at the left mastoid M1 and Driven Right Leg (DRL) at right mastoid M2. The electrodes when green which were in our case represent good signal quality as in Fig. 1. The hardware high pass filter and digital signal processing hardware performs various filtering and processing steps before the EEG signals are wirelessly transmitted to a USB dongle which can be connected to a computer to view and save the EEG data.

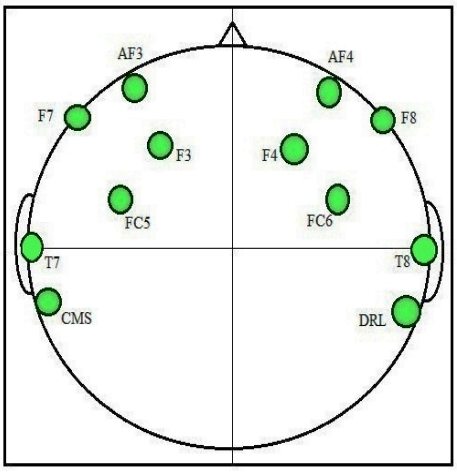

Figure 1. Scalp locations of the electrodes placed using Emotiv's gaming EEG headset

C. *Gustatory stimuli*

The taste stimuli used were 5% of citric acid extracted from lemon with pH 2; Sodium bicarbonate solution was made by dissolving baking soda in water, giving a solution of pH 9. Care was taken that harmless concentrations of standard consumables were used as the stimuli and quantity was maintained 10 ml.

D. *Experimental procedure*

The subjects were given detailed instruction about the experimental procedure and instructed to stay relaxed and with minimum physical movement throughout the experiment. The subject's hair was brushed properly to avoid external electrical interference. The wireless EEG headset from the Emotiv has been worn by the subject with electrodes placed according to 10-20 electrode placement system. The subject took 10 ml of the stimuli solution and the markers were given manually during the time when the stimuli were in subject's mouth.

After a brief interval of 24 hours the subject is instructed to observe the stimuli and remember the taste of the stimuli and markers were given manually.

E. *Data acquisition and analysis*

The EEG headset has M1 at the right mastoid which acts as ground reference point to which voltage of all other sensors is compared, and M2 at left mastoid reduces external electrical interference due to the DRL circuit design [5]. Signals from other electrodes were high pass filtered at 0.16 Hz cut-off, pre- amplified and low pass filtered at an 83 Hz cut-off. The analogue signals were digitized at 2048 Hz which is the fundamental sampling frequency of the device. The digitized signal is filtered and down sampled using a 5th order sinc notch filter (50-60 Hz) and low pass filtered. Finally the sampling frequency is close to 128 Hz, giving the effective bandwidth of 0.16-43 Hz. The above steps were pre-processing steps.

In order for the data to be suitable to our requirements we low pass filtered the data using a 30 Hz higher cut-off frequency and used a high pass filter of 5 Hz lower cut-off frequency. In the range of 3-4 Hz lie most of the eye blink artifacts which were eliminated during the high pass filtering. The signals were then epoched between -4 to 4 seconds at the marker and baseline corrected.

Data from all 10 channels have been processed with Complex Morlet wavelet transform where wavelet $\psi(t)$ is represented as in (1). It considers that high frequency data varies more rapidly in time domain. Hence we are able to differentiate between the high frequency bursts, which occur during the stimuli and other frequency variations [6].

$$\psi(t) = \frac{1}{\sqrt{2\pi\sigma^2}} e^{-i2\pi t} e^{-\frac{t^2}{2\sigma^2}} \qquad (1)$$

Where the width of the wavelet is $m = 2\pi\sigma$, σ being the parameter defining the number of oscillations.

Inter trail Phase Coherence (ITPC) measures the phase consistency over the epochs for the event [6]. Let $X(c, f, t, n)$ denote the time-frequency coefficient at channel c, frequency f, time t and epoch n of the EEG

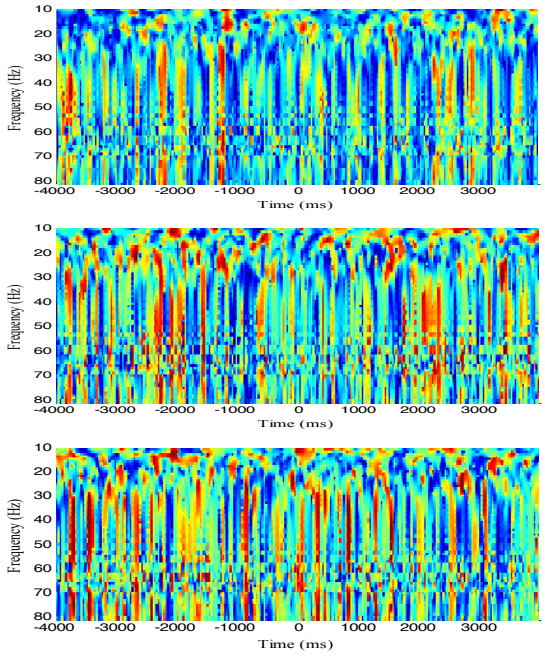

Figure 2. Time frequency representation for different stimuli (a) Normal state (b) Citric acid stimuli (c) Cognitive perception of the taste of Citric acid.

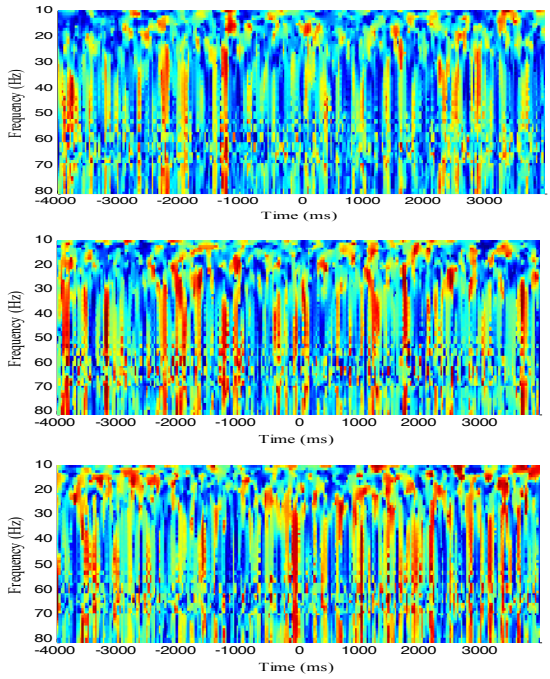

Figure 3. Time frequency representation for different stimuli (a) Normal state (b) Sodium bicarbonate stimuli (c) Cognitive perception of the taste of Sodium bicarbonate

signal represented in:

$$ITPC(c,f,t) = \frac{1}{N}\sum_{n}^{N}\frac{X(c,f,t,n)}{|X(c,f,t,n)|}. \qquad (2)$$

As all the epochs are given same weight for a particular stimulus, the measure of the phase consistency for different stimuli can be represented in time frequency spectrum individually, thereby allowing us to be able to compare them.

F. Classification results

The acidic and alkaline stimuli have shown a considerably greater amount of high frequency components in the time frequency spectrum than for the normal temporal activity. In Fig. 2 and Fig. 3 we show that acidic and alkaline solutions in time frequency domain changes throughout different states of the subject for one channel electrode. A very similar pattern of cognitive perception in comparison to actual stimuli or cognitive perception being more dominant than stimuli is visible. Also both have relatively higher frequency components than the normal temporal state. This is clearly visible at other channel locations considered for monitoring taste related EEG activity.

We can also observe that cognitive perception of acidic stimuli produces higher frequency components than cognitive perception of alkaline stimuli, which has not been discovered before as far as we know.

III. CONCLUSION

We have investigated EEG response to stimuli of acidic and alkaline pH levels, and were able to show with the time frequency spectrum that the taste perception of the stimuli produces more high frequency components than the actual stimuli. The cognitive perception of acidic stimuli produces relatively more high frequency components than cognitive perception of alkaline stimuli. By being able to conclude that Emotiv's Epoc headset can observe research quality EEG signals for taste related EEG patters, we show that taste stimulation and perception can be used as cognitive control tasks and be observed using a simple gaming headset. Our future work will aim towards implementing these cognitive perceptions into control tasks.

People tracking using synthetically generated depth maps

L. Vretenar i K. Lenac
Faculty of Engineering – University of Rijeka, Rijeka, Croatia
lvretenar@riteh.hr, klenac@riteh.hr

Abstract - Modern 3D sensors using time-of-flight and structured light technology are increasingly being used in a number of interesting applications. One such application is people tracking where the available 3D information enables more robust human detection and tracking methods than those based on classic video cameras. A large data set is typically required both for testing and tuning of the solution.

We describe a methodology for efficient development of 3D applications using synthetically generated depth maps to complement the available data set obtained with real cameras. To demonstrate the effectiveness of the approach, a case study in the area of people counting with 3D sensors is presented.

I. INTRODUCTION

People detection and tracking is an important field of research. There are many applications in robotics, human computer interaction, video surveillance, home automation, pedestrian detection and counting in intelligent transport systems, just to name a few. Recent years have seen the advent and widespread diffusion of commercially available 3D cameras that greatly increased the interest of computer vision research in 3D vision.

In this paper we address the problem of robust people detection and tracking using depth map images from commercially available consumer grade 3D sensors. If depth data is available the task of detecting and tracking an object becomes much easier. In particular separation of background and foreground with objects that lack consistency in color and texture is not difficult any more. The same is true for the perception of the shape of an object. Another advantage over RGB images is that depth images are less sensitive to changes in color and illumination.

One of the key challenges of developing a people tracking algorithm is the availability of the dataset on which to base the development, testing and comparison with other approaches. This dataset must be most representative of the situations that may occur during real usage in target application. Ideally the developed algorithm is expected to properly handle nearly all possible situations, i.e. to detect and track people no matter the clothing, size, haircut, gender, walking style, followed paths and gestures performed. Moreover the environment may vary and the scene may include non-human things, like pets, suitcases and other objects. The problem is that with real recordings it is difficult to obtain such a dataset, and only a very small subset of possible situations is typically available instead. In this paper we address this and other major challenges with real data recordings for 3D people tracking applications by using synthetically generated depth maps.

The remainder of the paper is organized as follows: In Section 2, we briefly describe currently available depth sensors and the underlying technologies and then review recent works on people detection and tracking using depth maps. Section 3 proposes the usage of synthetically generated videos to address important challenges during development of people tracking solutions. In Section 4 the specific method for generating synthetic depth videos is described in detail. In Section 5 a people counting solution developed using the proposed methodology is described as case study. Conclusions are drawn in Section 6.

II. RELATED WORK

Traditionally, 2D computer-vision camera systems have been used to detect people, track them, count their passages through designated areas, estimate their pose and detect unusual or important events. Many different RGB image based methods have been developed typically using blob based tracking with or without additional classification schemes based on color, texture or other local image properties, and using 2D or full 3D models of human beings.

Early 3D range systems were costly and slow. They consisted either of systems which used a laser to scan the environment or systems based on stereo vision. A detailed review of stereo vision algorithms may be found in [1]. For real-time application in embedded systems consider reading [2] and for a recent overview of passive 3D imaging systems refer to [3]. However recently new types of 3D sensors became available using structured light and time-of-flight technologies (see Table I) and a number of new algorithms started exploiting the available depth information, either using only depth information or combining it with color information available from an RGB camera which is typically mounted alongside depth camera. In Table I we present a comparison and an overview of currently available 3D sensors and technologies and highlight important differences between them helping to select the best sensor for the problem.

In every people tracking solution it is important to be able to recognize and distinguish humans from non human objects in the scene. For this classification task many approaches use machine learning techniques applied on

The work presented in this paper is supported by the University of Rijeka research grant Grant 13.09.2.2.16.

processed depth maps or on derived point clouds. They rely on the ground plane assumption which assumes that people stand or walk on the ground. So first the ground plane is estimated and then classification is performed only inside of a small number of regions of interest which are likely to contain people. With a reduced search space a more robust classification can be performed without too much computation burden. The PCL library project [4] among numerous algorithms for processing point clouds contains a module providing a method for detecting upright people in RGB-D point clouds. Recently a project called OpenPTrack [5] was started extending the existing algorithms for real-time people detection and tracking from 3D data to a multi-camera scenario. Built on top of PCL and ROS [6] the software currently works with Microsoft Kinect v1 and Mesa Imaging Swissranger SR4500.

III. APPROACH

A. *Challenges with real data*

Developing a new solution to people detection and tracking using only live and/or recorded data with real people is challenging. The major difficulties that must be overcome are:

- lack of ground truth

Testing of the algorithms with real recordings is difficult because of the lack of an available ground truth. Recordings must be carefully inspected and labeled using another method (typically human visual inspection) to allow quantitative analysis and comparison with other algorithms. In particular machine learning techniques assume the training examples to be labeled. Preparing the data in itself is a very time consuming process. Moreover once the dataset is built the learner is typically run multiple times in an iterative process of training the algorithm, analyzing the results, modifying the data or the learner, and repeating the process.

- only a small sample of possible situations can be recorded

When preparing the recording setup one has to make decisions on camera type, position, field of view etc. After a recording setup is prepared for a specific problem, only a finite and relatively small number of recordings may be recorded. Recording is a time consuming process in itself and the process cannot last indefinitely. With respect to the above, the space of all possible situations that is of interest for the application is huge.

- non repeatability

With real people it is difficult to exactly repeat the recorded scene and behavior. For example it may be necessary or convenient to produce identical recordings but with different cameras, in different lighting conditions or in a different moment.

- hard to automate

Even with the availability of human actors that perform according to a predefined script it is difficult to generate the desired situation as often as required..

B. *Using synthetically generated data*

If we were able to synthetically generate the missing data in a programmatic way the above listed problems would be solved.

The usage of synthetic data is not a new idea. In machine vision, and people detection and tracking in particular, synthetic images have often been used to enlarge the training data on which classification algorithms are based. In this way it is possible to create arbitrarily large training datasets. For example pose recognition tasks alone require large datasets just to account for all possible human sizes, poses and shapes. A procedure which enables synthetic creation of camera images of humans in arbitrary poses may produce such a dataset. The most impressive usage of synthetically generated 3D depth images was in [7] where a large amount of synthetically generated images to train algorithms for super real-time 3D body pose estimation.

In our approach we further extend this idea by using synthetically generated data not just to train a classification algorithm, but also as a useful aid in several key stages of algorithm development. In fact synthetically generated data may also provide other important benefits to the researcher.

TABLE I. 3D SENSOR TECHNOLOGIES

Principle of operation	ACTIVE Projects electromagnetic (IR) radiation and analyzes the reflection of this radiation from the object.						PASSIVE Relies solely on ambient light; combines two 2D image sensors and uses the disparity in viewpoints to derive depth information.	
Important factors influencing the sensor choice	Distance range depends on illumination power. Very poor outdoor performance. Cannot simultaneously overlap the sensing area of two sensors of the same type.						Problems with smooth uniform surfaces. Poor performance in low light scenarios.	
Technology	Structured light		Time-of-Flight				Stereoscopic vision	
Typically used sensors								
	Microsoft Kinect v1	Primesense Carmine	Microsoft Kinect v2	Mesa SR4000	Creative Senz3D	Softkinetic DS311	Point Grey Bumblebee	custom designs

Gaining key insights during problem analysis: a researcher could identify and analyze problematic or otherwise interesting situations. Situations that would be difficult to produce with real people can easily be simulated.

Fine tuning of the algorithm: by systematically running simulations it becomes easy to fine tune various thresholds and algorithm parameters.

Testing the algorithm performance: the algorithm can be thoroughly tested across a multitude of situations. Tests can be automated. New datasets can be pro grammatically generated to test untested scenarios.

Comparing with other algorithms: With synthetically generated images, ground-truth camera positions and orientations at each frame in a video sequence are available. This allows explicit measurement of algorithm accuracy and comparison using the same data.

It is important for synthetically generated data to be realistic, i.e. the differences with real data should not interfere too much with the algorithm. This is indeed the case in people detection and tracking, which is an area of research where synthetic data is particularly beneficial. In fact many machine vision algorithms pre-process the data, filter the noise and apply some kind of foreground/background separation prior to detection stage. It is in these steps that differences between real and synthetic video are filtered away and the result is a video which is practically indistinguishable from video recorded with a 3D sensor with real people.

This is also true in our solution described in Section V. A comparison of pre-processing results for real and synthetic data is shown in Figure 1.

The downside of using a synthetically generated data is that it's generation may be a time consuming task.

From our experience building the framework and automating the tasks requires a substantial initial effort, however once all the tools are in place the generation of further datasets, when needed, is straightforward. This allows easy generation of new videos taken from different camera positions, or with changed people characteristics or paths they follow. New persons can be added, new types of sensors substituted in the exact position of current sensors (i.e. from structured light to time-of-flight sensor), additional cameras can be added to existing scene, and so on. The existing dataset can be extended in a later moment. The labeling of the ground truth is performed automatically in all cases.

Such synthetically generated scenes can simulate situations that would be difficult to recreate without simulations. Some examples of hard to recreate situations include environments that we don't have access to and scenes with very tall people that are not easy to find, people wearing strange clothes, hats, various bags, people walking in each other’s arms etc.

In the next section we describe in detail the framework and the tools that we used to generate synthetic datasets of depth recordings.

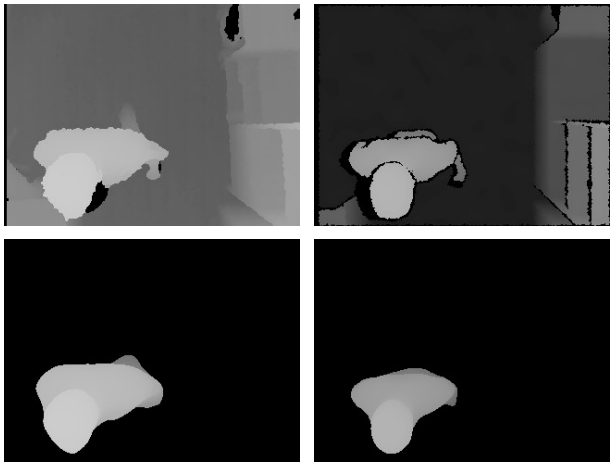

Figure 1. Comparison of real (left) and synthetic (right) depth recording of the same scene, with (bottom) and without pre-processing (top)

IV. Synthetic Depth Map Generation Framework

We evaluated a method for generating synthetic videos that would fit our problem domain easily and provide us with a work flow to simulate specific scenes and situations.

For this purpose we chose existing software solutions in the free/open source world for 3d modeling and sensor simulation.

Our method for generating synthetic depth images and video is as follows: 1. Model the scene we want to simulate; 2. Model the people in the scene; 3. Animate the people in the scene; 4. Position the sensors in the scene; 5. Generate depth images and video by simulating the sensors.

Central part of this work flow is the ability to model and simulate the depth sensors.

Among the listed tools for sensor simulation, one stands out for its focus on realistic sensor simulation and integration with professional modeling and animation tools. That is Blensor [9], an extension of the Blender project code and a plug in for the Blender modeling tool.

Our method centers on using Blensor as a tool to simulate the required 3d sensor images and videos, and as such extensively uses all Blender tools for modeling and animation.

Modeling of the scene, creating animations and positioning the sensors is all done inside Blender. In addition to using Blender, another tool was required to model people. For that we used a tool called MakeHuman [10] that can generate realistic models of humans in a format we can use inside Blender.

Modeling the scene: The scene is modeled inside Blender by using primitives such as planes, cubes and spheres. Those primitives are then deformed and subdivided to fit the shapes we desire. Such a model of a scene does not have to be very detailed. Since we are only interested in simulating the depth cameras we do not need the color information in a scene. That eliminates the need to add textures and color to the scene; in addition, depending on the depth resolution of a simulated sensor the geometry of the model does not need to be complex. Although the color is unnecessary for our simulation, we must still specify the reflectivity of the materials by setting the color intensity as Blensor uses the color intensity of an object to simulate the reflectivity of that object when simulating light rays from the sensor. In our simulations we used the default maximum reflectivity to simplify modeling and approximate the simulation.

Modeling the person: A model of a person is parametrically generated using the tool MakeHuman. The parameters that are of interest are the height and the weight of a person. The generated model is then exported in the native format of the tool and imported in the Blender scene using a Blender plug-in provided by MakeHuman. Such a imported model consists of a mesh and a skeletal rig. The skeletal rig is required for the animation and enables us to easily create our own poses and animations of the persons or map existing motion data to the rig.

Animating the scene: Animation of the scene consists of setting objects in specific poses by creating key-frames. Key-frames define the specific configuration of an object or the scene in a specific point in time. Animation is achieved by interpolation of poses and locations between two adjacent key-frames.

For complex animations, like human motion, existing databases of motion capture data exist. We chose to use CMU Graphics Lab Motion Capture Database obtained from mocap.cs.cmu.edu.

Positioning the sensors: Blensor uses existing camera objects in the scene to simulate the position and direction of the sensors. It is important to select the required sensor type inside Blensor and set the corresponding parameters for field of view, resolution and sensor specific functionality.

Generating depth images and video: For each sensor, Blensor can generate a depth map in Netpbm PGM format and a point cloud in PointCloud Library PCD format. Each scan consists of a ground truth scan, corresponding to the model from the sensors point of view, and a simulated scan containing simulated sensor noise dependent on the type and parameters of the sensor. If there is animation present in the model, such as the walking animation for a person, Blensor can generate a scan from a specified sensor for every frame of the animation.

V. Case Study: People Counting

A. System description

The purpose of the people counter application is detection of people in a scene and counting their direction of passage in the specified zones. The system consists of a depth camera positioned in a scene directly above a path we want to monitor and facing the floor, a networked embedded computer connected to the camera running the people counter algorithm and a networked desktop computer used to receive the counting data.

The depth camera we used was PrimeSense Carmine 1.08, a long range structured light sensor with a operating range of 0.8m – 3.5m, field of view of 57.5 x 45 degrees and resolution of 320 x 240 pixels. Embedded computer that is connected to the camera is an Raspberry PI, model B. The sensor provides depth images at the frame rate of 30 per second with each pixel representing a distance from the detected object in millimeters.

The people counter algorithm works by detecting people's heads and tracking their movement through the scene. This is a simplification possible by the mounting location of the sensor, which is mounted directly above peoples head. The advantage of this method is that an easy detection of a person is possible just by detection of a region that corresponds to the person's head. Visualization of the depth data, pre-processing and blob tracking are shown in Figure 3.

The following algorithm describes how the people counter application works:

```
for each depth frame:
  apply image filtering
  subtract background from the frame
  find blobs by finding all local minima
  match found blobs with previously found
    blobs
  check if a particular blob has crossed
    from one region to another
```

Image filtering: The raw depth frame is filtered with a median filter to eliminate the artifacts from the depth camera and down sampled to a 8 bit gray-scale image. Morphological operators like erode and dilate are applied to join regions with gaps do to occlusion of the sensor projector.

Background subtraction: A frame with an empty scene is selected as the base frame for the background subtraction. Since every pixel in the frame corresponds to the distance of the object to the camera, to subtract the background we only need to delete the pixels that are

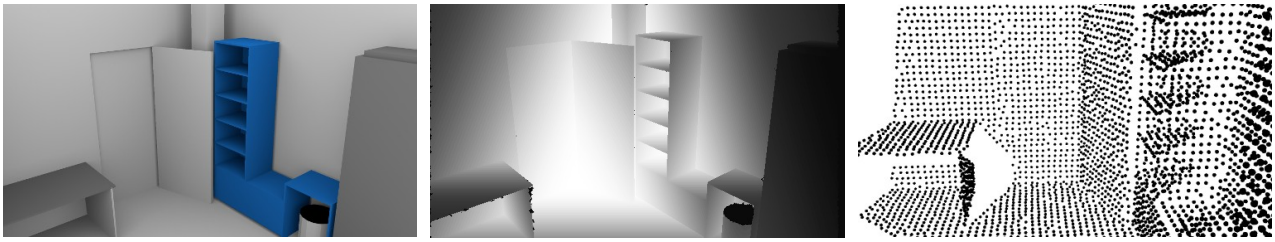

Figure 2. Scene model in Blender (left), depth map render (center), resulting point cloud (right)

close to the chosen background frame. All other pixels are closer to the camera then the background and are selected as detected objects.

Blob detection: Blobs are detected by finding all local minima points in the frame, which in ideal situations correspond with the top of a person's head. From those points a flood fill algorithm is performed to find all areas that correspond to a single persons head. Adjacent areas that did not contain local minima were discarded. All the found head areas are then marked as blobs to be tracked.

Blob tracking: To track the movement of people through time, new blobs corresponding to the heads of people are matched with the blobs found in the previous frame. The matching is done on the basis of two closest blobs within a minimum specified distance. If a new blob does not have a corresponding blob from the past frame, it eventually times out.

Passage counting: The scene is divided into three regions, corresponding to entry, exit and center. A tracked blob has to pass both region borders; the border between entry and middle, and the border between middle and exit; to be counted as an exit. The same logic applies in reverse to count an entry. The regions can be seen in Figure 3. Having the area be divided into three regions was necessary to eliminate possible flickering of a single blob around a single border, e.g. when a person stands in that place for more than a few frames.

B. Algorithm tuning

Parameters and tuning: Every step of the algorithm is parameterized in order to easily tune the algorithm to a specific environment and sensor.

Tuning is performed for following parameters: 1. Frame filter parameters; 2. Background subtraction threshold; 3. Local minima flood fill threshold; 4. Minimum and maximum blob size; 5. Minimum blob matching length; 6. Blob time-out duration; 7. Positions of region borders

Dataset: To get the best performance of the algorithm it was necessary to record a large dataset of depth videos and tune the parameters to the collected dataset.

A dataset of 38 depth video recordings was made using the long range and short range models of specified Carmine sensor, the recordings were taken of multiple scenes: various positions in the laboratory and of other rooms. The recordings were also taken on varying sensor heights from the floor and with different conditions: single person, multiple people, fast walking, waving hands, hugging together.

Additionally the laboratory was modeled as a scene and different scenarios were selected for simulation. Those scenarios consisted of a person walking through the scene in two directions, walking in circles and waiting, running through the scene and walking along the edge of the scene. Each scenario was modeled and animated using Blender, then rendered as a depth recording.

Since the real recorded dataset lacks ground truth measurements, the tuning was done by hand and was error prone. Creating synthetic video gives us an ability to generate large datasets with known ground truth, and with more control over the scene and the actions of people in the scene.

In the case of synthetically generated videos, the ground truth is known as the number of passages of a person through the scene. Additional information can be used as well, such as: the height of the person, the size of the head, the speed of the person, precise time the person enters the scene etc. Once the ground truth is known the tuning of the algorithm can be automated and only the situations in which the output of the algorithm is different from the ground truth can be analyzed.

C. Experimental results

Evaluation: Person detection is deemed successful if the algorithm's output, representing the counted number of passages through the scene for a selected synthetically generated depth recording, matches the known ground truth.

Additional scoring could be added by comparing the size of the persons head computed by the algorithm and known from the simulation. Other scoring metrics could include the tracking time of the person, proximity of the person to the border, and proximity to other people.

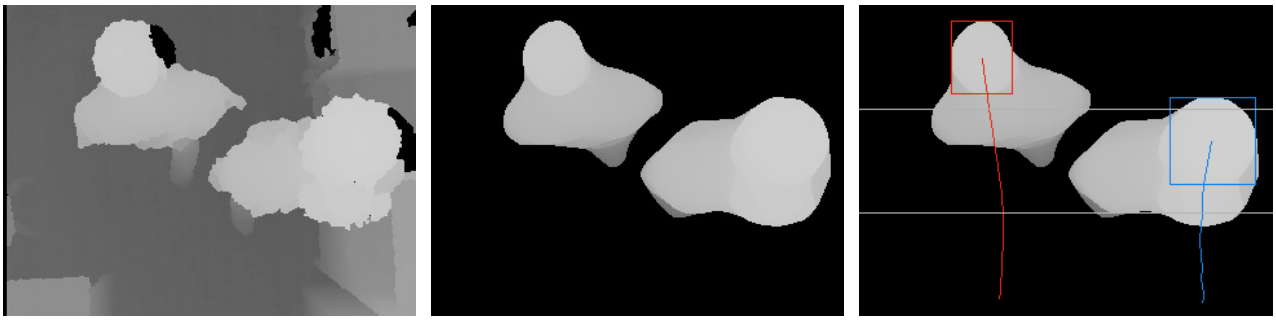

Figure 3. Raw depth frame from real sensor (left); pre-processed frame with background subtraction (center), head trackers and region separators (right)

Table II shows our results with the described scenarios when evaluated using the described passenger counter algorithm. Each scenario has a fixed number of passages of a single person through a scene. For each scenario we expect a certain number of passages to be detected, and we compare that value with the real number of detected passages by the algorithm. If the expected and real number of detected passages does not match, algorithm parameters are further tuned and the evaluation is re-run.

Qualitative results: The reader is invited to view the supplementary videos available at http://apaslab.riteh.hr/synthetic-depth-video/, or by mailing the authors.

Some successful detections and difficult scenarios are shown in Figure 4. The figure shows the detected person and its tracked path. In case of a successful detection and tracking, the rectangle represents a person's head, and the trailing line is the tracked path. Scenarios in which detection and tracking fail, such as a person running or walking along the edge help to further tune the algorithm until they are successfully tracked or detected.

TABLE II. Example run: simulated and detected passages through a scene

Scenario	Passages through scene in simulation (ground truth)	Passage counts by algorithm
Straight walk in a single direction	1	1
Straight walk, waving hands	1	1
Straight walk, loitering	1	1
Walk along the scene edges	1	0
Running in a single direction	1	0
Walk in a single direction, turn and walk back	2	2

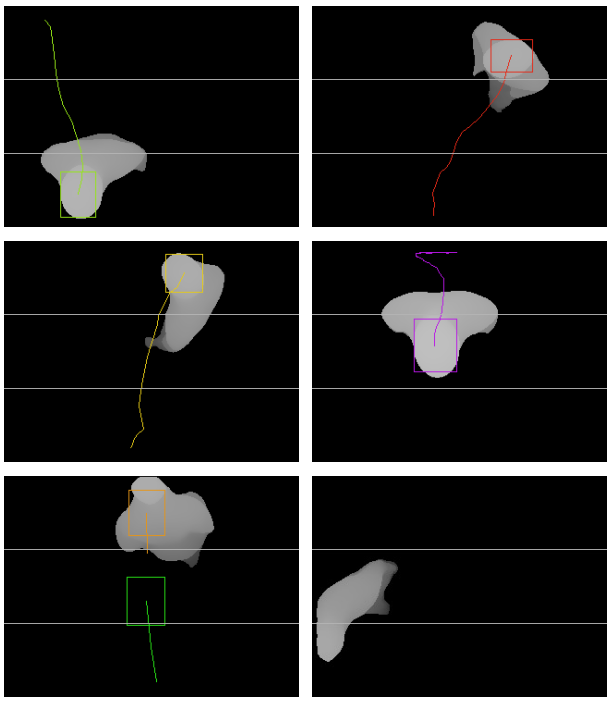

Figure 4. Results of applying people counter algorithm to synthetically generated depth data; successful tracking of a single person walking through the scene (top and center); person running (bottom left); person on the edge of sensor field of view (bottom right)

VI. Conclusions and Future Work

We have discussed the benefits of using synthetically generated depth maps in different key stages of the development of people tracking solutions that rely on 3D sensors. We have proposed and described a method and tools used for the generation of synthetic depth videos. The proposed method was used to develop a people counting solution. Its usage allowed for shorter development and testing times. We describe the algorithm and provide details of its implementation in a real embedded system. The solution was tested experimentally.

For future work we are planning to extend the described solution by implementing recent learning algorithms to improve the people detection from different camera positions. We are sure that the availability of large synthetically generated dataset and the capability to generate new data as needed will greatly benefit the development process.

Virtualizacija mrežnih funkcija u telekomunikacijama

Oliver Lovaković*

* Hrvatski Telekom/Sektor za razvoj sustava mreže i usluga, Zagreb, Hrvatska
oliver.lovakovic@t.ht.hr

Sažetak - Virtualizacija mrežnih funkcija (NFV, *Network Function Virtualization*) je novi koncept mrežne arhitekture u telekom industriji izgrađen na tehnologiji virtualizacije iz IT industrije s ciljem optimizacije troškova, bržeg razvoja te implementacije telekom usluga. Ovaj rad opisuje pogled na NFV od strane Hrvatskog Telekoma čija je osnovna arhitektura definirana DT projektom Terastream koji je prvotno implementiran upravo u HT-u. Također su prikazani status i planovi Hrvatskog Telekoma te preduvjeti koje je potrebno ostvariti za produkcijski rad u virtualiziranom mrežnom okružju. Posebni naglasak je na scenarij virtualizacije BRAS-a (*Broadband Remote Access Server*) kao posebno zanimljivog slučaja zbog specifičnih zahtjeva na kontrolnom i podatkovnom sloju za agregaciju xDSL korisnika. Virtualizacija vBRAS-a zbog toga predstavlja poseban izazov kako za proizvođače opreme tako i za telekom operatore.

I. UVOD

Situacija u telekom industriji zadnjih godina je takva da su telekomi suočeni sa kontinuiranim povećanjem IP podatkovnog prometa (i pratećih brzina) potaknuto širokopojasnim pristupom i novim Internet servisima te Internet poslovnim modelima. S poslovne strane postoje zahtjevi za kraćim vremenima uvođenja novih usluga te bitnim povećanjem broja usluga za lansiranje s mogućnošću ciljanja uskih korisničkih niša. Inzistira se na modelu koji bi omogućio mnogo pokušaja (i pogreški) pri lansiranju usluga, a koji s troškovne strane ne predstavlja bitan izdatak. S druge strane konkurencija u vidu OTT (*Over The Top*) igrača ili drugih telekoma negativno utječe na ostvarene prihode što rezultira da troškovi infrastrukture rastu brže od prihoda. Postojeće heterogene mreže i tehnologije teško se prilagođavaju gornjim zahtjevima i uz visoku cijenu. Povećanje troškova energije, navedena investicijska ograničenja, široki raspon ekspertiza potrebnih za upravljanje takvim kompleksnim mrežama upućuju na potrebu za promjenom postojećeg mrežnog koncepta u telekom industriji.

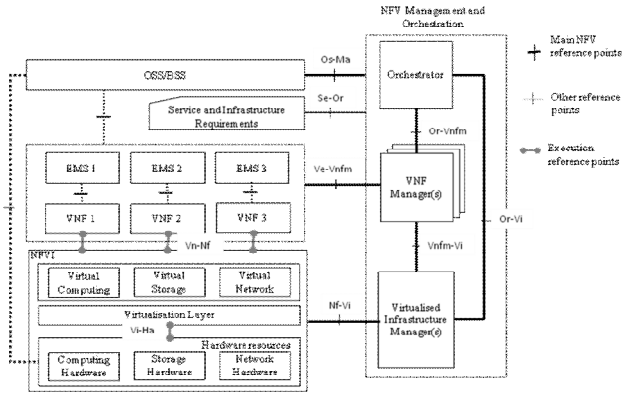
Sve to utjecalo je na razvoj novog koncepta mrežne arhitekture u telekom industriji - Virtualizacija mrežnih funkcija (NFV, *Network Function Virtualization*) izgrađenog pod okriljem ETSI-ja na tehnologiji virtualizacije iz IT industrije. Primarni cilj je povećanje efikasnosti kroz omogućavanje bržeg razvoja i implementacije telekom usluga uz optimizaciju troškova. Glavni pristup naslanja se na praćenje koncepta korištenja podatkovnih centara te računarstva iz oblaka (*Cloud Computing*) sa zadatkom da se isti proširi kako bi zadovoljio zahtjeve telekom industrije i to prvenstveno komunikacije u realnom vremenu (*Real-Time Communication*).

A. NFV organizacije

U tu svrhu je pri ETSI-ju početkom 2013. osnovana nova ISG (*Industry Specification Group*) grupa nazvana NFV (*Network Functions Virtualization*). Inicijativa je ubrzo privukla preko 200 kompanija (proizvođača i operatera) koji su doprinijeli u izradi osnovnih specifikacija NFV ekosustava u domeni arhitekture, zahtjeva, sigurnosti itd. Glavni moto grupe je korištenje standardne IT virtualizacijske tehnologije kako bi konsolidirali različite tipove opreme u standardne servere, preklopnike i medije za pohranu, koji mogu biti locirani u podatkovnim centrima, mrežnim čvorovima ili na lokaciji korisnika [1].

NFV arhitektura je prikazana na slici 1 .

NVF se u praksi često veže sa konceptom Programski upravljanih mreža (SDN, *Software Defined Networks*) kojem je cilj centralizirati i automatizirati upravljanje konfiguracijom mrežnih resursa. Dva su koncepta komplementarna prvenstveno iz razloga što SDN omogućuje dinamičko softversko mrežno povezivanje virtualiziranih mrežnih funkcija (*VNF, Virtual Network Function*) kreiranih u podatkovnim centrima sa korisnicima i ostalim funkcijskim blokovima potrebnih za realizaciju određene usluge. Dinamička priroda NFV-a se izvrsno nadopunjuje sa automatizmom i centraliziranim pristupom SDN orkestracije.



Slika 1. ETSI NFV arhitektura

NFV ekosustav se po ETSI NFV arhitekturi može podijeliti u slijedeće domene:

1. NFV Infrastruktura (NFVI)
2. Virtualizirane Mrežne Funkcije (VNF)
3. Upravljanje i orkestracija VNF aplikacija (NFV MANO, *Management and Orchestration*)

NFVI domena obuhvaća hardverske resurse i pripadajući virtualizacijski sloj koji definira na koji način se infrastruktura dijeli odnosno virtualizira.

VNF domena prikazuje softversku implementaciju mrežnih funkcija koja se izvršava na NFV infrastrukturi. NFV infrastruktura osigurava virtualne strojeve (VM, *Virtual Machines*) koji su zapravo virtualni kontejneri koje VNF aplikacije vide kao fizičke servere u kojima se izvršava njihov kod.

NFV MANO pokriva upravljanje životnim ciklusom i orkestraciju VNF aplikacija te hardverskih i softverskih resursa neophodnih za omogućavanje virtualizacije infrastrukture.

Upravljanje životnim ciklusom i orkestracija VNF aplikacija po ovom modelu je područje u kojem postoji znatan prostor za optimizaciju. Tako na primjer, ideja da svaka VNF ima svoje sustav za upravljanje (EMS, *Element Management System*) Postoji prostor za optimizaciju složene NFV arhitekture koja prepoznaje čak tri različita orkestracijska sloja – orkestraciju infrastrukture, aplikacija te sveobuhvatnu orkestraciju. Postoje inicijative u smjeru pronalaska zajedničkog načina za upravljanje VNF aplikacijama (npr. pomoću Netconf protokola uz prilagodbu Yang modela za svaku VNF aplikaciju) neovisno o dobavljaču softvera što bi omogućilo korištenje zajedničkog sustava za upravljanje konfiguracijom. Isto tako bi trebalo unificirati sučelje između VNF aplikacija i orkestracije istih kako bi pojednostavili i time unaprijedili robusnost arhitekture u orkestracijskom sloju (npr. također korištenjem Netconf protokola).

Glavni ciljevi i obećanja NFV inicijative su [1]:

- Smanjiti troškove opreme i energije (korištenjem komercijalno dostupnog hardvera, tzv. COTS, *Consumer of the Shelve*)
- Skratiti vrijeme razvoja i implementacije usluga (TTM, *Time To Market*)
- Omogućiti dijeljenje istih resursa za različite usluge i grupe korisnika te lako skaliranje resursa ovisno o trenutnom opterećenju
- Omogućiti dinamičniji ekosustav kroz razvoj i korištenje isključivo softverskih rješenja, tj. odvajanja razvoja softvera od hardvera (ulaze u igru mali inovativni igrači budući da nema potrebe za ulaganjem velikih sredstava u razvoj hardvera)

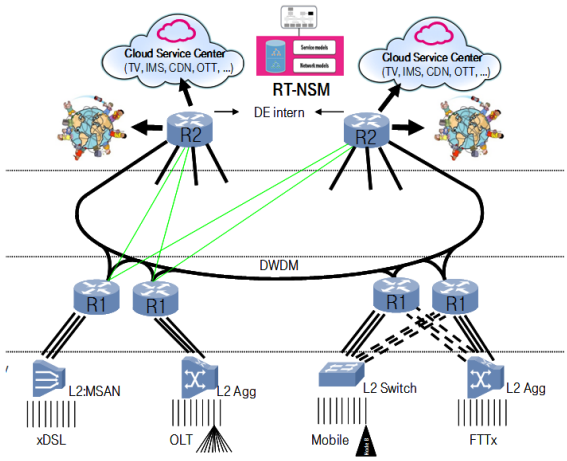
B. Status i planovi Hrvatskog Telekoma vezano uz NFV

Deutsche Telekom je jedan od osnivača NFV inicijative te kompanija koja snažno prati tehnološke inovacije. Hrvatski Telekom je kao dio DT grupe prepoznat kao telekom sa jakim tehničkim kompetencijama pa je kao takav izabran za pilot Terastream mrežnog koncepta. Terastream koncept je razvijen od strane DT-a s ciljem pojednostavnjenja mrežne arhitekture korištenjem slijedećih koncepata/tehnologija [2]:

- NFV (mrežne funkcije smještene su u posebnoj vrsti podatkovnih centara optimiziranoj za telekom potrebe - infrastrukturni podatkovni centri)
- SDN (popuno automatizirani sustav upravljanja mrežom i uslugama u realnom vremenu (RT NSM, *Real Time Network and Services Management*) upravlja životnim ciklusom kompletnog ekosustava)
- Pojednostavljena IP arhitektura (topologija s dva stupnja hijerarhije omogućava manji broj skokova između čvorova (*hop*) uz iznimno veliku širinu pojasa – 100 GE je osnova)

Glavni ciljevi Terastreama [2]:

- Smanjiti trošak transporta IP paketa zbog povećanja IP prometa pojednostavljenjem arhitekture
- Smanjiti broj tehnologija koje se koriste u prijenosu paketa (samo IP i optički prijenos)
- Integrirati IP i optičke mreže što je više moguće (integrirati OTN sučelja u rutere)
- Uvođenje IPv6 za sav interni promet (IPv4 je samo usluga koja se pruža korištenjem IPv6 infrastrukture L2TPv3 tunelima)
- Dimenzionirati mrežu da podržava sav IP promet bez gubitaka paketa



Slika 2. Terastream arhitektura

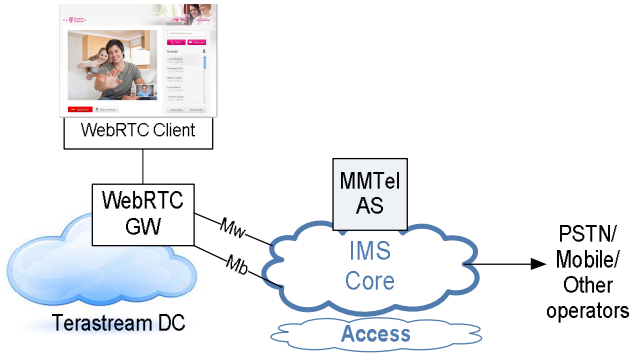
- Koristiti jednu mreže za sve usluge
- Potpuno automatizirani OSS sustavi (portal za upravljanje uslugom u realnom vremenu od strane korisnika…)
- Migracija mrežnih funkcionalnosti u DC (VNF aplikacije u infrastrukturnom podatkovnom centru)
- Iskoristiti *Open source* rješenja u najvećoj mogućoj mjeri (KVM, Openstack, OpenWRT…)

Testiranja u HT-u vezana uz virtualizaciju mrežnih funkcija vezana su uz Terastream pilote ili se odnose na testiranje VNF aplikacija instaliranih u Terastream podatkovnim centrima s ciljem dokazivanja ispravnosti koncepta (*Proof of Concept*). Posebno su izdvojeni slijedeći scenariji testirani u HT-u:

- Terastream pilot testiranja
- webRTC (*Real Time Communication*)
- virtualizacija IMS-a (*IP Mulitimedia Subsystem*)
- virtualizacija BRAS-a (*Broadband Remote Access Server*)

Terastream pilot je imao glavni cilj dokazati ispravnost koncepta za pružanje usluga rezidencijalnim korisnicima. Prva faza pilota (kraj 2012.) odnosila se na pružanje širokopojasne Internet usluge testnim korisnicima s ciljem testiranja VNF komponenti poput DHCP, DNS servera te AFTR (*Address Family Translation Resolution*). AFTR je bitna komponenta za uspostavu *Softwire* tunela (LW4o6, *Lightweigth IPv4 over IPv6*), neophodnog za prijenos IPv4 prometa preko IPv6 infrastrukture. Slijedeća faza pilota (kraj 2013.) ima za cilj testiranja pružanja 3play usluga u NFV Terastream ekosustavu.

WebRTC je tehnologija koja omogućava integraciju komunikacije u stvarnom vremenu sa *web* preglednicima. U Terastream podatkovni centar instalirali smo softver sa funkcijom webRTC *gateway*-a prema postojećem IMS sustavu s ciljem proširenja IMS usluga na web korištenjem scenarija „Učilice“. Implementacija i testiranje nisu prošli nezapaženo u telekom svijetu tako da je HT dobio nagradu Global Telekom Business za inovacije 2014. zajedno sa dobavljačem softvera – kompanijom Mavenir.



Slika 3. WebRTC shema

Virtualizacija IMS-a imala je za cilj pronaći rješenje za pružanje VoIP (*Voice Over IP*) usluge za fiksne korisnike spojene na Terastream mrežu. Cilj projekta je uz testiranje IMS funkcionalnosti i testiranje koncepta automatizacije i orkestracije same aplikacije.

Uz prethodno navedene scenarije HT provodi brojna testiranja NFV komponenti s glavnim ciljem istraživanja spremnosti pojedinih VNF aplikacija za produkcijski rad te istraživanja pouzdanosti i robusnosti Terastream arhitekture.

Terastream koncept se potvrdio u pilotima, ali ostaje još pokriti slijedeća područja kako bi se utvrdila stvarna spremnost za produkcijski rad:

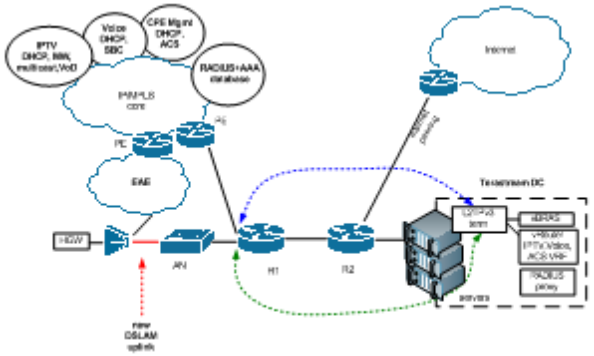
- Tehnološki (s ciljem istraživanja spremnosti dobavljača odnosno softvera za NFV)
- Operativni (s ciljem istraživanja kompleksnosti upravljanja životnim ciklusom NFV aplikacija te pratećih migracijskih planova)
- Ekonomski (troškovna usporedba scenarija migracije sa konvencionalnih mreža na NFV arhitekturu)
- Regulatorni (s naglaskom na veleprodajne modele)

Glavni ciljevi u slijedećem razdoblju vezani uz Terastream projekt te NFV implementaciju su dodavanje dodatnih VNF funkcija u podatkovni centar kako iste budu dostupne od strane dobavljača te podizanje stabilnosti i pouzdanosti svih komponenti Terastream infrastrukture (Infrastrukturni podatkovni centar, R1, R2…).

C. vBRAS kao poseban slučaj

Posebni naglasak stavljan je na scenarij virtualizacije BRAS-a potrebnom za agregaciju xDSL korisnika kao posebno zanimljivog slučaja zbog specifičnih zahtjeva na kontrolnom i podatkovnom sloju. Virtualizacija BRAS-a zbog toga predstavlja poseban izazov kako za proizvođače opreme tako i za telekom operatore. Glavni cilj je pronaći rješenje za migraciju xDSL pristupne opreme na Terastream mrežu. Ta oprema bazira se na PPPoE konceptu koji zahtjeva BRAS funkcionalnost. Scenarij je spojiti DSLAM uređaj na Terastream mrežu i osigurati BRAS funkcionalnosti u Terastream podatkovnom centru uz omogućavanje kontinuiteta usluge za korisnike sa starom CPE opremom (IAD, *Integrated Access Device*; STB, *Set top Box)*. Scenarij koji ne obuhvaća kompletnu zamjenu CPE opreme kod korisnika bitno pojednostavnjuje postupak migracije. Za IPTV, govornu uslugu te servis za upravljanje konfiguracijom CPE opremom koriste se servisne platforme smještene u konvencionalnoj mreži korištenjem vRouter VNF aplikacije koja se spaja na istu.

Sama Internet usluga se realizira preko vBRAS instance koja se izvršava u Terastream podatkovnom centru (osim Radius AAA komponente gdje koristimo



Slika 4. vBRAS scenarij

Radius Proxy server u podatkovnom centru koja šalje Radius poruke prema konvencionalnom Radius serveru).

Glavni arhitekturalni građevni blokovi rješenja su:

1. Terminator L2TPv3 tunela (terminira tunel od agregacijskog R1 rutera)

2. vBRAS (pruža iste funkcionalnosti kao i hardverski bazirani BRAS - PPPoE terminacija, AAA…)

3. vRouter (omogućava osiguravanje telekom VPN servisa – IPTV, VoIP, VPN za upravljanje CPE opremom)

4. Radius proxy (služi kao relej za Radius promet prema postojećoj centralnoj Radius bazi podataka)

Cilj testiranja bio je funkcionalno testirati kombinaciju rezidencijalnih usluga (3play) uz QoS sa kraja na kraj te testiranje performansi.

Zaključak je kako je samo rješenje zadovoljilo kriterije uz napomenu kako se ipak radi o kompleksnijem ekosustavu budući da je sama implementacija iziskivala prilagodbu (nadogradnju) operativnog sustava na samim serverima s ciljem poboljšanja performansi same vBRAS aplikacije (nadogradnja linux kernela). Isto upućuje na preveliku povezanost aplikacije sa infrastrukturom što se kosi sa osnovnim zahtjevom NFV-a. Procedure operativnog održavanja su također složenije budući da je samo snimanje prometa u svrhu detekcije potencijalnih problema bitno otežano činjenicom da vBRAS nema fizičkih sučelja na kojima je moguće snimati promet. U tu svrhu potrebno je redizajnirati koncept dizajna sustava za nadzor signalizacije i prilagoditi ga NFV okružju.

II. ZAKLJUČAK

NFV tehnologija doista pruža mnoge mogućnosti koje telekomi mogu pozitivno iskoristiti. Međutim, uz prethodno navedene prednosti postoje i brojni problemi koje treba riješiti ili barem umanjiti uzrokovani kompleksnošću ekosustava ili barem inkubacijskoj fazi NFV tehnologije [3]. HT-ova pozicija tehnološkog lidera u istraživanju NFV problematike otvorila je brojne nove probleme koje tek treba riješiti i kojih ostali nisu svjesni.

Tako implementacija podatkovnih centara odnosno pratećeg softvera (naglasak na Openstack instalacijama koje su prilagođene pojedinačnim potrebama operatera) postaje specifična pa je potrebna prilagodba raznim konceptima. Iako takva prilagodba optimizira ekosustav određenog operatora takav pristup otežava razvoj orkestracijskog i VNF softvera zbog bitnih razlika u infrastrukturnim postavkama od instalacije do instalacije.

Implementacija IPv6 protokola nije toliko raširena iako je standard već dugo vremena postoji. To je problem s kojim smo se susretali pri testiranju i istraživanju tržišta u potrazi za prikladnim VNF aplikacijama odnosno CPE opremom.

Nadzor prometa u oblaku je mnogo kompliciraniji nego u „starom“ svijetu fizičkih sondi. Promet između virtualnih strojeva (VM) na istom hardveru ne prelazi preko fizičkog sučelja tako da treba prilagoditi koncept nadzora prometa.

Open source softver demonstrira brojne prednosti u ovoj fazi implementacije. *Open source* zajednica se pokazala fleksibilnijom u razvoju NFV softvera od etabliranih dobavljača telekom rješenja. Oblak je za dobar dio tih proizvođača samo jedna nova platforma za instalaciju starog softvera uz manje prilagodbe. Nema posebne optimizacije softvera za oblak već se u pravilu softver kopira sa hardverske kartice sa određenom funkcijom (npr. signalizacijska) kopira u odgovarajući VM. Automatizacija i orkestracija te nadzor VNF aplikacija se nudi kroz proizvode/silose što se negativno odražava na cilj smanjenja ovisnosti o dobavljačima.

Operativni izazovi su bitno veći posebno zbog nejasne podjele odgovornosti u vritualiziranom okružju između organizacijskih cjelina i dobavljača (infrastruktura i aplikacija). Potreban je puno veći stupanj integracije IT i NT dijelova organizacije te poslova razvoja i operative. Isto tako u slijedećem razdoblju je potrebno staviti poseban naglasak na stabilnost i pouzdanost platforme koju tek treba verificirati na široj korisničkoj bazi i kroz dulje vremensko razdoblje.

PAPERS

The Relationship between Cultural Dimensions and the Quality of Communication in Education

B. Grobenski*,V. Vidacek-Hainš **
* Faculty of Organization and Informatics, Varaždin, Croatia
** Faculty of Organization and Informatics, Varaždin, Croatia
grobenski.bojana@gmail.com
vvidacek@foi.hr

Abstract - Culture is the collective programming of the mind distinguishing members of one group or category of people from others [1]. Each culture is different. Therefore, there are five dimensions of culture and this article explains and explores one of these: Power Distance (PD). This paper will outline the impact of these dimensions in educational institutions. In the study participated students from three countries (Croatia, Denmark, and Romania). The goal of this research is to determine how the students deal with a structured hierarchy and formal communication with a high level of Power Distance, rules and regulations. R**esearch shows what kind of communication and distance are in countries with low power distance (e.g. Denmark). A semantic differential instrument was used to process the survey results. We know that culture has an influence over education, i.e. Power Distance has an impact on the education of young people.** T**he paper also examines the influence of professors over students as well as the consequences of these impacts (level of formality of relations, the level of respect for student opinion, etc.). The possible models of improving the quality of communication and reducing the power of distance at the institutions of higher education will be explored. Keywords: Culture, Communication, Education, Hierarchy**

I. INTRODUCTION

Computers have had a big impact on interpersonal communication, particularly amongst young people and students, via computer-mediated communication (CMC). CMC can be also linked with the stress caused by intercultural differences [2].

Cultural differences do not disappear during technological modernisation. Students can develop international contacts and understanding of other cultures, nations and languages and therefore increase their intercultural competence.

In general, globalisation has presented the fact that modern society must learn to cooperate with each other [3]. The quality of communication in the international environment could be changed by using different information and communication tools. In spite of the fact that some implications of using ICT in education are positive, the negative implications of using ICT need to be considered [4].

The accessibility of ICT equipment is an important factor in enabling the quality of communication and is linked to the curricula of the higher education courses [5,6].

Educational attendance also relates to the digital development of countries. [7]. The combination of classical teaching methods supported by E-learning and computer mediated communication can be suitable for students and teachers in terms of their individual needs [8].

II. THEORETICAL FRAMEWORK

Culture represents a social pattern which includes behaviour in families, nations, organisations, etc. Also, culture includes tradition and behaviour in public and educational institutions and represents a way of creating ideas and views about other cultures and people from different cultures [9].

The number of projects about testing communication between speakers from different cultural backgrounds has grown in last few years.

Casrnir [10] says that communication should be approached with understanding and the realisation that people always change.

Because of that culture can not be seen as a static point. Traditionally, courses in intercultural communication that aimed to prepare university students to become effective intercultural communicators were designed to teach cognitive over affective learning, using lectures, readings and presentations [11].

Competence in intercultural communication has become a necessity for functioning effectively in our increasingly globalised and multicultural society.

A. Dimensions of Culture

The intercultural differences represent a challenge to all teams made up of individuals from different nations and cultures.

The literature review shows that several authors tried to operationalise culture through the use of multiple cultural dimensions.

The most famous and most widely used of these "models of cultural dimensions" was developed by Hofstede [12]. He described the five dimensions as follows: 1. Power-distance 2. Collectivism vs. individualism 3. Femininity vs. masculinity 4. Uncertainty avoidance 5. Long- vs. short-term orientation.

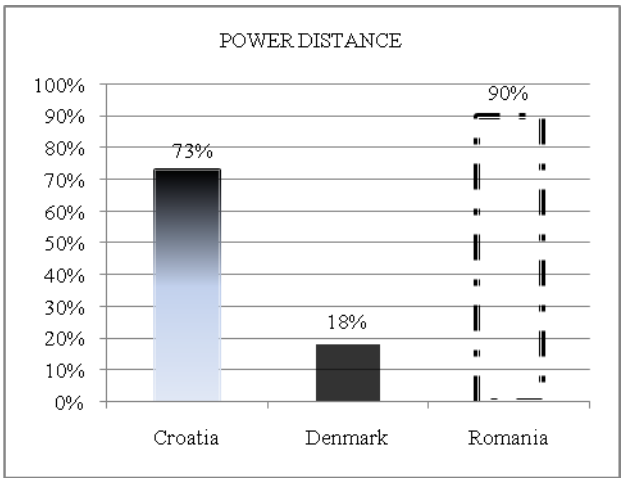
B. Power Distance

Here Power Distance (PD) will be explained. Power distance is the extent to which the less powerful members of organisations and institutions accept and expect that power is distributed unequally.

High PD cultures usually have centralised control. Low power distance implies greater equality and empowerment.

The cultures with high power distance retain a hierarchy, a decision-making structure, rules and regulations, and cultures with low power distance do just the opposite: they tend to balance [13].

According to Hofstede, the biggest power distance is in Romania, rank 2 is for Croatia and rank 3 for Denmark. Results are presented at Graph 1.



GRAPH 1: THE POWER DISTANCE FOR THREE EUROPEAN COUNTRIES

Source: http://geert-hofstede.com/croatia.html

II. RESEARCH

We know that culture has an influence over education, i.e. the dimension of power distance is in relation with the education of young people.

This research includes a representative number of students from Croatia, Romania and Denmark, in addition to analyses of the hierarchical division in the academic community, because when we observe PD all three countries are different.

A. Research goals

The research goal is to explore student opinion about structured hierarchy and power distance (PD) in communication in different countries (Denmark, Romania and Croatia). The case study of possible models of networking through informal ways of communication will be explored.

III. METHODOLOGY

A. Respondents

The first group of respondents were students of the Faculty of Organisation and Informatics (age 19-24, N= 109). In other groups were students from Romania (N = 43) and Denmark (N = 51). They represent the control group, i.e. a group which can be compared with the specified group tested by some empirical hypotheses [14].

B. Measuring Instruments

Author Grobenski B. developed a new questionnaire for this research. The items described power distance (PD) in a student's environment and the range of hierarchical divisions and rules.

The first four questions were demographic characteristics. The next three questions were designed as a scale for assessment of attitudes (from 1-5; e.g. 1- does not answer to e-mails, 5- answer the same day).

Questions from 8 to 11 are related to the student attitudes (answer Yes or No). The content of the items is related to the PD in communication.

The rest of the items are in the form of a semantic differential. The Semantic Differential (SD) is the psychometric tool in which bipolar scales are defined with contrasting adjectives at each end [15]. The respondent is asked to choose where his or her position is on the scale.

A questionnaire was implemented by a Google Docs tool in English and Croatian and sent to participants through closed groups on the Facebook social network. The survey was anonymous. The time required to fill out the surveys was 10 minutes.

IV. DATA ANALYSIS

The results for each item were analysed in terms of their basic statistic measurements: average /arithmetic mean (M) and standard deviation (SD).

Table 1 presents the answers to the Faculty's hierarchy: Does a hierarchical distribution of authority and responsibility exist in your academic community or college (Question 4), how long students do need to wait at the professors answers? (Question 5) how long do students need to wait at the assistants answers? (Question 6). These results indirectly measured the power distance in Croatia and other countries.

TABLE 1: POWER DISTANCE IN CROATIAN CULTURE

	N	Min	Max	Mean	Std. Deviation
4. Does a hierarchical distribution of authority and responsibility exist in your academic community or college?	109	1	5	2,14	1,28
5. Does it take a long time to get an answer from your professor?	109	1	5	3,66	0,81
6. Does it take a long time to get an answer from your assistant?	109	1	5	4,01	0,86
Valid N (list wise)	109				

The hierarchical division of powers and responsibilities (M = 2,14, SD = 1,28) shows that in the Croatian academic environment there exists a hierarchical division of powers and responsibilities: number 1 showing the existence of a hierarchy, and the number 5 showing a total absence of hierarchy.

A standard deviation was calculated for the scattering index. Deviation is less in the Question 5 (M = 3,66, SD = 0,81) and Question 6 (M = 4,01, SD = 0,86), which provides more relevant and accurate data.

This means that the time required for the teachers/assistants answers to students e-mail messages is "answers in a week" (3) and “answers in 2 to 3 days” (4). The results are acceptable for the Croatian academic community.

Table 2 shows the power distance in Romania. The results of the hierarchical division are shown in the Question 4 (M=1,93, SD=0,91). Considering that the arithmetical average is between 1 and 2, which means a very high level of hierarchy in the culture, i.e. a high level of power distance, it can be argued that the Romanian culture really stands out in its position in the academic environment.

Standard deviation shows a wide range of dispersion, i.e. a large deviation. Therefore the question remains about statistical significance.

When we observed Question 5 (M = 2,37, SD = 0,49) and Question 6 (M = 3,63, SD = 0,79), it can be concluded that the period of time to get an answer (e-mail) from teachers/assistants is in the mid-range (a month or a week).

In Danish culture (Table 3) the results are slightly different when compared with the results from the Croatian and Romanian cultures. Question 4 about the hierarchical division of powers and responsibilities (M = 3,53, SD = 0,64) shows a lower level of power distance. The arithmetical mean (M) is between 3 and 4, which means there are not less strong hierarchical divisions.

TABLE 2: POWER DISTANCE IN ROMANIAN CULTURE

	N	Min	Max	Mean	Std. Deviation
4. Does a hierarchical distribution of authority and responsibility exist in your academic community or college?	43	1	3	1,93	0,91
5. Does it take a long time to get an answer from your professor?	43	2	3	2,37	0,49
6. Does it take a long time to get an answer from your assistant?	43	2	4	3,63	0,79
Valid N (list wise)	43				

TABLE 3: POWER DISTANCE IN THE DANISH CULTURE

	N	Min	Max	Mean	Std. Deviation
4. Does a hierarchical distribution of authority and responsibility exist in your academic community or college?	51	2	4	3,53	0,64
5. Does it take a long time to get an answer from your professor?	51	3	5	4,24	0,65
6. Does it take a long time to get an answer from your assistant?	51	3	5	4,43	0,70
Valid N (list wise)	51				

The low level of power distance shows more equality and more balance in this culture. Answers to Question 5 (M=4,24, SD=0,65) and Question 6 (M=4,43, SD=0,70) showed that the period of time to get an answer (e-mail) from teachers/assistants is very short. The numbers 4 and 5 on the scale relate to a period of 2-3 days and an answer on the same day.

The results of the semantic differential in Croatia, Romania and Denmark are presented in Table 4. Croatian culture and the appropriate level of power distance is marked with red line, a blue line marks Romanian culture and a green line Danish culture.

TABLE 4: SEMANTIC DIFFERENTIAL FOR THREE EUROPEAN COUNTRIES

4	The existence of a hierarchy	Completely evident	1	2	3	4	5	Non-evident
5	The time of response from a professor	Did not reply	1	2	3	4	5	Replied the same day
6	The time of response from an assistant	Did not reply	1	2	3	4	5	Replied the same day

A. *Conclusions of the survey*

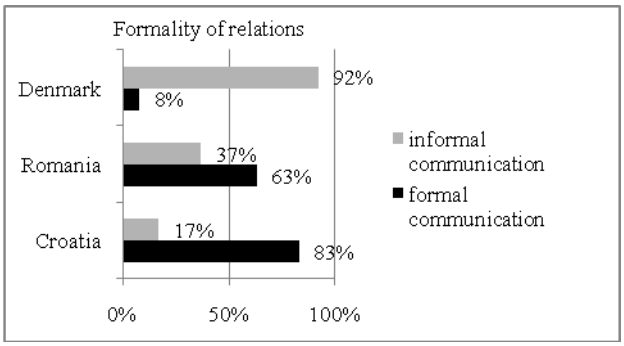
The research results show formality relations in the three analysed cultures and provide a clear display of formal or informal communication in the academic community of these particular cultures (Graph 2 and 3).

Croatian and Romanian students have slightly higher degree of formality comparing with Danish students (rank 3). Danish participants chose only a small proportion of formalities, and most of the answers speak of an informal and open communication.

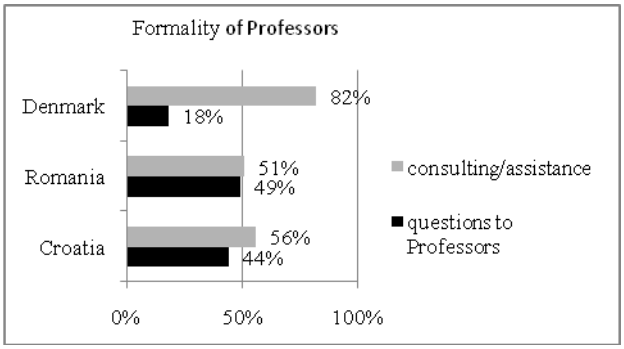
Therefore, the student can always ask for help and answers from professors or assistants. Croatian and Romanian students have more formal methods of communication with their professors and assistants. This can be connected with the final learning outcome of students working and learning.

Graph 4 shows how teachers and assistants in the relevant culture consider students opinions. Results show that level of openness in communication between students and professors is higher in Denmark (Rank 1).

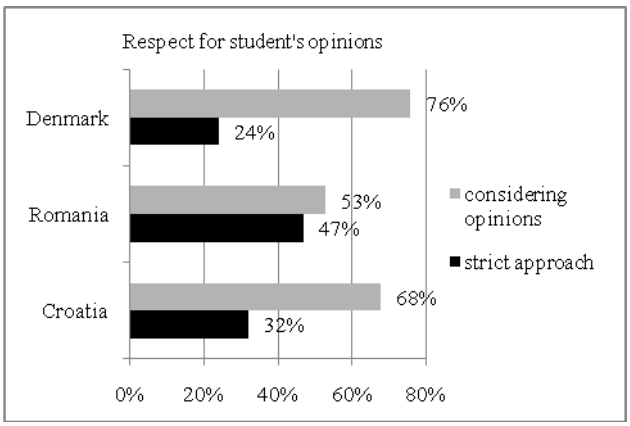
However, it is evident that in this part Croatian culture tends to be more similar with Danish culture than with Romanian culture.



GRAPH 2: THE LEVEL OF FORMALITY OF RELATIONS IN THREE EUROPEAN COUNTRIES



GRAPH 3: THE LEVEL OF FORMALITY OF PROFESSORS IN THREE EUROPEAN COUNTRIES



GRAPH 4: THE LEVEL OF RESPECT OF STUDENT OPINIONS IN THE ACADEMIC COMMUNITY IN THREE EUROPEAN COUNTRIES

V. IMPLEMENTATION OF RESULTS THROUGH CASE STUDIES

Possible ways of reducing the power distance in communication are through informal communication and networking. The possible networks between academic institutions and the general public can be volunteering projects, the popularisation of science, online student research symposiums, etc.

Practical examples showed that communication through volunteering project is less formal [16]. There is a lower power distance between teaching volunteers and student volunteers. The popularisation of science and communication with the public is an important way of informal communication between academic institutions and the general public. Scientific bars / SciBars are informal ways of presenting science in anon-academic environment, such as scientific cafes [17].

A student network in the international environment could be developed through international student online research symposiums. The main goal of this network is to encourage student creativity, ensure that students understand science better and develop their international communication competences [18]. Students work on a voluntary basis with their mentors. The power distance between students and mentors is lower and quality of communication is different.

VI. CONCLUSION

Foreign language, intercultural training and education programmes normally prescribe some manner of assessing participant performance / competence in a variety of academic and professional areas. It is clear that it is necessary to take into consideration cultural differences of participants and their different understanding. Results from this research show that Croatian and Romanian students have a much higher degree of formality compared to Danish students. This kind of relationship could be a barrier for developing openness in communication at academic institutions.

The quality of communication and the power distance at the academic institutions are different inside the academic curriculum, at projects linked to the local community and voluntary online communication. Case studies of volunteering projects organised by the students,

teachers and staff could reduce this distance in communication. Communication competences and social sensitivity could be developed thought different volunteering projects, online research symposiums and the popularisation of science. Further research will be focused on the compilation of case studies and examples of good practice at different countries

Abstract - Work, to an increasing amount, is based on collaboration between different partners; collaboration emphasizes the importance of communication between the collaborating parties. Increasingly, work is also becoming distributed and carried out in different geographical locations; distribution underlines the importance of managing and organizing work. The third important aspect characterizing current work is globalization; this refers to the multicultural characteristics of work and the need to understand the behavioral patterns of different (national) cultures. The paper addresses these three challenges related to the current work context. The approach points out the importance of a deep understanding of the characteristics of work – collaboration, distribution, and cultural diversity. Adaptive learning provides one potential solution to the challenges.

I. INTRODUCTION

This paper is focused on the changing role of collaboration. Our experience lies in information systems (IS) development and software engineering (SE) work. However, the analysis is easy to generalize and can be applied in different situations, which expect collaboration between parties separated in some way. IS development is a typical sector that demands close collaboration between different interest groups and roles of developers. In spite of keeping our discussion in common level, we keep IS development as our application context.

In this paper we will not go into detail regarding complex process models and the role of communication in them. We will try to simplify the discussion to follow the evolution of IS development during the decades as follows. *The era of simple systems*: The first information systems were simple "one man" projects and communication needs were minimal, limited to the interaction between the developer and the client. *The era of large systems*: Growth of ISs forced the division of development work and sharing responsibility for the large system between several developers. Additional communication was needed to supervise the work of the development team. *The era of complex systems*: The growth of system complexity led to the situation where the work must be divided hierarchically first between teams and then inside teams between individuals. In practice this leads to a growing complexity of communication patterns. *The era of systems of systems*: Complexity has grown further and part of the development activity originates from such sources that are not under centralized (one's own) management. From the communication point of view, the complexity grows because of the unmanaged parts of the whole. The reasons for this are manifold: the tendency towards reuse, integration of individual ISs to the Internet using open interfaces, etc.

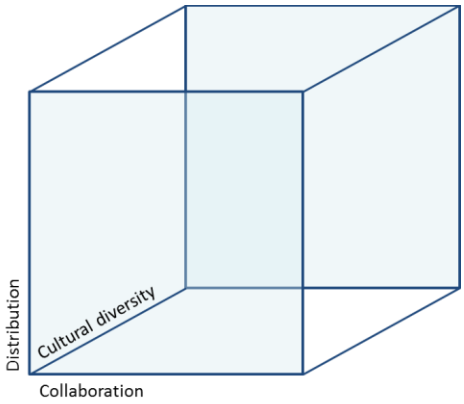

Figure 1. Communication complexity cube

The discussion above is slightly outside the scope of our paper, but included in this introductory part to clarify the progress that has led to the current state of the art. As mentioned earlier, in spite of using IS development (because it comes from our research field) as a case example, similar phenomena and progress are easy to find in many other sectors of society and business. Nor is the aim of our paper to focus on the communication patterns themselves – or only briefly, but to analyze three complexity factors related to communication. These are illustrated in Figure 1 in the form of a *communication complexity cube*.

The cube illustrates the space where (all) communication takes place (in any of the above discussed evolution phases and communication types). The three factors that interest us cover the degree of collaboration (x-axis), the degree of the distribution of work (in separate locations), and cultural diversity (multicultural teams). If we link this approach to the earlier evolution path, it is clear that when collaboration (amount of communication) increases, the consequence in most cases is first increasing distribution (transferring the work to such locations where (skilled) resources are available) and finally globalization (transferring work outside the geographical borders of the original location) is the response either to the still growing demand for resources or to benefit from the cost-effective use of globally available resources.

The communication complexity cube is used to structure our paper. The paper combines ideas derived from our cross-cultural collaboration related studies; results of this work are available in several earlier publications of the authors – some are also referred to in this paper. Section II provides a view to the typical aspects of IS development and software engineering work (our application context). Section III concentrates on analyzing the important aspects related to communication. An answer to the question "what actually is communication?" is sought in the collaboration context. Section IV gives a short overview of distribution ontology; this is a slightly more complex problem than just increasing the number of collaborating units, because part of it relates to how tightly they are bound together. Quite often distribution progress is also bound to the changes in the cultural base of the organization. Section V provides a short introduction to cultural differences and the means to manage the problems related to them. Section VI collects "tools" that are used to solve the problems encountered in the earlier sections. Section VII summarizes the paper.

II. ENGINEERING WORK – A PROCESS ORIENTED VIEW

The (very) simplified and generalized engineering process life cycle covers the following steps and communication needs:

- *requirements (elicitation, analysis and specification)*: communication between developers (system analysts), clients and other roles interested in the IS under development; the result is the answer to the question "what should the IS do?" and covers the functionality of the IS and related non-functional requirements (quality aspects);
- *design*: communication between different developers, in addition to the communication between the developing and client organizations; this step of engineering work transforms the requirements into the design that fills the architecture expectations of the system under development and provides the answer to the question "how should the IS be implemented?". The work covers two important tasks: (1) structuring the whole in architectural parts (top-down partitioning, covering both specification of components and interaction between them, with the focus on functionality) and (2) transformation of non-functional requirements into architecture, functionality or development process artefacts (goals);
- *implementation*: communication within the development team and in sufficient amount between the developer and client organizations; this step implements the IS requirements according to the defined architecture (principles) and results the implemented IS components; the focus is on the appropriate division of work and communication related to it; the role of client-developer communication is minimal;
- *integration (test)*: communication between developers having responsibility for separately developed IS components to guarantee their integrated operability; this step turns the development paradigm from top-down to bottom-up and puts the focus on actions guaranteeing the interaction between components; the role of client-developer communication is minimal;
- *system (test and) deployment*: the importance of client-developer communication is in focus again (as at the beginning of the engineering life cycle), where the client side is represented by different interest groups (and systems that interact with the system under development); after this the IS is deployed, the development part of the life cycle ends, and the *maintenance* phase starts;
- *(utilization and) maintenance*: this part of the IS life cycle, from the communication point of view, shares the features of the requirement step in an iterative manner and includes tasks related to change management in addition to the development tasks.

It is worth noticing that the engineering life cycle is just a part of a more comprehensive *process model* covering a wide variety of (grouped) processes. More details of these are available e.g. in [1;2] from the process structure point of view and in [3;4] from the process capability and organization maturity point of view. This material provides the means for a still more complex classification of communication needs as a part of IS development.

The implementation part of the engineering life cycle in practice may be done in several ways. Larry Boehm's conference paper [5] compares the traditional plan-driven development approach (discussed above) to the Agile approach. The Agile approach is based on the principles of the Agile manifesto [6]: "Individuals and interactions over processes and tools, Working software over comprehensive documentation, Customer collaboration over contract negotiation, Responding to change over following a plan". The traditional "plan-driven" approach points out the importance of following predefined plans, including the preplanned communication structure as part of it. The Agile approach, instead, points out the need for on-demand communication and flexibility, which means the growing importance of interaction between and within the interest groups and developer. The Agile approach on the organizational level is introduced by Andrew McAfee in his Organization 2.0 concept. In his book and www repository [7;8], McAfee introduces a novel communication and collaboration oriented organization culture, and compares it to the traditional approach called Organization 1.0 (as an analogy to the www context).

III. COLLABORATION AND COMMUNICATION

Jaakkola & Thalheim considered the characteristics of collaboration in connection with adaptive systems in [9]; Figure 2 summarizes the idea.

Collaboration - in connection with information systems development – is based on information processing by humans (H) and computers (C), the transfer of information between them and the transformations needed in the transfers. The nodes indicate individual sources of communication and the arrows between the nodes represent the communication (having direction).

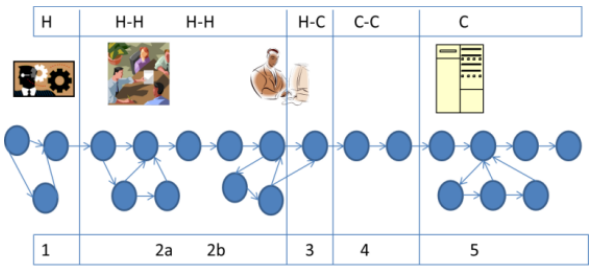

Figure 2. Characteristics of communication

According to Figure 2, information processing is done by humans (1) and computers (5). Individuals transfer their understanding either to other humans (2) or to computers (3). Teamwork is used in collaboration between humans (2a) and computers also collaborate in complex problem solving by dividing the processing responsibilities (4, 5). Typical processes include human and computer work, which requires the transfer of tasks from human to computer (systems) or vice versa.

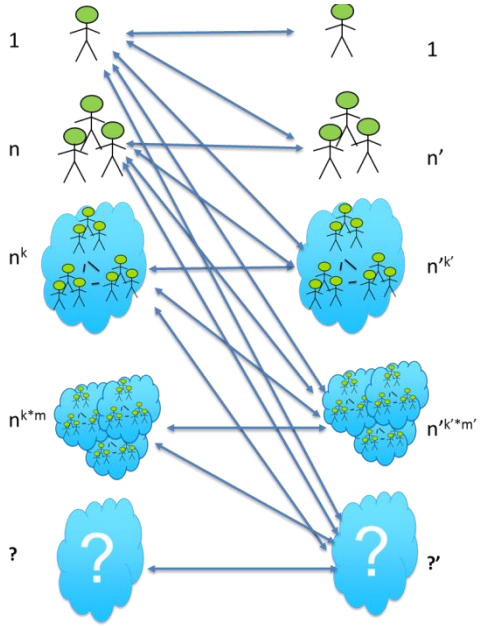

Figure 3. Degrees of collaboration complexity

Figure 3 illustrates different collaboration situations. The elements cover different collaboration parties (an individual, team, collaborative teams (in the cloud), collaboration between collaborative teams (cloud of clouds) and an unknown collaboration party (question mark cloud). The collaboration situations are marked with bidirectional arrows. The figure is self-explanatory: the complexity degree of the collaboration of one party increases in power when its complexity grows, and the complexity between parties is a multiplication of parties (1*1; 1*n'; $n^{k}*n'^{k'*m'}$). However, we agree that the idea described above does not fit reality: teamwork is organized (follows a pre-defined *teamwork process*), as is the collaboration between teams (follows a pre-defined *collaboration process*). These plan-driven (term adopted from [5]) work practices simplify the complexity and make it manageable (see [3; 4]).

The "question mark cloud" has not yet been explained. It covers the situation in which the collaboration partner is unknown; as a result this represents the most complicated situation – we have no opportunity to adapt ourselves to and learn the behavior of faceless partners. In software systems development, this situation is common when the system under development must be integrated to collaborate with existing common services; e.g., the utilization of open data as part of the information base provides in most cases only an API and interface specification for the developer without any opportunity to communicate with the data owner (see. e.g. [10; 11]).

Communication is an essential part of collaboration; the *information flow* between the collaborating parties binds the parties to work together. In [12], the essential communication elements are specified to cover: (1) the purpose of the communication; (2) the message transferred from the source (sender) to the target (receiver); (3) the interpretation of the message (meaning, understanding); (4) the structure of the message (structure of concepts and structural patterns); (5) the channel used for transformation (medium, connection) and (6) the context of the communication. Interpretation of the message is seen to be context-sensitive (i.e., in different contexts the interpretation may vary). The transfer of information (*message*) needs a *medium* to store the content and a *language* used for representation. The message itself is a *construction* of concepts. The conceptual *model* represents the structure of concepts from an individual collaborator's point of view. Figure 4 illustrates the role of the conceptual model in communication (for more details see [12]).

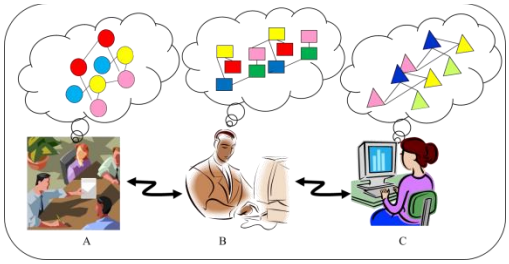

Figure 4. The role of conceptual models in communication

Every individual builds his/her own *private conceptual model* of the target. This is based on several personal properties; in this paper we especially want to emphasize the importance of (national) culture. In information flow the personal conceptual model is transformed (encoded) to the form accepted by the transfer medium (by the sender) and further transformed (decoded) to the conceptual model of the receiver. Figure 4 represents the differences of personal conceptual models using different shapes and structures. Our hypothesis is that one important source of misunderstanding and problems in collaboration has its roots in communication and especially in an inability to interact with conceptual models; transformations are not able to supply sufficient and exact content of the information (knowledge).

The discussion above contains somewhat philosophical aspects – which brings us slightly out of our

main competence areas. Therefore we will try to summarize shortly the main findings and link them to the next sections of this paper. The main point is the complexity of collaboration; this becomes an important issue in the organized distribution of work, which is handled in Section IV. Globalization (multicultural collaboration) increases the complexity further, as pointed out in Figure 1. Multicultural issues are discussed in Section V. Collaboration is represented as a set of information flows between collaborating partners (Figures 2 and 3). The transformations included in the flows need the adoption of a *common language* used to transfer the sender's private conceptual model to the intermediate model (encoding) for transfer and further interpretation of the intermediate model by the receiver (decoding). These languages as a solution to the co communication problem are discussed in Section VI.

IV. DISTRIBUTION OF WORK

Distribution of work is handled above (Figure 3) on a logical level. In practice, it is a question of organizational issues: an organization distributes the work based on either collaboration or on organizational needs. In both cases it is based on the strategic decisions of organizations and there are different motivation factors in the background: availability of resources, price of resources (work), location near important customers, extension of market, closer location to the sources of innovations.

Table 1. Organizational Distribution Taxonomy [13, p. 69].

	Intraorganizational		Interorganizational		Outside	
	One activity	Several activities	One activity	Several activities	One activity	Several activities
National	One site **(N1)**	Multiple sites **(N2)**	Out-sourcing **(N3)** Right-sourcing	Multi-sourcing **(N4)** Co-sourcing	Broker out-sourcing **(N5)** Right-sourcing	Broker multi-sourcing **(N6)** Broker co-sourcing
International	Off-shoring **(I1)** Near-shoring	Off-shoring **(I2)** Near-shoring	Offshore out-sourcing / near-sourcing **(I3)** Offshore right-sourcing	Offshore multi-sourcing **(I4)** Offshore co-sourcing	Broker offshore out-sourcing **(I5)** Broker offshore right-sourcing	Broker offshore multi-sourcing **(I6)** Broker offshore co-sourcing
	Insource		Outsource			

Distribution of work on the organizational level is always motivated by different business-related factors. As pointed out in Figure 1, distribution of work creates a need for increasing communication and increases the complexity of managing the work. In one-site distribution it is a question of teamwork; communication inside a team is easy and problems related to the division of work are solved by technical tools (e.g. in IS development by using version and configuration management tools, Integrated Development Environments – IDE; in a more general sense distributed work spaces, like Google Documents, Microsoft Office Online or by using different groupware platforms, like BSCW).

The taxonomy in Table 1 [13, p. 69] is divided into two rows (national and international (globalized) distribution), and six columns representing different types of distribution; the columns are grouped in *insourcing* and *outsourcing* (distribution inside and outside of an organization). Globalization (distribution in the international dimension) emphasizes a focus on the cultural differences between the global sites, which emphasizes the problems of cultural differences between the sites – multicultural teamwork. However, it is worth noticing that a multicultural work environment may also exist in one site and national organization-level collaboration in the case where employees represent different national cultures (which is becoming more and more common). The difference, however, is that on international level it is a question of *organizational* and *managerial* issues, on national level only *managerial* issues.

The organizational distribution categories in Table 1 indicate the following main types of distribution: *outsourcing* - transfer of work related to one activity outside one's own organization to an external contractor; *rightsourcing* - transfer of activities related to one activity to several external contractors; *multisourcing* - several activities outsourced to several contractors; *cosourcing* – several organizations have a permanent collaboration network to implement several related activities; the *broker* role indicates the situation in which the work is outsourced to independent external contractors that have loose connections to the "activity owner".

The aim of this section is to point out that distribution of work is no trivial matter but has several dimensions to be taken into account. The multicultural issues related to it are discussed in the next section of this paper. The author(s) have dealt with organizational issues in earlier papers ([14; 15; 16]).

V. CULTURAL ASPECTS

The culture-dependent features of human behavior are based on a layered structure: the lowest (innermost) layer represents the characteristics of human nature, the next culture, and the third (outermost) personality (Hofstede's pyramid model [17, p. 4-7]). National culture related practices are based on culture-dependent values, rituals, heroes, and symbols (onion model). The *cultural stereotype* is based on modeling cultural differences – typical features according to which people in different cultures differ from each other. There are several studies related to this topic; the most commonly used and widely known are the models of Hofstede [17] and Lewis [18]

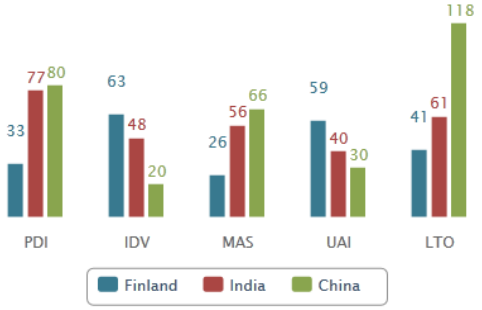

Figure 5. Stereotype analysis of Finland, India, and China according to the Hofstede model

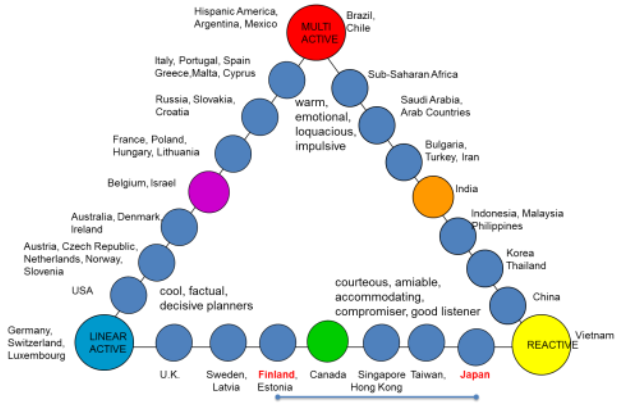

Figure 6. Cultural stereotypes according to Lewis' model.

The model of *Hofstede* [17] uses six dimensions (indices) providing a means to analyze behavioral differences between cultures:

- Power Distance (PDI): the extent to which power differences are accepted
- Individualism / Collectivism (IDV): the extent to which a society emphasizes the individual or the group
- Masculinity / Femininity (MAS): the general values in the society – hard / soft values
- Uncertainty avoidance (UAI): the extent that individuals in a culture are comfortable (or uncomfortable) with unstructured situations
- Long-term / Short-term orientation (LTO): the extent to which the delayed gratification of material, social, and emotional needs are accepted
- Indulgence / Restraint (IVR): acceptance of enjoying life and having fun vs. controlling life by strict social norms. This value is new and available only for few countries.

Figure 5 illustrates the cultural differences between three cultures: Finland, India, and China. It indicates the main sources of cultural collisions between Finland and other cultures in all dimensions and some similarity between China and India.

Table 2. Characteristics of cultural stereotypes according to Lewis' model

Linear-active	Multi-Active	Reactive
introvert	extrovert	introvert
patient	impatient	patient
plans ahead	plans grand outline	looks at general principles
does one thing at a time	does several things at once	reacts
punctual	not punctual	punctual
compartmentalizes activities	one activity influences another	sees whole picture
sticks to plans	changes plans	makes slight changes
sticks to facts	juggles facts	statements are promises
information from official sources	prefers oral information	information from official and oral sources
follows correct procedures	pulls strings	networks
completes action changes	completes human transactions	reacts to partners
likes fixed agendas	interrelates everything	thoughtful
uses memoranda	rarely writes memos	plans slowly
dislikes losing face	has ready excuses	must not lose face

The Lewis model ([18], Figure 6) defines three basic stereotype cultures (linear-active, multi-active, reactive) representing some of the cultures on the corners of a triangle and locates other cultures on the edges; location on the edge indicates the power of the influence of two of the basic stereotypes. Some behavioral characteristics related to the three basic stereotype cultures are shown in Table 2.

Reinecke [19; 20; 21] made an interesting study as an application of Hofstede's model. She studied user interface preferences in a multicultural context. The Hofstede index values are bound to the preferences of individual users in the context of information system usage. This aspect will be discussed in more detail in Section VI.

VI. MEANS FOR SUCCESS

A. *From problems to solutions*

The discussion above has mentioned the three-dimensional problem space in successful collaboration (Figure 1): communication, distribution, and cultural aspects. We will introduce five approaches that are beneficial as a partial solution related to these problems: adaptive processes, communication based on models, communication based on icons, adaptive user environments, and adaptation in a multicultural environment. We highlight the word "partial" in connection with the solutions, because the problems will still exist and we have to be able to find means for successful collaboration by understanding the sources of the problems and taking them into account in our behavior and reactions.

B. *Adaptive processes as a solution*

Statkaityte [22; 23] uses a process approach to support better quality in collaboration. The context of the studies is IS development; in the ICT business, mature organizations typically follow their predefined processes (e.g. following the principles defined by [1; 2; 3; 4] that are standardized in their quality management handbook).

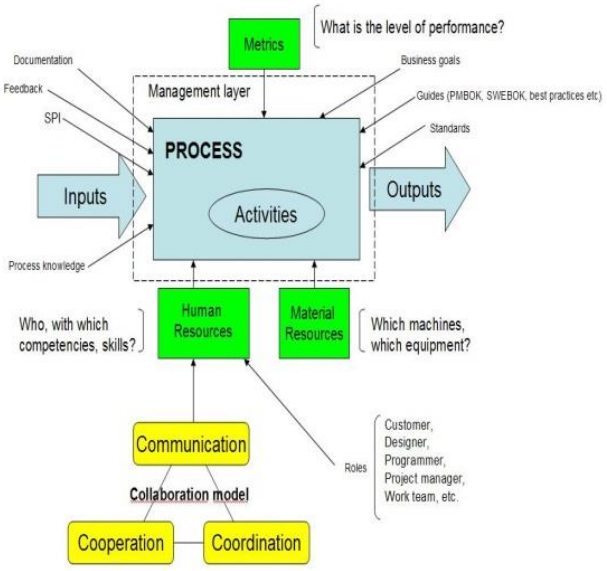

Figure 7. Culture-sensitive process definition

It is very typical that globally operating organizations apply the same processes all over the organization. In a way this helps to manage operations, but simultaneously

this approach does not take into account the differences of people from different cultures, nor does it take these differences as the driving force for some operations. There are differences in the culture sensitivity of processes: some engineering work processes are not culture-sensitive, but some human-related ones (organizing work, people management, communication-intensive processes, client interface related processes) are. In her thesis [22], Statkaityte has introduced an analysis tool called CSAM (Culture Sensitivity Analysis Model). The model extends a typical process model (components connected to the upper part of Figure 7) with human resources related factors derived from the collaboration model. The CSAM tool itself is based on Hofstede's dimensions, which are ranked for each process by the representatives of individual organizations.

C. *Models in communication*

Problems related to communication were discussed in detail in Section III. There are several sources of problems, among them the language used in communication and the conceptual models of the communicating partners. In the IS development concept, natural language is usually replaced by models – formal or semiformal. Using models in communication avoids the basic problems related to natural language: it is not exact, there are a lot of opportunities for misinterpretation, expression becomes long, and it does not provide means for abstractions.

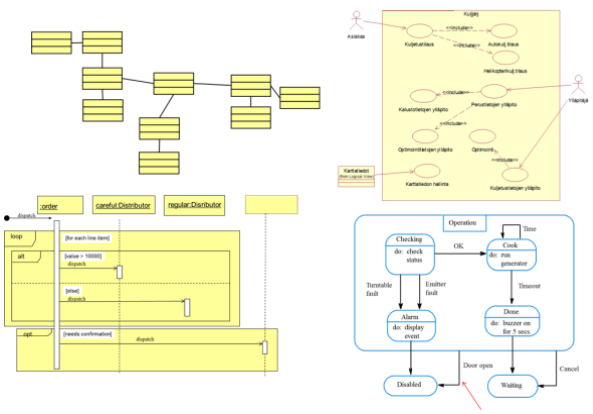

Figure 8. Semiformal model notations

The usefulness of languages in communication can be analyzed according to two factors: ease (naturalness) for users, and exactness. Unfortunately, these two factors are the opposite of each other. Natural language is easy, but not exact; formal language (Z, VDM, …) is exact, but needs special study to become useful. Semiformal languages are somewhere between these two extremes. The standardized (set of) communication language(s) in the IS development context is Unified Modeling Language (UML) [24; 25]. Figure 8 introduces some UML notations (class diagram, use case diagram, process diagram, and state chart diagram). The benefit of using this kind of visual notation, compared to the use of natural language, is its power for *abstractions*; only the elements in focus of the target system are illustrated in the model, non-important details are dispelled or used to complete the basic notation in the form of natural language explanations or using the OCL (Object Constraint Language) of UML.

D. *Icons in communication*

Khanom has studied communication in requirements engineering (RE) work.

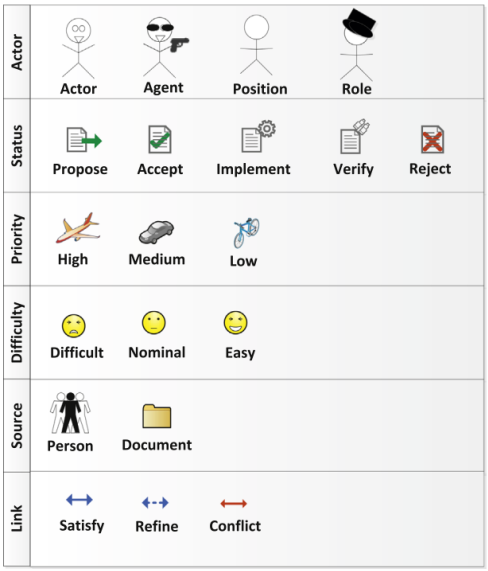

Figure 9. Elements of icon language used in RE [26]

RE is one of the most challenging phases of IS development [26; 27]. It is the starting point for further development and demands intensive communication between the client and the developer. Misunderstanding and the inaccurate specification of requirements is the main source of quality problems in information systems. In addition, wrongly interpreted requirements are also the main source of conflicts between customer and developer organizations. In her PhD thesis and related articles, Khanom has developed a basis for using icon languages as an essential part of communication in the RE context

Icons are used to visualize the requirements to make them more understandable for non-experts. The icon language proposed is culture-sensitive; the culture-related properties are based on Hofstede's dimensions according to an icon-based information modeling schema [27, p. 44] and User Preference Model [27, p. 45]. The metamodel binding the icons to the requirements specification are defined by a metamodel called Requirements Attribute Schema (RAS; [27, p. 41] developed a metamodel. The User Prefernce Model has some similarity with Reinecke's user model discussed below.

E. *Adaptive User Environments*

Reinecke's work combines user interface design with Hofstede's dimensions; in our case it is a question of human computer interaction related aspects (see Section III) in avoiding communication problems. Reinecke's work is based on two main components: the *User Model (UM)* and an *adaptive user interface* (called MOCCA; it implements 115 000 different culture-dependent user interface versions).

Reinecke's UM is based on the Cultural User Model Ontology defined in [21, p. 436]. It covers the user's

demographic data, like birth nationality, parents' culture, year of birth, political orientation, social structure, religion, educational level, and computer literacy. In addition, the model takes into account the time an individual has spent under the influence of a foreign culture. The "*user's extended national culture*" is a changed and enriched modification of the *culture by birth*; a mathematical model (simply length of stay / age in months; 21, p. 436]) is used to modify the parameter values as a consequence of the external cultural influence; we use the term "*adapted culture*" for this modified culture, because it is not only a question of extending the cultural base, but also "overwriting" (replacing), deleting, and modifying it.

Table 2. Relationships between Hofstede Dimensions and UI Design (modified from [21; 28])

Index	Low	High
PDI	• access variations, non-linear navigation • non-structured data allowed • most information at interface level, deep hierarchy not accepted • friendly messages • need for support is low	• linear navigation, few links, minimal amount of alternati • structured data expected • data in hierarchy, little data on top level • strict messages • support must be available
IDV	• traditional colors and images • image to text direction • high multimodality • colorful expression	• colors used to encode information • text to image direction • low multimodality • monotonous color map
MAS	• little saturation, pastel colors • exploration and different navigation paths allowed • personal content presentation and friendly communication	• high contrast, bright colors • restricted navigation possibilities • encouraging words in communication
UAI	• most information at interface level, complex interfaces • nonlinear navigation accepted • colors, typography and sound to maximize information	• organize information hierarchically • linear navigation paths, guided • redundancy and cues to avoid ambiguity
LTO	• reduced information density • content structured into small units	• most information at interface level • content can be arranged around a focal area

The studies of Myers and Tan [29] have a focus similar to that of Reinecke. They suggest that in the IS context the concept of "national culture" should recognize its emergent and dynamic nature: "It is something that is invented and re-invented and always in a state of flux". This points out an important aspect - people are forced/pressurized to change their traditions for several reasons and they are also constantly under the impact of foreign cultures. In the globalizing world, culture is becoming more and more global and does not follow national borders. This approach is handled in one new paper (Jaakkola & Thalheim) from the adaptive web information systems development point of view; not published, under work.

F. Adaptation of the Organization

The thesis of Harjamäki & Kostin-Harjamäki [30] analyzes the problems that may appear in an (IS development) organization between two groups from significantly different nationality backgrounds (India, Finland). In addition to the need for daily multicultural multi-site teamwork, there was the issue of acquisition, merger and organizational migration from Finnish ownership to Indian; there was pressure to adopt Indian culture at the Finnish sites of the company. The thesis argues that merging companies representing two different nationalities have everyday collisions due to culture differences. Problems relating to migration on a general level have been handled by (two of) the authors in [31]. Its findings also fit the company cases analyzed in the thesis.

The thesis proposes a *multicultural strategy development* to adapt the organizational and daily practices in this bi-cultural environment. It introduced (principles of) a tool for strategy development that guides adaptation strategy development in three steps: (1) Strategy goal analysis (ideas, vision, values); (2) Action points development (activities, processes, resources); (3) Implementation plan development. The thesis introduced a structured education/trainee package for the company to accelerate cultural adaptation. The package took into account the different roles and tasks in the organization and it covered needs of both trainers and trainees. The thesis introduces a five-level framework (maturity model) – Culture Intelligence Level (CIL), which defines the steps towards better management of multicultural aspects on the personal and organizational level.

VII. CONCLUSION

The paper focused on the analysis of problems that relate to collaboration. Three important aspects are identified for deeper analysis: communication, distribution of work, and cultural differences, which have increasing importance in the rapidly globalizing (business) world. All three aspects are handled in detail along with different problems related to globally distributed multicultural collaboration-based work. Our context comes from our own research area – information systems development – which is a typical example of work conducted by highly skilled experts (DCCI – Distributed Cross-cultural Collaborative Intellectual). The paper concluded the discussion by introducing five solutions for avoiding communication problems: Adaptive processes, Models in communication, Icons in communication, Adaptive User Environments, and Adaption of organizational practices. This paper does not go into all the solutions in detail. The solutions introduced are not possible to compare with each other – successful application is very context and situation dependent. Some of these have been handled in earlier publications by the authors, some belong to the further work planned on this interesting and important topic, which constantly raises new aspects for deeper study.

ACKNOWLEDGMENT

We would like to thank the Academy of Finland and the German Academic Exchange Service (DAAD) for supporting this research.

Abstract – The current economic crisis and high unemployment rates especially among younger than 25 years old requires also re-thinking of teaching practices. Universities should produce not only professional skills, but also strong business-oriented mindset. Our graduates should be able to create new innovative products, start new enterprises and be prepared to apply all learned skills in business. This mindset can be developed using project- and product-oriented (PPO) approach in teaching, where whole course is built up as a series of projects; the course assessment is based on individual projects, which should produce a finished product with some (commercial) value. We have successfully used this approach for several years; in the presentation is described a PPO oriented game programming course.

I. INTRODUCTION - WHY ?

Many educators still see their task in preparing students with technical skills needed to accomplish some technical tasks. They suppose, that in the work life somebody (employer) gives tasks what employee (their former student) carries out. But - from where should appear such employers? Traditional work and workplace, which workers visited for fixed hours in order to produce tangible, physical values is more and more divided into discrete tasks; more complex tasks (which are not yet accessible to robots) are assigned to humans just when they are needed. More and more people are becoming self-employed workers, who should themselves seek for new tasks to implement. They should constantly look for new ideas, invent new products and be able to materialize their ideas as commercial products.

Advancements in technology and rapid changes in human society are constantly reshaping our teaching/learning/training practices, both their content and form. Computers and robots have made obsolete many traditional professions and the temp is all the time accelerating - there are already opening hotels without human personnel - the whole staff are robots [1], in the next decade cars will become driverless, and every day there appear new examples of professions which are not needed any more. The whole concept of 'work' is rapidly changing. Traditional work and workplace, where workers come for fixed hours in order to produce tangible, physical values is vanishing. Big enterprises are reducing staff and outsourcing, work is more and more divided into discrete tasks that can be assigned to self-employed people just when they're needed [2].

Humans work will more and more be intellectual and creative. Mechanical work - moving around things or tools - this can and will do robots. But robots are (not yet) good at creative tasks - creating poetry, stories, movies, games - all kind of 'content' - everything, what we seek in WWW. There are already robot rock bands [3], computer-generated rock-stars [4], even computer-generated video games [5], but robots/computers are (yet) not very good creators of intellectual content, they are (not yet) good in Science and Math. For our current students these fields - creating intellectual, artistic and/or entertainment content (games) will be the most promising engagements in their future work. Game Programming is probably the easiest way for IT students to start earning as independent (Indie) game developer.

The tendency to become self-employed, independent entrepreneur is especially visible in all Information Technology (IT) fields - you can work everywhere, if you have a laptop with (wireless) Internet connection. Currently 26.2 million people in the EU are unemployed [6], especially high is unemployment rate among youth – e.g. in Croatia 52.4% of younger than 25 are unemployed [7]. The situation is somewhat similar in all post-soviet countries – the big soviet-time enterprises with obsolete technologies vanished and it takes time for some replacements to appear. In Estonia, especially in the IT field the employment situation is already improving – we have many new IT-enterprises (Skype, Playtech) and new innovations - the digital ID-card and mobile ID, digital parking, E-Residency Digital Citizenship etc. And all these innovative ideas come from individuals, from people, not from some big faceless organizations. In IT terminology – innovative ideas appear/emerge bottom-up, from individuals, not top-down, from big organizations.

The best prospect for our students is also not to seek employment from some big international corporations (who are outsourcing to cheaper countries) or to move out in hope to find greener pastures (the 'brain draw'). If they care for their country and its future then they have to do something for this future. In practice this means self-employment, becoming independent entrepreneur, inventing the future.

The task for educators is creating necessary attitudes, prepare students to be not only professionals in their field, but also businessmen. This is even more important than providing technical skills, especially in the rapidly developing IT field. Many of the technologies which we teach today would be obsolete in 5-10 years (some even quicker). In order to be competitive, to make living in IT should everyone himself keep track of IT technology developments – the 'lifelong study' is necessity. You should be able to find everything new, but also create 'added value' yourself - create new products, services, something what you can sell. Bill Gates and Steve Jobs did not graduate, but they had very good entrepreneurial

and innovative attitudes, created lot of 'added value' and could sell their products.

Being your own boss requires that you also think like a boss - not like an employee, who does, what he is told to do.

You should constantly seek for new opportunities, invent new approaches, technologies, products, new services and learn everything new what have invented others. And you should always bring your projects to (successful) end - commercially valuable product; nobody needs a half-working demos.

You should be able to communicate, to market yourself and your ideas and always be on lookout for better opportunities to advertise your projects, products and services.

This is the mindset, what we have to inculcate to our students.

II. How ?

The task - combining teaching of IT skills with developing entrepreneur's and advertiser's mindset can be certainly achieved in several ways. By our experience the most useful is the project- product oriented approach.

The project approach: the course is presented as a series of consecutive projects which are introduced in lecture and implemented during one (some in two) 90-min exercise in computer class.

The product approach - every project should end with a finished product, implemented in class (or – with working students - in home). There should be a tangible output, not just a vague impression of hearing/learning something new. Hearing something new is not yet learning this 'new' – you have to go through this 'new' step-by-step in order to learn it.

From our experience, communication is for many IT students a very 'weak spot'. They believe, that their most important skill what they have to accomplish is programming. But nobody will know about their value, skills and programs if they cannot advertise those abilities and not to computers, but to people – people decide, what to buy, who to promote; we are (still) governed (mostly) by people. Therefore with every individual project should be presented also an explanation/help of the project (in natural language – humans still use it). Correcting language in these texts takes often more time than pondering the value/assessment of the whole project.

III. Learning by chunks

Every project should give students some new knowledge, some new (interrelated) skills. Presenting a course as sequence of self-contained projects which finish with some product having practical value inevitably causes division of course content into chunks.

Chunking is the main mechanism of human memory. Importance of chunking was recognized already in the 1940s and 1950s in perception, learning and cognition studies (see e.g. [8], [9], [10]) and the concept has often been used also as a principle of course design (see e.g. [11]).

Chunking is the natural presentation style for most teachers but unfortunately not always present. The first author has (still terrifying) experience of the first lecture as a young student (math), which began without any introduction with 'Cantor Cut' – a term difficult to explain to non-mathematicians and also to fresh high school graduate.

New information should always be introduced in consumable chunks and always considering the context - the previous knowledge of receivers. This requires careful planning – a topic for the new project (chunk) should not be too simple (mostly repeating some earlier experience with some new twists – this is suitable for additional exercise), but also not too complex (should allow implementation in one 90min exercise). The best is, if students themselves consider what is important to know/do next. Student's curiosity can be ignited with questions – "But if we want to do/achieve this…?" and they can produce some surprisingly good results and start investigate some totally new technologies, e.g. in this course one student become fascinated with SVG (Scalable Vector Graphics) and implemented his own game using SVG (hand-written, no SVG editors were used) graphics.

IV. Classroom Projects

In the following is brief description of projects which the first author uses in his course "Game and Virtual World programming" in Tallinn University of Technology. Every project is a game (or some improvement to a game produced earlier). All games introduce some new theme/topic (chunk) and have been selected for their simplicity, so that students could create finished product (game) during one 90-min exercise in computer class.

This course is for first year IT students, thus does not require good programming skills. The main technology used in this course is HTML5 – canvas, JavaScript, CSS3. This is currently the most popular technique for communication and distribution of digital content and also most convenient technology for students to become indie (independent) game developers. In their individual projects (games) themselves discovered and used also other technologies, e.g. Unity3D.

Course requires some digital image and sound-handling skills needed to manage game graphics and sounds and proficiency in handling computer file system - if for a game is downloaded an external library, which often has a complicated structure (e.g. three.js [12] - 195 MB, 6 levels of sub-directories), then students should be able quickly find from the library necessary files. Nobody had any problems and several used already some external storage techniques (GitHub, Microsoft Cloud) for hosting their projects.

First Game - Mushroom Picker: introduction to HTML5 and canvas, creating canvas background image with CSS, placing three sprites (tree, hero and mushroom) to canvas, moving hero with arrow keys, checking hero-mushroom collisions; on collision the mushroom appears in another random location. Player has in limited time collect as many mushrooms as he/she can, so with finished product students could already start competitions.

Figure 1. The first game - player should collect mushrooms.

Next - improvements to the previous: animating hero (making steps, but still only in one direction - adding just three frames to hero sprite), replacing tree sprite with graphically more pleasing randomly selected ones.

In the next project was created sprite sheet for hero with animated movement in 4 directions, sprite sheets for various mushrooms and obstacles (tree stumps, stones), JavaScript loader for external objects (sprite sheets, sounds), JavaScript objects for animated hero and animated (growing and deteriorating) mushrooms and introduced several canvases: the underlying canvas - for static trees, the upper canvas - for dynamically moving/changing game objects.

In the following projects were considered tile-based and isometric games: tile-based game data structures, various types of isometric grid, placing objects to grid tiles with script, tile-based collision checking, hero movement along diagonal grid, sprite mask; physics was introduced with the Box2D library and 3D - with the three.js.

Figure 2. Mario in isometric wood, the wood is procedurally generated

Step-by step were introduced more complicating elements (title screen, level selection, use of webfonts), and more demanding techniques. And the results become more and more playable as 'real' games. The map was in several projects procedurally generated labyrinth, thus students could in new projects re-use many parts from previous projects.

Figure 3. Cristmas Game - Santa has to collect his lost parcels .

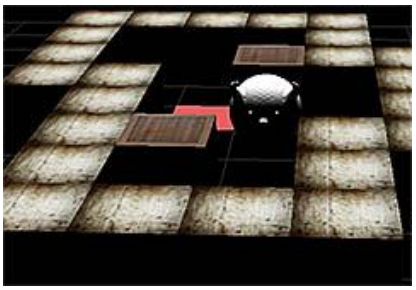

Figure 4. Sokoban - 3D game, created with tree.js library

V. HOMEWORK PROJECTS

Most of our students work, thus they prefer working at home. For all course (classroom) projects were created detailed tutorials, thus everyone could implement projects just inspecting the tutorial; even in computer class students asked very few questions, just studied the tutorials or googled to get answers for their problems.

In tutorials the main theme of a game was already set. Playing a variation of already existing game is not very exciting. Games are contemporary art, food for our intelligence; in order to become a successful game author one should introduce some new ideas, new twist create a totally new game. In order to pass the course all participants had to prepare two individual projects. The topic and implementation technique were free in both.

The first project was assessment of an existing game which students could freely select. For the assessment was prepared list of issues (game topic/flow, rating, implementation quality, graphics), which should be covered. This assessment (with pictures, video- and sound-clips from the game) should demonstrate communication skills and general understanding of games as a new media.

This task produced several technically very well implemented video trailers of commercial games.

The second (main) project was an individually designed and implemented game. This is not a simple task, but 96% of participants managed to present very interesting finished games. They had spent several weeks designing art, levels, and (in some projects) even complicated AI. The presented games covered very different themes: horizontal scrollers, racing, shooting (in deep space, defending villages in Ukraine), computer networks, kindergarten math education, exploring player's visual and mnemonic capabilities, fighting smoking etc. In the following are some images from presented games.

Figure 5. 'Lost Cat' (html5): player has to move a cat trough wilderness, full of angry dogs, who start actively pursue (AI) the cat.

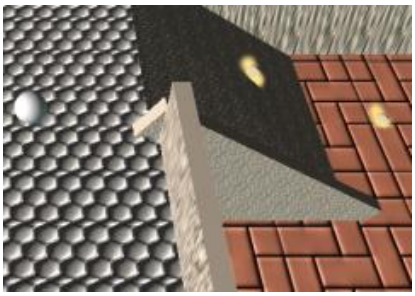

Figure 6. 'Vagabond Ball' (Unity) - player has to collect trophys and fight physics forces which try to move ball from playground.

Figure 7. 'Minimana' -(html5, all graphics - hand-written SVG), hero (red) has to collect mana (blue) but avoid falling mines (orange).

Figure 8. 'Smoking Game - Your way to the Grave' - player has to collect and destroy all sigarettes.

Several games produced in this course (in this and in previous years) have already been products with commercial value and have appeared in on-line shops (for Android or iPad) or in game sections of websites. This is the best achievement of this course.

mholenko@inf.uniri.hr

Abstract - This paper describes a collaborative learning process using Web 2.0 tools and ELARS (E-learning Activities Recommender System). The Web 2.0 approach stimulated the development of our own e-learning models that can be applied to different types of e-courses. Within the research project "E-learning Recommender System" a didactic model of using Web 2.0 tools in e-learning activities was developed. Combining LMS with Web 2.0 tools and using recommender system for personalization of activities make our courses at the Department of Informatics and Faculty of Teacher Education much more interested and challenged.

I. INTRODUCTION

New approaches in e-learning are based on teaching model using the constructivist theory of learning. This model is student-centred and it is using various Web 2.0 tools for collaboration, communication, sharing learning materials, tagging, etc. [8].

The learning process that includes social software in e-learning is called E-learning 2.0, due to Web 2.0 tools that are used to enhance the process of learning itself. Web 2.0 tools enable a shift from a distributive to a more collaborative mode in e-learning. In particular, the ease of use and simplicity of Web 2.0 technologies allow creating learning environments, which can realize activity-rich pedagogical models and facilitate students' development of competences [14].

Today students enter institution with some experience with Web 2.0 tools such as wikis, blogs, YouTube, Facebook, but they lack an awareness of how those tools can be used for learning [5]. Siemens and Matheos [15] suggested two trends in education: learners have freedom to access, create and recreate their learning content, and they have opportunities to interact outside of a learning system.

Student-centred didactical models presents the work in progress as part of the research project "E-learning Recommender System" with main goal to develop didactical models for realization of e-learning courses in Moodle based learning management system MudRi, supported by Web 2.0 tools and ELARS (E-learning Activities Recommender System). These courses will, besides the usual activities supported by LMS, include personal collaborative e-learning activities (e-tivities).

The second part of this paper describes the e-learning 2.0 process. The third part is explaining building parts of the model: e-tivities, Web 2.0 tools and ELARS recommender system. The fourth part gives overview of the "E-Learning Recommender System" project. The last part brings conclusions and future work plans.

II. E-LEARNING 2.0

While the first generation of e-learning has been oriented on distributing learning materials and modest communication between the participants of learning process, e-learning 2.0 includes changes that facilitate participation in learning as well as interaction and collaboration between students rather than continuous focus on subject matter knowledge.

E-learning 1.0 was based on the idea that teaching is transmissive task. Teacher present topics, distribute learning materials, and communicate with students about those learning materials. E-learing 2.0 emphasises the proactive role of the students. Learning is perceived as an interlinked social process, in which students use Web 2.0 tools to develop learning outcomes. They do not only use the already distributed learning materials, but also collaborate and extend their learning activities to open content on the internet [13, 14].

Many students did not traditionally participate in any decisions relating to their learning environment. E-learning 2.0 enables students to choose, create, share and publicize their learning materials [5]. Students are actually building their own personal learning environments not only with collecting (consuming) the learning materials but also with producing a significant amount of learning content [11].

While considering the pedagogical aspects of e-learning, it is necessary to include elements that comply

The research has been conducted under the project "E-learning Recommender System" (reference number 13.13.1.3.05) supported by University of Rijeka (Croatia).

with different theories of learning: behaviourism, cognitivism and constructivism. However, e-learning 2.0 promotes constructivism according to which students should be active participants who do not remember teaching materials literally, but create their own versions of the course content by exchanging views and opinions with their colleagues [6, 10]. The teacher is still an important participant of that process, although his/her main task is no longer transmitting the knowledge but guiding students in the process of acquiring knowledge [6].

The process of designing the e-learning 2.0 environments is grounded in socio-cultural learning, which is in a constant cognitive development with the power of dynamic social interaction. Cognitive learning focuses on learning processes and development trough creating, editing and remixing learning content socially and collaboratively [3].

From technological aspects, e-learning 2.0 can be supported with combination of functionalities of an LMS that are equal for all users, and appropriate third-party services available on the Web [6, 7]. Thus, the environment for e-learning 2.0 consists of a set of tools. Different students can use different tools and create their own personal learning environments (PLE) [6]. According to Attwell [1] and Costello and Shaw [4], PLE is not a specific tool, but rather a way of organizing resources. Although today Web 2.0 tools usually have a central place in PLEs, it can also be comprised of learning materials, peers, hardware, and other components that allow students to collect, process and share information and knowledge [8].

Today students need more than simply consuming the offered learning materials. They should be provided with challenging situations instead of ready-made instructions that are put in rigid and closed environments [16]. With PLE the learning outcomes change from knowledge acquisition to competence development, making students more motivated and satisfy.

III. USING WEB 2.0 TOOLS AND RECOMMENDER SYSTEM FOR E-TIVITIES

Didactical models developed during the research presented in this paper are in line with the e-learning 2.0 approach and are based on collaborative e-tivities. Web 2.0 tools enable realization of different e-tivities and therefore, represent one of the building parts of our didactical models. In addition, the personalization of e-tivities is achieved using the educational recommender system ELARS which extends the environment for e-learning.

A. E-tivities

An e-tivity is the interaction of a student with other students using specific tools [17]. It is achieved through completion of a task and oriented towards specific learning outcomes that should be achieved [8]. The components that constitute such activity are: the context within the activity occurs (the subject, the learning outcomes, and the environment within which the activity takes place), the pedagogy adopted (learning and teaching approaches) and the undertaken tasks. The task specifies the type of task, the resources (e.g. teaching and learning materials, tools), the interaction and roles of the participants involved (e.g. work in pairs or groups) [6].

Teacher, as an important participant of the e-learning process, designs a task. The task defines required learning materials, tools that can/should be used for e-tivity and mode of interaction between participants. For e-learning 2.0 more significant are e-tivities where the task is group-based and involves collaboration [6]. Besides defining a task, teacher should also support students during the e-tivity in order to encourage them for participation and collaboration with their peers.

B. Web 2.0 tools

Web 2.0 tools are shifting the e-learning process to personal learning environments (PLE) where students can organize and collect learning resources on their own way [1]. Depending on task, an e-tivity can be performed with one or more tools, which means that it is not necessary that all students use the same tools.

In the current stage of our research, developed didactical models include one of the nine Web 2.0 tools [8], described in the reminder of this section.

Blogger is a tool for publishing blogs. The characteristic of blog is commenting, tagging and linking. In the majority of blogs, visitors are allowed to write comments under each entry. This enables exchange of views between the author on the one hand and a group of people who all contribute by writing comments on the other. In order to facilitate subsequent retrieval of published records and searching similar content, records can be bookmarked by specifying keywords that categorizes the entry. Blogs can be individual or collaborative and connected in groups' topic. In e-learning environment, blogs can be used as a personal journal for learning. Students can independently express their opinions on learning materials as well as conclusions from learning.

Diigo is a tool for collecting and organizing bookmarks and other resources. In e-learning, it can be used for organizing and sharing favourite internet resources about learning topics. One of the goals is to create a common review on the teaching content.

Flickr is a tool for photo management and sharing. Some of the key elements of the Flickr are tags, common clustering and ranking of interesting facts. Students can store, organize and view photos within the group or individual e-tivities.

Google+ is a tool for social networking, sharing and communication. It can be used in e-learning with its *Circles* application that allows creating a group of users who can actively engage in the creation of content for the Web and participate in publishing and exchanging of learning materials working together. Furthermore, Google+ provides the tool called *Sparks*. This tool is looking for videos and articles that it considers interesting for the user. This service enables the teacher and students to monitor the current issues that can be applied in the

teaching process and update their knowledge of the potential new findings related to the topic.

Google Drive is a tool for creating and sharing documents (textual documents, spreadsheets, presentations, forms). Those applications allow students to create and edit documents online while collaborating with each other in real-time.

MindMeister is a tool for online mind mapping and brainstorming. A mind map is the most common teaching aid in all educational areas. During e-tivities, students can use this tool for presentations, for the purpose of allocating tasks, graphical explanation of concepts, for reviewing topics, to prepare for the assessment, the exchange of ideas and information and simultaneous work on the map.

SlideShare is a tool for sharing presentations. In e-learning, using this tool students can cooperate at the local level but also with a virtual community where they can make, share and collect teaching content.

Wikispaces is a tool for creating wikis. Wiki is very well suited to support collaborative online learning since it fosters collaborative writing. Therefore, it can be used in various forms to fit into e-tivities in which students need to summarize subject matter in a written form, present results of conducted WebQuest and similar.

YouTube is a tool for editing and sharing videos. As one of the most popular media tools YouTube has vast application in the teaching process. In e-learning environments, textual materials can be enhanced with animations and video content. In addition to the publication of teaching materials in videos, it can be used for displays of various examples, instructions, guest speakers recording, multimedia presentations, etc.

C. ELARS recommender system

Within this research a recommender system ELARS (E-Learning Activities Recommender System) was developed. It provides personalization in the context of collaborative e-tivities realized using Web 2.0 tools [7].

Recommender system is used in parallel to LMS and Web 2.0 tools [8]. Students use LMS to read previously prepared materials for learning, to get instructions, to communicate with each other and with the teachers and Web 2.0 tools to perform e-tivities. They use ELARS system, as a third component of the e-learning environment, to read recommendations before and during e-tivities.

Recommendations are generated based on several characteristics: student's learning styles, Web 2.0 tools preferences, knowledge level and activity level. Learning styles and tools preferences are collected explicitly using the feedback from users. Data regarding the other two characteristics are collected implicitly. Knowledge level is automatically calculated according to the results of (online) tests, while activity level is automatically estimated based on the data about students' interaction with the Web 2.0 tools. Activity level represent quantity and continuity of student's contributions relatively in respect to others students and group's contributions relatively in respect to other groups. The important part of our research are novel procedures for assessing student's (group's) activity level based on data collected from Web 2.0 tools.

Data regarding students' characteristics, including activity level, are used in recommendation rules in order to recommend possible students-collaborators, Web 2.0 tools or optional e-tivities, as well as to generate advices regarding participation in e-tivities [8].

IV. E-LEARNING RECOMMENDER SYSTEM PROJECT

Development of didactical models that can be applied to different types of e-courses was conducted within the research project "E-learning Recommender System".

A. Goals and Tasks

The purpose of the research was to improve the quality of higher education by introducing innovative computer technologies in the processes of teaching and learning and the promotion of new pedagogical approaches of e-learning 2.0 through the presentation of case studies.

The project included activities to meet specific objectives of the research:

- the development of algorithms and model of recommender system and its implementation
- the development of new models of learning based on collaborative learning and developed recommender system,
- the educational design with e-activities for different types of courses that will be realized in practice with the support of the recommender system,
- the designing the recommendations for the implementation of the developed didactical models and recommender system in the context of higher education.

B. Didactical models

Our didactical models are based on observing the process of e-learning as a sequence of (collaborative) e-tivities, on using Web 2.0 tools for their realization, and on using recommender system for personalization of e-learning process according to student’s characteristics [8].

Research provides scientific innovation in the field of e-learning with technological and pedagogical aspects. The recommender system, as one of the main results of the project, was used to determine personalized recommendations for the students in performing a sequence of collaborative e-activities with the help of learning management system and Web 2.0 tools.

In this way, with a new approach to the use of computer technology to support education, research promotes new pedagogical approaches that emphasize the need for collaborative learning and are based on the performance of e-activities.

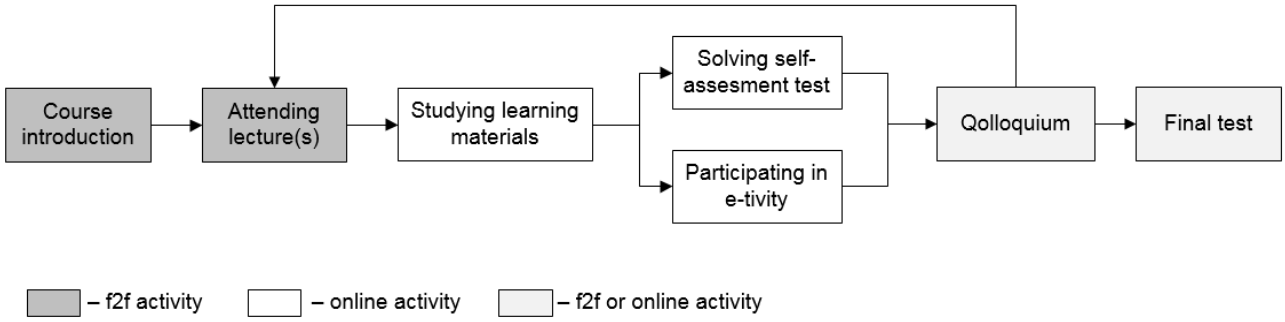

Figure 1. Course design by sequence of activities

It is expected that the application of the above mentioned learning model in practice result in increased performance and motivation of students which will be evaluated in the context of different types of e-courses that are conducted: face-to-face (f2f) courses with online available contents, mixed mode (blended learning) and fully online courses. For the purpose of the project some of e-learning courses in Moodle based LMS MudRi on University of Rijeka were adopted. The courses workflow includes individual and group-based e-tivities that are realized using Web 2.0 tools. The approach was used for two e-courses at the Department of Informatics ('Hypermedia in education' and 'Operational research') and currently is used for one e-course at the Faculty of Teacher Education ('Extracurricular informatics and technical activities'), University of Rijeka, Croatia.

During blended learning courses, a course introduction is followed by sequence of activities that are realized in f2f or online environment. These can, as shown in example presented on Fig. 1, include lectures in f2f environment in order to present subject matter to students. Students are usually required to study prepared learning materials that are available in LMS. Sometimes, students have opportunity to test their knowledge using online tests for self-assessment. In addition to self-assessment tests, e-tivities can also be used to ensure formative assessment before colloquiums. Depending on number of topics covered by the course, such sequence can be repeated. At the end, students' knowledge can be assessed using final test.

Personalization provided by the ELARS system is based on course learning design that describes the sequence of course activities. Between course activities, e-tivities (eLA) are the most important. Activities sequences can also contain f2f activities (FA), learning content activities (CA) and testing activities (TA). Besides that, it should be stressed out that planning e-tivities often requires planning additional e-tivities that are not directly oriented towards achievement of learning outcomes, but support the organization or personalization of e-tivities. Those are support activities (SA) and decision activities (DA).

ELARS system recommends collaborators if corresponding e-tivity is group-based. The system recommends the most appropriate tool for student or group to fulfil the aim of e-tivity if more than one tool is offered for its realization. Optional e-tivities are recommended when students are allowed to choose between several e-tivities and advice is offered during e-tivities, in order to encourage students to reach higher activity level. To enable this, the original recommendation model is developed.

Fig. 2 presents a didactic model with activities sequence that precedes the collaborative e-tivity personalized using ELARS recommender system. Before an e-tivity starts, students should get instructions with description of task they are supposed to do and other details relevant for the realization of the e-tivity (is it individual or group-based, duration, evaluation criteria, etc.). For that purpose, support activity is used.

In order to achieve personalization using recommendations, decision activities should be planned. If the e-tivity is group-based, collaborators recommendations are presented to students within corresponding decision activity in ELARS systems. Similarly, if there are several tools offered for the realization of the e-tivity, tools recommendations are presented. During e-tivity, additional support to students is provided in a form of advice regarding quantitative aspects of students' engagement. Therefore, students need to enter input data to the ELARS system in order to enable activity level calculation and advice generation. E-tivity can be followed by presentation of students' results in f2f environment.

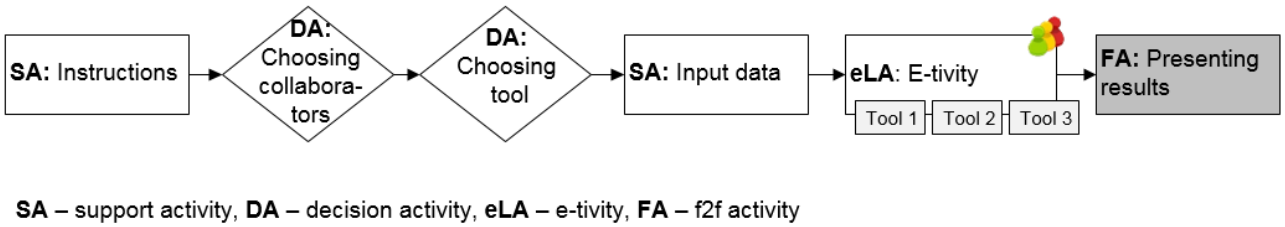

Figure 2. A didactic model of one e-tivity

C. Evaluation

The educational verification of e-learning model is in the progress, as well as the recommender system impact on student's performance in e-tivities.

We are now in stage of final evaluation that is conducted in order to determine the impact of the recommender system on student's performance during e-tivities and how collaboration affects the learning process itself. Before this final evaluation, several components were already tested. Selected Web 2.0 tools were previously used within e-learning courses. They found to be reliable, and that their performance matches the expectations and needs in practice [8]. Validation of the algorithms for assessing student's (group's) activity level was also conducted with aim to determine to what extent obtained values match the actual state [8].

Our goal is to determine whether proposed didactical models increase student's effectiveness and motivation for e-tivities included in e-courses. In addition, students' satisfaction with received recommendations will also be examined using questionnaires.

V. CONCLUSIONS

Development of didactical models described in this paper was enhanced with LMS, Web 2.0 tools and E-Learning Activities Recommender System - ELARS. Such e-learning environment is based on e-learning 2.0 approach that emphasize the need for including collaborative e-tivities in e-courses learning design.

Our future work will focus on creating didactical models for different types of higher education e-courses. In doing so, the extent of using f2f/online learning will be taken into account as well as number of students - a factor that could affect the realization of e-tivities. Since e-tivities included in the models are personalized with the ELARS recommender system further efforts will be made to improve the system. This include additional experiments to evaluate recommendation algorithms and making ELARS web application in line with the responsive web design, so it can be used on different devices, from desktop computer to smart phones. The recommender system will be open source coded and implemented to support large number of users via cloud service.

Project outcomes and results, including the examples of good practice, will be presented on the website. This will enable all interested parties to be acquainted with the developed models and facilitate their use in the broader academic community.

Abstract – This article has been produced through active research within EU funded project tasked to implement recognition of non-formal and informal learning (RPL) to Croatian higher education, including all needed supporting mechanisms such as information system. Aforementioned project is part of wider national activities following recommendation of Council of European Union from December 2012, setting task of full implementation of RPL systems until 2018 in all EU member states. Research presented within this articles started from desk research of current state of play in RPL implementation across EU countries, following development of research questions and organization of survey in order to better understand requirements and attitudes of key national stakeholders. Main results of both research activities and specific stakeholder's requirements supported by statistical analysis are presented within this article, following proposal of potential information system model. The model has been built following theoretical understandings, practical implementation achievements from other countries and specific national stakeholders' requirements, and it consists of architectural recommendations, data model, and description of key "use cases", all useful as a foundation of future RPL information system.

I. INTRODUCTION

There are currently number of terms used in order to address process of recognition of prior non-formal and informal learning (RPL) such as: validation of non-formal and informal learning (VNFIL), prior learning assessment (PLA), prior learning assessment and recognition (PLAR), recognition, validation and accreditation of learning (RVA) and others. Although term VNFIL is mostly used in EU policy documents, term RPL is most common in scientific literature, and will therefore be used throughout this article as well. In order to get full understanding of the very process, one of the commonly used, self-explanatory definition of recognition is:

"*The confirmation by a competent body that learning outcomes (knowledge, skills and/or competences) acquired by an individual in a formal, non-formal or informal setting have been assessed against predefined criteria and are compliant with the requirements of a validation standard. Validation typically leads to certification.*" [1]

In number of countries recognition of prior learning has been implemented before implementation of national qualifications framework (NQF), while in others RPL has been introduced as part of NQF development. Very beginning of RPL practices could be found in USA and France after Second World War in order to provide access to labor market and qualifications to former soldiers. Stated motive of widening access to the labor market for workers which would be otherwise left jobless or doing less paid jobs is one of key economic drives to implement RPL. Still, there are number of other equally valid motives for the RPL's implementation such as: widening possibilities to access education for non-traditional learners, improving effectiveness of educational systems as well as catching fast pace of advancement in technology validating knowledge and skills obtained on the job. Regardless of the motives, RPL and its implementation become part of the policy development agenda in EU since 2000 and Feira European Council [2], following the communication from the Commission, "Making a European Area for Lifelong Learning a reality" in November 2001 [3] and being emphasized in policy documents since. Most important advancement in RPL implementation in policy sense occurred in December 2012 when Council of European Union issued Recommendation [4], indicating that EU member states should implement RPL by 2018. Stated recommendation formally introduced another strong policy obligation for member states due to the fact that Council insisted that implementation of RPL should be done using "equal value" principle:

"***Qualifications*** *or, where applicable, parts of qualifications* ***obtained by*** *means of the* ***validation*** *of non-formal and informal learning experiences* ***comply with*** *agreed* ***standards*** *that are either* ***the same as****, or equivalent to,* ***the standards for qualifications obtained through formal education*** *programmes".*

Aforementioned principle which originates from Recommendation puts significant development requirements even to the countries which already implemented RPL. In essence, stated recommendation calls for implementation of "standards" against which validation should be organized in order to present document (i.e. qualification) of equal value as one that

would be otherwise obtained through formal education. Stated two requirements in a nutshell call for implementation of national qualifications framework or similar instrument which holds national qualifications standards and for implementation of such validation process that is capable of producing validation decisions reliable enough so that same qualification certificate (document) could be presented to RPL candidates and graduates from formal programs [5]. In stated circumstances number of currently used validation practices (i.e. formative and declarative methods) are challenged and might be changed by more reliable methods based on summative assessments, similar to those used in formal education. This, in turn, put significant focus on Quality Assurance (QA) and transparency of the overall qualification award process in order to protect public interest and confidence in national qualifications. One of the potential tools to implement such RPL provision is development of RPL IT system linked to national NQF System.

II. STATE OF PLAY IN CROATIA

Republic of Croatia started development of its national qualifications framework in May 2006 and after 7 years of constant consultations with numerous stakeholders in February 2013 Croatian Parliament adopted Act on Croatian Qualifications Framework [6]. Stated process lasted longer than expected due to the fact that Croatia selected to develop its own solution instead of copying successful models from other countries, that most probably wouldn't fit to our culture and educational context [7]. By-low on the CROQF register has been introduced by Ministry of Science, Education and Sports (MSES) in May 2014, and it introduced required legal framework to start development of NQF ICT system (registers) as well as formation of Sector Skills Councils (SSC's) and National Council for Human Resources Development. Aforementioned by-low provided also blueprints for Qualification (QS) and Occupational (OS) Standards elements and set stage for implementation of Quality Assurance in respect to specific processes brought by NQF. Number of QS's and OS's are currently being developed and national NQF ICT system is in production. Still, RPL as an important element of the NQF is missing its legal establishment in the form of another missing by-low on RPL and its support system in form of RPL ICT system, QA recommendations for RPL as well as required implementation capacity in relevant public organizations (i.e. Agencies in area of education).

During development of NQF, Croatia purposely selected RPL to be implemented as last NQF's element in order to best protect its citizens against potential misuse of RPL such occurred in South Africa [8] and some other countries. In order to support policy development of RPL in higher education, Agency for Science and Higher Education (ASHE) initiated EU funded project: "Competitive Croatian Higher Education for better Employment" in order to propose RPL implementation model for higher education including RPL ICT system. Research presented in this article have been organized within aforementioned project as a potential blueprint for future by-low and overall national development in this area, while part of its results focused on ICT system are presented in this article.

III. RESEARCH METHODOLOGY

Research of requirements for ICT system for RPL focused on desk research of best practices in EU member states, as well as on design of research instrument (survey questionnaire) and pursuance of two surveys involving most significant stakeholders who should use proposed system in higher education: higher educational staff and accreditation agency experts.

A. RPL implementation and ICT system - desk research

In order to support implementation of RPL in EU member states, Council of European Union tasked CEDEFOP to observe achievements and to constantly support development by issuance of concrete guidelines [1] and publication of up to date Inventory on RPL practices which has been so far updated five times (2004, 2005, 2008, 2010 and 2014) [9]. Within the stated guidelines, there are no concrete recommendations on the need to implement RPL support ICT system, but Guidelines suggests that RPL process should be transparent, quality assured, cost effective and linked to NQF in order to use published qualification's standards. According to the Inventory [10] which reviewed achievements of 33 countries (28 EU member states + Iceland, Liechtenstein, Norway, Switzerland, and Turkey, currently only 3 countries (Finland, France and Spain) have comprehensive RPL strategy covering all educational levels (education subsystems), another 10 countries have national strategy for RPL with some elements missing, 9 countries currently develop their national strategy and only 7 countries (including Croatia) have no legal framework for RPL at all. One of the recognized challenges in implementing RPL is lack of data collection on RPL at national level and CEDEFOP indicates that much remains to be done to establish such systems [11]. Through research of achievements for each of stated 33 countries it can be seen that most advanced of them do have ICT system to support their NQF (i.e. qualifications register), but only one project have been found to develop IT solutions to support RPL. Namely, Vita project initiated by total of 10 partners from 9 countries in 2012 and financed by EU funds to develop e-portfolio approach that will support primarily RPL clients and through formative testing add "evidence" of their achievement to personal Europass portfolio [12]. With its focus on assessment methods and its primary goal to support RPL candidates, we found almost none of the achievements within the project useful in our case tasked to designing comprehensive RPL system capable of supporting, candidates, providers and QA authorities.

Although we could not get useful inputs from other successful implementations of ICT systems for RPL due to early stage of development in this whole area, we managed to build on recent implementation references linked to QA [13] and the use of ICT in building e-portfolios [14], [15] in order to develop research questions for potential RPL providers in higher education and structured interviews with policymakers in MSES, ASHE, Student Union, Employers Association and Trade Unions.

B. *Sample information and research instruments*

In order to get better understanding on requirements for RPL and its ICT solution, research questions for structured interviews with policymakers and survey of potential providers (key stakeholder's groups) were organized in four groups with total of 22 items using five point Likert type scale with numeric representation as follows: 5 - Strongly agree, 4 - Agree, 3 - Neutral, 2 - Disagree and 1 - Strongly disagree with additional 0 - Do not know, do not want to answer option. Additional two questions have been used to determine respondent's role within higher education and his/hers knowledge of the concepts of RPL raging through 4 levels from: "Expert in RPL", "experienced in NQF", "understand concepts of Learning outcomes (LO's)" to "know nothing". Survey has been organized using paper based templates while structured interviews with key stakeholders involved recorded and later transcribed focus groups meetings held in three separate occasions during 2014. Most significant items relevant for requirements for ICT system were as shown in Table I.

TABLE I. KEY ITEMS RELEVANT TO RPL ICT SYSTEM

Question ID	*Question text*
Q6	Following recommendation of Council of European Union (2012/C 398/01), Croatia should implement RPL using "equal value" principle.
Q10	In order for RPL process to be valid and transparent, it is necessary to validate (assess) and document result of each learning outcome within unit of learning outcome, regardless of its size.
Q16	Validation processes are much more endangered by potential misuse and "sales of diplomas" than classical studying process (one that includes both acquiring and validation).
Q17	Validation process should be significantly more "protected" with QA system than classical educational process and this justifies more documenting.
Q18	It is justified to archive complete RPL candidate's documentation for future audit.
Q19	It is justified to insist on use of national ICT system for RPL to enter all candidate's data including digitalized assessment materials.
Q20	It is justified to insist on use of national survey system for RPL candidates in order to track their satisfaction with the process.
Q21	It is justified for RPL authorities to have anonymized on-line access to candidate's documentation.

Research sample included total of 71 respondents. Out of stated number, 57 were relevant as representatives of potential providers in higher education, representing most of Croatian Universities and Universities of Applied sciences, as shown in Table II.

TABLE II. DESCRIPTIVE INFORMATION ON SAMPLE

Target group affiliation	*Frequency*	*Percent*
(1) Teacher in HE	47	66,20%
(2) Administrative person in HE	10	14,08%
(3) Trade union or Employer	3	4,23%
(4) Student	6	8,45%
(5) Educational authority	2	2,82%
(6) Non of listed groups	3	4,23%
Total	**71**	**100,00%**

IV. RESEARCH RESULTS

Results for Q6 show that most of respondents support the idea of RPL implementation using "equal value" concept, as per Table III. Further research in order to determine whether knowledge on NQF and RPL significantly affects this attitude is done using one-way ANOVA with Levene's test of variance homogeneity, showing no significant difference in such attitude ($F(2,52) = 0.478$, $p = 0.623$) between respondents' groups.

TABLE III. Q6 RESULTS

Question	N	Mean	Std. Deviation	Std. Error Mean
Q6	56	3,68	1,081	0,144

Results for Q10 show even more positive attitude towards thorough assessment and documentation of each LO within the Unit of LO's, as per Table IV. Further research in order to determine whether knowledge on NQF and RPL significantly affects this attitude is done using one-way ANOVA with Levene's test of variance homogeneity, showing no significant difference in such attitude $F(2,52) = 1.795$, $p = 0.177$) between respondents' groups.

TABLE IV. Q10 RESULTS

Question	N	Mean	Std. Deviation	Std. Error Mean
Q10	55	4,16	0,918	0,124

Results for Q16 show that most of the respondents find RPL processes to be endangered by misuse and should be protected more than formal education, as per Table V. One-way ANOVA with results ($F(2,50) = 0.005$, $p = 0.995$) show no statistically significant differences between groups or respondents' attitudes.

TABLE V. Q16 RESULTS

Question	N	Mean	Std. Deviation	Std. Error Mean
Q16	55	3,56	1,183	0,159

Next set of five items have been logically connected trying to determine level of quality assurance and documentation of RPL, with very high positive results per each item as shown in Table VI.

TABLE VI. Q17 – Q21 RESULTS

Question	N	Mean	Std. Deviation
Q17	52	4,12	0,983
Q18	52	4,44	0,698
Q19	52	4,42	0,871
Q20	52	4,31	0,853
Q21	52	4	1,01

With such results, we also tested reliability of 5 item scale instrument with Cronbach's Alpha with result of 0,76 and 0,768 (Cronbach's Alpha Based on Standardized Items). Although on the margin of reliability, stated results allowed us to calculate group result for the whole item set with mean of 4,2577, Std. Deviation of 0,63535 and Std. Error Mean of 0,08811. One-way ANOVA with results $F(2,47) = 1.227$, $p = 0.302$) show again no statistically

significant differences between groups or respondents according to their knowledge on the RPL.

Results of structured interviews with stakeholders mostly corresponded to the results provided by survey respondents, with additional relatively specific requirements which partly even contradict to main conclusions that would be drawn from presented statistical results. Main specific requirements are as follows:

- Ministry of Science, Education and Sports insisted that future ICT RPL system should not be mandatory for RPL providers but should instead allow, through use of web services or other interoperability options, data collection also through use of ICT solutions institutions already have. In such circumstances institutions will be able to choose what system they will use, but with obligation to provide required data set per each candidate / validation.
- Agency for Science and Higher Education raised question of data and privacy protection and would like RPL providers to hold and care for most of the data such as assessment materials, with data collection only for most basic RPL data.
- Both institutions as well as some of the potential RPL providers from higher education argued that assessment data could be collected but should not be uploaded to any system outside the provider's institution.

Taking into consideration all shown stakeholder's requirements and attitudes, RPL implementation guidelines, available national legislation in the field as well as already proposed data model for CROQF register [16] we suggest that national RPL system should be designed following key recommendations in Table VII.

TABLE VII. DESIGN RECOMMENDATIONS FOR ICT SYSTEM

ID	*Design recommendation*
R1	System should be designed for provider's internal usage, with assessment data never leaving the provider's system.
R2	System should allow export of only key information set to future national RPL register.
R3	System should be connected with CROQF database in order to use definition of Units of learning outcomes, Qualifications Standards and list of accredited RPL providers in order to map candidate's results to relevant Units.
R4	System should allow RPL candidates and potential RPL candidates to search RPL provision through full text search and through selection of types and sectors qualifications belongs to, by automatic connection to CROQF database.
R5	System should allow potential RPL candidates to apply for validation to accredited provider on-line.
R6	System should allow creation of e-portfolio for candidates (collection of data and documents required in the process).
R7	System should allow RPL providers to manage: their own staff involved in RPL, RPL candidates and guidance processes.
R8	System should allow RPL providers to publish key information on their RPL provision useful to candidates.
R9	System should support already available identity management systems in Croatian higher education in order to allow seamless use and single sign-on (SSO).
R10	System should be developed as on-line application.
R11	System should keep detailed information about all RPL processes in order to guarantee more transparency.

V. RPL SYSTEM MODEL

Following recommendations for future RPL system, it is apparent that there will be a separate instance of system for each provider. Each provider will manage its instance, keeping assessment materials private with only key information set published to future national RPL register. That key information set is yet to be defined, but it is reasonable to assume that it will contain at least the same set as current classical educational process: candidate's full name, personal identification number, date of birth, address and information about achieved qualification.

A. System Architecture

We suggest that the system architecture should be comprised of at least components shown in Table VIII.

TABLE VIII. ARCHITECTURE COMPONENTS

Component	*Role*
HTML5 web application	Used by candidates and provider staff, this application should offer features for every step of RPL process, from candidate's search for RPL programs, through submitting documentation, to assessor's upload of assessment materials and finalizing process.
Relational database	Should be used for storing all actions on every RPL process, both key information set and all other relevant data such as assessment materials, candidate uploaded documents, users, roles, etc.
Key information set publisher	Since key information set must be uploaded to future national RPL register by means of web service, this component will allow managing such upload. It can be implemented as separate and secure module of web application, or as a completely separate application.
CROQF search engine	Used by candidates for searching for RPL programs, this component is best implemented as separate module for web application. It should be built as a rich wrapper around CROQF registers, forwarding candidates search requests to CROQF web service and retrieving CROQF codes as responses.

In order to guarantee transparency and allow possible future audit processes, each operation on every RPL process should be recorded in form of action log that will allow auditors to retrace process from its beginning to its end. To further improve action log, users should be grouped into roles, shown in Table IX.

TABLE IX. MINIMUM SET OF ROLES

Role	*Available features*
Candidate	Uses search features to locate units of learning outcomes, qualification standards and RPL programs, applies for RPL and provides necessary information and documents. On successful completion, can print informal certificates.
Provider Coordinator	Manages provider's list of counsellors and assessors and assigns counsellors to RPL processes
Provider Counsellor	Validates candidate submitted information and documents, communicates with candidate, conducts interviews with candidates, assigns assessors to RPL processes and prints formal certificates.
Provider Assessor	Uploads assessment questions and corresponding results and reviews and decides on successful or unsuccessful completion of PL processes.

RPL system should use an external system for user authentication. Such system should provide authentication based on at least AAI@EduHr (Croatian higher education authentication infrastructure), with preferably other popular options available, such as Google, Microsoft, Facebook, Twitter, LinkedIn, etc.

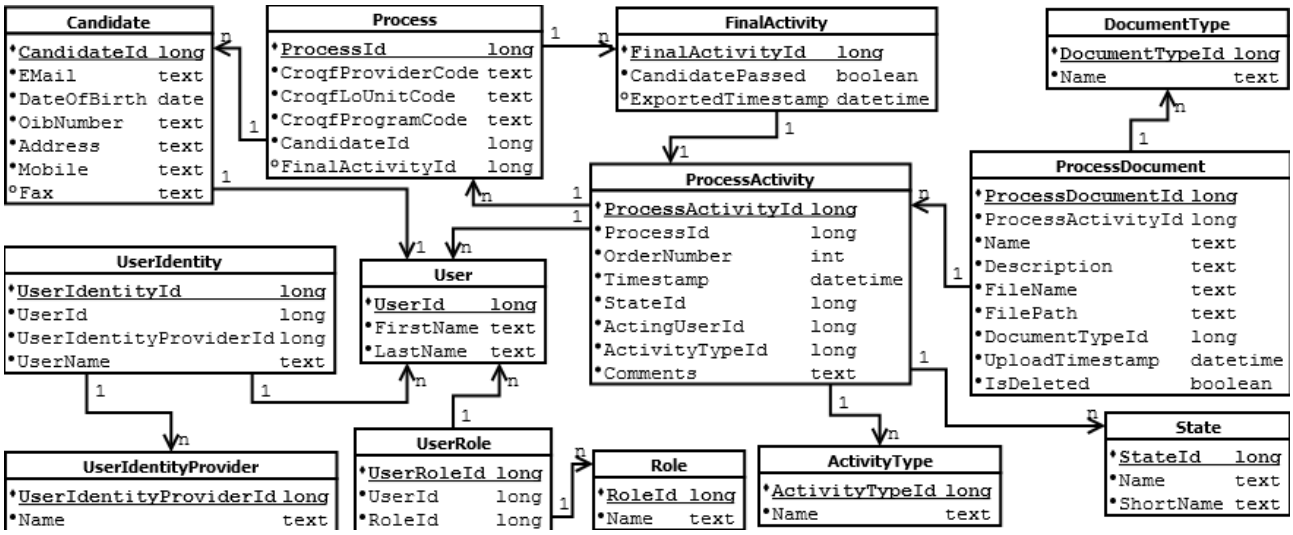

Figure 1. Relational model

B. *Relational model*

Relational model must be designed with action log as core requirement in mind. Figure 1 shows such relational model in its essential form. For brevity, only tables, mandatory columns with generic data types, primary and foreign keys and not null constraints are displayed. Actual platform-specific data types, additional constraints such as unique, default and check constraints, additional columns in existing tables and new tables should be added by implementer as deemed necessary, following good database design principles.

First core table is named Process and its purpose is to hold instances of RPL process, each linking CROQF codes for provider, unit of learning outcomes and RPL program to candidate. Each step of the process has its entry in table ProcessActivity. Each activity for the process has its type selected from a set of predefined types; it has an order number starting from 1 that should be used to sequence activities in timeline; timestamp when did the activity happen; state the process is in at the end of the activity, user who did the activity and user's comments. Table ProcessDocument is designed to hold uploaded documents, whether from candidate or from provider staff, with each document having a type set. Finally, fourth core table is FinalActivity which stands in 1:1 relationship with ProcessActivity. FinalActivity holds entries for only those activities that mark processes as completed and thus unchangeable. Stated is the reason why Process might point to such final activity, but only if the process is finished. Strictly, that foreign key is not necessary, but it is placed here in order to ensure easier querying. Lastly, FinalActivity has a nullable timestamp when this process' key information set was exported to national RPL register. Table X briefly explains other database tables.

C. *Important use cases specifications*

Although there are many more use cases applicable to a RPL ICT system, in this section only most essential ones will be outlined. Table XI describes them without going into much details.

TABLE X. EXPLANATION OF TABLES IN RELATIONAL MODEL

Table	*Purpose*
Role	A set of predefined roles from table IX
User	All users, regardless of their type
UserRole	Which user belongs to which role
UserIdentity Provider	A set of predefined providers, such as Aai@EduHr, Facebook, Google, LinkedIn, Twitter, etc.
UserIdentity	One or more identities for every user
Candidate	Only users that are candidates (1:1 relationship)
State	A set of predefined process states, such as CREATED, ACCEPTED, PENDING, VERIFIED, REJECTED, COMPLETED, FAILED, EXPORTED
Activity Type	A set of predefined activity types, such as: Initial Input of Candidate Data, Update of Candidate Data, Counsellor Assigned, Counsellor Messaged Candidate, Counsellor Verified Candidate, Assessor Assigned, Assessor Updated Assessment Documentation, Assessor Marked Process as Finished, Exported to RPL Authority
Document Type	A set of predefined document types, such as: Curriculum Vitae, School Diploma, Identity Card Scan, Assessment Question, Candidate Response, etc.

TABLE XI. MOST IMPORTANT USE CASES

ID	*Use case outline*
UC1	Candidate visits HTML5 web applications and uses browsing and/or searching application features to find appropriate Unit of learning outcomes, Qualification or RPL program from CROQF register.
UC2	Candidate signs in using any available authentication mechanism. Candidate initiates RPL processes for one or more Units of learning outcomes and provides necessary information and documents.
UC3	After signing in, candidate sees the state of her/his RPL processes, provides additionally information and documents requested by provider counsellors and prints informal certificates for successfully completed Qualifications.
UC4	Coordinator manages list of assessors and counsellors for provider, assigns counsellors to RPL processes and manages provider data available to potential candidates.
UC5	Counsellor validates candidate provided data and documents and communicates with candidate until they are validated. Once validated, assigns one or more assessors to process.
UC6	Assessor uploads assessment elements, such as questions, comments, results, and also marks RPL process as completed, either successfully or unsuccessfully.

VI. CONCLUSION

Research presented within this article, as well as key policy recommendations underpinning implementation of validation systems issued by Council of European Union, Cedefop, Unesco and others call for transparency, cost effectiveness and reliability of RPL processes in order to implement "equal value" based RPL provision. Starting from aforementioned wide and relatively nonconcrete implementation guidelines we recognized ICT support system for RPL as a means to an end, capable of supporting RPL candidates, providers and QA authorities as well as providing functional link to NQF and Qualifications standards required to support "equal value". Since we did not find any useful blueprints or ICT system's development recommendations through desk research of scientific articles and national RPL implementation documents in EU, we organized structured interweaves and survey research to better understand specific stakeholder's attitudes and requirements. As a result, we learned that predominant stakeholders' attitude goes in favor of strong documentation and transparency of RPL in Croatia in order to protect public interest and confidence in national qualifications (most of respondents strongly agree or agree mean=4,44 that all RPL data should be achieved for ex-post review, while similar majority mean=4,42 find RPL ICT system should be used also to store digitalized assessment results). Still, specific requirements of educational authorities (both ASHE and MSES) called for less centralized approach which would allow RPL providers to exchange only required minimum of data on each candidate and validation process with national ICT system, by use of its on-line interface or through interoperability with their existing applications. Furthermore, although most of the stakeholders through survey supported the idea that e.g. upload of digitalized assessment results for each RPL candidate is useful and justified in order for QA authority to have easy central access to relevant data for ex-post external audits, educational authorities as well as part of the providers do not share same idea mostly in order to protect candidate's privacy. In such circumstances use of RPL ICT solution is not rejected, but information and data that should be stored centrally and "controlled" by educational authorities is.

Proposed RPL ICT system design and its data model builds on results of presented research as well as other relevant recommendations, calling also for information provision for RPL candidates, importance of career guidance support and e-portfolios as an emerging tool. In order to produce future RPL ICT system for Croatian higher education, proposed model and blueprints could serve as a good starting point, but also one that lacks "real feel" test and inputs provided by very RPL candidates and RPL practitioners through interaction with the system. Due to the fact that Croatia still do not have legal framework for RPL and that there are currently no RPL providers nor candidates, further research on system usability from numerous roles is required in order to prepare documentation for full scale development of national solution. Still, with proposed approach focused on national database of all RPL relevant information, Croatia might be one of the countries fighting indicated EU level challenge of lack of RPL data for future development of national RPL provisions. For all aforementioned reasons, proposed ICT system design and data model, although developed through project in higher education and targeting mostly stakeholders relevant for this educational segment (level), requires no significant further development to cover all educational segments and become national RPL implementation infrastructure, if recognized by future by-low on RPL and future users.

ACKNOWLEDGMENT

This research would not be possible without team from Agency for Science and Higher Education who coordinated EU funded project within which work on implementation of RPL in Croatian higher education has been done. Thanks to Durdica, Emita and Aida. Thanks also to prof. Mile Dzelalija and University of Split for all the support.

Computer game Angry Birds in teaching physics

D. Robič* and R. Repnik*
* Faculty of Natural Sciences and Mathematics, University of Maribor, Maribor, Slovenia
robert.repnik@uni-mb.si, dominik.robic@student.um.si

Abstract -Information and communication technology (ICT) is very popular among children. A lot of children are playing computer games in their free time not knowing that some games are using game mechanics from actual physics. In this article we discuss how some computer games can be useful in teaching physics and which of them are appropriate for this purpose. Computer games are one of didactical tools that can make lessons more interesting for children and should not be excluded out of teaching. We check main characteristics of educational games and the main difference between none educational games. Our main focus is on popular Angry Birds in which we analyze the physics background of the game, where we try to determine different contents of physics and applicability in physics lessons on specific school level. We show an example proposal how to use Angry Birds in teaching physics in secondary school at topic projectile motion and which software is required to analyze data in the game. We also list additional examples with suitable physical content which are integrated in this computer game.

I. INTRODUCTION

Using computer in education and recreation is common nowadays [1]. Kids today are not only "digital natives" but are characterized with the term "always on generation". During the last decade many high quality e-learning materials were prepared in Slovenia for primary and secondary schools [2]. In those materials extensive use of multimedia and interactivity were used and even aesthetics of some learning materials was evaluated [3]. Should teachers produce such materials? From the analysis of the study programs they should [4]. Kids love such learning materials but as always it is evident that most of that technology is used for playing computer games [5]. For two decades people were trying to figure out why computer games are so motivating and why children spend so much time playing those [6]. The results were three features: challenge, fantasy and curiosity. Those three features are also very important in learning physics. Challenge helps at motivation to achieve our goals, fantasy helps at better imagination and explanation how things should work and curiosity drives people to figure out things that they didn't know. Some computer games use actual physics for their game mechanics and children are very eager to spend hours playing them. So why not use them as a teaching tools for physics [7]? A set of games that use physics as their game mechanics are very popular computer games Angry Birds. They are not specifically made for teaching though.

II. DIDACTIC ASPECT OF COMPUTER GAMES

As previously noted the use of ICT can be great motivational tool for teaching and learning, especially computer games can be great motivational tool. That leads to the games that were made specifically for teaching pupils. Computer games that were designed for learning are called educational games [8]. What make games »educational« are specific characteristics. Educational games should have educational content included in curricula that are based on level of users understanding. Educational games should also have appropriate methods for learning contents, which depends on nature of contents. For example we must distinguish between learning of knowledge, processes; procedures and casual principles. Each of those requires different learning methods that depend on content's complexity. Methods that are used for learning also affect game structure and game mechanics. Finally, what every educational game should have is a feedback system that provides players with information of learning success. In this description of key characteristics of educational games it is notable that game structure and game mechanics depends on game content and methods of learning [9]. This leads to another question. Why do children prefer playing classic computer games rather than educational computer games? Key element is that educational games are not primarily designed for fun only and major software companies do not develop educational games. Those companies have expert knowledge in computer graphics and games design but they have discovered that educational games are not commercial successful and revenue is too small for them. So to get good learning results with computer games we should either design and develop better educational games or find those computer games that are popular and could be used for educational purposes. In our case we focus on "Angry birds".

III. COMPUTER GAME ANGRY BIRDS

Angry bird's games are product from Finnish company Rovio entertainment. First game was released in year 2009 for Apple's iOS Android, Symbian and Windows Phone operating system. Since then Rovio entertainment upgraded the game that can also run on PC's and game consoles. It's addictive gameplay, comical style and low prize has increased its popularity irrelevant of the users age. Its popularity also encouraged the company to make

new sequels with different themes. From first game Angry Birds to latest sequel Angry Birds Transformers are listed eight more sequels, with different themes and game mechanics. Basic story in AB is about evil green pigs which stole eggs from birds which became angry. In game slingshot is used to shoot birds in a way to eliminate all green pigs (Fig. 1). Every level is limited with number of birds and their ability's which varies from bird to bird. Green pigs are sometimes protected with different building block which can be destroyed according to the different birds destructive properties. For example yellow birds can accelerate and are able to destroy wooden material. Each level increases difficulty and completion of some levels requires multiple trials and error. Despite increased difficulty on each successive level the game still remains attractive, addictive and motivates players to continue playing the game. Feedback of the success of the game is displayed with the stars. More stars you gain more successful you were in specific level. Final score is calculated based on your performance at specific level and is dependents on number of destroyed objects and number of birds used to eliminate all green pigs.

Figure 1: Different birds in the game have different properties, all we firstly shoot out from slingshot.

There are many sequels of Angry Birds and one is called Angry Birds Space where game environment is moved into space and gravity of objects affects bird's flight. At designing this sequel Rovio Entertainment worked with NASA which helped at programming gravity effects and also tested them in actual space [10]. Though games were not designed for educational use its game mechanics includes physics and makes them interesting for physics education.

IV. LEARNING WITH ANGRY BIRDS

We figured out that computer games Angry birds are appropriate for teaching physics so we will show an example how we can teach Physics of projectile motion with computer game Angry birds. But before we can check the physics of AB we have to make footage of AB gameplay and after that we have to analyze data in that footage. For that we will need some additional programs appropriate for classroom usage, for which we will give some examples.

A. LoiLo Game Recorder

Recommended software for making gameplay footage is a program called LoiLo Game Recorder. The program can be downloaded for free from their website (*http://loilo.tv/us/product/game_recorder)* and it can be easily installed on your computer. LoiLo Game Recorder is a program that enables us to record game sessions. It also supports Motion-JPEG file format that provides with the best balance between file size and image quality. For our purpose we recorded full HD videos and file size is still manageable. When program is installed simply start the program and the game in which recording will be made. Before playing a game press F6 on keyboard and program will start recording (Fig. 2). When playing a game is finished press F6 key again and the program will stop recording and save the footage in your PC's Video Directory. Now footage can be seen in program and it is ready for analysis.

Figure 2: User interface of program LoiLo.

At the benchmark test that was made using much known computer game Final Fantasy 14 the LoiLo Game Recorder showed the least performance loss compared to any competitor's non-free software [11]. To minimize the measurement errors at analysis of gameplay the footage must be smooth and without delays. To analyze the footage it is recommended to use program called Tracker.

B. Tracker

Tracker is a free video analysis and modelling tool built on the Open Source Physics (OSP) Java framework. It is designed to be used in physics education and can be easily run from USB drive. Requirements for using Tracker are small. For proper working it requires program Java 1.6 or higher which can be obtained on the internet. Tracker has a variety of tools to help user to analyze the data from recording where program shows what happened with physical quantity on the graphs. To analyze data from recording simply start program Tracker and open video that was made with program Loilo. Now different tools from program can be used to start the measurements. Tracker has a lot of tools to offer. Video analyzing tool is used to depart video frame by frame. Measurement analyzing tools is used for managing data in the graphs where we can set different graphs to see the final result of measurement. Calibration tools are used to set basic unit of measurement and set the starting point of measurements (Fig. 3) [12].

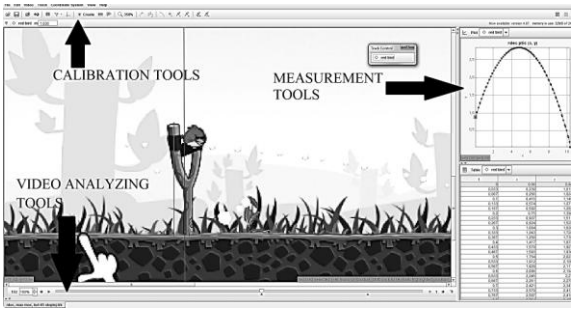

Figure 3: Program Tracker offers many tools for analyzing data.

Before acquiring the measurements for discussing physics problem, starting point of measurements needs to be appointed to define birds place in its space. This can be done with calibration tools where coordinate system is set in the foot of slingshot where also starting point is appointed. Setting a measuring unit is also mandatory and it can be also set in measuring tools. In this case it is recommend that measuring unit is set as slingshot size. When starting point and basic measuring unit is determined tracking tool can be used to track bird's movement in the footage. When tracking is finished the results of measurements are shown in the graphs.

V. PHYSICS OF ANGRY BIRDS

After analyzing the data with program Tracker physics of the game can be discussed. Projectile motion is a case of motion which can be described as motion in two dimensions, in vertical and horizontal way. In this particular case air resistance can be neglected because the game wasn't designed to include air resistance in projectile motion. The bird was shot with the slingshot where its initial speed ($\vec{v}_0$) is:

$$\vec{v}_0 = (v_{0x},\ v_{0y}), \tag{1}$$

where v_{0x} is size of the horizontal component of initial velocity and v_{0y} size of the vertical component of initial velocity [13].

Only gravity affects the birds trajectory that's why acceleration of angry bird is equal to the gravitational acceleration ($\vec{g}$) which is on Earth 9.8 m/s^2.
It's is known that the horizontal component of velocity is not changing in size because acceleration only got vertical component. That's why the movement of bird in time t can be defined as:

$$x_{finished} = (v_{0x}\cos\theta)t + x_{starting}\,, \tag{2}$$

where $x_{finished}$ is location where the bird has finished movement in time t in his horizontal path and $x_{starting}$ is initial location from where bird has started moving in horizontal path. θ is angle from which the bird was shot from the slingshot [13]. Result from the measurements are shown on the graph (Fig. 4) on which it is shown that body was moving in horizontal direction with constant velocity v_{0x} which is equal to 3.31 unit/s [14].

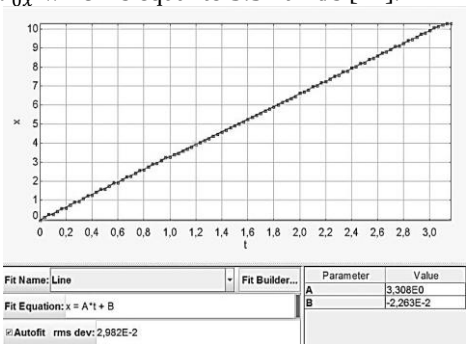

Figure 4: Measurements of horizontal movement.

For motion in vertical direction it is known that acceleration is equally accelerated, that's why motion in vertical direction can be defined as:

$$y_{highest} = (v_{0y}\sin\theta)t - \frac{1}{2}gt^2 + y_{starting}, \tag{3}$$

where $y_{starting}$ is starting hight from which birds was shot in vertical direction from angle θ and $y_{highest}$ is the maximum height that bird will reach in at time t. If the game happened on Earth acceleration would be equal to gravitational acceleration g. In the measurement can be noted that vertical motion fits to quadratic equation. From equation (3) we can see that acceleration (*A* in Fig. 5) in vertical direction is *a*/2. Which gives us as result acceleration which is equal to 1.9 unit/ s^2 . From measurment we can also read the vertical component of velocity (*B* in Fig. 5) which is 2.8 unit/s and height (*C* in Fig. 5) 0.8 unit [15].

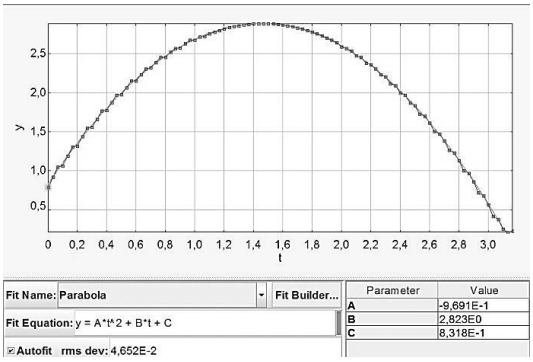

Figure 5: Measurements of vertical movement.

Size of games basic unit can be determined from measurements. In this case measured acceleration in vertical motion was 1.9 unit/s^2. Because we assumed that the experiment is happening on Earth, acceleration should be equal to gravitational acceleration which is 9.8 m/s^2 [14,15]. From this fact the size of basic unit can be calculated leading to result that slingshot was approximately 5.1 m high, because size of the slingshot was set as basic unit. Now that the basic unit of the game is known, velocity in vertical and horizontal direction can be also calculated by simply multiplying measured values with 5.1 m. This leads to results that v_{0y} is equal to 14.2 m/s and v_{0x} is equal to 16.7 m/s. Initial velocity can be also calculated using equation:

$$v_0 = \sqrt{{v_{0x}}^2 + {v_{0y}}^2}, \tag{4}$$

leading to result where v_0 was 21.9 m/s. Starting height $h_{starting}$ from which the bird was shot can be also read and calculated from measurements and is 4.2 m. When starting height is calculated also maximum height h can be calculated:

$$h = \frac{v_{0y}^2}{2g} + h_{starting} \tag{5}$$

resulting that maximum hight h was 14.5 m. It is also interesting from which angel the bird was shot:

$$\theta = \tan^{-1}\left(\frac{v_{0y}}{v_{0x}}\right). \tag{6}$$

Using previous equation for calculating angle the result is $\theta = 40.4°$. So we have all needed information to calculate also the range of bird's flight. For this purpose we use the following equation:

$$d = \frac{v_0}{g}\sqrt{{v_0}^2 + 2gh_{starting}}, \tag{7}$$

where range d equals 52.8 m. Similar results can be obtained reading measurements where range is 10.5 units which is 53.0 m. Range that we calculated is not exactly the same as the range that was measured. This can be can explained as an error of measurements.

VI. Applicability of Angry Birds

We have seen how we can analyze physics at red angry bird that has no special abilities. This type of analysis and understanding would be more appropriate for pupils in secondary school, but it can be also used in primary school. We could teach children in primary school how to use programs LoiLo and Tracker for simple analysis not only in Angry Birds but also in any other experiment footage. There is much more physics that Angry Birds can offer for physics lessons. For example it would be interesting to research, what is the initial acceleration and midair acceleration of yellow angry bird when we use its special ability. It would be also interesting to check physics background of blue angry bird where we would check what is happening with momentum when it splits in tree same sized angry birds if the mass of all birds is the same. Used materials in the game are also interesting for further analysis (Fig. 6). We could study how different angry birds affect the same material and on which material the influence of one specific bird is the most effective.

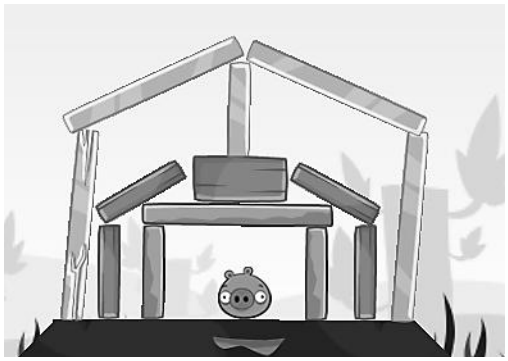

Figure 6: Different materials are used in the game Angry Birds, with different properties.

VII. Conclusion

In this article we determined that use of ICT in education is a necessary competence that every teacher should acquire during his education. In the present time and even more in the future, ICT *is*/*will be* one of the main teaching and learning tools. Collecting game experiences we also learned the difference between educational games and fun computer games. We found out that only some computer games (like Angry Birds), could be appropriate material for teaching because of its motivational fun factor. In educational games designers mostly forget about it because their focus is on teaching. Game mechanics is obstructed by learning processes, in which most children forget that learning new things can also be fun. We used two programs (LoiLo Game Recorder and Tracker) for analysis of selected sequences of the game. We showed an example how we could use computer game Angry Birds for teaching projectile motion where we explain physics of game mechanics. This can be done in secondary school but also in some cases in primary school physics course. At the end we checked applicability of Angry Birds and how it can be used for additional analyses in further physics lesions. Determine adequate games (high motivational fun factor, with real physics related game mechanics) and using them in teaching is of high importance, because the students will be more motivated for study in physics course and the knowledge will be better. Of course, nothing can replace the knowledge resulting out of real experimental work experiences in the teaching natural science subjects, especially physics. So the adequate educational games should be introduced in the teaching as supplement to experiment and not as substitution.

Towards Blended Learning: A Case Study

Petri Linna, Harri Keto and Timo Mäkinen
Tampere University of Technology / Pori unit, Pori, Finland
e-mail: petri.linna@tut.fi

Abstract - University education is in the middle of a technological and pedagogical revolution. Traditional models are under considerable pressure to change. In this paper, we introduce a case where IT education was radically challenged by new possibilities. The case is a small university department, which runs a Master's degree program for an annual intake of about 60 students. The students study while working either full or part-time. Thus, the key challenge is to enable an efficient balance between work and studies especially by supporting distance learning. This means that the location and schedule of studies have to be flexible. One way has been to increase the multiformity of the pedagogical methods. For example, teaching is moving increasingly toward the flipped classroom method. In addition to the teachers' own video production, external academic Internet sources have been used and experiments have also been made of using external Massive Open Online Course materials for example in executing web development and database courses. This paper is a summary and analysis of the observations from the viewpoint of the students, teachers, and administration. Some plans and future intentions are also presented.

I. INTRODUCTION

During the last decade a lot has been invested in the utilization of different technologies in higher education teaching. However, now the turning point is being reached in which major changes can be seen in the pedagogy of teaching [1], in organizational structures, in the education needs of the labor force as well as in technologies.

In historical terms, society has just fairly recently moved from the industrial era to the information society. Now the direction is toward social, communicational, and technologically networked societies. Jan van Dijk [2] and Manuel Castells [3] use the term the network society, where communication and technological revolutions will affect societies, enterprises, and individuals in many ways (see also [4]). The world will be networked on many levels, which will also change the needs of education, such as more need for internationalizing with cross-cultural competency.

The education needs and structures have changed in different eras and attempts have been made to clarify and investigate future trends in many quarters, but mainly the trends are always somehow connected to the fast development of technology [5]. According to the NMC Horizon reports [6],[7], which focuses on the future of education, the trends of the near future in teaching are the rise of social media and social networks. This trend has also been noticed and tested in the case department [4]. The teachers' roles will change from traditional lecturer to personal education trainers and controllers. Teachers might take on new roles, for example lecturers who offer only mass teaching and producers of open and interactive educational material.

The trend of open education courses, materials, and their utilization will be huge in the near future. The multiformity of teaching, in other words blended learning will increase as different technologies and cloud services and applications especially in mobile devices develop continuously. Mobile devices will also change teaching in other ways, for example the ADP classes of schools will become a thing of the past when students bring their own devices (known as BYOD). Mobile devices also bring an opportunity for personalized studying and serious educational games in teaching. In personalized studying, the student's development is estimated, encouraged, and controlled with different techniques and only the necessary teaching materials are selected. The last future trend according to the report will be virtual and remote laboratories. Added reality and virtual environments bring new opportunities to teaching by removing the challenges of distance learning. [6],[7]

A strong increasing trend of digitalization is connected to companies. The viewpoint of universities is that it is important to know what the educational needs of enterprises are and also which are the most suitable techniques and pedagogies now and in the future. The Future Work Skills 2020 report [8], made by the Delphi technique, lists six main drivers which have an effect on the background of the need for future work skills: extreme longevity, the computational world, the rise of smart machines and systems, new media ecology, superstructured organizations, and globally connected worlds. These drivers lead to ten important skills, and examples of them are cross-cultural competency and virtual collaboration. One of the results is that workers will need to be adaptable lifelong learners.

Companies wish to have high-quality education for their employees, and that the education should correspond to their exact skills needs quickly. These educational needs can vary rapidly as companies react to global situations, as the Horizon reports [6], [7] had noted. Senge [9] introduces a five-step model of learning organizations, in which one of the steps is personal mastery. If organizations want to develop and grow, personal learning is always needed thus enabling an increase in human capital. The challenge is to educate rapidly and reasonably. Secondly, workers who are simultaneously studying would need to obtain as many different flexible methods as possible to combine company, home, and studying as well as possible.

Universities also have to pay attention to the challenges and strategic goals of the European Union [10] which include the global competition challenge where new skills are needed for the labor market. The goal is for 40% of the population to have a higher degree and for about 15% of adults to participate in lifelong learning.

The above-mentioned matters cause a global competition challenge between universities, when distances lose their significance and likewise the role of the implementer of courses (materials and the course itself).

The case university of this paper is quite a small department. The Tampere University of Technology, Pori unit, offers education leading to a Master's degree in Management and Information Technology. Postgraduate studies leading to the degrees of Doctor of Science in Technology and Doctor of Philosophy can also be completed. The major subjects are Software Engineering and Data Management, Network Management and Information Security, and Industrial Engineering and Management. The Pori unit is part of the University Consortium of Pori, which is a center of 2800 students, 170 experts and four universities operating networked in a multi-science environment. The focus is on multidisciplinary studying and adult education.

The Pori unit became a provider of multiform learning officially in fall 2013. This is relatively late in terms of the progress of the technique. Multiform learning was seen as a solution offering flexible education for students and a solution competition for new students. The solution seems easy, but multiform learning is not an actual solution yet, because it contains an innumerable number of different methods and ways of teaching. The right combinations must be found by trial and error.

In practice, the transition to multiform learning adds a large number of new questions to be solved. Furthermore, for the teachers the transition to multiform learning creates a great opportunity to develop new kinds of teaching pedagogies and use new technologies, but the resistance to change is a challenge. Here are listed some example questions, which should be solved: How are the courses scheduled? How are the physical distances solved? How are (remote, network, electronic) examinations arranged? How are the materials distributed? How are the training sessions and laboratories arranged? How is communication secured? How are student motivated to use eLearning? What is the commitment of students and teachers like? How are the needs for pedagogical change established and utilized?

The research question of this paper is how to enable multiform learning flexibly and effectively now and in the near future for students who are simultaneously working in enterprises.

In the second chapter the growing trend of open education is examined, especially MOOC (Massive Open Online Courses). Can it provide some solutions for multiform learning and teaching? Does MOOC enable the transfer to the flipped class pedagogical method? The Pori unit had already studied the possibilities of open education in the AVARAS project. Next, in the KASKU project, the utilization of open courses and of open materials in teaching will be studied in basic teaching as well as in continuing education.

In the third chapter of this paper, the case of the Pori unit is introduced. It describes students' and teachers' experiences of multiform learning and teaching, and analyzes the results.

The last chapter is conclusion and results of paper.

II. THIRD PARTY MOOCS AS PART OF CURRICULA AND MULTIFORM LEARNING

Massive open online courses (MOOC) are on online studying opportunities, which anyone can participate in despite their background, wealth, or place of residence. The courses usually last about ten weeks, consisting of short videos, exercises, and articles to study. In general, no mark is given when the course has been completed. Universities began to offer MOOCs on a large scale in 2012. [11]

The phenomenon began in the United States, and has led to several consortia for delivering their courses via the Internet. The best-known actors on the scene are Coursera [12] and Udacity [13], which are funded by a group of large investors. Their aim is to develop businesses around the courses. There are also non-commercial course operators of which the most famous is edX [14]. British universities have set up their own consortium, FutureLearn [15]. It was estimated that there were over six million MOOC students in the world by the end of 2013. In Finland, the pioneer is the University of Helsinki [16], which currently offers eight programming-related MOOCs. [11]

At the beginning of this year, the Pori Department of Tampere University of Technology established the three-year KASKU project to develop its educational processes. One of the work packages (WPs) of the project focuses on MOOCs. The aim of the WP is not to produce its own large-scale online courses but to utilize MOOCs of other universities as part of the department's curriculum.

The department in this case is relatively small. The annual intake is only about 60 students, who already have a bachelor's degree in some technical branch. An increasing number of students are working while carrying out their studies. Recently, the Pori Department has also offered international students the opportunity to conduct their studies on the campus. Despite the small number of students with a heterogeneous background, and with very limited chances to be present at lectures, the goal of the department is to offer a versatile selection of courses in its curriculum while keeping the costs at a reasonable level. Third-party MOOCs have been seen as a promising opportunity to achieve at least one part of the goal.

So far, four ways to apply MOOCs have been identified: 1) A third-party MOOC implements a standard course directly; 2) A MOOC replaces a standard course for international students; 3) A MOOC implements a course, of which the content is not completely fixed; 4) MOOCs or their modules are used as parts of a standard course. The flipped classroom is seen as a promising pedagogical approach when applying MOOCs. It

describes a reversal of traditional teaching: students first study new material outside of class, and class time is used to do the harder work of applying that knowledge through problem-solving exercises, for example [17].

In the Pori Department, an example of the first case is the Server Side Web Development course, which is based on the MOOC of University of Helsinki [18]. The MOOC is in Finnish, and it offers students a study book and a set of automatically checked exercises. Teachers who apply the course will also receive ready-made questions for examinations.

The example of the second case is the Databases MOOC offered by Stanford University [19], replacing Pori's Introduction to Databases (in Finnish) for international students. The Stanford course is modularized into several mini-courses that offer the flexibility to apply only certain parts.

The Pori curriculum includes a course, of which the content is not fixed, called Special Topics in Software Engineering (SE). Such a course can be implemented by any proper SE-MOOC, being an example of the third way to apply MOOCs. For example, the School of Information Sciences of the University of Tampere gives credits for the completion of any appropriate Coursera course [20].

There are standard courses that do not match any available MOOCs. However, there might be MOOCs or MOOC modules that cover parts of the course. In Pori, the basic course of Web Development represents such a case, discussing several topics of the theme briefly. For example, Udacity [13], Code School [21], and Codecamedy [22] offer introductory level web development courses online. The course material of Udacity can be accessed free of charge, but students have to pay for extra services such as guidance and a certificate. Code School charges for their courses with a few exceptions while Codecamedy's offering is free.

III. CASE, PORI UNIT

During the past two years, the Pori unit of the Tampere University of Technology has been making the transition towards the utilization of multiform teaching methods. From the viewpoint of an educational institution this can be seen as a focusing of the strategy with technological possibilities. To concentrate especially on students in working life means strong support for flexible studies that are independent of time and place. This means the deployment of modern communication technology but also a methodological revolution.

At the starting point, some fundamental decisions and presumptions were made. Firstly, a new official alternative path of studies was released. It included a promise to organize teaching so that studies alongside daily work would be well supported. It should be noticed that the decision and the announcement was made even before practical detailed plans had been made. Because this was a public marketing level promise and both new organizational and methodological practices should be implemented, a strong analogy to the radical process improvement approach can be drawn (see [23]). It was trusted that the practical arrangements would succeed if the vision was clear enough. This relied mostly on the view that the most critical part of the practical arrangements was to make a suitable schedule for the involvement of the students in the teaching. Secondly, an assumption was made that the pedagogical challenges could be worked out by individual courses and teachers. Later on this will be explained as some kind of experimental way to put theory into practice. This kind of strategy relies on the motivation and interest of individual teachers. Thirdly, the implementation had to start almost immediately. So it was not possible to acquire new technology or infrastructure during the preparatory work period. The teaching and the delivery of the material had to be based on the existing infrastructure and available tools.

The practical implementation started as follows. It was planned that an alternative path student would be able to graduate three or four years from the starting point. Because of the available time and resources it was clear that not all major subjects at the Pori unit could be offered on the alternative path. The same limitation concerned secondary subjects. Therefore the decision about major subject and secondary subject had to be made before launching the marketing activities. For those lectures and exercises where the attendance of the students was desirable or compulsory, the teaching was scheduled for Thursday evenings and Fridays. Saturdays were also originally expected to be required but during the planning this was left out. The idea was to leave enough time for personal homework and studies between contact sessions. The detailed schedule was then announced.

In comparison to the previous implementation of courses, fewer contact sessions were included in the new implementation. Careful analysis of content was needed. The decision on what to include in the contact sessions and what to leave to the responsibility of the students themselves was left to the teacher in charge.

The other main difference from the past was the increasing utilization of video material. Although first efforts to produce videos existed, there was no wider experience about using videos as a teaching material. The production of videos was started first by a small group of active teachers. The first videos were screen capture recordings with lecture slides and the teacher's voice. The free version of Screencast-O-Matic software was first used as a tool. The other technology was the Adobe Connect computer conference system, which was available via the Finnish University and Research Network (Funet). The latter technology was also used in real-time teaching. Very soon it was understood that a more powerful editing tool was needed. The commercial Camtasia Studio software was acquired for each teacher. The open source learning platform Moodle had been used in courses before, so it was natural that delivery of videos was implemented in Moodle.

After half a year, a summary of the teachers' experiences with the technology was made. The main findings were:

- Free and open source based tools are available. Their usability is good enough to be used as a starting point to capture experiences
- The limitations of free and open source based tools were the lack of editing properties and the limited length of video
- Professional video production software is recommended
- The encoding of video should be standardized within the organization

After the end of the first academic year, an overview of video material was made. Three kinds of videos were produced by five teachers for seven different courses:

- 7 short videos, length of 5 minutes or less
- 25 videos from 5 to 20 minutes in length
- 36 videos of over 20 minutes in length

The number of videos of over 20 minutes comes mainly from two mathematics courses with total coverage by video. In addition to the above, 15 external videos of different length were used and one course also utilized international MOOC material. Both of these categories are expected to grow in the future.

Also, after the first academic year a questionnaire was made about students' experiences. The main findings were:

- The educational videos were regarded as especially useful because of time- and place-independence and the possibility of repetition.
- The training done freely on the network were considered useful.
- More video material is hoped for.
- Giving of feedback should be developed.

Training in mathematics were also tried using Adobe Connect sessions. It was noticed that:

- The students are surprisingly passive, the relation of active and passive students was about 3/20
- The students expect ready-made solutions
- It is distinctly more difficult for the teacher to get a feel for the students' know-how compared to contact teaching
- The students do not utilize all the possibilities offered

During the discussion it was stated that it is recommended to keep contact training to ensure that the students will work. Feedback must be collected during the course and the student's know-how must be regularly ensured by measuring it somehow. Also, attention has to be paid to the students' activation.

IV. CONCLUSION

The universities are under a great deal of pressure to change. It is of the utmost importance to the case unit to offer the education which responds to the future skills need in companies and is flexible for students working at the same time. It is important to be able to utilize the supply of open teaching from major universities and find the means to cope with international competition by universities. It is also crucial to find the means with which to offer more tailored methods for studying.

The paper presented experiences of multiform learning and teaching in the Pori unit. The technology has not been found a problem. There are a lot of free or cheap tools available. Instead, the challenge lies on the pedagogical side. The teachers have had to find a suitable multiform teaching way for their own course. In some cases, the contact and situation awareness with the students has disappeared. Furthermore, the change in attitude has been a significant factor, for the students as well as the teachers. Changing from the old accustomed ways takes time.

The paper showed the development plans for the near future joining as a utilizer and provider of open course and materials. MOOCs can be seen as the transitioning to a networking society where multilevel networks help each other. Students and teachers around the world can help each other globally without ever seeing each other face to face. MOOC is not revolutionary technically but it is in terms of its massiveness and ideology. Its huge spread in the U.S.A and soon in Europe will be an amazing educational driver for change and it will probably change universities in very many ways. For example, it creates totally new possibilities for students to personalize their own study content and timetable, to become internationalized through the network, and at the same time to work flexibly in companies.

The results of transferring to multiform learning were successful. The numbers of applicants have increased. In the developing of the teaching it has been now invested considerably more. The KASKU-project is an example of the significant development projects which new teaching ways are developed as flipped class method and MOOCs. The lecture recording system, Echo360, and an electric examination are the next developing steps enabling more flexibility to the students. The teaching of the mathematics has received special praise from the students because the videoed lectures will make the viewing of lectures possible again many times. The mathematics has been a traditionally big stumbling block, but now this challenge can be facilitated. The transition to the multiform learning has helped to correspond to the case university unit to national but in the future also to an international competition for the students. After two year experiences the teaching is moving towards the flipped classroom method where the focus is on the ensuring of the learning and the studying is performed more communal using web-based collaboration tools.

The use of HILL online e-learning environment in language teaching

Mari Linna and Annika Valo
Information Technology, Satakunta University of Applied Sciences, Pori, Finland
mari.linna@samk.fi

Abstract - Due to an increasing number of adult students there is a need to create new forms of teaching. Blended or online learning is nowadays current practice also in language teaching, with new technical solutions constantly being taken into use. At Satakunta University of Applied Sciences (SAMK) in Finland, HILL, an online lecture system and e-learning environment is used in teaching. The aim of HILL is to provide adult students with an e-learning environment that facilitates combining of studies, work and family life. Students can follow lectures via HILL from anywhere and interact with the lecturer or participants. Sessions can also be recorded. The HILL concept was developed in cooperation between SAMK, IBM, Cisco and AKG. It has been used in teaching since 2010. For example, in November 2014 there were about 300 HILL sessions and 3000 users, and the number is increasing rapidly. Languages have been taught in SAMK via HILL since 2012. This is a case study concentrating on the possibilities and challenges that blended learning via HILL has brought into language learning.

I. INTRODUCTION

The use of electronic educational technology has brought many possibilities as well as challenges into teaching and learning. Studying online started to become popular in the end of 1990s, with the aim to make studying equal for all, despite of a student´s residential area [1].

The terms online learning, e-learning, multimedia learning, computer-based learning, Internet-based learning and virtual education can be used when talking about computer-assisted language learning. Blended learning can refer to any combination of different methods of learning, different learning environments and different learning styles [2], but in it, students learn at least in part via digital and online media with some element of student control over time, place, path or pace [3]. Students study at different times and in different places, but sometimes meet with other students and the teacher (e.g. lessons can be held via a video conference program and the teacher can be available online during certain hours) [1].

Blended learning offers new possibilities to education, especially to adult education [4]; it saves time and travelling costs, helps students to combine studies, work and family life and makes it possible for students to study according to their own timetable. [1] reminds that in order to succeed, online learning also requires a functional technical environment.

There is no one way to learn a language, just as there is no one way to teach it [2]. The rapid growth in the use of learning technologies, particularly the use of the Internet and Web-based communication, is providing language teachers and students with many more opportunities to explore the most suitable mix of teaching for a given task [2].

Blended language learning (i.e., integrating the use of technology into classroom-based learning and teaching) is still a relatively new concept, but when "appropriately" implemented, blended learning can significantly improve the learning experience [2].

In a study of students who have participated in Web-based distance learning in the United States (Noel-Levitz, Inc.,2006), students responded that the quality of instruction, the responsiveness of e-teachers to students' needs, and timely feedback from e-teachers are important factors in e-learning [2].

Indeed, in online and blended learning, communication is regarded to be an essential factor through which a teacher can support students, their motivation and commitment to studies [4]. The lack of key tools for human communication - including tone of voice, eye contact, body language, and so forth – create challenges for online learning [5]. Without communication, online learning can become simply a way of sharing information, but through communication it can become a real learning and working environment [1].

Blended learning can be said to provide a more individualized learning experience, more personalized learning support, support and encourage independent and collaborative learning, increase student engagement in learning, accommodate a variety of learning styles, provide a place to practice the target language beyond the classroom, provide a less stressful practice environment for the target language, provide flexible study, anytime or anywhere, to meet learners' needs and help students develop valuable and necessary twenty-first century learning skills [2].

The role of a teacher and a student has changed in online learning. [6] defines teacher as someone who supports and facilitates students' learning. Traditional teacher responsibilities such as generating resources and leading discussion shifts to learners in online learning. The focus has moved from passive transferring of knowledge from teachers to students taking a more active role in their learning [6]. E-learning also takes much

more self-discipline and self-motivation than a face-to-face class, and that blended learning requires a new way of mastering a teacher´s time management.

Students are seen as active participants who manage their own learning experience [1, 7]. They are not passive knowledge-*absorbers* but active knowledge-*generators* who assume responsibility for constructing and managing their own learning experience. However, it can be added that for many adult learners who are used to education in a lecture-based environment, interaction and collaboration is not intuitive and they may feel comfortable in a passive student role [7].

II. THE HILL CONCEPT

To support blended learning, HILL, an e-learning environment has been in development in the Huittinen unit of the Satakunta University of Applied Sciences (SAMK) since the 1990s.

SAMK's adult education in business administration was centralized in Huittinen in 2010. As 97 percent of the almost 400 adult students in the Huittinen unit study while working, SAMK was looking for a solution that would allow adult students to attend classroom teaching without being physically present at the school. This would make it easier for them to fit their studies, work and family life together [8].

The solution was developed by combining different technologies under the HILL online lecture system, which is the result of cooperation between SAMK's Faculty of Business and Culture Huittinen, IBM and Cisco. Based on a video conferencing system, the solution gives you a realistic feeling of being in the classroom without actually being there. The teacher can focus on teaching like in a normal classroom situation [8].

The first classroom utilizing the new technology was introduced at the Huittinen campus in August 2011 and the second at the beginning of 2012 [8].

The classroom where the teaching takes place is equipped with a Cisco video conferencing system including a display screen, HD cameras and microphones, as well as a SMARTBoard interactive whiteboard. The teaching situation is transmitted online by the Cisco Webex Meeting Center [8]. Sound technology is provided by AKG.

Only the teacher needs to be present in the classroom. Students need a multimedia computer and a working Internet connection. Through their browsers, students can see what is going on in the classroom, listen to the discussions of all parties, participate in the discussions and see the material that is being distributed or written on the whiteboard in the same way as a student present in the classroom [8].

In HILL concept, it is possible to teach online either in Meeting Center or Training Center. In Training Center, students can be divided into small groups, which is useful for practicing oral skills in a language (small group discussions, etc.).

Since January 2015, almost all language teaching except certain written exams is conducted via HILL. HILL enables work in pairs or in small groups as small group sessions for a desired number of people in each group can be formed. This is vital for language learning as students can practice their oral skills in small groups, just like in a class room setting.

III. STUDYING LANGUAGES ONLINE VIA HILL

In SAMK, the students study different languages at least three or five credits, depending on the degree programme. The obligatory languages are English and Swedish. Before entering the obligatory language course in English or Swedish, students' language skills are tested. If they do not reach the target level - B1 in Swedish and B2 in English in A Common European Framework of Reference for Languages - [9], a refresher course is recommended for them. In addition, there are courses in German, French, Russian and Spanish available. Most courses are studied in a traditional class room setting, but adult students in Huittinen unit study in the HILL e-learning environment. Also in other SAMK units, HILL is used in studying languages but not as widely as in Huittinen. The students in Huittinen are studying towards a degree in Business Administration, and they complete their whole education via HILL.

Until the beginning of the year 2015, HILL was used in language studies in the same way as in all other subjects. One course included three three-hour lessons. During those lessons, students were able to participate either by being present in the class room in person or online via HILL. It was also possible to watch a recording of the lesson later on. But, as students did not get enough practice in their oral skills this way, a change was needed. From January 2015, a new form of studying was introduced.

In the new mode, there are only two sessions that students attend in the classroom: an introductory lesson and a written exam. The student can participate in the introduction lesson also via HILL.

When studying online it is essential to have a good, functional learning platform. In SAMK, the virtual learning environment Moodle is used. After the introduction lesson, the students start studying in Moodle according to the instructions by the teacher. During the course the students have to participate in at least two or four, depending on the course, obligatory oral skills training lessons via HILL. In HILL there is a Training center for this purpose. During these oral skills training lessons, pronunciation, oral skills and communication skills are studied. The students are given several options for times of the lessons where they can choose the best one for themselves. The oral lessons are held mainly on Fridays or Saturdays or later on in the evening during the weekdays. This way the students can combine their studies and working life.

Besides these obligatory oral skills training lessons, students are given a possibility to enter voluntary lessons, so called "question lessons", where students can ask questions about for example exercises, or anything related to the course. Especially grammar topics can raise questions where students might need some support from the teacher. During these voluntary lessons, the teacher is available via HILL answering the students' questions and explaining unclear issues. HILL is also used for having oral presentations and oral exams. Written exams are still taken traditionally in a class room.

Studying foreign languages has many aspects: reading and vocabulary, oral skills and pronunciation, writing, listening comprehension and communication skills. Combining HILL and Moodle has created an efficient way of blended learning in foreign languages. Language teachers in SAMK have completed the Eurolta-Eurovolt education. Eurolta-Eurovolt concentrates especially on the problematic questions in teaching languages online [10]. All of these aspects mentioned above are taken into account when planning a blended learning language course. It is rather straightforward to create written exercises, e.g. reading comprehensions, vocabulary exercises and writing essays, in the Moodle, but for practicing oral skills, pronunciation and communication skills, HILL is ideal. Audio and video exercises in Moodle are also used. They are seen as a good way to practice pronunciation and also communication skills if worked in pairs. Different kinds of online language programs, grammar sites and other linguistic websites are used. When possible, such textbook is chosen which includes electronic material, e.g. listening comprehension exercises, read texts and the right answers that can be put online. These kinds of textbooks are very suitable for blended learning as they give students a freedom to choose when and where they want to study.

During spring 2015, four language courses have followed this new way of studying languages online via HILL: a refreshers' course both in English and in Swedish and an obligatory language course concentrating on specific vocational language, both in English and in Swedish. Besides students from Business Administration, students from Health and Welfare have participated in the refreshers' courses. The language courses concentrating on vocational language learning have been intended for Business Administration students in the Huittinen unit. They complete their whole education via HILL, but the students in Health and Welfare take only some courses or do parts of a study module via HILL. The extent of refreshers` courses is two credits and the obligatory vocational language courses are five credits. This spring there have been 154 students participating in these courses. The students were asked to fill in a questionnaire about blended language learning via HILL. 45 students returned their answers. In the questionnaire, the students were asked 1) to describe blended language learning via HILL, 2) to write about the similarities and differences compared to traditional studying in a class room, 3) to name pros and cons in blended language learning and also 4) to make suggestions for how to develop language teaching via HILL in the future.

Students described studying languages via HILL mainly in a positive way. Most students used phrases like efficient, easy, activating, interesting, pleasant, meaningful, excellent and good. They described studying being different and unusual but surprisingly easy, fun, relaxing, handy and inspiring. They felt that they had got teaching of good quality. The students explained that they liked independent distance studies and described HILL as a flexible and functional concept which makes it possible to combine studies and working life.

Language teachers see HILL as a very efficient answer to the challenges among blended learning. Using HILL requires that teachers are familiar with the technology to be able to take advantage of the different possibilities that the HILL concept offers. They also need to be aware of the pedagogic solutions that are suitable and meaningful for teaching languages online via HILL. In addition, they need courage to exploit new possibilities that they have not used before.

IV. STUDYING LANGUAGES ONLINE VERSUS TRADITIONAL STUDYING IN A CLASS ROOM

There are similarities as well as differences in blended language learning compared to traditional studying in a class room. Most students were of the opinion that studying online requires more from a student; more active involvement, motivation, self-discipline and skills of an independent way of studying. Some students felt they would have needed more support from the teacher. Some people wished for more feedback from the teacher; you can feel quite alone studying online. Especially if a long time has passed since a student has studied languages, he or she would need more support from the teacher and feel more comfortable with traditional face-to-face classes.

The students found studying online more efficient since you really concentrate on studying, rather than for example chatting with the person sitting next to you in the class room. You are able to concentrate better on the actual topic. Some also mentioned that they wanted to study more in order to be able to participate more actively during online HILL lessons. However, one student said that it is easier to skip lessons and stay in the background via HILL.

Several students mentioned that they are more courageous using their oral skills online via HILL than in a traditional class room setting. They found it easier to practice their communication skills online. They felt it was somehow more relaxing than in a class room. They could let go of needless self-criticism more easily; they felt it was easier to ask and make comments online and they did not have to be afraid or ashamed of failure in the same way. Studying online was also described as more democratic and flexible than studying in a class room. The students felt that online learning requires clearer instructions of the teacher, e.g. in Moodle. A student has

to be able to get the idea of an exercise independently without the help of a teacher.

Students saw also that one big difference was a possibility to get a fast answer to your question. When studying online you had to sometimes wait longer in order to get the answer while in a class room you could have got the answer right away from the teacher. One difference mentioned was also the fact that you did not get to know other students or the teacher as well as during traditional contact lessons. Forming personal contacts online is more challenging. Some also mentioned that it was sometimes difficult to concentrate on teacher´s pronunciation via HILL having headphones on than in person. Sometimes the voice is not clear enough and it makes listening more demanding.

Yet, some students saw that there are not so many differences when the technology or recording of a lesson is working. Also, according to some students in the study it is important that students possess quite good computer skills. Some students mentioned that technical problems have inhibited their learning sometimes; for example, sometimes the students' audio system has not worked properly. They find studying rather similar to traditional studying in a class room. Compared to a traditional class room a few described online learning being challenging and one found it lonely. Someone missed meeting other students and teacher in person. Also, someone felt it is a bit difficult to take part in common discussions naturally, so he or she rather stays silent. Also a student commented that it is just too easy to stay silent when online.

The students found several positive aspects in online learning. The most typical answers were related to time and place. It was very good that they could study when it is best for them. They can create own timetables for studying. They can also study where they want. They don´t have to use time or money travelling to school. It was also mentioned that studying at home, in a safe and familiar environment creates comfort. You did not have any extra voices during lessons via HILL like in a class room. Having headphones on made it easier to concentrate on the lesson without outside distractions. It was peaceful to study.

Studying online was also described as a more efficient way of learning. Since you have to take more responsibility of your own studies you also learn more. Studying online can be more rewarding because when you have to challenge yourself and then succeed, it feels better. Someone also mentioned the fact that you can participate in lessons if you are sick. This is true, you might be able to participate in e.g. one hour's lesson via HILL but you would not be able to drive to school. Students mentioned that you can also use online dictionaries and other online materials better all the time while studying online. It was also found as a positive thing that you can listen to recorded HILL lessons or other study videos several times, take breaks if you need, and then continue again. The students were very pleased with the HILL concept from the viewpoint of oral skills training lessons and "question hours" where they can ask linguistic questions.

For a teacher, the same kind of positive aspects are appreciated. Also, for a teacher HILL provides flexibility: you do not necessarily have to travel to school to give lessons but you can also give them from home, for example. Teachers can plan their own timetables more freely and work during the time of day that suits them best. Using HILL and blended language learning creates interesting challenges to a teacher: he or she constantly needs to search for better online learning solutions.

The cons from the point of view of teachers include that there is a lack of face-to-face communication. For example, teachers cannot notice it if someone does not comprehend something because they cannot see the students in the same way as in a class room as they are not in the same room. The students themselves need to be active and inform the teacher about any unclear issues and ask if they have questions. Online teaching also requires more time and effort from the teacher, and more time is needed also to answer email messages since students contact teachers more frequently than when the teacher and students regularly meet in a class room. Also, time has to be reserved for learning to master the online teaching system properly.

Getting to know students and forming teacher-student relationships is more challenging for teachers when teaching online. However, HILL helps in this as teachers can hear and see the students almost as if they were present in the class room.

V. CONCLUSION

There are many different online learning solutions for learning languages, and at SAMK, HILL has answered adult students' needs as students are able to combine their studies, work and family life. HILL has also enabled blended language learning, and particularly well the practice of oral and communication language skills. With HILL, adult students are able to stay in contact and in interaction with the teacher and other students, which increases the sense of belonging to the same group.

Due to HILL and the idea of blended language learning, better results are being achieved in learning languages. In blended learning, it is possible to take different learning styles and students' personalities into account. In that way, teacher can create different kinds of exercises and learning experiences and make it easier for different kinds of learners to learn. Also shy and sensitive students have a possibility to express themselves online and in that way achieve better results than before. Blended language learning requires surely more of a student but it can also give more.

The learning results have reached a better level also because of a change in the role of a student. They no longer get all information given, instead they have to work harder for it and take more responsibility for their

own learning. Through responsibility comes motivation and so, more learning takes place.

Blended learning requires more from a teacher than traditional teaching in a class room; active development and re-evaluation of one's own teaching methods and way of being a teacher; mastering the technology involved; initiative and willingness to develop methods for students to learn in the best way possible. At least in the beginning, teachers need additional resources for teaching online, and it is imperative that teachers moving into teaching online should get all the possible support and training needed.

The basis of blended learning is a stable technical solution, which also came up in many replies.

During spring 2015, the way languages are being studied online via HILL has been renewed. Students are still wishing for even more oral language lessons and "question hours". Also, according to students, more teachers (also teachers of other subjects than languages and also in other units in SAMK) should take small group discussions into use in HILL.

Blended learning offers various possibilities for language learning. The HILL concept and methods of teaching are constantly being developed to even better meet the needs of modern language learning.

Information Literacy Assessment at the University of Zagreb: an Undergraduate Students' Perspective

M. Pavlovski* and I. Dunđer*
* University of Zagreb, Faculty of Humanities and Social Sciences/Department of Information and Communication Sciences, Zagreb, Croatia
mpavlovs@ffzg.hr, ivandunder@gmail.com

Abstract - Information literacy represents the set of skills that enables individuals to identify, locate, evaluate and utilise relevant information for a certain task. This paper presents results of a survey regarding information literacy, carried out on undergraduate students of the Department of Information and Communication Sciences at the Faculty of Humanities and Social Sciences, University of Zagreb. Previous surveys had asserted the need to include information literacy or information competencies, differentiated from already present tool literacy or technological competencies, in students' curricula on the University. The aim of this survey was to analyse the students' information competencies as well as examine the students' attitude towards introducing an undergraduate course, during which they would learn how to efficiently search for information in the electronic environment while preparing seminar papers and exams. Furthermore, to gain an insight into the students' information retrieval accuracy in course-related research, the authors of this paper shall evaluate their information behaviour, i.e. investigate whether the students develop an overall research plan or search in relevant information sources, e.g. peer-reviewed databases etc. The research results can be helpful to determine the importance of information awareness at this level of education.

I. INTRODUCTION

Information literacy or information competencies of students, their ability to discern relevant from irrelevant information during research used for personal and professional purposes, has been the subject of a numerous quantity of papers in the field of information and communication sciences [1]. Differences between tool literacy or technological competencies and information literacy, defined as a term that represents the set of skills that enables individuals to identify, locate, evaluate and utilise relevant information for a certain task, have been evaluated in different studies locally, in Croatia, and globally. Concerning the skills of undergraduate students at the Department of Information and Communication Sciences at the Faculty of Humanities and Social Sciences, University of Zagreb, in their information retrieval accuracy in course-related research, evaluations on the information behaviour have previously been done on previous generations. The main question is do undergraduate students of newer generations feel the need that information literacy or information competencies should be included in students' curricula?

II. RELATED WORK

According to [2], information behaviour represents the totality of human behaviour in relation to sources and channels of information, including both active and passive information-seeking, and information use, those activities a person may engage in when identifying his or her own needs for information, searching for such information in any way, and using it or transferring that information. In other words, it describes the user's information need, the way of seeking, disseminating and using information in different contexts [3].

The American Library Association states that information literate persons "know how to learn because they know how knowledge is organised, how to find information and how to use information in such a way that others can learn from them. They are people prepared for lifelong learning, because they can always find the information needed for any task or decision at hand" [4, 5].

According to a research, "information behaviour patterns are significantly influenced by the ever increasing sophistication of information resources and technological developments. A crucial element of information behaviour research is applied to the design of information literacy strategies" [6]. Furthermore, current educational systems thrive for student-centred active, flexible and problem-based learning, which emphasises the students' independent information seeking [6].

A survey shows that the majority of students are familiar with the concept of e-learning, consider it supplementary to traditional learning and that the contents they use most often are presentations used in lectures, submission of homework and seminar papers, course descriptions and reading lists. Furthermore, the authors conclude that they "believe that this type of research should be conducted regularly on an annual basis, thus enabling e-learning to be improved" [7].

Another research concluded, that "it would be wrong to claim that users are incapable of finding information by themselves as it would be wrong to claim users are

completely independent in forming their information queries. Accepting the fact that we have moved from system-centred to user-centred information environment would make a good start. Developing course curricula and library activities according to that would mean a great step forward, a step everyone involved in education process has to take in form of an interdisciplinary activity" [8]. The results that arose in this work concluded that information sources and the ways of retrieving information should be part of the curriculum, and that future information specialist (i.e. students of the Department of Information and Communication Sciences) should have more opportunities to learn about information, specifically in an electronic environment, as part of their formal education [8].

One article states that with the introduction and extensive use of electronic information in classrooms the need for information literacy competencies which are necessary for the learning process became more than apparent. "Hence, the ability to meaningfully interact with a wealth of information is deemed more important than ever. More specifically, this correlation has been proved by numerous investigations and studies confirming that academic success and the effectiveness of learning depends on competencies in accessing, evaluating, synthesising, communicating and ethically using information" [9, 10, 11].

The authors also affirm that "although the conceptual core of information literacy, with its emphasis on acquiring abilities that enable one to ethically seek, use and create information, has remained quite stable since the term was first introduced, theoretical foundations of information literacy as well as ideas related to its practical applications and processes have constantly been subject to revision and re-examination" [12].

Reference [13] states that information literacy can be approached as an object of teaching as well as an object of learning, and that it is interesting to evaluate the opinions of undergraduate students on the ways of implementing information literacy in the curricula and their high response percentage to introducing professional education of the subject in one or more courses.

III. RESEARCH METHODOLOGY

The research method was an online survey, which was conducted via the Omega system (https://omega.ffzg.hr/), a customised version of the Moodle Learning Management System (LMS) at the Faculty of Humanities and Social Sciences, introduced in the academic year 2004/2005 [6]. The research carried in February 2015. Two courses ("Information sources and service" and "Machine translation") were researched by means of the survey method.

Undergraduate students were asked to anonymously complete a voluntary questionnaire that consisted of ten questions: one closed question asked for a short answer, two questions provided multiple choice answers, one open-ended required the students to write down their own opinion, two questions used grading from 1 to 5, and the last four questions were used to gather data about the students' gender, age, study groups and year of study. The two questions (questions 3 and 5) that used grading from 1 to 5, 1 being the lowest and 5 the highest value, asked students to grade their competencies using the following information sources/tools: Google, Google Scholar, the library and databases (of scientific publications and citations), and to grade the corresponding availabilities.

The first question asked the students to choose which of the aforementioned sources/tools they use in preparation of seminar papers and exams, whereas the second question asked them to write which one of the four they use most often.

The fourth question asked the students who of the following they consult when looking for guidance in using information sources/tools: colleagues, teachers, family members, other. The option "other" was provided with a blank space in order to enable writing potential answers.

Question 6 was two-fold. It asked students if they did or did not think there is a need to include professional education of information literacy or information competencies as part of one or more courses at the undergraduate level of study. They had a choice between answering "Yes" or "No" and a blank space was added for the students to write an explanation of their answer, independently and regardless of their affirmative or negative opinion.

Questions 7 and 8 were about identifying gender, and age, respectively. Students' age was divided into three possible categories: from 18 to 20, from 21 to 25, and over 25. The last two (questions 9 and 10) had blank spaces in which students could write their study group and year of study.

IV. RESEARCH RESULTS

The questionnaire was finished by 40% of the students (i.e. 18, out of 45 students enrolled in both courses), of which all were undergraduates. The responses from graduate students were not taken into consideration for the results of this survey. The following table gives an overview of students' gender, age and year of study (Table I).

TABLE I. INFORMATION ON RESPONDENTS

Gender	*Male*	6 (33.33%)
	Female	12 (66.66%)
Age	*18-20*	1 (5.55%)
	21-25	17 (94.4 %)
	> 25	0
Year of study	*First*	1 (5.55%)
	Second	0
	Third	17 (94.4 %)
Total number of respondents	18	

The first question asked the students to choose which of the following information sources/tools they use in

preparation of seminar papers and exams: Google, Google Scholar, library and databases. Fig. 1 shows that Google is used by all of the respondents (18), Google Scholar by 9, the library by 16 and databases by 11 students. Google Scholar is therefore not being used by 50% of the respondents.

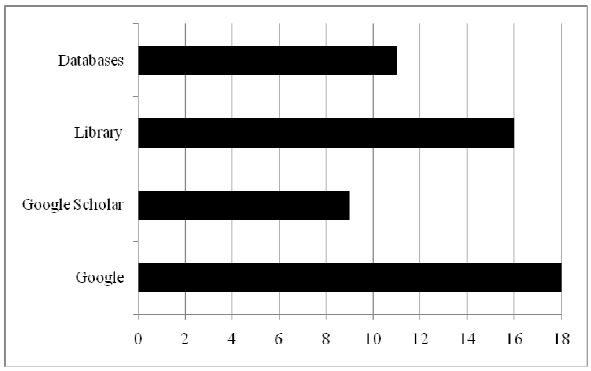

Figure 1. Usage of information sources/tools while preparing seminar papers and exams.

The second question asked which of the four aforementioned information sources/tools they use most often. Google is the most used tool for 10 students, followed by the library (6), whereas Google Scholar and databases are most often used only by 2 students, as shown in Fig. 2.

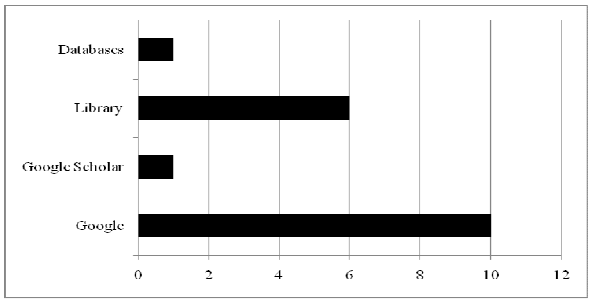

Figure 2. What information source/tool do you use most often?

The third question asked the students to estimate their competencies in using the aforementioned information sources/tools, on a scale ranging from 1 to 5. Fig. 3 shows average values of the respondents' answers.

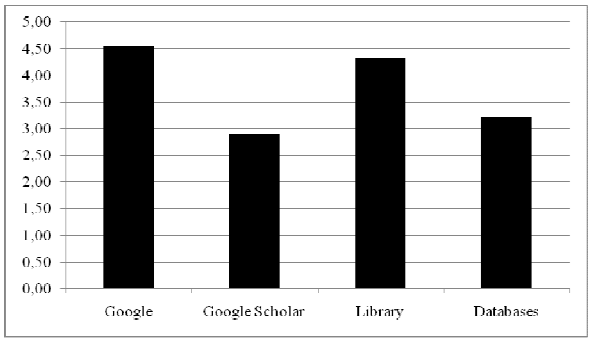

Figure 3. On a scale from 1 to 5, estimate your competencies in using the aforementioned information sources/tools.

For Google, 10 students graded their competencies with a 5, and 8 students with a 4. Grades lower than 4 were not given. For Google Scholar, 2 students graded it with a 5, 5 with a 4, 5 with a 3, 1 with a 2, and 5 with a 1. It is evident that Google Scholar is graded much lower, i.e. almost 30% of the respondents have no competencies whatsoever in using Google Scholar. Regarding the library, 9 students graded their competency in using it with a 5, 6 with a 4, 3 with a 3 and none with a 2 or 1. Concerning their proficiency in database research, 2 students graded it with a 5, 6 students with a 4, and also 6 students with a 3, 2 with a 2 and 2 with a 1. Highest average score is given to Google (4.56), followed by the library (4.33), databases (3.22) and then Google Scholar (2.89).

One multiple choice question (question 4) asked who is assisting them in using the information sources/tools. "Colleagues" had the highest response (17), followed by "teachers" (8) and "family members" (1). The option "other" had also one response: "persons I feel are experts in the particular field".

The fifth question asked students to grade the accessibility of the information sources/tools. For Google, 9 students graded its accessibility with a 5, 8 with a 4, 1 with a 3 and none with 2 or 1. For Google Scholar, 1 student graded its accessibility with a 5, 5 with a 4, 8 with a 3, 1 with a 2, and 3 with a 1. Three students graded the library's accessibility with a 5, 9 with a 4, 5 with a 3, none with a 2, and 1 with a 1. Regarding the databases, 2 students graded its accessibility with a 5, 10 students with a 4, 3 with a 3, 2 with a 2 and 1 with a 1.

Average values of the respondents' answers are presented in Fig. 4, showing an evident trend similar to the trend in question three, indicating correlation to a certain extent between competencies in using information sources/tools and their availability. Namely, again highest average score is given to Google (4.44), followed by the library (3.72), databases (3.56) and Google Scholar (3.00)

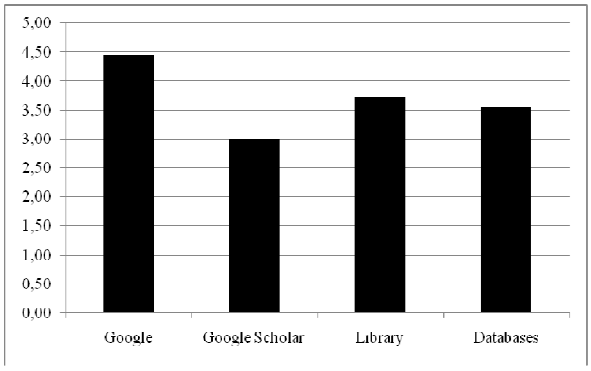

Figure 4. On a scale from 1 to 5, grade the availability of the following information sources/tools.

The sixth question was divided into two parts. For the first part of the question, 17 students answered "Yes" and 1 answered "No". This shows that almost all of the respondents think that inclusion of professional education of information literacy or information competencies as part of one or more courses at the undergraduate level of

study is necessary. Of the 18 students, 16 decided to explain their answer, whereas 2 students left the space for explanation blank.

In their explanations, they mostly agree that for their study, but also in terms of lifelong learning as a whole, information literacy skills are needed for easier finding of relevant information and the correct use of information. Some students believe that, regardless of the study group undergraduate students should obtain an "elementary knowledge" about information literacy and its use in the academic environment for a more efficient completion of scholarly tasks.

Furthermore, some of the respondents stated that education of information literacy should not be introduced only at the Department of Information and Communication Sciences, but at the level of the whole Faculty.

According to one student, information literacy should become an obligatory course for all students at the undergraduate level, starting from the first semester, as it is "obvious that information science students are more competent regarding information literacy, due to Department courses that impose the use of repositories, databases and the completion of different tasks that require a selection of relevant information."

Some students mentioned that colleagues from other study groups often refer to them and ask them for advice in searching for literature using library catalogues and different types of repositories.

As mentioned by one of the respondents, some of the students are not capable of forming correct queries to find relevant information on Google.

They also emphasise that in today's digital environment it is essential to correctly use, seek, find and evaluate information, and that those skills will be of use not only in further education, but in life and professional career as well.

One student pointed out that information literacy should be taught on a practical basis, during an internship in "relevant companies". This would possibly allow future employment at that company.

Students also mentioned that there are a couple of courses related to elementary skills in information literacy, but they assert the need for one course with the possibility of evaluating each students' information competencies, which offers individual, expert tasks to those more proficient users.

As already shown in Table 1, 66.66% of the respondents were female, 94.4% were in the age category "21-25" and in the third year of study. Only 1 student was in the age category "18-20".

All of the students study "Information Sciences" as single (10) or double major (8), e.g. Croatian language and literature (1), German language and literature (1), English language and literature (1), Philosophy (1), Japanology (2), Russian language and literature (1), Turkology (1). There was 1 student of the first study year, none from the second year and 17 of the respondents were students of the third year.

V. CONCLUSION

For the investigation and deeper analysis of information literacy, it is interesting to explore the students' perspectives on the need to integrate information literacy into curricula. Exactly this was examined in this research, which was conducted in form of a survey regarding information literacy on a sample of 18 undergraduate students of the Department of Information and Communication Sciences at the Faculty of Humanities and Social Sciences, University of Zagreb. Students at the undergraduate level of study show that key sources to course-related information are Google, the library and colleagues, rarely teachers, and almost never databases and family members.

They evaluate their information competencies mostly high for using Google and the library, and mostly average when using Google Scholar and databases.

The students graded the accessibility of information sources/tools mostly average, with Google being graded the most accessible, followed by libraries and databases.

Out of the 18 students who responded to the survey, 17 answered "Yes" to the question if they thought there is a need to include professional education of information literacy or information competencies as part of one or more courses at the undergraduate level of study.

The main default of this research is the relatively small sample. Still, representativeness is not always guaranteed by sample size. Namely, in this research the research focus was on identifying information behaviour trends and investigating whether the students develop an overall research plan or search in relevant information sources, databases etc.

This paper has shown that in order to optimise information behaviour, according to students, introducing one or more information literacy courses is of importance for students of all levels. Further research would include sample enlargement and shifting the focus to graduate students.

Tiny Operating System Kernel for Education Purposes

Samir Ribić*, Adnan Salihbegović*
* University of Sarajevo/Faculty of Electrical Engineering, Sarajevo, Bosnia and Herzegovina
samir.ribic@etf.unsa.ba, adnan.salihbegovic@ etf.unsa.ba

Abstract - The operating systems courses are often organized according to three basic approaches: as user-centric, theoretically oriented with the explanation of the principles of operation, or through analysis and modification of the kernel source code. While the third approach is the most illustrative, it requires the most of the time at the expense of broader analysis of implementation for different algorithms of the operating systems. Hence, the frequent approach is the development of small kernel, instead of analysing those that are in wider use. In this paper we will present a simple kernel, with a minimal size of source code, which can be fully described in 90 minutes of classroom teaching, but still large enough to be installed and started on a typical PC. This educational version of a kernel includes the basic functions of any OS core: video, keyboard, disk, file system, memory, processes and threads.

I. INTRODUCTION

Most of the faculties and collages that educate students in the field of computer science and engineering and information systems have in their curricula the course in operating systems. Within the variety of taught courses on this fundamentally important subject, three basic approaches have come up so far.

Within the study programmes oriented towards information systems and technologies, the most frequent are user-oriented courses, inclining towards the practical problems like installation, configuration and administration of the operating systems.

Theoretical analysis of algorithms that arise in the implementation of operating systems is an approach that is dominant in operating systems courses at the universities oriented towards computer science. The advantage of this approach is the bigger picture that students acquire on the structure of operating systems; the disadvantage being that the perception of the operating systems remains abstract.

The approach of introducing the principle of operation of operating systems through the explanation and source code development of an operating system kernel can be successfully applied if the students have sufficient preceding knowledge. This approach offers better understanding and acceptance by the student's operating systems fundamentals, but leaves less room for teaching alternative approaches and examples.

II. REVIEW OF RELATED COURSES

Size of the OS source code is a term that has a completely different meaning in the industrial applications and education. For example, one megabyte represents about 20,000 lines of source code. While stored on the disk is negligible quantity, when printed out on paper will contain about 500 pages, the amount of study content for whose explanation an entire semester will be required.

This of course, will be unacceptable as teaching content, because describing and explaining only the source code will produce rather monotonous way of teaching. Operating systems that are used in the real world applications (the Windows NT kernel and Linux), are much greater, for example Windows 7 has 2 million, and Linux 3.10 has 17 million lines of code, and it is only for kernel. Therefore, their source code cannot be suitable teaching tool for the study of the principles of operating systems. Some authors explain portions of complete kernels. Windows Research Kernel contains around 830,000 lines of code [1] and is available to educational institutions, with special agreements with Microsoft. Despite the mentioned size it cannot be executed independently. There are also textbooks centred over particular OS design, but use only short code snippets or pseudocode [2].

If it is desired that the source code of the operating system kernel is an addition to the theoretical consideration of the principles of operating systems, as an illustration of the kernel operation on a real machine, more practical and feasible are examples with smaller size of code. Frequently, older versions of successful operating systems are used or teachers develop their own version of small operating systems.

The most common approach is to develop the kernel, which resembles the UNIX kernel. This is not a surprise, considering the popularity of the UNIX having its roots among the university communities.

Minix [3] is the most famous educational operating system. Partly is UNIX compatible and explained in the cited book, together with the theory of operating systems accompanying the parts of source code itself. The OS length is around 16 000 lines, so the whole course can be organized based on this reference. Minix can be also used for high reliability systems, and its architecture is with micro-kernel.

Xinu [4] is also used as a kernel around which popular book on operating systems has been written. The first version was intended for the PDP-11 machine, followed by the versions for IBM PC [5], the Motorola 68000 systems, Mips, Spark and recently ARM based machines.

The approach to the subject in the book is easily acceptable. Xinu contains around 8000 lines of code, but does not enter into the scope of the file system. When installed on PCs it relies on MS-DOS calls to work with files.

Nachos [6] is written in object-oriented languages, there are C ++ and Java version, with the addition of C and MIPS assembly code. It contains around 5,000 lines of code, and runs in a virtual environment.

Old versions of Unix and Linux kernel are also used for educational purposes. At MIT university for teaching the design of operating systems, for long period of time, the old version of Unix V6, with 8300 lines of code has been used. After the students were wondering about the purpose of learning the outdated system on the old platform written in an ancient version of the C language, under name XV6 it was ported to the 80386 platform [7].

In the case of Linux, version 0.11 was the first version capable of independent execution; it had 14,000 lines of code. Annotated version of this kernel was mentioned in reference [8]. After code reduction down to the 5000 lines, new OS named Qutenix was created [9].

If the kernel is freed from design requirements to be similar to Unix, smaller kernels are also possible. Geekos [10], with the source code of around 3000 lines is an example of the kernel that is designed to be small and therefore easy to understand, and not burdened with a request for similarity to Unix or Windows. However, this operating system does not have its file system.

In reference [11] educational version of OS is described that similar to floppy based CP/M operating system, with considerable limitations (files with size up to 13KB and processes up to 64KB). The source code has only 1200 lines, which makes it the smallest educational version of kernel OS we have discovered during this research.

III. KERNEL STRUCTURE

A. *The principles of kernel design*

For students, to understand the principles of operating systems and yet not spend too much time in the analysis of the source code, the specific minimalist kernel of the operating system was developed. The design principles were as follows:

The kernel has to be able to run independently on real physical hardware, and not only on the virtual machine. It should not be dependent on any existing operating system. To make it runnable on wide spectrum of computers, kernel is designed for 386-compatible PCs in 32 bit mode, with peripherals that include an IDE drive, keyboard and text display.

Alternatively, it can run under qemu emulator, available at http://wiki.qemu.org/Main_Page. In order to clarify some technical specifics for this environment, we used information from the website http://wiki.osdev.org.

The kernel is written in C, except for the boot sector, part of the code to save registers and very short routines for input/output and interrupt stack structure that are coded in assembly language.

TABLICA I. KERNEL FILES, LAYERED

Files	Role	Line
bootsect.asm	Load kernel, switch to protected mode	85
string.c	String operation routine	41
ports.c	I/O mapping instructions	25
video.c	Display of text on the screen	58
hello.c	Greeting message	10
testvideo.c	Video subsystem test	
keyboard.c	Keyboard driver	147
testkbd.c	Keyboard test	
interrupt.c	Interrupt implementation	145
testinter.c	Interrupt test	
diskio.c	Direct access to IDE HD	47
testdisk.c	Disk test	
files.c	File system	278
testfiles.c	Files test	
memory.c	Linear page memory	104
testmemory.c	Memory test	
sched.c	Scheduler	138
syscall.c	System calls	90
testproc.c	Scheduler test	
Kernel total lines of code		1168

It was necessary to include in the kernel the range of functionalities like: inputs/outputs, the organization of memory, disk, file system and scheduling processes. Developed kernel can be used for simple algorithms in the realization of subsystems (first fit in memory, continuous allocation in a file system, cooperative round robin scheduling process), with the possibility that students through exercises implement more advanced algorithms, or get acquainted with them theoretically.

The kernel is organized in layers for didactical reasons. Each new source code file can use the previous ones, while with the addition of the main function, may represent a unified entity. The Table I lists the source code files with their length in number of lines. The table also represents the order in which these files are processed. The test files are called after explaining to the students the operation of individual subroutines, and also include kernel main program core. The acronym for kernel name is LEKOS (Layered Educational Kernel of Operating System).

With an average rate of kennel code explanation of 15 lines per minute, with all intermediate stages of compiling and displaying various demonstration examples, standard 90 minutes of laboratory exercises suffices for a complete presentation of kernel structure and operation. In the subsequent part of the paper, the implementation of kernel subsystems with code snippets for shorter routines will be demonstrated.

B. *Bootstrap subroutine*

This is the only subroutine written in assembly language. The boot sector has to be of the max. size of 512 bytes and finished with the signature. It consists of two main parts, 16 bit and 32 bit. Sixteen-bit segment of the code is executed at 000: 7c00 calling two times BIOS interrupt 13h. These interrupt calls pass the adequate parameters via registers. The first call resets disk controller, the second call transfers some sectors from the

disk into the RAM. With this transfer, the file with kernel is loaded with into the memory. In the second half of the sixteen bit segment GDTR register is loaded to point to a table that simply maps the memory segments for linear addressing. After changing the value of CR0 register, program switches to protected mode.

Thirty-two bit part of the Bootstrap subroutine sets the segment registers, stack pointer and jumps into the kernel. The boot sector contains descriptor table, required to transform Intel segment architecture into a linear one. The table consists of only three descriptors: one is empty, one for code and one for data.

C. String routines

The operating system is running on an empty machine. Since the programmer has no standard C library at disposal, several necessary functions for operation with strings have to be provided. These functions can be implemented purely in C language. The realized functions are: strncmp, strncpy and itoa.

D. Mapping of I/O ports

The standard C language does not have built-in access to I/O mapped peripherals. Therefore, it is necessary to use assembler routines, but they are easily encapsulated in the appropriate subroutines using inline assembler built into the GCC. For example, to read eight bit data, the following function is used:

```
unsigned char in(unsigned short _port){
   unsigned char result;
   __asm__("in %%dx,%%al":
        "=a" (result):"d" (_port));
    return result;
}
```

E. Video driver

In order to enable the greeting message to appear on the screen as the first step in work with the operating system kernel, the next step is to display message on the text screen. The first part of a simple video driver is positioning the cursor. The cursor position is held in the variable `cursorpos`, containing 80*row+column memory location. Its value can be read and changed with the following simple functions `SetCursor` and `GetCursor`. In subroutine `hardwarecursor`, the registers on ports 0x3D4 and 0x3D5 are used, with which the text cursor is switched on.

Textmode video buffer on PCs is located on the absolute address 0xB8000. Access to the textmode memory is in the form of a matrix with 80 columns, in format of ASCII characters for every character on the screen. The screen deletion is accomplished by inserting a character with the code 0 or 32 at desired location in video memory. Printing of the text on the screen is done with subroutine `Print` containing a loop that inserts ASCII codes into the message, skipping the attributes in video memory, while subroutine `PrintNum` prints integer value calling atoi function before `Print`.

```
void PrintNum(int num) {
    char text[20];
    itoa(num,text);
    Print(text);
}
```

```
void Print(const char * msg) {
    unsigned long i;
    unsigned char *vmem;
    vmem= (unsigned char *)0xB8000;
    vmem += cursorpos<<1; i = 0;
    while (msg[i] != 0) {
     *vmem = msg[i++]; vmem += 2;
    }
    cursorpos += i;
    hardwarecursor();
}
```

What is left for laboratory exercises or homeworks are: scrolling functions, printing special characters such as CR / LF etc.

F. Keyboard driver

The relatively easy part of this driver works directly with scan codes. When the key is pressed (0x64h port returns on zero bit the value of 1), the value of the pressed key can be read from port 0x60h.

```
unsigned char GetScanCode(){
  static char code;
  if(in(0x64) & (0x01)) code = in(0x60);
  else code = 0;
  return code;
}
```

Larger part of this driver is a subroutine that converts the scanned code in ASCII, in cases with SHIFT, CTRL combination and direct keypress. Three tables are used: `kbdshift`, `kbdctl` and `kbdnorm`, which enable the conversion of scanned code into ASCII codes.

```
char * kbdnorm=
"\0\0331234567890-=\b\tqwertyuiop[]\n,\0asdfghjk
l;\''`\0\\zxcvbnm,./'\0\0\0 ";
```

The subroutine `ScanToAscii` is looking whether the keypress is one of the: Shift, Caps Lock, Ctrl and Alt keys, etc., and on that basis, include or exclude certain flags. According to a combination of flags, the selection of the adequate conversion table is carried out. Reading of the key at this stage is performed by subroutine `WaitKey`, and demo program displays pressed keys on the screen:

```
char WaitKey(){
  int keycode = 0;
  while(!keycode) keycode = GetScanCode();
  return ScanToAscii(keycode);
}
```

For the lab. exercises and homework assignments the implementation of other keyboard layout, support for function keys and numeric keypad can be added.

G. Interrupt driver

The next task in kernel development was to avoid busy wait. For this purpose the interrupts are used. In protected mode IDTR register points to the interrupt vector table. Each element of this table consists of eight bytes. Segment part of the descriptor is always set to the value of 8, since the memory was previously linearized, and flags are set to the same value for all interrupt descriptors. Therefore, only the lower and higher 16-bit offset values are set. Setting of the beginning of this table is done with machine instruction command `LIDT` that is incorporated in the C subroutine. In a similar way, the routines for switching on and off of interrupts are included, for example

```
void disable_interrupts () {
  __asm__ ("cli");
}
```

Early interrupt controllers on the PC computers were setting vectors for processing hardware interrupts starting from IRQ0, on interrupt vectors from 8 onwards. This is still implied configuration. Since the 80386 processor, these vectors are used for other purposes, on these addresses processor exceptions are generated. Therefore, it is necessary to remap the interrupt vectors so that the hardware requirements are processed from vector 32 onwards, what is implemented in routine `PIC_remap` consisting mainly of `out` instructions.

Format of the C subroutine is not the same as format of interrupt routines. Therefore, the routines that are executed in the interrupts have certain assembly instructions at the beginning and the end, in order to have the correct format of the stack.

The first of these is related to keyboard keypress reading. Received scan code of the pressed key is placed in a circular buffer. The routine for reading the keyboard takes over the character from this buffer. These functions are implemented as in the following section of code.

```
char kbdbuffer[256];
  unsigned int readchar,storedchar;
  void kbdirq() {
  static unsigned char c;
  __asm__ __volatile__("pushal; ");
  c=GetScanCode();
  if (c != 0) {
   storedchar=(storedchar+1) % 256;
   kbdbuffer[storedchar]=c;
  }
  out(0x20,0x20);
  __asm__ __volatile__
     (" popal; leave ; iret");
}

unsigned char readintscancode() {
  if (readchar!=storedchar) {
    readchar=(readchar+1) % 256;
    return kbdbuffer[readchar];
  }
  else
   return 0;
}
```

Second implemented interrupt is the timer interrupt. Its task is simple, increases the counter by one every 10 ms.

```
void Clock() {
  __asm__ __volatile__("pushal");
  elapsedtime++;
  out(0x20,0x20);
  __asm__ __volatile__
   (" popal ; leave ; iret");
}
```

The initialization of interrupt system sets the interrupt table and activates interrupt vectors for these two interrupts. Demo program shows the keyboard presses while time passes. For the sake of exercises, critical section to control the access to keyboard buffer can be added, processing of the interrupts generated by the serial port, or implementation of the processor exceptions.

H. Disk driver

Although their use in new PCs increasingly rare, as an external memory device an IDE hard drive is used, because it is the simplest kind of disk access at a low level. With these types of disk drives the ports 0x1f1 to 0x1f7 are used to send LBA or CHS address of the first sector in a group that user wants to transfer to RAM memory, with the information how much sectors wants to transfer. By sending the values to port 0x1f7, the command is activated which starts the transfer in one direction or another. After that, the values can be read or written. The subroutines for writing or reading blocks of data from disk are very similar, they send the LBA addresses to appropriate ports and read or write data.

```
int WriteHDBlock(void* buf,int first,int num ){
  int i;
  unsigned short* dat = (unsigned short*) buf;
  while(num > 0 ){
    while( in(0x1f7) & 0x80 ){} //Wait
    out(0x3f6,2);
    out(0x1f2,1);  //sector count
    out( 0x1f3,first & 0xff  );
    out( 0x1f4,(first >>8) & 0xff  );
    out( 0x1f5,(first >>16) & 0xff );
    out( 0x1f6,((first >>24) & 0x0f)|0xe0
    out(0x1f7,0x30);       //start write
    while( in(0x1f7) & 0x80 ){}
    for(i=0;i<256;++i, dat +=1)
      outw(0x1f0,*dat);
    --num;
    ++first_sector;
   }
   return 1;
}
```

Demonstration example of this subsystem is displaying on the screen the bytes on disk where the kernel of the operating system is stored.

I. File system

The file system was designed to be as simple as possible. Therefore, the directory was implemented with only one level, with a continuous allocation of files on disk. Nevertheless, data structures that describe the elements of the directory, beside the data on the name and the position of the file on disk, include the field directory, which allows extension on directories with two or more levels. Directory structure contains information on all the files on the disk, and about open files. These structures are resident in tables `dirtable` and `opentable`.

Opening of the file directory copies element with forwarded location number in the directory table, to the free location in the table of open files, while filling the elements of open files table that do not exist in the table directory. Separate routine `OpenFile` searches for file with the specified name and call `OpenFileByNumber`.

Modifications in the file content result in writing of the element directory on the disk, which is done by procedure `SaveDirEntry`. This procedure calculates the position of the specific element of the file directory structure on disk, and writes this in the block.

```
int SaveDirEntry(unsigned int num) {
  if (num<0 || num>=maxfiles)
    return -EINVALID;
  int dirsperblock=512/sizeof(struct direntry);
  int relposondisk=num/dirsperblock;
  int direntrytowrite=relposondisk*dirsperblock;
  WriteHDBlock( &(dirtable[direntrytowrite]),
  dirtableondisk+ relposondisk,1 );
  return OK;
}
```

Directory structure can recognise as the file type: free region, allocated regular file, and file that is type of directory. Deleting of the file is simply achieved by conversion of its content into free zone, to convert its directory content into the free zone, as seen in the following part of the code:

```
int DeleteFile(char * name) {
  int i;
  struct direntry * cde;
  cde=dirtable;
  for (i=0;i<maxfiles;i++,cde++)
    if(cde->entrytype==REGULARFILE)
      if(!strncmp( cde->name,name, NAMELEN) {
        cde->entrytype=FREEZONE;
        return SaveDirEntry(i);
      }
  return -EFILENOTFOUND;
}
```

Subroutine for file creation, due to the continuous allocation of space on disk, needs to contain its maximum size as parameter. After that, the best fit algorithm finds free block on the disk among previously allocated files. Closing of the file simply changes the status field in the table of open files. Positioning is also easy to implement:

```
int SeekFile(int fd,char* buffer,int pos) {
  if (fd<0 || fd>=maxopenfiles)
    return -EINVALID;
  if(opentable[fd].status!=OPEN)
    return -EINVALID;
  if (pos>=opentable[fd].actualsizeinbytes)
     pos=opentable[fd].actualsizeinbytes-1;
  opentable[fd].currentseekpos=pos;
 return pos;
}
```

Writing to a file begins with finding of its position blocks on the disk, and then the first of them is loaded into the buffer. After that, the data is transferred from the user buffer in the buffer disk block. When the cursor reaches the end of the buffer, the block is written to the disc. Here the care should be taken, that recorded blocks do not exceed the limit set for that file. If more blocks are written than the current length, the corresponding element in the directory stricter is updated to the value of new length. Reading of the file from disk also uses the value taken from the position in the open file, to calculate its position on the disk. Thereafter, the function is called to read sectors from the disk into memory.

Initialization sets the initial values of the relevant variables and loads into memory the directory structure. Demo program includes writing, deleting, additions and displays of several created files. Further lab. exercises can include addition of subroutines for directory search and modification of starting location of partitions.

J. Memory management

In the operating system, memory between 0 and 640 KB is reserved for kernel and its tables, while the custom applications are allocated memory space above 1 MB. The memory management module is implemented with two strategies, one for the physical memory and one for virtual memory. The physical memory block is represented by memTable element.

This element comes with a series of simple structures containing start address and bit valued fields indicating the length and population percentage. Initialization of the memory subsystem sets the table of the physical memory elements as blocks of 128 megabytes, beginning with address 0x100000.

`AllocMemory` will assign the first available block. The physical memory is allocated through continuous allocation, first fit algorithm, and unused portion of the memory block hole becomes the new block for allocation.

```
void * AllocMemory(int size) {
  int i;
  if (maxused>=TABLELEN)
    return (void *) EOUTMEMORY;
  for (i=0; i<=maxused; i++) {
    if ((memtable[i].length>=size) &&
    (memtable[i].busy==0)) {
       memtable[i].busy=1;
       if (memtable[i].length>size) {
         memtable[++maxused].busy=0;
         memtable[maxused].startaddress=
           memtable[i].startaddress+size;
         memtable[maxused].length=
           memtable[i].length-size;
         memtable[i].length=size;
       }
       return (void *) memtable[i].startaddress;
    }
  }
  return (void *) EOUTMEMORY;
}
```

The routine for freeing occupied block of physical memory takes care of recombination of neighbouring memory holes.

Although we implemented simplest algorithms, the power of Intel processors allows us to implement some more advanced topics, virtual addresing and relocation. Processes can see the memory differently, as it is the case when mapping of the virtual memory. Routines `ActivatePaging` and `LinearMode` change registers CR0 and CR3 and hereby change paging mode to be enabled or disabled. Paging mode is on two levels.

The address space of each process up to 4 megabytes is seen as being between the addresses 0 and 4MB, and is pre-mapped to the corresponding physical address above 1MB. As Intel processors are using paging on two levels, requiring two tables, one representing the directory page (with only one element used) and the other representing the page table (with 1024 elements). The first megabyte in that table is mapped equally for all processes, while the remaining three megabytes of virtual memory space is mapped into memory separately for each process.

K. Processes

For the sake of simplicity, the scheduler is of cooperative type. That means that processes or threads in the kernel must periodically call the system calls, which carry out scheduling. To save pre-empted context of the process or thread, the `jmp_buf` structure is used, to preserve the statuses of the registers and prepare for jump. The command `setjmp` prepares the return point and with command `longjmp` jumping back to one of predefined return points is performed.

The structure `task_t` contains process control block. It consists of the process status, the pointer to its memory and the pages of `setjmp` content registers. Process control blocks are arranged in variable sized array. The scheduler works in the cooperative version of Round Robin

principle. When the scheduler function is called, `setjmp` saves the state of currently executing process, the table of memory pages is changed and then with `longjmp` command advances to the next process.

```
void schedule(void) {
  unsigned prev;
  static int cr0;
  prev = current;
  do {
   current++; // round-robin switch to next task
   if(current >= NUM_TASKS)
      current = 0;
  } while (g_tasks[current].state!=READY);
  idlecpu=(prev==current==0);
  if(setjmp(g_tasks[prev].regcontext) != 0)
     return;
  ActivatePaging ( g_tasks[current].pagetable);
  longjmp(g_tasks[current].regcontext, 1);
}
```

Starting a new process allocates memory with the size of 3 MB, sets registers, pre-maps the memory, and if it is not a system thread, loads the file with the process code, and adds the values in the process table. The completion of the process frees allocated memory, and calls the scheduler.

```
void Terminate(int pid) {
  if (pid >=0 && pid < NUM_TASKS ) {
    setprocstate(pid,DELETED);
    LinearMode();
    FreeMemory(g_tasks[pid].memoryblock);
    schedule();
  }
}
```

L. System calls

Since the scheduler is of the cooperative type, the system calls are, beside the basic function, extended with the call to scheduler, as in the following example:

```
int _OpenFile(char * name) {
  int i=OpenFile(name);
  schedule();
  return i;
}
```

IV. CHANGES IN EDUCATIONAL PROCESS

In the academic year 2014/2015, at the faculty of Electrical engineering, University of Sarajevo, described minimalistic kernel was introduced as part of lab. exercises. After explaining each kernel layer group and writing different versions of main program, gcc compiler and nasm assembler compile previously processed layers and execute them under QEMU. Then it is ported to any PC with IDE drive, to be executed on real hardware.

In previous years, on the operating systems course, as an example of operating system source code, the older and newer versions of Linux or Minix were used. However, very small number of students was able to follow the source code and modules of these OS systems, while the lecturing time for their complete description was not sufficient.

Experimenting with developed kernel, showed that kernel structure and code can be completely described within laboratory exercises lasting two teaching hours (90 minutes). This demonstration has followed the completion of the theoretical part of the course on operating systems, so the students were prepared to follow the topic. However, if it is desired to include more independent work of students on working with kernel and making their own modifications, more teaching and laboratory hours are required.

V. CONCLUSION

Minimalist operating systems do not strive to be used in real world applications, but can be of great importance as an educational tool to display the principles of operating systems structure and organization. Making use of the simplest algorithms, the developed operating system kernel has fulfilled its objective and purpose, to illustrate the practical side of the operating systems role and inner working, while not spending too much time on its explanation, at the expense of theoretical considerations and approaches.

Usage of Compulsory Content in Secondary School Education

Renato Barisic
University College Algebra, Zagreb, Croatia
renato.barisic@racunarstvo.hr

Abstract - Modern information and communication technologies suited to be used in the educational process have to bridge the gap between the desires of today's students for modern educational content and compulsory literature in the form of printed textbooks. This paper presents the results of research on use of printed textbooks in the Humanities, Social and Natural Sciences and Engineering in the third and fourth grade of secondary school. The survey lasted for three years and was conducted among 3.217 students from 79 secondary schools from 16 Croatian counties. An analysis of research on the use of printed textbooks in the final years of secondary school shows that a significant number of textbooks are used on a small scale during the day at school and even to a lesser extent during independent work at home. The aim of this paper is to highlight the need to find alternative and complementary solutions whose application should modernize the educational process and present courses to students in an attractive and motivating way on a variety of devices that today's students have at home, at school and on the move.

I. INTRODUCTION

To meet legal forms, all schools at the beginning of the school year prescribe the necessary literature for each class, but its usage in the class is constantly getting lesser. Teachers, who want to improve the teaching process, in order to adjust the class to the thoughts and needs of the contemporary students, are forced to use various additional formally approved or not approved teaching resources or to create new content that will best represent the specific teaching unit to the students. It is hard to say if these kind of innovative teachers are currently a majority or a minority, but we must urgently think about the changes in the approach to teaching, especially in the introduction of new interactive content into everyday teaching process.

The printed textbook in the new school remains almost the only means of creative communication mediation between teachers and students. Since educational material is investigated in the teaching process, as the teaching process means drawing up an inventory of ideas, and teachers mediate this investigation, both the teaching process and teachers are direct and necessary participants in textbook creation. The teaching process can in this context be seen as the symbiosis of the overall education. Qualitative restructuring and redesign are done by those who mediate textbook content – teachers and students [1].

It is not easy to understand the increasingly complex global events, to see facts within the framework of objective context and to think critically about means of information. This requires huge efforts in creating a strategy to train students for life-long learning. Computer-based instruction (including the use of e-textbook) surely provides flexible individualized learning. It increases motivation and students' self-esteem because it helps them earn their knowledge. Nevertheless, the computer itself does not necessarily mean that the children will develop divergent thinking, creativity, collaboration, responsibility in decision making, democratic behavior, etc. The priority task of educational sciences is to investigate ways to bring educational media under certain standards and to suggest criteria for their design, so as to make them carriers of society progress [2].

Daily creation and sharing of unlimited amounts of information is no longer possible to be followed with the traditional printed resources due to the slowness of their occurrence and the inability to change content in the time of new knowledge creation and technological achievements. Even if we do not raise doubts about the accuracy, completeness or timeliness of the classic printed textbooks, we need to rethink whether a teaching aid in that form is suitable for the education of modern technology minded young generations and consider whether the modern tech-savvy teachers would use classic printed teaching tool as the first choice for high-quality transmission of knowledge in educational institutions of the 21st century [3].

This paper will show results of the research that lasted for three school years and included third grade and fourth grade secondary school students from technical schools and gymnasiums from almost all Croatian counties. The aim of research was to collect information directly from the secondary school students and to find out do they use printed textbooks at school and at home. The aim of this paper is to show research results and to highlight the obvious need for finding alternative and complementary solutions whose application should modernize the educational process and present courses to students in an attractive and motivating way.

II. METHODOLOGY

A. Method

Survey using a printed questionnaire was a selected data collection method. Prior to conducting the survey the

permission was sought from the responsible persons: principal, school counselor, psychologist or teacher. The survey was carried out in groups, on a voluntary basis, using paper format questionnaire, for one or two classes that were present in the classroom at the same time. At the beginning of the survey the interviewer demonstrated the questionnaire to students and they were given filling instructions. Interviewer emphasized that the survey is completely anonymous and does not collect any personal or school data. Time to fill in the questionnaire was limited to 10 minutes.

B. Instrument

Data collection instrument was a questionnaire. A questionnaire completed by the students consists of general questions and questions about the use of printed textbooks and digital content.

General questions about age, gender, type of school, and the direction of the class are primarily used for the analysis and presentation of the structure of the respondents according to various criteria. Given that the target sample were students of third and fourth grade of secondary school, the question about respondents' age offered a choice between 13 and 19. Question about gender could be responded by circling M for male or F for female. When asked about the type of school, the students could respond with T for technical school or with G for gymnasium. The question about the direction of education is set up as an open question which could be responded by free writing. The last question is a general question about the current grade with possible answers 1 to 4. It is axiomatic that the target population was fourth grade and third grade at times. Still, there was an option of circling first grade or second grade if someone from the lower grade appears.

Questions about the use of printed textbooks are set as a closed set of multiple choice questions. Question about the use of printed textbooks during the school was constructed in the form of a table where the columns highlight three main divisions: subject, at school, at home. In the subject column is a list of subjects in the Humanities (Croatian, Foreign language, History, Religion, Ethics), Social Sciences (Politics and Economy), Natural Sciences (Mathematics, Physics, Geography) and Engineering (Computer Science, Information Science). In the group of columns at school and at home, there are subdivisions offered intensities: never, rarely, often or very often. With this approach the students were able to immediately designate the usage intensity of printed textbooks at school and at home for one course.

C. Sample

Data was collected during three school years: 2012/2013, 2013/2014 and 2014/2015. First school was included at 22nd November 2012 and the last one at 6th March 2015.

Numbers of included students, secondary schools and counties by each school year could be seen in Fig. 1.

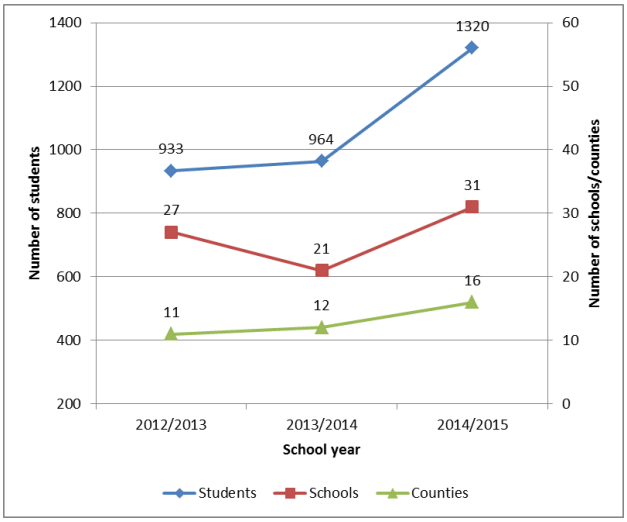

Figure 1. Number students, secondary schools and counties included in the research

III. RESULTS

Fig. 2. shows number and share of students by their age.

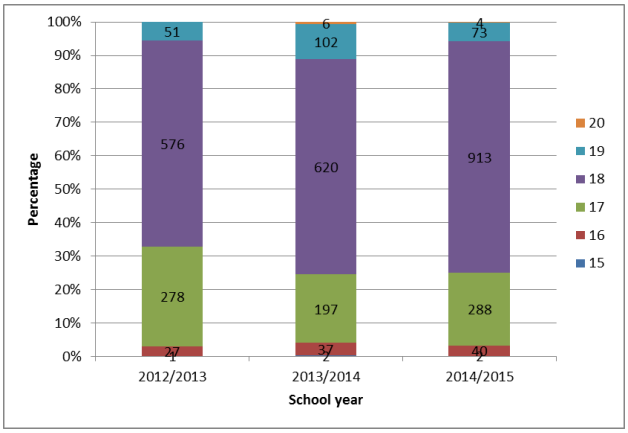

Figure 2. Number and share of students by age

Fig. 3. shows number and share of students by their gender.

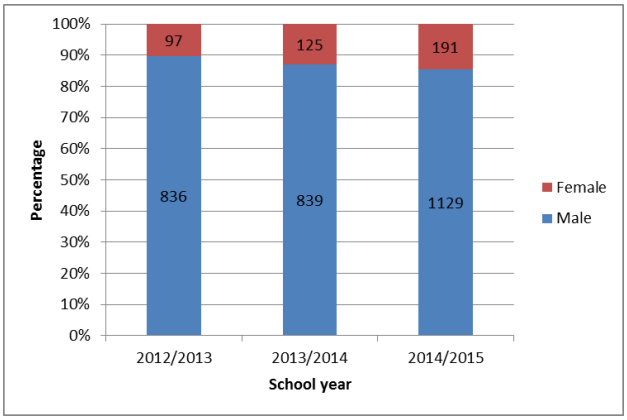

Figure 3. Number and share of students by gender

Fig. 4. shows number and share of students by their grade.

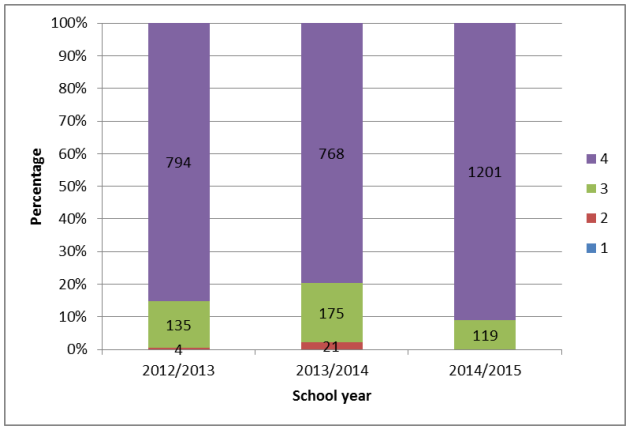

Figure 4. Number and share of students by grade

Fig. 5. shows number and share of students by the type of secondary school.

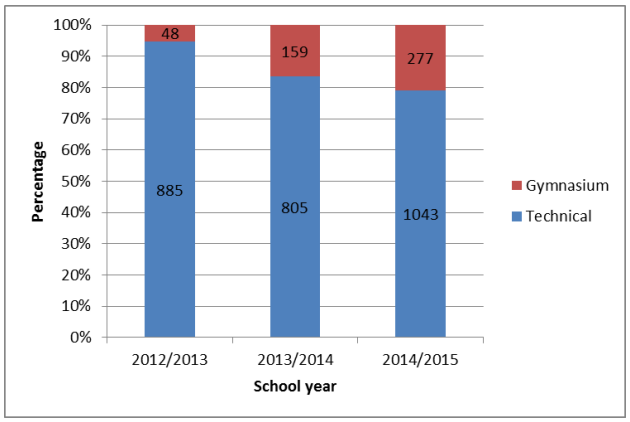

Figure 5. Number and share of students by school type

Next figures show summary of student answers about using printed textbooks during study at school and at home. Data is sorted descending by the number of answers for intensity Very often so the first column shows subject with the best percentage of Very often use, second subject have smallest percentage and so on.

Fig. 6. shows data about printed textbooks usage during work in the classroom at school collected during school year 2012/2013, fig. 7. shows data collected during school year 2013/2014 and fig. 8. shows the most recent data from school year 2014/2015.

Fig. 9. shows data about printed textbooks usage during students' independent work at home collected during school year 2012/2013, fig. 10. shows data collected during school year 2013/2014 and fig. 11. shows the most recent data from school year 2014/2015.

IV. CONCLUSION

Modern students need new approaches, motivation and learning processes that will align the teaching practices with new technologies, modern educational approaches and reform tendencies. In today's world of intense use of top quality audio-visual, communication and computer technology achievements, the acceptability and usability of printed textbooks is questionable because they are no longer a medium that is acceptable to students and that motivates them to acquire new knowledge and new skills, and are no longer a medium of choice in the search for new, complete and updated information. Information and communication technologies have enabled that with the use of the Internet there are no longer limits to publishing, retrieving and exchanging information. Search and access to information is instantaneous, and the sources of information can be multiple and thereby contribute to authenticate the information found. Even more important than the search are the speed of publishing new information and the speed of updating existing information. The methods of publication or updating information on the Internet are measured in seconds and minutes while the process of publication or updating information in printed textbooks and the release of new editions can wait for months and often years.

Results of shown research, conducted among students of third and fourth grade of secondary schools on use of printed textbooks from nine subjects in Humanities, Social and Natural Sciences and Engineering, show that textbooks in only three (Mathematics, Foreign language, Croatian) of nine courses are regularly (sum of Very often and Often is more than 50 percent) used in the classroom at school, and in only one (Mathematics) of nine are used regularly during independent work at home.

Research has shown that there are a significant number of subjects for which the classical printed textbooks are very little used and some hardly used (Religion/Ethics, Politics and Economy, Computer Science). This especially applies to use of those textbooks at home, but it is evident that the usage at school for the majority of analyzed subjects are not much better.

Shown results indicate that students are not motivated and do not want to significantly use printed textbooks and that maybe teachers do not insist on printed textbooks usage at school and at home. As could be seen, the data for all three years of research are very similar and in majority almost identical, so these trends warn us and call us for urgent action.

Online Learning Efficiency in the Humanities

Smiljana Gartner, Marjan Krašna
Faculty of Arts, University of Maribor, Maribor, Slovenia
smiljana.gartner@um.si, marjan.krasna@um.si

Abstract – Online learning or web-assisted learning has become common over the past decade. Various studies have established that it is appropriate for learning in the areas of technology, natural sciences and skills. The arts and humanities are more reluctant to use the new technology, since it seems less naturally suited to their disciplines. Is it possible that the arts and humanities can not find such an approach effective, or does it require a mental change on the part of the of lecturers? We tested three different approaches to acquiring student feedback: (1) the traditional classroom lecture, (2) studying with documents from Moodle, and (3) studying with interactive multimedia learning materials.

In our research (in the course The Basics of Philosophical Thought) we have discovered that students who are digital natives still perceive traditional classroom lectures as more useful in the sense of understanding the reading materials than the other two approaches. This was evident in the students' homework, grades and survey analysis but not in time management. Given assembled data, we suggest that the optimal approach would be to provide e-learning materials prior to the lectures because this would allow students to participate actively in the lectures. If we use online interactive multimedia learning materials, most students still require live communication, which is not always feasible when online learning is the whole method. The online multimedia study approach could therefore be effective in the analytical philosophy course, but it would require a huge mental change on the part of all stakeholders.

Keywords: online learning, humanities, educational method comparison, e-learning materials.

I. INTRODUCTION

In the last decade Slovenian universities accepted the Bologna guidelines and reformed the higher education system into a three-level system. The background ideas are inspiring: an individual approach to students, an active student, interactivity, student-centered study etc. However, the reality of the present financial crisis has meant less money for education. Economic reality, also known as rationalization, is manifested in larger student groups in seminars and for laboratory practice (from 30 to 70), minimized contact hours, transfer of hours to individual student work, and a great many assessments. This has had the following consequences:

- a teacher-centered approach and passive students (in the classroom);
- student and teacher off site preparation, production and verification of coursework and homework;
- many small tasks without comprehension of the topic or of the course as a whole and
- a leak of time for deep understanding of specific topics or themes.

If learning is a constructive process (the constructivist view), where a student builds or deepens an internal illustration of knowledge and is therefore an active process involving individual experience, then we are failing in this objective. The following claims about study objectives sounds like a science fiction at public universities in Slovenia [1]:

- that objectives should be negotiated with students based on their own needs,
- that learning activities should emerge from within the contexts of the student's life,
- that students should work together with peers in the social construction of personally significant meaning, and
- that evaluation should be personalized.

A solution to this discrepancy and a potential benefit to all stakeholders lie in computer-based learning, online learning or web-assisted learning. Although it is evident that such techniques are appropriate in natural sciences and for learning skills, we can also find positive results from the social sciences (especially psychology and language learning) [2] [3] [4] [5] [6]. Nevertheless, the humanities are different, thus posing a dilemma. Can philosophy (the most fundamentally abstract science) benefit from ICT? Benefits are obviously greatest in the sciences, where the level of abstraction is lower. Therefore, we want to know how to incorporate communication, interaction and cooperation (the key elements of philosophy courses) and to analyze how students react to different didactic approaches in Philosophy.

II. METHODOLOGY

We tested three different approaches to acquiring student feedback.

The first approach was *traditional classroom study*. Although this approach is usually understood as lectures with textbooks, notes, exercises and an examination at the end, courses in analytical philosophy, including ours, also comprise the response-based approach, argumentation, class debate, group discussion, active reading, solving case studies and using computer supported learning (presentations and video material). Because of

rationalization, however, these methods have been curtailed.

The second approach was *studying with documents from the electronic classroom* (hereafter called ***online elementary study***). Students were given reading material, online notes and presentations.

The third approach was *studying with interactive multimedia learning materials*, where students had webpages and links, online notes, reading material, online case studies, video, online interaction with a lecturer and quizzes (hereafter called ***online multimedia study***). We use an approach that was previously developed for other students in the design of multimedia learning materials for our course [7] [8] [9].

The data presented here were gathered during the winter semester of 2013/2014 among 1st year students (N=29) in the course "*The Basics of Philosophical Thought*". Students were divided into three groups, each of which used all three of these approaches.

In the study quantitative methods were used, including a questionnaire (N=22, twenty one female, one male) about student self-evaluation of the three approaches in terms of study hours and grades received for their homework. The questionnaire for students consisted of nine questions/claims (two independent variables and seven dependent). Three questions/claims were simple closed questions with a single answer:

- How often do you raise questions?
- I prefer classes where I can participate;
- In lectures and seminars I prefer … (activity in lectures)

We also provided several closed questions:

- Working on-line enables me …;
- The role of a lecturer should be …; and
- a question with eleven sub-questions about the preferred approach to studying).

One question on the questionnaire was open-ended: What do you think are the advantages and disadvantages of the three approaches to studying?.

Students had to submit their homework after every theme, and in their homework they needed to specify the time taken to grasp the theme.

Where applicable, students used a three-level grading scale, responses to which have the following meanings: 1 (mostly true, max); 0 (sometimes true, average), and −1 (mostly not true, min). We decided to use this scale for psychological reasons. Anyone can immediately see the positive and negative aspect of the grade, and the grading process involves more thorough reasoning. For the statistical analysis, we later transcoded the values -1, 0 and 1 to the values 1, 2 and 3.

Our research was based on the hypothesis that multimedia is one of the most useful methods for a response-based approach and that it enables independent learning. Students are considered "digital natives"; they are therefore familiar with ICT and do not need instructions for using such multimedia learning materials. Such an approach facilitates independent work habits, where a student can build an internal illustration of knowledge, while being actively involved. The most important feature, especially in the case of Philosophy, is that the student has the ability to "remove the four walls of the classroom, which seems to be form of prison to reluctant learners and open up a borderless world" [2].

III. RESULTS AND DISCUSSION

A. Most attractive aspects of online learning in a Philosophy course

The most positive aspect of this approach is time management. More than 95% of students think that online learning approach enables them time self-management (Table I). The open-ended question yielded the same results about the positive and negative aspects of these three different approaches. (Table II)

Table I: Working on-line enables me...

Row Labels	Self-managing time	%
0 (No)	1	4.54
1 (Yes)	21	95.45
Grand Total	22	100.00

Table II: Self managing time (open question)

	classroom	Online - elementary	Online - multimedia
time	1.24	2.33	2.76

There are differences (Table II and Table III) between the online multimedia study and online elementary study approaches. One reason for this could be time constraint with the online multimedia approach. Both quizzes and online lecturer access were available for a limited period of time. In the classroom approach, students had to be present one hour per week, with additional two optional hours per week. The rest of their study hours were up to them, and any additional time - even the smallest amount - added to their assignments was perceived as a restriction and consequently as an inability to self-manage their time. This is interesting because, when one is reading demanding philosophical texts, having a lecturer by your side is always an advantage. One explanation could be that students are unfamiliar with online multimedia study. a hypothesis which is compatible with the finding that it is important to give students time to familiarize themselves with the tools, the work and the whole online multimedia study environment [10].

Another positive aspect involves access to course material. Students can access learning materials at all times and also have more time for studying (reading articles and watching video material). Moreover, on-line multimedia study is more attractive and offers more interaction than the online elementary study approach (*see* Table III). Therefore, if we want to talk about the positive aspects of the on-line approach, this must mean the on-line multimedia study approach.

Table III: Positive aspects of on-line approaches

	Count of online multimedia	%	Count of online elementary	%
Time-managment	8	40%	12	60%
Reading material	3	15%	3	15%
Communication, interaction	4	20%	1	5%
Interest	4	20%	2	10%
Remembering	1	5%	2	10%
Grand Total	20	100%	20	100%

B. Least attractive aspects of on-line learning in a Philosophy course

Activity and motivation

The results of students' preferences about being active are interesting. Namely 81.82% of students answered that they liked lectures where they could participate, 18.18% that they did not (Table IV). At the same time, more than half the students (59.09%) said that they would rather just listen during classes, 18.18% of students chose listening and raising questions (2); 22.73% of students chose listening and debating (3) as preferable activities (Table V). Even more, 72.73 % of students claimed that during the class they rarely ask anything, 18.18 ask occasionally, 4.45% very often, whiled 4.55 never (Table VI).

Table IV: Participating in class

	responses	%
1 (yes)	18	81.82
2 (no)	4	18.18
Grand Total	22	100.00

Table V: Activity during the lecture

	responses	%
1	13	59.09
2	4	18.18
3	5	22.73
Grand Total	22	100.00

Table VI: Asking questions during the lecture

choices	responses	%
1	1	4.54
2	16	72.73
3	4	18.18
5	1	4.55
Grand Total	22	100.00

We can infer that they would like to be active but not in such a way as to be singled out in front of the group by asking questions or debating. This is especially because, in class Philosophy, the most common replies to student assertions are "Why?" and "How come?", with which they are learning to justify every claim and to make arguments supported by evidence. For some students these queries could be, at least initially, quite stressful. This is good information for the multimedia approach in Philosophy class because we can prepare interactive exercises and learning methods that avoid forcing a student to endure needless individual scruting.

At the same time, students think that being in the classroom is more motivating; there are fewer chances to skip the study material, and they have higher levels of concentration (Table VII). By comparing the online multimedia study approach and the online elementary study approach, we can infer that students have lower levels of concentration in the multimedia approach but are still more motivated. Taking into account the answers to the on open question, they are more motivated because the video material and quizzes are more interesting; they have the feeling that they are more active, but their thoughts can easily be diverted to something else on the internet. With these factors in mind, it is understandable that with online multimedia there are fewer opportunities to skip the study material.

Table VII: Concentration, activity and motivation

	classroom	Online - elementary	Online - multimedia
Concentration	2.57	2.00	1.81
being inactive	1.71	2.33	1.95
motivation	2.62	1.76	2.10
skiping the studying material	1.71	2.57	2.29

When we considered whether concentration is influenced by the online-elementary and online-multimedia types of study as compared to the classroom type, we discovered that there are no significant differences between the classroom vs. online-elementary groups ($\chi^2 = 6.33; P = 0.176$), and the same is true for classroom vs. online-multimedia ($\chi^2 = 7.55; P = 0.110$) . There are however significant differences between the groups classroom vs. online-elementary ($\chi^2 = 10.72; P = 0.030$) and also classroom vs. online-multimedia ($\chi^2 = 11.43; P = 0.022$) in the level of student activity. Interestingly, we discovered no significant difference between classroom and online-elementary in motivation ($\chi^2 = 4{,}84; P = 0.304$) , but there are significant differences between classroom and online multimedia ($\chi^2 = 13.11; P = 0.011$) in motivation. There are no significant differences in the area of skipping learning materials between types of study ($\chi^2 = 2.76; P = 0.598$), ($\chi^2 = 6.32; P = 0.177$).

Understanding, knowledge retention and depth of knowledge (course material, instructions)

Students still think that the most effective way to study philosophy, i.e. to understand (100%), to memorize (77.27%) and to acquire depth of knowledge (77.27%) is in the classroom (Table VIII). This is especially true in cases where the classroom experience means having to read demanding articles. The main reason is the presence of the lecturer and interaction with her and with other students (Table IX). From Table IX, we can again find differences between the online multimedia and online elementary study approaches. Thus, with the multimedia approach, they also had the chance to have an interactive conversation with the lecturer at a predetermined time, but no one used it. The reason could be, again, unfamiliarity with this approach because asking questions, peer teaching, seeing how and what others are doing and collaboration among peers are some of the main elements of the online multimedia study approach. [11]

Table VIII: Working on-line enables me to ...

	Understandi material	%	Acquire depth of knowledge	%	Remember	%
0 (No)	22	100.00	17	77.27	17	77.27
1 (Yes)	0	0.00	5	22.73	5	22.73
Grand Total	22	100.00	22	100.00	22	100.00

Table IX: Understanding and remembering

	classroom	Online - elementary	Online – multimedia
Remembering	2.62	1.86	1.95
Interaction with lecturer	2.76	1.48	1.67
Understanding the reading material	2.76	1.76	1.90
Understanding instructions	2.81	1.57	1.76

In the case of remembering, we discovered significant differences between the groups classroom vs. online-elementary ($\chi^2 = 16.63; P = 0.002$) and classroom vs online-multimedia ($\chi^2 = 18.27; P = 0.001$) . In interaction with the teacher, significant differences are expected and confirmed between classroom vs. online-elementary ($\chi^2 = 22.30; P = 0.000$) and classroom vs online-multimedia ($\chi^2 = 11.47; P = 0.022$) . In understanding the reading materials, we discovered no significant differences between classroom and online-elementary ($\chi^2 = 7.89; P = 0.096$) , but there are significant differences between the classroom and online-multimedia groups ($\chi^2 = 10.84; P = 0.028$). Using non-parametric Friedman test we discovered that there are significant differences between groups in understanding of the reading materials (Table X).

Table X: Non-parametric Friedman test

	$\bar{R}$	$\chi 2$	P
classroom	2.67	17.82	0.000
online elementary	1.60		
online multimedia	1.74		

Interestingly, there are also significant differences between groups in understanding instructions classroom vs. online-elementary ($\chi^2 = 7.38; P = 0.025$) and classroom vs. online-multimedia ($\chi^2 = 15.33; P = 0.000$)

Elapsed time and degree of effort put into the work

According to most students, working online did not enable them to work less (86.36%), and they had to invest the same or more time and effort in online learning, while at the same time they think their work has less depth (Table XI). However, there is a huge difference between the online multimedia study approach and the online elementary study approach. What we can see in Table XII is that the time elapsed while finishing a task depends on the theme and approach. "Exercise 2" was about contemporary ethical dilemmas like euthanasia, abortion and genetic engineering, including considerable video material; therefore, students needed less time to complete the tasks. "Exercise 4", on the other hand, was about abstract theories and comprised only reading material. Students in the classroom used half the time in comparison to those that working with online multimedia, and a third of the time compared with students using the online elementary method. Therefore, when a lesson includes considerable reading material, a lecturer is irreplaceable for directing the reading of articles, extracting the most important parts, explaining complicated issues and making analogies with contemporary (ethical, political) dilemmas (Table XII, column four, i. e. "Exercise 4"). She can do this by asking questions and so engaging students even more. If this works, then the same thing could be used in the online multimedia study approach and consequently form a positive aspect of its use. This is compatible with a research study which stated that "*active involvement of the facilitator is needed in the process of interaction, communication, and discussion, especially in the forum because this activity is a priority for learning via website*" [10], as well as with the assertion that online teaching will generally result in a significant increase in teacher effort per student [11].

Table XI: Working on-line enables me...

Row Labels	Least amount of work	%
0 (No)	19	86.36
1 (Yes)	3	13.64
Grand Total	22	100.00

Table XII: Average time taken for the work in hours

	Exercise 2	Exercise 3	Exercise 4	Exercise 5
classroom	3.28	3.74	1.68	4.40
online elementary	3.06	4.16	6.23	6.47
online multimedia	2.82	2.56	4.04	4.80
Total Average	3.05	3.59	4.09	5.14

IV. CONCLUSION AND RECOMMENDATIONS

The main question we tried to answer was: "*Is it possible that the humanities (specifically Philosophy) cannot find online multimedia study approach effective, or will it require a mental change on the part of the lecturers and students?*" This is especially because the constructivist approach is crucial in courses of analytic philosophy; i.e., a student is constructing or deepening an internal illustration of knowledge and it is therefore an active process through her own experience. Students work together with peers in the social construction of personally significant meaning, and the program is very individualized. In our research (in the course The Basics of Philosophical Thought), we discovered that students who are digital natives still perceive traditional classroom lectures as more useful in the sense of understanding, extending and comprehending the course materials. This was evident in the students' homework and survey analysis but not for their time management or motivation. Although there is a discrepancy between what students think would work for them or what they would like to have and what they are prepared to invest, the online elementary approach is the least effective. But because the positive aspects of working in the classroom were understanding, asking questions and having guidance from the lecturer, all of these could be accomplished through the online multimedia study approach. Therefore,

the following conclusions can be drawn for a class in analytic philosophy:

(i) the online course must be the multimedia type because, according to our research, although the online approach allows students time self-management, freedom and autonomy, only with multimedia study are students active; they participate, they try to understand and comprehend material and they can experience almost all instructional elements as in the classroom;

(ii) even though these students are digital natives, they do not know how to use online multimedia materials and services. Therefore, we need to be aware that, for success in studying, they must learn how to use multimedia or at least must become familiar with it (for example, using online consultation, online interactivity with other students etc.);

(iii) if we use the online multimedia approach, it is better to apply to the whole course (or in combination with classroom instruction i.e., blended learning), otherwise, it could be difficult for them to switch between different approaches.

From the assembled data, we suggest that the optimal approach at this moment would be to provide e-learning materials prior to the lectures because this would facilitate active student participation in lectures. If we use online interactive multimedia learning materials, most students still require live communication, which is not always feasible when the online learning is the only option.

Thinking that the university would save a lot of money by implementing an online multimedia study approach is the wrong way to go; if we want students to develop, to achieve the same or better results than with using the traditional, classroom, approach, we need to invest money. As with any other approach, to achieve any goal, it needs to be properly done, and this means allowing for additional education for students as well for lecturers. Preparation of an online multimedia course and its effective implementation means considerable knowledge and a great deal of work outside the classroom. Therefore, we would need new criteria and new standards for judging the work of lecturers, ones where lecturers would not be judged on hours in the classroom but on hours invested in the successful accomplishment of the goals and aims of the course [12]. Therefore, implementing an online multimedia study approach, even if this could be a very effective approach for a course in philosophy, we should be very careful. First, people might think that teachers are available 24/7, which would jeopardize their private time and raise stress levels to the maximum and, second, because teachers would not be in the traditional classroom, people could think that they were doing no work, so – who needs lecturers anymore?

Of course, we can overcome these obstacles by implementing the idea of an online classroom in the sense of a virtual online classroom, with everyone present online at a certain time, but then (i) everyone would need to have a complete set of multimedia equipment. However, (ii) at the same time we would be reducing what the students stated as an absolute preference: i. e., time self-management while (iii) debating, the sharing of opinions and dealing with opponents through verbal and non-verbal communication would still be missing.

Therefore, our answer is, yes, it is possible for a philosophy course to find the online multimedia study approach effective, but it will requires a huge mental adjustment on the part of all stakeholders.

Designing m-learning materials for language learning

Dejan Pukšič, Marjan Krašna
University of Maribor, Faculty of Arts, Department for Slavic languages & Department of Pedagogy Maribor, Slovenia
dejan.puksic@student.um.si, marjan.krasna@um.si

Abstract: There are hot debates if e-learning and m-learning are the same thing. This is a dilemma only for those who were now participate in the m-learning learning material production. From technical perspective we might see this just as viewport constraint. But those constraints have high implication into the background thinking processes. Classical windows navigation cannot be used and if we want m-learning materials to be successful we need to pay special attention to the just-in-time learning. Much effort needs to apply to the context when and where information is searched and displayed to statistically predict following user requests. Only such materials that are successful in prediction of user's actions are successful as learning materials and do not becomes "digital rubbish" on mobile device. The article is focused on the design of m-learning for Slovene language on level A1 and A2 which is of paramount importance for further motivation for language learning.

Keywords: language learning, m-learning, haptic user interface, design and development,

I. INTRODUCTION

It is common belief that Google will solve language barriers in the near future. Promising video can be seen on YouTube but reality is somehow different. It is possible to translate between languages if text in one language is written in specific way [1]. Such translations are not perfect but sufficient. For the purpose of understanding the text all linguistic subtleties are not required. But there are also another topics in the language. Each living language has phrases and understanding the phrase and proper translation/interpretation is still domain of the human being. According to these facts it is now the right time for the question: "Should I learn another language?" Answer to this question is not the easiest in today's fast moving World. But if the answer is "Yes" than it becomes our business.

There are many levels of competences of foreign language. In this article we are going to apply the "Common European Framework of Reference for Languages". As an educational institution for teachers and even language teachers we have many foreigners who attend language courses for different purposes. Foreign students from the students exchange come for one semester, some student want to study in our country and there are even some who want to live in our country. Their motivation is different but they all want to become familiar with the language on different scale. The first contact with the foreign language is the most important for the perseverance and further learning. If frustration level reaches certain level people generally give up and stops with the attempt to learn further. We wanted to reduce frustration level for Slovenian language learning on the level A1 and A2. Slovenian language is one of the oldest language since it still has dual and cases and as such is not easiest for learning. Especially it is hard for translation from foreign language into Slovene since some information for translation is missing and brute force approach misses the context. From Google translate we can observe much better translation from Slovene to other language than in the opposite direction. Other online translation has the same problems. How is it possible to help learners to decrease their frustration level? There are many possibilities. From the past we know dictionaries with the translation of most common sentence. In contemporary mobile world we can use mobile devices to ease the old principle and such software are available on the software markets. From the analysis of such software we discovered that we could do better. Applying the principle missed in the other software – "*just in time*" language assistant we could provide learners with the right information at the right time. This could be achieved in two distinct principles: applying artificial intelligence module or statistical analysis for the best scenario. It is possible that artificial intelligence would give us the best results but it would require much more computational power than contemporary portable devices can offer. On the other hand statistical approach is much more energy efficient and suitable for portable devices but it requires intelligent multilevel planning. It is necessary to recognize the situation where the user is when he/she needs the language help and what are the best possible next language helps he/she will need. In general this is not feasible therefore we need to compromise. The compromise is the intelligent user interface that minimizes the search of the right linguistic help. Designing such interface from the scratch is difficult therefore we set our initial aim to provide students with the tool to ease the accredited language course from the (government?) which are the mandatory course for all foreigners who wants to learn Slovene for different purposes.

II. M-LEARNING VS. E-LEARNING

It is not without the reason to say that today new countries are first visited on the web. Later it continues in the real environment among the people communicating in that countries language. Today people in the western world are multilingual and visiting foreign countries is not such linguistic and mental shock of being shut out from the conversation. English is speaking all over the World is a phrase that becomes reality and basic communication is feasible. But we all know that speaking English and "*spekin Englis*" can be a problem in anything but fundamental communication. Therefore anyone who travels frequently knows the phrase "*spikin inglish good*" used in any response and in all situations. At that time technologically advanced humans resort to the Google all mighty on its portable "*smart*" device. What should be simple is not always the case in foreign country with inadequate ICT infrastructure or "*kidney priced*" Internet services. Therefore despite the 65% of world population have smarphones (and growing) [2] free Wi-Fi is generally not available and roaming costs are simply too high to be useful. In such cases we start to understand the differences between e-learning and m-learning. Language e-learning projects are mainly reserved for controlled learning environment in school or at home but m-learning modules are included into the other real life situations where talking and language understanding is natural part of the learning. General aim of mobile learning known from all its definitions is "*anywhere and anytime*". M-learning materials developer should foresee and recognize potential learning environments. He/she should pretty well know the users of language application (MALL – Mobile Assisted Language Learning), and what are their users' habits. On the other hand it is paramount to know where the mobile application will be used, in domestic or foreign environment, is the web available or not, and which functionality of the phone should be included into the application. All those constraints were taken into account when we design the pilot application for mobile learning of Slovene language as foreign language – application BlaBla™.

III. MOBILE ENVIRONMENT

In the mobile application development many questions arose. M-learning materials design and development is no exception in this process. From the perspective of the e-learning materials development it is just another device and no big deal. But deeper understanding the mobile environment shows us that we cannot dismiss this topic so lightly [3]. In the recent years we can find the changes in the m-learning perspective where m-learning materials should be distinguished from e-learning materials in general. Mobile environment is full of selective disturbances, from physical contacts to sound and light oscillations that are not present in controlled e-learning environment (home or in school) [4]. Therefore the transition of e-learning materials to the mobile device is not the valid option since they are meant to be used in controlled environments. M-learning is still considered the extension of the e-learning but the developer soon discover that this is not the case. User interface needs to be designed differently for mobile devices and in totally new mobile context.

A. Mobile context

Mobile context has changed since smart mobile devices are not only portable versions of other stationary devices. They presents specific technological segment of devices. The main perpetrator for this is the touch sensitive display that defined the mobile phone devices as devices that have phone app on them. Therefore the only correlation between previous mobile phones and smart mobile phones are three apps (phone app, messaging app and ringing app) with addition of speaker and microphone. Smartphone is therefore phone only by its name and does many other things that are far beyond the phone's primary purpose. It was proven that haptic user interfaces are more suitable for learning than interfaces with the proxy (mouse, touchpad, or keyboard) because the system react to the direct sensomotoric coordination i.e. moving the body part (touch). Interaction with the e-learning content is direct and does not need mental translation [5] [6, p. 2]. This can be best observed with the young kids that master tablets and smartphones without any training. The keyboard, mouse and other input devices are strange to them completely and they are not capable to establish cognitive link and transform the movement of proxy devices to the virtual world (mouse forward/backward is screen up/down) [5]. Any deviation from this natural interface proves to be unsuccessful on the long run and application that were not designed with that in mind were soon forgotten. Applications for smart devices need to be designed for smart devices or face consequences – loss of effectiveness and user frustration.

B. Touch screen

Basic guidelines for handheld user interfaces design derive from Shneiderman's fundamentals rules for effective interaction between human and PC assurance [7, pp. 74, 75]. Some are general guidelines like: 1. Enable shortcuts to the regular users, 2. Assure information feedback, 3. Cascade design of user interface etc. As we see these guidelines are of no use in the m-learning application for language learning design. Even after its redesign in 2004 [8, p. 3751–3754] they are still obsolete since in 2004 were no contemporary smart mobile devices. Mobile ideology has changed significantly since 2004 and users behavior perspective is now fully focused on haptic displays. New design proposals were prepared for m-learning materials development for haptic user interfaces that are good foundation for our language learning m-learning materials [9, p. 227]:

1. Navigation needs to be simple, clear on all levels and consistent throughout the application (#consistency)
2. Application needs to be user friendly and enable user to master its user interface in minutes (#ergonomics)
3. Learning topics needs to be designed and organized to prevent frequent scrolling (#scalability)
4. Only relevant information for learning processes needs to be presented (#relevance)

5. Text should be limited to the least possible volume (but not more) and information should be presented with images, animations, and videos (#minimalistic)
6. Control over learning processes is the users domain (#control)

IV. BLABLA™

Application BlaBla™ was designed and developed according to the previous guidelines to support the intensive language course of Slovene language for foreign exchange students – EILC (Erasmus Intensive Language Course) [10]. The intensive Slovene course is designed for students to motivate them for language learning and support them in the predetermined situations. Our pilot research was to prove the concept only therefore not all topics are implemented. But those that were implemented were carefully selected to get the best possible response form the users using m-learning materials for language learning the first time. Application has four (4) thematic parts from the beginning of language learning for foreigners on the level A1/A2 (Alphabet & Numbers, Introduce yourself, Describe your family and What are you wearing). These topics were selected because of the two years' analysis of the most probable scenarios where students encounter themselves in the communication with the natives who do not speak foreign language. Our goal was to help foreign student to retrieve their knowledge in the routine situations and speech environments with interactive multimedia elements and learning games.

To achieve #consistency and #ergonomics we situate the navigation elements on the permanent locations where Android operating system would naturally put them. Application was developed for Android system since the analysis shows that most smartphone users that came to the Slovenia use Android (79%) (for our courses 54,2%). Application has menu, buttons, icons and interactive contents. All interactive e-learning content was located in the ellipsoid thumb location reach – primary control area. Others less frequent elements (system commands, exit, menu, background theory explanation) were located outside this primary area.

Figure 1: Phone control area.

Putting less frequent commands and exit button in the secondary control area we minimize the possibility to accidentally trigger them. Small screens are still challenge to effective display of educational content the application of the #minimalistic rule and #scalability was used for chunking the content into fundamental parts – learning pads (least possible size m-learning module).

Figure 2: Chunk of lesson.

Such small chunks present one situation (question and answer) where both speech positions are presented to better understand the situation. Chunks of knowledge are in the coherent relation with other chunks and they are

designed not to overload the learners. Learning chunks include only #relevant content presented in such way that they seems natural and generic in all mobile operation systems (i.e. calendar view for number presentation, communication windows for SMS and social interaction). Wherever possible we use pictograms and/or single words. Transition between chunks were designed to encourage learners to continue learning even they have full #control over the application and can always exit. At the end of lessons learners have the ability to enter the learning game to verify their acquired knowledge or they can continue with the next lessons. All lessons are in the thumbs reach and navigation enables quick search between stored lessons to retrieve relevant content in the specific situation.

Figure 3: Educational game and quiz.

Figure 4: Navigation in the language learning application.

V. RESEARCH

In our pilot research 24 students (12 male and 12 female) from Czech Republic, Estonia, Finland, Lithuania, Hungary, Norway, Portugal, Spain, and Turkey were included. Students' age was between 21 and 25 years. We prepare two groups of 12 students based on their devices. Other 12 students were the control group. Students from the experimental group were given the application to use it during the intensive Slovene course. Small groups render more complex analysis questionable but for the purpose of our pilot research descriptive part is sufficient.

Table 1: Usefulness of application

	No.	%
Not at all	0	0
Ok, but too few topics	3	25%
Useful	7	58,3%
Very helpful to me	2	16,7%

Research has shown that more than half of attendants assess the application as useful (58.3%). Even those who decide that application have too few topic actually did not assess that application was not useful but just need to be filled with the additional lectures/topics. Since no one have assessed application as not useful at all we can confirm that our approach was the right one.

Table 2: Which visual mode you have found most effective in the individual options?

	No.	%

Tap-on-word	4	33,3%
Tap-on-pictogram	2	16,7%
Tap-on-picture	3	25%
Allareequally effective	3	25%

Mobile devices require extensive attention in the visualization of the content. Small screen prevents the display of anything but essential for given learning topic. Learning "*just in time*" requires prediction for the situations where learners would require assistance and fast mental flow from device to the user. Despite pictograms and images presents least cognitive load users decide to use text (reference language of the application) as favorite navigation. The answer to this question could be the topic of another research. Processing of images is always in the primary language (mother's thong) of the learner but in the multilingual environment (system notification in another language) possible require high mental load in the language switching which is not always simple even for the fluent speaker. This phenomenon would really require another research.

Table 3: Do you find the language theory section useful?

	No.	%
Not at all	2	16,7%
Ok but too complex	3	25%
Useful	7	58,3%
Very helpful to me	0	0

Theoretical grammar background can be a problem for heterogeneous learning groups. Learners originate from different language groups and socio-environmental background and topics in language they learn may be totally alienated from their perception of language. Learners have also different attitude to the grammar. Language specialist want to understand the background of mental structure of the sentences while others want to use language in the day to day activities only (for the beginning). To understand why the grammar is not useful for (some) students we need to ask different questions and expand research in that area. Probably this research would be more useful in the higher level of language learning (B1/B2). But even at this lower level of language learning we receive positive feedback from 83.3% of students. It is evident that grammar should be explained accordingly to the capabilities of the learners and that is always problematical since grammar is the basic building blocks that has only one explanation.

Table 4: Do you find the native sound support useful?

	No.	%
Not at all	0	0
Ok but I don't really need it	4	33,3%
Useful	3	25%
Very helpful to me	5	41,7%

Sound of the language (pronunciation) gives the learner full immersion into the language learning. Only correct pronunciation enables foreigners to join the conversation in one language space. Analysis show that speaking language is "ok" but depends on learning group. Slavic learning group rarely used language pronunciation but students from another language groups did. This give us the feedback that we could include students' primary language as the differentiation factor into the design of the m-learning language application.

Table 5: Do you find learning games useful?

	No.	%
Not at all	1	8,3%
Ok but too easy	4	33,3%
Useful	5	41,7%
Very helpful to me	2	16,7%

Learning games were the easiest and most effective motivation for drill and practice in knowledge acquisition. This known fact was confirmed by 91.7% of our students. In our test application we include only one type of the game/quiz ("pick the right answer"). We would probably get much better results if more games' types. From the 33.3% of students we also receive the feedback that quizzes were too easy. Therefore we could prepare more complex quizzes for them but there is always a fine line between too easy and too difficult. We never wanted to get into too difficult area since this would frustrate learners and probably move them away from the language learning.

Table 6: What would you add to the application?

	No.	%
More topics	10	83,3%
More sounds	1	8,3%
More theory	1	8,3%
More games	0	0

As expected most users would like more topics in the application. Therefore m-learning has the bright future and should be considered the valuable paradigm in the future TLS (Teaching, Studying, and Learning) processes. Students' feedback from this application was of a high importance for language learning. We were able to verify our expectations and acquire new knowledge about language learning students. Probably most important consideration in the application design and development is the "*content for the users*" and not "*users, here you have content*".

VI. CONCLUSION

Mobile learning (m-learning) is the way where "anywhere and anytime" changes the "map" of learning. It introduces the new paradigm to the TLS (teaching, learning, studying) processes what were not possible 10 years ago. In the past and even today we recreate proxy real situations to teach some topics but with the m-learning we can challenge the learning in all life situations. This is particularly useful in the language learning – where "just in time" gets effective meaning. Learning of language with the book and sound recordings in the classroom is still not dead but it is a dead way to learn the language. Smartphones as the learning aid have the ability to change that to the live language learning. It is not the problem of lack of technology because at least half of the people own at least one smartphone. Key to

the success is therefore not the classical infrastructure for language learning but mobile language learning. Mobile learning application for language learning needs to be designed accordingly to the new quality standards where haptic user interface have to be fully respected. Haptic user interfaces enables direct contact with the knowledge and multitude of new opportunities how to structure learning materials. Despite multiple tries to define rules for m-learning design this area remains virtually "untouched" in the expectation of the next big thing to ease the language learning.

marina.popovic@student.um.si, dcveles@gmail.com, marjan.krasna@um.si

Abstract: Cooperation today is on a global scale and anyone is welcomed to participate. Global standard in education means that ICT becomes backbone of the education infrastructure and incorporated to the educational paradigm. Europe dictates that student and teacher mobility is almost mandatory. Our intention was to see the difference between two countries that should start using their ICT in education concurrently. With the historical overview, contemporary research on comparison of study programs, and students' opinion we provide the comparison that shows potential for cooperation and mobility. Today's students are digital native in both country and in the article we are present the differences through their views and opinions. We constraint our research on students of educational study programs in three universities in Slovenia and one in Serbia.

Keywords: ICT, education, university study programs, special didactics, student survey

I. INTRODUCTION

ICT in education is the driving force to change curricula at all levels of education. New generations grow with it and use them on a daily basis. These generations, one defined as "*digital natives*", are now more "*always on*" generation. Whoever lectures the students know that students who supposed to listen the lecturer are actually always present on their social networks. Their ability to check the validity of the knowledge they get is instant.

New generation of student require better learning materials. Books are fine but too time consuming. The changes are constant and all present. Though we have introduced ICT in education of teachers in the previous century [1] it is still evident that we have not done enough. From the past project reports "Status and trends of application of ICT in Slovenian schools" it is evident that growth of ICT is not self-evident and require funding [2] [3] [4]. But in the last decade we have huge development in e-learning materials production where university level of education was excluded. [5]

It is evident that we need to prepare teachers to this new reality and give them instruction how to use and prepare their didactically suited and aesthetically pleased learning materials [6] [7] [8] [9] and according to their study discipline [10].

II. HISTORICAL OVERVIEW

The majority of developing countries, among them also former Yugoslavia started the implementation of computers in the educational system relatively late and uncontrolled. The process of implementation only started in the era of microcomputers. Usually it was a centralized system of equipping mostly with imported computers due to the fact that there was no computer industry of their own for these countries in the early eighties. In Yugoslavia, including Slovenia, programmed courses came into effect in the seventies. [11] Until 1970 computers were too expensive and too, while teachers had to make their own teaching materials, sadly without the wanted effect and result. As a consequence there was a minor usage of computers in schools. [12] In every educational institution following the SFRY there was only a few qualified teachers able to teach ICT and computer technology and a few of those using computers for their work. [13] [11]

In the time line below, we will expose events that were crucial for the development of computer science and technology in individual areas:

Table I: Historical presentation of events

1968	First meeting of the Initiative group for the usage of cybernetics in pedagogy in Zagreb.
1970	Joint meeting of representatives of SFRY`s Institutes of Education in Čatež.
1970	SLO: Implementation of computer technology as a course in 3rd and 4th year of secondary schools.
1971	Federal agreement (document) titled The Suggestion of long-term Modernization of Educational Activities in SFRJ, international conference of innovations in educational technology in Subotica, the annual school of andragogy with a seminar themed by PUK and learning with the help of a computer in Poreč.
1971	First international research center for programmed courses and implementation of computers – Multimedia center of the Referral center of University of Zagreb.
1972	Start of computerization of schools in Slovenia and other republics.
1972	The establishment and operation of Computer center for programmed learning (RCPU) led by Aleksandra Kornhauser.
1974	I. Bratka and V. Rajković write the first textbook titled Introduction into Computer Technology and Collection of Tasks by a group of authors.
1976 – 1979	RCPU is leading and coordinating the project Computer Technology Courses in Guided Education.
1979	SLO: Computer technology becomes a regular subject in 4 year programs of technical schools.

In a period of ten years a lot of events took place that contributed to the development of computer technology, although we have to emphasize that considering the time of the early start of implementation of computer technology as a study course in secondary schools, there are still schools today with no ICT or computer technology courses.

Table II: Historical presentation of events

1983 - 1984	SI Introduction of optional courses, extracurricular activities and supplementary education for teachers in the field of computer technology.
1985	SI: The establishment of a work-group i.e. a computer technology commission led by V. Rajković. Ivan Gerlič was in charge of educating teachers. The objective was to develop a course of computer technology and encourage its usage in Slovenia.
1985	SI: The establishment of the Center for computer technology in education at the Faculty for Pedagogy in Maribor, where the objective was to increase the usage of computers with didactical courses.
1986	An organized and mass implementation of computers in education starts in other republics and countries
1986	SI: COMPUTER IN SCHOOL – designing a politics of equipping Slovenian schools. The first appendix, Computers in School is published within the magazine Upbringing and Education that deals with problems that occur with the usage of a computer, and a book collection Computer Horizons.
1987	SI: The subject of Computer technology in secondary schools is added a chapter of informatics and therefore a new subject arises, Informatics and computer technology – ICT.
1987	Yugoslavian conference titled Computer in Education which conclusions and observations were a basis for further politics and strategy in implementing computers and contemporary informatics technologies into education. There was also a debate of the politics of modernization of educational technology.
1987	SI: Project COMPUTER DAY – intended for all teachers of primary schools and guiding counsellors of Institution of RS of Education.
1987	SI: Implementation of the following projects: CIRCLING CIRCLES, LOGO in primary schools, and MEASUREMENT COMPUTER in secondary schools, ROBOTICS in primary and secondary schools.
1989	SI: Within the project of DUCK-89 (RAČEK-89) an action of an organized purchase of computers and publishing of a book collection The Duck`s Little Book (containing mostly manuals for educating teachers) is carried out.
1989	SI: A new publication NIT is published – New Informatics Technologies, which substitutes the dropped appendix Computers in School of the magazine Upbringing and Education.
1990	SI: Project DUCK-90 – computers and licensed software is bought by a large number of primary and secondary schools.

In the early nineties the first implementations of projects of unified equipping of secondary schools and HR secondary schools with personal computers have started. It was already known at that time that the action of equipping schools with computers is not a one-time action but a long-term process, which is supposed to develop continuously.

The development of computer industry has picked up speed and it still shows no decline while the hardware is getting even more functional, more powerful and what is most important more financially available to masses. [13]

Following the disintegration of Yugoslavia, Slovenia led a new path of developing computer science and computerization of schools as an independent country. Towards the end of the nineties, Slovenia has moved away from others previously more or less equal Yugoslavian republics and continued to develop for herself, which has gained her advantage over others.

Table III: Slovenian project for ICT in education

1992	With the project PETRA a process of computerization of the fifth grade of primary school is implemented. Courses such as Slovene, Art and Technology are taught with the help of a computer. Beside that the project brought novelties such as team teaching and learning, team learning for teachers and the development of didactics of ICT.
1994 – 2000	Realization of a six year program Computer literacy - RO – creates opportunities for computerization of schools on the educational as well as on the organizational level. It included all stages of Slovenian education from pre-school to university.
1994	Project SCHOOL TOLAR (ŠOLSKI TOLAR) – enables the creation and implementation of the RO program.
1999-2000	The Institution of RS for Education produces a project of Computerization of subjects. It consists of three projects. PIKA - computerization of educational activities in kindergartens and lower grades of primary school. TIMKO – team learning and team teaching with informatics technology from 5th to 9th grade of primary school, in gymnasium and in four year secondary technical education. VESNA – searching for new ideas and fresh incentives of Computerization in kindergartens, primary and secondary schools along with their education within the project`s frame.
2001-2003	IKT strategy in Slovenian educational system is based upon the results of the RO program – Computer literacy (Računalniško opismenjevanje). (Čampelj, 2001)

In the time of Yugoslavia the development of computerization was on a different path, for it was slower in Serbia than it was in Slovenia, which has few advantages in this area. The disintegration of Yugoslavia came as a great blow for Serbia because there was a status quo at that time in the field of computerization. After the disintegration there were other factors that impeded the development of computer science.

The reason for Serbia starting to develop the IKT technology later, at the beginning of 21st century was in its long-lasting period of economic and political isolation at the end of 20th century.

Table IV: Serbia's project for ICT in education [14]

1992-1999	The biggest decrease of the development of IKT.
2000 -	Intensive and fast development of the IKT.
2004	Ministry of Education contributes the IKT equipment for more than 2.000 teachers of primary and secondary schools.

Table V: Internet speed.

	SI		SRB	
	F	f(%)	f	f(%)
from 1 Mbit/s	12	7.74	16	16.67
from 1 Mbit/s to 5 Mbit/s	40	25.81	10	10.42
from 5 Mbit/s to 15 Mbit/s	47	30.32	28	29.17
from 15 Mbit/s to 50 Mbit/s	30	19.35	38	39.58
from 50 Mbit/s to 100 Mbit/s	22	14.19	3	3.13
more than 100 Mbit/s	4	2.58	1	1.04

It is evident from the table that the average data transfer rate from the internet among Slovenian students is at its peak from 5 Mbit/s to 15 Mbit/s (30%), while the average data transfer rate among Serbian students is from 15 Mbit/s to 50Mbit/s (39%), which shows that on average Serbian students have a faster data transfer rate. More Slovenian students found themselves in the ratio from 50 Mbit/s to 100 Mbit/s (14%), while there are only three Serbian students in that level. The results were not expected and they show that infrastructure is not the obstacle to the use of ICT in education. According to the results it can be said that Serbia, especially the area of Vojvodina, has been developing fast in the field of computer science in the last few years.

Table VI: The application of ICT in education within didactical courses.

			Country		Total
			SI	SRB	
Application of ICT	YES	Count	88	42	130
		% within country	45.8%	31.3%	39.9%
	NO	Count	104	92	196
		% within country	54.2%	68.7%	60.1%
Total		Count	192	134	326
		% within country	100.0%	100.0%	100.0%

Regarding the Pearson Chi-square test it is evident that there are significant differences between countries ($\chi2$=6.911, p= 0.009). Data also shows that 54% of students of Slovenian universities think ICT is not present enough within the didactical courses Therefore we could not show that Slovenian students have unified opinion about the presence of IKT. In Serbia the difference is more obvious, 68% of students think there is not enough of ICT within their courses. It can be concluded that the ICT is more present in Slovenian study programs but obviously not enough. We believe the result is expected because there is often a lack of interest with the lecturers for improving their own teaching strategies that would require ICT.

Table VII: ICT knowledge between study programs

			Country		Total
			SI	SRB	
ICT knowledge	YES	Count	76	116	192
		% within country	39.6%	85.3%	58.5%
	NO	Count	116	20	136
		% within country	60.4%	14.7%	41.5%
Total		Count	192	136	328
		% within country	100.0%	100.0%	100.0%

The table shows results we have not expected. In Serbia 85% of students claim they get enough information on ICT in their study programs, while Slovenian students are not even near this numbers (39.6%). Statistical differences is significant ($\chi2$=73.743, p=0.000). The result was certainly not expected but we are pleased to see that despite the late development of computer science and introduction of ICT it has extended among study programs. Slovenia has to improve certain areas renovations of study programs with a more ICT inclusion into the curricula.

Table VIII: Use of ICT equipment

	SI		SRB	
	F	f(%)	f	f(%)
Computer	188	98.43	129	94.85
Tablet PC	59	30.89	20	14.71
Smartphone	168	87.96	77	56.62
Internet	184	96.34	86	63.24
Video	62	32.46	17	12.50
Sound	35	18.32	8	5.88
Other	2	1.05	0	0.00

Students could chose more options in this research question. Slovenian and Serbian students use computers most of the time (more than 90%). Internet is firmly in the second place and smart phone in the third though Slovenian students show a higher use of those (smart phones). The table shows that Slovenian students are more distributed among the variety of ICT equipment (or services) than the Serbian students. These elements are influenced by a factor of availability to a variety of equipment.

Table IX: Use of ICT equipment among lecturers in classes/practice for special didactics

			Country		Total
			SI	SRB	
Use_of_ICT_lectures	mostly no	Count	14	1	15
		% within country	7.4%	0.7%	4.6%
	rarely	Count	79	122	201
		% within country	42.0%	89.1%	61.8%
	often, not always	Count	83	13	96
		% within country	44.1%	9.5%	29.5%
	always	Count	12	1	13
		% within country	6.4%	0.7%	4.0%
Total		Count	188	137	325
		% within country	100.0%	100.0%	100.0%

Students in Serbia were very critical of their lecturers because 89% of them think their lecturers do not use enough of ICT equipment, while in Slovenia opinions are divided, which causes a significant statistical difference ($\chi2$= 82.597, p= 0.000). In Slovenia 42% of students think the ICT is not used often enough and another 43% think opposite. Regarding that it can be concluded that Serbian students demands more use of IKT equipment among their lecturers, although Slovenian lecturers have a lot to do to reach a satisfying level of everyday use of IKT equipment. The lecturers are the ones that can teach students how to use certain learning strategies in classes because students will not learn them by themselves for it is not systematic and it would take too much time.

Table X: Use of ICT for study deliverables production.

	SI		SRB	
	F	f (%)	F	f (%)
Web classrooms	88	46.81	22	16.06
e-materials	147	78.19	80	58.39
Web encyclopedias	108	57.45	50	36.50
Specialized data bases	100	53.19	38	27.74
Texts from other educational institutions	98	52.13	89	64.96
Multimedia elements	138	73.40	26	18.98

Student use ICT to make materials needed for their studies. Slovenian students mostly use multimedia elements (73%) and e-materials (78%), interestingly on the

last place is the use of web classrooms (46%) despite Moodle is used on every educational institution in Slovenia. In Serbia the most used elements represent texts from other educational institutions and e-materials, while at the last place is also the web classrooms. According to these results we can conclude that students should probably be more informed on the use of those elements and introduce them as a very practical and interesting tool with the production of various works.

Table XI: Respect of copyright materials

			Country		Total
			SI	SRB	
Respect of copyright materials	DA	Count	147	21	168
		% within country	78.6%	15.3%	51.9%
	NE	Count	40	116	156
		% within country	21.4%	84.7%	48.1%
Total		Count	187	137	324
		% within country	100.0%	100.0%	100.0%

Due to the fact that students produce many seminar works during the study years and should respect the legal authors' and copyright agreements. The biggest differences among Slovenian and Serbian students have been noticed here as 78% of students think that faculties in Slovenia respect those rights, while 84% of students in Serbia think that their faculties do not have an adequate system for that issue. That caused a significant statistical difference ($\chi 2$=137.206, p=0.000). Every faculty needs to respect reserved rights with no exception and therefor a lot of efforts need to be put into solving this issue.

Table XII: uniformity of citation system

			Country		Total
			SI	SRB	
Uniformity of citation	1	Count	169	124	293
		% within country	90.9%	90.5%	90.7%
	2	Count	17	13	30
		% within country	9.1%	9.5%	9.3%
Total		Count	186	137	323
		% within country	100.0%	100.0%	100.0%

Different study programs use different citation systems of citing the other work in their deliverables (seminars work, diplomas, master and doctoral thesis). A high percentage of students from Serbia as well as Slovenia, even 90% think that there should be a uniformed citation system, with no statistically significant difference ($\chi 2$=0.011, p= 0.915) between countries. This shows that a uniformed citation system would solve many issues and avoid inconveniences when students use different citation system for each discipline or even each lecturer. The result was expected because the variety of citation' systems causes many frustration between students. To speculate in that matter a little we do not want only one citation system. But it would be nice to have such standards (e.g. APA, IEEE) which are supported in contemporary Microsoft Word and solve those problems and inconveniences forever.

III. CONCLUSION

Based on the historical review of events and survey, which was conducted in Slovenia and Serbia, we got surprising and unexpected results. According to the data from the 90th where the difference between the two countries was the largest, is now steadily decline. It becomes evident that the use of ICT in education in Slovenia declines as country is griped in the constant economic crisis. On the other hand Serbia, whose economic situation is no better, slowly and steadily grows. Professors and students must be aware of the importance of ICT whose purpose and use is versatile. On the other hand technology itself is not enough and countries must educate professors to use it. It is also wrong perception that young generation will know how to use ICT efficiently and effectively without any help and instructions. No matter what we do "digital natives" will use the ICT technology in ever greater extent and we ought to be prepared for them.

From the results of our research it is evident that the advancement in ICT is not self-sustained. If there are no incentives the advancement stall and eventually even decline. There should be multilevel incentives from funding the hardware and infrastructure to the increased payment to those who use ICT in education more often than the others. Young generation of teachers are ICT literate and capable to use ICT in the whole educational spectrum. But environment where they are not stimulated rapidly decrease their competences. Ever present changes of the educational system where each new government almost completely changes policy is no incentive for the teachers in general. ICT is inherently fast changing and policy changes create almost unimaginable and in most cases unwanted consequences.

We are always bound to the past in all aspects. It is now becomes evident that some society can advance faster than the other if they build on the solid foundations. Elaborate systems are not easy to change and they become increasingly rigid by established rules for almost everything. At least one aspect in the rigid rules is good – established procedures assures general compatibility of the study results. Any student who graduates in all levels of education in Slovenia will comply with the standard of respecting the copyright materials and their work should never be categorized as copyright infringement. Slovenian students are well aware of this problem but Serbian students will have to learn this in the very near future. For the future research it would be very useful to include more countries and study disciplines to the research. We suspect that results published in the yearly self-evaluation reports in the matter of quality assurance of faculties and universities in Europe and around the World are not equally understand among their students and in some cases even their employees.

Abstract – After introducing e-assessment into laboratory and seminar teaching of physics in a biomedical university study program the improved final practical exam passing rate was observed. The final practical exam passing rate increased from approximately 60% to more than 80%. Encouraged by these results, in this paper we will try to show a correlation between the results of e-assessments collected during continuous monitoring of student performance and their success in final tests using neural networks as modeling method. The models will be built using various sets of data collected during three academic years. Aside from the impact on the final practical exam passing rate, the models should help us in dealing with the missing data problems. Some data are missing due to technical problems and some due to errors in student handling of e-application. In this paper we have observed data collected by two types of e-assessment. The first type of e-assessment is carried out during laboratory exercises and it influences the formation of the final grade. The second type of e-assessment is performed during seminars and has no impact on the final grade.

I. INTRODUCTION

The e-assessment results collected during continuous monitoring of student performance could be used for modeling and predicting student success in final exams. Similar models are described in [1] and [2]. During the process of data preprocessing we will always observe that there are some data missing. The question is which method would be optimal for dealing with the missing data in these specific models.

The general rule in dealing with the missing data is that the missing data could be simply ignored if they occur randomly and the conclusions could be drawn based on the observed data only. If the data are not missing randomly, ignoring the missing data leads to a systematic bias [3]. In that case some imputation techniques should be used.

Intuitively, it could be presumed that students obtaining better results in final exams would have less missing data, meaning that they are more conscious regarding their obligations but then it could be the pure technical clumsiness or the data could be missing due to some technical reasons. The thing is that we don't really know why the data are missing and are they missing randomly or not in this specific situation.

In order to deal with this issue we will build models in two ways: in the way that the missing data will be simply ignored and in the way that null value will be imputed instead of the missing data.

This paper will begin by the digest of the up-to-date papers elaborating the handling of missing data in prediction models. Afterwards, the dataset and the methodology will be described. The paper will be concluded by discussing the results and presenting conclusions, limitations and guidelines for the future work.

II. LITERATURE REVIEW

According to [4] and [5] there are three possible modes for missing data. The data could be missing completely at random meaning that the missing data are not related to the study variables. In the second mode, data are missing at random and the probability of an instance having an attribute with a missing value may depend on the known values, but not on the value of the missing data itself. In the third mode, data are not missing at random, meaning that the probability of an instance having an attribute with a missing value could depend on the value of that attribute.

Imputation is a term describing a procedure of replacing the missing values in a dataset with some presumable values. The missing data treatment is independent of the learning algorithm used. This allows the user to select the most suitable imputation method for each situation [6].

As stressed by [7] many works in the literature have demonstrated that the benefits of imputation methods depend mainly on the problem domain, the size of the available dataset and missingness patterns.

Clinical trials databases are the most frequently used and described when researching the missing data problems. Substantial instances of missing data are a serious problem that undermines the scientific credibility of causal conclusions from clinical trials. The assumption that analysis methods can compensate for such missing data are not justified, so aspects of trial design that limit the likelihood of missing data should be an important objective [5].

In the work of [7] several imputation methods based on statistical techniques were applied, for instance mean, hot-deck and multiple imputation and some methods based on machine learning techniques like multi-layer perceptron (MLP), self organization maps (SOM) and k-nearest neighbor (KNN). The data on demographic, therapeutic and recurrence-survival information from women with operable invasive breast cancer were used. The accuracies of predictions on early cancer relapse were measured using artificial neural networks (ANNs), in which different ANNs were estimated using the datasets with imputed missing values [7].

The industrial data are also submitted to imputations. Reference [8] analyzed one database with instrumentation maintenance and test records for an industrial process considering the selection of appropriate imputation methods.

In the paper of [9] ten clinical trials databases were used to explore and compare nine different approaches to missing attribute values.

Reference [10] reviewed the routines to incorporate observations with incomplete variables in regression models in the context of a motivating example from a large health services research dataset.

The approaches to characterize patterns of bias in missing data were considered by [11]. They sought to determine the specific attributes that predict the missingness of data values [11].

In the work of [12] the authors strived to understand better the problem of dropouts in higher education. They processed the data using data mining methods: logistic regression, decision trees and neural networks. The models are compared to select the one which best predicts the student dropout. They applied the method of missing values replacements called "Most frequent value" and "Tree imputation".

The authors generally agree that there is no the universal rule how to handle the missing data problem and that the approach should be attuned to the specific problem. This paper will consider routines for handling missing data problem in educational prediction models.

III. METHODOLOGY

In this paper we have observed data collected by two types of continuous e-assessment. The first type of e-assessment is carried out during laboratory exercises and it has the minor influence the formation of the final grade. The second type of e-assessment is performed during seminars and has no impact on the final grade. The continuous e-assessments are accomplished by a web-application named *Pitalica*, which has been developed in order to allow the teacher to quickly assess students at the beginning of each exercise. It is assumed that a student will spend approximately 5 minutes on a computer answering to 4-6 questions related to the exercise that he/she is about to work off. This way, a student has the feed-back on his performance in terms of number of points achieved for a specific matter covered by an exercise [13].

The second type of e-assessment is performed during seminars and the idea is to motivate students to prepare for the seminars and to participate actively during seminars which would hopefully lead to better exam performance [14].

The topics elaborated through lectures and seminars are examined either by means of three written midterm exams (12 multiple-choice questions each) and by a final exam.

The practical exam is performed after the course and it is graded as pass/fail. During the practical exam a student has to carry out the practical assignment which only involves elements of the practical exercises performed during the course. In order to pass the practical exam the calculated result has to be +/- 10% correct and a student is expected to synthesize the knowledge acquired during laboratory practicals. Passing the practical exam is the prerequisite to take the oral part of the final exam.

After introducing e-assessment into laboratory and seminar teaching of physics course in a biomedical university study program the improved final practical exam passing rate was observed. The final practical exam passing rate increased from approximately 60% to more than 80%.

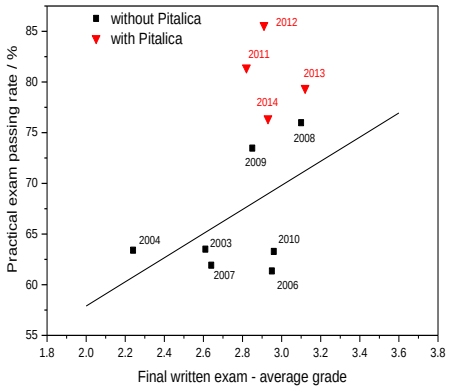

Figure 1. Linear regression fitted on Practical Exam passing rate/ Final Written Exam average grade (no Web-quiz) data, 2003-2014

Encouraged by these results we built models for predicting student performance using continuous e-assessment data as attributes and exam success data as class labels.

A. *Dataset preprocessing*

TABLE I. Number of students enrolled in Physics course, study program Medicine

Year	All instances	Reduced dataset (instances with missing data are removed from the dataset)
2014	284	217
2013	291	184
2012	262	191
Total	**837**	**592**

The datasets used in this paper are described in Table I.

The student performance prediction model is proposed using the results achieved at the first midterm exam (FME), the second midterm exam (SME), the third midterm exam (TME), all three midterm exams (AME) and the final practical exam (FPE) as the class labels.

The attributes for specific models are described in Table II.

All models are calculated using 2 datasets: reduced dataset (m_R), where instances with missing data are removed from the dataset and complete dataset (m_A) where nulls are imputed instead of the missing values. Nulls have been chosen for imputation since it is presumed that it would be the result if the student would have responded. Also, students who failed a certain question have null registered also for the time attribute.

B. *Modelling*

Tables with results accumulated by means of *Pitalica* during e- assessment on seminars and practicals and mid-term and final exam results were stored in a database. The data were exported to the format which can be processed by Rapid Miner 5.3 tool [15].

Neural Networks (NN) have been used for prediction models by [16, 17, 18, 12 and 19]. NN are computational models inspired by neuropsychology where a nerve cell functioning principle has been used [20]. A multi-layer neural network consists of large number of units (neurons) joined together in a pattern of connections. Input units receive information to be processed, output units present the results of the processing and units in between are called hidden units.

There is an issue is how to properly determine the size of the hidden layer since an underestimate of the number of neurons can lead to poor approximation and generalization capabilities. Too large number of nodes can result in over fitting and eventually make the search for the global optimum more difficult [21].

NN are used in this paper for modeling since the non-linearity of the neural network is able to overcome poor embeddings resulting from zero and mean [3] and there are reported good results in educational prediction models using NN [12].

IV. RESULTS

TABLE II. DESCRIPTION OF MODELLS, ATTRIBUTES AND CLASS LABELS

Model	**Atributes Description**		**Values**
m_1	Results - *Pitalica* – seminars 1 and 2 – for each student and for each question	binominal	=[0, 1]
m_2	Results - *Pitalica* – seminars 1,2 and 3 – for each student and for each question	binominal	=[0, 1]
m_3	Results - *Pitalica* – seminars 1,2,3 and 4 – for each student and for each question	binominal	=[0, 1]
m_4	Results and time - *Pitalica* – seminars 1,2,3 and 4 – for each student and for each question	binominal and numeric	=[0, 1] =[0 – 30]
m_5	Results - *Pitalica* – seminars 1,2,3 and 4 – sum of scores for a seminar for each student	numeric	=[0, 15]
m_6	Results and time - *Pitalica* – seminars 1,2,3 and 4 – sum of scores and total time for a seminar for each student	numeric	=[0 – 450]
m_7	Time - *Pitalica* – seminars 1 and 2 – for each student and for each question	numeric	=[0 – 30]
m_8	Time - *Pitalica* – seminars 1,2 and 3 – for each student and for each question	numeric	=[0 – 30]
m_9	Time - *Pitalica* – seminars 1,2,3 and 4 – for each student and for each question	numeric	=[0 – 30]
m_{10}	Total time - *Pitalica* – seminars 1,2,3 and 4 – sum of time for each student	numeric	=[0, 450]
m_{11}	Results - *Pitalica* – practicals- for each student for each question	binominal	=[0, 1]
m_{12}	Time - *Pitalica* – practicals-for each student for each question	numeric	=[0 – 120]
m_{13}	Results and time - *Pitalica* – practicals	binominal and numeric	=[0, 1] =[0 – 120]
Class label	**Class Labels Description**		**Values**
y_1	FME = result of first midterm exam	binominal	=[0, 1]
y_2	SME = result of second midterm	binominal	=[0, 1]
y_3	TME = result of third midterm exam	binominal	=[0, 1]
y_4	AME = result of all midterm exams	binominal	=[0, 1]
y_5	FPE = result of final practical exam	binominal	=[0, 1]

When comparing accuracy results of models using the reduced dataset (m_R) and models using complete dataset (m_A) with imputed nulls instead of the missing values it could be observed that models using incomplete data have consistently better accuracy for a few of percents.
Regardless of the dataset used the most successful models are the ones having as attributes the results of *Pitalica* at seminars 1,2,3 and 4 – sum of scores for a seminar for each student.

The best model (m_{R5}, accuracy 92,13%) has as attributes the results of *Pitalica* at seminars 1,2,3 and 4 – sum of scores for a seminar for each student using reduced set of data and as the class label has the results of the first midterm exam (FME) as shown in Table III.

TABLE III. ACCURACY FOR SELECTED CLASS LABELS AND MODELS, TWO DATASETS USED

Dataset: reduced					
accur %	FME_R	SME_R	TME_R	AME_R	FPE_R
m_{R1}	86,52	66,29	75,84	67,98	80,90
m_{R2}	84,83	67,42	72,47	66,29	79,78
m_{R3}	84,27	64,61	73,30	64,61	82,00
m_{R4}	85,96	65,17	74,72	62,92	79,78
m_{R5}	92,13	70,22	83,71	66,29	87,08
m_{R6}	91,01	68,54	83,71	67,42	87,64
m_{R7}	83,15	64,04	73,60	64,04	83,15
m_{R8}	82,58	61,80	71,91	61,24	78,09
m_{R9}	85,39	62,36	70,79	61,80	78,65
m_{R10}	91,57	69,66	83,15	67,98	87,08
m_{R11}	87,64	67,54	75,28	67,98	80,34
m_{R12}	84,83	64,61	71,91	66,86	80,34
m_{R13}	85,96	70,22	76,40	65,17	80,34
Dataset: all instances					
accur %	FME_A	SME_A	TME_A	AME_A	FPE_A
m_{A1}	85,52	66,29	74,90	61,53	80,88
m_{A2}	84,83	63,75	73,51	62,55	75,30
m_{A3}	84,86	64,61	73,03	62,55	76,89
m_{A4}	84,86	65,74	73,31	65,54	75,70
m_{A5}	89,24	71,71	83,71	66,53	87,08
m_{A6}	89,24	69,32	80,08	67,42	83,72
m_{A7}	81,67	61,75	73,60	64,04	79,68
m_{A8}	80,08	63,35	71,92	59,76	74,50
m_{A9}	83,27	63,36	69,32	60,16	75,30
m_{A10}	83,24	68,92	78,88	67,98	83,27
m_{A11}	82,47	68,92	72,91	63,35	80,34
m_{A12}	80,88	64,61	68,53	58,57	84,27
m_{A13}	82,87	67,33	76,40	64,54	80,34

It could be also observed in Table III that adding time attributes (total time used at *Pitalica* seminars, m_6 compared to m_5) the accuracy of models decreases slightly. It could point to the greater impact of the factors not connected to knowledge and ability to the time spent for solving e-quizzes. The time consumed for e-quizzes by a student could be affected also by technical problems due to communication to the server. It could be also determined by a student strategy of solving problems since some students answer to questions as soon as they perceive the true answer and some students mark the chosen answer only when the time is up.

When considering results of Pitalica at seminars for each student and for each question the best accuracy results are achieved when modeling using the results of the first two seminars irrespective of the dataset used (reduced or imputed). The first two seminars have greater number of questions (28 out of totally 48) and the matter included in those two seminars is mostly questioned at the first midterm exam (FME).

The influence of the *Pitalica* results of the third and the fourth seminars to the accuracy results when modeling to SME (result of the second midterm exam) and TME (result of the third midterm exam) is respectively smaller and it is connected to the smaller models accuracy.

The accuracies of models m_1 and m_2 with SME and TME as class labels respectively, using both datasets, confirm the tendency.

In order to rank the models according to accuracy indicator the Wilcoxon Matched Pairs Test was calculated using Statistica 12.5.

Table IV contains the Wilcoxon Matched Pairs Test scores calculated for models using the reduced dataset (FME_R, SME_R, TME_R, AME_R, FPE_R) and the dataset with imputed nulls (FME_A, SME_A, TME_A, AME_A, FPE_A). It could be concluded that there is a statistically significant difference in accuracy for models using the reduced dataset and the dataset with imputed nulls.

Exceptionally, when modeling to SME (result of the second midterm exam) the accuracies of models using the reduced dataset (SME_R) compared to accuracies of models using dataset with imputed nulls (SME_A) do not show significant difference (Table IV). This exception could be explained by the fact that the second midterm exam questions the field of electricity (which is supported by *Pitalica* seminar) and the field of thermodynamics (not supported by *Pitalica* seminar). The thermodynamics questions always outnumber the electricity questions in the second midterm exam and the thermodynamics also proves to be more difficult for students.

TABLE IV. WILCOXON MATCHED PAIRS TEST

	Wilcoxon Matched Pairs Test Marked tests are significant at p <.05000	
Pair of Variables	statistical significance	p-value
FME_R & FME_A	significant	0,002874
SME_R & SME_A	not significant	0,878482
TME_R & TME_A	significant	0,021825
AME_R & AME_A	significant	0,036659
FPE_R & FPE_A	significant	0,036659

V. CONCLUSION

Since reduced models gave significantly better prediction accuracy than the models with imputed nulls instead of the missing values we could conclude that in this specific situation, the data are missing at random or that null value is not a good substitute. In order to resolve

this ambivalent inference, in a future research one could use some other technique of imputation of the missing values as for example hot-deck.

Hot-deck imputation is a method in which each missing value is replaced with an observed response from a "similar" unit. This theory is extensively used in practice, but it is still not developed as well as some other imputation methods [22]. Methods based on machine learning techniques like k-nearest neighbor (KNN) could be the further possibility.

Abstract - Creativity and innovation play a key role in the present. Program Europa2020 declared a need of strengthening the knowledge triangle - education, research and innovation. Based on this, the changes are happening in education from the perspective of the knowledge society, focusing on one of the basic elements of innovation - creativity and its role in education. In the paper the OpenInn project and its outcome – OpenInn portal, an on-line source of information concerned creativity enhancement and tool for creative cooperation among its users – Knowledge Generation House, will be presented.

I. INTRODUCTION

Globalization, competition, rapid changes in technology and other factors have prompted companies, institutions such as schools, to ensure that knowledge is being created, transferred and shared in their organizations. Based on [1], [3], [10], [22], [38], [31] organisations are organizational spaces in which the learning processes on the individual, group and organizational levels are enabled and taking place. This suggests a new way of thinking about how people work together and the need for the greater emphasis on reviewing past practices and experiences [16].

In 2010, the "Creative Learning and Innovative Teaching" [4] has been published, where the strong emphases on broad, flexible and motivating education that recognises the different talents of all children and delivers excellence for everyone is highlighted rather than just improving literacy and numeracy skills. We need to support the creative learning process and try to connect it with practice.

Torrance and Myers [34] provide an excellent framework for describing the creative learning process: „Becoming sensitive to or to be aware of problems, deficiencies, gaps in knowledge, missing elements, disharmonies, and so on; bringing together available information; defining the difficulty or identifying the missing element; searching for solutions, making hypotheses, and modifying and retesting them; perfecting them: and finally communicating the results.". Treffinger [35] proposed a practical model for describing three different levels of creative learning, with consideration of both cognitive and affective dimensions at each level. The three levels are divergent functions (level I), complex thinking and feeling processes (level II), and involvement in real challenges (level III) as illustrated on the Figure 1.

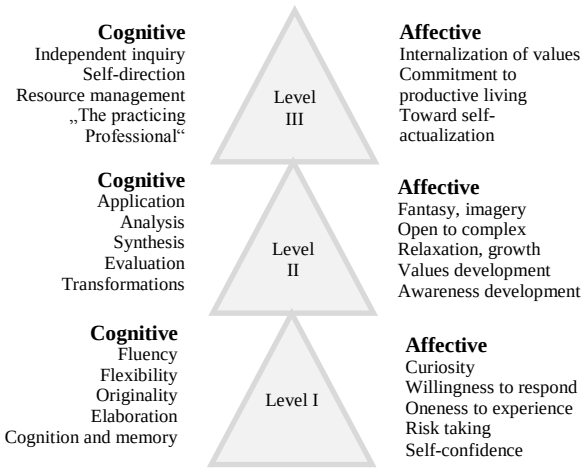

Figure 1. Creative learning model [35]

Teaching for creativity must consider the new opportunities presented by information technology. New technologies offer unprecedented opportunities for young people to broaden their horizons; to find new modes of creativity and to deepen their understanding of the world around them. The number of Internet users are rapidly increasing as mentioned in the Figure 2. Internet user penetration has reached 40% globally, 78% in developed countries and 32% in developing countries [30].

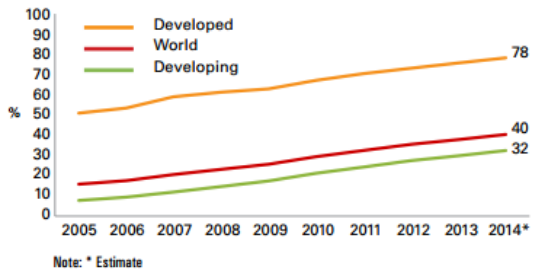

Figure 2. Percentage of Individuals using the Internet [30]

The similar situation is also in Slovakia. In 2013, 74% of Slovaks reported using the internet at least once weekly (regular users, internet users going on-line weekly), above the EU average of 72%. Slovakia exhibited slightly lower rates of daily use of the internet (frequent users, internet users on a daily basis), with 61% of the population reporting going online every day, compared to an EU average of 62%. In 2013, 15% of the population had still never used the internet; lower than in 2012 and lower than the EU average of 20% (individuals who have never used the internet).[8].

The growing number of Internet users has strong relationship to the younger generation [5] which grew up surrounded by digital media – roughly referring to individuals born in the early 1980s or later – displays significantly different learning styles from previous cohorts. Several terms have been used to describe this generation of learners, for example "digital natives" [20]. Bayne and Ross [2] have argued that the persistence of this image of the "Netgeneration" or Digital Native student has a strong relationship to the logic of the market and a culture of enterprise and it is evident in advertising that these ideas are clearly reinforced by marketing aimed at the education sector. New Millenium Learners [5] are using a mix of ICT elements, digital media for their own personal learning needs, mixing and matching different tools and capitalising on social computing applications to build networked, extended communities of interconnected learners who exchange ideas, query issues, provide support and check progress.

In Slovakia, in 2012, 43% of Slovaks had low or no digital skills, compared to 47% for the EU average. Disadvantaged people (i.e. individuals who are aged 55-74, low educated and/or unemployed, retired or inactive) in Slovakia are less digitally skilled than is average in the EU. Within the workforce, skills are higher; 34% of the workforce has low or no digital skills. On average in the EU, the figure is 39%.

Furthermore, the Commission Communication "New Skills for New Jobs" [28] calls for the education, training and employment policies of the Member States to focus on increasing and adapting skills and providing better learning opportunities at all levels, in order to develop the workforce that is highly skilled and responsive to the needs of the economy. The use of ICT must be supported by the strategy of the learning organisation. In higher education classrooms a variety of software tools and free web applications should be used to enhance learning, communication, and engagement, the use of social media, and other content such as Web 2.0. Based on [7], [15] Web 2.0 is a platform on which innovative technologies have been built and also a space where users are as important as the content they upload and share with others. It includes social networks, such as MySpace, Facebook, social bookmarking, creative works, such as podcasts, videocasts, blogs, content aggregation and organization, and remixing or mash-ups of content from different content providers into new forms [15].

Schools also have resources available through these technologies to transform methods of teaching and learning. OpenInn project has created new frontiers linking together education and the corporate world of innovation and supported the creative learning process in the schools by using Web 2.0. The SP4CE project (Strategic Partnership for Creativity and Entrepreneurship - grant agreement 2014-1-PL01-KA200-003341) is widening this approach for further utilisation especially in business environment.

II. OPENINN PROJECT

OpenInn project is aimed at sketching a new Pedagogical and Organisational Model for communities and individuals as an example to explore their innovative potentials proceeding the strengthening of their self-esteem. The project approached the great challenges of bridging the implementation gap in ICT-use for enhancing creativity in lifelong learning [27].

Nine institutions, Technical University of Košice from Slovakia, Univeridade do Porto (Portugal), Università delle LiberEtà del Fvg (Italy), Petko Rachov Slaveikov Secondary School (Bulgary), Aarhus Social and Health Care College (Denmark), Bremen Institut für Produktion und Logistik GmbH (Germany), TREBAG Vagyon –és projektmenedzser Kft. (Hungary), Fondo Formación Euskadi (FFE - Spain), LiNK MV (Germany) decided to promote and prepare the project OpenInn with following aims [27]:

- Bridge the implementation gap in the use of ICT in a creative way to support learning and social coherence linking together different sectors.
- Support the evolvement of a stable positive self-esteem both for learners and for facilitators in the learning environment. By reassuring the self-esteem through autonomous learning, it also generates inner motivation for learning.
- Increase opportunities for utilisation of intellectual capital of young talents and groups at-risk.
- Produce a comprehensive e-Assessment Model containing the theoretical concept and didactics for creativity, with topics including: ways to support the learner to introduce new ideas, evaluating and rewarding creative results, methods for giving instructions to reach innovative solutions, providing autonomy for creative expression both for not-yet ICT users and advanced level users in their specific sectors.
- Create the 'Knowledge Generating House' as an innovative social network for exploring creative potentials. Users could use the platform when looking for ideas expressed by others and by utilization of their own inner potentials as well. This generates a new learning experience, where not only young talents, but groups at-risk from falling behind the educational system can be actively engaged in creating and inventing. By collaborating with others, they can attain new perspectives for understanding a case and developing it, and by the new perspectives they are able to understand themselves better. This reassures their self-esteem and makes the base for exploring their inner potentials.

This project is aimed at implementing the Open Innovation concept in the educational sector to develop a new learning paradigm which utilises the potentials of ICT for learners aged 15 and above. There is an importance of leaving the model open for more sectors of the educational field because the field of use can be still in a process of evolution depending on the end users. This concept was targeted to the following groups [23], [27]: talented youth in higher and secondary education in the partnership institutions and their international network; groups at risk of falling behind the educational system in secondary, higher education, vocational training and adults wanting or needing to further explore their capabilities; teachers and facilitators of talented youth and groups at-risk in secondary, higher education, vocational training or adult education.

The results of this project could be used in the long-term for the following target groups: students with a specific research or scientific interest, experts, SMEs, managers of large enterprises, non-profit organisations and groups that need more support in order to be able to use the portal for enhancing creativity.

III. OPENINN PORTAL

As mentioned above, main outcomes of OPENINN project are gathered in OpenInn portal, available via openinn.eu .

To main project results [24] could be integrated:

- *The Guide to Creativity* (an e-Assessment Model) - a complex electronic educational material, which can serve as a "guide" for teachers using KGH, respectively for teachers interested in innovation trends in education and in innovative didactics for enhancing creativity.
- *The Knowledge Generating House* - on-line ideation tool,
- *Demo video and video guide* to OpenInn portal and Knowledge Generating House,
- *OpenInn Guidebook* - user manual for the Knowledge Generating House with explanations of all features developed,
- *OpenInn project website* with all information about the project, partnership, activities done, etc.

The portal is multilingual – all information is available in nine languages: Bulgarian, Danish, English, German, Hungarian, Italian, Portuguese, Slovak and Spanish.

A. Guide to Creativity

The Guide to Creativity (GtC) presents on-line material for teachers and also for managers interested in innovation trends in education and in innovative didactics for enhancing creativity. The material is divided into modules containing:

- ways of how to support the learner when introducing new ideas,
- ways of how to evaluate and reward creative results,
- methods for giving instructions to reach innovative solutions, providing autonomy for creative expression, both for teachers who are not-yet computer users to those who are advanced internet users.

Every module includes:

- the self-learning material called "Pedagogical background" that provides the reader with comprehensive theoretical background about the Open Innovation principle and its possible usage in the field of addressing and assessing creativity in an educational context,
- the ICT Tools section - a list of ICT tools, their descriptions and the ways how they can be used in an educational context. Every item contains three sections based on the level of a potential user's digital literacy: without the necessity to use ICT tools; using basic level ICT tools; using innovative and advanced level of ICT tools.
- The Practical examples section – presents a collection of particular scenarios describing how to apply ICT for teaching and learning to increase creativity. The 25 scenarios were developed for different educational contexts as well as for the different digital literacy of the users. Rather than consecutive order, the scenarios are presented as single independent items, assigned to two different categories: particular educational sector (secondary school student, vocational student, university student, and adult learner), level of ICT skills (non-ICT user or beginner, basic ICT skills, advances ICT skills).
- The Resource library contains more interesting teaching and learning material about enhancing creativity which is not used in the previous sections.

Because GtC is an on-line material, each part can be used independently from others, but it is cross linked to draw connections from one material to another.

B. Knowledge Generating House

The Knowledge Generating House (KGH) [25] represents an on-line ideation tool based on the principle of crowd sourcing (the practice of engaging a 'crowd' of external individuals for a common goal, for example solving problems and producing things [26]). This principle is usually used by companies in process of designing the new products or services. The use of external resources for increasing innovative potential is generally called open innovation. In connection to this principle, KGH supports the development of new ideas, implements a kind of online brainstorming, offering commenting, and voting for ideas.

These activities are divided into three main parts (Figure 5): place for collaborative learning ('Innovation e-Learning Rooms' for brainstorming and mind-mapping), space for uploading documents (like academic studies, thesis, and portfolios) and individual 'creativity assessment' (based on the level of activity, provided ideas etc.).

Using KGH after the registration to the system, users can actively contribute by adding public or private challenges, ideas to challenges, votes for ideas, and comments on ideas.

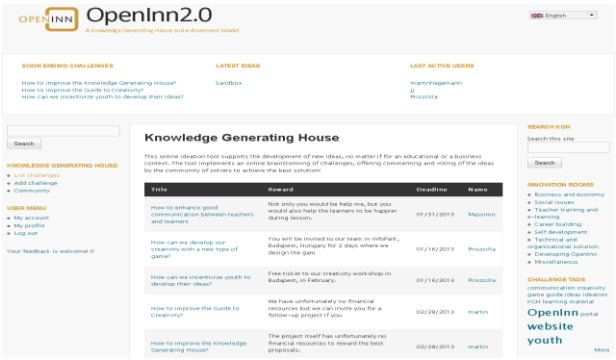

Figure 3. Knowledge Generating House home page

C. *Pilot testing of the portal*

One of the phases of development any software product is pilot testing of the pre-final/beta version. Pilot testing was aimed at testing the functionality and quality of every part of the OpenInn portal. In connection to target groups and main objectives of the project, the partnership decided to provide tests with three pilot-group tests with the portal - 2 pilot-groups with 10-30 students/learners including one teacher/facilitator and one pilot-group only for teachers with 5-20 persons [26].

Besides 25 national pilots done in Danish, German, Italian, Portugal, Slovak, Spanish language, one international pilot involving 4 partner-countries (Denmark, Hungary, Germany and Bulgaria) was realized in English, so that students were able to use the portal with peers online from other countries. Together 357 persons participated on the pilots involving different educational institutions, based on project's target groups: secondary schools, vocational schools, universities and adult education institutions and with different ICT skills level - no ICT, basic ICT and advanced ICT.

TABLE I. SUMMARY OF PILOT TESTING ATTENDANTS DIVIDED ON THE BASIS OF THEIR ICT SKILLS AND EDUCATIONAL SECTOR [26]

Education sector	**ICT skills**		
	No ICT users	***Basic***	***Advanced***
Secondary schools		49	42
Vocational trainings	23	33	28
Universities		21	119
Adult education		23	23

During the pilot testing users created 113 different challenges included in various Innovation rooms (Business and economy, Social issues, Teacher training and e-learning, Career building, Self-development, Technical and organizational solution, Developing OpenInn, Miscellaneous), added 165 new ideas to these challenges and 155 comments.

During pilot testing the testers were asked to use different parts of OpenInn portal and at the end of testing to fill out the on-line feedback questionnaire. In context of the project objectives and our interest in users' opinion about the portal, the partnership decided to divide the feedback into following parts:

- Basic information about participants – general information about recipient such as his/her sex, ICT skills of participant and her/his opinion on creativity and previous experience with some tool for enhancing creativity.
- OpenInn portal evaluation – contained questions about OpenInn portal itself (e.g. navigation on the site, graphic design, browsing tools of the portal, …).
- Evaluation of KGH – questions concerned especially about evaluation of KGH and its navigation, functionality like adding new challenges, forums, ideas, comments, etc. and quality of developed scenarios.
- Evaluation of the Guide to Creativity, its concrete parts – the pedagogical background, practical examples, ICT tools.

291 users took part in the final feedback, what represents 82% of all pilot test participants. The achieved results could be briefly generalized as follows:

- About 80% users agreed or strongly agreed, that developed OpenInn portal is easy to use and navigate, has clear layout and format, has easy-readable content and has sufficient response time. Concerning OpenInn portal structure and functionality, the pilot tests participants appreciated sharing ideas with others and possibility to get opinion from other users as also the overall layout, with the different areas visible in the top and menu to the left, placement of different articles.

  Almost 75% of users agreed or strongly agreed, that KGH part is also easy to navigate, easy to add new challenges, ideas, votes or comments, easy to find existing challenges, ideas or comments. The majority of respondents thought the possibility to read ideas from others and sharing the contributions and the simple way to add challenges, ideas, comments and votes and possibility of get response from several different countries to be the best feature of the KGH for the supporting creativity itself.
- The last specialized part of OpenInn portal - Guide to Creativity – and its subparts were evaluated only by teachers, what means 28% of all respondents' feedback. The majority of them agreed or strongly agreed that all developed parts are clear and easy to understand, well and logically structured and suitable to support creativity in teaching and learning (Figures 5-7).

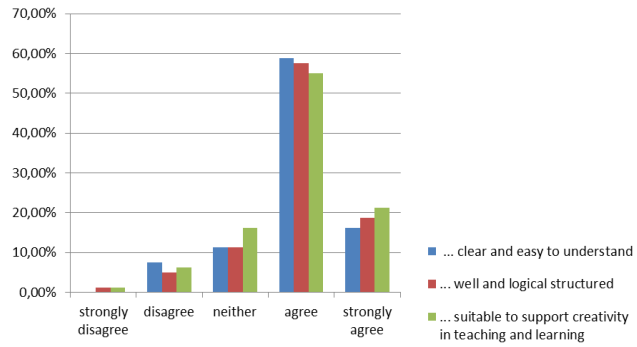

Figure 6. Evaluation of the GtC: ICT TOOLS

IV. CONCLUSION

Organizations and companies at the forefront of development are already experimenting with the „open innovation" concept, inviting experts outside the company to take part in developing new products or services. New connections are established using social networking sites. Innovation, research and development (R&D) is driven by new ideas and new perspectives which are vital characteristics of the fresh mind of youth.

Their activity could be marked as a key factor for the development of innovations in practice. That is why it is important to introduce new, creative approaches in education that would allow people to educate a generation of critical, but also innovative thinking. The developed OpenInn portal and its part Knowledge Generating House could be a tool which helps to build not only creativity of teachers and students, but also the bridge between educational institutions and practices. By saying that, the Knowledge Generating House supports the development of new ideas, whether in an educational or a business context. It offers possibility to create challenges for public or private ideation, in school or business environment, with material or non-material reward.

The OpenInn approach contains a new assessment model and innovative didactics for enhancing creativity with topics including ways to support the learner to introduce new ideas, evaluating and rewarding creative results, methods for giving instructions to reach innovative solutions, providing autonomy for creative expression both for "not-yet" ICT users and advanced level users in their specific sectors. OpenInn enhances creativity and self-realization as well as learning in formal and informal education. It builds on the method of open innovation to empower young talents to be visionaries and contribute to ~~a~~ new R&D knowledge in the future [27]. The viability of the portal could be confirmed by increasing numbers of the registered users (495), challenges (133) and ideas (205), created after the end of the project.

The OpenInn project outputs are used and further utilised within SP4CE project which addresses directly aims and needs identified in Bruges Communiqué on enhanced European cooperation in vocational education and training, especially defined there "improving the quality and efficiency of VET and enhancing its attractiveness and relevance" and "Enhancing creativity, innovation and entrepreneurship". All project results and project actions will be connected with promoting take-up of innovative practices in education, training by supporting personalised learning approaches, collaborative learning and critical thinking, strategic use of Information and

Communication Technologies (ICT), Open Educational Resources (OER), open and flexible learning, virtual mobility and other innovative learning methods. The mentoring & coaching scheme will be introduced. Teams will have support provided by mentors (from teachers/trainers staff) and coaches (from the enterprises staff.

ACKNOWLEDGMENT

This work has been kindly funded by the European Commission through project SP4CE - Strategic Partnership for Creativity and Entrepreneurship *(Grant agreement 2014-1-PL01-KA200-003341).*

* Department of Applied Mathematics and Business Informatics
Faculty of Economics, Technical University of Košice, Slovakia
dana.palova@tuke.sk, martin.vejacka@tuke.sk

Abstract – The European Commission developed the Europe 2020 strategy for sustainable and inclusive growth and it was adopted by the European Council in June 2010. The EC agreed on five main objectives; one of them is to raise the employment rate of citizens 20 to 64 years old to 75 % by 2020. EU member states implemented these objectives into their national policies. In that way, the employment is at the heart of many EU policies. Based on data for 2013, the employment of persons aged 15 to 64 was at 64.1 % in EU-28. By gradual integration of new members into the EU the process of opening common marketplace becomes continuous and brings new businesses. From the perspective of accounting, in case of operating of company at new markets is appropriate that accountants are able to keep track of accountancy of other countries. Our experience shows that complications are common, so extensive consortium of educational institutions acting in the field of the education decided to create a tool facilitating and integrating accounting information. The aim of the paper is to present FASTER platform an on-line platform for accountants' education and job seeking – the result of FASTER project.

I. INTRODUCTION

Reporting and accounting in general has important role in market economy, since it enables tracking and enterprise financial planning. In the field of accounting, the importance of practical experience is indubitable. Exactly the experience allows new graduates to increase their value on the job market. Therefore, allowing of practical experience acquiring must be one of priorities in accounting education across EU states. Furthermore, accounting skills and knowledge are often important for the people with an education in other fields. Information on differences in area of accounting procedures and standards is often not available and unclear. In many cases education is provided mainly at theoretical level with lack of practical accounting skills training. Deficiency of praxis is one of reasons of young people high rates of unemployment [1].

Within EU-28 states accounting standards and procedures still differ, complicating the collaboration of various international companies and projects the accounting practice. Education in the field of accounting often lacks proper, extensive and suitable use of ICT [2]. Educational institutions offering cross-border accounting courses focus mostly only international standards, but rarely cover these differences between particular accounting systems in EU countries. Training and education in accounting is also provided by lifelong learning institutions. EU supports further practical training even after graduation (at secondary or tertiary schools), basically on lifelong time basis. In addition to that, using the flexible working conditions, for example part-time work, distant working or work from home, improvements in the availability of childcare facilities, providing more opportunities for lifelong learning, or facilitating job mobility, the labor market should be stimulated. Therefore lifelong learning, mobility and improvement of the education quality and efficiency are the basic objectives of the European Strategic Framework for Education and Training [1].

FASTER was an international cooperation EU project with aim to provide address these issues in accounting education area by creating online platform allowing education in accounting, standards and procedures comparison and job seeking and mobility in area of accounting across EU states. Consortium of five universities from five EU states proposed and developed online platform to address problem of praxis deficiency and job seeking in the field of accounting. This platform serves for users in all countries of consortium with the prospect of expansion to serve also other EU-28 states.

II. FASTER PROJECT

Project FASTER (Financial and Accounting Seminars Targeting European Regions) is a project on distance education and lifelong learning, funded by the European Union. The project started in January 2012 and ended in December 2013. The project product, FASTER platform, may be considered as an answer on EU Priorities on Knowledge Society and Innovation with objectives such as improving the quality and intensity of investments in human capital for the upgrade of the education system, investing in the future, promoting reforms in the education system and improving access and basic skill levels for all [3].

As was mentioned above, the project aims were based on Europe 2020 strategy objective, especially support long-term career advancement, international mobility of employees in accountancy branch, as well as graduates with degrees in disciplines other than accounting, or people employed in business, with the foundation studies to become a professional accountant. Special attention was placed on mature and motivated student seeking a

career in accounting for which no prior professional experience will be required. This group of people represents the group at risk due to their high unemployment [4]. With respect to these priorities, the project objectives could be summarized into following:

- to produce a modern technological e-learning & knowledge-sharing environment on finance and accounting which allows both students and professionals in pursuit of lifelong learning to gain practical knowledge on their discipline, but not restricted to national borders. The platform proposes besides e-learning environment also a job seeking mechanism.
- to link studies & working environment and widen transnational pursuit of jobs in finance & accounting.
- to offer new incentives and produce a prototype ICT environment expandable to all languages and to all disciplines.

Connected to the project focus – to help people to understand accounting and practice it at the same time in a friendly, step-by-step learning virtual accounting office environment - the final platform represents an interesting tool for wide groups of users [5]:

- educational institutions – academics and students in the field of accountancy,
- people interested in vocational training,
- public institutions and private companies, potentially looking for employees in area of accounting,
- jobseekers
- and consultants operating in the field of accountancy.

On the project cooperated five educational institutions from different EU member states: Athens University of Economics and Business (Greece), Sofia University "St. Kliment Ohridski" (Bulgaria), City University, London (United Kingdom), University of Warsaw (Poland), Technical University of Kosice (Slovakia). The consortium developed a European e-learning tool supporting European collaboration in the field of Finance and Accounting – FASTER platform described below in more details.

FASTER project activities could be shortly described via following timeline table:

TABLE I. BRIEF TIMESCHEDULE OF FASTER PLATFORM DESIGN

Date	Activity	Outcome
January – March 2012	Collection of users' requirements via questionnaires and interviews	Requirement analysis & specifications
June – July 2012	Collection of sources for Part A – literature (e-books, books, journals, legislations, etc.) on accounting, glossary, interesting and important links from particular states and EU as whole	FASTER Platform - Part A
August – October 2012	Development of on-line study material content for 8 different modules Analysis of platform processes and functionality	FASTER platform – Part B Platform first (pre-alpha version) architecture design
February – July 2013	Development of jobseeking part – searching for the employers, job positions, functionality for uploading CVs, employer-employee communication, arrangement of appointment Translation of all parts of platform Pilot using of platform by partnership	FASTER Platform - Part C Multilingual platform / Alpha version Bug report on Alpha version
September - November 2013	FASTER platform pilot testing by target groups members	FASTER platform pilot users' feedbacks Bug report on final version of platform
November – December 2013	Improvement of platform based on pilot test outcomes	Final version of FASTER platform

Besides platform development activities we did also many different exploitation and dissemination activities in order to provide the appropriate ground of exploitation of the product after the project's lifetime. We used mostly:

- transfer of results to target groups - in order to successfully transfer information about FASTER project we have set several communication channels and conducted several dissemination activities:
  - directly via pilot tests,
  - printing and distributing the newsletters (in 2012, 2013), poster (Figure 1) and brochures (Figure 2) via mail,

Figure 1. FASTER project official poster

Figure 2. FASTER project brochure

- different publications in the press - advertisements (electronic media, newspapers, TV interviews); press releases about opportunities, ideas and exploitation of FASTER platform in teaching accounting,
- publishing multimedia advertising multilingual spot,
- organization of two information days and various on-line events,
- distribution of information about project events and activities connected with project via e-mail,
- providing LinkedIn social communication channel with aim to establish contacts to accounting professionals,
- developing official FASTER web-site and its national versions (Figure 3) available at http://www.fasterproject.eu.

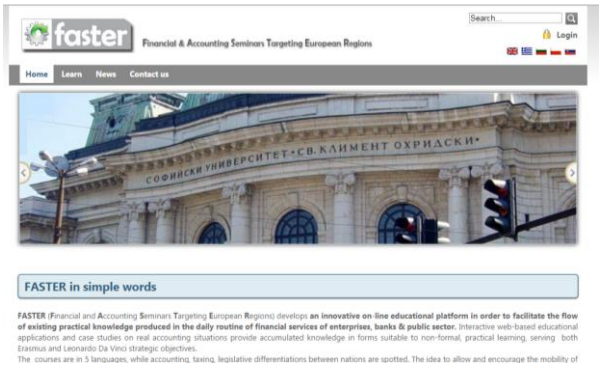

Figure 3. Official FASTER project web-site

- integration of FASTER platform in partners' universities' curricula - during the pilot testing period and afterward the partners integrated the FASTER platform to their curricula, for example: Accounting Information Systems, Financial Accounting, Financial reporting standards, Basic Accounting, Accounting, Accounting, Auditing and Fiscal Consulting, Accounting of Public Administration, Economic Information Systems,
- organization of FASTER track on international conference - 6th Conference EuroMed 2013. Track title was "e-learning web based models for business and accounting: Requirements, procedures, implementation experiences and implications on lifelong learning".
- setting up ICT – Accounting Network and National Support Groups:
  - *ICT - Accounting network group* of people from members the FASTER target groups created with aim to serve the project as the initial international pool of exploitation and dissemination.
  - *National Support Groups (NSG)* formed in each country from scientists and professionals from universities, accounting offices, financial organizations, from both private and public sector. The intention of the NSG is to provide support to the project and to represent the interests of each key player and country. The NSGs had a role to help steer and advise the project team and the implementation of the FASTER platform.

To achieve quality and fulfill requirements of further exploitation in real life, partnership used different evaluation of all sub-processes done during project lifetime:

- *during design phase* - analysis of future user requirements via on-line questionnaires and interviews,
- *during pilot testing phase* – analysis of feedbacks of pilot users.

At the same time the partnership developed different supporting groups of people, helping to partners fulfill project objectives in accurate way for defined target groups:

- *Accounting Network and National Support Groups*, described above. These support groups had to follow the project team activities and outcomes and to give an advice how to improve it.
- *External Evaluation Committee* - an external mechanism of results and outcomes evaluation throughout the project implementation.

III. FASTER PLATFORM

The FASTER platform is the main outcome of the FASTER project. User requirements on FASTER platform were investigated by a survey conducted in Bulgaria, Greece, Poland and Slovakia at the beginning of the project (see Table I). Four potential target groups (graduates and undergraduate students, academics, employers, people interested in vocational training) were addressed in this survey. Respondents evaluated usefulness of planned features of FASTER platform and suggested any additional functionalities of a platform [6].

Following numbers of respondents participated on user requirement analysis:

- 354 graduates and undergraduate students,
- 40 people interested in vocational training,

- 33 academics and
- 24 employers.

All groups of potential users in average indicated that on-line platform would be very useful for teaching accounting in form of web-based educational applications, case studies on real accounting situations and also for job seeking. Detailed responses are in following table:

TABLE II. USEFULNESS OF PLATFORM PARTS RATED BY POTENTIAL USERS

All countries	Students	Academics	Employers	People interested in vocational training
Educational part	3.87	4.39	4.33	4.03
Jobseeking part	4.27	4.27	4.33	4.20

1-5 Likert scale (1: not useful at all – 5: very useful), Source: [7]

Based on data presented in Table II, the FASTER platform has potential to fill out a large gap existing in education and practice in the field of accounting. The respondents of this survey demanded the opportunity of practical training by exercises and applications as the most important and useful feature of future platform. The FASTER project consortium took results of this analysis into account during creation of FASTER platform.

The platform now includes laboratory with bibliographical resources and glossary with 734 terms in all five consortium national languages (English, Greek, Bulgarian, Slovak and Polish). The bibliographical sources contain 182 journals' titles, 371 book's titles, 255 legislation related internet links, 164 e-books, 69 Web sites.

The FASTER platform educational core consists of eight e-learning modules in following accounting sections:

1. Financial Accounting,
2. Accounting Plans,
3. Accounting for Public Limited Companies (S.A.) – Limited Liability Companies (Ltd) – Groups of Companies,
4. Tax Accounting,
5. Balance Sheet Issues,
6. Analysis of Financial Statements - Business Valuation,
7. Accounting ERP,
8. International Accounting Standards.

Content of each of these 8 e-modules consists of succinct summary of relevant theory in given accounting area, practical applications and examples of use, exercises including self-assessment testing, questions (yes/no or multiple choice answers) and additional suggested reading material for given topics.

Third main pillar of FASTER platform is a jobseeker feature that allows advertising jobs positions or posting CVs of people looking for job in the field of accounting. This feature of the platform facilitates connection between education and labor market, where requirements of employers can be met by skills and competences of job candidates. So the jobseeker part of FASTER platform supports job mobility in the field of accounting across EU states [8].

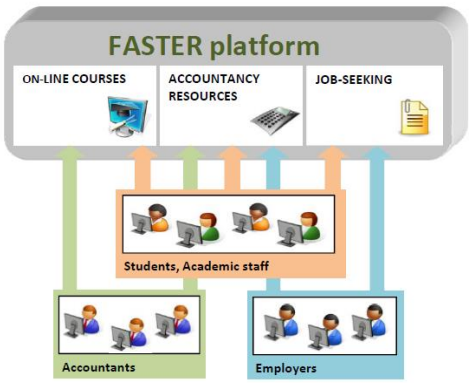

Figure 4. Schematic representation of FASTER platform

After establishing initial version of FASTER platform in 2013, its pilot testing was conducted. The platform's compliance with user requirements and its technical and educational qualities were tested. Testers were from project target groups and relevant institutions such as the academic and student community, SMEs, employers and accounting offices, financial services of governmental agencies and local authorities [9].

The pilot testing was realized in three stages:

1. Initial stage – selection of testing subjects through application forms in each consortium country
2. Pilot testing of the FASTER platform by selected testers.
3. Evaluation by filling out evaluation forms

TABLE III. NUMBER OF PILOT TEST PARTICIPANT IN PROJECT COUNTRIES

State/Target group	***Greece***	***Poland***	***Bulgaria***	***United Kingdom***	***Slovakia***	***Total***
Academics	5	4	5	18	9	41
Students	46	97	24	19	53	239
People interested in vocational training	10	16	5	17	37	85
Employers	11	4	5	13	6	39

Pilot testing participants evaluated functionality of the platform, clarity of its layout and format, easiness to use, content of the platform, accuracy of information and usefulness for teaching, learning and job seeking.

Pilot testers highly evaluated the most of functionalities of the FASTER platform including job seeker feature. They highlighted practical exercises and case studies. Mainly technical problems were denoted as

negatives, for example slow reaction time of servers, exercises solving issues, very long process of creating exercises or problems of displaying in some web browsers. All problems reported in external pilot testing were addressed by the project consortium before releasing final version of platform to the general public. The FASTER platform fulfilled users' requirements according overall evaluation of pilot testing.

The final version of FASTER platform (Figure 5) is public and open accessible via following link: http://platform.fasterproject.eu/Homepage.

Figure 5. Initial page of FASTER platform

IV. INTEGRATION OF FASTER PLATFORM TO EDUCATION

Integration of FASTER to education was and still stays one of most important FASTER platform exploitation tool. During the pilot testing almost every partner integrated FASTER to one or more subject curricula educated at their institution. In more detail the integration took place in the following universities and subjects (Table IV) [9]:

TABLE IV. LIST OF SUBJECTS REALISED BY PARTNERSHIP USED FOR FASTER INTEGRATION

Subject description	Modules
Athens University of Economics and Business	
• Accounting Information Systems	
Presentation of basic principles of Accounting Information Systems. It provides the necessary theoretical and technical background required in order for students to understand the interconnection between business and accounting processes and the use of information systems.	All 8 modules
University of Warsaw	
• Financial Accounting	
The course aims at acquainting students with regulatory framework and accountancy rules, financial accounting system, which is a logical, complete and compact system, describing assets, sources of their financing, business activities.	M1, M2, M3
• Financial reporting standards	
The course aims at familiarizing students with the principles of financial reporting standards. At the end of the course students will be able to prepare balance sheet, profit and loss account, notes to the financial statements, cash flow statement and statement of changes in equity, based on information from the books and records of the company	
• Basic Accounting	
The course aims at acquainting students with regulatory framework and accountancy rules, financial accounting system, which is a logical, complete and compact system, describing assets, sources of their financing, business activities.	M1, M5
Sofia University "St. Kliment Ohridski"	
• Accounting	
The course aims to teach the students about the main accounting principles and rules, the accounting objects – assets, equity, liabilities, revenues, costs and financial result, the preparation of the financial statements.	Partially all 8 modules
Technical University of Kosice	
• Accounting	
The content of the subject covers chapters: The nature and importance of accounting, The structure of the accounting information system, Business asset, Sources of property, Balance Sheet, Economic operation, Active marketing operations, Account, An accounting documentation, Synthetic and analytical evidence, Checking the formal correctness of the accounting records, The financial statements, Financial statements.	Partially all 8 modules
• Auditing and Fiscal Consulting	
The content of the subject covers: Auditing profession, auditor independence and auditor liability and the client; Fundamentals of auditing, other assurance services, activities prior to contract and audit planning; Internal control system. Sampling in auditing; The application of audit procedures in the audit cycles; The basic objectives of the audit cycle, the main business cycles, control objectives and control procedures; Influence the results of the audit to the auditor's report; Completion of the audit and the audit opinion formulation, the auditor's report; Administration of taxes and fees, auditor's code of ethics, code of conduct tax adviser.	M4, M5, M6, M7, M8
• Accounting of Public Administration	
The content of the subject cover accounting procedures and framework chart of accounts to budget organizations, municipalities and higher territorial units and accounting for the accounting group 0, group 1, group 2, group 3, group 4, group 5, group 6 and group 7 and closing the books and preparing of financial statements.	All 8 modules
• Economic Information Systems	
The goal of subject is using information and communication technologies to learn to operate a small virtual company from its inception to annual financial statements. The course provides practical experience in accounting, marketing and building economic information system of a modern company.	M1, M2, M3

* The abbreviations of modules: M1 - Financial Accounting; M2 - Accounting Plan; M3 - Accounting of Public Limited Companies (S.A), Limited Liability Companies (Ltd.), Groups of Companies; M4 - Tax Accounting; M5 - Balance Sheet Issues; M6 - Analysis of Financial Statements - Business Valuation, M7 - Accounting ERP; M8 - International Accounting Standards

As is presented above, in Table IV, partnership integrated 8 modules in different combinations developed under FASTER project into 9 subject curricula concerned on various parts of accounting, auditing and economic information systems.

Integration process should be generally described by following phases [10]:

1. Initially, a lecturer explained to students the aims, usefulness and functionalities of the FASTER platform. During this lesson, instructions for the registration demonstration of the usage of the platform were provided.
2. Students used FASTER platform during laboratorial part of the courses and asked to study particular part of subject using platform courses and sources at their homes, to exercise themselves what they have learned during the lectures solving the tasks and activities provided by platform. In case of problems they have possibility to consult the problems via e-mail or on other face-to-face lessons.
3. All students were asked to evaluate platform and its parts using evaluation forms.

Presented integration validates the fact, that the FASTER platform should be useful in education as a whole but only a part. Students may use only those modules and their content that they currently need within the particular subject. During pilot testing particular partners used the platform within education process of full-time students as well of external students, who usually miss a teacher's explanation communicated during the face-to-face lessons.

V. CONCLUSION

Based on previous information can be concluded, that FASTER consortium developed an innovative on-line educational platform for wide group of people: graduate and undergraduate students of economics, people interested in lifelong learning. FASTER platform presents multilingual tool for facilitating the flow of existing practical knowledge which is not limited by national boundaries. The platform also provides connectivity between study and work experience and expands the interstate job-seeking in the field of accounting.

In the context of employment and social cohesion the gradual increase the practical training in education FASTER supports the development of those skills and abilities which are needed to cope with the ever-changing labor market. In that context users of FASTER platform will be able to appropriate integrate into a professional and business environment.

As final conclusion it could be stated that versatility of educational part of the platform ensures more sustainability of FASTER platform in educating of future accountants, economists but also of people only vocationally interested on the field of accounting.

ACKNOWLEDGMENT

This research has been kindly funded by the European Commission through the LLP Project FASTER: Financial and Accounting Seminars Targeting European Regions (No. 518894-LLP-1-2011-1-GR-KA3-KA3MP). I also wish to acknowledge my gratitude and appreciation to all the FASTER project partners for their contribution during the development of research presented in this paper.

User Knowledge Development in the Field of Electronic Services and Their Security in Slovakia

M. Vejačka*, J. Bucko*
*Department of Applied Mathematics and Business Informatics
Faculty of Economics, Technical University of Košice, Slovakia
jozef.bucko@tuke.sk, martin.vejacka@tuke.sk

Abstract - Computerization of society and electronic government are current problems of society and its development is the part of all governments' program declarations in the European Union. Despite of the well-built internet infrastructure, Slovakia is still tail ranking, when considering the level of development of electronic services and their use by the general public. The precondition for improving this situation is to increase the level of knowledge about electronic communication, its security and trust in these services. Theoretical knowledge and practical skills in the area of electronic services are developed during undergraduate studies at the Faculty of Economics. The aim of this paper is to present the development of knowledge and skills in this area among Slovak students of third grade at our faculty, during the years from 2009 to 2014. Students' knowledge is evaluated and compared by newly constructed index. Data were collected by a questionnaire survey during each year in the period. Results of evaluation and comparison are briefly presented and assessed.

I. INTRODUCTION

Globalization lays high demands on the EU member states in the effective use of modern information and communication technologies (ICT) in almost every area of human activity. Active use of ICT and the global computer literacy of the EU citizens in general is one of these demands. Digitalization of offline processes in various life aspects is a necessity. Effective use of electronic communication is one of requirements of digitalization.

In the center of activities is a secure electronic communication between population of state and institutions of public administration, so called e-government. The concept of e-government is the subject of many studies and different definitions of this term. The phrase "Electronic government and governance" as a synonym for e-government covering all administrative functions of public administration and civil performed electronically by using information and communication technologies [1].

The primary objective of electronic delivery of public services is to replace or minimize necessity of personal visits of public administration offices, shorten reaction time for processing and issuing the required documents and to streamline public services provided [2]. According to Means and Schneider, e-government is defined as the relationship between the government, the "customers" (businesses, citizens, but also other governments), and its "suppliers" (well, businesses, citizens and other governments) realized using electronic means [3]. In this area Slovakia still lags behind the developed EU countries.

The last decades have brought a rapid increase in the form of information sharing systems based on cloud technologies. The basis of these technologies is electronic services directly enabling their use. The degree of safety and trust in these services determine the rate of active usage of cloud solutions. Trust and security aspects in the development of these cloud platforms were and are at the aim of the research activities of the European FP6 and FP7 projects (e.g. FLUID-WIN, SECURE, SERENITY, SWAMI, HYDRA, SEAMLESS etc.).

One of the reasons for the electronic services usage in Slovakia is lower literacy populations regarding security of the services and the related lack of confidence to use these services. Building trust in any new technology is a very complex process. Our goal is to raise awareness in the area and increase the number of given technology users. The best way to achieve this goal is the active inclusion of these issues in the teaching process at universities. An important part of the course is theoretical knowledge of the issue as well as practical experience with technology enabling increasing the security of electronic communication, such as the active use of electronic signatures. In line with this fact, we have integrated into the education process the course Electronic Services in Banking. The course is included in the schedule of teaching third year of study in Finance, Banking and Investment field of study.

II. EDUCATION IN THE FIELD OF ELECTRONIC SERVICES

The Faculty of Economics at Technical university of Kosice provides education in specializations of Finance, Banking and Investment and Public Administration and Regional Development. Electronic services in banking and e-government are in the scope of studies at this faculty in the course of Electronic Services in Banking (ESIB). It

provides combination of skills acquisition in e-learning environment with theoretical seminar on topics related with electronic services in banking and also in public administration.

Additional topics are discussed in essays which are integral parts of this course. Essays are aimed at students' real-life experience with chosen topic related to electronic services and informatization. Students get to know various forms of electronic banking in both theoretically and practically. Great importance is attributed to security of given electronic banking form and building trust in its use. Our previous research showed that security of electronic banking perceived by its users has significant influence on its acceptance by its users [4]. Significant part of course represents the electronic signature topic. Course participants acquaint with principles of electronic signature (in form of digital signature) and with its practical use in secure electronic communication [5].

For teaching support of this course, Learning Management System (LMS) Moodle is used, which is used for e-learning in general at our faculty. Second important tool in this course is Electronic Online Bank. It is virtual bank administered to our faculty by company UNICOM for free for educational purposes. Its software is antiquated, but it might be used for technological demonstration and testing of multiple forms of electronic banking and their authorization [6]. Virtual bank supports digital signature authorization and the most of e-banking forms up to modern, but excluding mobile banking for smartphones. Third tool supporting education process within ESIB course is the faculty's certification authority based on EJCBA open source authority. It provides the possibility of digital signature certificates issuance and their management.

Thus, the main themes of ESIB course are as follows:

A. Electronic signature and secure communication

B. Internet Banking,

C. Home Banking,

D. Mobile Banking and Smart Banking.

A. Electronic signature and secure communication

Practical skills as long as theory in the field of electronic signature are main aim of this part of our course. Main topics of electronic signature introduced are symmetric and asymmetric encryption (RSA), digital and electronic signature, legislation, software applications and Public Key Infrastructure (PKI). Signing, encryption and following decryption and signature verification is practically demonstrated and tested by students. File and email encryption is supported by Mozilla Thunderbird and freeware GPG4win. Possibilities of electronic signature usage are theoretically outlined and discussed.

Faculty's certification authority is used for Public Key Infrastructure (PKI) theoretical as well as practical introduction. Students apply for certificate and acquire it from our certification authority and they further use it in for all eligible purposes practically. Manuals for certificates usage are available at certification authority webpage.

B. Internet banking

Second part of our course is dedicated to the Internet banking as the most used technology in area of electronic banking. Emphasis in this topic is on security and safety of internet banking using. Therefore multiple ways of authentication and authorization are discussed. In praxis basic login and password are often complemented with additional security element. Grid card, One-Time password and digital signature are supported in our virtual bank. Students try various forms of payments, collections, electronic statements in internet banking of our virtual bank.

C. Homebanking

Homebanking in our course is understood as electronic banking form, primarily intended for institutional clients and enterprises where communication between client and bank is supported dedicated homebanking software from the bank, while the actual data is transferred via network. Homebanking is often integrated with accounting software or firm's ERP system. Students test about active and passive account homebanking operations, importing and exporting banking operations [5].

D. Mobile banking and Smart banking

Mobile banking represents group of electronic banking forms. In this part of Electronic Services in Banking course students get to know multiple forms of mobile banking from WAP banking and GSM banking up to Smart banking. In recent years, smart banking (e-banking in smartphones) recorded very strong growth in usage thanks to rapid spread of smartphones. Students may practically test WAP banking and GSM banking in our electronic online bank. Smart banking is practically tested on demo application.

III. METHODOLOGY OF VECTORS COMPOSITION

Improving and increasing the efficiency of public administration and the transition to computerization is closely related to the promotion and development of personal skills of citizens, businesses and public officials at all levels. Universities should ensure the development of skills across the informatics society to the issues of electronic signature and secure electronic communications, as well as handle the safe use of electronic services. Not only by teaching appropriate courses and training of future professionals and savvy users in this area, as well as the implementation of scientific and development projects focused on his issue.

The weakest link of each system in terms of security is still human factor and unsafe behavior when working with ICT. Knowledge of the issues of secure communication and level of trust in these technologies has been the subject of research by an electronic questionnaire. Research, the knowledge and use of electronic services is realized since the year 2009. The questionnaire is distributed electronically to students of ESIB course using Google documents. It consists of 3 areas covered 18 questions and the demographic section containing 4 questions. Over 97% respondents were from Slovakia in age range from 20 to 22 years, because our survey was

distributed only to students of our course. In each year approximate number of respondents was 120 students. The first part of the questionnaire examines the issue of knowledge on electronic services in general. The second part of the questionnaire is dedicated to electronic signature and the third part is devoted to the issue of electronic communications with public administration (e-government).

For expression of the degree of the issue knowledge we have defined the vector of knowledge of electronic security services and electronic communications.

We have labeled this vector with symbol $\vec{V}_k$. This vector pf knowledge consists of three individual vectors (components):

$\vec{I}_{es}$ - individual vector of electronic services knowledge

$\vec{I}_{sig}$ - individual vector of electronic signature knowledge

$\vec{I}_{eg}$ - individual vector of e-government knowledge

Individual vectors are an expression of partial sections of the questionnaire. In terms of questionnaire results processing methodology, individual vectors have maximum of 1. Consequently, knowledge vector electronic services and electronic communications we express in a natural way, as a linear combination of the individual vectors:

$$\vec{V}_k = a \times \vec{I}_{es} + b \times \vec{I}_{sig} + c \times \vec{I}_{eg} , \qquad (1)$$

where *a, b, c* are calculated values of the knowledge of the examined area by the processing of the questionnaire.

$a,b,c \in \langle 0,1 \rangle$, (or 0 - 100%)

The length of the resulting vector $|\vec{V}_k|$ can be expressed by expression:

$$\left|\vec{V}_k\right| = \sqrt{a^2 + b^2 + c^2} , \qquad (2)$$

it will express the level of knowledge of electronic security services and electronic communications, $\left|\vec{V}_k\right| \in \langle 0, \sqrt{3} \rangle$, (or 0,100%)

Then we defined the index knowledge of electronic security services and electronic communications and identified by the symbol I_k. Index may have values from ⟨0, 1⟩ and it can be expressed as the following ratio:

$$I_k = \frac{|\vec{V}_k|}{\sqrt{3}} , \qquad (3)$$

IV. RESEARCH SURVEY AND RESULTS

The vector of knowledge $|\vec{V}_k|$ was from answers on 18 questions of the questionnaire, from which 16 were multi-choice and self-assessment questions and two questions were direct responses formation. The respondents were students of ESIB course. For processing the questionnaire we used scoring method of estimating weights of criteria, which is a known method of multicriterial evaluation for questionnaire processing [7]. Based on the quantitative methods we judged different types of response to these issues questionnaire (b_i) and then we calculated the corresponding weights (v_i) the individual responses according the following formula:

$$v_i = \frac{b_i}{\sum_{i=1}^{k} b_i} , \qquad (4)$$

Based on the method of scoring, we rated initial ratings answers of individual issues and expressed the corresponding weights of the responses as follows:

TABLE I. QUESTIONAIRE ANSWERS AND THEIR WEIGHTS

Question/ Answer	b_i	v_i
1. Have you ever used any of the electronic services?		
Email	1	0.07
Electronic banking services	2	0.13
Purchase in e-shop	3	0.20
Electronic payment	4	0.27
Card payment on the internet	5	0.33
2. Which service of these is the safest according to you?		
Email	1	0.08
Electronic banking services	4	0.31
Purchase in e-shop	3	0.23
Electronic payment	3	0.23
Card payment on the internet	2	0.15
All of above are safe	1	0.08
3. Which of following services do you trust at least?		
Email	5	0.23
Electronic banking services	2	0.09
Purchase in e-shop	3	0.14
Electronic payment	3	0.14
Card payment on the internet	4	0.18
I don't trust all of above	5	0.23
4. What would increase your trust in given services?		
Reading short publication on this topic	2	0.11
Viewing website on this issue	2	0.11
Watching popularisation TV show about it	3	0.16
Visiting expert lecture on this topic	3	0.16

Listening to my friends' experience	4	0.21
Trying out on demoversion myself	5	0.26
5. Have you ever used electronic (digital) signature?		
No	0	0.00
1 – 2 times	2	0.20
Less than 5 times	3	0.30
I use it more frequently	5	0.50
6. Do you know, what is electronic signature used for?		
Yes	5	0.71
No	0	0.00
I am not sure	2	0.29
7. Do you know, what are prerequisites of electronic signature using in Slovakia?		
Yes	4	0.40
Yes, probably	3	0.30
I am not sure	2	0.20
No, probably	1	0.10
I do not know at all	0	0.10
8. Do you know the difference between certificate and electronic signature?		
Yes	3	0.50
Yes, probably	2	0.33
I am not sure, but I heard about it	1	0.17
No, I never heard about it	0	0.00
9. Where you can acquire personal certificate?		
Local administration office	0	0.00
Registration authority	2	0.20
Certification authority	5	0.50
Court or notary	0	0.00
Bank	3	0.30
10. Which of electronic signatures has nore general validity?		
Commercial	3	0.33
Warranted	5	0.56
Does not matter, both are equal	1	0.11
11.How much does commercial certificate cost in Slovakia?		
Less than 10 EUR	0	0.00
10 – 20 EUR	2	0.25
20 – 30 EUR	3	0.38
30 – 40 EUR	2	0.25
40 – 50 EUR	1	0.13
More than 50 EUR	0	0.00
12. Would you like to use electronic (digital) signature?		
Yes	5	0.71
No	0	0.00
I am not sure	2	0.29
13. What form of communication with public administration do you prefer?		
Personal contact	0	0.00
Written form	1	0.11
By phone	3	0.33
Electronic (email, web form)	5	0.56
14. If you would need electronic signature for electronic communication with public administration, would you use it?		
Yes	5	0.71
No	0	0.00
I do not know	2	0.29

Investigation of skills and knowledge using electronic is underway since 2009 to the present by a questionnaire, which is distributed via Google docs [8]. In this paper we investigated the evolution of the calculated index during period of 2009 - 2014. The results are summarized in the following tables and graphs.

TABLE II. RESEARCH RESULTS FOR PERIOD 2009 - 2014

Year	**a**	**b**	**c**	**V_k**	**I_k**
2009	0.6198	0.5344	0.8750	1.1980	0.6917
2010	0.7262	0.5599	0.8198	1.2300	0.7101
2011	0.6997	0.5145	0.8065	1.1852	0.6843
2012	0.7366	0.5586	0.8125	1.2307	0.7106
2013	0.7471	0.5510	0.8224	1.2402	0.7160
2014	0.7982	0.5869	0.7540	1.2450	0.7188
Total	0.7364	0.5532	0.8034	1.2223	0.7057

Table II shows the values of a, b, c components of vectors individual vectors and calculated magnitude of the vector of knowledge (V_k) and index of knowledge (I_k). The detected values show a small increase in knowledge and use of electronic services (17.8%), as well as small increase in knowledge of the issues of electronic signatures (5.25%). Surprising result however is the decrease in trust and willingness to communicate with the public administration electronically almost during whole period. This decrease is probably an indicator of a lack of awareness in this field among young people, as well as the lagging implementation of the objectives of e-government building.

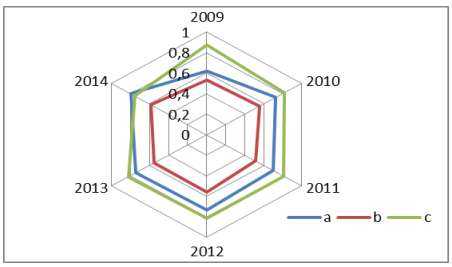

Figure 1. Index of knowledge components during period 2009 - 2014

Figure 1 presents these data graphically. For these values, we expressed the change of index of knowledge in security electronic services and electronic communications I_k (Figure. 2) from 2009 to 2014. The index reached the 2014 level of almost 0.72, what is a slight increase of almost 0.03 since 2009. Surprisingly, the level of knowledge fell in 2011. It suggests lower level of knowledge or less effort of our course students in 2011.

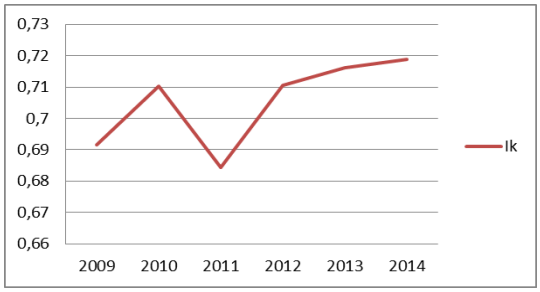

Figure 2. Index of knowledge during period 2009 - 2014

Another reason of decrease of knowledge index in 2011 might be also decrease of trust in e-government in Slovakia, because of the case of dysfunctional electronic tax system introduction named KONS at the time. This system had to be replaced by the old one virtually immediately after its implementation. This case is still not resolved by the Slovak court [9].

Furthermore respondents of our survey might be skeptical about functionality of e-government processes, because these processes are electronic mirror of paper processes without consideration of their optimization for electronic environment.

Since 2011 respondents had to respond to questionnaire twice, before and after completion of our course. The total average values (for all years in total) of knowledge index are presented in the following table and figure.

TABLE III. TOTAL AVERAGE INDEX OF KNOWLEDGE VALUES BEFORE AND AFTER COURSE

Period	a	b	C	V_k	I_k
Before course	0.736	0.533	0.803	1.222	0.706
After course	0.804	0.738	0.800	1.353	0.781

As we expected, after the course completion values of knowledge vector V_k and knowledge index I_k are higher than before course completion. It is obvious that the global awareness of the issue among students was increased by almost 0.08 and reached 0.781. However, the individual vector of e-government knowledge (I_{eg} - parameter c) slightly decreased. It shows the same trend as the decrease of this parameter in the overall development of the knowledge index (see above).

Vector of electronic services knowledge (I_{es} - parameter a) grew by almost 7%, which roughly corresponds to an increase whole index of knowledge. The highest increase was recorded by knowledge vector of electronic signature (I_{sig} - parameter b) by 0.20, which refers to the fact that the issue of electronic signature, the safety of this technology and its use is still not well known.

Results of our research suggest that our course helps to promote knowledge in areas of electronic services in banking and electronic signature in the conditions of Slovak republic. However in the area of e-government we should improve course contents to better support knowledge and skills necessary for e-government usage.

The following chart shows a comparison of the different vectors and the index of knowledge. Left column always represents status before the course completion and right column status after the completing the course.

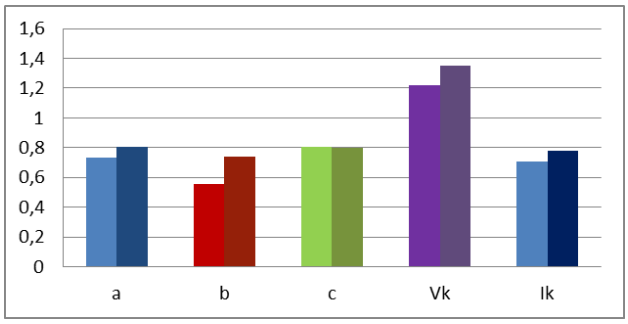

Figure 3. Total average vector components and final index before and after ESIB course completion during perioad of 2009 - 2014

V. CONLUSION

The aim of our paper was to highlight the importance of education in the field of electronic services security and electronic signature in Slovakia, as well as their use for communication with the public administration as one of the important indicators of the successful development of e-government. The necessity of raising awareness and active inclusion in the education process was tested questionnaire research conducted among students of third year of bachelor study at Faculty of Economics, Technical university of Košice in Slovakia during the years from 2009 until 2014.

The results of the questionnaire were processed by the method of points assigning and then calculating the weights of individual answers based on knowledge of the area in each year of research. By defining appropriate vectors of knowledge and the overall knowledge vector (V_k), overall index of knowledge was calculated. The results correspond with our expectations, although paradoxically a decline in student interest in the development of e-government was recorded. It indicates declining trust in the success of development and active use of these services in Slovakia, although the overall interest of the electronic signature and electronic services has increased. We can confirm that in the field of electronic services in Slovakia lacks efficient and effective campaign and education. Electronic services in banking and public administration promotion needs to be strengthened.

We will continue in this research, with the expectation of what results we achieve in the next period, which might be strongly influenced by the fact that in Slovakia started in 2014 to issue electronic identity cards, which allows to each owner an active use of electronic signature technology. Early information on low percentage of issuance of identification cards with digital signature included indicates still low interest of Slovak citizen to use electronic services with assistance of digital signature. This fact suggests that awareness rising in this area is increasingly needed.

A Course in Digital System Design using Unified E2LP Platform

Ivan Kastelan, Nebojsa Pjevalica, Miodrag Temerinac
University of Novi Sad, Faculty of Technical Sciences
Novi Sad, Serbia
ivan.kastelan@rt-rk.uns.ac.rs

Abstract - Computer engineering education has a strong dependence on laboratory work. Teaching students in the lab does not always consist of teaching the required course material, but also of a vast number of tutorials on different platforms. In many cases, these tutorials take significant amount of time which could be better spent doing actual course material. For that reason, E2LP project has developed a platform to be used in multiple courses, covering majority of the computer engineering curriculum. This paper presents a first step in the curriculum - a course in digital system design with laboratory exercises which are implemented on E2LP platform. The platform not only gives students hands-on experience with design and verification of digital systems, but it also provides a bridge between hardware and software because using the same platform in future courses allows students to re-use their results from previous courses and continue building their knowledge. First impression of students is positive about the experience with the platform and their feeling of usefulness of the course for their career.

I. INTRODUCTION

Embedded systems are invisible electronics and corresponding software that bring intelligence to objects, processes and devices. The main challenge in engineering education for embedded systems is a complex interdisciplinary approach which includes understanding of various systems based on different technologies and system solution optimizations.

The significance of laboratory work in electrical engineering education has been widely recognized. It provides engineering education personnel to transform passive listener's students into active learners, thus stimulating students to actively participate in the learning process [1]. Moreover, knowledge obtained through laboratory hands-on experience has proven to be more profound and more lasting.

Increased role of computer based embedded systems in various industrial applications has produced a growing need for embedded system engineers. As of today, the job market is very competitive for highly qualified electronics systems engineers [2]. Furthermore, the European Centre for the Development of Vocational Training (Cedefop) in its publication "Skills supply and demand in Europe, Medium-term forecast up to 2020" [3] predicts that increase of 10.7% in new engineering positions across all disciplines in Europe will be reached up to 2020, compared to the 2010 level. Similar projections are available for USA by the Bureau of Labor Statistics, U.S. Department of Labor in "Occupational Outlook Handbook, 2010-11 Edition" [4] and Asia given in "Employment Outlook Asia: Focus on China and India" written by Mary Anne Thompson [5]. Consequently, many technical faculties have put more emphasis on embedded systems learning by introducing a number of active learning laboratory-based courses [6].

A typical approach in the field of computer engineering education is to have a group of courses for a specific computer engineering topic. Usually, these courses comprise a set of laboratory assignments which are performed using different hardware platforms for each particular course, thus introducing high cost requirements for learning equipment. Further, the dynamics necessary to address industry needs have put teaching personnel under significant pressure to adequately design the laboratory environment for the courses, since updates of the learning environment in an embedded systems course are necessary on a regular basis to keep it relevant. Having this in mind, it is not hard to imagine technical faculties ending up with a set of different and often inconsistent laboratory setups and teaching platforms used throughout the curriculum. As a result, efficiency of laboratory work in embedded systems learning usually suffers from introduced overhead (30%) in both the time and the effort necessary to get students familiar with hardware platforms and software tools for each course. An on-going E2LP project [7]-[11] started with the goal of reducing this overhead in engineering education and providing a unified learning platform which will cover the most of the computer engineering curriculum, allowing students to concentrate on important topics in each course, rather than unnecessary tutorials on using different platforms.

The main body of the E2LP platform is the base board with FPGA connected to a wide range of interfaces – audio, video, communication, memory and user I/O. Additionally the base board can be connected to one extension board via the standardized Mezzanine interface. This paper will focus on presenting the base board of the E2LP platform and how it was applied in teaching the introductory course in digital system design at the Faculty of Technical Sciences, University of Novi Sad, during the fall 2014 semester. This course is the first in which the platform was introduced to the students and it is expected

The research leading to these results has received funding from the European Union's Seventh Framework Programme (FP7/2007-2013) under grant agreement nº 317882.

to be the first in a sequence of courses using the E2LP platform in the computer engineering curriculum. Continuation of the platform usage in future courses will also allow students to feel the connection of materials learned during their studies, in a way that they will be able to reuse or extend results from the previous projects in future courses.

The rest of the paper is organized as follows: section 2 provides an overview of the E2LP platform. Section 3 discusses the theoretical instructions in the course. Section 4 gives an overview of laboratory exercises which use the E2LP platform. Section 5 summarizes the results from evaluation of the course. Finally, section 6 gives some concluding remarks.

II. E2LP Platform Overview

In order to overcome the large amount of lost time in tutorials of different platforms given to students, E2LP project was established to implement a unified platform which will be used in the complete curriculum in computer engineering studies. The Digital System Design course, which is the topic of this paper, presents the first course in the curriculum which uses the platform.

E2LP Platform consists of:

- Base Board, with Xilinx Spartan-6 FPGA,
- Extension boards based on microprocessors.

Digital System Design course uses only the Base Board, as it needs only FPGA for implementation of digital systems students design on labs.

The key building modules of the E2LP Base Board (Fig. 1, 2) are:

- Xilinx Spartan-6 FPGA,
- ARM-based control processor,
- Mezzanine connector to extension board (Xilinx FMC LPC standard),
- DDR2, flash and multimedia card memory,
- user interface (8 switches, 6 buttons, 8 LEDs, alphanumeric LCD screen),
- snapwire connector (8 pins),
- CVBS video encoder and decoder,
- video output (VGA, HDMI),
- audio sub-system,
- communication interfaces (USB, Ethernet, RS232 and Infra-red).

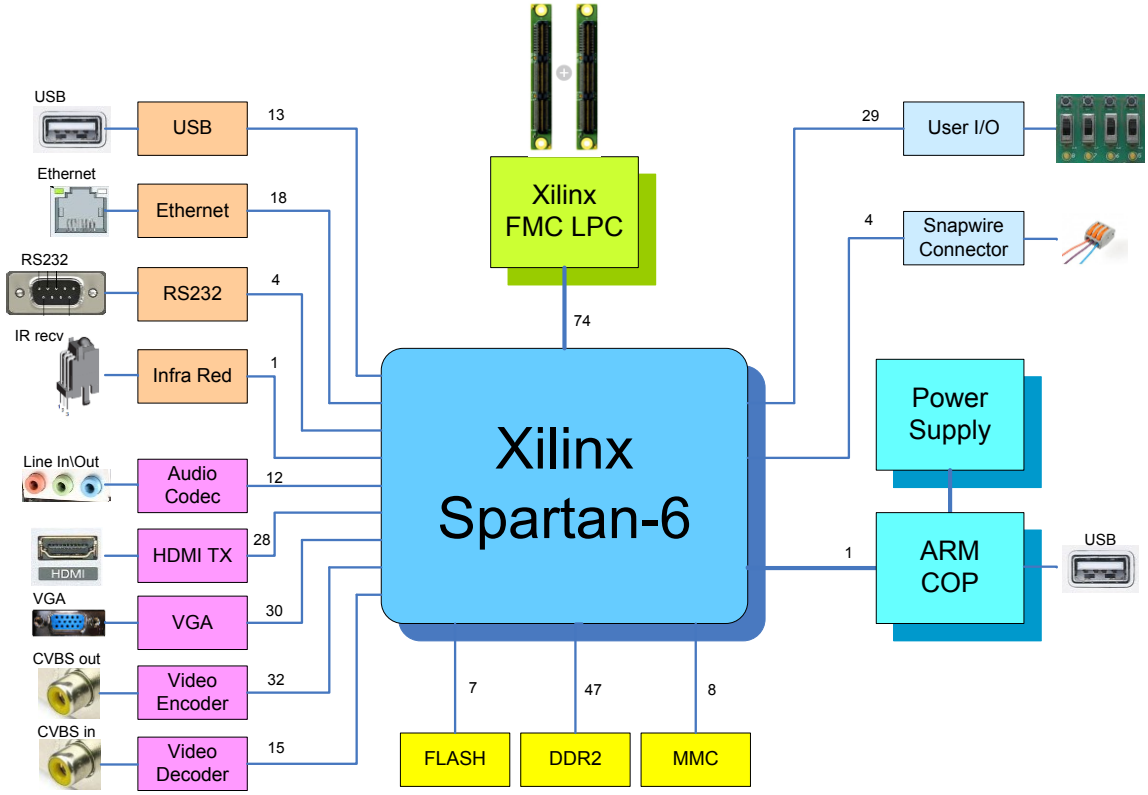

Figure 1. E2LP Base Board schematic overview

Figure 2. E2LP Base Board top view (up) and side view with some of the multimedia and communication interfaces connected to FPGA (down)

III. THEORETICAL LECTURES

Theoretical part of the course consists of introducing students to the field of digital system design, first by short introduction to digital electronics, followed by introducing the concepts of combinational circuits, sequential circuits and finite state machines. The course, since it is being offered in a computer engineering curriculum, has a goal of teaching students principles of processor design. After going through introductory topics, lectures proceed in the direction of processor design, first teaching fundamental concepts – processor architecture, memory design and data flow. Final step is teaching about the complete RISC processor design example and touching the topics of pipelining and timings inside a processor. Table 1 gives an overview of lectures each week of the course.

Since this course is the only course in digital systems for many students who are taking it, because they continue their undergraduate studies in software-oriented direction, in previous years we tried to give them a feel of as many topics in digital systems as it was possible within one semester. Some of the topics taught were: programmable logic, PAL (Programmable Array Logic), PLA (Programmable Logic Array), architectures of FPGA's, DDR (Double Data Rate) memory designs. All these topics were mentioned in at most one session per topic or several topics. The outcome of this approach, which we noticed after a few years of using it, was that students did not learn much about these topics, but had less time to spend on important topics which were the core of the course.

TABLE I. LECTURES IN DIGITAL SYSTEM DESIGN COURSE

No	**Lectures in Digital System Design course**
	Lecture Topic (per week)
1	Introduction
2	Digital logic circuits – technologies, properties
3	Boolean algebra, minimization
4	Combinational circuits – decoders, coders, multiplexers, demultiplexers, comparators
5	Arithmetic in digital systems – arithmetic circuits, number presentations, adders, ALU
6	Sequential circuits – registers, counters
7	Finite state machines, minimization
8	Information coding in digital systems
9	Memories, processor architectures
10	Control units
11	Timings in processor design
12	Review

As a trial for change, in the academic year 2014/15 we changed lectures from the previous year using the simplistic approach to teaching. We concentrated only on core topics of the course and each of them received more time in the schedule. The results of this approach, as results in section V show, are that more students learned the core topics better and their overall passing percentage in the course increased. Future generations will tell whether this was just a peak generation, but we are confident to continue using this simplistic approach in lectures.

Additionally, students were encouraged to study lecture materials by giving them optional homework tasks which required advanced understanding of material presented in the lectures. Significant group of students worked on these tasks as they were motivated by earning bonus points. The outcome was better understanding as reflected in final scores of students, presented in Section V.

Lectures were appended with auditory exercises which were held in 90 minute sessions every two weeks. There students had an opportunity to practice problems with the help of a teaching assistant. These sessions were also modified to use simplistic approach – concentrating on core material and not spending too much time on advanced and general digital systems topics.

TABLE II. AUDITORY EXERCISES IN THE COURSE

No	**Auditory Exercises in Digital System Design course**
	Exercise Topic (per session)
1	Digital logic circuits
2	Combinational circuits
3	Sequential circuits
4	Finite state machines
5	Computation structures - processors

IV. LABORATORY EXERCISES

Laboratory exercises concentrated on developing students experience in designing digital systems from scratch, simulating them and synthesizing for a real platform. For most of the students, this was the first touch with a real platform and making their system work on it produced large amount of satisfaction which further fostered learning experience.

Laboratory exercises for E2LP platform were developed from an earlier set of exercises [9] which was used on another platform. This academic year we introduced simplistic approach in the lab too, as we increased the number of tutorials and reduced the number of graded exercises. Overall, the laboratory exercise structure is given in table 3.

More detailed explanation of laboratory exercises can be found in our earlier work [9]. The changes we introduced this year, in addition to increasing the amount of tutorials, were:

- Processor design exercise was reduced from three to one, with an optional final project involving what the previous exercises 6 and 7 were,
- Each exercise was divided into two parts – homework part and problem part which was solved during the lab,

Approach to designing tasks for students in the laboratory exercise can be done in two ways:

- Students could extend a previously written design by a professor or a teaching assistant, or
- Students could design their system from scratch.

TABLE III. LABORATORY EXERCISES IN THE COURSE

No	**Laboratory Exercises in Digital System Design course**
	Exercise Topic (per session)
1	Tutorial – Digital logic circuits
2	Tutorial – Combinational circuits
3	Problem 1 – Multiplexers, adders
4	Tutorial – Sequential circuits
5	Problem 2 – Stopwatch
6	Tutorial – Finite state machines
7	Problem 3 – Car lights FSM
8	Tutorial – Complex digital systems
9	Problem 4 – Printing name on LCD
10	Tutorial – Computation structures
11	Problem 5 – Basic processor design

While the first method is good when students are learning something, our opinion is that this method leads to a significant overhead in the amount of required understanding of someone else's work in order to perform a small addition. Therefore, in each of the laboratory exercises, students were asked to design the digital system from scratch. While these systems could not be very complex, due to the limited time students have during the week, they were individual solutions and at the end of each lab, students had a finished system which was working on a real platform in real time.

E2LP platform based on a Xilinx FPGA was chosen as opposed to already available solutions because it is a custom-made solution which can easily be modified in-house to meet the needs of increasingly developing modern ways of education. Additionally, this course will teach students how to work with the platform and make their future courses on the same platform easier and faster to start and really concentrate on important topics in each of the courses. Additionally, results from this course, e.g. a designed processor, can be used as starting points in the labs in future courses. One example is the Computer System Design course where students can continue building their processor with more advanced instructions, introduce pipeline, etc.

V. RESULTS FROM THE FALL 2014 SEMESTER

The students' final grade was determined based on points earned in the following aspects of the course:

- Participation in the lectures
- Laboratory exercises
- Midterm exams
- Final exam
- Optional bonus points

Table 4 summarizes the distribution of points throughout the individual course assignments.

TABLE IV. GRADE DISTRIBUTION

%	**Grading in Digital System Design course**
	Assignment
5	Participation in lectures
20	Laboratory exercises
15	Midterm exam 1
20	Midterm exam 2
40	Final exam
0+	Optional bonus points

In previous years, students had to pass only laboratory exercises during the semester, while all exams could be repeated whole year in exam periods. Compared to earlier years, this year we introduced a final exam and made midterm exams passable only during the semester. This made rules for passing even stricter than previous years, but it also added a motivation for students to study more during the semester, which in turn led to better results as it will be shown later.

Evaluation of the course in the fall semester in academic year 2014/15 was performed in the following ways:

- Comparing students grades with earlier generations,
- At the end of each graded laboratory exercises, students filled in the Lab Feedback Questionnaire (LFQ),
- At the end of the course, students filled two questionnaires: Motivated Strategies for Learning Questionnaire (MSLQ) and the Computer System Usage Questionnaire (CSUQ).

While the analysis of MSLQ and CSUQ results is not yet available at the time of writing this paper, this section will summarize students' responses in LFQ's and their grades, as well as some comments student left in final questionnaires.

Comparing the grades with earlier generations (Table 5), we can notice a significant improvement in the percentage of students who passed the course which shows that our simplistic approach improved students' knowledge and understanding of core material. Point average improved from previous year, but did not improve significantly from 2012/13 which is expected, since the grade distribution should contain all grades in a normal distribution to be fair. This shows that our grade distribution remained fair, but more students successfully finished the course which is the main goal of education after-all. It should be noted that midterm exams and final exam were of the same difficulty as in previous years and that the rules for passing were even stricter than previous years due to the introduction of the final exam. Point averages are based on 100 points total and the whole table is based on results after the first exam period in the end of January.

TABLE V. STUDENTS' SUCCESS IN THE COURSE

	Grades over 3 generations of students		
	2014/15	2013/14	2012/13
Total students	235	229	206
Passed students	158	96	115
% Pass	67.2	41.9	55.8
Points average	63.1	52.7	61.1

Students were asked at the end of each graded exercise to fill the Lab Feedback Questionnaire (LFQ) and mark the effectiveness of the lab experiment on the scale from 1 to 10 in each of the following categories:

1. Clarity of theoretical explanations
2. Clarity of technical instructions, exercises and problems
3. Total time and efforts required
4. Ease of use of the environment – software issues
5. Ease of use of the platform
6. Assistant support – was the lab assistant helpful
7. To what extent you think you learned something valuable
8. Overall satisfaction

Fig. 3 shows their responses for the overall satisfaction. The total of 235 students attended the course and a part of them filled up to 5 LFQ's. It can be seen that the lab exercises in the course were well perceived by students in general.

Below we summarize some of the comments of students on how the course can be further improved in the future (taken from final MSLQ):

- "Better alignment of the lab assistants regarding criteria for student grading."
  (6/53 of students posted comment of that type.)
  It turned out that dispersion of the student grades and as more critical dispersion of the requirements per each grade depends on the assistant personally. Such outcome is a consequence of relatively high number of lab assistants - 10 and also a relatively high number of grades – up to 4 points per lab, plus an optional bonus point. It could be improved at least by decreasing number of grades to 3 in total for the next generation.
- "Number of lab classes should be increased."
  (5/53 of students posted comment of that type.)
  Comment placed generally, but points mostly to one lab exercise, problem 4 (LCD) with request for additional time and preparation needed for accomplishment of this, more complex lab.
- "Compliments for professor and assistants..."
  (3/53 of students posted comment of that type)
- "No complains."
  (2/53 of students posted comment of that type)
- "Tutorial lectures could be better."
  (1/53 of students posted comment of that type)
- "Literature should be better"
  (1/53 of students posted comment of that type)
- Empty comment space
  (30/53 of students left empty comment field in the survey)

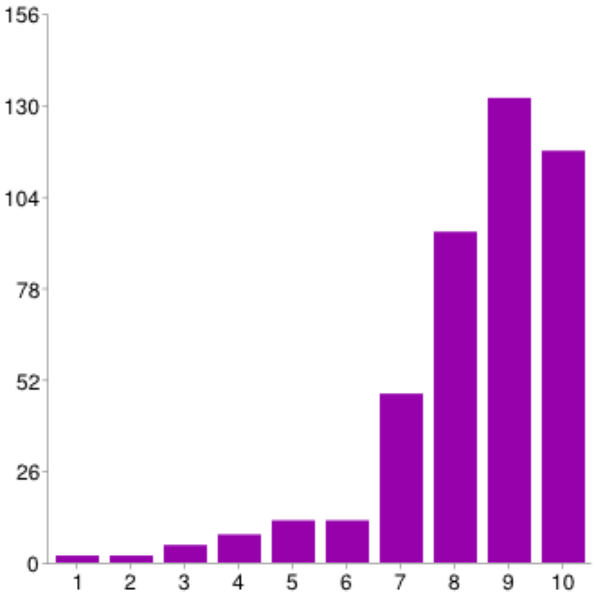

Figure 3. Overall satisfaction with the course labs

VI. CONCLUSIONS

Feedback from students showed that the changes we made in the course were well accepted. Course grades support this as the students showed better knowledge of the core material which motivates us to continue using the simplistic approach to teaching and refrain from teaching unnecessary broad material in the course.

In the future, platform will be used by the same generation of students in the courses in computer system design, signal processing, computer networks, system software and application programming courses when the education benefit of using the same platform in multiple courses will be better known. As for the Digital System Course, it will be improved by responding to most frequent student comments, e.g. by balancing the grading criteria between lab assistants. We will continue to use the simplistic approach as it proved to be a good practice.

Improving education experience with Augmented Reality (AR)

Bojan Kraut and Jelena Jeknić
Alcyone d. o. o., Maribor, Slovenia
bojan.kraut@alcyone.si
jelena.jeknic@alcyone.si

In the modern world, information is everything. It is important that it can be accessed from anywhere and at any time. What is even more important is that information must be relevant to the user and presented in such a manner that it is easily understood.

Emerging technologies, such as augmented reality (AR) might within short period of time be widely accepted, as smart-phones are today. If this happens, it will probably change the way we perceive information and our reality. AR is not hype any more – it is a solid technology that is already used in some creative applications.

One area which might significantly benefit in the future from this technology is the education process. AR tools could guide students through learning process in enhanced way, as AR can upgrade traditional books with a digital layer. We think it will improve both, teaching and learning experience, and bring interactive dimension into the whole picture. We also predict that this new layer will encompass several senses which could speed up memorization process. Furthermore, AR learning method might raise common understanding of the learning material. Moreover, learning activities could be supervised by a mentor or automated process which might also lead to a lower school dropout rate.

Our still-in-progress ARAVET project is exploring mentioned predictions about AR learning method. We will present the results we have so far.

I. INTRODUCTION

Nowadays, information is a key to success. For decision makers it is important they have instant information access from anywhere.

On the other hand, with today's flood of information, decision making process can sometimes be overloaded. Computerized services offer centralized information management, user access control, information categorization and indexation, as well as full text search, but retrieved data are not always relevant to the query, which negatively influence decision making process. Without proper personalized presentation, content filtering and classification, decision makers are often left with excessive data that can impose a cognitive barrier for them.

As mentioned, it is important in which form the data are presented to the decision makers. Sophisticated technology, like augmented reality (AR), offers insight into data on a different level, as it combines real world with the digital one, giving users enhanced information presentation.

AR needs rich user collaborative interfaces, content filtering and real time personalization, and all these functions demand huge computing power. Rising use of cloud computing is addressing some of these issues. Therefore, in this paper, we offer a quick overview of current computing technology improvements and cloud systems that are significantly enhancing information processing. Moreover, we will glance over evolving adaptive systems, which can accommodate individual user experience and optimize learning process. As learning depends on information perception, we will also try to explain how information flow is processed inside the human mind and how do people perceive reality.

At the end, we will show our ARAVET results, which indicate that AR can be very useful in learning process as it can improve perception of received information.

II. POWER OF PROCESSING

Most computers still follow Von Neumann's computer architecture, where instructions are performed sequentially, but really fast. However, recent research in quantum and parallel computing have introduced next generation machines which process information differently and much faster than contemporary computers. Similarly to our brain, new computers are processing instructions concurrently. This kind of processing is not limited to a single processor, as instructions execution often includes multi-core systems or even more than one computer in form of computer clusters.

These days, we already have computer systems built from computers connected with each-other, forming global processing systems with thousands and thousands of cores that can process information extremely fast, which is needed for improved real-time user experience and development of Internet of things (IoT). Today, almost any electronic device can be connected to the web and it can send its sensory data to the cloud services. Moreover, these devices could also offer additional processing power, and therefore, enhance the overall performance of the system.

Moore's law [1] predicts that computer processing power will be doubled every 18 months. Reference [3]

predicts that by 2019 a 4000$ computing device could have computational capability of a human brain (20 quadrillion calculations per second). According to reference [3], by 2029 a 1000$ personal computer might be 1000 times more powerful than human brain. So, artificial intelligence might be recognized as conscious entity. The same reference also predicts that, it will be possible to use implants directly connected to the human nerve system or brain to enhance information processing. Experimental testing already proved that with use of a computer, information from human brain can be read and written directly into the brain [2]. There are also predictions saying that by the end of 2099 human brain could be completely reverse engineered and all aspects of brain functioning might be finally understood [3].

Namely, computing power could soon offer unimaginable possibilities resulting in self-adaptive global systems that could connect millions of people into collaborative environments, where user behavior could be analyzed in real-time. New technologies might offer creation of user tailored education process, where students could follow personalized curriculum adapted to their own learning skills. So, the whole education experience could be completely personalized and provided in an optimal way.

III. LEARNING

A. Nervous system and human brain

Learning is an elementary process. It starts in the womb and continues during our whole life. Senses provide us with information about our environment and nervous system transfers the electric impulses to our brain with speed up to 100 meters per second [4], where information is processed. Information processing is a base for human cognition, creating logical abstracts, reasoning, information classification and categorization.

Average human brain consists of 86 billion neurons and uses typically 100 W of power, which represents merely 20 % of the whole body energy consumption [5]. On the other hand, gorilla's brain has about 28 billion neurons, or around 33 % capacity of human brain [6]. Each neuron is capable of making around 1000 connections, representing roughly 1000 potential synapses, which mostly do the work of data storage. If we multiply each of these 100 billion neurons by approximately 1000 connections each neuron can make, we get 100 trillion data points, or about 100 terabytes of information [5].

Until recently, we believed that animals were incapable of processing information in the way we do it. However, tests on chimpanzees reveal, that they can be significantly better at certain tasks, especially those connected with motor skills and rapid movement processing [6]. Their brains are wired differently then human's, therefore, they are specialized for other purposes. Still, their overall intelligence is on the level of a three-year-old child. An experiment performed on a group of chimpanzees and human toddlers revealed, that humans, unlike other species, are capable of connecting with each other to obtain the information they need in order to solve a problem. This was something chimpanzees were not able to do. Researchers suggested that humans are born to share their thoughts [6].

Social collaboration is crucial for humans, so that they can better understand the world around them. Digital age raised this interaction to an unprecedented level. Today, almost everyone is connected to the Internet and everybody is exchanging all sorts of information. Information exchange has never been so easy and so momentous. On the other hand, modern communication often lacks emotional components.

B. Types of learning

To better understand the learning process, we are presenting various human personality types that significantly influence learning process [7].

In general, we can differentiate 7 types of learning, tightly coupled with types of human personality [7]:

- Visual (spatial) learners use pictures, images and spatial understanding, with as many colors and other visual media as possible. Good learning tools for visual learning are: spatial organization layouts with important words, mind maps, words replaced with images and extensive use of colors.
- Aural (auditory-musical) learners prefer the use of sound, rhythm and music to enhance their learning process. Very often, background recordings are used to help achieve special effects of visualization. Aural learners also use mnemonics (systems for improving and assisting the memory) and with the help of rhyme and melody they can better memorize the content. Music influences and enhances our emotions, and therefore learning.
- Verbal (linguistic) learners prefer the use of words, both in speech and writing. So, techniques involving speaking and writing such as word-based techniques of assertions and scripting help a lot this kind of learners. Reading content aloud with dramatic and varied intonation and/or role playing with others also enhances linguistic type of learning.
- Physical (kinesthetic) learners use body, hands and sense of touch. The use of physical objects helps this type of learning, too.
- Solitary (intrapersonal) type of learning is best when working alone and using self-study techniques of learning. Alignment of personal beliefs and values with goals and objectives is also helpful. Building associations and visualizations of feelings and modeling are very important, as all these techniques use the

influence of thoughts. Being creative with role playing enhances solitary type of learning.

- Social (interpersonal) learning promotes studying and learning in groups. This type of leaning is activated when a person works with others as much as possible. Role playing is very important in social learning, as it promotes interactions with others. During social learning it is recommended to extensively share thoughts with others through assertion, visualization, etc. Working in group to practice behaviors or procedures helps understand problem variations.
- Logical (mathematical) learning is based on understanding the reason behind something. This type of learning is best when extracting key points from material, making associations, especially when the content is illogical or irrational. The use of method which makes the object of learning fit into wider content, introducing skills, as well as thinking systems helps out logical learners a lot.

There might be even more types of learning that scientist haven't identified yet. Our senses and human personality significantly influence our learning process. As everyone has a different perception of the world around them, it is of a huge importance that each individual receives the information according to the nature of their own specific mind.

AR can play significant role here, as it can address different senses and personalize user experience. Therefore, it can boost performance of individuals and additionally stimulate their interests. With help of interactive technology, individual user interaction can be analyzed and then optimized to fit the needs of students.

C. Processing the information

Research done at Massachusetts institute of technology (MIT) [8] discovered that memories are stored in individual brain cells and when scientist stimulated specific brain cells, certain memory was recalled. Removing those cells resulted in loss of specific memory.

As previously mentioned, our brain's information processing is influenced by the type of person's nature. Almost all people have one dominant sense. For most of them it is vision. This means that people process visual information much better that information perceived by other senses [9]. The reason for this lies in our brain specialization.

Interestingly, smell is unusually effective at evoking memory. When smell is used to evoke a certain memory, person can remember 10-50 % more than without smell stimulation [9]. Marketers have recognized this as a very important marketing trigger, so they include it in their marketing activities to boost sales.

People who function in multi-sensory environments always perform better than those in uni-sensory environments. Their memory recall is better, and their memory lasts longer, even after 20 years from the moment of memory creation [9].

Having that in mind, students could use multi-sensory stimulation techniques to develop multi-sensory study skills and improve their memorization and thus the learning process. AR could help achieve that as it offers a multi-sensory interactive knowledge transfer environment.

According to new research, scientists discovered they can rewire our brain with special training. One type of such training can lead to partial synesthesia, where brain gets information in a multi-sensory way [9].

Synesthesia [9] is a neurological phenomenon in which stimulation of one sensory or cognitive pathway leads to automatic, involuntary experiences in a second sensory or cognitive pathway. People who report such experiences are known as synesthetes. So, simply put, synesthesia is a condition in which one type of stimulation evokes the sensation of another, as when the hearing of a sound produces the visualization of a color.

In the most common form of synesthesia, also known as grapheme, color synesthesia or color-graphemic synesthesia, letters or numbers are perceived as inherently colored. In spatial-sequence, or number synesthesia, numbers, months of the year, and/or days of the week elicit precise locations in space (e.g. 1980 may be "farther away" than 1990), or may appear as a three-dimensional map (clockwise or counterclockwise).

Only certain types of synesthesia have been evaluated by scientific research. It is very difficult to grasp this phenomenon and analyze it, as awareness and manifestation of synesthetic perception varies from person to person.

Synesthetes can remember significantly more information in comparison to average people. Special sets of exercises can also help our brain develop synesthetic functions. However, our brain would need constant practice to retain these functions, as synesthesia is not a natural condition for the majority of people. Psychological research has demonstrated that synesthetic experiences can have measurable behavioral consequences. Functional neuroimaging studies have identified differences in patterns of brain activation. Many studies [9] found out that synesthesia improves creative processes. Psychologists and neuroscientists, who studied synesthesia, have been infatuated by not only its inherent appeal, but also, by the insights it may give into cognitive and perceptual brain processes that differ between synesthetes and non-synesthetes.

AR can stimulate several senses at the same time, leading to improved learning skills (with practice – brain can be rewired to optimize performance) and memorization. With improved AR interfaces additional senses (five senses – sight, sound, taste, smell and touch) could improve cognition of information, and therefore learning process.

IV. AUGMENTED REALITY

A. Definition

Augmented reality (AR) is a live, direct or indirect view of a physical, real-world environment whose elements are augmented (or supplemented) by computer-generated sensory input such as sound, video, graphics or GPS data. It is a variation of virtual environment (VE), or virtual reality, as it is more commonly called. VE technologies completely immerse a user inside a synthetic environment [10]. While immersed, the user cannot see the real world around him. In contrast, AR allows the user to see the real world, with virtual objects super-imposed upon or composited with the real world. Therefore, AR supplements reality, rather than completely replacing it. AR is related to a more general concept called mediated reality, in which a view of reality is modified by a computer [10]. As a result, the technology enhances one's current perception of reality. Virtual reality replaces the real world with a simulated one. Augmentation of visual information is presented in semantic context, coherently with environmental elements and in real-time, similarly to synchronized sports scores on TV during a match.

With the help of advanced AR technology (e.g. adding computer vision and object recognition), the information about surrounding real world of a user becomes interactive and digitally manipulated, as artificial information about the environment and its objects can be overlaid on the real world.

Nowadays, AR is often related to mobile applications, but the concept is much wider and implications are almost limitless. Some new cars cockpits are already equipped with futuristic dashboards where information is projected directly onto the windscreen, giving drivers additional view on their surroundings [11]. Furthermore, Special Forces and astronauts use hi-tech helmets, where information is projected onto their visors [11].

In a few years, we might have special contact lenses that will display all kinds of information directly to our eyes [11]. These lenses could be connected to the Internet through our mobile devices. If such technology is to be developed, it would bring unimaginable new possibilities to our everyday life. People would be in constant interaction over several interfaces with everyone and everything. The reality as we know it could blend completely with the digital world.

B. Augmented reality in learning process

In the past, information (thus knowledge), was collected in form of books and, before printing was invented, the books were hand copied by erudite people. In today's world, the information is changing and emerging so fast that information on the print materials (paper books) is often outdated the moment it is printed out. Digital information can be easily edited, and therefore constantly validated. It can also be interactive and users can always retrieve up-to-date content, use bookmarks, 3D models or social networks, where they can collaborate with other users and exchange ideas and questions about educational material.

AR brings many advantages for teachers, as well, as it helps analyze the learning process of students and identify the elements that could be improved.

The final goal is to bring highly personalized learning content to the students which will help them learn faster, easier and better. As AR offers human and content interaction, students could stay more active during their learning process. They could be offered the opportunity to improve the learning content and even become content creators by giving their positive or negative remarks. Additionally, AR presentation layers could offer better understanding and access to social knowledge. Moreover, the multi-sensory presentation might significantly improve the memorization of the content.

Development of sophisticated user interfaces could be very beneficiary for learning process, as digital content can be endless and it can be downloaded on demand in real time from the servers and presented to the students any way they want. With personalization and interactivity, automatic algorithms could monitor the progress of individual students and then tailor curriculums according to their progress, skills and understanding.

As active contributors, students could leave notes and enrich printed content. Notes could be synchronized over cloud services and all active users could retrieve the change instantly. Teachers could improve the content, as well, according to remarks, links, images and data schemes, offering their students better understanding of the learning material.

Contemporary printed materials offer solid learning content which can be read by students at anytime. However, additional digital layer could offer performance of tests and experiments related to the content. In this way, students could better understand the processes described in the learning material, as they could see different visual and audible presentations and simulations of the explained process.

For an example, diesel engine in printed material is usually showed as a scheme of engine's internal structure, however a digital layer on a tablet can present interactive model of the engine, so students could (re)move the engine body parts and observe the simulation of the ignition cycle, etc. With interactive model, students could also change initial parameters, resulting in different model behavior.

The possibilities of such learning material presentations could be of immense help in medicine, engineering, rehabilitation, pharmacy, IT, etc.

In the long term, AR might improve users' sensor experience and provide them with the way to expand their senses to electromagnetic field, infrared and ultraviolet vision, ultrasonic and subsonic hearing, stereo phonic vision, etc.

Additionally, implementation of direct memory manipulation could significantly shorten learning process, so, students could focus on better processing and connecting the information and not just on memorizing it.

The application of this futuristic technology might provide solutions for controlling phantom limbs, robots or other remote objects [12].

V. ARAVET PROJECT

Our ARAVET project (Augmented Reality Application on the Field of Vocational Education and Training) started in 2013 as a Leonardo da Vinci project. Organizations from eight different countries are involved in this project. Each organization contributes with its own specific skills and knowledge from areas of technology, education and design. ARAVET project suggests that introduction of new technologies could drastically improve existing learning techniques and users' experience.

Implementation of AR in our pilot project introduced a digital information layer into existing books. So, books were enriched with digital content, connected to special markers. This enriched view was accessible through user smart-phones or tablets. Students could access 3D models and perform pre-animated actions to additionally visualize educational material.

In scope of our project three different fields were chosen for implementation of AR in order to better demonstrate the advantages of its use.

Firstly, we have chosen textile industry and we have implemented AR technology into the learning model of a sewing machine. Students could perform different actions on the sewing machine (from changing the bobbin to inserting a thread into a needle).

Secondly, we have implemented AR to help students learn about electronics. An operation cycle of the diode was presented with AR technology. Students were able to reverse the electric current and see why it stopped working. The interior of the diode was presented with a flow of electrons, so students could see this concept in a way they would never be able to experience if they were just reading about it from the ordinary textbook.

We have also implanted AR technology in the field of informatics. The AR implementation was used in learning materials about logic concepts and electronic gates (AND, OR, XOR and NOR).

All the results of our pilot testing (data were collected through surveys and then statistically analyzed) revealed that when using AR enhanced materials students understood the content much easier and faster than when using traditional learning techniques.

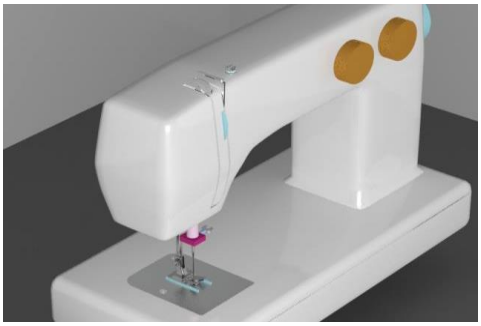

Figure 1: Sewing machine with animated actions

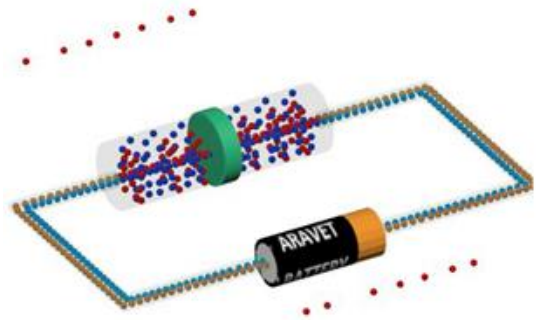

Figure 2: Animated diode behavior and electron flow

71% of the students understood the meaning of Augmented Reality in the way it was explained in the computer lab with examples from the Internet (with the use of mobile devices).

64% of the students found AR enhanced software easy to use and understood the way it functions.

Students were indecisive concerning usage of AR software. They neither agreed nor disagreed that AR software should replace the real device (e.g. sewing machine) during learning process.

62% of the students believed that AR software can help them better understand certain meanings.

59% of the students thought AR software is very interesting for using in the classroom during school lessons.

79% of the students understood very well the way that AR devices work.

55% of the students believed that AR software helped them understand specific meaning faster.

71% of the students were satisfied with the given instructions concerning AR software.

All the results confirm that AR is technology which could really improve understanding of educational material, especially in those fields, where it is important to understand the processes in detail.

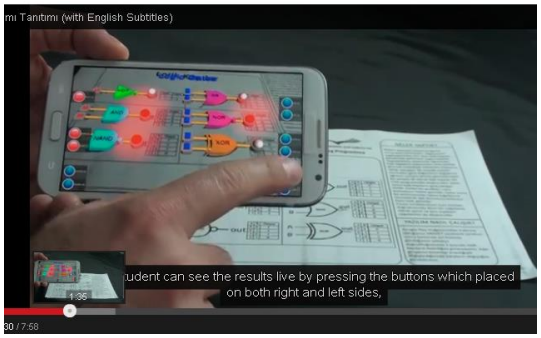

Figure 3: Virtual logical elements for testing the behavior of the printed elements

VI. CONCLUSION

In the future, the boundary between the real world and the digital one might fade away, as modern technologies offer personalized reality. In constant connection with global grid, technology offers instant access to any kind of information, no matter what kind of device user uses.

AR is a perfect example of how users can remove the boundary between the two worlds and equip the real world with digital data. Furthermore, bionic interfaces for human body might additionally improve capabilities of humans beyond anything we know today. Such systems might also provide an in depth insight into user interactions, behavior patterns and learning processes as data could be collected and stored in cloud based services for further analysis.

AR can provide interactive interfaces that enhance a process of learning and content editing in such a way, that current generation of students could learn faster, better and retain knowledge longer than before.

Evolving technology could lead to better understanding of the nature of the human mind and learning processes. This could also help improve machine learning and automated services that support learning processes.

Project ARAVET, with its limited scope, proved that digital data provided through AR interfaces can already supplement static content and improve student understanding of the processes described in the educational material. Moreover, it proved that students have positive attitude towards new technology and its use.

For now, AR is limited due to inadequate hardware. However, even this form can improve user experience. Next generation user interfaces might have the ability to present information in multi-sensory way or even connect directly to our nervous system and offer whole new range of sensors to improve human experience. With evolving next generation user interfaces AR might become commonly accepted as mobile technology is today.

Introduction of the automated assessment of homework assignments in a university-level programming course

Marko Poženel, Luka Fürst, and Viljan Mahnič
University of Ljubljana, Faculty of Computer and Information Science, Večna pot 113, SI-1000 Ljubljana, Slovenia
Email: {marko.pozenel,luka.fuerst,viljan.mahnic}@fri.uni-lj.si

***Abstract*—Modern teaching paradigms promote active student participation, encouraging teachers to adapt the teaching process to involve more practical work. In the introductory programming course at the Faculty of Computer and Information Science, University of Ljubljana, Slovenia, homework assignments contribute approximately one half to the total grade, requiring a significant investment of time and human resources in the assessment process. This problem was alleviated by the automated assessment of homework assignments. In this paper, we introduce an automated assessment system for programming assignments that includes dynamic testing of student programs, plagiarism detection, and a proper presentation of the results. We share our experience and compare the introduced system with the manual assessment approach used before.**

Keywords: automated grading, dynamic testing, programming education

I. Introduction

The ever-growing use of information technology tools in education compels us to reconsider many facets of the education process [1]. Several tasks that once had to be performed manually have been at least partially automated, such as the assessment of the knowledge absorbed by the students. In the area of programming education, the idea of automated assessment of programming assignments, the goal of which is to write a program to perform a given task, has been around for several decades [2]. In 1960, Hollingsworth [3] described probably the first program for grading programming assignments. He immediately recognized the savings in time and a possibility to teach larger group of students. We can conclude that automated assessment (and grading) of computer programs has been present since the very beginning of programming education.

The assessment of student obligations represents an important and often challenging part in the pedagogical process. Focusing on programming assignments, substantial resources are needed to manage their manual assessment, since there are many aspects related to a good program that have to be considered [4], [5]. As a result, the idea of automation or at least partial automation of the assessment process began to appear [6]. The automated assessment process is not suitable for all types of student assignments and cannot be equally effectively used in all areas. Hollingsworth [3] realized that the assignments (problems) have to be properly structured for the automated assessment to be effective. Douce et al. [7] stated that student task specifications should be defined more precisely if they are to be assessed automatically. It follows that automated assessment can be used effectively if the student's assignment is clearly defined and if its result is measurable and unambiguous and can be verified according to a strictly defined procedure [8]. One of the fields that meet all the requirements is programming.

Ala-Mutka [5] summarized the results of an internal survey on assessment practices in computer science courses. Almost three quarters of the respondents assessed the students in their courses on the basis of their practical work. While the assignments were most commonly submitted electronically, they were still predominantly assessed in a manual way. Ala-Mutka concluded that many teachers still see the possibilities of computer aided assessment to be limited to simple tasks such as multiple-choice questions at quizzes.

In theory, automated assessment of programming assignments is not very difficult to achieve. Above all, the assessment system should check the output results of student programs against the predefined correct values. However, by having access to appropriate tools and metrics, the quality and structure of programs can also be checked [9], [4]. Unfortunately, automated assessment of programs combined with hundreds of student submissions can lead to a serious problem — source code plagiarism. However, by incorporating tools for detecting plagiarism, we can also provide a greater validity of the assessment [6].

Depending on the degree of automation, assessment applications are divided into automated and semi-automated ones. Both groups use automated testing of programs. The difference is that a fully automated system tests individual components and evaluates the assignment according to the predefined criteria. It is usually used for smaller assignments. For larger assignments, it is not always possible to assess all aspects of a good programming solution. In that case, a semi-automated system is often used. In such a system, the human evaluator uses the partial results of the automated testing of less complex program parts, focuses on the assessment of demanding tasks, and makes decisions to assign correct grade. The final grade thus still depends on the human evaluator [5], [10].

Several approaches to automated program assessment can be found in literature. Typically, they are all based on two basic principles: testing the program in action, or evaluation

of its code and structure. Program assessment is based on the assumption that certain measurable attributes can be extracted from the program and can then be compared to the model or solution [5]. For an educational use, the results of the comparison also have to be backed up with the pedagogical goals of the course. The assessment of a program includes the assessment of its quality, such as correctness, complexity, reliability, coding standards, etc., and therefore involves practices and techniques that are used in software testing. Software testing can be classified into two groups according to whether the program has to be executed during evaluation or has to be evaluated statically from the program code: dynamic analysis and static analysis.

Dynamic testing techniques can be further divided into two categories: black-box testing and white-box testing. In black-box testing, a program is evaluated on the basis of its functional behavior. White-box testing comprises the analysis of the program code and of the code structure. The aim of the above two techniques is to create test cases that clearly show whether the tested program has errors or not. The test cases should have a good coverage over the program model and specifications in order to avoid misleading feedback information that can further lead to incorrect final grades [4]. When testing the students' programs using dynamic testing, we have to take into account bugs, possible malicious code inserts, and programs that could accidentally cause the collapse of the system [5].

In the introductory programming course at the Faculty of Computer and Information Science, University of Ljubljana (UL-FCIS in the following text), we recently, in 2014/15, adopted automated grading of programming assignments, mostly as a result of the growing awareness of the deficiencies of our previous assessment approach. In this paper, we present the system that we introduced for the purpose of the automatic grading of programming assignments. The system can be broadly classified into the dynamic black-box testing category. However, in one of the assignments, a part of the grade was also obtained using code analysis. In the future, we might increase the proportion of white-box testing techniques in the grading process.

The rest of this paper is structured as follows: In Section II, we briefly present the introductory programming course at UL-FCIS. In Section III, we describe our assessment system before the introduction of automated grading. In Section IV, we present our automated grading system in detail. With Section V, we conclude our paper.

II. The introductory programming course at UL-FCIS

The course 'Basic Programming' at UL-FCIS teaches the fundamentals of procedural and object-oriented programming in Java. The syllabus of the course covers control structures, arrays, classes and objects, inheritance, and fundamentals of computer graphics. The course is taught in the first semester of the first year. It comprises 15 weeks of formal lectures and 13 weeks of lab sessions. In each block of lectures (three consecutive hours per week), the lecturer introduces a programming subject and presents several basic examples to the entire body of approximately 250 students simultaneously. The lab sessions are held in small groups (15–30 students) supervised by one or two teaching assistants, depending on the size of the group [11].

In the Basic Programming course, we strive for constant improvement. In the academic year 2009/10, UL-FCIS adopted the so-called Bologna reform, which calls for a more active, student-centered way of learning with a greater emphasis on regular work. In the spirit of the Bologna reform, we introduced a system for the cooperative development of computer programs [11] to the lab sessions. In our programming course, we are also faced with a very diverse student population with varied prior knowledge. In order to animate the course and motivate students with programming skills, we introduced board game programming competitions [12]. Our last improvement was the introduction of the automated grading of homework assignments.

III. The grading system before introducing automated assessment

Throughout the history of the Basic Programming course, several grading systems have been in use. In this section, we describe the grading system between the academic years 2009/10 (i.e., immediately after the adoption of the Bologna reform) and 2013/14 (before the introduction of automated assessment), inclusive. The Bologna reform prompted us to redesign the grading system, since it recommends that approximately 50% of the student's final grade be obtained through his or her regular work during the semester, e.g., by homework assignments. Before that, the grade was determined almost exclusively by the final written exam. The homework assignments were part of the student's obligations, but they contributed at most a few bonus points to his or her grade.

During the years 2009/10–2013/14, the students were given three programming assignments per semester. For each assignment, the students had one week to finish it at home and submit it. At the next week's lab sessions, they had to implement three independent upgrades to the homework assignment. The teaching assistants then assessed the submitted homework assignments together with the upgrades. Both were assessed during the lab sessions right after the deadline for finishing the upgrades. A greater attention was devoted to the upgrades (3 upgrades $\times$ 2 points = 6 points out of 10) than to the homework assignment (4 points out of 10).

The grading system described above did have some advantages. Above all, plagiarism did not make much sense. A student who did not implement the basic assignment and did not understand the code in detail had little or no chance to implement the upgrades. Besides that, the student's work was assessed in a face-to-face manner right after the submission deadline, thus giving the student an immediate, albeit a severely time-limited feedback. (On average, we had only two minutes per student.)

Unfortunately, our old assessment system also suffered from a number of disadvantages. The greatest problem was that a lot of effort was required to prepare comprehensive and easily upgradeable homework assignments and diverse upgrades. The teaching staff for the programming course strove to prepare a set of mutually distinct homework assignments for each of the three grading weeks in a semester and for each lab session group so that each group of students could have a unique pair of a homework assignment and a set of three upgrades. The students were typically divided into 9 groups, which means that, in principle, as many as 9 distinct assignments and 27 distinct upgrades had to be prepared for *each* of the three grading weeks during the course. In practice, the number of distinct homework assignments was somewhat lower (usually, we prepared 5–6 distinct assignments per grading week), but then the number of distinct upgrade sets per assignment had to be even larger. The uniqueness of the upgrade sets was a means to to fight against academic dishonesty [13], [14], but the effort required to ensure it was tremendous. Besides that, it was often difficult to prepare a balanced set of assignments and upgrades for different groups, and the students might have had a different view of what 'balanced' is than the teaching staff.

Since the assistants could, on average, devote only two minutes to each student, the grading procedure was highly superficial: run the program once or perhaps twice, take a quick look at the program code, exchange a few words with the student, and decide on the grade within the scale of 0–10. Such a grading approach could hardly be considered optimal. Not only that it assesses the student's work on the basis of shallow, first-impression 'metrics', but it also features some typical human-factor problems such as the halo effect and disagreements between different assessors (teaching assistants) about the relative importance of individual aspects of the student's work.

IV. Introduction of automated assessment

A. Objectives

After a few years of experience, the disadvantages of our grading system have made themselves increasingly felt. Besides that, we started to participate in the organization of national programming competitions, where automated assessment of programming assignments had already been in effect. Both factors served as an incentive to introduce an automated assessment system. Thereby, we hoped that we could achieve the following goals:

1) Increase the objectivity of the assessment process.
2) Increase the amount of 'productive' time spent with the students.
3) Impart on the students the importance of creating correct programs according to a given specification, and of verifying them through a comprehensive set of tests, without actually naming concepts such as 'unit test', 'test-driven development', etc.
4) Reduce the excessive burden placed on the teaching assistants, and enable them to invest their time into the improvement of lab sessions, homework assignments (with a fewer number of distinct assignments, we can devote more time to each of them), and the grading process itself.

Whether, and to what extent, we have achieved these objectives will be discussed in Section V. Before that, we shall describe our assessment system in detail.

B. Overview of the assessment system

By the introduction of our new grading system, we abolished the upgrades and the distinct sets of assignments for each grading week. The entire body of students received the same set of assignments. This decision made it possible to increase the number of assignments to 10, approximately one per week. On the one hand, weekly assignments encourage the students to practice on a regular basis, while on the other, the relative importance of each individual assignment is lower than in our old system.

After the teaching assistants prepare an assignment, the students have to submit their solution within 9 days (between Friday and next Sunday) to the Moodle online classroom, which, at UL-FCIS, has been successfully used for several years. To facilitate the automated assessment, the names of the students' programs (Java classes) have to follow a strict naming scheme. For each assignment, a student might earn a maximum of 10 points, giving 100 possible points in total. The points received from the assignments contribute one half to the final grade; the other half is earned on the final exam.

All assignments are assessed automatically. The teaching assistants prepare the test cases, feed the students' submissions and the test cases to the system, and wait for the results. The necessary (but not sufficient) condition for a student's program to receive any points at all is that it successfully compiles. If it does, it is evaluated by a number of test cases. The proportion of successfully passed test cases determines the grade. For example, if the student's program passes 34 test cases out of 50, he or she will receive $(34/50) \times 10 = 6.8$ points. (In 2014/15, the points were actually rounded up to the nearest integer. In the future, however, we shall refrain from rounding and work with fractional points.)

For each assignment, the students were given 10 so-called *public* test cases, which were divided into classes of increasing difficulty. One of the assignments, for instance, required that the students write a program for counting the blobs (4-connected contiguous areas of ones) in a given binary (zero-one) matrix. The public test cases for this assignment were divided into 6 classes:

- In the test cases 1–4, every blob in the input matrix consisted of a single cell, and so a program that simply counts the number of ones in the matrix would pass all four tests.
- In the test cases 5–6, blobs could also take the form of horizontal or vertical lines.
- In the test case 7, blobs could also take the form of full rectangles. Still, no general flood-fill algorithm was required for this case.

- In the test case 8, every line of each blob consisted of a single consecutive sequence of ones. Even in this case, the students could do without performing flood-fill.
- In the test case 9, blobs could take an arbitrary shape. However, they were comparably small so that a recursive flood-fill algorithm would not run out of stack space.
- In the test case 10, blobs could take an arbitrary shape and could fill up the entire 1000-by-1000 matrix, which means that — owing to Java's default stack limitations — only an iterative flood-fill algorithm was guaranteed to work in this case.

The public test cases are called 'public' because every student can view them and test his or her program on them. However, the programs are graded on a separate set of 50 *hidden* test cases, which are made publicly available only after the grading process for the current assignment has finished. The hidden test cases are guaranteed to be divided into the same number of classes as the public ones, and in each class, the number of hidden test cases is proportional to the number of public ones. In the example given above, the hidden test cases 1–20 belonged to the first class, the test cases 21–30 to the second, the test cases 31–35 to the third, etc.

By dividing the test case set into different classes, we encourage the students to develop their programs in a stepwise manner; especially a beginner is expected to start with the first class (matrices with single-cell blobs in the blob-counting example), then move up to the second, etc. Despite the diversity of the public test cases, they are, of course, not guaranteed to cover all possible boundary cases. Some boundary cases might be deliberately covered only by the hidden test cases. The students are therefore warned not to rely on the public test cases exclusively; they are advised to write additional test cases on their own.

Having the test cases divided into classes of increasing difficulty serves another purpose: to make the students think about the efficiency of their programs, without actually operating with the $O(.)$ or $\Theta(.)$ notation. Although computational complexity belongs to a course on algorithms and data structures rather than to a basic programming course, the earlier the students become aware of the fact that efficiency matters, the better.

C. Input-output assessment

For a majority of the assignments, including the blob-counting one presented in Section IV-B, each public and hidden test case is divided into a *test input* and the *expected output* for that input. The program reads its input from the standard input and writes its output to the standard output, and the grading system compares, for each hidden test case, the produced output with the expected one. In the text of the programming assignment, we provide the exact format of both the input and the output, as well as the bounds of individual components of the input. For instance, we might state that the first line of the input contains an integer $a \in [1, 10^9]$, a space, and an integer $b \in [a, 10^9]$. To enable the students to focus on the programming problem rather than on the output format, the expected output is, in most assignments, composed of a single integer. We use real numbers only when absolutely necessary.

D. Assessment through test classes

In some assignments, the students have to write a set of Java classes containing a set of methods with predefined signatures. In such cases, each public and hidden test case consists of a *test class* and the corresponding expected output. The test class creates a set of objects of the classes written by the student, invokes one or more methods of them, and prints the results. The results are then compared to the corresponding expected output. Again, to be able to pass any test case at all, the student's classes have to compile successfully.

In one of the assignments of this type, the students had to write a pair of classes (`Point` and `Line`) to represent points and lines in the two-dimensional space. Each class had to contain a number of methods. Here are three of them:

- `double distance(Point p)` in the class `Point`: Returns the distance between the point `p` and `this` point.
- `Point projection(Point p)` in the class `Line`: Returns the orthogonal projection of the point `p` onto `this` line.
- `double distance(Point p)` in the class `Line`: Returns the distance between the point `p` and `this` line.

This was the only assignment in which the grade was not obtained exclusively by black-box testing. In addition to the number of correct method call results, we also considered the 'elegance' of individual methods, which contributed up to 20% of the grade. We defined (and made it known to the students) that a method is elegant if it calls other methods in a meaningful way. For example, the most elegant way to calculate the distance between a line l and a point P is to determine the orthogonal projection P' of P onto l (by calling the method `projection`) and calculate the distance between P and P' (by calling the first method `distance`). The orthogonal projection of a point P onto a line l can itself be found in an 'elegant' way: as the intersection between l and the orthogonal line passing through P (both operations had to be programmed as methods, too). Since, for this assignment, we could uniquely define a canonical graph of method calls, the elegance was determined simply by comparing the canonical graph with the graph implicitly defined by the student's program. We counted the number of edges present in the program's graph and obtained an objective and meaningful measure of elegance.

E. Assessment of computer graphics assignments

The goal of a computer graphics assignment is to write a program that produces a bitmap based on given data using the Java graphics framework. The bitmap in Fig. 1, for example, is based on an array representing the relative heights of the bars. In such assignments, each test case is composed of a test class and the corresponding bitmap file. The test class calls the student-supplied drawing method, passing to it the desired width and height of the bitmap and the underlying data for producing the bitmap. The bitmap created by that method is

then compared against the reference bitmap on a pixel-by-pixel basis. To allow for rounding-off errors, the grading system considers that the two bitmaps match at a given position (i, j) if for the pixel at (i, j) in the reference bitmap there exists a same-colored pixel within the square $(i - 1,\ j - 1)$, ..., $(i + 1,\ j + 1)$ in the program-created bitmap, and vice versa. The points contributed by individual pairs of matching pixels are inversely weighted by the total number of pixels of that color, since we want to ensure that a short thin blue line counts exactly the same as a large red-filled rectangle. To be able to compare the bitmaps on an element-by-element basis, every logical element (or set of elements) of the bitmap has to be painted with a distinct color. For example, the bitmap in Fig. 1 consists of four sets of elements: orange bar fillings, red bar borders, blue connecting line, and white background. Each set of elements contributes 25% to the grade.

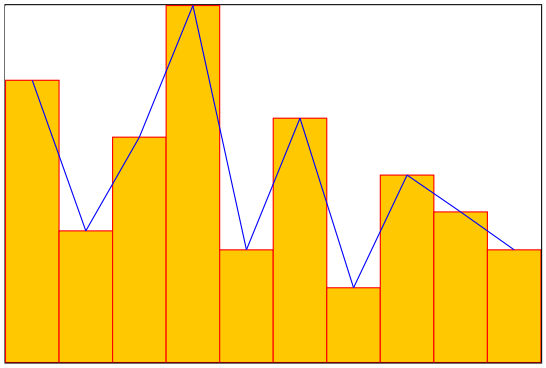

Fig. 1: The expected output for a sample assignment.

In addition to producing an output bitmap, the student might have to write additional methods for computing the dimensions or offsets of certain elements based on the bitmap size. The student might thus receive some points for understanding basic coordinate-system transformations, even if he or she fails to produce a bitmap. In the example of Fig. 1, the student could be requested to write a method to compute the height of a given bar based on the bitmap dimensions and the corresponding data value.

F. Plagiarism

To detect plagiarism, we employ the Stanford University Moss system, which quickly and fairly reliably points out potential occurrences of plagiarism even in the face of substantial code changes. Unfortunately, as many as 75 (out of 279) students were caught at least once, either as plagiarists or as overly 'generous' authors. The actual number of plagiarism occurrences was probably even higher, but in several borderline cases we decided against a punishment. One of the reasons for a high number of offenders was the mild penalty: zero points for each plagiarized assignment, with no additional penalty for repeated offenses.

G. Time and memory controls, security, etc.

For each test case, the program is given 3 seconds to produce an output. After that period, the Linux `timeout` command forcibly terminates the program and considers that test case to be failed. Memory consumption is bounded by the Java virtual machine itself. Security is ensured by running the programs under a designated non-privileged user account on a Linux machine.

H. User interface

The students obtain a command-line tool to grade their programs against a given set of test cases. This simple-to-use tool supports all three modes of testing (input-output, test classes, and bitmap-vs-bitmap). The tool presents the test results in form of an HTML report, which can be viewed in a browser. Both in the output of the command-line tool and in the HTML report, different possible test outcomes (pass, fail, timeout, exception) are represented by different colors. For each test case, the report shows both the input (or the test class) and the expected output; in the case of a mismatch, the program-produced output is shown as well. If a test case triggers an exception, the accompanying message is fully displayed. The student can thus quickly spot the test cases that he or she still has to work on. Figure 2 displays a sample run of the command-line tool and the corresponding HTML report.

V. Discussion and Conclusion

Have we fulfilled the objectives stated in Section IV-A? First, the assessment process is now undoubtedly more objective than it used to be. The computer grader is immune to the halo effect and other human-related imperfections. Second, the amount of 'productive' time spent with students has also increased: before the year 2014/15, three out of 13 lab session weeks were completely devoted to the assessment of assignments (through upgrades). Now, we are able to devote all 13 weeks to solving sample programming assignments, answering student questions, etc. The third objective was constantly being addressed through the rigorous definitions of input and output, through a diverse *and* imperfect set of public test cases (which covered a significant 'area' of the space of possible inputs but deliberately not every boundary case), by encouraging the students to write additional test cases themselves, and by the 'ruthless' automated grading system itself, in which only the number of passed test cases count. As for our fourth objective, however, we have to admit that the assistants might have had even *more* work than before. However, a large amount of time was devoted to the construction of the system itself; to the conversion of our old lab session programming assignments and more than 60 extra assignments (intended for ungraded practice) to a new format, and to the preparation of the corresponding test case sets; to the preparation of course material for three extra lab session weeks; to the renovation of the lab sessions themselves (the assistants shifted further towards the 'guide on the side' principle, while still functioning as a 'sage on the stage' when presenting the solutions to the assignments to the entire classroom); and, last but not least, to plagiarism detection and highly unpleasant email 'negotiations' with the

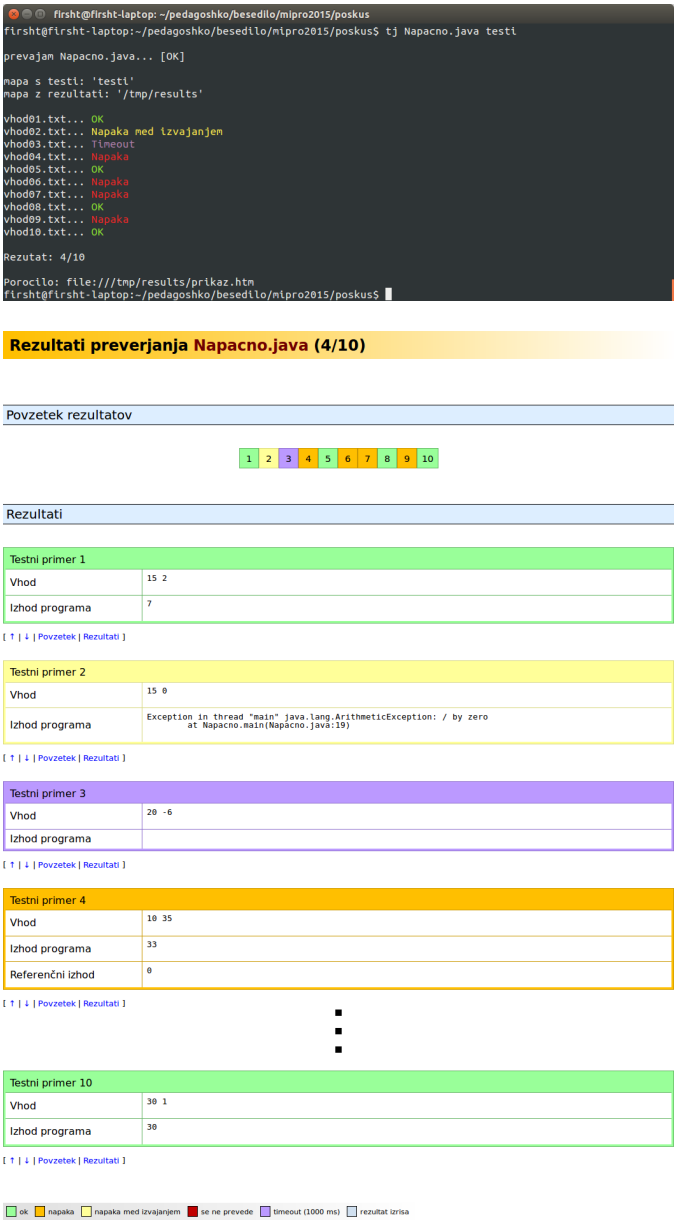

Fig. 2: A sample run of the grading program and (a part of) the corresponding HTML report.

accused offenders, most of which, nevertheless, eventually admitted their misdeed in the face of overwhelming evidence.

Unfortunately, plagiarism is definitely one of the problems brought about by our new assessment system. To cope with it, we intend to increase the penalty and to engage the designated faculty-level committee in case of repeated offenses. Another difference with the previous system is that the feedback provided to the students is limited to pass/fail for individual test cases. However, the test cases, if properly prepared, provide much more information than simple binary output. They can make the student think about different possible boundary cases and about the efficiency of his or her program. Implicitly, they guide the student in a stepwise development of the program.

While the test cases themselves cannot check adherence to coding standards or 'elegance', these concepts could, to a certain degree, be checked as well. In Section IV-D, we showed an example where 'elegance' was translated into a well-defined concept that could be easily checked. In the future, we shall investigate other ways to extend the system beyond simple pass/fail checks.

Despite certain imperfections, we consider the introduction of automated assessment to be a step forward in our pedagogical process. We have not yet conducted a survey about the students' views on automated assessment, but judging from the general anonymous remarks that we received at the end of the semester, the students seem to be satisfied with the new system. For the next year, we plan a more thorough preparation of the students to the grading system. In the lab sessions, we shall consistently use the system from the very beginning, and we shall introduce an ungraded pre-assignment to enable the students to become fully familiar with the system before the actual grading takes place.

Informatics Education and Requirements of Current Practice

L. Révészová
Faculty of Economics Technical University of Košice
Department of Applied Mathematics and Business Informatics, Košice, Slovakia
libusa.reveszova@tuke.sk

Abstract - Bill Gates in 1999 wrote: "Your ability to gain, process and use information decides whether you will belong to winners or losers." Since then, the meaning of his words has been constantly increasing. We often recognize an attitude that the primary issues in the development, implementation and effective application of informatics and ICT in current practice are modern technical devices, computers, hardware and software. These are surely very important part of it, however the key part consists of competent people. Investments into informatization of society and new technology are often very high. The efficiency of these investments depends on users, their motivation, interest and proper education. What are the real information competencies and students knowledge gained during their school informatics education? How can they use these knowledge and competencies? The article summarizes the results of the research of information competencies of secondary school graduates who entered the first grade at the Faculty of Economics, Technical University in Košice. We also deal with the experience in teaching and discuss the base of knowledge and methods which have been implemented into the informatics subjects at our faculty.

I. INTRODUCTION

Economists, politicians, publicists still more often talk about a new economy as a new system of organization of financial, enterprise and business activities based on intense work with information and knowledge. Knowledge plays an important role in all types of economic systems, even in the simple ones. For example: knowledge about grain growing in agrarian society, about mining and quarrying, building in industrial society, etc. (see Table 1.)

TABLE I. CIVILIZATION WAVES, ACCORDING TO [1]

Time ago	Society	Sources	Work/tools
1 million years	Primitive	Animals, seeds, fruits	Man-hunter/bow Women-counter/hands
15 000 years	Agrarian	Soil, home animals	Agricultural workers and stockbreeders/soil
300 years	Industrial	Fossil fuels, metals	Workers/machines
40 years	Information	Information	Managers/ICT

Knowledge has become even more important since the industrial revolution. The degree of including information and knowledge into economic activities is today so high that it introduces significant structural and qualitative changes in economic operations and changes the basic presumptions of getting competitive advantages.

We are currently preparing students for jobs that don't yet exist; using technologies that haven't been invented in order to solve such problems that we don't even know about them.

How technological progress in the 21st century will impact on labour market outcomes remains to be seen. Throughout history, technological progress has vastly shifted the composition of employment (see Table 1) from agriculture and the artisan shop, to manufacturing and clerking, to service and management occupations [2].

In a speech at the Harvard University in 1943 Winston Churchill observed that "*the empires of the future will be empires of the mind.*" He might also have added the battles for talent, as it is suggested in a paper from The Economist ("A survey about talent: The battle for Brainpower", in The Economist, Oct. 5th 2006). The old battles for natural resources are still with us. But they are being supplemented by new ones for talent not just among companies but also among countries. Our world is a world of brainpower. This explains why many international organizations focus on the idea of "putting people and their competence first" [3].

Human capital and the educational process of the population play a central role for the knowledge-based society development.

II. ESSENTIAL REQUIREMENTS FOR SUSTAINABLE COMPETITIVE ADVANTAGE AND LONG-RUN DEVELOPMENT

Long run development and competitive advantage are no longer to be interpreted with respect to the lower labour cost, but much more in a direct correlation with the competences, talent and the stock of intellectual capital and intangible assets.

The concept of intellectual capital is not new; in fact the economist Nassau mentions "intellectual capital" as an important factor of production in his book, published more than 150 years ago in 1836. The term "human capital" was

first introduced by Theodore Schultz (Nobel Prize winner). In 1963, Schultz was writing about the necessity of investments in education in order to increase the agricultural productivity in the USA. In 1975, Gary Becker developed a theory of human capital, which stated that the level of education and the experience of a person add up as determinant factors of their income. Economists highlighted the importance of intellectual capital as a production factor in comparison to traditional economic assets [3].

Nick Bontis defines intellectual capital of nations as "*the hidden values of individuals, enterprises, institutions, communities and regions that are the current and potential sources for wealth creation*" [4].

Intellectual capital implies human, system and market elements. Human capital refers to what people can do individually and collectively. The system component represents the knowledge in the firm which is independent from people and includes patents, contracts, databases, and information and production technology. The market component consists of the relationships between the organization and outsiders, e.g. suppliers, distributors and customers. According to this definition the components of the intellectual capital were divided into 3 parts [3], [5]:

- Human capital – can be defined as the employees characteristics that can be transformed into resources for the organization and which cannot be replaced by machines or cannot be transformed into codified knowledge.
- Organizational capital – encompasses all the intangible elements internal to the company that cannot be expressed directly on the balance sheet. This includes structural appropriateness, informal processes, quality of organizational governance or R&D productivity, tacit knowledge and brands but isn't limited to this list.
- Relational capital – can be considered to be external to the company. It comprises the outside connections that a company has; this includes customers, suppliers, partners or other types of stakeholders or organizations that are in some way relevant to the companies' activity.

The advancement in information and communication technology (ICT) has greatly enhanced the productivity of intellectual capital and intangible capital investment in the past several decades. The proliferation of software and computerized information systems (IS) as new forms of intangible assets is the most obvious change the IT revolution brought about. But more crucial, it increases the effectiveness of many other knowledge investment endeavors. For example, progress in communication technology and new media increased the reach of firms' marketing efforts. The discovering of the Internet made realization of many new business models possible, especially in the service sector. Computer networks make searching and sharing of information within and between all kinds of entities easier and faster. The use of computer software facilitated innovative work that produces knowledge assets [6].

Success of modern institutions and companies depends on engaging in a wide range of knowledge-building activities, such as designing new products and services, processes and business models, training employees, marketing brands, developing computerized assets, communicating within and outside the organization and acquiring information about markets and competitors. These activities mostly do not create any physical assets. However, they create knowledge-based resources indispensable in generating new values and not only financial returns. The nature of these activities is not very different from an investment into physical capital which both generate productive resources for the future.

The new world of work demands higher levels of expert thinking and complex communication. These skills are the keys to unlock a lifetime of learning and creative work. The set of the 21st century skills needed in current practice is focused on critical thinking, problem solving, communication, collaboration, creativity, innovation, imagination and invention. The 21st century global economy requires abilities mentioned above to continually invent new and better services and products for the global marketplace.

Market restructuring, accentuation of knowledge and increasing labour requirements carry demands on the education system. All kinds of graduates should become adequately skilled workforce. The education system should be changed simultaneously with requirements of the labour market, to adapt to these changes and react flexibly "to provide" applicable graduates.

III. INFORMATICS EDUCATION – WHAT IS NEEDED

Computer Science/Informatics is a young discipline. Its scope and focus have changed continuously over the past seven decades. The first computers ran numerical software for defense applications. In the 70´s, the advent of mainframe computers broadened the scope to include commercial applications. In parallel, large-scale circuit integration allowed exponential increases in computing power (Moore's law). In the 80´s, the convergence between IT and telecommunications opened the way for the Internet, the Web and the Information Society. In the 90´s, another very important, but less visible, revolution started with the dissemination of embedded systems technologies. More than 95 % of the chips produced today are for embedded applications. These are electronic components integrating software and hardware jointly and specifically of any kind: mobile phones, cameras, home appliances, cars, aircraft, trains, medical devices etc. In 2008, the average person used about 230 embedded chips every day [7].

Table II shows society´s educational goals throughout the ages in general (according to [8]) and Fig. 1 shows the structure and components of the skills, knowledge, and expertise students need to master to work and live successfully in the 21st century [8]. The rainbow illustrates the desired student outcomes most needed for our times including learning through additional school subjects and contemporary content themes, combined with 21st century skills. The framework adds to the additional subjects interdisciplinary 21st century themes relevant to some of the key issues and problems of our times, such as global awareness, environmental, health, financial, civic literacy. Finally, the core subjects and interdisciplinary 21st century themes are surrounded by the three sets of skills most demanded in the 21st century:

- learning and innovation skills,
- information, media, and technology skills,
- life and career skills[8].

As we think about what to teach our students today, (when there is a rapid development in Informatics) the authors in [8] recommend to consider the following questions:

- What will the world be like "x" years from now when our students have left school? Think about what life was like "x" years ago and all the changes we have seen had happened. Then imagine what will happen in the next "x" years.
- What skills will our students need to be successful in this world you have imagined "x" years from now?
- What were the conditions that made our high-performance learning experiences so powerful?
- What would learning be like if it were designed around our answers to the first three questions?

TABLE II. SOCIETY´S EDUCATIONAL GOALS THROUGHOUT THE AGES, ACCORDING TO [8]

Age	Goals for Education
Primitive	carry traditions and values forward;
Agrarian	pass on farming knowledge and traditions to the next generation; raise children in the ethnic, religious, and cultural traditions of parents and ancestors;
Industrial	learn the past knowledge of a trade, craft, or profession and pass this on to the next generation; maintain one´s own culture and values amid a diversity of traditions in urban life; connect with other cultures and geographies as communication and transportation expand;
Knowledge	quickly learn traditional knowledge in a field and apply its principles across other fields to create new knowledge and innovations; build identity from and compassion for a wide range of cultures and traditions; participate in a wide diversity of traditions and multicultural experiences; blend traditions and global citizenship into new traditions and values to pass on;

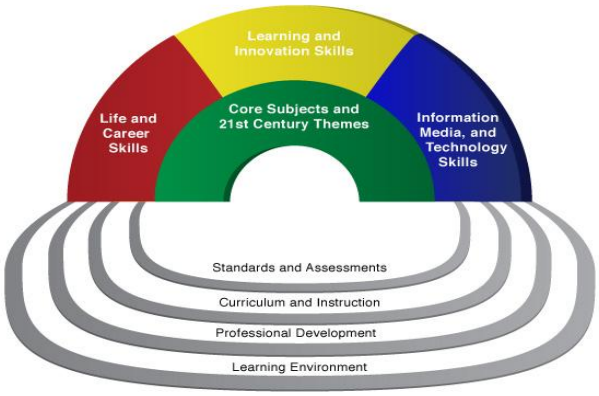

Figure 1. The 21st Century Knowledge-and-Skills Rainbow, [8]

Computer Science/Informatics subjects curricula seldom recognize the importance of system and fail to provide a holistic view of the discipline. There are the following recommendations in [7]:

- Teach students how to think in terms of systems (design processes, tools, interaction with users and physical environment).
- Teach principles rather than facts (foundations, architectures, protocols, compilers, simulation, etc.). Courses are very often descriptive and present details that can be acquired later as needed along professional life.
- Students should be prepared to deal with the constant change induced by technology and applications. They also should be kept aware of the limitations of existing theory of computing.
- Put emphasis on information and computation as universal concepts which are applicable not only to computers and provide the background for triggering critical thinking, understanding and mastering the digital world.

Informatics education in general should prepare young people for a world that doesn't yet exist, involving technologies that have not yet been invented, and that present technical and ethical challenges of which we are not yet aware [9].

Computer Science/Informatics should be a practical subject, where invention and resourcefulness are encouraged. Pupils are expected to apply the academic principles they have learned to the understanding of real-world systems, and to the creation of purposeful artifacts. This combination of principles, practice, and invention makes it an extraordinarily useful and an intensely creative subject, suffused with excitement, both visceral ("it works!") and intellectual ("that is so beautiful"). Students studying computing gain insight into computational systems of all kinds, whether or not they include computers. Computational thinking influences fields such as biology, chemistry, linguistics, psychology, economics and statistics. It allows us to solve problems, design systems and understand the power and limits of human and machine intelligence. It is a skill that empowers, and that all students should be aware of and

have some competence in. Furthermore, students who can think computationally are better able to conceptualize and understand computer-based technology, and so are better equipped to function in a modern society [9].

IV. INFORMATICS EDUCATION – REAL STATE

The evaluation of the knowledge base and ICT skills of students (entering the first year at the Faculty of Economics, Technical University in Košice) we consider as a very important step in determining the content and methods of our effective teaching. That is why in the first seminar in the subject Informatics I students (secondary school graduates) fill in a questionnaire which is focused on their general knowledge of informatics/computer science and their real ICT and problem solving skills. In this paper we present evaluation of students' responses in the period 2003 - 2013 with participation of 1755 students.

Fig. 2 presents an average percentage of respondents, who worked with the mentioned terms, programs or applications. These are needed for solving the next problems and tasks in the questionnaire.

As we can see in Fig. 2 nearly 100 % respondents are familiar with working with text editor, operating systems, using internet services and search machines. In the field of working with spreadsheet program and software for presentation also in the fields of informatics elementary terms, basics of hardware and architecture of computer, internet protocols programming languages the percentage is decreasing, in spite of the fact that these fields are a part of compulsory informatics curriculum. The surprising fact is that gradually fewer students are familiar with algorithms, basics of computer networks (e.g. topology) and databases systems.

We also want to find out how students can use their knowledge and skills to solve next problems:

1. Define/describe user requirements for a simple information system (IS) in a DVD rental where we want to install new and effective electronic IS based on modern ICT instead of "old-styled paper" IS.
2. Characterize, define, describe by your own words what does the next concept mean in general:

   2.1. system,

   2.2. information system,

   2.3. model.

Fig. 3, Fig. 4, Fig. 5 and Fig. 6 show evaluation of students´ answers and solutions. In the following graphs it can be seen the tendency of students´ knowledge development throughout the years.

In the first task we divided students' solutions according to their quality into following five levels:

- A – acceptable; it was possible to recognize functions and requirements of IS, there were structure and hierarchy between requirements, there were some graphical expressions.

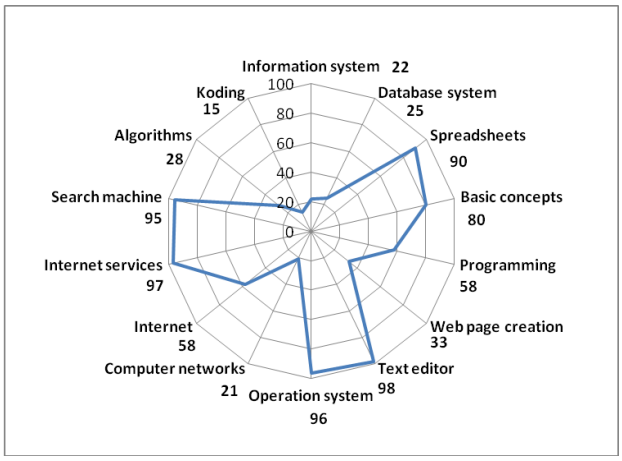

Figure 2. Average percentage – content of informatics education

- B – mostly continuous text with effort to design database tables or web site; partly incomplete.
- C – extensive continuous text with typical lack of exactness, structure, relationships; extent from ½ sheet to 2 sheets.
- D – text in extent from few lines to ½ of sheet; totally unsatisfactory.
- E – no elaboration; most of these students said: "I don´t know what to write.".

In evaluation of the second task we divided students' answers according to their quality into the levels: satisfactory, partial and unsatisfactory. In case 2.1 we monitored the appearance of two basics components – elements and relations in the system. In case 2.2 we considered a satisfactory answer to be one which enumerates at least three functions of IS (collection, saving, processing, analysis, presenting, information provision). In case 2.3 we searched connection of real object with model, purpose, simplification. The answers to these questions were evaluated individually by qualitative analysis of the students´ texts.

We have concluded from the evaluation of the questionnaire, that there is a lack of students´ ability to solve simple problems, in spite of the fact, that they worked with concepts system, IS and model every day in different forms. Despite the informatization of all aspects

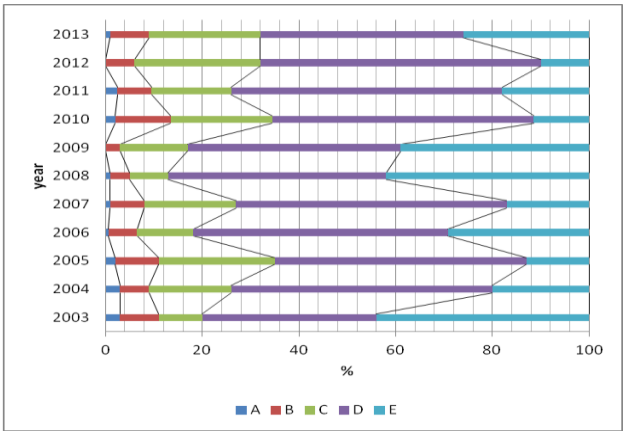

Figure 3. Comparison of evaluation IS user requirements description in percentage

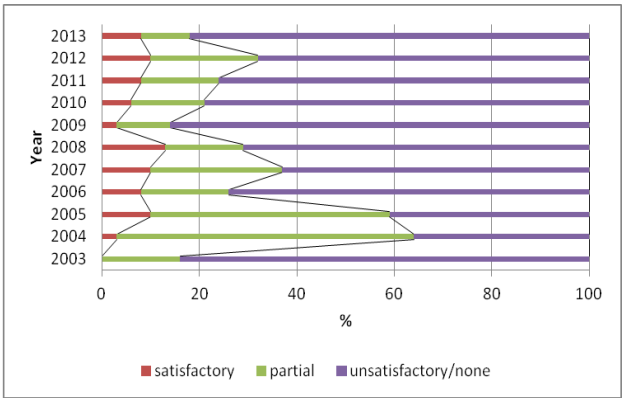

Figure 4. Comparison of evaluation of system definition in percentage

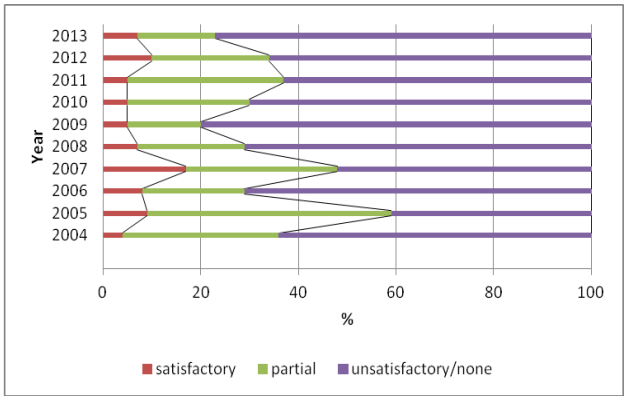

Figure 6. Comparison of evaluation of model definition in percentage

of live and development of ICT the ability of students to solve problems using informatics knowledge and ICT skills is not improving. As we can see in Fig. 2 the education is focused on handling different packages of applications´ programs. The algorithmic approach, use of knowledge for creating "something new" and interdisciplinary relations are often missing. Our findings confirm analyses, researches and facts from current practice.

According to [10] and [11] there is a visible decrease of employers´ satisfaction with the quality of graduates from all kinds of schools entering the labour market. In employers´ opinions graduates are not well prepared especially in those areas which they consider important: problem solving competencies, understanding instructions, ability to decide, will to learn new things, skills to work with information and use of computers.

The importance of problem solving skills is confirmed by PISA a PIAAC assessment. The OECD Programme for International Student Assessment (PISA) and its extension through the Survey of Adult Skills, a product of the Programme for the International Assessment of Adult Competencies (PIAAC) assessed the proficiency of pupils and adults in literacy, numeracy and problem solving in technology-rich environments. These skills are key information-processing competencies that are relevant to adults in many social contexts and work situations, and necessary for fully integrating and participating in the labour market, education and training, and social and civic

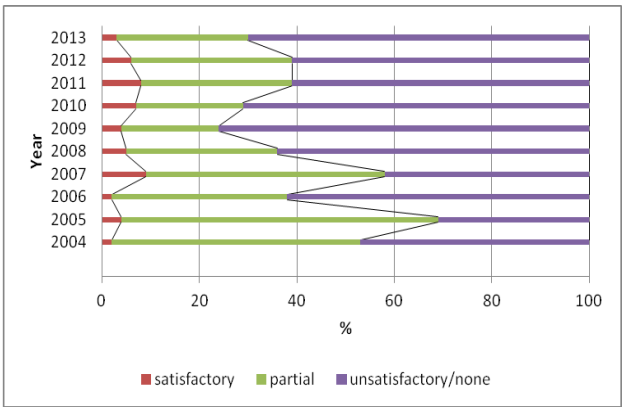

Figure 5. Comparison of evaluation of information system definition in percentage

life [12]. The analysis of results from the problem-solving assessment shows that, on average across OECD countries, only about one in five students is able to solve very straightforward problems. According to [13], [14] our students and adult population achieved a significantly lower score than the average of OECD countries.

V. INNOVATIVE WAY OF TEACHING

Considering the questionnaire results it is necessary at first to integrate level of students´ knowledge in the basics of computer science and using of basic applications in the scale and content similar to ECDL standard (first term).

To develop students' creativity, logical thinking and problem solving skills in the second term we developed an innovative manner of teaching. The students are taking part in projects of building IS in one of various types of virtual firms, companies or institutions. Except the traditional methods of teaching, as lectures and practices, we mostly used e-learning, learning-by-doing and project method. In this innovative way we are trying to transform the problem solving process into an active process of cognition. We agree that problem solution can be considered to be a very valuable skill for an individual and also for the whole society according to [15].

We assume that through designing, developing and conducting the investigative IS user requirements formulation we not only create attractive opportunities for students to employ their knowledge and experience in a complex way, neither we only provide them with productive learning environments for developing their digital, computational and social competencies, but we do more. We also facilitate the development of general problem solving skills of our students. During the investigations they were facing the problems they had never seen nor practiced before in any school subject. We also developed supplementary strategies for building modern constructionist informatics education, employ digital technology to open new directions for learning – project-based, immersion learning compatible with the Caperton and Papert's vision for education [16].

The area of creation and integration of IS is suitable to prove the importance of the above mentioned components of intellectual capital – human capital, organizational capital and relational capital. Informatics can therefore serve as a quality prerequisite for specialized subjects like

e-business, e-banking, Economics information systems [17], [18], [19].

VI. CONLUSION

Recent decades witnessed a significant increase in the share of jobs that require high levels of creative problem-solving skills. Our findings as well as international researches show that the ability of our students in problem solving area in ICT rich environment does not reach satisfactory level. It is necessary to consider, that people and their knowledge and skills, effective using of ICT are the most important components in development of our society. If universities want to prepare graduates according to current practice requirements they have to change their curricula and methods of teaching and learning.

In this new "digital world", information is available almost anywhere at almost any time, computer power is ubiquitous, communication of vast amounts of information is almost instantaneous, and storage capacities seem infinite. But these powerful capabilities only benefit those who have learned to use them effectively. Any citizen of a modern country needs the skills to use IT and its devices intelligently. All of Europe's citizens need to be educated in both digital literacy and informatics. Digital literacy covers fluency with computer tools and the Internet. Informatics covers the science behind information technology. Informatics is a distinct science, characterized by its own concepts, methods, body of knowledge and open issues. It has emerged, in a role similar to that of mathematics, as a cross-discipline field underlying today's scientific, engineering and economic progress. Informatics is a major enabler of technology innovation, the principal resource for Europe's drive to become an information society, and the key to the future of Europe's economy [20].

Informatics encourages and facilitates the process of collecting, cultivating, and organizing information digitally so that it can be better utilized by the community, businesses, organizations, and individuals. Informatics aims at improving the human experience by bridging the digital divide to bring people, information, and technology together so that technology can be put to work for solving complex problems facing humanity today.

Integrating Learning Management System and Faculty Information System – Service Oriented Approach

Petar Bjeljac *, Igor Zečević * and Branko Perišić *
* Faculty of Technical Sciences, Novi Sad, Serbia
pbjeljac@uns.ac.rs, igor.zecevic@uns.ac.rs, perisic@uns.ac.rs

Abstract - The current era of information technologies opens new challenges brings new approaches concerning the use of computer supported Learning Management Systems (LMS). Nowadays, the majority of higher education institutions utilize information systems for handling administrative data, while some of them have successfully introduced one or more LMSes. On the other hand, the majority of LMSes rely on an encapsulated subset of administrative data, causing data redundancy with the administrative database. If the LMS supports learning activities which need to be scored, there is a strong need for reverse flow of relevant data from LMSes back to the administrative system. The need for the development of a moderation layer becomes a must. In this paper a brief analysis of the developed architecture of a moderation layer, the state of the art and the further development direction concerning the Faculty of Technical Sciences in Novi Sad information system architecture extending to the LMS integration are presented. A service oriented approach for two-way data exchange between these systems is proposed as a flexible solution.

I. INTRODUCTION

The proliferation of IT use is causing changes in all aspects of life. Among these changes, a change to the learning process has been made by the expanding use of Learning management systems (LMS) on higher education institutions.

An LMS [1] is "a software application that automates the administration, tracking, and reporting of training events". These systems ease student-teacher communication, as well as the distribution of teaching materials. However, several problems rise due to the amount of administrative tasks teaching staff needs to execute in order to prepare this system to adequately support the teaching process.

Learning management systems contain different types of data:

- Course structure data;
- Teacher and student data;
- Group and enrollment data; and
- Grading data.

On the other hand, in most cases the faculties already have an existing system (or several systems) for handling this type of data. These systems are called Faculty Information Systems (FIS). A Faculty Information System is a single system, or a set of systems, used for executing administrative tasks at higher education institutions (student, staff, course administration etc.).

In this paper, a solution for integrating LMSes with an existing FIS, using a service oriented approach, is presented. The paper focuses on a prototype implementation, providing data exchange from the FIS to LMSes. This is initial work in the process of integrating these separate systems into one complete solution for handling administrative, as well as teaching tasks at faculty level.

The rest of the article is organized as follows. The second chapter describes the current Information System (IS) state at the Faculty of Technical Sciences (FTS) in Novi Sad, which is used as proof of concept in this research. Furthermore, the custom requirements for the integration process are analyzed. The third chapter presents existing solutions and compares them to these requirements. It also gives a description of an existing standard for integrating LMSes. In the fourth chapter, a solution, based on RESTful web services is described. Finally, in chapter five, conclusions are made and the directions for future work are outlined.

II. CURRENT STATE AT THE FTS

The Faculty of Technical Sciences in Novi Sad is the largest faculty at the University of Novi Sad, with approximately 13000 active students and 1000 members of teaching staff. It consists of 13 departments, with 87 study programs. The teaching process administration for such large institutions presents a complex task, which has been supported for years using several information systems, building a custom FIS for the FTS (Fig. 1). This IS consists of the following elements:

- The Accreditation IS – used for structuring courses and preparing study programmes for the accreditation process;
- The Human resources IS (HRIS) – used for the administration of teaching and non-teaching staff; and

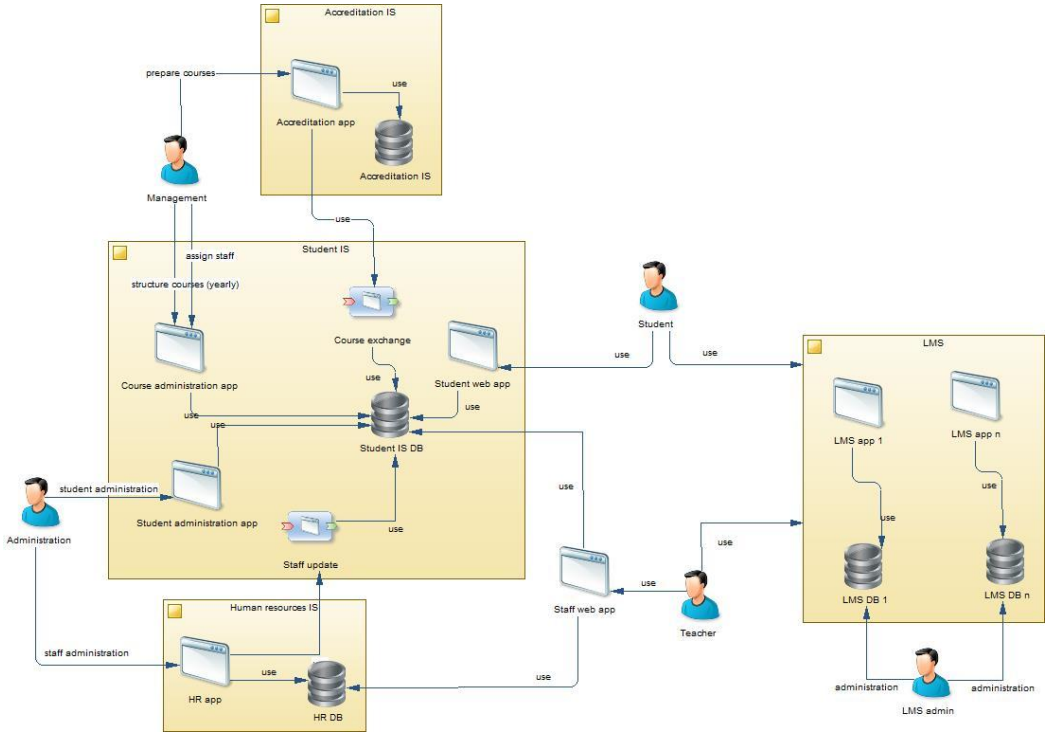

Figure 1. IS state at the FTS

- The Student IS (SIS) – used for the administration of students and their grades, as well as real-time course administration and distribution of teachers and students to courses.

In the last couple of years, several departments have made effort in adopting the use of contemporary LMSes in their teaching process. Currently, three departments use an LMS to support their teaching process: The Department of computer sciences uses Canvas LMS [2], whereas the Department of industrial engineering and management, as well as the Department of electronics use implementations of Moodle LMS [3], adapted to their specific needs. As oposed to other FIS subsystems, the LMSes have not been centrally implemented by the FTS IT service, primarily due to the fact that a compromise on using one exclusive LMS system at faculty level has not been made. These systems represent separate systems, with no level of integration with the FIS.

The following requirements for the integration process emerge:

1. A flexible solution, easily extendable to new LMSes, as only 3 out of 13 departments have an LMS, whereas other departments may decide to implement and use a different one.
2. Secure data transfer, as student and staff data is, and should remain, confidential to third parties.
3. An easily usable and understandable integration interface, in order to ease the integration process for the developers implementing the LMSes.
4. A quickly and easily implementable prototype, in order to test the level of usability of such solution for our IS.

III. EXISTING SOLUTIONS

The problem of integrating an LMS with other systems is not new. How the author states in [1] LMSes need an integration with an existing HR system in order to track employees on courses. In higher education institutions, this extends to integration with a Student administration system, in order to execute the same task with students in focus.

Most LMSes, like [2] [3] [4] [5], offer a simple way for data exchange (primarily import) using Comma Separated Value (CSV) or some other format of files. However, using this approach, files containing potentially confidential data, need to be manually imported by the administrator, exposing them to potential data theft. An even larger setback for this integration approach is the fact that different LMSes often use different file and data formats, so a separate data export script would need to be implemented for each system.

Most modern LMSes also have an Application Programing Interface (API), solving the problem of data file exposure. However, the different format (API) problem still remains.

In [6], the authors suggest an approach based on direct data integration. The LMS communicates directly with a copy of the SIS database to access data about users. This approach, although more generic, is not applicable in our case, due to the fact that the LMSes are not centrally implemented and controlled by the FTS IT service.

The same author in [7] states the disadvantage of direct data integration in the process of updating SIS data, for example importing grades back to SIS, due to the lack of authentication, as well as data validation. Here, a business logic level integration is proposed, in order to include the business-level validation of data.

The authors in [8] propose two levels of integration – data and functional integration. An interface is created for data to be exchanged between SIS and LMS. Furthermore, the functional integration of these systems, enabling the user to log in to each of these systems and directly use the functions from the other, is presented. However, no further details about the integration process are available.

A. *Learning Information Services specification*

Learning Information Services (LIS) Specification [9] is a standard created by the IMS Global Learning Consortium. LIS defines the process for exchanging information which describes people, groups, memberships, courses and outcomes within the context of learning. The specification defines six different types of exchange services:

- Person Management Services – data about students and teaching staff;
- Group Management Services – data about study groups on courses;
- Membership Management Services – data about membership for students and teaching staff – connecting them to courses and groups;
- Course Management Services – courses and course structure;
- Outcomes Management Services – grade-book data; and
- Bulk Data Exchange Management Services – bulk exchange of all data.

These services enable the integration of all LMSes supporting the LIS standard with any IS able to provide interfaces based on the specification. An integration process in full compliance with the Learning information services (LIS) specification is presented in [10].

Although this is a complete solution, based on an industry standard, the standard has not yet been supported by all LMS vendors, and is currently not considered as a solution in the case of FTS. However, this standard represents a base for our proposed solution.

IV. PROPOSED SOLUTION

Analyzing the requirements, as well as existing work in this area, we propose a prototype implementation for a data integration system for exchanging data from our FIS to the LMS. This approach is based on the LIS specification data model and service interfaces, and the implementation of these interfaces using service oriented approach.

A. *SOA, REST, JSON*

Service oriented architecture (SOA) is [11] an architectural style that supports service orientation. Services are defined [12] as course grained, discoverable software entities that exist as a single instance and interact with applications and other services through a loosely coupled (often asynchronous), message based communication mode.

Representational State Transfer (REST) is an architectural model for building distributed applications based on three distinct concepts: representation, state, and transfer [13]:

- Representation: Data or resources are encoded as representations of the data or the resource. These representations are transferred between clients and servers.
- State: All of the necessary state, needed to complete a request, must be provided with the request. The clients and servers are inherently stateless. A client cannot rely on any state stored in the server, while the server cannot rely on any state stored in the client. This does not, however, pertain to the data stored by servers or clients; only to the connection state that is needed to complete transactions.
- Transfer: The representations and the state can be transferred between client and servers.

REST is most often implemented as a combination of the Hypertext Transfer Protocol (HTTP) and TCP/IP. With this instantiation of REST, HTTP requests are used to transfer representations of resources between clients and servers.

JSON (JavaScript Object Notation) [14] is a lightweight data-interchange format, easy for humans to read and write. Compared to XML, JSON is [15] faster and uses fewer resources, and is on the other hand as widely supported in programming languages as XML.

B. *The implementation*

Based on the nature of our system, required to support several different types of LMSes, a solution based on a web service implementation on the FIS side is proposed. This approach to the integration process requires a plug-in (extension) to be implemented on the LMS side in order to access the functions. The proposed architecture for our solution is presented in Fig. 2. The system covers the complete integration process, with a Single Sign On (SSO) Service providing access to all LMS systems directly from the student/staff application, and a Data Exchange Service, responsible for handling data import/export tasks. The scope of this paper covers the implementation of Data Exchange Services allowing data export from the FIS.

The web services implemented are based on the LIS specification and consist of the following functions:

- Course export
- Groups export
- Student export
- Teacher export
- Course membership export

- Group membership export

The data model for all these web services contains two segments – input and out parameters. Here we present a more detailed description of these services and the data exchanged.

1) Course export

The course export service provides an interface for exporting data about courses and course structure to the LMS.

Input parameters:

- School year
- Semester
- Study program

Output parameters:

- Unique id – containing data about the school year, semester, study program and course
- Name – full course name
- Short name – an abbreviation for the course name

2) Group export

The group export service provides an interface for exporting data about student groups on a specific course.

Input parameters:

- Course id – the id received from the Course export service

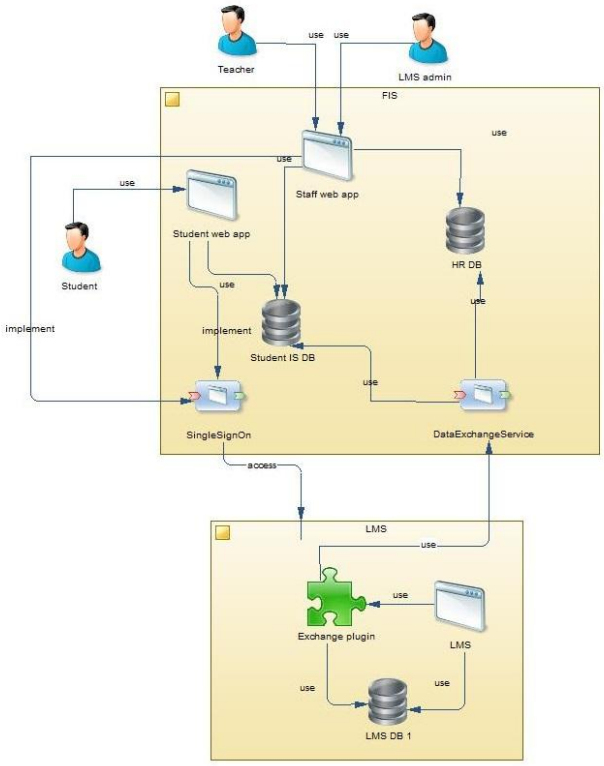

Figure 2. Proposed architecture

Output parameters:

- Unique id – containing data about the course and group
- Group name - a descriptive name for the group

3) Student export

The student export service provides an interface for exporting data about students enrolled in a specific course.

Input parameters:

- Course id – the id received from the Course export service; if empty, all active students are returned

Output parameters:

- Unique id – the id received from the Course export service; student id from the SIS
- First name
- Last name
- E-mail address

4) Teacher export

The teacher export service provides an interface for exporting data about teaching staff responsible for teaching activities on a specific course.

Input parameters:

- Course id – if empty all active teaching staff are returned

Output parameters:

- Unique id – id from the HRIS
- First name
- Last name
- E-mail address
- Office
- Phone number

5) Course membership export

The membership export service provides an interface for exporting data about student and teacher distribution enrolled on a specific course.

Input parameters:

- Course id

Output parameters:

- Student id/Teacher id

6) Group membership export

The membership export service provides an interface for exporting data about student and teacher distribution in groups on a specific course.

Input parameters:

- Course id

Output parameters:

- Student id/Teacher id
- Group id

Apart from these functions, an interface for importing grades from the LMS back to the SIS is planned to be implemented in the Data Exchange Service component of our system. However, this interface is out of the scope of this paper.

Fig. 3 presents the class model which supports these interfaces, without attribute details.

Due to REST and JSON simplicity of use and low resource requirements, a decision has been made to implement web services based on these specifications. An example of use is the call to the Teacher export service, which is made as a simple HTTP GET call to an address in the following format:

```
[serveraddress]/teachers/2014.1.L.1.1.SRP.SE1.13
.SE0011
```

where `2014.1.L.1.1.SRP.SE1.13.SE0011` is the courseId received from the Course export service.

The responce received is in JSON format:

```
{"teachers":[{"teacherId":"N361","firstName":"Br
anko","lastName":"Perišić","email":"perisic@uns.
ac.rs","office":null,"phoneNum":"0214852244"},{"
teacherId":"N1649","firstName":"Petar","lastName
":"Bjeljac","email":"pbjeljac@uns.ac.rs","office
":null,"phoneNum":"0214852246"}]}
```

and can be imported into the LMS.

V. Conclusion

The proliferation of learning management systems use in contemporary educational process opens several challenges to the institutional integrated information system development. However, a large drawback in the adoption of LMSes by institutions and teachers is the amount of redundant administrative work needed for their utilization. This is due to the unavoidable heterogeneity and the lack of integration support mechanisms being the common situations that have to be addressed.

The solution based on RESTful web services, with JSON as the data exchange format, presented in this paper, is easy to implement and use, and represents an open solution that may be extended and improved in a simple manner. Furthermore, the fact that we use a data model similar to the one in LIS specification enables simpler implementation of plug-ins needed for the exchange of data and an easy understanding of all the concepts used. The initial tests were subjected on four courses, on a subset of approx. 300 students and five members of teaching staff. The approach has proved to satisfy all specific requirements at the Faculty of Technical Sciences.

Future work directions are: the implementation of services needed for the import of grade-books back to the SIS; the implementation of an authentication and authorization mechanism for these services; the implementation of a Single Sign On (SSO) solution, enabling users to login to one system (SIS), and use functions from other systems (LMS).

Evaluating the effect of the automatic assessment introduction in the ADS1 course practical work

I. Rožanc and J. Mihelič
Faculty of Computer and Information Science, University of Ljubljana, Večna pot 113, SI-1000 Ljubljana, Slovenia
{igor.rozanc, jure.mihelic}@fri.uni-lj.si

Abstract - The introduction of modern teaching and assessing approaches importantly enhance the quality of teaching. Apart beneficial effects such as effective knowledge presentation, better communication and easier practical work execution, changes include risk to ruin good results of well-established teaching routine.

This paper is motivated by recent changes of the content, structure and assessing method of practical work of the Algorithms and Data Structures 1 course, which is taught at the FCIS at the University of Ljubljana. The most critical part was the introduction of automatic assessing of practical work as it considerably elevated the number of shorter tasks to be handed in on time by students.

In our work the effect of such approach is objectively evaluated. First, the previous and current assessment data is used to examine the number and distribution of results for students involved in practical work. Second, the current grades are analyzed to check the correlation with previous grades obtained manually. Next, the results of a student questionnaire are presented, which confirm the successful introduction of new approach. Finally, our experience is summarized to support similar initiatives elsewhere.

I. INTRODUCTION

In Slovenian higher education the principles of Bologna reform [1] were adopted recently. Its implementation caused important changes in the structure of university programs such as uniform length of study, course selectiveness and on credits based promotion. Additionally a new teaching style was implemented to enhance efficiency of study with the emphasis on practical student work, which must be concurrently evaluated and later incorporated into final course grade.

In practice we deal with requirement to upgrade the practical work (i.e. exercises) with more student-assistant interaction, more student tasks of different types and more task assessments. The amount of assistant work is growing towards uncontrollable level, especially in cases of the courses with large number of students.

The introduction of modern (automated) teaching and assessing approaches can be of a great aid. Among well-known beneficial effects such as modern knowledge presentation and upgraded interaction with new ways of communication they especially ease exercises execution by supporting automatic submission and assessment with appropriate tools. However, the elevated use of automatic tools has pitfalls, too. Important aspect of assistant's work is now the preparation of interactive materials and fraud detection instead of face-to-face communication between student and assistant. Additionally the implementation of new approaches can ruin the beneficial effects of a well-established teaching routine.

The optimal relation between the automated and non-automated approaches is obviously different from case to case. In this paper we present the experience gained at the Faculty of Computer and Information Science (FCIS) of the University of Ljubljana on this aspect. It was motivated by recent changes of the content, structure and assessing method of the Algorithms and Data Structures 1 (ADS1) course, which is taught at our undergraduate professional program of computer and information science. Our aim is to analyze available data to confirm expected advantages and detect issues of new approach. This experience can provide valuable advice for university teachers with similar mission, as in case of research works with similar motivation [2, 3].

ADS1 is one of basic programming courses. In academic year 2010/11 it was performed for the first time in the Bologna compliant way, but with a moderate involvement of automatic tools only [4]. At first the students had to solve a few big programming projects during the laboratory work, and they had to present (defend) the solutions to the assistant during a face-to-face meeting. Then and there all the issues were discussed and a grade was determined.

In academic year 2014/15 a new lecturer started to teach the course and consequently the changes of content and organization were introduced. The most important change was the introduction of the automatic assessment of exercises. Students now solve much more tasks of different types, and the main part of solution delivery and assessment is automated.

We are able to collect enough past and current data to objectively evaluate the effect of this change. Thus we focus our work on statistical analysis of this data with the aim to discover which approach yields better outcome. Additionally, the results of an anonymous student questionnaire are analyzed to add an alternative view of these topics.

In the second section the ADS1 course is presented with focus on its content, structure and assessment changes. The third section describes the analysis background with data and statistical analysis selection. In the fourth section the actual analysis results are presented in detail and discussed. Finally the paper is concluded with a main findings and a proposal for future work.

II. THE ADS1 COURSE DESCRIPTION

The ADS1 course contains the first part of the classical ADS content as defined in the IEEE curricula for the Computer Engineering [5]. As such it is aimed at teaching selected chapters of programming concepts and data structures, while its successor course ADS2 appends the remaining part of the ADS content.

The ADS1 is taught in the first semester of the second year of study. It is part of undergraduate professional program, which has intentionally a large number of free choice courses to enhance the adaptation of student curricula to his or her wishes [6, 7]. The ADS1 course is formally a free choice course, but in practice all students chose to study it as it is a necessary prerequisite for most of the free choice courses students choose in future.

The implemented changes aim to enhance the course performance in an effective way. Thus we preserved good solutions and upgraded the others. E.g. previous and current course's teaching style remained similar, but major changes are in course's topics (i.e. contents), it's performing in practice (i.e. structure) and especially in the implementation of exercises grading (i.e. assessment).

A. The content differences

The contents of the previous ADS1 course was aimed on the measurement and analysis of algorithm complexity, introduction of some programing paradigms (e.g. divide and conquer) and (especially) on detailed presentation of the data structures (ADT, simple and complex data types, diverse implementations of data structures). Important emphasis was given to the actual implementation of data structures in Java. A majority of tasks at the exercises were of programming nature, too.

With new teacher the division of topics between ADS1 and ADS2 courses changed. Some additional topics emerged in the ADS1 course (i.e. arithmetic algorithms, sorting algorithms, dynamic and greedy algorithms), and some data structures are now covered in ADS2. The lectures are now presented at a higher level of abstraction using pseudo code. The actual programming tasks are now present at some exercises only, and a lot of non-programming tasks are given to students, too.

B. The structure differences

The main organizational differences were introduced in the practical execution of the course, especially at the level of the exercises. Previously the main part of each the ADS1 exercise was the presentation of programming examples, which were solved and explained in detail by assistants. The student participation was obligatory and they had to be involved in discussion. The course was (and is still) efficiently supported by Moodle [8].

The main student's obligation was to solve four (or five) big programming projects, which had to be finished in two weeks and then correctly presented to the assistant on time (sharp deadline). Additionally just before the end of semester the students had to participate at a theoretical quiz. The last (and the most difficult) obligation for student was written final exam. The oral exams were performed in exceptional cases only.

Due to last year's changes the exercises are now performed in a different way. Only the initial part of each exercise is devoted to example presentation. In remaining time the students solve smaller programming tasks alone. If they don't complete the solution on site, they have to finish it at home. The solution has to be delivered before next exercise using Moodle. The big programming projects are preserved as well, but now the students solve only three middle size projects in two weeks. The solutions of projects are automatically assessed by a custom made tool. Instead of one big quiz many small automatically assessed Moodle quizzes are introduced. Each is devoted to a single lecture topic and contains 5 to 10 questions. As before the students have to pass a written exam, and the oral exam is performed rarely.

C. The assessing differences

In both previous and current approach the students earn up to 50 points before the final exam (at exercises) and up to 50 points at the final exam. To participate at the final exam they have to earn at least 25 points at exercises. 25 points are required to pass the final exam, too. Thus 50 points is needed for positive grade and the final grade is calculated from the sum of all points.

Previously (before academic year 2014/15) the total of exercises points was calculated as a sum of up to 40 points for programming projects (4 times 10 points) and up to 10 points for quiz. Currently the students earn up to 10 points with 12 small programming tasks, up to 30 points with three programming projects (3 times 10 points) and up to 10 points with 18 short quizzes. The final exam brings the same amount of points as before, but before it consisted of four programming exercises. Now the final exam consists of 6 shorter tasks.

The main difference is the use of automatic assessment. Before the Moodle was used to hand in the required solutions, but the assessment was performed manually by assistants. Now the programming projects use a special tool to hand in and assess solutions, and the quizzes are automatically assessed by Moodle. Only the small tasks and the exams are still checked manually.

D. The automatic assessment

A special tool was developed for the automatic assessment of programming projects written in Java. There are well-known tools (i.e. Marmoset [9]) and initiatives to automate part of assessment process [10], but we preferred to build a customized tool to exactly meet our requirements. Here a short description of functionality without technical details is given only.

The tool runs on a dedicated UNIX server, where all students and assistants have their own account. First each programming project has to be carefully configured by specifying tests (solutions for various inputs and points for of correct answers), the deadline and the time between two admissions. All programs use the precisely defined standard input and output format only. The students have to follow the instructions to correctly conduct the automatic assessment.

The students copy solutions for an active project to their account directory as one java file. Then they run a

script, which compiles the sources and executes several prepared tests. Each test can contain more inputs, and each result of test execution has to syntactically precisely match the predefined output. Successful execution is awarded with a predefined amount of points, and the points for all tests are summarized into final score. The complexity of tests usually gradually increases. It is possible to test different characteristics, e.g. the test can measure the execution time: if the calculation takes too much time, it fails.

After the execution of all tests the student receives the results on-line. Additionally, the outputs of all tests are in the predefined form placed into a dedicated directory. Students usually compile solutions frequently with the aim to concurrently solve issues and meet the desired grade. When the project assessment is over, a special plagiarism check (i.e. Moss [11]) is performed on all solutions. Only after manual control of all discovered similar solutions the grades become officially valid.

The automatic assessment of quizzes is conducted by Moodle. This system has some limitations, but it suffices for our needs, if we carefully prepare the questions.

III. ANALYSIS BACKGROUND

To make an objective comparison of both approaches we have to analyze the effect of introduced changes. Thus, we carefully select suitable data for analysis, prepare it to be correctly used and select appropriate statistical analysis to be performed on data.

A. The data selection

Previous ADS1 teaching performance is analyzed on data from four consecutive academic years: 2010/11, 2011/12, 2012/13 and 2013/14. The current ADS1 performance analysis use data from the academic year 2014/15 only. Four groups of data are used for analysis:

a) The course selection data is used to determine the exact number of ADS1 students per academic year;
b) The assessment results of laboratory work contain detailed data on points earned by student for all programming projects, tasks and quizzes. Only the sum of all points per student (namely **exercise points**) is used to determine the number and distribution of exercises results per academic year;
c) The examination results contain exact student's points for each task on each exam. However only the **final grades** for 14 exam terms are used to analyze the number and distribution of the examination results per academic year;
d) The data from anonymous ADS1 questionnaire are used to demonstrate student opinion on current course execution. The questionnaire was performed in January 2015. 31 students answered on 19 questions (with Likert [12] scale answers) and on one free-form answer.

B. The data preparation

Most data were obtained from the official faculty student information system StudIS [13], some from assistant's personal archive and from a specially prepared questionnaire. All collected data can be considered accurate and complete. Unfortunately, certain sets of data are not consistent and they must be manipulated to be properly compared.

a) As we use aggregated values only, the course selection data don't need any preparation.

b) This is not the case for the exercise data. Because of the unreliable data for unsuccessful students we use cumulative results for the students who collected enough laboratory work points to be able to participate at the final exam only. The number of unsuccessful students is still shown. As the required number of points for successful laboratory work changed over years, different limits were used for different academic years: 10 points in 2010/11 and 2011/12, 20 points in 2012/13 and 25 points in 2013/14 and 2014/15.

c) The examination data has two issues: (i) the unequal distribution of positive and negative grades and (ii) missing data for current academic year as only two terms are concluded by now.

   (i) The use of only one negative grade (5) in examination causes unequal distribution between positive (normal distribution) and negative (only one value) grades. This error propagates into inaccurate statistical results (i.e. mean value, standard deviation). By analyzing positive grades only a lot of important information in lost, so we act differently. Our solution is to change all values 5 into values from the range 5 to 1 in the same distribution as positive grades from 6 to 10 are. Such data preparation is artificial, but still much closer to the real student results.

   (ii) The successful students pass the exam on 1st or 2nd term, while the 3rd term is mostly reserved for bad students. As this year's 3rd ADS1 term will be in September 2015, we compared only the results for first two terms in each academic year.

d) The questionnaire data contains many questions about lectures, which are omitted in analysis. Thus we analyzed two questions on exercises execution in general, three on quizzes, three on small programing tasks, two on programming projects and one on automatic assessment. Additionally, the most notable free form answers are taken into account only.

C. The statistic analysis selection

After the careful selection and preparation of good quality data the statistical analysis are selected.

First, many general characteristics may be recognized by applying simple statistical analysis such as sample count, percentage, mean values and standard deviation values calculation. We perform such analysis on exercise data, examination data and questionnaire data.

Second, to statistically prove approximate equality the right statistic test has to be selected. As we have approximately normal distribution of exercise and examination data we could choose t-test, but z-test is a better choice as standard deviation can be computed. In our case we selected **large sample z-test for the difference between two mean values** [12]. To correctly perform z-test the necessary conditions must be checked first: the test variables must be independent, sample large enough and normally distributed. Histograms and normal distribution plots are used to show if the data is approximately compliant with normal distribution. Next, suitable hypothesis are formulated and tested. Technically we define an original hypothesis H_1 and an alternate null hypothesis H_0 for both cases, which we try to prove false during the process. Using this test we try to confirm with statistical significant probability (usually 97%) that the mean number of exercise points and grade of the previous and current course are related as hypothesis states.

Finally in case of non-structured data (as free-form opinion in questionnaire) a non-formal analysis is needed.

IV. ANALYSIS RESULTS AND DISCUSSION

A. *The simple analysis of the exercise data*

Results in Table I show the basic characteristics of the exercises data by academic year: the number of students, who selected the ADS1 course, the number (and percentage) of those, who succeeded to collect enough points and passed the exercises, the mean (average) number of exercise points and the standard deviation of those points. The first four (five) columns contain data for previous (manual) approach, while the last column presents data for current (automatized) approach.

TABLE I. THE BASIC CHARACTERISTICS OF EXERCISE DATA

	2010/ 11	**2011/ 12**	**2012/ 13**	**2013/ 14**	**2010 - 2013**	**2014/ 15**
Total number of ADS1 students	217	141	132	142	632	129
Number of students with enough points	104	84	87	111	386	108
% of students with enough points	47,93	59,91	65,91	78,17	61,08	83,72
Mean number of exercise points (μ)	27,05	25,98	28,52	30,75	28,21	34,06
Standard deviation of exercise points (σ)	7,79	8,29	3,94	4,40	6,61	7.45

The data in first two columns are unreliable as they contain "old" non-Bologna students, who were enrolled for ADS1 exercises, but who did not participate actually. In fact only the last two columns are directly comparable as in last two years the same rules were applied.

Still two clear tendencies may be recognized from the table: the group of successful students rapidly grows and the average number of points notably grows (in the last three years) as well. This demonstrates the success of new approach, thus a larger number of smaller tasks and automatized solution handling ease the work for students. The lower mean values of exercises points before 2013/14 are a consequence of different rules applied, however this is not the case for last two years.

B. *The distribution of the exercises points*

To gain more insight, the distribution of exercise points is analyzed. The Figure 1 presents the histogram of exercise points for five consecutive academic years (2010-2014). Considering the issues explained earlier we focus on the data for last two years (green and red line on graph), which prove similar characteristics.

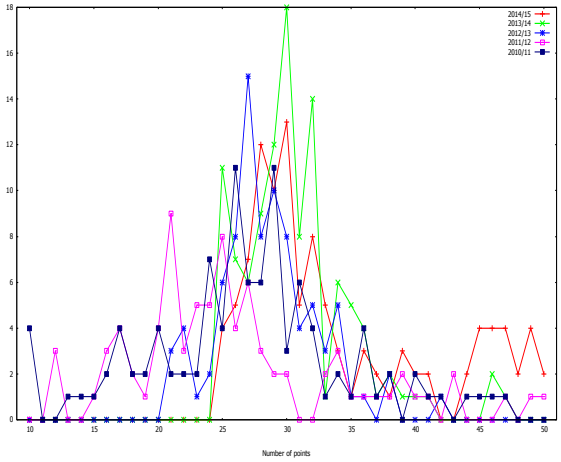

Figure 1. The histogram of the exercise points for academic years 2010/11 – 2014/15

Students are very motivated to collect enough points to pass the limit of 25 points, but to achieve more is obviously too demanding for most of them. There is a smaller group of excellent students with almost all points, thus the curve has a main peak in the middle and another one at the right edge. The data is not entirely normally distributed, but it is close enough as demonstrated in distribution plot (containing data for last two years) on the Figure 2.

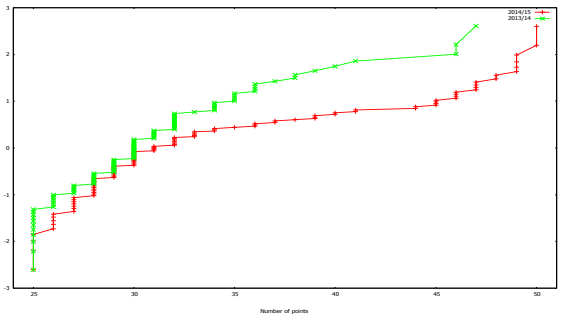

Figure 2. The distribution plot of the exercise points for academic years 2013/14 and 2014/15

C. *The hypotesis testing for the exercise points*

By hypothesis testing (using z-test) we can be even more accurate. All the necessary conditions are valid: variables are independent (as we compare results for different students in different academic years), we analyze much more samples than minimum 30 and our data is approximately compliant with normal distribution.

Let our exercise hypothesis state that the mean values of exercise points are now higher than previously. More precisely the difference between mean value of previous and current exercise points is 2 or more, while null hypothesis claims the opposite. If we define previous data as X and current data as Y then the hypothesis are (1):

$$H_{P1}: \mu_{Py} - \mu_{Px} > 2 \quad (1)$$
$$H_{P0}: \mu_{Py} - \mu_{Px} \leq 2$$

The mean values (averages) μ and standard deviations σ shown in Table 1 enable us to calculate **z-score** and **P-values** for H_{P1} and H_{P0} hypothesis. Table II summarizes the final results on the data for academic year 2013/14 and for all years together. The result for 2013/14 (111 totally compatible samples) is the correct one, while the other result (on bigger sample) requires careful interpretation.

TABLE II. THE EXERCISE HYPOTHESIS RESULTS

	z-score	P-value	H_{P0} rejected?
2013/14	**-3,14**	**0,0008**	**Y**
2010-2013	-11.44	<0,0001	Y

The P-value is in both cases very small and strongly rejects the null hypothesis, thus making our hypothesis confidently plausible. If we set the required confidence limit to usual 3%, the same can be claimed even for difference of 2.5.

D. The simple analysis of examination data

To demonstrate the basic characteristics of examination data a similar analysis was performed as in case A. Results in Table III demonstrate the number of exam terms, the number of all exams, the number and percentage of exams with positive grade, the mean positive grade, the mean grade and its standard deviation for same range of academic years. The data was previously manipulated as described before.

TABLE III. THE BASIC CHARACTERISTICS OF EXAMINATION DATA

	2010/ 11	2011/ 12	2012/ 13	2013/ 14	2010 – 2013	2014/ 15
Number of exam terms	3	3	3	3	12	2
Total number of ADS1 exams	172	120	130	160	582	119
Number of exams with positive grade	88	85	91	109	373	74
% of exams with positive grade	51,16	70,83	70,00	68,12	64,09	62,18
Mean positive final grade	6,96	7,03	6,97	7,31	7,01	7,51
Mean final grade (μ)	5,91	6,26	6,00	5,83	5,92	6,60
Standard deviation of final grade (σ)	1,88	1,85	1,75	2,07	1,85	2,25

All examination data can be considered valid as they reflect the result of similar final exam despite issues in the exercise data. The exercises points are evaluated as a part of total exam points, but only when the student collects enough points for correct exam task solutions.

The effect of unsuccessful "old" non-Bologna students may be recognized in pass rate for academic year 2010/11, but latter the pass rate becomes very stable till current year, when it suddenly drops. In light of exercise results this is a surprise, especially because of the missing third term data. Obviously the sample for current year is too small and actually reflects the effect of one exam term with too difficult tasks.

On the other hand the mean positive grades are very much synchronized, and, as expected, with clear growing tendency in last two years. More fluctuation may be recognized for mean value of all grades, but still the mean value for current data seems to be considerably better. Our further analyses are focused on all final grades.

E. The distribution of the final grades

In Figure 3 is the histogram of final grades for each academic year between 2010/11 and 2014/15. To be objective the data for the first and second exam terms are analyzed only.

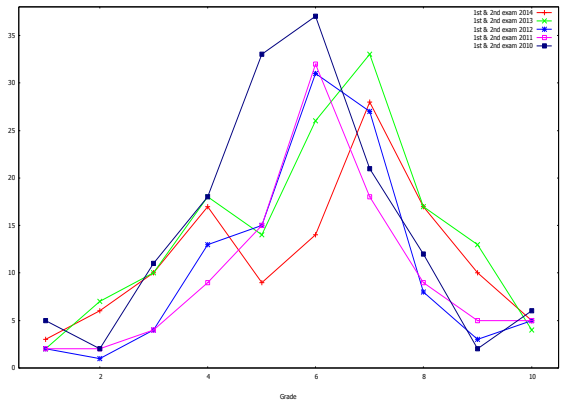

Figure 3. The histogram of the final grades for academic years 2010/11 – 2014/15

All histograms show approximately normal distribution with central peak moved to the right. Due to high average grade and previously described manipulation of negative grades the histograms for the last two years demonstrate even two peaks. The distribution plots of final grades for 1st exam term in years 2013/14, 2014/15 and for years from 2010 till 2013 are presented in Figure 4.

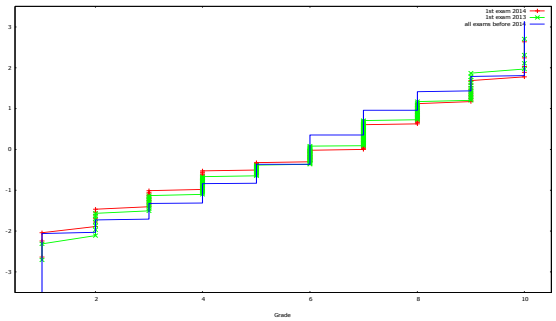

Figure 4. The final grades distribution plot for academic years 2013/14 and 2014/15

F. The hypotesis testing for the final grades

The hypothesis testing is applied to prove the final grades for current (automated) approach are considerably higher. The final grades hypothesis states the difference of mean final grades for previous and current data differ for at least 0.5. For previous data X and current data Y we define the following original and null hypothesis (2):

$$H_{G1}: \mu_{Gy} - \mu_{Gx} > 0.5 \quad (2)$$
$$H_{G0}: \mu_{Gy} - \mu_{Gx} \leq 0.5$$

The hypothesis testing follows the same steps as in case C. The results are presented in Table IV.

TABLE IV. THE FINAL GRADES HYPOTHESIS RESULTS

	z-score	P-value	H_{G0} rejected?
2013/14	-1,65	0,0495	N (3%), Y (5%)
2010-2013	**-2.34**	**0,0096**	**Y**

The hypothesis is strongly plausible as we consider all data to be consistent. If we use just the data from academic year 2013/14, the hypothesis may be confirmed with a lower confidence rate (95%) only.

G. *The questionnaire analysis*

To complete the picture the analysis of questionnaire results is performed. From 19 questions with answers in Likert [12] range from 1 (bad) to 5 (excellent) only 11 were considered relevant as they express opinions on (i) exercises in general, (ii) quizzes, (iii) programming tasks, (iv) programming projects and (v) automatized assessment. For each topic the questions were aimed on the quantity, the difficulty and the expected effect. The basic results are presented in Table V. The histogram with distribution of answers is shown in Figure 5.

TABLE V. THE BASIC QUESTIONNAIRE RESULTS

	Exercises	Quizzes	Tasks	Project	Automatic assessment
Number of answers	62	93	92	62	31
Average grade	4,19	3,48	3,46	3,38	4,35

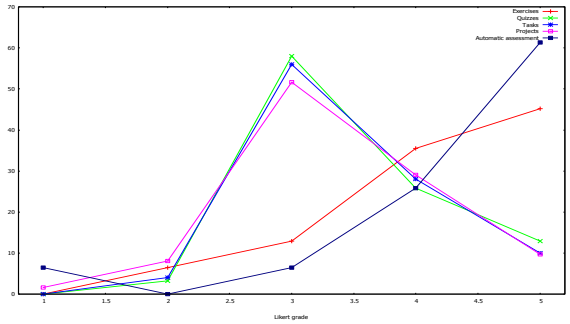

Figure 5. The histogram of the questionnaire answers

The results demonstrate that students like the new exercise approach and especially automatic assessment, while the results on different types of tasks are slightly positive only. Similar conclusion can be recognized from relevant free-form answers: the practical work was very well performed and at right level of difficulty, automatic assessment of programming projects is great. Some students like quizzes and programming tasks as they force them to study regularly, but on the other hand many of them complained over too much work with them.

Only one student would like to have more programming oriented lectures and exercises (as before). Still not much can be claimed as we don't have similar questionnaire results from previous years and current ADS1 students don't have experience with such course performance to be able to objectively judge.

V. CONCLUSION

After the careful analysis of different types of relevant data we established the following conclussions:

First, in many aspects (e.g. the distribution of exercise and examination data) the effects of previous (especially last year's) and current approach are totally comparable.

Second, due to considerable experience with ADS1 teaching, effort invested and accurate data collected we are able to confidently show that some results (e.g. the exercises points and final grades) are better than before.

Third, the automatic assessment works well and it is praised by students. It causes different structure of tasks and projects, which at the end enable higher grades.

Finally, the relation between grades earned and actual knowledge is not clear. Some incompatible results (e.g. low current exam pass rate) point out this question. Unfortunately, the actual knowledge is difficult to directly measure and we don't have better data to use. In this view the previous approach was better as the actual discussion with students enabled a better understanding of their issues.

Apart these results this paper presents a demonstration on how to use suitable statistical analysis to point out selected characteristics. In future we plan to perform similar analysis for other courses, which are in the process of modification.

Abstract— **The research study is focused on the exploration and analyses of development methodologies of e-learning software and proposes a model and a framework for approaching such development, while applied it on a particular practical application E-Learn SEEU were has been implemented and tested the proposed model as well as evaluated with the users. Analyses of the current methodologies and best practices in e-learning, comparison of e-learning with m-learning as well as analyses of development of e-learning software has been realized. Also developed a software solution to test the proposed model and apply the framework as well as tested and evaluated it with the users using questionnaire. In conclusions insights are provided and recommendations are stated based on the study results realized.**

Keywords—e-learning, m-learning, e-learning software, model and framework for e-learning, software engineering reliability

I. INTRODUCTION

Today many technological innovations are redefining higher education, where students have to read many books, publications and articles during their studies. Teachers have to provide a number of lists of books and publications in many fields for their students. As an alternative teaching method, universities have adopted E-learning courses. By development of new pedagogical and technological methods of teaching and computer based devices, e-learning has rapidly emerged over the past few decades as an effective alternative to traditional education. E-learning models are attempts to develop frameworks to address the concerns of the learner and challenges presented by the technology so that online learning can take place in effective way [1]. Using web technology teachers can make their tasks more effectively. Instead of distributing materials separately to each of the students, a teacher can host it on the web so that students can download it when they need. According to [2], e-learning is also a very learner-centered form of education, and given its inherent need to archive teaching material, can be a useful platform for storing and sharing information. Teachers want to create course websites in a flexible way and quickly update and publish already existing Word, Excel or PDF documents. A Web-based teaching tool that enables to do such teaching tasks as distributing documents and exercises on the subject being taught will improve the teaching quality. Therefore, our purpose with this study was to explore the ability of an e-learning tool, for teachers and students for managing academic literature, and providing subject lists with literature for users.

II. LITERATURE REVIEW

There's a broad literature on e-learning published from around 2000. Different authors use different terminologies including online learning, Internet learning, distributed learning, networked learning, tele-learning, virtual learning, computer-assisted learning, web based-learning and distance learning instead of e-learning [3] [4] [5], which makes it difficult to develop a general definition for e-learning. So, there is no clear and explicit definition of the concept of e-Learning. Sigala [6] portrayed the Internet as an education platform for students, enabling them to receive educational materials and interact with teachers and peers in ways that previoulsy may have been impossible. According to [6], Internet is not the only method for delivering e-learning; in his definition includes several other methods such as TV, CD-ROM, utilized to provide distance education. Anderson [3] in his book used the term online learning throughout and he defines online learning as "[t]he use of the Internet to access learning materials; to interact with the content, instructor, and other learners; and to obtain support during the learning process, in order to acquire knowledge, to construct personal meaning, and to grow from the learning experience"; Itmazi [4] defines e-learning as "the use of new multimedia technologies and the Internet to improve the quality of learning by faciliating access to resources and services as well as remote exchanges and collaboration."

According to [5], the definition of e-learning comprises a lot more than online learning,virtual learning, distributed learning, networked or web-based learning. As the letter "e" in e-learning stands for the word "electronic", e-learning incorporates all educational activities that are carried out by individuals or groups working online or offline, and synchronously or asynchronously via networked or standalone computers and other electronic devices. Naidu [5], various types of e-learning activities down into the following modalities:

Fig. 1. E-learning modalities

2.1 Individualized self-paced, based on Naidu [5]

2.1.1 Online

In this type of learning an individual learner accesses learning materials online

2.1.2 Offline

In this type of learning an individual learner accesses learning materials offline (without Internet)

2.2 Group Based

2.2.1 Synchronous

In this type of learning a group of learners work together in real time via Intranet or Internet. Syncrhonous e-Learning is a method of e-Learning where interactions between the learners and instructors happen in real time [8]. It is commonly supported by media such as videoconferencing and chat, teleconferencing etc. The advantage of this type of learning is that it is independent of the geographical location and distance, and for learners online learning knows no time zones [3];

2.2.2 Asynchronous

In this type of learning a group work together through Intranet or Internet, but there is a time delay during exchanges among groups. Asycnchronous e-Learning is a method of e-Learning where interactions between learners and instructors happens independent of time and space. So, learners are in situation to interact with course materials and with instructors at a time of their choosing [8]. According to [10], the most common type of e-learning being used by different universities is asynchronous e-learning.

Research study by [7] on what university teachers think e-learning is good for in their teaching, where e-learning was conceived of as a medium, from the analysis found that e-learning as a medium can provide information to students, as a medium support 'occasional' online communication, as a medium help for engaging students in online discussions and as a medium support knowledge-buidling tasks. To ensure its success, e-Learning depends on its delivery method and content. And for this reason, e-Learning modules have to be interesting, interactive and informative in order to be effective [8]. The research discussed by [9] demonstrates that asynchronous and synchronous e-learning complement each other and support different purposes. The advance of e-learning has been influenced by numerous software programs, such as Moodle, Blackboard system, and others. So, students are enabled to be in constant contact with their professors virtually. A MOOC (Massive Open Online Course) is a course of study made available over the Internet (usually through videos and other materials) without charge to a very large number of people. According to [11], over the last few years, the MOOCs phenomenon has become widely acknowledged as crucial for freely accessible courses provided by international institutes for informal as well formal education.

III. ANALYSES E-LEARNING COMPARED TO M-LEARNING

Mobile learning or m-learning is an intersection of online learning and mobile computing [12]. That is an electronic learning (e-learning) accessed by mobile devices. Mobile Learning (m-Learning) is a new stage of the progress of distance learning (d-Learning) and electronic learning (e-Learning). According to [13] m-Learning is a new stage of e-learning that makes possible the ability to learn everywhere at any time with this enabling the well known paradigm "any time any location". M-learning is achieved by the use of mobile and portable devices such as PDA, cell phones, portable computers and Tablet PC [13]. One of the expected outcomes of m-learning is to minimize the dimensional constraint of time and location. In general it promised flexibility, convenience and the ability to learn at any time and any place and at learner own place.

IV. RESEARCH METHODOLOGY AND HYPOTHESES

The main goals of this research study are:

1. Analyze existing e-learning software systems.
2. Focus on issues that relate to the users' requirements and to establish them as structural elements.
3. Validate, test, evaluate software to ensure the proper fun ctioning of the software.
4. Develop a model to integrate, to engineer systems thinki ng, learning processes using the system and adequate doc umentation.
5. Utilize and use techniques to increase reliability during software development and describe the challenges for ac hieving these goals.

The main hypotheses addressed in this research study are as follows:

1. The use of the methodologies and best practices involved in development of e-learning
   software can be used to increase the "level of learning" (det ermined by "knowledge transfer" and "learning outcome") by using software.

2. Proposed Framework of recommendations and guidelines for learning systems can increase "level of learning"

V. ANALYSIS OF ISSUES IN E-LEARNING SOFTWARE

In order to establish and implement their e-learning system, institutions must carefully assess the factors that could affect the systems usability within the structure, because new systems can fail if the end users do not accept to use them. There are a lot of research studies in the area of e-learning but only small number of them addresses the critical area and issues in the field [15]. According to the experience of [16], implementation of e-Learning systems still facing a number of challenges, such as students IT skills, performance levels, cost, availability of resources, etc. [17] pointed out that "in general, like any information systems, user acceptance and usage are important primary measures of system success". Therefore, students involvement and acceptance of e-learning must be considered, as the major step toward implementing and developing a successful e-learning system [18]. E-learning system designers must decide which of the multiple available features should be implemented to assist specific target groups and maintain their satisfaction level [19].

VI. PROPOSED MODEL FOR DEVELOPING E-LEARNING SOFTWARE

Due to the large number of issues and challenges facing the E-learning, there is a need of new model, in order to explain and clarify the basic phases that study specific problems that may occurs at each phase.

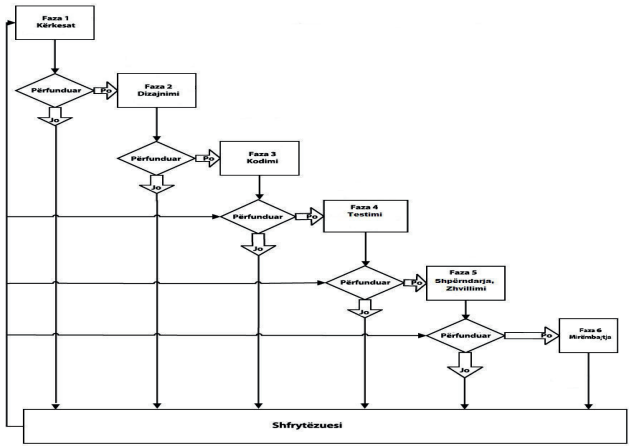

Fig 2. Proposed model of e-learning

In software engineering, the Systems Development Life Cycle (SDLC) concept underpins many kinds of software development methodologies, which can form the framework for planning and controlling the creation of an specified system [20]. There are many and different definitions and models for SDLC.

According to [23] , the systems developers must first identify the optimal requirements and definitions so that applications be as powerful and reliable. The proposed model is based on Waterfall model and includes six components (phases) of the process of developing reliable software for e-learning.

This model is based on strong management and proven tools, techniques and methodologies that are characterized by the key elements of the model. After each stage is defined, development goes on the next stages, so firstly one phase has to be completed before moving onto the next phase. After the requirement analysis has been done, the next phase was the design and coding using laravel framework [24] and PHP. After the coding, the following phases are testing, deployment and maintenance.

VII. CONCEPTUAL DEVELOPMENT OF "*E-Learn SEEU"*

e-learn SEEU developed as software for teachers and students, in order to create course websites in a flexible way and quickly update and publish already existing Word, Excel, PDF documents or any other format.

Search is the same as in Google; you can search either by author or subject and you can find uploaded materials that you care for only a few seconds, if available.

With a few more clicks, you can have your own account, create your own subjects where you and other registered users can personalize their profile and can upload materials. The search options is available to all visitors; create, upload and delete only to registered users.

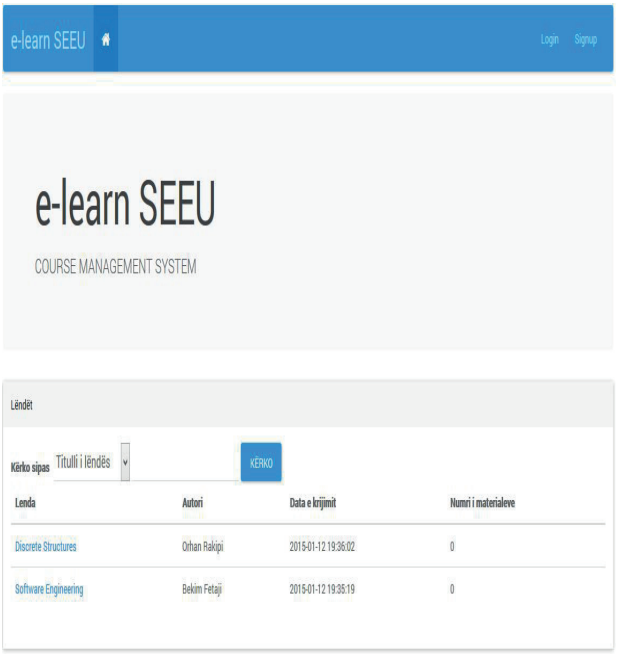

Fig 3. e-Learn SEEU

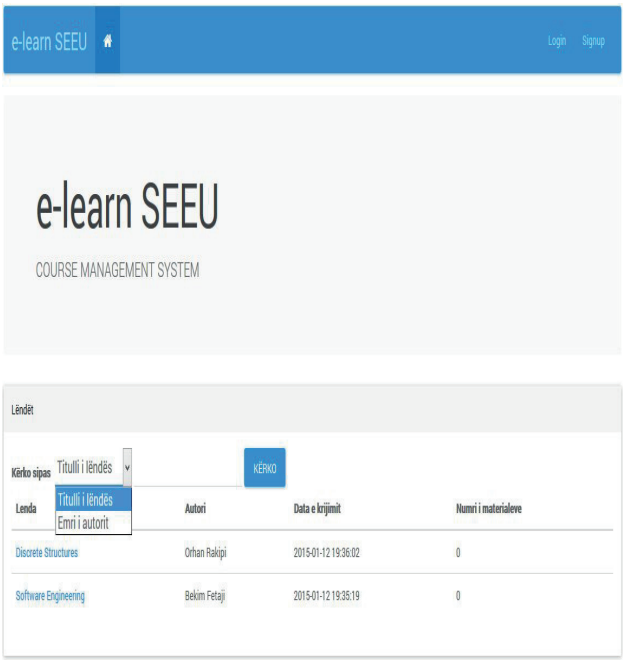

Fig 4. Search option, either by subject or author

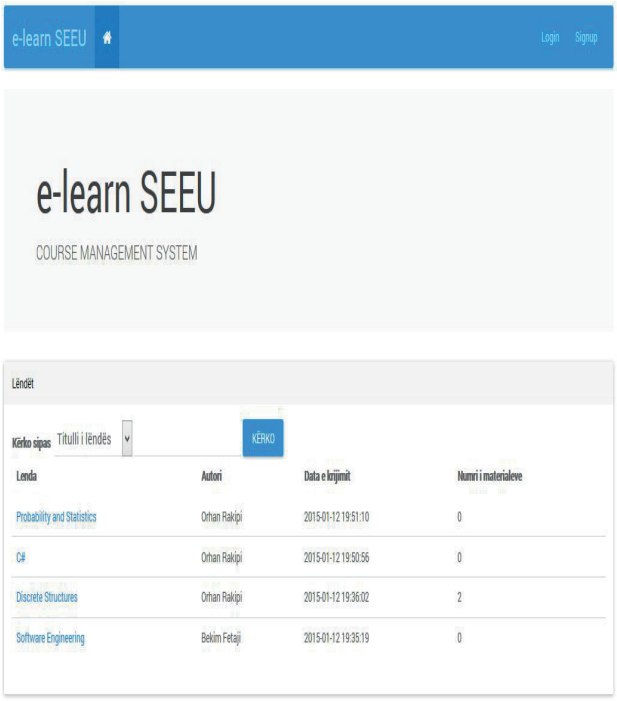

Fig 5. After creation of subjects and uploaded materials (date of creation and number of materials is shown)

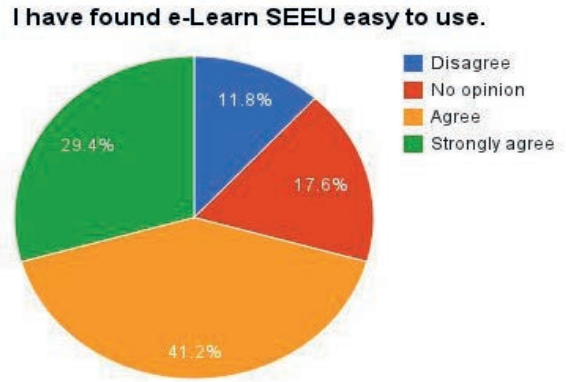
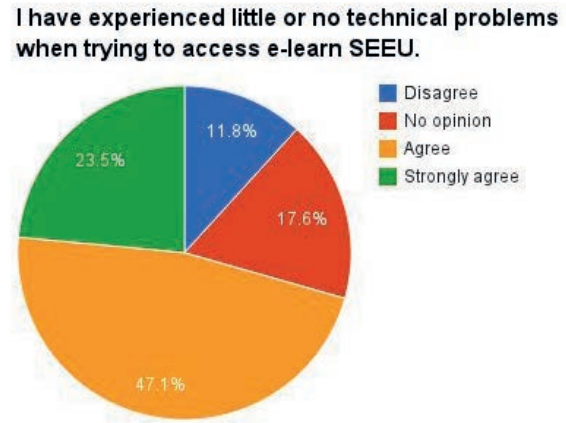
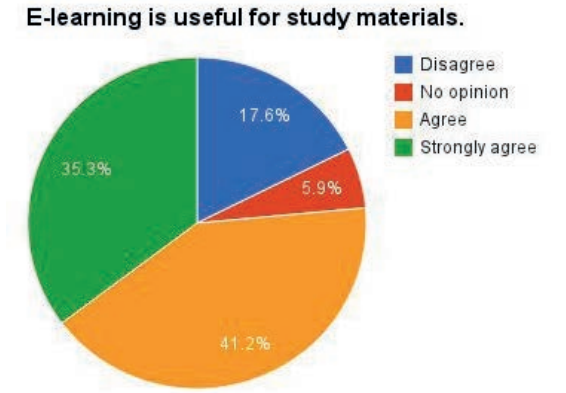
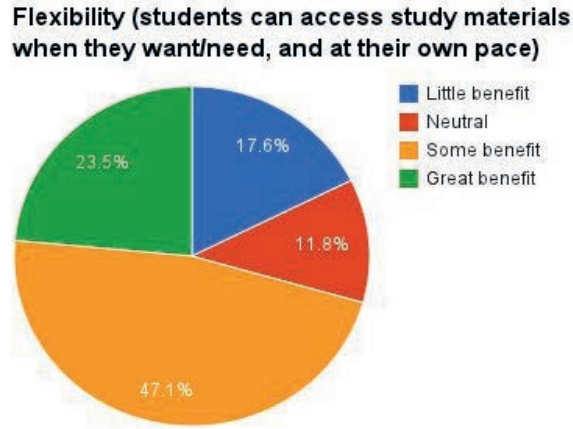
VIII. RESULTS AND DATA ANALYSIS

There were 17 responses from the participants in the questionnaire that had 8 questions and an option for additional comments and addressed the main identified issues regarding e-learning and the proposed model e-learn SEEU. Indicate the benefit level characterizing each one of the following qualities related to e-learn SEEU web application.









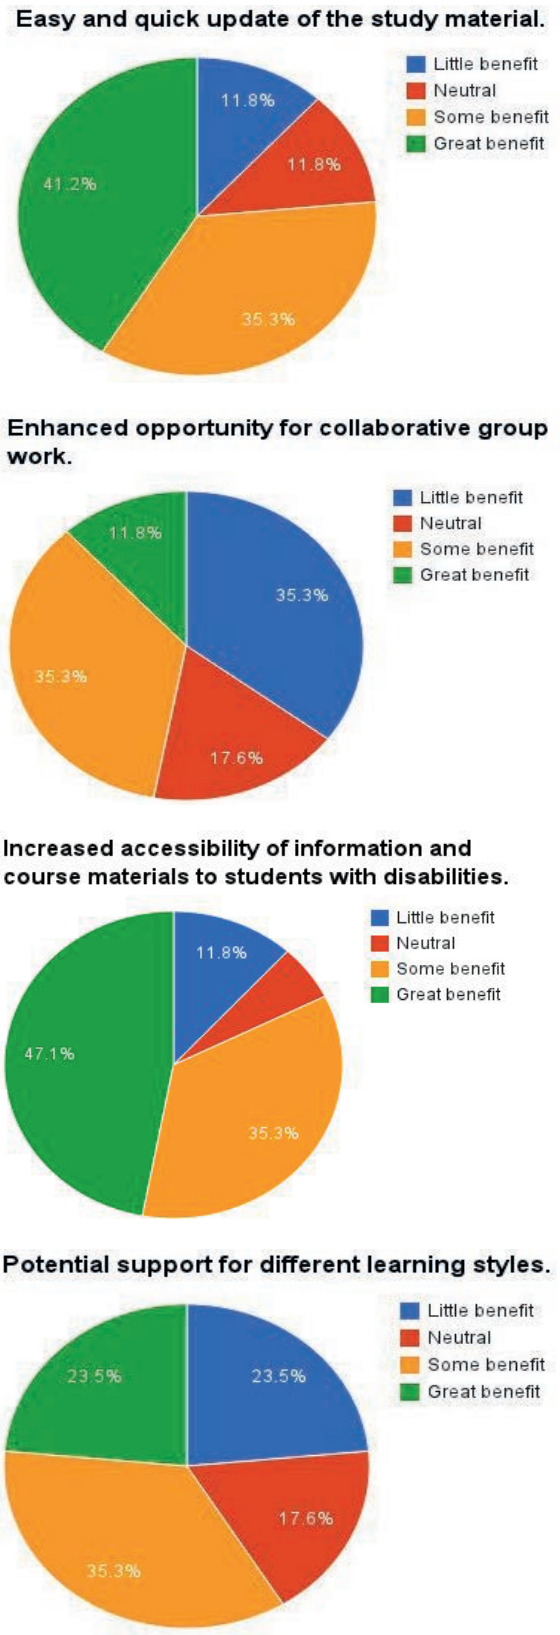


Fig 6. User Feedback Analyses

IX. PROPOSED FRAMEWORK

Laravel is a web application, framework with expressive and elegant syntax, that tries to ease the development by simplifying the common tasks used in the majority of web projects, such as authentication, routing, caching and sessions. It's accessible and powerful, providing tools needed for large applications. Inversion of control container, migration system, tightly integrated unit testing support, are some of the tools needed to build any application with which we are tasked [25]. Modern PHP frameworks, like Laravel, follow the Model-View-Controller (MVC). The MVC design pattern is very popular in the web development space, composed from the three components to the architectural pattern, which are the model, view and the controller [26].

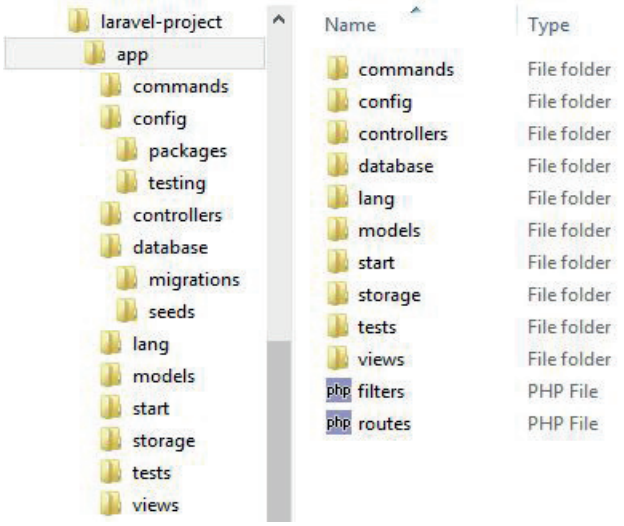

Fig 7. Laravel project directory structure

In order to implement e-learn SEEU, we have used Laravel framework with PHP, where the main pages are as follows:

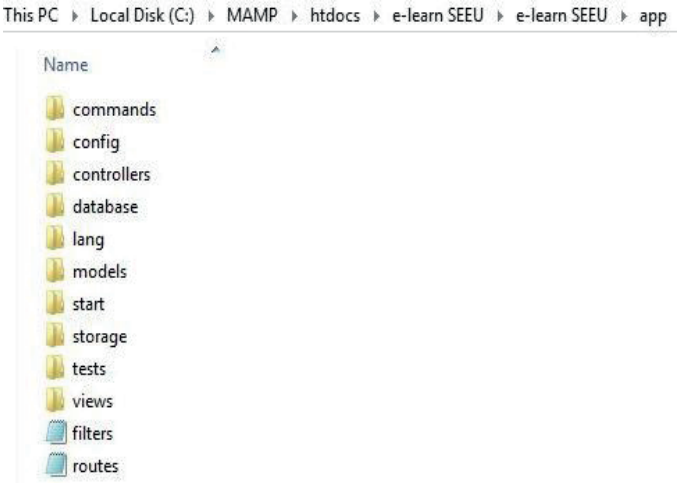

Fig 8. E-learn SEEU project directory structure

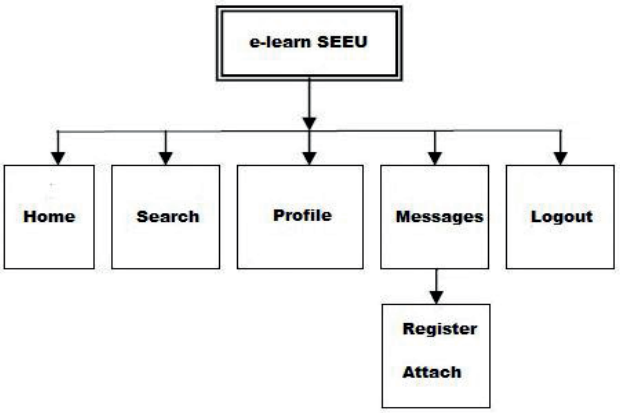

Fig 9. Overview of the e-Learn SEEU system

The version of the e-learn SEEU contains the following components :

- Home – move to the index page
- Search – any visitor can search either by subject or author
- Profile – any visitor can create his profile
- Messages – for any successful or unsuccesful registration, edit, or attachment message appears
- Logout – logout from the system

X. CONCLUSION

Based on the literature review, as the most significant steps toward implementing and developing a successful e-learning system are the students involvement and acceptance of e-learning, deciding which of the multiple features should be implemented, in order to assisst specific groups and maintain their satisfaction. Also, identifying the optimal requirements and definitions is considered as a major step in order application to be powerful and reliable.

We have reviewed the literature and developed an e-learn SEEU model that can faciliate interaction between student and lecturers virtually. The primary objective is premised on flexibility, benefits, easy to use, access and quick update materials through adaptation of different technologies. The participants in the questionnaire as an instrument to evaluate the system, have found e-learn SEEU to be a beneficial model and convenient platform. An effecient way to improve the system according them should be integration of the different modules, such as possibility for creating the online quizzes and taking them, audio and video lectures, etc, that should be considered as future work. Also they agree that e-learning can have great benefit for students with disabilities by increasing accessibility of information and course materials to them.

Based on the feedback and evaluations we can conclude that this study has indications to have positive effect on the improvement of the design concept e-learning software, as well as serve as a good reference for the further studies on the development of e-learning software.

Hands-on System Programming Labs & Projects Based on E2LP Platform

B. Kordic*, V. Marinkovic*, M. Popovic* and I. Kastelan*
* University of Novi Sad, Faculty of Technical Sciences, Novi Sad, Serbia
branislav.kordic@rt-rk.com

Abstract - This paper presents a set of laboratory exercises and student's projects developed for an E2LP embedded learning platform. The E2LP is educational and research embedded platform composed of base and daughter boards based on FPGA and ARM, respectively. The exercises and student's projects cover different topics in embedded and real-time system developments. The main goals of the exercises is to introduce writing Android kernel modules and devices, and multithreaded user space applications using cross-compiling tool chain for embedded platforms and systems. In course of their projects, students implement real-time support for various virtual and hardware peripherals such as RS-232, VGA, LCD, random generator number, encryption device, and etc. The exercises and projects are basic functional building blocks of a global project which provide simple text/chat communication between two E2LP boards. The achieved results are positive and promising.

I. INTRODUCTION

Industry needs for educated, high-skills, well-trained and experienced embedded engineers are constantly growing, which put high bars on a relevant university faculties. In general, active university teachers involved in different areas of a computer engineering has difficult task to fulfil this demand due to rapid technology changes as well as learning process changes. Teaching embedded systems and real-time system programming is always challenging and not easy task because beginners, for the very first time, face with bare hardware, complex and not so user-friendly tools, and minimal system software support. As a result of efforts to make embedded development more suitable and more productive for the beginners and teachers, in the recent past different case studies [1] and cognitive methodologies [2] were introduced to improve that process.

Laboratory exercises and projects are very important part in a student's education. It is essential because they provide a chance for students to tryout and evaluate their theoretical knowledge, and thus upgrade its practical experience. No doubts, maintaining laboratory has its own benefits and drawbacks [3]. Nowadays, in a different educational fields, a remote and e-learning technologies are widely accepted and are in common use, as well as a new technologies like augmented reality [4]. The remote learning laboratory for embedded learning was also introduced. The remote laboratory is equipped with different kind of embedded boards and measurement equipment tools which are monitored locally and controlled over the Interned within a Web browser [3] [5], which is a significant improvement in the area of embedded engineering education.

Maintaining a course laboratory syllabus aligned with industry needs and keeping it attractive and usable from student's point of view is difficult from many reasons: (i) a set of real-time system programming and embedded development exercises highly depend on hardware specification of underlying platform, and its migration to other platform are very time consuming, (ii) various embedded boards based on ARM, MIPS, FPGA, advanced microcontrollers and etc. are available on the market, but none of them, for a reasonable price, can't provide comprehensive set of available peripherals, and (iii) a system user interface is more likely implemented as a minimalistic interactive command line driven tool, which today is, unattractive for students and beginners which want to enter in a world of embedded systems.

A few years ago the E2LP project was introduced bold and ambitious project with its goals to create a unified, comprehensive, and viable embedded engineering learning platform for student's use [5]. The E2LP platform provides FPGA based base-board and two extension-boards equipped with ARM-v7 and DSP processors. Advantage of the E2LP board compared to other embedded platform on the market are manifold because it covers a very wide range of disciplines which embedded systems engineers should learn about – hardware design, digital systems, computer systems, signal processing, networking and communications, system and application software [5].

Professors and assistants at the University of Novi Sad, Faculty of Technical Sciences in the academic year 2014/2015 for a first time use the E2LP base and DSP based extension boards as the dominant learning platforms for a Real-time systems 2 course. After initial investment of significant time and effort to adapt existing and develop new exercises, which are not part of startup kit, for running on the E2LP boards, and if we take into account that we did not exceeded its full potential, seems that using the E2LP boards in long term will really pay off.

The rest of the paper is organized as follows: section one briefly introduce the E2LP architecture and architecture of DSP based extension board, chapter three in details describe student's exercises and projects, and section four conclude the paper with the final remarks and future work.

II. E2LP Platform Architecture Overview

A. The E2LP Architecure

As already introduced in the previous section, the acronym E2LP stands for *Embedded Engineering Learning Platform*. In its specification, the E2LP platform include a FPGA base board, a microcontroller extensions board based on ARM-v7 series, and a DSP extension board based on Marvell ARMADA 1500 processor [3]. The both extensions boards are also called the daughter boards. At the moment when exercises for a Real-time systems 2 course was developed, the DSP daughter board was fully functional and the microcontroller daughter board is still work in progress. Fig. 1 show the E2LP base-board and DSP based daughter board in its laboratory casing. In the Fig 1 is marked the DSP extension board.

B. The E2LP Base Board Overview

The E2LP base board is a backbone of the E2LP system. It is equipped with various peripherals which are intended to be used in Digital Systems Design Principles, Real-time systems, Operating systems, Digital signal processing and Network programming courses. The available peripherals covers wide range of functionality starting from a set of ordinary LE diodes and push buttons to a complex peripherals like an Ethernet. The comprehensive list of available peripherals on the E2LP base board is given in the Table I.

The core of E2LP base board is Xilinx Spartan-6 FPGA to which are connected all available peripherals. The FPGA provide more flexibility in a case that specific peripherals need to interconnect on a custom way. Of course, the nature of the FPGA also provide us the ability to implement additional functional components which are not already available such as pseudo-random generators, timers, communication protocols, signal processing filters, and etc. The FPGA keep the main role in the E2LP because it is used to handle most of signals between daughter boards and peripherals on the base board.

Concerning a software support, on the E2LP base-board are available (i) a mandatory house-keeping software which held the board in fully operational state, (ii) and a custom FPGA firmware. Depending of course

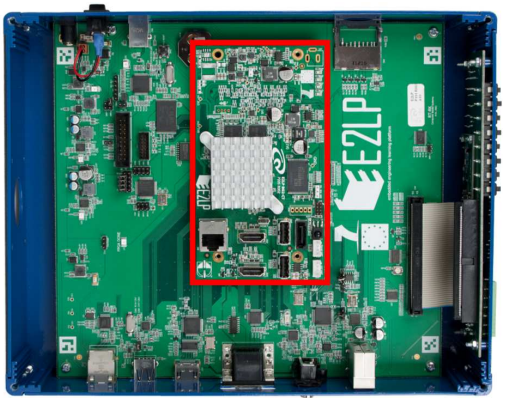

Figure 1. The E2LP FPGA Base and DSP Extension Boards in Laboratory Casing

TABLE I. The List of Peripherlas on The E2LP Base Board

Peripheral Class	Peripherals
High-speed communication	Ethernet, USB
Low-speed communication	RS-232, I2C, SPI, Infra-Red
User I/O	GPIO pins, LEDs, DIP Switches, Push Buttons, Snap-Wire Connector, LCD 16x2 Character Display
Audio/Video	Audio Codec, VGA, CVBS, HDMI
Mass Storage	SD-Card

the FPGA custom firmware may be different in order to suite the course specific needs.

C. The E2LP DSP Based Extension Board Overview

The E2LP DSP based extension board relay on a Marvell's ARMADA 1500 processor. The ARMADA 1500 is high-end dual-core ARM v7-compatible processor intended for use in cut-edge multimedia devices such as a Set-Top-Boxes, smart Digital TVs, tablets, and etc. With Marvell's QDeo video post processing technology the ARMADA 1500 processor is the central component of the Google TV 2.0 platform. In addition to the QDeo technology, it also integrates a 3D graphic core and audio post-processor for advanced video and audio processing algorithms.

The DSP based extension board is connected to the E2LP base board via Mezzanine connection. Using the Mezzanine connection and GPIO pins available on the extension board some of peripherals on the E2LP base board are also available on the extension board. For instance, from the extension board may be directly accessed to the LEDs, DIP switches, push buttons and RS-232. Peripherals on the DSP based extension board are mainly intended for exterior usage, USB, HDMI, LAN interfaces, and for debugging purpose, dedicated RS-232 interface.

The extension board based on ARMADA 1500 is suitable for implementing laboratory exercises and student's projects in field of 1D and 2D signal processing, low level and algorithm optimizations, computer networks, real-time systems, and different areas of application development. The application development is possible due the Android operating system. One of the most attractive and exciting regarding the DSP based extension board is the fact that on-top of its hardware is running a custom version of Android *Jelly Been* OS. The custom version of Android JB OS is ported in order to support hardware features available on the E2LP boards. Further, the Android itself, as the fastest growing operating system on the market today, provide to teachers and students a chance to develop different kind of application and system software from JAVA and WEB based Graphic User Interface (GUI) applications to low level Linux kernel and device driver development.

III. System Programming Course Overview

In the recent past a set of laboratory exercises in field of a digital systems design for a FPGA based board like

the E2LP base board was introduced [6]. Further, the presented results based on student's questioners tell us that even more changeling exercises could be attractive to the students. Based on lessons learned, the exercises and student's projects developed for the Real-time systems 2 course try to comprise the core knowledge about real-time and embedded system programming with the challenging and attractive problems which may be interesting to the students and beginners in the field of embedded systems.

During the course, both the E2LP base and DSP based extension boards are used. The E2LP (FPGA) board is used to handle low level signal communication between peripherals on the E2LP base board and software modules on the DSP based extension board. In the Fig. 2 E2LP software stack layers architecture is given. The house-keeping software ships with the E2LP base board and it is not relevant for the course. The FPGA custom software is specially tailored to suit the needs of the course. Due to the limitation that only a few peripherals located on the E2LP base board are interconnected with the E2LP extension board through the Mezzanine connection, a simple communication protocol which overcome this drawback is developed. In its essence, the communication protocol provide control of all peripherals available on the E2LP base board using the GPIO pins from the E2LP extension board side. More information about communication protocol, how it work, and which peripherals are supported is available in [7]. In the Fig. 2 the Android kernel and user space which is running on the E2LP daughter board are depicted – daughter board based on Marvell ARMADA 1500 processor. All exercises and projects are performed on the daughter board.

A. Laboratory Prerequisites

From a prerequisite's point of view, the laboratory hardware equipment and software needed for class lecturing are quite ordinary, and it follows:

1. The E2LP kit (may share among the students)
2. A PC running any Linux distribution
3. A cross-compile toolchain and an Android Debug Bridge (ADB) tool

The E2LP kit include the FPGA base and DSP extension boards. One E2LP kit may be shared among the students during the exercises. The cross-compile toolchain and ADB tool is necessary to compile a source code for ARM architecture and to download binaries to the target (Marvell's ARMADA 1500) platform, respectively.

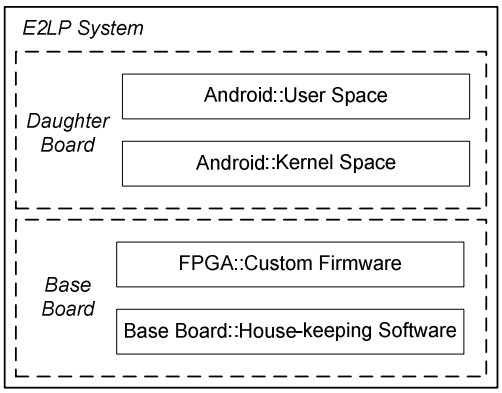

Figure 2. The E2LP Software Stack Layers Architecture

B. The Exercises Overview

The exercises are divided in a two subclasses. The exercises from both subleases are in according to the taxonomy described in [2]. The first subclass is about user space programming. It deals with common multithreading programming topics. The main goals of the exercises which covers user space programing are following:

1. Basics about using cross-compiler toolchain and embedded tools
2. Introduction to the multithreading concepts using POSIX standard (*pthread* library)
3. Thread synchronization and data-race problems
4. Introduction to mutual exclusion objects and semaphores
5. The consumer-producer problem implementation

The second subclass of the exercises cover a Linux kernel and device driver development. As the exercises regarding user space development, the exercises about the Linux kernel development include demonstrative exercises (tutorials) and exercises with specific problems which students have to solve. The Linux kernel development exercises demonstrate how kernel modules (drivers) should write and how it works in real operating systems. The following topics are covered:

1. Write a simple and complex (virtual) device drivers using referent examples
2. Develop a simple GPIO driver to handle LEDs and push buttons on the E2LP base board

C. The Projects Overview

In general, each project consists from its user space and kernel space part. In the kernel space part functionality which students have to implement is defined. Not necessary, but in the common case, the students have to develop a Linux device driver for a specific peripheral, i.e. to provide real-time system handler for a particular peripherals on the E2LP base or daughter board. The exceptions are virtual devices and devices implemented in the FPGA such are encryption device and random generator number device. The user space part is used to develop a simple test application which should implement a relevant use cases in order to tests driver's basic functionality. For instance, in the case of a RS-232 (UART) driver, the user space application is used to test send and receive functionality. Based on the student's affinity, it also may choose project which is entirely done in the Linux user space. Also, depending on a projects difficulty and complexity, the students may be split into a groups of two or three students. In Table II is given a basic set of the projects with functionality which should be implemented.

The projects described in the Table II defines a set of basic functional blocks which are used to compose a simple text/chat application on top of the E2LP platform.

TABLE II. PROJECT'S BRIEF DESCRIPTION

Linux device driver	Functionality
RS-232	Implement read/write commands using *pooling* mechanism.
RS-232	Implement read/write commands using *inerrupts* mechanism.
LCD	Implement read/write and reset commands. Enable text rotating.
VGA, HDMI, CVBS	Implement resolution change, text and background update, font size and font color change.
Encryption	Implement encryption functionality using random generator number in FPGA. Provide random generator's seed initialization.

The simple texting application is used to demonstrate sending and receiving a short text message between two E2LP platforms. In application composition VGA or other video output interface like HDMI or CVBS are involved, as well as RS-232 and encryption module for communication between two boards module. The LCD could be used to show communication protocol's commands which is developed in user space application. In the Table II are not shown the projects regarding communication protocol development. As mentioned before, if students are interested in user space applications they may work on a communication protocol development. It is mandatory that the protocol relay on the RS-232 device driver.

The idea behind the student's projects integration in a simple small scale global project is to demonstrate integration process which is inevitable part of any industrial project. At his phase, the students have to modify and fix an issues raised in the integration phase. The integration process is done by the course instructor.

IV. CONLUSION

In this paper we presented a set of student's laboratory exercises and projects intended to be used on the E2LP base and DSP based extension boards. The exercises and projects are mainly developed for a course about real-time system software, and embedded systems, but it may be used as solid background for other kind of courses and trainings. During semester, in the Linux based operating system students learn how to develop and integrate (i) user space applications, (ii) write multithreaded applications, (iii) develop kernel module drivers and devices, and (iv) write drivers for real peripherals using *pool* and *interrupt* mechanism. Students also learn how to use cross-compiler toolchain and embedded debugging tools which are common in embedded systems. At the end of semester, the output is a simple text/chat application which is composed of student's projects. The achieved results, based on a student's feedback, are positive and promising.

Test and verification process plays important role in the education of future engineers. The presented set of laboratory exercises and projects do not cover any of test and validation frameworks such as CUnit, CppUnit, JUnit, or other kind of frameworks which are using script languages. In order to improve this area of education, in the future it is necessary to make one of the frameworks available for running on the E2LP DSP extension board.

Recently various embedded boards are equipped with a couple of cores and plenty of operational memory, which provide to end user more space to develop and investigate more complex and time consuming tasks like image processing or non-trivial mathematical and chemical simulations. Along with supporting the test and verification frameworks, the goal in further work on the E2LP boards is to provide to students one of the powerful frameworks for parallel processing such as Intel's Threading Building Block and Cilk, and OpenMP.

No doubt, the main advantage of E2LP board is the DSP based extension board with Android OS support. This provide ability to teachers to develop a different classes of exercises targeting topics in communications networks and protocols, real-time and non-real system software, as well as JAVA, GUI, and WEB based application software. In the future, good compromise between the available E2LP boards and software development is to combine already developed exercises for the Real-time system course 2 and define new exercises, in the area of GUI development, which can be used to control the underlining hardware. This approach provide to students comprehensive view on computer stack architecture in one modern operating system like the Android.

ACKNOWLEDGMENT

The research leading to these results has received funding from the European Union's Seventh Framework Programme (FP7/2007-2013) under Grant Agreement No 317882.

marton@ef.uns.ac.rs

Abstract - Universal dissemination of digital technology has produced a convincing alternative to printed university textbooks, workbooks and handbooks, changing the approach to their production, distribution and use, whilst irreversibly transforming the reading habits and means of knowledge acquisition of the student population made of members of the Net generation. Being continuously and ubiquitously exposed to digital and network technologies while growing up, they effortlessly and instinctively developed ICT skills at an admirable level. Multitasking, being on-line and use of collaborative environments come naturally to current generations of students, which is an essential prerequisite for the introduction and use of Wiki-systems as an alternative to printed university literature. Positive and negative aspects of such systems are the subject of analysis in this paper, as well as the proposal of a possible scenario for developing Wiki learning materials in a particular environment.

I. INTRODUCTION

Despite the evident increase in sales of e-books (Forrester Research predicts that revenues from e-book sales will amount to 3 billion dollars in 2015 [1]), research results suggest that printing business is not losing momentum: more than 2 billion copies of books, 350 million copies of magazines and 24 billion of newspapers are printed in the United States alone, which consumes around 68 million tons of paper [1].

Business aspects are present in the university textbook publishing as well. The key motif is the potential profit, divided amongst a great number of participants in the chain from authors to students: editors, publishers, printers, distributors, persons involved in the development of study programmes, etc. [2]

Although, according to some sources, electronic textbooks are deemed more cost-effective – given that they do not incur printing costs, distribution costs are reduced to a reasonable minimum, there are no holding costs associated with (obsolete) inventory, and the fact that they can be printed in full or partially if necessary [2] – opposite opinions have emerged. They point out some particular costs that do not exist with printed textbooks: hardware costs (e-readers), costs of software updates, potential costs of replacing lost hardware, etc. [3]

Even if there are reservations about cost effectiveness of e-books, it seems that there is no doubt about their following advantages: digital textbooks contain up-to-date, current information presented using text, graphics, videos and other formats; they enable quick search, text highlighting, electronic comments, incorporate easily searchable glossaries and other tools that support reading and making notes. In addition to that, students can take many books with them, owing to the portability of e-readers, which was not the case with printed books. However, issues associated with e-books have emerged, such as readers' preference of printed textbooks over e-books, legal consequences of using and sharing materials in electronic formats etc. [2]

In context of the debate between printed and electronic books, Wiki-textbooks present themselves as sort of a hybrid. Developed using Wiki technology, they combine attributes of both printed and electronic textbooks, as well as classic Wikis, with the aim to make the most of their advantages and overcome their limitations.

Wiki-textbooks, or more specifically, students' participation in their development, can also be observed in the context of acquiring Web 2.0 literacy and knowledge management competencies. Collaboration in finding existing knowledge, creating and/or acquiring new knowledge, storing, retrieving, applying and re-use of knowledge [4] is a necessity that a knowledge-based economy imposes on modern organizations. Realization of these activities is virtually impossible without Web 2.0 technologies [5]. Therefore, Web 2.0 literacy and knowledge management operations are competencies that students need to gain throughout the course of their studies, in order to suffice in skills and knowledge required for applying for knowledge-based jobs immediately after receiving their degrees.

Considering that the traditional way of learning, based mostly on acquisition of knowledge from conventional printed (but also electronic) textbooks, workbooks and handbooks, does not fully facilitate acquisition of aforementioned competencies, this paper builds on a presumption that they can be significantly improved thru inclusion of students into collaborative development of Wiki-based university content that would become an alternative to printed and electronic university publications.

Reasonableness of this assumption is explored thru an overview of learning ways of the Net generations (to which most of the current students belong), examination of possibilities of Wikis as e-learning tools, contrasting positive and negative experiences of introducing Wikis in university education and an outline of selected segments of research that the authors had carried out on students at the Faculty of Economics in Subotica, which was focused

on their readiness to participate in the development of a Wiki system.

II. NET GENERATION

Digital and network technologies have had a determining impact on the current generation of students throughout their childhoods. Hence, they have effortlessly and instinctively developed ICT skills at an admirable level [6]. Networking, multitasking, interactivity and use of collaborative environments have become a part of their everyday activities [7, 8, 9, 10], which is reflected in terms widely used to describe this generation: the Net generation, millenians, www generation, digital generation, N-generation, generation E, cyberkids, Dot-com generation, Next generation etc. [11, 12, 13, 14, 15, 16]. However, besides the ICT skills, their distinctive characteristics involve individuality and narcissism [17], as well as the yearning to be entertained in every situation [18].

Sophisticated use of digital technology and a significantly different approach to information and media has led to changes in ways that members of the Net generation think and learn. At the same time, expectations towards the education system have undergone changes [19]. As far as in 2001, Prensky [7] had determined that there are divergences between the Net generation's way of learning and one imposed by the existing educational system: changes in the Net generation's way of learning are not just incremental, but there is an evident discontinuity in the way information is processed. Present generation's way of thinking is fundamentally different than one of their predecessors. Members of the Net generation are also called 'digital natives', while professors – who were not born in the digital era, but became fascinated by it at some point of their lives and accepted many of its benefits – are referred to as 'digital immigrants' [7]. The latter, speaking a language learnt in the pre-digital era, in fact "... are struggling to teach a population that speaks an entirely new language" [7].

The idea of substituting the traditional, industrial model of education with collaborative learning has emerged as a solution to a growing gap between 'digital natives' and 'digital immigrants', for which "we need an entirely new modus operandi for how the subject matter, course materials, texts, written and spoken word, and other media (the content of higher education) are created" [20]. Considerations on new ways of teaching and learning presented in Figure 1. speak in favour of aforementioned assumptions.

Traditional learning	**New learning**
Teacher-centered instruction	Student-centered learning
Single-sense stimulation	Multisensory stimulation
Single-path progression	Multipath progression
Single media	Multimedia
Isolated work	Collaborative work
Information delivery	Information exchange
Passive learning	Active/inquiry-based learning
Factual, knowledge-based learning	Critical thinking/informed decisions
Reactive response	Proactive/planned action
Isolated artificial context	Authentic, real world context

Figure 1. New ways to teach and learn [9]

III. WIKI SYSTEMS

Wikis are one of the most popular Web 2.0 applications. Of several key concepts that have led to the explosive increase in popularity of Web 2.0 applications [21], Wikis mostly rely on Wisdom of crowds and Architecture of Participation. Wisdom of Crowds, as one of the manifestation forms of the Harnessing the Power of the Crowds principle [21], "is the basic idea of Web 2.0-style thinking, starting from the viewpoint that the solution to the problem, proposed collectively but independently by individuals comprising a large group, the so-called 'crowd', is better in quality than a solution offered by the most intelligent group member" [22]. Architecture of Participation reflects the idea that a Web 2.0 based service should be easy to use. Such characteristics eliminate obstacles to accessing and using the service, encourage and ease mass participation in its usage. Furthermore, mass participation contributes to the quality of a Web 2.0 based service, owing to the effect of principles of wisdom of crowds.

In practice, these ideas are implemented in a way that Wiki users interactively, collaboratively and incrementally edit existing and add new content to the Wiki system, thus constantly increasing knowledge repositories under permanent community based peer revision.

Eide and Eide [23], who studied the potential of applying Wikis in education, have pointed out that they promote critical, analytical, creative, intuitive and associative thinking and represent a powerful medium for accessing and sharing quality information.

Kokkinaki [24] highlights the potential of wikis reflected in the fact that it gives the student, as an individual, the opportunity to give their way of learning a specific identity, while improving their teamwork skills at the same time [22]. Karasavvidis [25] believes that, for several reasons listed below, Wikis have the greatest potential of all Web 2.0 tools:

- A regular web browser is sufficient for their use;
- Level of skill necessary to create and modify Wiki content is relatively low;
- Wikis facilitate individual work, as well as collaboration, communication and evaluation;
- Wikis support different types of educational activities, such as: collective learning, collective generation of databases, improvement of interaction among students, on-line classes and assessment, collaborative generation of materials, creation of Wiki textbooks, etc.

Wikis can also be used for brainstorming, group projects, meeting, support, creating various lists, (e.g. glossary of terms), preparing answers to FAQ, building repositories of relevant documents, assembling link collections (social bookmarking), building a group portfolio [26], posting homework/course material/study guides, peer review and feedback [9] etc. In addition to that, Wiki does provide students with unconstrained access in terms of place and time, allowing each individual to choose the work pace that suits those best [5].

Hypothetically, adoption of Wiki-technologies should stimulate positive qualitative changes in the education system. However, these expectations have not been completely realized (or not even to a desirable extent) [5], which can be concluded from the results of several studies that will be referenced in the following section.

IV. University Experience in the Application of Wiki Systems

The common idea in all examined studies is that development of Wiki-textbooks necessitates significant efforts of both teachers and students [2, 25, 27, 28, 29, 30]. These studies pointed out several positive aspects of Wiki-textbooks:

- Students are better motivated for creating quality content due to the awareness that their work will be presented to the public (even just within the group);
- Process of developing wiki textbooks stimulates group work, collaboration, knowledge sharing;
- Assigning credits (ETCS) for correcting other' errors motivates students to read those parts of Wiki-textbooks they normally would skip;
- Development of Wiki-textbooks results in better familiarization with the learning materials;
- Teachers work more closely with students and the group as a whole;
- Students become aware of the responsibility associated with the decisions what to include and what to exclude from Wiki-textbooks;
- Students who participate in the development of Wiki-textbooks achieve better grades in their exams.

However, the mentioned studies [2, 25, 27, 28, 29, 30] point more to the negative aspects, that is, problems associated with Wiki-textbooks. Of all the mentioned problems, the following particularly stand out:

- Challenging coordination of implementation activities;
- Failure to complete activities within the set timeframe;
- Students' concerns about fairness of the system used for evaluating (assigning credit) of efforts put into developing parts of Wiki-textbooks.
- Frequent frustrations caused by the lack of skills necessary for using Wiki-systems.
- Students' general need to protect (so to say, copyright) their ideas, i.e. parts of Wiki-textbooks they worked on, combined with the simultaneous disregard for their colleagues contribution;
- Anxiety due to public availability of texts entered in the Wiki-textbook (this was identified as a motivational factor as well);
- Contrary to the expectations, altruism often did not develop among students (or at least not to a desirable level);
- A relatively small number of students provide significant contribution to the development of Wiki-textbooks, while contribution of most students is negligible;
- Student prefer lower grades over the obligation to use a Wiki-system and participate in on-line collaboration;
- Students prefer individual work over on-line collaboration;
- Students' satisfaction from using Wiki system and collaboration in the content development is not at a desirable level;
- Students consider that they would achieve better final grades if they work individually;
- After a certain amount of time, there were no new contributions to Wiki;
- Students regard development of Wiki-textbooks as an excessively demanding task, both in terms of time and effort to be put into writing, entering content, reading, etc.;
- Plagiarism: copy-paste has become a regular method for 'loading' Wikis;
- Students complain over limited possibilities for communication (discussions) thru Wiki systems;
- Apart from live discussions in the classroom, online discussions within the wiki system are scarce;
- Wiki-textbook development project encourages competition more than it encourages collaboration;
- Students are sceptical about their understanding of certain concept;
- Students are reluctant to contribute and make changes to the text entered by their colleagues, although they have constructive ideas;
- Unbalanced 'depth' of content: superficially written texts were mainly a result of a copy-paste strategy and considerably greater in length than texts that were more devoted to the essence of the issue and required more work;

- Students are used to learning from authoritative texts that mostly reflect dominant theories within a discipline, authored by leading experts in their respective fields; texts originated from collaboration on developing Wiki textbooks were not deemed authoritative by students;
- Students were worried that every mistake, vagueness or inconsistency in their texts might adversely affect their final grade.

As a result of the analysis of identified positive and negative experiences related to development of Wiki-textbooks presented in the literature, the following suggestions and recommendations were proposed [2, 25, 27, 28, 29, 30]:

- Organize an in-depth training for using Wiki-systems and give students more time to adapt to a new medium;
- Define explicit rules on participation, convey them to students in a clear manner and insist on the netiquette;
- Instructor should convince students that revision is a natural, inevitable part of creating Wiki-content, and that it does not imply that the original text was wrong;
- Consider giving a list of chapters and titles for the future Wiki-textbook before the development commences.

V. RESEARCH RESULTS

On the basis of mentioned experiences in the introduction of Wiki systems into university education, with specific traits of the Net generation in mind [31], the authors have conducted a research on students' willingness to participate in the development of a Wiki system at the Faculty of Economics in Subotica [5]. A summary of research results is given in the following text.

A questionnaire was sent to the addressees of 216 third-year and fourth-year undergraduate students, selected by random sampling. 75% of students have responded to the request to participate in the survey. 90 of the respondents were male (55.56%), while 72 (44.44%) were female. Structure of respondents according to the grade point average criterion conforms to the normal distribution: 9.88% students had a grade point average between 6.00 and 6.99, 39.51% between 7.00 and 7.99, 38.27% between 8.00 and 8.99, while 12.35% respondents had a grade point average of 9.00 or more. 100% of respondents stated that they use computers and internet. 81.25% of respondents stated that they have the ability to access the Internet using their smartphones, which goes in favour of the assumption that students are able to access the (future) student Wiki virtually anytime and anywhere.

All respondents (100%) stated that they use Wikipedia. The greatest portion (60.49%) of students use it on a weekly basis. However, there are significantly less active Wikipedia users: only 12.35% of respondents had participated in creation or modification of its content. In spite of relatively frequent use of Wikipedia, one third of respondents do not use it when preparing for exams. It can be said that students who use Wikipedia for preparing exams do not have a clear vision on its potential benefits for this purpose: 49.05% of respondents have stated that Wikipedia is useful for exam preparation, i.e. 50.95% disagreed with that claim (10% = "I agree completely", 0% = "I disagree completely"). Moreover, less than 10% of respondents have stated that they do not verify information obtained from Wikipedia at all, 62.96% verify them sometimes, while 14.81% do it often.

Students have rated the idea to develop a student Wiki on a certain topic within lectures and exercises thru student-teacher cooperation with an average score of 4.40 (1=lowest score; 5=best score).

Proposals that the content of student Wiki be a part of the exam material and that activities on building the student Wiki be additionally valued in the assessment of the final grade were scored similarly high: the average scores were 4.25 and 4.16, respectively. The idea that each student would be obliged to participate in the development of the student Wiki was not accepted that well; it was scored with an average grade of 2.77. However, when students were offered a choice between participation in the development of a student Wiki for a higher final grade and non-participation in the development, but with a lower grade, the results clearly suggested that most students would prefer to take part in the Wiki development. To be specific, only less than a 5% of surveyed students have said that they would accept a lower grade not to participate in the development of a student Wiki. Just less than 15% of students were indecisive, while almost 70% stated their readiness to participate in the development of the Student Wiki for a higher grade. The category 'other', which included 11.11% responses, contained answers such as: "It depends on other responsibilities", "It depends on the topic that Wiki would cover", "Depends on my free time", "It depends on the professor I would have to work with", etc.

Idea to make the student Wiki accessible to public received an average grade of 2.77, while the idea to make it accessible only thru the Faculty's intranet with user authentication received somewhat better grade of 3.79 (1=lowest score; 5=best score).

When it comes to reviewing the content of the student Wiki, surveyed students have unanimously expressed their wish that professors be involved as active reviewers of the content developed by students (average grade of 4.37), while the idea that selected students help professors in reviewing the content for bonus points received somewhat lower average score of 4.03. The idea that the review would not be done by professors, but be assigned to students instead, was not accepted well and was scored with an average of 2.66. Defining and applying strict rules for referencing sources in the material uploaded to the student Wiki was received a score of 4.17.

When asked which they would prefer – that the content uploaded to student Wiki be signed with their real names or pseudonyms (professors would know the real identities), 38.27% of students answered that they would prefer pseudonyms, while 56.68% answered that they would prefer that their real names be clearly stated. The

remaining respondents did not express their attitudes toward this. Pivoting of collected data showed that students with lower academic performance throughout their studies would prefer anonymity, while the option to have their names clearly stated was more frequently chosen by students with a greater grade point average, as was expected. It was similar with teamwork: students with a lower grade point average were readier to accept teamwork that those with a high grade point average.

VI. Proposition of a Possible Scenario for Developing a Wiki-textbook

Based on results from selected research on the application of Wiki systems in university education, with regard for specific student preferences related to their participation in the development of a Wiki system and, of course, characteristic traits of the Net generation, the authors have defined a set of assumption to guide the development of Wiki-textbooks in several courses within the Business Informatics study programme at the Faculty of Economics in Subotica. A brief overview of these assumptions is given below:

- Wiki system would consist of two parts: a core textbook and content created by students. The core textbook would be a source of 'authoritative' texts which would provide students with information on dominant theories and ideas within a particular discipline. It would be cataloged and categorized by a relevant institution and could serve as a proof of compliance with requirements for the appointment of professors or associates to certain university positions.
- Students' proposals on possible improvements or additions to the textbooks should be much welcomed. Bearing in mind the fact that errors in the content of a core textbook can go unnoticed even by reviewers and that the data in the textbook may become obsolete, students would be able to point to possible faults in the textbook, or suggest new sources of up-to-date or more detailed data. Students would be encouraged to point to the parts of the textbook which they think are not written clearly enough or lack in content. It would also be considered a great contribution if students could find sources with different perspectives of particular topics covered by the textbooks, since that would help to reduce the subjectivity of content to the least extent.
- It would be assumed that use of Web 2.0 applications and services (including Wikis) in the context of education differs to their use for personal reasons. Therefore, students would be acquainted with the techniques for using Wiki systems in detail, thru an extensive training for all Wiki-related activities: writing, editing content review, etc. Using prepared examples, students would be comprehensively trained in the use of the Wiki system, rules, spelling, grammar, formatting, desirable and unacceptable writing styles, netiquette, etc.
- Traditional seminar papers would be replaced with activities on creating, i.e. supplementing the present Wiki content. Structure of the content which would be added to the Wiki would be predetermined, but open for all students' suggestions, amendments and contributions.
- Topics on which students should enrich the Wiki system should be similar in terms of complexity. Each student would be assigned a particular topic, while teamwork and collaboration would be achieved thru organized checkpoint and brainstorming meetings where students would be able to make their comments, express criticism and commendations for the work of their peers and the group as a whole. This would involve students in directing the development of the Wiki system, but also encourage them, or even compel them to read content posted by their peers.
- Wiki content would be checked for plagiarism by use of specialized web services. Faculty of Economics in Subotica has been using Ephorus successfully for a number of years. Special attention would be devoted to referencing used sources of information and constant review by professors.
- The Wiki would be one of a closed type, accessible to registered users, which would help reduce students' anxiety over the public availability of their texts.
- Students would contribute to the Wiki under their real names. Each student should be awarded a grade for their work on the Wiki, just like with seminar papers. Wiki content created by students would not become a part of the exam material, which would be limited to the content of the core textbook.
- At the end of each semester, the core textbook would be supplemented with the best sections of the students' part of Wiki, of course, with proper author credits.
- Comparison of students' contribution to development of the Wiki system and their final grades would be presented at the final checkpoint meeting, where every student would have the opportunity to share their opinion.

VII. Conclusion

Wiki-textbooks still cannot be considered 'mature', but that should not be an obstacle to considering (and applying) them as an alternative to the traditional and electronic textbooks, in the context of creating new, different relations between stakeholders of the education system [2]. Wiki-textbooks put more emphasis on interaction among students (as opposed to traditional lectures), P2P collaboration, study programmes with a focus on students thru 'production' of knowledge in which students take part as well, by using (mostly free) digital resources, as well as traditional ones [5]. In such scenario, the primary goals of learning change as well: memorizing

and attaining factual knowledge give way to critical thinking, decision making, synthesis and integration of knowledge and skills [3]. This can be considered as an arising, new educational culture, which enables students to reach competencies required by the knowledge-based economy.

Based on educational potential of Wikis, specific traits of the Net generation to which most of current students belong, positive and negative experiences in the application of Wiki-systems in university education and specific attitudes of students at the Faculty of Economics in Subotica towards the development of a Wiki-system, the paper presented a concise initial proposal of a possible scenario for developing a Wiki- textbook within several courses in the Business Informatics study programme. This briefly presented possible scenario for developing Wiki textbooks is a starting point for further in-depth discussions and research, prior to its experimental implementation.
